ANALOG DEVICES

How to Find Product Data in This Databook

THIS VOLUME

Contains Data Sheets, Selection Guides and a wealth of background information on signal conversion and a wide variety of components for analog signal processing.

It is one member of a three-volume, 2,800-page set of Databooks describing and specifying Linear, Conversion and DSP products from Analog Devices, Inc., in IC, hybrid and assembled form for measurement, control and real-world signal processing.

IF YOU KNOW THE MODEL NUMBER

Turn to the product index at the back of the book and look up the model number. You will find the Volume-Section-Page location of data sheets bound into this volume.

If you're looking for a form-and-function-compatible version of a product originally brought to market by some other manufacturer (second source), add our "AD" prefix and look it up in the index.

IF YOU DON'T KNOW THE MODEL NUMBER

Find your function in the list on the opposite page or in the Table of Contents on pages 1–5 through 1–10. Turn directly to the appropriate Section. You will find a functional Selection Guide at the beginning of the Section. The Selection Guides (and the "Orientation" that usually accompanies them) will help you find the products that are the closest to satisfying your need. Use them to compare all products in the category by salient criteria.

IF YOU CAN'T FIND IT HERE . . . ASK!

If it's not a signal conversion product, it's probably in one of the two sister volumes, the *Linear Products Databook* or the *DSP Products Databook*. If you don't already own these volumes, you can have them FREE by getting in touch with Analog Devices or the nearest sales office, or phoning (617)-329-4700, Extension 3392.

See Worldwide Service Directory on pages 15–9 and 15–10 at the back of this volume for our sales office phone numbers.

General Information
Contents

1

Analog Devices designs, manufactures and sells worldwide sophisticated electronic components and subsystems for use in real-world signal processing. More than six hundred standard products are produced in manufacturing facilities located throughout the world. These facilities encompass all relevant technologies, including several embodiments of CMOS, BiMOS, bipolar and hybrid integrated circuits, each optimized for specific attributes – and assembled products in the form of potted modules, printed-circuit boards and instrument packages.

State-of-the-art technologies have been utilized (and in many cases invented) to provide timely, reliable, easy-to-use advanced designs at realistic prices. Our popular IC products are available in both conventional and surface-mount packages (SO, LCC, PLCC), and many of our assembled products employ surface-mount technology to reduce manufacturing costs and overall size. More than twenty years of successful applications experience and continuing vertical integration insure that these products are oriented to user needs. The ongoing application of today's state-of-the-art and the invention of tomorrow's state-of-the-art processes strengthen the leadership position of Analog Devices in standard data-acquisition and signal-processing products and make us a strong contender in high-performance mixed-signal ASICs.

MAJOR PROGRESS

Since publication of our *1988 Data Conversion Products Databook*, more than 40 significant new data conversion products have been introduced; they run the gamut from brand new product categories and technologies to new standard products (with improvements in price, performance or design) to augmented second-source products. They are all classified and summarized in this Volume, along with existing products that are desirable for use in new designs.

Major new data conversion products include hybrid and monolithic products with high levels of performance and integration, complete and fully guaranteed specifications, and attractive price. For high-speed A/D conversion, these include: the AD9005 (12 bit, 10 MSPS), AD9006 and AD9016 (6 bit, 500 MSPS) with direct and demultiplexed 1:2 output, AD9011 (8 bit, 100 MSPS), AD9028 (8 bit, 300 MSPS) also with direct and demultiplexed 1:2 output, and the AD9048 (8 bit, 20 MSPS). High-speed D/A conversion is available with the AD9712 and AD9713 DACs, providing 100 MSPS and 80 MSPS update rates, respectively.

A variety of speed, functionality, and resolution combinations are available from the AD7769 dual 8-bit ADC and DAC I/O port, the AD7237 and AD7247 dual 12-bit DAC (8+4- or 12-bit parallel data loading), AD662 12-bit single-supply DAC, the AD7840 14-bit DAC (serial or parallel data loading), the AD7772 12-bit, 10 μs serial output ADC, and the AD7871 and AD7872 14-bit ADCs (serial only or serial/parallel data interface). Higher performance is achieved with the AD1679 and AD1779 14-bit, 100 KSPS ADCs with byte-wide and fully parallel interface, the AD1377 16-bit, 10 μs ADC, the AD1362 16-channel, 10 μs ADC, the AD1334 ADC with 4 channels of simultaneous or independent sampling (well-suited for DSP applications), and the AD1330 which provides A/D conversions at 100 KSPS with 18-bit dynamic range and 12 bits of resolution in a floating-point output format.

Digital audio needs are met with the optimized AD1856 (16 bit) and AD1860 (18 bit) DACs, both of which minimize the need for external components; video applications are served by the ADV453, ADV471, ADV476, and ADV478 video DACs plus internal RAM which provide a variety of color resolution, pixel density, and color palette choices. Conversion support circuitry includes the monolithic AD684 quadruple sample/hold amplifier for simultaneous sampling, and the AD1154 and AD386 16-bit sample or track/hold devices. Switching and routing of wide-band signals is facilitated by the AD9300 4-channel video multiplexer.

THE 1989/90 DATA CONVERSION PRODUCTS DATABOOK

This Volume provides complete technical data on Analog Devices "data conversion" products – designed to process, condition and otherwise operate between *analog signals* and *digital signals*. One of a set of three volumes, it is accompanied by the *DSP Products Databook*, dedicated to products for high-performance digital signal-processing (i.e., *digital-to-digital*), and the *Linear Products Databook*, which covers products involved in spanning the interface *between analog signals and analog results.*

The product data in this book is intended primarily for the majority of users who are concerned with new designs. For this reason, those existing and available products that offer little if any unique advantage over newer products in future designs are included in the Index and their data sheets are available from us separately – but they aren't published in this book.

This book includes:

- Comprehensive data sheets on more than 193 significant product families:
- Orientation material and selection guides for rapid product finding;
- A representative list of available Analog Devices technical publications on real-world analog and digital signal-processing;
- Worldwide Service Directory; and
- Product Index to all three volumes.

TECHNICAL SUPPORT

Our extensive technical literature discusses the technology and applications of products for precision measurement and control. Besides tutorial material and comprehensive data sheets, including a large amount in our Databooks, we offer Application Notes, Application Guides, Technical Handbooks (at reasonable prices), and several free serial publications; for example, *Analog Productlog* provides brief information on new products being introduced, and *Analog Dialogue*, our technical magazine, provides in-depth discussions of new developments in analog and digital circuit technology as applied to data acquisition, signal processing, control, and test. *DSPatch* is a quarterly newsletter that brings its reader up-to-date applications information on our DSP products and the general field of digital signal processing. We maintain a mailing list of engineers, scientists, and technicians with a serious interest in our products. In addition to Databook catalogs – and general short-form selection guides, – we also publish several short-form catalogs on specific product families. You will find typical publications described on pages 15-6 to 15-8 at the back of the book.

SALES OFFICES

Backing up our design and manufacturing capabilities and our extensive array of publications is a network of sales offices and representatives throughout the United States and most of the world. They are staffed by experienced sales and applications engineers, and many of them maintain a local stock of Analog Devices products. Our Worldwide Service Directory, as of the publication date, appears on pages 15-9 and 15-10 at the back of the book.

RELIABILITY

The manufacture of reliable products is a key objective at Analog Devices. The primary focus is the Companywide Quality Improvement Process (QIP). In addition, we maintain facilities that have been qualified under such standards as MIL-M-38510 for ICs in the U.S. and Ireland and MIL-STD-1772 for hybrids. More than 25 of our products – both proprietary and second-source – have qualified for JAN part numbers; others are in the process. A larger number of products – including many of the newer ones just starting the JAN qualification process – are specifically characterized on Standard Military Drawings (SMDs). Most of our ICs are available in versions that comply with MIL-STD-883C Class B. We publish a *Military Products Databook* for designers who specify ICs and hybrids for military contracts (the 1987 issue contains data on nearly 150 available product families). A newsletter, *Analog Briefings*, provides current information about the status of reliability at ADI.

Our PLUS program makes available standard devices (commercial and industrial grades, plastic or ceramic packaging) for *any* user with demanding application environments, at a small premium. Subjected to stringent screening, similar to MIL-STD-883 test methods, they are often suffixed "/+" and are available from stock.

PRODUCTS NOT FOUND IN THE SELECTION GUIDES

For maximum usefulness to designers of new equipment, we have limited the contents of selection guides to products most likely to be used for the design of new circuits and systems. If the model number of a product you are interested in is not in the Index, turn to page 15-4 at the back of this volume where you will find a list of older products for which data sheets are available upon request. On page 15-5 you will find a guide to substitutions (where possible) for products no longer available.

PRICES

Accurate, up-to-date prices are an important consideration in making a choice among the many available product families. Since prices are subject to change, current price lists and/or quotations are available upon request from our sales offices.

Digital-to-Analog Converters

FACTORS IN CHOOSING A D/A CONVERTER

In this catalog there are listed some 57 different families of digital-to-analog converters (DACs). If one were to consider all the variations, there would be several times that number to choose among. The reason for so many different types is the number of degrees of freedom in selection – technological, functional, performance and package. Complete information on converters may be found in the 700-page book, *Analog-Digital Conversion Handbook*, published by Prentice-Hall, Inc.

FUNCTIONAL CHARACTERISTICS

The basic structure of all conventional D/A converters involves a network of precision resistors, a set of switches and some form of level-shifting to adapt the switch drives to the specified logic levels. In addition, the device may contain output-conditioning circuitry, an output amplifier, a reference amplifier, an on-board reference, on-board buffer registers (single- or dual-rank), configuration conditioning and even high-voltage isolation.

Basic DAC

This form which supplies a current, and consequently a small voltage across its internal impedance or an external low-impedance load, is used principally for high speed, for example, the 10ns HDM-1210. Basic current-output DACs, such as the AD565A, are inherently fast, but additional elements (such as an output op amp), furnished by the user to meet overall system specs, slow down the conversion. Some popular CMOS IC devices, such as the AD7543 and the AD7524, are quite simple (and correspondingly low in cost), but they usually require a buffering op amp.

While the basic DAC function is almost always linear, there are exceptions. For example, the AD7111 LOGDAC, which has linear two-quadrant analog response, has a digitally controlled exponential gain function, i.e., 0.375dB per bit; thus its gain at the input code 1000 0000 (binary 128) is -48dB (48×0.375), and the analog output swing for 10V p-p input is 0.04 p-pV_{IN} to $\exp -\left(\frac{0.375N}{20}\right)$.

Output Conditioning

The analog quantity that is the "output" of a DAC, representing the input digital data may be a "gain" (multiplying DAC), a current and/or a voltage. In order to obtain a substantial voltage output at low impedance, an op amp is required. It is often provided by the DAC itself (whether monolithic, modular or hybrid), but many permit the user to choose an external op amp that will meet the particular needs of the application in stability, speed and cost.

Almost all types of DACs provide one or more feedback resistors; they are matched to, and thermally track, resistances in the network so that an external op amp, if used, will not require an external feedback resistor that might introduce tracking errors. If more than one feedback resistor is provided, a choice of analog output voltage ranges becomes available, e.g., 0 – 5V full-scale or 0 – 10V full-scale. If bipolar output-voltage ranges are specified, a bipolar-offset resistor is provided to subtract a half-scale value from the current flowing through the op amp summing point; it is usually derived from the DAC's reference (or analog) input to avoid additional tracking error. Multiplying DACs use an internal or external op amp for bipolar offset.

In order to avoid difficulties, the user must pay special attention to the specified output polarity, its relationship to the reference (if external) and to the input digital code. This can be especially tricky if the output is bipolar and the input requires a complementary (negative-true) digital coding. Another such case is where a current-output DAC, specified for a particular output-voltage polarity when used with an inverting op amp, is used in a mode that develops an output voltage passively (without the op amp) across an external resistive load. In addition to polarity, in this case, the user should be aware of the output-compliance constraint and the specified resistive component of output impedance.

Reference Input

The reference may be specified as external or internal, fixed or variable, single polarity or bipolar. If internal, it may be permanently connected (as in the AD561) or optionally connectible (as in the AD565A). If the DAC is a 4-quadrant multiplying type, the reference (or "analog input") is external, variable and bipolar (e.g., AD7533, AD7541, AD7541A, etc.). The user should check a converter's specifications to determine whether the full-scale accuracy specifications are overall or subdivided into a converter-gain spec and a reference spec.

Digital Data

There a number of ways in which converters differ in regard to the input data: first, the *coding* must be appropriate (binary, offset-binary, twos complement, BCD, arbitrary, etc.), and its sense should be understood (positive-true, negative-true). The *resolution* (number of bits) must be sufficient; in addition, the specifications must be checked to ascertain that the 2^n distinct binary input codes will not only be accepted, but that also they will (if necessary) correspond to 2^n output values in a monotonic progression at any temperature in the operating range with sufficient accuracy. Analog Devices offers DACs with resolutions of 8, 10, 12, 14, 16 and 18 bits. The *data levels* accepted by the converter must be checked (TTL, ECL, low-voltage CMOS, high-voltage CMOS), as must the input loading imposed by the converter and the supply conditions under which the converter will respond to the data. Check the data notation (is the MSB Bit 1 or Bit (n-1)?) – misinterpretation can lead to connecting the data bits in backward order.

If *buffer registers* are desired, the converter should have an appropriate buffer configuration (for example, the AD558 and AD7226 have a set of TTL buffers; the AD667 and AD7224 have two ranks of buffering).

Controls

If the DAC has external digital controls – for example, register strobes – their drive levels, digital sense (true or false), loading and timing must be considered. The function and use of configuration controls (where present), such as serial/parallel, short-cycle or chip-select decoding, should be understood, and the appropriate ways of disabling them when not needed should be employed.

Many DACs are specifically designed to interface directly to the bus of the computer or microprocessor. These DACs provide the necessary control and handshake lines, as well as the data bit buffers, to minimize and often eliminate the interface circuitry

required. The bus timing should be studied with respect to the timing provided by the DAC interface, especially as the processor performs a data-write cycle to the DAC. Systems with higher speed clocks require either shorter DAC strobe times (such as the AD767) or the use of processor-wait states when the DAC is addressed. DACs for video applications, such as the AD9701, provide special control lines unique to CRT applications (e.g. blanking, sync and reference level display).

STATIC AND DYNAMIC PERFORMANCE SPECIFICATIONS

All DACs are specified using terms such as accuracy, linearity, offset, defined and explained below. These static, or "dc," parameters are necessary and sufficient for many applications; they may not be sufficient for others, such as those in digital signal processing, adaptive filtering, or waveform generation. Dynamic, ac specifications define how the DAC performs using parameters such as signal-to-noise ratio (SNR), intermodulation distortion (IMD) and total harmonic distortion (THD). These specifications characterize the performance of the DAC output in applications where the envelope of output changes and output timing errors are critical.

POWER SUPPLIES

Appropriate power supplies should be made available considering the logic levels and analog output signals to be employed into the system. The appropriate degree of power-supply stability to meet the accuracy specs should be employed. In many cases separate analog and digital grounds are required; ground wiring should follow best practice to minimize digital interference with high-accuracy analog signals while ensuring that a connection between the grounds can always exist at one point, even if the "mecca" point is inadvertently unplugged from the system.

SPECIFICATIONS AND TERMS

Definitions of the performance specifications and related information are provided on the next few pages in alphabetical order.

Accuracy, Absolute
Error of a D/A converter is the difference between the actual analog output and the output that is expected when a given digital code is applied to the converter. Sources of error include gain (calibration) error, zero error, linearity errors and noise. Error is usually commensurate with resolution, i.e., less than $2^{-(n+1)}$, or "1/2LSB" of full scale. However, accuracy may be much better than resolution in some applications; for example, a 4-bit reference supply having only 16 discrete digitally chosen levels would have a resolution of 1/16, but it might have an accuracy to within 0.01% of each ideal value.

Absolute accuracy measurements should be made under a set of standard conditions with sources and meters traceable to an internationally accepted standard.

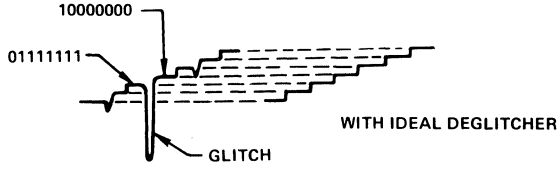
Accuracy, Relative
Relative accuracy error, expressed in %, ppm or fractions of 1LSB is the deviation of the analog value at any code (relative to the full analog range of the device transfer characteristics) from its theoretical value (relative to the same range) after the full-scale range (FSR) has been calibrated. Since the discrete analog output values corresponding to the digital input values ideally lie on a straight line, the relative accuracy error of a linear DAC can be interpreted as a measure of nonlinearity (*see Linearity*).

Compliance-Voltage Range
For a current-output DAC, the maximum range of (output) terminal voltage for which the device will provide the specified current-output characteristics.

Common-Mode Rejection (CMR)
The ability of an amplifier to reject the effect of voltage applied to both input terminals simultaneously. Usually a logarithmic expression representing a "common-mode rejection ratio" e.g., 1,000,000:1 (CMRR) or 120dB (CMR). A CMRR of 10^6:1 means that a 1V common-mode voltage passes through the device as though it were a differential input signal of 1 microvolt.

Common-Mode Voltage
An undesirable signal picked up in a circuit by both wires making up the circuit, with reference to an arbitrary "ground." Amplifiers differ in their ability to amplify a desired signal accurately in the presence of a common-mode voltage.

Deglitcher
As the input code to a DAC is increased or decreased by small changes, it passes through what is known as major and minor transitions. The most major transition is at half-scale when the DAC switches around the MSB and all switches change state, i.e., 0111 1111 to 1000 0000. If, at major transitions, the switches are faster (or slower) to switch off than on, this means that for a short time the D/A will give a zero (or full-scale) output and then return to the required 1LSB above the previous reading. Such large transient spikes which differ widely in amplitude and are extremely difficult to filter out are commonly known as "glitches," hence, a deglitcher is a device which removes these glitches or reduces them to a set of small, uniform pulses. It normally consists of a fast sample-hold circuit which holds the output constant until the switches reach equilibrium. Glitch energy is smallest in fast-switching DACs driven by fast logic gates that have little time skew between 0-1 and 1-0 transitions.



Feedthrough
Undesirable signal coupling around switches or other devices that are supposed to be turned off or provide isolation, e.g., *feedthrough error* in a multiplying DAC. It is variously specified in %, ppm, fractions of 1LSB or fractions of 1 volt with a given set of inputs at a specified frequency.

Four-Quadrant
In a multiplying DAC, "four quadrant" refers to the fact that both the reference signal and the number represented by the digital input may be of either positive or negative polarity. A four-quadrant multiplier is expected to obey the rules of multiplication for algebraic sign.

Gain
The "gain" of a converter is that analog scale-factor setting that provides the nominal conversion relationship, e.g., 10V span for a full-scale code change in a fixed-reference converter. For fixed-reference converters where the use of the internal reference is optional, the converter gain and the reference may be specified separately. Gain- and zero-adjustment are discussed under *Zero*.

Harmonic Distortion (and Total Harmonic Distortion)
The DAC is driven by the digitized representation of a sine wave. The ratio of the rms sum of the harmonics of the DAC output to the fundamental value is the THD. Usually only the lower order harmonics are included such as second through fifth:

$$\text{THD} = 20 \log \frac{(V_2^2 + V_3^2 + V_4^2 + V_5^2)^{1/2}}{V_1}$$

where V_1 is the rms amplitude of the fundamental and V_2, V_3, V_4 and V_5 are the rms amplitudes of the individual harmonics.

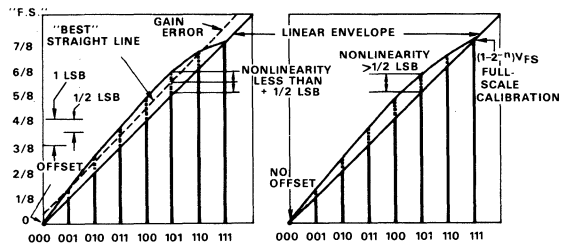
Intermodulation Distortion
The DAC is driven by the digitized representation of two combined sine waves of frequencies f_a and f_b. As with any imperfectly linear device, distortion products (of order m+n) are produced at sum and difference frequencies of $mf_a \pm nf_b$ where m, n = 0, 1, 2, 3, ... Intermodulation terms are those for which m or n is not equal to zero. The second order terms include $(f_a + f_b)$ and $(f_a - f_b)$ and the third order terms are $(2f_a + f_b)$, $(2f_a - f_b)$, $(f_a + 2f_b)$ and $(f_a - 2f_b)$. IMD is defined as:

$$\text{IMD} = 20 \log \frac{\text{(rms sum of the sum and difference distortion products)}}{\text{rms amplitude of the fundamental}}$$

Least-Significant Bit (LSB)
In a system in which a numerical magnitude is represented by a series of binary (i.e., two-valued) digits, the LSB is that bit that carries the smallest value or weight. For example, in the natural binary number 1101 (decimal 13, or $2^3 + 2^2 + 0 + 2^0$), the rightmost digit is the LSB. Its analog weight, relative to full scale is 2^{-n} where n is the number of binary digits. It represents the smallest analog change that can be resolved by an n-bit converter.

Linearity
Linearity error of a converter (also *integral nonlinearity*, see *Linearity, Differential*), expressed in %, ppm of full-scale range or (sub)multiples of 1LSB, is a deviation of the analog values in a plot of the measured conversion relationship from a straight line. The straight line can be either a "best straight line" determined empirically by manipulation of the gain and/or offset to equalize maximum positive and negative deviations of the actual transfer characteristics from this straight line; or it can be a straight line passing through the end points of the transfer characteristic after they have been calibrated (sometimes referred to as "end-point" linearity). End-point linearity error is similar to *relative accuracy* error.

For multiplying D/A converters, the *analog* linearity error, at a specified digital code, is defined in the same way as for multipliers, i.e., by deviation from a "best straight line" through the plot of the analog output-input response.



a. ½LSB Nonlinearity Achieved By Arbitrary Location of "Best Straight Line".

b. Nonlinearity Reference is Straight Line Through End Points. Nonlinearity >½LSB for Curve of a.

Comparison of Linearity Criteria for 3-Bit D/A Converter. Straight Line Through End Points is Easier to Measure, Gives More Conservative Specification.

Linearity, Differential
Any two adjacent digital codes should result in measured output values that are exactly 1LSB apart (2^{-n} of full scale for an n-bit converter). Any deviation of the measured "step" from the ideal difference is called *differential nonlinearity* expressed in (sub)multiples of 1LSB. It is an important specification because a differential linearity error greater than 1LSB can lead to nonmonotonic response in a D/A converter and missed codes in an A/D converter (see *Differential Linearity* in the A/D converter section for an illustration).

Monotonic
A DAC is said to be monotonic if the output either increases or remains constant as the digital input increases with the result that the output will always be a single-valued function of the input. The specification "monotonic" (over a given temperature range) is sometimes substituted for a *differential nonlinearity* specification since differential nonlinearity less than 1LSB is a sufficient condition for monotonic behavior.

Most-Significant Bit (MSB)
In a system in which a numerical magnitude is represented by a series of binary (i.e., two-valued) digits, the MSB is that digit (or bit) that carries the largest value of weight. For example, in the natural binary number 1101 (decimal 13, or $2^3 + 2^2 + 0 + 2^0$), the leftmost "1" is the MSB with a weight of 2^{n-1}, or 8LSBs. Its analog weight, relative to a DAC's full-scale span, is 1/2. In bipolar DACs, the MSB indicates the polarity of the number represented by the rest of the bits.

Multiplying DAC
A multiplying DAC differs from a fixed-reference DAC in being designed to operate with varying (or ac) reference signals. The output signal of such a DAC is proportional to the product of the "reference" (i.e., analog input) voltage and the fractional equivalent of the digital input number (see also *four-quadrant*).

Noise, Peak and rms
Internally generated random noise is not a major factor in D/A converters, except at extreme resolutions (e.g., DAC1138) and dynamic ranges (AD7111). Random noise is characterized by rms specifications for a given bandwidth or as a spectral density (current or voltage per root hertz); if the distribution is Gaussian, the probability of peak-to-peak values exceeding 7x the rms value is less than 0.1%.

Of much greater importance in DACs is interference in the form of high-amplitude low-energy (hence low-rms) spikes appearing at the DAC's output caused by coupling of digital signals in a surprising variety of ways; they include coupling via stray capacitance, via power supplies, via inadequate ground systems, via feedthrough and by glitch generation. Their presence underscores the necessity for maximum application of the designer's art, including layout, shielding, guarding, grounding, bypassing and deglitching.

Offset
For almost all bipolar converters (e.g., ± 10-volt output), instead of actually generating negative currents to correspond to negative numbers, a unipolar DAC is used and the output is offset by half full scale (1MSB). For best results, this offset voltage or current is derived from the same reference supply that determines the gain of the converter.

This makes the zero point of the converter independent of thermal drift of the reference because the 1/2 scale offset cancels the weight of the MSB at zero, independently of the amplitude of both.

Power-Supply Sensitivity
The sensitivity of a converter to changes in the power-supply voltages is normally expressed in terms of percent-of-full-scale change in analog output value (of fractions of 1LSB) for a 1% dc change in the power supply, e.g., $0.05\%/1\%\Delta V_S$). Power supply sensitivity may also be expressed in relation to a specified dc shift of supply voltage. A converter may be considered "good" if the change in reading at full scale does not exceed ± 1/2LSB for a 3% change in power supply. Even better specs are necessary for converters designed for battery operation.

Quantizing Uncertainty (or "Error")
The analog continuum is partitioned into 2^n discrete ranges for n-bit processing. All analog values within a given range of output (of a DAC) are represented by the same digital code usually assigned to the nominal midrange value. For applications in which an analog continuum is to be restored, there is an inherent quantization uncertainty of ± 1/2LSB due to limited resolution, in addition to the actual conversion errors. For applications in which discrete output levels are desired (e.g., digitally controlled power supplies or digitally controlled gains), this consideration is not relevant.

Resolution
An n-bit binary converter should be able to provide 2^n distinct and different analog output values corresponding to the set of n-bit binary words. A converter that satisfies this criterion is said to have a *resolution* of n bits. The smallest output change that can be resolved by a linear DAC is 2^{-n} of the full-scale span. However, a nonlinear device, such as the AD7111 LOGDAC, has a logarithmic gain resolution of 0.375/88.5dB = 1:256dB which corresponds to a gain increment of 4.25%/step or 26,600:1.

Settling Time
The time required, following a prescribed data change, for the output of a DAC to reach and remain within a given fraction (usually ± 1/2LSB) of the final value. Typical prescribed changes are full scale, 1MSB and 1LSB at a major carry. Settling time of current-output DACs is quite fast. The major share of settling time of a voltage-output DAC is usually contributed by the settling time of the output op amp circuit.

Signal-to-Noise Ratio
Signal-to-Noise Ratio (SNR) is the measured signal to noise at the output of the converter. The signal is the rms magnitude of the fundamental. Noise is the rms sum of all the nonfundamental signals up to half the sampling frequency. SNR is dependent on the number of quantization levels used in the digitization process; the more levels, the smaller the quantization noise. The theoretical SNR for a sine wave is given by:

$$SNR = (6.02N + 1.76)\ dB$$

where N is the number of bits. Thus for an ideal 8-bit converter, SNR = 50dB.

Slew Rate (or Slewing Rate)
Slew rate of a device or circuit is a limitation in the rate of change of output voltage, usually imposed by some basic circuit consideration such as limited current to charge a capacitor. Amplifiers with slew rate of a few V/μs are common and moderate in cost. Slew rates greater than about 75 volts/μs are usually seen only in more sophisticated (and expensive) devices. The output slewing speed of a voltage-output D/A converter is usually limited by the slew rate of the amplifier used at its output (if one is used).

Stability
Stability of a converter usually applies to the insensitivity of its characteristics to time, temperature, etc. All measurements of stability are difficult and time consuming, but stability vs. temperature is sufficiently critical in most applications to warrant universal inclusion of temperature coefficients in tables of specifications (see "Temperature Coefficient").

Staircase
A voltage or current increasing in equal increments as a function of time and having the appearance of a staircase (in a time plot) generated by applying a pulse train to a counter and the output of the counter to the input of a DAC.

A very simple A/D converter can be built by comparing a staircase from a DAC with the unknown analog input. When the DAC output exceeds the analog input by a fraction of 1LSB, the count is stopped and the code corresponding to the count is the digital output.

Switching Time
In a DAC, the switching time is the time it takes for the switch to change from one state to the other ("delay time" plus "rise time" from 10% – 90%) but does not include settling time, e.g., to <1/2LSB.

Temperature Coefficients

In general, temperature instabilities are expressed as %/°C, ppm/°C, as fractions of 1LSB/°C or as a change in a parameter over a specified temperature range. Measurements are usually made at room temperature and at the extremes of the specified range, and the temperature coefficient (tempco, T.C.) is defined as the change in the parameter divided by the corresponding temperature change. Parameters of interest include *gain, linearity, offset* (bipolar) and *zero*.

Gain Tempco: Two factors principally affect converter gain stability with temperature.

a) In fixed-reference converters, the reference source will vary with temperature. For example, the tempco of an AD581L is generally less than 5ppm/°C.
b) The reference circuitry and switches may add another 3ppm/°C in good 12-bit converters (e.g. AD566K/T). High resolution converters require much better tempcos for accuracy commensurate with the resolution.

Linearity Tempco: Sensitivity of linearity ("integral" and/or differential linearity) to temperature (in % FSR/°C or ppm FSR/°C) over the specified range. Monotonic behavior is achieved if the differential nonlinearity is less than 1LSB at any temperature in the range of interest. The *differential nonlinearity temperature coefficient* may be expressed as a ratio, as a maximum change over a temperature range and/or implied by a statement that the device is monotonic over the specified temperature range.

Offset Tempco: The temperature coefficient of the all-DAC-switches-off (minus full scale) point of a bipolar converter (in % FSR/°C or ppm FSR/°C) depends on three major factors:

a) The tempco of the reference source
b) The voltage zero-stability of the output amplifier
c) The tracking capability of the bipolar-offset resistors and the gain resistors

Unipolar Zero Tempco (in % FSR/°C or ppm FSR/°C): The temperature stability of a unipolar fixed-reference DAC is principally affected by current leakage (current-output DAC) and offset voltage and bias current of the output op amp (voltage-output DAC).

Total Unadjusted Error

Total unadjusted error is a comprehensive specification which includes internal voltage reference error, relative accuracy, gain and offset errors.

Zero- and Gain-Adjustment Principles

The output of a unipolar DAC is set to zero volts in the all-bits-off condition. The gain is set for F.S.$(1 - 2^{-n})$ with all bits on. The "zero" of an offset-binary bipolar DAC is set to $-$F.S. with all bits off, and the gain is set for $+$F.S.$(1 - 2^{-(n-1)})$ with all bits on. The data sheet instructions should be followed.

ANALOG DEVICES

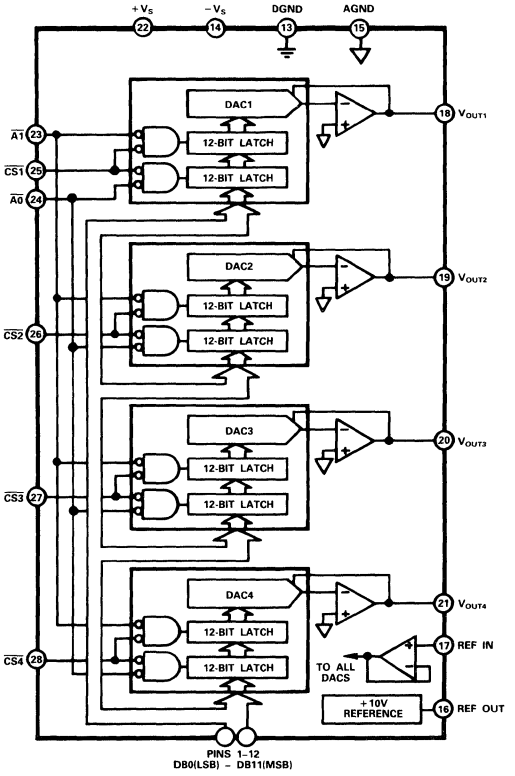
Quad 12-Bit Microprocessor-Compatible D/A Converter

AD390*

FEATURES

Four Complete 12-Bit DACs in One IC Package
Linearity Error ±1/2LSB T_{min} – T_{max} (AD390K, T)
Factory-Trimmed Gain and Offset
Buffered Voltage Output
Monotonicity Guaranteed Over Full Temperature Range
Double-Buffered Data Latches
Includes Reference and Buffer
Fast Settling: 8μs max to ±1/2LSB

AD390 FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD390 contains four 12-bit high speed voltage-output digital-to-analog converters in a compact 28-pin hybrid package. The design is based on a proprietary latched 12-bit DAC chip which reduces chip count and provides high reliability. The AD390 is ideal for systems requiring digital control of many analog voltages where board space is at a premium. Such applications include automatic test equipment, process controllers, and vector-scan displays.

The AD390 is laser-trimmed to ±1/2LSB max nonlinearity (AD390KD, TD) and absolute accuracy of ±0.05 percent of full scale. The high initial accuracy is made possible by the use of thin-film scaling resistors on the monolithic DAC chips. The internal buried zener voltage reference provides excellent temperature drift characteristics (20ppm/°C) and an initial tolerance of ±0.03% maximum. The internal reference buffer allows a single common reference to be used for multiple AD390 devices in large systems.

The individual DACs are accessed by the $\overline{CS1}$ through $\overline{CS4}$ control inputs and the $\overline{A0}$ and $\overline{A1}$ lines. These control signals permit the registers of the four DACs to be loaded sequentially and the outputs to be simultaneously updated.

The AD390 outputs are calibrated for a ±10V output range with positive-true offset binary input coding. A 0 to +10V version is available on special order.

The AD390 is packaged in a 28-lead ceramic package and is specified for operation over the 0 to +70°C and −55°C to +125°C temperature range.

PRODUCT HIGHLIGHTS

1. The AD390 offers a dramatic reduction in printed circuit board space requirements in systems using multiple DACs.
2. Each DAC is independently addressable, providing a versatile control architecture for simple interface to microprocessors. All latch enable signals are level-triggered.
3. The output voltage is trimmed to a full scale accuracy of ±0.05%. Settling time to ±1/2LSB is 8 microseconds maximum.
4. An internal 10 volt reference is available or an external reference can be used. With an external reference, the AD390 gain TC is ±5ppm/°C maximum.
5. The proprietary monolithic DAC chips provide excellent linearity and guaranteed monotonicity over the full operating temperature range.
6. The 28-pin double-width hybrid package provides extremely high functional density. No external components or adjustments are required to provide the complete function.
7. The AD390SD and AD390TD feature guaranteed accuracy and linearity over the −55°C to +125°C temperature range.

NOTES

[1]Timing specifications appear in Table II.

[2]The AD390 outputs are guaranteed stable for load capacitances up to 300pF.

[3] ± 10V range is standard. A 0 to 10V version is also available. To order, use the following part numbers:

AD50207-1	J Grade
AD50207-2	K Grade
AD50207-3	S Grade
AD50207-4	T Grade
AD50207-7	S/883B Grade
AD50207-8	T/883B Grade

[4]FSR means Full Scale Range and is equal to 20V for a ± 10V range.

[5]Crosstalk is defined as the change in any one output as a result of any other output being driven from − 10V to + 10V into a 2kΩ load.

[6]The AD390 can be used with supply voltage as low as ± 11.4V, Figure 10.

Specifications subject to change without notice.

Digital Circuit Details

DATA AND CONTROL SIGNAL FORMAT

The AD390 accepts 12-bit parallel data in response to control signals $\overline{CS1}$-$\overline{CS4}$, $\overline{A0}$ and $\overline{A1}$ The input registers are double-buffered, allowing any register to be updated independently of the others. As detailed in Table I, the four chip select lines are used to address the DAC register of interest. It is permissible to have more than one chip select active at any time. The first rank register of a given DAC is loaded by bringing the appropriate chip select and $\overline{A0}$ both low. The second rank register of any DAC can then be loaded by bringing the appropriate chip select $\overline{A1}$ both low. If $\overline{CS1}$-$\overline{CS4}$ are all brought low coincident with $\overline{A1}$ low, all four DAC outputs will be updated to the value in the corresponding first rank register. All control inputs are level-triggered and may be hard-wired low to render any register (or group of registers) transparent.

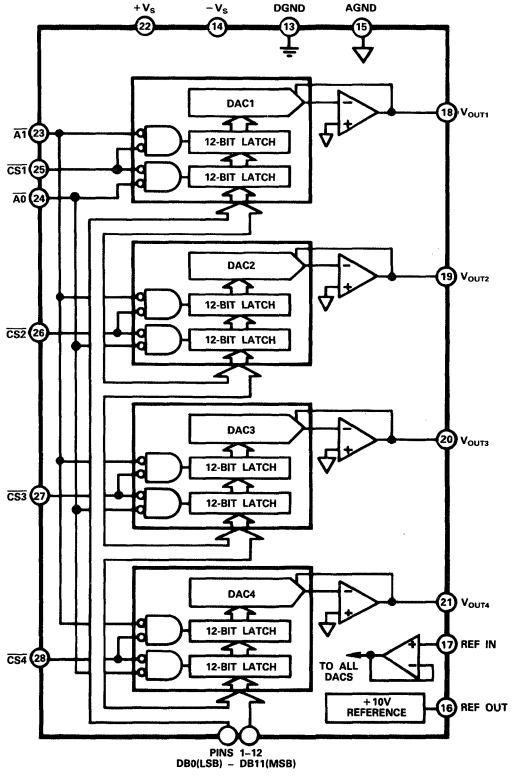

Figure 1. AD390 Functional Block Diagram

$\overline{CS1}$	$\overline{CS2}$	$\overline{CS3}$	$\overline{CS4}$	$\overline{A1}$	$\overline{A0}$	Operation

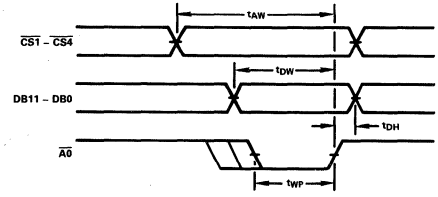
Table I. AD390 Truth Table

TIMING

The AD390 control signal timing is fairly straightforward. $\overline{A0}$, $\overline{A1}$ and $\overline{CS1}$-$\overline{CS4}$ must be concurrently valid for at least 100ns for a desired operation to occur. When loading data from a bus into the first rank register, the data inputs must be stable for at least 50ns before any control signal returns high. Data can change immediately after the control signals are inactive. When loading the second rank registers from the first rank, it is possible to exercise the chip select inputs at the same time as $\overline{A1}$. DAC settling time is measured from the falling edge of whichever control signal last becomes valid.

WRITE CYCLE #1
(Load First Rank from Data Bus; $\overline{A1}$ = 1)



WRITE CYCLE #2
(Load Second Rank from First Rank; $\overline{A0}$ = 1)

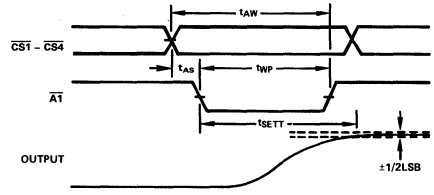


Figure 2. Timing Diagrams

Symbol	Parameter	Min	Typ	Max	Units

Table II. AD390 Timing Specifications

INTERFACING THE AD390 TO MICROPROCESSORS

The AD390 control logic provides simple interface to microprocessors. The latches are fast enough to operate with even the fastest processors.

16-Bit Processors

The AD390 is a 12-bit resolution DAC system and is easily interfaced to 16-bit wide data buses. Several possible addressing configurations exist.

In the circuit of Figure 3, the AD390 second rank registers are made transparent by hard-wiring $\overline{A1}$ low. A system $\overline{WR}$ signal is used to drive the $\overline{A0}$ control input and a 74LS138 decoder driven from the least significant address bits provides the active-low $\overline{CS1}$ through $\overline{CS4}$ signals. In this circuit, only one DAC at a time may be updated. If simultaneous update of all four DACs is required, a slightly different addressing scheme is used. The circuit shown in Figure 4 allows selection of either register of any DAC at the expense of larger memory space requirements. In this circuit, address lines A0 through A3 each select a single DAC of the four contained in the AD390. The use of a separate address line for each DAC allows several DACs to be accessed

simultaneously. The address lines are gated by the simultaneous occurrence of a system $\overline{WR}$ and the appropriately decoded base address. Selection of first rank or second rank register for any DAC is done by using two additional address bits. The AD390 thus occupies a block of 64 memory word locations but offers considerable flexibility in DAC updating.

In this addressing scheme, the A5 and A4 lines divide the 64 locations into 4 blocks. When both A5 and A4 are high, no operation occurs. When A5 and A4 are both low, data written into any one of the DACs (selected by A3-A0) will immediately update that analog output. In the address block where A4 is low and A5 is high, data is written into the first rank register of the selected DAC (or DACs). When A5 is low and A4 is high, data previously written into the first rank register of the selected DAC is transferred to the second rank register, which updates the analog output. It is particularly useful to perform a $\overline{WR}$ operation with A5 low, A4 high, and A3 through A0 all low (base address plus 32) since this action will cause all four DAC outputs to be simultaneously updated to the values previously written into the first rank registers.

In both addressing schemes shown, A0 represents the least significant *word address* bit. In most 16-bit systems this will be the A1 address line. Data may reside in either the 12MSBs (left-justified) or the lower 12 bits (right-justified). Left justification is useful when the data word represents a binary fraction of full scale, while right-justified data usually represents an integer value between 0 and 4095.

8-Bit Processors

Since the AD390 is designed to accept data in 12-bit words, an external latch is required in order to interface with 8-bit buses. Thus each DAC in the AD390 occupies 2 memory locations. The choice of data format is similar to the choice in the 16-bit bus interface. The data can either be right-justified (one byte contains the 8LSBs and another the 4MSBs in the bottom half of the byte) or left-justified (where one byte contains the 8MSBs and another the 4LSBs in the top half of the byte). The addressing scheme illustrated in Figure 6 allows 12-bit data to be sent to the first rank register of any DAC in a right-justified format. The first rank register of DAC occupies two memory locations–a write to the even (A0 low) address stores the 4MSBs of the DAC data in a 74LS173 quad latch. When the 8LSBs are written to the odd address (A0 = 1), the eight bits present on the data bus and the four bits held in the 74LS173 are strobed into the first rank register of the selected DAC. Address bits A1 through A4 select the DAC to be addressed, while A6 and A5 enable either the first or second rank register (or both) as in the 16-bit interface of Figure 4.

Analog Circuit Details

REFERENCE CONNECTIONS

The AD390 is equipped with a precision internal reference voltage of 10.00 volts, trimmed to within ±3 millivolts. This reference is available for external use and can typically supply up to 3.5 milliamps of output current. In normal operation, this reference is connected to pin 17 (REF IN), which establishes the ±10 volt output scale. The internal reference is sufficiently accurate for most applications, however, if a master system reference is available, or if a range other than ±10V (±10.24V, for example) is desired, an external reference may be used. It is recommended that the reference used with the AD390 be at least 5 volts and at most 11 volts to preserve specified linearity.

Digital Input Code	Analog Output Voltage	
0000 0000 0000	−10.000V	− Full Scale
0100 0000 0000	−5.000V	− 1/2 Scale
1000 0000 0000	0.000V	Zero
1000 0000 0001	+4.88mV	+1LSB
1100 0000 0000	+5.000V	+ 1/2 Scale
1111 1111 1111	+9.9951V	+ Full Scale − 1LSB

Table III. AD390 Analog Output vs. Digital Input (±V Scale)

GROUNDING RULES

The AD390 includes two ground connections in order to minimize system accuracy degradation arising from grounding errors. The two ground pins are designated DGND (pin 13) and AGND (pin 15). The DGND pin is the return for the supply currents of the AD390, and serves as the reference point for the digital input thresholds. Thus DGND should be connected to the same ground as the digital circuitry which drives the AD390.

Pin 15, AGND, is the high quality analog ground connection. This pin should serve as the reference point for all analog circuitry which follows the AD390. It is recommended that any analog signal path carrying significant currents have its own return connection to pin 15 as shown in Figure 7.

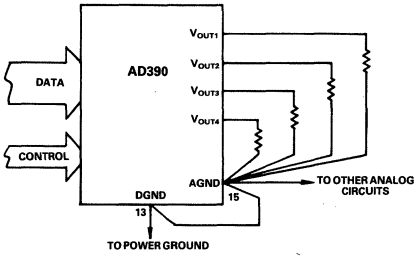

Figure 7. Recommended Ground Connections

Several complications arise in practical systems, particularly if the load is referred to a remote ground. These complications include dc gain errors due to wiring resistance between DAC and load, noise due to currents from other circuits flowing in power ground return impedances, and offsets due to multiple load currents sharing the same signal ground returns. While the AD390 outputs are accurately developed between the output pin and pin 15 (AGND), delivering these signals to remote loads can be a problem. These problems are compounded if a current booster stage is used, or if multiple AD390 packages are used. Figure 8 illustrates the parasitic impedances which influence output accuracy.

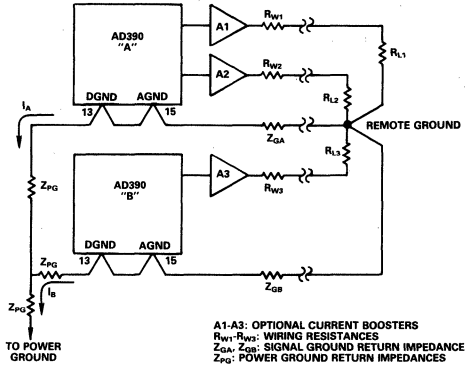

Figure 8. Grounding Errors in Multiple-AD390 Systems

An output buffer configured as a subtractor as shown in Figure 9 can greatly reduce these errors. First, the effects of voltage drops in wiring resistances is eliminated by sensing the voltage directly at the load with R4. The voltage drops caused by currents flowing through Z_{GA} are eliminated by sensing the remote ground directly with R3. Resistors R1 through R4 should be well matched in order to achieve maximum rejection of the voltage appearing across Z_{GA}. Resistors matched to within one percent (including the effects of R_{W2} and R_{W3}) will reduce ground interaction errors by a factor of 100.

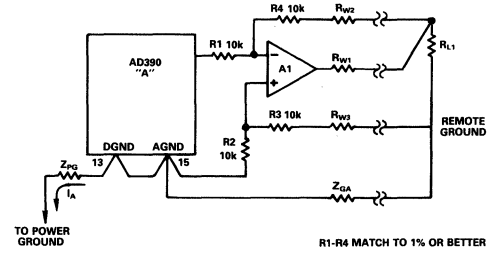

Figure 9. Use of Subtractor Amplifier to Preserve Accuracy

POWER SUPPLY DECOUPLING

The power supplies used with the AD390 should be well filtered and regulated. Local supply decoupling consisting of a 10μF tantalum capacitor in parallel with 0.1μF ceramic is suggested. The decoupling capacitors should be connected between the AD390 supply pins and the load ground (ideally the AGND pin). If an output booster is used, its supplies should also be decoupled to the load ground.

OPERATION FROM ±12 VOLT SUPPLIES

The AD390 may be used with ±12 volt ±5% power supplies if certain conditions are met. The most important limitation is the output swing available from the output op amps. These amplifiers are capable of swinging only as far as 3 volts from either supply. Thus, the normal ±10 volt output range cannot be used. Changing the output scale is accomplished by changing the reference voltage. With a supply of ±11.4 volts (5% less than ±12V), the output range is restricted to a maximum ±8.4V swing. It may be useful to scale the output at ±8.192 volts (yielding a scale factor of 4 millivolts per LSB). The required 8.192V reference can be derived from a precision, low TC divider from the internal +10.000V reference. The only restriction is that the total load resistance presented to the +10.000V reference output must be at least 10kΩ for −55°C to +125°C temperature range 12 volt applications. Figure 10 shows a suggested circuit to set up a ±8.192V output range. Multiple AD390 units can share the same resistive divider-generated reference since the REF IN terminal is very high impedance.

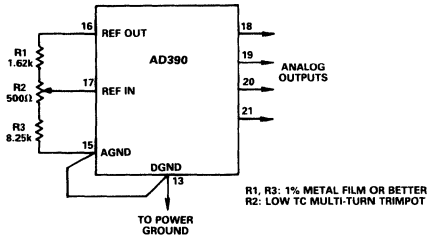

Figure 10. Connections for ±8.192V Full Scale (Recommended for ±12V Power Supplies)

IMPROVING FULL-SCALE STABILITY

In large systems using multiple AD390s, it may be desirable for all devices to share a common reference. While it is possible to use the reference output for one device to provide a reference for all devices, use of an external precision reference can greatly improve system accuracy and temperature stability. The external reference should be at least +5V and at most +11V to preserve DAC linearity.

The AD2710 is a suitable reference source for such systems. It features a guaranteed maximum temperature coefficient of ±1ppm/°C, compared with the 10 to 20ppm/°C drift of the AD390 internal reference. The combination of the AD2710LN and AD390KD shown in Figure 11 will yield a multiple-DAC system with maximum full-scale drift of ±6ppm/°C and excellent tracking.

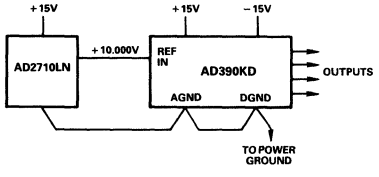

Figure 11. Low Drift AD390 Configuration

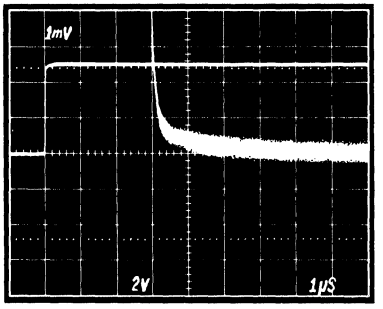
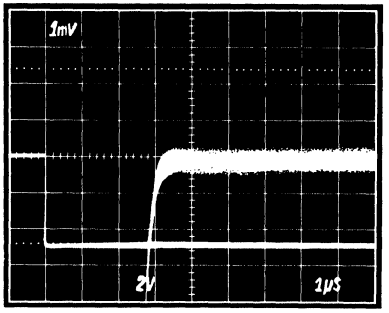
OUTPUT CURRENT BOOSTING

The output amplifiers used in the AD390 are capable of supplying a ±10 volt swing into a resistive load of 2kΩ or greater. Stability is guaranteed for load capacitance up to 300pF. Larger load capacitance may cause severe overshoot and possible oscillation. The settling characteristic of the AD390 output amplifier is shown in Figure 12.



a. All Bits OFF-to-ON



b. All Bits ON-to-OFF

Figure 12. AD390 Settling Characteristic

In many applications, including automatic test equipment, the load presented to the AD390 may be less than 2kΩ or include large capacitance. In such cases, it is advisable to use a buffer amplifier capable of delivering rated output to the most severe load anticipated. The AD382, for example, can supply ±10V into a 200Ω load and the AD3554 is suitable for load resistances down to 100Ω. In applications where errors due to output boosting must be minimized, the composite amplifier shown in Figure 13 provides excellent dc stability as well as 100mA output drive capability.

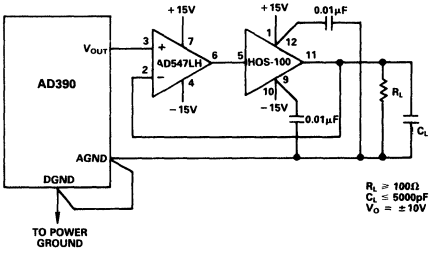


Figure 13. Composite Amplifier for Increased Output Drive

APPLICATIONS

The functional density of the AD390 permits complex analog functions to be produced under digital control, where board space requirements would otherwise be prohibitive. Multiple-output plotters, multi-channel displays and complex waveform generation and multiple programmable voltage sources can all be implemented with the AD390 in a fraction of the space which would be needed if separate DACs were used.

PROGRAMMABLE WINDOW COMPARATOR

The AD390 can be used to perform limit testing of responses to digitally-controlled input signals. For example, two DACs may be used to generate software-controlled test conditions for a component or circuit. The response to these input conditions can either be completely converted from analog to digital or simply tested against high and low limits generated by the two remaining DACs in the AD390.

In the circuit of Figure 14 two AD311 voltage comparators are used with an AD390 to test the output of a 5 volt power supply regulator. The AD390 V_{OUT1} output (through an appropriate current booster) drives the input to the regulator to simulate variations in input voltage. The output of the regulator is applied to comparators 1 and 2, with their outputs wire-ORed with LED indicators as shown. The test limits for each comparator are programmed by the AD390 V_{OUT2} and V_{OUT3} outputs. When the output of the device under test is within the limits, both comparators are off and D1 lights. If the output is above or below the limits, either D4 or D5 lights.

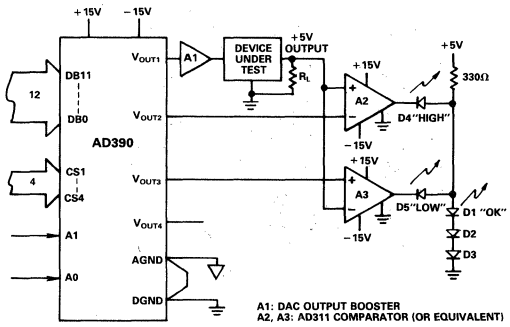

Figure 14. Programmable Window Comparator Used In Power Supply Testing

USING THE AD390 FOR ANALOG-TO-DIGITAL CONVERSION

Many systems require both analog output and analog input capability. While complete integrated circuit analog-to-digital converters (such as the AD574A) are readily available, the AD390 can be used as the precision analog section of an ADC if some external logic is available. Several types of analog-to-digital converters can be built with a DAC, comparator, and control logic, including staircase, tracking, and successive-approximation types. In systems which include a microprocessor, only a comparator must be added to the AD390 to accomplish the ADC function since the processor can perform the required digital operations under software control. A suitable circuit is shown in Figure 15. The AD311 comparator compares the unknown input voltage to one of the AD390 outputs for the analog-to-digital conversion, while the other three outputs are used as normal DACs. The diode clamp shown limits the voltage swing at the comparator input and improves conversion speed. With careful layout, a new comparison can be performed in less than 10 microseconds, resulting in 12-bit successive approximation conversion in under 120 microseconds. The benefit of the AD390 in this application is that one ADC and three DACs can be implemented with only two IC packages (the AD390 and the comparator).

ANALOG DEVICES

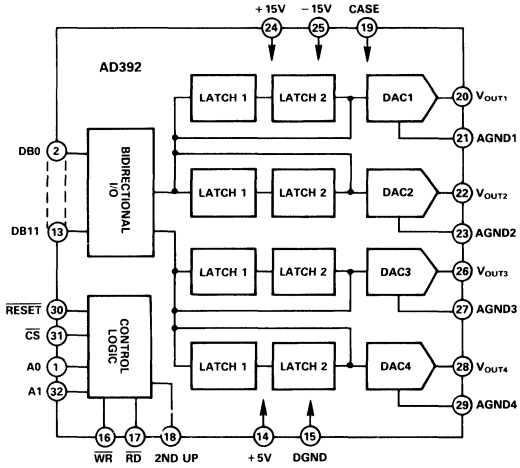
Complete Quad 12-Bit D/A Converter with Readback

AD392

FEATURES

- **Data Readback Capability**
- **Four Complete, Voltage Output, 12-Bit DACs in One 32-Pin Hermetic Package**
- **Fast Bus Access: 40ns max, T_{min}-T_{max}**
- **Asynchronous Reset to Zero Volts**
- **Minimum of Two TTL Load Drive (Readback Mode)**
- **Double-Buffered Data Latches**
- **Monotonicity Guaranteed T_{min}-T_{max}**
- **Linearity Error ±1/2LSB**
- **Low Digital-to-Analog Feedthrough, 2nV·sec typ**
- **Factory Trimmed Gain and Offset**
- **Low Cost**

AD392 FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD392 is a quad 12-bit, high speed, voltage output digital-to-analog converter with readback in a 32-pin hermetically sealed package. The design is based on a custom IC interface to complete 12-bit DAC chips which reduces chip count and provides high reliability. The AD392 is ideal for systems requiring digital control of many analog voltages and for the monitoring of these analog voltages especially where board space is a premium. Such applications include ATE, robotics, process controllers and precision filters.

Featuring maximum access time of 40ns, the AD392 is capable of interfacing to the fastest of microprocessors. The readback capability provides a diagnostic check between the data sent from the microprocessor and the actual data received and transferred to the DAC. When $\overline{\text{RESET}}$ is low, all four DACs are simultaneously set to (bipolar) zero providing a known starting point.

The AD392 is laser-trimmed to ±1/2LSB integral linearity and ±1LSB max differential linearity at +25°C. Monotonicity is guaranteed over the full operating temperature range. The high initial accuracy and stability over temperature are made possible by the use of precision thin-film resistors.

The individual DAC registers are accessed by the address lines A0 and A1 and control lines $\overline{\text{CS}}$ and 2ND UP. These control signals permit the registers of the four DACs to be loaded sequentially and the outputs to be simultaneously updated.

The AD392 outputs are calibrated for a ±10V output range with positive true offset binary input coding.

The AD392 is packaged in a 32-lead metal platform DIP and is hermetically sealed. The AD392 is specified for operation over the 0 to +70°C temperature range.

PRODUCT HIGHLIGHTS

1. The AD392 is packaged in a 32-pin DIP and is a complete solution to space constraint multiple DAC applications.
2. Readback capability provides system monitor of DAC output useful in ATE, robotics or any closed-loop system.
3. Fast bus access time of 40ns maximum allows for fast system updating compatible with high speed microprocessing.
4. Simultaneous reset to zero volts output is extremely useful for system calibration or simply when all DAC outputs must initially start at zero volts.
5. Readback drive capability of two TTL loads virtually eliminates the need to buffer.
6. Each DAC is independently addressable, providing a versatile control architecture for simple interface to microprocessors.
7. Monolithic DAC chips provide excellent linearity and guaranteed monotonicity over the full operating temperature range.
8. Low digital-to-analog feedthrough (2nV·sec typ) is maintained to assure DAC accuracy.

SPECIFICATIONS (V_{CC} = +15V, V_{EE} = −15V, V_{DD} = +5V, T_A +25°C, unless otherwise specified)

Parameter	AD392 Min	AD392 Typ	AD392 Max	Units	Comments

NOTES
[1] V_{OUT} = V_{DD} or DGND.
[2] Referenced to trailing rising edge of $\overline{WR}$.
[3] Digital-to-Analog Glitch Impulse: This is a measure of the amount of charge injected from the digital inputs to the analog outputs when the inputs change state. Specified as the area of the glitch in nV-secs.
[4] Crosstalk is defined as the change in any one output as a result of any other output being driven from −10V to +10V into a 2kΩ load.
[5] θ_{JC} approximately 10°C/W.
[6] $+V_{CC}$, $+V_{DD}$, $-V_{EE}$ are ±10%.

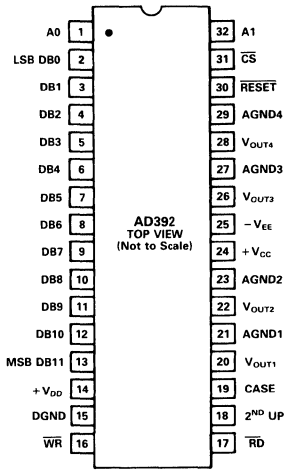
Specifications subject to change without notice.

ABSOLUTE MAXIMUM RATINGS*

$+V_{CC}$ to AGND (Any DAC) . . . . . 0 to +18V
$-V_{EE}$ to AGND (Any DAC) . . . . . 0 to −18V
$+V_{DD}$ to DGND . . . . . −0.3V to +7V
Digital Inputs to DGND
(Pins 1-13, 16-18, 30-32) . . . . . −0.3V to +7V
Analog Outputs (Pins 20, 22, 26, 28)
Short Circuit Duration . . . . . Indefinite
($+V_{CC}$, $-V_{EE}$ or AGND)
Storage Temperature . . . . . −65°C to +150°C

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stess rating only and functional operation at or above this specification is not implied. Exposure to above maximum rating conditions for extended periods may affect device reliability.

PIN CONFIGURATION



2

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

Model	Temperature Range	Gain Error	Linearity Error T_{min}-T_{max}	Package Option*
AD392JV	0 to +70°C	±4LSB	±1LSB	DH-32A

*See Section 14 for package outline information.

Theory of Operation

The AD392 is a quad 12-bit digital-to-analog converter with readback capability. The analog portion of the AD392 includes four bipolar process digital-to-analog converters. Each DAC contains current steering switches and a resistor ladder network which is laser-wafer trimmed for 12-bit accuracy. A precision output amplifier for voltage out operation and an internal highly stable voltage reference are all integrated on a single chip. The DAC is fixed to run in bipolar, 20V span analog output mode as shown in Table I.

Data Input			Analog Output	Analog Output Voltage	
1111	1111	1111	$+1\cdot(V_{REFIN})\left\{\frac{2047}{2048}\right\}$	+9.9951V	+Full Scale − 1LSB
1100	0000	0000	$+1\cdot(V_{REFIN})\left\{\frac{1024}{2048}\right\}$	+5.000V	+1/2 Scale
1000	0000	0001	$+1\cdot(V_{REFIN})\left\{\frac{1}{2048}\right\}$	+4.88mV	+1LSB
1000	0000	0000	$+1\cdot(V_{REFIN})\left\{\frac{0}{2048}\right\}$	+0.000V	Zero
0111	1111	1111	$-1\cdot(V_{REFIN})\left\{\frac{1}{2048}\right\}$	−4.88mV	−1LSB
0100	0000	0000	$-1\cdot(V_{REFIN})\left\{\frac{1024}{2048}\right\}$	−5.000V	−1/2 Scale
0000	0000	0000	$-1\cdot(V_{REFIN})\left\{\frac{2048}{2048}\right\}$	−10.000V	−Full Scale

Table I. AD392 Bipolar Code Table.

The digital portion of the AD392 includes the readback function, control logic and registers all integrated on a custom IC. Data can be latched into any one of the first rank registers by selecting the correct combination of address lines (A0 and A1) and $\overline{CS}$. The second rank registers are controlled by the 2ND UP control line. Use of the 2ND UP line enables the DACs to be updated simultaneously. The digital word can be readback from the second rank registers by asserting the correct address lines, 2ND UP and $\overline{RD}$ command. The $\overline{RD}$ and $\overline{WR}$ commands control the bidirectional I/O port. The AD392 features a $\overline{RESET}$ command for simultaneous update of all DACs to 0 volts out. This is useful for easy system calibration.

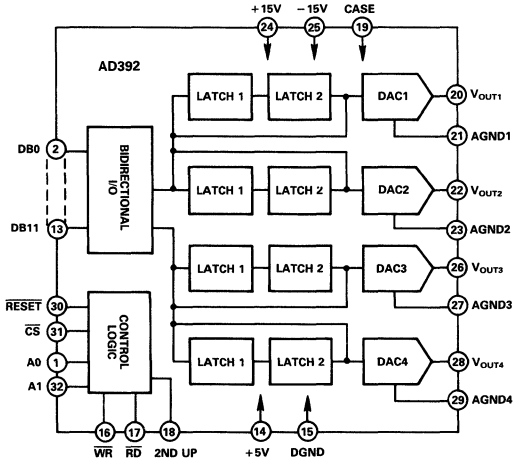

Figure 1. AD392 Block Diagram

DATA AND CONTROL SIGNAL FORMAT

The double buffered registers of the AD392 are addressed by the $\overline{CS}$, A1 and A0 lines. Each rank of registers is 12 bits wide and is presented in a straight offset binary notation. The first rank of registers are loaded sequentially, with valid $\overline{CS}$, A1, A0 on the trailing rising edge of $\overline{WR}$. The second rank of registers, on the other hand, are loaded simultaneously with the data which is in their corresponding first rank registers, with a valid $\overline{CS}$ and positive pulse of the 2ND UP command. (Note: All second rank registers can be made transparent by tieing the 2ND UP line to a Logic "1".) The data loaded into the second rank registers represents the actual digital code which is on the input of the individual DACs. This data can be read back through the data port, with valid $\overline{CS}$, A1 and A0, by taking the $\overline{RD}$ line to a Logic "0". The AD392 also features an asyncronous reset to zero volts for all four DACs by applying a negative pulse to the $\overline{RESET}$ line. Executing a reset replaces the contents of both ranks of registers with the bipolar zero code (MSB equals Logic "1", all other bits equal Logic "0".)

$\overline{CS}$	A1	A0	$\overline{WR}$	$\overline{RD}$	$\overline{RESET}$	2ND Up	Output
1	X	X	X	X	1	X	Chip Read/Write Disable
X	X	X	X	X	0	X	MSBs Go to 1, All Others Go to 0
0	X	X	X	X	1	1	All 2ND Rank Latches Transparent
0	X	X	X	X	1	0	All 2ND Rank Latches Latched
0	0	0	1	0	1	X	Read Back DAC1 2ND Rank
0	0	0	⌐	1	1	X	Write to 1ST Rank DAC1
0	0	1	1	0	1	X	Read Back DAC2 2ND Rank
0	0	1	⌐	1	1	X	Write to 1ST Rank DAC2
0	1	0	1	0	1	X	Read Back DAC3 2ND Rank
0	1	0	⌐	1	1	X	Write to 1ST Rank DAC3
0	1	1	1	0	1	X	Read Back DAC4 2ND Rank
0	1	1	⌐	1	1	X	Write to 1ST Rank DAC4

Symbols: X = Don't Care
1 = Logic High
0 = Logic Low
⌐ = Positive Trailing Edge Triggered

Table II. AD392 Truth Table

TIMING

The timing diagrams (Figures 2 and 3) illustrate the precise relationship between control signals, address signals and the data. The address lines ($\overline{CS}$, A1, A0) as well as the data (D0-D11) must be valid a minimum of 15ns before a $\overline{WR}$ is executed, and the data must remain valid a minimum of 15ns after the $\overline{WR}$ has been executed. Minimum pulse width for the $\overline{WR}$, 2ND UP and $\overline{RESET}$ commands is 15ns. Similarly, the address lines ($\overline{CS}$, A1, A0) must be valid a minimum of 15ns before a $\overline{RD}$ is executed. Data will be valid a maximum of 40ns after $\overline{RD}$ goes low. (Note: This is a MAXIMUM and, therefore, data should be off the bus just before $\overline{RD}$ goes low to avoid bus contention problems, i.e., damage to the device, data bus oscillations which may result in latching erroneous data in the registers.) Data will be off the bus a maximum of 30ns after $\overline{RD}$ goes high. (Note: This is a MAXIMUM and, therefore, the data read should be completed just before $\overline{RD}$ goes high to avoid reading erroneous data.) DAC settling time is measured from the trailing rising edge of the $\overline{WR}$ signal.

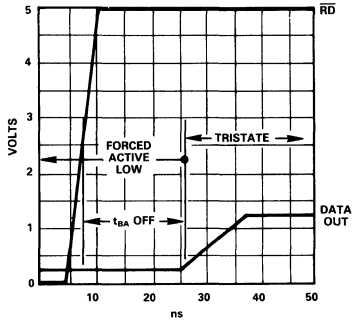

Figure 4. Typical Bus Access Off Time (t_{BA} Off)

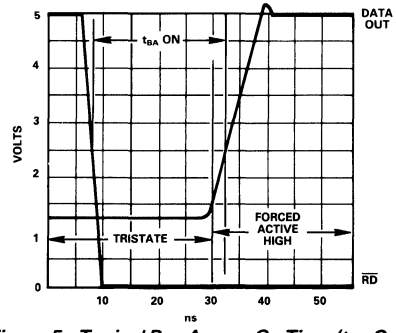

Figure 5. Typical Bus Access On Time (t_{BA} On)

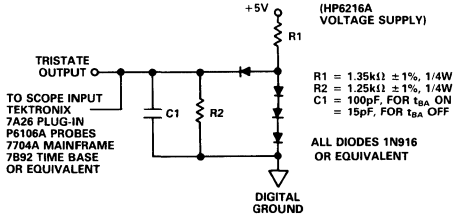

Figure 6. Standard Tristate Load Circuit

SETTLING TIME

The output amplifiers used in the AD392 are capable of supplying a ±10 volt swing into a resistive load of 2kΩ or greater. The settling characteristics of the output amplifier is shown in Figure 7. The test setup used to determine settling time is shown in Figure 8.

POWER SUPPLY DECOUPLING

The power supplies used with the AD392 should be well filtered and regulated. Internally the $+V_{CC}$ and $-V_{EE}$ supplies are independently decoupled about each DAC with 0.039μF chip capacitors to their corresponding AGND. Therefore, if the grounding scheme of Figure 9 is used, it should be sufficient to place a 4.7μF tantalum electrolytic capacitor across the $+V_{CC}$ and $-V_{EE}$ supplies. Decoupling the $+V_{DD}$ supply to DGND should be done in the same manner, however, using a parallel combination of 0.047μF ceramic and a 4.7μF tantalum electrolytic capacitor.

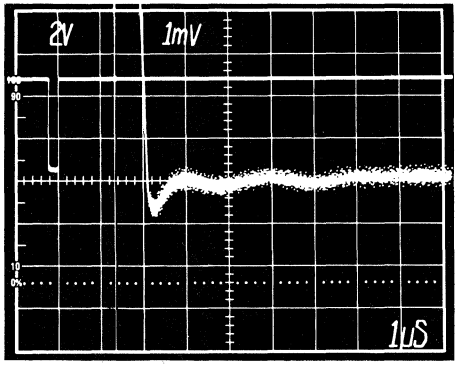

Figure 7. AD392 V_O Settling 20V Step

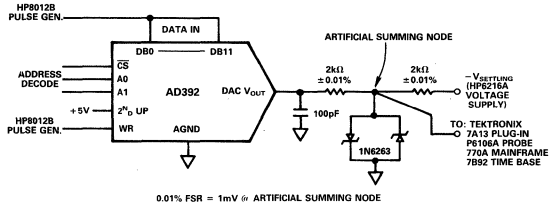

Figure 8. AD392 V_O Settling Time Circuit

GROUNDING RULES

The AD392 has been designed with four independent DAC analog grounds and a separate digital ground return pin. The analog ground pins are not only the reference points for the individual voltage outputs, they also serve as the return path for the switched DAC bit input currents. These rapidly switching currents may be as large as several milliamps for each DAC and, therefore, should be returned to a low impedance node to avoid code dependent linearity errors, digital-to-analog feed-through and crosstalk between DAC outputs. It is recommended that all four DAC analog grounds and the digital ground be tied together at the package for optimal performance. $+V_{CC}$ and $-V_{EE}$ grounds can be tied together back at the system supply and brought up to the AD392 together, whereas the $+V_{DD}$ ground is tied to the other grounds at the package and not back at the system supply. This configuration is recommended because the DAC bit input currents are sourced from the $+V_{DD}$ supply and should return by the shortest possible path and not down the analog return (see Figure 9 for details.).

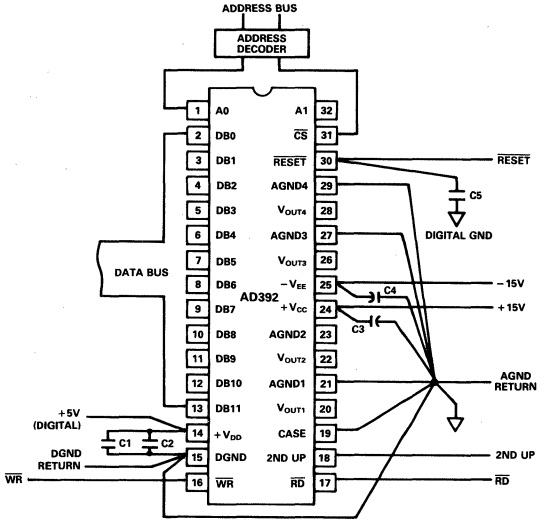

Figure 9. AD392 Recommended Circuit Schematic

CIRCUIT DETAILS

The following two suggestions are intended to aid the user in the normal operation of the AD392:

1. *Bus Termination*: The bidirectional tristateable port of the AD392 (as well as the digital inputs) should not be allowed to "float". These functions are provided by a custom CMOS integrated circuit having an input control circuit which is essentially the common gate contact of a pair of P and N channel MOS devices connected in series between the $+V_{DD}$ and DGND supply lines. An unterminated bus allows the gate potential to float to a point where both channels are partially "on" creating an ohmic path across the supply. Therefore, to avoid excessive supply current drain and possible reflections of the digital signal the bus should be terminated in its characteristic impedance to DGND.
2. *Digital Signal Integrity and the $\overline{\text{RESET}}$ line*: The AD392 has been designed to respond to extremely fast data rates and as a result must operate with a "clean" bus to ensure that valid data is being transmitted (i.e., transients on the bus that cross thresholds with sufficient duration, 5ns-10ns, may cause data to become invalid just before a $\overline{\text{WR}}$ command). If the $\overline{\text{RESET}}$ line is not connected to this "clean" bus (i.e., connected to some sort of power on reset circuitry), then it is recommended that this line be decoupled with a minimum of 1000pf capacitor to avoid an unwanted asynchronous zero volt reset on all four DACs. If this signal is not used, it should be tied to $+V_{DD}$ at the package.

ANALOG DEVICES

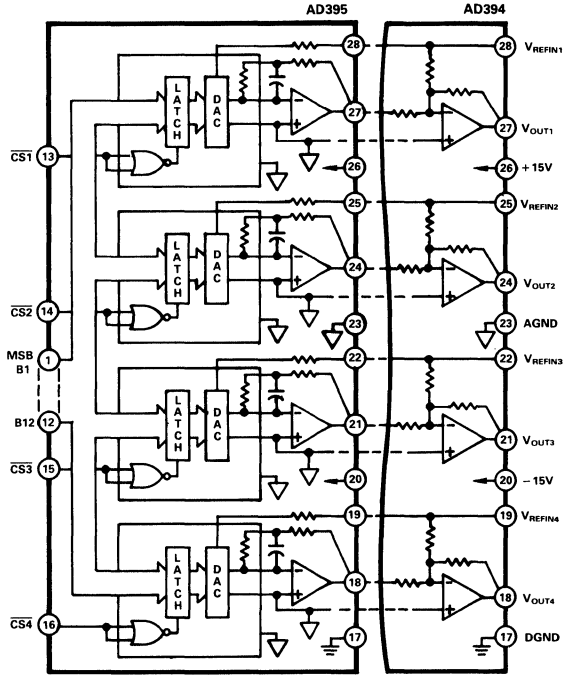
μP-Compatible Multiplying Quad 12-Bit D/A Converters

AD394/AD395

FEATURES

- **Four Complete 12-Bit CMOS DACs with Buffer Registers**
- **Linearity Error ±1/2LSB T_{min}-T_{max} (AD394, AD395K,T)**
- **Factory-Trimmed Gain and Offset**
- **Precision Output Amplifiers for V_{OUT}**
- **Full Four Quadrant Multiplication per DAC**
- **Monotonicity Guaranteed Over Full Temperature Range**
- **Fast Settling: 15μs Max to ±1/2LSB**
- **Available to MIL-STD-883 (See ADI Military Catalog)**

AD394/AD395 FUNCTIONAL BLOCK DIAGRAMS



PRODUCT DESCRIPTION

The AD394 and AD395 contain four 12-bit, high-speed, low power, voltage output multiplying digital-to-analog converters in a compact 28-pin hybrid package. The design is based on a proprietary latched 12-bit CMOS DAC chip which reduces chip count and provides high reliability. The AD394 and AD395 both are ideal for systems requiring digital control of many analog voltages where board space is at a premium and low power consumption a necessity. Such applications include automatic test equipment, process controllers, and vector stroke displays.

Both the AD394 and the AD395 are laser-trimmed to ±1/2LSB max differential and integral linearity (AD394, AD395K,T) and full scale accuracy of ±0.05 percent at 25°C. The high initial accuracy is made possible by the use of precision laser trimmed thin-film scaling resistors.

The individual DAC registers are accessed by the $\overline{CS1}$ through $\overline{CS4}$ control pins. These control signals allow any combination of the DAC select matrix to occur (see Table III). Once selected, the DAC is loaded with a single 12-bit wide word. The 12-bit parallel digital input interfaces to most 12- and 16-bit bus systems.

The AD394 outputs (V_{REFIN} = +10V) provide a ±10V bipolar output range with positive-true offset binary input coding. The AD395 outputs (V_{REFIN} = −10V) provide a 0V to +10V unipolar output range with straight binary input coding.

Both the AD394 and the AD395 are packaged in a 28-lead ceramic package and are available for operation over the 0 to +70°C and −55°C to +125°C temperature range.

PRODUCT HIGHLIGHTS

1. The AD394, AD395 offer a dramatic reduction in printed circuit board space in systems using multiple DACs.
2. The use of CMOS DACs provides low power consumption.
3. Each DAC is independently addressable, providing a versatile control architecture for simple interface to microprocessors. All latch enable signals are level-triggered.
4. The output voltage is trimmed to a full scale accuracy of ±0.05%. Settling time to ±1/2LSB is 15 microseconds maximum.
5. Maximum gain TC of 5ppm/°C is achievable by both the AD394 and the AD395.
6. The monolithic CMOS DAC chips provide excellent linearity and guaranteed monotonicity over the full operating temperature range.
7. The 28-pin double-width hybrid package provides extremely high functional density.
8. Two or four quadrant multiplication can be achieved simply by applying the appropriate input voltage signal to the selected DAC's reference (V_{REFIN}).
9. Both the AD394S,TD and AD395S,TD feature guaranteed accuracy and linearity over the −55°C to +125°C temperature range.

NOTES

[1]AD394 and AD395 S and T grades are available to MIL-STD-883, Method 5008, Class B. See Analog Devices Military Catalog (1987) for proper part number and detail specification.

[2]Timing specifications appear in Table IV and Figure 5.

[3]Code tables and graphs appear on Theory of Operation page.

[4]FSR means Full Scale Range and is equal to 20V for a ±10V bipolar range and 10V for 0 to 10V unipolar range.

[5]Integral nonlinearity is a measure of the maximum deviation from a straight line passing though the endpoints of the DAC transfer function.

[6]For AD395 (unipolar), DAC register loaded with 0000 0000 0000, V_{REFIN} = 20V p-p, 10kHz sinewave. For AD394 (bipolar), V_{REFIN} = 20V p-p, 60 and 400Hz.

[7]This is a measure of the amount of charge injected from the digital inputs to the analog outputs when the inputs change state. It is usually specified as the area of the glitch in nVs and is measured with V_{REFIN} = AGND.

[8]Digital crosstalk is defined as the change in any one output's steady state value as a result of any other output being driven from V_{OUTMIN} to V_{OUTMAX} into a 2kΩ load by means of varying the digital input code.

[9]Reference crosstalk is defined as the change in any one output as a result of any other output being driven from V_{OUTMIN} to V_{OUTMAX} @10kHz into a 2kΩ load by means of varying the amplitude of the reference signal.

[10]The AD394 and the AD395 can be used with supply voltages as low as ±11.4V, Figure 10.

ABSOLUTE MAXIMUM RATINGS*

$+V_S$ to DGND . . . . . −0.3V to +17V
$-V_S$ to DGND . . . . . +0.3V to −17V
Digital Inputs (Pins 1-16) to DGND . . . . . −0.3V to +7V
V_{REFIN} to DGND . . . . . ±25V
AGND to DGND . . . . . ±0.6V
Analog Outputs (Pins 18, 21, 24, 27)
. . . . . Indefinite Short to AGND or DGND
Momentary Short to $\pm V_S$

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

MIL-STD-883

The rigors of the military/aerospace environment, temperature extremes, humidity, mechanical stress, etc., demand the utmost in electronic circuits. The AD394, AD395, with the inherent reliability of integrated circuit construction, were designed with these applications in mind. The hermetically-sealed, low profile DIP package takes up a fraction of the space required by equivalent modular designs and protect the chips from hazardous environments. To further insure reliability, the AD394, AD395 are both fully compliant to MIL-STD-883 Class B, Method 5008.

Consult Analog Devices Military Catalog for proper ordering part number and detail specification.

Theory of Operation

The AD394 quad DAC provides four-quadrant multiplication. It is a hybrid IC comprised of four monolithic 12-bit CMOS multiplying DACs and eight precision output amplifiers. Each of the four independent-buffered channels has an independent reference input capable of accepting a separate dc or an ac signal for multiplying or for function generation applications. The CMOS DACs act as digitally programmable attenuators when used with a varying input signal or, if used with a fixed dc reference, the DAC would act as a standard bipolar output DAC. In addition, each DAC has a 12-bit wide data latch to buffer the converter when connected to a microprocessor data bus.

The AD395 quad DAC provides two-quadrant multiplication and is comprised of four 12-bit CMOS multiplying DACs and four precision output amplifiers. The two-quadrant-multiplication function arises from a straight-binary digital input multiplied by a bipolar analog input which results in two-quadrant multiplication. The AD395 can also operate as a standard unipolar DAC when a fixed dc reference is applied to V_{REFIN}.

MULTIPLYING MODE

The figures below show the transfer function for each model. The diagrams indicate an area over which many different combinations of the reference input and digital input can result in a particular analog output voltage. The highlighted transfer line in each diagram indicates the transfer function if a fixed reference is at the input. The digital codes above each diagram indicate the mid and endpoints of each function. The relationship between the reference input (V_{REFIN}) the digital input code and the analog output is given in Tables I and II below. Note that the reference input signal sets the slope of the transfer function (and determines the full scale output at code 111 . . 111) while the digital input selects the horizontal position in each diagram.

DATA AND CONTROL SIGNAL FORMAT

The AD394 and AD395 accept 12-bit parallel data in response to control signals $\overline{CS1}$-$\overline{CS4}$. As detailed in Table III, the four chip select lines are used to address the DAC register of interest. It is permissible to have more than one chip select active at any time. If $\overline{CS1}$-$\overline{CS4}$ are all brought low coincident, all four DAC outputs will be updated to the value located on the data bus. All control inputs are level-triggered and may be hard-wired low to render any register (or group of registers) transparent.

$\overline{CS1}$	$\overline{CS2}$	$\overline{CS3}$	$\overline{CS4}$	Operation
1	1	1	1	All DACs Latched
0	1	1	1	Load DAC 1 From Data Bus
1	0	1	1	Load DAC 2 From Data Bus
1	1	0	1	Load DAC 3 From Data Bus
1	1	1	0	Load DAC 4 From Data Bus
0	0	0	0	All DACs Simultaneously Loaded

Table III. DAC Select Matrix

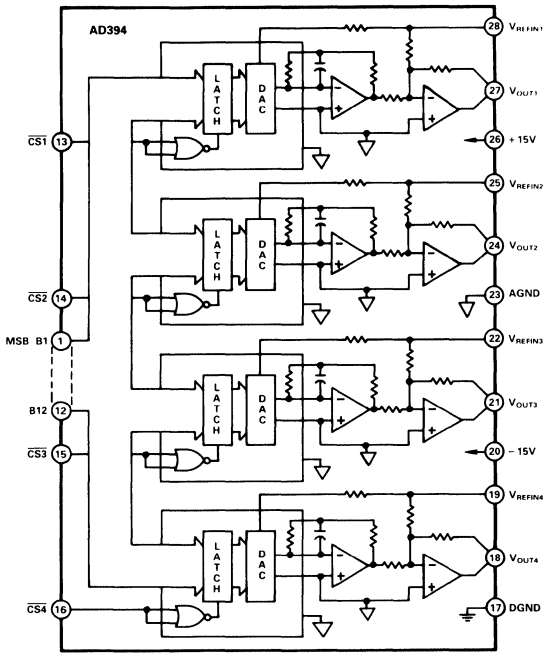

Figure 4. AD394 (Bipolar) Functional Block Diagram

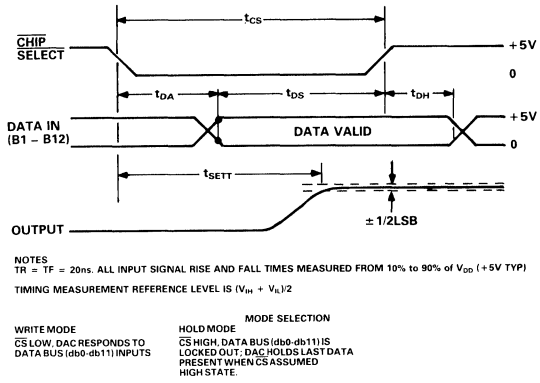
TIMING

The AD394, AD395 control signal timing is very straightforward. $\overline{CS1}$-$\overline{CS4}$ must maintain a minimum pulsewidth of at least 380ns for a desired operation to occur. When loading data from a bus into a 12-bit wide data latch, the data must be stable for at least 210ns before returning CS to a high state. When the $\overline{CS}$ is low, the data latch is transparent allowing the data at the input to propagate through to the DAC. Data can change immediately after the chip select returns high. DAC settling time is measured from the falling edge of the active chip select.

Symbol	Parameter	T_{min} to T_{max}	Units
t_{CS}	Chip Select Pulse Width	380	ns min
t_{DA}	Data Access Time	0	ns min
t_{DS}	Data Set-Up Time	210	ns min
t_{DH}	Data Hold Time	10	ns min

Table IV. AD394, AD395 Timing Specifications



NOTES
TR = TF = 20ns. ALL INPUT SIGNAL RISE AND FALL TIMES MEASURED FROM 10% to 90% of V_{DD} (+5V TYP)

TIMING MEASUREMENT REFERENCE LEVEL IS $(V_{IH} + V_{IL})/2$

MODE SELECTION

WRITE MODE	HOLD MODE
$\overline{CS}$ LOW, DAC RESPONDS TO DATA BUS (db0-db11) INPUTS	$\overline{CS}$ HIGH, DATA BUS (db0-db11) IS LOCKED OUT; DAC HOLDS LAST DATA PRESENT WHEN CS ASSUMED HIGH STATE.

Figure 5. Timing Diagram

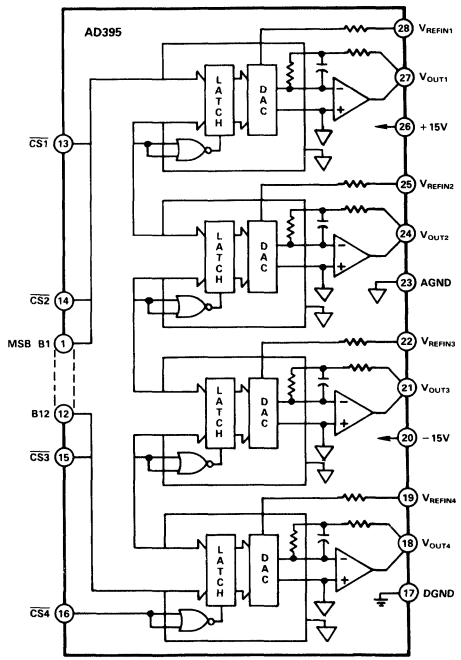


Figure 6. AD395 (Unipolar) Functional Block Diagram

Analog Circuit Details

GROUNDING RULES

The AD394 and AD395 include two ground connections in order to minimize system accuracy degradation arising from grounding errors. The two ground pins are designated DGND (pin 17) and AGND (pin 23). The DGND pin is the return for the supply currents of the AD394, AD395 and serves as the reference point for the digital input thresholds. Thus DGND should be connected to the same ground as the circuitry which drives the digital inputs.

Pin 23, AGND, is the high-quality analog ground connection. This pin should serve as the reference point for all analog circuitry associated with the AD394, AD395. It is recommended that any analog signal path carrying significant currents have its own return connection to pin 23 as shown in Figure 7.

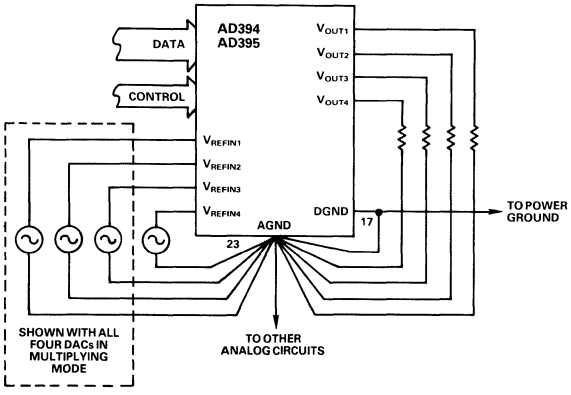

Figure 7. Recommended Ground Connections

Several complications arise in practical systems, particularly if the load is referred to a remote ground. These complications include dc gain errors due to wiring resistance between DAC and load, noise due to currents from other circuits flowing in power ground return impedances, and offsets due to multiple load currents sharing the same signal ground returns. While the DAC outputs are accurately developed between the output pin and pin 23 (AGND), delivering these signals to remote loads can be a problem. These problems are compounded if a current booster stage is used, or if multiple AD394, AD395 packages are used. Figure 8 illustrates the parasitic impedances which influence output accuracy.

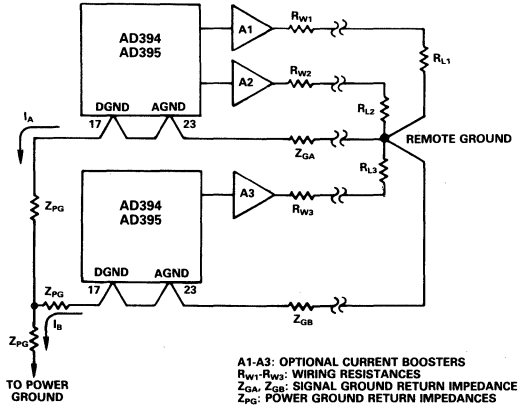

Figure 8. Grounding Errors in Multiple-AD394, AD395 Systems

An output buffer configured as a subtractor as shown in Figure 9 can greatly reduce these errors. First, the effects of voltage drops in wiring resistances is eliminated by sensing the voltage directly at the load with R4. The voltage drops caused by currents flowing through Z_{GA} are eliminated by sensing the remote ground directly with R3. Resistors R1 through R4 should be well matched in order to achieve maximum rejection of the voltage appearing across Z_{GA}. Resistors matched to within one percent (including the effects of R_{W2} and R_{W3}) will reduce ground interaction errors by a factor of 100.

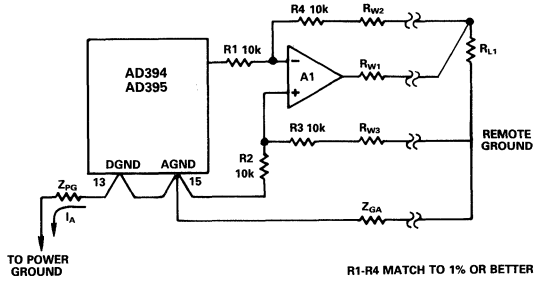

Figure 9. Use of Subtractor Amplifier to Preserve Accuracy

OPERATION FROM ±12 VOLT SUPPLIES

The AD394, AD395 may be used with ±12 volt ±5% power supplies if certain conditions are met. The most important limitation is the output swing available from the output op amps. These amplifiers are capable of swinging only as far as 3 volts from either supply. Thus, the normal ±10 volt output range cannot be used. Changing the output scale is accomplished by changing the reference voltage. With a supply of ±11.4 volts (5% less than ±12V), the output range is restricted to a maximum ±8.4V swing. It may be useful to scale the output at ±8.192 volts (yielding a scale factor of 4 millivolts per LSB).

Figure 10 shows a suggested circuit to set up a ±8.192V output range. To help prevent poor gain drift due to possible mismatch between R_{IN} and $R_{THEVENIN}$ of divider network it is recommended to buffer the potentiometer wiper voltage with an OP-07.

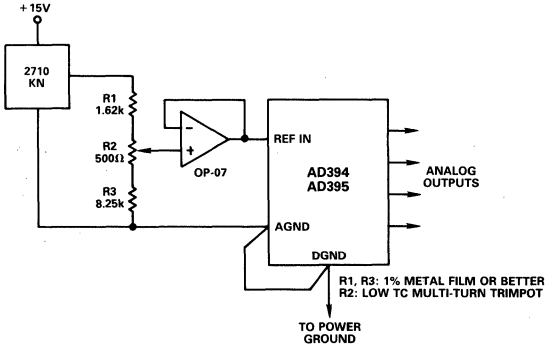

Figure 10. Connections for ±8.192V Full Scale (Recommended for ±12V Power Supplies)

POWER SUPPLY DECOUPLING

The power supplies used with the AD394, AD395 should be well filtered and regulated. Local supply decoupling consisting of a 10μF tantalum capacitor in parallel with 0.1μF ceramic is suggested. The decoupling capacitors should be connected between the AD394 supply pins and the AGND pin. If an output booster is used, its supplies should also be decoupled to the load ground.

IMPROVING FULL-SCALE STABILITY

In large systems using multiple DACs, it may be desirable for all devices to share a common reference. A precision reference can greatly improve system accuracy and temperature stability.

The AD2710 is a suitable reference source for such systems. It features a guaranteed maximum temperature coefficient of ±1ppm/°C. The combination of the AD2710LN and AD394, AD395 shown in Figure 11 will yield a multiple-DAC system with maximum full-scale drift of ±6ppm/°C and excellent tracking.

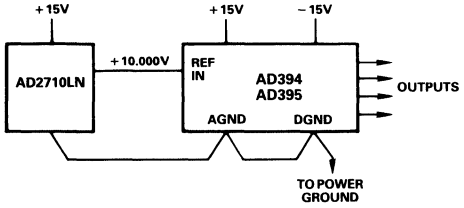

Figure 11. Low Drift AD394, AD395 Configuration

Applications

INTERFACING THE AD394, AD395 TO MICROPROCESSORS

The AD394, AD395 control logic provides simple interface to microprocessors. The individual latches allow for multi-DAC interfacing to a single data bus.

16-BIT PROCESSORS

The AD394, AD395 are 12-bit resolution DAC systems and are easily interfaced to 16-bit wide data buses. Several possible addressing configurations exist.

In the circuit of Figure 12, a system write signal is used to control the decoded address lines and a 74LS139 decoder driven from the least significant address bits provides the active-low $\overline{CS1}$ through $\overline{CS4}$ signals. In the circuit of Figure 12, address lines A0 and A1 each select a single DAC of the four contained in the AD394 or AD395. The use of a separate address line for each DAC allows several DACs to be accessed simultaneously. The address lines are gated by the simultaneous occurrence of a system $\overline{WR}$ and the appropriately decoded base address.

In the addressing scheme shown, A0 represents the least significant word address bit. Data may reside in either the 12MSBs (left-justified) or the 12LSBs (right-justified). Left justification is useful when the data word represents a binary fraction of full scale, while right-justified data usually represents an integer value between 0 and 4095.

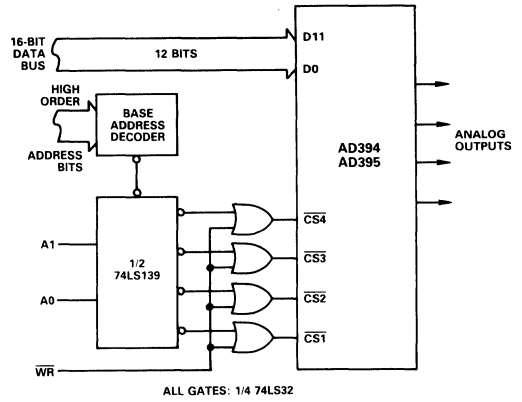

Figure 12. AD394, AD395 16-Bit Bus Interface

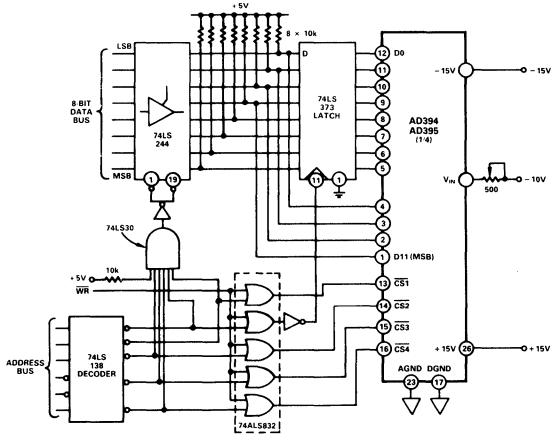
8-BIT PROCESSORS

The circuit of Figure 13 shows the general principles for connecting the AD394 or the AD395 to an 8-bit data bus. The 74LS244 buffers the data bus; its outputs are enabled when the DAC address appears on the address bus. The first byte sent to the DAC is loaded to the 74LS373 octal latch and, when the second byte is sent to the DAC, it is combined with the first byte to create a 12-bit word. The connections shown are for right-hand justified data. $\overline{CS}$ and $\overline{WR}$ inputs to the DAC are also gated, and when active, the DAC is loaded. Pull-up resistors at the output of the 74LS244 buffer ensure that the inputs to the DAC do not float at an ill-defined level when the DAC is not being addressed. This method of connecting 12-bit DACs to an 8-bit data bus is most cost effective when multiple DACs are utilized for 8-bit data bus applications.



NOTE:
UNUSED HEX INVERTER INPUTS SHOULD BE TIED LOW. ALL OTHER GATE INPUTS SHOWN SHOULD BE TIED HIGH TO +5V THROUGH A 10kΩ RESISTOR.

Figure 13. AD394, AD395 8-Bit Data Bus Interface

Applications

The functional density of the AD394 and AD395 permits complex analog functions to be produced under digital control, where board space requirements would otherwise be prohibitive. Multiple-output plotters, multi-channel displays and complex waveform generation and multiple programmable voltage sources can all be implemented with the AD394 or AD395 in a fraction of the space which would be needed if separate DACs were used.

USING THE AD394 FOR ANALOG-TO-DIGITAL CONVERSION

Many systems require both analog output and analog input capability. While complete integrated circuit analog-to-digital converters (such as the AD574A) are readily available, the AD394 can be used as the precision analog section of an ADC if some external logic is available. Several types of analog-to-digital converters can be built with a DAC, comparator, and control logic, including staircase, tracking, and successive-approximation types. In systems which include a microprocessor, only a comparator must be added to the AD394 to accomplish the ADC function since the processor can perform the required digital operations under software control. A suitable circuit is shown in Figure 14. The AD311 comparator compares the unknown input voltage to one of the AD394 outputs for the analog-to-digital conversion, while the other three outputs are used as normal DACs. The diode clamp shown limits the voltage swing at the

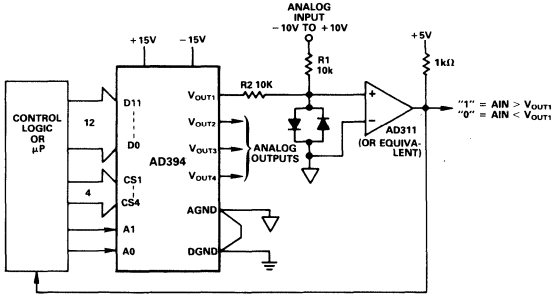


Figure 14. Using One AD394 Output for A/D Conversion

comparator input and improves conversion speed. With careful layout, a new comparison can be performed in less than 15 microseconds, resulting in 12-bit successive approximation conversion in under 180 microseconds. The benefit of the AD394 in this application is that one ADC and three DACs can be implemented with only two IC packages (the AD394 and the comparator).

PROGRAMMABLE WINDOW COMPARATOR

The AD395 can be used to perform limit testing of responses to digitally-controlled input signals. For example, two DACs may be used to generate software-controlled test conditions for a component or circuit. The response to these input conditions can either be completely converted from analog to digital or simply tested against high and low limits generated by the two remaining DACs in the AD395.

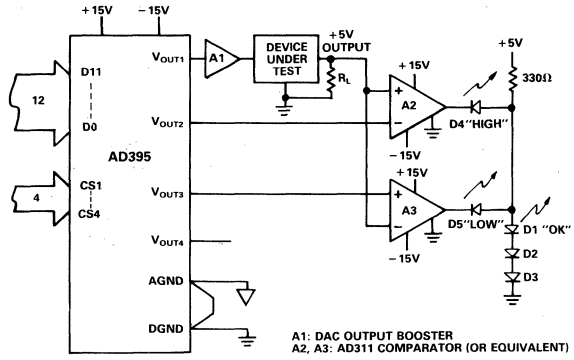

Figure 15. Programmable Window Comparator Used in Power-Supply Testing

In the circuit of Figure 15, two AD311 voltage comparators are used within AD395 to test the output of a 5 volt power-supply regulator. The AD395 V_{OUT1} output (through an appropriate current booster) drives the input to the regulator to simulate variations in input voltage. The output of the regulator is applied to comparators 1 and 2, with their outputs wire-ORed with LED indicators as shown. The test limits for each comparator are programmed by the AD395 V_{OUT2} and V_{OUT3} outputs. When the output of the device under test is within the limits, both comparators are off and D1 lights. If the output is above or below the limits, either D4 or D5 lights.

AD395 AS A MULTIPLIER AND ATTENUATOR

So far, it has been assumed that the reference voltage V_{REFIN} is fixed. In fact, V_{REFIN} can be any voltage within the range ($-11V < V_{REFIN} < +11V$). It can be negative, positive, sinusoidal or whatever the user prefers. This leads to the name "Multiplying D/A Converters" because the output voltage, V_{OUT}, is proportional to the product of the digital input word and the voltage at the V_{REFIN} terminal.

$$V_{OUT} = -1 \cdot (V_{REFIN}) \cdot \frac{D}{(4096)} \qquad (0<D<4095)$$

D is the fractional binary value of the digital word applied to the converter. The AD395 multiplies the digital input value by the analog input voltage at V_{REFIN} for any value of V_{REFIN} up to 22V p-p. This in itself is a powerful tool. Any applications requiring precision multiplication with minimal zero offset and very low distortion should consider the AD395 as a candidate. One popular use for AD395 is as a audio frequency attenuator. The audio signal is applied to the V_{REFIN} input and the attenuation code is applied to the DAC; the output voltage is the product of the two – an attenuated version of the input. The maximum attenuation range obtainable utilizing 12-bits is 4096:1 or 72db.

Monotonicity Guaranteed Over Full MIL Temp. Range
Low Power – 780mW Max
Small 28 Lead, Hermetic Double DIP Package
MIL-STD-883 Processing Available

PRODUCT DESCRIPTION

The AD396 is a high-speed microprocessor compatible Quad 14-bit digital-to-analog converter. The AD396 contains four 14-bit, low power multiplying digital-to-analog converters followed by precision voltage output amplifiers all in a compact 28-pin hybrid package. The design is based on a proprietary latched 14-bit CMOS DAC chip which reduces chip count and provides high reliability.

The AD396 (K, T) is laser-trimmed to ±1LSB max differential and integral linearity, and to full-scale accuracy of ±0.05 percent at 25°C. The high initial accuracy is made possible by the use of precision laser trimmed thin-film scaling resistors.

The individual DAC registers are accessed by the $\overline{CS1}$ through $\overline{CS4}$ control pins. These control signals allow any combination of the DAC select matrix to occur (see Table III). Once selected, the DAC is loaded with right-justified data in two bytes from an 8-bit data bus. Standard Chip Select and Memory Write logic is used to access the DACs. Address lines A0, and A1, control internal register loading and transfer.

The AD396 outputs (V_{REF} = +10V) provide a ±10V bipolar output range with positive-true offset binary input coding.

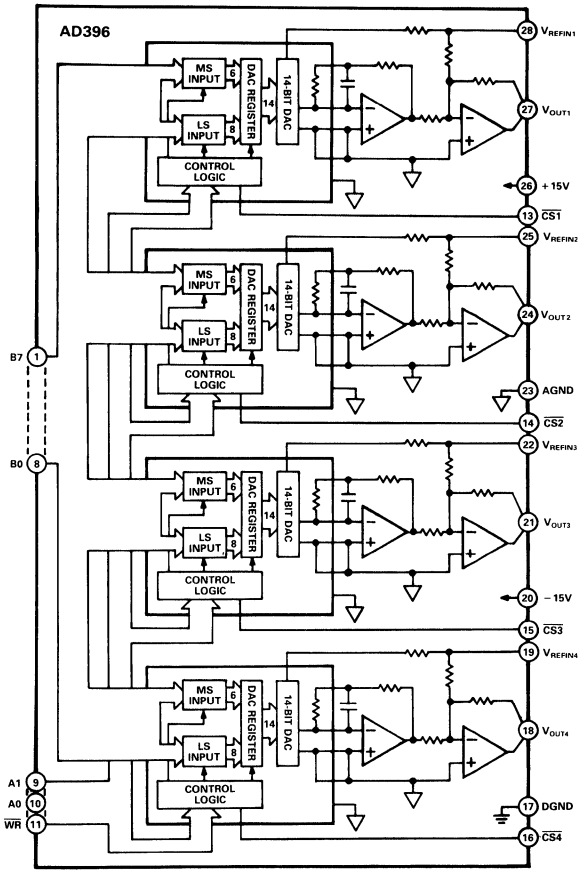
The AD396 is packaged in a 28-lead ceramic DIP package and is available for operation over the 0 to +70°C and −55°C to +125°C temperature range.

The AD396 is for systems requiring digital control of many analog voltages where board space is at a premium and low power consumption a necessity. Such applications include automatic test equipment, process controllers, and vector stroke displays.

PRODUCT HIGHLIGHTS

1. The AD396 offers a dramatic reduction in printed circuit board space in systems using multiple DACs.
2. The use of CMOS DACs provides low power consumption.
3. Each DAC is independently addressable, providing a versatile control architecture for simple interface to microprocessors. All latch enable signals are level-triggered.
4. The output voltage is trimmed to a full-scale accuracy of ±0.05%. Settling time to ±1/2LSB is 15 microseconds maximum.
5. Maximum gain TC of 5ppm/°C is achievable by the AD396.

AD396 FUNCTIONAL BLOCK DIAGRAM



6. The monolithic CMOS DAC chips provide excellent linearity and guaranteed monotonicity over the full operating temperature range.
7. The 28-pin double-width hybrid package provides extremely high functional density.
8. Four quadrant multiplication can be achieved simply by applying the appropriate input voltage signal to the selected DACs reference (V_{REFIN}).
9. The AD396S, T features guaranteed accuracy and linearity over the −55°C to +125°C temperature range.
10. MIL-STD-883 processing is available. See Analog Devices Military Data Sheet for further information.
11. Protection against power supply surges is included within the AD396.

NOTES
[1]AD396S and T grades are available to MIL-STD-883, Method 5008, Class B.
[2]Timing specifications appear in Table IV and Figure 3.
[3]Code tables and graphs appear on Theory of Operation page.
[4]FSR means Full Scale Range and is equal to 20V for a ±10V bipolar range.
[5]Integral nonlinearity is a measure of the maximum deviation from a straight line passing though the endpoints of the DAC transfer function.
[6]For AD396 (bipolar), DAC register loaded with 00 0000 0000 0000, V_{REFIN} = 20V p-p, 60 and 400Hz.
[7]This is a measure of the amount of charge injected from the digital inputs to the analog outputs when the inputs change state. It is usually specified as the area of the glitch in nVs and is measured with V_{REFIN} = AGND.
[8]Digital crosstalk is defined as the change in any one output's steady state value as a result of any other output being driven from V_{OUTMIN} to V_{OUTMAX} into a 2kΩ load by means of varying the digital input code.
[9]Reference crosstalk is defined as the change in any one output as a result of any other output being driven from V_{OUTMIN} to V_{OUTMAX} @10kHz into a 2kΩ load by means of varying the amplitude of the reference signal.
[10]The AD396 can be used with supply voltages as low as ±11.4V, Figure 7.

Specifications subject to change without notice.

Momentary Short to $\pm V_S$

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

2

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

MIL-STD-883

The rigors of the military/aerospace environment, temperature extremes, humidity, mechanical stress, etc., demand the utmost in electronic circuits. The AD396 with the inherent reliability of intergrated circuit construction, was designed with these applications in mind. The hermetically-sealed, low profile DIP package takes up a fraction of the space required by equivalent modular designs and protect the chips from hazardous environments. To further insure reliabilty, the AD396S,T/883B are fully compliant to MIL-STD-883 Class B, Method 5008. See Analog Devices Military Data Sheet for further information.

AD396TD	−55°C to +125°C	± 8LSB	±1LSB	DH-28A

*See Section 14 for package outline information.

Theory of Operation

The AD396 quad DAC provides four-quadrant multiplication. It is a hybrid comprised of four monolithic 14-bit CMOS multiplying DACs and eight precision output amplifiers. Each of the four independent-buffered channels has an independent reference input capable of accepting a separate dc or ac signal for multiplying or for function generation applications. The CMOS DACs act as digitally programmable attenuators when used with a varying input signal or, if used with a fixed dc reference, the DAC would act as a standard bipolar output DAC. In addition, each DAC has data latches to buffer the converter when connected to a microprocessor data bus.

MULTIPLYING MODE

Figure 1 shows the transfer function for the AD396. The diagram indicates an area over which many different combinations of the reference input and digital input can result in a particular analog output voltage. The highlighted transfer line in the diagram indicates the transfer function for a fixed reference at the input. The digital codes above the diagram indicates the mid and endpoints of the function. The relationship between the reference input (V_{REFIN}), the digital input code, and the analog output is given in Table I below. Note that the reference input signal sets the slope of the transfer function (and determines the full-scale output at code 111..111) while the digital input selects the horizontal position in each diagram.

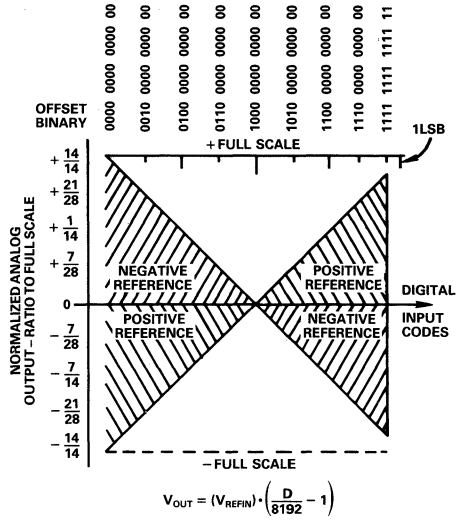

Figure 1. AD396 as a Four-Quadrant Multiplier of Reference Input and Digital Input

DATA INPUT			ANALOG OUTPUT	ANALOG OUTPUT VOLTAGE V_{REFIN} = +10 VOLTS

Table I. AD396 Bipolar Code Table

DATA AND CONTROL SIGNAL FORMAT

The AD396 accepts 14-bit data by loading two separate input registers off an 8-bit data bus, and then loading the internal DAC register. The LS (least significant) register is loaded with the bottom 8-bits of the 14-bit word by selecting the appropriate address lines (see Table II). The MS (most significant) register is loaded with the top 6-bits in a similar manner. The $\overline{CS}$ and $\overline{WR}$ line must also be asserted to load the registers. The internal DAC register can then be loaded with the 14-bit data word. The appropriate DAC or DACs are selected by asserting $\overline{CS1}$-$\overline{CS4}$ (see Table III). If $\overline{CS1}$-$\overline{CS4}$ are all brought low coincidentally, all four DAC outputs will be updated to the value located in the DAC register. When $A_1 = 0$ and $A_0 = 0$ all DAC registers are transparent so by placing all 0s or 1s on the data inputs the user can load the DACs to zero or full scale in one write operation. This provides simple system calibration.

$\overline{WR}$	$\overline{CS}$	A1	A0	Function
X	1	X	X	Device not selected
1	X	X	X	No data transfer
0	0	0	0	DAC loaded directly from Data Bus
0	0	0	1	MS Input Register loaded from Data Bus
0	0	1	0	LS Input Register loaded from Data Bus
0	0	1	1	DAC Register loaded from Input Registers.

Table II. Truth Table

$\overline{CS1}$	$\overline{CS2}$	$\overline{CS3}$	$\overline{CS4}$	Operation
1	1	1	1	All DACs Latched
0	1	1	1	Load DAC 1 From Data Register
1	0	1	1	Load DAC 2 From Data Register
1	1	0	1	Load DAC 3 From Data Register
1	1	1	0	Load DAC 4 From Data Register
0	0	0	0	All DACs Simultaneously Loaded

Table III. DAC Select Matrix

TIMING

The AD396 timing is shown in Figure 3, and has a few restrictions as stated in Table IV. $\overline{WR}$ must maintain a minimum pulse width of 240ns for desired operation to occur. When loading data in from the data bus, data must be stable for at least 180ns before returning $\overline{WR}$ to a high state. The Data must be held constant for at least 30ns after $\overline{WR}$ goes high to assure latching of valid data. DAC settling time is measured from the falling edge of the $\overline{WR}$ command.

Table IV. Timing Characteristics

GROUNDING RULES

The AD396 includes two ground connections in order to minimize system accuracy degradation arising from grounding errors. The two ground pins are designated DGND (Pin 17) and AGND (Pin 23). The DGND pin is the return for the supply currents of the AD396 and serves as the reference point for the digital input thresholds. Thus DGND should be connected to the same ground as the circuitry which drives the digital inputs.

Pin 23, AGND, is the high-quality analog ground connection. This pin should serve as the reference point for all analog circuitry associated with the AD396. It is recommended that any analog signal path carrying significant currents have its own return connection to Pin 23 as shown in Figure 4.

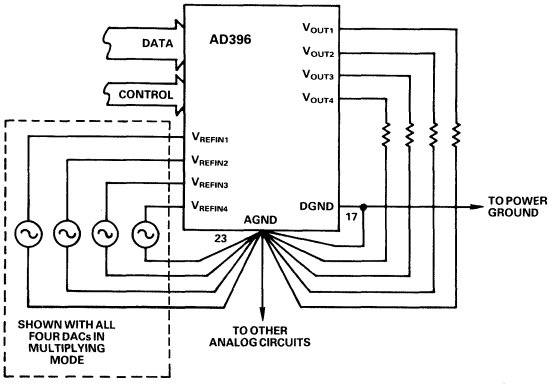

Figure 4. Recommended Ground Connections

Several complications arise in practical systems, particularly if the load is referred to a remote ground. These complications include dc gain errors due to wiring resistance between DAC and load, noise due to currents from other circuits flowing in power ground return impedances, and offsets due to multiple load currents sharing the same signal ground returns. While the DAC outputs are accurately developed between the output pin and Pin 23 (AGND), delivering these signals to remote loads can be a problem. These problems are compounded if a current booster stage is used, or if multiple AD396 packages are used. Figure 5 illustrates the parasitic impedances which influence output accuracy.

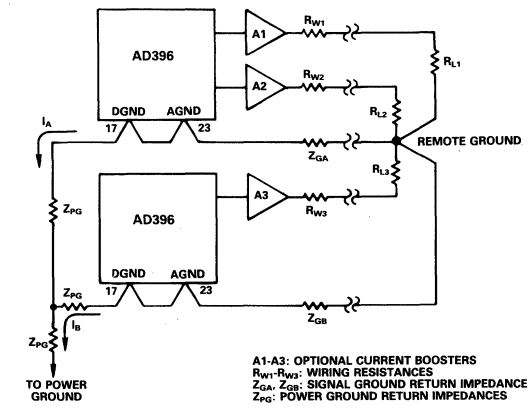

Figure 5. Grounding Errors in Multiple-AD396 Systems

An ouput buffer configured as a subtractor as shown in Figure 6 can greatly reduce these errors. First, the effects of voltage drops in wiring resistances is eliminated by sensing the voltage directly at the load with R4. The voltage drops caused by currents flowing through Z_{GA} are eliminated by sensing the remote gound directly with R3. Resistors R1 through R4 should be well matched in order to achieve maximum rejection of the voltage appearing across Z_{GA}. Resistors matched to within one percent (including the effects of R_{W2} and R_{W3}) will reduce ground interaction errors by a factor of 100.

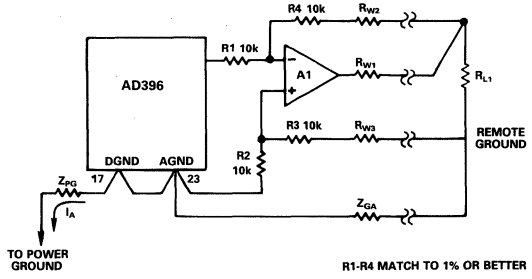

Figure 6. Use of Subtractor Amplifier to Preserve Accuracy

OPERATION FROM ±12V SUPPLIES

The AD396 may be used with ±12 volt ±5% power supplies if certain conditions are met. The most important limitation is the output swing available from the output op amps. These amplifiers are capable of swinging only as far as 3 volts from either supply. Thus, the normal ±10 volt output range cannot be used. Changing the output scale is accomplished by changing the reference voltage. With a supply of ±11.4 volts (5% less than ±12V), the output range is restricted to a maximum ±8.4 swing. It may be useful to scale the output at ±8.192 volts (yielding a scale factor of 1 millivolt per LSB).

Figure 7 shows a suggested circuit to set up a ±8.192V output range. To help prevent poor gain drift due to possible mismatch between R_{IN} and $R_{THEVENIN}$ of the divider network it is recommended to buffer the potentiometer wiper voltage with an OP-07.

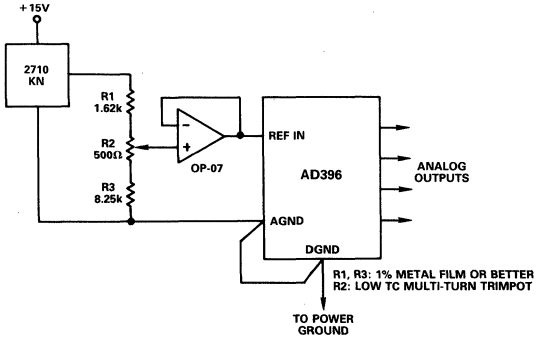

Figure 7. Connections for ±8.192V Full Scale (Recommended for ±12V Power Supplies)

POWER SUPPLY DECOUPLING

The power supplies used with the AD396 should be well filtered and regulated. Local supply decoupling consisting of a 10μF tantalum capacitor in parallel with 0.1μF ceramic is suggested. The decoupling capacitors should be connected between the AD396 supply pins and the AGND pin. If an output booster is used, its supplies should also be decoupled to the load ground.

IMPROVING FULL-SCALE STABILITY

In large systems using multiple DACs, it may be desirable for all devices to share a common reference. A precision reference can greatly improve system accuracy and temperature stability.

The AD2710 is a suitable reference source for such systems. It features a guaranteed maximum temperature coefficient of ± 1ppm/°C. The combination of the AD2710LN and AD396 shown in Figure 8 will yield a multiple-DAC system with maximum full-scale drift of ± 6ppm/°C and excellent tracking.

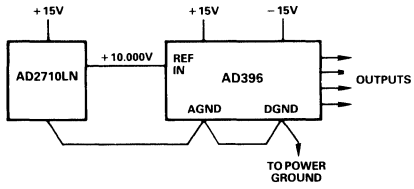

Figure 8. Low Drift AD396 Configuration

Applications

USING THE AD396 IN AUTOMATIC TEST EQUIPMENT

Most Automatic Test Equipment requires multiple accurate analog voltage thresholds which must be under microprocessor control. The AD396 is useful in such an application where space is at a premium and accuracy is essential.

The circuit in Figure 9 demonstrates how the AD396 is used to set up four different voltage thresholds (1 threshold per DAC).

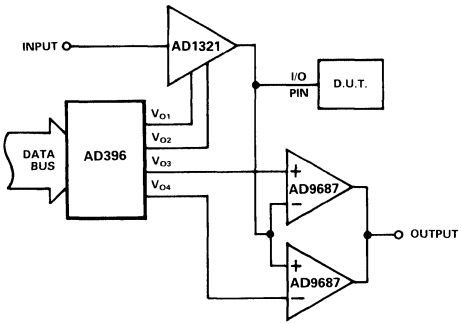

Figure 9. AD396 in ATE Systems

A fixed reference is used for the V_{REFIN} input of each of the multiplying DACs. The digital code corresponding to the desired voltage output is put on the bus, and the $\overline{\text{CHIP SELECT}}$ for the proper DAC is asserted. Two of the four DACs are used to set logic thresholds on the AD345 pindriver. The AD345 pindriver will then accurately test the logic thresholds on an I/O pin of the DUT (Device Under Test). The pindriver tests the pin by driving the pin to the proper logic thresholds set by the DACs. The response from the I/O pin will then enter the AD9687 dual comparator. The other two DACs are used to set the voltage threshold for either a Logic HI (2.2V-5.0V) or a Logic LO (0V-0.8V). This is done by placing the upper voltage limit on the positive terminal of the higher comparator, and the lower voltage limit on the negative terminal of the lower comparator. The response can then be accurately tested if it is either a Logic HI or LO by looking if the output value of the pin falls within the designated window.

THE AD396 IN SYNCHRO-TO-DIGITAL CONVERTERS

The AD396 is useful in navigation systems where a Synchro-to-Digital Converter is needed. The Synchro-to-Digital Converter is used to measure angular position and is needed to measure pitch in the x-y-z axes and roll in the x-y-z axes. An S-D converter has three inputs and two converters are needed for this application. Each S-D converter uses two multiplying DACs and the accuracy of the S-D converter depends on the accuracy of the multiplying DAC.

The outputs of the transformer are Vsinwt(sinθ) and Vsinwt(cosθ). These two outputs are applied to the V_{REF} inputs of the DACs whose digital input words are proportional to the sine and cosine of angle θ as shown in Figure 10. The output of the cosine multiplier is given by Vsinwt(sinθ)(cosϕ), and the output of the sine multiplier is given by Vsinwt(cosθ)(sinϕ). These signals are subtracted by the error amplifier to give the error signal which is:

$$Vsinwt(\sin\theta\cos\phi - \cos\theta\sin\phi) = Vsinwt(\sin\theta - \phi)$$

This error signal is demodulated by the phase sensitive detector which utilizes the system reference voltage and a dc error signal proportional to sin(θ-ϕ) is produced. The dc error signal is fed back via an integrator and V.C.O. to drive the up-down counter until the error signal is nulled. The contents of the up-down counter give a binary representation of the angular position. For more information on synchro-to-digital conversion the reader is referred to Analog Devices Synchro & Resolver Conversion Handbook.

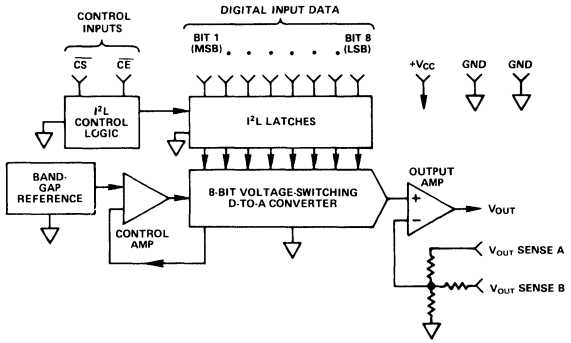
DACPORT Low-Cost Complete µP-Compatible 8-Bit DAC

AD557

FEATURES
Complete 8-Bit DAC
Voltage Output – 0 to 2.56V
Internal Precision Band-Gap Reference
Single-Supply Operation: +5V (±10%)
Full Microprocessor Interface
Fast: 1µs Voltage Settling to ±1/2LSB
Low Power: 75mW
No User Trims Required
Guaranteed Monotonic Over Temperature
All Errors Specified T_{min} to T_{max}
Small 16-Pin DIP or 20-Pin PLCC Package
Low Cost

AD557 FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD557 DACPORT™ is a complete voltage-output 8-bit digital-to-analog converter, including output amplifier, full microprocessor interface and precision voltage reference on a single monolithic chip. No external components or trims are required to interface, with full accuracy, an 8-bit data bus to an analog system.

The low cost and versatility of the AD557 DACPORT are the result of continued development in monolithic bipolar technologies.

The complete microprocessor interface and control logic is implemented with integrated injection logic (I^2L), an extremely dense and low-power logic structure that is process-compatible with linear bipolar fabrication. The internal precision voltage reference is the patented low-voltage band-gap circuit which permits full-accuracy performance on a single +5V power supply. Thin-film silicon-chromium resistors provide the stability required for guaranteed monotonic operation over the entire operating temperature range, while laser-wafer trimming of these thin-film resistors permits absolute calibration at the factory to within ±2.5LSB; thus, no user-trims for gain or offset are required. A new circuit design provides voltage settling to ±1/2LSB for a full-scale step in 800ns.

The AD557 is available in two package configurations. The AD557JN is packaged in a 16-pin plastic, 0.3"-wide DIP. For surface mount applications, the AD557JP is packaged in a 20-pin JEDEC standard PLCC. Both versions are specified over the operating temperature range of 0 to +70°C.

PRODUCT HIGHLIGHTS

1. The 8-bit I^2L input register and fully microprocessor-compatible control logic allow the AD557 to be directly connected to 8- or 16-bit data buses and operated with standard control signals. The latch may be disabled for direct DAC interfacing.
2. The laser-trimmed on-chip SiCr thin-film resistors are calibrated for absolute accuracy and linearity at the factory. Therefore, no user trims are necessary for full rated accuracy over the operating temperature range.
3. The inclusion of a precision low-voltage band-gap reference eliminates the need to specify and apply a separate reference source.
4. The AD557 is designed and specified to operate from a single +4.5V to +5.5V power supply.
5. Low digital input currents, 100µA max, minimize bus loading. Input thresholds are TTL/low voltage CMOS compatible.
6. The single-chip, low power I^2L design of the AD557 is inherently more reliable than hybrid multichip or conventional single-chip bipolar designs.

NOTES

[1]Relative Accuracy is defined as the deviation of the code transition points from the ideal transfer point on a straight line from the offset to the full scale of the device. See "Measuring Offset Error" on AD558 data sheet.

[2]Passive pull-down resistance is 2kΩ.

[3]Settling time is specified for a positive-going full-scale step to ± 1/2LSB. Negative-going steps to zero are slower, but can be improved with an external pull-down.

[4]The full-scale output voltage is 2.55V and is guaranteed with a +5V supply.

[5]A monotonic converter has a maximum differential linearity error of ± 1LSB.

[6]See Figure 7.

Specifications shown in **boldface** are tested on all production units at final electrical test.

Specifications subject to change without notice.

Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CIRCUIT DESCRIPTION

The AD557 consists of four major functional blocks fabricated on a single monolithic chip (see Figure 1). The main D/A converter section uses eight equally weighted laser-trimmed current sources switched into a silicon-chromium thin-film R/2R resistor ladder network to give a direct but unbuffered 0mV to 400mV output range. The transistors that form the DAC switches are PNPs; this allows direct positive-voltage logic interface and a zero-based output range.

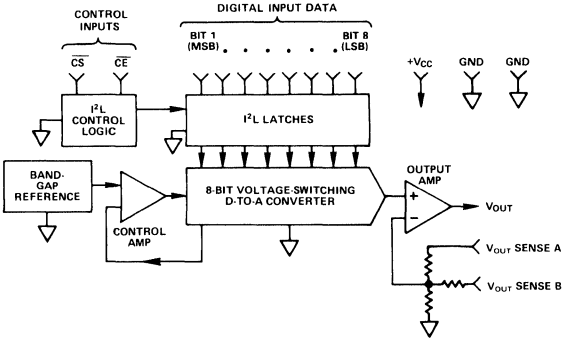

Figure 1. Functional Block Diagram

The high-speed output buffer amplifier is operated in the noninverting mode with gain determined by the user-connections at the output range select pin. The gain-setting application resistors are thin film laser trimmed to match and track the DAC resistors and to assure precise initial calibration of the output range, 0V to 2.56V. The amplifier output stage is an NPN transistor with passive pull-down for zero-based output capability with a single power supply.

The internal precision voltage reference is of the patented band-gap type. This design produces a reference voltage of 1.2V and thus, unlike 6.3V temperature-compensated zeners, may be operated from a single, low-voltage logic power supply. The microprocessor interface logic consists of an 8-bit data latch and control circuitry. Low power, small geometry and high speed are advantages of the I^2L design as applied to this section. I^2L is bipolar process compatible so that the performance of the analog sections need not be compromised to provide on-chip logic capabilities. The control logic allows the latches to be operated from a decoded microprocessor address and write signal. If the application does not involve a µP or data bus, wiring $\overline{CS}$ and $\overline{CE}$ to ground renders the latches "transparent" for direct DAC access.

Digital Input Code			Output
Binary	Hexadecimal	Decimal	Voltage
0000 0000	00	0	0
0000 0001	01	1	0.010V
0000 0010	02	2	0.020V

0001 0000	10	16	0.160V
0111 1111	7F	127	1.270V
1000 0000	80	128	1.280V
1100 0000	C0	192	1.920V
1111 1111	FF	255	2.55V

CONNECTING THE AD557

The AD557 has been configured for low cost and ease of application. All reference, output amplifier and logic connections are made internally. In addition, all calibration trims are performed at the factory assuring specified accuracy without user trims. The only connection decision to be made by the user is whether the output range desired is unipolar or bipolar. Clean circuit board layout is facilitated by isolating all digital bit inputs on one side of the package; analog outputs are on the opposite side.

UNIPOLAR 0 TO +2.56V OUTPUT RANGE

Figure 2 shows the configuration for the 0 to +2.56V full-scale output range. Because of its precise factory calibration, the AD557 is intended to be operated without user trims for gain and offset; therefore, no provisions have been made for such user trims. If a small increase in scale is required, however, it may be accomplished by slightly altering the effective gain of the output buffer. A resistor in series with V_{OUT} SENSE will increase the output range. Note that decreasing the scale by putting a resistor in series with GND will not work properly due to the code-dependent currents in GND. Adjusting offset by injecting dc at GND is not recommended for the same reason.

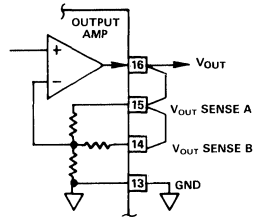

Figure 2. 0 to 2.56V Output Range

BIPOLAR −1.28V TO +1.28V OUTPUT RANGE

The AD557 was designed for operation from a single power supply and is thus capable of providing only a unipolar 0 to +2.56V output range. If a negative supply is available, bipolar output ranges may be achieved by suitable output offsetting and scaling. Figure 3 shows how a ±1.28V output range may be achieved when a −5V power supply is available. The offset is provided by the AD589 precision 1.2V reference which will operate from a +5V supply. The AD711 output amplifier can provide the necessary ±1.28V output swing from ±5V supplies. Coding is complementary offset binary.

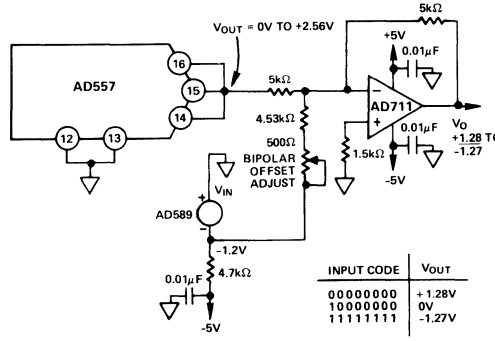

Figure 3. Bipolar Operation of AD557 from ±5V Supplies

Applications

GROUNDING AND BYPASSING

All precision converter products require careful application of good grounding practices to maintain full rated performance. Because the AD557 is intended for application in microcomputer systems where digital noise is prevalent, special care must be taken to assure that its inherent precision is realized.

The AD557 has two ground (common) pins; this minimizes ground drops and noise in the analog signal path. Figure 4 shows how the ground connections should be made.

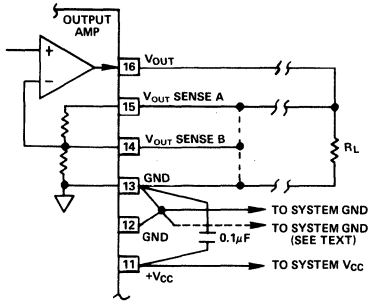

Figure 4. Recommended Grounding and Bypassing

It is often advisable to maintain separate analog and digital grounds throughout a complete system, tying them common in one place only. If the common tie-point is remote and accidental disconnection of that one common tie-point occurs due to card removal with power on, a large differential voltage between the two commons could develop. To protect devices that interface to both digital and analog parts of the system, such as the AD557, it is recommended that common ground tie-points should be provided at *each* such device. If only one system ground can be connected directly to the AD557, it is recommended that analog common be selected.

USING A "FALSE" GROUND

Many applications, such as disk drives, require servo control voltages that swing on either side of a "false" ground. This ground is usually created by dividing the +12V supply equally and calling the midpoint voltage "ground."

Figure 5 shows an easy and inexpensive way to implement this. The AD586 is used to provide a stable 5V reference from the system's +12V supply. The op amp shown likewise operates from a single (+12V) supply available in the system. The resulting output at the V_{OUT} node is ±2.5V around the "false" ground point of 5V. AD557 input code vs. V_{OUT} is shown in Figure 6.

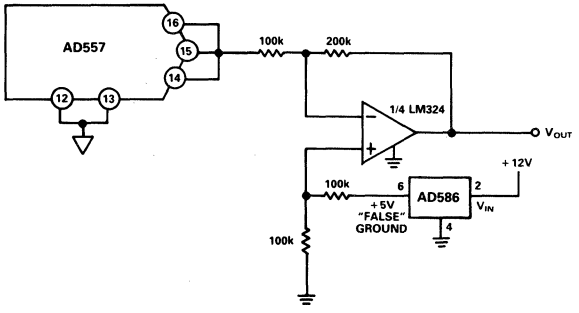

Figure 5. Level Shifting the AD557 Output Around a "False" Ground

TIMING AND CONTROL

The AD557 has data input latches that simplify interface to 8- and 16-bit data buses. These latches are controlled by Chip Enable ($\overline{CE}$) and Chip Select ($\overline{CS}$) inputs. $\overline{CE}$ and $\overline{CS}$ are internally "NORed" so that the latches transmit input data to the DAC section when both $\overline{CE}$ and $\overline{CS}$ are at Logic "0". If the application does not involve a data bus, a "00" condition allows for direct operation of the DAC. When either $\overline{CE}$ or $\overline{CS}$ go to Logic "1," the input data is latched into the registers and held until both $\overline{CE}$ and $\overline{CS}$ return to "0." (Unused $\overline{CE}$ or $\overline{CS}$ inputs should be tied to ground.) The truth table is given in Table I. The logic function is also shown in Figure 6.

Input Data	$\overline{CE}$	$\overline{CS}$	DAC Data	Latch Condition
0	0	0	0	"transparent"
1	0	0	1	"transparent"
0	∫	0	0	latching
1	∫	0	1	latching
0	0	∫	0	latching
1	0	∫	1	latching
X	1	X	previous data	latched
X	X	1	previous data	latched

Notes: X = Does not matter
∫ = Logic Threshold at Positive-Going Transition

Table I. AD557 Control Logic Truth Table

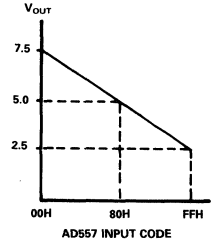

Figure 6. AD557 Input Code vs. Level Shifted Output in "False" Ground Configuration

In a level-triggered latch such as that used in the AD557, there is an interaction between the data setup and hold times and the width of the enable pulse. In an effort to reduce the time required to test all possible combinations in production, the AD557 is tested with $T_{DS} = T_W = 225ns$ at 25°C and 300ns at T_{min} and T_{max}, with $T_{DH} = 10ns$ at all temperatures. Failure to comply with these specifications may result in data not being latched properly.

Figure 7 shows the timing for the data and control signals, $\overline{CE}$ and $\overline{CS}$ are identical in timing as well as in function.

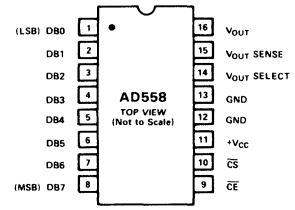
DACPORT Low-Cost Complete µP-Compatible 8-Bit DAC

AD558*

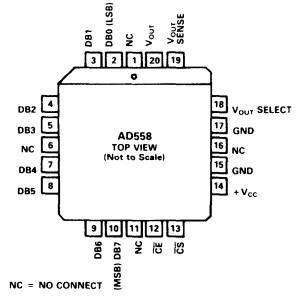
FEATURES

Complete 8-Bit DAC
Voltage Output – 2 Calibrated Ranges
Internal Precision Band-Gap Reference
Single-Supply Operation: +5V to +15V
Full Microprocessor Interface
Fast: 1µs Voltage Settling to ±1/2LSB
Low Power: 75mW
No User Trims
Guaranteed Monotonic Over Temperature
All Errors Specified T_{min} to T_{max}
Small 16-Pin DIP, 20-Pin PLCC and LCC Packages
Single Laser-Wafer-Trimmed Chip for Hybrids
Low Cost

AD558 PIN CONFIGURATION (DIP)



AD558 PIN CONFIGURATION (PLCC AND LCC)



PRODUCT DESCRIPTION

The AD558 DACPORT™ is a complete voltage-output 8-bit digital-to-analog converter, including output amplifier, full microprocessor interface and precision voltage reference on a single monolithic chip. No external components or trims are required to interface, with full accuracy, an 8-bit data bus to an analog system.

The performance and versatility of the DACPORT is a result of several recently-developed monolithic bipolar technologies. The complete microprocessor interface and control logic is implemented with integrated injection logic (I^2L), an extremely dense and low-power logic structure that is process-compatible with linear bipolar fabrication. The internal precision voltage reference is the patented low-voltage band-gap circuit which permits full-accuracy performance on a single +5V to +15V power supply. Thin-film silicon-chromium resistors provide the stability required for guaranteed monotonic operation over the entire operating temperature range (all grades), while recent advances in laser-wafer-trimming of these thin-film resistors permit absolute calibration at the factory to within ±1LSB; thus no user-trims for gain or offset are required. A new circuit design provides voltage settling to ±1/2LSB for a full-scale step in 800ns.

The AD558 is available in four performance grades. The AD558J and K are specified for use over the 0 to +70°C temperature range, while the AD558S and T grades are specified for -55°C to +125°C operation. The "J" and "K" grades are available either in 16-pin plastic (N) or hermetic ceramic (D) DIPS. They are also available in 20-pin JEDEC standard PLCC packages. The "S" and "T" grades are available in 16-pin hermetic ceramic DIP packages and 20-pin LCC packages.

PRODUCT HIGHLIGHTS

1. The 8-bit I^2L input register and fully microprocessor-compatible control logic allow the AD558 to be directly connected to 8- or 16-bit data buses and operated with standard control signals. The latch may be disabled for direct DAC interfacing.
2. The laser-trimmed on-chip SiCr thin-film resistors are calibrated for absolute accuracy and linearity at the factory. Therefore, no user trims are necessary for full rated accuracy over the operating temperature range.
3. The inclusion of a precision low-voltage band-gap reference eliminates the need to specify and apply a separate reference source.
4. The voltage-switching structure of the AD558 DAC section along with a high-speed output amplifier and laser-trimmed resistors give the user a choice of 0V to +2.56V or 0V to +10V output ranges, selectable by pin-strapping. Circuitry is internally compensated for minimum settling time on both ranges; typically settling to ±1/2LSB for a full-scale 2.55 volt step in 800ns.
5. The AD558 is designed and specified to operate from a single +4.5V to +16.5V power supply.
6. Low digital input currents, 100µA max, minimize bus loading. Input thresholds are TTL/low voltage CMOS compatible over the entire operating V_{CC} range.

NOTES

[1]The AD558 S & T grades are available processed and screened to MIL-STD-883 Class B. Consult Analog Devices' Military Databook for details.

[2]Relative Accuracy is defined as the deviation of the code transition points from the ideal transfer point on a straight line from the offset to the full scale of the device. See "Measuring Offset Error".

[3]Operation of the 0 to 10 volt output range requires a minimum supply voltage of +11.4 volts.

[4]Passive pull-down resistance is 2kΩ for 2.56 volt range, 10kΩ for 10 volt range.

[5]Settling time is specified for a positive-going full-scale step to ± 1/2LSB. Negative-going steps to zero are slower, but can be improved with an external pull-down.

[6]The full range output voltage for the 2.56 range is 2.55V and is guaranteed with a +5V supply, for the 10V range, it is 9.960V guaranteed with a +15V supply.

[7]A monotonic converter has a maximum differential linearity error of ±1LSB.

[8]See Figure 7.

Specifications shown in **boldface** are tested on all production units at final electrical test.

Specifications subject to change without notice.

(continued from features page)

7. The single-chip, low power I^2L design of the AD558 is inherently more reliable than hybrid multi-chip or conventional single-chip bipolar designs. The AD558S and T grades which are specified over the -55°C to +125°C temperature range, are available processed to MIL-STD-883, Class B.
8. All AD558 grades are available in chip form with guaranteed specifications from +25°C to T_{max}. MIL-STD-883, Class B visual inspection is standard on Analog Devices bipolar chips. Contact the factory for additional chip information.

CIRCUIT DESCRIPTION

The AD558 consists of four major functional blocks, fabricated on a single monolithic chip (see Figure 2). The main D to A converter section uses eight equally-weighted laser-trimmed current sources switched into a silicon-chromium thin-film R/2R resistor ladder network to give a direct but unbuffered 0mV to 400mV output range. The transistors that form the DAC switches are PNPs; this allows direct positive-voltage logic interface and a zero-based output range.

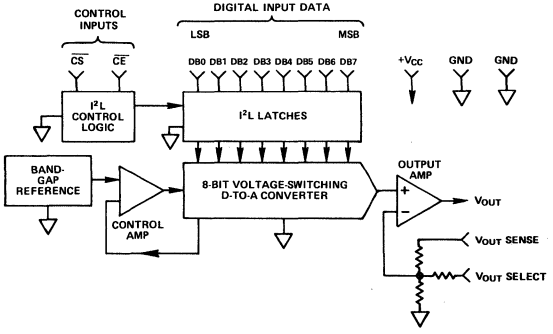

Figure 2. AD558 Functional Block Diagram

The high-speed output buffer amplifier is operated in the non-inverting mode with gain determined by the user-connections at the output range select pin. The gain-setting application resistors are thin-film laser-trimmed to match and track the DAC resistors and to assure precise initial calibration of the two output ranges, 0V to 2.56V and 0V to 10V. The amplifier output stage is an NPN transistor with passive pull-down for zero-based output capability with a single power supply.

The internal precision voltage reference is of the patented band-gap type. This design produces a reference voltage of 1.2 volts and thus, unlike 6.3 volt temperature-compensated zeners, may be operated from a single, low-voltage logic power supply. The microprocessor interface logic consists of an 8-bit data latch and control circuitry. Low-power, small geometry and high-speed are advantages of the I^2L design as applied to this section. I^2L is bipolar process compatible so that the performance of the analog sections need not be compromised to provide on-chip logic capabilities. The control logic allows the latches to be operated from a decoded microprocessor address and write signal. If the application does not involve a μP or data bus, wiring $\overline{CS}$ and $\overline{CE}$ to ground renders the latches "transparent" for direct DAC access.

MIL-STD-883

The rigors of the military/aerospace environment, temperature extremes, humidity, mechanical stress, etc., demand the utmost in electronic circuits. The AD558, with the inherent reliability of integrated circuit construction, was designed with these applications in mind. The hermetically-sealed, low profile DIP package takes up a fraction of the space required by equivalent modular designs and protects the chip from hazardous environments. To further ensure reliability, military-temperature range AD558 grades S and T are available screened to MIL-STD-883. For more complete data sheet information consult the Analog Devices' Military Databook.

CHIP AVAILABILITY

The AD558 is available in laser-trimmed, passivated chip form. AD558J and AD558T chips are available. Consult the factory for details.

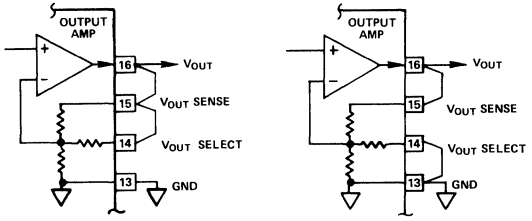
Input Logic Coding

CONNECTING THE AD558

The AD558 has been configured for ease of application. All reference, output amplifier and logic connections are made internally. In addition, all calibration trims are performed at the factory assuring specified accuracy without user trims. The only connection decision that must be made by the user is a single jumper to select output voltage range. Clean circuit-board layout is facilitated by isolating all digital bit inputs on one side of the package; analog outputs are on the opposite side.

Figure 3 shows the two alternative output range connections. The 0V to 2.56V range may be selected for use with any power supply between +4.5V and +16.5V. The 0V to 10V range requires a power supply of +11.4V to +16.5V.

Because of its precise factory calibration, the AD558 is intended to be operated without user trims for gain and offset; therefore no provisions have been made for such user-trims. If a small increase in scale is required, however, it may be accomplished by slightly altering the effective gain of the output buffer. A resistor in series with V_{OUT} SENSE will increase the output range.



a. 0V to 2.56V Output Range *b. 0V to 10V Output Range*

Figure 3. Connection Diagrams

For example if a 0V to 10.24V output range is desired (40mV = 1LSB), a nominal resistance of 850Ω is required. It must be remembered that, although the internal resistors all ratio-match and track, the *absolute* tolerance of these resistors is typically ±20% and the *absolute* TC is typically -50ppm/°C (0 to -100ppm/°C). That must be considered when re-scaling is performed. Figure 4 shows the recommended circuitry for a full-scale output range of 10.24 volts. Internal resistance values shown are nominal.

NOTE: Decreasing the scale by putting a resistor in series with GND will not work properly due to the code-dependent currents in GND. Adjusting offset by injecting dc at GND is not recommended for the same reason.

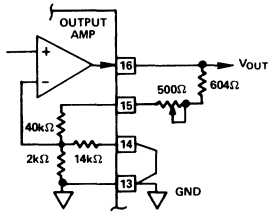


Figure 4. 10.24V Full-Scale Connection

GROUNDING AND BYPASSING*

All precision converter products require careful application of good grounding practices to maintain full rated performance. Because the AD558 is intended for application in microcomputer systems where digital noise is prevalent, special care must be taken to assure that its inherent precision is realized.

The AD558 has two ground (common) pins; this minimizes ground drops and noise in the analog signal path. Figure 5 shows how the ground connections should be made.

It is often advisable to maintain separate analog and digital grounds throughout a complete system, tying them common in one place only. If the common tie-point is remote and accidental disconnection of that one common tie-point occurs due to card removal with power on, a large differential voltage between the two commons could develop. To protect devices that interface to both digital and analog parts of the system, such as the AD558, it is recommended that common ground tie-points should be provided at *each* such device. If only one system ground can be connected directly to the AD558, it is recommended that analog common be selected.

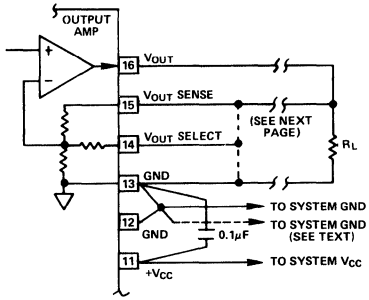

Figure 5. Recommended Grounding and Bypassing

POWER SUPPLY CONSIDERATIONS

The AD558 is designed to operate from a single positive power supply voltage. Specified performance is achieved for any supply voltage between +4.5V and +16.5V. This makes the AD558 ideal for battery-operated, portable, automotive or digital main-frame applications.

The only consideration in selecting a supply voltage is that, in order to be able to use the 0V to 10V output range, the power supply voltage must be between +11.4V and +16.5V. If, however, the 0V to 2.56V range is to be used, power consumption will be minimized by utilizing the lowest available supply voltage (above +4.5V).

TIMING AND CONTROL

The AD558 has data input latches that simplify interface to 8- and 16-bit data buses. These latches are controlled by Chip Enable ($\overline{CE}$) and Chip Select ($\overline{CS}$) inputs. $\overline{CE}$ and $\overline{CS}$ are internally "NORed" so that the latches transmit input data to the DAC section when both $\overline{CE}$ and $\overline{CS}$ are at Logic "0". If the application does not involve a data bus, a "00" condition allows for direct operation of the DAC. When either $\overline{CE}$ or $\overline{CS}$ go to Logic "1", the input data is latched into the registers

*For additional insight, "An IC Amplifier Users' Guide to Decoupling, Grounding and Making Things Go Right For A Change", is available at no charge from any Analog Devices Sales Office.

and held until both $\overline{CE}$ and $\overline{CS}$ return to "0". (Unused $\overline{CE}$ or $\overline{CS}$ inputs should be tied to ground.) The truth table is given in Table I. The logic function is also shown in Figure 6.

Input Data	$\overline{CE}$	$\overline{CS}$	DAC Data	Latch Condition
0	0	0	0	"transparent"
1	0	0	1	"transparent"
0	↓	0	0	latching
1	↓	0	1	latching
0	0	↓	0	latching
1	0	↓	1	latching
X	1	X	previous data	latched
X	X	1	previous data	latched

Notes: X = Does not matter
↓ = Logic Threshold at Positive-Going Transition

Table I. AD558 Control Logic Truth Table

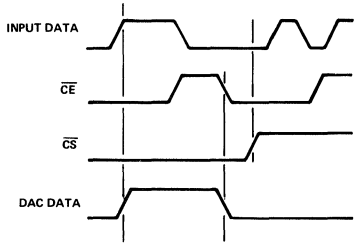

Figure 6. AD558 Control Logic Function

In a level-triggered latch such as that in the AD558 there is an interaction between data setup and hold times and the width of the enable pulse. In an effort to reduce the time required to test all possible combinations in production, the AD558 is tested with $t_{DS} = t_W = 200ns$ at 25°C and 270ns at T_{min} and T_{max}, with $t_{DH} = 10ns$ at all temperatures. Failure to comply with these specifications may result in data not being latched properly.

Figure 7 shows the timing for the data and control signals; $\overline{CE}$ and $\overline{CS}$ are identical in timing as well as in function.

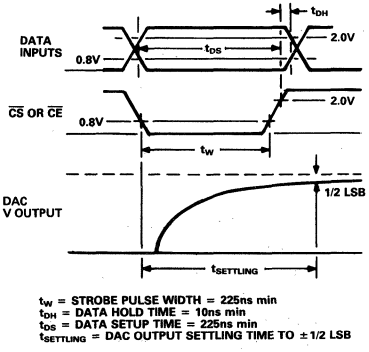

Figure 7. AD558 Timing

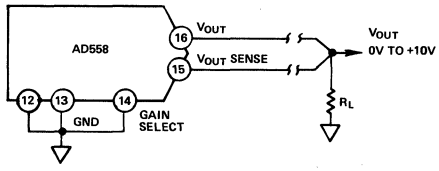
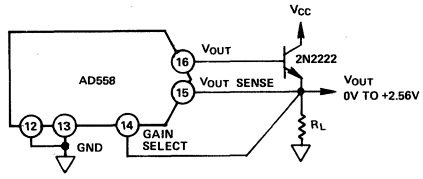
USE OF V_{OUT} SENSE

Separate access to the feedback resistor of the output amplifier allows additional application versatility. Figure 8a shows how I X R drops in long lines to remote loads may be cancelled by putting the drops "inside the loop." Figure 8b shows how the separate sense may be used to provide a higher output current by feeding back around a simple current booster.



a. Compensation for I x R Drops in Output Lines



b. Output Current Booster

Figure 8. Use of V_{OUT} Sense

OPTIMIZING SETTLING TIME

In order to provide single-supply operation and zero-based output voltage ranges, the AD558 output stage has a passive "pull-down" to ground. As a result, settling time for negative-going output steps may be longer than for positive-going output steps. The relative difference depends on load resistance and capacitance. If a negative power supply is available, the negative-going settling time may be improved by adding a pull-down resistor from the output to the negative supply as shown in Figure 9. The value of the resistor should be such that, at zero voltage out, current through that resistor is 0.5mA max.

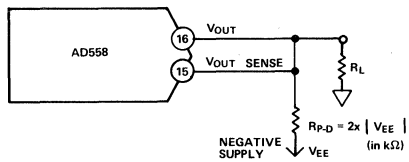


Figure 9. Improved Settling Time

BIPOLAR OUTPUT RANGES

The AD558 was designed for operation from a single power supply and is thus capable of providing only unipolar (0V to +2.56 and 0V to 10V) output ranges. If a negative supply is available, bipolar output ranges may be achieved by suitable output offsetting and scaling. Figure 10 shows how a ±1.28 volt output range may be achieved when a −5 volt power supply is available. The offset is provided by the AD589 precision 1.2 volt reference which will operate from a +5 volt supply. The AD544 output amplifier can provide the necessary ±1.28 volt output swing from ±5 volt supplies. Coding is complementary offset binary.

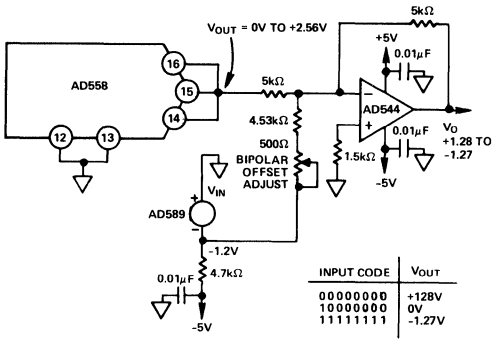

Figure 10. Bipolar Operation of AD558 from ±5V Supplies

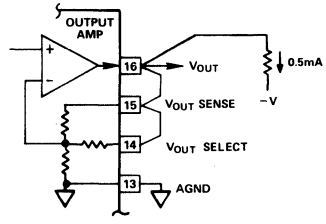
MEASURING OFFSET ERROR

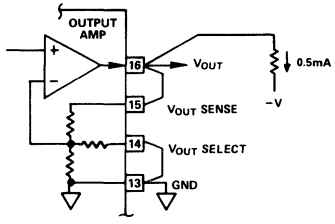
One of the most commonly specified end-point errors associated with real-world nonideal DACs is offset error.

In most DAC testing, the offset error is measured by applying the zero-scale code and measuring the output deviation from 0 volts. There are some DACs, like the AD558 where offset errors may be present but not observable at the zero scale, because of other circuit limitations (such as zero coinciding with single-supply ground) so that a nonzero output at zero code cannot be read as the offset error. Factors like this make testing the AD558 a little more complicated.

By adding a pulldown resistor from the output to a negative supply as shown in Figure 11, we can now read offset errors at zero code that may not have been observable due to circuit limitations. The value of the resistor should be such that, at zero voltage out, current through the resistor is 0.5mA max.



a. 0V to 2.56V Output Range



b. 0V to 10V Output Range

Figure 11. Offset Connection Diagrams

INTERFACING THE AD558 TO MICROPROCESSOR DATA BUSES

The AD558 is configured to act like a "write only" location in memory that may be made to coincide with a read only memory location or with a RAM location. The latter case allows data previously written into the DAC to be read back later via the RAM. Address decoding is partially complete for either ROM or RAM. Figure 12 shows interfaces for three popular microprocessor systems.

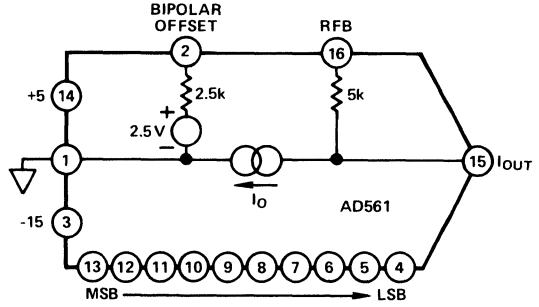
FEATURES
- **Complete Current Output Converter**
- **High Stability Buried Zener Reference**
- **Laser Trimmed to High Accuracy (1/4LSB Max Error, AD561K, T)**
- **Trimmed Output Application Resistors for 0 to +10, ±5 Volt Ranges**
- **Fast Settling – 250ns to 1/2LSB**
- **Guaranteed Monotonicity Over Full Operating Temperature Range**
- **TTL/DTL and CMOS Compatible (Positive True Logic)**
- **Single Chip Monolithic Construction**
- **Available in Chip Form**

AD561 FUNCTIONAL BLOCK DIAGRAM

TO-116



PRODUCT DESCRIPTION

The AD561 is an integrated circuit 10-bit digital-to-analog converter combined with a high stability voltage reference fabricated on a single monolithic chip. Using 10 precision high-speed current-steering switches, a control amplifier, voltage reference, and laser-trimmed thin-film SiCr resistor network, the device produces a fast, accurate analog output current. Laser trimmed output application resistors are also included to facilitate accurate, stable current-to-voltage conversion; they are trimmed to 0.1% accuracy, thus eliminating external trimmers in many situations.

Several important technologies combine to make the AD561 the most accurate and most stable 10-bit DAC available. The low temperature coefficient, high stability thin-film network is trimmed at the wafer level by a fine resolution laser system to 0.01% typical linearity. This results in an accuracy specification of ±1/4LSB max for the K and T versions, and 1/2LSB max for the J and S versions.

The AD561 also incorporates a low noise, high stability subsurface zener diode to produce a reference voltage with excellent long term stability and temperature cycle characteristics which challenge the best discrete zener references. A temperature compensation circuit is laser-trimmed to allow custom correction of the temperature coefficient of each device. This results in a typical full-scale temperature coefficient of 15ppm/°C; the T.C. is tested and guaranteed to 30ppm/°C max for the K and T versions, 60ppm/°C max for the S, and 80ppm/°C for the J.

The AD561 is available in four performance grades. The AD561J and K are specified for use over the 0 to +70°C temperature range and are available in either a 16-pin hermetically-sealed ceramic DIP or a 16-pin molded plastic DIP. The AD561S and T grades are specified for the -55°C to +125°C range and are available in the ceramic package.

PRODUCT HIGHLIGHTS

1. Advanced monolithic processing and laser trimming at the wafer level have made the AD561 the most accurate 10-bit converter available while keeping costs consistent with large volume integrated circuit production. The AD561K and T have 1/4LSB max relative accuracy and 1/2LSB max differential nonlinearity. The low T.C. R-2R ladder guarantees that all AD561 units will be monotonic over the entire operating temperature range.
2. Digital system interfacing is simplified by the use of a positive true straight binary code. The digital input voltage threshold is a function of the positive supply level; connecting V_{CC} to the digital logic supply automatically sets the threshold to the proper level for the logic family being used. Logic sink current requirement is only 25μA.
3. The high speed current steering switches are designed to settle in less than 250ns for the worst case digital code transition. This allows construction of successive-approximation A/D converters in the 3 to 5μs range.
4. The AD561 has an output voltage compliance range from -2 to +10 volts, thus allowing direct current-to-voltage conversion with just an output resistor, omitting the op amp. The 40MΩ open collector output impedance results in negligible errors due to output leakage currents.

SPECIFICATIONS ($T_A = +25°C$, $V_{CC} = +5V$, $V_{EE} = -15V$, unless otherwise specified)

CIRCUIT DESCRIPTION

A simplified schematic with the essential circuit features of the AD561 is shown in Figure 1. The voltage reference, CR1, is a buried zener (or subsurface breakdown diode). This device exhibits far better all-around performance than the NPN base-emitter reverse-breakdown diode (surface zener), which is in nearly universal use in integrated circuits as a voltage reference. Greatly improved long term stability and lower noise are the major benefits the buried zener derives from isolating the breakdown point from surface stress and mobile oxide charge effects. The nominal 7.5 volt device (including temperature compensation circuitry) is driven by a current source to the negative supply so that the positive supply can be allowed to go as low as 4.5 volts. The temperature coefficient of each diode is determined individually; this data is then used to laser trim a compensating circuit to balance the overall T.C. to zero. The typical resulting T.C. is 0 to ±15ppm/°C.

The negative reference level is inverted and scaled by A_1 to give a +2.5 volt reference (which can be driven by the low positive supply). The AD561, packaged in the 16-pin DIP, has the +2.5 volt reference (REF OUT) connected directly to the input of the control amplifier (REF IN). The buffered reference is not directly available externally except through the 2.5kΩ bipolar offset resistor.

The 2.5kΩ scaling resistor and control amplifier A_2 then force a 1mA reference current to flow through reference transistor Q1, which has a relative emitter area of 8A. This is accomplished by forcing the bottom of the ladder to the proper voltage. Since Q_1 and Q_2 have equal emitter areas and have equal 5kΩ emitter resistors, Q_2 also carries 1mA. The ladder voltage drop constrains Q_7 (with area 4A) to carry only 0.5mA; Q_8 carries 0.25mA, etc.

The first four significant bit cells are scaled exactly in emitter area to match Q_1 for optimum V_{BE} and V_{BE} drift match, as well as for beta match. These effects are insignificant for the lower order bits, which account for a total of only 1/16 of full scale. However, the 18mV V_{BE} difference between two matched transistors carrying emitter currents in a ratio of 2:1 must be corrected. This is done by forcing 120μA through the 150Ω interbase resistors. These resistors and the R-2R ladder resistors are actively laser-trimmed at the wafer level to bring total device accuracy to better than 1/4LSB. Sufficient ratio accuracy in the last two bits is obtained by simple emitter area ratio such that it is unnecessary to use additional area for ladder resistors. The current in Q_{16} is added to the ladder to balance it properly but is not switched to the output; thus full scale is 1023/1024 x 2mA.

The switching cell of Q_3, Q_4, Q_5 and Q_6 serves to steer the cell current either to ground (BIT 1 low) or to the DAC output (BIT 1 high). The entire switching cell carries the same current whether the bit is on or off, thus minimizing thermal transients and ground current errors. The logic threshold, which is generated from the positive supply (see Digital Logic Interface) is applied to one side of each cell.

AD562/AD563*

FEATURES

True 12-Bit Accuracy
Guaranteed Monotonicity Over Full Temperature Range
Hermetic 24-Pin DIP
TTL/DTL and CMOS Compatibility
Positive True Logic

PRODUCT DESCRIPTION

The AD562/AD563 are monolithic 12-bit digital-to-analog converters consisting of especially designed precision bipolar switches and control amplifiers and compatible high stability silicon chromium thin film resistors. The AD563 also includes its own internal voltage reference.

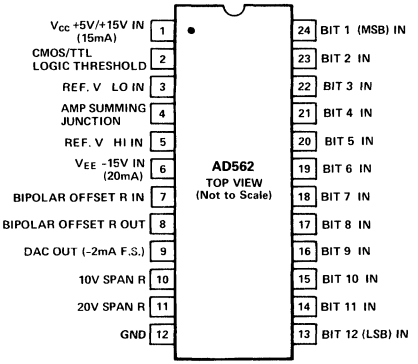
A unique combination of advanced circuit design, high stability SiCr thin film resistor processing and laser trimming technology provide the AD562/AD563 with true 12-bit accuracy. The maximum error at +25°C is limited to ±½LSB on all versions and monotonicity is guaranteed over the full operating temperature range.

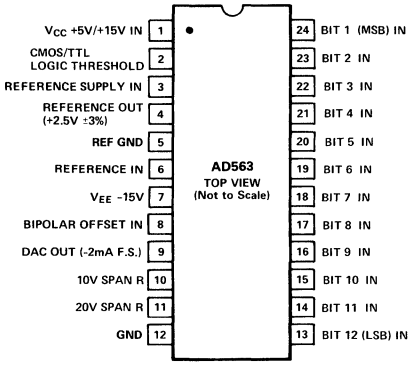
The AD562 and AD563 are recommended for high accuracy 12-bit D/A converter applications where true 12-bit performance is required, but low cost and small size are considerations. Both devices are also ideal for use in constructing A/D conversion systems and as building blocks for higher resolution D/A systems. J and K versions are specified for operation over the 0 to +70°C temperature range, the S and T for operation over the extended temperature range, -55°C to +125°C. All are packaged in a 24-pin, hermetically sealed, ceramic, dual-in-line package.

PRODUCT HIGHLIGHTS

1. The AD562 multiplies in two quadrants when a varying reference voltage is applied. When multiplication is not required, the AD563 is recommended with its internal low drift voltage reference.
2. True 12-bit resolution is achieved with guaranteed monotonicity over the full operating temperature range. Voltage outputs are easily implemented by using an external operational amplifier and the AD562/AD563s internally provided feedback resistors.
3. The devices incorporate a newly developed and fully differential, non-saturating precision current switching cell structure which provides increased immunity to supply voltage variation and also reduces nonlinearities due to thermal transients as the various bits are switched; nearly all critical components operate at constant power dissipation.

AD562, AD563 PIN CONFIGURATIONS





4. The thin film resistor network contains gain, range, and bipolar offset resistors so that various output voltage ranges can be programmed by changing connections to the device terminal leads. Thin film resistors are laser trimmed while the device is powered to accurately calibrate all scale factors. The scale factors are dependent upon the tracking coefficient (<±2ppm/°C) of these resistors, rather than upon their absolute temperature coefficients.
5. TTL or CMOS input can be accommodated for supply voltages from +5V to +15V.
6. Positive true logic eliminates the need for additional inverter components.

THE AD562/AD563 OFFERS TRUE 12-BIT RESOLUTION OVER FULL TEMPERATURE RANGE

Accuracy: Analog Devices defines accuracy as the maximum deviation of the actual DAC output from the ideal analog output (a straight line drawn from 0 to F.S. − 1LSB) *for any bit combination.* The AD563, for example, is laser trimmed to ¼LSB (0.006% of F.S.) maximum error at +25°C for K, S and T versions . . . ½LSB for the J version.

Monotonicity: A DAC is said to be monotonic if the output either increases or remains constant for increasing digital inputs such that the output will always be a single-valued function of the input. All versions of the AD562/AD563 are monotonic over their full operating temperature range.

Differential Nonlinearity: Monotonic behavior requires that the differential nonlinearity error be <1LSB both at 25°C and over the temperature range of interest. Differential nonlinearity is the measure of the variation in analog value, normalized to full scale, associated with a one LSB change in digital input code. For example, for a 10V full-scale output, a change of one LSB in the digital input code should result in a 2.4mV change in the analog output (10V x 1/4096 = 2.4mV). If in actual use, however, a one LSB change in the input code results in a change of 1.3mV in analog output, the differential nonlinearity would be 1.1mV, or 0.011% of F.S. The differential nonlinearity temperature coefficient must also be considered if the device is to remain monotonic over its full operating temperature range. A differential nonlinearity temperature coefficient of 1ppm/°C could, under worst case conditions for a temperature change of +25°C to +125°C, add 0.01% (100°C x 1ppm/°C) of error. The resulting error could then be as much as 0.006% + 0.01% = 0.016% of F.S. (1LSB represents 0.024% of F.S.). All versions of the AD563 are 100% tested to be monotonic over the full operating temperature range.

UNIPOLAR DAC's

STEP I . . . OUTPUT RANGE

Determine the output range required. For +10V F.S., connect the external operational amplifier output to Pin 10 and leave Pin 11 unconnected. For +5V F.S., connect the external op amp output to Pin 10 and short Pin 11 to Pin 9.

STEP II . . . ZERO ADJUST

Turn all bits OFF and adjust R_1 until op amp output is 0 volts.

STEP III . . . GAIN ADJUST

Turn all bits ON for binary DAC's (bits 1, 4, 5, 8, 9 and 12 ON for BCD DAC's). Adjust R_2 until op amp output is:

BINARY	BCD
4.9988V for +5V Range	4.9950 for +5V Range
9.9976 for +10V Range	9.9900 for +10V Range

BIPOLAR DAC's

STEP I . . . OUTPUT RANGE

Determine the output range required. For ±10V F.S., connect the external op amp output to Pin 11 and leave Pin 10 unconnected. For ±5V F.S., connect the external op amp output to Pin 10 and leave Pin 11 unconnected. For ±2.5V F.S., connect the external op amp output to Pin 10 and short Pin 11 to Pin 9.

STEP II . . . OFFSET ADJUST

Turn all bits OFF and adjust R_3 until op amp output is:

-2.5000V for ±2.5V Range
-5.0000V for ±5V Range
-10.0000V for ±10V Range

STEP III . . . GAIN ADJUST (Bipolar Zero)

Turn bit 1 ON for Binary DAC's (bits 2 and 4 ON for BCD DAC's). Adjust R_2 until op amp output is 0 volts.

ANALOG DEVICES

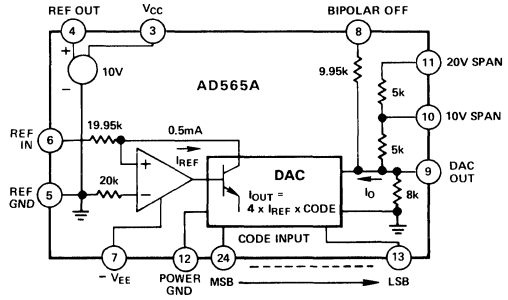
High-Speed 12-Bit Monolithic D/A Converters

AD565A*/AD566A*

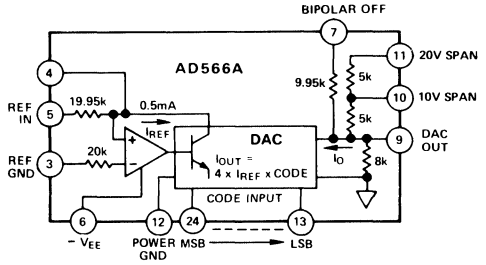
FEATURES

- Single Chip Construction
- Very High-Speed Settling to 1/2LSB
  - AD565A: 250ns max
  - AD566A: 350ns max
- Full-Scale Switching Time: 30ns
- Guaranteed for Operation with ±12V Supplies: AD565A with -12V Supply: AD566A
- Linearity Guaranteed Over Temperature: 1/2LSB max (K, T Grades)
- Monotonicity Guaranteed Over Temperature
- Low Power: AD566A = 180mW max; AD565A = 225mW max
- Use with On-Board High-Stability Reference (AD565A) or with External Reference (AD566A)
- Low Cost

AD565A FUNCTIONAL BLOCK DIAGRAM



AD566A FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD565A and AD566A are fast 12-bit digital-to-analog converters which incorporate the latest advances in analog circuit design to achieve high speeds at low cost.

The AD565A and AD566A use 12 precision, high-speed bipolar current-steering switches, control amplifier and a laser-trimmed thin-film resistor network to produce a very fast, high accuracy analog output current. The AD565A also includes a buried zener reference that features low-noise, long-term stability and temperature drift characteristics comparable to the best discrete reference diodes.

The combination of performance and flexibility in the AD565A and AD566A has resulted from major innovations in circuit design, an important new high-speed bipolar process, and continuing advances in laser-wafer-trimming techniques (LWT). The AD565A and AD566A have a 10-90% full-scale transition time less than 35ns and settle to within ±1/2LSB in 250ns max (350ns for AD566A). Both are laser-trimmed at the wafer level to ±1/8LSB typical linearity and are specified to ±1/4LSB max error (K and T grades) at +25°C. High speed and accuracy make the AD565A and AD566A the ideal choice for high-speed display drivers as well as fast analog-to-digital converters.

The laser trimming process which provides the excellent linearity is also used to trim both the absolute value and the temperature coefficient of the reference of the AD565A resulting in a typical full-scale gain TC of 10 ppm/°C. When tighter TC performance is required or when a system reference is available, the AD566A may be used with an external reference.

***Covered by Patent Nos.: 3,803,590; RE 28,633; 4,213,806; 4,136,349; 4,020,486; 3,747,088.**

AD565A and AD566A are available in four performance grades. The J and K are specified for use over the 0 to +70°C temperature range while the S and T grades are specified for the -55°C to +125°C range. All are packaged in a 24-pin, hermetically sealed, ceramic, dual-in-line package.

PRODUCT HIGHLIGHTS

1. The wide output compliance range of the AD565A and AD566A are ideally suited for fast, low noise, accurate voltage output configurations without an output amplifier.
2. The devices incorporate a newly developed, fully differential, nonsaturating precision current switching cell structure which combines the dc accuracy and stability first developed in the AD562/3 with very fast switching times and an optimally-damped settling characteristic.
3. The devices also contain SiCr thin film application resistors which can be used with an external op amp to provide a precision voltage output or as input resistors for a successive approximation A/D converter. The resistors are matched to the internal ladder network to guarantee a low gain temperature coefficient and are laser-trimmed for minimum full-scale and bipolar offset errors.

SPECIFICATIONS (T_A = +25°C, V_{CC} = +15V, V_{EE} = −15V, unless otherwise specified)

MODEL	AD565AJ MIN	AD565AJ TYP	AD565AJ MAX	AD565AK MIN	AD565AK TYP	AD565AK MAX	UNITS

Current (available for external loads)[3]	1.5	2.5		1.5	2.5		mA
POWER DISSIPATION		225	345		225	345	mW

NOTES

[1] The digital inputs are guaranteed but not tested over the operating temperature range.

[2] The power supply gain sensitivity is tested in reference to a V_{CC}, V_{EE} of ±15V dc.

[3] For operation at elevated temperatures the reference cannot supply current for external loads. It, therefore, should be buffered if additional loads are to be supplied.

Specifications subject to change without notice.

GROUNDING RULES

The AD565A and AD566A bring out separate reference and power grounds to allow optimum connections for low noise and high-speed performance. These grounds should be tied together at one point, usually the device power ground. The separate ground returns are provided to minimize current flow in low-level signal paths. In this way, logic return currents are not summed into the same return path with analog signals.

CONNECTING THE AD565A FOR BUFFERED VOLTAGE OUTPUT

The standard current-to-voltage conversion connections using an operational amplifier are shown here with the preferred trimming techniques. If a low offset operational amplifier (AD510L, AD517L, AD741L, AD301AL, AD OP-07) is used, excellent performance can be obtained in many situations without trimming (an op amp with less than 0.5mV max offset voltage should be used to keep offset errors below 1/2LSB). If a 50Ω fixed resistor is substituted for the 100Ω trimmer, unipolar zero will typically be within ±1/2LSB (plus op amp offset), and full scale accuracy will be within 0.1% (0.25% max). Substituting a 50Ω resistor for the 100Ω bipolar offset trimmer will give a bipolar zero error typically within ±2LSB (0.05%).

The AD509 is recommended for buffered voltage-output applications which require a settling time to ±1/2LSB of one microsecond. The feedback capacitor is shown with the optimum value for each application; this capacitor is required to compensate for the 25 picofarad DAC output capacitance.

FIGURE 1. UNIPOLAR CONFIGURATION

This configuration will provide a unipolar 0 to +10 volt output range. In this mode, the bipolar terminal, pin 8, should be grounded if not used for trimming.

STEP I . . . ZERO ADJUST

Turn all bits OFF and adjust zero trimmer R1, until the output reads 0.000 volts (1LSB = 2.44mV). In most cases this trim is not needed, but pin 8 should then be connected to pin 12.

STEP II . . . GAIN ADJUST

Turn all bits ON and adjust 100Ω gain trimmer R2, until the output is 9.9976 volts. (Full scale is adjusted to 1LSB less than nominal full scale of 10.000 volts.) If a 10.2375V full scale is desired (exactly 2.5mV/bit), insert a 120Ω resistor in series with the gain resistor at pin 10 to the op amp output.

FIGURE 2. BIPOLAR CONFIGURATION

This configuration will provide a bipolar output voltage from -5.000 to +4.9976 volts, with positive full scale occurring with all bits ON (all 1's).

STEP I . . . OFFSET ADJUST

Turn OFF all bits. Adjust 100Ω trimmer R1 to give -5.000 volts output.

STEP II . . . GAIN ADJUST

Turn ON All bits. Adjust 100Ω gain trimmer R2 to give a reading of +4.9976 volts.

Please note that it is not necessary to trim the op amp to obtain full accuracy at room temperature. In most bipolar situations, an op amp trim is unnecessary unless the untrimmed offset drift of the op amp is excessive.

FIGURE 3. OTHER VOLTAGE RANGES

The AD565A can also be easily configured for a unipolar 0 to +5 volt range or ±2.5 volt and ±10 volt bipolar ranges by using the additional 5k application resistor provided at the 20 volt span R terminal, pin 11. For a 5 volt span (0 to +5 or ±2.5), the two 5k resistors are used in parallel by shorting pin 11 to pin 9 and connecting pin 10 to the op amp output and the bipolar offset either to ground for unipolar or to REF OUT for the bipolar range. For the ±10 volt range (20 volt span) use the 5k resistors in series by connecting only pin 11 to the op amp output and the bipolar offset connected as shown. The ±10 volt option is shown in Figure 3.

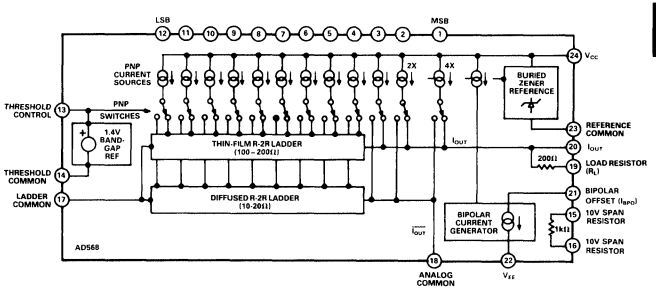
12-Bit Ultrahigh Speed Monolithic D/A Converter

AD568

FEATURES

- **Ultrahigh Speed: Current Settling to 1LSB in 35ns**
- **High Stability Buried Zener Reference on Chip**
- **Monotonicity Guaranteed Over Temperature**
- **10.24mA Full-Scale Output Suitable for Video Applications**
- **Integral and Differential Linearity Guaranteed Over Temperature**
- **0.3" "Skinny DIP" Packaging**
- **Variable Threshold Allows TTL and CMOS Interface**

AD568 FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD568 is an ultrahigh-speed, 12-bit digital-to-analog converter (DAC) settling to 0.025% in 35ns. The monolithic device is fabricated using Analog Devices' Complementary Bipolar (CB) Process. This is a proprietary process featuring high-speed NPN and PNP devices on the same chip without the use of dielectric isolation or multichip hybrid techniques. The high speed of the AD568 is maintained by keeping impedance levels low enough to minimize the effects of parasitic circuit capacitances.

The DAC consists of 16 current sources configured to deliver a 10.24mA full-scale current. Multiple matched current sources and thin-film ladder techniques are combined to produce bit weighting. The DAC's output is a 10.24mA full scale (FS) for current output applications or a 1.024V FS unbuffered voltage output. Additionally, a 10.24V FS buffered output may be generated using an onboard 1kΩ span resistor with an external op amp. Bipolar ranges are accomplished by pin strapping.

Laser wafer trimming insures full 12-bit linearity. All grades of the AD568 are guaranteed monotonic over their full operating temperature range. Furthermore, the output resistance of the DAC is trimmed to 100Ω ± 1.0%. The gain temperature coefficient of the voltage output is 30ppm/°C max (K).

The AD568 is available in three performance grades. The AD568JQ and KQ are available in 24-pin cerdip (0.3") packages and are specified for operation from 0 to +70°C. The AD568SQ features operation from −55°C to +125°C and is also packaged in the hermetic 0.3" cerdip.

PRODUCT HIGHLIGHTS

1. The ultrafast settling time of the AD568 allows leading edge performance in waveform generation, graphics display and high-speed A/D conversion applications.
2. Pin strapping provides a variety of voltage and current output ranges for application versatility. Tight control of the absolute output current reduces trim requirements in externally-scaled applications.
3. Matched on-chip resistors can be used for precision scaling in high-speed A/D conversion circuits.
4. The digital inputs are compatible with TTL and +5V CMOS logic families.
5. Skinny DIP (0.3") packaging minimizes board space requirements and eases layout considerations.

Definitions

LINEARITY ERROR (also called INTEGRAL NON-LINEARITY OR INL): Analog Devices defines linearity error as the maximum deviation of the actual analog output from the ideal output (a straight line drawn from 0 to FS − 1LSB) for any bit combination expressed in multiples of 1LSB. The AD568 is laser trimmed to 1/4LSB (0.006% of FS) maximum linearity error at +25°C for the K version and 1/2LSB for the J and S versions.

DIFFERENTIAL LINEARITY ERROR (also called DIFFERENTIAL NONLINEARITY or DNL): DNL is the measure of the variation in analog value, normalized to full scale, associated with a 1LSB change in digital input code. Monotonic behavior requires that the differential linearity error not exceed 1LSB in the negative direction.

MONOTONICITY: A DAC is said to be monotonic if the output either increases or remains constant as the digital input increases.

UNIPOLAR OFFSET ERROR: The deviation of the analog output from the ideal (0V or 0mA) when the inputs are set to all 0s is called unipolar offset error.

BIPOLAR OFFSET ERROR: The deviation of the analog output from the ideal (negative half-scale) when the inputs are set to all 0s is called bipolar offset error.

BIPOLAR ZERO ERROR: The deviation of the analog output from the ideal half-scale output of 0V (or 0mA) for bipolar mode when only the MSB is on (100.....00) is called bipolar zero error.

GAIN ERROR: The difference between the ideal and actual output span of FS − 1LSB, expressed in % of FS, or LSB, when all bits are on.

GLITCH IMPULSE: Asymmetrical switching times in a DAC give rise to undesired output transients which are quantified by their glitch impulse. It is specified as the net area of the glitch in nV-sec or pA-sec.

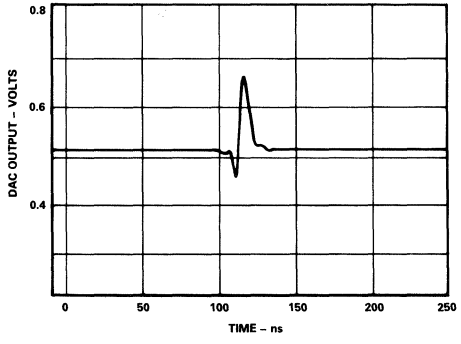

Figure 2. AD568 Glitch Impulse

COMPLIANCE VOLTAGE: The range of allowable voltage at the output of a current-output DAC which will not degrade the accuracy of the output current.

SETTLING TIME: The time required for the output to reach and remain within a specified error band about its final value, measured from the digital input transition.

Connecting the AD568

UNBUFFERED VOLTAGE OUTPUT

Unipolar Configuration

Figure 3 shows the AD568 configured to provide a unipolar 0 to +1.024V output range. In this mode, the bipolar offset terminal, Pin 21, should be grounded if not used for offset trimming.

The nominal output impedance of the AD568 with Pin 19 grounded has been trimmed to 100Ω, ±1%. Other output impedances can be generated with an external resistor, R_{EXT}, between Pins 19 and 20. An R_{EXT} equalling 300Ω will yield a total output resistance of 75Ω, while an R_{EXT} of 100Ω will provide 50Ω of output resistance. Note that since the full-scale output current of the DAC remains 10.24mA, changing the load impedance changes the unbuffered output voltage accordingly. Settling time and full-scale range characteristics for these load impedances are provided in the specifications table.

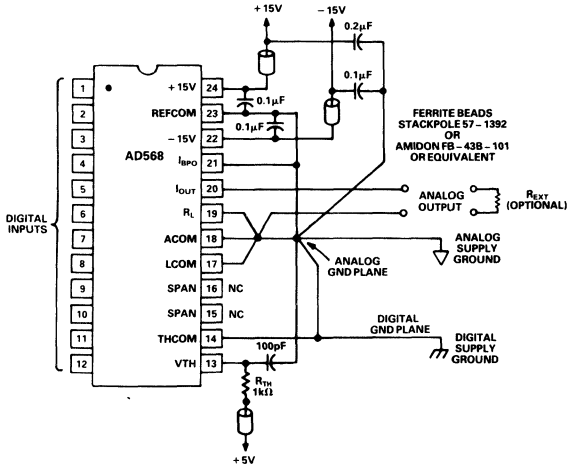

Figure 3. Unipolar Output Unbuffered 0 to +1.024V

Bipolar Configuration

Figure 4 shows the connection scheme used to provide a bipolar output voltage range of 1.024V. The bipolar offset (−0.512V) occurs when all bits are OFF (00 . . . 00), bipolar zero (0V)

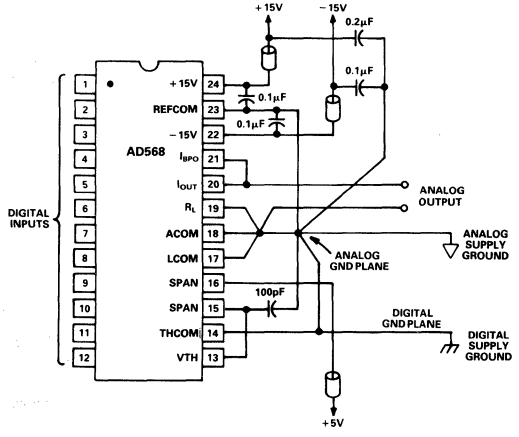

Figure 4. Bipolar Output Unbuffered ±0.512V

occurs when the MSB is ON with all other bits OFF (10 . . . 00), and full-scale minus 1LSB (0.51175V) is generated when all bits are ON (11 . . . 11). Figure 5 shows an optional bipolar mode with a 2.048V range. The scale factor in this mode will not be as accurate as the configuration shown in Figure 4, because the laser-trimmed resistor R_L is not used.

Figure 4 also demonstrates how the internal span resistor may be used to bias the V_{TH} pin (Pin 13) from a 5V supply. This eliminates the requirement for an external R_{TH} in applications that do not require the precision span resistor.

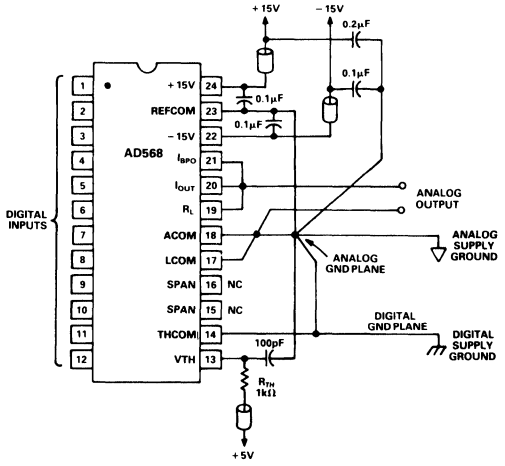

Figure 5. Bipolar Output Unbuffered ± 1.024V

Optional Gain and Zero Adjustment

The gain and offset are laser trimmed to minimize their effects on circuit performance. However, in some applications, it may be desirable to externally reduce these errors further. In those cases, the following procedures are suggested.

UNIPOLAR MODE: (Refer to Figure 6)

Step 1 – Set all bits (BIT 1–BIT 12) to Logic "0" (OFF) – note the output voltage. This is the offset error.

Step 2 – Set all bits to Logic "1" (ON). Adjust the gain trim resistor so that the output voltage is equal to the desired full scale minus 1LSB plus the offset error measured in step 1.

Step 3 – Reset all bits to Logic "0" (OFF). Adjust the offset trim resistor for 0V output.

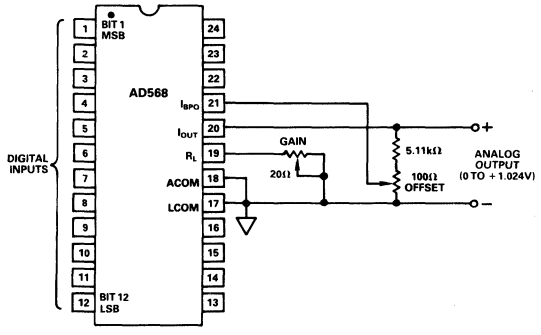

Figure 6. Unbuffered Unipolar Gain and Zero Adjust

BIPOLAR MODE (Refer to Figure 7)

Step 1 – Set bits to offset binary "zero" (10 . . . 00). Adjust the zero resistor to produce 0V at the DAC output. This removes the bipolar zero error.

Step 2 – Set all bits to Logic "1" (ON). Adjust gain trim resistor so the output voltage is equal to the desired full-scale minus 1LSB.

Step 3 – (Optional) If precise trimming of the bipolar offset is preferred to trimming of bipolar zero: set all bits to Logic "0" (OFF). Trim the zero resistor to produce the desired negative full scale at the DAC output.

Note: this may slightly compromise the bipolar zero trim.

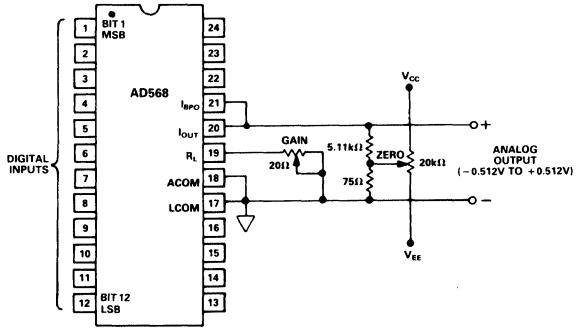

Figure 7. Bipolar Unbuffered Gain and Zero Adjust

BUFFERED VOLTAGE OUTPUT

For full-scale outputs of greater than 1V, some type of external buffer amplifier is required. The AD840 fills this requirement perfectly, settling to 0.025% from a 10V full-scale step in less than 100ns.

A 1kΩ span resistor has been provided on chip for use as a feedback resistor in buffered applications. Using R_{SPAN} (Pins 15, 16) introduces a 100mW code-dependent power source onto the chip which may generate a slight degradation in linearity. Maximum linearity performance can be realized by using an external span resistor.

Unipolar Inverting Configuration

Figure 8 shows the connections for producing a − 10.24V full-scale swing. This configuration uses the AD568 in the current output mode into a summing junction at the inverting input terminal of the external op amp. With the load resistor R_L grounded, the DAC has an output impedance of 100Ω. This produces a noise gain of 11 from the noninverting terminal of the op amp, and hence, satisfies the stability criterion of the AD840 (stable at a gain of 10). The addition of a 5pF compensation capacitor across the 1kΩ feedback resistor produces optimal settling. Lower noise gain can be achieved by connecting R_L to I_{OUT}, increasing the DAC output impedance to approximately 200Ω, and reducing the noise gain to 6 (illustrated in Figure 9). While the output in this configuration will feature improved noise performance, it is somewhat less stable and may suffer from ringing. The compensation capacitance should be increased to 7pF to maintain stability at this reduced gain.

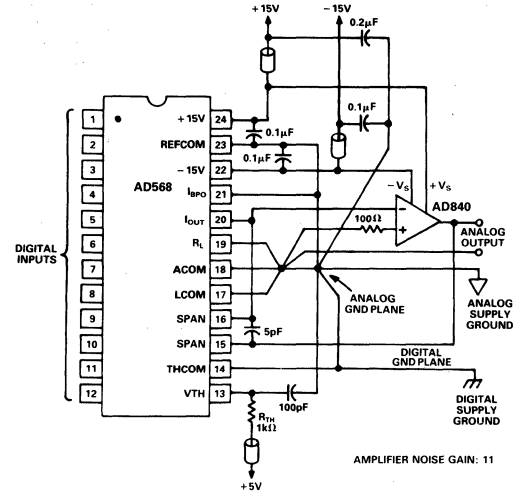

Figure 8. Unipolar Output Buffered 0 to −10.24V

Bipolar Inverting Configuration

Figure 9 illustrates the implementation of a +5.12V to −5.12V bipolar range, achieved by connecting the bipolar offset current, I_{BPO}, to the summing junction of the external amplifier. Note that since the amplifier is providing an inversion, the full-scale output voltage is −5.12V, while the bipolar offset voltage (all bits OFF) is +5.12V at the amplifier output.

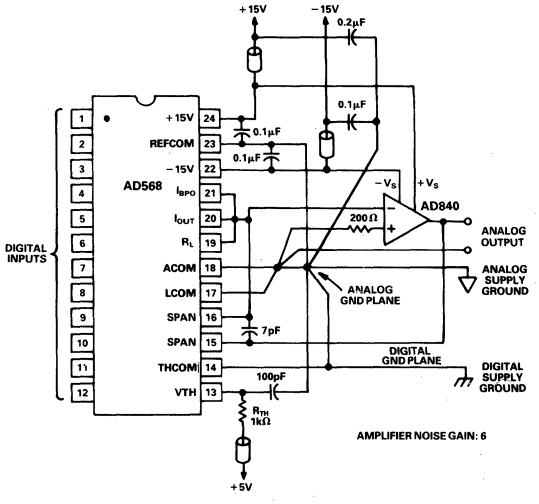

Figure 9. Bipolar Output Buffered ±5.12V

Noninverting Configuration

If a positive full-scale output voltage is required, it can be implemented using the AD568 in the unbuffered voltage output mode followed by the AD840 in a noninverting configuration (Figure 10). The noise gain of this topology is 10, requiring only 5pF across the feedback resistor to optimize settling.

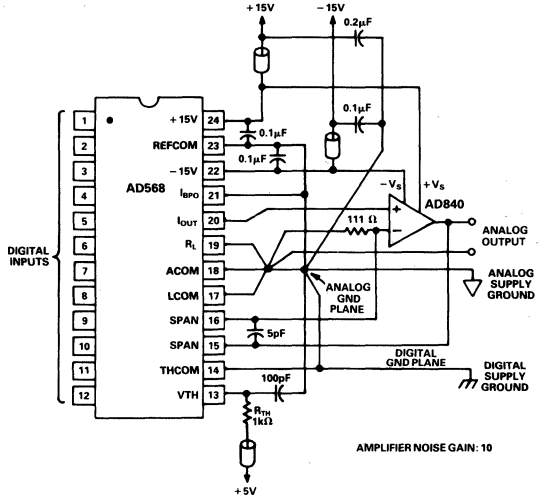

Figure 10. Unipolar Output Buffered 0 to +10.24V

Guidelines for Using the AD568

The designer who seeks to combine high speed with high precision faces a challenging design environment. Where tens of milliamperes are involved, fractions of an ohm of misplaced impedance can generate several LSBs of error. Increasing bandwidths make formerly negligible parasitic capacitances and inductances significant. As system performance reaches and exceeds that of the measurement equipment, time-honored test methods may no longer be trustworthy. The DAC's placement on the boundary between the analog and digital domains introduces additional concerns. Proper RF techniques must be used in board design, device selection, supply bypassing, grounding, and measurement if optimal performance is to be realized. The AD568 has been configured to be relatively easy to use, even in some of the more treacherous applications. The device characteristics shown in this datasheet are readily achievable if proper attention is paid to the details. Since a solid understanding of the circuit involved is one of the designer's best weapons against the difficulties of RF design, the following sections provide illustrations, explanations, examples, and suggestions to facilitate successful design with the AD568.

Current Output vs. Voltage Output

As indicated in Figures 3 through 10, the AD568 has been designed to operate in several different modes depending on the external circuit configuration. While these modes may be categorized by many different schemes, one of the most important distinctions to be made is whether the DAC is to be used to generate an output voltage or an output current. In the current output mode, the DAC output (Pin 20) is tied to some type of summing junction, and the current flowing from the DAC into this summing junction is sensed (e.g., Figures 8 and 9). In this mode, the DAC output scale is insensitive to whether the load resistor, R_L, is shorted (Pin 19 connected to Pin 20), or grounded (Pin 19 connected to Pin 18). However, this does affect the output impedance of the DAC current and may have a significant impact on the noise gain of the external circuitry. In the voltage output mode, the DAC's output current flows through its own internal impedance (perhaps in parallel with an external impedance) to generate a voltage, as in Figures 3, 4, 5, and 10. In this

case, the DAC output scale is directly dependent on the load impedance. The temperature coefficient of the AD568's internal reference is trimmed in such a way that the drift of the DAC output in the voltage output mode is centered on zero. The current output of the DAC will have an additional drift factor corresponding to the absolute temperature coefficient of the internal thin-film resistors. This additional drift may be removed by judicious placement of the 1kΩ span resistor in the signal path. For example, in Figures 8 and 9, the current flowing from the DAC into the summing junction could suffer from as much as 150ppm/°C of thermal drift. However, since this current flows through the internal span resistor (Pins 15 and 16) which has a temperature coefficient that matches the DAC ladder resistors, this drift factor is compensated and the buffered voltage at the amplifier output will be within specified limits for the voltage output mode.

Output Voltage Compliance

The AD568 has a typical output compliance range of +1.2V to −2.0V (with respect to the LCOM Pin). The current-steering output stages will be unaffected by changes in the output terminal voltage over that range. However, as shown in Figure 11, there is an equivalent output impedance of 200Ω in parallel with 15pF at the output terminal which produces an equivalent error current if the voltage deviates from the ladder common. This is a linear effect which does not change with input code. Operation beyond the maximum compliance limits may cause either output stage saturation or breakdown resulting in nonlinear performance. The positive compliance limit is not affected by the positive power supply, but is a function of output current and the logic threshold voltage at V_{TH}, Pin 13.

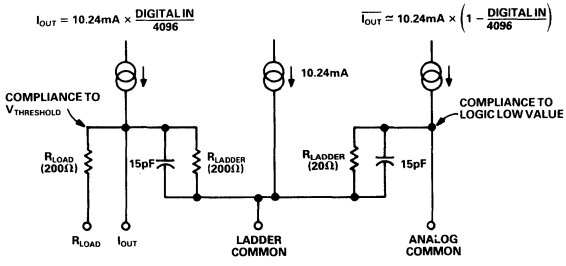

Figure 11. Equivalent Output

Digital Input Considerations

The AD568 uses a standard positive true straight binary code for unipolar outputs (all 1s full-scale output), and an offset binary code for bipolar output ranges. In the bipolar mode, with all 0s on the inputs, the output will go to negative full scale; with 111 . . . 11, the output will go to positive full scale less 1LSB; and with 100 . . 00 (only the MSB on), the output will go to zero.

The threshold of the digital inputs is set at 1.4V and does not vary with supply voltage. This is provided by a bandgap reference generator, which requires approximately 3mA of bias current achieved by tying R_{TH} to any $+V_L$ supply where

$$R_{TH} = \left(\frac{+V_L - 1.4V}{3mA}\right).$$

The input lines operate with small input currents to easily achieve interface with unbuffered CMOS logic. The digital input signals to the DAC should be isolated from the analog output as much as possible. To minimize undershoot, ringing, and possible digital feedthrough noise, the interconnect distances to the DAC inputs should be kept as short as possible. Termination resistors may improve performance if the digital lines become too long. The digital input should be free from large glitches and ringing and have maximum 10% to 90% rise and fall times of 5ns. Figure 12 shows the equivalent digital input circuit of the AD568.

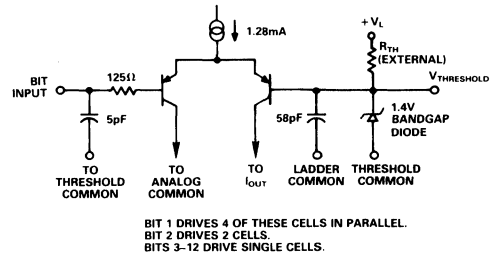

Figure 12. Equivalent Digital Input

Due to the high-speed nature of the AD568, it is recommended that high-speed logic families such as Schottky TTL, high-speed CMOS, or the new lines of FAST* TTL be used exclusively. Table I shows how DAC performance can vary depending on the driving logic used. As this table indicates, STTL, HCMOS, and FAST represent the most viable families for driving the AD568.

DAC PERFORMANCE VS. DRIVE LOGIC[1]

Logic Family	10-90% DAC Rise Time[2]	DAC SETTLING TIME[2,3] 1%	0.1%	0.025%	Glitch[4] Impulse	Maximum Glitch Excursion
TTL	11ns	18ns	34ns	50ns	2.5nV-s	240mV
LSTTL	11ns	28ns	46ns	80ns	950pV-s	160mV
STTL	9.5ns	16ns	33ns	50ns	850pV-s	150mV
HCMOS	11ns	24ns	38ns	50ns	350pV-s	115mV
FAST*	12ns	16ns	36ns	42ns	1.0nV-s	250mV

[1]All values typical, taken in test fixture diagrammed in Figure 13.
[2]Measurements are made for a 1V full-scale step into 100ΩDAC load resistance.
[3]Settling time is measured from the time the digital input crosses the threshold voltage (1.4V) to when the output is within the specified range of its final value.
[4]The worst case glitch impulse, measured on the major carry. DAC full scale is 1V.

Table I.

The variations in settling times can be attributed to differences in the rise time and current driving capabilities of the various families. Differences in the glitch impulse are predominantly dependent upon the variation in data skew. Variations in these specs occur not only between logic families, but also between different gates and latches within the same family. When selecting a gate to drive the AD568 logic input, pay particular attention to the propagation delay time specs: t_{PLH} and t_{PHL}. Selecting the smallest delays possible will help to minimize the settling time, while selection of gates where t_{PLH} and t_{PHL} are closely matched to one another will minimize the glitch impulse resulting from data skew. Of the common latches, the 74374 octal flip-flop provides the best performance in this area for many of the logic families mentioned above.

***FAST is a registered trademark of Fairchild Camera and Instrumentation Corporation.**

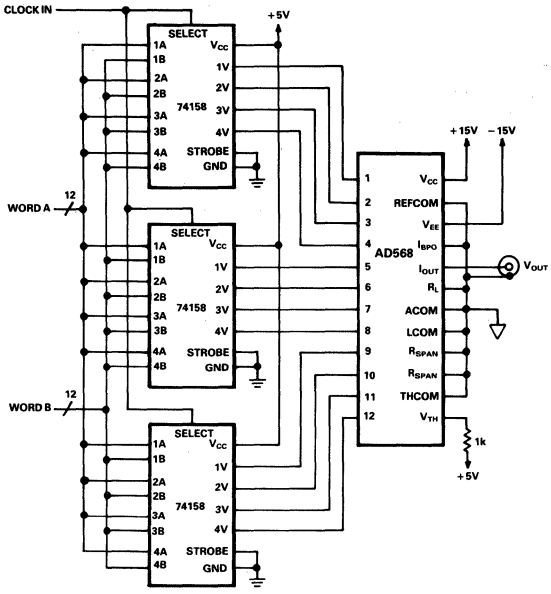

Figure 13. Test Setup for Glitch Impulse and Settling Time Measurements

Settling Time Considerations

As can be seen from Table I and the specifications page, the settling time of the AD568 is application dependent. The fastest settling is achieved in the current-output mode, since the voltage-output mode requires the output capacitance to be charged to the appropriate voltage. The DAC's relatively large output current helps to minimize this effect, but settling-time sensitive applications should avoid any unnecessary parasitic capacitance at the output node of voltage output configurations. Direct measurement of the fine scale DAC settling time, even in the voltage output mode, is extremely tricky: analog scope front ends are generally incapable of recovering from overdrive quickly enough to give an accurate settling representation. The plot shown in Figure 14 was obtained using Data Precision's 640 16-bit sampling head, which features the quick overdrive recovery characteristic of sampling approaches combined with high accuracy and relatively small thermal tail.

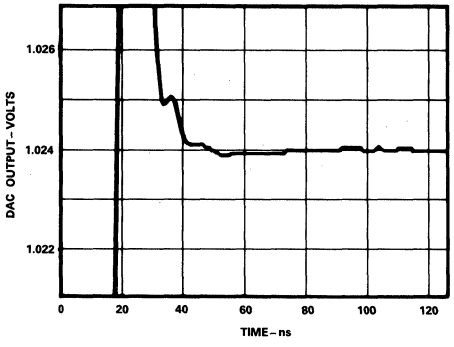

Figure 14. Zero to Full-Scale Settling

Glitch Considerations

In many high-speed DAC applications, glitch performance is a critical specification. In a conventional DAC architecture such as the AD568 there are two basic glitch mechanisms: data skew and digital feedthrough. A thorough understanding of these sources can help the user to minimize glitch in any application.

DIGITAL FEEDTHROUGH – As with any converter product, a high-speed digital-to-analog converter is forced to exist on the frontier between the noisy environment of high-speed digital logic and the sensitive analog domain. The problems of this interfacing are particularly acute when demands of high speed (greater than 10MHz switching times) and high precision (12 bits or more) are combined. No amount of design effort can perfectly isolate the analog portions of a DAC from the spectral components of a digital input signal with a 2ns risetime. Inevitably, once this digital signal is brought onto the chip, some of its higher frequency components will find their way to the sensitive analog nodes, producing a digital feedthrough glitch. To minimize the exposure to this effect, the AD568 has intentionally omitted the on-board latches that have been included in many slower DACs. This not only reduces the overall level of digital activity on chip, it also avoids bringing a latch clock pulse on board, whose opposite edge inevitably produces a substantial glitch, even when the DAC is not supposed to be changing codes. Another path for digital noise to find its way onto a converter chip is through the reference input pin. The completely internal reference featured in the AD568 eliminates this noise input, providing a greater degree of signal integrity in the analog portions of the chip.

DATA SKEW – The AD568, like many of its slower predecessors, essentially uses each digital input line to switch a separate, weighted current to either the output (I_{OUT}) or some other node (ANALOG COM). If the input bits are not changed simultaneously, or if the different DAC bits switch at different speeds, then the DAC output current will momentarily take on some incorrect value. This effect is particularly troublesome at the "carry points", where the DAC output is to change by only one LSB, but several of the larger current sources must be switched to realize this change. Data skew can allow the DAC output to move a substantial amount towards full scale or zero (depending upon the direction of the skew) when only a small transition is desired. Great care was taken in the design and layout of the AD568 to ensure that switching times of the DAC switches are symmetrical and that the length of the input data lines are short and well matched. The glitch-sensitive user should be equally diligent about minimizing the data skew at the AD568's inputs, particularly for the 4 or 5 most significant bits. This can be achieved by using the proper logic family and gate to drive the DAC, and keeping the interconnect lines between the logic outputs and the DAC inputs as short and as well matched as possible, particularly for the most significant bits. The top 6 bits should be driven from the same latch chip if latches are used.

Glitch Reduction Schemes

BIT-DESKEWING – Even carefully laid-out boards using the proper driving logic may suffer from some degree of data-skew induced glitch. One common approach to reducing this effect is to add some appropriate capacitance (usually several pF) to each of the 2 or 3 most significant bits. The exact value of each capacitor for a given application should be determined experimentally, as it will be dependent on circuit board layout and the type of driving logic used. Table II presents a few examples of how the glitch impulse may be reduced through passive deskewing.

BIT DELAY GLITCH REDUCTION EXAMPLES[1]

Logic Family	Gate	Uncompensated Glitch	Compensation Used	Compensated Glitch
HCMOS	74157	350pV-s	C2 = 5pF	250pV-s
STTL	74158	850pV-s	R1 = 50Ω, C1 = 7pF	600pV-s

NOTE
[1]Measurements were made using a modified version of the fixture shown in Figure 13, with resistors and capacitors placed as shown in Figure 15. Resistance and capacitance values were set to zero except as noted.

Table II.

As Figure 15 indicates, in some cases it may prove useful to place a few hundred ohms of series resistance in the input line to enhance the delay effect. This approach also helps to reduce some of the digital feedthrough glitch, as the higher frequency spectral components are being filtered out of the most significant bits' digital inputs.

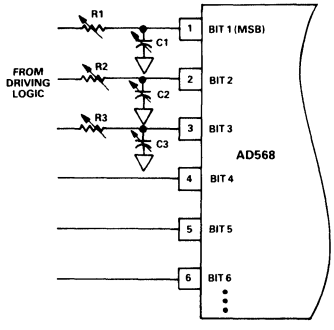

Figure 15. R-C Bit Deskewing Scheme

THRESHOLD SHIFT – It is also possible to reduce the data skew by shifting the level of logic voltage threshold, V_{TH} (Pin 13). This can be readily accomplished by inserting some resistance between the THRESHOLD COM pin (Pin 14) and ground, as in Figure 16. To generate threshold voltages below 1.4V, Pin 13 may be directly driven with a voltage source, leaving Pin 14 tied to the ground plane. As Note 2 in Table III indicates, lowering the threshold voltage may reduce output voltage compliance below the specified limits, which may be of concern in an unbuffered voltage output topology.

Table III shows the glitch reduction achieved by shifting the threshold voltage for HCMOS, STTL, and FAST logic.

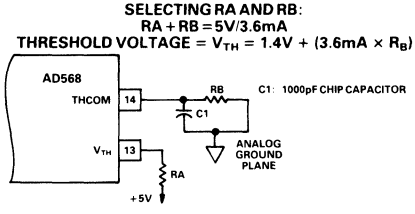

Figure 16. Positive Threshold Voltage Shift

THRESHOLD SHIFT FOR GLITCH IMPROVEMENT[1]

Logic Family	Gate	Uncompensated Glitch	Modified Threshold[2]	Resulting Glitch
HCMOS	74HC158	350pV-s	1.7V	150pV-s
STTL	74S158	850pV-s	1.0V	200pV-s
FAST	74F158	1000pV-s	1.3V	480pV-s

NOTES
[1]Measurements made on a modified version of the circuit shown in Figure 13, with a 1V full scale.
[2]Use care in any scheme that lowers the threshold voltage since the output voltage compliance of the DAC is sensitive to this voltage. If the DAC is to be operated in the voltage output mode, it is strongly suggested that the threshold voltage be set at least 200mV above the output voltage full scale.

Table III.

Deglitching

Some applications may prove so sensitive to glitch impulse that reduction of glitch impulse by an order of magnitude or more is required. In order to realize glitch impulses this low, some sort of sample-and-hold amplifier (SHA)-based deglitching scheme must be used.

There are high-speed SHAs available with specifications sufficient to deglitch the AD568, however most are hybrid in design at costs which can be prohibitive. A high performance, low cost alternative shown in Figure 17 is a discrete SHA utilizing a high-speed monolithic op amp and high-speed DMOS FET switches.

This SHA circuit uses the inverting integrator architecture. The AD841 operational amplifier used (300MHz gain bandwidth product) is fabricated on the same high-speed process as the AD568. The time constant formed by the 200Ω resistor and the 100pF capacitor determines the acquisition time and also band limits the output signal to eliminate slew induced distortion.

A discrete drive circuit is used to achieve the best performance from the SD5000 quad DMOS switch. This switch driving cell is composed of MPS571 RF npn transistors and an MC10124 TTL to ECL translator. Using this technique provides both high speed and highly symmetrical drive signals for the SD5000 switches. The switches are arranged in a single-throw double-pole (SPDT) configuration. The 360pF "flyback" capacitor is switched to the op amp summing junction during the hold mode to keep switching transients from feeding to the output. This capacitor is grounded during sample mode to minimize its effect on acquisition time.

Circuit layout for a high speed SHA is almost as critical as the design itself. Figure 17 shows a recommended layout of the deglitching cell for a double sided printed circuit board. The layout is very compact with care taken that all critical signal paths are short.

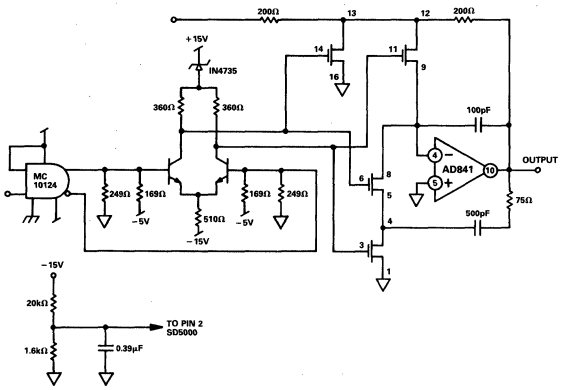

Figure 17. High Performance Deglitcher

Grounding Rules

The AD568 brings out separate reference, output, and digital power grounds. This allows for optimum management of signal ground currents for low noise and high-speed settling performance. The separate ground returns are provided to minimize changes in current flow in the analog signal paths. In this way, logic return currents are not summed into the same return path with the analog signals.

It is important to understand which supply and signal currents are flowing in which grounds so that they may be returned to the proper power supply in the best possible way.

The majority of the current that flows into the V_{CC} supply (Pin 24) flows out (depending on the DAC input code) either the ANALOG COMMON (Pin 18), the LADDER COMMON (Pin 17), and/or I_{OUT} (Pin 20).

The current in the LADDER COMMON is configured to be code independent when the output current is being summed into a virtual ground. If I_{OUT} is operated into its own output impedance (or in any unbuffered voltage output mode) the current in LADDER COMMON will become partially code dependent.

The current in the ANALOG COMMON (Pin 18) is an approximate complement of the current in I_{OUT}, i.e., zero when the DAC is at full scale and approximately 10mA at zero input code.

A relatively constant current (not code dependent) flows out the REFERENCE COMMON (Pin 23).

The current flowing out of the V_{EE} supply (Pin 22) comes from a combination of reference ground and BIPOLAR OFFSET (Pin 21). The plus and minus 15V supplies are decoupled to the REFERENCE COMMON.

The ground side of the load resistor R_L, ANALOG COMMON and LADDER COMMON should be tied together as close to the package pins as possible. The analog output voltage is then referred to this node and thus it becomes the "high quality" ground for the AD568. The REFERENCE COMMON (and Bipolar offset when not used), should also be connected to this node.

All of the current that flows into the V_{TH} terminal (Pin 13) from the resistor tied to the 5V logic supply (or other convenient positive supply) flows out the THRESHOLD COMMON (Pin 14). This ground pin should be returned directly to the digital ground plane on its own individual line.

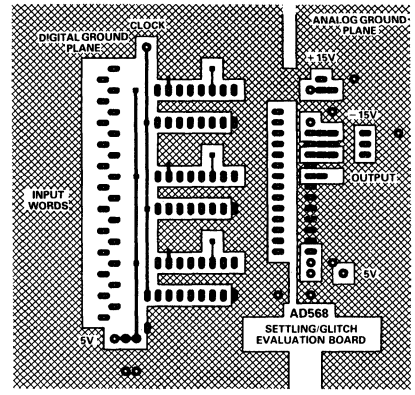
The +5V logic supply should be decoupled to the THRESHOLD COMMON.

Because the V_{TH} pin is connected directly to the DAC switches it should be decoupled to the analog output signal common.

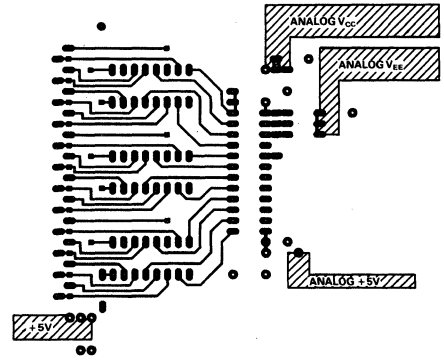
In order to preserve proper operation of the DAC switches, the digital and analog grounds need to eventually be tied together. This connection between the ground planes should be made within 1/2" of the DAC.

The Use of Ground and Power Planes

If used properly, ground planes can perform a myriad of functions on high-speed circuit boards: bypassing, shielding, current transport, etc. In mixed signal design, the analog and digital portions of the board should be distinct from one another, with the analog ground plane covering analog signal traces and the digital ground plane confined to areas covering digital interconnect.



Component Side



Foil Side

Figure 18. Printed Circuit Board Layout

The two ground planes should be connected at or near the DAC. Care should be taken to insure that the ground plane is uninterrupted over crucial signal paths. On the digital side, this includes the digital input lines running to the DAC and any clock lines. On the analog side, this includes the DAC output signal as well as the supply feeders. The use of wide runs or planes in the routing of power lines is also recommended. This serves the dual function of providing a low series impedance power supply to the part as well as providing some "free" capacitive decoupling to the appropriate ground plane. Figure 18 illustrates the PC board used for the circuit shown in Figure 13. This design was constructed on a simple two-layer board and illustrates many of the points discussed above. If more layers of interconnect are available, even better results are possible.

Using The Right Bypass Capacitors

Probably the most important external components associated with any high-speed design are the capacitors used to bypass the power supplies. Both selection and placement of these capacitors can be critical and, to a large extent, dependent upon the specifics of the system configurations. The dominant consideration in selection of bypass capacitors for the AD568 is minimization of series resistance and inductance. Many capacitors will begin to look inductive at 20MHz and above, the very frequencies we are most interested in bypassing. Ceramic and film-type capacitors generally feature lower series inductance than tantalum or electrolytic types. A few general rules are of universal use when approaching the problem of bypassing:

Bypass capacitors should be installed on the printed circuit board with the shortest possible leads consistent with reliable construction. This helps to minimize series inductance in the leads. Chip capacitors are optimal in this respect.

Some series inductance between the DAC supply pins and the power supply plane often helps to filter out high-frequency power supply noise. This inductance can be generated using a small ferrite bead.

High-Speed Interconnect and Routing

It is essential that care be taken in the signal and power ground circuits to avoid inducing extraneous voltage drops in the signal ground paths. It is suggested that all connections be short and direct, and as physically close to the package as possible, so that the length of any conduction path shared by external components will be minimized. When runs exceed an inch or so in length, some type of termination resistor may be required. The necessity and value of this resistor will be dependent upon the logic family used.

For maximum ac performance, the DAC should be mounted directly to the circuit board; sockets should not be used as they introduce unwanted capacitive coupling between adjacent pins of the device.

Applications

1μs, 12-BIT SUCCESSIVE APPROXIMATION A/D CONVERTER

The AD568's unique combination of high speed and true 12-bit accuracy can be used to construct a 12-bit SAR-type A/D converter with a sub-μs conversion time. Figure 19 shows the configuration used for this application. A negative analog input voltage is converted into current and brought into a summing junction with the DAC current. This summing junction is bidirectionally clamped with two Shottky diodes to limit its voltage excursion from ground. This voltage is differentially amplified and passed to a high-speed comparator. The comparator output is latched and fed back to the successive approximation register, which is then clocked to generate the next set of codes for the DAC.

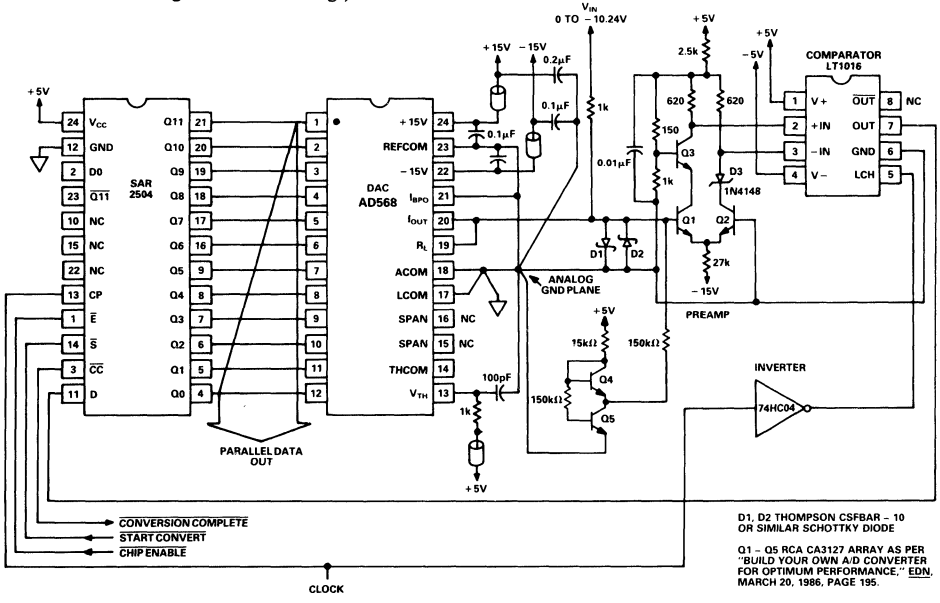


Figure 19. AD568 1μs Successive Approximation A/D Application

Circuit Details

Figure 20 shows an approximate timing budget for the A/D converter. If 12 cycles are to be completed in 1μs, approximately 80ns is allowed for each cycle. Since the Shottky diodes clamp the voltage of the summing junction, the DAC settling time approaches the current-settling value of 35ns, and hence uses up less than half the timing budget.

To maintain simplicity, a simple clock is used that runs at a constant rate throughout the conversion, with a duty cycle of approximately 90%. If absolute speed is worth the additional complexity, the clock frequency can be increased as the conversion progresses since the DAC must settle from increasingly smaller steps.

When seeking a cycle time of less than 100ns, the delays generated by the older generation SAR registers become problematic. Newer, higher speed SAR logic chips are becoming available in the classic 2504 pinout that cuts the logic overhead in half. One example of this is Zyrel's ZR2504.

Finding a comparator capable of keeping up with this DAC arrangement is fairly difficult: it must respond to an overdrive of 250μV (1LSB) in less than 25ns. Since no inexpensive comparator exists with these specs, special arrangements must be made. The LT1016 comparator provides relatively quick response, but requires at least 5mV of overdrive to maintain this speed. A discrete preamplifier may be used to amplify the summing junction voltage to sufficiently overdrive the comparator. Care must be exercised in the layout of the preamp/comparator block to avoid introducing comparator instability with the preamp's additional gain.

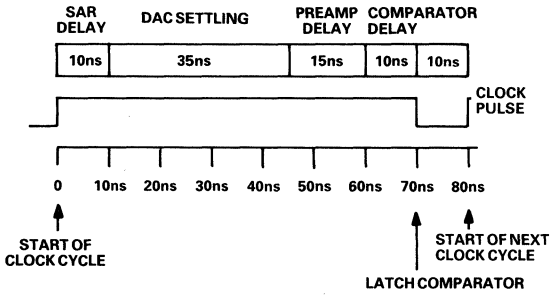

Figure 20. Typical Clock Cycle for a 1μs SAR A/D Converter

HIGH-SPEED MULTIPLYING DAC

A powerful use for the AD568 is found in multiplying applications, where the DAC controls the amplitude of a high-speed signal. Specifically, using the AD568 as the control voltage input signal for the AD539 60MHz analog multiplier and AD5539 wide-band op amp, a high-speed multiplying DAC can be built.

In the application shown in Figure 21, the AD568 is used in a buffered voltage output mode to generate the input to the AD539's control channel. The speed of the AD568 allows oversampling of the control signal waveform voltage, thereby providing increased spectral purity of the amplitude envelope that modulates the analog input channels.

The AD568 is configured in the unbuffered unipolar output mode. The internal 200Ω load resistor creates the 0-1V FS output signal, which is buffered and amplified to a 0-3V range suitable for the control channel of the AD539.

A 500Ω input impedance exists at Pin 1, the input channel. To provide a buffer for the 0-1V output signal from the AD568 looking into the impedance and to achieve the full-scale range, the AD841, high-speed, fast settling op amp is included. The gain of 3 is achieved with a 2kΩ resistor configured in follower mode with a 1kΩ pot and 500Ω resistor. A 20kΩ pot with connections to Pins 3, 4 and 12 is provided for offset trim.

The AD539 can accept two separate input signals, each with a nominal full-scale voltage range of ±2V. Each signal can then be simultaneously controlled by the AD568 signal at the common input channel, V_X. The current outputs from the two signal channels, Pins 11 and 14, applied to the AD5539 in a subtracting configuration, provide the voltage output signal:

$$V_{OUT} = \frac{D}{4096} \times \frac{V_{Y1} - V_{Y2}}{2V} \quad (0 \leq D \leq 4095)$$

For applications where only a single channel is involved, channel 2, V_{Y2}, is tied to ground. This provides:

$$V_{OUT} = \frac{D}{4096} \times \frac{V_{Y1}}{2V} \quad (0 \leq D \leq 4095)$$

Some AD539 circuit details: The control amplifier compensation capacitor for Pin 2, C_C, must have a minimum value of 3000pF to provide circuit stability. For improved bandwidth and feedthrough, the feedthrough capacitor between Pins 1 and 2 should be 5-20% of C_C. A Schottky diode at Pin 2 can improve recovery time from small negative values of V_X. Lead lengths along the path of the high-speed signal from AD568 should be kept at a minimum.

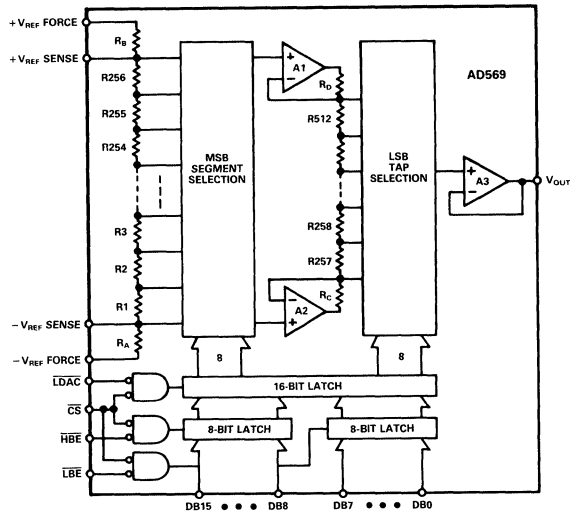
AD569 FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD569 is a monolithic 16-bit digital-to-analog converter (DAC) manufactured in Analog Devices' BiMOS II process. BiMOS II allows the fabrication of low power CMOS logic functions on the same chip as high precision bipolar linear circuitry. The AD569 chip includes two resistor strings, selector switches, decoding logic, buffer amplifiers, and double-buffered input latches.

The AD569's voltage-segmented architecture insures 16-bit monotonicity over time and temperature. Integral nonlinearity is maintained at ±0.01%, while differential nonlinearity is ±0.0004%. The on-chip, high-speed buffer amplifiers provide a voltage output settling time of 3μs to within ±0.001% for a full-scale step.

The reference input voltage which determines the output range can be either unipolar or bipolar. Nominal reference range is ±5V and separate reference force and sense connections are provided for high accuracy applications. The AD569 can operate with an ac reference in multiplying applications.

Data may be loaded into the AD569's input latches from 8- and 16-bit buses. The double-buffered structure simplifies 8-bit bus interfacing and allows multiple DACs to be loaded asynchronously and updated simultaneously. Four TTL/LSTTL/5V CMOS-compatible signals control the latches: $\overline{CS}$, $\overline{LBE}$, $\overline{HBE}$, and $\overline{LDAC}$.

The AD569 is available in five grades: J and K versions are specified from 0 to +70°C and are packaged in a 28-pin plastic DIP and 28-pin PLCC package; AD and BD versions are specified from −25°C to +85°C and are packaged in a 28-pin ceramic DIP. The SD version, also in a 28-pin ceramic DIP, is specified from −55°C to +125°C.

PRODUCT HIGHLIGHTS

1. Monotonicity to 16 bits is insured by the AD569's voltage-segmented architecture.
2. The output range is ratiometric to an external reference or ac signal. Gain error and gain drift of the AD569 are negligible.
3. The AD569's versatile data input structure allows loading from 8- and 16-bit buses.
4. The on-chip output buffer amplifier can supply ±5V into a 1kΩ load, and can drive capacitive loads of up to 1000pF.
5. Kelvin connections to the reference inputs preserve the gain and offset accuracy of the transfer function in the presence of wiring resistances and ground currents.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ESD SENSITIVITY

The AD569 features input protection circuitry consisting of large "distributed" diodes and polysilicon series resistors to dissipate both high-energy discharges (Human Body Model) and fast, low-energy pulses (Charged Device Model). Per Method 3015.2 of MIL-STD-883C, the AD569 has been classified as a Category A device.

Proper ESD precautions are strongly recommended to avoid functional damage or performance degradation. Charges as high as 4000 volts readily accumulate on the human body and test equipment and discharge without detection. Unused devices must be stored in conductive foam or shunts, and the foam should be discharged to the destination socket before devices are removed. For further information on ESD precautions, refer to Analog Devices' ESD Prevention Manual.

FUNCTIONAL DESCRIPTION

The AD569 consists of two resistor strings, each of which is divided into 256 equal segments (see Figure 3). The 8MSBs of the digital input word select one of the 256 segments on the first string. The taps at the top and bottom of the selected segment are connected to the inputs of the two buffer amplifiers A1 and A2. These amplifiers exhibit extremely high CMRR and low bias current, and thus accurately preserve the voltages at the top and bottom of the segment. The buffered voltages from the segment endpoints are applied across the second resistor string, where the 8LSBs of the digital input word select one of the 256 taps. Output amplifier A3 buffers this voltage and delivers it to the output.

Buffer amplifiers A1 and A2 leap-frog up the first string to preserve monotonicity at the segment boundaries. For example, when increasing the digital code from $00FF_H$ to 0100_H, (the first segment boundary), A1 remains connected to the same tap on the first resistor, while A2 jumps over it and is connected to the tap which becomes the top of the next segment. This design guarantees monotonicity even if the amplifiers have offset voltages. In fact, amplifier offset only contributes to integral linearity error.

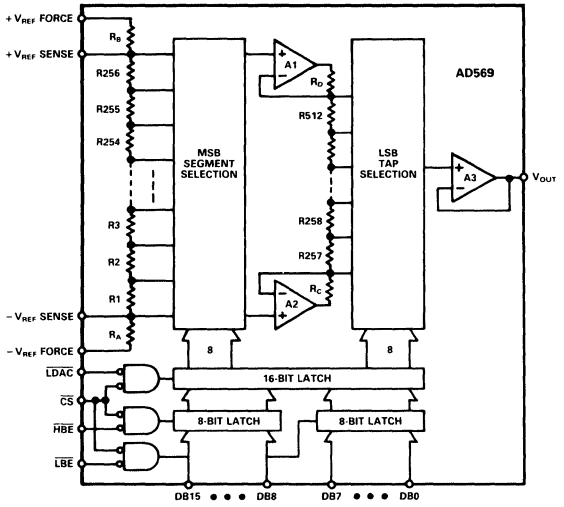

Figure 3. AD569 Block Diagram

CAUTION

It is generally considered good engineering practice to avoid inserting integrated circuits into powered-up sockets. This guideline is especially important with the AD569. An empty, powered-up socket configures external buffer amplifiers in an open-loop mode, forcing their outputs to be at the positive or negative rail. This condition may result in a large current surge between the reference force and sense terminals. This current surge may permanently damage the AD569.

ANALOG CIRCUIT DETAILS

Definitions

LINEARITY ERROR: Analog Devices defines linearity error as the maximum deviation of the actual, adjusted DAC output from the ideal output (a straight line drawn from 0 to FS-1LSB) for any bit combination. The AD569's linearity is primarily limited by resistor uniformity in the first divider (upper byte of 16-bit input). The plot in Figure 4 shows the AD569's typical linearity error across the entire output range to be within ±0.01% of full scale. At 25°C the maximum linearity error for the AD569JN, AD and SD grades is specified to be ±0.04%, and ±0.024% for the KN and BD versions.

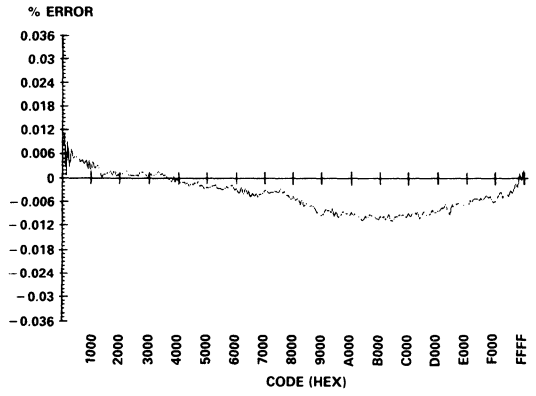

Figure 4. Typical Linearity

MONOTONICITY: A DAC is monotonic if the output either increases or remains constant for increasing digital inputs. All versions of the AD569 are monotonic over their full operating temperature range.

DIFFERENTIAL NONLINEARITY: DNL is the measure of the change in the analog output, normalized to full scale, associated with a 1LSB change in the digital input code. Monotonic behavior requires that the differential linearity error be less than 1LSB over the temperature range of interest. For example, for a ±5V output range, a change of 1LSB in digital input code should result in a 152μV change in the analog output (1LSB = 10V/65,536). If the change is actually 38μV, however, the differential linearity error would be −114μV, or −3/4LSB. By leapfrogging the buffer amplifier taps on the first divider, a typical AD569 keeps DNL within ±38μV (±1/4LSB) around each of the 256 segment boundaries defined by the upper byte of the input word (see Figure 5). Within the second divider, DNL also typically remains less than ±38μV as shown in Figure 6. Since the second divider is independent of absolute voltage, DNL is the same within the rest of the 256 segments.

OFFSET ERROR: The difference between the actual analog output and the ideal output ($-V_{REF}$), with the inputs loaded with all zeros is called the offset error. For the AD569, Unipolar Offset is specified with 0V applied to $-V_{REF}$ and Bipolar Offset is specified with −5V applied to $-V_{REF}$. Either offset is trimmed by adjusting the voltage applied to the $-V_{REF}$ terminals.

BIPOLAR ZERO ERROR: The deviation of the analog output from the ideal half-scale output of 0.0000V when the inputs are loaded with 8000_H is called the Bipolar Zero Error. For the AD569, it is specified with ±5V applied to the reference terminals.

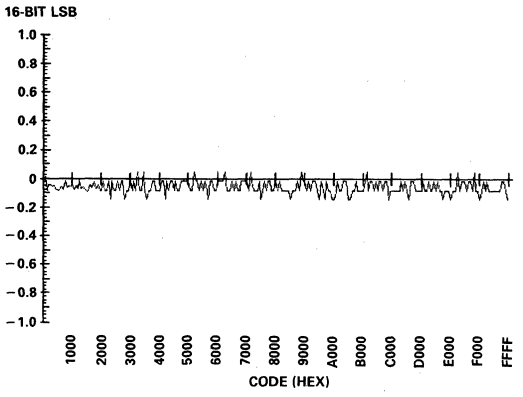

Figure 5. Typical DNL at Segment Boundary Transitions

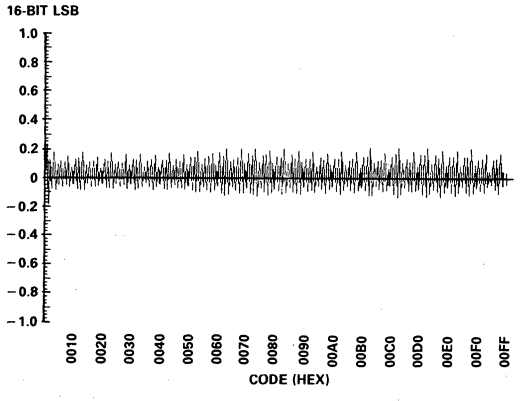
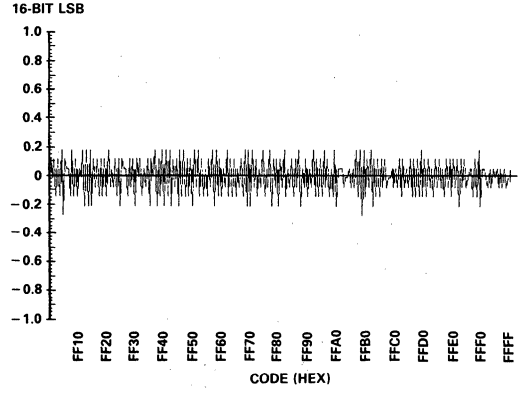


a. Segment 1



b. Segment 256

Figure 6. Typical DNL Within Segments

MULTIPLYING FEEDTHROUGH ERROR: This is the error due to capacitive feedthrough from the reference to the output with the input registers loaded with all zeroes.

FULL-SCALE ERROR: The AD569's voltage dividing architecture gives rise to a fixed full-scale error which is independent of the reference voltage. This error is trimmed by adjusting the voltage applied to the $+V_{REF}$ terminals.

DIGITAL-TO-ANALOG GLITCH IMPULSE: The charge injected into the analog output when a new input is latched into the DAC register gives rise to the Digital-to-Analog Glitch Impulse. Glitches can be due to either time skews between the input bits or charge injection from the internal switches. Glitch Impulse for the AD569 is mainly due to charge injection, and is measured with the reference connections tied to ground. It is specified as the area of the glitch in nV-secs.

TOTAL ERROR: The worst-case Total Error is the sum of the fixed full-scale and offset errors and the linearity error.

POWER SUPPLY AND REFERENCE VOLTAGE RANGES

The AD569 is specified for operation with ±12 volt power supplies. With ±10% power supply tolerances, the maximum reference voltage range is ±5 volts. Reference voltages up to ±6 volts can be used but linearity will degrade if the supplies approach their lower limits of ±10.8 volts (12 volts – 10%).

If ±12 volt power supplies are unavailable in the system, several alternative schemes may be used to obtain the needed supply voltages. For example, in a system with ±15V supplies, a single Zener diode can be used to reduce one of the supplies to 9 volts with the remaining one left at 15 volts. Figure 7a illustrates this scheme. A 1N753A or equivalent diode is an appropriate choice for the task. Asymmetrical power supplies can be used since the AD569's output is referenced to $-V_{REF}$ only and thus floats relative to logic ground (GND, Pin 18). Assuming a worst-case ±1.5 volt tolerance on both supplies (10% of 15 volts), the maximum reference voltage ranges would be +6 and −2 volts for $+V_S = +15V$ and $-V_S = -9V$, and +2 to −8 volts for $+V_S = 9V$ and $-V_S = -15V$.

Alternately, two 3V Zener diodes or voltage regulators can be used to drop each ±15 volt supply to ±12 volts, respectively. In Figure 7b, 1N746A diodes are a good choice for this task.

A third method may be used if both ±15 volt and ±5 volt supplies are available. Figure 7c shows this approach. A combination of $+V_S = +15V$ and $-V_S = -5V$ can support a reference range of 0 to 6 volts, while supplies of $+V_S = +5V$ and $-V_S = -15V$ can support a reference range of 0 to −8 volts. Again, 10% power supply tolerances are assumed.

NOTE: Operation with $+V_S = +5V$ alters the input latches' operating conditions causing minimum write pulse widths to extend to 1μs or more. Control signals $\overline{CS}$, $\overline{HBE}$, $\overline{LBE}$, and $\overline{LDAC}$ should, therefore, be tied low to render the latches transparent.

No timing problems exist with operation at $+V_S = 9V$ and $-V_S = -15V$. However, 10% tolerances on these supplies generate a worst-case condition at $-V_S = -16.5V$ and $+V_S = +7.5V$ (assuming $+V_S$ is derived from a +15V supply). Under these conditions, write pulse widths can stretch to 200ns with similar degradation of data setup and hold times. However, ±0.75V tolerances (±5%) yield minimal effects on digital timing with write pulse widths remaining below 100ns.

Finally, Figure 7d illustrates the use of the combination of an AD588 and AD569 in a system with ±15 volt supplies. As shown, the AD588 is connected to provide ±5V to the reference inputs of the AD569. It is doing double-duty by simultaneously regulating the supply voltages for the AD569 through the use of the level shifting zeners and transistors. This scheme utilizes the capability of the outputs of the AD588 to source as well as sink current. Two other benefits are realized by using this approach. The first is that the AD569 is no longer directly connected to the system power supplies. Output sensitivity to variations in those supplies is, therefore, eliminated. The second benefit is

that, should a zener diode fail (a short circuit would be the most likely failure), the supply voltage decreases. This differs from the situation where the diode is used as a series regulator. In that case, a failure would place the unregulated supply voltage on the AD569 terminal.

Figure 7. Power Supply Options

ANALOG CIRCUIT CONNECTIONS

The AD569 is intended for use in applications where high resolution and stability are critical. Designed as a multiplying D/A converter, the AD569 may be used with a fixed dc reference or an ac reference. V_{REF} may be any voltage or combination of voltages at $+V_{FORCE}$ and $-V_{FORCE}$ that remain within the bounds set for reference voltages as discussed in the power supply range section. Since the AD569 is a multiplying D/A converter, its output voltage, V_{OUT}, is proportional to the product of the digital input word and the voltage at the reference terminal. The transfer function is $V_{OUT} = D \cdot V_{REF}$ where D is the fractional binary value of the digital word applied to the converter using offset-binary coding. Therefore, the output will range from $-V_{REF}$ for a digital input code of all zeros (0000_H) to $+V_{REF}$ for an input code of all ones ($FFFF_H$).

For applications where absolute accuracy is not critical, the simple reference connection in Figure 8 can be used. Using only the reference force inputs, this configuration maintains linearity and 16-bit monotonicity, but introduces small, fixed offset and gain errors. These errors are due to the voltage drops across resistors R_A and R_B shown in Figure 9. With a 10V reference voltage, the gain and offset errors will range from 80 to 100mV. Resistors R_A and R_B were included in the first resistor string to avoid degraded linearity due to uneven current densities at the string's endpoints. Similarly, linearity would degrade if the reference voltage were connected across the reference sense terminals. Note that the resistance between the force and sense terminals cannot be measured with an ohmmeter; the layout of the thin-film resistor string adds approximately 4kΩ of resistance (R_S) at the sense tap.

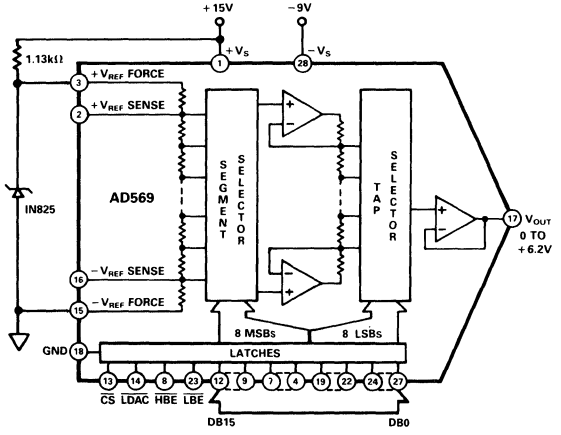

Figure 8. Simple Reference Connection

For those applications in which precision references and high accuracy are critical, buffer amplifiers are used at $+V_{REF}$ and $-V_{REF}$ as shown in Figure 10 to force the voltage across resistors R1 to R256. This insures that any errors induced by currents flowing through the resistances of the package pins, bond wires, aluminum interconnections, as well as R_A and R_B are minimized. Suitable amplifiers are the AD517, AD OP-07, AD OP-27, or the dual amplifier, the AD712. Errors will arise, however, as the buffer amplifiers' bias currents flow through R_S (4kΩ). If the bias currents produce such errors, resistance can be inserted at the noninverting terminal (R_{BC}) of the buffer amplifiers to compensate for the errors.

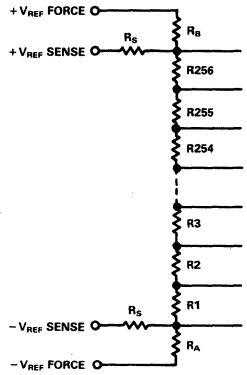

Figure 9. MSB Resistor Divider

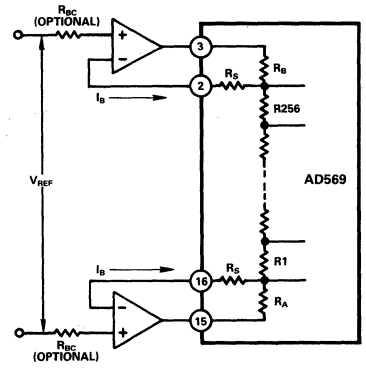

Figure 10. Reference Buffer Amplifier Connections

Figures 11, 12, and 13 show reference configurations for various output ranges. As shown in Figure 11, the pin-programmable AD588 can be connected to provides tracking ±5V outputs with 1-3ppm/°C temperature stability. Buffer amplifiers are included for direct connection to the AD569. The optional gain and balance adjust trimmers allow bipolar offset and full-scale errors to be nulled. In Figure 12, the low-cost AD586 provides +5V reference. A dual op amp, the AD712, buffers the reference input terminals preserving the absolute accuracy of the AD569. The optional noise-reduction capacitor and gain adjust trimmer allow further elimination of errors. The low-cost AD584 offers 2.5V, 5V, 7.5V, and 10V options and can be connected for ±5V tracking outputs as shown in Figure 13. Again, an AD712 is used to buffer the reference input terminals.

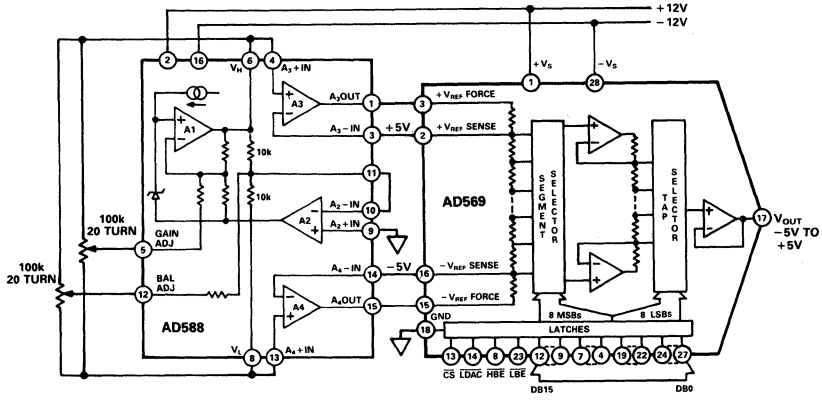

Figure 11. Ultralow Drift ±5V Tracking Reference

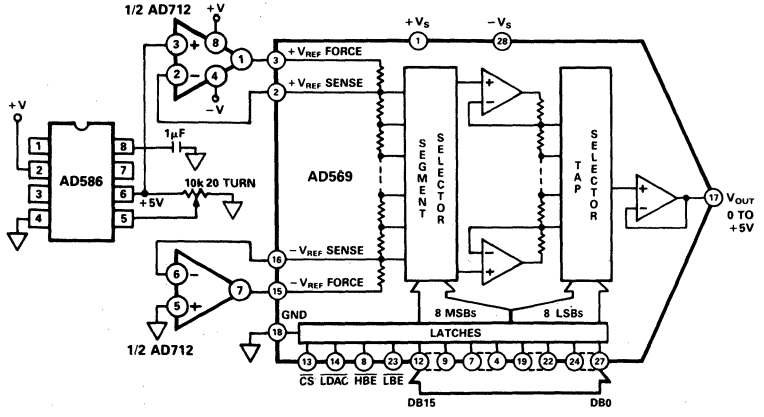

Figure 12. Low-Cost ±5V Reference

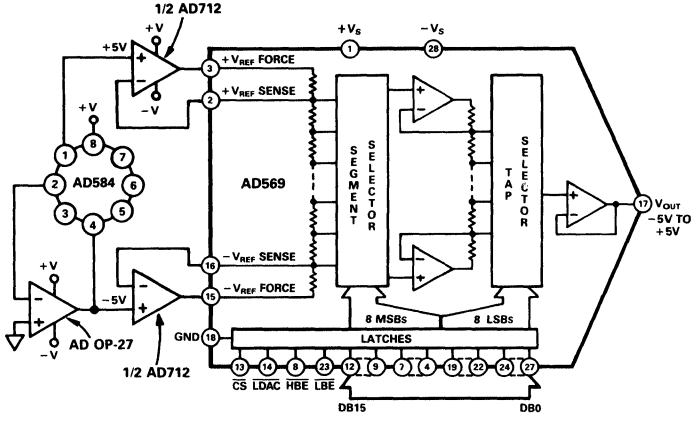

Figure 13. Low-Cost ±5V Tracking Reference

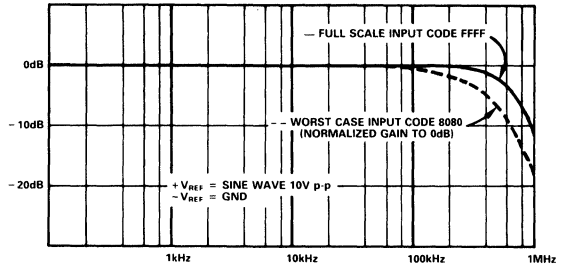
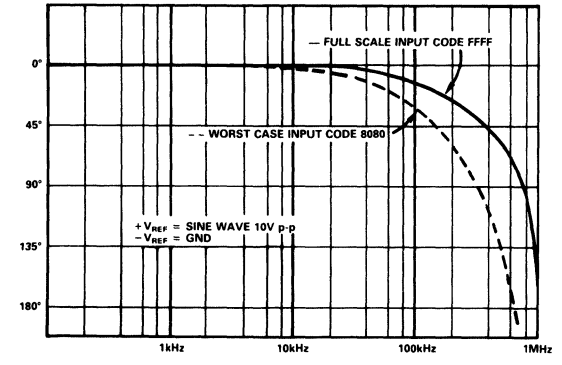
MULTIPLYING PERFORMANCE

Figure 14 illustrates the gain and phase characteristics of the AD569 when operated in the multiplying mode. Full-power bandwidth is shown in Figure 14a and the corresponding phase shift is shown in Figure 14b. Performance is plotted for both a full-scale input of $FFFF_H$ and an input of 8080_H. An input represents worst-case conditions because it places the buffer taps at the midpoints of both dividers. Figure 15 illustrates the AD569's ability to resolve 16-bits (where 1LSB is 96dB below full scale) while keeping the noise floor below −130dB with an ac reference of 1V rms at 200Hz.

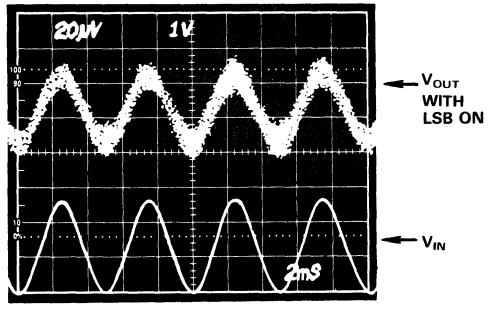


a. Bandwidth

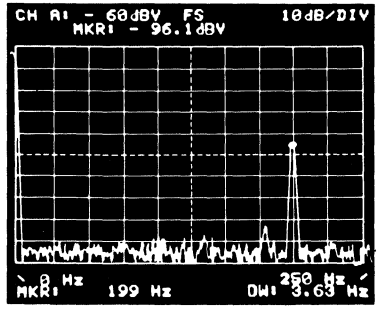


b. Phase Shift

Figure 14. Full Power Multiplying Performance



a. Time Domain



b. Frequency Domain

Figure 15. Multiplying Mode Performance (Input Code 0001_H)

Multiplying feedthrough is due to capacitive coupling between the reference inputs and the output. As shown in Figure 16, under worst-case conditions (hex input code 0000), feedthrough remains below −100dB at ac reference frequencies up to 10kHz.

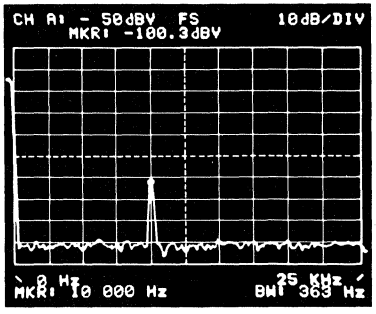


Figure 16. Multiplying Feedthrough

BYPASSING AND GROUNDING RULES

It is generally considered good engineering practice to use bypass capacitors on the device supply voltage pins and to insert small valued resistors in the supply lines to provide a measure of decoupling between various circuits in a system. For the AD569, bypass capacitors of at least 4.7μF and series resistors of 10Ω are recommended. The supply voltage pins should be decoupled to Pin 18.

NOISE

In high-resolution systems, noise is often the limiting factor. A 16-bit DAC with a 10 volt span has an LSB size of 152μV (−96dB). Therefore, the noise floor must remain below this level in the frequency ranges of interest. The AD569's noise spectral density is shown in Figures 17 and 18. The lowband noise spectrum in Figure 17 shows the 1/f corner frequency at 1.2kHz and Figure 18 shows the wideband noise to be below 40nV/$\sqrt{Hz}$.

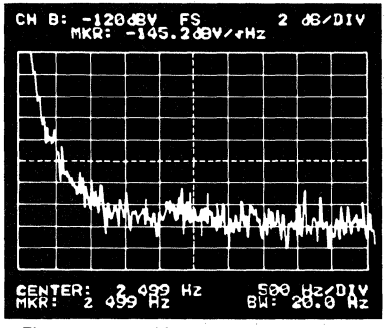

Figure 17. Lowband Noise Spectrum

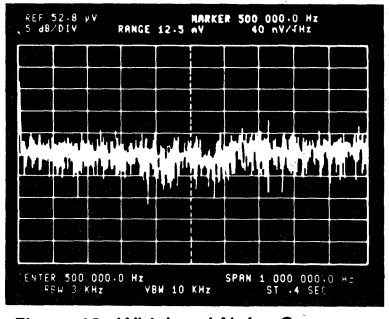

Figure 18. Wideband Noise Spectrum

DIGITAL CIRCUIT CONNECTIONS

The AD569's truth table appears in Table I. The High Byte Enable ($\overline{HBE}$) and Low Byte Enable ($\overline{LBE}$) inputs load the upper and lower bytes of the 16-bit input when Chip Select ($\overline{CS}$) is valid (low). A similar strobe to Load DAC ($\overline{LDAC}$) loads the 16-bit input into the DAC register and completes the DAC update. The DAC register can either be loaded with a separate write cycle or synchronously with either of the 8-bit registers in the first rank. A simultaneous update of several AD569s can be achieved by controlling their $\overline{LDAC}$ inputs with a single control signal.

$\overline{CS}$	$\overline{HBE}$	$\overline{LBE}$	$\overline{LDAC}$	OPERATION
1	X	X	X	No Operation
X	1	1	1	No Operation
0	0	1	1	Enable 8MSBs of First Rank
0	1	0	1	Enable 8LSBs of First Rank
0	1	1	0	Enable 16-Bit DAC Register
0	0	0	0	All Latches Transparent

Table I. AD569 Truth Table

All four control inputs latches are level-triggered and active low. When the DAC register is loaded directly from a bus, the data at the digital inputs will be reflected in the output any time $\overline{CS}$, $\overline{LDAC}$, $\overline{LBE}$ and $\overline{HBE}$ are low. Should this not be the desired case, bring $\overline{LDAC}$ (or $\overline{HBE}$ or $\overline{LBE}$) high before changing the data. Alternately, use a second write cycle to transfer the data to the DAC register or delay the write strobe pulse until the appropriate data is valid. Be sure to observe the appropriate data setup and hold times (see Timing Characteristics).

Whenever possible, the write strobe signal should be applied to $\overline{HBE}$ and $\overline{LBE}$ with the AD569's decoded address applied to $\overline{CS}$. A minimum pulse width of 60ns at $\overline{HBE}$ and $\overline{LBE}$ allows the AD569 to interface to the fastest microprocessors. Actually, data can be latched with narrower pulses, but the data setup and hold times must be lengthened.

16-Bit Microprocessor Interfaces

Since 16-bit microprocessors supply the AD569's complete 16-bit input in one write cycle, the DAC register is often unnecessary. If so, it should be made transparent by grounding $\overline{LDAC}$. The DAC's decoded address should be applied to $\overline{CS}$, with the write strobe applied to $\overline{HBE}$ and $\overline{LBE}$ as shown in the 68000 interface in Figure 19.

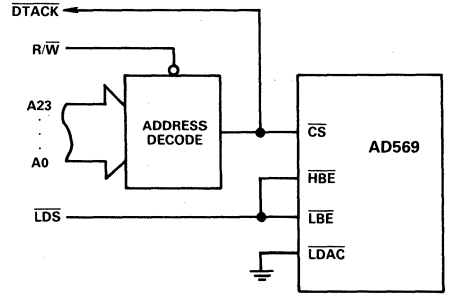

Figure 19. AD569/68000 Interface

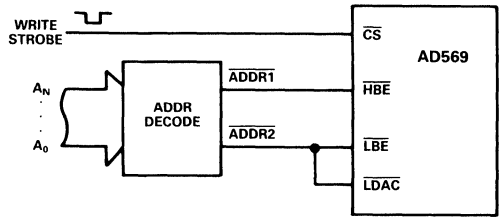
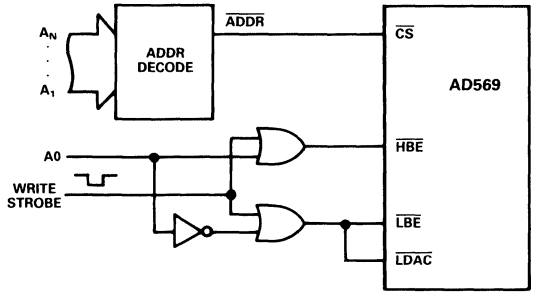


a. Simple Interface



b. Fast Interface

Figure 20. 8-Bit Microprocessor Interface

8-Bit Microprocessor Interfaces

Since 8-bit microprocessors require two write cycles to provide the AD569's 16-bit input, the DAC register must be utilized. It is most often loaded as the second byte enters the first rank of latches. This synchronous load method, shown in Figure 20, requires $\overline{LDAC}$ to be tied to either $\overline{LBE}$ or $\overline{HBE}$, depending upon the byte loading sequence. In either case, the propagation delay through the first rank gives rise to longer timing requirements as shown in Figure 2. If the DAC register ($\overline{LDAC}$) is controlled separately using a third write cycle, the minimum write pulse on $\overline{LDAC}$ is 70ns, as shown in Figure 1.

Two basic methods exist for interfacing the AD569 to an 8-bit microprocessor's address and control buses. In either case, at least one address line is needed to differentiate between the upper and lower bytes of the first rank ($\overline{HBE}$ and $\overline{LBE}$). The simplest method involves applying the two addresses directly to $\overline{HBE}$ and $\overline{LBE}$ and strobing the data using $\overline{CS}$ as shown in Figure 20a. However, the minimum pulse width on $\overline{CS}$ is 70ns with a minimum data setup time of 60ns. If operation with a shorter pulse width is required, the base address should be applied to $\overline{CS}$ with an address line gated with the strobe signal to supply the $\overline{HBE}$ and $\overline{LBE}$ inputs (see Figure 20b). However, since the write pulse sees a propagation delay, the data still must remain valid at least 20ns after the rising edge of the delayed write pulse.

OUTPUT SETTLING

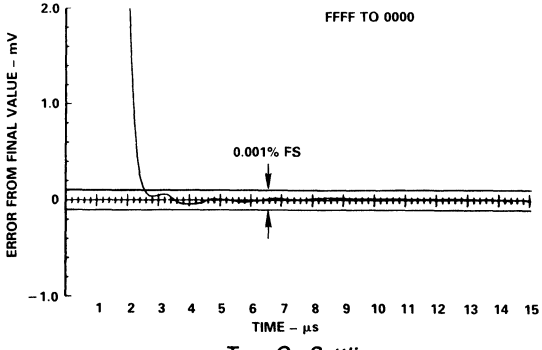
The AD569's output buffer amplifier typically settles to within ±0.001% FS of its final value in 3μs for a 10V step. Figure 21 shows settling for negative and positive full-scale steps with no load applied. Capable of sourcing or sinking 5mA, the output buffer can also drive loads of 1kΩ and 1000pF without loss of stability. Typical settling to 0.001% under these worst-case conditions is 4μs, and is guaranteed to be a maximum of 6μs. The plots of Figure 21 were generated using the settling test procedure developed specifically for the AD569.

Subranging 16-Bit ADC

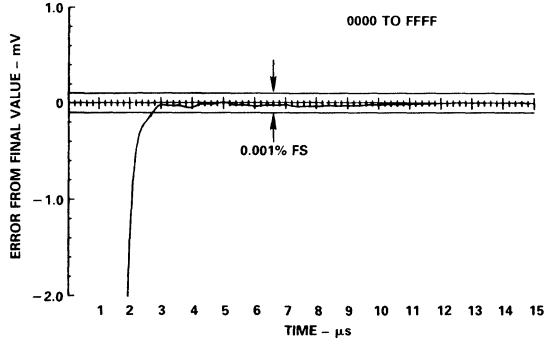
The subranging ADC shown in Figure 22 completes a conversion in less than 20μs, including the sample-hold amplifier's sample time. The sample-hold amplifier is allocated 5μs to settle to 16 bits.

Before the first flash, the analog input signal is routed through the AD630 at a gain of +1. The lower AD7820 quantizes the signal to the 8-bit level within 1.4μs, and the 8-bit result is routed to the AD569 via a digital latch which holds the 8-bit word for the AD569 and the output logic.

The AD569's reference polarity is reversed so that a full-scale output is −5V and zero scale is 0V, thereby subtracting an 8-bit approximation from the original sampled signal. The residue from the analog subtraction is then quantized by the second 8-bit flash conversion to recover the 8LSBs. Even though only the AD569's upper 8MSBs are used, the AD569's accuracy defines the A/D converter's overall accuracy. Any errors are directly reflected in the output.



a. Turn-On Settling



b. Turn-Off Settling

Figure 21. Full-Scale Output Settling

Preceding the second flash, the residue signal must be amplified by a factor of 256. The OP-37 provides a gain of 25.6 and the AD630 provides another gain of 10. In this case, the AD630 acts as a gain element as well as a channel control switch. The second flash conversion yields a 9-bit word. This provides one extra bit of overlap for digital correction of any errors that occurred in the first flash. The correction bit is digitally added to the first flash before the entire 16-bit output is strobed into the output register.

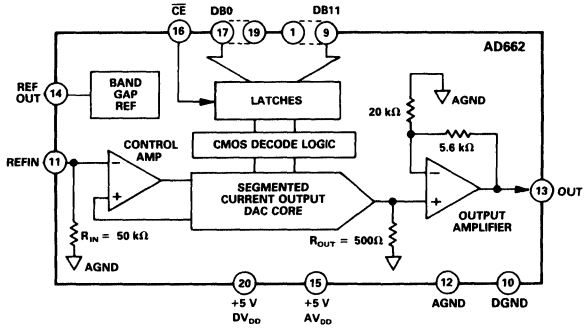
20-Pin Cerdip and Plastic Packages

AD662 FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD662 DACPORT™ is a complete 12-bit voltage output DAC specified to operate on a single +5 V power supply. The converter combines 1023 individual current sources and a 2-bit binary weighted DAC, high stability voltage reference, and an on-chip output amplifier to achieve 12-bit resolution and monotonicity over temperature.

Microprocessor compatibility is accomplished with an on-chip data latch, allowing a direct interface between the AD662 and a 16-bit digital bus. The latch responds to write pulses as short as 35 ns, for easy use with the fastest available microprocessors.

Functional completeness of the 12-bit DACPORT provides designers of single supply systems with a complete interface solution that was previously unavailable.

The AD662 is available in two performance grades over commercial, industrial, and military temperature ranges. The device is available in 20-pin plastic and cerdip packages. The AD662J, A, and S grades provide 4 LSB integral nonlinearity (INL), while the K, B, and, T grades provide 2 LSB INL, over temperature.

PRODUCT HIGHLIGHTS

1. The AD662 is a complete voltage output DAC with a voltage reference, an output amplifier, and digital latches on a single chip.
2. Device performance is optimized for single +5 V supply operation.
3. The output amplifier is capable of driving to within 3 mV of ground.
4. The data latch responds to write pulse widths as short as 35 ns, assuring direct interface with the industry's fastest microprocessors.
5. Output settling time is 3 μs to within 1/2 LSB of the final value.
6. Low power consumption of the device, 55 mW, makes it ideal for applications that are power constrained such as portable or battery-operated equipment.

DACPORT is a trademark of Analog Devices, Inc.

Table I. Output Voltage vs. Input Code

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

Definitions

LINEARITY ERROR (also called INTEGRAL NONLINEARITY or INL): Analog Devices defines linearity error as the maximum deviation of the actual analog output from the ideal output (a straight line drawn from 0 to FS) for any bit combination expressed in multiples or fractions of 1 LSB. The AD662 requires no trimming to achieve 2 LSB (0.048% of FS) maximum INL at +25°C for the K, B, and T versions and 4 LSB for the J, A, and S versions.

DIFFERENTIAL LINEARITY ERROR (also called DIFFERENTIAL NONLINEARITY or DNL): DNL is the measure of the variation in analog value, normalized to full scale, associated with a 1 LSB change in digital input code. Monotonic behavior requires that the differential linearity error not exceed 1 LSB in the negative direction.

MONOTONICITY: A DAC is said to be monotonic if the output either increases or remains constant as the digital input increases.

ZERO ERROR: Zero error is the difference between the actual DAC output with respect to analog ground and zero when all bits are set to 0, expressed in % of FS, mV or LSBs.

GAIN ERROR: The DAC's gain error is the difference between the ideal and actual outputs of FS − 1 LSB, expressed in % of FS, mV or LSB, when all bits are on.

SETTLING TIME: Settling time is the time required for the output to reach and remain within a specified error band about its final value, measured from the digital input transition. Figure 1 exhibits the AD662's settling time characteristics from zero to full scale. See the section Output Considerations for more details.

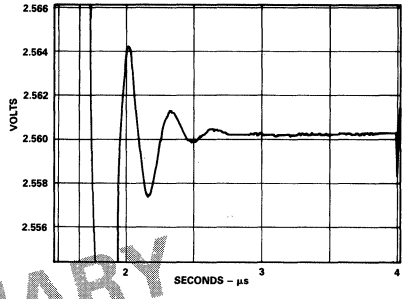

Figure 1. Code 0 to Full Scale Settling Time

Circuit Description

The AD662 consists of four functional blocks as shown in the AD662 functional block diagram on the previous page. These blocks are a 12-bit current output DAC, a bandgap reference, an output amplifier, and digital decode logic. The top 10 bits of the current output DAC are realized by 1023 identical current source segments. An additional 2-bit binary current source DAC creates the lower 2 bits. As the input code increases, the current sources turn on sequentially. The inherently monotonic current output flows from the DAC through the resistor, R_{OUT}, and appears as an unbuffered voltage output at an input terminal of the output amplifier. The internal bandgap reference circuit produces a temperature stable 2.0 V reference when the REFOUT pin is externally connected to the REFIN pin. The unbuffered full scale value is set equal to the voltage input at REFIN by the control amplifier. Therefore, when utilizing the internal 2.0 V reference, the voltage at the top terminal of R_{OUT} swings from 0 to 2.0 V. The output amplifier then takes the unbuffered output from the current-output DAC and amplifies it by a factor of 1.28 to provide a low impedance voltage output which ranges from 0 to 2.56 V.

An advanced 2.0 µm BiCMOS process provides the low power, high speed and high density implementation of the digital interface. This interface consists of TTL/CMOS converters, 12-bit data latch, and decode logic. All digital inputs are TTL compatible. The level triggered latches have an active low $\overline{CE}$ as the control signal, allowing a direct interface with industry standard microprocessors and digital signal processors. Hard-wiring $\overline{CE}$ low renders the latches "transparent" for direct DAC access.

INTERNAL/EXTERNAL REFERENCE

The AD662 has an internal bandgap reference circuit that is laser trimmed to produce a temperature stable 2 V reference when REFIN is externally connected to REFOUT. The full scale trim of the device is performed with the internal reference. The reference is intended only for this purpose and not for driving any external load. To insure the specified performance of the device, when using the internal reference, it is recommended to add an external decoupling capacitor of at least 1 µF as shown in Figure 2.

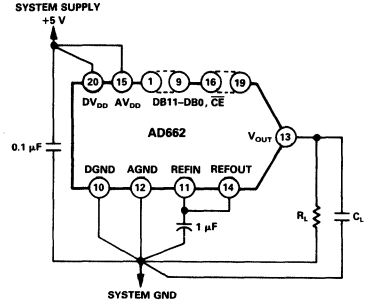

Figure 2. Internal Reference Configuration

The REFIN/REFOUT configuration demonstrates that the AD662 can operate with either the on-chip reference or an external reference. The external reference can be used to set a different full scale value to further improve temperature stability, or to reduce 1/f noise contribution from the reference. A user has to simply apply an external voltage reference to REFIN. REFOUT may be either open or connected to REFIN. When REFOUT is left open, the input impedance at REFIN is the specified value of 50 kΩ, typical. The output impedance of REFOUT is 12 kΩ, typical. Consequently, when REFIN and REFOUT are connected, the input impedance of REFIN becomes 9.0 kΩ, typical. Figure 3 exhibits a scheme to achieve a programmable full scale output between 1.58 V and 2.56 V. It is not recommended to reduce the full scale voltage any further than 1.58 V because the output noise will exceed an LSB level.

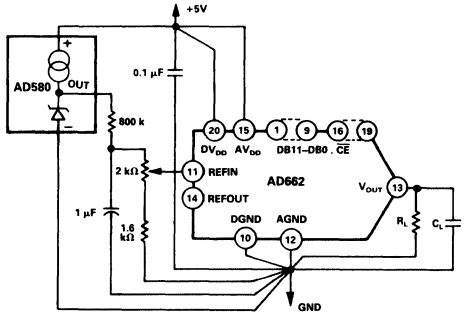

Figure 3. External Reference Configuration

TIMING AND CONTROL

The AD662 has a 12-bit latch that simplifies interface to a 12-bit (or wider) data bus. The latch is controlled by the Chip Enable ($\overline{CE}$) input. If the application does not involve a data bus, wiring $\overline{CE}$ low allows direct operation of the DAC.

The data latch is level triggered and acquires data from the data bus during the time period when $\overline{CE}$ is low. When $\overline{CE}$ goes high, the data is latched into the register and held until $\overline{CE}$ returns low. The minimum time required for the data to be present on the bus before $\overline{CE}$ returns high is called the data setup time (t_{DS}) as seen in Figure 4. The data hold time(t_{DH}) is the amount of time that the data has to remain on the bus after $\overline{CE}$ goes high. The AD662 is specified for t_{DS} = 25 ns and t_{DH} = 0 ns for minimum $\overline{CE}$ pulse width (t_{PW}) of 35 ns, allowing direct interface with the fastest microprocessors and controllers.

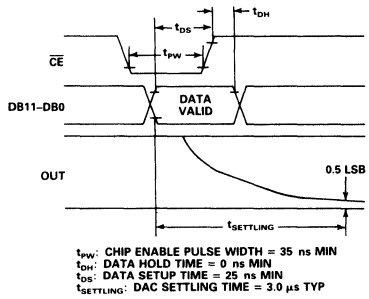

Figure 4. Timing Diagram

OUTPUT CONSIDERATIONS

The AD662 has an internal output amplifier which provides the specified low impedance output. The amplifier drives the output down to the zero offset value from ground when the input code is 000H. The output maintains its specified linearity for all the codes from 000H to FFFH when the output sources up to 5 mA of output current. When the output sinks current for input codes below 048H, however, the output impedance increases up to 10 Ω typical. This output impedance determines the lowest possible output level for a given sink current. The transfer curve will be nonlinear at this level and stay flat for inputs below it. This situtuation is illustrated in Figure 5. For example, the output stays at about 50 mV for input codes between 000H and 050H when the output is sinking 5 mA.

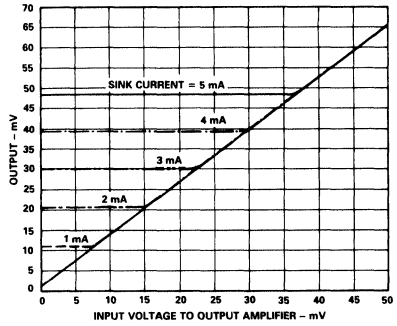

Figure 5. Output Voltage for Sink Current of 0 to 5 mA

The settling time from 0 to full scale is 3 µs. However, the settling time of the DAC from full scale towards 0 will increase for final values below approximately 25 mV (Code 40). For a system which requires 3 µs settling for all the code transitions, it is recommended to disregard the codes below 40 and to refer the output to a pseudoground at 25 mV above AGND. Figure 6 illustrates the settling time for the AD662 from 0 to full scale and then from full scale back to 0. Figures 1 and 7 are enlargements of the respective settling times circled in Figure 6.

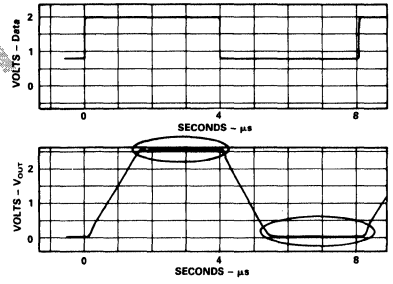

Figure 6. Settling Time

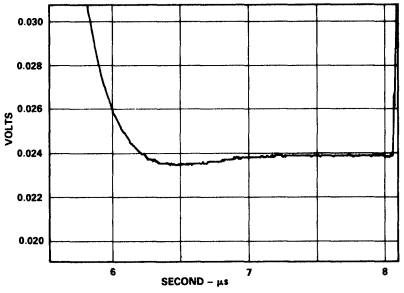

Figure 7. Full Scale to Code 40 Settling Time

When the internal reference is used, it is highly recommended to filter the internal reference output by adding an external capacitor of at least 1 µF from REFIN (= REFOUT) to AGND. Otherwise, noise from the reference will dominate the total output noise and will exceed an LSB level. The total output noise is largest at full scale because the DAC core has the

maximum number of current sources connected to its output. The measured output white noise is 68 nV/$\sqrt{Hz}$. The corner frequency for 1/f noise is approximately 15 kHz. The output amplifier has its −3 dB frequency at about 1 MHz. This data results in a total output noise of about 79 μV rms from 0.1 Hz at full scale. Figure 8 illustrates the output noise versus frequency with a 1 μF cap from REFIN and REFOUT to AGND.

The output of the AD662 is protected against short circuits to ground and the supply. However, short circuits to another 5 V supply through resistances in the 30 Ω to 120 Ω range may cause device damage and should be avoided.

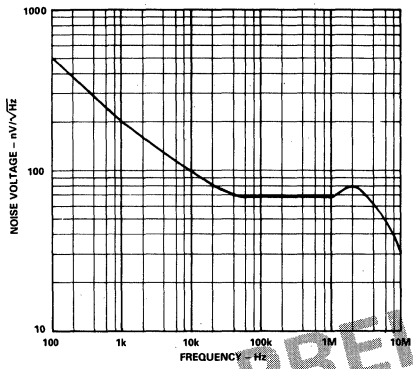

Figure 8. Output Noise vs. Frequency

GROUNDING RULES

The AD662 has two ground connections, digital ground (DGND) at Pin 10 and analog ground (AGND) at Pin 12. The AGND pin is the "high quality" ground reference point for the device. Any external loads or external reference should be referred to this ground. In order to minimize a voltage drop across Pin 12 and the reference point, care should be taken to provide a system reference point as close to Pin 12 as possible. Note that the AD662 typically has 10 mA analog ground current and a 0.1 Ω series resistance between AGND, Pin 12, and the system reference point would result in an additional offset of 1 mV (equivalent to 1.6 LSBs). The digital ground returns current from the digital portion of the device and should be tied to the analog ground at one point, usually the device power ground. This should be as close to the device as possible in order to avoid a differential voltage across these two ground pins. Differential voltage across two ground pins will degrade the accuracy of the device. Figures 2 and 9 illustrate connections for proper operation of the device.

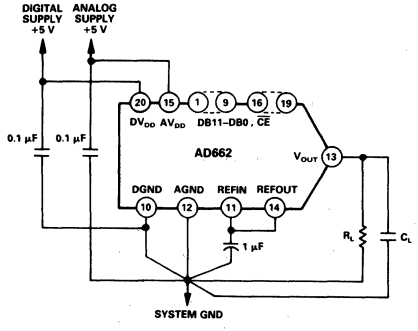

Figure 9. Output Configuration Using Two Supplies

POWER SUPPLY AND DECOUPLING

The AD662 has two power supply pins, digital V_{DD} at Pin 20 and analog V_{DD} at Pin 15. Specified device performance is achieved for a supply voltage between 4.5 V and 5.5 V at both pins. The AD662 is designed to operate from a single power supply, although it has two supply pins. Figure 2 shows this configuration. The two supply pins should be tied at one point to the single system supply and should be decoupled to one system ground point. Figure 10 is the measured PSRR of the output at full scale when the analog and digital V_{DD}s are tied together.

When it is impractical or uneconomical to provide a quiet single system supply, the user can use two system supplies as shown in Figure 9. The analog V_{DD} at Pin 15 should be the "high quality" supply in this case. Decoupling capacitors should be used on both supply pins. They should be located as near as possible to the device. The digital V_{DD} should be bypassed to the digital ground pin and likewise for analog V_{DD} and ground.

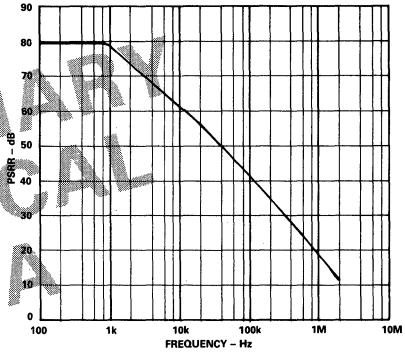

Figure 10. PSRR vs. Frequency

BIPOLAR OPERATION

The AD662 was designed for operation from a single +5 V supply and is capable of providing a unipolar output range. When a negative supply is available in a system, bipolar output ranges can be achieved by properly offsetting and scaling the output. Figure 11 shows an example of this application and Figure 12 is a photo of its settling time characteristics. The precision voltage reference, AD589, provides the offset and determines the bipolar zero level. The BiFET amplifier, AD711, provides the buff-

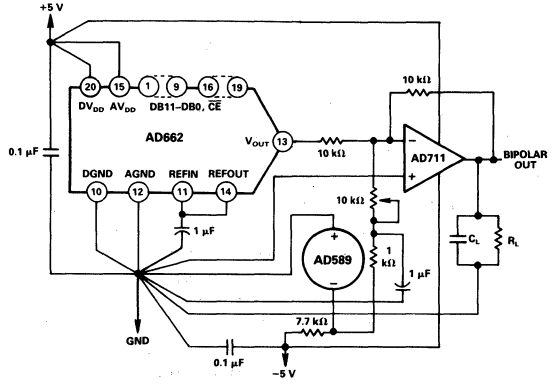

Figure 11. Bipolar Buffered Output ±1.28 V

ered output. In the case of the circuit shown in Figure 11, the bipolar signal range is ±1.28 V. If we adjust the bipolar zero with the 10 kΩ potentiometer to be 0 V, the input code, FFFH, will produce a nominal −1.2794 V and 000H will give +1.28 V.

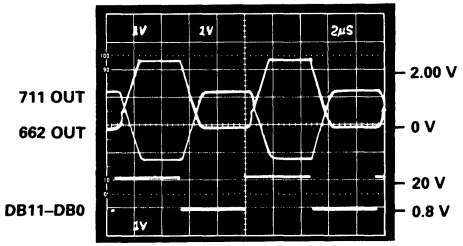

Figure 12. Settling Time Characteristics

Applications

MICROPROCESSOR INTERFACE

The high speed digital interface of the AD662 facilitates its use with a wide variety of microprocessors and microcontrollers. The 12-bit single buffered input register accepts 12-bit parallel load data from processors such as the ADSP-2101, TMS320 series, 80386, and microcontrollers such as the 8096. Several illustrative examples follow.

ADSP-2100 – AD662 INTERFACE

Figure 13 demonstrates the AD662 interfaced to an ADSP-2100A. With a clock frequency of 12.5 MHz, and instruction execution in one 80 ns cycle, the digitial signal processor supports the AD662 interface with one hardware wait state.

ADSP-2100A starts a data memory write operation by providing the converter's memory mapped address on the DMA bus. The decoded address generates $\overline{CE}$ for the converter. $\overline{CE}$, together with some glue logic and latches, is used to force the ADSP-2100A into a one cycle wait state by generating DMACK. The write operation to the AD662 is thus started and completed within two processor cycles (160 ns). At clock speeds of 6 MHz, no wait states are necessary.

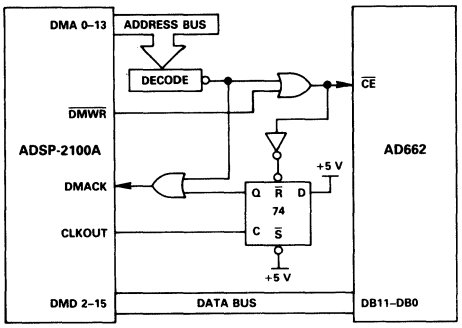

Figure 13. AD662 Interface to ADSP-2100A

ADSP-2101 or ADSP-2102 – AD662 INTERFACE

Figure 14 demonstrates the AD662 interfaced to an ADSP-2101/ADSP-2102. With a clock frequency of 12.5 MHz, and instruction execution in one 80 ns cycle, the digital signal processor supports the AD662 interface with one software wait state.

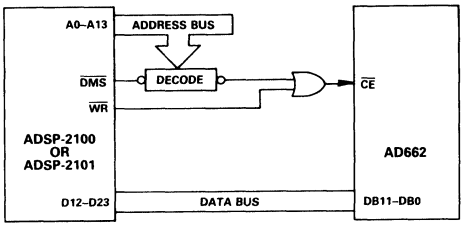

Figure 14. AD662 Interface to ADSP-2101/ADSP-2102

ADSP-2101/ADSP-2102 starts the data memory write operation by providing the converter's memory mapped address on its address bus and by asserting DMS. The decoded address generates $\overline{CE}$ for the converter. This allows the converter's 12-bit input latch to be loaded with the value on the data bus. The write operation to the AD662 is extended by a software wait state and completed within two processor cycles (160 ns).

TMS320C25 – AD662 INTERFACE

Figure 15 illustrates the AD662 interface to a TMS320C25 digital signal processor using the I/O port capability. The $\overline{IS}$ signal distinguishes the I/O address space from the local program/data memory space is used to enable 74F138 decoder. The decoded port address is then gated with the R/$\overline{W}$ and $\overline{STRB}$ to provide the AD662 $\overline{CE}$. As shown, this interface will support a 40 MHz processor without wait states.

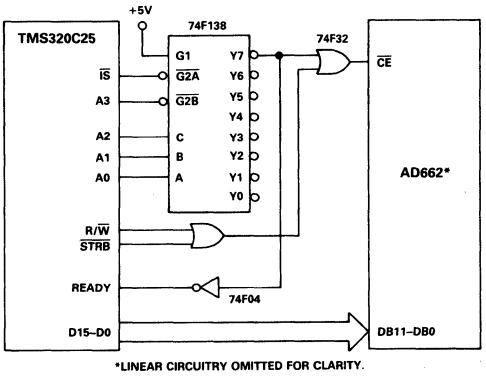

Figure 15. AD662 Interface to TMS32C25

80386 – AD662 INTERFACE

The AD662 interface to the 80386 microprocessor is shown in Figure 16. The processor's $\overline{WR}$ signal is gated with a decoded address to provide $\overline{CE}$ for the AD662. As $\overline{WR}$ returns high, valid data is latched into the DAC.

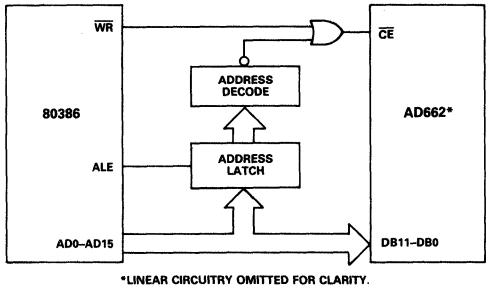

Figure 16. 80386 – AD662 Interface

8096 – AD662 INTERFACE

The circuit of Figure 17 shows the interface between the 8096 16-bit microcontroller and the AD662. In this application, the 8096 external bus width is programmed via the chip configuration register to operate as a standard 16-bit multiplexed address/data bus. A write cycle to the DAC outputs the low order address/data to Port 3 and the high order to Port 4. The ALE signal then latches the address which is decoded and gated with $\overline{WR}$ to control the AD662 $\overline{CE}$. Data is latched into the DAC on the rising edge of $\overline{WR}$ updating the analog output. The cycle is now complete.

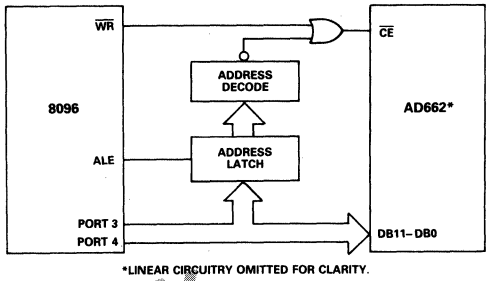

Figure 17. 8096 – AD662 Interface

Bipolar Around +5 V

A popular use for the AD662 can be found in disk drive and other +12 V supply applications. The AD662 can be easily applied to create a bipolar swing around +5 V in a +12 V system by properly offsetting and scaling its output. Figure 18 illustrates a circuit which has an output swing of ±2 V around a bipolar zero point of +5 V. A high precision voltage reference, AD689, creates +8.192 V from the +12 V system supply. This output is resistively divided to produce a temperature-stable bipolar zero point at +5 V. The AD847 acts as a buffer for this voltage and drives the AD662. The output amplifier AD711 provides the proper scaling and offsetting. Gain and bipolar zero of the output are trimmed by 10 kΩ and 5 kΩ potentiometer, respectively. To trim the gain, the output of the AD711 is measured at input code 800H (to be +5V, ideally) first. Then the gain is trimmed at code 000H to achieve an ouput of +2 V plus the measured value at code 800H. The bipolar zero can then be trimmed by adjusting the output to +5 V for an input code of 800H. The 2 pF capacitor cancels a parasitic capacitance at the negative input terminal of AD711 and improves its settling characteristics. This capacitance value should be properly chosen for a given circuit board. The scope photo, Figure 19, shows settling characteristics of this circuit with the outputs of AD662 and AD711 on the same scale.

- Avionics

PRODUCT DESCRIPTION

The AD664 is four complete 12-bit, voltage-output DACs on one monolithic IC chip. Each DAC has a double-buffered input latch structure and a data readback function. All DAC read and write operations occur through a single microprocessor-compatible I/O port.

The I/O port accomodates 4-, 8- or 12-bit parallel words allowing simple interfacing with a wide variety of microprocessors. A reset to zero control pin is provided to allow a user to simultaneously reset all DAC outputs to zero, regardless of the contents of the input latch. Any one or all of the DACs may be placed in a transparent mode allowing immediate response by the outputs to the input data.

The analog portion of the AD664 consists of four DAC cells, four output amplifiers, a control amplifier and switches. Each DAC cell is an inverting R-2R type. The output current from each DAC is switched to the on-board application resistors and output amplifier. The output range of each DAC cell is programmed through the digital I/O port and may be set to unipolar or bipolar range, with a gain of one or two times the reference voltage. All DACs are operated from a single external reference.

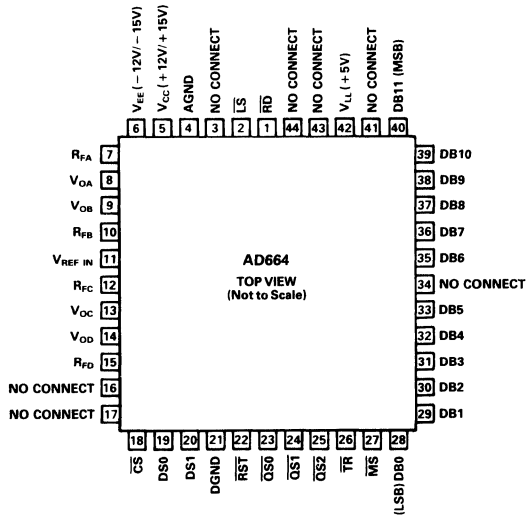
The functional completeness of the AD664 results from the combination of Analog Devices' BiMOS II process, laser-trimmed thin-film resistors and double-level metal interconnects.

PRODUCT HIGHLIGHTS

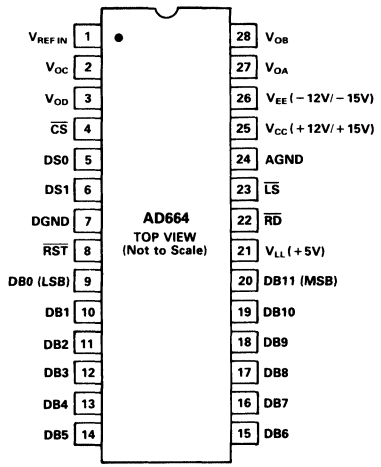
1. The AD664 provides four voltage-output DACs on one chip offering the highest density 12-bit D/A function available.
2. The output range of each DAC is fully and independently programmable.
3. Readback capability allows verification of contents of the internal data registers.
4. The asynchronous RESET control returns all D/A outputs to zero volts.
5. DAC-to-DAC matching performance is specified and tested.

AD664 PIN CONFIGURATIONS

44-Pin Package



28-Pin DIP Package



6. Linearity error is specified to be 1/2LSB at room temperature and 1LSB maximum.
7. DAC performance is guaranteed to be monotonic over the full operating temperature range.
8. Readback buffers have tristate outputs.
9. Multiplying-mode operation allows use with fixed or variable, positive or negative external references.

NOTES
[1]A minimum power supply of ±12.0V is required for 0 to +10V and ±10V operation.
A minimum power supply of ±11.4V is required for −5V to +5V operation.
[2]Bipolar zero error is the difference from the ideal output (0 volts) and the actual output voltage with code 100 000 000 000 applied to the inputs.
[3]Linearity error is defined as the maximum deviation of the actual DAC output from the ideal output (a straight line drawn from 0 to F.S. −1LSB)
[4]FSR means Full-Scale Range and is 20V for ±10V range and 10V for ±5V range.
[5]A minimum power supply of ±12.0V is required for a 10V reference voltage.
[6]Analog Ground Current is input code dependent.
[7]Gain error matching is the largest difference in gain error between any two DACs in one package.
[8]Offset error matching is the largest difference in offset error between any two DACs in one package.
[9]Bipolar zero error matching is the largest difference in bipolar zero error between any two DACs in one package.
[10]Linearity error matching is the difference in the worst case linearity error betweeen any two DACs in one package.
[11]44-pin versions only.
[12]Timing specifications are relative to $\overline{CS}$.
*For V_{CC}<13V and V_{EE}<−13V. Voltage not to exceed 11V maximum.

Specifications subject to change without notice.

Specifications in **boldface** are tested on all production units at final electrical test. Results from those tests are used to calculate outgoing quality levels. All min and max specifications are guaranteed, although only those shown in **boldface** are tested on all production units.

ABSOLUTE MAXIMUM RATINGS*

(Specifications apply to all grades except where noted)

V_{LL} to DGND	0 to +7V
V_{CC} to DGND	0 to +18V
V_{EE} to DGND	−18V to 0V
Soldering	+300°C, 10sec
Power Dissipation	1000mW
AGND to DGND	−1V to +1V
Reference Input	−11V to +11V
V_{CC} to V_{EE}	0 to +36V
Digital Inputs	−0.3V to +7V
Analog Outputs	Indefinite Shorts to V_{CC}, V_{LL}, V_{EE} and GND

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

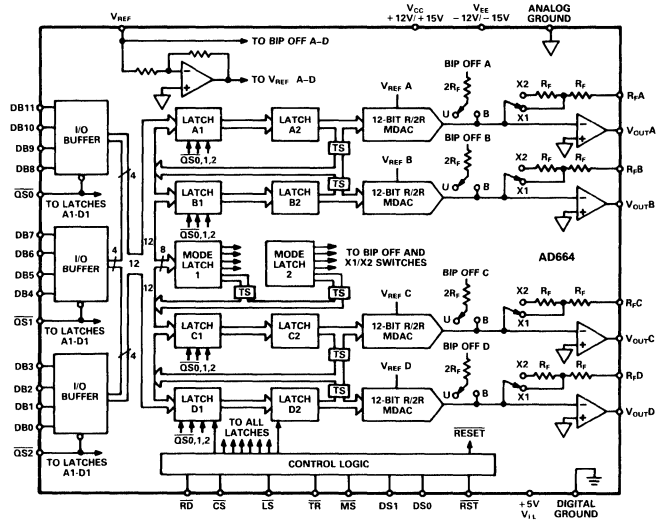

Figure 1a. 44-Pin Block Diagram

FUNCTIONAL DESCRIPTION

The AD664 combines four complete 12-bit voltage output D/A converters with a fast, flexible digital input/output port on one monolithic chip. It is available in two forms, a 44-pin version shown in Figure 1a and a 28-pin version shown in Figure 1b.

44-Pin Versions

Each DAC offers flexibility, accuracy and good dynamic performance. The R-2R structure is fabricated from thin-film resistors which are laser-trimmed to achieve 1/2LSB linearity and guaranteed monotonicity. The output amplifier combines the best features of the bipolar and MOS devices to achieve good dynamic performance and low offset. Settling time is under 10μs and each output can drive a 5mA, 500pF load. Short-circuit protection allows indefinite shorts to V_{LL}, V_{CC}, V_{EE} and GND. The output and span resistor pins are available separately. This feature allows a user to insert current-boosting elements to increase the drive capability of the system, as well as to overcome parasitics.

Digital circuitry is implemented in CMOS logic. The fast, low power, digital interface allows the AD664 to be interfaced with most microprocessors. Through this interface, the wide variety of features on each chip may be accessed. For example, the input data for each DAC is programmed by way of 4-, 8-, 12- or 16-bit words. The double-buffered input structure of this latch allows all four DACs to be updated simultaneously. A readback feature allows the internal registers to be read back through the same digital port, as either 4-, 8- or 12-bit words. When disabled, the readback drivers are placed in a high impedance (tristate) mode. A TRANSPARENT mode allows the input data to pass straight through both ranks of input registers and appear at the DAC with a minimum of delay. One D/A may be placed in the transparent mode at a time, or all four may be made transparent at once. The MODE SELECT feature allows the output range and mode of the DACs to be selected via the data bus inputs. An internal mode select register stores the selections. This register may also be read back to check its contents. A RESET-TO-ZERO feature allows all DACs to be reset to 0 volts out by strobing a single pin.

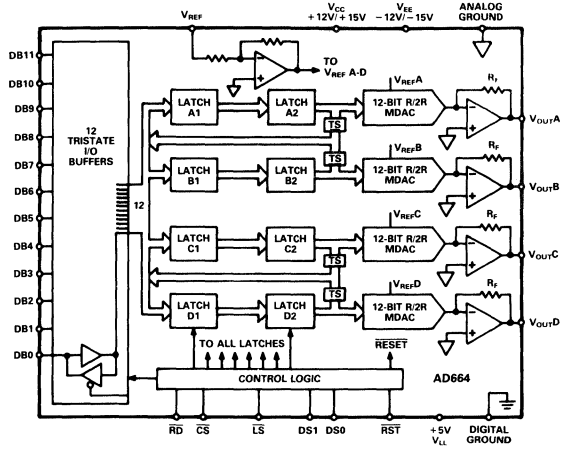

Figure 1b. 28-Pin Block Diagram

28-Pin Versions

The 28-pin versions are dedicated versions of the 44-pin AD664. Each offers a reduced set of features from those offered in the 44-pin version. This accommodates the reduced number of package pins available. Data is written and read with 12-bit words only. Output range and mode select functions are also not available in 28-pin versions. As an alternative, users specify either the UNI (unipolar, 0 to V_{REF}) models or the BIP (bipolar, $-V_{REF}$ to V_{REF}) models depending on the application requirements. Finally, the transparent mode is not available on the 28-pin versions.

	Mode = UNI	Mode = BIP
Gain = 1	000000000000 = 0V 100000000000 = $V_{REF}/2$ 111111111111 = V_{REF} − 1LSB	000000000000 = $-V_{REF}/2$ 100000000000 = 0V 111111111111 = $V_{REF}/2$ − 1LSB
Gain = 2	000000000000 = 0V 100000000000 = V_{REF} 111111111111 = $2 \times V_{REF}$ − 1LSB	000000000000 = $-V_{REF}$ 100000000000 = 0V 111111111111 = $+V_{REF}$ − 1LSB

Table I. Transfer Functions

DEFINITIONS OF SPECIFICATIONS

LINEARITY ERROR: Analog Devices defines linearity error as the maximum deviation of the actual, adjusted DAC output from the ideal analog output (a straight line drawn from 0 to FS − 1LSB) for any bit conbination. This is also referred to as relative accuracy. The AD664 is laser-trimmed to typically maintain linearity errors at less than ± 1/4LSB.

MONOTONICITY: A DAC is said to be monotonic if the output either increases or remains constant for increasing digital inputs such that the output will always be a nondecreasing function of input. All versions of the AD664 are monotonic over their full operating temperature range.

DIFFERENTIAL LINEARITY: Monotonic behavior requires that the differential linearity error be less than 1LSB both at 25°C as well as over the temperature range of interest. Differential nonlinearity is the measure of the variation in analog value, normalized to full scale, associated with a 1LSB change in digital input code. For example, for a 10V full-scale output, a change of 1LSB in digital input code should result in a 2.44mV change in the analog output (V_{REF} = 10V, Gain = 1, 1LSB = 10V × 1/4096 = 2.44mV). If in actual use, however, a 1LSB change in the input code results in a change of only 0.61mV (1/4LSB) in analog output, the differential nonlinearity error would be −1.83mV, or −3/4LSB.

GAIN ERROR: DAC gain error is a measure of the difference between the output span of an ideal DAC and an actual device.

UNIPOLAR OFFSET ERROR: Unipolar offset error is the difference between the ideal output (0V) and the actual output of a DAC when the input is loaded with all "0s" and the MODE is unipolar.

BIPOLAR ZERO ERROR: Bipolar zero error is the difference between the ideal output (0V) and the actual output of a DAC when the input code is loaded with the MSB = "1" and the rest of the bits = "0" and the MODE is bipolar.

SETTLING TIME: Settling time is the time required for the output to reach and remain within a specified error band about its final value, measured from the digital input transition.

CROSSTALK: Crosstalk is the change in an output caused by a change in one or more of the other outputs. It is due to capacitive and thermal coupling between outputs.

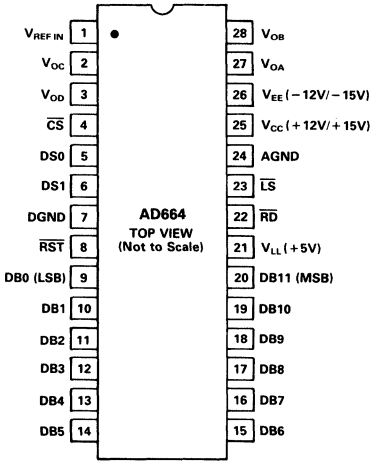
REFERENCE FEEDTHROUGH: The portion of an ac reference signal that appears at an output when all input bits are low. Feedthrough is due to capacitive coupling between the reference input and the output. It is specified in decibels at a particular frequency.

REFERENCE 3dB BANDWIDTH: The frequency of the ac reference input signal at which the amplitude of the full-scale output response falls 3dB from the ideal response.

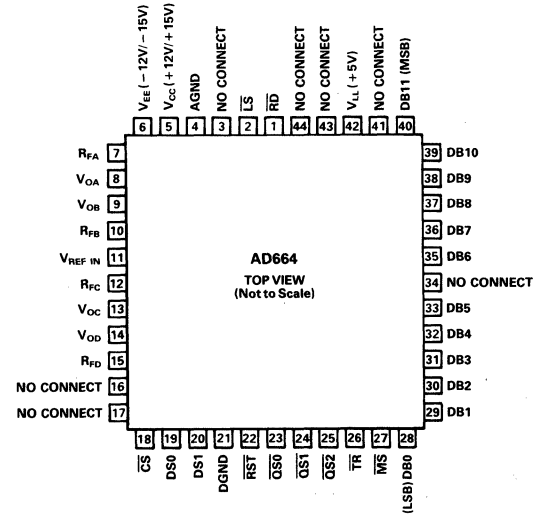
GLITCH IMPULSE: Glitch impulse is an undesired output voltage transient caused by asymmetrical switching times in the switches of a DAC. These transients are specified by their net area (in nV-sec) of the voltage vs. time characteristic.

PIN CONFIGURATIONS

28-Pin DIP Package



44-Pin Package



ANALOG CIRCUIT CONSIDERATIONS

Grounding Recommendations

The AD664 has two pins, designated ANALOG and DIGITAL ground. The analog ground pin is the "high quality" ground reference point for the device. A unique internal design has resulted in low analog ground current. This greatly simplifies management of ground current and the associated induced voltage drops. The analog ground pin should be connected to the analog ground point in the system. The external reference and any external loads should also be returned to analog ground.

The digital ground pin should be connected to the digital ground point in the circuit. This pin returns current from the logic portions of the AD664 circuitry to ground.

Analog and digital grounds should be connected at one point in the system. If there is a possibility that this connection be broken or otherwise disconnected, then two diodes should be connected between the analog and digital ground pins of the AD664 to limit the maximum ground voltage difference.

Power Supplies and Decoupling

The AD664 requires three power supplies for proper operation. V_{LL} powers the logic portions of the device and requires +5 volts. V_{CC} and V_{EE} power the remaining portions of the circuitry and require +12V to +15V and −12V to −15V, respectively. V_{CC} and V_{EE} must also be a minimum of two volts greater then the maximum reference and output voltages anticipated.

Decoupling capacitors should be used on all power supply pins. Good engineering practice dictates that the bypass capacitors be located as near as possible to the package pins. V_{LL} should be bypassed to digital ground. V_{CC} and V_{EE} should be decoupled to analog ground.

Driving the Reference Input

The reference input of the AD664 can have an impedance as low as 1.3kΩ. Therefore, the external reference voltage must be able to source up to 7.7mA of load current. Suitable choices include the 5V AD586, the 10V AD587 and the 8.192V AD689.

The architecture of the AD664 derives an inverted version of the reference voltage for some portions of the internal circuitry. This means that the power supplies must be at least 2V greater than both the external reference and the inverted external reference.

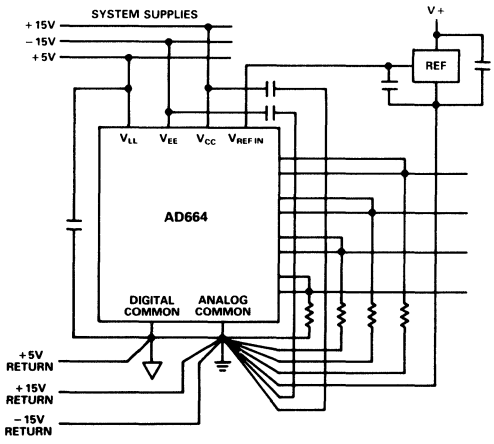


Figure 2. Recommended Circuit Schematic

Output Considerations

Each DAC output can source or sink 5mA of current to an external load. Short-circuit protection limits load current to a maximum load current of 40mA. Load capacitance of up to 500pF can be accomodated with no effect on stability. Should an application require additional output current, a current boosting element can be inserted into the output loop with no sacrifice in accuracy. Figure 3 details this method.

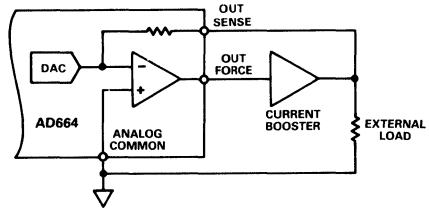

Figure 3. Current-Boosting Scheme

AD664 output voltage settling time is 10μs maximum. Figure 4 shows the output voltage settling time with a fixed 10V reference, gain = 1 and all bits switched from 1 to 0.

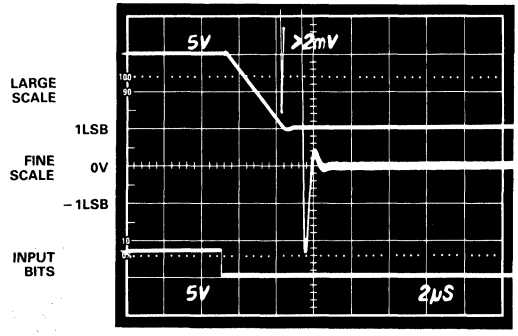

Figure 4. Settling Time; All Bits Switched from On to Off

Alternately, Figure 5 shows the settling characteristics when the reference is switched and the input bits remain fixed. In this case, all bits are "on", the gain is 1 and the reference is switched from −5V to +5V.

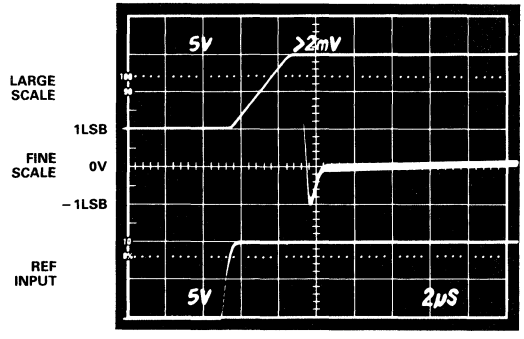

Figure 5. Settling Time; Input Bits Fixed, Reference Switched

Multiplying Mode Performance
Figure 6 illustrates the typical open-loop gain and phase performance of the output amplifiers of the AD664.

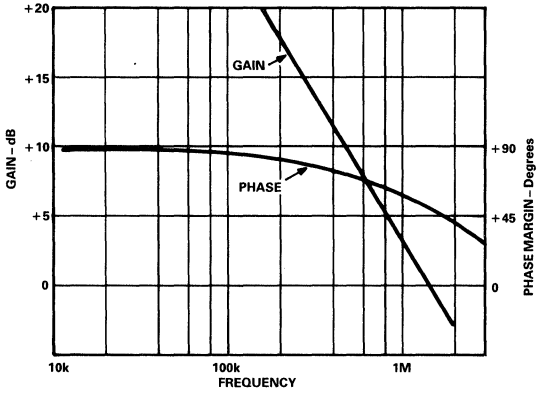

Figure 6. Gain and Phase Performance of AD664 Outputs

Crosstalk
Crosstalk is a spurious signal on one DAC output caused by a change in the output of one or more of the other DACs. Crosstalk can be induced by capacitive, thermal or load current induced feedthrough. Figure 7 shows typical crosstalk. DAC B is set to output 0 volts. The outputs of DAC A, C and D switch 2kΩ loads from 10V to 0V. The first disturbance in the output of DAC B is caused by digital feedthrough from the input data lows. The second disturbance is caused by analog feedthrough from the other DAC outputs.

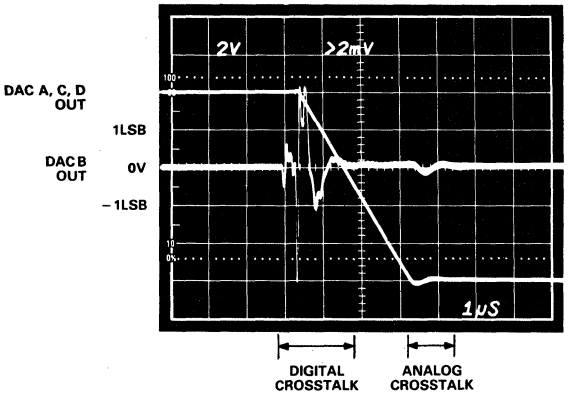

Figure 7. Output Crosstalk

Output Noise
Wideband output noise is shown in Figure 8. This measurement was made with a 7MHz noise bandwidth, gain = 1 and all bits on. The total rms noise is approximately one fifth the visual peak-to-peak noise.

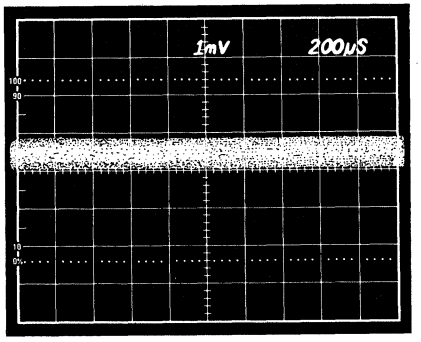

Figure 8. Typical Output Noise

As Table II shows, the AD664 makes a wide variety of operating modes available to the user. These modes are accessed or programmed through the high-speed digital port of the quad DAC. On-board registers program and store the DAC input codes and the DAC operating mode data. All registers are double-buffered to allow for simultaneous updating of all outputs. Register data may be read back to verify the respective contents. The digital port also allows transparent operation. Data from the input pins can be sent directly through both ranks of latches to the DAC.

Partial address decoding is performed by the DS0, DS1, $\overline{QS0}$, $\overline{QS1}$ and $\overline{QS2}$ address bits.

The $\overline{RST}$ pin provides a simple method to reset all output voltages to zero. Its advantages are speed and low software overhead.

INPUT DATA
In general, two types of data will be input to the registers of the AD664, input code data and mode select data. Input code data sets the DAC inputs while the mode select data sets the gain and range of each DAC.

The versatile I/O port of the AD664 allows many different types of data input schemes. For example, the input code for just one of the DACs may be loaded and the output may or may not be updated. Or, the input codes for all four DACs may be written, and the outputs may or may not be updated.

The same applies for MODE SELECTION. The mode of just one or many of the DACs may be rewritten and the user can choose to immediately update the outputs or wait until a later time to transfer the mode information to the outputs.

A user may also write both input code and mode information into their respective first ranks and then update all second ranks at once.

Finally, transparent operation allows data to be transferred from the inputs to the outputs. This feature is useful, for example, in a situation where one of the DACs is used in an A/D converter. The SAR register could be connected directly to a DAC by using the transparent mode of operation. Another use for this feature would be during system calibration where the endpoints of the transfer function of each DAC would be measured. For example, if the full-scale voltages of each DAC were to be measured, then by making all four DACs transparent and putting all "1s" on the input port, all four DACs would be at full-scale. This requires far less software overhead than loading each register individually.

The following sections detail the timing requirements for various data loading schemes.

Function	DS1,DS0	$\overline{LS}$	$\overline{MS}$	$\overline{TR}$	$\overline{QS0}$, $\overline{1}$, $\overline{2^1}$	$\overline{RD}$	$\overline{CS}$	$\overline{RST}$
Load 1st Rank (data)

2nd Rank	XX	1	0	1	XXX	1	1→0	1
Readback Mode[1]	XX	X	0	1	00X	0	1→0	1

Notes: X = don't care.
[1]For 44-pin versions only
[2]For $\overline{MS}$, $\overline{TR}$, $\overline{LS}$ = 0, a $\overline{MS}$ 1st write occurs.

Table II. AD664 Digital Truth Table

Load and Update One DAC Output

In this first example, the object is simply to change the output of one of the four DACs on the AD664 chip. The procedure is to select the address bits that indicate the DAC to be programmed, pull LATCH SELECT($\overline{LS}$) low, pull CHIP SELECT($\overline{CS}$) low, release $\overline{LS}$ and then release $\overline{CS}$. When $\overline{CS}$ goes low, data enters the first rank of the input latch. As soon as $\overline{LS}$ goes high, the data is transferred into the second rank and produces the new output voltage. During this transfer, $\overline{MS}$, $\overline{TR}$, $\overline{RD}$ and $\overline{RST}$ should be held high.

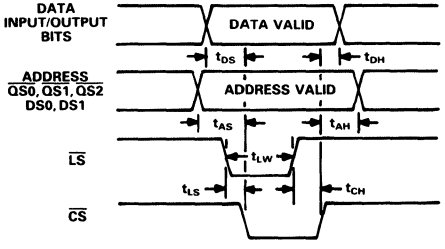

Figure 9. Update Output of a Single DAC

Preloading the First Rank of One DAC

In this case, the object is to load new data into the first rank of one of the DACs but *not* the output. As in the previous case, the address and data inputs are placed on the appropriate pins. $\overline{LS}$ is then brought to "0" and then $\overline{CS}$ is asserted. Note that in this situation, however, $\overline{CS}$ goes high before $\overline{LS}$ goes high. The input data is prevented from getting to the second rank and affecting the output voltage.

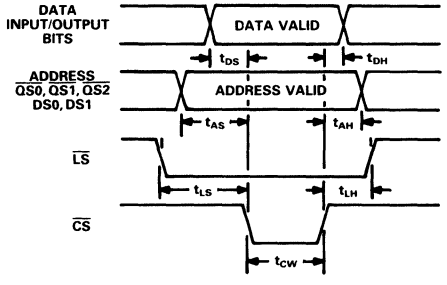

Figure 10. Preload First Rank of a DAC

This allows the user to "preload" the data to a DAC and strobe it into the output latch at some future time. The user could do this by reproducing the sequence of signals illustrated in the next section.

Update Second Rank of a DAC

Assuming that a new input code had previously been placed into the first rank of the input latches, the user can update the output of the DAC by simply pulling $\overline{CS}$ low while keeping $\overline{LS}$, $\overline{MS}$, $\overline{TR}$, $\overline{RD}$ and $\overline{RST}$ high. Address data is not needed in this case. In reality, all second ranks are being updated by this procedure, but only those which receive data different from that already there would manifest a change. Updating the second rank does not change the contents of the first rank.

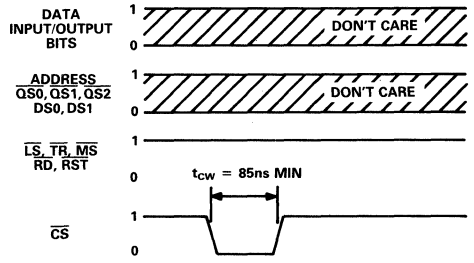

Figure 11. Update Second Rank of a DAC

The same options that exist for individual DAC input loading also exist for multiple DAC input loading. That is, the user can choose to update the first and second ranks of the registers *or* preload the first ranks and then update them at a future time.

Load and Update Multiple DAC Outputs

The following examples demonstrate two ways to update all DAC outputs. The first method involves doing all data transfers during one long $\overline{CS}$ low period. Note that in this case, shown in Figure 12, $\overline{LS}$ returns high before $\overline{CS}$ goes high. Data hold time, relative to an address change, is 70ns. This updates the outputs of all DACs simultaneously.

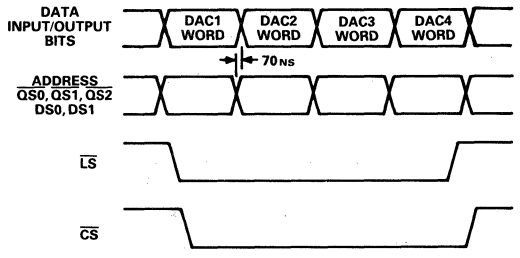

Figure 12. Update All DAC Outputs

The second method involves doing a $\overline{CS}$ assertion (low) and an $\overline{LS}$ toggle separately for each DAC. It is basically a series of preload operations (Figure 10). In this case, illustrated in Figure 13, two $\overline{LS}$ signals are shown. One, labelled $\overline{LS}$, goes high before $\overline{CS}$ returns high. This transfers the "new" input word to the DAC outputs sequentially. The second $\overline{LS}$ signal, labelled Alternate $\overline{LS}$, stays low until $\overline{CS}$ returns high. Using this sequence loads the first ranks with each "new" input word but doesn't update the DAC outputs. To then update all DAC outputs simultaneously would require the signals illustrated in Figure 11.

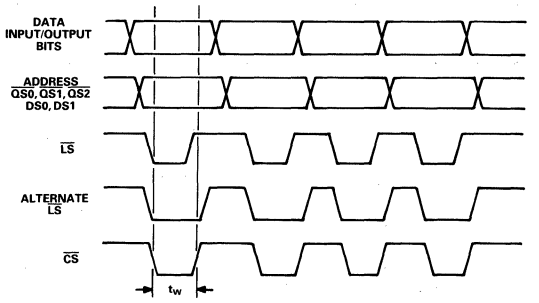

Figure 13. Load and Update Multiple DACs

Preload Multiple First Rank Registers

The first ranks of the DAC input registers may be preloaded with new input data without disturbing the second rank data. This is done by transferring the data into the first rank by bringing $\overline{CS}$ low while $\overline{LS}$ is low. But $\overline{CS}$ must return high before $\overline{LS}$. This prevents the data from the first rank from getting into the second rank. A simple second rank update cycle as shown in Figure 11 would move the "preloaded" information to the DACs.

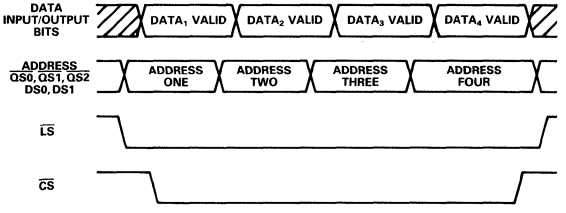

Figure 14. Preload First Rank Registers

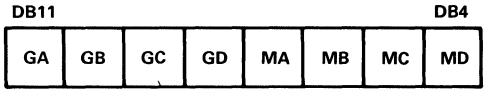
Selecting Gain Range and Modes (44-Pin Versions)

The AD664's mode select feature allows a user to configure the gain ranges and output modes of each of the four DACs. On-board switches take the place of up to eight external relays that would normally be required to accomplish this task. The switches are programmed by the mode select word entered via the data I/O port. The mode select word is eight bits wide and occupies the topmost eight bits of the input word. The last four bits of the input word are "don't cares."

Figure 15 shows the format of the MODE SELECT word. The first four bits determine the gain range of the DAC. When set to be a gain of 1, the output of the DAC spans a voltage of 1 times the reference. When set to a gain of 2, the output of the DAC spans a voltage of 2 times the reference.

The next four bits determine the mode of the DAC. When set to UNIPOLAR, the output goes from 0 to REF or 0 to 2REF. When the BIPOLAR mode is selected, the output goes from −REF/2 to REF/2 or −REF to REF.



GX = "0", GAIN = 1
GX = "1", GAIN = 2
MX = "0", UNIPOLAR
MX = "1", BIPOLAR

Figure 15. Mode Select Word Format

Load and Update Mode of One DAC

In this next example, the object is to load new mode information for one of the DACs into the first rank of latches and then immediately update the second rank. This is done by putting the new mode information (8-bit word length) onto the databus. Then $\overline{MS}$ and $\overline{LS}$ are pulled low. Following that, $\overline{CS}$ is pulled low. This loads the mode information into the first rank of latches. $\overline{LS}$ is then brought high. This action updates the second rank of latches (and, therefore, the DAC outputs). The load cycle ends when $\overline{CS}$ is brought high.

In reality, this load cycle really updates the modes of all the DACs, but the effect is to only change the modes of those DACs whose mode select information has actually changed.

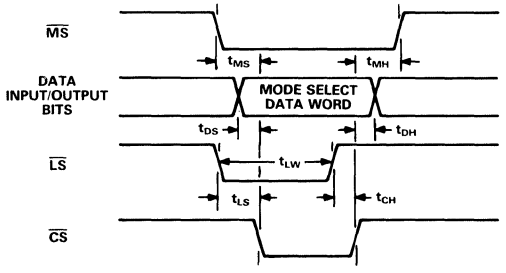


Figure 16. Load and Update Mode of One DAC

Preloading the Mode Select Register

Mode data can be written into the first rank of the mode select latch without changing the modes currently being used. This feature is useful when a user wants to preload new mode information in anticipation of strobing that in at a future time. Figure 17 illustrates the correct sequence of control signals to accomplish this task. (A second rank load requires $\overline{CS}$ = 320ns.)

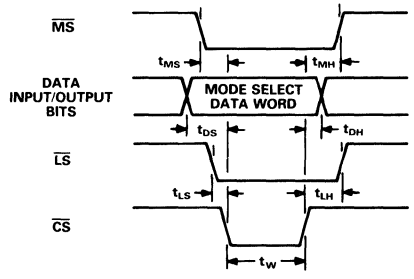

Figure 17. Preload Mode Select Register

Transparent Mode Operation (44-Pin Versions)

Transparent operation allows data from the inputs of the AD664 to be transferred into the DAC registers without the intervening step of being latched into the first rank of latches. Two modes of transparent operation exist, the "partially transparent" mode and a "fully transparent" mode. In the "partially transparent" mode, one of the DACs is transparent while the remaining three continue to use the data latched into their respective input registers. Both modes require a 12-bit wide input word!

The fully transparent mode is selected by asserting lows on $\overline{QS0}$, $\overline{QS1}$, $\overline{QS2}$, $\overline{TR}$ and $\overline{CS}$ while asserting highs on $\overline{LS}$, $\overline{MS}$ and $\overline{RD}$. Figure 18 illustrates the correct timing relationships for those signals. Address setup and $\overline{TR}$ setup times are 0ns minimum.

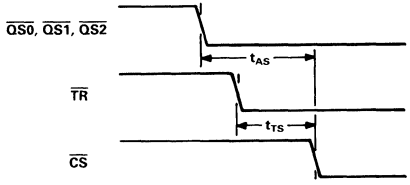

Figure 18. Fully Transparent Operation

The partially transparent mode of operation is achieved by setting $\overline{QS0}$, $\overline{QS1}$, $\overline{QS2}$, $\overline{LS}$ and $\overline{TR}$ low while $\overline{RD}$ and $\overline{MS}$ are high. The address of the transparent DAC is asserted on DS0 and DS1. Figure 19 illustrates the correct sequence of those signals. The required minimum setup times for $\overline{QS0}$, $\overline{QS1}$, $\overline{QS2}$, DS0, DS1, $\overline{TR}$ and $\overline{LS}$ are again 0ns.

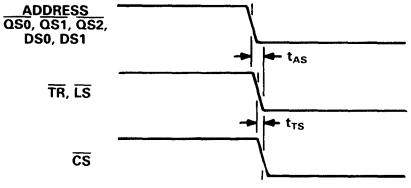

Figure 19. Partially Transparent Operation

OUTPUT DATA

Two types of outputs may be obtained from the internal data registers of the AD664 chip, mode select and DAC input code data. Readback data may be in the same forms in which it can be entered; 4-, 8-, and 12-bit wide words (12 bits only for 28-pin versions).

DAC Data Readback

DAC input code readback data is obtained by setting the address of the DAC (DS0, DS1) and Quads ($\overline{QS0}$, $\overline{QS1}$, $\overline{QS2}$) on the address pins and bringing the $\overline{RD}$ and $\overline{CS}$ pins low. The timing diagram for a DAC code readback operation appears in Figure 20.

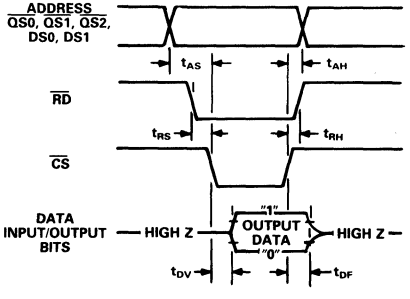

Figure 20. DAC Input Code Readback

Mode Data Readback

Mode data is read back in a similar fashion. By setting $\overline{MS}$, $\overline{QS0}$, $\overline{QS1}$, $\overline{RD}$ and $\overline{CS}$ low while setting $\overline{TR}$ and $\overline{RST}$ high, the mode select word is presented to the I/O port pins. Figure 21 shows the timing diagram for a readback of the mode select data register.

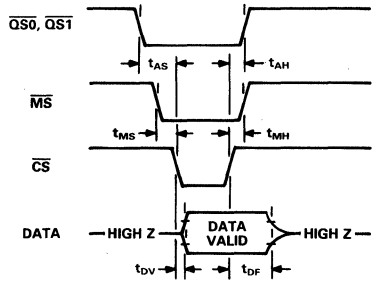

Figure 21. Mode Select Readback

OUTPUT LOADS

Readback timing is tested with the output loads shown in Figure 22.

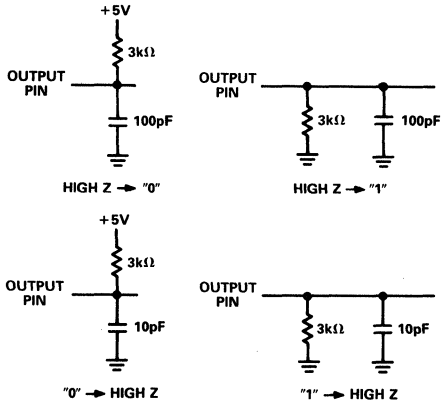

Figure 22. Output Loads

Asynchronous Reset Operation

The asynchronous reset signal shown in Figure 23 may be asserted at any time. A minimum pulse width (t_{RW}) of 90ns is required. The reset feature is designed to return all DAC outputs to 0 volts regardless of the mode or range selected. In the 44-pin versions, the modes are reset to unipolar 10V span (gain of 1), and the input codes are rewritten to be "0s." Previous DAC code and mode information is erased.

In the 28-pin versions of the AD664, the mode remains unchanged, the appropriate input code is rewritten to reset the output voltage to 0 volts. As in the 44-pin versions, the previous input data is erased.

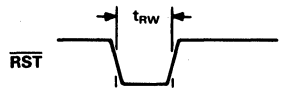

Figure 23. Asynchronous Reset Operation

At power-up, an AD664 may be activated in either the read or write modes. While, at the device level, this will not produce any problems, at the system level it may. Analog Devices recommends the addition of a simple power-on reset scheme to any system where the possibility of an unknown start-up state could be a problem. The simplest version of this scheme is illustrated in Figure 24.

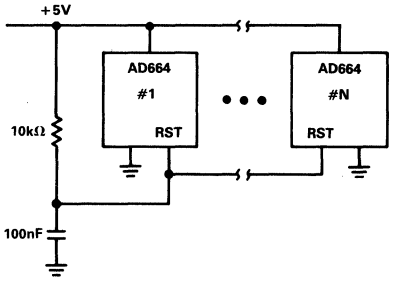

Figure 24. Power-On Reset

It is obvious from inspection that the scheme shown in Figure 24 is only appropriate for systems in which the $\overline{RST}$ pin is otherwise not used. Should the user wish to use the $\overline{RST}$ pin, an additional logic gate may be included to combine the power-on reset with the reset signal.

Interfacing the AD664 To Microprocessors

The AD664 is easy to interface with a wide variety of popular microprocessors. Common architectures include processors with dedicated 8-bit data and address buses, an 8-bit bus over which data and address are multiplexed, an 8-bit data and 16-bit address partially muxed, and separate 16-bit data and address buses.

AD664 addressing can be accomplished through either memory-mapped or I/O techniques. In memory-mapped schemes, the AD664 appears to the host microprocessor as RAM memory. Standard memory addressing techniques are used to select the AD664. In the I/O schemes, the AD664 is treated as an external I/O device by the host. Dedicated I/O pins are used to address the AD664.

MC6801 Interface

In Figures 25a-25d, we illustrate a few of the various methods that can be used to connect an AD664 to the popular MC6801 microprocessor. In each of these cases, the MC6801 is intended to be configured in its expanded, nonmultiplexed mode of operation. In this mode, the MC6801 can address 256 bytes of external memory over 8-bit data (Port 3) and 8-bit address (Port 4) buses. Eight general-purpose I/O lines (Port 1) are also available. On-board RAM and ROM provide program and data storage space.

In Figure 25a, the three least significant address bits (P40, P41 and P42) are employed to select the appropriate on-chip addresses for the various input registers of the AD664. Three I/O lines (P17, P16 and P15) are used to select various operating features of the the AD664. IOS and E(nable) are combined to produce an appropriate $\overline{CS}$ signal. This addressing scheme leaves the five most significant address bits and five I/O lines free for other tasks in the system.

Figure 25b shows another way to interface an AD664 to the MC6801. Here we've used the six least significant address lines to select AD664 features and registers. This is a purely memory-mapped scheme while the one illustrated in Figure 25a uses some memory-mapping as well as some dedicated I/O pins. In Figure 25b, two address lines and all eight I/O lines remain free for other system tasks.

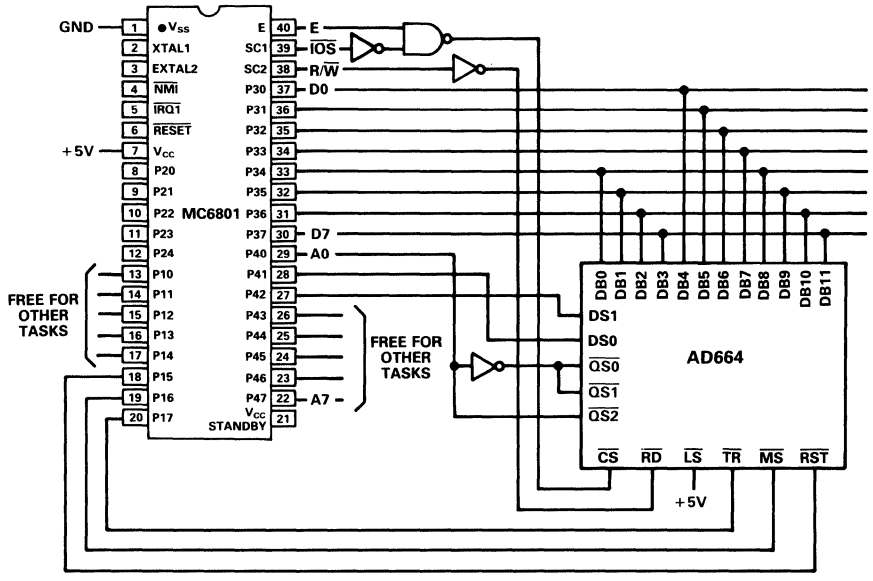

Figure 25a. Simple AD664 to MC6801 Interface

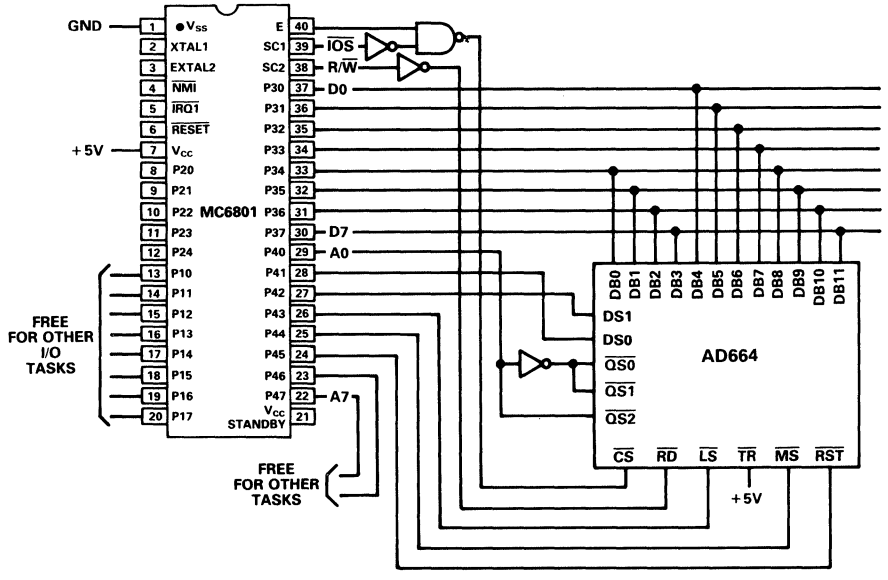

Figure 25b. Alternate AD664 to MC6801 Interface

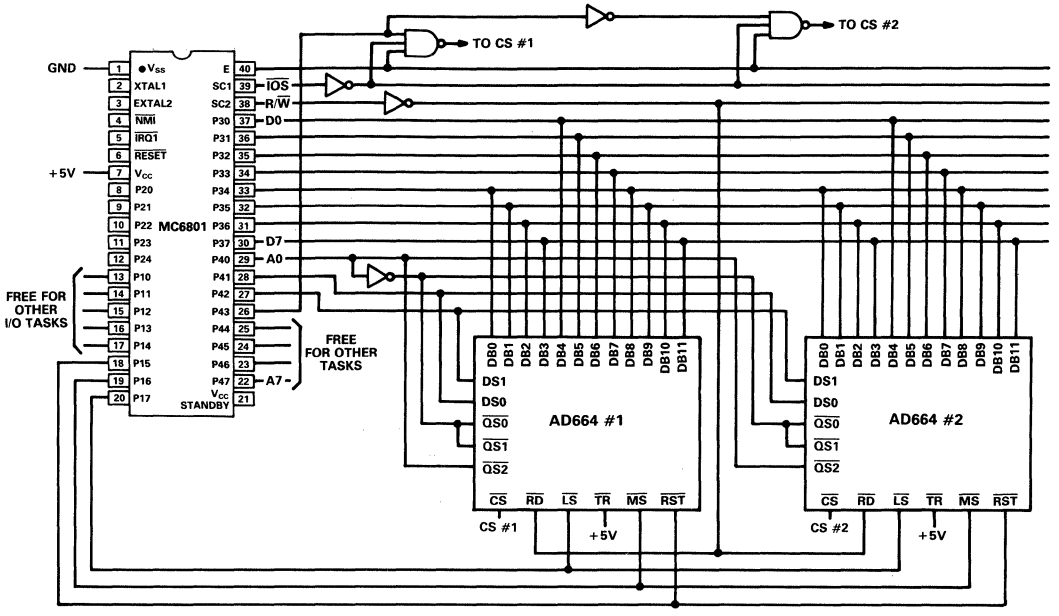

Figure 25c. Interfacing Two AD664s to an MC6801

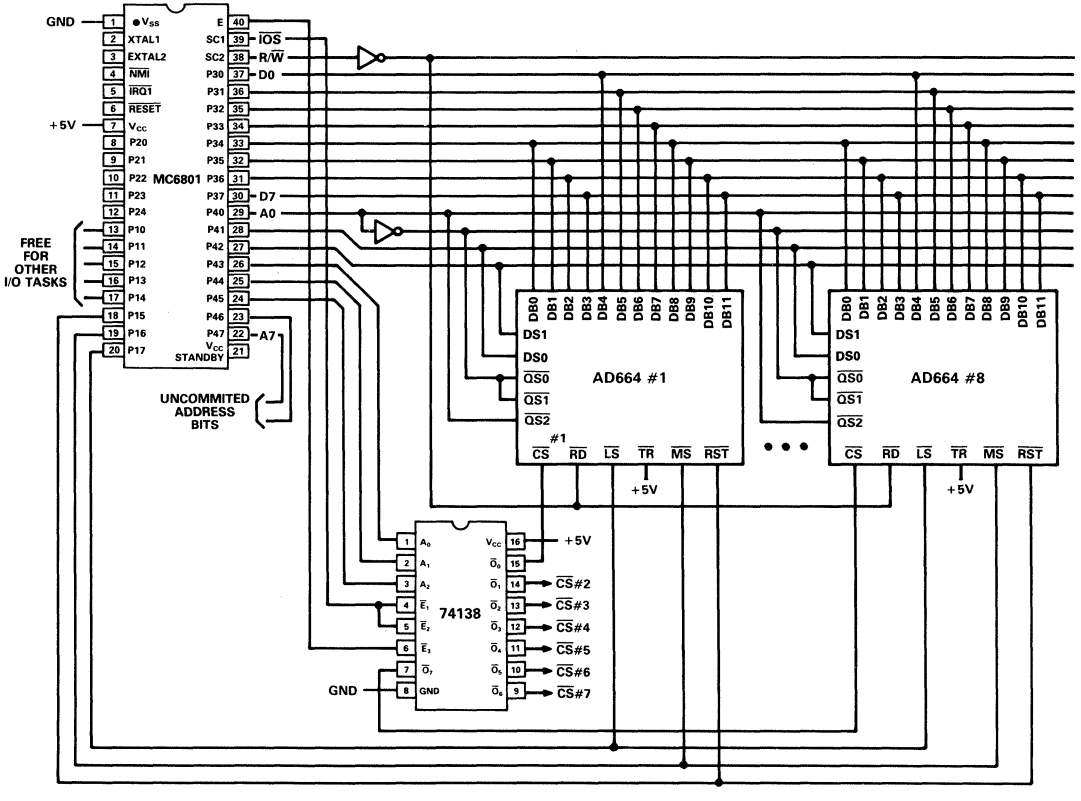

Figure 25d. Interfacing Eight AD664s to an MC6801

Expansion of the scheme employed in Figure 25a results in that shown in Figure 25c. Here, two AD664s are connected to an MC6801, providing a total of eight 12-bit, software programmable DACs. Again, the three least significant bits of address are used to select the on-chip registers of the AD664. IOS and E, as well as a fourth address bit, are decoded to provide the appropriate $\overline{CS}$ signals. Four address and five I/O lines remain uncommitted.

A slightly more sophisticated approach to system expansion is illustrated in Figure 25d. Here, a 74LS138 (1-of-8 decoder) is used to address one of the eight AD664s connected to the MC6801. The three least significant address bits are used to select on-chip register and DAC. The next three address bits are used to select the appropriate AD664. IOS and E gate the 74LS138 output.

The schemes in Figure 25 illustrate some of the trade-offs which a designer may make when configuring a system. For example, the designer may use I/O lines instead of address bits or vice versa. This decision may be influenced by other I/O tasks or system expansion requirements. He/she can also choose to implement only a subset of the features available. Perhaps the $\overline{RST}$ pin isn't really needed. Tying that input pin to V_{LOGIC} frees up another I/O or address bit. The same consideration applies to mode select. In all of these cases $\overline{TR}$ is shown tied to V_{LOGIC}, because the MC6801 cannot provide the 12-bit-wide input word required for the transparent mode. In situations where transparent operation isn't required, and mode select is also not needed, the designer may consider specifying the DIP version of the device (either the UNI or BIP version).

Each of the schemes illustrated in Figure 25 operates with an MC6801 at clock rates up to and including 1.5MHz. Similar schemes can be derived for other 8-bit microprocessors and microcontrollers such as the 8051/8086/8088/6502, etc. One such scheme developed for the 8051/AD664 is illustrated in Figure 26.

8051 Interface

Figure 26 shows the AD664 combined with an 8051 μcontroller chip. Three LSBs of address provide the quad and DAC select signals. Control signals from Port 1 select various operating modes such as readback, mode select and reset as well as providing the $\overline{LS}$ signal. Read and write signals from the 8051 are decoded to provide the $\overline{CS}$ signal.

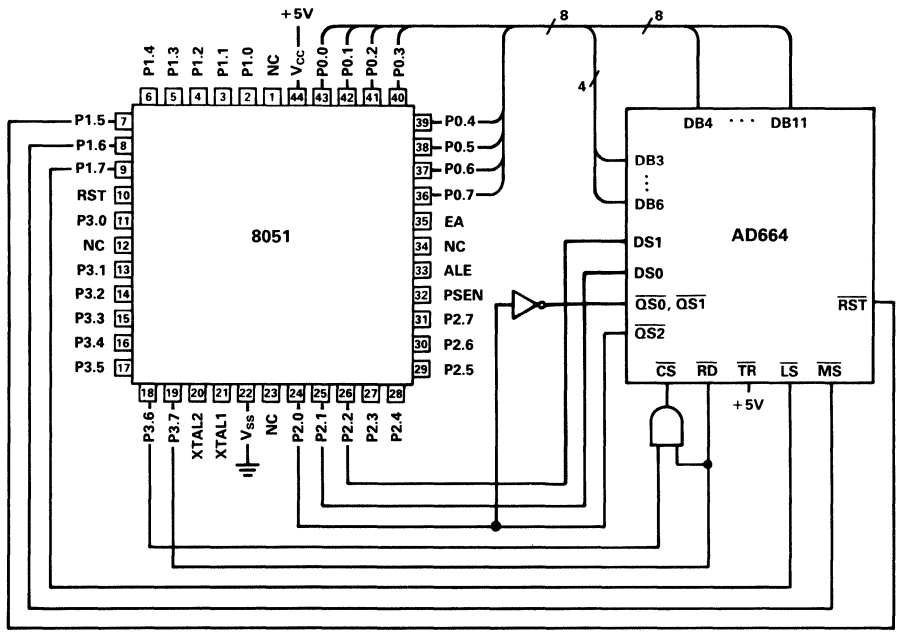

Figure 26. AD664 to 8051 Interface

IBM PC* Interface

Figure 27 illustrates a simple interface between an IBM PC and an AD664. The three least significant address bits are used to select the Quad and DAC. The next two address bits are used for $\overline{LS}$ and $\overline{MS}$. In this scheme, a 12-bit input word requires two load cycles, an 8-bit word and a 4-bit word. Another write is required to transfer the word or words previously written to the second rank. A 12-bit-wide word again requires at least two read cycles; one for the 8MSBs and four for the LSBs. The page select signal produces a $\overline{CS}$ strobe for any address from 300H to 31FH.

Table III. IBM PC Memory Map

The following IBM PC Basic routine produces four output voltage ramps from one AD664. Line numbers 10 through 70 define the hardware addresses for the first and second ranks of DAC registers as well as the first and second ranks of the mode select register. Program variables are initialized in line numbers 110 through 130. Line number 170 writes "0s" out to the first rank and, then, the second rank of the mode select register.

Line numbers 200 through 320 calculate output voltages. Finally line numbers 410 through 450 update the first, then the second ranks of the DAC input registers. Hardware registers may be read with the "INP" instruction. For example, the contents of the DAC A register may be accessed with the following command: Line# A=INP(DACA).

Simple AD664 to MC68000 Interface

Figure 28 shows an AD664 connected to an MC68000. In this memory-mapped I/O scheme, the "left-justified" data is written in one 12-bit input word. Four address bits are used to perform the on-chip D/A selection as well as the various operating features. The R/$\overline{W}$ signal controls the $\overline{RD}$ function and system reset controls $\overline{RST}$.

This scheme can be converted to write "right-justified" data by connecting the data inputs to DATA bits D0 through D11 respectively. Other options include controlling the $\overline{QS0}$, $\overline{QS1}$ and $\overline{QS2}$ pins with $\overline{UDS}$ and $\overline{LDS}$ to provide a way to write 8-bit input and read 8-bit output words.

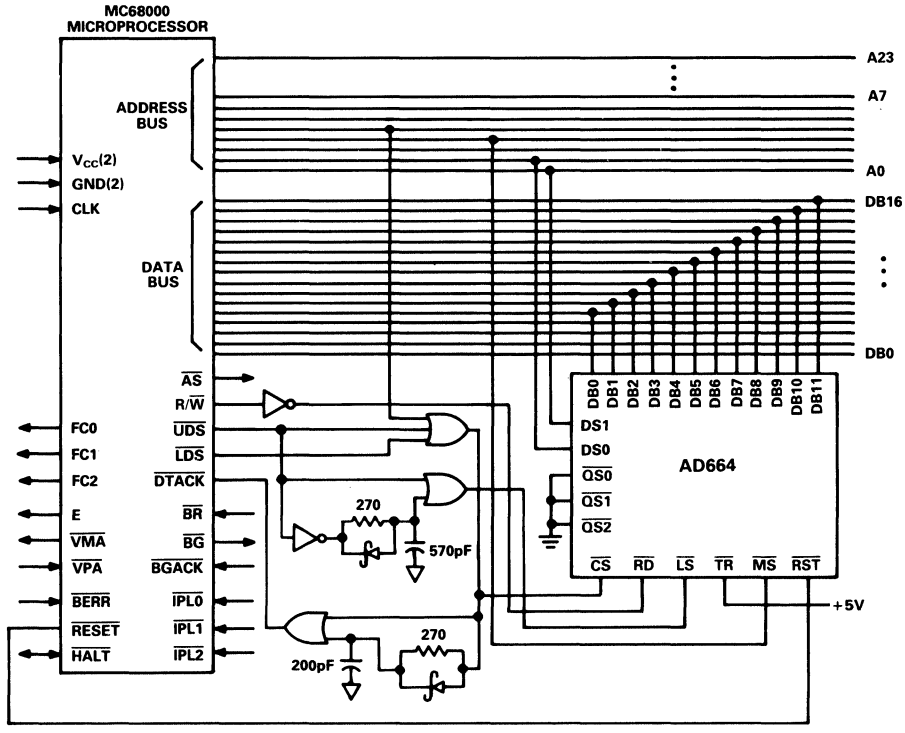

Figure 28. AD664 to MC68000 Interface

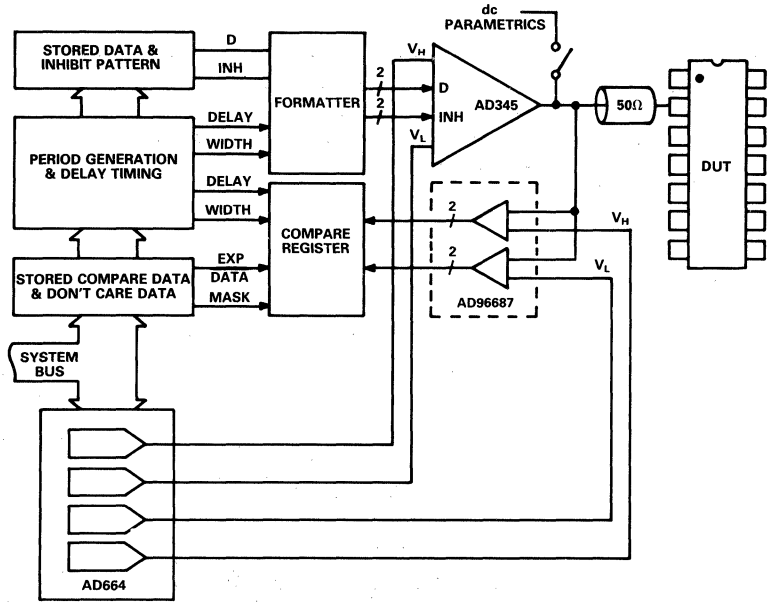

Figure 29. AD664 in a "Tester-Per-Pin" Architecture

APPLICATIONS OF THE AD664

"Tester-Per-Pin" ATE Architecture

Figure 29 Shows the AD664 used in a single channel of a digital test system. In this scheme, the AD664 supplies four individual output voltages. Two are provided to the V_{HIGH} and V_{LOW} inputs of the AD345 pin driver I.C. to set the digital output levels. Two others are routed to the inputs of the AD96687 dual comparator to supply reference levels of the readback features. This approach can be replicated to give as many channels of stimulus/readback as the tester has pins. The AD664 is a particularly appropriate choice for a large-scale system because the low power requirements (under 500mW) ease power supply and cooling requirements. Analog ground currents of 600μA or less make the ground current management task simpler. All DACs can be driven from the same system reference and will track over time and temperature. Finally, the small board area required by the AD664 (and AD345 and AD96687) allows a high functional density.

X-Y Plotters

Figure 30 is a block diagram of the control section of a microprocessor-controlled X-Y pen plotter. In this conceptual exercise, two of the DACs are used for the X-channel drive and two are used for the Y-channel drive. Each provides either the coarse or fine movement control for its respective channel. This approach offers increased resolution over some other approaches.

A designer can take advantage of the reset feature of the AD664 in the following manner. If the system is designed such that the "HOME" position of the pen (or galvanometer, beam, head or similar mechanism) results when the outputs of all of the DACs are at zero, then no system software is required to home the pen. A simple reset signal is sufficient.

Similarly, the transparent feature could be used to the same end. One code can be sent to all DACs at the same time to send the pen to the home position. Of course, this would require some software where the previous example would require only a single reset strobe signal!

Drawing scaling can be achieved by taking advantage of the AD664's software programmable gain settings. If, for example, an "A" size drawing is created with gain settings of 1, then a "C" size drawing can be created by simply resetting all DAC gains to 2 and redrawing the object. Conversely, a "C" size drawing created with gains of 2 can be reduced to "A" size simply by changing the gains to 1 and redrawing. The same principal applies for conversion from "B" size to "D" size or "D" size to "B" size. The multiplying capability of the AD664 provides another scaling option. Changing the reference voltage provides a proportional change in drawing size. Inverting the reference voltage would invert the drawing.

Swapping digital input data from the X channel to the Y channel would rotate the drawing 90 degrees.

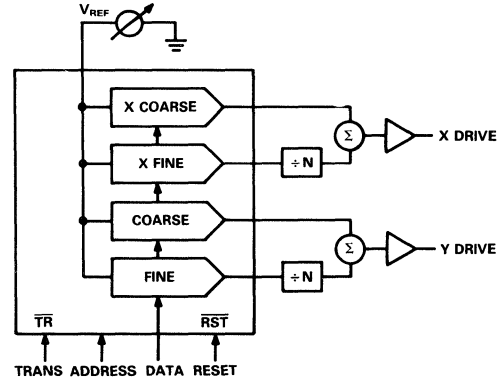

Figure 30. X-Y Plotter Block Diagram

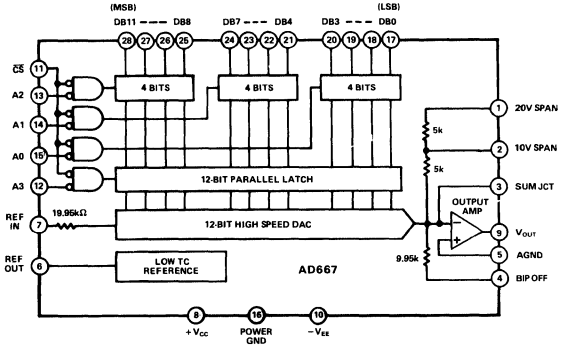
Microprocessor-Compatible 12-Bit D/A Converter

AD667*

FEATURES

- **Complete 12-Bit D/A Function**
  - **Double-Buffered Latch**
  - **On Chip Output Amplifier**
  - **High Stability Buried Zener Reference**
- **Single Chip Construction**
- **Monotonicity Guaranteed Over Temperature**
- **Linearity Guaranteed Over Temperature: 1/2LSB max**
- **Settling Time: 3μs max to 0.01%**
- **Guaranteed for Operation with ±12V or ±15V Supplies**
- **Low Power: 300mW Including Reference**
- **TTL/5V CMOS Compatible Logic Inputs**
- **Low Logic Input Currents**

AD667 FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD667 is a complete voltage output 12-bit digital-to-analog converter including a high stability buried Zener voltage reference and double-buffered input latch on a single chip. The converter uses 12 precision high speed bipolar current steering switches and a laser trimmed thin film resistor network to provide fast settling time and high accuracy.

Microprocessor compatibility is achieved by the on-chip double-buffered latch. The design of the input latch allows direct interface to 4-, 8-, 12-, or 16-bit buses. The 12 bits of data from the first rank of latches can then be transferred to the second rank, avoiding generation of spurious analog output values. The latch responds to strobe pulses as short as 100ns, allowing use with the fastest available microprocessors.

The functional completeness and high performance in the AD667 results from a combination of advanced switch design, high speed bipolar manufacturing process, and the proven laser wafer-trimming (LWT) technology. The AD667 is trimmed at the wafer level and is specified to ±1/4LSB maximum linearity error (K, B grades) at 25°C and ±1/2LSB over the full operating temperature range.

The subsurface (buried) Zener diode on the chip provides a low-noise voltage reference which has long-term stability and temperature drift characteristics comparable to the best discrete reference diodes. The laser trimming process which provides the excellent linearity, is also used to trim the absolute value of the reference as well as its temperature coefficient. The AD667 is thus well suited for wide temperature range performance with ±1/2LSB maximum linearity error and guaranteed monotonicity over the full temperature range. Typical full scale gain T.C. is 5ppm/°C.

***Covered by Patent Numbers 3,803,590; 3,890,611; 3,932,863; 3,978,473; 4,020,486; and others pending.**

The AD667 is available in five performance grades. The AD667J and K are specified for use over the 0 to +70°C temperature range and are available in a 28-pin molded plastic DIP (N) or PLCC (P) package. The AD667S grade is specified for the −55°C to +125°C range and is available in the ceramic DIP (D) or LCC (E) package. The AD667A and B are specified for use over the −25°C to +85°C temperature range and are available in either a 28-pin hermetically sealed ceramic DIP (D) or LCC (E) package.

PRODUCT HIGHLIGHTS

1. The AD667 is a complete voltage output DAC with voltage reference and digital latches on a single IC chip.
2. The double-buffered latch structure permits direct interface to 4-, 8-, 12-, or 16-bit data buses. All logic inputs are TTL or 5 volt CMOS compatible.
3. The internal buried Zener reference is laser-trimmed to 10.00 volts with a ±1% maximum error. The reference voltage is also available for external application.
4. The gain setting and bipolar offset resistors are matched to the internal ladder network to guarantee a low gain temperature coefficient and are laser-trimmed for minimum full scale and bipolar offset errors.
5. The precision high speed current steering switch and on-board high speed output amplifier settle within 1/2LSB for a 10V full scale transition in 2.0μs when properly compensated.

NOTES
[1]The digital input specifications are 100% tested at +25°C, and guaranteed but not tested over the full temperature range.
[2]Adjustable to zero.
[3]FSR means "Full Scale Range" and is 20V for ±10V range and 10V for the ±5V range.
[4]A minimum power supply of ±12.5V is required for a ±10V full scale output and ±11.4V is required for all other voltage ranges.

Specifications subject to change without notice.

Specifications shown in boldface are tested on all production units at final electrical test. Results from those tests are used to calculate outgoing quality levels. All min and max specifications are guaranteed, although only those shown in boldface are tested on all production units.

THE AD667 OFFERS TRUE 12-BIT PERFORMANCE OVER THE FULL TEMPERATURE RANGE

LINEARITY ERROR: Analog Devices defines linearity error as the maximum deviation of the actual, adjusted DAC output from the ideal analog output (a straight line drawn from 0 to F.S. – 1LSB) for any bit combination. The AD667 is laser trimmed to 1/4LSB (0.006% of F.S.) maximum error at +25°C for the K and B versions and 1/2LSB for the J, A and S versions.

MONOTONICITY: A DAC is said to be monotonic if the output either increases or remains constant for increasing digital inputs such that the output will always be a nondecreasing function of input. All versions of the AD667 are monotonic over their full operating temperature range.

DIFFERENTIAL NONLINEARITY: Monotonic behavior requires that the differential linearity error be less than 1LSB both at +25°C and over the temperature range of interest. Differential nonlinearity is the measure of the variation in analog value, normalized to full scale, associated with a 1LSB change in digital input code. For example, for a 10 volt full scale output, a change of 1LSB in digital input code should result in a 2.44mV change in the analog output (1LSB = 10V × 1/4096 = 2.44mV). If in actual use, however, a 1LSB change in the input code results in a change of only 0.61mV (1/4LSB) in analog output, the differential linearity error would be −1.83mV, or −3/4LSB. The AD667K and B grades have a max differential linearity error of 1/2LSB, which specifies that every step will be at least 1/2LSB and at most 1 1/2 LSB.

ANALOG CIRCUIT CONNECTIONS

Internal scaling resistors provided in the AD667 may be connected to produce bipolar output voltage ranges of ±10, ±5 or ±2.5V or unipolar output voltage ranges of 0 to +5V or 0 to +10V.

Gain and offset drift are minimized in the AD667 because of the thermal tracking of the scaling resistors with other device components. Connections for various output voltage ranges are shown in Table I.

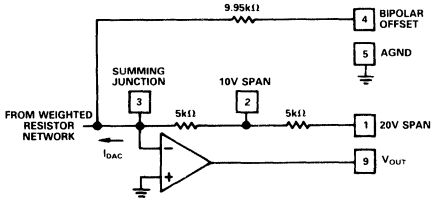

Figure 1. Output Amplifier Voltage Range Scaling Circuit

UNIPOLAR CONFIGURATION (Figure 2)

This configuration will provide a unipolar 0 to +10 volt output range. In this mode, the bipolar offset terminal, pin 4, should be grounded if not used for trimming.

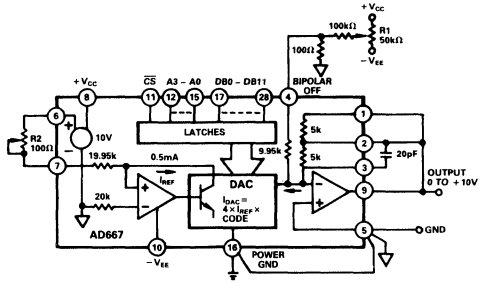

Figure 2. 0 to +10V Unipolar Voltage Output

STEP I . . . ZERO ADJUST

Turn all bits OFF and adjust zero trimmer R1, until the output reads 0.000 volts (1LSB = 2.44mV). In most cases this trim is not needed, and pin 4 should be connected to pin 5.

STEP II . . . GAIN ADJUST

Turn all bits ON and adjust 100Ω gain trimmer R2, until the output is 9.9976 volts. (Full scale is adjusted to 1LSB less than nominal full scale of 10.000 volts.)

BIPOLAR CONFIGURATION (Figure 3)

This configuration will provide a bipolar output voltage from −5.000 to +4.9976 volts, with positive full scale occurring with all bits ON (all 1's).

STEP I . . . OFFSET ADJUST

Turn OFF all bits. Adjust 100Ω trimmer R1 to give −5.000 volts output.

STEP II . . . GAIN ADJUST

Turn ON all bits. Adjust 100Ω gain trimmer R2 to give a reading of +4.9976 volts.

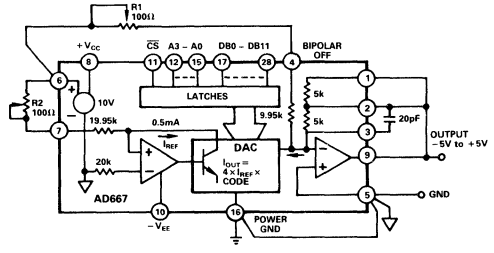

Figure 3. ±5V Bipolar Voltage Output

Output Range	Digital Input Codes	Connect Pin 9 to	Connect Pin 1 to	Connect Pin 2 to	Connect Pin 4 to
±10V	Offset Binary	1	9	NC	6 (through 50Ω fixed or 100Ω trim resistor)
±5V	Offset Binary	1 and 2	2 and 9	1 and 9	6 (through 50Ω fixed or 100Ω trim resistor)
±2.5V	Offset Binary	2	3	9	6 (through 50Ω fixed or 100Ω trim resistor)
0 to +10V	Straight Binary	1 and 2	2 and 9	1 and 9	5 (or optional trim – See Figure 2)
0 to +5V	Straight Binary	2	3	9	5 (or optional trim – See Figure 2)

Table I. Output Voltage Range Connections

INTERNAL/EXTERNAL REFERENCE USE

The AD667 has an internal low-noise buried zener diode reference which is trimmed for absolute accuracy and temperature coefficient. This reference is buffered and optimized for use in a high speed DAC and will give long-term stability equal or superior to the best discrete zener reference diodes. The performance of the AD667 is specified with the internal reference driving the DAC since all trimming and testing (especially for full scale error and bipolar offset) is done in this configuration.

The internal reference has sufficient buffering to drive external circuitry in addition to the reference currents required for the DAC (typically 0.5mA to Ref In and 1.0mA to Bipolar Offset). A minimum of 0.1mA is available for driving external loads. The AD667 reference output should be buffered with an external op amp if it is required to supply more than 0.1mA output current. The reference is typically trimmed to ±0.2%, then tested and guaranteed to ±1.0% max error. The temperature coefficient is comparable to that of the full scale TC for a particular grade.

If an external reference is used (10.000V, for example), additional trim range must be provided, since the internal reference has a tolerance of ±1%, and the AD667 full-scale and bipolar offset are both trimmed with the internal reference. The gain and offset trim resistors give about ±0.25% adjustment range, which is sufficient for the AD667 when used with the internal reference.

It is also possible to use external references other than 10 volts. The recommended range of reference voltage is from +8 to +11 volts, which allows both 8.192V and 10.24V ranges to be used. The AD667 is optimized for fixed-reference applications. If the reference voltage is expected to vary over a wide range in a particular application, a CMOS multiplying DAC is a better choice.

Reduced values of reference voltage will also permit the ±12 volt ±5% power supply requirement to be relaxed to ±12 volts ±10%.

It is not recommended that the AD667 be used with external feedback resistors to modify the scale factor. The internal resistors are trimmed to ratio-match and temperature-track the other resistors on the chip, even though their absolute tolerances are ±20%, and absolute temperature coefficients are approximately −50ppm/°C. If external resistors are used, a wide trim range (±20%) will be needed and temperature drift will be increased to reflect the mismatch between the temperature coefficients of the internal and external resistors.

Small resistors may be added to the feedback resistors in order to accomplish small modifications in the scaling. For example, if a 10.24V full-scale is desired, a 140Ω 1% low-TC metal-film resistor can be added in series with the internal (nominal) 5k feedback resistor, and the gain trim potentiometer (between pins 6 and 7) should be increased to 200Ω. In the bipolar mode, increase the value of the bipolar offset trim potentiometer also to 200Ω.

GROUNDING RULES

The AD667 brings out separate analog and power grounds to allow optimum connections for low noise and high speed performance. These grounds should be tied together at one point, usually the device power ground. The separate ground returns are provided to minimize current flow in low-level signal paths.

The analog ground at pin 5 is the ground point for the output amplifier and is thus the "high quality" ground for the AD667; it should be connected directly to the analog reference point of the system. The power ground at pin 16 can be connected to the most convenient ground point; analog power return is preferred. If power ground contains high frequency noise beyond 200mV, this noise may feed through the converter, thus some caution will be required in applying these grounds.

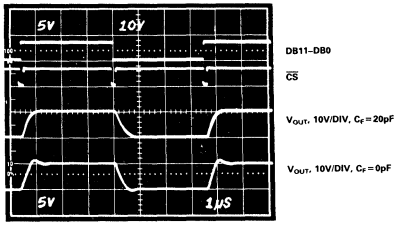
It is also important to apply decoupling capacitors properly on the power supplies for the AD667 and the output amplifier. The correct method for decoupling is to connect a capacitor from each power supply pin of the AD667 to the analog ground pin of the AD667. Any load driven by the output amplifier should also be referred to the analog ground pin.

OPTIMIZING SETTLING TIME

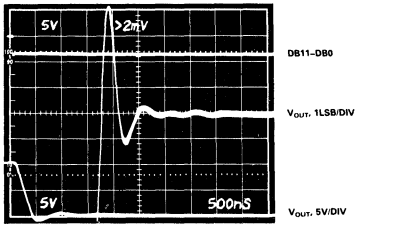
The dynamic performance of the AD667's output amplifier can be optimized by adding a small (20pF) capacitor across the feedback resistor. Figure 4 shows the improvement in both large-signal and small-signal settling for the 10V range. In Figure 4a, the top trace shows the data inputs (DB11–DB0 tied together), the second trace shows the CS pulse (A3–A0 tied low), and the lower two traces show the analog outputs for C_F = 0 and 20pF respectively.

Figures 4b and 4c show the settling time for the transition from all bits on to all bits off. Note that the settling time to ±1/2LSB for the 10V step is improved from 2.4 microseconds to 1.6 microseconds by the addition of the 20pF capacitor.

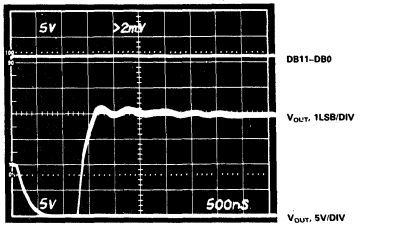
Figures 4d and 4e show the settling time for the transition from all bits off to all bits on. The improvement in settling time gained by adding C_C = 20pF is similar.



a. Large Scale Settling



b. Fine-Scale Settling, C_F = 0pF



c. Fine-Scale Settling, C_F = 20pF

Figure 4. Settling Time Performance

e. Fine-Scale Settling, $C_F = 20pF$

Figure 4. Settling Time Performance (Continued)

DIGITAL CIRCUIT DETAILS

The bus interface logic of the AD667 consists of four independently addressable registers in two ranks. The first rank consists of three four-bit registers which can be loaded directly from a 4-, 8-, 12-, or 16-bit microprocessor bus. Once the complete 12-bit data word has been assembled in the first rank, it can be loaded into the 12-bit register of the second rank. This double-buffered organization avoids the generation of spurious analog output values. Figure 5 shows the block diagram of the AD667 logic section.

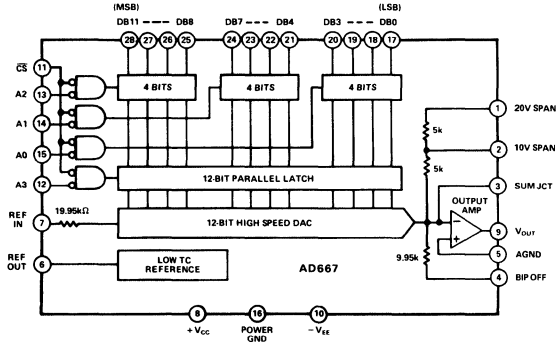

Figure 5. AD667 Block Diagram

The latches are controlled by the address inputs, A0-A3, and the $\overline{CS}$ input. All control inputs are active low, consistent with general practice in microprocessor systems. The four address lines each enable one of the four latches, as indicated in Table II.

All latches in the AD667 are level-triggered. This means that data present during the time when the control signals are valid will enter the latch. When any one of the control signals returns high, the data is latched.

It is permissible to enable more than one of the latches simultaneously. If a first rank latch is enabled coincident with the second rank latch, the data will reach the second rank correctly if the "WRITE CYCLE #1" timing specifications are met.

$\overline{CS}$	A3	A2	A1	A0	Operation
1	X	X	X	X	No Operation
X	1	1	1	1	No Operation
0	1	1	1	0	Enable 4 LSBs of First Rank
0	1	1	0	1	Enable 4 Middle Bits of First Rank
0	1	0	1	1	Enable 4 MSBs of First Rank
0	0	1	1	1	Loads Second Rank from First Rank
0	0	0	0	0	All Latches Transparent

"X" = Don't Care

Table II. AD667 Truth Table

INPUT CODING

The AD667 uses positive-true binary input coding. Logic "1" is represented by an input voltage greater than 2.0V and logic "0" is defined as an input voltage less than 0.8V.

Unipolar coding is straight binary, where all zeroes (000_H) on the data inputs yields a zero analog output and all ones (FFF_H) yields an analog output 1LSB below full scale.

Bipolar coding is offset binary, where an input code of 000_H yields a minus full-scale output, an input of FFF_H yields an output 1LSB below positive full scale, and zero occurs for an input code with only the MSB on (800_H).

The AD667 can be used with two's complement input coding if an inverter is used on the MSB (DB11).

DIGITAL INPUT CONSIDERATIONS

The threshold of the digital input circuitry is set at 1.4 volts and does not vary with supply voltage. The input lines can thus interface with any type of 5 volt logic. The configuration of the input circuit is shown in Figure 6.

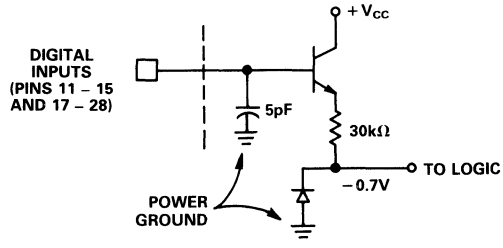

Figure 6. Equivalent Digital Input Circuit

The AD667 data and control inputs will float to a logic 0 if left open. It is recommended that any unused inputs be connected to power ground to improve noise immunity.

Fanout for the AD667 is 100 when used with a standard low power Schottky gate output device.

8-BIT MICROPROCESSOR INTERFACE

The AD667 interfaces easily to 8-bit microprocessor systems of all types. The control logic makes possible the use of right- or left-justified data formats.

Whenever a 12-bit DAC is loaded from an 8-bit bus, two bytes are required. If the program considers the data to be a 12-bit binary fraction (between 0 and 4095/4096), the data is left-justified, with the eight most significant bits in one byte and the remaining bits in the upper half of another byte. Right-justified data calls for the eight least significant bits to occupy one byte, with the 4 most significant bits residing in the lower half of another byte, simplifying integer arithmetic.

DB11	DB10	DB9	DB8	DB7	DB6	DB5	DB4
DB3	DB2	DB1	DB0	X	X	X	X

a. Left Justified

X	X	X	X	DB11	DB10	DB9	DB8
DB7	DB6	DB5	DB4	DB3	DB2	DB1	DB0

b. Right Justified

Figure 7. 12-Bit Data Formats for 8-Bit Systems

Figure 8 shows an addressing scheme for use with an AD667 set up for left-justified data in an 8-bit system. The base address is decoded from the high-order address bits and the resultant active-low signal is applied to $\overline{CS}$. The two LSBs of the address bus are connected as shown to the AD667 address inputs. The latches now reside in two consecutive locations, with location X01 loading the four LSBs and location X10 loading the eight MSBs and updating the output.

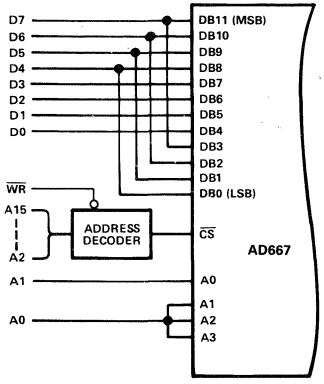

Figure 8. Left-Justified 8-Bit Bus Interface

Right-justified data can be similarly accommodated. The overlapping of data lines is reversed, and the address connections are slightly different. The AD667 still occupies two adjacent locations in the processor's memory map. In the circuit of Figure 9, location X01 loads the 8LSBs and location X10 loads the 4MSBs and updates the output.

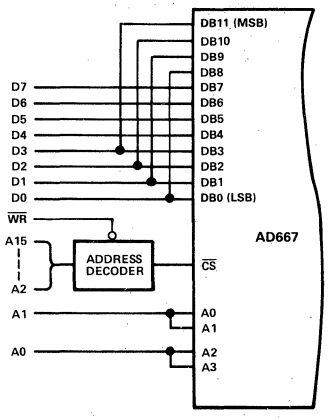

Figure 9. Right-Justified 8-Bit Bus Interface

USING THE AD667 WITH 12- AND 16-BIT BUSES

The AD667 is easily interfaced to 12- and 16-bit data buses. In this operation, all four address lines (A0 through A3) are tied low, and the latch is enabled by $\overline{CS}$ going low. The AD667 thus occupies a single memory location.

This configuration uses the first and second rank registers simultaneously. The $\overline{CS}$ input can be driven from an active-low decoded address. It should be noted that any data bus activity during the period when $\overline{CS}$ is low will cause activity at the AD667 output. If data is not guaranteed stable during this period, the second rank register can be used to provide double buffering.

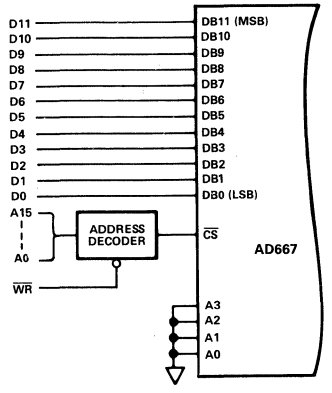

Figure 10. Connections for 12- and 16-Bit Bus Interface

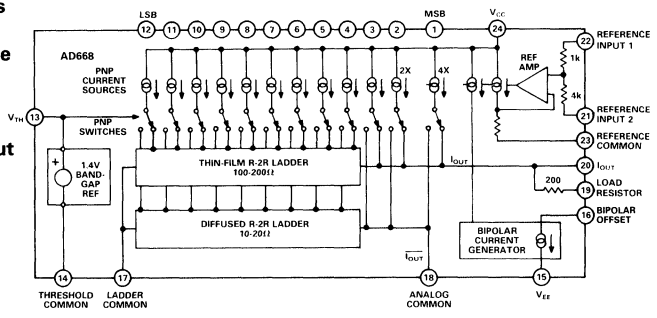
12-Bit Ultrahigh Speed Multiplying D/A Converter

AD668

FEATURES

- **Ultrahigh Speed: Current Settling to 1 LSB in 50 ns for a Full Scale Change in Digital Input. Voltage Settling to 1 LSB in 80 ns for a Full Scale Change in Analog Input**
- **25 MHz Reference Bandwidth**
- **Monotonicity Guaranteed over Temperature**
- **10.24 mA Current Output or 1.024 V Voltage Output**
- **Integral and Differential Linearity Guaranteed over Temperature**
- **0.3" "Skinny DIP" Packaging**

AD668 FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD668 is an ultrahigh speed, 12-bit, multiplying digital-to-analog converter, providing outstanding accuracy and speed performance in responding to both analog and digital inputs. The AD668 provides a level of performance and functionality in a monolithic device that exceeds that of many contemporary hybrid devices. The part is fabricated using Analog Devices' Complementary Bipolar (CB) Process, which features high-speed NPN and PNP devices on the same chip without the use of dielectric isolation. The AD668's design capitalizes on this proprietary process in combination with standard low-impedance circuit techniques to provide its unique combination of speed and accuracy in a monolithic part.

The wideband reference input is buffered by a high gain, closed loop reference amplifier. The reference input is essentially a 1 V, high impedance input, but trimmed resistive dividers are provided to readily accommodate 5 V and 1.25 V references. The reference amplifier features an effective small signal bandwidth of 25 MHz, and an effective slew rate of 3% of full scale/ns.

Multiple matched current sources and thin film ladder techniques are combined to produce bit weighting. The output range can nominally be taken as a 10.24 mA current output or a 1.024 V voltage output. Varying the analog input can provide modulation of the DAC full scale from 10% to 120% of its nominal value. Bipolar outputs can be realized through pin-strapping to provide two quadrant operation without additional external circuitry.

Laser wafer trimming insures full 12-bit linearity and excellent gain accuracy. All grades of the AD668 are guaranteed monotonic over their full operating temperature range. Furthermore, the output resistance of the DAC is trimmed to 100 Ω ±1.0%.

The AD668 is available in three performance grades. The AD668JQ and KQ are available in 24-pin cerdip (0.3") packages and are specified for operation from 0 to +70°C. The AD668SQ features operation from −55°C to +125°C and is also packaged in the hermetic 0.3" cerdip.

PRODUCT HIGHLIGHTS

1. The fast settling time of the AD668 provides suitable performance for waveform generation, graphics display, and high-speed A/D conversion applications.
2. The high bandwidth reference channel allows high frequency modulation between analog and digital inputs.
3. The AD668's design is configured to allow wide variation of the analog input, from 10% to 120% of its nominal value.
4. The AD668's combination of high performance and tremendous flexibility makes it an ideal building block for a variety of high speed, high accuracy instrumentation applications.
5. The digital inputs are readily compatible with both TTL and 5 V CMOS logic families.
6. Skinny DIP (0.3") packaging minimizes board space requirements and eases layout considerations.

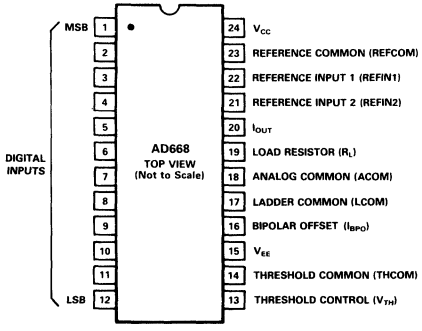
NOTES
[1]Measured in I_{OUT} mode. Specified at nominal full-scale reference.
[2]Measured in V_{OUT} mode, unless otherwise specified.
[3]Total resistance.
[4]At the major carry, driven by HCMOS logic.
[5]Measured at 15 V ±10% and 12 V ±10%.
[6]See Section 14 for package outline information.

*Same as AD668J.
Specifications shown in **boldface** are tested on all production units at final electrical test.
Specifications subject to change without notice.

PIN CONFIGURATION



FUNCTIONAL DESCRIPTION

The AD668 is designed to combine excellent performance with maximum flexibility. The functional block diagram and the simple transfer functions provided below will provide the user with a basic grasp of AD668's operation. Examples of typical circuit configurations are provided in the section APPLYING THE AD668. Subsequent sections contain more detailed information useful in optimizing DAC performance in high-speed, high resolution applications.

DAC Transfer Function

The AD668 may be used either in a current-output mode (with the DAC output connected to a virtual ground) or a voltage-output mode (DAC output connected to a resistive load.)

In current output mode:

Unipolar Mode

$$I_{OUT} = \frac{V_{IN}}{V_{NOM}} \times \frac{\text{DAC code}}{4096} \times 10.24\ \text{mA}$$

Bipolar Mode

$$I_{OUT} = \frac{V_{IN}}{V_{NOM}} \times \frac{\text{DAC code}}{4096} \times 10.24\ \text{mA} - \frac{V_{IN}}{V_{NOM}} \times 5.12\ \text{mA}$$

In voltage output mode:

$$V_{OUT} = I_{OUT} \times R_{LOAD}$$

(for both unipolar and bipolar modes)

Where:

V_{IN} – the analog input voltage.

V_{NOM} – the nominal full scale of the reference voltage: 1 V, 1.25 V, or 5 V, determined by the wiring configuration of Pins 21 and 22. (See APPLYING THE AD668.)

DAC code – the numerical representation of the DAC's digital inputs; a number between 0 and 4095.

R_{LOAD} – the resistance of the DAC output node; the maximum this can be is 200 Ω (the internal DAC ladder resistance). The on-board load resistor (Pin 19) has been trimmed so that its parallel combination with the DAC ladder resistance is 100 Ω (±1%).

Bipolar mode – produces a bipolar analog output from the digital input by offsetting the normal output current with a precision current source. This offset is achieved by connecting Pin 16 to the DAC output. In the unipolar mode, Pin 16 should be grounded.

Operating Limits:

$$0.1 < \frac{V_{IN}}{V_{NOM}} < 1.2$$

$0 < V_{IN}/V_{NOM} < 0.1$ constitutes an undervoltage condition and is subject to the specified recovery time.

$1.2 < V_{IN}/V_{NOM}$ constitutes an overvoltage condition. This can saturate the DAC transistors, resulting in decreased response time and can, over extended time, damage the part through excessive power dissipation.

The small signal 3 dB bandwidth of the V_{IN} channel is 25 MHz. The large signal 3 dB bandwidth is approximately 20 MHz.

V_{OUT} is limited by the specified output compliance: −2 V to +1.2 V.

APPLYING THE AD668

The following are some typical circuit configurations for the AD668. These represent only a sample of possible implementations.

5 V REFIN, 1 V UNIPOLAR, UNBUFFERED VOLTAGE OUTPUT

Figure 1 shows a typical topology for generating an unbuffered voltage output. R_L (Pin 19) is grounded, producing a 100 Ω DAC output resistance that generates a 1.024 V output when the DAC current is at its full scale of 10.24 mA. The presence of low impedance loads will effect the output voltage swing directly: an external load of 300 Ω will yield a total output resistance of 75 Ω, and a full scale output of 0.768 V. An external 100 Ω will reduce the total output resistance to 50 Ω and the full scale voltage swing will drop to 0.512 V. Since the bipolar offset current is not used in this configuration, Pin 16 is connected to the analog ground plane.

The input divider has been connected to produce a 5 V full scale reference input by shorting REFIN1 to the analog ground plane and using REFIN2 as the reference input. With a 5 V nominal full scale, the 10% to 120% reference input range falls between 0.5 V and 6 V. The effective input resistance in this mode is 5 kΩ (±20%). The ratio of the input divider has been intentionally skewed by 50 Ω to provide an optional external fine trim for gain adjust. A trim range of ±1% is provided by the 100 Ω trimming potentiometer shown in Figure 1. If trimming is not desired, a 50 Ω resistor may be used in place of the potentiometer to produce the specified gain accuracy, or, if a +1% nominal gain error is tolerable, the resistor may be omitted altogether.

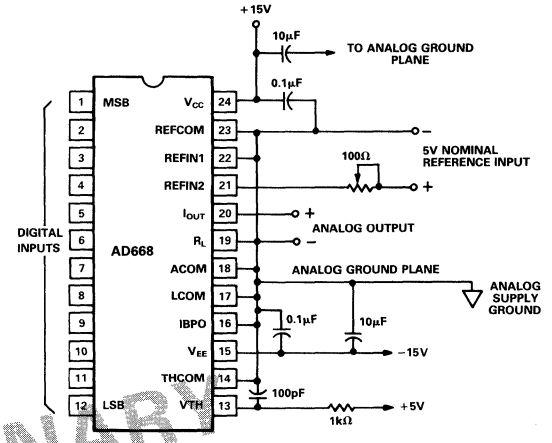


Figure 1. 5 V REFIN, 1 V Unipolar Unbuffered Voltage Output

5 V REFIN, 2 V BIPOLAR, UNBUFFERED VOLTAGE OUTPUT

Figure 2 demonstrates how a larger unbuffered voltage output swing can be realized. R_{LOAD} (Pin 19) is tied to the DAC output (Pin 20) to produce an output resistance of roughly 200 Ω. It should be noted that this impedance is not trimmed, and may vary by as much as 20%, but this can be compensated by adjusting the reference voltage. It is also important to note that limitations in the DAC output compliance would prohibit use of a 2 V unipolar output voltage swing.

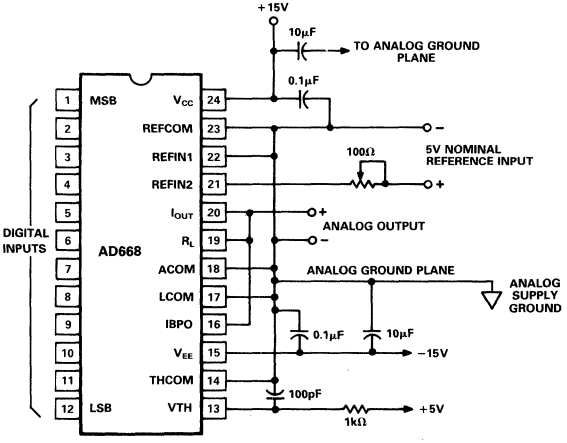

Figure 2. 5 V REFIN, −1 V to +1 V Unbuffered Bipolar Voltage Output

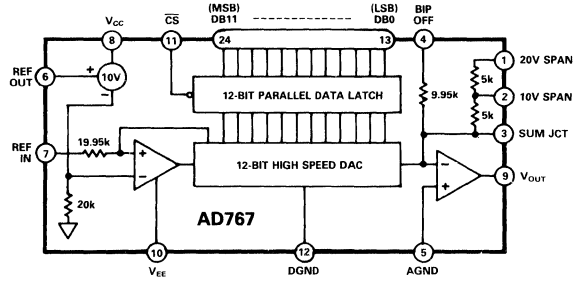
Microprocessor-Compatible 12-Bit D/A Converter

AD767*

FEATURES

- **Complete 12-Bit D/A Function**
  - **On-Chip Output Amplifier**
  - **High Stability Buried Zener Reference**
- **Fast 40ns Write Pulse**
- **0.3" Skinny DIP and PLCC Packages**
- **Single Chip Construction**
- **Monotonicity Guaranteed Over Temperature**
- **Settling Time: 3μs max to 1/2LSB**
- **Guaranteed for Operation with ±12V or ±15V Supplies**
- **TTL/5V CMOS Compatible Logic Inputs**

AD767 FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD767 is a complete voltage output 12-bit digital-to-analog converter including a high stability buried Zener reference and input latch on a single chip. The converter uses 12 precision high-speed bipolar current steering switches and a laser-trimmed thin-film resistor network to provide high accuracy.

Microprocessor compatibility is achieved by the on-chip latch. The design of the input latch allows direct interface to 12-bit buses. The latch responds to strobe pulses as short as 40ns, allowing use with the fastest available microprocessors.

The functional completeness and high performance of the AD767 result from a combination of advanced switch design, high-speed bipolar manufacturing process, and the proven laser wafer-trimming (LWT) technology.

The subsurface (buried) Zener diode on the chip provides a low-noise voltage reference which has long-term stability and temperature drift characteristics comparable to the best discrete reference diodes. The laser trimming process which provides the excellent linearity is also used to trim the absolute value of the reference as well as its temperature coefficient. The AD767 is thus well suited for wide temperature range performance with ± 1/2LSB maximum linearity error and guaranteed monotonicity over the full temperature range. Typical full-scale gain T.C. is 5ppm/°C.

PRODUCT HIGHLIGHTS

1. The AD767 is a complete voltage output DAC with voltage reference and digital latches on a single IC chip.
2. The input latch responds to write pulse widths as short as 40ns assuring direct interface with the industry's fastest microprocessors.
3. The internal buried Zener reference is laser-trimmed to 10.00 volts with a ± 1% maximum error. The reference voltage is also available for external application.
4. The gain setting and bipolar offset resistors are matched to the internal ladder network to guarantee a low gain temperature coefficient and are laser trimmed for minimum full-scale and bipolar offset errors.
5. The precision high-speed current steering switches and on-board high-speed output amplifier settle within 1/2LSB for a 10V full-scale transition in 3.0μs when properly compensated.

NOTES

[1]AD767 "S" specifications shown for information only. Consult Analog Devices Military Databook or contact factory for a controlled specification sheet.

[2]AD767A Chips specifications are tested at +25°C and, when in boldface, at +85°C. They are typical at −25°C.

[3]The digital input specifications are 100% tested at +25°C, and guaranteed but not tested over the full temperature range.

[4]Adjustable to zero.

[5]FSR means "Full-Scale Range" and is 20V for ±10V range and 10V for the ±5V range.

[6]A minimum power supply of ±12.5V is required for a ±10V full-scale output and ±11.4V is required for all other voltage ranges.

Specifications subject to change without notice.

Specifications shown in boldface are tested on all production units at final electrical test (except per Notes 1 and 2). Results from those tests are used to calculate outgoing quality levels. All min and max specifications are guaranteed, although only those shown in boldface are tested on all production units.

Analog Circuit Details

THE AD767 OFFERS TRUE 12-BIT PERFORMANCE OVER THE FULL TEMPERATURE RANGE

LINEARITY ERROR: Analog Devices defines linearity error as the maximum deviation of the actual, adjusted DAC output from the ideal analog output (a straight line drawn from 0 to F.S. – 1LSB) for any bit combination. This is also referred to as relative accuracy. The AD767 is laser trimmed to typically maintain linearity errors at less than ±1/8LSB for the K and B versions and ±1/2LSB for the J, A and S versions. Linearity over temperature is also held to ±1/2LSB (K/B) or ±1LSB (J/A/S).

MONOTONICITY: A DAC is said to be monotonic if the output either increases or remains constant for increasing digital inputs such that the output will always be a nondecreasing function of input. All versions of the AD767 are monotonic over their full operating temperature range.

DIFFERENTIAL NONLINEARITY: Monotonic behavior requires that the differential linearity error be less than 1LSB both at +25°C as well as over the temperature range of interest. Differential nonlinearity is the measure of the variation in analog value, normalized to full scale, associated with a 1LSB change in digital input code. For example, for a 10 volt full-scale output, a change of 1LSB in digital input code should result in a 2.44mV change in the analog output (1LSB = 10V × 1/4096 = 2.44mV). If in actual use, however, a 1LSB change in the input code results in a change of only 0.61mV (1/4LSB) in analog output, the differential nonlinearity error would be −1.83mV, or −3/4LSB.

GAIN ERROR: DAC gain error is a measure of the difference between an ideal DAC and the actual device's output span. All grades of the AD767 have a maximum gain error of 0.2% FS. However, if this is not sufficient, the error can easily be adjusted to zero (see Figures 2 and 3).

UNIPOLAR OFFSET ERROR: Unipolar offset error is a combination of the offset errors of the voltage-mode DAC and the output amplifier and is measured when the AD767 is configured for unipolar outputs. It is present for all codes and is measured with all "0s" in the DAC latches. This is easily adjustable to zero when required.

BIPOLAR ZERO ERROR: Bipolar zero errors result from errors produced by the DAC and output amplifier when the AD767 is configured for bipolar output. Again, as with unipolar offset and gain errors, this is easily adjusted to zero when required.

ANALOG CIRCUIT CONNECTIONS

Internal scaling resistors provided in the AD767 may be connected to produce bipolar output voltage ranges of ±10, ±5 or ±2.5V or unipolar output voltage ranges of 0 to +5V or 0 to +10V.

Gain and offset drift are minimized in the AD767 because of the thermal tracking of the scaling resistors with other device components. Connections for various output voltage ranges are shown in Table I.

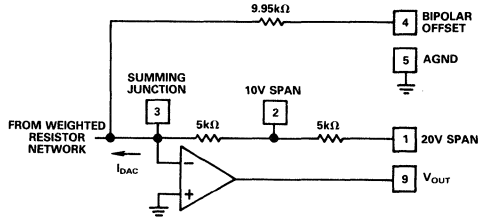

Figure 1. Output Amplifier Voltage Range Scaling Circuit

UNIPOLAR CONFIGURATION (Figure 2)

This configuration will provide a unipolar 0 to +10 volt output range. In this mode, the bipolar offset terminal, Pin 4, should be grounded if not used for trimming.

STEP I . . . ZERO ADJUST

Turn all bits OFF and adjust zero trimmer R1, until the output reads 0.000 volts (1LSB = 2.44mV). In most cases this trim is not needed, and Pin 4 should be connected to Pin 5.

STEP II . . . GAIN ADJUST

Turn all bits ON and adjust 100Ω gain trimmer R2 until the output is 9.9976 volts. (Full scale is adjusted to 1LSB less than nominal full scale of 10.000 volts.)

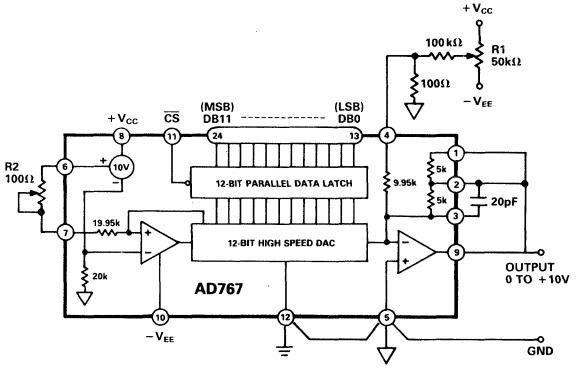

Figure 2. 0 to +10V Unipolar Voltage Output

Output Range	Digital Input Codes	Connect Pin 9 to	Connect Pin 1 to	Connect Pin 2 to	Connect Pin 4 to
±10V	Offset Binary	1	9	NC	6 (through 50Ω fixed or 100Ωtrim resistor)
±5V	Offset Binary	1 and 2	2 and 9	1 and 9	6 (through 50Ω fixed or 100Ωtrim resistor)
±2.5V	Offset Binary	2	3	9	6 (through 50Ω fixed or 100Ωtrim resistor)
0 to +10V	Straight Binary	1 and 2	2 and 9	1 and 9	5 (or optional trim – See Figure 2)
0 to +5V	Straight Binary	2	3	9	5 (or optional trim – See Figure 2)

Table I. Output Voltage Range Connections

BIPOLAR CONFIGURATION (Figure 3)

This configuration will provide a bipolar output voltage from −5.000 to +4.9976 volts, with positive full scale occurring with all bits ON (all 1s).

STEP I . . . OFFSET ADJUST

Turn OFF all bits. Adjust 100Ω trimmer R1 to give −5.000 volts output.

STEP II . . . GAIN ADJUST

Turn ON all bits. Adjust 100Ω gain trimmer R2 to give a reading of +4.9976 volts.

STEP III . . . BIPOLAR ZERO ADJUST (Optional)

In applications where an accurate zero output is required, set the MSB ON, all other bits OFF, and readjust R1 for zero volts output.

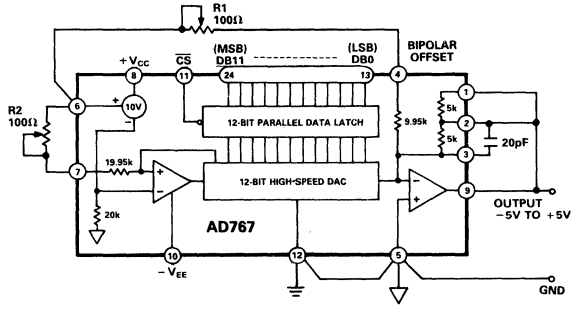

Figure 3. ±5V Bipolar Voltage Output

INTERNAL/EXTERNAL REFERENCE USE

The AD767 has an internal low-noise buried Zener diode reference which is trimmed for absolute accuracy and temperature coefficient. This reference is buffered and optimized for use in a high-speed DAC and will give long-term stability equal or superior to the best discrete Zener reference diodes. The performance of the AD767 is specified with the internal reference driving the DAC since all trimming and testing (especially for full-scale error and bipolar offset) is done in this configuration.

The internal reference has sufficient buffering to drive external circuitry in addition to the reference currents required for the DAC (typically 0.5mA to Ref In and 1.0mA to Bipolar Offset). A minimum of 0.1mA is available for driving external loads.

The AD767 reference output should be buffered with an external op amp if it is required to supply more than 0.1mA output current. The reference is typically trimmed to ±0.2%, then tested and guaranteed to ±1.0% max error. The temperature coefficient is comparable to that of the full-scale TC for a particular grade.

If an external reference is used (10.000V, for example), additional trim range must be provided, since the internal reference has a tolerance of ±1%, and the AD767 full-scale and bipolar offset are both trimmed with the internal reference. The gain and offset trim resistors give about ±0.25% adjustment range, which is sufficient for the AD767 when used with the internal reference.

It is also possible to use external references other than 10 volts. The recommended range of reference voltage is from +8 to +10.5 volts, which allows both 8.192V and 10.24V ranges to be used. The AD767 is optimized for fixed-reference applications. If the reference voltage is expected to vary over a wide range in a particular application, a CMOS multiplying DAC is a better choice.

Reduced values of reference voltage will also permit the ±12 volt ±5% power supply requirement to be relaxed to ±12 volts ±10%.

It is not recommended that the AD767 be used with external feedback resistors to modify the scale factor. The internal resistors are trimmed to ratio-match and temperature-track the other resistors on the chip, even though their absolute tolerances are ±20%, and absolute temperature coefficients are approximately −50ppm/°C. If external resistors are used, a wide trim range (±20%) will be needed and temperature drift will be increased to reflect the mismatch between the temperature coefficients of the internal and external resistors.

Small resistors may be added to the feedback resistors in order to accomplish small modifications in the scaling. For example, if a 10.24V full scale is desired, a 140Ω 1% low-TC metal-film resistor can be added in series with the internal (nominal) 5k feedback resistor, and the gain trim potentiometer (between Pins 6 and 7) should be increased to 200Ω. In the bipolar mode, increase the value of the bipolar offset trim potentiometer also to 200Ω.

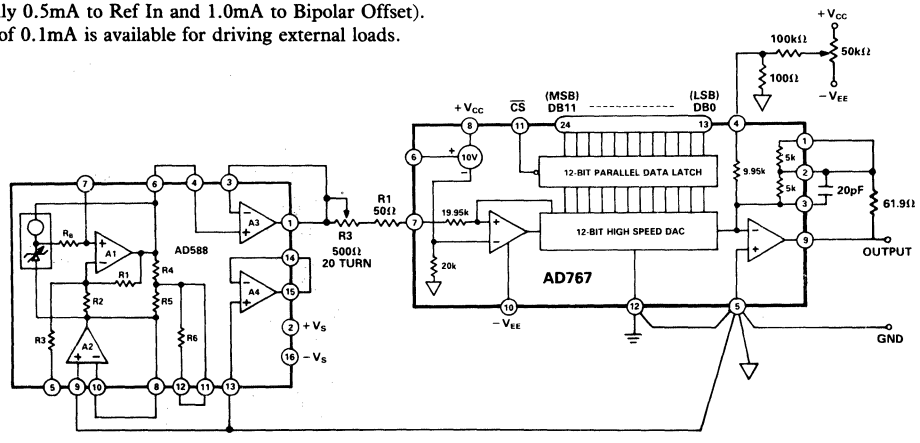

Figure 4. Using the AD767 with the AD588 High Precision Reference

USING THE AD767 WITH THE AD588 HIGH PRECISION VOLTAGE REFERENCE

The AD767 is specified for gain drift from 15ppm/°C to 30ppm/°C (depending on grade) using its internal 10 volt reference. Since the internal reference contributes the majority of this drift, an external high-precision voltage reference will greatly improve performance over temperature. As shown in Figure 4, the 10 volt output from the AD588 is used as the reference. With a 1.5ppm/°C output voltage drift the AD588 contributes less than 1/2LSB gain drift when used with the AD767 over the industrial temperature range. Using this combination may result in apparent increases in full-scale error due to the differences between the internal reference by which the device is laser trimmed and the external reference with which the device is actually applied. The AD767 internal reference is specified to be 10 volts ±100mV whereas the AD588 is specified as 10 volts ±1mV. This may result in up to 101mV of apparent full-scale error beyond the ±25mV specified AD767 gain error. The 500Ω potentiometer in series with the reference input allows adequate trim range to null this error.

GROUNDING RULES

The AD767 brings out separate analog and power grounds to allow optimum connections for low noise and high-speed performance. These grounds should be tied together at one point, usually the device power ground. The separate ground returns are provided to minimize current flow in low-level signal paths.

The analog ground at Pin 5 is the ground point for the output amplifier and is thus the "high quality" ground for the AD767; it should be connected directly to the analog reference point of the system. The power ground at Pin 12 can be connected to the most convenient ground point; analog power return is preferred. If power ground contains high frequency noise beyond 200mV, this noise may feed through the converter, thus some caution will be required in applying these grounds.

It is also important to apply decoupling capacitors properly on the power supplies for the AD767. The correct method for decoupling is to connect a capacitor from each power supply pin of the AD767 to the analog ground pin of the AD767. Any load driven by the output amplifier should also be referred to the analog ground pin.

OPTIMIZING SETTLING TIME

The dynamic performance of the AD767's output amplifier can be optimized by adding a small (20pF) capacitor across the feedback resistor. Figure 5 shows the improvement in both large-signal and small-signal settling for the 10V range. In Figure 5a, the top trace shows the data inputs (DB11–DB0 tied together), the second trace shows the CS pulse, and the lower two traces show the analog outputs for C_F = 0 and 20pF respectively.

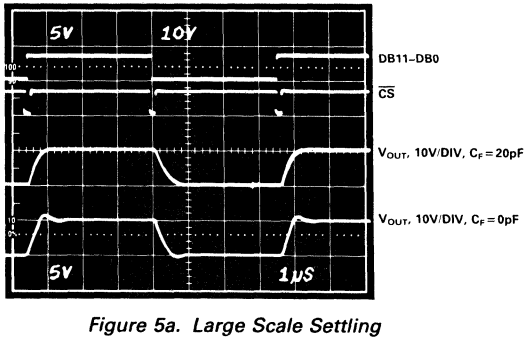

Figure 5a. Large Scale Settling

Figures 5b and 5c show the settling time for the transition from all bits on to all bits off. Note that the settling time to ±1/2LSB for the 10V step is improved from 2.4 microseconds to 1.6 microseconds by the addition of the 20pF capacitor.

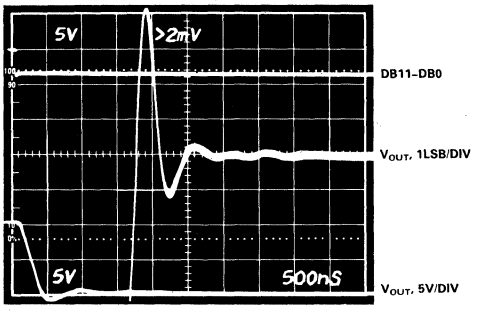

Figure 5b. Fine-Scale Settling, C_F = 0pF

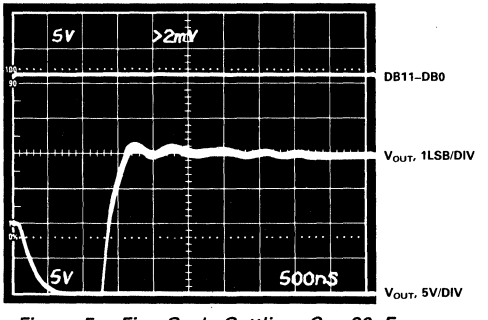

Figure 5c. Fine-Scale Settling, C_F = 20pF

Figures 5d and 5e show the settling time for the transition from all bits off to all bits on. The improvement in settling time gained by adding C_C = 20pF is similar.

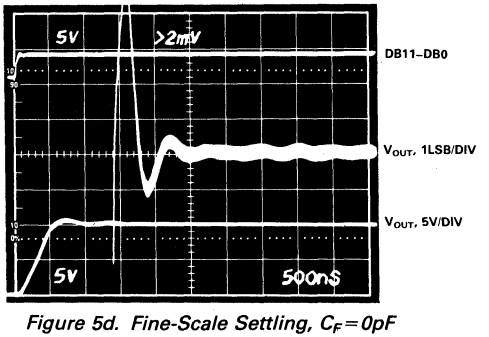

Figure 5d. Fine-Scale Settling, C_F = 0pF

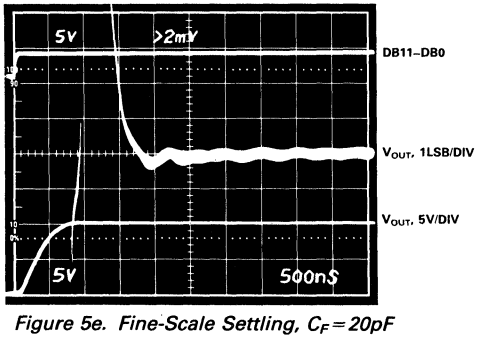

Figure 5e. Fine-Scale Settling, C_F = 20pF

DIGITAL INPUT CONSIDERATIONS

The threshold of the digital input circuitry is set at 1.4 volts and does not change with supply voltage. Thus the AD767 digital interface may be driven with any of the popular types of 5 volt logic.

A good engineering practice is to connect unused inputs to power ground to improve noise immunity. Unconnected data and control inputs will float to logic 0 if left open.

The low digital input current of the AD767 eliminates the need for buffer/drivers required by many monolithic converters using bipolar technology. A single low-power Schottky gate, for example, will drive several AD767s when connected to a common bus.

INPUT CODING

The AD767 uses positive-true binary input coding. Logic "1" is represented by an input voltage greater than 2.0V, and logic "0" is defined as an input voltage less than 0.8V.

Unipolar coding is straight binary, where all zeroes (000_H) on the data inputs yields a zero analog output and all ones (FFF_H) yields an analog output 1LSB below full scale.

Bipolar coding is offset binary, where an input code of 000_H yields a minus full-scale output, an input of FFF_H yields an output 1LSB below positive full scale, and zero occurs for an input code with only the MSB on (800_H).

The AD767 can be used with twos complement input coding if an inverter is used on the MSB (DB11).

MICROPROCESSOR INTERFACE

The AD767, with its 40ns minimum $\overline{CS}$ pulse width, may be easily interfaced to any of today's high-speed microprocessors. The 12-bit single buffered input register will accept 12-bit parallel data from processors such as the 68000, 8086, TMS320 series, and the Analog Devices ADSP-2100. Several illustrative examples follow.

68000 – AD767 INTERFACE

Figure 6 illustrates the AD767 interface to a 68000 microprocessor. An active low decoded address is OR'ed with the processor's R/$\overline{W}$ signal to provide $\overline{CS}$ and latch data into the AD767. Later in the bus cycle the processor issues the upper ($\overline{UDS}$) and lower ($\overline{LDS}$) data strobes which are gated with the decoded address to provide $\overline{DTACK}$ and terminate the bus cycle. As shown, this interface will support a 12.5MHz 68000 system.

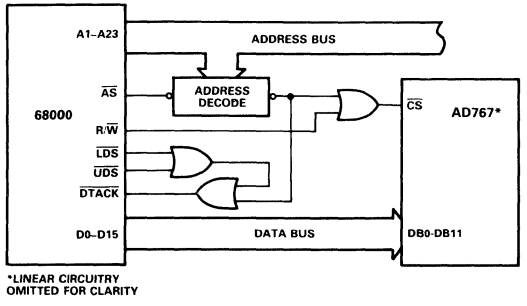

Figure 6. 68000 – AD767 Interface

8086 – AD767 INTERFACE

Interfacing the AD767 to the 8086 16-bit microprocessor requires a minimal amount of external components. A 10MHz 8086, for example, generates a 165ns low write pulse which may be gated with a decoded address to provide $\overline{CS}$ for the AD767. As $\overline{WR}$ returns high valid data is latched into the DAC. See Figure 7.

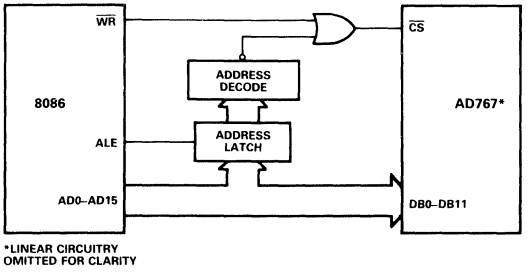

Figure 7. 8086 – AD767 Interface

TMS32010 – AD767 INTERFACE

The high-speed digital interface of the AD767 facilitates its use with the TMS32010 microprocessor at speeds up to 20MHz. In the three multiplexed LSBs of the address bus, PA2 – PA0 are decoded as a port address and OR'ed with the low write enable to generate $\overline{CS}$ for the DAC. A simple OUT xx,y instruction will output the data word stored in memory location xx to any one of eight port locations y.

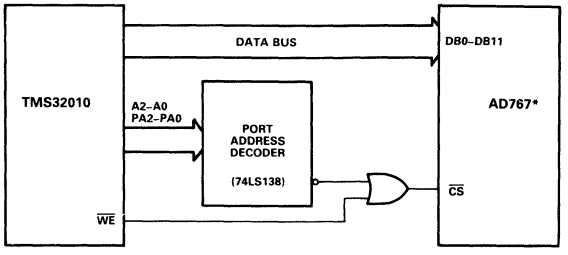

Figure 8. TMS32010 – AD767 Interface

TMS32020 – AD767 INTERFACE

Interfacing the AD767 to the TMS32020 microprocessor is easily achieved by using the TMS32020 I/O port capability. The $\overline{IS}$ signal distinguishes the I/O address space from the local program/data memory space and is used to enable a 74LS138 decoder. The decoded port address is then gated with the R/$\overline{W}$ and $\overline{STRB}$ signals to provide the AD767 $\overline{CS}$.

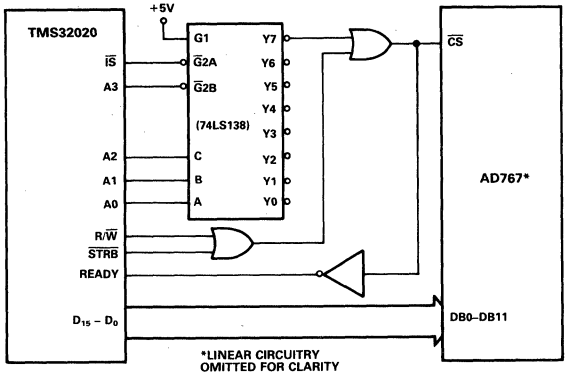

Figure 9. TMS32020 – AD767 Interface

ADSP-2100 – AD767 INTERFACE

The ADSP-2100 single chip DSP processor may be interfaced to the AD767 as shown in Figure 10. With a clock frequency of 32MHz, and instruction execution in a single 125ns cycle, the processor will support the AD767 interface with a single wait state.

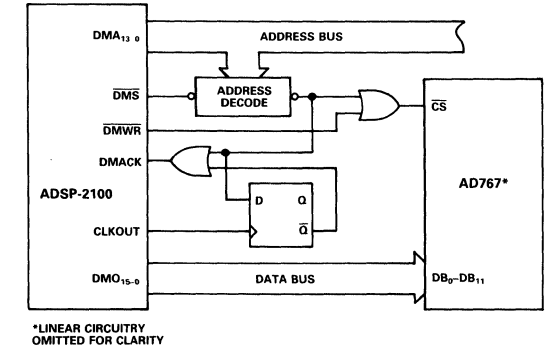

Figure 10. ADSP-2100 – AD767 Interface

At the beginning of the data memory access cycle the processor provides a 14-bit address on the DMA bus. The $\overline{DMS}$ signal is then asserted enabling a LOW address decode. Valid data is now placed on the data bus and $\overline{DMWR}$ is issued. $\overline{DMWR}$ is OR'ed with the LOW address decode to generate the AD767 $\overline{CS}$.

The LOW decoded address is also gated with the $\overline{Q}$ output of a D flip-flop to hold DMACK (Data Memory Acknowledge) LOW. This forces the processor into a wait state and extends the AD767 $\overline{CS}$ by 1 clock cycle. The rising edge of CLKOUT latches $\overline{Q}$ HIGH bringing DMACK HIGH. The cycle is now complete.

TMS320C25 – AD767 INTERFACE

Figure 11 illustrates the AD767 interface to a TMS320C25 digital signal processor. Due to the high-speed capability of the processor (40MHz), a single wait state is required and is easily generated using MSC. A 20MHz TMS320C25 however, does not require wait states and should be interfaced using the circuit shown in Figure 9.

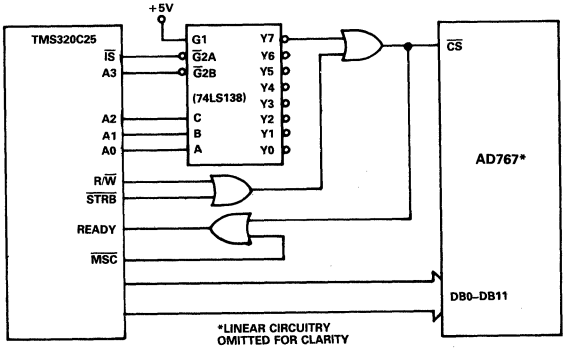

Figure 11. TMS320C25 – AD767 Interface

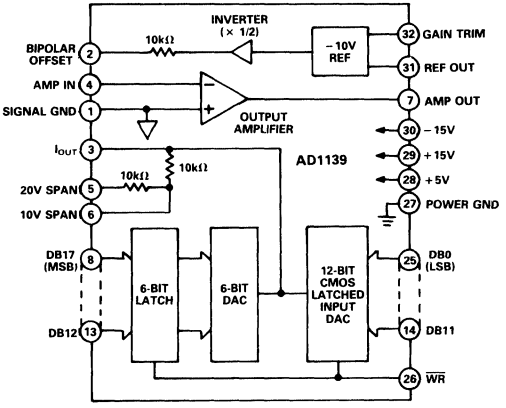
High Accuracy, 18-Bit Digital-to-Analog Converter

AD1139

FEATURES
- **18-Bit Resolution**
- **Low Nonlinearity**
  - **Differential: ±1/2LSB max**
  - **Integral: ±1/2LSB max**
- **High Stability**
  - **Differential TC: ±1ppm/°C max**
  - **Integral TC: ±1/2ppm/°C max**
  - **Gain TC (with Reference): ±4ppm/°C max**
- **Fast Settling**
  - **Full Scale: 40μs to ±0.00019%**
  - **LSB: 6μs to ±0.00019%**
- **Small Hermetic 32-Lead Triple DIP Package**
- **Low Cost**

APPLICATIONS
- **Automatic Test Equipment**
- **Scientific Instrumentation**
- **Beam Positioners**
- **Digital Audio**

AD1139 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD1139 is the first DAC offering 18-bit resolution (1 part in 262,144) and true 18-bit accuracy in a component size hybrid package. A proprietary bit switching technique provides high accuracy, speed and stability without compromising small size or low cost.

The AD1139 is a complete DAC with precision internal reference, latched data inputs and a quality output voltage amplifier. The analog output voltage ranges are pin programmable to +5V, +10V, ±5V and ±10V. Current output is also provided for use with external amplifiers. The internal precision −10V reference has a low ±3ppm/°C maximum temperature coefficient and is available for ratiometric applications.

The AD1139K is a true 18-bit accurate DAC with ±1/2LSB maximum differential and integral nonlinearity. The differential and integral nonlinearity temperature stability is guaranteed at ±1ppm/°C maximum and ±1/2ppm/°C maximum, respectively.

The AD1139 settles to within ±1/2LSB at 18 bits (±0.00019%) in 40μs for a full-scale step (10V). The glitch energy is a low 400mV × 500ns for a major carry, and wideband output noise is only 15μV.

The AD1139 operates from ±15V dc and +5V dc power supplies. Digital inputs are 5V CMOS compatible with binary input coding for unipolar output ranges and offset binary coding for bipolar ranges.

PRODUCT HIGHLIGHTS

1. Eighteen-bit resolution with ±1/2LSB maximum differential and integral nonlinearity in a hermetic 32-lead triple DIP package.
2. Complete DAC with internal reference, stable low-noise output amplifier, latched DAC inputs, reference output and internal application resistors for programmable output voltage ranges.
3. Temperature compensated internal precision reference with ±0.1% maximum initial accuracy and ±3ppm/°C maximum tempco.
4. Four pin programmable output voltage ranges (+5V, +10V, ±5V, ±10V) and current output available (−1mA, ±0.5mA).
5. The 18-bit parallel input latch assists in microprocessor interface.
6. Accurate measurements of the DAC's output are unusually simple since the AD1139 does *not* suffer from code dependent ground current errors.
7. True analog output remote sense capability.

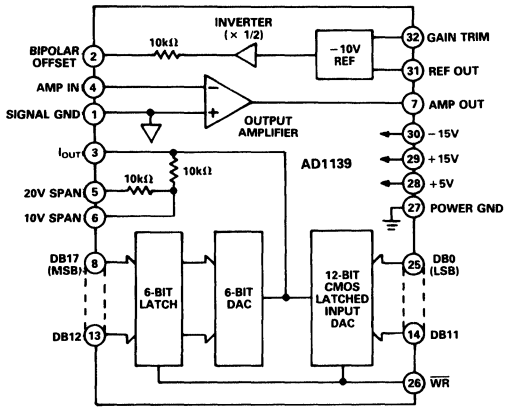
NOTES
*Specifications same as AD1139J.
[1]Initial Errors are adjustable to zero via external potentiometers (see Figure 1).
[2]FSR means Full-Scale Range.
[3]Temperature stability of linearity is guaranteed to a 1% AQL, Level II sampling plan per MIL-STD-105.
[4]See Figure 7 for typical long-term linearity stability vs. temperature. Also, see the BURN-IN section on page 6 for caution against preconditioning by the user.
[5]Figure 9 provides typical LSB and full-scale settling time to within 1/2LSB at 12- to 18-bit resolutions.
[6]Current Output Operation is structured for input to the summing junction of an amplifier.
Specifications subject to change without notice.



AD1139 Functional Block Diagram

ANALOG OUTPUT RANGE

The AD1139 is pin programmable to provide a variety of analog outputs, either current or voltage. A unipolar output current of 0 to −1mA is available at Pin 3 and can be offset by 0.5mA (connect Pin 2 to Pin 3) for a biolar output of ±0.5mA. Output voltage ranges (+5V, +10V, ±5V and ±10V) are available at Pin 7 by connecting the current output (Pin 3) to the amplifier input (Pin 4) and the appropriate internal feedback resistors to the amplifier output (Pin 7) as shown in Figure 1.

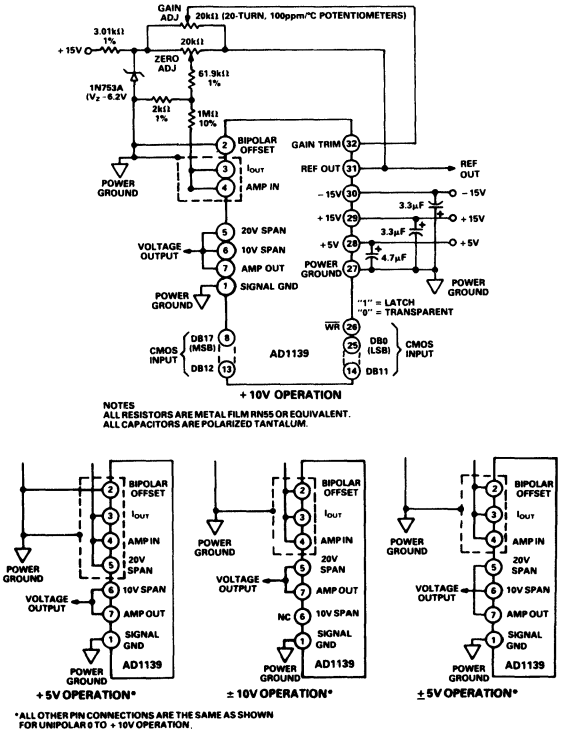


Figure 1. Output Voltage and Trim Configuration

OFFSET & GAIN CALIBRATION

Initial offset and gain errors can be adjusted to zero by potentiometers as shown in Figure 1. The offset adjust range is *plus 0.03% to minus 0.02% of full scale range* (wiper of potentiometer to REF OUT equals plus 0.03%). The gain adjust range is *plus 0.06% to minus 0.08% of full scale range* (wiper to REF OUT equals plus 0.06%). Measurement instruments used should be capable of resolving 1μV at plus full scale for the chosen output range and within 1μV of zero.

Procedure:

UNIPOLAR MODE

1. Apply a digital input of all "0s."
2. Adjust the offset potentiometer until a 0.000000V output is obtained.
3. Apply a digital input of all "1s."
4. Adjust the gain potentiometer until plus full-scale output is obtained (see Table I for exact value).

BIPOLAR MODE

1. Apply a digital input of 100 . . . . . 000.
2. Adjust the offset potentiometer until a 0.000000V output is obtained.
3. Apply a digital input of all "1s."
4. Adjust the gain potentiometer until plus full-scale output is obtained (see Table I for exact value).

	Code 000 00	Code 111 . . . 11	
Unipolar +5V	0.000000V	+4.999981V	
+10V	0.000000V	+9.999962V	
	Code 100 00	**Code 111 . . . .11**	**Code 000 . . . .00**
Bipolar ±5V	0.000000V	+4.999962V	− 5.000000V
±10V	0.000000V	+9.999924V	−10.000000V

Table I. Full-Scale and Offset Calibration Voltages

Symbol	Parameter	Requirement
t_{DS}	Data Setup Time	160ns min
t_{DH}	Data Hold Time	120ns min
t_{WR}	Write Pulse Width	200ns min

Table II. Timing Requirements

TIMING DIAGRAM & LATCH CONTROL

Timing requirements for the AD1139 are shown in Table II. The timing diagram is shown in Figure 2. The WRite line controls an 18-bit wide data input latch. This latch is transparent when the WRite line is LOW, allowing all bits to be accessed directly. When the WRite line is activated HIGH, the data present at the inputs is held in the latch and the appropriate analog voltage is seen at the output.

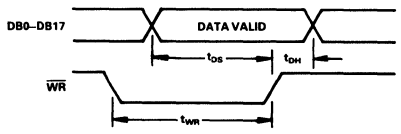

Figure 2. AD1139 Timing Diagram

GROUNDING & GUARDING

The current from measurement ground (Pin 1) is small and independent of the digital input code to the DAC. This greatly simplifies making error free analog measurements. Connect this high quality ground to the system's or application's high quality ground. Connect the DAC's power ground (Pin 27) to the system return, also connect the system's high quality ground to the system return. *It is most important that the measurement ground (Pin 1) and power ground (Pin 27) be connected externally for proper circuit operation.*

The current output pin (I_{OUT}, Pin 3) is sensitive to external noise sources, such as digital input lines. This pin and any components connected to this pin should be surrounded by a grounded guard as shown in Figure 3.

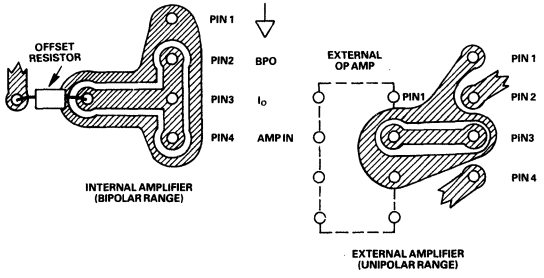

Figure 3. Guarding Recommendations

REMOTE SENSE APPLICATION

The AD1139's remote sense capability allows driving heavy loads or long cables without the usual, accompanying gain errors. By sensing at the load, as described in Figure 4, the load current will pass through the amplifier's output and the power ground, but not through the sense lines. The potential gain errors that would be induced by this load current are therefore minimized. The load should not exceed ± 10mA or 2 nanofarads to insure proper operation of the AD1139's internal output amplifier.

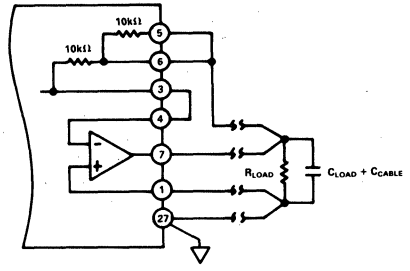

Figure 4. Remote Sensing

RATIOMETRIC DAC TESTING APPLICATION

The AD1139's highly stable reference output can be conveniently used in the testing of other high resolution DACs. Figure 5 describes how the REF OUT (Pin 31) is used as the external reference input to a device-under-test. The gain of the device-under-test will now accurately track the AD1139's gain and eliminate reference contribution to gain error.

When used as a reference DAC to test the integral and differential linearity of 14- and 16-bit DACs, the AD1139 provides a measurement capability with just 1/16LSB of uncertainty at 14 bits.

Gain and offset errors of the device-under-test (D.U.T.) may be accounted for in software. Once zeroed, the integral linearity error can be measured as the difference between the reference DAC (AD1139) and the D.U.T. as seen at the digital voltmeter.

The differential linearity error is then determined by incrementing or decrementing the D.U.T. digital input by 1LSB, and comparing the new output at the DVM with the previous output. The difference between these two measurements should be exactly one ideal LSB. The amount of disagreement from one ideal LSB is the differential linearity error.

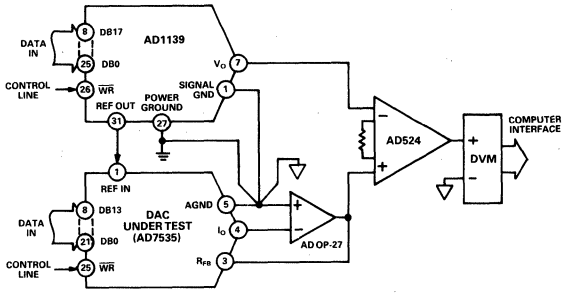

Figure 5. Ratiometric DAC Testing

IBM* PC INTERFACE

Figure 6 illustrates a typical IBM personal computer interface which uses three 8-bit external latches and two decoder chips. The three HCT374 latches are connected to the data bus (D0 through D7). The HCT138 decoder chip decodes the address bus and enables each latch, including the AD1139's internal DAC latch, to see the appropriate digital word. The HCT688 chip and the HCT138 decoder define the I/O address space where the four latches will reside. In the Figure 6 example, they reside in the address space as shown in Table III.

I/O Address	Selected Latch	Data Bits
380H	Low Byte	DB0–DB7
381H	Mid Byte	DB8–DB15
382H	High Byte	DB16, DB17
383H	AD1139 Latch	DB0–DB17

Table III. IBM Interface Address Locations

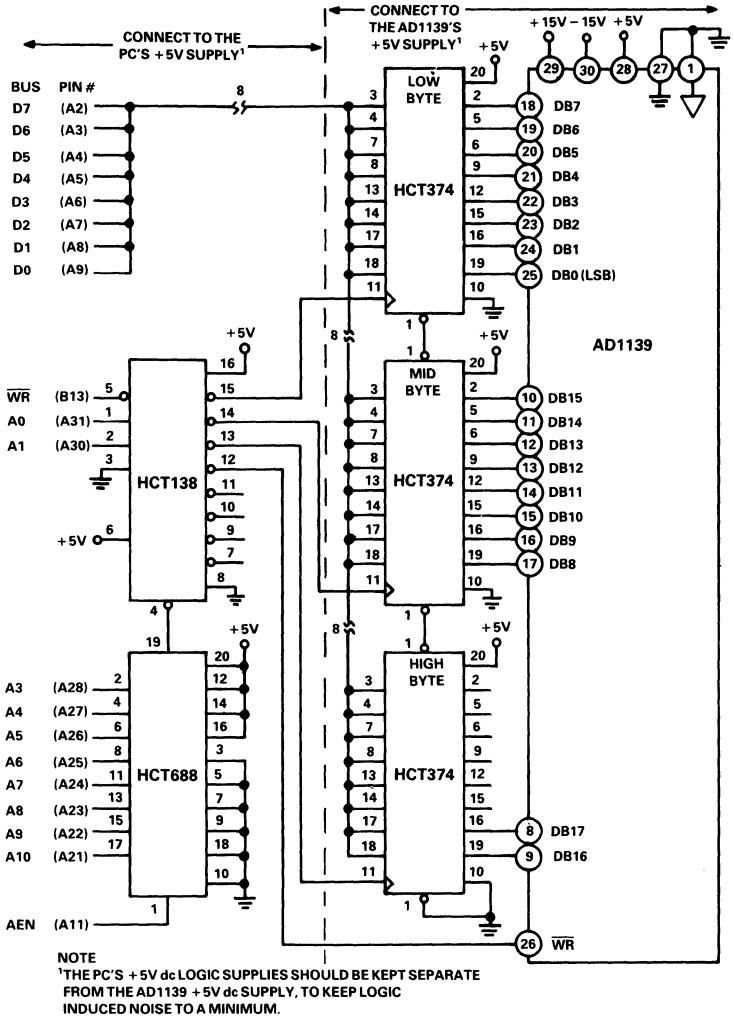

Figure 6. AD1139 to IBM PC Compatible Interface

LONG-TERM STABILITY VS. TEMPERATURE

Adjusting the linearity of any DAC after it is installed in the application is often difficult or impossible. It is preferable to maintain some specified accuracy over the useful working life of the product (commonly 5 to 10 years). Stable linearity performance over time can, therefore, be a very important parameter for the DAC.

Accelerated testing to determine the *expected linearity stability over time* can be accomplished by two different methods. Linearity is first measured at +25°C. The DAC is then operated at a fixed elevated temperature for an extended period of time. The DAC is then retested at +25°C, and the change in linearity error vs. time is calculated. The ARRHENIUS EQUATION (used in reliability calculations) can be used to determine what the acceleration factor is from +25°C to the elevated test temperature. Knowing the acceleration factor and the linearity error vs. time at the elevated temperature, one could calculate the expected long-term stability of linearity at nominal temperatures.

A second test method determines how long it will take for the linearity to shift by a specific error band (we chose ±2ppm for our example) at any specified temperature. The first step is to measure the linearity at a moderately elevated temperature (e.g., +85°C) and then monitor how long it takes at this temperature to reach the error band limit. The second step is to perform the same test at a much higher elevated temperature (e.g., +125°C). The two resulting time vs. temperature points are then plotted on semilog paper. A line drawn through the two points allows extrapolation to the length of time expected to reach the error band (±2ppm) at other temperatures, including +25°C.

Figure 7 shows how long it would take for the AD1139's linearity to drift ±2ppm (1/2LSB) at any operating temperature. The uppermost plot shows stability under storage conditions (no power), and the lower plot shows the AD1139's operating stability (under power). The *operating vs. storage* difference is due to the 10°C temperature rise when the AD1139 is powered.

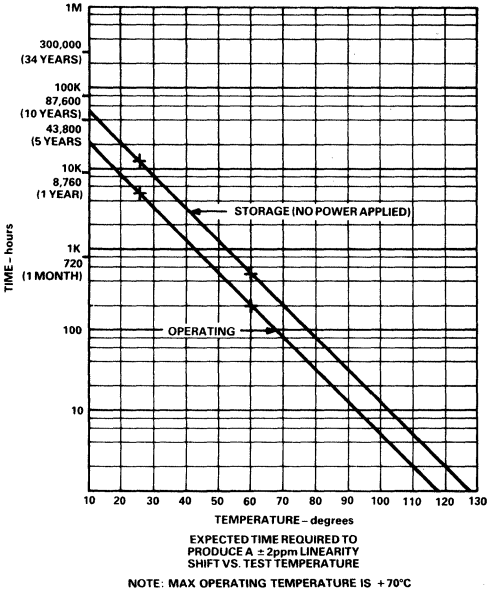

Figure 7. Nonlinearity vs. Time/Temperature

BURN-IN

All AD1139s undergo a 168 hour, powered burn-in @125°C, prior to laser trimming. This burn-in produces the optimum stability for the resistor network and eliminates infancy defects.

As shown in Figure 7, exposure to elevated temperatures produces an acceleration of the normal aging process. Preconditioning/burn-in employed by the user will lead to premature linearity shifts outside of the initial guaranteed specifications. The ADI warranty will not cover DACs that exhibit this type of *forced* premature specification degradation.

EXTERNAL AMPLIFIER FOR HIGH SPEED OR HIGH OUTPUT CURRENT

The AD1139's internal output amplifier is optimized for very low noise, dc stable applications with moderate settling time. Applications requiring higher speed or more output current can use an external amplifier, such as shown in Figure 8. The AD711 settles to within 16 bits in only 6μs for a unipolar full scale step. Other amplifiers may be chosen for differing tradeoffs. The noise gain seen by the output amplifier, depends on the output voltage range selected (see Table IV). The amplifier selected must be stable at the noise gain corresponding to the output range.

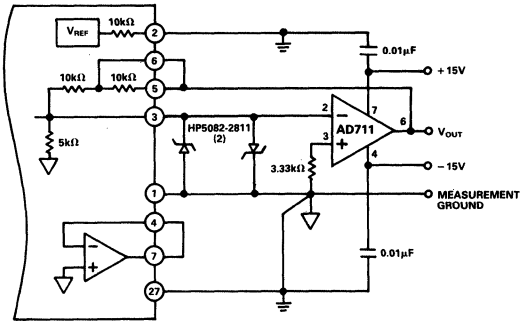

Figure 8. External Amplifier for High Speed

Output Voltage Range	Noise Gain
0 to +5V	2
0 to +10V	3
±5V	4
±10V	7

Table IV. Noise Gain vs. Output Voltage Range

SETTLING TIME

The LSB step and full-scale step typical settling times, to within ±1/2LSB at 18 bits, are shown in the Specification Table. Figure 9 graphically presents the typical settling times to within ±1/2LSB at resolutions from 12 to 18 bits.

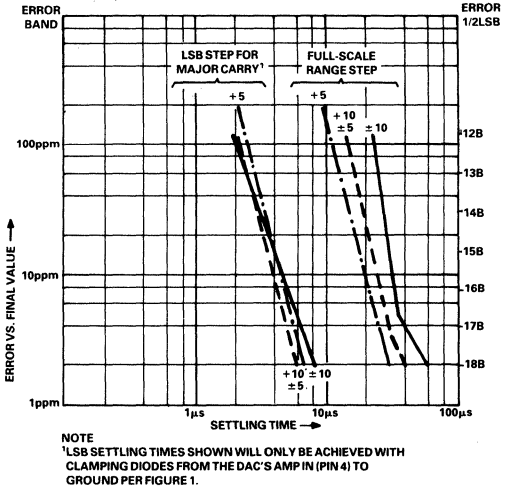

Figure 9. Settling Time vs. Resolution

ANALOG DEVICES

Low Cost 16-Bit Digital-to-Analog Converter

AD1145

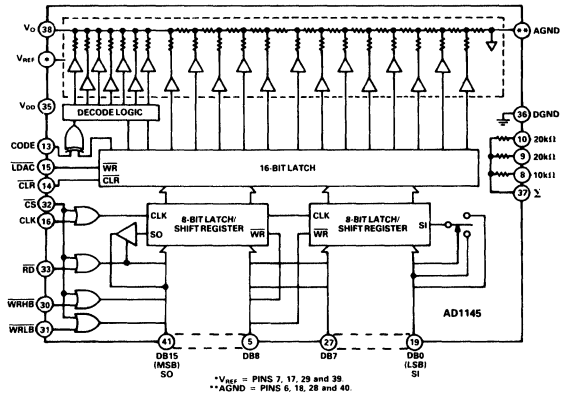
FEATURES

- 16-Bit Resolution
- Low Nonlinearity
  - Differential: ±3/4LSB max
  - Integral: ±1LSB max
- Relative Accuracy: ±0.003% max
- Fast Full-Scale Settling: 6μs to ±1/2LSB
- High Stability
  - Monotonic to 16 Bits: +15°C to +35°C
  - Offset TC: ±0.1ppm/°C max
  - Gain TC: ±0.1ppm/°C max
- Double Buffered Digital Input
- Parallel and Serial Data Input
- Single +5V Supply Operation
- Low Power Consumption: 2.5mW
- Small Size: 44-Pad Plastic LLCC
- Low Cost

APPLICATIONS

- Automatic Test Equipment
- Scientific Instrumentation
- Machine Control
- Digital Audio
- Robotics

AD1145 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD1145 is a double-buffered, 16-bit resolution DAC with ±3/4LSB maximum differential and ±1LSB maximum integral nonlinearity. Size comparable to the smallest monolithic DACs and high reliability are owed to its proprietary two-chip construction. A custom CMOS integrated circuit and laser-trimmed, thin-film resistor network provide 16-bit accuracy, excellent temperature stability and low power consumption.

The AD1145 offers an unparalleled combination of low cost, high accuracy, small size and convenient design-in features. The AD1145 directly interfaces with 8- and 16-bit microprocessors or can be used in stand-alone applications. Digital input coding is binary for unipolar output and offset binary or twos complement for bipolar output. Data can be written to the DAC in either a parallel or a serial mode. Serial data readback is available for error checking.

A clear line allows resetting the DAC output to zero volts on command. Power-up automatically resets the DAC output to zero volts following a power failure as required in machine control applications. All outputs may be simultaneously updated in a multiple DAC system.

Internal application resistors allow a wide variety of pin programmable output voltage ranges (+5V, +10V, −5V, −10V, ±5V and ±10V). The AD1145 may be operated off of a single +5V reference/supply, consuming only 2.5mW of power.

A 5 volt full-scale output step settles to within ±1/2LSB in just 6 microseconds. Wideband noise (100kHz) is only 50 microvolts peak-to-peak.

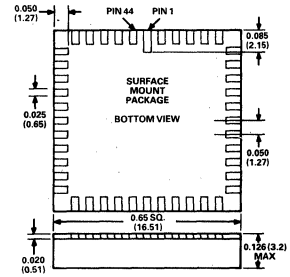
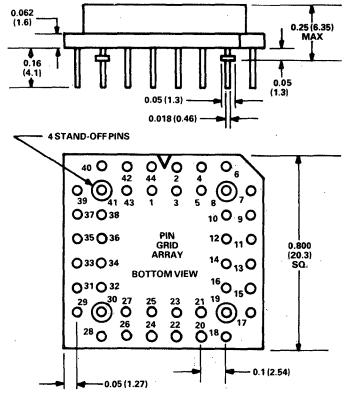
PLASTIC LEADLESS CHIP CARRIER*



44-PIN GRID ARRAY*



*PACKAGE NOTES:
A post assembly *water wash* cycle may trap water between the surface mount device and P.C. board. A drying period should be observed before operation (e.g., 65°C bake for 1 hour).
See Table VI for recommended sockets.

AD1145 PIN DESIGNATIONS

PIN	MNEMONIC	DESCRIPTION
1, 11, 12, 23, 34	NC	No Connection
2	DB11	Data Bit 11
3	DB10	Data Bit 10
4	DB9	Data Bit 9
5	DB8	Data Bit 8
6, 18, 28, 40	AGND	Analog Ground
7, 17, 29, 39	V_{REF}	Voltage Reference Input
8	10K	10kΩ Application Resistor
9, 10	20K	20kΩ Application Resistors
13	CODE	Selects Digital Input Code
14	$\overline{CLR}$	Clear, Active Low, Asynchronous
15	LDAC	Load DAC Register, Active Low Asynchronous
16	CLK	Clock, Rising Edge Triggered
19	DB0/SI	Data Bit 0 (LSB), Serial Input
20	DB1	Data Bit 1
21	DB2	Data Bit 2
22	DB3	Data Bit 3
24	DB4	Data Bit 4
25	DB5	Data Bit 5
26	DB6	Data Bit 6
27	DB7	Data Bit 7
30	$\overline{WRHB}$	Write High Byte, Active Low
31	$\overline{WRLB}$	Write Low Byte, Active Low
32	$\overline{CS}$	Chip Select, Active Low
33	$\overline{RD}$	Readback, Active Low
35	V_{DD}	Digital Power Supply
36	DGND	Digital Ground
37	Σ	Application Resistor Common
38	V_O	DAC Voltage Output
41	DB15/SO	Data Bit 15 (MSB), Serial Output
42	DB14	Data Bit 14
43	DB13	Data Bit 13
44	DB12	Data Bit 12

OUTPUT AMPLIFIER AND REFERENCE

The users choice of output amplifier and reference to complement the AD1145 will have a direct effect on the overall accuracy, speed and precision of the complete DAC circuit. The AD1145 can be optimized accordingly for a wide range of applications. Internal application resistors are provided to obtain output voltage ranges of 0 to 5V, 0 to 10V, 0 to −5V, 0 to −10V, ±5V, and ±10V. External resistors can be used for custom output voltage ranges as shown in Figure 2.

The AD1145's high impedance (5kΩ) voltage output must be buffered to drive a load since resistive loading at the output introduces a gain error (e.g., 50MΩ load resistance introduces a 0.01% gain error). Op amp bias current flows through the DAC output impedance to introduce an offset term (e.g., 100 nanoamps bias current introduces a 0.01% offset error).

In the noninverting mode the inputs of the operational amplifier swing between 0 and +5 volts. Therefore, to maintain 16-bit linearity the common-mode rejection ratio of the operational amplifier must be at least 96dB over a 5 volt range. Special consideration must be given to offset voltage, offset drift, bias current, bias drift, common-mode rejection, slew rate, and settling time when selecting an operational amplifier. High quality BiFET amplifiers, such as the AD711, are recommended.

The linearity and settling time for the AD1145 have a direct correlation to the output impedance and recovery time of the voltage reference. Therefore, a reference with a fast recovery time and low output impedance, such as the AD586, is recommended. When choosing a voltage reference, gain error and temperature drift must also be considered. A typical reference and output amplifier hookup is shown in Figure 1.

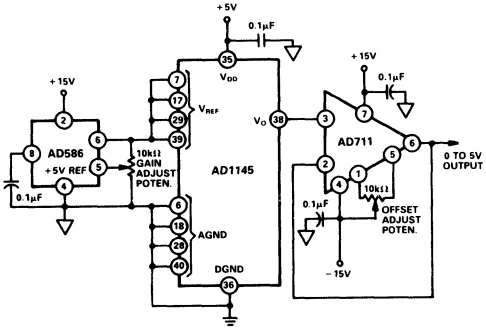


Figure 1. AD1145 Configured for a 0 to 5V Output with External Reference and Unity Gain Amplifier.

OFFSET AND GAIN CALIBRATION

The AD1145 has virtually no offset or gain errors of its own. When connected in a system, such as that shown in Figure 1, the system errors are nulled with external potentiometers. Offset error is nulled by adjusting the offset voltage of the output amplifier. Gain error is nulled by adjusting the output voltage of the external reference. The voltmeter used to measure the output must be capable of 1μV resolution. Offset adjustment should be done before gain adjustment.

UNIPOLAR MODE CALIBRATION

1. Apply a digital input of all "0"s.
2. Adjust the offset potentiometer until a 0.00000V output is obtained.
3. Apply a digital input of all "1"s.
4. Adjust the gain potentiometer until plus full-scale output is obtained. (see Table I for full-scale value).

BIPOLAR MODE CALIBRATION

1. Apply a digital input of all "0"s (for offset binary coding) or 8000 Hex (for twos complement coding).
2. Adjust the offset potentiometer until minus full-scale output is obtained (see Table I for value).
3. Apply a digital input of all "1"s (for offset binary coding) or 7FFF Hex (for twos complement coding).
4. Adjust the gain potentiometer until plus full-scale output is obtained (see Table I for full-scale value).

Range	Input Code (Hex)		Output
Unipolar:			
0V to 5V	0000		0.00000V
	FFFF		4.999924V
0V to 10V	0000		0.00000V
	FFFF		9.999848V
	Offset	**Twos Comp**	
Bipolar:			
−5V to +5V	0000	8000	−5.00000V
	FFFF	7FFF	+4.999848V
−10V to +10V	0000	8000	−10.00000V
	FFFF	7FFF	+9.999695V

TIMING DIAGRAM

The timing requirements of the AD1145 are shown in Table II. The timing diagrams for both serial and parallel input modes of operation as well as serial output operation are shown in Figure 3. The serial output mode enables the user to read back data written to the AD1145.

Symbol	Parameter	Requirement
t_{DS}	Data Setup Time	25ns
t_{DH}	Data Hold Time	10ns
t_{WR}	Write Pulse Width	25ns
t_{CWS}	Chip Select to Write Setup	0ns
t_{CWH}	Chip Select to Write Hold	0ns

Table II. Timing Requirements

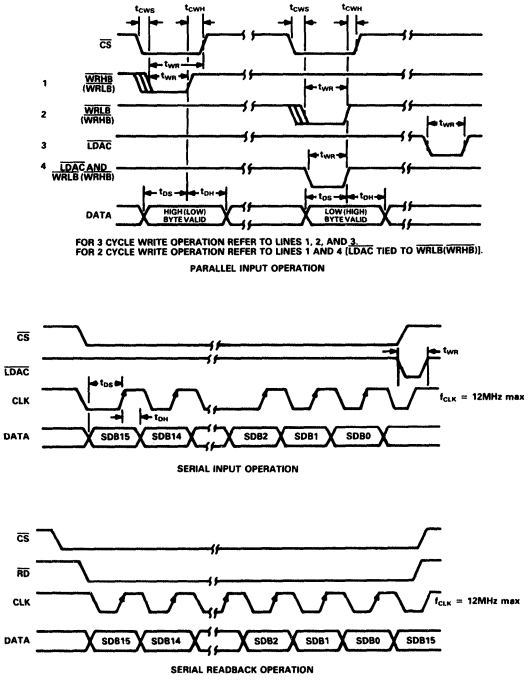

Figure 3. Timing Diagrams

The AD1145 has eight control lines. A brief description of each line follows:

$\overline{CS}$ is the Chip Select line and allows multiple AD1145s to share the same input bus. The desired DAC is selected with the $\overline{CS}$ line. A low on this line enables $\overline{WRLB}$, $\overline{WRHB}$, CLK, and $\overline{RD}$ of the selected DAC.

$\overline{WRLB}$ is the WRite line for the Low Byte input register. A low on this line makes the register transparent. A high level latches the input data into the register.

$\overline{WRHB}$ is the WRite line for the High Byte input register. Operation is the same as $\overline{WRLB}$.

$\overline{LDAC}$ is the Load line for the DAC register. A low on this line makes the DAC register transparent. A high level latches the data from the input registers into the DAC register. $\overline{LDAC}$ operates independently of $\overline{CS}$.

CLK is the line used to CLocK serial data into or out of the input registers. Data is moved on each positive transition of CLK. Note that CLK must be held high for parallel operation.

$\overline{RD}$ is the ReaD line. A low on this line enables the serial output function and also connects the serial output to the serial input.

$\overline{CLR}$ is the CLeaR line. A low on this line clears the DAC output to zero volts regardless of input coding. $\overline{CLR}$ operates independently of $\overline{CS}$.

CODE determines the input coding of the DAC. A low on this line inverts the MSB for twos complement coding. A high does not invert the MSB (for binary and OBN codes).

PARALLEL OPERATION

The AD1145 is fully compatible with either 8- or 16-bit microprocessor systems. In an 8-bit system, data may be loaded using either two or three instruction cycles, with either the high byte or the low byte being loaded first. Typical load sequences are (1) load high byte, load low byte, load DAC register, or (2) load high byte, load low byte and DAC register. With a 16-bit system, data may be loaded using either one, or two, instruction cycles, or the DAC may be operated with all of its registers transparent. Table III illustrates the AD1145's parallel operation as a function of its control lines. Note that CLK and $\overline{RD}$ must be held high for parallel operation.

$\overline{CLR}$	$\overline{CS}$	$\overline{WRLB}$	$\overline{WRHB}$	$\overline{LDAC}$	OPERATION
0	X	X	X	X	Reset DAC Output to Zero Volts.
1	0	0	0	0	Input and DAC Registers are Transparent.
1	0	0	0	1	Load High Byte and Low Byte Input Registers.
1	0	0	1	0	Load DAC Register from High Byte Register and Transparent Low Byte Inputs.
1	0	0	1	1	Load Low Byte Input Register.
1	0	1	0	0	Load DAC Register from Low Byte Register and Transparent High Byte Inputs.
1	0	1	0	1	Load High Byte Input Register.
1	0	1	1	0	Load DAC Register from Input Registers.
1	1	X	X	0	Load DAC Register from Input Registers.
1	1	X	X	1	No Operation.
1	X	1	1	1	No Operation.

Table III. Parallel Operation Truth Table

SERIAL OPERATION

In the serial mode, data is written from DB0/SI into the input register on each positive going transition of the clock. For error checking, data can also be readback from the input register to DB15/SO. The serial output is switched internally to the serial input in the readback mode so that the data is recirculated as it is read. In this way the data is restored after 16 clock cycles. The data in the DAC register and hence the DAC output voltage is unchanged during readback. Table IV shows the serial operation of the AD1145 as it relates to the status of the control lines.

INPUT CODING

The AD1145 accepts data in twos complement, offset binary, or straight binary formats. The code pin either *inverts* or *not inverts*

$\overline{CLR}$	$\overline{CS}$	CLK	$\overline{RD}$	$\overline{LDAC}$	OPERATION
0	x	x	x	x	Reset DAC Output to Zero Volts.
1	0	↑	1	1	Clock Serial Data from DB0/SI into Input Register.
1	0	↑	0	1	Clock Serial Data from Input Register out to DB15/SO.
1	x	x	x	0	Load DAC Register.
1	x	↓	x	1	No Operation.

Table IV. Serial Operation Truth Table

the MSB. If code is low, the MSB is inverted for twos complement coding. If code is high, the MSB is true for straight binary and offset binary coding. See Table V for further detail.

CLEAR LINE OPERATION

The clear line, in conjunction with the code line, resets the DAC output to zero volts. For straight binary operation CODE should be tied to $+V_{DD}$, the MSB will not be inverted, the DAC register gets reset to 0000H, and the AD1145's output is reset to zero volts. For twos complement operation, CODE is tied to DGND, the MSB is inverted, the DAC register is reset to 1/2 full scale, and the AD1145's output is reset to zero volts. For offset binary operation CODE is tied to $\overline{CLR}$. In this way the MSB is not inverted in normal operation but on CLEAR the MSB gets inverted, the DAC register is reset to 1/2 full scale, and the AD1145's output is reset to zero volts. Table V shows the clear operation as a function of CODE input.

CLR	CODE	OPERATION
0	0	BIPOLAR CLEAR (Twos Complement, Offset Binary)
0	1	UNIPOLAR CLEAR (Binary)
1	0	MSB INVERTED (Twos Complement)
1	1	MSB TRUE (Binary, Offset Binary)

Table V. Clear Operation Truth Table

POWER-UP RESET

In the event of a power failure, the DAC output is automatically reset to zero volts upon power-up. When CODE is high, the DAC is reset to zero for a unipolar clear. When CODE is low, the DAC is reset to 1/2 full scale for a bipolar clear (zero volt output).

GROUNDING AND GUARDING

The AD1145 is a precision D/A converter with 76μV LSB resolution at a FSR of 5V. Special care must be taken to insure proper layout, grounding, and guarding. Analog and digital grounds should be individually star pointed and then tied together at a single point near the measurement point. High-speed digital inputs should be kept separate from low level analog outputs. Power supplies should be locally bypassed around all high-speed components and at the power supply input to the printed circuit board. All high impedance nodes such as the DAC output and amplifier inputs are sensitive to interference from the digital input lines. They should be surrounded by low impedance guard tracks at all times. Figure 2 shows the proper guarding of the AD1145 depending on output configuration.

SINGLE SUPPLY OPERATION

The AD1145 can operate with V_{DD} connected to V_{REF}. If CMOS is used to drive the DAC inputs, the static current drawn from V_{DD} will be less than 10μA. If TTL is used to drive the DAC inputs, the static current draw will be increased to about 3mA depending on the digital input. Therefore, the reference must be well buffered to avoid code dependent errors when TTL inputs are used. Figure 4 shows the AD1145 operating from a single supply.

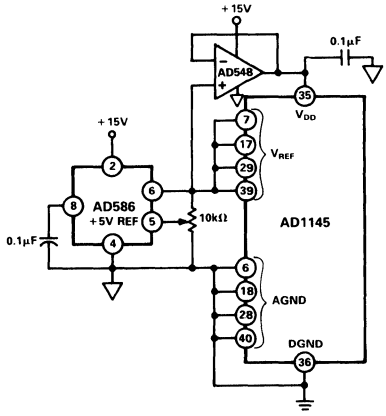

Figure 4. Single Supply Configuration

MULTIPLYING DAC OPERATION

The AD1145 operates as a two quadrant multiplying DAC over a limited voltage range. V_{REF} can vary between 3 and 6 volts. V_{DD} must track V_{REF} within +0.6 and −0.3 volts. Logic levels will vary with V_{DD}, with a logic low being less than $1/3V_{DD}$ and a logic high being greater than $2/3V_{DD}$. V_{DD} and V_{REF} may be tied together provided the reference voltage is well buffered.

A useful application of the multiplying feature is to set the reference voltage to 4.096 volts and configure the DAC as shown in Figure 2b for ±10V range. This provides a ±8.192 volt full-scale output for a bit weight of 0.25mV per LSB.

MULTIPLE DAC APPLICATION

The AD1145 is well suited for applications using multiple DACs sharing the same data bus, as in automated test equipment. Figure 5 shows a typical multiple DAC hookup. Note that the $\overline{WRLB}$, $\overline{WRHB}$, $\overline{LDAC}$, $\overline{RD}$, $\overline{CLR}$, and CLK lines from each DAC are tied together. A separate chip select ($\overline{CS}$) line is provided to individually select each DAC. Data can be written to one or all DACs by appropriate selection of the chip select lines. All DACs may be simultaneously updated by strobing the $\overline{LDAC}$ line. A separate CODE line is provided for each DAC so that they may be independently configured for unipolar and bipolar coding.

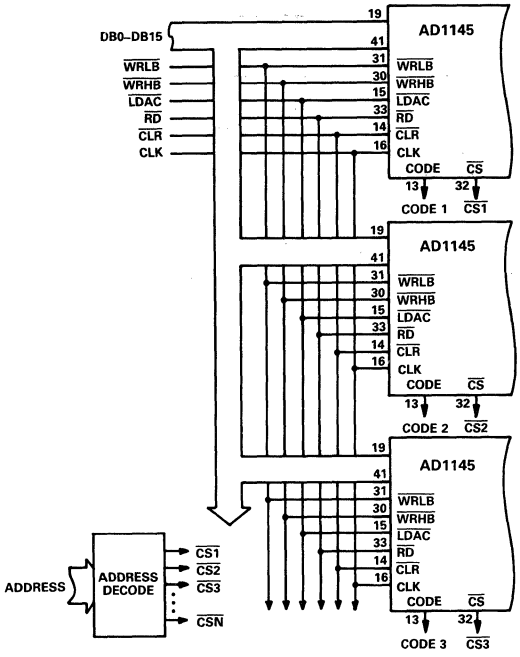

Figure 5. Multiple DAC Application

PARALLEL READBACK

Full parallel readback can be achieved by adding two 74ALS990 octal D-type read-back latch chips as shown in Figure 6. These latches also reduce digital feedthrough from the data bus; an important consideration in high accuracy systems.

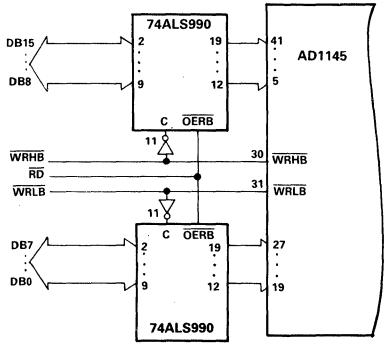

Figure 6. Parallel Readback

PACKAGE INFORMATION

The AD1145 is packaged in a 44-pad glass epoxy chip carrier. This package is ideal for automated surface mounting due to its excellent dimensional tolerances and planarity. As the package is made from the same material as printed circuit boards, it has the same temperature coefficient of expansion. This minimizes stress and maximizes product reliability. Standard JEDEC leadless chip carrier sockets such as those manufactured by Textool can be used for testing. For conventional through-hole mounting, the AD1145 is also available in a PGA package. See Table VI for recommended sockets.

Simple 8-Bit and 16-Bit Data Bus Connections

The AD1145 can be configured to directly connect to an 8-bit or 16-bit data bus. An 8-bit microprocessor requires at least two write cycles to supply 16 bits of input data. Utilizing the AD1145's high byte and low byte input registers, one byte at a time is loaded from the 8-bit bus. The 16-bit DAC register can be latched during or after the second byte write operation. Figure 7 shows a typical AD1145 connection to an 8-bit bus. Note that the three logic gates can be eliminated if two address lines are available.

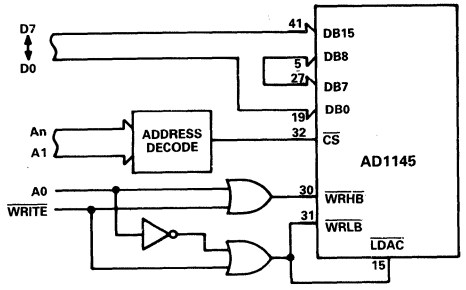

Figure 7. 8-Bit Microprocessor Interface

A 16-bit microprocessor supplies a complete 16-bit input in a single write cycle. This eliminates the requirement for the individual high byte and low byte input latches. Figure 8 shows a typical AD1145 connection to a 16-bit bus. The 16-bit DAC register is made transparent by grounding the $\overline{\text{LDAC}}$ line or can be strobed for full double buffering.

GENERAL DESCRIPTION

The AD1147 and AD1148 are 16-bit resolution, hybrid, latched input, digital-to-analog converters. Their two 8-bit latched input DACs allow direct offset and gain correction via microprocessor interface.

The AD1147 and AD1148 are constructed as hybrids in a compact 32-pin, triple wide dual-in-line package. Precision CMOS switches and a laser-trimmed thin-film resistor network are used to provide 16-bit accuracy and excellent temperature stability.

The Main (16-bit) DAC is loaded as a 16-bit word. The offset and gain correction DACs are each loaded as 8-bit words. The AD1147 multiplexes both correction DACs' inputs with the Main DAC's eight LSBs. This pin sharing allows for additional pin connections providing: external reference input, a current output and feedback resistors for voltage output ranges of 0 to +5V, 0 to +10V, ±5V and ±10V.

The AD1148 correction DACs' inputs are separate from the Main DAC's. The gain correction DAC's inputs are multiplexed with the offset DAC's 8-bit inputs. This allows for a separate 8-bit bus interface with the correction DACs – common in applications such as Automatic Test Equipment.

ANALOG OUTPUT RANGE

The AD1148 is internally connected for ±10 volts output range.

The AD1147 is pin programmable to provide a variety of analog outputs, either current or voltage. A unipolar output current of 0 to −2mA is available at pin 5, and can be offset by 1mA (by connecting pin 28 to pin 29) for a bipolar output of ±1mA. Output voltage ranges (+5V, +10V, ±5V and ±10V) are available at pin 32 by connecting the current output (pin 5) to the amplifier input (pin 4) and the appropriate internal feedback resistors to the amplifier output (pin 32) as shown in Figure 1.

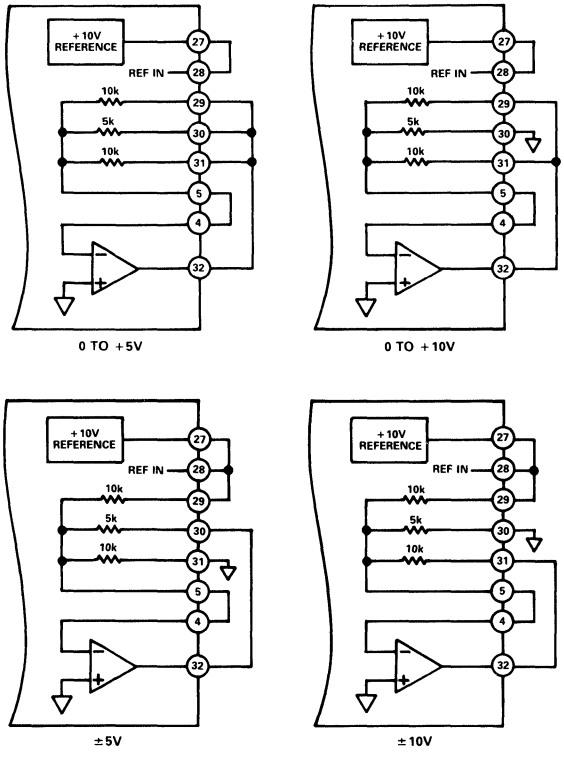

Figure 1. AD1147 Analog Output Range Pin Programming

TIMING DIAGRAM

The timing requirements for the models AD1147 and AD1148 are shown in Table I. The timing diagrams for the MAIN 16-bit DAC and the 8-bit Correction DACs are shown in Figure 2. The three control lines operate as follows:

$\overline{WR}$/M is the write line for the main DAC. The latches are transparent when the write line is low, and latched when the write line goes high.

$\overline{WR}$/C is the write line for the correction DACs. Operation is the same as above.

O/$\overline{G}$ selects between the offset correction DAC and the gain correction DAC. A high level on this pin selects the offset DAC. A low level selects the gain DAC.

SYMBOL	PARAMETER	REQUIREMENT
Main DAC		
t_{DS}	Data Setup Time	140ns min
t_{DH}	Data Hold Time	120ns min
t_{WR}	Write Pulse Width	250ns min
Correction DACs		
t_{CS}	O/$\overline{G}$ To Write Setup Time	200ns min
t_{CH}	O/$\overline{G}$ To Write Hold Time	20ns min

t_{DH}	Data Valid To Write Hold	0ns min
t_{WR}	Write Pulse Width	100ns min

Table I. Timing Requirements

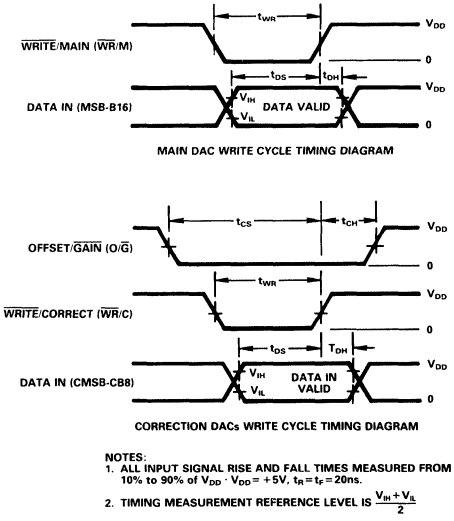

Figure 2. AD1147 and AD1148 Timing Diagrams

OFFSET AND GAIN CALIBRATION

Initial offset and gain errors can be adjusted to zero using the two internal 8-bit calibration DAC's. There are three control lines used in the calibration sequence: $\overline{WR}$/M is the write line for the Main (16-bit) DAC – the latches are transparent when the write line is low, and latched when the write line goes high; $\overline{WR}$/C is the write line for the correction DACs and operates the same as $\overline{WR}$/M; O/$\overline{G}$ selects between the offset correction DAC and the gain correction DAC – a high level on this pin selects the offset DAC and a low level selects the gain DAC.

Offset and Gain calibrations are performed as follows:

1. With $\overline{WR}$/M low, set the digital inputs of the Main DAC to "000....00" (in unipolar mode) or "100....00" (in bipolar mode).
2. Set $\overline{WR}$/M high to latch the digital input into the Main DAC.
3. With $\overline{WR}$/C low and O/$\overline{G}$ high, adjust the digital inputs of the offset correction DAC until the Main DAC's output

voltage (pin V_O) is as close to 0.000000 volts as possible. Note that incrementing the digital input produces a more negative voltage output.

4. Set $\overline{WR}$/C high to latch the digital input into the offset correction DAC.
5. With $\overline{WR}$/M low, set the digital input of the Main DAC to "111....11".
6. Set $\overline{WR}$/M high to latch the digital input into the Main DAC.
7. With $\overline{WR}$/C low and O/$\overline{G}$ low, adjust the digital inputs of the gain correction DAC until the Main DAC's output voltage (pin V_O) is as close as possible to the positive full-scale voltage shown below in Table II. Note that incrementing the digital input produces a more negative voltage output.
8. Set $\overline{WR}$/C high to latch the digital input into the gain correction DAC.
9. Calibration is complete. Set $\overline{WR}$/M low and begin/resume normal digital-to-analog conversion via the Main DAC.

Output Voltage Range	Positive Full-Scale Voltage
0 to +5 volts	+4.999924 volts
0 to +10 volts	+9.999847 volts
±5 volts	+4.999847 volts
±10 volts	+9.999695 volts

Table II. Gain Calibration

GROUNDING AND GUARDING

The current from the measurement ground pin (MGND) is constant, independent of digital input, for ease of making measurements. This is the high quality ground for the AD1147 and AD1148. It should be connected to the high quality ground in the application. Power ground (PGND) should be connected to measurement ground (MGND) at the measurement point.

The current output pin (I_O) of the AD1147 is sensitive to interference from the digital input lines. It should be surrounded by a grounded guard at all times. When using the AD1147 in the voltage output mode, both the "I_O" and "AMP IN" pins should be guarded (see Figure 3).

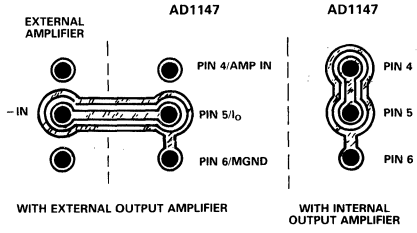

Figure 3. Typical Guarding Techniques

EXTERNAL AMPLIFIER FOR LOW DRIFT VOLTAGE OUTPUT OR HIGH OUTPUT CURRENT

The internal output amplifier of the AD1147 is designed for high-speed applications that require fast settling times. An external precision operational amplifier like the AD OP-07C can be applied when lower offset (less than 20μV/°C) is important (see Figure 4). Simply connect the current output (Pin 5) to the inverting input of the amplifier and connect the proper feedback resistors as shown in Figure 1. Be certain to keep the current output-amplifier's input connection short and surrounded by a grounded guard. To avoid degrading the gain drift performance of the DAC, always use the internal feedback resistors, since they are matched to the internal current weighting resistors of the DAC. It is also good practice to connect the negative input (Pin 4, AMP IN) of the unused internal output amplifier to its output (Pin 32, V_O).

The current drift of the AD1147 is typically 350pA/°C from +15°C to +35°C. When using the AD OP-07, the total offset drift of the output signal will typically be less than 2μV/°C.

As a second example, a high output current amplifier can be connected to the AD1147 to create a programmable power supply. The configuration is the same as shown for the AD OP-07C in Figure 4.

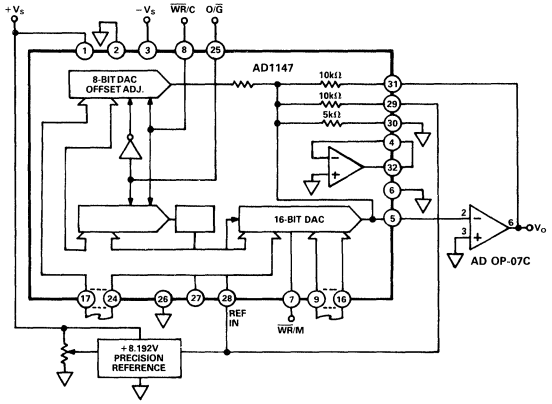

Figure 4. Precision DAC with ±8.192V F.S. Output Voltage

FULL FOUR-QUADRANT MULTIPLYING DAC

The AD1147 is a full four-quadrant multiplying DAC and can be used with references varying between +12 and −12 volts. Typical linearity vs. external reference voltage is shown in Figure 5. Output voltage ranges other than those provided can be obtained by connecting the appropriate reference voltage to "REF IN" (Pin 28), (see Figure 4). The DAC output voltage can be calculated as follows:

$$\text{UNIPOLAR } V_O = \frac{\text{DIGITAL INPUT}}{2^{16}} \times \frac{V_{REF}}{5k} \times R_{fb}$$

$$\text{BIPOLAR } V_O = \frac{\text{DIGITAL INPUT}}{2^{16}} \times \frac{V_{REF}}{5k} \times R_{fb} - \frac{V_{REF}}{10k}$$

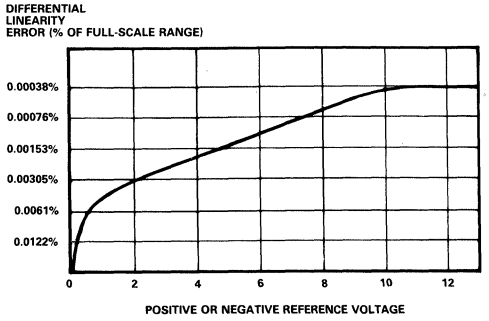

Figure 5. Typical Differential Linearity vs. External Reference Voltage

8-BIT MICROPROCESSOR INTERFACE

The AD1147/AD1148 can easily be operated with an 8-bit bus by the addition of an octal latch. The 16-bit Main DAC is loaded from the 8-bit bus as two 8-bit bytes. Figure 6 shows the configuration when using a 74HC573 octal latch.

The eight most significant bits are latched into the 74HC573 by setting the "latch enable" control line low. The eight least significant bits are then placed on the bus. Now all sixteen bits can be simultaneously latched into the Main DAC by setting $\overline{WR}$/M high.

The offset and gain correction DAC's are calibrated as they were for 16-bit microprocessor applications. See the "OFFSET AND GAIN CALIBRATION" section of this data sheet.

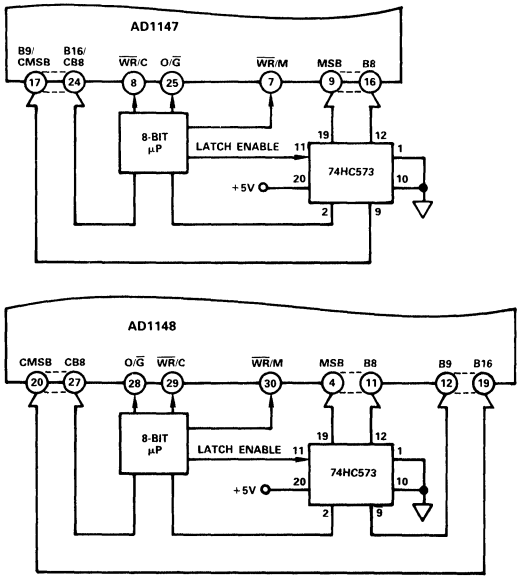

Figure 6. Connections for 8-Bit Bus Interface

AUTOMATIC TESTING OF 12-BIT ADC'S AND DAC'S

The AD1147 and AD1148 can be used as a reference DAC to automatically test the integral and differential linearity of 12-bit ADCs and DACs. An ideal reference DAC should be an order of magnitude more accurate than the devices to be tested. The AD1147 and AD1148 are sixteen times more accurate than the devices to be tested and therefore can be considered ideal.

The general test procedures for ADCs and DACs are shown below. Before actual testing proceeds, calibrate the offset and gain of the AD1147 or AD1148 (see "OFFSET AND GAIN CALIBRATION" section of this data sheet).

ADC TESTING (refer to Figures 7 and 8).

The differential nonlinearity of ADC's is the difference between the actual code widths of the analog input voltage vs. the ideal, one LSB, code widths of a perfect converter. A code width is the range of analog input voltage which produces the desired digital output word.

A code width can be measured by determining the analog input voltage at which the transition occurs from the code under test to its next lower digital output code and then differencing that analog value with the same determined for the transition from the code under test to its next higher digital output code.

Virtually all converters exhibit a degree of noise. This will necessitate an averaging technique to determine the analog input value for a code transition – where a reduction in analog input voltage produces a majority of the lower digital code decisions and an analog input increase produces a majority of the higher digital code decisions.

Begin testing by calibrating the offset and gain of the ADC under test per the manufacturer's instructions. Set the digital inputs of the reference DAC to the nominal value of the desired transition edge (produces an analog input to the device under test that is either 1/2LSB below or 1/2LSB above the ideal analog input for the code under test). Increment or decrement this digital input until the Device Under Test (D.U.T.) outputs the digital code below the transition 50% of the time and the digital code above the transition 50% of the time. Record this digital input and repeat the procedure for the next transition of the nominal code to be measured. Compare this second digital input with the recorded input. The difference between these two digital values is the width of the code being measured. A perfect code width is 16 counts of the reference DAC. Each count more, or less than 16, corresponds to a differential linearity error of 1/16LSB for the D.U.T. The arithmetic average of the two digital input values is the center of the code being tested. Each count of difference between this actual code center and the ideal, nominal code center represents an integral linearity error of 1/16LSB.

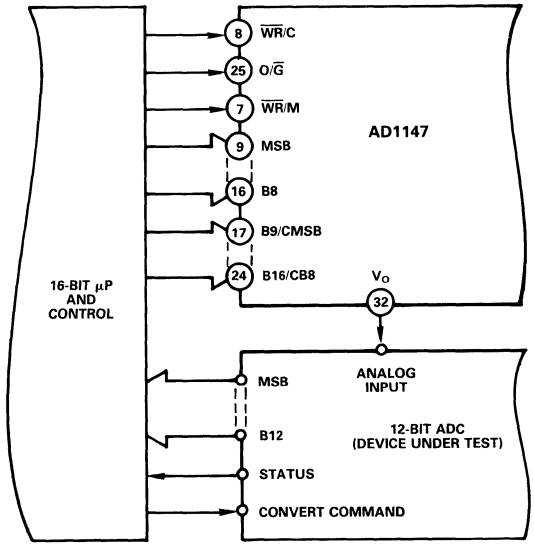

Figure 7. ADC Testing

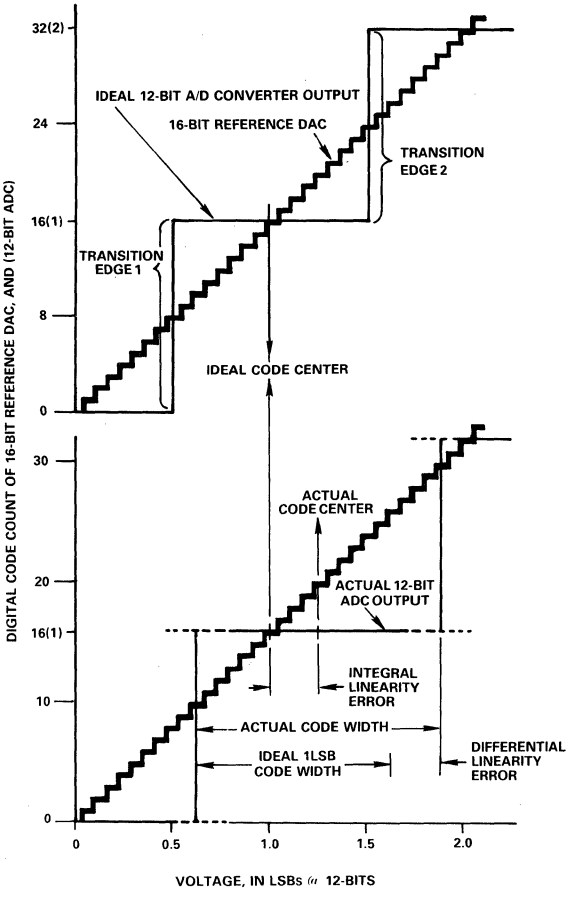

Figure 8. 12-Bit ADC Linearity Testing

DAC TESTING (refer to Figure 9).
To test 12-bit DACs begin with offset and gain calibration of the DAC under test per the manufacturer's instructions. Set the digital inputs of the reference DAC and the D.U.T. to the desired code. Latch this digital input into the reference DAC. The DACs' outputs are differenced and amplified by an AD524A instrumentation amplifier. The voltage error between the DACs is the integral linearity error.

Now null the meter and then increment or decrement the digital input to the D.U.T. only, by one LSB. The meter reading will correspond to the code width of the new digital input word. The deviation of this voltage from the ideal value of one LSB is the differential linearity error of the D.U.T.

ANALOG DEVICES

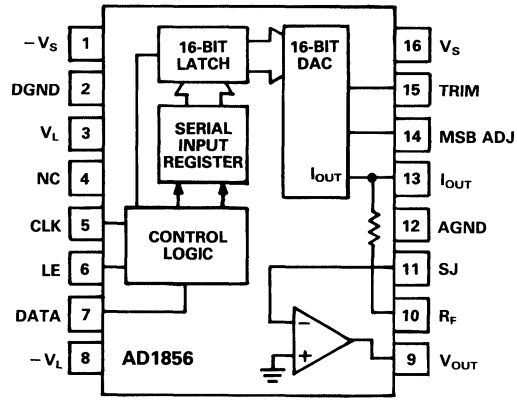
16-Bit PCM Audio DAC

AD1856

FEATURES
0.0025% THD
Fast Settling Permits 2×, 4× or 8× Oversampling
±3V Output
Optional Trim Allows Superlinear Performance
±5V to ±12V Operation
16-Pin Plastic DIP Package
Serial Input

APPLICATIONS
Compact Disc Players
Digital Audio Amplifiers
DAT Recorders and Players
Synthesizers and Keyboards

AD1856 FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD1856 is a monolithic 16-bit PCM Audio DAC. Each device provides a voltage output amplifier, 16-bit DAC, 16-bit serial-to-parallel input register and voltage reference. The digital portion of the AD1856 is fabricated with CMOS logic elements that are provided by Analog Devices' BiMOS II process. The analog portion of the AD1856 is fabricated with bipolar and MOS devices as well as thin film resistors.

This combination of circuit elements, as well as careful design and layout techniques, results in high performance audio playback. Laser trimming of the linearity error affords extremely low total harmonic distortion. An optional linearity trim pin is provided to allow residual differential linearity error at midscale to be eliminated. This feature is particularly valuable for low distortion reconstructions of low amplitude signals. Output glitch is also small contributing to the overall high level of performance. The output amplifier achieves fast settling and high slew rates, providing a full ±3V signal at load currents up to 8mA. The output amplifier is short circuit protected and can withstand indefinite shorts to ground.

The serial input interface consists of the clock, data and latch enable pins. The serial 2s complement data word is clocked into the DAC, MSB first, by the external data clock. The latch enable signal transfers the input word from the internal serial input register to the parallel DAC input register. The input clock can support a 10MHz clock rate. This serial input port is compatible with popular digital filter chips used in consumer audio products. These filters operate at oversampling rates of 2×, 4× and 8× sampling frequency.

The AD1856 can operate with ±5V to ±12V power supplies making it suitable for both the portable and home-use markets. The digital supplies, V_L and $-V_L$, can be separated from the analog supplies, V_S and $-V_S$, for reduced digital crosstalk. Separate analog and digital ground pins are also provided.

Power dissipation is 110mW typical with ±5V supplies and is a typical 300mW when ±12V supplies are used.

The AD1856 is packaged in a 16-pin plastic DIP and incorporates the industry-standard pinout. Operation is guaranteed over the temperature range of −25°C to +70°C and over the voltage supply range of ±4.75 to ±13.2V.

PRODUCT HIGHLIGHTS

1. Total harmonic distortion is 100% tested.
2. MSB trim feature allows superlinear operation.
3. The AD1856 operates with ±5V to ±12V supplies.
4. Serial interface is compatible with digital filter chips.
5. 1.5μs settling time permits 2×, 4× and 8× oversampling.
6. No external components are required.
7. 96dB dynamic range.
8. ±3V or ±1mA output capability.
9. 16-bit resolution.
10. 2s complement serial input words.
11. Low cost.
12. 16-pin plastic DIP package.

SPECIFICATIONS (typical at T_A = +25°C and ±5V supplies unless otherwise noted)

2

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

Definition of Specifications

TOTAL HARMONIC DISTORTION

Total Harmonic Distortion (THD) is defined as the ratio of the square root of the sum of the squares of the values of the harmonics to the value of the fundamental input frequency. It is expressed in percent (%) or decibels (dB).

THD is a measure of the magnitude and distribution of linearity error and differential linearity error. The distribution of these errors may be different, depending on the amplitude of the output signal. Therefore, to be most useful, THD should be specified for both large and small signal amplitudes.

SETTLING TIME

Settling Time is the time required for the output to reach and remain within a specified error band about its final value, measured from the digital input transition. It is the primary measure of dynamic performance.

DYNAMIC RANGE

Dynamic Range is the specification that indicates the ratio of the smallest signal the converter can resolve to the largest signal it is able to produce. As a ratio, it is usually expressed in decibels (dB). The theoretical dynamic range of an n-bit converter is approximately (6×n) dB. In the case of the 16-bit AD1856, that is 96dB. The actual dynamic range of a converter is less than the theoretical value due to limitations imposed by noise and quantization and other errors.

BIPOLAR ZERO ERROR

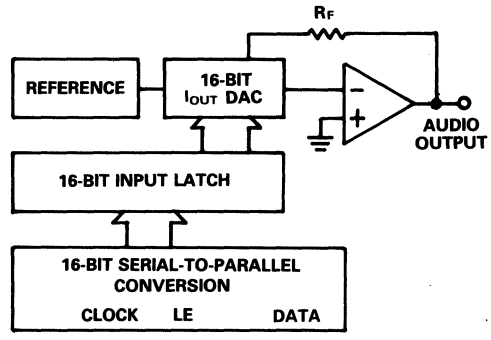
Bipolar Zero Error is the deviation in the actual analog output from the ideal output (0V) when the 2s complement input code representing half scale (all 0s) is loaded in the input register.

DIFFERENTIAL LINEARITY ERROR

Differential Linearity Error is the measure of the variation in analog value, normalized to full scale, associated with a 1LSB change in the digital input. Monotonic behavior requires that the differential linearity error not exceed 1LSB in the negative direction.

MONOTONICITY

A D/A converter is monotonic if the output either increases or remains constant as the digital input increases.



AD1856 Block Diagram

FUNCTIONAL DESCRIPTION

The AD1856 is a complete, monolithic 16-bit PCM audio DAC. No additional external components are required for operation. As shown in the block diagram, each chip contains a voltage reference, an output amplifier, a 16-bit DAC, a 16-bit input latch and a 16-bit serial-to-parallel input register.

The voltage reference consists of a bandgap circuit and buffer amplifier. This circuitry produces an output voltage that is stable over time and temperature changes.

The 16-bit D/A converter uses a combination of segmented decoder and R-2R architectures to achieve consistent linearity and differential linearity. The resistors which form the ladder structure are fabricated with silicon-chromium thin film. Laser trimming of these resistors further reduces linearity error resulting in low output distortion.

The output amplifier uses both MOS and bipolar devices to produce low offset, high slew-rate and optimum settling time. When combined with the onboard feedback resistor, the output op amp can convert the output current of the AD1856 to a voltage output.

ANALOG CIRCUIT CONSIDERATIONS

GROUNDING RECOMMENDATIONS

The AD1856 has two pins, designated ANALOG and DIGITAL ground. The analog ground pin is the "high quality" ground reference point for the device. The analog ground pin should be connected to the analog common point in the system. The output load should also be connected to that same point.

The digital ground pin returns ground current from the digital logic portions of the AD1856 circuitry. This pin should be connected to the digital common point in the system.

As illustrated in Figure 1, the analog and digital grounds should be connected together at one point in the system.

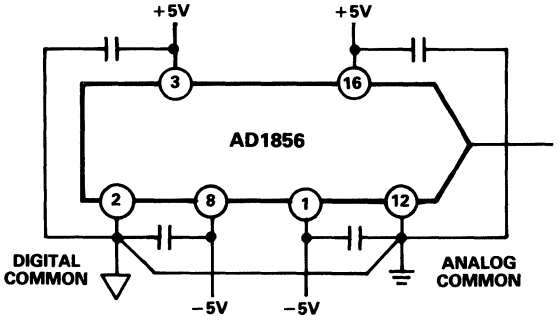


Figure 1. Recommended Circuit Schematic

POWER SUPPLIES AND DECOUPLING

The AD1856 has four power supply input pins. $\pm V_S$ provide the supply voltages to operate the linear portions of the DAC including the voltage reference, output amplifier and control amplifier. The $\pm V_S$ supplies are designed to operate from ±5V to ±12V.

The $\pm V_L$ supplies operate the digital portions of the chip including the input shift register and the input latching circuitry. The $\pm V_L$ supplies are also designed to operate from ±5V to ±12V subject only to the limitation that $-V_L$ may not be more negative than $-V_S$.

Decoupling capacitors should be used on all power supply pins. Furthermore, good engineering practice suggests that these capacitors be placed as close as possible to the package pins as well as the common points. The logic supplies, $\pm V_L$, should be decoupled to digital common; and the analog supplies, $\pm V_S$, should be decoupled to analog common.

The use of four separate power supplies will reduce feedthrough from the digital portion of the system to the linear portions of the system, thus contributing to good performance. However,

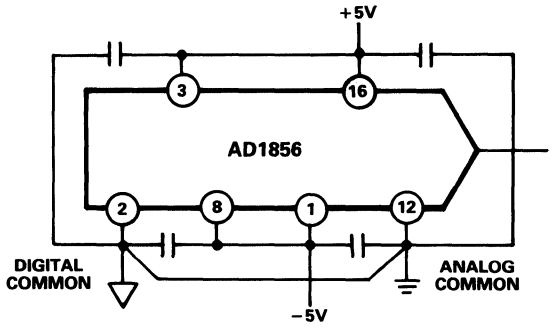

Figure 2. Alternate Recommended Schematic

four separate voltage supplies are not necessary for good circuit performance. For example, Figure 2 illustrates a system where only a single positive and a single negative supply are available. Given that these two supplies are within the range of ±5V to ±12V, they may be used to power the AD1856. In this case, the positive logic and positive analog supplies may both be connected to the single positive supply. The negative logic and negative analog supplies may both be connected to the single negative supply. Performance would benefit from a measure of isolation between the supplies introduced by using simple low-pass filters in the individual power supply leads.

As with most linear circuits, changes in the power supplies will affect the output of the DAC. Analog Devices recommends that well regulated power supplies with less than 1% ripple be incorporated into the design of any system using these devices.

TOTAL HARMONIC DISTORTION

The THD figure of an audio DAC represents the amount of undesirable signal produced during reconstruction and playback of an audio waveform. The THD specification, therefore, provides a direct method to classify and choose an audio DAC for a desired level of performance.

Analog Devices tests and grades all AD1856s on the basis of THD performance. A block diagram of the test setup is shown in Figure 3. In this test setup, a digital data stream, representing a 0db, −20dB or −60dB sine wave is sent to the device under test. The frequency of this waveform is 990.5Hz. Input data is sent to the AD1856 at a $4\times F_S$ rate (176.4kHz). The AD1856 under test produces an analog output signal with the on-board op amp.

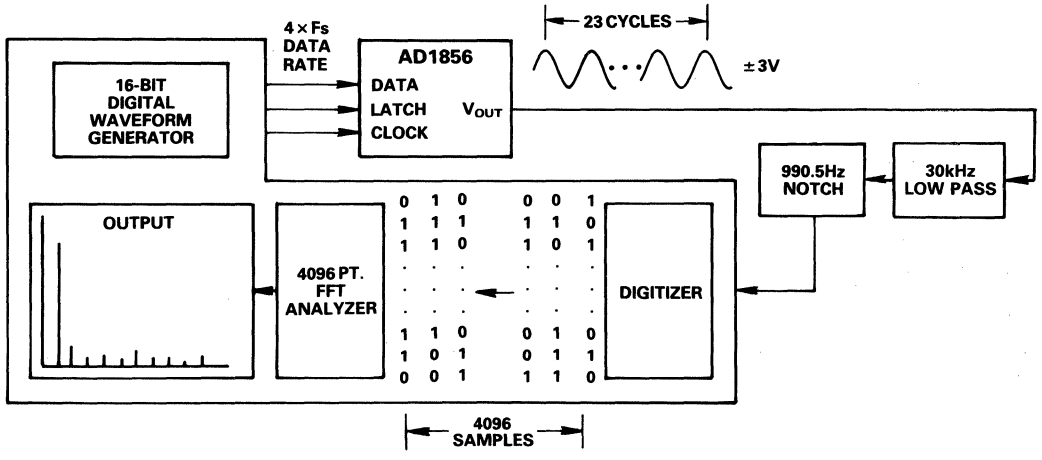

Figure 3. Block Diagram of Distortion Test Circuit

The automatic test equipment digitizes 4096 samples of the output test waveform, incorporating 23 complete cycles of sine wave. A 4096 point FFT is performed on the results of the test. Based on the first 9 harmonics of the fundamental 990.5Hz output wave, the total harmonic distortion of the device is calculated. Neither a deglitcher nor an MSB trim is used during the THD test.

The circuit design, layout and manufacturing techniques employed in the production of the AD1856 result in excellent THD performance. Figure 4 shows the typical unadjusted THD performance of the AD1856 for various amplitudes of a 1kHz output signal. As can be seen, the AD1856 offers excellent performance, even at amplitudes as low as −60dB. Figure 5 illustrates the typical THD vs. frequency performance.

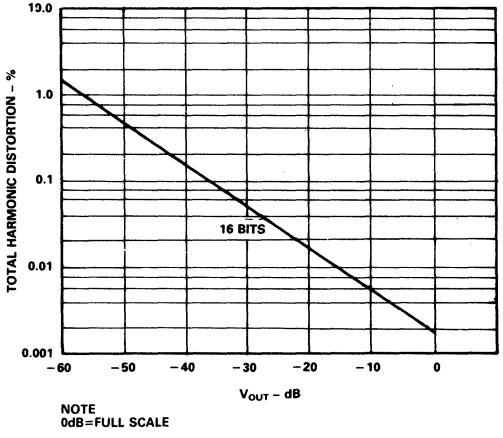

Figure 4. Typical Unadjusted THD vs. Amplitude

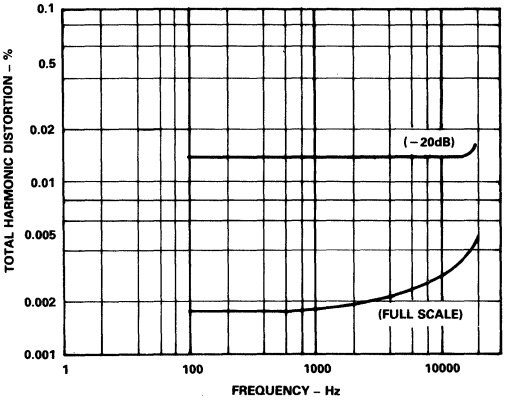

Figure 5. Typical THD vs. Frequency

OPTIONAL MSB ADJUSTMENT

Use of an optional adjustment circuit allows residual differential linearity error around midscale to be eliminated. These errors are especially important when low amplitude signals are being reproduced. In those cases, as the signal amplitude decreases, the ratio of the midscale differential linearity error to the signal amplitude increases and THD increases.

Therefore, for best performance at low output levels, the optional MSB adjust circuitry shown in Figure 6 may be used. This circuit allows the differential linearity error at midscale to be zeroed out. However, no adjustments are required to meet data sheet specifications.

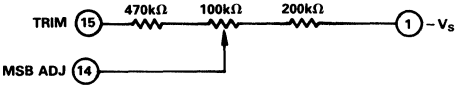

Figure 6. Optional THD Adjust Circuit

DIGITAL CIRCUIT CONSIDERATIONS

Input Data

Data is transmitted to the AD1856 in a bit stream composed of 16-bit words with a serial, MSB first format. Three signals must be present to achieve proper operation: the Data, Clock and Latch Enable signals. Input data bits are clocked into the input register on the rising edge of the Clock signal. The LSB is clocked in on the 16th clock pulse. When all data bits are loaded, a low-going Latch Enable pulse updates the DAC input. Figure 7 illustrates the general signal requirements for data transfer for the AD1856.

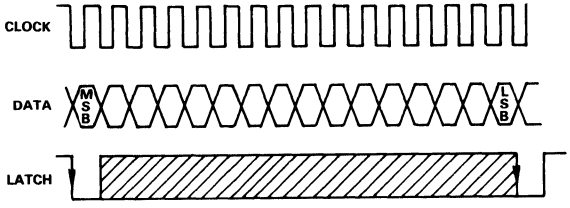

Figure 7. Signal Requirements of AD1856

Figure 8 provides the specific timing requirements that must be met in order for the data transfer to be accomplished properly.

The input pins of the AD1856 are both TTL and 5V CMOS compatible, independent of power supply voltages used.

The input requirements illustrated in Figures 7 and 8 are compatible with the data outputs provided by popular DSP filter chips used in digital audio playback systems. The AD1856 input clock can run at a 10MHz rate. This clock rate will allow data transfer rates for 2×, 4× or 8× oversampling reconstruction. The application section of this data sheet contains additional guides for using the AD1856 with various DSP filter chips available from Sony, NPC and Yamaha.

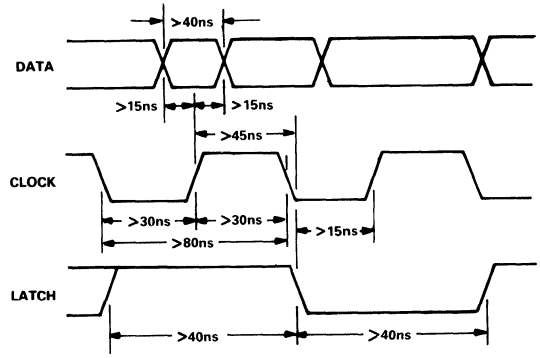

Figure 8. Timing Relationships of Input Signals

APPLICATIONS OF THE AD1856 PCM AUDIO DAC

The AD1856 is a versatile digital-to-analog converter designed for applications in consumer digital audio equipment. Portable, car and home compact disc player, digital audio-amplifier and DAT systems can all use the AD1856. Various circuit architectures are popular in these systems. They include stereo playback sections featuring one DAC per system, one DAC per audio channel (left/right) or even multiple DACs per channel. Furthermore, these architectures use different output reconstruction rates to accomplish these functions including reproduction at the sample rate F_S (1×), at twice the sample rate(2×F_S), at four times the sample rate (4×F_S) and even at eight times the sample rate (8×F_S). F_S is 44.1kHz for CD and 48kHz for DAT applications.

One DAC per System

Figure 9 shows a circuit using one AD1856 per system to reproduce both stereo channels of a typical first generation digital

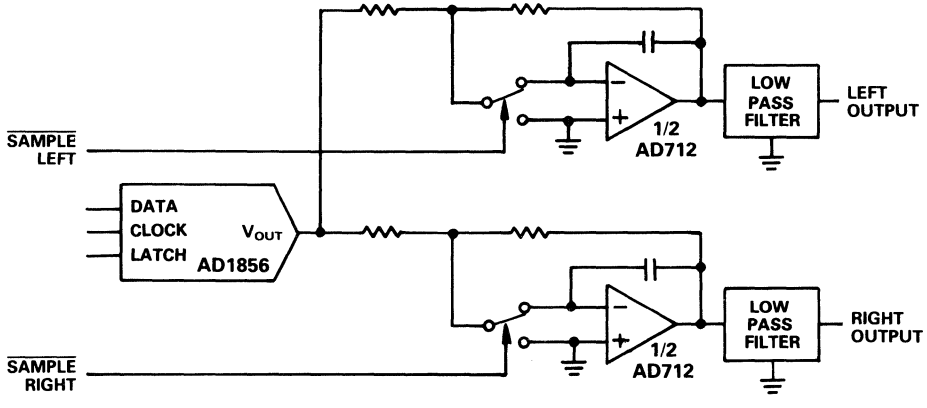

Figure 9. AD1856 in a One DAC per System Architecture

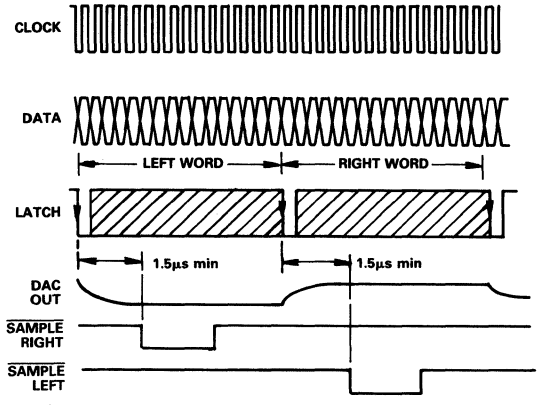

Figure 10. Control Signals for One DAC Circuit

audio system. The input data is fed to the AD1856 in a format which alternates between left channel data and right channel data. The output of the AD1856 is switched between the left channel and right channel output sample/hold amplifiers (SHAs). The SHAs demultiplex and deglitch the output of the AD1856. The timing diagram for the control signals for this circuit is shown in Figure 10.

The architecture illustrated in Figure 9 is suitable for low-end home or portable systems. However, its usefulness in mid- or high-end digital audio reproduction is limited by the phase delay which is introduced in the multiplexed output. This phase delay is due to the fact that the information contained in the input bit stream represents left and right channel audio sampled simultaneously but reconstructed alternately. One obvious solution to this problem may be arrived at by incorporating a third, noninverting SHA to delay the output of one channel to "catch up to" the other channel. This eliminates the phase shift by restoring simultaneous reproduction. This solution is illustrated in Figure 11.

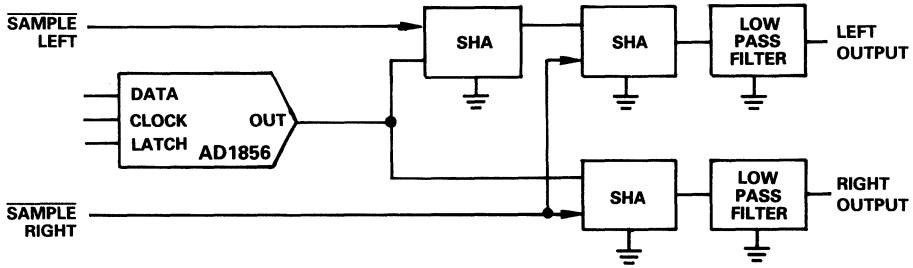

Figure 11. Third SHA Eliminates Phase Delay

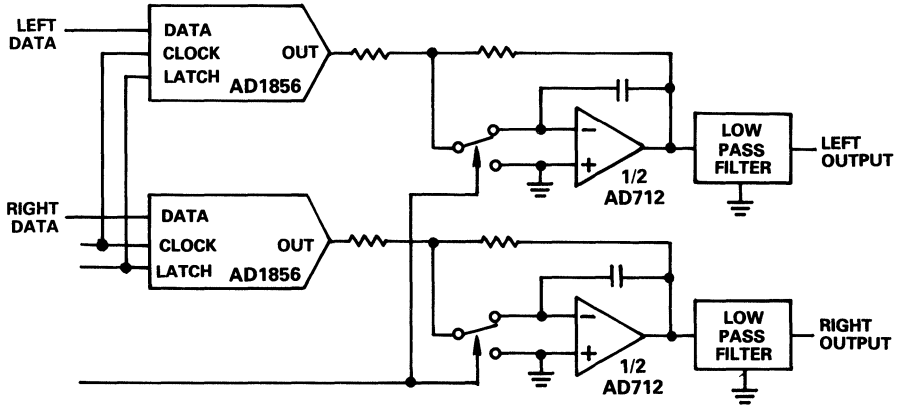

Figure 12. One DAC per Channel Architecture

One DAC per Channel

Another approach used to eliminate phase delay between left and right channels employs one DAC per channel. In this architecture, the input data bit streams for the left channel and the right channel are simultaneously sent and latched into each DAC. This "second generation" approach, shown in Figure 12, is suitable for higher performance digital-audio playback units.

Two DACs per Channel (Four DAC System)

Another architecture uses two DACs per channel. In this scheme, shown in Figure 13, each DAC reproduces one half of the output waveform. The advantage obtained is that midscale differential linearity error no longer effects the zero-crossing points of the waveforms. Its effects are shifted to the points where the output waveform crosses ±3/4 full scale. The result is that THD performance for low amplitude signals is greatly improved. Not shown in Figure 13 is a VLSI circuit required to separate the incoming data into the appropriate form required by each DAC.

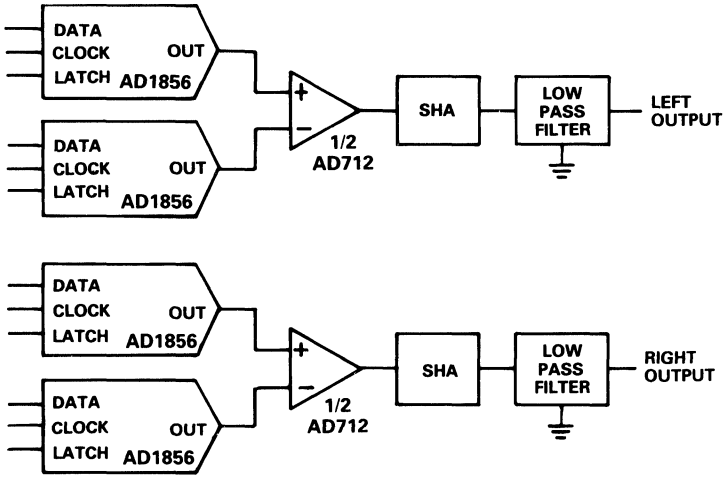

Figure 13. Two DACs per Channel Eliminate Midscale Distortion from the Zero-Crossing Points

DIGITAL FILTERING AND OVERSAMPLING

Oversampling is a term which refers to playback techniques in which the reconstruction frequency used is an integral (2 or more) multiple of the original quantized data rate. For example, in compact disc stereo digital audio playback units, the original quantized data sample rate is 44.1kHz. Popular oversampling rates are 2× or 4× F_S yielding reconstruction rates of 88.2 and 176.4kHz, respectively.

Oversampling is used to ease the performance constraints of the low-pass filters which usually follow the reconstruction DAC. In any signal reconstructed from sampled data, unwanted frequency components are introduced in the output spectrum; these components are centered at the reconstruction frequency. When a 44.1kHz reconstruction frequency is used, the actual frequency band of interest is 20Hz to 20kHz, and the band of unwanted "image" frequency components extends from 44.1kHz to approximately 24kHz and from 44.1kHz to 64kHz.

These unwanted components must be removed with a low-pass filter of very high order. First generation digital audio systems often use low-pass filters of 9, 11 and even 13 poles. Linear implementations of these filters are expensive, difficult to manufacture and can produce distortion due to varying group delay characteristics.

When a 2× reconstruction frequency (88.2kHz) is used, the lowest unwanted frequency components now extend down to approximately 68kHz. A 4× rate (176.4kHz) has unwanted components extending down to approximately 156kHz. The filter response needed to remove these frequency components can now be less steep. This means that a lower order filter may be used resulting in less distortion at lower cost. Linear filters with 3 or 5 poles are adequate to do the job and are quite common in digital audio products employing oversampling techniques.

Oversampling techniques require that the serial input data stream run at the same integral multiple of the original data rate. So, while the constraints on the output low-pass filter are eased, the constraints on the serial digital input port and the settling time of the output stage are not.

The actual oversampling operation takes place in the digital filter chip which is located "upstream" from the DAC. The digital filter accepts data from the media and adds the additional reconstruction points according to the algorithm and coefficients stored in the filter chip. Since the digital filters actually interpolate these additional reconstruction points, they have earned the name "interpolation filters."

The AD1856 is compatible with popular digital filter chips used in digital audio products such as the NPC SM5807, NPC SM5805, Yamaha YM3414, and Sony CXD1136.

DUAL DAC, 4× F_S OVERSAMPLING ARCHITECTURE

Figure 14 illustrates the use of an NPC digital filter chip with two AD1856 audio DACs. This scheme achieves four times oversampling reconstruction with a dedicated DAC per channel. In this example of a typical compact disc player application, the digital filter chip accepts serial input words from the digital decoder/processor at a 44.1kHz sample rate. Through the use of oversampling, the SM5807 transmits data to the two DACs at a 176.4kHz rate. The serial DAC input data is sent out of the DOUT pin to the serial inputs of the DACs. Left channel and right channel data are sent alternately down the same wire. The Left/Right Channel Output signal, $\overline{\text{LRCO}}$ and two logic gates demultiplex the data clock signals from BCKO. In this example, the BCKO rate is 192×F_S. However, a 196×F_S clock can be used if $\overline{\text{SCSL}}$ is wired to a logic zero. Finally, left and right channel deglitching signals are provided. At the user's option, these signals may be used to control external sample-hold amplifiers in order to obtain optimal performance.

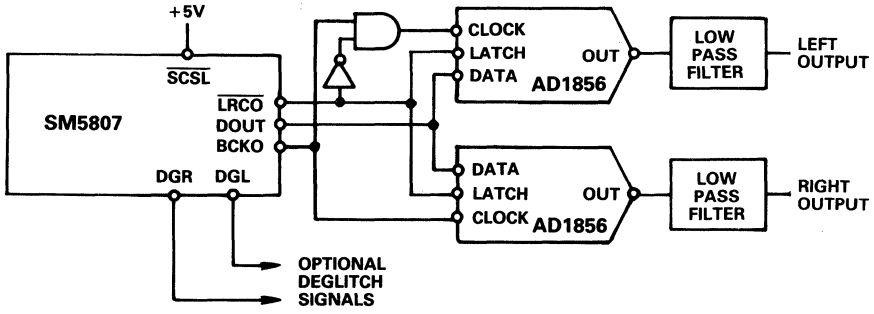

Figure 14. NPC SM5807 and AD1856 Interface

ACHIEVING 8× F_S OVERSAMPLING WITH AD1856S AND YAMAHA YM3414

Figure 15 illustrates the combination of a Yamaha YM3414 digital filter chip and two AD1856 audio DACs. In this scheme, the use of a 16.9344MHz clock allows an 8 times oversampling rate for extremely high performance. In addition, a lower-order low-pass filter may be used without sacrificing performance. The DAC input data is simultaneously transmitted to the input registers of the DACs through dedicated left and right channel output pins on the YM3414. As before, optional sample/hold signals are provided.

ANALOG DEVICES

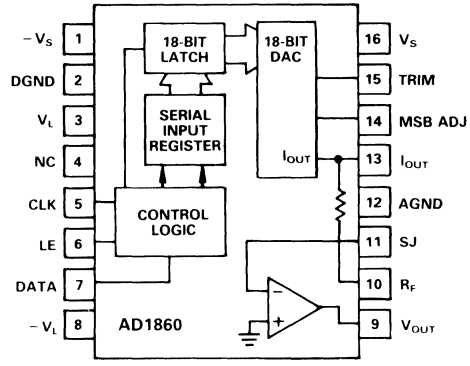
18-Bit PCM Audio DAC

AD1860

FEATURES
- 0.002% THD + Noise
- Fast Settling Permits 8× Oversampling
- ±3V Output
- Optional Trim Allows Superlinear Performance
- ±5V to ±12V Operation
- 16-Pin Plastic DIP and SOIC Packages
- Industry Standard Pinout
- 2s Complement, Serial Input

APPLICATIONS
- High End Compact Disc Players
- Digital Audio Amplifiers
- DAT Recorders and Players
- Synthesizers and Keyboards

AD1860 FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD1860 is a monolithic 18-bit PCM Audio DAC. Each device provides a voltage output amplifier, 18-bit DAC, 18-bit serial to parallel input register and voltage reference. The digital portion of the AD1860 is fabricated with CMOS logic elements that are provided by Analog Devices' BiMOS II process. The analog portion of the AD1860 is fabricated with bipolar and MOS devices as well as thin film resistors.

This combination of circuit elements, as well as careful design and layout techniques, results in high performance audio playback. Laser trimming of the linearity error affords extremely low total harmonic distortion. An optional linearity trim pin is provided to allow residual differential linearity error at midscale to be eliminated. This feature is particularly valuable for low distortion reproductions of low amplitude signals. Output glitch is also small contributing to the overall high level of performance. The output amplifier achieves fast settling and high slew rates, providing a full ±3V signal at load currents up to 8mA. When used in current output mode, the AD1860 provides a ±1mA output signal. The output amplifier is short circuit protected and can withstand indefinite shorts to ground.

The serial input interface consists of the clock, data and latch enable pins. The serial 2s complement data word is clocked into the DAC, MSB first, by the external data clock. The latch enable signal transfers the input word from the internal serial input register to the parallel DAC input register. The input clock can support a 12.5MHz data rate. This serial input port is compatible with second generation digital filter chips used in consumer audio products. These filters operate at oversampling rates of 2×, 4× and 8× sampling frequencies.

The AD1860 can operate with ±5V to ±12V power supplies making it suitable for both the portable and home use markets. The digital supplies, V_L and $-V_L$, can be separated from the analog supplies, V_S and $-V_S$, for reduced digital crosstalk. Separate analog and digital ground pins are also provided.

Power dissipation is 110mW typical with ±5V supplies and is 225mW typical when +5V/−12V supplies are used.

The AD1860 is available in either a 16-pin plastic DIP or a 16-pin plastic SOIC surface mount package. Operation is guaranteed over the temperature range of −25°C to +70°C and over the voltage supply range of ±4.75 to ±13.2V.

PRODUCT HIGHLIGHTS

1. 18-bit resolution provides 108dB dynamic range.
2. No external components are required.
3. Operates with ±5V to ±12V supplies.
4. 16-pin DIP or space saving SOIC package.
5. 110mW power dissipation.
6. 1.5μs settling time permits 2×, 4× and 8× oversampling.
7. ±3V or ±1mA output capability.
8. THD + Noise is 100% tested.

TOTAL HARMONIC DISTORTION + NOISE

Total Harmonic Distortion plus Noise (THD+N) is defined as the ratio of the square root of the sum of the squares of the values of the harmonics and noise to the value of the fundamental input frequency. It is usually expressed in percent (%).

THD+N is a measure of the magnitude and distribution of linearity error, differential linearity error, quantization error and noise. The distribution of these errors may be different, depending on the amplitude of the output signal. Therefore, to be most useful, THD+N should be specified for both large and small signal amplitudes.

SETTLING TIME

Settling Time is the time required for the output to reach and remain within a specified error band about its final value, measured from the digital input transition. It is a primary measure of dynamic performance.

DYNAMIC RANGE

Dynamic Range is the specification that indicates the ratio of the smallest signal the converter can resolve to the largest signal it is able to produce. As a ratio, it is usually expressed in decibels (dBs). The theoretical dynamic range of an n-bit converter is (6×n) dB. In the case of the 18-bit AD1860, that is 108dB. The actual dynamic range of a converter is less than the theoretical value due to limitations imposed by noise and other errors.

MIDSCALE ERROR

Midscale Error, or bipolar zero error, is the deviation of the actual analog output from the ideal output (0V) when the 2s complement input code representing half scale is loaded in the input register.

DIFFERENTIAL LINEARITY ERROR

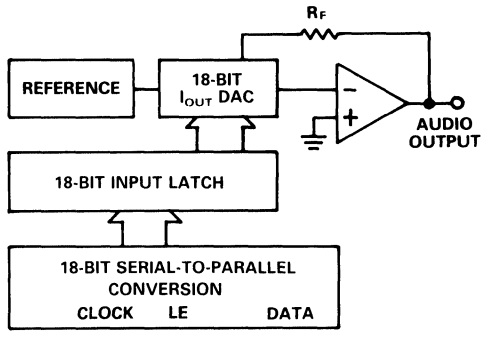
Differential Linearity Error is the measure of the variation in analog value, normalized to full scale, associated with a 1LSB change in the digital input. Monotonic behavior requires that the differential linearity error not exceed 1LSB in the negative direction.

MONOTONICITY

A D/A converter is monotonic if the output either increases or remains constant as the digital input increases.

SIGNAL-TO-NOISE RATIO

The Signal-to-Noise Ratio is defined as the ratio of the amplitude of the output with no signal present to the amplitude of the output when a full-scale output is present. This is measured with a standard A-Weight filter.



AD1860 Block Diagram

FUNCTIONAL DESCRIPTION

The AD1860 is a complete monolithic 18-bit PCM Audio DAC. No additional external components are required for operation. As shown in the block diagram, each chip contains a voltage reference, an output amplifier, an 18-bit DAC, an 18-bit input latch and an 18-bit serial to parallel input register.

The voltage reference consists of a bandgap circuit and buffer amplifier. This combination of elements produces a reference voltage that is unaffected by changes in temperature and age. The DAC output voltage, which is derived from the reference voltage, is also unaffected by these environmental changes.

The output amplifier uses both MOS and bipolar devices to produce low offset, high slew rate and optimum settling time. When combined with the on chip feedback resistor, the output op amp converts the output current of the AD1860 to a voltage output.

The 18-bit D/A converter uses a combination of segmented decoder and R-2R architecture to achieve consistent linearity and differential linearity. The resistors which form the ladder structure are fabricated with silicon chromium thin film. Laser trimming of these resistors further reduces linearity error resulting in low output distortion.

The input register and serial to parallel converter are fabricated with CMOS logic gates. These gates allow the achievement of fast switching speeds and low power consumption. This contributes to the overall low power dissipation of the AD1860.

Analog Circuit Considerations

GROUNDING RECOMMENDATIONS

The AD1860 has two pins, designated Analog and Digital ground. The analog ground pin is the "high quality" ground reference point for the device. The analog ground pin should be connected to the analog common point in the system. The output load should also be connected to that same point.

The digital ground pin returns ground current from the digital logic portions of the AD1860 circuitry. This pin should be connected to the digital common point in the system.

As illustrated in Figure 1, the analog and digital grounds should be connected together at one point in the system.

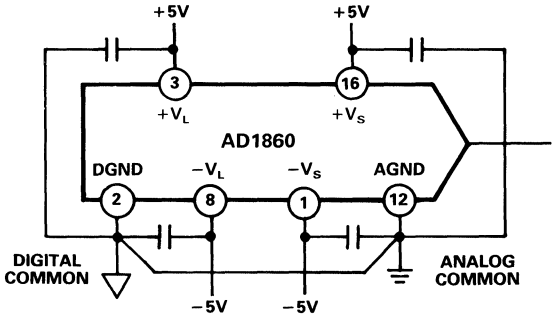


Figure 1. Recommended Circuit Schematic

POWER SUPPLIES AND DECOUPLING

The AD1860 has four power supply input pins. $\pm V_S$ provide the supply voltages to operate the linear portions of the DAC including the voltage reference, output amplifier and control amplifier. The $\pm V_S$ supplies are designed to operate from ±5V to ±12V.

The $\pm V_L$ supplies operate the digital portions of the chip including the input shift register and the input latching circuitry. The $\pm V_L$ supplies are also designed to be operated from ±5V to ±12 V subject only to the limitation that $-V_L$ may not be more negative than $-V_S$.

Decoupling capacitors should be used on all power supply pins. Furthermore, good engineering practice suggests that these capacitors be placed as close as possible to the package pins as well as the common points. The logic supplies, $\pm V_L$, should be decoupled to digital common; and the analog supplies, $\pm V_S$, should be decoupled to analog common.

The use of four separate power supplies will reduce feedthrough from the digital portion of the system to the linear portion of the system, thus contributing to good performance. However, four separate voltage supplies are not necessary for good circuit performance. For example, Figure 2 illustrates a system where only a single positive and a single negative supply are available.

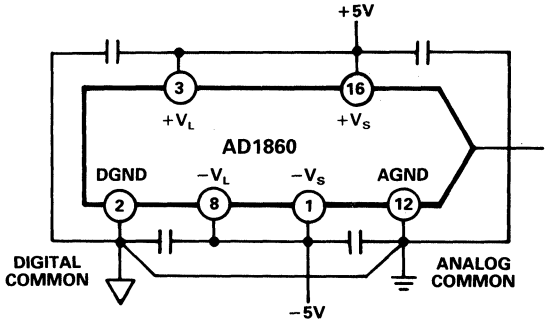

Figure 2. Typical Power Supply Sensitivity

Given that these two supplies are within the range of ±5V to ±12V, they may be used to power the AD1860. In this case, the positive logic and positive analog supplies may both be connected to the single positive supply. The negative logic and negative analog supplies may both be connected to the single negative supply. Performance would benefit from a measure of isolation between the supplies introduced by using simple low pass filters in the individual power supply leads.

As with most linear circuits, changes in the power supplies will affect the output of the DAC. Analog Devices recommends that well regulated power supplies with less than 1% ripple be incorporated into the design of any system using these devices.

TOTAL HARMONIC DISTORTION + NOISE

The THD figure of an audio DAC represents the amount of undesirable signal produced during reconstruction and playback of an audio waveform. The THD specification, therefore, provides a direct method to classify and choose an audio DAC for a desired level of performance.

By combining noise measurement with THD measurement, a THD+N specification is produced. This specification measures all undesirable signal produced by the DAC, including harmonic products of the test tone as well as noise.

Analog Devices tests and grades all AD1860s on the basis of THD+N performance. A block diagram of the test setup is shown in Figure 3. In this test setup, a digital data stream representing a 0dB, −20dB or −60dB sinewave is sent to the device under test. The frequency of this waveform in 990.5 Hz.

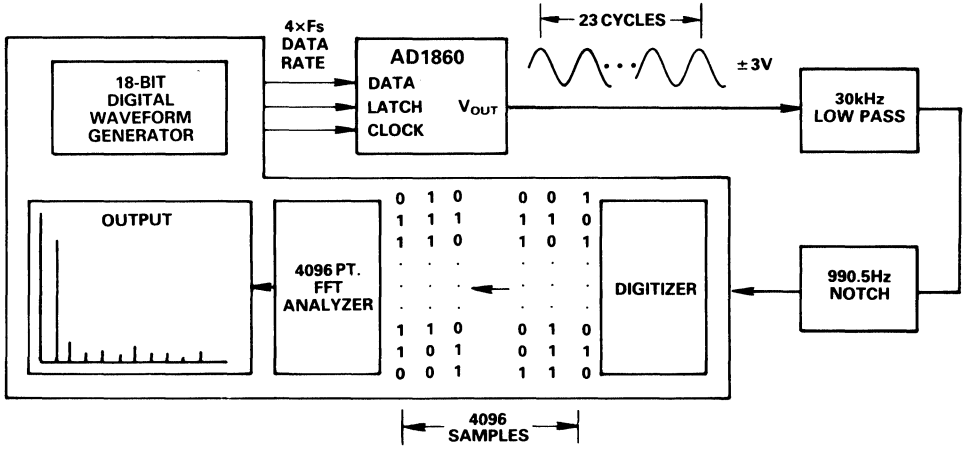

Figure 3. Block Diagram of DistortionTest Circuit

Input data is sent to the AD1860 at a $4\times F_S$ rate (176.4kHz). The AD1860 under test produces an output signal with its onboard op amp. The automatic test equipment digitizes 4096 samples of the output test waveform, incorporating 23 complete cycles of the sinewave. A 4096 point FFT is performed on the results of the test. Based on the harmonics of the fundamental 990.5Hz test tone and the noise components, the total harmonic distortion + noise of the device is calculated. Neither a deglitcher nor an MSB trim is used during this test.

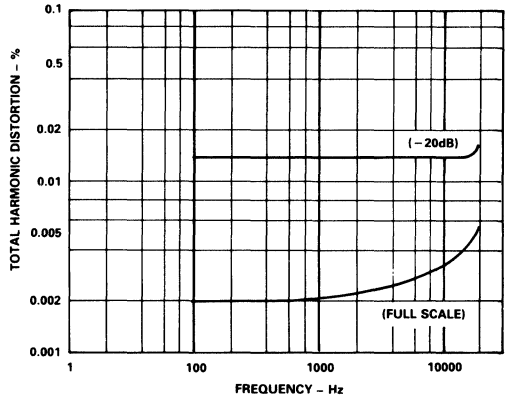

Figure 4. Typical THD vs Frequency

The circuit design, layout and manufacturing techniques employed in the production of the AD1860 result in excellent THD performance. Figure 4 shows the typical unadjusted THD performance of the AD1860 for various amplitudes and frequencies of output signals. As can be seen, the AD1860 offers excellent performance, even at low amplitudes.

OPTIONAL MSB ADJUSTMENT

Use of an optional adjust circuitry allows residual differential linearity error around midscale to be eliminated. This error is especially important when low amplitude signals are being reproduced. In those cases, as the signal amplitude decreases, the ratio of the midscale differential linearity error to the signal amplitude increases, thereby increasing THD.

Therefore, for best performance at low output levels, the optional MSB adjust circuitry shown in Figure 5 may be used to improve performance.

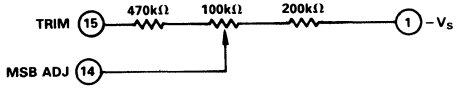

Figure 5. Optional THD Adjust Circuit

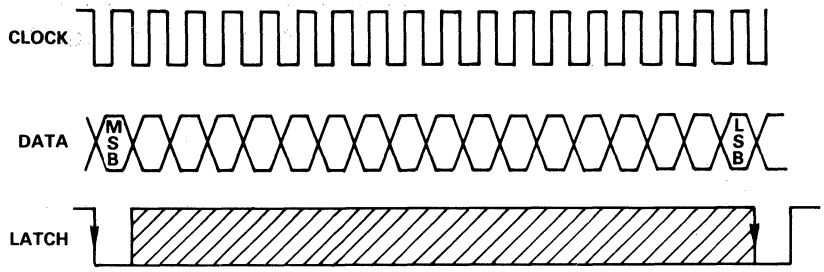

Figure 6. Signal Requirements for AD1860

DIGITAL CIRCUIT CONSIDERATIONS

Input Data

Data is transmitted to the AD1860 in a bit stream composed of 18-bit words with a serial, MSB first format. Three signals must be present to achieve proper operation. They are the Data, Clock and Latch Enable signals. Input data bits are clocked into the input register on the rising edge of the Clock signal. The LSB is clocked in on the 18th clock pulse. When all data bits are loaded, a low-going Latch Enable pulse updates the DAC input. Figure 6 illustrates the general signal requirements for data transfer for the AD1860.

Timing

Figure 7 illustrates the specific timing requirements that must be met in order for the data transfer to be accomplished properly. The input pins of the AD1860 are both TTL and 5V CMOS compatible, independent of the power supplies used. The input requirements illustrated in Figures 6 and 7 are compatible with the data outputs provided by popular DSP filter chips used in digital audio playback systems. The AD1860 input clock can run at a 12.5MHz rate. This clock rate will allow data transfer rates for 2×, 4× or 8× oversampling reconstruction. The application section of this datasheet contains additional guides for using the AD1860 with various DSP filter chips available from Sony, NPC and Yamaha.

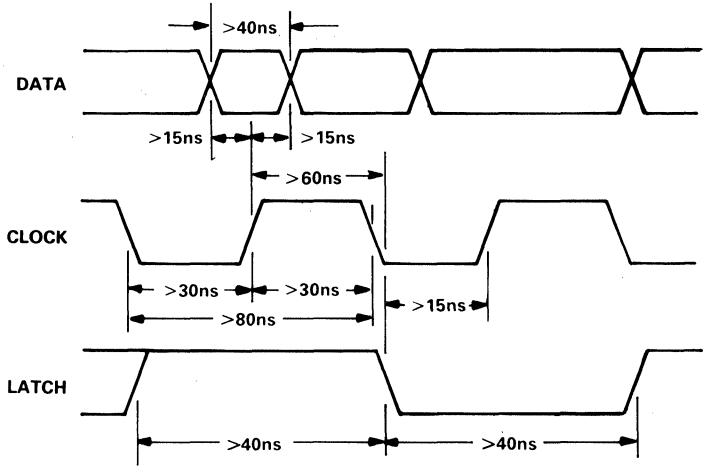

Figure 7. Timing Relationships of Input Signals

APPLICATIONS OF THE AD1860 PCM AUDIO DAC

The AD1860 is a versatile digital-to-analog converter designed for applications in consumer digital audio equipment. Portable, car and home compact disc player, digital audio amplifier and DAT schemes can all use the AD1860. Various circuit architectures are popular in these systems. They include stereo playback sections featuring one DAC per system, one DAC per audio channel (left/right) or multiple DACs per channel. Furthermore, these architectures use different output reconstruction rates to accomplish these functions including reproduction at the sample rate F_S (1×), at twice the sample rate (2×F_S), at four times the sample rate (4×F_S) and even at eight times the sample rate (8×F_S). F_S is 44.1kHz for CD and 48kHz for DAT applications.

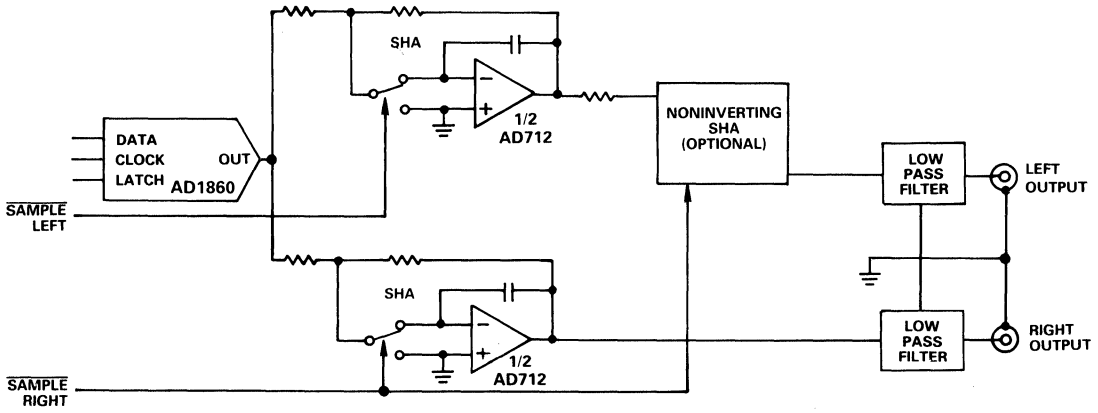

Figure 8. AD1860 in a One DAC per System Architecture

One DAC per System

Figure 8 shows a circuit using one AD1860 per system to reproduce both channels of a typical first generation stereo digital audio system. The input data is fed to the AD1860 in a format which alternates between left channel data and right channel data. The output of the AD1860 is switched between the left channel and right channel output sample/hold amplifiers (SHAs). The SHAs demultiplex and deglitch the output of the AD1860. The timing diag-am for the control signals for this circuit are shown in Figure 9.

However, when only two SHAs are used, the actual system performance is limited by the phase delay introduced by the demultiplexed format. This undesirable phase delay is caused by the fact that the data words presented to the inputs of the DAC represent samples taken at precisely the same point in time. But when reconstructed and demultiplexed by a single DAC, these same outputs occur at slightly different times.

By incorporating a noninverting SHA into the circuit, the phase delay can be eliminated. In Figure 8, the optional SHA ensures that the left channel output appears at the same time as the right channel output. This minor change to the circuit eliminates the artificially induced phase delay by restoring simultaneous outputs.

Following the outputs of the SHAs are low pass filters. These filters are required in any sampled data system to remove unwanted aliased components introduced by the sample and reconstruction operations.

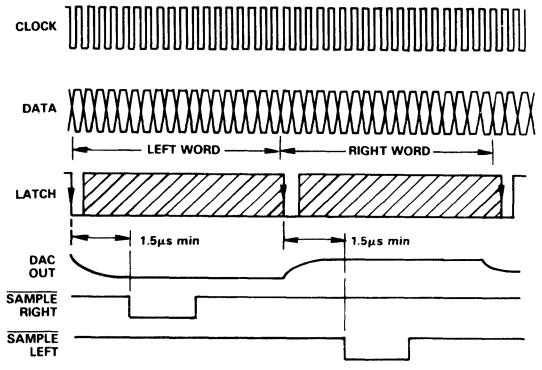

Figure 9. Control Signals for One DAC Circuit

One DAC per Channel

A second approach used to eliminate phase delay between left and right channels employs one DAC per channel. In this architecture, the input data bitstream for each channel is transmitted and then latched into the input register of each DAC. This "second generation" approach is illustrated in Figure 10. A standard implementation of a low pass filter is shown at the output of each DAC. An optional sample/hold amplifier could be connected between the DACs and the LPFs to deglitch the outputs. This is not required, however, to achieve the specified performance.

Two DACs per Channel

Another architecture uses two DACs per channel. In this scheme each DAC reproduces one half of the output waveform. The advantage obtained with this structure is that midscale differential linearity error no longer affects the zero crossing points of the waveforms. Its effects are shifted to the points where the output waveform crosses ±3/4 full scale. The result is that THD performance for low amplitude signals is greatly improved.

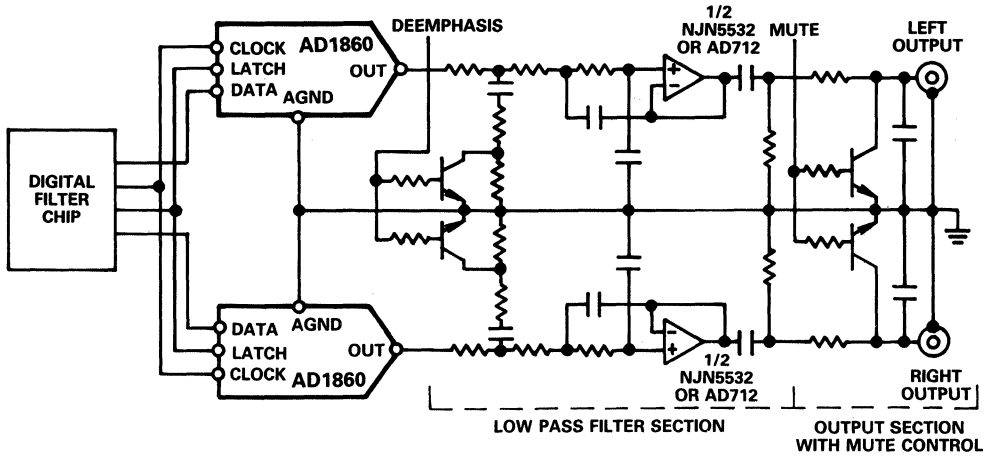

Figure 10. One DAC per Channel Architecture with LPF

DIGITAL FILTERING AND OVERSAMPLING

Oversampling is a term which refers to playback techniques in which the reconstruction frequency used is an integral (2 or more) multiple of the original quantized data rate. For example, in compact disc stereo digital audio playback units, the original quantized data sample rate is 44.1kHz. Popular oversampling rates are 2× or 4×F_S, yielding reconstruction rates of 88.2 and 176.4kHz, respectively.

Oversampling is used to ease the performance constraints of the low pass filters which follow the reconstruction DAC. In any signal reconstructed from sampled data, unwanted frequency components are introduced in the output spectrum; these components are centered at the reconstruction frequency. When a 44.1kHz reconstruction frequency is used, the actual frequency band of interest is 20Hz to 20kHz, and the band of unwanted "image" frequency components extends from 44.1kHz to approximately 24kHz. These unwanted components must be removed with a low-pass filter of very high order. First generation digital audio systems often used low-pass filters of 9, 11 and even 13 poles. Linear implementations of these filters are expensive, difficult to manufacture and can produce distortion due to varying group delay characteristics.

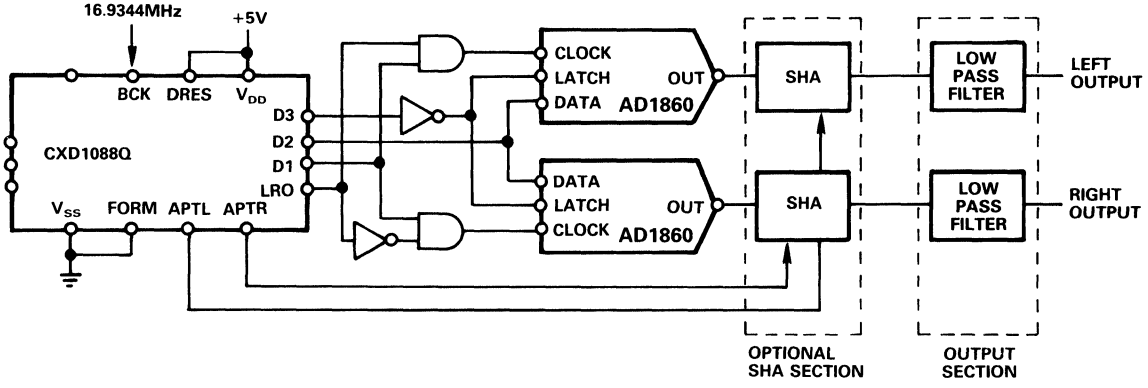
When a 2×reconstruction frequency (88.2kHz) is used, the lowest frequency components now extend down to approximately 68kHz. A 4×rate (176.4kHz) has unwanted components extending down to approximately 156kHz. The filter response needed to remove these frequency components can now be less steep. This means that a lower order filter may be used resulting in less distortion at lower cost. Linear filters with 3 or 5 poles, as shown in Figure 10, are adequate to do the job and are quite common in digital audio products employing oversampling techniques.

Oversampling techniques require the serial input data stream to run at the same integral multiple of the original data rate. So, while the constraints on the output low-pass filter are eased, the constraints on the serial digital input port and the settling time of the output stage are not.

The actual oversampling operation takes place in the digital filter chip (DSP) which is located "upstream" from the DAC. The digital filter accepts data from the media and adds the additional reconstruction points according to the algorithm and coefficients stored in the filter chip. Since the digital filters actually interpolate these additional reconstruction points, they have earned the name "interpolation filters".

The AD1860 is compatible with popular digital filter chips used in digital audio products such as the Sony CXD1088, the Yamaha YM3434 and the NPC SM5813.

Figure 11 illustrates the combination of a second generation digital filter chip, the Sony CXD1088, and the AD1860 audio DAC. The digital filter chip provides 18-bit data words to the DACs at $4\times F_S$. Very high performance can be achieved.



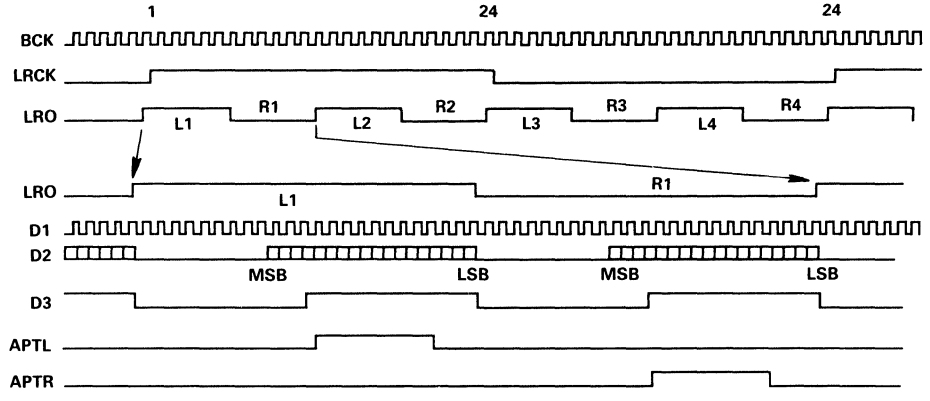


Figure 11. $4\times F_S$ with the CXD1088Q

Figure 12 illustrates the combination of a Yamaha YM3434 digital filter chip and two AD1860 audio DACs. This combination of components results in $8\times F_S$ oversampling reconstruction rates. This rate allows the use of lower order output low pass filters than would be required with lower oversampling rates, without sacrificing performance. In this high performance CD player application, the DAC input data is simultaneously transmitted to the input registers of the DACs through dedicated left and right channel output pins on the YM3434. This implementation does not require any external components to achieve the full 108dB dynamic range afforded by the 18-bit AD1860 audio DAC. As before, optional sample/hold signals are provided.

Figure 13 shows the schematic for $8\times F_S$ when two AD1860s are used with an NPC SM5813AP/APT digital filter chip. As can be seen, this application is very similar to the one shown in Figure 12. See Figure 10 for an example of a typical LPF.

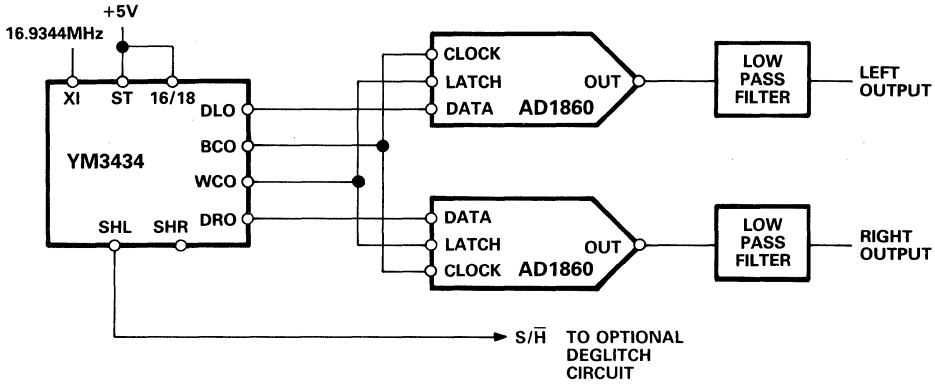

Figure 12. YM3434 and AD1860 Achieve $8\times F_S$

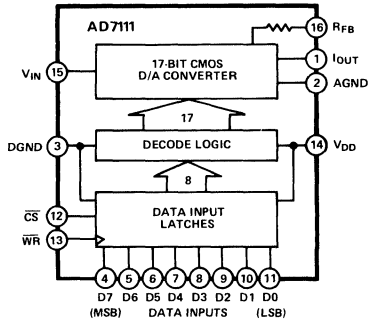
AD7111 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The LOGDAC™ AD7111 is a CMOS multiplying D/A converter which can attenuate an analog input signal over the range 0 to −88.5dB in 0.375dB steps.

The degree of attenuation is determined by an 8-bit data word which is latched into on-chip data latches using microprocessor compatible control signals $\overline{CS}$ and $\overline{WR}$. Operating frequency range of the device is from dc to several hundred kHz.

The device is available in a standard 16-pin DIP and in a 20-terminal surface mount package.

*U.S. Patent No. 4521764
LOGDAC is a trademark of Analog Devices, Inc.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

2

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

TERMINOLOGY

RESOLUTION: Nominal change in attenuation when moving between two adjacent codes.

MONOTONICITY: The device is monotonic if the analog output decreases (or remains constant) as the digital code increases.

FEEDTHROUGH ERROR: That portion of the input signal which reaches the output when all digital inputs are high. See section on Applications.

OUTPUT LEAKAGE CURRENT: Current which appears on the I_{OUT} terminal with all digital inputs high.

TOTAL HARMONIC DISTORTION: A measure of the harmonics introduced by the circuit when a pure sinusoid is applied to the input. It is expressed as the harmonic energy divided by the fundamental energy at the output.

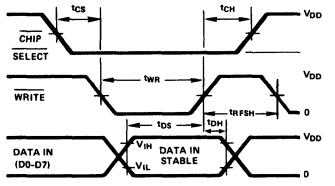
ACCURACY: The difference (measured in dB) between the ideal transfer function as listed in Table I and the actual transfer function as measured with the device.

OUTPUT CAPACITANCE: Capacitance from I_{OUT} to ground.

DIGITAL TO ANALOG GLITCH IMPULSE: The amount of charge injected from the digital inputs to the analog output when the inputs change state. This is normally specified as the area of the glitch in either pA-Secs or nV-Secs depending upon whether the glitch is measured as a current or voltage signal. Glitch impulse is measured with V_{IN} = AGND.

PROPAGATION DELAY: This is a measure of the internal delays of the circuit and is defined as the time from a digital input change to the analog output current reaching 90% of its final value.

WRITE CYCLE TIMING DIAGRAM



NOTES:
1. ALL INPUT SIGNAL RISE AND FALL TIMES MEASURED FROM 10% TO 90% OF V_{DD}. V_{DD} = +5V, $t_r = t_f$ = 20ns.
2. TIMING MEASUREMENT REFERENCE LEVEL IS $\frac{V_{IH} + V_{IL}}{2}$

CIRCUIT DESCRIPTION

GENERAL CIRCUIT INFORMATION

The AD7111 consists of a 17-bit R-2R CMOS multiplying D/A converter with extensive digital logic. The logic translates the 8-bit binary input into a 17-bit word which is used to drive the D/A converter. Input data on the D7–D0 bus is loaded into the input data latches using $\overline{CS}$ and $\overline{WR}$ control signals. The rising edge of $\overline{WR}$ latches the input data and initiates the internal data transfer to the decoder. A minimum time t_{RFSH}, the refresh time, is required for the data to propagate through the decoder before a new data write is attempted.

The transfer function for the circuit of Figure 1 is given by:

$$V_O = -V_{IN}\ 10\ \exp - \frac{0.375\ N}{20}$$

or

$$\left|\frac{V_O}{V_{IN}}\right| \text{ dB} = -0.375\ N$$

Where 0.375 is the step size (resolution) in dB and N is the input code in decimal for values 0 to 239. For $240 \leqslant N \leqslant 255$ the output is zero. Table I gives the output attenuation relative to 0dB for all possible input codes.

The graphs on the last page give a pictorial representation of the specified accuracy and monotonic ranges for all grades of the AD7111. High attenuation levels are specified with less accuracy than low attenuation levels. The range of monotonic behavior depends upon the attenuation step size used. For example, the AD7111L is guaranteed monotonic in 0.375dB steps from 0 to -54dB inclusive and in 0.75dB steps from 0 to -72dB inclusive. To achieve monotonic operation over the entire 88.5dB range it is necessary to select input codes so that the attenuation step size at any point is consistent with the step size guaranteed for monotonic operation at that point.

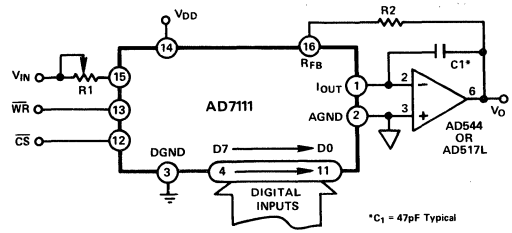

Figure 1. Typical Circuit Configuration

EQUIVALENT CIRCUIT ANALYSIS

Figure 2 shows a simplified circuit of the D/A converter section of the AD7111 and Figure 3 gives an approximate equivalent circuit.

The current source $I_{LEAKAGE}$ is composed of surface and junction leakages and as with most semiconductor devices, approximately doubles every 10°C—see Figure 11. The resistor R_O as shown in Figure 3 is the equivalent output resistance of the device which varies with input code (excluding all 0's code) from 0.8R to 2R. R is typically 11kΩ. C_{OUT} is the capacitance due to the N channel switches and varies from about 60pF to 185pF depending upon the digital input. For further information on CMOS multiplying D/A converters refer to "Application Guide to CMOS Multiplying D/A converters" which is available from Analog Devices, Publication Number G479—15—8/78.

Table I. Ideal Attenuation in dB vs. Input Code

DYNAMIC PERFORMANCE

The dynamic performance of the AD7111 will depend upon the gain and phase characteristics of the output amplifier, together with the optimum choice of PC board layout and decoupling components. Figure 4 shows a printed circuit layout which minimizes feedthrough from V_{IN} to the output in multiplying applications. Circuit layout is most important if the optimum performance of the AD7111 is to be achieved. Most application problems stem from either poor layout, grounding errors, or inappropriate choice of amplifier.

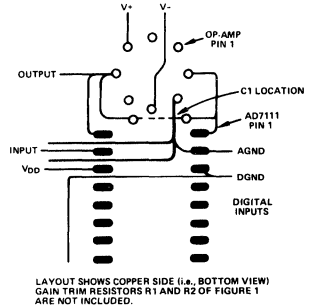

Figure 4. Suggested Layout for AD7111 and Op-Amp

It is recommended that when using the AD7111 with a high speed amplifier, a capacitor (C1) be connected in the feedback path as shown in Figure 1. This capacitor, which should be between 30pF and 50pF, compensates for the phase lag introduced by the output capacitance of the D/A converter. Figures 5 and 6 show the performance of the AD7111 using the AD517, a fully compensated high gain superbeta amplifier, and the AD544, a fast FET input amplifier. The performance without C1 is shown in the middle trace and the response with C1 in circuit is shown in the bottom trace.

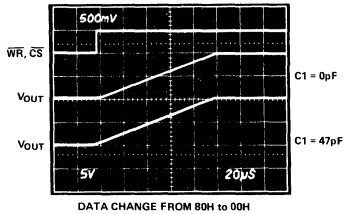

Figure 5. Response of AD7111 with AD517

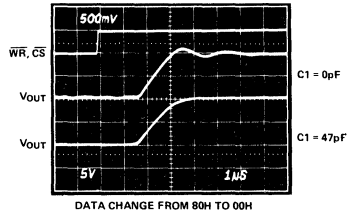

Figure 6. Response of AD7111 with AD544

In conventional CMOS D/A converter design parasitic capacitance in the N-channel D/A converter switches can give rise to glitches on the D/A converter output. These glitches result from digital feedthrough. The AD7111 has been designed to minimize these glitches as much as possible.

For operation beyond 250kHz, capacitor C1 may be reduced in value. This gives an increase in bandwidth at the expense of a poorer transient response as shown in Figures 6 and 12. In circuits where C1 is not included the high frequency roll-off point is primarily determined by the characteristics of the output amplifier and not the AD7111.

Feedthrough and absolute accuracy are sensitive to output leakage current effects. For this reason it is recommended that the operating temperature of the AD7111 be kept as close to 25°C as is practically possible, particularly where the device's performance at high attenuation levels is important. A typical plot of leakage current vs. temperature is shown in Figure 11.

Some solder fluxes and cleaning materials can form slightly conductive films which cause leakage effects between analog input and output. The user is cautioned to ensure that the manufacturing process for circuits using the AD7111 does not allow such films to form. Otherwise the feedthrough, accuracy and maximum usable range will be affected.

STATIC ACCURACY PERFORMANCE

The D/A converter section of the AD7111 consists of a 17-bit R-2R type converter. To obtain optimum static performance at this level of resolution it is necessary to pay great attention to amplifier selection, circuit grounding, etc.

Amplifier input bias current results in a dc offset at the output of the amplifier due to the current flowing through the feedback resistor R_{FB}. It is recommended that an amplifier with an input bias current of less than 10nA be used (e.g., AD517 or AD544) to minimize this offset.

Another error arises from the output amplifier's input offset voltage. The amplifier is operated with a fixed feedback resistance, but the equivalent source impedance (the AD7111 output impedance) varies as a function of attenuation level. This has the effect of varying the "noise" gain of the amplifier, thus creating a varying error due to amplifier offset voltage. It is recommended that an amplifier with less than 50µV of input offset be used (such as the AD517 or AD OP-07) in dc applications. Amplifiers with higher offset voltage may cause audible "thumps" in ac applications due to dc output changes.

The AD7111 accuracy is specified and tested using only the internal feedback resistor. Any Gain Error (i.e., mismatch of R_{FB} to the R-2R ladder) that may exist in the AD7111 D/A converter circuit results in a constant attenuation error over the whole range. The AD7111 accuracy is specified relative to 0dB attenuation, hence "Gain" trim resistors—R1 and R2 in Figure 1—can be used to adjust $V_{OUT} = V_{IN}$ precisely (i.e., 0dB attenuation) with input code 00000000. The accuracy and monotonic range specifications of the AD7111 are not affected in any way by this gain trim procedure. For the AD7111L/C/U grades, suitable values for R1 and R2 of Figure 1 are R1 = 500Ω, R2 = 180Ω; for the K/B/T grades suitable values are R1 = 1000Ω, R2 = 270Ω. For additional information on gain error the reader is referred to Application Note "Gain Error and Gain Temperature Coefficient of CMOS Multiplying DACs" by Phil Burton available from Analog Devices Inc., Publication Number E630–10–6/81.

ANALOG DEVICES

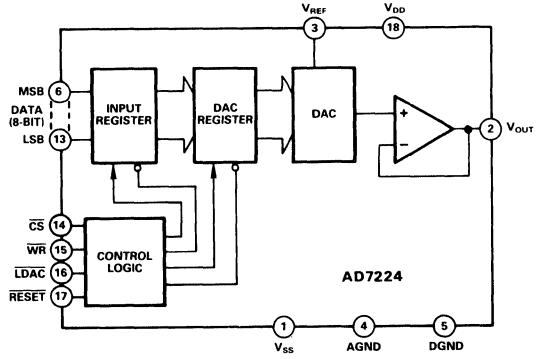
LC²MOS 8-Bit DAC with Output Amplifier

AD7224

FEATURES

8-Bit CMOS DAC with Output Amplifier
Operates with Single or Dual Supplies
Low Total Unadjusted Error:
Less than 1/2LSB Over Temperature
µP-Compatible with Double Buffered Input
Standard 18-Pin DIPs and 20-Terminal Surface Mount Packages

AD7224 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7224 is a precision 8-bit, voltage-output, digital-to-analog converter with output amplifier and double buffered interface logic on a monolithic CMOS chip. No external trims are required to achieve full specified performance for the part.

The double buffered interface logic consists of two 8-bit registers–an input register and a DAC register. Only the data held in the DAC register determines the analog output of the converter. The double buffering allows simultaneous update in a system containing multiple AD7224's. Both registers may be made transparent under control of three external lines, $\overline{CS}$, $\overline{WR}$ and $\overline{LDAC}$. With both registers transparent, the $\overline{RESET}$ line functions like a zero override; a useful function for system calibration cycles. All logic inputs are TTL and CMOS (5V) level compatible and the control logic is speed compatible with most 8-bit microprocessors.

Specified performance is guaranteed for input reference voltages from +2V to +12.5V when using dual supplies. The part is also specified for single supply operation using a reference of +10V. The output amplifier is capable of developing +10V across a 2kΩ load.

The AD7224 is fabricated in an all ion-implanted high speed Linear Compatible CMOS (LC²MOS) process which has been specifically developed to allow high speed digital logic circuits and precision analog circuits to be integrated on the same chip.

PRODUCT HIGHLIGHTS

1. DAC and Amplifier on CMOS Chip:
   The single-chip design of the 8-bit DAC and output amplifier is inherently more reliable than multi-chip designs. CMOS fabrication means low power consumption (35mW typical with single supply).
2. Low Total Unadjusted Error:
   The fabrication of the AD7224 on Analog Devices Linear Compatible CMOS (LC²MOS) process, coupled with a novel DAC switch-pair arrangement, enables an excellent total unadjusted error of less than 1LSB over the full operating temperature range.
3. Single or Dual Supply Operation:
   The voltage-mode configuration of the AD7224 allows operation from a single power supply rail. The part can also be operated with dual supplies giving enhanced performance for some parameters.
4. Versatile Interface Logic:
   The high speed logic allows direct interfacing to most microprocessors. Additionally, the double buffered interface enables simultaneous update of the AD7224 in multiple DAC systems. The part also features a zero override function.

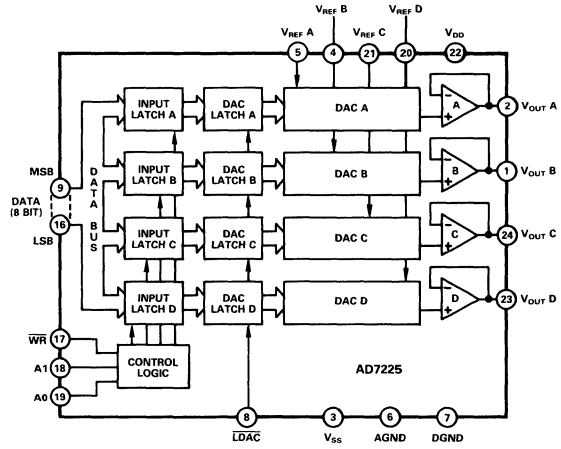
µP Compatible with Double-Buffered Inputs
Simultaneous Update of All Four Outputs
Operates with Single or Dual Supplies
No User Trims Required
Skinny 24-Pin DIPs and 28-Terminal Surface Mount Packages

AD7225 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7225 contains four 8-bit voltage output digital-to-analog converters, with output buffer amplifiers and interface logic on a single monolithic chip. Each D/A converter has a separate reference input terminal. No external trims are required to achieve full specified performance for the part.

The double-buffered interface logic consists of two 8-bit registers per channel–an input register and a DAC register. Control inputs A0 and A1 determine which input register is loaded when $\overline{WR}$ goes low. Only the data held in the DAC registers determines the analog outputs of the converters. The double-buffering allows simultaneous update of all four outputs under control of $\overline{LDAC}$. All logic inputs are TTL and CMOS (5V) level compatible and the control logic is speed compatible with most 8-bit microprocessors.

Specified performance is guaranteed for input reference voltages from +2V to +12.5V when using dual supplies. The part is also specified for single supply operation using a reference of +10V. Each output buffer amplifier is capable of developing +10V across a 2kΩ load.

The AD7225 is fabricated on an all ion-implanted high-speed Linear Compatible CMOS (LC² MOS) process which has been specifically developed to integrate high-speed digital logic circuits and precision analog circuitry on the same chip.

PRODUCT HIGHLIGHTS

1. DACs and Amplifiers on CMOS Chip:
   The single-chip design of four 8-bit DACs and amplifiers allows a dramatic reduction in board space requirements and offers increased reliability in systems using multiple converters. Its pinout is aimed at optimizing board layout with all analog inputs and outputs at one end of the package and all digital inputs at the other.
2. Single or Dual Supply Operation:
   The voltage-mode configuration of the AD7225 allows single supply operation. The part can also be operated with dual supplies giving enhanced performance for some parameters.
3. Versatile Interface Logic:
   The AD7225 has a common 8-bit data bus with individual DAC latches, providing a versatile control architecture for simple interface to microprocessors. The double-buffered interface allows simultaneous update of the four outputs.
4. Separate Reference Input for Each DAC:
   The AD7225 offers great flexibility in dealing with input signals with a separate reference input provided for each DAC and each reference having variable input voltage capability.

CIRCUIT INFORMATION

D/A SECTION

The AD7225 contains four, identical, 8-bit voltage-mode digital-to-analog converters. Each D/A converter has a separate reference input. The output voltages from the converters have the same polarity as the reference voltages, allowing single supply operation. A novel DAC switch pair arrangement on the AD7225 allows a reference voltage range from +2V to +12.5V on each reference input.

Each DAC consists of a highly stable, thin-film, R-2R ladder and eight high-speed NMOS, single-pole, double-throw switches. The simplified circuit diagram for channel A is shown in Figure 1. Note that AGND is common to all four DACs.

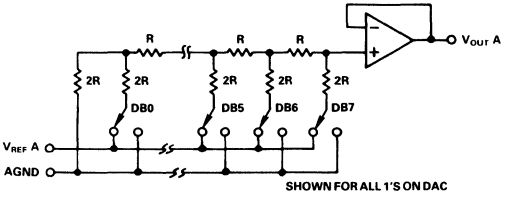

Figure 1. D/A Simplified Circuit Diagram

The input impedance at any of the reference inputs is code dependent and can vary from 11kΩ minimum to infinity. The lowest input impedance at any reference input occurs when that DAC is loaded with the digital code 01010101. Therefore, it is important that the reference presents a low output impedance under changing load conditions. The nodal capacitance at the reference terminals is also code dependent and typically varies from 15pF to 35pF.

Each V_{OUT} pin can be considered as a digitally programmable voltage source with an output voltage of:

$$V_{OUTX} = D_X \cdot V_{REFX}$$

where D_X is fractional representation of the digital input code and can vary from 0 to 255/256.

The output impedance is that of the output buffer amplifier.

OP-AMP SECTION

Each voltage mode D/A converter output is buffered by a unity gain noninverting CMOS amplifier. This buffer amplifier is capable of developing +10V across a 2kΩ load and can drive capacitive loads of 3300pF.

The AD7225 can be operated single or dual supply; operating with dual supplies results in enhanced performance in some parameters which cannot be achieved with single supply operation. In single supply operation (V_{SS} = 0V = AGND) the sink capability of the amplifier, which is normally 400μA, is reduced as the output voltage nears AGND. The full sink capability of 400μA is maintained over the full output voltage range by tying V_{SS} to −5V. This is indicated in Figure 2.

Settling-time for negative-going output signals approaching AGND is similarly affected by V_{SS}. Negative-going settling-time for single supply operation is longer than for dual supply operation. Positive-going settling-time is not affected by V_{SS}.

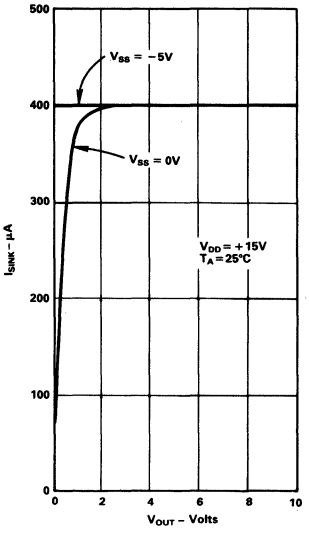

Figure 2. Variation of I_{SINK} with V_{OUT}

Additionally, the negative V_{SS} gives more headroom to the output amplifiers which results in better zero code performance and improved slew-rate at the output, than can be obtained in the single supply mode.

DIGITAL SECTION

The AD7225 digital inputs are compatible with either TTL or 5V CMOS levels. All logic inputs are static-protected MOS gates with typical input currents of less than 1nA. Internal input protection is achieved by an on-chip distributed diode between DGND and each MOS gate. To minimize power supply currents, it is recommended that the digital input voltages be driven as close to the supply rails (V_{DD} and DGND) as practically possible.

INTERFACE LOGIC INFORMATION

The AD7225 contains two registers per DAC, an input register and a DAC register. Address lines A0 and A1 select which input register will accept data from the input port. When the $\overline{WR}$ signal is LOW, the input latches of the selected DAC are transparent. The data is latched into the addressed input register on the rising edge of $\overline{WR}$. Table I shows the addressing for the input registers on the AD7225.

Only the data held in the DAC register determines the analog output of the converter. The $\overline{LDAC}$ signal is common to all four DACs and controls the transfer of information from the input registers to the DAC registers. Data is latched into all four DAC registers simultaneously on the rising edge of $\overline{LDAC}$. The $\overline{LDAC}$ signal is level triggered and therefore the DAC

A1	A0	Selected Input Register
L	L	DAC A Input Register
L	H	DAC B Input Register
H	L	DAC C Input Register
H	H	DAC D Input Register

Table I. AD7225 Addressing

registers may be made transparent by tying $\overline{LDAC}$ LOW (in this case the outputs of the converters will respond to the data held in their respective input latches). $\overline{LDAC}$ is an asynchronous signal and is independent of $\overline{WR}$. This is useful in many applications. However, in systems where the asynchronous $\overline{LDAC}$ can occur during a write cycle (or vice versa) care must be taken to ensure that incorrect data is not latched through to the output. In other words, if $\overline{LDAC}$ is activated prior to the rising edge of $\overline{WR}$ (or $\overline{WR}$ occurs during $\overline{LDAC}$), then $\overline{LDAC}$ must stay LOW for t_6 or longer after $\overline{WR}$ goes HIGH to ensure correct data is latched through to the output. Table II shows the truth table for AD7225 operation. Figure 3 shows the input control logic for the part and the write cycle timing diagram is given in Figure 4.

$\overline{WR}$	$\overline{LDAC}$	Function
H	H	No Operation. Device not selected
L	H	Input Register of Selected DAC Transparent
↓	H	Input Register of Selected DAC Latched
H	L	All Four DAC Registers Transparent (i.e. Outputs respond to data held in respective input registers)
		Input Registers are Latched
H	↓	All Four DAC Registers Latched
L	L	DAC Registers and Selected Input Register Transparent
		Output follows Input Data for Selected Channel.

Table II. AD7225 Truth Table

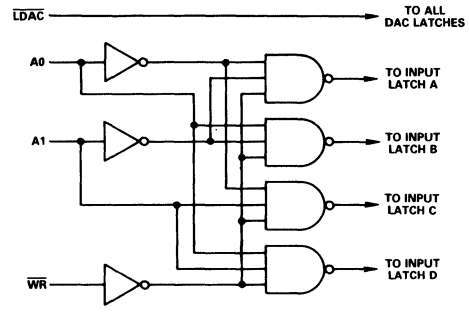

Figure 3. Input Control Logic

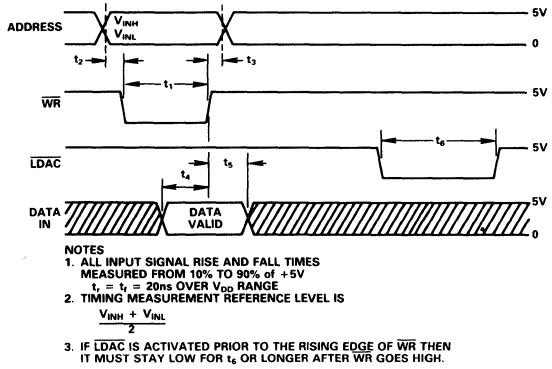

Figure 4. Write Cycle Timing Diagram

UNIPOLAR OUTPUT OPERATION

This is the basic mode of operation for each channel of the AD7225, with the output voltage having the same positive polarity as V_{REF}. The AD7225 can be operated single supply (V_{SS} = AGND) or with positive/negative supplies (see op-amp section which outlines the advantages of having negative V_{SS}). Connections for the unipolar output operation are shown in Figure 5. The voltage at any of the reference inputs must never be negative with respect to DGND. Failure to observe this precaution may cause parasitic transistor action and possible device destruction. The code table for unipolar output operation is shown in Table III.

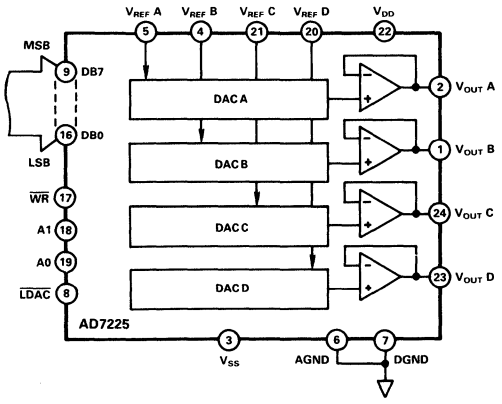

Figure 5. Unipolar Output Circuit

0000 0001	$+V_{REF}\left(\frac{1}{256}\right)$
0000 0000	0V

Note: $1LSB = (V_{REF})(2^{-8}) = V_{REF}\left(\frac{1}{256}\right)$

Table III. Unipolar Code Table

BIPOLAR OUTPUT OPERATION

Each of the DACs of the AD7225 can be individually configured to provide bipolar output operation. This is possible using one external amplifier and two resistors per channel. Figure 6 shows a circuit used to implement offset binary coding (bipolar operation) with DAC A of the AD7225. In this case

$$V_{OUT} = \left(1 + \frac{R2}{R1}\right) \cdot (D_A V_{REF}) - \left(\frac{R2}{R1}\right) \cdot (V_{REF})$$

With R1 = R2

$$V_{OUT} = (2D_A - 1) \cdot V_{REF}$$

where D_A is a fractional representation of the digital word in latch A. ($0 \leq D_A \leq 255/256$)

Mismatch between R1 and R2 causes gain and offset errors and, therefore, these resistors must match and track over temperature. Once again the AD7225 can be operated in single supply or from positive/negative supplies. Table IV shows the digital code versus output voltage relationship for the circuit of Figure 6 with R1 = R2.

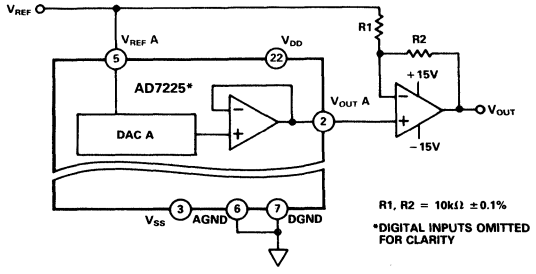

Figure 6. AD7225 Bipolar Output Circuit

Table IV. Bipolar (Offset Binary) Code Table

AC REFERENCE SIGNAL

In some applications it may be desirable to have ac reference signals. The AD7225 has multiplying capability within the upper (V_{DD} – 4V) and lower (2V) limits of reference voltage when operated with dual supplies. Therefore ac signals need to be ac coupled and biased up before being applied to the reference inputs. Figure 7 shows a sine wave signal applied to V_{REF} A. For input signal frequencies up to 50kHz the output distortion typically remains less than 0.1%. The typical 3dB bandwidth figure for small signal inputs is 800kHz.

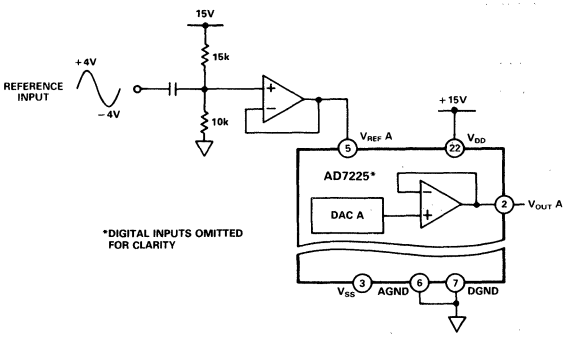

Figure 7. Applying an AC Signal to the AD7225

GROUND MANAGEMENT AND LAYOUT

Since the AD7225 contains four reference inputs which can be driven from ac sources (see AC REFERENCE SIGNAL section) careful layout and grounding is important to minimize analog crosstalk between the four channels. The dynamic performance of the four DACs depends upon the optimum choice of board layout. Figure 8 shows the relationship between input frequency and channel-to-channel isolation. Figure 9 shows a printed circuit board layout which is aimed at minimizing crosstalk and feed-through. The four input signals are screened by AGND. V_{REF} was limited to between 2V and 3.24V to avoid slew rate limiting effects from the output amplifier during measurements.

ANALOG DEVICES

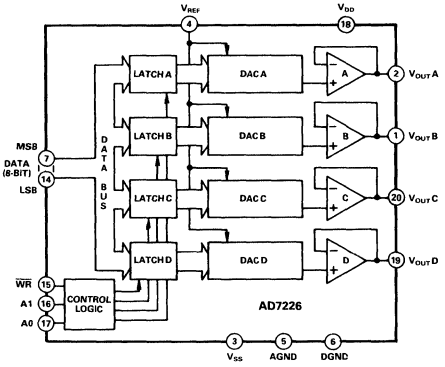
LC²MOS Quad 8-Bit D/A Converter

AD7226

FEATURES
- Four 8-Bit DACs with Output Amplifiers
- Skinny 20-Pin DIPs and 20-Terminal Surface Mount Packages
- Microprocessor Compatible
- TTL/CMOS Compatible
- No User Trims
- Single Supply Operation Possible

APPLICATIONS
- Process Control
- Automatic Test Equipment
- Automatic Calibration of Large System Parameters e.g., Gain/Offset

AD7226 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7226 contains four 8-bit voltage-output digital-to-analog converters, with output buffer amplifiers and interface logic on a single monolithic chip. No external trims are required to achieve full specified performance for the part.

Separate on-chip latches are provided for each of the four D/A converters. Data is transferred into one of these data latches through a common 8-bit TTL/CMOS (5V) compatible input port. Control inputs A0 and A1 determine which DAC is loaded when $\overline{WR}$ goes low. The control logic is speed-compatible with most 8-bit microprocessors.

Each D/A converter includes an output buffer amplifier capable of driving up to 5mA of output current. The amplifiers' offsets are laser-trimmed during manufacture, thereby eliminating any requirement for offset nulling.

Specified performance is guaranteed for input reference voltages from +2V to +12.5V with dual supplies. The part is also specified for single supply operation at a reference of +10V.

The AD7226 is fabricated in an all ion-implanted high speed Linear Compatible CMOS (LC²MOS) process which has been specifically developed to allow high speed digital logic circuits and precision analog circuits to be integrated on the same chip.

PRODUCT HIGHLIGHTS

1. DAC-to-DAC Matching:
   Since all four DACs are fabricated on the same chip at the same time, precise matching and tracking between the DACs is inherent.
2. Single Supply Operation:
   The voltage mode configuration of the DACs allows the AD7226 to be operated from a single power supply rail.
3. Microprocessor Compatibility:
   The AD7226 has a common 8-bit data bus with individual DAC latches, providing a versatile control architecture for simple interface to microprocessors. All latch enable signals are level triggered.
4. Small Size:
   Combining four DACs and four op-amps plus interface logic into either a small, 0.3" wide, 20-pin DIP or a 20-terminal surface mount package allows a dramatic reduction in board space requirements and offers increased reliability in systems using multiple converters. Its pinout is aimed at optimizing board layout with all the analog inputs and outputs at one end of the package and all the digital inputs at the other.

NOTES
[1]To order MIL-STD-883, Class B processed parts, add/883B to part number. Contact your local sales office for military data sheet. For U.S. Standard Military Drawing (SMD), see DESC drawing #5962-87802.
[2]See Section 14 for package outline information.
[3]Also available in SOIC package (AD7226KR).
[4]PLCC: Plastic Leaded Chip Carrier.
[5]LCCC: Leadless Ceramic Chip Carrier.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

INTERFACE LOGIC INFORMATION

Address lines A0 and A1 select which DAC will accept data from the input port. Table I shows the selection table for the four DACs with Figure 1 showing the input control logic. When the $\overline{WR}$ signal is LOW, the input latches of the selected DAC are transparent and its output responds to activity on the data bus. The data is latched into the addressed DAC latch on the rising edge of $\overline{WR}$. While $\overline{WR}$ is high the analog outputs remain at the value corresponding to the data held in their respective latches.

AD7226 Control Inputs			AD7226
$\overline{WR}$	A1	A0	Operation
H	X	X	No Operation Device Not Selected
L	L	L	DAC A Transparent
↑	L	L	DAC A Latched
L	L	H	DAC B Transparent
↑	L	H	DAC B Latched
L	H	L	DAC C Transparent
↑	H	L	DAC C Latched
L	H	H	DAC D Transparent
↑	H	H	DAC D Latched

L = Low State, H = High State, X = Don't Care

Table I. AD7226 Truth Table

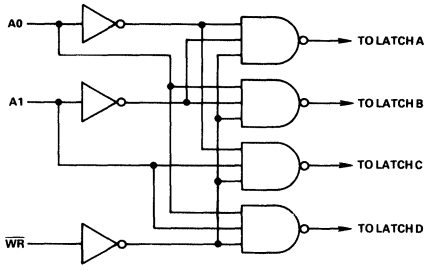

Figure 1. Input Control Logic

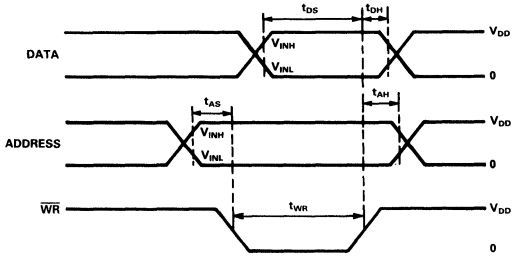

Figure 2. Write Cycle Timing Diagram

Unipolar Output Operation

This is the basic mode of operation for each channel of the AD7226, with the output voltages having the same positive polarity as $+V_{REF}$. The AD7226 can be operated single supply (V_{SS} = AGND) or with positive/negative supplies (see op-amp section which outlines the advantages of having negative V_{SS}). Note that the voltage at V_{REF} must never be negative with respect to DGND in order to prevent parasitic transistor turn-on. Connections for the unipolar output operation are shown in Figure 3.

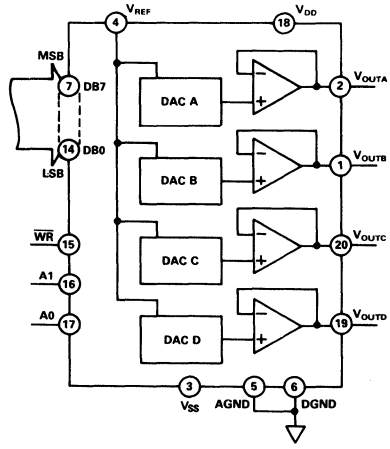

Figure 3. Unipolar Output Circuit

Bipolar Output Operation

Each of the DACs of the AD7226 can be individually configured to provide bipolar output operation. This is possible using one external amplifier and two resistors per channel. Figure 4 shows a circuit used to implement offset binary coding (bipolar operation) with DAC A of the AD7226. In this case

$$V_{OUT} = \left(1 + \frac{R2}{R1}\right) \cdot (D_A V_{REF}) - \left(\frac{R2}{R1}\right) \cdot (V_{REF})$$

With R1 = R2

$$V_{OUT} = (2D_A - 1) \cdot V_{REF}$$

where D_A is a fractional representation of the digital word in latch A.

Mismatch between R1 and R2 causes gain and offset errors and therefore these resistors must match and track over temperature. Once again the AD7226 can be operated in single supply or from positive/negative supplies.

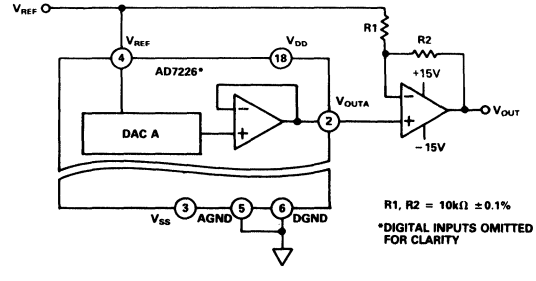

Figure 4. AD7226 Bipolar Output Circuit

GROUND MANAGEMENT

AC or transient voltages between AGND and DGND can cause noise at the analog output. This is especially true in microprocessor systems where digital noise is prevalent. The simplest method of ensuring that voltages at AGND and DGND are equal is to tie AGND and DGND together at the AD7226. In more complex systems where the AGND and DGND intertie is on the backplane, it is recommended that two diodes be connected in inverse parallel between the AD7226 AGND and DGND pins (IN914 or equivalent).

3-PHASE SINE WAVE

The circuit of Figure 5 shows an application of the AD7226 in the generation of 3-phase sine waves which can be used to control small 3-phase motors. The proper codes for synthesising a full sine wave are stored in EPROM, with the required phase-shift of 120° between the three D/A converter outputs being generated in software.

Data is loaded into the three D/A converters from the sine EPROM via the microprocessor or control logic. Three loops are generated in software with each D/A converter being loaded from a separate loop. The loops run through the look-up table producing successive triads of sinusoidal values with 120° separation which are loaded to the D/A converters producing 3 sine wave voltages 120° apart. A complete sine wave cycle is generated by stepping through the full look-up table. If a 256-element sine wave table is used then the resolution of the circuit will be 1.4° (360°/256). Figure 7 shows typical resulting waveforms. The sine waves can be smoothed by filtering the D/A converter outputs.

The fourth D/A converter of the AD7226, DAC D, may be used in a feedback configuration to provide a programmable reference voltage for itself and the other three converters. This configuration is shown in Figure 5. The relationship of V_{REF} to V_{IN} is dependent upon digital code and upon the ratio of R_F to R and is given by the formula

$$V_{REF} = \frac{(1 + G)}{(1 + G.D_D)} \cdot V_{IN}$$

where $G = R_F/R$

and D_D is a fractional representation of the digital word in latch D.

Alternatively, for a given V_{IN} and resistance ratio, the required value of D_D for a given value of V_{REF} can be determined from the expression

$$D_D = (1 + R/R_F) \cdot \frac{V_{IN}}{V_{REF}} - \frac{R}{R_F}$$

Figure 6 shows typical plots of V_{REF} versus digital code for three different values of R_F. With $V_{IN} = +2.5V$ and $R_F = 3R$ the peak-to-peak sine wave voltage from the converter outputs will vary between +2.5V and +10V over the digital input code range of 0 to 255.

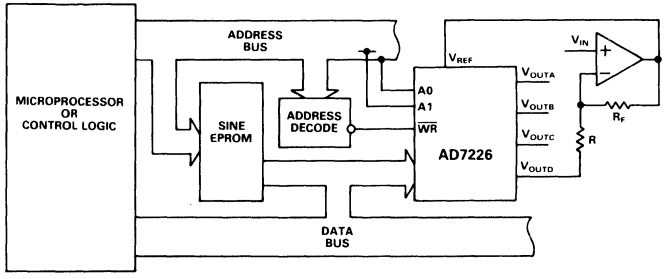

Figure 5. 3-Phase Sine Wave Generation Circuit

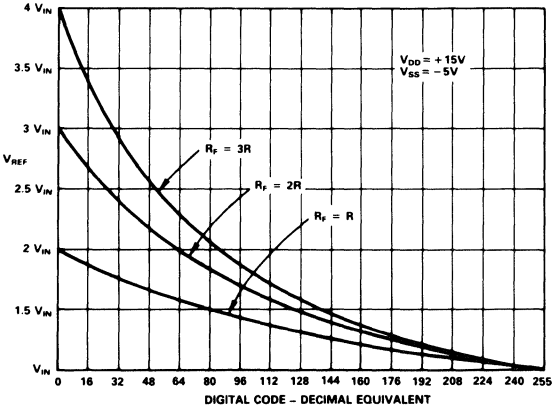

Figure 6. Variation of V_{REF} with Feedback Configuration

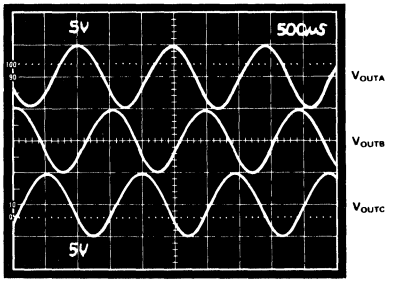

Figure 7. 3-Phase Sine Wave Output

STAIRCASE WINDOW COMPARATOR

In many test systems, it is important to be able to determine whether some parameter lies within defined limits. The staircase window comparator of Figure 8a is a circuit which can be used, for example, to measure the V_{OH} and V_{OL} thresholds of a TTL device under test. Upper and lower limits on both V_{OH} and V_{OL} can be programmably set using the AD7226. Each adjacent pair of comparators forms a window of programmable size. If V_{TEST} lies within a window then the output for that window will be high. With a reference of 2.56V applied to the V_{REF} input, the minimum window size is 10mV.

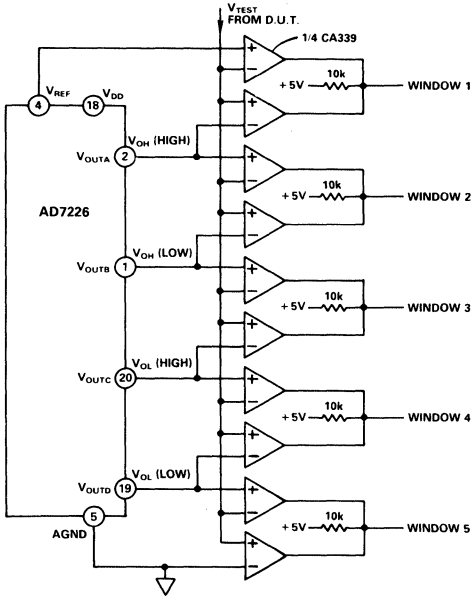

Figure 8a. Logic Level Measurement

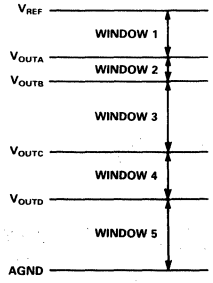

Figure 8b. Window Structure

The circuit can easily be adapted to allow for overlapping of windows as shown in Figure 9a. If the three outputs from this circuit are decoded then five different nonoverlapping programmable windows can again be defined.

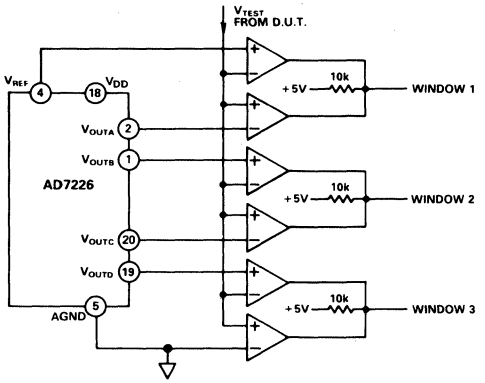

Figure 9a. Overlapping Windows

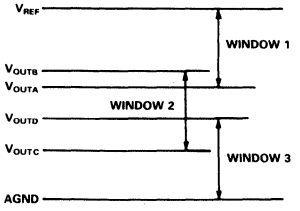

Figure 9b. Window Structure

OFFSET ADJUST

Figure 10 shows how the AD7226 can be used to provide programmable input offset voltage adjustment for the AD544 op amp. Each output of the AD7226 can be used to trim the input offset voltage on one AD544. The 620kΩ resistor tied to +10V provides a fixed bias current to one offset node. For symmetrical adjustment, this bias current should equal the current in the other offset node with the half-full scale code (i.e. 10000000) on the DAC. Changing the code on the DAC varies the bias current and hence provides offset adjust for the AD544. For example, the input offset voltage on the AD544J, which has a maximum of ±2mV, can be programmably trimmed to ±10μV.

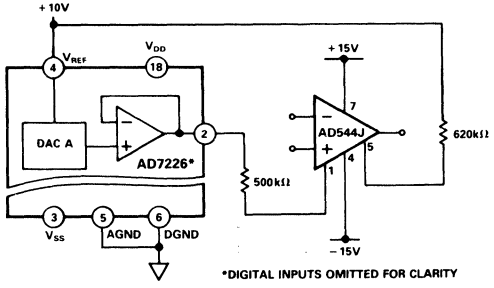

Figure 10. Offset Adjust for AD544

ANALOG DEVICES

LC²MOS Octal 8-Bit DAC

AD7228

FEATURES

Eight 8-Bit DACs with Output Amplifiers
Operates with Single or Dual Supplies

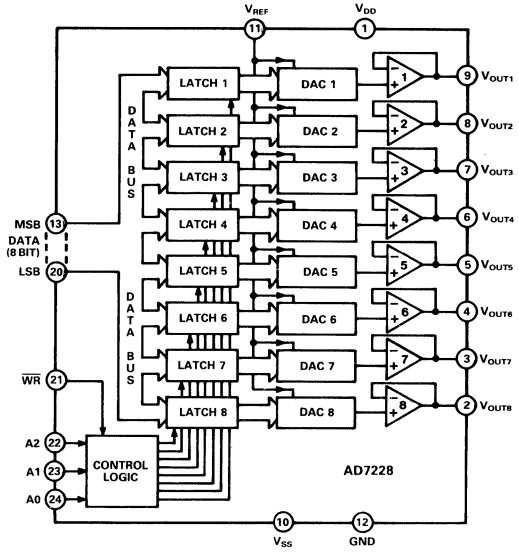
AD7228 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7228 contains eight 8-bit voltage-mode digital-to-analog converters, with output buffer amplifiers and interface logic on a single monolithic chip. No external trims are required to achieve full specified performance for the part.

Separate on-chip latches are provided for each of the eight D/A converters. Data is transferred into the data latches through a common 8-bit TTL/CMOS (5V) compatible input port. Address inputs A0, A1 and A2 determine which latch is loaded when $\overline{WR}$ goes low. The control logic is speed compatible with most 8-bit microprocessors.

Specified performance is guaranteed for input reference voltages from +2 to +10V when using dual supplies. The part is also specified for single supply operation using a reference of +10V. Each output buffer amplifier is capable of developing +10V across a 2kΩ load.

The AD7228 is fabricated on an all ion-implanted, high-speed, Linear Compatible CMOS (LC²MOS) process which has been specifically developed to integrate high-speed digital logic circuits and precision analog circuits on the same chip.

PRODUCT HIGHLIGHTS

1. Eight DACs and Amplifiers in Small Package:
   The single-chip design of eight 8-bit DACs and amplifiers allows a dramatic reduction in board space requirements and offers increased reliability in systems using multiple converters. Its pinout is aimed at optimizing board layout with all analog inputs and outputs at one side of the package and all digital inputs at the other.
2. Single or Dual Supply Operation:
   The voltage-mode configuration of the DACs allows single supply operation of the AD7228. The part can also be operated with dual supplies giving enhanced performance for some parameters.
3. Microprocessor Compatibility:
   The AD7228 has a common 8-bit data bus with individual DAC latches, providing a versatile control architecture for simple interface to microprocessors. All latch enable signals are level triggered and speed compatible with most high-performance 8-bit microprocessors.

NOTES
[1]Sample tested at 25°C to ensure compliance. All input rise and fall times measured from 10% to 90% of +5V, $t_R = t_F = 5$ns.
[2]Timing measurement reference level is $\frac{V_{INH} + V_{INL}}{2}$

INTERFACE LOGIC INFORMATION

Address lines A0, A1 and A2 select which DAC accepts data from the input port. Table I shows the selection table for the eight DACs with Figure 1 showing the input control logic. When the $\overline{WR}$ signal is low, the input latch of the selected DAC is transparent, and its output responds to activity on the data bus. The data is latched into the addressed DAC latch on the rising edge of $\overline{WR}$. While $\overline{WR}$ is high, the analog outputs remain at the value corresponding to the data held in their respective latches.

AD7228 Control Inputs				AD7228
$\overline{WR}$	A2	A1	A0	Operation
H	X	X	X	No Operation Device Not Selected
L	L	L	L	DAC 1 Transparent
↑	L	L	L	DAC 1 Latched
L	L	L	H	DAC 2 Transparent
L	L	H	L	DAC 3 Transparent
L	L	H	H	DAC 4 Transparent
L	H	L	L	DAC 5 Transparent
L	H	L	H	DAC 6 Transparent
L	H	H	L	DAC 7 Transparent
L	H	H	H	DAC 8 Transparent

H = High State L = Low State X = Don't Care

ABSOLUTE MAXIMUM RATINGS*

V_{DD} to GND	−0.3V, +17V
V_{DD} to V_{SS}	−0.3V, +24V
Digital Input Voltage to GND	−0.3V, V_{DD} +0.3V
V_{REF} to GND	−0.3V, V_{DD} +0.3V
V_{OUT} to GND[1]	V_{SS}, V_{DD}
Power Dissipation (Any Package) to +75°C	1000mW
Derates above 75°C by	2.0mW/C
Operating Temperature	
Commercial	0 to +70°C
Industrial	−25°C to +85°C
Extended	−55°C to +125°C
Storage Temperature	−65°C to +150°C
Lead Temperature (Soldering, 10secs)	+300°C

NOTE
[1]Outputs may be shorted to any voltage in the range V_{SS} to V_{DD} provided that the power dissipation of the package is not exceeded. Typical short circuit current for a short to GND or V_{SS} is 50mA.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

CIRCUIT INFORMATION

D/A SECTION

The AD7228 contains eight identical, 8-bit, voltage-mode digital-to-analog converters. The output voltages from the converters have the same polarity as the reference voltage, allowing single supply operation. A novel DAC switch pair arrangement on the AD7228 allows a reference voltage range from +2V to +10V. Each DAC consists of a highly stable, thin-film, R-2R ladder and eight high-speed NMOS switches. The simplified circuit diagram for one channel is shown in Figure 3. Note that V_{REF} (Pin 11) and GND (Pin 12) are common to all eight DACs.

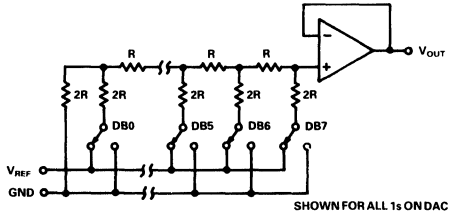

Figure 3. D/A Simplified Circuit Diagram

The input impedance at the V_{REF} pin of the AD7228 is the parallel combination of the eight individual DAC reference input impedances. It is code dependent and can vary from 2kΩ to infinity. The lowest input impedance occurs when all eight DACs are loaded with digital code 01010101. Therefore, it is important that the external reference source presents a low output impedance to the V_{REF} terminal of the AD7228 under changing load conditions. Due to transient currents at the reference input during digital code changes a 0.1μF (or greater) decoupling capacitor is recommended on the V_{REF} input for dc applications. The nodal capacitance at the reference terminal is also code dependent and typically varies from 120pF to 350pF.

Each V_{OUT} pin can be considered as a digitally programmable voltage source with an output voltage:

$$V_{OUTN} = D_N \cdot V_{REF}$$

where D_N is a fractional representation of the digital input code and can vary from 0 to 255/256.

The output impedance is that of the output buffer amplifier as described in the following section.

OP AMP SECTION

Each voltage-mode D/A converter output is buffered by a unity gain noninverting CMOS amplifier. This buffer amplifier is tested with a 2kΩ and 100pF load but will typically drive a 2kΩ and 500pF load.

The AD7228 can be operated single or dual supply. Operating the part from single or dual supplies has no effect on the positive-going settling time. However, the negative-going settling time to voltages near 0V in single supply will be slightly longer than the settling time for dual supply operation. Additionally, to ensure that the output voltage can go to 0V in single supply, a transistor on the output acts as a passive pull-down as the output voltage nears 0V. As a result, the sink capability of the amplifier is reduced as the output voltage nears 0V in single supply. In dual supply operation, the full sink capability of 400μA at 25°C is maintained over the entire output voltage range. The single supply output sink capability is shown in Figure 4. The negative V_{SS} also gives improved output amplifier performance allowing an extended input reference voltage range and giving improved slew rate at the output.

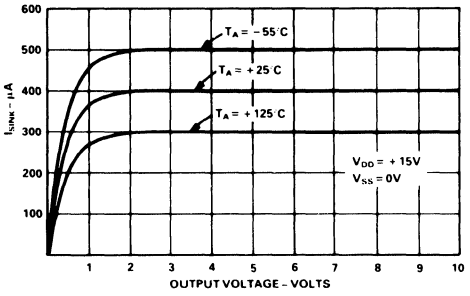

Figure 4. Single Supply Sink Current

The output broadband noise from the amplifier is 300μV peak-to-peak. Figure 5 shows a plot of noise spectral density versus frequency.

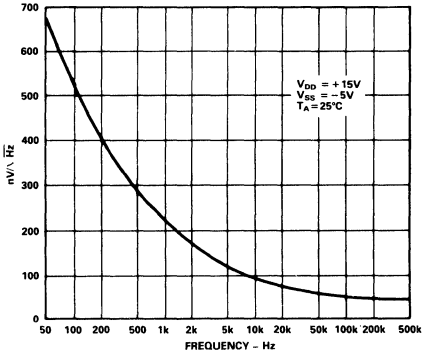

Figure 5. Noise Spectral Density vs. Frequency

DIGITAL INPUTS

The AD7228 digital inputs are compatible with either TTL or 5V CMOS levels. All logic inputs are static-protected MOS gates with typical input currents of less than 1nA. Internal input protection is achieved by on-chip distributed diodes.

SUPPLY CURRENT

The AD7228 has a maximum I_{DD} specification of 22mA and a maximum I_{SS} of 20mA over the −55°C to +125°C temperature range. This maximum current specification is actually determined by the current at −55°C. Figure 6 shows a typical plot of power supply current versus temperature.

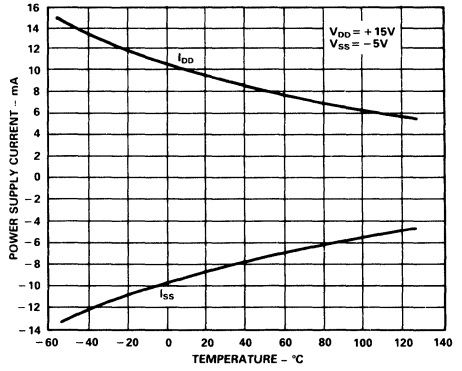

Figure 6. Power Supply Current vs. Temperature

APPLYING THE AD7228

UNIPOLAR OUTPUT OPERATION

This is the basic mode of operation for each channel of the AD7228, with the output voltage having the same positive polarity as V_{REF}. Connections for unipolar output operation are shown in Figure 7. The AD7228 can be operated from single or dual supplies as outlined earlier. The voltage at the reference input must never be negative with respect to GND. Failure to observe this precaution may cause parasitic transistor action and possible device destruction. The code table for unipolar output operation is shown in Table II.

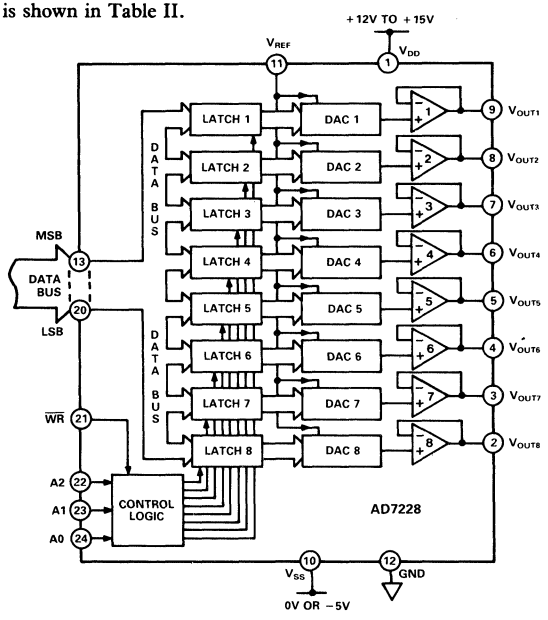

Figure 7. Unipolar Output Circuit

DAC Latch Contents MSB LSB	Analog Output
1111 1111	$+V_{REF}\left(\frac{255}{256}\right)$
1000 0001	$+V_{REF}\left(\frac{129}{256}\right)$
1000 0000	$+V_{REF}\left(\frac{128}{256}\right) = +\frac{V_{REF}}{2}$
0111 1111	$+V_{REF}\left(\frac{127}{256}\right)$
0000 0001	$+V_{REF}\left(\frac{1}{256}\right)$
0000 0000	0V

Note: $1LSB = (V_{REF})(2^{-8}) = V_{REF}\left(\frac{1}{256}\right)$

Table II. Unipolar Code Table

BIPOLAR OUTPUT OPERATION

Each of the DACs on the AD7228 can be individually configured for bipolar output operation. This is possible using one external amplifier and two resistors per channel. Figure 8 shows a circuit used to implement offset binary coding (bipolar operation) with DAC 1 of the AD7228. In this case

$$V_{OUT} = \left(1 + \frac{R2}{R1}\right) \cdot (D_1 \cdot V_{REF}) - \left(\frac{R2}{R1}\right) \cdot (V_{REF})$$

With R1 = R2

$$V_{OUT} = (2D_1 - 1) \cdot (V_{REF})$$

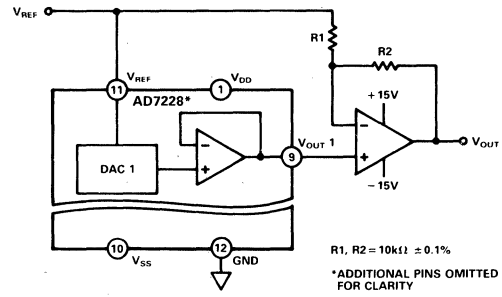

Figure 8. Bipolar Output Circuit

where D_1 is a fractional representation of the digital word in latch 1 of the AD7228. ($0 \leq D_1 \leq 255/256$)

Mismatch between R1 and R2 causes gain and offset errors, and therefore, these resistors must match and track over temperature. Once again, the AD7228 can be operated from single supply or from dual supplies. Table III shows the digital code versus output voltage relationship for the circuit of Figure 8 with R1 = R2.

DAC Latch Contents MSB LSB	Analog Output
1111 1111	$+V_{REF}\left(\frac{127}{128}\right)$
1000 0001	$+V_{REF}\left(\frac{1}{128}\right)$
1000 0000	0V
0111 1111	$-V_{REF}\left(\frac{1}{128}\right)$
0000 0001	$-V_{REF}\left(\frac{127}{128}\right)$
0000 0000	$-V_{REF}\left(\frac{128}{128}\right) = -V_{REF}$

Table III. Bipolar Code Table

AC REFERENCE SIGNAL

In some applications it may be desirable to have an ac signal applied as the reference input to the AD7228. The AD7228 has multiplying capability within the upper (+10V) and lower (+2V) limits of reference voltage when operated with dual supplies. Therefore, ac signals need to be ac coupled and biased up before being applied to the reference input. Figure 9 shows a sine-wave signal applied to the reference input of the AD7228. For input frequencies up to 50kHz, the output distortion typically remains less than 0.1%. The typical 3dB bandwidth for small signal inputs is 800kHz.

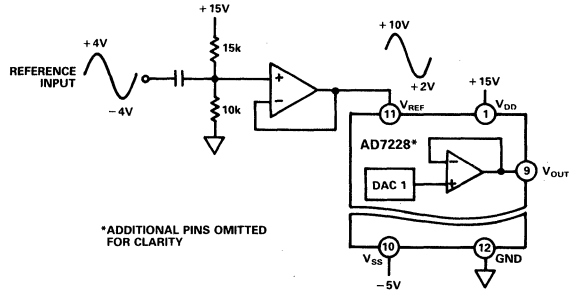

Figure 9. Applying an ac Signal to the AD7228

TIMING DESKEW

A common problem in ATE applications is the slowing or "rounding-off" of signal edges by the time they reach the pin-driver circuitry. This problem can easily be overcome by "squaring-up" the edge at the pin-driver. However, since each edge will not have been "rounded-off" by the same extent, this "squaring-up" could lead to incorrect timing relationship between signals. This effect is shown in Figure 10a.

The circuit of Figure 10b shows how two DACs of the AD7228 can help in overcoming this problem. The same two signals are applied to this circuit as were applied in Figure 10b. The output of each DAC is applied to one input of a high-speed comparator, and the signals are applied to the other inputs. Varying the output voltage of the DAC effectively varies the trigger point at which the comparator flips. Thus the timing relationship between the two signals can be programmably corrected (or deskewed) by varying the code to the DAC of the AD7228. In a typical application, the code is loaded to the DACs for correct timing relationships during the calibration cycle of the instrument.

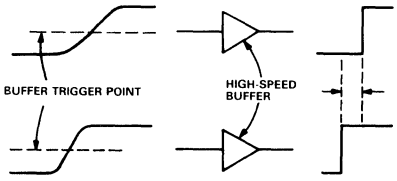

Figure 10a. Time Skewing Due to Slowing of Edges

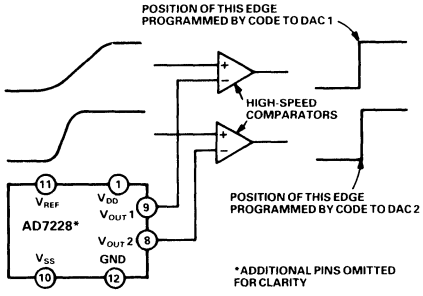

Figure 10b. AD7228 Timing Deskew Circuit

COARSE/FINE ADJUST

The DACs on the AD7228 can be paired together to form a coarse/fine adjust function as indicated in Figure 11. The function is achieved using one external op amp and a few resistors per pair of DACs.

DAC1 is the most significant or coarse DAC. Data is first loaded to this DAC to coarsely set the output voltage. DAC2 is then used to fine tune this output voltage. Varying the ratio of R1 to R2 varies the relative effect of the coarse and fine DACs on the output voltage. For the resistor values shown, DAC2 has a resolution of 150μV in a 10V output range. Since each DAC on the AD7228 is guaranteed monotonic, the coarse adjustment and fine adjustment are each monotonic. One application for this is as a set-point controller (see "Circuit Applications of the AD7226 Quad CMOS DAC" available from Analog Devices, Publication Number E873-15-11/84).

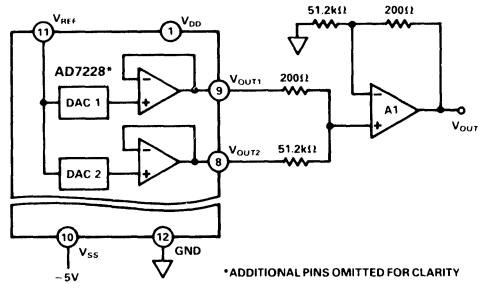

Figure 11. Coarse/Fine Adjust Circuit

SELF-PROGRAMMABLE REFERENCE

The circuit of Figure 12 shows how one DAC of the AD7228, in this case DAC1, may be used in a feedback configuration to provide a programmable reference for itself and the other seven converters. The relationship of V_{REF} to V_{IN} is expressed by

$$V_{REF} = \frac{(1+G)}{(1+G \cdot D_1)} \cdot V_{IN} \quad \text{where } G = R2/R1$$

Figure 13 shows typical plots of V_{REF} versus digital code, D_1, for three different values of G. With $V_{IN} = 2.5V$ and $G = 3$ the voltage at the output varies between 2.5V and 10V giving an effective 10-bit dynamic range to the other seven converters. For correct operation of the circuit, V_{SS} should be $-5V$ and R1 greater than 6.8kΩ.

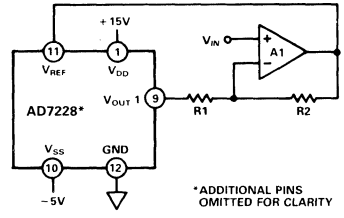

Figure 12. Self-Programmable Reference

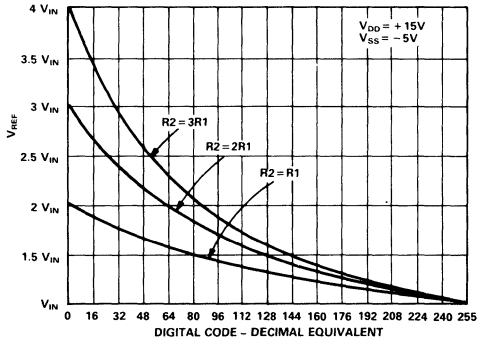

Figure 13. Variation of V_{REF} with Feedback Configuration

5V SINGLE SUPPLY OPERATION

The AD7228 can be operated from a single +5V power supply resulting in only slightly degraded accuracy performance from the part. Figure 14 shows a typical plot of relative accuracy for the part with 5V V_{DD} and a reference voltage of +1.23V. One important parameter which retains its specified performance is differential nonlinearity which remains within ±1LSB ensuring that the DACs on the AD7228 remain monotonic over the output voltage range.

The output transfer function sits on top of the amplifier offset voltage. Since the reference voltage is reduced, the offset voltage amounts to a few LSBs. For parts with a true negative offset (when V_{SS} = −5V), the transfer function does not move off the bottom rail for the first few LSBs of code. After this the transfer function will continue as normal. The relative accuracy plot of Figure 14 is for a part with a true positive offset.

The required overhead voltage of 3.5V must be maintained between V_{DD} and the reference voltage which limits the reference voltage range. However, operating the part from a single +5V supply gives a considerable reduction in power dissipation (to typically 50mW). The digital input threshold levels and digital input currents are not affected by operating the part from the single +5V supply.

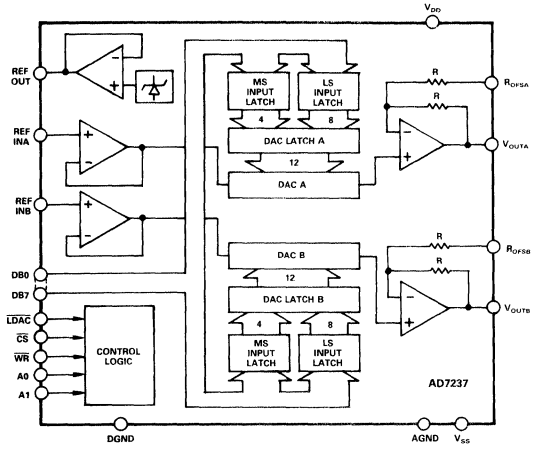
FEATURES

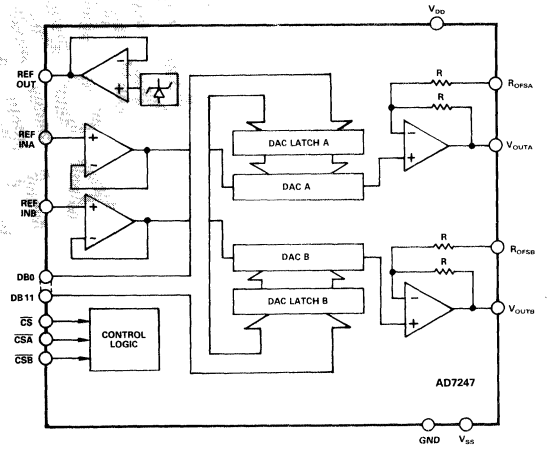
Complete Dual 12-Bit DAC Comprising
- **Two 12-Bit CMOS DACs**
- **On-Chip Voltage Reference**
- **Output Amplifiers**
- **Reference Buffer Amplifiers**

Parallel Loading Structure: AD7247
(8+4) Loading Structure: AD7237
Single or Dual Supply Operation
Low Power – 150 mW typ in Single Supply

AD7237 FUNCTIONAL BLOCK DIAGRAM



AD7247 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7237/AD7247 is a complete, dual, 12-bit, voltage output digital-to-analog converter with output amplifiers and Zener voltage reference on a monolithic CMOS chip. No external user trims are required to achieve full specified performance.

Both parts are microprocessor compatible, with high speed data latches and interface logic. The AD7247 accepts 12-bit parallel data which is loaded into the respective DAC latch using the $\overline{WR}$ input and a separate Chip Select input for each DAC. The AD7237 has a double buffered interface structure and an 8-bit wide data bus with data loaded to the respective input latch in two write operations. An asynchronous $\overline{LDAC}$ signal on the AD7237 updates the DAC latches and analog outputs.

A REF OUT/REF IN function is provided which means that the on-chip 5 V reference or an external reference can be used to supply the reference voltage for the part. For single supply operation, two output ranges of 0 to +5 V and 0 to +10 V are available, while an additional ±5 V range is available with dual supplies. The output amplifiers are capable of developing +10 V across a 2 kΩ load to GND.

The AD7237/AD7247 is fabricated in Linear Compatible CMOS (LC²MOS), an advanced, mixed technology process that combines precision bipolar circuits with low power CMOS logic. Both parts are available in a 24-pin plastic and hermetic dual-in-line package (DIP) and are also packaged in a 28-terminal plastic leaded chip carrier (PLCC).

DACPORT is a trademark of Analog Devices, Inc.

PRODUCT HIGHLIGHTS

1. The AD7237/AD7247 is a dual 12-bit DACPORT™ on a single chip. This single chip design offers considerable space saving and increased reliability over multichip designs.
2. Between them the AD7237 and AD7247 offer a versatile interface arrangement to either 8-bit or 16-bit data bus structures.

SPECIFICATIONS (V_{DD} = +15 V, ±5%, V_{SS} = 0 V or −15 V ±5%, AGND = DGND (GND) = 0 V, REF IN = +5 V, R_L = 2 kΩ, C_L = 100 pF. All Specifications T_{min} to T_{max} unless otherwise noted.)

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

TERMINOLOGY

RELATIVE ACCURACY (LINEARITY)

Relative Accuracy, or endpoint linearity, is a measure of the maximum deviation of the DAC transfer function from a straight line passing through the endpoints of the transfer function. It is measured after allowing for zero and full scale errors and is expressed in LSBs or as a percentage of full scale reading.

DIFFERENTIAL NONLINEARITY

Differential Nonlinearity is the difference between the measured change and the ideal 1 LSB change between any two adjacent codes. A specified differential nonlinearity of ±0.9 LSB max over the operating temperature range ensures monotonicity.

SINGLE SUPPLY LINEARITY AND GAIN ERROR

The output amplifiers of the AD7237/AD7247 can have true negative offsets even when the part is operated from a single +15 V supply. However, because the negative supply rail (V_{SS}) is 0 V, the output cannot actually go negative. Instead, when the output voltage is less than the (negative) offset voltage, the output voltage sits at 0 V, resulting in the transfer function shown in Figure 1. This "knee" is an offset effect, not a linearity error, and the transfer function would have followed the dotted line if the output voltage could have gone negative.

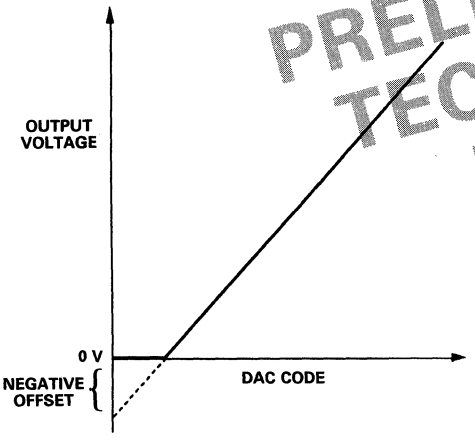

Figure 1. Effect of Negative Offset (Single Supply)

Normally, linearity is measured between zero (all 0s input code) and full scale (all 1s input code) after offset and full scale have been adjusted out or allowed for, but this is not possible in single supply operation if the offset is negative, due to the knee in the transfer function. Instead, linearity of the AD7237/AD7247 in the unipolar mode is measured between full scale and the lowest code which is guaranteed to produce a positive output voltage. This code is calculated from the maximum specification for negative offset. For the J, A, K, B versions, the linearity is measured between Codes 3 and 4095. For the S grade, linearity is measured between Code 5 and Code 4095.

UNIPOLAR OFFSET ERROR

Unipolar Offset Error is the measured output voltage from V_{OUTA} or V_{OUTB} with all zeros loaded into the DAC latches when the DACs are configured for unipolar output. It is a combination of the offset errors of the DAC and output amplifier.

BIPOLAR ZERO ERROR

Bipolar Zero Error is the voltage measured at V_{OUTA} or V_{OUTB} when the DAC is connected in the bipolar mode and loaded with code 2048. It is due to a combination of offset errors in the DAC, amplifier offset and mismatch in the application resistors around the amplifier.

FULL SCALE ERROR

Full Scale Error is a measure of the output error when the amplifier output is at full scale (for the bipolar output range full scale is either positive or negative full scale). It is measured with respect to the reference input voltage and includes the offset errors.

DIGITAL FEEDTHROUGH

Digital Feedthrough is the glitch impulse injected for the digital inputs to the analog output when the data inputs change state, but the data in the DAC latches is not changed.

For the AD7237 it is measured with $\overline{LDAC}$ held high. For the AD7247 it is measured with $\overline{CSA}$ and $\overline{CSB}$ held high.

DIGITAL CROSSTALK

Digital crosstalk is the glitch impulse transferred to the output of one converter due to a change in digital code to the DAC latch of the other converter. It is specified in nV secs.

DIGITAL-TO-ANALOG GLITCH IMPULSE

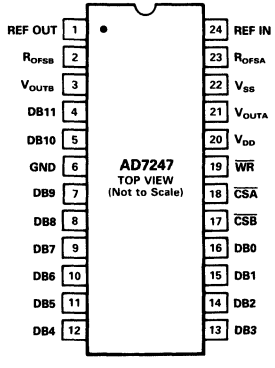
This is the voltage spike that appears at the output of the DAC when the digital code changes before the output settles to its final value. The energy in the glitch is specified in nV secs and is measured for a 1 LSB change around the major carry transition (0111 1111 1111 to 1000 0000 0000).

AD7247 PIN FUNCTION DESCRIPTION (DIP PIN NUMBERS)

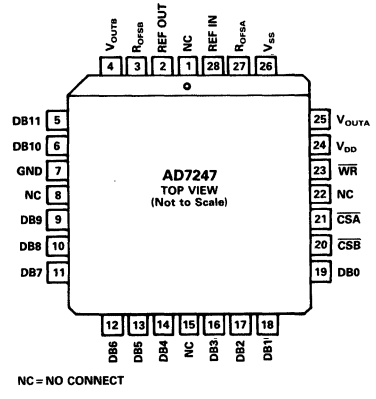
Pin	Mnemonic	Description
1	REF OUT	Voltage Reference Output. The internal 5 V analog reference is provided at this pin. To operate the part with internal reference, REF OUT should be connected to REF IN.
2	R_{OFSB}	Output Offset Resistor for DAC B. This input configures the output ranges for DAC B. It is connected to V_{OUTB} for the +5 V range, to GND for the +10 V range and to REF IN for the ±5 V range.
3	V_{OUTB}	Analog Output Voltage from DAC B. This is the buffer amplifier output voltage. Three different output voltage ranges can be chosen: 0 to +5 V, 0 to + 10 V and ± 5 V. The amplifier is capable of developing +10 V across a 2 kΩ resistor to GND.
4	DB11	Data Bit 11 (MSB).
5	DB10	Data Bit 10.
6	GND	Ground. Ground reference for all on-chip circuitry.
7–15	DB9–DB1	Data Bit 9 to Data Bit 1.
16	DB0	Data Bit 0 (LSB).
17	$\overline{CSB}$	Chip Select Input for DAC B. Active low logic input. DAC B is selected when this input is active.
18	$\overline{CSA}$	Chip Select Input for DAC A. Active low logic input. DAC A is selected when this input is active.
19	$\overline{WR}$	Write Input. $\overline{WR}$ is an active low logic input which is used in conjunction with $\overline{CSA}$ and $\overline{CSB}$ to write data to the DAC latches.
20	V_{DD}	Positive Supply, +15 V.
21	V_{OUTA}	Analog Output Voltage from DAC A. This is the buffer amplifier output voltage. Three different output voltage ranges can be chosen: 0 to +5 V, 0 to +10 V and ±5 V. The amplifier is capable of developing +10 V across a 2 kΩ resistor to GND.
22	V_{SS}	Negative Supply, −15 V.
23	R_{OFSA}	Output Offset Resistor for DAC A. This input configures the output ranges for DAC A. It is connected to V_{OUTA} for the +5 V range, to GND for the +10 V range and to REF IN for the ±5 V range.
24	REF IN	Voltage Reference Input. The common reference voltage for both DACs is applied to this pin. It is internally buffered before being applied to both DACs. The nominal reference voltage for correct operation of the AD7247 is 5 V.

AD7247 PIN CONFIGURATIONS

DIP



PLCC



NC = NO CONNECT

AD7237 PIN FUNCTION DESCRIPTION (DIP PIN NUMBERS)

Pin	Mnemonic	Description
1	REF INA	Voltage Reference Input for DAC A. The reference voltage for DAC A is applied to this pin. It is internally buffered before being applied to the DAC. The nominal reference voltage for correct operation of the AD7237 is 5 V.
2	REF OUT	Voltage Reference Output. The internal 5 V analog reference is provided at this pin. To operate the part with internal reference REF OUT should be connected to REF INA, REF INB.
3	REF INB	Voltage Reference Input for DAC B. The reference voltage for DAC B is applied to this pin. It is internally buffered before being applied to the DAC. The nominal reference voltage for correct operation of the AD7237 is 5 V.
4	R_{OFSB}	Output Offset Resistor for DAC B. This input configures the output ranges for DAC B. It is connected to V_{OUTB} for the +5 V range, to AGND for the +10 V range and to REF INB for the ±5 V range.
5	V_{OUTB}	Analog Output Voltage from DAC B. This is the buffer amplifier output voltage. Three different output voltage ranges can be chosen: 0 to +5 V, 0 to +10 V and ±5 V. The amplifier is capable of developing +10 V across a 2 kΩ resistor to GND.
6	AGND	Analog Ground. Ground reference for DACs, reference and output buffer amplifiers.
7	DB7	Data Bit 7.
8–10	DB6–DB4	Data Bit 6 to Data Bit 4.
11	DB3	Data Bit 3/Data Bit 11 (MSB).
12	DGND	Digital Ground. Ground reference for digital circuitry.
13	DB2	Data Bit 2/Data Bit 10.
14	DB1	Data Bit 1/Data Bit 9.
15	DB0	Data Bit 0 (LSB)/Data Bit 8.
16	A0	Address Input. Least significant address input for input latches. A0 and A1 select which of the four input latches data is written to (see Table II).
17	A1	Address Input. Most significant address input for input latches.
18	$\overline{CS}$	Chip Select. Active low logic input. The device is selected when this input is active.
19	$\overline{WR}$	Write Input. $\overline{WR}$ is an active low logic input which is used in conjunction with $\overline{CS}$, A0 and A1 to write data to the input latches.
20	$\overline{LDAC}$	Load DAC. Logic input. A new word is loaded into the DAC latches from the respective input latches on the falling edge of this signal.
21	V_{DD}	Positive Supply, +15 V.
22	V_{OUTA}	Analog Output Voltage from DAC A. This is the buffer amplifier output voltage. Three different output voltage ranges can be chosen: 0 to +5 V, 0 to +10 V and ±5 V. The amplifier is capable of developing +10 V across a 2 kΩ resistor to GND.
23	V_{SS}	Negative Supply, −15 V.
24	R_{OFSA}	Output Offset Resistor for DAC A. This input configures the output ranges for DAC A. It is connected to V_{OUTA} for the +5 V range, to AGND for the +10 V range and to REF INA for the ±5 V range.

INTERFACE LOGIC INFORMATION – AD7247

Table I shows the truth table for AD7247 operation. The part contains a single, parallel 12-bit latch for each DAC. It can be treated as two independent DACs, each with its own $\overline{CS}$ input and a common $\overline{WR}$ input. $\overline{CSA}$ and $\overline{WR}$ control the loading of data to the DAC A latch while $\overline{CSB}$ and $\overline{WR}$ control the loading of the DAC B latch. If $\overline{CSA}$ and $\overline{CSB}$ are both low, with $\overline{WR}$ low, the same data will be written to both DAC latches. All control signals are level triggered and therefore either or both latches can be made transparent. Input data is latched to the respective latch on the rising edge of $\overline{WR}$. Figure 2 shows the input control logic for the AD7247, while the write cycle timing diagram for the part is shown in Figure 3.

$\overline{CSA}$	$\overline{CSB}$	$\overline{WR}$	Function
X	X	1	No Data Transfer
1	1	X	No Data Transfer
0	1	0	DACA Latch Transparent
1	0	0	DACB Latch Transparent
0	0	0	Both DAC Latches Transparent

X = Don't Care.

Table I. AD7247 Truth Table

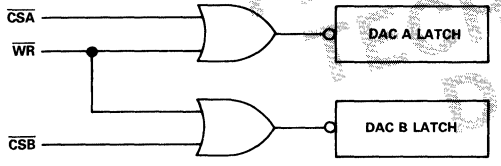

Figure 2. AD7247 Input Control Logic

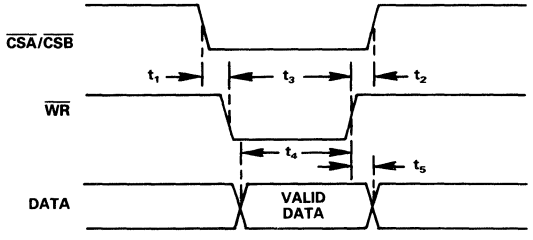

Figure 3. AD7247 Write Cycle Timing Diagram

INTERFACE LOGIC INFORMATION – AD7237

The input loading structure on the AD7237 is configured for interfacing to microprocessors with an 8-bit-wide data bus. The part contains two 12-bit latches per DAC – an input latch and a DAC latch. Each input latch is further subdivided into a least significant 8-bit latch and a most significant 4-bit latch. Only the data held in the DAC latches determines the outputs from the part. The input control logic for the AD7237 is shown in Figure 4, while the write cycle timing diagram is shown in Figure 5.

$\overline{CS}$, $\overline{WR}$, A0 and A1 control the loading of data to the input latches. The eight data inputs accept right-justified data. Data can be loaded to the input latches in any sequence. Provided that $\overline{LDAC}$ is held high, there is no analog output change as a result of loading data to the input latches. Address lines A0 and A1 determine which latch data is loaded to when $\overline{CS}$ and $\overline{WR}$ are low. The selection of the input latches is shown in the truth table for AD7237 operation in Table II.

The $\overline{LDAC}$ input controls the transfer of 12-bit data from the input latches to the DAC latches. Both DAC latches, and hence both analog outputs, are updated at the same time. The $\overline{LDAC}$ signal is level triggered and data is latched into the DAC latch on the rising edge of $\overline{LDAC}$. The $\overline{LDAC}$ input is asynchronous and independent of $\overline{WR}$. This is useful in many applications especially in the simultaneous updating of multiple AD7237s. However, care must be taken while exercising $\overline{LDAC}$ during a write cycle. If an $\overline{LDAC}$ operation overlaps a $\overline{CS}$ and $\overline{WR}$ operation, there is a possibility of invalid data being latched to the output. To avoid this, $\overline{LDAC}$ must remain low after $\overline{CS}$ or $\overline{WR}$ return high for a period equal to or greater than t_8, the minimum $\overline{LDAC}$ pulse width.

$\overline{CS}$	$\overline{WR}$	A1	A0	$\overline{LDAC}$	Function
1	X	X	X	1	No Data Transfer
X	1	X	X	1	No Data Transfer
0	0	0	0	1	DAC A LS Input Latch Transparent
0	0	0	1	1	DAC A MS Input Latch Transparent
0	0	1	0	1	DAC B LS Input Latch Transparent
0	0	1	1	1	DAC B MS Input Latch Transparent
1	1	X	X	0	DACA and DACB DAC Latches Updated Simultaneously from the Respective Input Latches

X = Don't Care.

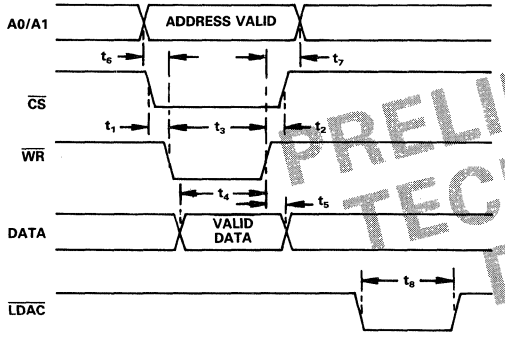

Figure 5. AD7237 Write Cycle Timing Diagram

APPLYING THE AD7237/AD7247

The internal scaling resistors provided on the AD7237/AD7247 allow several output voltage ranges. The part can produce unipolar output ranges of 0 to +5 V or 0 to +10 V and a bipolar output range of ±5 V. Connections for the various ranges are outlined below. Since each DAC has its own R_{OFS} input, the two DACs on each part can be set up for different output ranges.

Unipolar (0 to +10 V) Configuration

The first of the configurations provides an output voltage range of 0 V to +10 V. This is achieved by connecting the output offset resistor, R_{OFSA}, or R_{OFSB}, to GND (AGND for AD7237). In this configuration, the AD7237/AD7247 can be operated from single or dual supplies. Figure 6 shows the connection diagram for unipolar operation for DAC A of the AD7237, while the table for output voltage versus digital code in the DAC latch is shown in Table III. Similar connections apply to the AD7247.

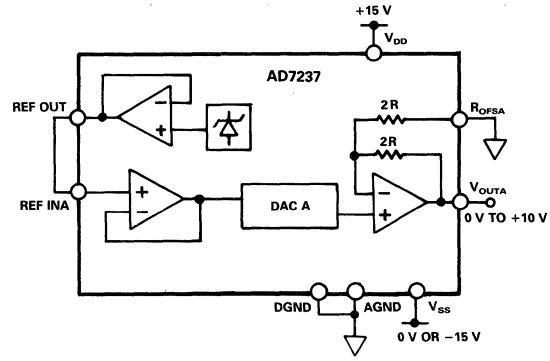

Figure 6. Unipolar (0 to +10 V) Configuration

DAC Latch Contents MSB LSB	Analog Output, V_{OUT}
1111 1111 1111	+2 · REF IN · (4095/4096)
1000 0000 0001	+2 · REF IN · (2049/4096)
1000 0000 0000	+2 · REF IN · (2048/4096) = +REF IN
0111 1111 1111	+2 · REF IN · (2047/4096)
0000 0000 0001	+2 · REF IN · (1/4096)
0000 0000 0000	0 V

Note: 1 LSB = REF IN/2048.

Table III. Unipolar Code Table (0 to+10 V Range)

Unipolar (0 to +5 V) Configuration

The 0 to +5 V output voltage range is achieved by tying R_{OFSA} or R_{OFSB} to V_{OUTA} or V_{OUTB}. Once again, the AD7237/AD7247 can be operated single supply or from dual supplies. The table for output voltage versus digital code is as in Table III, with 2 · REF IN replaced by REF IN. Note, for this range, 1LSB = REF IN · (2^{-12}) = (REF IN/4096).

Bipolar Configuration

The bipolar configuration for the AD7237/AD7247, which gives an output range of −5 V to +5 V, is achieved by connecting R_{OFSA}, or R_{OFSB}, to REF IN. The AD7237/AD7247 must be operated from dual supplies to achieve this output voltage range. The code table for bipolar operation is shown in Table IV.

DAC Latch Contents MSB LSB	Analog Output, V_{OUT}
1111 1111 1111	+REF IN · (2047/2048)
1000 0000 0001	+REF IN · (1/2048)
1000 0000 0000	0V
0111 1111 1111	−REF IN · (1/2048)
0000 0000 0001	−REF IN · (2047/2048)
0000 0000 0000	−REF IN · (2048/2048) = −REF IN

Note: 1 LSB = REF IN/2048.

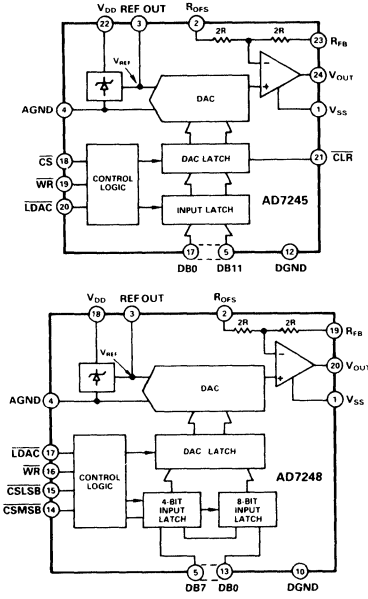
AD7245/AD7248 FUNCTIONAL BLOCK DIAGRAMS



GENERAL DESCRIPTION

The AD7245/AD7248 is a complete 12-bit, voltage-output, digital-to-analog converter with output amplifier and Zener voltage reference on a monolithic CMOS chip. No external trims are required to achieve full specified performance for the part.

The part features double-buffered interface logic with a 12-bit input latch and 12-bit DAC latch. The data held in the DAC latch determines the analog output of the converter. The AD7245 accepts 12-bit parallel data which is latched into the input latch on the rising edge of $\overline{CS}$ or $\overline{WR}$. The AD7248 has an 8-bit-wide data bus, and data is loaded to the input latch in two write operations, an 8-bit LSB load and a 4-bit MSB load. The input data must be right justified. For both parts, an asynchronous $\overline{LDAC}$ signal transfers data from the input latch to the DAC latch. The AD7245 also has a $\overline{CLR}$ signal on the DAC latch which allows features such as power-on reset to be implemented. All logic inputs are level triggered and are TTL and CMOS (5V) level compatible, while the control logic is speed compatible with most microprocessors.

The on-chip 5V buried Zener diode provides a low-noise, temperature compensated reference for the DAC. The gain setting resistors allow a number of ranges at the output: 0 to +5V, 0 to +10V when using single supply and 0 to +5V, −5V to +5V when operated in dual supplies. The output amplifier is capable of developing +10V across a 2kΩ load to GND.

The AD7245/AD7248 is fabricated in an all ion-implanted, high-speed linear, compatible CMOS (LC²MOS) process. The AD7245 is packaged in a small, 0.3"-wide, 24-pin DIP and 28-terminal surface mount packages. The AD7248 is available in a 0.3"-wide, 20-pin DIP and 20-terminal surface mount packages.

PRODUCT HIGHLIGHTS

1. Complete 12-Bit DACPORT™
   The AD7245/AD7248 is a complete, voltage output, 12-bit DAC on one chip. This single-chip design of the DAC reference and output amplifier is inherently more reliable than multichip designs.
2. Microprocessor Compatibility
   The parallel loading structure of the AD7245 allows connection to microprocessors with a 16-bit-wide data bus. The AD7248 is aimed at microprocessors which have an 8-bit-wide data bus structure. The high-speed logic of both parts allows direct interfacing to most modern microprocessors. Additionally, the double buffered interface enables simultaneous update of the AD7245/AD7248 in multiple DAC systems.

DACPORT is a trademark of Analog Devices, Inc.

NOTES

[1]For the S Version only: V_{DD} = +12V ±5% to +15V ±5%

[2]Temperature ranges are as follows:
J Version, 0 to +70°C
A Version, −25°C to +85°C
S Version, −55°C to +125°C.

[3]See Terminology.

[4]FSR means Full-Scale Range and is 5V with R_{OFS} connected to R_{FB}, V_{OUT} and 10V with R_{OFS} connected to GND and R_{FB} connected to V_{OUT}.

[5]This error is calculated with respect to the reference voltage and is measured after the offset error has been allowed for.

[6]This error is calculated w.r.t. an ideal 4.9988V (on the 5V range) or 9.9976V (on the 10V range).
It includes the effects of internal voltage reference, gain and offset errors.

[7]Full-scale T.C. = ΔFS/ΔT, where ΔFS is the full-scale change from T_A = +25°C to T_{min} or T_{max}.

[8]Control inputs are $\overline{CS}$, $\overline{WR}$, $\overline{LDAC}$ and $\overline{CLR}$ for AD7245 and $\overline{CSMSB}$, $\overline{CSLSB}$, $\overline{WR}$ and $\overline{LDAC}$ for AD7248.

[9]Sample tested at +25°C to ensure compliance.

[10]The metal lid on the AD7245 (only) ceramic (D-24A) package is connected to Pin 12 (DGND).

Specifications subject to change without notice.

NOTES

[1]For the S Version only: V_{DD} = +12V ±5% to +15V ±5%; V_{SS} = −12V ±5% to −15V ±5%.

[2]Temperature ranges are as follows:
J Version, 0 to +70°C
A Version, −25°C to +85°C
S Version, −55°C to +125°C.

[3]See Terminology.

[4]FSR means Full-Scale Range and is 5V with R_{OFS} connected to R_{FB}, V_{OUT} and 10V with R_{OFS} connected to GND and R_{FB} connected to V_{OUT}.

[5]This error is calculated with respect to the reference voltage and is measured after the offset error has been allowed for.

[6]This error is calculated w.r.t. an ideal 4.9988V (on the 5V range) or 9.9976V (on the 10V range).
It includes the effects of internal voltage reference, gain and offset errors.

[7]Full-scale T.C. = ΔFS/ΔT, where ΔFS is the full-scale change from T_A = +25°C to T_{min} or T_{max}.

[8]Control inputs are $\overline{CS}$, $\overline{WR}$, $\overline{LDAC}$ and $\overline{CLR}$ for AD7245 and $\overline{CSMSB}$, $\overline{CSLSB}$, $\overline{WR}$ and $\overline{LDAC}$ for AD7248.

[9]Sample tested at +25°C to ensure compliance.

[10]The metal lid on the AD7245 (only) ceramic (D-24A) package is connected to Pin 12 (DGND).

Specifications subject to change without notice.

NOTE
[1]The output may be shorted to voltages in this range provided the power dissipation of the package is not exceeded.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

TERMINOLOGY

RELATIVE ACCURACY
Relative Accuracy, or end-point nonlinearity, is a measure of the actual deviation from a straight line passing through the end-points of the DAC transfer function. It is measured after allowing for zero and full scale and is normally expressed in LSBs or as a percentage of full-scale reading.

DIFFERENTIAL NONLINEARITY
Differential Nonlinearity is the difference between the measured change and the ideal 1LSB change between any two adjacent codes. A specified differential nonlinearity of ± 1LSB max over the operating temperature range ensures monotonicity.

DIGITAL FEEDTHROUGH
Digital Feedthrough is the glitch impulse injected from the digital inputs to the analog output when the inputs change state. It is measured with $\overline{LDAC}$ high and is specified in nV secs.

DAC GAIN ERROR
DAC Gain Error is a measure of the output error between an ideal DAC and the actual device output with all 1s loaded after offset error has been allowed for. It is therefore defined as:

Measured Value – Offset – Ideal Value

where the ideal value is calculated relative to the actual reference value.

UNIPOLAR OFFSET ERROR
Unipolar Offset Error is a combination of the offset errors of the voltage-mode DAC and the output amplifier and is measured when the part is configured for unipolar outputs. It is present for all codes and is measured with all 0s in the DAC register.

BIPOLAR ZERO OFFSET ERROR
Bipolar Zero Offset Error is measured when the part is configured for bipolar output and is a combination of errors from the DAC and output amplifier. It is present for all codes and is measured with a code of 2048 (decimal) in the DAC register.

AD7245 PIN FUNCTION DESCRIPTION (DIP PIN NUMBERS)

Pin	Mnemonic	Description
1	V_{SS}	Negative Supply Voltage (0V for single supply operation).
2	R_{OFS}	Bipolar Offset Resistor. This provides access to the on-chip application resistors and allows different output voltage ranges.
3	REF OUT	Reference Output. The on-chip reference is provided at this pin and is used when configuring the part for bipolar outputs.
4	AGND	Analog Ground.
5	DB11	Data Bit 11. Most Significant Bit (MSB).
6–11	DB10–DB5	Data Bit 10 to Data Bit 5.
12	DGND	Digital Ground.
13–16	DB4–DB1	Data Bit 4 to Data Bit 1.
17	DB0	Data Bit 0. Least Significant Bit (LSB).
18	$\overline{CS}$	Chip Select Input (Active LOW). The device is selected when this input is active.
19	$\overline{WR}$	Write Input (Active LOW). This is used in conjunction with $\overline{CS}$ to write data into the input latch of the AD7245.
20	$\overline{LDAC}$	Load DAC Input (Active LOW). This is an asynchronous input which when active transfers data from the input latch to the DAC latch.
21	$\overline{CLR}$	Clear Input (Active LOW). When this input is active the contents of the DAC latch are reset to all 0s.
22	V_{DD}	Positive Supply Voltage.
23	R_{FB}	Feedback Resistor. This allows access to the amplifier's feedback loop.
24	V_{OUT}	Output Voltage. Three different output voltage ranges can be chosen: 0 to +5V, 0 to +10V or −5V to +5V.

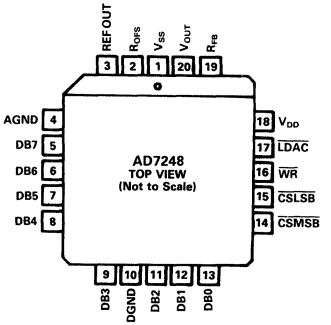
PLCC



SINGLE SUPPLY LINEARITY AND GAIN ERROR

The output amplifier of the AD7245/AD7248 can have a true negative offset even when the part is operated from a single positive power supply. However, because the lower supply rail to the part is 0V, the output voltage cannot actually go negative. Instead the output voltage sits on the lower rail and this results in the transfer function shown across. This is an offset effect and the transfer function would have followed the dotted line if the output voltage could have gone negative. Normally, linearity is measured after offset and full scale have been adjusted or allowed for. On the AD7245/AD7248 the negative offset is allowed for by calculating the linearity from the code which the amplifier comes off the lower rail. This code is given by the negative offset specification. For example, the single supply linearity specification applies between Code 3 and Code 4095 for the 25°C specification and between Code 5 and Code 4095 over the T_{min} to T_{max} temperature range. Since gain error is also measured after offset has been allowed for, it is calculated between the same codes as the linearity error. Bipolar linearity and gain error are measured between Code 0 and Code 4095.

CIRCUIT INFORMATION

D/A SECTION

The AD7245/AD7248 contains a 12-bit voltage-mode digital-to-analog converter. The output voltage from the converter has the same positive polarity as the reference voltage allowing single supply operation. The reference voltage for the DAC is provided by an on-chip buried-Zener diode.

The DAC consists of a highly stable, thin-film, R-2R ladder and twelve high-speed NMOS single-pole, double-throw switches. The simplified circuit diagram for this DAC is shown in Figure 1.

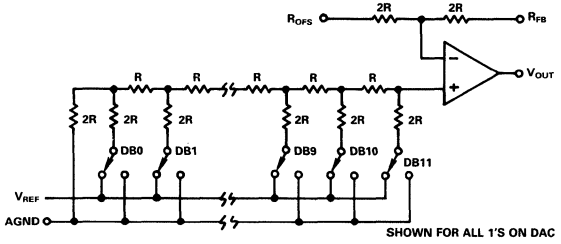

Figure 1. D/A Simplified Circuit Diagram

The input impedance of the DAC is code dependent and can vary from 8kΩ to infinity. The input capacitance also varies with code, typically from 50pF to 200pF.

OP AMP SECTION

The output of the voltage-mode D/A converter is buffered by a noninverting CMOS amplifier. The user has access to two gain setting resistors which can be connected to allow different output voltage ranges (discussed later). The buffer amplifier is capable of developing up to 10V across a 2kΩ load to GND.

The output amplifier can be operated from a single positive power supply by tying V_{SS} = AGND = 0V. The amplifier can also be operated from dual supplies to allow a bipolar output range of −5V to +5V. *The amplifier should not be configured for the 0 to +10V output range when V_{SS} is more negative than −5V.* For dual supply operation on this range a V_{SS} of −5V should be applied to the part. The advantage of having dual supplies for the unipolar output ranges are faster settling time to voltages near 0V, full-sink capability of 2.5mA maintained over the entire output range and elimination of the effects of negative offset on the transfer characteristic (outlined previously). Figure 2 shows the sink capability of the amplifier for single supply operation.

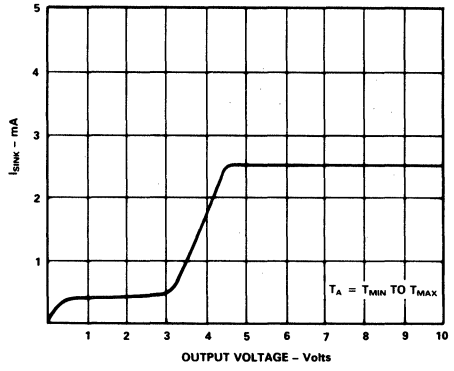

Figure 2. Typical Single Supply Sink Current vs. Output Voltage

The small-signal (200mV p-p) bandwidth of the output buffer amplifier is typically 1MHz. The output noise from the amplifier is low with a figure of 25nV/$\sqrt{Hz}$ at a frequency of 1kHz. The broadband noise from the amplifier has a typical peak-to-peak figure of 150μV for a 1MHz output bandwidth. There is no significant difference in the output noise between single and dual supply operation.

VOLTAGE REFERENCE

The AD7245/AD7248 contains an internal low-noise buried-Zener diode reference which is trimmed for absolute accuracy and temperature coefficient. The reference is internally connected to the DAC. Since the DAC has a variable input impedance at its reference input the Zener diode reference is buffered. This buffered reference is available to the user to drive the circuitry required for bipolar output ranges. It can be used as a reference for other parts in the system provided it is externally buffered. The reference will give long-term stability comparable with the best discrete Zener reference diodes. The performance of the AD7245/AD7248 is specified with internal reference, and all the testing and trimming is done with this reference. The reference should be decoupled at the REF OUT pin and recommended decoupling components are 10μF and 0.1μF capacitors in series with a 10Ω resistor. A simplified schematic of the reference circuitry is shown in Figure 3.

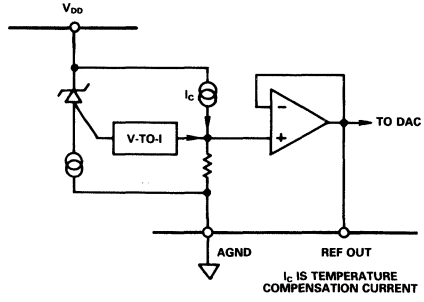

Figure 3. Internal Reference

DIGITAL SECTION

The AD7245/AD7248 digital inputs are compatible with either TTL or 5V CMOS levels. All data inputs are static-protected MOS gates with typical input currents of less than 1nA. The control inputs sink higher currents (150μA max) as a result of the fast digital interfacing. Internal input protection of all logic inputs is achieved by on-chip distributed diodes.

The AD7245/AD7248 features a very low digital feedthrough figure of 10nV secs in a 5V output range. This is due to the voltage-mode configuration of the DAC. Most of the impulse is actually as a result of feedthrough across the package. Normally, ceramic packages show more feedthrough than the other packages because of the metal lid. However, on the AD7245, the lid of the ceramic package is connected to DGND (Pin 12), and this reduces the feedthrough. The AD7248 metal lid is not connected to DGND on the package, but this can be done externally to reduce the feedthrough.

INTERFACE LOGIC INFORMATION – AD7245

Table I shows the truth table for AD7245 operation. The part contains two 12-bit latches, an input latch and a DAC latch. $\overline{CS}$ and $\overline{WR}$ control the loading of the input latch while $\overline{LDAC}$ controls the transfer of information from the input latch to the DAC latch. All control signals are level-triggered; and therefore either or both latches may be made transparent, the input latch by keeping $\overline{CS}$ and $\overline{WR}$ "LOW", the DAC latch by keeping $\overline{LDAC}$ "LOW". Input data is latched on the rising edge of $\overline{WR}$.

The data held in the DAC latch determines the analog output of the converter. Data is latched into the DAC latch on the rising edge of $\overline{LDAC}$. This $\overline{LDAC}$ signal is an asynchronous signal and is independent of $\overline{WR}$. This is useful in many applications. However, in systems where the asynchronous $\overline{LDAC}$ can occur during a write cycle (or vice versa) care must be taken to ensure that incorrect data is not latched through to the output. For example, if $\overline{LDAC}$ goes LOW while $\overline{WR}$ is "LOW", then the $\overline{LDAC}$ signal must stay LOW for t_7 or longer after $\overline{WR}$ goes high to ensure correct data is latched through to the output.

$\overline{CLR}$	$\overline{LDAC}$	$\overline{WR}$	$\overline{CS}$	Function
H	L	L	L	Both Latches are Transparent
H	H	H	X	Both Latches are Latched
H	H	X	H	Both Latches are Latched
H	H	L	L	Input Latches Transparent
H	H	↓	L	Input Latches Latched
H	L	H	H	DAC Latches Transparent
H	↓	H	H	DAC Latches Latched
L	X	X	X	DAC Latches Loaded with all 0s
↓	H	H	H	DAC Latches Latched with All 0s and Output Remains at 0V or −5V
↓	L	L	L	Both Latches are Transparent and Output Follows Input Data

H = High State L = Low State X = Don't Care

Table I. AD7245 Truth Table

The contents of the DAC latch are reset to all 0s by a low level on the $\overline{CLR}$ line. With both latches transparent, the $\overline{CLR}$ line functions like a zero override with the output brought to 0V in the unipolar mode and −5V in the bipolar mode for the duration of the $\overline{CLR}$ pulse. If both latches are latched, a "LOW" pulse on the $\overline{CLR}$ input latches all 0s into the DAC latch and the output remains at 0V (or −5V) after the $\overline{CLR}$ line has returned "HIGH". The $\overline{CLR}$ line can be used to ensure powerup to 0V on the AD7245 output in unipolar operation and is also useful, when used as a zero override, in system calibration cycles.

Figure 4 shows the input control logic for the AD7245 and the write cycle timing for the part is shown in Figure 5.

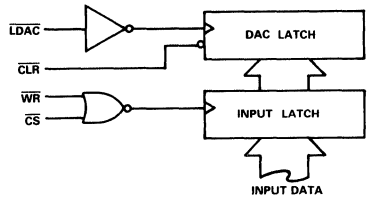

Figure 4. AD7245 Input Control Logic

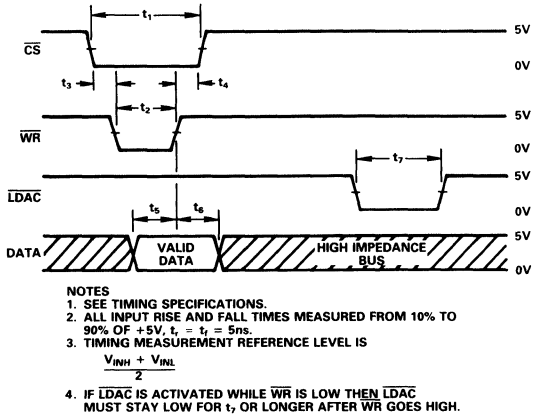

Figure 5. AD7245 Write-Cycle Timing Diagram

INTERFACE LOGIC INFORMATION – AD7248

The input loading structure on the AD7248 is configured for interfacing to microprocessors with an 8-bit-wide data bus. The part contains two 12-bit latches – an input latch and a DAC latch. Only the data held in the DAC latch determines the analog output from the converter. The truth table for AD7248 operation is shown in Table II, while the input control logic diagram is shown in Figure 6.

$\overline{CSMSB}$, $\overline{CSLSB}$ and $\overline{WR}$ control the loading of data from the external data bus to the input latch. The eight data inputs on the AD7248 accept right-justified data. This data is loaded to the input latch in two separate write operations. $\overline{CSLSB}$ and $\overline{WR}$ control the loading of the lower 8-bits into the 12-bit-wide latch. The loading of the upper 4-bit nibble is controlled by $\overline{CSMSB}$ and $\overline{WR}$. All control inputs are level triggered, and input data for either the lower byte or upper 4-bit nibble is latched into the input latches on the rising edge of $\overline{WR}$ (or either $\overline{CSMSB}$ or $\overline{CSLSB}$). The order in which the data is loaded to the input latch (i.e., lower byte or upper 4-bit nibble first) is not important.

The $\overline{LDAC}$ input controls the transfer of 12-bit data from the input latch to the DAC latch. This $\overline{LDAC}$ signal is also level triggered, and data is latched into the DAC latch on the rising edge of $\overline{LDAC}$. The $\overline{LDAC}$ input is asynchronous and independent of $\overline{WR}$. This is useful in many applications especially in the simultaneous updating of multiple AD7248 outputs. However, in systems where the asynchronous $\overline{LDAC}$ can occur during a write cycle (or vice versa) care must be taken to ensure that

incorrect data is not latched through to the output. In other words, if $\overline{LDAC}$ goes low while $\overline{WR}$ and either $\overline{CS}$ input are low (or $\overline{WR}$ and either $\overline{CS}$ go low while $\overline{LDAC}$ is low), then the $\overline{LDAC}$ signal must stay low for t_7 or longer after $\overline{WR}$ returns high to ensure correct data is latched through to the output. The write cycle timing diagram for the AD7248 is shown in Figure 7.

An alternate scheme for writing data to the AD7248 is to tie the $\overline{CSMSB}$ and $\overline{LDAC}$ inputs together. In this case exercising $\overline{CSLSB}$ and $\overline{WR}$ latches the lower 8 bits into the input latch. The second write, which exercises $\overline{CSMSB}$, $\overline{WR}$ and $\overline{LDAC}$ loads the upper 4-bit nibble to the input latch and at the same time transfers the 12-bit data to the DAC latch. This automatic transfer mode updates the output of the AD7248 in two write operations. This scheme works equally well for $\overline{CSLSB}$ and $\overline{LDAC}$ tied together provided the upper 4-bit nibble is loaded to the input latch followed by a write to the lower 8 bits of the input latch.

$\overline{CSLSB}$	$\overline{CSMSB}$	$\overline{WR}$	$\overline{LDAC}$	Function
L	H	L	H	Loads LS Byte into Input Latch
L	H	↓	H	Latches LS Byte into Input Latch
↓	H	L	H	Latches LS Byte into Input Latch
H	L	L	H	Loads MS Nibble into Input Latch
H	L	↓	H	Latches MS Nibble into Input Latch
H	↓	L	H	Latches MS Nibble into Input Latch
H	H	H	L	Loads Input Latch into DAC Latch
H	H	H	↓	Latches Input Latch into DAC Latch
H	L	L	L	Loads MS Nibble into Input Latch and Loads Input Latch into DAC Latch
H	H	H	H	No Data Transfer Operation

H = High State L = Low State

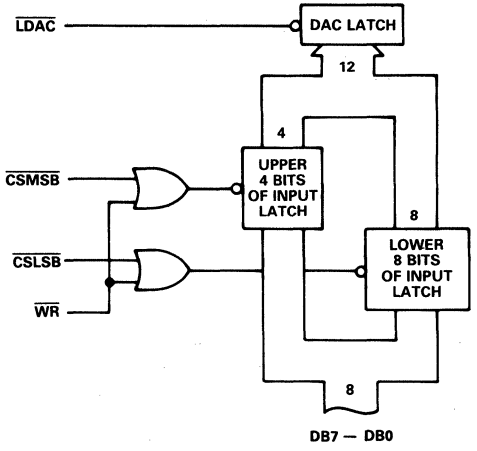

Figure 6. AD7248 Input Control Logic

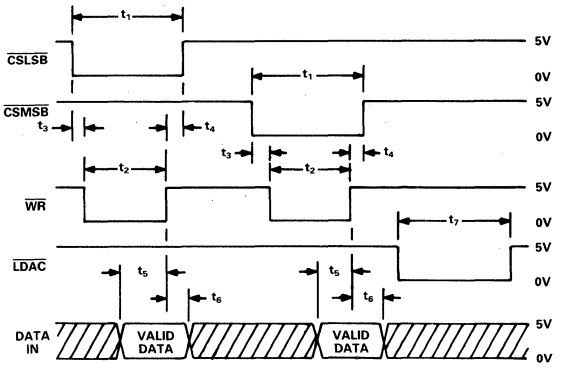

Figure 7. AD7248 Write Cycle Timing Diagram

APPLYING THE AD7245/AD7248

The internal scaling resistors provided on the AD7245/AD7248 allow several output voltage ranges. The part can produce unipolar output ranges of 0V to +5V or 0V to +10V and a bipolar output range of −5V to +5V. Connections for the various ranges are outlined below.

UNIPOLAR (0V to +10V) CONFIGURATION

The first of the configurations provides an output voltage range of 0V to +10V. This is achieved by connecting the bipolar offset resistor, R_{OFS}, to AGND and connecting R_{FB} to V_{OUT}. In this configuration the AD7245/AD7248 can be operated single supply (V_{SS} = 0V = AGND). If dual supply performance is required, a V_{SS} of −5V should be applied. Note that a V_{SS} supply more negative than −5V should not be applied to the AD7245/AD7248 when it is configured for a 0 to +10V output range. Figure 8 shows the connection diagram for unipolar operation while the table for output voltage versus the digital code in the DAC latch is shown in Table III.

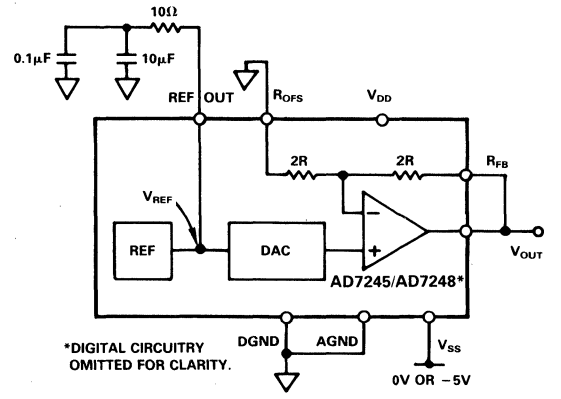

Figure 8. Unipolar (0 to +10V) Configuration

DAC Latch Contents MSB LSB	Analog Output, V_{OUT}
1111 1111 1111	$+2 \cdot V_{REF} \cdot \left(\frac{4095}{4096}\right)$
1000 0000 0001	$+2 \cdot V_{REF} \cdot \left(\frac{2049}{4096}\right)$
1000 0000 0000	$+2 \cdot V_{REF} \cdot \left(\frac{2048}{4096}\right) = +V_{REF}$
0111 1111 1111	$+2 \cdot V_{REF} \cdot \left(\frac{2047}{4096}\right)$
0000 0000 0001	$+2 \cdot V_{REF} \cdot \left(\frac{1}{4096}\right)$
0000 0000 0000	0V

NOTE: $1LSB = 2 \cdot V_{REF}(2^{-12}) = V_{REF}\left(\frac{1}{2048}\right)$

Table III. Unipolar Code Table (0V to +10V Range)

UNIPOLAR (0V to +5V) CONFIGURATION

The 0V to +5V output voltage range is achieved by tying R_{OFS}, R_{FB} and V_{OUT} together. For this output range the AD7245/AD7248 can be operated single supply (V_{SS} = 0V) or dual supply. The table for output voltage versus digital code is as in Table III, with $2 \cdot V_{REF}$ replaced by V_{REF}. Note that for this range

$$1LSB = V_{REF}(2^{-12}) = V_{REF} \cdot \frac{1}{4096}.$$

BIPOLAR CONFIGURATION

The bipolar configuration for the AD7245/AD7248, which gives an output voltage range from −5V to +5V, is achieved by connecting the R_{OFS} input to REF OUT and connecting R_{FB} and V_{OUT}. The AD7245/AD7248 must be operated from dual supplies to achieve this output voltage range. The code table for bipolar operation is shown in Table IV.

DAC Latch Contents MSB LSB	Analog Output, V_{OUT}
1111 1111 1111	$+V_{REF} \cdot \left(\frac{2047}{2048}\right)$
1000 0000 0001	$+V_{REF} \cdot \left(\frac{1}{2048}\right)$
1000 0000 0000	0V
0111 1111 1111	$-V_{REF} \cdot \left(\frac{1}{2048}\right)$
0000 0000 0001	$-V_{REF} \cdot \left(\frac{2047}{2048}\right)$
0000 0000 0000	$-V_{REF} \cdot \left(\frac{2048}{2048}\right) = -V_{REF}$

NOTE: $1LSB = 2 \cdot V_{REF}(2^{-11}) = V_{REF}\left(\frac{1}{2048}\right)$

Table IV. Bipolar Code Table

AGND BIAS

The AD7245/AD7248 AGND pin can be biased above system GND (AD7245/AD7248 DGND) to provide an offset "zero" analog output voltage level. With unity gain on the amplifier ($R_{OFS} = V_{OUT} = R_{FB}$) the output voltage, V_{OUT} is expressed as:

$$V_{OUT} = V_{BIAS} + D \cdot V_{REF}$$

where D is a fractional representation of the digital word in the DAC latch and V_{BIAS} is the voltage applied to the AD7245/AD7248 AGND pin.

Because the current flowing out of the AGND pin varies with digital code, the AGND pin should be driven from a low impedance source. A circuit configuration is outlined for AGND bias in Figure 9 using the AD589, a +1.23V bandgap reference.

If a gain of 2 is used on the buffer amplifier the output voltage, V_{OUT} is expressed as

$$V_{OUT} = 2(V_{BIAS} + D \cdot V_{REF})$$

In this case care must be taken to ensure that the maximum output voltage is not greater than V_{DD} −3V. The $V_{DD} - V_{OUT}$ overhead must be greater than 3V to ensure correct operation of the part. Note that V_{DD} and V_{SS} for the AD7245/AD7248 must be referenced to DGND (system GND). The entire circuit can be operated in single supply with the V_{SS} pin of the AD7245/AD7248 connected to system GND.

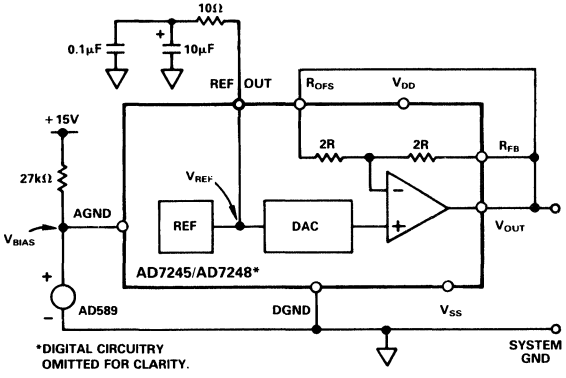

Figure 9. AGND Bias Current

PROGRAMMABLE CURRENT SINK

Figure 10 shows how the AD7245/AD7248 can be configured with a power MOSFET transistor, the VN0300M, to provide a

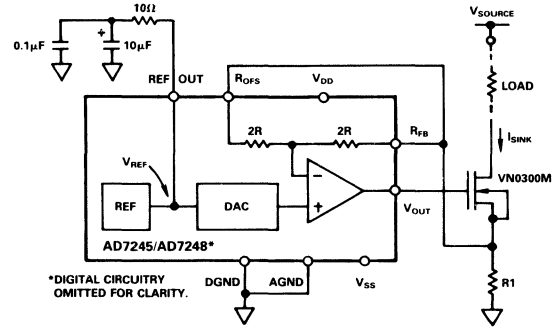

Figure 10. Programmable Current Sink

programmable current sink from V_{DD} or V_{SOURCE}. The VN0300M is placed in the feedback of the AD7245/AD7248 amplifier. The entire circuit can be operated in single supply by tying the V_{SS} of the AD7245/AD7248 to AGND. The sink current, I_{SINK}, can be expressed as:

$$I_{SINK} = \frac{D \cdot V_{REF}}{R1}$$

Using the VN0300M, the voltage drop across the load can typically be as large as (V_{SOURCE} −6V) with V_{OUT} of the DAC at +5V. Therefore, for a current of 50mA flowing in the R1 (with all 1s in the DAC register) the maximum load is 200Ω with V_{SOURCE} = +15V. The VN0300M can actually handle currents up to 500mA and still function correctly in the circuit, but in practice the circuit must be used with larger values of V_{SOURCE} otherwise it requires a very small load.

Since the tolerance value on the reference voltage of the AD7245/AD7248 is ±0.2%, then the absolute value of I_{SINK} can vary by ±0.2% from device to device for a fixed value of R1.

Because the input bias current of the AD7245/AD7248's op amp is only of the order of pA's, its effect on the sink current is negligible. Tying the R_{OFS} input to the R_{FB} input reduces this effect even further and prevents noise pickup which could occur if the R_{OFS} pin was left unconnected.

The circuit of Figure 10 can be modified to provide a programmable current source to AGND or $-V_{SINK}$ (for $-V_{SINK}$, dual supplies are required on the AD7245/AD7248). The AD7245/AD7248 is configured as before. The current through R1 is mirrored with a current mirror circuit to provide the programmable source current (see CMOS DAC Application Guide, Publication No. G872-30-10/84, for suitable current mirror circuit). As before the absolute value of the source current will be affected by the ±0.2% tolerance on V_{REF}. In this case the performance of the current mirror will also affect the value of the source current.

FUNCTION GENERATOR WITH PROGRAMMABLE FREQUENCY

Figure 11 shows how the AD7245/AD7248 can be configured with the AD537, voltage-to-frequency converter and the AD639, trigonometric function generator to provide a complete function generator with programmable frequency. The circuit provides square-wave, triwave and sinewave outputs, each output of ±10V amplitude.

The AD7245/AD7248 provides a programmable voltage to the AD537 input. Since both the AD7245/AD7248 and AD537 are guaranteed monotonic, the output frequency will always increase with increasing digital code. The AD537 provides a square-wave output which is conditioned for ±10V by amplifier A1. The AD537 also provides a differential triwave output. This is conditioned by amplifiers A2 and A3 to provide the ±1.8V triwave required at the input of the AD639. The triwave is further scaled by amplifier A4 to provide a ±10V output.

Adjusting the triwave applied to the AD639 adjusts the distortion performance of the sine wave output, (+10V in configuration shown). Amplitude, offset and symmetry of the triwave can affect the distortion. By adjusting these, via VR1 and VR2, an output sine wave with harmonic distortion of better than −50dB can be achieved at low and intermediate frequencies.

Using the capacitor value shown in Figure 11 for C_F (i.e. 680pF) the output frequency range is 0 to 100kHz over the digital input code range. The step size for frequency increments is 25Hz. The accuracy of the output frequency is limited to 8 or 9 bits by the AD537, but it is guaranteed monotonic to 12 bits.

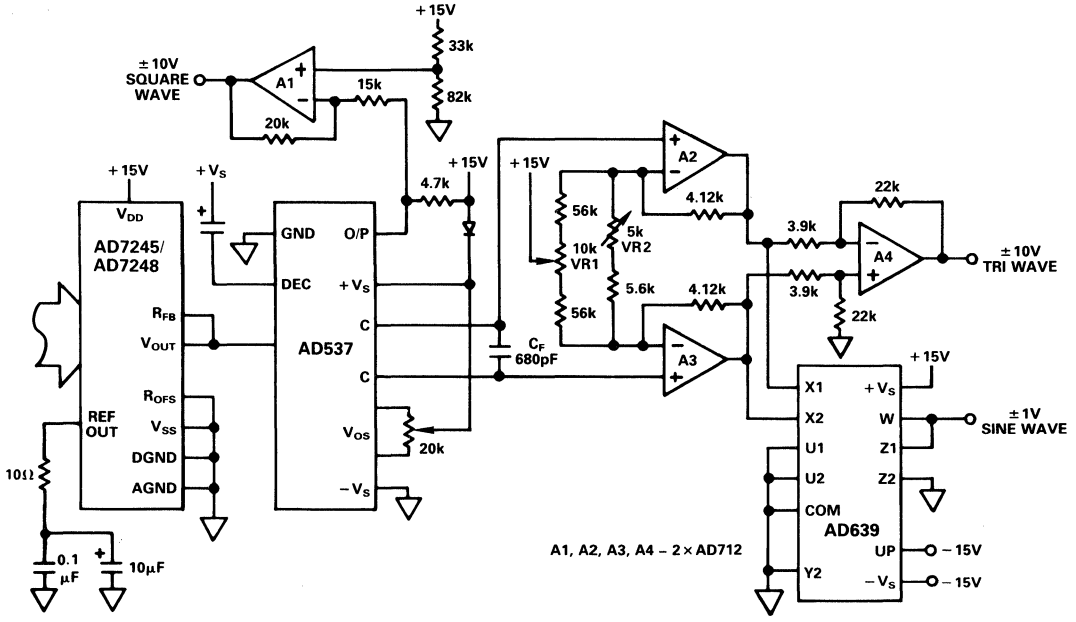

Figure 11. Programmable Function Generator

MICROPROCESSOR INTERFACING – AD7245

AD7245 – 8086A INTERFACE

Figure 12 shows the 8086 16-bit processor interfacing to the AD7245. In the setup shown the double-buffering feature of the DAC is not used and the $\overline{LDAC}$ input is tied LOW. AD0-AD11 of the 16-bit data bus are connected to the AD7245 data bus (DB0-DB11). The 12-bit word is written to the AD7245 in one MOV instruction and the analog output responds immediately. In this example the DAC address is D000. A software routine for Figure 12 is given in Table V.

Table V. Sample Program for Loading AD7245 from 8086

In a multiple DAC system the double-buffering of the AD7245 allows the user to simultaneously update all DACs. In Figure 13, a 12-bit word is loaded to the input latches of each of the DACs in sequence. Then, with one instruction to the appropriate address, $\overline{CS4}$ (i.e., $\overline{LDAC}$) is brought LOW, updating all the DACs simultaneously.

AD7245 – MC68000 INTERFACE

Interfacing between the MC68000 and the AD7245 is accomplished using the circuit of Figure 14. Once again the AD7245 is used in the single-buffered mode. A software routine for loading data to the AD7245 is given in Table VI. In this example the AD7245 is located at address E000, and the 12-bit word is written to the DAC in one MOVE instruction.

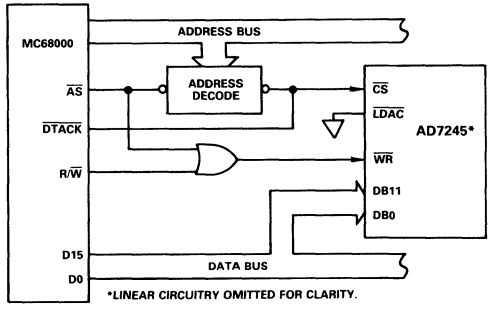

Figure 14. AD7245 to 68000 Interface

MICROPROCESSOR INTERFACING – AD7248

Figure 15 shows the connection diagram for interfacing the AD7248 to both the 8085A and 8088 microprocessors. This scheme is also suited to the Z80 microprocessor, but the Z80 address/data bus does not have to be demutiplexed. Data to be loaded to the AD7248 is right-justified. The AD7248 is memory mapped with a separate memory address for the input latch high byte, the input latch low byte and the DAC latch. Data is first written to the AD7248 input latch in two write operations. Either the high byte or the low byte data can be written first to the AD7248 input latch. A write to the AD7248 DAC latch address transfers the input latch data to the DAC latch and updates the output voltage. Alternatively, the $\overline{LDAC}$ input can be asynchronous or can be common to a number of AD7248s for simultaneous updating of a number of voltage channels.

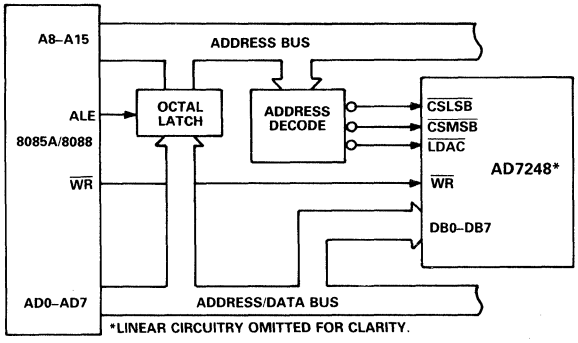

Figure 15. AD7248 to 8085A/8088 Interface

A connection diagram for the interface between the AD7248 and 68008 microprocessor is shown in Figure 16. Once again, the AD7248 acts as a memory mapped device and data is right-justified. In this case the AD7248 is configured in the automatic transfer mode which means that the high byte of the input latch has the same address as the DAC latch. Data is written to the AD7248 by first writing data to the AD7248 low byte. Writing data to the high byte of the input latch also transfers the input latch contents to the DAC latch and updates the output.

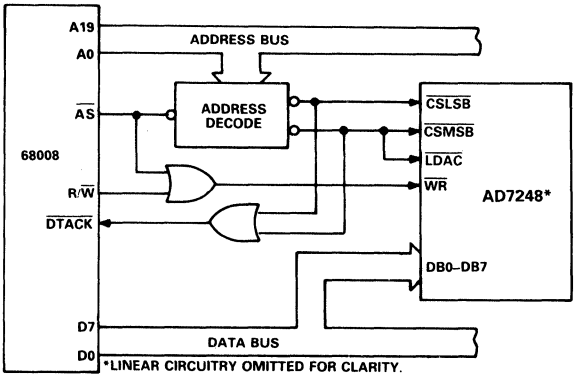

Figure 16. AD7248 to 68008 Interface

An interface circuit for connections to the 6502 or 6809 microprocessors is shown in Figure 17. Once again, the AD7248 is memory mapped and data is right-justified. The procedure for writing data to the AD7248 is as outlined for the 8085A/8088. For the 6502 microprocessor the $\phi 2$ clock is used to generate the $\overline{WR}$, while for the 6809 the E signal is used.

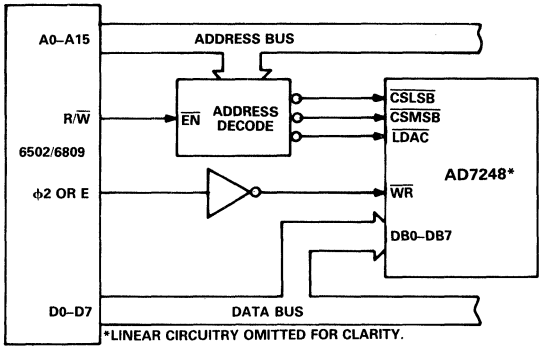

Figure 17. AD7248 to 6502/6809 Interface

Figure 18 shows a connection diagram between the AD7248 and the 8051 microprocessor. The AD7248 is port mapped in this interface and is configured in the automatic transfer mode. Data to be loaded to the input latch low byte is output to Port 1. Output Line P3.0, which is connected to $\overline{CSLSB}$ of the AD7248, is pulsed to load data into the low byte of the input latch. Pulsing the P3.1 line, after the high byte data has been set up on Port 1, updates the output of the AD7248. The $\overline{WR}$ input of the AD7248 can be hardwired low in this application because spurious address strobes on $\overline{CSLSB}$ and $\overline{CSMSB}$ do not occur.

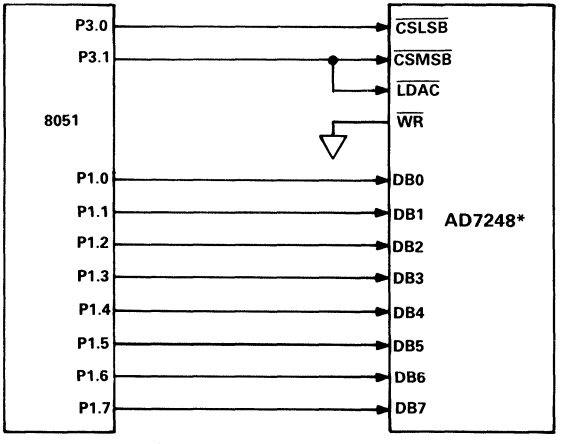

Figure 18. AD7248 to MCS-51 Interface

ANALOG DEVICES

CMOS 8-Bit Buffered Multiplying DAC

AD7524

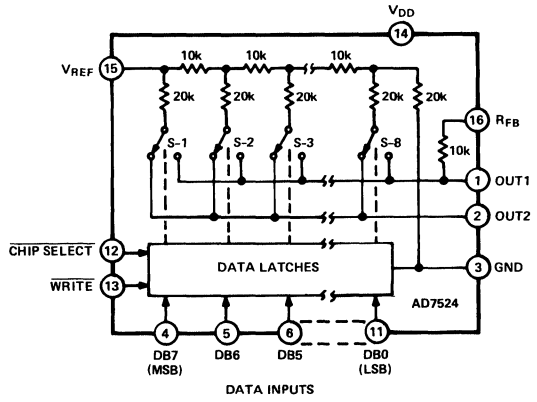
FEATURES

- Microprocessor Compatible (6800, 8085, Z80, Etc.)
- TTL/CMOS Compatible Inputs
- On-Chip Data Latches
- End Point Linearity
- Low Power Consumption
- Monotonicity Guaranteed (Full Temperature Range)
- Latch Free (No Protection Schottky Required)

APPLICATIONS

- Microprocessor Controlled Gain Circuits
- Microprocessor Controlled Attenuator Circuits
- Microprocessor Controlled Function Generation
- Precision AGC Circuits
- Bus Structured Instruments

AD7524 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7524 is a low cost, 8-bit monolithic CMOS DAC designed for direct interface to most microprocessors.

Basically an 8-bit DAC with input latches, the AD7524's load cycle is similar to the "write" cycle of a random access memory. Using an advanced thin-film on CMOS fabrication process, the AD7524 provides accuracy to 1/8LSB with a typical power dissipation of less than 10 milliwatts.

A newly improved design eliminates the protection Schottky previously required and guarantees TTL compatibility when using a +5V supply. Loading speed has been increased for compatibility with most microprocessors.

Featuring operation from +5V to +15V, the AD7524 interfaces directly to most microprocessor buses or output ports.

Excellent multiplying characteristics (2- or 4-quadrant) make the AD7524 an ideal choice for many microprocessor controlled gain setting and signal control applications.

2

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

TERMINOLOGY

RELATIVE ACCURACY: A measure of the deviation from a straight line through the end points of the DAC transfer function. Normally expressed as a percentage of full scale range. For the AD7524 DAC, this holds true over the entire V_{REF} range.

RESOLUTION: Value of the LSB. For example, a unipolar converter with n bits has a resolution of $(2^{-n})(V_{REF})$. A bipolar converter of n bits has a resolution of $[2^{-(n-1)}][V_{REF}]$. Resolution in no way implies linearity.

GAIN ERROR: Gain Error is a measure of the output error between an ideal DAC and the actual device output. It is measured with all 1s in the DAC after offset error has been adjusted out and is expressed in LSBs. Gain Error is adjustable to zero with an external potentiometer.

FEEDTHROUGH ERROR: Error caused by capacitive coupling from V_{REF} to output with all switches OFF.

OUTPUT CAPACITANCE: Capacity from OUT1 and OUT2 terminals to ground.

OUTPUT LEAKAGE CURRENT: Current which appears on OUT1 terminal with all digital inputs LOW or on OUT2 terminal when all inputs are HIGH. This is an error current which contributes an offset voltage at the amplifier output.

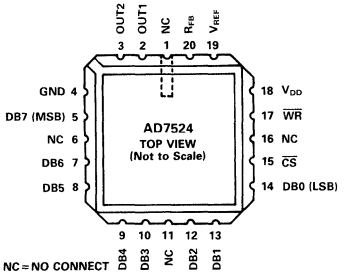
LCCC



CIRCUIT DESCRIPTION

CIRCUIT INFORMATION

The AD7524, an 8-bit multiplying D/A converter, consists of a highly stable thin film R-2R ladder and eight N-channel current switches on a monolithic chip. Most applications require the addition of only an output operational amplifier and a voltage or current reference.

The simplified D/A circuit is shown in Figure 1. An inverted R-2R ladder structure is used – that is, the binarily weighted currents are switched between the OUT1 and OUT2 bus lines, thus maintaining a constant current in each ladder leg independent of the switch state.

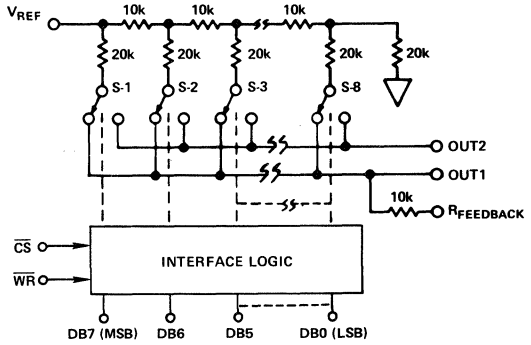


Figure 1. AD7524 Functional Diagram

EQUIVALENT CIRCUIT ANALYSIS

The equivalent circuit for all digital inputs LOW is shown in Figures 2. In Figure 2 with all digital inputs LOW, the reference current is switched to OUT2. The current source $I_{LEAKAGE}$ is composed of surface and junction leakages to the substrate while the $\frac{1}{256}$ current source represents a constant 1-bit current drain through the termination resistor on the R-2R ladder. The "ON" capacitance of the output N-channel switches is 120pF, as shown on the OUT2 terminal. The "OFF" switch capacitance is 30pF, as shown on the OUT1 terminal. Analysis of the circuit for all digital inputs high is similar to Figure 2 however, the "ON" switches are now on terminal OUT1, hence the 120pF appears at that terminal.

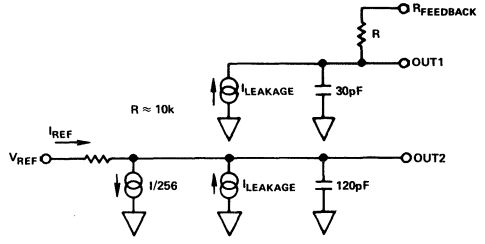

Figure 2. AD7524 DAC Equivalent Circuit – All Digital Inputs Low

INTERFACE LOGIC INFORMATION

MODE SELECTION

AD7524 mode selection is controlled by the $\overline{CS}$ and $\overline{WR}$ inputs.

WRITE MODE

When $\overline{CS}$ and $\overline{WR}$ are both LOW, the AD7524 is in the WRITE mode, and the AD7524 analog output responds to data activity at the DB0–DB7 data bus inputs. In this mode, the AD7524 acts like a nonlatched input D/A converter.

HOLD MODE

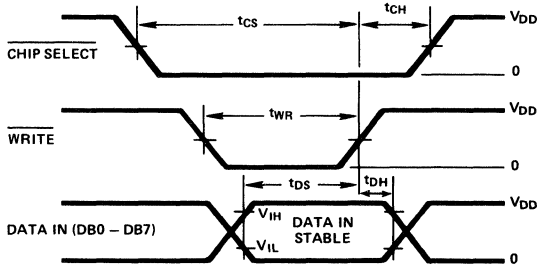
When either $\overline{CS}$ or $\overline{WR}$ is HIGH, the AD7524 is in the HOLD mode. The AD7524 analog output holds the value corresponding to the last digital input present at DB0–DB7 prior to $\overline{WR}$ or $\overline{CS}$ assuming the HIGH state.

MODE SELECTION TABLE

$\overline{CS}$	$\overline{WR}$	MODE	DAC RESPONSE
L	L	Write	DAC responds to data bus (DB0 – DB7) inputs
H	X	Hold	Data bus (DB0 – DB7) is locked out;
X	H	Hold	DAC holds last data present when $\overline{WR}$ or $\overline{CS}$ assumed HIGH state.

L = Low State, H = High State, X = Don't Care.

WRITE CYCLE TIMING DIAGRAM



NOTES:
1. All input signal rise and fall times measured from 10% to 90% of V_{DD}. V_{DD} = +5V, $t_r = t_f$ = 20ns; V_{DD} = +15V, $t_r = t_f$ = 40ns.
2. Timing Measurement Reference level is $\frac{V_{IH} + V_{IL}}{2}$
3. $t_{DS} + t_{DH}$ is approximately constant at 145ns min at +25°C, V_{DD} = +5V and t_{WR} = 170ns min. The AD7524 is specified for a minimum t_{DH} of 10ns, however, in applications where $t_{DH} > 10$ns, t_{DS} may be reduced accordingly up to the limit t_{DS} = 65ns, t_{DH} = 80ns.

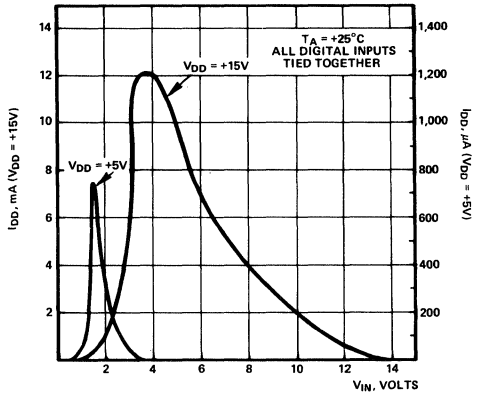


Figure 3. Supply Current vs. Logic Level

Typical plots of supply current, I_{DD}, versus logic input voltage, V_{IN}, for V_{DD} = +5V and V_{DD} = +15V are shown above.

CMOS Dual 8-Bit Buffered Multiplying DAC

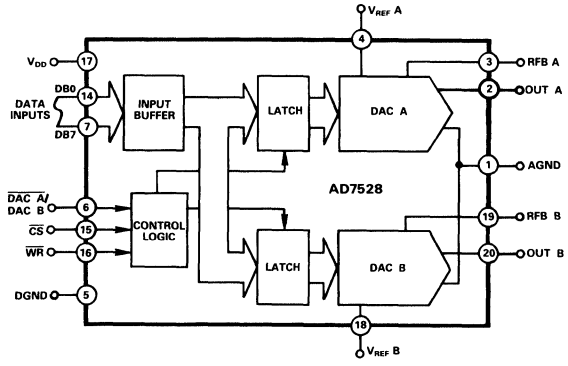
AD7528

FEATURES
- On-Chip Latches for Both DACs
- +5V to +15V Operation
- DACs Matched to 1%
- Four Quadrant Multiplication
- TTL/CMOS Compatible
- Latch Free (Protection Schottkys not Required)

APPLICATIONS

Digital Control of:
- Gain/Attenuation
- Filter Parameters
- Stereo Audio Circuits
- X–Y Graphics

AD7528 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7528 is a monolithic dual 8-bit digital/analog converter featuring excellent DAC-to-DAC matching. It is available in skinny 0.3″ wide 20-pin DIPs and in 20-terminal surface mount packages.

Separate on-chip latches are provided for each DAC to allow easy microprocessor interface.

Data is transferred into either of the two DAC data latches via a common 8-bit TTL/CMOS compatible input port. Control input $\overline{\text{DAC A}}$/DAC B determines which DAC is to be loaded. The AD7528's load cycle is similar to the write cycle of a random access memory and the device is bus compatible with most 8-bit microprocessors, including 6800, 8080, 8085, Z80.

The device operates from a +5V to +15V power supply, dissipating only 20mW of power.

Both DACs offer excellent four quadrant multiplication characteristics with a separate reference input and feedback resistor for each DAC.

PRODUCT HIGHLIGHTS

1. DAC to DAC matching: since both of the AD7528 DACs are fabricated at the same time on the same chip, precise matching and tracking between DAC A and DAC B is inherent. The AD7528's matched CMOS DACs make a whole new range of applications circuits possible, particularly in the audio, graphics and process control areas.
2. Small package size: combining the inputs to the on-chip DAC latches into a common data bus and adding a $\overline{\text{DAC A}}$/DAC B select line has allowed the AD7528 to be packaged in either a small 20-pin 0.3″ wide DIP or in 20-terminal surface mount packages.

NOTES

[1]Temperature Ranges are J, K, L Versions; −40°C to +85°C
A, B, C Versions; −40°C to +85°C
S, T, U Versions; −55°C to +125°C

[2]Specification applies to both DACs in AD7528.

[3]Logic inputs are MOS Gates. Typical input current (+25°C) is less than 1nA.

[4]Guaranteed by design but not production tested.

[5]These characteristics are for design guidance only and are not subject to test.

Specifications subject to change without notice.

INTERFACE LOGIC INFORMATION

DAC Selection:
Both DAC latches share a common 8-bit input port. The control input $\overline{\text{DAC A}}$/DAC B selects which DAC can accept data from the input port.

Mode Selection:
Inputs $\overline{\text{CS}}$ and $\overline{\text{WR}}$ control the operating mode of the selected DAC. See Mode Selection Table below.

Write Mode:
When $\overline{\text{CS}}$ and $\overline{\text{WR}}$ are both low the selected DAC is in the write mode. The input data latches of the selected DAC are transparent and its analog output responds to activity on DB0–DB7.

Hold Mode:
The selected DAC latch retains the data which was present on DB0–DB7 just prior to $\overline{\text{CS}}$ or $\overline{\text{WR}}$ assuming a high state. Both analog outputs remain at the values corresponding to the data in their respective latches.

$\overline{\text{DAC A}}$/DAC B	$\overline{\text{CS}}$	$\overline{\text{WR}}$	DAC A	DAC B
L	L	L	WRITE	HOLD
H	L	L	HOLD	WRITE
X	H	X	HOLD	HOLD
X	X	H	HOLD	HOLD

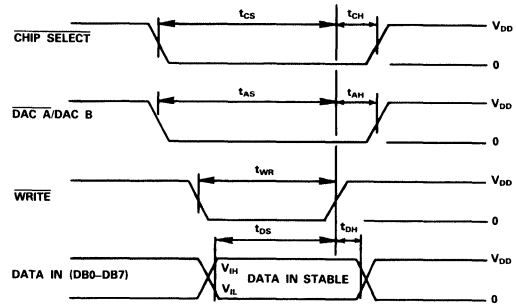
L = Low State H = High State X = Don't Care

Mode Selection Table

CAUTION:

1. ESD sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subjected to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts.
2. Do not insert this device into powered sockets. Remove power before insertion or removal.

WRITE CYCLE TIMING DIAGRAM



NOTES:
1. ALL INPUT SIGNAL RISE AND FALL TIMES MEASURED FROM 10% TO 90% OF V_{DD}.
   V_{DD} = +5V, t_r = t_f = 20ns;
   V_{DD} = +15V, t_r = t_f = 40ns.
2. TIMING MEASUREMENT REFERENCE LEVEL IS $\frac{V_{IH}+V_{IL}}{2}$

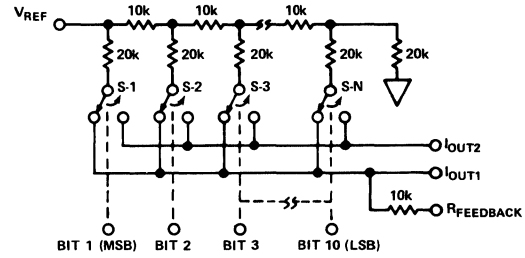
CMOS Low Cost 10-Bit Multiplying DAC

AD7533

FEATURES
- Lowest Cost 10-Bit DAC
- Low Cost AD7520 Replacement
- Linearity: 1/2, 1 or 2LSB
- Low Power Dissipation
- Full Four-Quadrant Multiplying DAC
- CMOS/TTL Direct Interface
- Latch Free (Protection Schottky not Required)
- End-Point Linearity

APPLICATIONS
- Digitally Controlled Attenuators
- Programmable Gain Amplifiers
- Function Generation
- Linear Automatic Gain Control

AD7533 FUNCTIONAL BLOCK DIAGRAM



DIGITAL INPUTS (DTL/TTL/CMOS COMPATIBLE)

Logic: A switch is closed to I_{OUT1} for its digital input in a "HIGH" state.

GENERAL DESCRIPTION

The AD7533 is a low cost 10-bit 4-quadrant multiplying DAC manufactured using an advanced thin-film-on-monolithic-CMOS wafer fabrication process.

Pin and function equivalent to the industry standard AD7520, the AD7533 is recommended as a lower cost alternative for old AD7520 sockets or new 10-bit DAC designs.

AD7533 application flexibility is demonstrated by its ability to interface to TTL or CMOS, operate on +5V to +15V power, and provide proper binary scaling for reference inputs of either positive or negative polarity.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

2

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

TERMINOLOGY

RELATIVE ACCURACY: Relative accuracy or end-point nonlinearity is a measure of the maximum deviation from a straight line passing through the endpoints of the DAC transfer function. It is measured after adjusting for ideal zero and full scale and is expressed in % of full-scale range or (sub) multiples of 1LSB.

RESOLUTION: Value of the LSB. For example, a unipolar converter with n bits has a resolution of (2^{-n}) (V_{REF}). A bipolar converter of n bits has a resolution fo $[2^{-(n-1)}]$ (V_{REF}). Resolution in no way implies linearity.

SETTLING TIME: Time required for the output function of the DAC to settle to within 1/2LSB for a given digital input stimulus, i.e., 0 to Full Scale.

GAIN ERROR: Gain error is a measure of the output error between an ideal DAC and the actual device output. It is measured with all 1s in the DAC after offset error has been adjusted out and is expressed in Least Significant Bits. Gain error is adjustble to zero with an external potentiometer.

FEEDTHROUGH ERROR: Error caused by capacitive coupling from V_{REF} to output with all switches OFF.

OUTPUT CAPACITANCE: Capacity from I_{OUT1} and I_{OUT2} terminals to ground.

OUTPUT LEAKAGE CURRENT: Current which appears on I_{OUT1} terminal with all digital inputs LOW or on I_{OUT2} terminal when all inputs are HIGH.

CIRCUIT DESCRIPTION

GENERAL CIRCUIT INFORMATION

The AD7533, a 10-bit multiplying D/A converter, consists of a highly stable thin film R-2R ladder and ten CMOS current switches on a monolithic chip. Most applications require the addition of only an output operational amplifier and a voltage or current reference.

The simplified D/A circuit is shown in Figure 1. An inverted R-2R ladder structure is used – that is, the binarily weighted currents are switched between the I_{OUT1} and I_{OUT2} bus lines, thus maintaining a constant current in each ladder leg independent of the switch state.

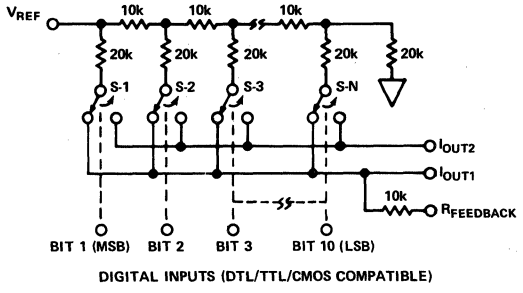

Figure 1. AD7533 Functional Diagram

One of the CMOS current switches is shown in Figure 2. The geometries of devices 1, 2 and 3 are optimized to make the digital control inputs DTL/TTL/CMOS compatible over the full military temperature range. The input stage drives two inverters (devices 4, 5, 6 and 7) which in turn drive the two output N channels. The "ON" resistances of the switches are binarily sealed so the voltage drop across each switch is the same. For example, switch 1 of Figure 2 was designed for an "ON" resistance of 20Ω, switch 2 for 40Ω, and so on. For a 10V reference input, the current through switch 1 is 0.5mA, the current through switch 2 is 0.25mA, and so on, thus maintaining a constant 10mV drop across each switch. It is essential that each switch voltage drop be equal if the binarily weighted current division property of the ladder is to be maintained.

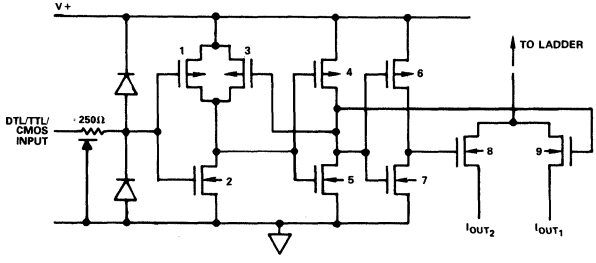

Figure 2. CMOS Switch

EQUIVALENT CIRCUIT ANALYSIS

The equivalent circuits for all digital inputs high and all digital inputs low are shown in Figures 3 and 4. In Figure 3 with all digital inputs low, the reference current is switched to I_{OUT2}. The current source $I_{LEAKAGE}$ is composed of surface and junction leakages to the substrate while the $\frac{I}{1024}$ current source represents a constant 1-bit current drain through the termination resistor on the R-2R ladder. The "ON" capacitance of the output N channel switch is 100pF, as shown on the I_{OUT2} terminal. The "OFF" switch capacitance is 35pF, as shown on the I_{OUT1} terminal. Analysis of the circuit for all digital inputs high, as shown in Figure 4, is similar to Figure 3; however, the "ON" switches are now on terminal I_{OUT1}, hence the 100pF at that terminal.

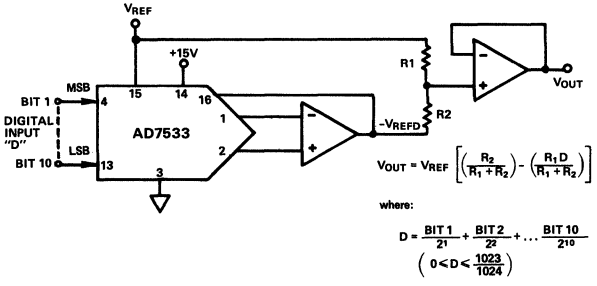
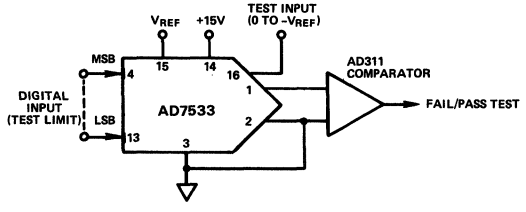
MODIFIED SCALE FACTOR AND OFFSET



DIGITALLY PROGRAMMABLE LIMIT DETECTOR



LC²MOS µP-Compatible 14-Bit DAC

AD7534

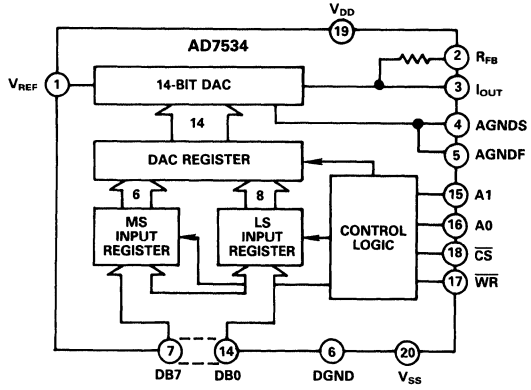
FEATURES

- All Grades 14-Bit Monotonic Over the Full Temperature Range
- Full 4-Quadrant Multiplication
- Microprocessor Compatible with Double Buffered Inputs
- Exceptionally Low Gain Temperature Coefficient, 0.5ppm/°C typ
- Small 20-Pin DIP and Surface Mount Package
- Low Output Leakage (<20nA) Over the Full Temperature Range

APPLICATIONS

- Microprocessor Based Control Systems
- Digital Audio Reconstruction
- High Precision Servo Control
- Control and Measurement in High Temperature Environments

AD7534 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7534 is a 14-bit monolithic CMOS D/A converter which uses thin-film resistors and laser trimming to achieve excellent linearity.

The device is configured to accept right-justified data in two bytes from an 8-bit data bus. Standard Chip Select and Memory Write logic is used to access the DAC. Address lines A0 and A1 control internal register loading and transfer.

A novel low leakage configuration (patent pending) enables the AD7534 to exhibit excellent output leakage current characteristics over the specified temperature range.

The device is fully protected against CMOS "latch up" phenomena and does not require the use of external Schottky diodes or the use of a FET Input op amp. The AD7534 is manufactured using the Linear Compatible CMOS (LC²MOS) process. It is speed compatible with most microprocessors and accepts TTL or CMOS logic level inputs.

PRODUCT HIGHLIGHTS

1. Guaranteed Montonicity
   The AD7534 is guaranteed monotonic to 14-bits over the full temperature range for all grades.
2. Low Output Leakage
   By tying V_{SS} (Pin 20) to a negative voltage, it is possible to achieve a low output leakage current at high temperatures.
3. Microprocessor Compatibility
   High speed input control (TTL/5V CMOS compatible) allows direct interfacing to most of the popular 8-bit and 16-bit microprocessors.
4. Monolithic Construction
   For increased reliability and reduced package size – 0.3" 20-pin DIP and 20-terminal surface mount package.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

UNIPOLAR BINARY OPERATION (2-QUADRANT MULTIPLICATION)

Figure 2 shows the circuit diagram for unipolar binary operation. With an ac input, the circuit performs 2-quadrant multiplication. The code table for Figure 2 is given in Table I.

Capacitor C1 provides phase compensation and helps prevent overshoot and ringing when high speed op-amps are used.

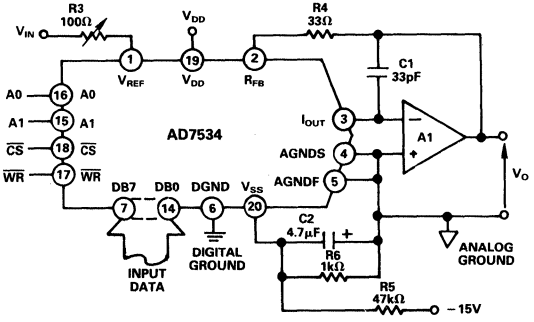

Figure 2. Unipolar Binary Operation

Binary Number In DAC Register	Analog Output, V_{OUT}
MSB LSB	
11 1111 1111 1111	$-V_{IN}\left(\frac{16383}{16384}\right)$
10 0000 0000 0000	$-V_{IN}\left(\frac{8192}{16384}\right) = -1/2\,V_{IN}$
00 0000 0000 0001	$-V_{IN}\left(\frac{1}{16384}\right)$
00 0000 0000 0000	0V

Table I. Unipolar Binary Code Table for AD7534

WR	CS	A1	A0	Function
X[1]	1	X	X	Device not selected
1	X	X	X	No data transfer
0	0	0	0	DAC loaded directly from Data Bus[2]
0	0	0	1	MS Input Register loaded from Data Bus
0	0	1	0	LS Input Register loaded from Data Bus
0	0	1	1	DAC Register loaded from Input Registers.

NOTES
1. X = Don't Care
2. When $A_1 = 0$, $A_0 = 0$ all DAC registers are transparent, so by placing all 0s or all 1s on the data inputs the user can load the DAC to zero or full-scale output in one write operation. This facility simplifies system calibration.

BIPOLAR OPERATION (4-QUADRANT MULTIPLICATION)

The recommended circuit diagram for bipolar operation is shown in Figure 3. Offset binary coding is used.

With the DAC loaded to 10 0000 0000 0000, adjust R3 for V_O = 0V. Alternatively, one can omit R3 and R4 and adjust the ratio of R7 and R8 for V_O = 0V. Full scale trimming can be accomplished by adjusting the amplitude of V_{IN} or by varying the value of R9.

Resistors R7, R8 and R9 should be matched to 0.003%. Mismatch of R7 and R8 causes both offset and full scale error. When operating over a wide temperature range, it is important that the resistors be of the same type so that their temperature coefficient match.

The code table for Figure 3 is given in Table II.

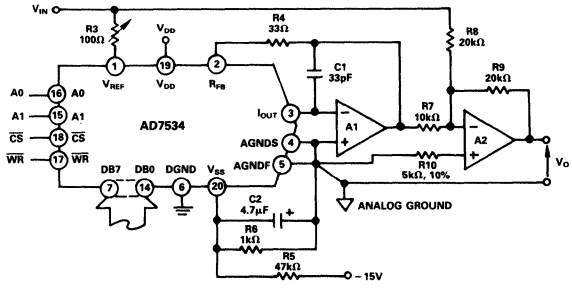

Figure 3. Bipolar Operation

Binary Number in DAC Register MSB LSB	Analog Output
11 1111 1111 1111	$+V_{IN}\left(\frac{8191}{8192}\right)$

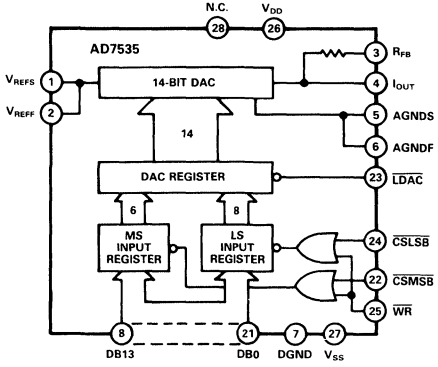
AD7535 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7535 is a 14-bit monolithic CMOS D/A converter which uses laser trimmed thin-film resistors to achieve excellent linearity.

Standard Chip Select and Memory Write logic is used to access the DAC.

A novel low leakage configuration (patent pending) enables the AD7535 to exhibit excellent output leakage current characteristics over the specified temperature range.

The device is fully protected against CMOS "latch up" phenomena and does not require the use of external Schottky diodes or the use of a FET Input op-amp. The AD7535 is manufactured using the Linear Compatible CMOS (LC²MOS) process. It is speed compatible with most microprocessors and accepts TTL or CMOS logic level inputs.

PRODUCT HIGHLIGHTS

1. Guaranteed Monotonicity
   The AD7535 is guaranteed monotonic to 14-bits over the full temperature range for all grades.
2. Low Output Leakage
   By tying V_{SS} (Pin 27) to a negative voltage, it is possible to achieve a low output leakage current at high temperatures.
3. Microprocessor Compatibility
   High speed input control (TTL/5V CMOS compatible) allows direct interfacing to most of the popular 8-bit and 16-bit microprocessors. When interfacing to 8-bit processors $\overline{CSMSB}$ and $\overline{CSLSB}$ are separate and the 8-bit data bus is connected to both the MS Input Register and the LS Input Register. For straight 14-bit parallel loading $\overline{CSMSB}$ and $\overline{CSLSB}$ are tied together giving one chip select to load the 14-bit word.

UNIPOLAR BINARY OPERATION (2-QUADRANT MULTIPLICATION)

Figure 2 shows the circuit diagram for unipolar binary operation. With an ac input, the circuit performs 2 quadrant multiplication. The code table for Figure 2 is given in Table I.

Capacitor C1 provides phase compensation and helps prevent overshoot and ringing when high-speed op amps are used.

NOTE X = Don't Care

BIPOLAR OPERATION (4-QUADRANT MULTIPLICATION)

The recommended circuit diagram for bipolar operation is shown in Figure 3. Offset binary coding is used.

With the DAC loaded to 10 0000 0000 0000, adjust R1 for $V_O = 0$V. Alternatively, one can omit R1 and R2 and adjust the ratio of R5 and R6 for $V_O = 0$V. Full-scale trimming can be accomplished by adjusting the amplitude of V_{IN} or by varying the value of R7.

Resistors R5, R6 and R7 should be ratio matched to 0.006%. Mismatch of R5 and R6 causes both offset and full-scale error. When operating over a wide temperature range, it is important that the resistors be of the same type so that their temperature coefficients match.

A range of precision voltage dividers, manufactured by Vishay, offers a suitable solution to implementing the bipolar circuit described above. The resistor networks are TCR and Ratio Matched, giving excellent performance over temperature.

The code table for Figure 3 is given in Table II.

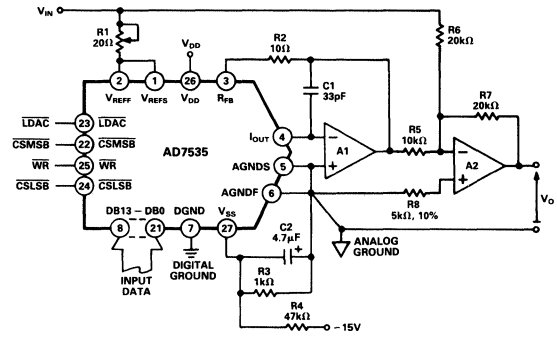

Figure 3. Bipolar Operation

ANALOG DEVICES

LC²MOS 14-Bit µP-Compatible DAC

AD7536

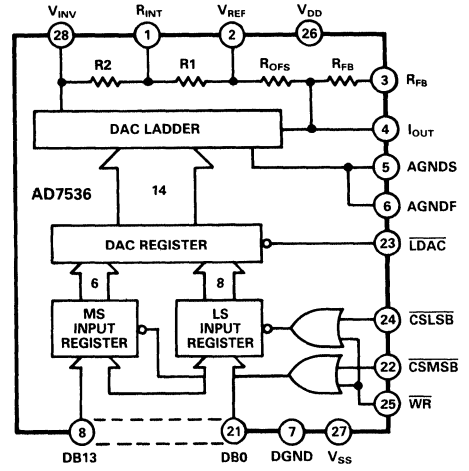
FEATURES

- Full 4-Quadrant Multiplication without External Resistors
- All Grades 14-Bit Monotonic over the Full Temperature Range
- Low Output Leakage (<20nA) over the Full Temperature Range
- Low Gain Temperature Coefficient, 2ppm/°C

APPLICATIONS

- Control and Measurement in High Temperature Environments
- Digital Audio
- Precision Servo Control
- All Microprocessor Based Control Systems

AD7536 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7536 is a 14-bit monolithic CMOS D/A converter. The part is laser trimmed and specified as a dedicated bipolar DAC. The resistors needed for 4-quadrant multiplication are contained on the chip. Thus, the user requires only the AD7536, a voltage reference and two op-amps for bipolar operation. The AD7536 has the same low leakage configuration (patent pending) as the other members of the 14-bit CMOS DAC family. The excellent output leakage current characteristics also ensure exceptional stability of linearity and gain error over the full temperature range.

The device is speed compatible with most microprocessors and accepts TTL or 5V CMOS logic level inputs. There is standard Chip Select and Memory Write logic for easy interfacing. The AD7536 has full protection against CMOS "latch-up" phenomena and does not require the use of external Schottky diodes or the use of a FET Input op-amp.

PRODUCT HIGHLIGHTS

1. Bipolar Operation
   The AD7536 gives the user 4-Quadrant Multiplication without any external resistors.
2. Guaranteed Monotonicity
   14-bit monotonicity is guaranteed over the full temperature range for all grades.
3. Low Output Leakage
   The device has excellent output leakage current characteristics at all temperatures.

BIPOLAR OPERATION
(4-Quadrant Multiplication)

Figure 2 shows the AD7536 connected for bipolar operation. Specified accuracy is attained without the need for expensive closely matched external resistors. R1 and R2 provide an optional gain adjustment and capacitor C1 helps prevent overshoot and ringing when high-speed op-amps are used. The −300mV bias voltage for V_{SS} is derived from R3, R4 and C2.

Table I shows the Offset Binary Code Table obtained with the circuit of Figure 2. It should be noted that the user can get a 2's Complement transfer function by inverting the MSB of the DAC word.

Binary Number in DAC Register (MSB LSB)	Analog Output V_{OUT}
11 1111 1111 1111	$+V_{IN}\left(\frac{8191}{8192}\right)$

10 0000 0000 0000	0V
00 0000 0000 0001	$-V_{IN}\left(\frac{8191}{8192}\right)$
00 0000 0000 0000	$-V_{IN}\left(\frac{8192}{8192}\right) = -V_{IN}$

Table I. Offset Binary Code Table for AD7536

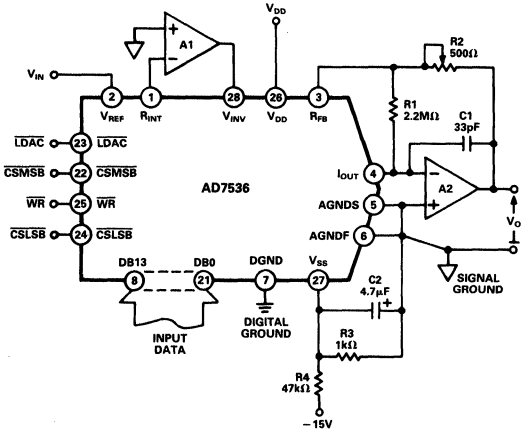

Figure 2. AD7536 Operation

OFFSET AND GAIN ADJUSTMENT FOR FIGURE 2.

Offset Adjustment

1. Adjust offset of amplifier A1 so that potential at R_{INT} is <10μV with respect to Signal Ground.
2. Load DAC register with 10 0000 0000 0000.
3. Adjust offset of amplifier A2 until V_O = 0V (<10μV).

Gain Adjustment

1. Load DAC register with all 1's.
2. Trim potentiometer R2 so that $V_O = +V_{IN}\frac{(8191)}{(8192)}$

For high-temperature applications, resistors and potentiometers should have a low Temperature Coefficient. In many applications, because of the excellent Offset Error, Full Scale Error and Gain T.C. specifications of the AD7536, trimming of the Offset and Gain is not necessary.

ANALOG DEVICES

LC²MOS (8 + 4) Loading Dual 12-Bit DAC

AD7537

FEATURES
- Two 12-Bit DACs in One Package
- DAC Ladder Resistance Matching: 0.5%
- Space Saving Skinny DIP and Surface Mount Packages
- 4-Quadrant Multiplication
- Low Gain Error (1LSB max Over Temperature)
- Byte Loading Structure
- Fast Interface Timing

APPLICATIONS
- Automatic Test Equipment
- Programmable Filters
- Audio Applications
- Synchro Applications
- Process Control

GENERAL DESCRIPTION

The AD7537 contains two 12-bit current output DACs on one monolithic chip. A separate reference input is provided for each DAC. The dual DAC saves valuable board space, and the monolithic construction ensures excellent thermal tracking. Both DACs are guaranteed 12-bit monotonic over the full temperature range.

The AD7537 has a 2-byte (8LSBs, 4MSBs) loading structure. It is designed for right-justified data format. The control signals for register loading are A0, A1, $\overline{CS}$, $\overline{WR}$ and $\overline{UPD}$. Data is loaded to the input registers when $\overline{CS}$ and $\overline{WR}$ are low. To transfer this data to the DAC registers, $\overline{UPD}$ must be taken low with $\overline{WR}$.

Added features on the AD7537 include an asynchronous $\overline{CLR}$ line which is very useful in calibration routines. When this is taken low, all registers are cleared. The double buffering of the data inputs allows simultaneous update of both DACs. Also, each DAC has a separate AGND line. This increases the device versatility; for instance one DAC may be operated with AGND biased while the other is connected in the standard configuration.

The AD7537 is manufactured using the Linear Compatible CMOS (LC²MOS) process. It is speed compatible with most microprocessors and accepts TTL, 74HC and 5V CMOS logic level inputs.

PRODUCT HIGHLIGHTS

1. DAC to DAC Matching:
   Since both DACs are fabricated on the same chip, precise matching and tracking is inherent. Many applications which are not practical using two discrete DACs are now possible. Typical matching: 0.5%.
2. Small Package Size:
   The AD7537 is available in both 0.3" wide 24-pin DIPs and in 28-terminal surface mount packages.
3. Wide Power Supply Tolerance:
   The device operates on a +12V to +15V V_{DD}, with ±10% tolerance on this nominal figure. All specifications are guaranteed over this range.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

CIRCUIT INFORMATION – D/A SECTION

The AD7537 contains two identical 12-bit multiplying D/A converters. Each DAC consists of a highly stable R-2R ladder and 12 N-channel current steering switches. Figure 2 shows a simplified D/A circuit for DAC A. In the R-2R ladder, binary weighted currents are steered between I_{OUTA} and AGNDA. The current flowing in each ladder leg is constant, irrespective of switch state. The feedback resistor R_{FBA} is used with an op amp to convert the current flowing in I_{OUTA} to a voltage output.

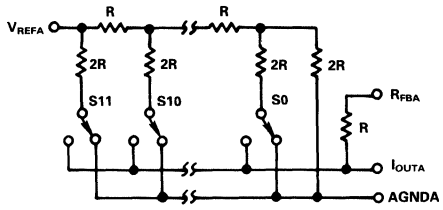

Figure 2. Simplified Circuit Diagram for DAC A

EQUIVALENT CIRCUIT ANALYSIS

Figure 3 shows the equivalent circuit for one of the D/A converters (DAC A) in the AD7537. A similar equivalent circuit can be drawn for DAC B.

C_{OUT} is the output capacitance due to the N-channel switches and varies from about 50pF to 150pF with digital input code. The current source I_{LKG} is composed of surface and junction leakages and approximately doubles every 10°C. R_0 is the equivalent output resistance of the device which varies with input code.

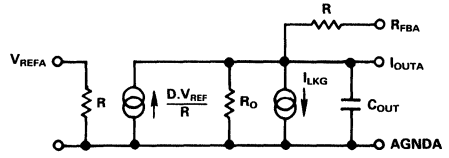

Figure 3. Equivalent Analog Circuit for DAC A

DIGITAL CIRCUIT INFORMATION

The digital inputs are designed to be both TTL and 5V CMOS compatible. All logic inputs are static protected MOS gates with typical input currents of less than 1nA.

ANALOG DEVICES

LC²MOS µP-Compatible 14-Bit DAC

AD7538

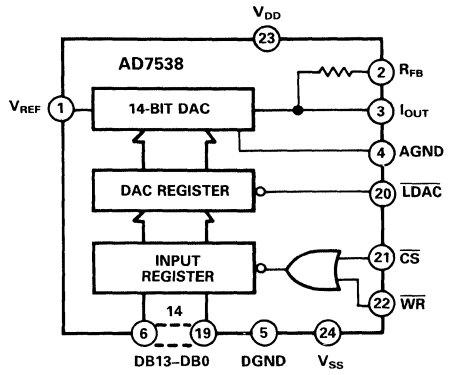
FEATURES

- All Grades 14-Bit Monotonic over the Full Temperature Range
- Low Cost 14-Bit Upgrade for 12-Bit Systems
- 14-Bit Parallel Load with Double Buffered Inputs
- Small 24-Pin, 0.3" DIP
- Low Output Leakage (<20nA) over the Full Temperature Range

APPLICATIONS

- Microprocessor Based Control Systems
- Digital Audio
- Precision Servo Control
- Control and Measurement in High Temperature Environments

AD7538 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7538 is a 14-bit monolithic CMOS D/A converter which uses laser trimmed thin-film resistors to achieve excellent linearity.

The DAC is loaded by a single 14-bit wide word using standard Chip Select and Memory Write Logic. Double buffering, which is optional using $\overline{\text{LDAC}}$, allows simultaneous update in a system containing multiple AD7538s.

A novel low leakage configuration (U.S. Patent No. 4,590,456) enables the AD7538 to exhibit excellent output leakage current characteristics over the specified temperature range.

The AD7538 is manufactured using the Linear Compatible CMOS (LC²MOS) process. It is speed compatible with most microprocessors and accepts TTL or CMOS logic level inputs.

PRODUCT HIGHLIGHTS

1. Guaranteed Monotonicity
   The AD7538 is guaranteed monotonic to 14-bits over the full temperature range for all grades.
2. Low Cost
   The AD7538, with its 14-bit dynamic range, affords a low cost solution for 12-bit system upgrades.
3. Small Package Size
   The AD7538 is packaged in a small 24-pin, 0.3" DIP.
4. Low Output Leakage
   By tying V_{SS} (Pin 24) to a negative voltage, it is possible to achieve a low output leakage current at high temperatures.
5. Wide Power Supply Tolerance
   The device operates on a +12 to +15V V_{DD}, with a ±5% tolerance on this nominal figure. All specifications are guaranteed over this range.

SPECIFICATIONS[1] (V_{DD} = +11.4V to +15.75V[2], V_{REF} = +10V; V_{PIN3} = V_{PIN4} = 0V, V_{SS} = −300mV All specifications T_{min} to T_{max} unless otherwise stated.)

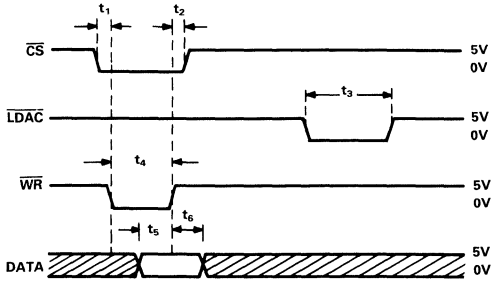
*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

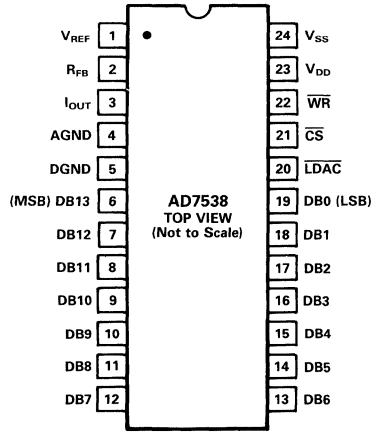
ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.



NOTES
1. ALL INPUT SIGNAL RISE AND FALL TIMES MEASURES FROM 10% TO 90% OF +5V. $t_r = t_f$ = 20ns.
2. TIMING MEASUREMENT REFERENCE LEVEL IS $\frac{V_{IH} + V_{IL}}{2}$
3. If $\overline{LDAC}$ IS ACTIVATED PRIOR TO THE RISING EDGE OF $\overline{WR}$, THEN IT MUST STAY LOW FOR t_3 or LONGER AFTER $\overline{WR}$ GOES HIGH.

Figure 1. AD7538 Timing Diagram

PIN CONFIGURATION



TERMINOLOGY

RELATIVE ACCURACY
Relative accuracy or end-point nonlinearity is a measure of the maximum deviation from a straight line passing through the end-points of the DAC transfer function. It is measured after adjusting for zero error and full-scale error and is normally expressed in Least Significant Bits or as a percentage of full-scale reading.

DIFFERENTIAL NONLINEARITY
Differential nonlinearity is the difference between the measured change and the ideal 1LSB change between any two adjacent codes. A specified differential nonlinearity of ±1LSB max over the operating temperature range ensures monotonicity.

GAIN ERROR
Gain error is a measure of the output error between an ideal DAC and the actual device output. It is measured with all 1s in the DAC after offset error has been adjusted out and is expressed in Least Significant Bits. Gain error is adjustable to zero with an external potentiometer.

DIGITAL-TO-ANALOG GLITCH IMPULSE
The amount of charge injected from the digital inputs to the analog output when the inputs change state is called Digital-to-Analog Glitch Impulse. This is normally specified as the area of the glitch in either pA-secs or nV-secs depending upon whether the glitch is measured as a current or voltage. It is measured with V_{REF} = AGND.

OUTPUT CAPACITANCE
This is the capacitance from I_{OUT} to AGND.

OUTPUT LEAKAGE CURRENT
Output Leakage Current is current which appears at I_{OUT} with the DAC register loaded to all 0s.

MULTIPLYING FEEDTHROUGH ERROR
This is the ac error due to capacitive feedthrough from V_{REF} terminal to I_{OUT} with DAC register loaded to all zeros.

X	1	1	No operation.

NOTE: X = Don't Care.

23	V_{DD}	+12V to +15V supply input.
24	V_{SS}	Bias pin for High Temperature Low Leakage configuration. To implement low leakage system, the pin should be at a negative voltage. See Figures 4 and 5 for recommended circuitry.

CIRCUIT INFORMATION

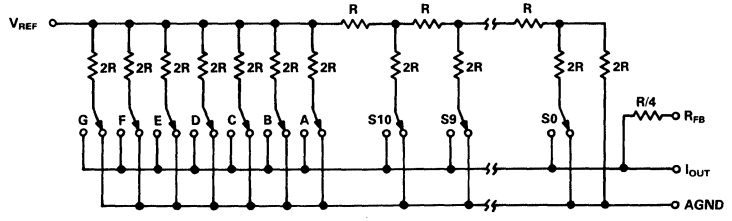

Figure 2. Simplified Circuit Diagram for the AD7538 D/A Section

D/A SECTION

Figure 2 shows a simplified circuit diagram for the AD7538 D/A section. The three MSBs of the 14-bit Data Word are decoded to drive the seven switches A-G. The 11 LSBs of the Data Word consist of an R-2R ladder operated in a current steering configuration.

The R-2R ladder current is 1/8 of the total reference input current. 7/8 I flows in the parallel ladder structure. Switches A-G steer equally weighted currents between I_{OUT} and AGND.

Since the input resistance at V_{REF} is constant, it may be driven by a voltage source or a current source of positive or negative polarity.

EQUIVALENT CIRCUIT ANALYSIS

Figure 3 shows an equivalent circuit for the analog section of the AD7538 D/A converter. The current source $I_{LEAKAGE}$ is composed of surface and junction leakages. The resistor R_O denotes the equivalent output resistance of the DAC which varies with input code. C_{OUT} is the capacitance due to the current steering switches and varies from about 90pF to 180pF (typical values) depending upon the digital input. $g(V_{REF}, N)$ is the Thevenin equivalent voltage generator due to the reference input voltage, V_{REF}, and the transfer function of the DAC ladder, N.

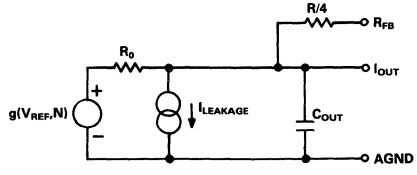

Figure 3. AD7538 Equivalent Analog Output Circuit

DIGITAL SECTION

The digital inputs are designed to be both TTL and 5V CMOS compatible. All logic inputs are static protected MOS gates with typical input currents of less than 1nA. To minimize power supply currents, it is recommended that the digital input voltages be driven as close as possible to 0 and 5V logic levels.

UNIPOLAR BINARY OPERATION (2-QUADRANT MULTIPLICATION)

Figure 4 shows the circuit diagram for unipolar binary operation. With an ac input, the circuit performs 2 quadrant multiplication. The code table for Figure 4 is given in Table I.

Capacitor C1 provides phase compensation and helps prevent overshoot and ringing when high-speed op amps are used.

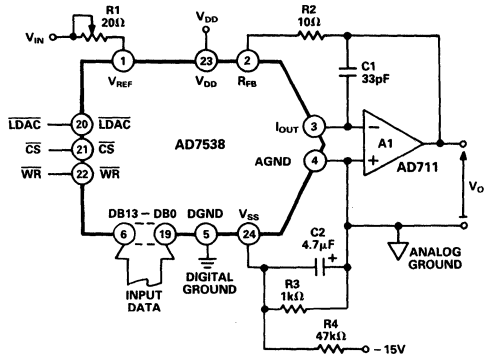

Figure 4. Unipolar Binary Operation

Binary Number In DAC Register	Analog Output, V_{OUT}
MSB LSB	
11 1111 1111 1111	$-V_{IN}\left(\frac{16383}{16384}\right)$
10 0000 0000 0000	$-V_{IN}\left(\frac{8192}{16384}\right) = -1/2\,V_{IN}$
00 0000 0000 0001	$-V_{IN}\left(\frac{1}{16384}\right)$
00 0000 0000 0000	0V

Table I. Unipolar Binary Code Table for AD7538

For zero offset adjustment, the DAC register is loaded with all 0s and amplifier offset (V_{OS}) adjusted so that V_{OUT} is 0V. Adjusting V_{OUT} to 0V is not necessary in many applications, but it is recommended that V_{OS} be no greater than (25×10^{-6}) (V_{REF}) to maintain specified DAC accuracy (see Applications Hints).

Full-scale trimming is accomplished by loading the DAC register with all 1s and adjusting R1 so that $V_{OUTA} = -V_{IN}(16383/16384)$. For high temperature operation, resistors and potentiometers should have a low Temperature Coefficient. In many applications, because of the excellent Gain T.C. and Gain Error specifications of the AD7538, Gain Error trimming is not necessary. In fixed reference applications, full scale can also be adjusted by omitting R1 and R2 and trimming the reference voltage magnitude.

BIPOLAR OPERATION (4-QUADRANT MULTIPLICATION)

The recommended circuit diagram for bipolar operation is shown in Figure 5. Offset binary coding is used. The code table for Figure 5 is given in Table II.

With the DAC loaded to 10 0000 0000 0000, adjust R1 for $V_O = 0V$. Alternatively, one can omit R1 and R2 and adjust the ratio of R5 and R6 for $V_O = 0V$. Full-scale trimming can be accomplished by adjusting the amplitude of V_{IN} or by varying the value of R7.

The values given for R1, R2 are the minimum necessary to calibrate the system for resistors, R5, R6, R7 ratio matched to 0.1%. System linearity error is independent of resistor ratio matching and is affected by DAC linearity error only.

When operating over a wide temperature range, it is important that the resistors be of the same type so that their temperature coefficients match.

For further information see "CMOS DAC Application Guide", 3rd Edition, Publication Number G872b–8–1/89 available from Analog Devices.

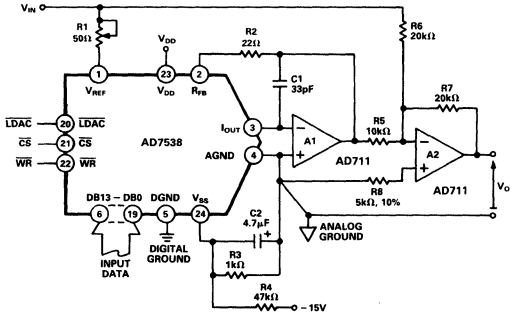

Figure 5. Bipolar Operation

Binary Number in DAC Register MSB LSB	Analog Output V_{OUT}

10 0000 0000 0000	0V
01 1111 1111 1111	$-V_{IN}\left(\frac{1}{8192}\right)$
00 0000 0000 0000	$-V_{IN}\left(\frac{8192}{8192}\right)$

Table II. Bipolar Code Table for Offset Binary Circuit of Figure 5.

LOW LEAKAGE CONFIGURATION

For CMOS Multiplying D/A converters, as the device is operated at higher temperatures, the output leakage current increases. For a 14-bit resolution system, this can be a significant source of error. The AD7538 features a leakage reduction configuration (U.S. Patent No. 4,590,456) to keep the leakage current low over an extended temperature range. One may operate the device with or without this configuration. If V_{SS} (Pin 24) is tied to AGND then the DAC will exhibit normal output leakage current at high temperatures. To use the low leakage facility, V_{SS} should be tied to a voltage of approximately $-0.3V$ as in Figures 4 and 5. A simple resistor divider (R3, R4) produces approximately $-300mV$ from $-15V$. The capacitor C2 in parallel with R3 is an integral part of the low leakage configuration and must be $4.7\mu F$ or greater. Figure 6 is a plot of leakage current versus temperature for both conditions. It clearly shows the improvement gained by using the low leakage configuration.

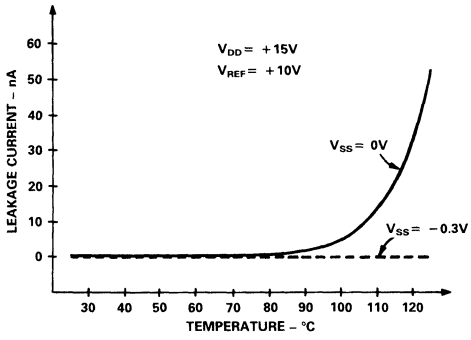

Figure 6. Graph of Typical Leakage Current vs. Temperature for AD7538

PROGRAMMABLE GAIN AMPLIFIER

The circuit shown in Figure 7 provides a programmable gain amplifier (PGA). In it the DAC behaves as a programmable resistance and thus allows the circuit gain to be digitally controlled.

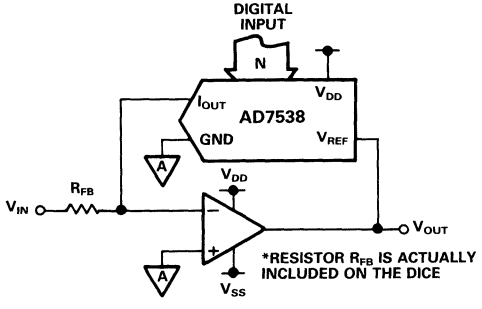

Figure 7. Programmable Gain Amplifier (PGA)

The transfer function of Figure 7 is:

$$\text{Gain} = \frac{V_{OUT}}{V_{IN}} = -\frac{R_{EQ}}{R_{FB}} \quad (1)$$

R_{EQ} is the equivalent transfer impedance of the DAC from the V_{REF} pin to the I_{OUT} pin and can be expressed as

$$R_{EQ} = \frac{2^n R_{IN}}{N} \quad (2)$$

Where: n is the resolution of the DAC

N is the DAC input code in decimal

R_{IN} is the constant input impedance of the DAC ($R_{IN} = R_{LAD}$)

Substituting this expression into Equation 1 and assuming zero gain error for the DAC ($R_{IN} = R_{FB}$) the transfer function simplifies to

$$\frac{V_{OUT}}{V_{IN}} = -\frac{2^n}{N} \quad (3)$$

The ratio $N/2^n$ is commonly represented by the term D and, as such, is the fractional representation of the digital input word.

$$\frac{V_{OUT}}{V_{IN}} = -\frac{2^n}{N} = \frac{-1}{D} \quad (4)$$

Equation 4 indicates that the gain of the circuit can be varied from 16,384 down to unity (actually 16,384/16,383) in 16,383 steps. The all 0s code is never applied. This avoids an open-loop condition thereby saturating the amplifier. With the all 0s code excluded there remains $2^n - 1$ possible input codes allowing a choice of $2^n - 1$ output levels. In dB terms the dynamic range is

$$20 \log_{10} \frac{V_{OUT}}{V_{IN}} = 20 \log_{10} (2^n - 1) = 84dB.$$

APPLICATION HINTS

Output Offset: CMOS D/A converters in circuits such as Figures 4 and 5 exhibit a code dependent output resistance which in turn can cause a code dependent error voltage at the output of the amplifier. The maximum amplitude of this error, which adds to the D/A converter nonlinearity, depends on V_{OS}, where V_{OS} is the amplifier input offset voltage. To maintain specified accuracy with V_{REF} at 10V, it is recommended that V_{OS} be no greater than 0.25mV, or (25×10^{-6}) (V_{REF}), over the temperature range of operation. The AD711 is a suitable op amp. The op amp has a wide bandwidth and high slew rate and is recommended for ac and other applications requiring fast settling.

General Ground Management: Since the AD7538 is specified for high accuracy, it is important to use a proper grounding technique. AC or transient voltages between AGND and DGND can cause noise injection into the analog output. The simplest method of ensuring that voltages at AGND and DGND are equal is to tie AGND and DGND together at the AD7538. In more complex systems where the AGND and DGND intertie is on the backplane, it is recommended that two diodes be connected in inverse parallel between the AD7538 AGND and DGND pins (1N914 or equivalent).

MICROPROCESSOR INTERFACING

The AD7538 is designed for easy interfacing to 16-bit microprocessors and can be treated as a memory mapped peripheral. This reduces the amount of external logic needed for interfacing to a minimal.

AD7538-8086 INTERFACE

Figure 8 shows the 8086 processor interface to a single device. In this setup the double buffering feature (using $\overline{\text{LDAC}}$) of the DAC is not used. The 14-bit word is written to the DAC in one MOV instruction and the analog output responds immediately.

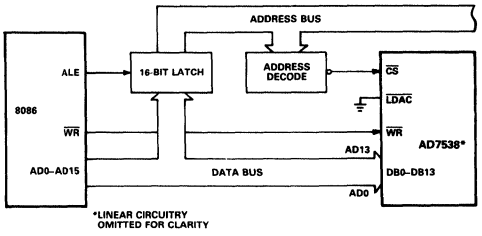

Figure 8. AD7538 – 8086 Interface Circuit

In a multiple DAC system the double buffering of the AD7538 allows the user to simulatenously update all DACs. In Figure 9, a 14-bit word is loaded to the Input Registers of each of the DACs in sequence. Then, with one instruction to the appropriate address, CS4 (i.e., LDAC) is brought low, updating all the DACs simultaneoulsy.

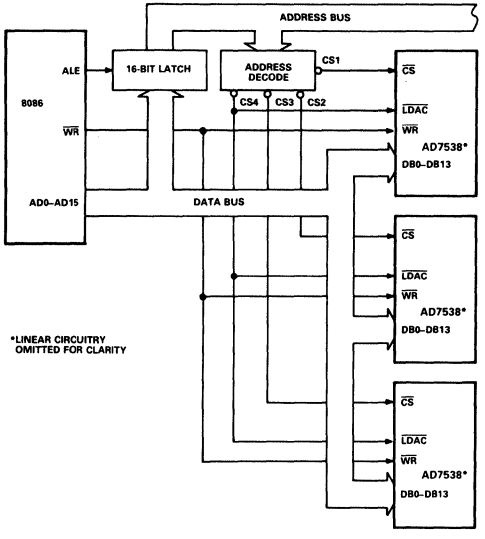

Figure 9. AD7538 – 8086 Interface: Multiple DAC System

AD7538-MC68000 INTERFACE

Figure 10 shows the MC68000 processor interface to a single device. In this setup the double buffering feature of the DAC is not used and the appropriate data is written into the DAC in one MOVE instruction.

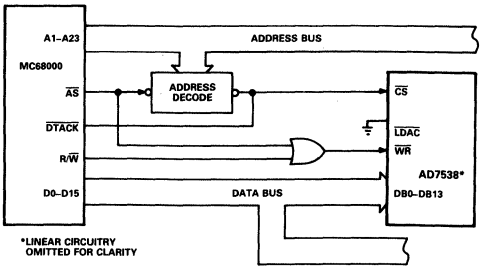

Figure 10. AD7538 – MC68000 Interface

DIGITAL FEEDTHROUGH

The digital inputs to the AD7538 are directly connected to the microprocessor bus in the preceding interface configurations. These inputs will be constantly changing even when the device is not selected. The high frequency logic activity on the bus can feed through the DAC package capacitance to show up as noise on the analog output. To minimize this Digital Feedthrough isolate the DAC from the noise source. Figure 11 shows an interface circuit which uses this technique. All data inputs are latched from the bus by the $\overline{\text{CS}}$ signal. One may also use other means, such as peripheral interface devices, to reduce the Digital Feedthrough.

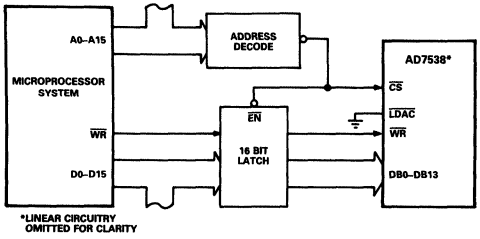

Figure 11. AD7538 Interface Circuit Using Latches to Minimize Digital Feedthrough

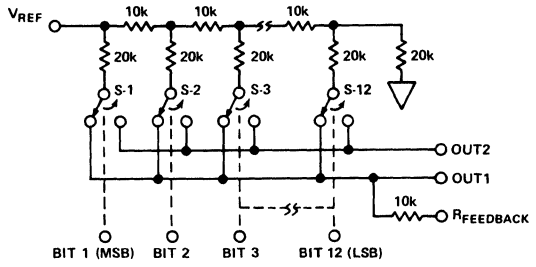
CMOS 12-Bit Monolithic Multiplying DAC

AD7541A

FEATURES
- Improved Version of AD7541
- Full Four Quadrant Multiplication
- 12-Bit Linearity (End-Point)
- All Parts Guaranteed Monotonic
- TTL/CMOS Compatible
- Low Cost
- Protection Schottky Not Required
- Low Logic Input Leakage

AD7541A FUNCTIONAL BLOCK DIAGRAM



DIGITAL INPUTS (DTL/TTL/CMOS COMPATIBLE)
Logic: A switch is closed to I_{OUT1} for its digital input in a "HIGH" state.

GENERAL DESCRIPTION

The Analog Devices' AD7541A is a low cost, high performance 12-bit monolithic multiplying digital to analog converter. It is fabricated using advanced, low noise, thin film on CMOS technology and is available in a standard 18-pin DIP and in 20-terminal surface mount packages.

The AD7541A is functionally and pin compatible with the industry standard AD7541 device and offers improved specifications and performance. The improved design ensures that the device is latch-up free so no output Schottky protection diodes are required.

This new device uses laser wafer trimming to provide full 12-bit end-point linearity with several new high performance grades.

PRODUCT HIGHLIGHTS

Compatability: The AD7541A can be used as a direct replacement for any AD7541–type device. As with the Analog Devices AD7541, the digital inputs are TTL/CMOS compatible and have been designed to have a $\pm 1\mu A$ maximum input current requirement so as not to load the driving circuitry.

Improvements: The AD7541A offers the following improved specifications over the AD7541:

1. Gain Error for all grades has been reduced with premium grade versions having a maximum gain error of ±3LSB.
2. Gain Error temperature coefficient has been reduced to 2ppm/°C typical and 5ppm/°C maximum.
3. Digital to analog charge injection energy for this new device is typically 20% less than the standard AD7541 part.
4. Latch-up proof.
5. Improvements in laser wafer trimming provides 1/2LSB max differential nonlinearity for top grade devices over the operating temperature range (vs. 1LSB on older 7541 types).
6. All grades are guaranteed monotonic to 12 bits over the operating temperature range.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

2

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

TERMINOLOGY

RELATIVE ACCURACY

Relative accuracy or endpoint nonlinearity is a measure of the maximum deviation from a straight line passing through the endpoints of the DAC transfer function. It is measured after adjusting for zero and full scale and is expressed in % of full scale range or (sub)multiples of 1LSB.

DIFFERENTIAL NONLINEARITY

Differential nonlinearity is the difference between the *measured* change and the *ideal* 1LSB change between any two adjacent codes. A specified differential nonlinearity of ±1LSB max over the operating temperature range insures monotonicity.

GAIN ERROR

Gain error is a measure of the output error between an ideal DAC and the actual device output. For the AD7541A, ideal maximum output is $-\left(\frac{4095}{4096}\right)(V_{REF})$. Gain error is adjustable to zero using external trims as shown in Figures 4, 5 and 6.

OUTPUT LEAKAGE CURRENT

Current which appears at OUT1 with the DAC loaded to all 0s or at OUT2 with the DAC loaded to all 1s.

MULTIPLYING FEEDTHROUGH ERROR

AC error due to capacitive feedthrough from V_{REF} terminal to OUT1 with DAC loaded to all 0s.

OUTPUT CURRENT SETTLING TIME

Time required for the output function of the DAC to settle to within 1/2LSB for a given digital input stimulus, i.e., 0 to Full Scale.

PROPAGATION DELAY

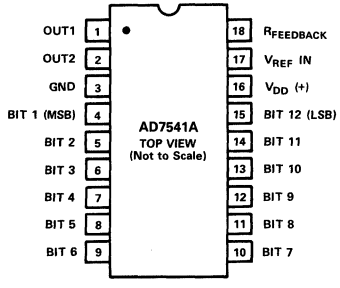
This is a measure of the internal delay of the circuit and is measured from the time a digital input changes to the point at which the analog output at OUT1 reaches 90% of its final value.

DIGITAL-TO-ANALOG CHARGE INJECTION (QDA)

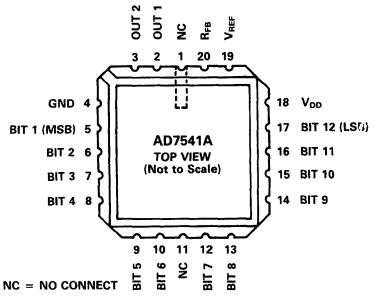
This is a measure of the amount of charge injected from the digital inputs to the analog outputs when the inputs change state. It is usually specified as the area of the glitch in nV secs and is measured with V_{REF} = GND and a Model 50K as the output op amp, C1 (phase compensation) = 0pF.

PIN CONFIGURATIONS

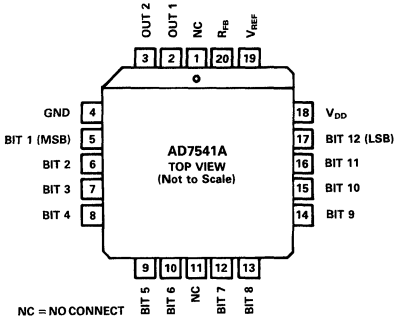
DIP



LCCC



PLCC



GENERAL CIRCUIT INFORMATION

The simplified D/A circuit is shown in Figure 1. An inverted R-2R ladder structure is used–that is, the binarily weighted currents are switched between the OUT1 and OUT2 bus lines, thus maintaining a constant current in each ladder leg independent of the switch state.

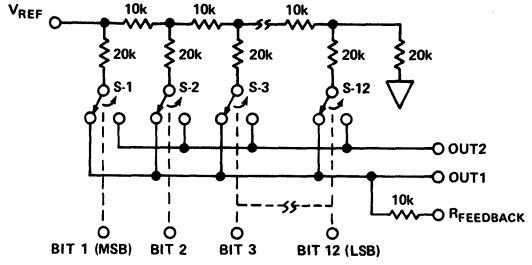


Figure 1. AD7541A Functional Diagram (Inputs "High")

The input resistance at V_{REF} (Figure 1) is always equal to R_{LDR} (R_{LDR} is the R/2R ladder characteristic resistance and is equal to value "R"). Since R_{IN} at the V_{REF} pin is constant, the reference terminal can be driven by a reference voltage or a reference current, ac or dc, of positive or negative polarity. (If a current source is used, a low temperature coefficient external R_{FB} is recommended to define scale factor.)

EQUIVALENT CIRCUIT ANALYSIS

The equivalent circuits for all digital inputs LOW and all digital inputs HIGH are shown in Figures 2 and 3. In Figure 2 with all digital inputs LOW, the reference current is switched to OUT2. The current source $I_{LEAKAGE}$ is composed of surface and junction leakages to the substrate, while the I/4096 current source represents a constant 1-bit current drain through the termination resistor on the R-2R ladder. The "ON" capacitance of the output N-channel switch is 200pF, as shown on the OUT2 terminal. The "OFF" switch capacitance is 70pF, as shown on the OUT1 terminal. Analysis of the circuit for all digital inputs HIGH, as shown in Figure 3 is similar to Figure 2; however, the "ON" switches are now on terminal OUT1, hence the 200pF at that terminal.

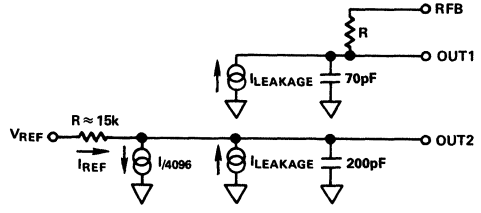

Figure 2. AD7541A DAC Equivalent Circuit All Digital Inputs LOW

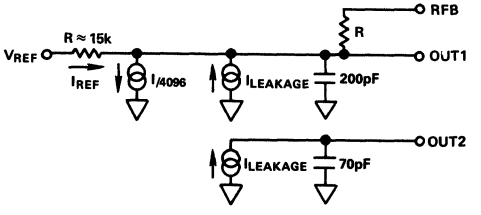

Figure 3. AD7541A DAC Equivalent Circuit All Digital Inputs HIGH

Applications

UNIPOLAR BINARY OPERATION (2-QUADRANT MULTIPLICATION)

Figure 4 shows the analog circuit connections required for unipolar binary (2-quadrant multiplication) operation. With a dc reference voltage or current (positive or negative polarity) applied at pin 17, the circuit is a unipolar D/A converter. With an ac reference voltage or current the circuit provides 2-quadrant multiplication (digitally controlled attenuation). The input/output relationship is shown in Table II.

R1 provides full scale trim capability [i.e.–load the DAC register to 1111 1111 1111, adjust R1 for $V_{OUT} = -V_{REF}$ (4095/4096)]. Alternatively, Full Scale can be adjusted by omitting R1 and R2 and trimming the reference voltage magnitude.

C1 phase compensation (10 to 25pF) may be required for stability when using high speed amplifiers. (C1 is used to cancel the pole formed by the DAC internal feedback resistance and output capacitance at OUT1).

Amplifier A1 should be selected or trimmed to provide $V_{OS} \leq$ 10% of the voltage resolution at V_{OUT}. Additionally, the amplifier should exhibit a bias current which is low over the temperature range of interest (bias current causes output offset at V_{OUT} equal to I_B times the DAC feedback resistance, nominally 11kΩ). The AD544L is a high-speed implanted FET-input op amp with low factory-trimmed V_{OS}.

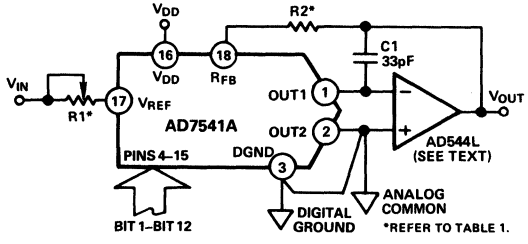

Figure 4. Unipolar Binary Operation

Trim Resistor	JN/AQ/SD	KN/BQ/TD
R1	100Ω	100Ω
R2	47Ω	33Ω

Table I. Recommended Trim Resistor Values vs. Grades

Binary Number in DAC MSB	LSB	Analog Output, V_{OUT}
1111 1111	1111	$-V_{IN}\left(\frac{4095}{4096}\right)$
1000 0000	0000	$-V_{IN}\left(\frac{2048}{4096}\right) = -1/2\,V_{IN}$
0000 0000	0001	$-V_{IN}\left(\frac{1}{4096}\right)$
0000 0000	0000	0 Volts

Table II. Unipolar Binary Code Table for Circuit of Figure 4

BIPOLAR OPERATION (4-QUADRANT MULTIPLICATION)

Figure 5 and Table III illustrate the circuitry and code relationship for bipolar operation. With a dc reference (positive or negative polarity) the circuit provides offset binary operation. With an ac reference the circuit provides full 4-quadrant multiplication.

With the DAC loaded to 1000 0000 0000, adjust R1 for V_{OUT} = 0V (alternatively, one can omit R1 and R2 and adjust the ratio of R3 to R4 for V_{OUT} = 0V). Full scale trimming can be accomplished by adjusting the amplitude of V_{REF} or by varying the value of R5.

As in unipolar operation, A1 must be chosen for low V_{OS} and low I_B. R3, R4 and R5 must be selected for matching and tracking. Mismatch of 2R3 to R4 causes both offset and Full Scale error. Mismatch of R5 to R4 or 2R3 causes Full Scale error. C1 phase compensation (10pF to 50pF) may be required for stability, depending on amplifier used.

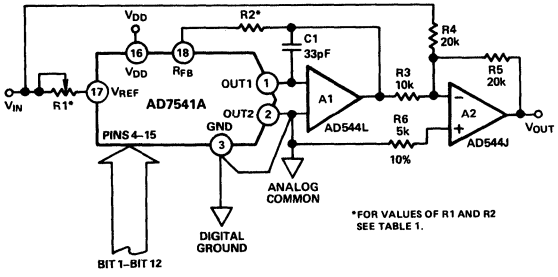

Figure 5. Bipolar Operation (4-Quadrant Multiplication)

Binary Number in DAC MSB LSB	Analog Output, V_{OUT}
1111 1111 1111	$+V_{IN}\left(\frac{2047}{2048}\right)$
1000 0000 0001	$+V_{IN}\left(\frac{1}{2048}\right)$
1000 0000 0000	0V
0111 1111 1111	$-V_{IN}\left(\frac{1}{2048}\right)$
0000 0000 0000	$-V_{IN}\left(\frac{2048}{2048}\right)$

Table III. Bipolar Code Table for Offset Binary Circuit of Figure 5

Figure 6 shows an alternative method of achieving bipolar output. The circuit operates with sign plus magnitude code and has the advantage that it gives 12-bit resolution in each quadrant compared with 11-bit resolution per quadrant for the circuit of Figure 5. The AD7592 is a fully protected CMOS change-over switch with data latches. R4 and R5 should match each other to 0.01% to maintain the accuracy of the D/A converter. Mismatch between R4 and R5 introduces a gain error.

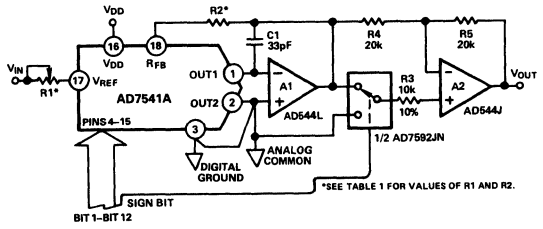

Figure 6. 12-Bit Plus Sign Magnitude Operation

Sign Bit	Binary Number in DAC MSB LSB	Analog Output, V_{OUT}
0	1111 1111 1111	$+V_{IN} \cdot \left(\frac{4095}{4096}\right)$
0	0000 0000 0000	0 Volts
1	0000 0000 0000	0 Volts
1	1111 1111 1111	$-V_{IN} \cdot \left(\frac{4095}{4096}\right)$

Note: Sign bit of "0" connects R3 to GND.

Table IV. 12-Plus Sign Magnitude Code Table for Circuit of Figure 6

APPLICATIONS HINTS

Output Offset: CMOS D/A converters exhibit a code dependent output resistance which in turn can cause a code dependent error voltage at the output of the amplifier. The maximum amplitude of this offset, which adds to the D/A converter nonlinearity, is 0.67 V_{OS} where V_{OS} is the amplifier input offset voltage. To maintain monotonic operation it is recommended that V_{OS} be no greater than $(25 \times 10^{-6})(V_{REF})$ over the temperature range of operation. Suitable op amps are AD517L and AD544L. The AD517L is best suited for fixed reference applications with low bandwidth requirements: it has extremely low offset (50μV) and in most applications will not require an offset trim. The AD544L has a much wider bandwidth and higher slew rate and is recommended for multiplying and other applications requiring fast settling. An offset trim on the AD544L may be necessary in some circuits.

Digital Glitches: One cause of digital glitches is capacitive coupling from the digital lines to the OUT1 and OUT2 terminals. This should be minimized by screening the analog pins of the AD7541A (pins 1, 2, 17, 18) from the digital pins by a ground track run between pins 2 and 3 and between pins 16 and 17 of the AD7541A. Note how the analog pins are at one end of the package and separated from the digital pins by V_{DD} and GND to aid screening at the board level. On-chip capacitive coupling can also give rise to crosstalk from the digital to analog sections of the AD7541A, particularly in circuits with high currents and fast rise and fall times.

Temperature Coefficients: The gain temperature coefficient of the AD7541A has a maximum value of 5ppm/°C and a typical value of 2ppm/°C. This corresponds to worst case gain shifts of 2LSBs and 0.8LSBs respectively over a 100°C temperature range. When trim resistors R1 and R2 are used to adjust full scale range, the temperature coefficient of R1 and R2 should also be taken into account. The reader is referred to Analog Devices Application Note "Gain Error and Gain Temperature Coefficient of CMOS Multiplying DACs", Publication Number E630c–5–3/86.

SINGLE SUPPLY OPERATION

Figure 7 shows the AD7541A connected in a voltage switching mode. OUT1 is connected to the reference voltage and OUT2 is connected to GND. The D/A converter output voltage is available at the V_{REF} pin (pin 17) and has a constant output impedance equal to R_{LDR}. The feedback resistor R_{FB} is not used in this circuit.

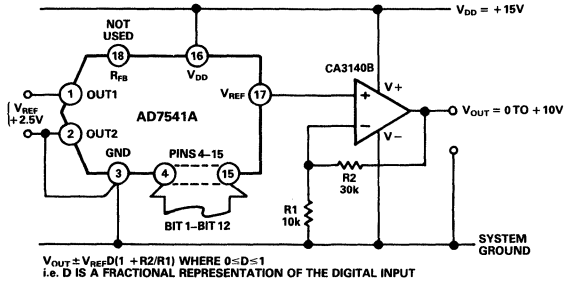

Figure 7. Single Supply Operation Using Voltage Switching Mode

The reference voltage must always be positive. If OUT1 goes more than 0.3V less than GND an internal diode will be turned on and a heavy current may flow causing device damage (the AD7541A is, however, protected from the SCR latch-up phenomenon prevalent in many CMOS devices). Suitable references include the AD580 and AD584.

The loading on the reference voltage source is code dependent and the response time of the circuit is often determined by the behavior of the reference voltage with changing load conditions. To maintain linearity, the voltage at OUT1 should remain within 2.5V of GND, for a V_{DD} of 15V. If V_{DD} is reduced from 15V or the reference voltage at OUT1 increased to more than 2.5V the differential nonlinearity of the DAC will increase and the linearity of the DAC will be degraded.

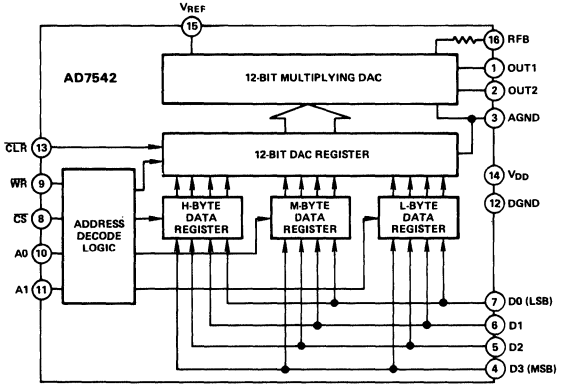
- **Latch Free (Protection Schottky Not Required)**

AD7542 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7542 is a precision 12-bit CMOS multiplying DAC designed for direct interface to 4- or 8-bit microprocessors.

The functional diagram shows the AD7542 to consist of three 4-bit data registers, a 12-bit DAC register, address decoding logic and a 12-bit CMOS multiplying DAC. Data is loaded into the data registers in three 4-bit bytes, and subsequently transferred to the 12-bit DAC register. All data loading or data transfer operations are identical to the WRITE cycle of a static RAM. A clear input allows the DAC register to be easily reset to all zeros when powering up the device.

The AD7542 is manufactured using an advanced thin-film on monolithic CMOS fabrication process. Multiplying capability, low power dissipation, +5V operation, small size (16-pin DIP and 20 terminal surface mount packages) and easy µP interface make the AD7542 ideal for many instrumentation, industrial control and avionics applications.

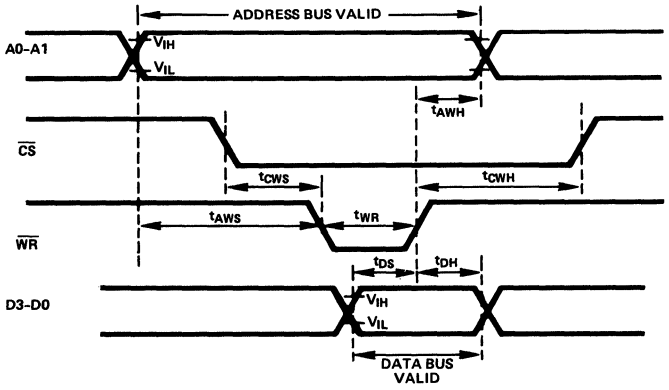
*COMMENTS: Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.



NOTE: TIMING MEASUREMENT REFERENCE LEVEL IS $\frac{V_{IH} + V_{IL}}{2}$

TERMINOLOGY

RELATIVE ACCURACY

Relative accuracy or endpoint nonlinearity is a measure of the maximum deviation from a straight line passing through the endpoints of the DAC transfer function. It is measured after adjusting for zero and full scale and is expressed in % or ppm of full scale range or (sub) multiples of 1LSB.

DIFFERENTIAL NONLINEARITY

Differential nonlinearity is the difference between the *measured* change and the *ideal* 1LSB change between any two adjacent codes. A specified differential nonlinearity of ±1LSB max over the operating temperature range insures monotonicity.

GAIN ERROR

Gain is defined as the ratio of the DAC's Full Scale output to its reference input voltage. An *ideal* AD7542 would exhibit a gain of –4095/4096. Gain error is adjustable using external trims as shown in Figures 4 and 5.

OUTPUT LEAKAGE CURRENT

Current which appears at OUT1 with the DAC register loaded to all 0s or at OUT2 with the DAC register loaded to all 1s.

MULTIPLYING FEEDTHROUGH ERROR

AC error due to capacitive feedthrough from V_{REF} terminal to OUT1 with DAC register loaded to all 0s.

PIN	MNEMONIC	FUNCTION
1	OUT1	DAC current output bus. Normally terminated at op amp virtual ground
2	OUT2	DAC current output bus. Normally terminated at ground
3	AGND	Analog Ground
4	D3	Data Input (MSB)
5	D2	Data Input
6	D1	Data Input
7	D0	Data Input (LSB)
8	$\overline{CS}$	Chip Select Input
9	$\overline{WR}$	WRITE Input
10	A0	Address Bus Input
11	A1	Address Bus Input
12	DGND	Digital Ground
13	$\overline{CLR}$	Clear Input
14	V_{DD}	+5V Supply Input
15	V_{REF}	Reference Input
16	R_{FB}	DAC Feedback Resistor

Table I. Pin Function Description (DIP Pin Numbers)

Analog Circuit Description

GENERAL CIRCUIT INFORMATION

The AD7542, a 12-bit multiplying D/A converter, consists of a highly stable thin film R-2R ladder and twelve N-channel current switches on a monolithic chip. Most applications require the addition of only an output operational amplifier and a voltage or current reference.

The simplified D/A circuit is shown in Figure 2. An inverted R-2R ladder structure is used—that is, the binarily weighted currents are switched between the OUT1 and OUT2 bus lines, thus maintaining a constant current in each ladder leg independent of the switch state.

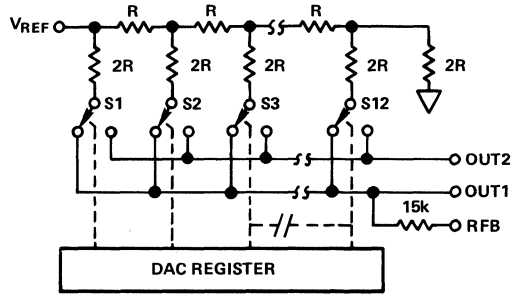

Figure 2. D/A Simplified Circuit Diagram

One of the current switches is shown in Figure 3. The input resistance at V_{REF} (Figure 2) is always equal to R_{LDR} (R_{LDR} is the R/2R ladder characteristic resistance and is equal to value "R"). Since R_{IN} at the V_{REF} pin is constant, the reference terminal can be driven by a reference voltage or a reference current, ac or dc, of positive or negative polarity. (If a current source is used, a low temperature coefficient R_{FB} is recommended to define scale factor.)

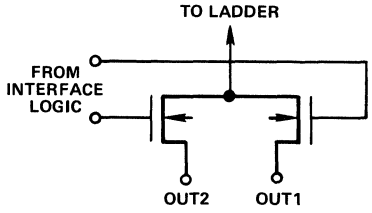

Figure 3. N-Channel Current Steering Switch

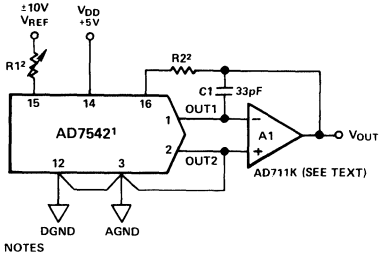
UNIPOLAR BINARY OPERATION (2-QUADRANT MULTIPLICATION)

Figure 4 shows the analog circuit connections required for unipolar binary (2-quadrant multiplication) operation. The logic inputs are omitted for clarity. With a dc reference voltage or current (positive or negative polarity) applied at V_{REF}, the circuit is a unipolar D/A converter. With an ac reference voltage or current the circuit provides 2-quadrant multiplication (digitally controlled attenuation). The input/output relationship is shown in Table II.

R1 provides full scale trim capability [i.e.—load the DAC register to 1111 1111 1111, adjust R1 for $V_{OUT} = -V_{REF}$ (4095/4096)]. Alternatively, Full Scale can be adjusted by omitting R1 and R2 and trimming the reference voltage magnitude.

C1 phase compensation (10 to 33pF) may be required for stability when using high speed amplifiers. (C1 is used to cancel the pole formed by the DAC internal feedback resistance and output capacitance at OUT1).

Amplifier A1 should be selected or trimmed to provide $V_{OS} \leq 10\%$ of the voltage resolution at V_{OUT}. Additionally, the amplifier should exhibit a bias current which is low over the temperature range of interest (bias current causes output offset at V_{OUT} equal to I_B times the DAC feedback resistance, nominally 15kΩ). The AD711K is a high-speed implanted FET-input op amp with low, factory-trimmed V_{OS}.



NOTES

1000 0000 0000	$-V_{REF}\left(\frac{2048}{4096}\right) = -1/2\ V_{REF}$
0000 0000 0001	$-V_{REF}\left(\frac{1}{4096}\right)$
0000 0000 0000	0V

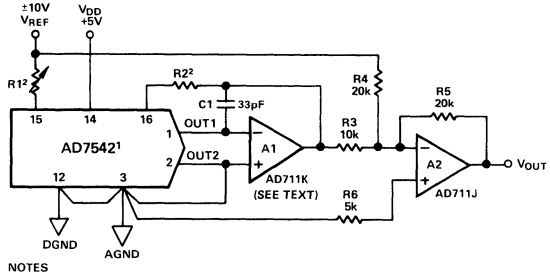
Table II. Unipolar Binary Code Table for Circuit of Figure 4

BIPOLAR OPERATION (4-QUADRANT MULTIPLICATION)

Figure 5 and Table III illustrate the circuitry and code relationship for bipolar operation. With a dc reference (positive or negative polarity) the circuit provides offset binary operation. With an ac reference, the circuit provides full 4-quadrant multiplication.

With the DAC register loaded to 1000 0000 0000, adjust R1 for V_{OUT} = 0V (alternatively, one can omit R1 and R2 and adjust the ratio of R3 to R4 for V_{OUT} = 0V). Full scale trimming can be accomplished by adjusting the amplitude of V_{REF} or by varying the value of R5.

As in unipolar operation, A1 must be chosen for low V_{OS} and low I_B. R3, R4 and R5 must be selected for matching and tracking. Mismatch of R3 to R4 causes both offset and Full Scale error. Mismatch of R5 to R4 or R3 causes Full Scale error. C1 phase compensation (10pF to 25pF) may be required for stability.



NOTES
1. LOGIC INPUTS OMITTED FOR CLARITY, DIP PIN NUMBERS SHOWN.

INTERFACE LOGIC

INTERFACE LOGIC INFORMATION

The AD7542 is designed to interface as a memory-mapped output device.

A typical system configuration is shown in Figure 6. $\overline{CS}$ is the decoded *device* address, and is derived by decoding the three higher order address bits. A0 and A1 is the AD7542 *operation* address, and is decoded internally in the AD7542 to point to the desired loading operation (i.e., load high byte, middle byte, low byte or DAC register). Table IV shows the AD7542 truth table.

All data loading operations are identical to the write cycle of a RAM as shown in Figure 1.

Additionally, the $\overline{CLR}$ input allows the AD7542 DAC register to be cleared asynchronously to 0000 0000 0000. When operating the AD7542 in a unipolar mode (Figure 4), a CLEAR causes the DAC output to assume 0V. In the bipolar mode (Figure 5), a CLEAR causes the DAC output to go to $-V_{REF}$.

In summary:

1. The AD7542 DAC register can be asynchronously cleared with the $\overline{CLR}$ input.
2. Each AD7542 requires 4 locations in memory.
3. Performing any of the four basic loading operations (i.e. load low byte data register, middle byte data register, high byte data register or 12-bit DAC register) is accomplished by executing a memory WRITE operation to the applicable address location for the required DAC operation.

AD7542 Control Inputs					AD7542 Operation	
A_1	A_0	$\overline{CS}$	$\overline{WR}$	$\overline{CLR}$		
X	X	X	X	0	Resets DAC 12-Bit Register to Code 0000 0000 0000

[6] These control signals are level triggered.

Table IV. AD7542 Truth Table

AD7542 INTERFACE TO MC6800

A typical 6800 system configuration is shown in Figure 6. Since the AD7542 contains four registers each AD7542 is assigned four locations in memory. A0 and A1 provides the operational addresses and are decoded internally to point to the desired register. Register loading is accomplished by executing a memory WRITE instruction to one of the four addresses. Table V gives a sample loading subroutine written in re-entrant form.

Choosing an arbitrary start address of PPQQ, locations PPQQ, PPQQ+1 and PPQQ+2 select the low, middle and high byte registers respectively while address PPQQ+3 selects the 12-bit DAC register. The 12-bit data to be passed to the subroutine is stored in locations XXYY and XXYY+1. The four most significant data bits are assumed to occupy the lower half of XXYY+1.

Table V. Sample Routine for AD7542–6800 Interface

AD7542 INTERFACE TO 8085

A typical 8085 system configuration is shown in Figure 7. The AD7542 $\overline{CS}$ input is decoded from the three high order address lines A13–A15. The 8085 $\overline{WR}$ output is directly connected to the $\overline{WR}$ input of the AD7542. Table VI gives a sample loading subroutine written in re-entrant form. The 12-bit data to be passed to the subroutine is stored in locations XXYY and XXYY+1. The four most significant data bits are assumed to occupy the lower half of XXYY+1. As before, arbitrary addresses PPQQ to PPQQ+3 select the low byte, middle byte, high byte and DAC registers respectively.

```

Table VI. Sample Routine for AD7542–8085 Interface

APPLICATION HINTS

The AD7542 is a precision 12-bit multiplying DAC designed for system interface. To ensure system performance consistent with AD7542 specifications, careful attention must be given to the following points:

1. GENERAL GROUND MANAGEMENT: Voltage differences between the AD7542 AGND and DGND cause loss of accuracy (dc voltage difference between the grounds introduces gain error. AC or transient voltages between the grounds cause noise injection into the analog output). The simplest method of ensuring that voltages at AGND and DGND are equal is to tie AGND and DGND together at the AD7542. In more complex systems where the AGND-DGND intertie is on the back-plane, it is recommended that diodes be connected back-to-back between the AD7542 AGND and DGND pins (1N914 or equivalent).
2. OUTPUT AMPLIFIER OFFSET: CMOS DACs exhibit a code-dependent output resistance which in turn causes a code-dependent amplifier noise gain. The effect is a nonlinearity term at the amplifier output which depends on V_{OS} (V_{OS} is amplifier input offset voltage). This nonlinearity term adds to the R/2R nonlinearity. To maintain specified operation, it is recommended that amplifier V_{OS} be no greater than 10% of the DAC's output resolution over the temperature range of interest [output resolution = V_{REF} (2^{-n}) where n is the number of bits exercised].
3. HIGH FREQUENCY CONSIDERATIONS: AD7542 output capacitance works in conjunction with the amplifier feedback resistance to add a pole to the open loop response. This not only reduces closed loop bandwidth, but can also cause ringing or oscillation if the spurious pole frequency is less than the amplifier's 0dB crossover frequency. Stability can be restored by adding a phase compensation capacitor in parallel with the feedback resistor.
4. GAIN TEMPERATURE COEFFICIENTS: The gain temperature coefficient of the AD7542 has a maximum value of 5ppm/°C and a typical value of 2ppm/°C. This corresponds to gain shifts of 2.0LSBs and 0.82LSBs respectively over a 100°C temperature range. When trim resistors are used to adjust full-scale range as shown in Figures 4 and 5 the temperature coefficient of R1 and R2 should be taken into account. It may be shown that the additional gain temperature coefficients introduced by R1 and R2 may be approximately expressed as follows: –

$$\text{Temperature Coefficient contribution due to R1} = -\frac{R_1}{R_{IN}}(\gamma_1 + 300)$$

$$\text{Temperature Coefficient contribution due to R2} = +\frac{R_2}{R_{IN}}(\gamma_2 + 300)$$

Where γ_1 and γ_2 are the temperature coefficients in ppm/°C of R1 and R2 respectively and R_{IN} is the DAC input resistance at the V_{REF} terminal (pin 2). For high quality wirewound resistors and trimming potentiometers γ is of the order of 50ppm/°C. It will be seen that if R1 and R2 are small compared with R_{IN}, their contribution to gain temperature coefficient will also be small. For the standard AD7542 gain error specification of ±3LSBs it is recommended that R1 = 50Ω and R2 = 25Ω. With γ = 50 these values result in an overall maximum gain error temperature coefficient of:

$$5 + \frac{0.025}{8}(50 + 300) = 6\text{ppm/°C}$$

However, if the AD7542GTD is used which has a specified gain error of ±1LSB, then with R1 = 10Ω and R2 = 5Ω the overall maximum gain temperature coefficient is increased by only 0.25ppm/°C. Where possible R1 should be a select on test fixed resistor since the resulting gain temperature coefficient will be tighter in all cases. For further gain T.C. information refer to application note, "Gain Error and Gain Temperature Coefficients of CMOS Multiplying DACs", Publication Number E630–10–6/81 available from Analog Devices.

5. For additional information on multiplying DACs refer to "CMOS DAC Application Guide," Publication Number G872a–15–4/86, available from Analog Devices.

ANALOG DEVICES

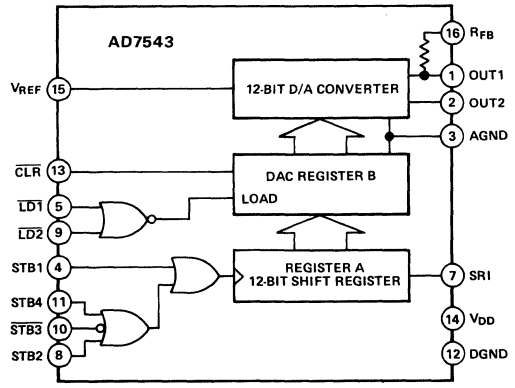
CMOS Serial Input 12-Bit DAC

AD7543

FEATURES

- Resolution: 12 Bits
- Nonlinearity: ±1/2LSB T_{min} to T_{max}
- Low Gain T.C.: 2ppm/°C typ, 5ppm/°C max
- Serial Load on Positive or Negative Strobe
- Asynchronous CLEAR Input for Initialization
- Full 4-Quadrant Multiplication
- Low Multiplying Feedthrough: 1LSB max @ 10kHz
- Requires no Schottky Diode Output Protection
- Low Power Dissipation: 40mW max
- +5V Supply
- Small Size: 16-Pin DIP or 20-Terminal Surface Mount Package
- Low Cost

AD7543 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7543 is a precision 12-bit monolithic CMOS multiplying DAC designed for serial interface applications.

The DAC's logic circuitry consists of a 12-bit serial-in parallel-out shift register (Register A) and a 12-bit DAC input register (Register B). Serial data at the AD7543 SRI pin is clocked into Register A on the leading or trailing edge (user selected) of the strobe input. Once Register A is full its contents are loaded into Register B under control of the LOAD inputs.

Initialization is simplified by the use of the CLR input which provides an asynchronous reset of Register B.

Packaged in 16-pin DIP and 20-pin LCCC and PLCC, the AD7543 features excellent gain T.C. (2ppm/°C typ; 5ppm/°C max), +5V operation and latch-free operation. (No protection Schottky Diodes required.)

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

TERMINOLOGY

RELATIVE ACCURACY
Relative accuracy or endpoint nonlinearity is a measure of the maximum deviation from a straight line passing through the endpoints of the DAC transfer function. It is measured after adjusting for ideal zero and full scale and is expressed in % or ppm of full-scale range or (sub) multiples of 1LSB.

DIFFERENTIAL NONLINEARITY
Differential nonlinearity is the difference between the *measured* change and the *ideal* 1 LSB change between any two adjacent codes. A specified differential nonlinearity of ±1 LSB max over the operating temperature range ensures monotonicity.

GAIN ERROR
Gain is defined as the ratio of the DAC's Full Scale output to its reference input voltage. An *ideal* AD7543 would exhibit a gain of −4095/4096. Gain error is adjustable using external trims.

OUTPUT LEAKAGE CURRENT
Current which appears at OUT1 with Register B loaded to all 0's or at OUT 2 with Register B loaded to all 1's.

MULTIPLYING FEEDTHROUGH ERROR
AC error due to capacitive feedthrough from V_{REF} terminal to OUT1 with DAC register loaded to all 0's.

PIN	MNEMONIC	FUNCTION
1	OUT1	DAC current output bus. Normally terminated at op amp virtual ground
2	OUT2	DAC current output bus. Normally terminated at AGND
3	AGND	Analog Ground
4	STB1	Register A Strobe 1 input, see Table II
5	$\overline{LD1}$	DAC Register B Load 1 input. When $\overline{LD1}$ and $\overline{LD2}$ go low the contents of Register A are loaded into DAC Register B
6	N/C	No Connection
7	SRI	Serial Data Input to Register A
8	STB2	Register A Strobe 2 input, see Table II
9	$\overline{LD2}$	DAC Register B Load 2 input. When $\overline{LD1}$ and $\overline{LD2}$ go low the contents of Register A are loaded into DAC Register B

11	STB4	Register A Strobe 4 input, see Table II
12	DGND	Digital Ground
13	$\overline{CLR}$	Register B CLEAR input (active LOW), can be used to asynchronously reset Register B to 0000 0000 0000
14	V_{DD}	+5V Supply Input
15	V_{REF}	Reference input. Can be positive or negative dc voltage or ac signal
16	R_{FB}	DAC Feedback Resistor

Table I. Pin Function Description, DIP Configuration

INTERFACE LOGIC INFORMATION

Shown in the AD7543 Functional Diagram Register A is a 12-bit shift register. Serial data appearing at pin SRI is clocked into the shift register on the leading (rising) edge of STB1, STB2 or STB4 or on the leading (falling) edge of STB3. Table II defines the various logic states required on the Register A control inputs, while Figure 1 illustrates the Register A loading sequence.

Once Register A is full, the data is transferred to Register B by bringing $\overline{LD1}$ and $\overline{LD2}$ momentarily LOW.

Register B can be asynchronously reset to 0000 0000 0000 by bringing $\overline{CLR}$ momentarily LOW. This allows the DAC output voltage to be set to a known condition, thus simplifying system initialization procedure. When operating the AD7543 in the unipolar circuit, a CLEAR causes the DAC output voltage to equal 0V. When using the bipolar circuit, a CLEAR causes the DAC output to equal $-V_{REF}$.

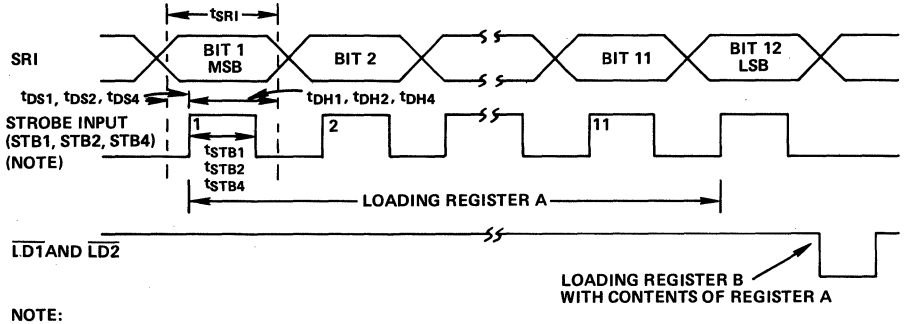

Figure 1. Timing Diagram

AD7543 Logic Inputs							AD7543 Operation	Notes
Register A Control Inputs				Register B Control Inputs				
STB4	$\overline{STB3}$	STB2	STB1	$\overline{CLR}$	$\overline{LD2}$	$\overline{LD1}$

ANALOG DEVICES

CMOS 12-Bit Buffered Multiplying DAC

AD7545

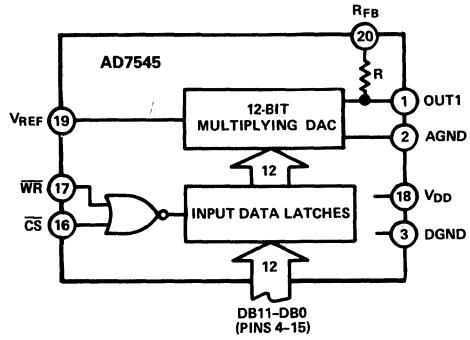
FEATURES
- 12-Bit Resolution
- Low Gain T.C.: 2ppm/°C typ
- Fast TTL Compatible Data Latches
- Single +5V to +15V Supply
- Small 20-Pin 0.3" DIP and 20-Terminal Surface Mount Packages
- Latch Free (Schottky Protection Diode Not Required)
- Low Cost
- Ideal for Battery Operated Equipment

GENERAL DESCRIPTION

The AD7545 is a monolithic 12-bit CMOS multiplying DAC with on-board data latches. It is loaded by a single 12-bit wide word and interfaces directly to most 12- and 16-bit bus systems. Data is loaded into the input latches under the control of the $\overline{CS}$ and $\overline{WR}$ inputs; tying these control inputs low makes the input latches transparent allowing direct unbuffered operation of the DAC.

The AD7545 is particularly suitable for single supply operation and applications with wide temperature variations.

AD7545 FUNCTIONAL BLOCK DIAGRAM



The AD7545 can be used with any supply voltage from +5V to +15V. With CMOS logic levels at the inputs the device dissipates less than 0.5mW for V_{DD} = +5V.

NOTES

[1] Temperature Ranges as follows: J, K, L, GL versions; 0 to +70°C
A, B, C, GC versions; -25°C to +85°C
S, T, U, GU versions; -55°C to +125°C

[2] This includes the effect of 5ppm max gain TC.

[3] Guaranteed but not tested.

[4] DB0-DB11 = 0V to V_{DD} or V_{DD} to 0V.

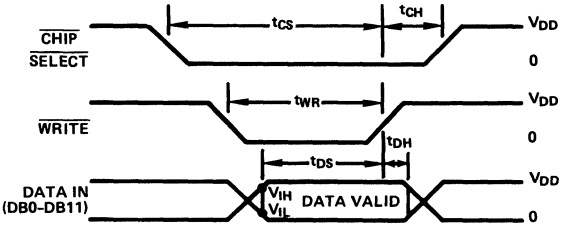
[5] Feedthrough can be further reduced by connecting the metal lid on the ceramic package to DGND.

[6] Logic inputs are MOS gates. Typical input current (+25°C) is less than 1nA.

[7] Sample tested at +25°C to ensure compliance.

Specifications subject to change without notice.

WRITE CYCLE TIMING DIAGRAM



MODE SELECTION

WRITE MODE:	HOLD MODE:
$\overline{CS}$ and $\overline{WR}$ low, DAC responds to data bus (DB0–DB11) inputs.	Either $\overline{CS}$ or $\overline{WR}$ high, data bus (DB0–DB11) is locked out; DAC holds last data present when $\overline{WR}$ or $\overline{CS}$ assumed high state.

NOTES:
V_{DD} = +5V; $t_r = t_f$ = 20ns
V_{DD} = +15V; $t_r = t_f$ = 40ns
All input signal rise and fall times measured from 10% to 90% of V_{DD}.
Timing measurement reference level is $V_{IH} + V_{IL}/2$.

Storage Temperature	−65°C to +150°C
Lead Temperature (Soldering, 10secs)	+300°C

NOTES
*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation at or above this specification is not implied. Exposure to above maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

APPLICATION HINTS

Output Offset: CMOS D/A converters exhibit a code dependent output resistance which in turn causes a code dependent amplifier noise gain. The effect is a code dependent differential nonlinearity term at the amplifier output which depends on V_{OS} where V_{OS} is the amplifier input offset voltage. To maintain monotonic operation it is recommended that V_{OS} be no greater than (25×10^{-6}) (V_{REF}) over the temperature range of operation. Suitable op amps are AD517L and AD544L. The AD517L is best suited for fixed reference applications with low bandwidth requirements: it has extremely low offset (50μV) and in most applications will not require an offset trim. The AD544L has a much wider bandwidth and higher slew rate and is recommended for multiplying and other applications requiring fast settling. An offset trim on the AD544L may be necessary in some circuits.

General Ground Management: AC or transient voltages between AGND and DGND can cause noise injection into the analog output. The simplest method of ensuring that voltages at AGND and DGND are equal is to tie AGND and DGND together at the AD7545. In more complex systems where the AGND and DGND intertie is on the backplane, it is recommended that two diodes be connected in inverse parallel between the AD7545 AGND and DGND pins (1N914 or equivalent).

Digital Glitches: When $\overline{WR}$ and $\overline{CS}$ are both low the latches are transparent and the D/A converter inputs follow the data inputs. In some bus systems, data on the data bus is not always valid for the whole period during which $\overline{WR}$ is low and as a result invalid data can briefly occur at the D/A converter inputs during a write cycle. Such invalid data can cause unwanted glitches at the output of the D/A converter. The solution to this problem, if it occurs, is to retime the write pulse $\overline{WR}$ so that it only occurs when data is valid.

Another cause of digital glitches is capacitive coupling from the digital lines to the OUT1 and AGND terminals. This should be minimized by screening the analog pins of the AD7545 (Pins 1, 2, 19, 20) from the digital pins by a ground track run between pins 2 and 3 and between pins 18 and 19 of the AD7545. Note how the analog pins are at one end of the package and separated from the digital pins by V_{DD} and DGND to aid screening at the board level. On-chip capacitive coupling can also give rise to crosstalk from the digital to analog sections of the AD7545, particularly in circuits with high currents and fast rise and fall times. This type of crosstalk is minimized by using V_{DD} = +5 volts. However, great care should be taken to ensure that the +5V used to power the AD7545 is free from digitally induced noise.

Temperature Coefficients: The gain temperature coefficient of the AD7545 has a maximum value of 5ppm/°C and a typical value of 2ppm/°C. This corresponds to worst case gain shifts of 2LSBs and 0.8LSBs respectively over a 100°C temperature range. When trim resistors R1 and R2 are used to adjust full scale range, the temperature coefficient of R1 and R2 should also be taken into account. The reader is referred to Analog Devices Application Note "Gain Error and Gain Temperature Coefficient of CMOS Multiplying DACs", Publication Number E630–10–6/81.

BASIC APPLICATIONS

Figures 1 and 2 show simple unipolar and bipolar circuits using the AD7545. Resistor R1 is used to trim for full scale. The "G" versions (AD7545GLN, AD7545GCQ, AD7545GUD) have a guaranteed maximum gain error of ±1LSB at +25°C (V_{DD} = +5V) and in many applications it should be possible to dispense with gain trim resistors altogether. Capacitor C1 provides phase compensation and helps prevent overshoot and ringing when using high speed op amps. Note that all the circuits of Figures 1 and 2 have constant input impedance at the V_{REF} terminal.

The circuit of Figure 1 can either be used as a fixed reference D/A converter so that it provides an analog output voltage in the range 0 to $-V_{IN}$ (note the inversion introduced by the op amp) or V_{IN} can be an ac signal in which case the circuit behaves as an attenuator (2-Quadrant Multiplier). V_{IN} can be any voltage in the range $-20 \leqslant V_{IN} \leqslant +20$ volts (provided the op amp can handle such voltages) since V_{REF} is permitted to exceed V_{DD}. Table II shows the code relationship for the circuit of Figure 1.

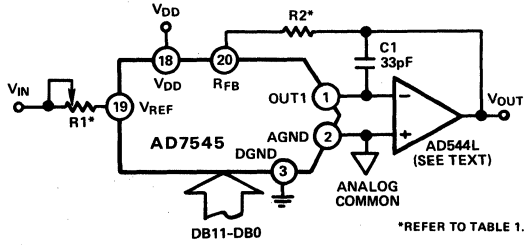

Figure 1. Unipolar Binary Operation

TRIM RESISTOR	J/A/S	K/B/T	L/C/U	GL/GC/GU
R1	500Ω	200Ω	100Ω	20Ω
R2	150Ω	68Ω	33Ω	6.8Ω

0000	0000	0000	0 Volts

Table II. Unipolar Binary Code Table for Circuit of Figure 1

Figure 2 and Table III illustrate the recommended circuit and code relationship for bipolar operation. The D/A function itself uses offset binary code and inverter U_1 on the MSB line converts 2's complement input code to offset binary code. If appropriate, inversion of the MSB may be done in software using an exclusive –OR instruction and the inverter omitted. R3, R4 and R5 must be selected to match within 0.01% and they should be the same type of resistor (preferably wirewound or metal foil), so that their temperature coefficients match. Mismatch of R3 value to R4 causes both offset and full scale error. Mismatch of R5 to R4 and R3 causes full scale error.

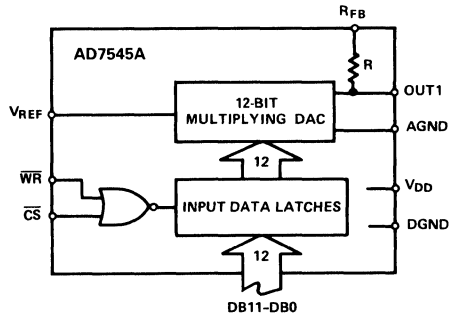
CMOS 12-Bit Buffered Multiplying DAC

AD7545A

FEATURES
Improved Version of AD7545
Fast Interface Timing
All Grades 12-Bit Accurate
Small 20-Pin 0.3" DIP and
20-Terminal Surface Mount Package
Low Cost

AD7545A FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7545A, a 12-bit CMOS multiplying DAC with internal data latches, is an improved version of the industry standard AD7545. This new design features a $\overline{WR}$ pulse width of 100ns which allows interfacing to a much wider range of fast 8-bit and 16-bit microprocessors. It is loaded by a single 12-bit wide word under the control of the $\overline{CS}$ and $\overline{WR}$ inputs; tying these control inputs low makes the input latches transparent allowing unbuffered operation of the DAC.

NOTES

[1] Temperature Ranges as follows:

K, L versions; 0 to +70°C
B, C versions; −25°C to +85°C
T, U versions; −55°C to +125°C

[2] Sample tested to ensure compliance.

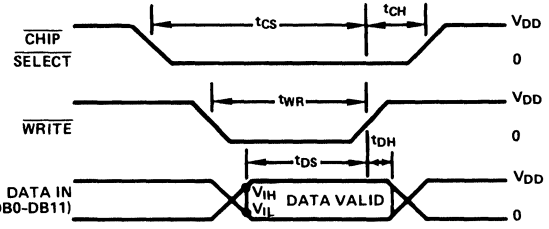
[3] DB0-DB11 = 0V to V_{DD} or V_{DD} to 0V.

[4] Feedthrough can be further reduced by connecting the metal lid on the ceramic package to DGND.

[5] Logic inputs are MOS gates. Typical input current (+25°C) is less than 1nA.

Specifications subject to change without notice.

WRITE CYCLE TIMING DIAGRAM



MODE SELECTION

WRITE MODE:	HOLD MODE:
$\overline{CS}$ and $\overline{WR}$ low, DAC responds to data bus (DB0-DB11) inputs.	Either $\overline{CS}$ or $\overline{WR}$ high, data bus (DB0-DB11) is locked out; DAC holds last data present when $\overline{WR}$ or $\overline{CS}$ assumed high state.

NOTES:
V_{DD} = +5V; $t_r = t_f$ = 20ns
V_{DD} = +15V; $t_r = t_f$ = 40ns
All input signal rise and fall times measured from 10% to 90% of V_{DD}.
Timing measurement reference level is $\frac{V_{IH} + V_{IL}}{2}$.

Storage Temperature	−65°C to +150°C
Lead Temperature (Soldering, 10sec)	+300°C

NOTES

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation at or above this specification is not implied. Exposure to above maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

APPLICATION HINTS

Output Offset: CMOS D/A converters in circuits such as Figures 1 and 2 exhibit a code dependent output resistance which in turn can cause a code dependent error voltage at the output of the amplifier. The maximum amplitude of this error, which adds to the D/A converter nonlinearity, depends on V_{OS}, where V_{OS} is the amplifier input offset voltage. To maintain specified accuracy with V_{REF} at 10V, it is recommended that V_{OS} be no greater than 0.25mV, or (25×10^{-6}) (V_{REF}), over the temperature range of operation. Suitable op amps are AD517 and AD711. The AD517 is best suited for fixed reference applications with low bandwidth requirements: it has extremely low offset (150µV max for lowest grade) and in most applications will not require an offset trim. The AD711 has a much wider bandwidth and higher slew rate and is recommended for multiplying and other applications requiring fast settling. An offset trim on the AD711 may be necessary in some circuits.

General Ground Management: AC or transient voltages between AGND and DGND can cause noise injection into the analog output. The simplest method of ensuring that voltages at AGND and DGND are equal is to tie AGND and DGND together at the AD7545A. In more complex systems where the AGND and DGND intertie is on the backplane, it is recommended that two diodes be connected in inverse parallel between the AD7545A AGND and DGND pins (1N914 or equivalent).

Invalid Data: When $\overline{WR}$ and $\overline{CS}$ are both low, the latches are transparent and the D/A converter inputs follow the data inputs. In some bus systems, data on the data bus is not always valid for the whole period during which $\overline{WR}$ is low, and as a result invalid data can briefly occur at the D/A converter inputs during a write cycle. Such invalid data can cause unwanted signals or glitches at the output of the D/A converter. The solution to this problem, if it occurs, is to retime the write pulse $\overline{WR}$ so that it only occurs when data is valid.

Digital Glitches: Digital glitches result due to capacitive coupling from the digital lines to the OUT1 and AGND terminals. This should be minimized by screening the analog pins of the AD7545A (Pins 1, 2, 19, 20) from the digital pins by a ground track run between Pins 2 and 3 and between Pins 18 and 19 of the AD7545A. Note how the analog pins are at one end (DIP) or side (LCC and PLCC) of the package and separated from the digital pins by V_{DD} and DGND to aid screening at the board level. On-chip capacitive coupling can also give rise to crosstalk from the ditigal-to-analog sections of the AD7545A, particularly in circuits with high currents and fast rise and fall times. This type of crosstalk is minimized by using V_{DD} = +5 volts. However, great care should be taken to ensure that the +5V used to power the AD7545A is free from digitally induced noise.

Temperature Coefficients: The gain temperature coefficient of the AD7545A has a maximum value of 5ppm/°C and a typical value of 2ppm/°C. This corresponds to worst case gain shifts of 2LSBs and 0.8LSBs respectively over a 100°C temperature range. When trim resistors R1 and R2 (such as in Figure 4) are used to adjust full-scale range, the temperature coefficient of R1 and R2 should also be taken into account. The reader is referred to Analog Devices Application Note "Gain Error and Gain Temperature Coefficient to CMOS Multiplying DACs", Publication Number E630c–5–3/86.

BASIC APPLICATIONS

Figures 1 and 2 show simple unipolar and bipolar circuits using the AD7545A. Resistor R1 is used to trim for full scale. The L, C, U grades have a guaranteed maximum gain error of ±1LSB at +25°C, and in many applications it should be possible to dispense with gain trim resistors altogether. Capacitor C1 provides phase compensation and helps prevent overshoot and ringing when using high-speed op amps. Note that all the circuits of Figures 1 and 2 have constant input impedance at the V_{REF} terminal.

The circuit of Figure 1 can either be used as a fixed reference D/A converter so that it provides an analog output voltage in the range 0 to $-V_{IN}$ (note the inversion introduced by the op amp) or V_{IN} can be an ac signal in which case the circuit behaves as an attenuator (2-Quadrant Multiplier). V_{IN} can be any voltage in the range $-20 \leq V_{IN} \leq +20$ volts (provided the op amp can handle such voltages) since V_{REF} is permitted to exceed V_{DD}. Table II shows the code relationship for the circuit of Figure 1.

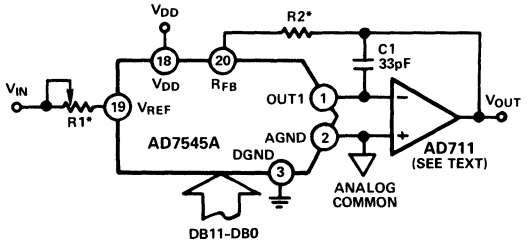

Figure 1. Unipolar Binary Operation

TRIM RESISTOR	K, B, T	L, C, U
R1	50Ω	20Ω
R2	27Ω	6.8Ω

Table I. Recommended Trim Resistor Values vs. Grades

Binary Number in DAC Register			Analog Output
1111	1111	1111	$-V_{IN}\left\{\frac{4095}{4096}\right\}$
1000	0000	0000	$-V_{IN}\left\{\frac{2048}{4096}\right\} = -1/2\ V_{IN}$
0000	0000	0001	$-V_{IN}\left\{\frac{1}{4096}\right\}$
0000	0000	0000	0 Volts

Table II. Unipolar Binary Code Table for Circuit of Figure 1.

Figure 2 and Table III illustrate the recommended circuit and code relationship for bipolar operation. The D/A function itself uses offset binary code, and inverter U_1 on the MSB line converts 2's complement input code to offset binary code. If appropriate, inversion of the MSB may be done in software using an exclusive – OR instruction and the inverter omitted. R3, R4 and R5 must be selected to match within 0.01%, and they should be the same type of resistor (preferably wire-wound or metal foil), so that their temperature coefficients match. Mismatch of R3 value to R4 causes both offset and full-scale error. Mismatch of R5 to R4 causes full-scale error.

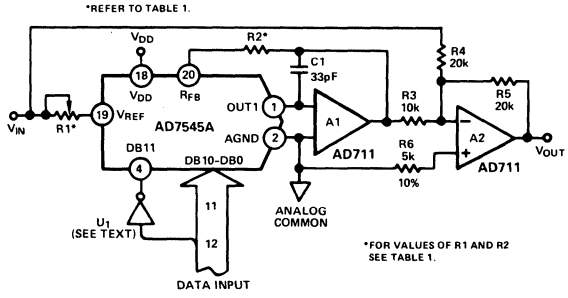

Figure 2. Bipolar Operation (2's Complement Code)

Data Input			Analog Output
0111	1111	1111	$+V_{IN} \cdot \left\{\frac{2047}{2048}\right\}$
0000	0000	0001	$+V_{IN} \cdot \left\{\frac{1}{2048}\right\}$
0000	0000	0000	0 Volts

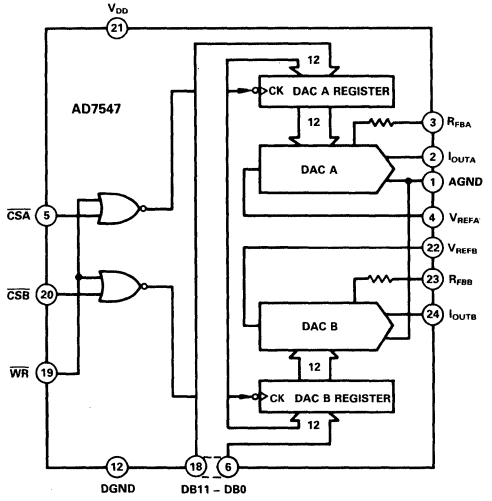
AD7547 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7547 contains two 12-bit current output DACs on one monolithic chip. Also on-chip are the level shifters, data registers and control logic for easy microprocessor interfacing. There are 12 data inputs. $\overline{CSA}$, $\overline{CSB}$, $\overline{WR}$ control DAC selection and loading. Data is latched into the DAC registers on the rising edge of $\overline{WR}$. The device is speed compatible with most microprocessors and accepts TTL, 74HC and 5V CMOS logic level inputs.

The D/A converters provide 4-quadrant multiplication capabilities with separate reference inputs and feedback resistors. Monolithic construction ensures that thermal and gain error tracking is excellent. 12-bit monotonicity is guaranteed for both DACs over the full temperature range.

The AD7547 is manufactured using the Linear Compatible CMOS (LC²MOS) process. This allows fast digital logic and precision linear circuitry to be fabricated on the same die.

PRODUCT HIGHLIGHTS

1. DAC to DAC Matching:
   Since both DACs are fabricated on the same chip, precise matching and tracking is inherent. Many applications which are not practical using two discrete DACs are now possible. Typical matching: 0.5%.
2. Small Package Size:
   The AD7547 is available in both 0.3" wide, 24-pin DIPs and in 28-terminal surface mount packages.
3. Wide Power Supply Tolerance:
   The device operates on a +12V to +15V V_{DD}, with ±10% tolerance on this nominal figure. All specifications are guaranteed over this range.

$\overline{CSA}$	$\overline{CSB}$	$\overline{WR}$	FUNCTION
X	X	1	No Data Transfer
1	1	X	No Data Transfer
↓	↓	0	A Rising Edge on $\overline{CSA}$ or $\overline{CSB}$ Loads Data to the Respective DAC from the Data Bus

NOTES
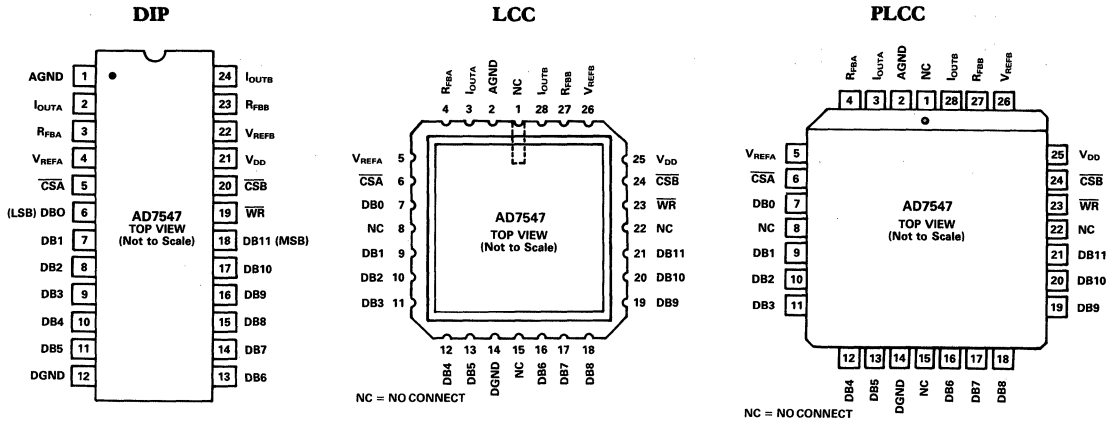
[1]To order MIL-STD-883, Class B processed parts, add /883B to part number. Contact your local sales office for military data sheets.
[2]Analog Devices reserves the right to ship ceramic packages (D-24A)in lieu of cerdip packages (Q-24).
[3]See Section 14 for package outline information.
[4]PLCC: Plastic Leaded Chip Carrier.
[5]LCCC: Leadless Ceramic Chip Carrier.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

PIN CONFIGURATIONS



PIN FUNCTION DESCRIPTION

PIN	MNEMONIC	DESCRIPTION
1	AGND	Analog Ground.
2	I_{OUTA}	Current output terminal of DACA.
3	R_{FBA}	Feedback resistor for DACA.
4	V_{REFA}	Reference input to DACA.
5	$\overline{CSA}$	Chip Select Input for DAC A. Active low.
6-18	DB0-DB11	12 data inputs, DB0 (LSB) – DB11 (MSB).
12	DGND	Digital Ground.
19	$\overline{WR}$	Write Input. Data transfer occurs on rising edge of $\overline{WR}$. See Table I.
20	$\overline{CSB}$	Chip Select Input for DACB. Active low.
21	V_{DD}	Power supply input. Nominally + 12V to + 15V with ± 10% tolerance.
22	V_{REFB}	Reference input to DACB.
23	R_{FBB}	Feedback resistor of DACB.
24	I_{OUTB}	Current output terminal of DACB.

CIRCUIT INFORMATION

D/A SECTION

The AD7547 contains two identical 12-bit multiplying D/A converters. Each DAC consists of a highly stable R-2R ladder and 12 N-channel current steering switches. Figure 2 shows a simplified D/A circuit for DAC A. In the R-2R ladder, binary weighted currents are steered between I_{OUTA} and AGND. The current flowing in each ladder leg is constant, irrespective of switch state. The feedback resistor R_{FBA} is used with an op-amp to convert the current flowing in I_{OUTA} to a voltage output.

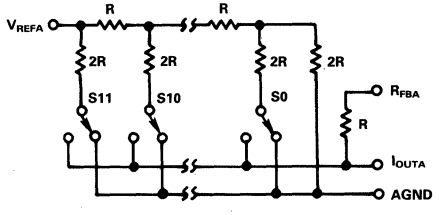


Figure 2. Simplified Circuit Diagram for DACA

EQUIVALENT CIRCUIT ANALYSIS

Figure 3 shows the equivalent circuit for one of the D/A converters (DAC A) in the AD7547. A similar equivalent circuit can be drawn for DACB. Note that AGND is common to both DAC A and DAC B.

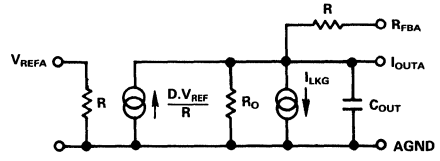

Figure 3. Equivalent Analog Circuit for DACA

C_{OUT} is the output capacitance due to the N-channel switches and varies from about 50pF to 150pF with digital input code. The current source I_{LKG} is composed of surface and junction leakages and approximately doubles every 10°C. R_0 is the equivalent output resistance of the device which varies with input code.

DIGITAL CIRCUIT INFORMATION

The digital inputs are designed to be both TTL and 5V CMOS compatible. All logic inputs are static-protected MOS gates with typical input currents of less than 1nA.

ANALOG DEVICES

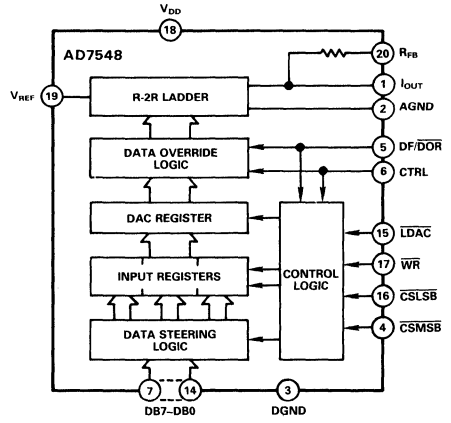
LC²MOS 8-Bit µP-Compatible 12-Bit DAC

AD7548

FEATURES
- 8-Bit Bus Compatible 12-Bit DAC
- All Grades 12-Bit Monotonic Over Full Temperature Ranges
- Operation Specified at +5V, +12V or +15V Power Supply
- Low Gain Drift of 5ppm/°C Maximum
- Full 4 Quadrant Multiplication
- Skinny DIP and Surface Mount Packages

APPLICATIONS
- 8-Bit Microprocessor Based Control Systems
- Programmable Amplifiers
- Function Generation
- Servo Control

AD7548 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7548 is a 12-bit monolithic CMOS D/A converter for use with 8-bit bus microprocessors. Data is loaded in two bytes to input holding registers as shown in the block diagram opposite. The AD7548 can be configured to accept either left- or right-justified data, least significant byte or most significant byte first, using standard TTL compatible control inputs.

A separate load DAC control input allows the user the choice of updating the analog output coincident with loading new data to the DAC input register or at any time after the data loading event. This feature is especially important in multi-DAC systems where simultaneous update of all DACs is required.

The new Linear Compatible CMOS (LC²MOS) process used in the manufacture of the AD7548 allows precision thin-film linear circuitry and high-speed low-power CMOS logic to be integrated on the same small chip. The high-speed logic allows direct interfacing to most of the popular 8-bit microprocessors.

PRODUCT HIGHLIGHTS

1. Microprocessor Compatibility
   High speed input control (TTL/5V CMOS compatible) allow direct interfacing to most of the popular 8-bit microprocessors.
2. Guaranteed Monotonicity
   The AD7548 is guaranteed monotonic to 12-bits over the full temperature range for all grades and at all specified supply voltages.
3. Selectable Data Input Format
   Left- or right-justified data, least significant or most significant byte first. This allows the AD7548 to be interfaced with microprocessors using either Motorola or Intel-type data formatting.
4. Monolithic Construction
   For increased reliability and reduced package size – 0.3″ 20-pin DIP and 20-terminal surface mount packages.
5. Single Supply Operation – See Figure 8.
6. Low Gain Error and Gain Error T.C.

ABSOLUTE MAXIMUM RATINGS*

(T_A = +25°C unless otherwise noted)

V_{DD} (pin 18) to DGND	+17V
V_{REF} (pin 19) to AGND	±25V
V_{RFB} (pin 20) to AGND	±25V
Digital Input Voltage (pins 4–17) to DGND	−0.3V, V_{DD}+0.3V
$V_{PIN\ 1}$ to DGND	−0.3V, V_{DD}+0.3V
AGND to DGND	−0.3V, V_{DD}+0.3V
Power Dissipation (Any Package)	
To +75°C	450mW
Derates above +75°C	6mW/°C
Operating Temperature Range	
Commercial (J, K versions)	0 to +70°C
Industrial (A, B versions)	−40°C to +85°C
Extended (S, T versions)	−55°C to +125°C
Storage Temperature	−65°C to +150°C
Lead Temperature (Soldering, 10secs)	+300°C

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

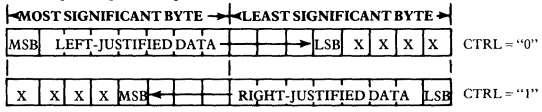
[5]LCCC: Leadless Ceramic Chip Carrier.

PIN FUNCTION DESCRIPTION

PIN	MNEMONIC	DESCRIPTION
1	I_{OUT}	DAC current OUT bus. Normally terminated at virtual ground of output amplifier.
2	AGND	Analog Ground.
3	DGND	Digital Ground.
4	$\overline{CSMSB}$	Chip Select Most Significant (MS) Byte. Active Low Input. Used in combination with $\overline{WR}$ to load external data into the input register or in combination with $\overline{WR}$ and $\overline{LDAC}$ to load external data into both input and DAC registers.
5	DF/$\overline{DOR}$	Data Format/Data Override. When this input is LOW, data in the DAC register is forced to one of two override codes selected by CTRL. When the override signal is removed, the DAC output returns to reflect the value in the DAC register. With DF/$\overline{DOR}$ HIGH, CTRL selects either a left or right justified input data format. For normal operation, DF/$\overline{DOR}$ is held HIGH.

DF/$\overline{DOR}$	CTRL	FUNCTION
0	0	DAC register contents overridden by all 0's
0	1	DAC register contents overriden by all 1's
1	0	Left-justified input data selected
1	1	Right-justified input data selected

6	CTRL	Control Input. See pin 5 description.



X = Don't care states.

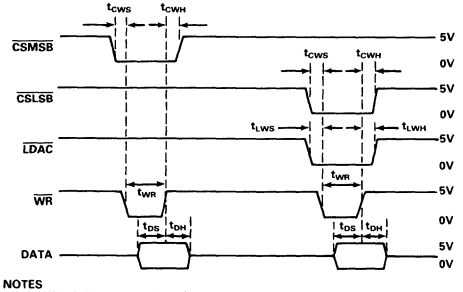
7	DB7	Data Bit 7. Most Significant Bit (MSB).
8	DB6	Data Bit 6.
9	DB5	Data Bit 5.
10	DB4	Data Bit 4.
11	DB3	Data Bit 3.
12	DB2	Data Bit 2.
13	DB1	Data Bit 1.
14	DB0	Data Bit 0. Least Significant Bit (LSB).
15	$\overline{LDAC}$	Load DAC Input, active LOW. This signal, in combination with others, is used to load the DAC register from either the input register or the external data bus.
16	$\overline{CSLSB}$	Chip Select Least Significant (LS) Byte. Active LOW input. Used in combination with $\overline{WR}$ to load external data into the input register or in combination with $\overline{WR}$ and $\overline{LDAC}$ to load external data into both input and DAC registers.
17	$\overline{WR}$	WRITE Input. This active low signal, in combination with others is used in loading external data into the AD7548 input register and in transferring data from the input register to the DAC register.

$\overline{WR}$	$\overline{CSMSB}$	$\overline{CSLSB}$	$\overline{LDAC}$	FUNCTION
0	1	0	1	Load LS Byte to Input Register.
0	1	0	0	Load LS Byte to Input Register and DAC Register.
0	0	1	1	Load MS Byte to Input Register.
0	0	1	0	Load MS Byte to Input Register and DAC Register.
0	1	1	0	Load Input Register to DAC Register.
1	X	X	X	No Data Transfer

18	V_{DD}	+5V to +15V Supply Input.
19	V_{REF}	Reference Voltage Input.
20	R_{FB}	Feedback Resistor. Used for normal D/A conversion.

CONTROL INPUT INFORMATION

Figure 1a shows the data load timing diagram for the AD7548. Figure 1b shows the simplified input control structure of the AD7548.



NOTES
1. ALL INPUT SIGNAL RISE AND FALL TIMES MEASURED FROM 10% TO 90% OF +5V. $t_r = t_f = 20ns$.
2. TIMING MEASUREMENT REFERENCE LEVEL IS $\frac{V_{IH} + V_{IL}}{2}$
3. $\overline{CSMSB}$ (PIN 4) AND $\overline{CSLSB}$ (PIN 16) MAY BE INTERCHANGED.
4. FOR LEFT-JUSTIFIED DATA CTRL = +0V WITH DF/$\overline{DOR}$ = +5V. FOR RIGHT-JUSTIFIED DATA CTRL = +5V WITH DF/$\overline{DOR}$ = +5V.

Figure 1a. AD7548 Timing Diagram

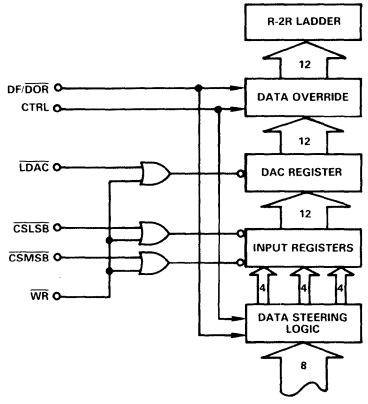


Figure 1b. Simplified AD7548 Input Control Structure

GENERAL CIRCUIT INFORMATION

The simplified D/A circuit is shown in Figure 2. An inverted R-2R ladder structure is used, which steers binarily weighted currents between I_{OUT} and AGND, thus maintaining a constant current in each ladder leg independent of the switch state.

The input resistance at V_{REF} is constant and equal to the value "R" in Figure 2. Since the input resistance is constant, the reference terminal can be driven by a reference voltage or a reference current, ac or dc, of positive or negative polarity. (If a current source is used, a low temperature coefficient external R_{FB} is recommended to define scale factor).

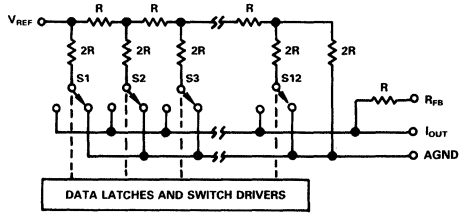

Figure 2. AD7548 Simplified Functional Diagram

EQUIVALENT CIRCUIT ANALYSIS

Figure 3 shows an equivalent circuit for the analog section of the AD7548 D/A converter. The current source $I_{LEAKAGE}$ is composed of surface and junction leakages. The resistor R_O, denotes the equivalent output resistance of the DAC which varies with input code (excluding all 0's code) from 0.8R to 2R, where R is typically 11kΩ. C_{OUT} is the capacitance due to the current steering switches and varies from about 50pF to 120pF (typical values) depending upon the digital input. g(V_{REF}, N) is the Thevenin equivalent voltage generator due to the reference input voltage, V_{REF}, and the transfer function of R-2R ladder, N.

For further information on CMOS multiplying D/A converters refer to "Application Guide to CMOS Multiplying D/A Converters" available from Analog Devices, Publication Number G479–15–8/78.

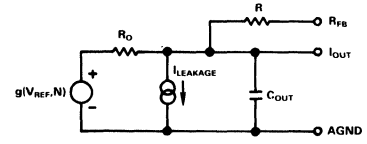

Figure 3. AD7548 Equivalent Analog Output Circuit

DATA LOADING

The AD7548 accepts incoming data in either left-justified format or right-justified format depending on the control inputs DF/$\overline{DOR}$ and CTRL.

(See pin description of DF/$\overline{DOR}$ and CTRL on preceding page).

Two operating modes are possible for controlling the transfer of data from the input register to the DAC register, the automatic transfer mode and the strobed transfer mode.

AUTOMATIC TRANSFER MODE

This is the simplest and fastest method of transferring data to the DAC register. It is facilitated by connecting $\overline{LDAC}$ to either $\overline{CSMSB}$, as shown in Figure 10, or $\overline{CSLSB}$.

Figure 4 shows the timing diagram for automatic transfer of 8 +4-bit data to the DAC register. The first write cycle loads the first byte of data to the input register. The second write cycle loads the second byte of data to the input register and automatically transfers both bytes to the DAC register.

Updating a single byte (High or Low) in the DAC register can be achieved in one write cycle using the automatic transfer mode.

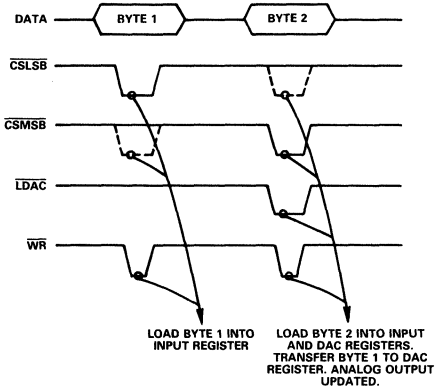

Figure 4. Automatic Transfer Mode

STROBED TRANSFER MODE

Figure 5 shows the timing diagram for the strobed transfer of 8 +4-bit data to the DAC register. Three write cycles are required for this transfer mode. The first two write cycles sequentially load bytes 1 and 2 into the input register. The third write cycle transfers data from the input register to the DAC register.

The strobed transfer mode allows the DAC registers of several AD7548's to be updated simultaneously, as shown in Figure 13, by means of a master strobe signal connected to the $\overline{LDAC}$ of each device.

A single byte of data (High or Low) can be transferred to the DAC register in two write cycles using the strobed transfer mode.

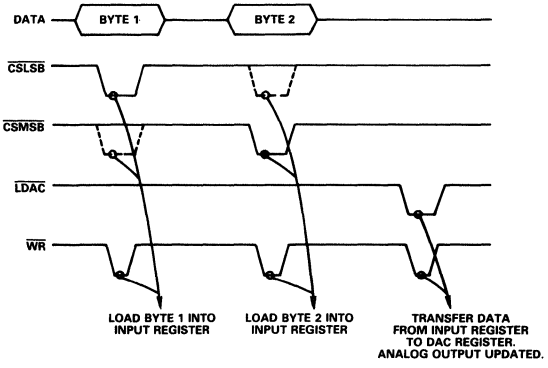

Figure 5. Strobed Transfer Mode

DATA OVERRIDE

The contents of the DAC register can be overridden by pulling DF/$\overline{DOR}$ (pin 5) LOW. The CTRL (pin 6) input then determines whether the DAC register data is overidden by all 0s (CTRL LOW) or all 1s (CTRL HIGH). This feature allows the user to calibrate the AD7548 in circuits such as Figure 6 without calling on the microprocessor to load calibration data.

UNIPOLAR BINARY OPERATION (2-QUADRANT MULTIPLICATION)

Figure 6 shows the analog circuit connections required for unipolar binary operation. With a dc input voltage or current (positive or negative polarity) applied at pin 19, the circuit is a unipolar D/A converter. With an ac input voltage the circuit provides 2-quadrant multiplication (digitally controlled attenuation).

Table I shows the code relationship for the circuit of Figure 6.

For full scale trimming the DAC register is loaded with 1111 1111 1111. This is most easily accomplished by using the data override function. R1 is then adjusted for $V_{OUT} = -V_{IN}$ (4095/4096). Alternatively full scale can be adjusted by omitting R1 and R2 and trimming the reference voltage magnitude.

Capacitor C1 provides phase compensation and helps prevent overshoot and ringing when using high speed op amps.

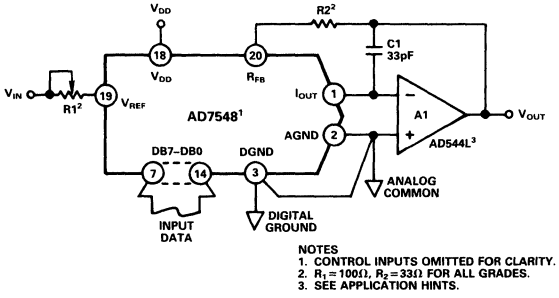

Figure 6. Unipolar Binary Operation

Binary Number in DAC Register MSB LSB	Analog Output, V_{OUT}
1111 1111 1111	$-V_{IN}\left(\frac{4095}{4096}\right)$
1000 0000 0000	$-V_{IN}\left(\frac{2048}{4096}\right) = -1/2V_{IN}$
0000 0000 0001	$-V_{IN}\left(\frac{1}{4096}\right)$
0000 0000 0000	0V

Table I. Unipolar Binary Code Table for Circuit of Figure 6

BIPOLAR OPERATION (4-QUADRANT MULTIPLICATION)

Figure 7 and Table II illustrate the recommended circuit and code relationship for bipolar operation. The circuit uses offset binary input coding. However, 2's complement coding can be accommodated if the MSB is inverted (done in software) before data is loaded into the DAC.

With the DAC register loaded to 1000 0000 0000, adjust R1 for $V_{OUT} = 0V$ (alternatively one can omit R1 and R2 and adjust the ratio of R3 and R4 for $V_{OUT} = 0V$). Full scale trimming can be accomplished by adjusting the amplitude of V_{IN} or by varying the value of R5.

R3, R4 and R5 must be selected to match within 0.01% and they should be the same type of resistor (preferably metal film) so that their temperature coefficients match. Mismatch of R3 to R4 causes both offset and full scale error. Mismatch of R5 to R4 and R3 causes full scale error.

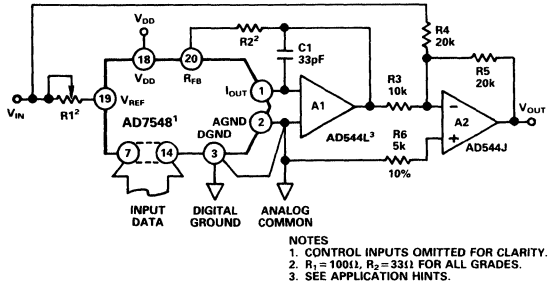

Figure 7. Bipolar Operation (Offset Binary Coding)

Binary Number in DAC Register MSB LSB	Analog Output, V_{OUT}
1111 1111 1111	$+V_{IN}\left(\frac{2047}{2048}\right)$
1000 0000 0001	$+V_{IN}\left(\frac{1}{2048}\right)$
1000 0000 0000	0V
0111 1111 1111	$-V_{IN}\left(\frac{1}{2048}\right)$
0000 0000 0000	$-V_{IN}\left(\frac{2048}{2048}\right)$

Table II. Bipolar Code Table for Offset Binary Circuit of Figure 7

SINGLE SUPPLY OPERATION

Figure 8 shows the AD7548 connected in a voltage switching mode. The input voltage is connected to I_{OUT}. The D/A converter output voltage is taken from the V_{REF} pin and has a constant impedance equal to R. R_{FB} is not used in this circuit. The input voltage V_{IN} must always be positive with respect to AGND in order to prevent an internal diode from turning on. To maintain linearity the input voltage should remain within 2.5V of AGND with V_{DD} from +12V to +15V.

The output voltage V_{OUT} of Figure 8 is expressed as

$$V_{OUT} = (V_{IN})\,(D)\left(\frac{R_1 + R_2}{R_1}\right)$$

Where D is a fractional representation of the digital input word ($0 \leq D \leq 4095/4096$).

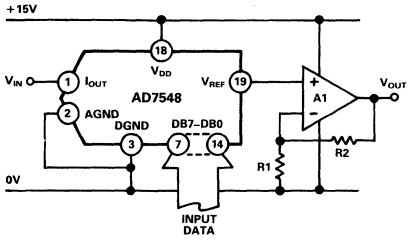

Figure 8. Single Supply Operation Using Voltage Switching Mode

APPLICATION HINTS

Output Offset: CMOS D/A converters in circuits such as Figures 6 and 7 exhibit a code dependent output resistance which in turn cause a code dependent amplifier noise gain. The effect is a code dependent differential nonlinearity term at the amplifier output which, depends on V_{OS} where V_{OS} is the amplifier input offset voltage. To maintain monotonic operation it is recommended that V_{OS} be no greater than $(25 \times 10^{-6})(V_{REF})$ over the temperature range of operation. Suitable op amps are AD517L and AD544L. The AD517L is best suited for fixed reference applications with low bandwidth requirements: it has extremely low offset (50μV) and in most applications will not require an offset trim. The AD544L has a much wider bandwidth and higher slew rate and is recommended for multiplying and other applications requiring fast settling. An offset trim on the AD544L may be necessary in some circuits.

General Ground Management: AC or transient voltages between AGND and DGND can cause noise injection into the analog output. The simplest method of ensuring that voltages at AGND and DGND are equal is to tie AGND and DGND together at the AD7548. In more complex systems where the AGND and DGND intertie is on the backplane, it is recommended that two diodes be connected in inverse parallel between the AD7548 AGND and DGND pins (1N914 or equivalent).

Temperature Coefficients: The gain temperature coefficient of the AD7548 has a maximum value of 5ppm/°C and typical value of 2ppm/°C. This corresponds to worst case gain shifts of 2LSBs and 0.8LSBs respectively over a 100°C temperature range. When trim resistors R1 and R2 are used to adjust full scale range, the temperature coefficient of R1 and R2 should also be taken into account. The reader is referred to Analog Devices Application Note "Gain Error and Gain Temperature Coefficient of CMOS Multiplying DACs", Publication Number E630–10–6/81.

High Frequency Considerations: AD7548 output capacitance works in conjunction with the amplifier feedback resistance to add a pole to the open loop response. This can cause ringing or oscillation. Stability can be restored by adding a phase compensation capacitor in parallel with the feedback resistor.

Feedthrough: The dynamic performance of the AD7548 will depend upon the gain and phase stability of the output amplifier, together with the optimum choice of PC board layout and decoupling components. A suggested printed circuit layout for Figure 6 is shown in Figure 9 which minimizes feedthrough from V_{REF} to the output in multiplying applications.

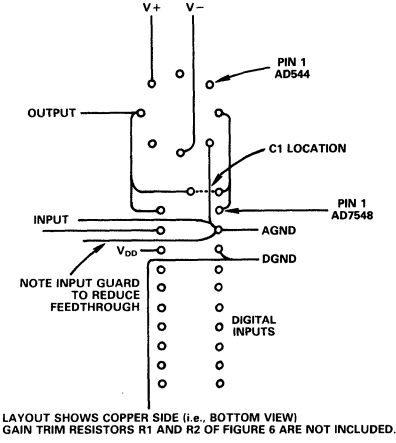

Figure 9. Suggested Layout for AD7548 and Op Amp

For additional information on multiplying DACs refer to "Application Guide to CMOS Multiplying D/A Converters", Publication Number G479–15–8/78, available from Analog Devices.

MICROPROCESSOR INTERFACING

AD7548 – MC6800 INTERFACE

A typical 6800 configuration using the automatic transfer mode of the AD7548 is shown in Figure 10. Table III gives a sample loading routine written in re-entrant form. Data load and store instructions use extended addressing. The 12-bit data to be passed to the subroutine is stored in locations XXYY and XXYY + 1. The data is considered right-justified with the four most significant bits occupying the lower half of XXYY + 1. The AD7548 is assigned a base address of PPQQ. This address selects the low byte register of the AD7548. Address PPQQ + 1 selects both the high byte register and the $\overline{\text{LDAC}}$ control input.

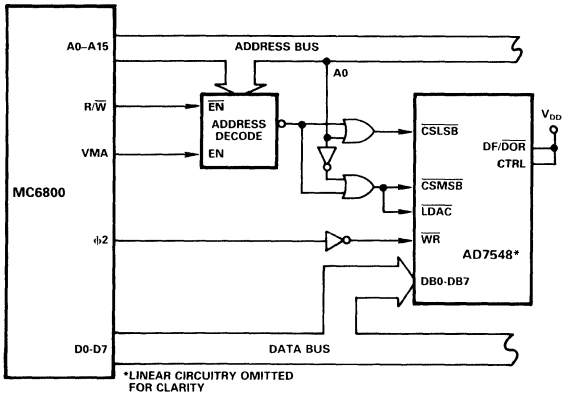

Figure 10. AD7548 – MC6800 Interface (Automatic Transfer Mode)

	JSR	WWZZ	Jump to AD7548 subroutine
WWZZ	PSH A		Push A onto stack
	TPA		
	PSH A		Push CCR onto stack
	LDA A	$XXYY	
	STA A	$PPQQ	Load low byte to AD7548
	LDA A	$XXYY + 1	
	STA A'	$PPQQ + 1	Load high byte to AD7548 and update analog output
	PUL A		
	TAP		Pull CCR from stack
	PUL A		Pull A from stack
	RTS		Return to main program

Table III. Sample Routine for AD7548 – MC6800 Interface

AD7548 – 8085A INTERFACE

Figure 11 shows a typical AD7548 to 8085A microprocessor interface configured for automatic transfer of 8 + 4-bit right-justified data. Table IV gives a sample loading routine written in re-entrant form. The 12-bit data to be passed to the subroutine is stored in locations XXYY and XXYY + 1. The four most significant data bits occupy the lower half of XXYY + 1. As before, addresses PPQQ and PPQQ + 1 select the $\overline{\text{CSLSB}}$ and $\overline{\text{CSMSB}}/\overline{\text{LDAC}}$ control inputs respectively. Since only two instructions (LHLD, SHLD) are required to both fetch and load the 12-bit data word to the AD7548, it may be more efficient to insert these instructions as required in the main program rather than use a subroutine such as illustrated here.

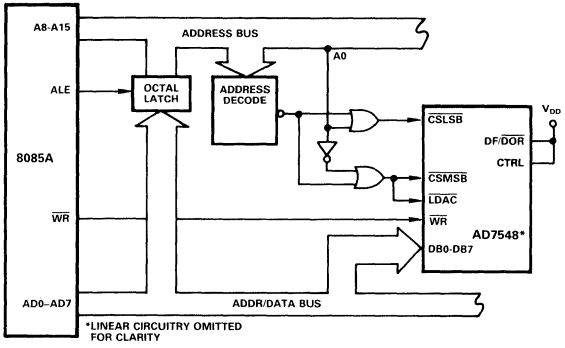

Figure 11. AD7548 – 8085A Interface (Automatic Transfer Mode)

	CALL	7548	
7548	PUSH	PSW	Push register contents onto stack
	PUSH	H	
	LHLD	XXYY	Fetch 12-bit data
	SHLD	PPQQ	Load 12-bit data
	POP	H	Pop register contents from stack
	POP	PSW	
	RET		Return to main program

Table IV. Sample Routine for AD7548–8085A Interface

AD7548 – MC6809 INTERFACE

The AD7548 can be interfaced to the MC6809 microprocessor as shown in Figure 12 for automatic transfer of 8 +4-bit data. Similar to the 8085A instructions LHLD and SHLD, the 6809 has two instructions to fetch and store 12-bit (16-bit) data to the AD7548, LDD and STD. However, in the 6809, the high byte of data is moved first, then the low byte (this is the opposite of the 8085A). This means that if the 12-bit data is assumed to reside at addresses XXYY and XXYY+1 then XXYY must contain the high byte. It also means that the address decoding logic of Figure 11 must be slightly changed so that the even-order AD7548 address, PPQQ from before, selects the $\overline{CSMSB}$ input to load the high byte first. In this automatic transfer configuration $\overline{LDAC}$ is tied to the $\overline{CSLSB}$ input. The AD7548 analog output can thus be updated using only two instructions as follows:

```
LDD     $XXYY
STD     $PPQQ
```

The strobed transfer configuration is shown in Figure 13 with a dedicated decoder output assigned to each chip select input. The common $\overline{LDAC}$ signal allows simultaneous update of both AD7548 DAC registers.

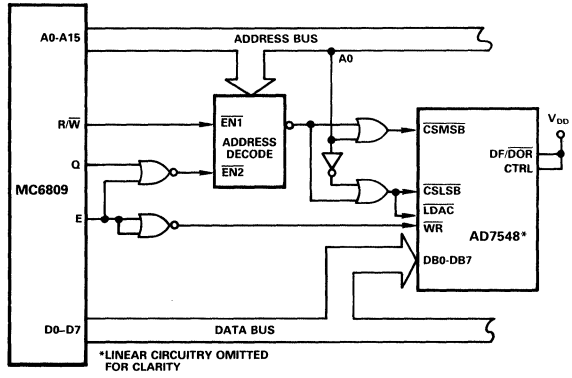

Figure 12. AD7548 – MC6809 Interface (Automatic Transfer Mode)

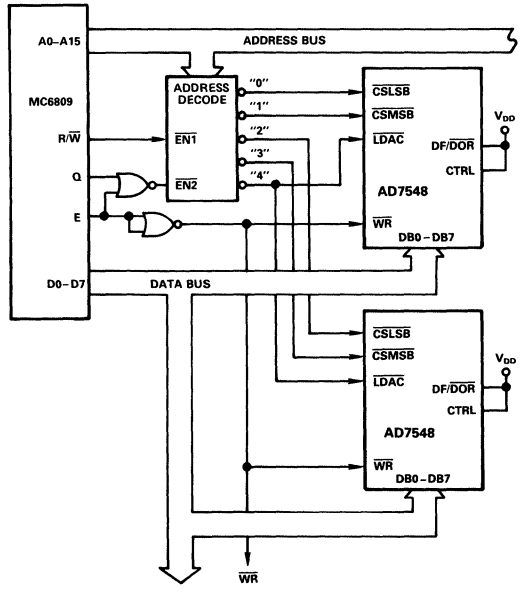

Figure 13. AD7548 – MC6809 Interface (Strobed Transfer Mode)

AD7548 – 6502 INTERFACE

Figure 14 shows a typical AD7548 to 6502 microprocessor interface configured for automatic transfer of right-justified data. As a programming example, Figure 15 shows a flow chart for producing a 12-bit (4095-step-max) voltage ramp under 6502 control. Index registers X and Y of the 6502 form a 12-bit counter with the X-register holding the low byte of data and the Y-register the high byte. Table V shows the program listing. The X-register is compared with FF_H and the Y-register with 10_H to determine when the ramp voltage has reached its maximum value (FFF_H). By changing the comparison data in the program the maximum ramp output voltage can be varied from levels corresponding to FFF_H down to 000_H. In the program listing of Table V the AD7548 has been assigned contiguous addresses 0400 (low byte) and 0401 (high byte and DAC register).

AD7548 – Z80 INTERFACE

Figure 16 shows a typical AD7548 to Z80 microprocessor interface configured for automatic transfer of right-justified data. Similar to the 8085A and 6809 cases, 16-bit load instructions are available in the Z80 which can fetch and load 12-bit data to the AD7548. Since the low byte of data is moved first and assuming the 12-bit data resides at addresses XXYY and XXYY + 1, address XXYY must contain the low byte. As before, addresses PPQQ and PPQQ + 1 select the AD7548 $\overline{\text{CSLSB}}$ and $\overline{\text{CSMSB}}$/$\overline{\text{LDAC}}$ control inputs respectively. Choosing the Z80 register pair BC to hold the 12-bit data, the two instructions required to update the AD7548 analog output are as follows:

```
LD BC, (XXYY)
LD (PPQQ), BC
```

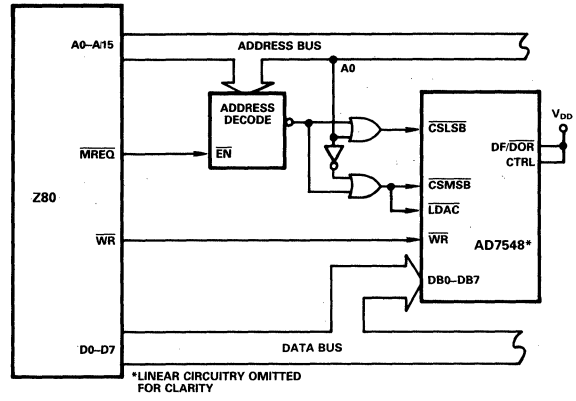

Figure 16. AD7548 – Z80 Interface (Automatic Transfer Mode)

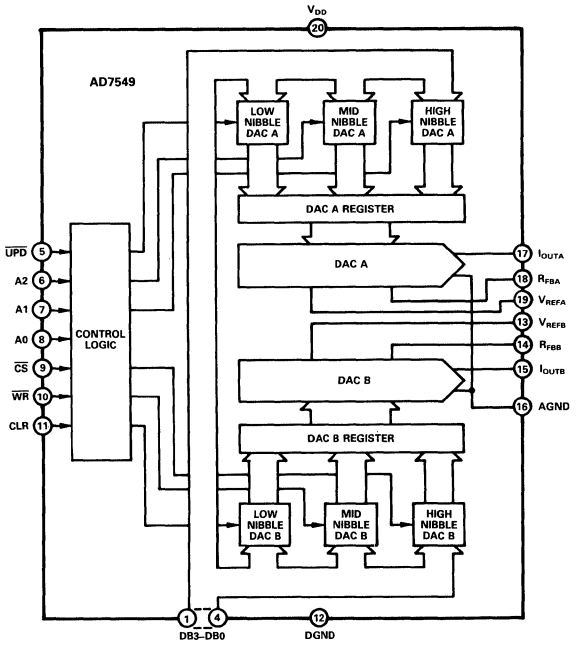
LC²MOS
Dual 12-Bit µP-Compatible DAC

AD7549

FEATURES
- Two Doubled Buffered 12-Bit DACs
- 4-Quadrant Multiplication
- Low Gain Error (3LSBs max)
- DAC Ladder Resistance Matching: 1%
- Space Saving Skinny DIP and Surface Mount Packages
- Latch-Up Proof

APPLICATIONS
- Programmable Filters
- Automatic Test Equipment
- Microcomputer Based Process Control
- Audio Systems
- Programmable Power Supplies
- Synchro Applications

AD7549 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7549 is a monolithic dual, 12-bit, current output D/A converter. It is packaged in both 0.3″ wide 20-pin DIPs and in 20-terminal surface mount packages. Both DACs provide four quadrant multiplication capabilities with a separate reference input and feedback resistor for each DAC. The monolithic construction ensures excellent thermal tracking and gain error tracking between the two DACs.

The DACs in the AD7549 are each loaded in three 4-bit nibbles. The control logic is designed for easy processor interfacing. Input and DAC register loading is accomplished using address lines A0, A1, A2 and $\overline{CS}$, $\overline{WR}$ lines. A logic high level on the CLR input clears all registers. Both DACs may be simultaneously updated using the $\overline{UPD}$ input.

The AD7549 is manufactured using the Linear Compatible CMOS(LC²MOS) process. It is speed compatible with most microprocessors and accepts TTL, 74HC or 5V CMOS logic level inputs.

PRODUCT HIGHLIGHTS

1. Small package size: the loading structure adopted for the AD7549 enables two 12-Bit DACs to be packaged in either a small 20-pin 0.3″ DIP or in 20-terminal surface mount packages.
2. DAC to DAC matching: since both DACs are fabricated on the same chip, precise matching and tracking is inherent. This opens up applications which otherwise would not be considered, i.e., Programmable Filters, Audio Systems, etc.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

TERMINOLOGY

RELATIVE ACCURACY
Relative accuracy or endpoint nonlinearity is a measure of the maximum deviation from a straight line passing through the endpoints of the DAC transfer function. It is measured after adjusting for zero error and full scale error and is normally expressed in Least Significant Bits or as a percentage of full scale reading.

DIFFERENTIAL NONLINEARITY
Differential nonlinearity is the difference between the measured change and the ideal 1LSB change between any two adjacent codes. A specified differential nonlinearity of 1LSB max over the operating temperature range ensures montonicity.

FULL-SCALE ERROR
Full scale error or gain error is a measure of the output error between an ideal DAC and the actual device output. Full scale error is adjustable to zero.

OUTPUT CAPACITANCE
This is the capacitance from I_{OUTA} or I_{OUTB} to AGND.

DIGITAL-TO-ANALOG GLITCH IMPULSE
The amount of charge injected into the analog output when the inputs change state is called Digital-to-Analog Glitch Impulse. This is normally specified as the area of the glitch in either pA-secs or nV-secs depending upon whether the glitch is measured as a current or voltage signal. Digital charge injection is measured with V_{REFA} and V_{REFB} equal to AGND.

OUTPUT LEAKAGE CURRENT
Output Leakage Current is current which appears at I_{OUTA} or I_{OUTB} with the DAC registers loaded to all zeros.

MULTIPLYING FEEDTHROUGH ERROR
This is the error due to capacitive feedthrough from V_{REFA} to I_{OUTA} or V_{REFB} to I_{OUTB} with the DAC registers loaded to all zeros.

CHANNEL-TO-CHANNEL ISOLATION
Channel-to-Channel Isolation refers to the proportion of input signal from one DAC's reference input which appears at the output of the other DAC, expressed as a ratio in dB.

DIGITAL CROSSTALK
The glitch impulse transferred to the output of one converter due to a change in digital input code to the other converter is defined as Digital Crosstalk and is specified in nV-secs.

Table I. AD7549 Truth Table

UNIPOLAR BINARY OPERATION (2-QUADRANT MULTIPLICATION)

Figure 2 shows the circuit diagram for unipolar binary operation. With an ac input, the circuit performs 2-quadrant multiplication. The code table for Figure 2 is given in Table II.

Operational amplifiers A1 and A2 can be in a single package (i.e. AD644) or separate packages (AD544). Capacitors C1 and C2 provide phase compensation to help prevent overshoot and ringing when high speed op-amps are used.

For zero offset adjustment, the appropriate DAC register is loaded with all O's and amplifier offset adjusted so that V_{OUTA} or V_{OUTB} is at a minimum (i.e. $\leq 120\mu V$). Full scale trimming is accomplished by loading the DAC register with all 1's and adjusting R1 (R3) so that V_{OUTA} (V_{OUTB}) = $-V_{IN}$ (4095/4096). In fixed reference applications, full scale can also be adjusted by omitting R1, R2, R3, R4 and trimming the reference voltage magnitude.

BIPOLAR OPERATION (4-QUADRANT MULTIPLICATION)

The recommended circuit diagram for bipolar operation is shown in Figure 3. Offset binary coding is used.

With the appropriate DAC register loaded to 1000 0000 0000, adjust R1 (R3) so that V_{OUTA} (V_{OUTB}) = 0V. Alternatively, R1, R2 (R3, R4) may be omitted and the ratios of R6, R7 (R9, 10) varied for V_{OUTA} (V_{OUTB}) = 0V. Full scale trimming can be accomplished by adjusting the amplitude of V_{IN} or by varying the value of R5 (R8).

Resistors R5, R6, R7 (R8, R9, R10) must be ratio matched to 0.01%. When operating over a wide temperature range, it is important that the resistors be of the same type so that their temperature coefficients match.

The code table for Figure 3 is given in Table III.

APPLICATION HINTS

Output Offset: CMOS D/A converters in circuits such as Figures 2 and 3 exhibit a code dependent output resistance which in turn can cause a code dependent error voltage at the output of the amplifier. The maximum amplitude of this offset, which adds to the D/A converter nonlinearity, depends on V_{OS} where V_{OS} is the amplifier input offset voltage. To maintain monotonic operation, it is recommended that V_{OS} be no greater than $(25 \times 10^{-6})(V_{REF})$ over the temperature range of operation. Suitable op amps are AD644L, AD517L and AD544L. The AD517L is best suited for fixed reference applications with low bandwidth requirements: it has extremely low offset (50μV) and in most applications will not require an offset trim. The AD544L has a much wider bandwidth and higher slew rate and is recommended for multiplying and other applications requiring fast settling. An offset trim on the AD544L may be necessary in some circuits.

Temperature Coefficients: The gain temperature coefficient of the AD7549 has a maximum value of 5ppm/°C and typical value of 1ppm/°C. This corresponds to worst case gain shifts of 2LSBs and 0.4LSBs respectively over a 100°C temperature range. When trim resistors R1(R3) and R2(R4) are used to adjust full scale range, the temperature coefficient of R1(R3) and R2(R4) should also be taken into account.

High Frequency Considerations: AD7549 output capacitance works in conjunction with the amplifier feedback resistance to add a pole to the open loop response. This can cause ringing or oscillation. Stability can be restored by adding a phase compensation capacitor in parallel with the feedback resistor.

Feedthrough: The dynamic performance of the AD7549 depends upon the gain and phase stability of the output amplifier, together with the optimum choice of PC board layout and decoupling components. A suggested printed circuit layout for Figure 2 is shown in Figure 4 which minimizes feedthrough from V_{REFA}, V_{REFB} to the output in multiplying applications.

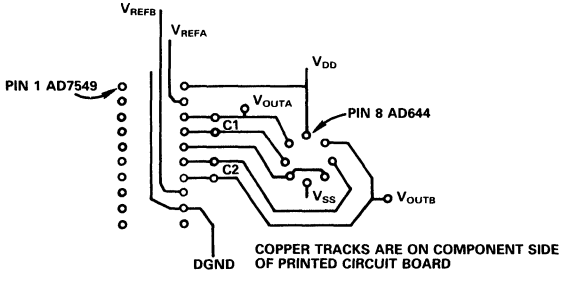

Figure 4. Suggested Layout for AD7549 with AD644 (Dual Op Amp)

AD7549 – 8085A INTERFACE

A typical interface circuit for the AD7549 and the 8085A microprocessor is given in Figure 5. Only the bottom 4 bits of the microprocessor data bus are used. The address decoder provides both the $\overline{CS}$ and $\overline{UPD}$ signals for the DAC. Address lines A0, A1, A2 select one of six DAC Input Registers for accepting data. In applications where simultaneous loading of the DACs is required then the $\overline{UPD}$ pin must be used to strobe both DAC registers. Otherwise, $\overline{UPD}$ may be tied high and address lines A0-A2, in conjunction with $\overline{CS}$ and $\overline{WR}$ signals, will select each DAC register separately (see Pin Function Description).

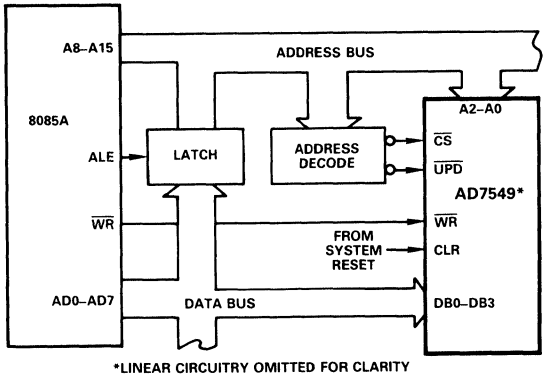

Figure 5. AD7549–8085A Interface

AD7549 – Z80 INTERFACE

Figure 6 shows the AD7549 connected to the Z80 microprocessor. The interface structure is similar to that for the 8085A.

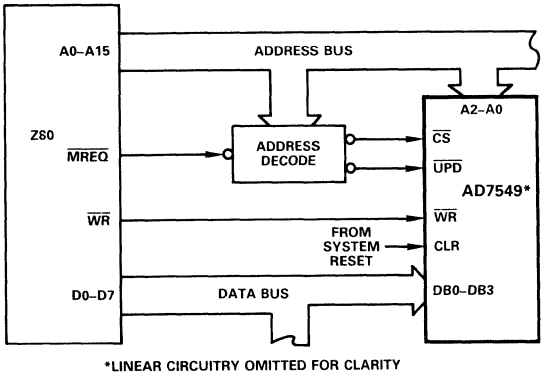

Figure 6. AD7549–Z80 Interface

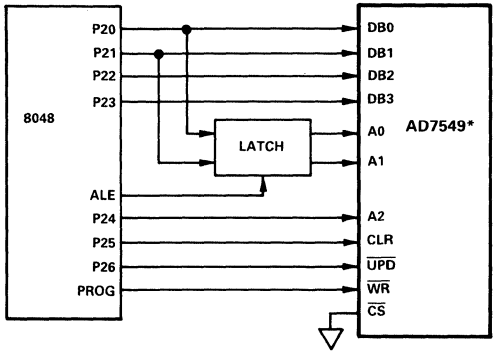
AD7549 – 8048 INTERFACE

The AD7549 can be interfaced to the 8048 single component microcomputer using the circuit of Figure 7. A minimum number of I/O lines are needed. The system is easily expanded by using extra port lines to provide Chip Selects for more AD7549's. The advantage of this interface lies in its simplicity. In either single or multiple DAC applications both the software and chip select decoding are simplified over what would be required if the devices were memory mapped in a conventional manner.



*LINEAR CIRCUITRY OMITTED FOR CLARITY

Figure 7. AD7549–8048 Interface

The combination of 8048 system and AD7549 is particularly suitable for dedicated control applications. By adding reference and output circuitry a complete control system can be configured with a minimum number of components.

AD7549 – MC6809 INTERFACE

Figure 8 is the interface circuit for the popular MC6809 8-bit microprocessor. $\overline{CS}$ and $\overline{UPD}$ signals are decoded from the address for the simultaneous update facility while the $\overline{WR}$ pulse is provided by inverting the microprocessor clock, E.

Figure 8. AD7549–MC6809 Interface

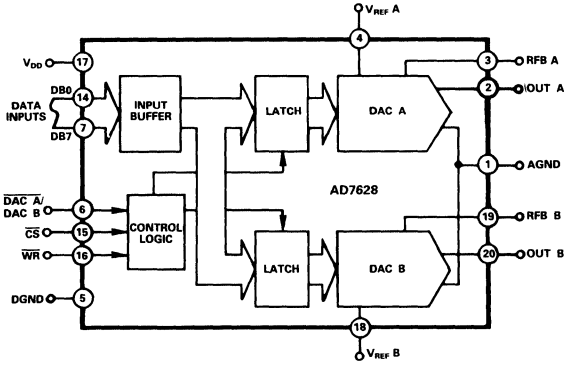
CMOS Dual 8-Bit Buffered Multiplying DAC

AD7628

FEATURES
- On-Chip Latches for Both DACs
- +12V to +15V Operation
- DACs Matched to 1%
- Four Quadrant Multiplication
- TTL/CMOS Compatible from +12V to +15V
- Latch Free (Protection Schottkys not Required)

APPLICATIONS
- Disk Drives
- Programmable Filters
- X-Y Graphics
- Gain/Attenuation

AD7628 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7628 is a monolithic dual 8-bit digital/analog converter featuring excellent DAC-to-DAC matching. It is available in skinny 0.3" wide 20-pin DIPs and in 20-terminal surface mount packages.

Separate on-chip latches are provided for each DAC to allow easy microprocessor interface.

Data is transferred into either of the two DAC data latches via a common 8-bit TTL/CMOS compatible input port. Control input $\overline{\text{DAC A}}$/DAC B determines which DAC is to be loaded. The AD7628's load cycle is similar to the write cycle of a random access memory, and the device is bus compatible with most 8-bit microprocessors, including 6502, 6809, 8085, Z80.

The device operates from a +12V to +15V power supply and is TTL-compatible over this range. Power dissipation is a low 20mW.

Both DACs offer excellent four quadrant multiplication characteristics with a separate reference input and feedback resistor for each DAC.

PRODUCT HIGHLIGHTS

1. DAC to DAC matching: since both of the AD7628 DACs are fabricated at the same time on the same chip, precise matching and tracking between DAC A and DAC B is inherent. The AD7628's matched CMOS DACs make a whole new range of applications circuits possible, particularly in the audio, graphics and process control areas.
2. Small package size: combining the inputs to the on-chip DAC latches into a common data bus and adding a $\overline{\text{DAC A}}$/DAC B select line has allowed the AD7628 to be packaged in either a small 20-pin 0.3" wide DIP or in 20-terminal surface mount packages.
3. TTL-Compatibility: All digital inputs are TTL-compatible over a +12V to +15V power supply range.

T Version: −55°C to +125°C

[2]Specification applies to both DACs in AD7628.

[3]Guaranteed by design but not production tested.

[4]Logic inputs are MOS Gates. Typical input current (+25°C) is less than 1nA.

Specifications subject to change without notice.

INTERFACE LOGIC INFORMATION

DAC Selection:
Both DAC latches share a common 8-bit input port. The control input $\overline{DAC\ A}$/DAC B selects which DAC can accept data from the input port.

Mode Selection:
Inputs $\overline{CS}$ and $\overline{WR}$ control the operating mode of the selected DAC. See Mode Selection Table below.

Write Mode:
When $\overline{CS}$ and $\overline{WR}$ are both low the selected DAC is in the write mode. The input data latches of the selected DAC are transparent and its analog output responds to activity on DB0–DB7.

Hold Mode:
The selected DAC latch retains the data which was present on DB0–DB7 just prior to $\overline{CS}$ or $\overline{WR}$ assuming a high state. Both analog outputs remain at the values corresponding to the data in their respective latches.

$\overline{DAC\ A}$/DAC B	$\overline{CS}$	$\overline{WR}$	DAC A	DAC B
L	L	L	WRITE	HOLD
H	L	L	HOLD	WRITE
X	H	X	HOLD	HOLD
X	X	H	HOLD	HOLD

L = Low State H = High State X = Don't Care

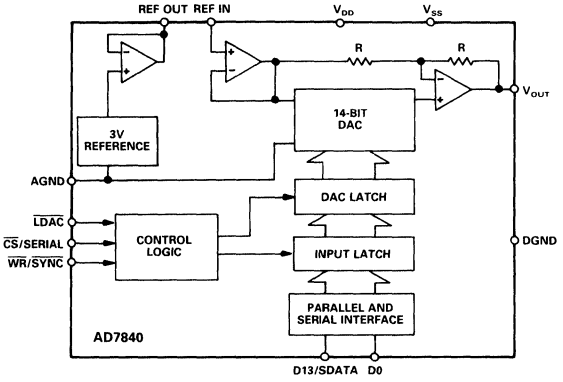
AD7840 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7840 is a fast, complete 14-bit voltage output D/A converter. It consists of a 14-bit DAC, 3V buried Zener reference, DAC output amplifier and high speed control logic.

The part features double-buffered interface logic with a 14-bit input latch and 14-bit DAC latch. Data is loaded to the input latch in either of two modes, parallel or serial. This data is then transferred to the DAC latch under control of an asynchronous $\overline{LDAC}$ signal. A fast data setup time of 21ns allows direct parallel interfacing to digital signal processors and high speed 16-bit microprocessors. In the serial mode, the maximum serial data clock rate can be as high as 6MHz.

The analog output from the AD7840 provides a bipolar output range of ±3V. The AD7840 is fully specified for dynamic performance parameters such as signal-to-noise ratio and harmonic distortion as well as for traditional dc specifications. Full power output signals up to 20kHz can be created.

The AD7840 is fabricated in linear compatible CMOS (LC^2MOS), an advanced, mixed technology process that combines precision bipolar circuits with low power CMOS logic. The part is available in a 24-pin plastic and hermetic dual-in-line package (DIP) and is also packaged in a 28-terminal plastic leaded chip carrier (PLCC).

PRODUCT HIGHLIGHTS

1. Complete 14-Bit D/A Function
   The AD7840 provides the complete function for creating ac signals and dc voltages to 14-bit accuracy. The part features an on-chip reference, an output buffer amplifier and 14-bit D/A converter.
2. Dynamic Specifications for DSP Users
   In addition to traditional dc specifications, the AD7840 is specified for ac parameters including signal-to-noise ratio and harmonic distortion. These parameters along with important timing parameters are tested on every device.
3. Fast, Versatile Microprocessor Interface
   The AD7840 is capable of 14-bit parallel and serial interfacing. In the parallel mode, data setup times of 21ns and write pulse widths of 45ns make the AD7840 compatible with modern 16-bit microprocessors and digital signal processors. In the serial mode, the part features a high data transfer rate of 6MHz.

SPECIFICATIONS (V_{DD} = +5V ±5%, V_{SS} = −5V ±5%, AGND = DGND = 0V, REF IN = +3V, R_L = 2kΩ, C_L = 100pF. All specifications T_{min} to T_{max} unless otherwise noted.)

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

PIN FUNCTION DESCRIPTION

DIP Pin No.	Pin Mnemonic	Function
1	$\overline{CS}$/SERIAL	Chip Select/Serial Input. When driven with normal logic levels, it is an active low logic input which is used in conjunction with $\overline{WR}$ to load parallel data to the input latch. For applications where $\overline{CS}$ is permanently low, an R, C is required for correct power-up (see $\overline{LDAC}$ input). If this input is tied to V_{SS}, it defines the AD7840 for serial mode operation.
2	$\overline{WR}/\overline{SYNC}$	Write/Frame Synchronization Input. In the parallel data mode, it is used in conjunction with $\overline{CS}$ to load parallel data. In the serial mode of operation, this pin functions as a Frame Synchronization pulse with serial data expected after the falling edge of this signal.
3	D13/SDATA	Data Bit 13(MSB)/Serial Data. When parallel data is selected, this pin is the D13 input. In serial mode, SDATA is the serial data input which is used in conjunction with $\overline{SYNC}$ and SCLK to transfer serial data to the AD7840 input latch.
4	D12/SCLK	Data Bit 12/Serial Clock. When parallel data is selected, this pin is the D12 input. In the serial mode, it is the serial clock input. Serial data bits are latched on the falling edge of SCLK when $\overline{SYNC}$ is low.
5	D11/FORMAT	Data Bit 11/Data Format. When parallel data is selected, this pin is the D11 input. In serial mode, a logic 1 on this input indicates that the MSB is the first valid bit in the serial data stream. A logic 0 indicates that the LSB is the first valid bit (see Table I).
6	D10/JUSTIFY	Data Bit 10/Data Justification. When parallel data is selected, this pin is the D10 input. In serial mode, this input controls the serial data justification (see Table I).
7–11	D9—D5	Data Bit 9 to Data Bit 5. Parallel data inputs.
12	DGND	Digital Ground. Ground reference for digital circuitry.
13–16	D4—D1	Data Bit 4 to Data Bit 1. Parallel data inputs.
17	D0	Data Bit 0 (LSB). Parallel data input.
18	V_{DD}	Positive Supply, +5V± 5%.
19	AGND	Analog Ground. Ground reference for DAC, reference and output buffer amplifier.
20	V_{OUT}	Analog Output Voltage. This is the buffer amplifier output voltage. Bipolar output range (±3V with REF IN = +3V).
21	V_{SS}	Negative Supply Voltage, −5V ±5%.
22	REF OUT	Voltage Reference Output. The internal 3V analog reference is provided at this pin. To operate the AD7840 with internal reference, REF OUT should be connected to REF IN. The external load capability of the reference is 500μA.
23	REF IN	Voltage Reference Input. The reference voltage for the DAC is applied to this pin. It is internally buffered before being applied to the DAC. The nominal reference voltage for correct operation of the AD7840 is 3V.
24	$\overline{LDAC}$	Load DAC. Logic input. A new word is loaded into the DAC latch from the input latch on the falling edge of this signal (see Interface Logic Information section). The AD7840 should be powered-up with $\overline{LDAC}$ high. For applications where $\overline{LDAC}$ is permanently low, an R, C is required for correct power-up (see Figure 19).

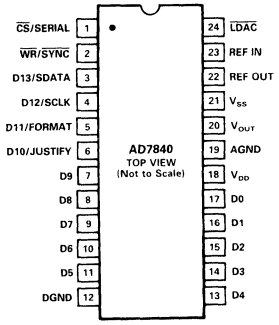
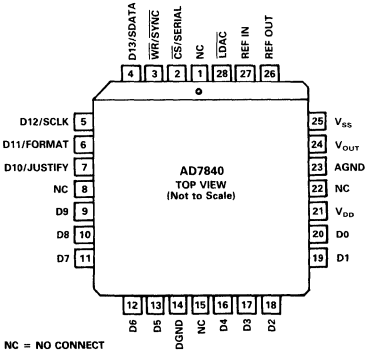
PIN CONFIGURATIONS

DIP



PLCC



NC = NO CONNECT

D/A SECTION

The AD7840 contains a 14-bit voltage mode D/A converter consisting of highly stable thin film resistors and high speed NMOS single-pole, double-throw switches. The simplified circuit diagram for the DAC section is shown in Figure 1. The three MSBs of the data word are decoded to drive the seven switches A—G. The 11LSBs switch an 11-bit R-2R ladder structure. The output voltage from this converter has the same polarity as the reference voltage, REF IN.

The REF IN voltage is internally buffered by a unity gain amplifier before being applied to the D/A converter and the bipolar bias circuitry. The D/A converter is configured and scaled for a 3V reference and the device is tested with 3V applied to REF IN. Operating the AD7840 at reference voltages outside the ± 5% tolerance range may result in degraded performance from the part.

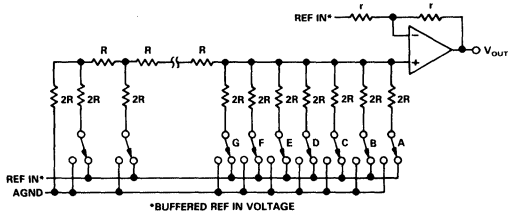


Figure 1. DAC Ladder Structure

INTERNAL REFERENCE

The AD7840 has an on-chip temperature compensated buried Zener reference (see Figure 2) which is factory trimmed to 3V ±10mV. The reference voltage is provided at the REF OUT pin. This reference can be used to provide both the reference voltage for the D/A converter and the bipolar bias circuitry. This is achieved by connecting the REF OUT pin to the REF IN pin of the device.

The reference voltage can also be used as a reference for other components and is capable of providing up to 500μA to an external load. The maximum recommended capacitance on REF OUT for normal operation is 50pF. If the reference is required for external use, it should be decoupled to AGND with a 200Ω resistor in series with a parallel combination of a 10μF tantalum capacitor and a 0.1μF ceramic capacitor.

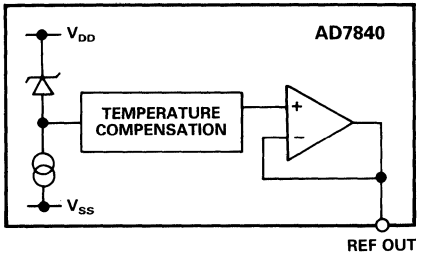

Figure 2. Internal Reference

EXTERNAL REFERENCE

In some applications, the user may require a system reference or some other external reference to drive the AD7840 reference input. Figure 3 shows how the AD586 5V reference can be conditioned to provide the 3V reference required by the AD7840 REF IN. An alternate source of reference voltage for the AD7840 in systems which use both a DAC and an ADC is to use the REF OUT voltage of ADCs such as the AD7870 and AD7871. A circuit showing this arrangement is shown in Figure 20.

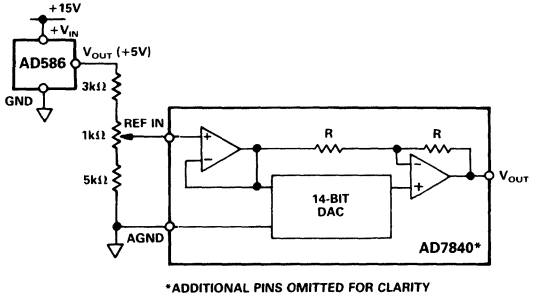

Figure 3. AD586 Driving AD7840 REF IN

OP AMP SECTION

The output from the voltage mode DAC is buffered by a non-inverting amplifier. Internal scaling resistors on the AD7840 configure an output voltage range of ±3V for an input reference voltage of +3V. The arrangement of these resistors around the output op amp is as shown in Figure 1. The buffer amplifier is capable of developing ±3V across a 2kΩ and 100pF load to ground and can produce 6V peak-to-peak sine wave signals to a frequency of 20kHz. The output is updated on the falling edge of the $\overline{\text{LDAC}}$ input. The amplifier settles to within 1/2LSB of its final value in typically less than 2.5μs.

The small signal (200mV p-p) bandwidth of the output buffer amplifier is typically 1MHz. The output noise from the amplifier is low with a figure of 30nV/$\sqrt{\text{Hz}}$ at a frequency of 1kHz. The broadband noise from the amplifier exhibits a typical peak-to-peak figure of 150μV for a 1MHz output bandwidth. Figure 4 shows a typical plot of noise spectral density versus frequency for the output buffer amplifier and for the on-chip reference.

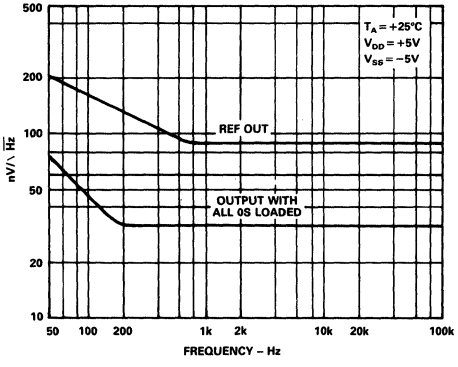

Figure 4. Noise Spectral Density vs. Frequency

TRANSFER FUNCTION

The basic circuit configuration for the AD7840 is shown in Figure 5. Table II shows the ideal input code to output voltage relationship for this configuration. Input coding to the DAC is 2s complement with 1LSB = FS/16,384 = 6V/16,384 = 366μV.

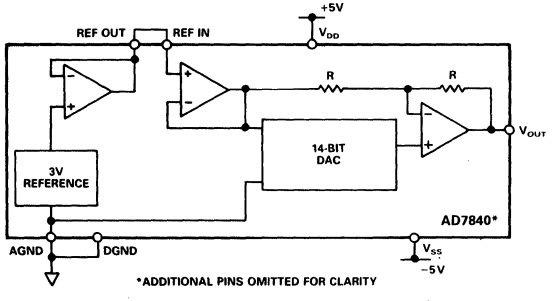

Figure 5. AD7840 Basic Connection Diagram

DAC Latch Contents MSB LSB	Analog Output, V_{OUT}*
0 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1	+2.999634V

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	0V
1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1	−0.000366V
1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1	−2.999634V
1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	−3V

*Assuming REF IN = +3V.

Table II. Ideal Input/Output Code Table

The output voltage can be expressed in terms of the input code, N, using the following expression:

$$V_{OUT} = \frac{2 \times N \times REFIN}{16384} \quad -8192 \leq N \leq +8191$$

INTERFACE LOGIC INFORMATION

The AD7840 contains two 14-bit latches, an input latch and a DAC latch. Data can be loaded to the input latch in one of two basic interface formats. The first is a parallel 14-bit wide data word; the second is a serial interface where 16 bits of data are serially clocked into the input latch. In the parallel mode, $\overline{\text{CS}}$ and $\overline{\text{WR}}$ control the loading of data. When the serial data format is selected, data is loaded using the SCLK, $\overline{\text{SYNC}}$ and SDATA serial inputs. Data is transferred from the input latch to the DAC latch under control of the $\overline{\text{LDAC}}$ signal. Only the data in the DAC latch determines the analog output of the AD7840.

Parallel Data Format

Table III shows the truth table for AD7840 parallel mode operation. The AD7840 normally operates with a parallel input data format. In this case, all 14 bits of data (appearing on data inputs D13 (MSB) through D0 (LSB)) are loaded to the AD7840 input latch at the same time. $\overline{\text{CS}}$ and $\overline{\text{WR}}$ control the loading of this data. These control signals are level-triggered; therefore, the input latch can be made transparent by holding both signals at a logic low level. Input data is latched into the input latch on the rising edge of $\overline{\text{CS}}$ or $\overline{\text{WR}}$.

The DAC latch is also level triggered. The DAC output is normally updated on the falling edge of the $\overline{\text{LDAC}}$ signal. However, both latches cannot become transparent at the same time. Therefore, if $\overline{\text{LDAC}}$ is hardwired low, the part operates as follows; with $\overline{\text{LDAC}}$ low and $\overline{\text{CS}}$ and $\overline{\text{WR}}$ high, the DAC latch is transparent. When $\overline{\text{CS}}$ and $\overline{\text{WR}}$ go low (with $\overline{\text{LDAC}}$ still low), the input latch becomes transparent but the DAC latch is disabled. When $\overline{\text{CS}}$ or $\overline{\text{WR}}$ return high, the input latch is locked out and the DAC latch becomes transparent again and the DAC output is updated. The write cycle timing diagram for parallel data is shown in Figure 6. Figure 7 shows the simplified parallel input control logic for the AD7840.

$\overline{CS}$	$\overline{WR}$	$\overline{LDAC}$	Function
H	X	H	Both Latches Latched
X	H	H	
L	L	H	Input Latch Transparent
H	H	L	Input Latch Latched
H	X	L	DAC Latch Transparent
X	H	L	Analog Output Updated
↓	↓	L	Input Latch Transparent DAC Latch Data Transfer Inhibited
L	↑	L	Input Latch Is Latched
↑	L	L	DAC Latch Data Transfer Occurs

X = Don't Care

Table III. Parallel Mode Truth Table

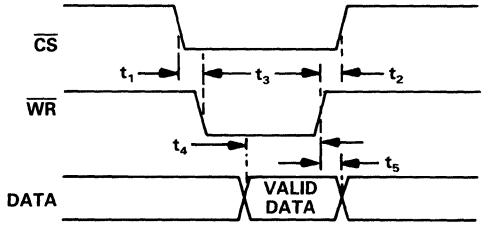

Figure 6. Parallel Mode Timing Diagram

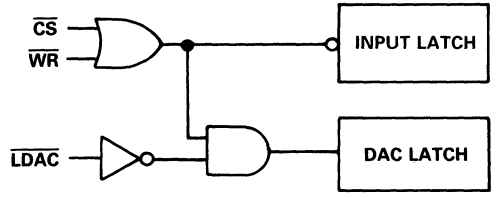

Figure 7. AD7840 Simplified Parallel Input Control Logic

Serial Data Format

The serial data format is selected for the AD7840 by connecting the $\overline{CS}$/SERIAL line to −5V. In this case, the $\overline{WR}$/$\overline{SYNC}$, D13/SDATA, D12/SCLK, D11/FORMAT and D10/JUSTIFY pins all assume their serial functions. The unused parallel inputs should not be left unconnected to avoid noise pickup. Serial data is loaded to the input latch under control of SCLK, $\overline{SYNC}$ and SDATA. The AD7840 expects a 16-bit stream of serial data on its SDATA input. Serial data must be valid on the falling edge of SCLK. The $\overline{SYNC}$ input provides the frame synchronization signal which tells the AD7840 that valid serial data will be available for the next 16 falling edges of SCLK. Figure 8 shows the timing diagram for serial data format.

Although 16 bits of data are clocked into the AD7840, only 14 bits go into the input latch. Therefore, two bits in the stream are don't cares since their value does not affect the input latch data. The order and position in which the AD7840 accepts the 14 bits of input data depends upon the FORMAT and JUSTIFY inputs. There are four different input data modes which can be chosen (see Table I in the Pin Function Description section).

The first mode (M1) assumes that the first two bits of the input data stream are don't cares, the third bit is the LSB and the last (or 16th bit) is the MSB. This mode is chosen by tying both the FORMAT and JUSTIFY pins to a logic 0. The second mode (M2; FORMAT = 0, JUSTIFY = 1) assumes that the first bit in the data stream is the LSB, the fourteenth bit is the MSB and the last two bits are don't cares. The third mode (M3; FORMAT = 1, JUSTIFY = 0) assumes that the first two bits in the stream are again don't cares, the third bit is now the MSB and the sixteenth bit is the LSB. The final mode (M4; FORMAT = 1, JUSTIFY = 1) assumes that the first bit is the MSB, the fourteenth bit is the LSB and the last two bits of the stream are don't cares.

As in the parallel mode, the $\overline{LDAC}$ signal controls the loading of data to the DAC latch. Normally, data is loaded to the DAC latch on the falling edge of $\overline{LDAC}$. However, if $\overline{LDAC}$ is held low, then serial data is loaded to the DAC latch on the sixteenth falling edge of SCLK. If $\overline{LDAC}$ goes low during the transfer of serial data to the input latch, no DAC latch update takes place on the falling edge of $\overline{LDAC}$. If $\overline{LDAC}$ stays low until the serial transfer is completed, then the update takes place on the sixteenth falling edge of SCLK. If $\overline{LDAC}$ returns high before the serial data transfer is completed, no DAC latch update takes place. Figure 9 shows the simplified serial input control logic for the AD7840.

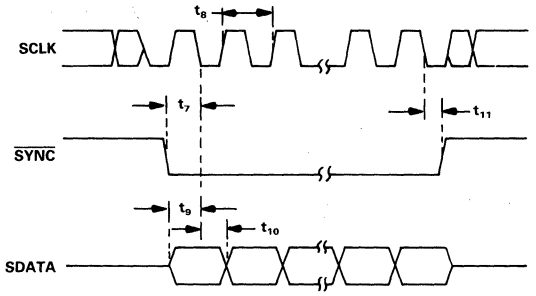

Figure 8. Serial Mode Timing Diagram

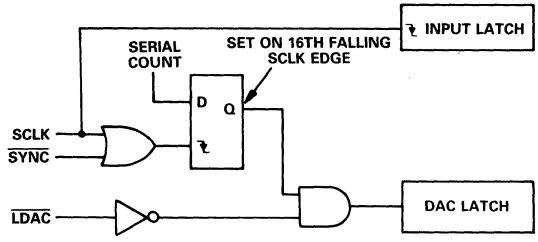

Figure 9. AD7840 Simplified Serial Input Control Logic

AD7840 DYNAMIC SPECIFICATIONS

The AD7840 is specified and 100% tested for dynamic performance specifications as well as traditional dc specifications such as integral and differential nonlinearity. These ac specifications are required for the signal processing applications such as speech synthesis, servo control and high speed modems. These applications require information on the DAC's effect on the spectral content of the signal it is creating. Hence, the parameters for which the AD7840 is specified include signal-to-noise ratio, harmonic distortion and peak harmonics. These terms are discussed in more detail in the following sections.

Signal-to-Noise Ratio (SNR)

SNR is the measured signal-to-noise ratio at the output of the DAC. The signal is the rms magnitude of the fundamental. Noise is the rms sum of all the nonfundamental signals up to half the sampling frequency (fs/2) excluding dc. SNR is dependent upon the number of quantization levels used in the digitization process; the more levels, the smaller the quantization noise. The theoretical signal to noise ratio for a sine wave output is given by

$$SNR = (6.02N + 1.76)dB \quad (1)$$

where N is the number of bits. Thus for an ideal 14-bit converter, SNR = 86dB.

Figure 10 shows a typical 2048 point Fast Fourier Transform (FFT) plot of the AD7840KN with an output frequency of 1kHz and an update rate of 100kHz. The SNR obtained from this graph is 81.8dB. It should be noted that the harmonics are taken into account when calculating the SNR.

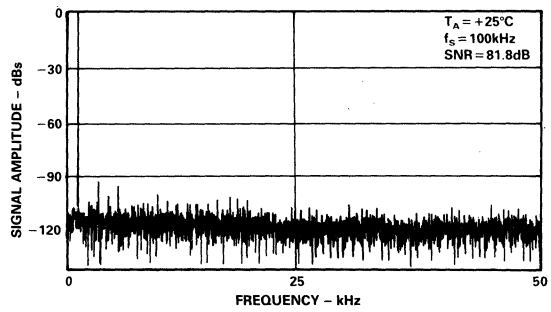

Figure 10. AD7840 FFT Plot

Effective Number of Bits

The formula given in (1) relates the SNR to the number of bits. Rewriting the formula, as in (2), it is possible to get a measure of performance expressed in effective number of bits (N).

$$N = \frac{SNR - 1.76}{6.02} \quad (2)$$

The effective number of bits for a device can be calculated directly from its measured SNR.

Harmonic Distortion

Harmonic distortion is the ratio of the rms sum of harmonics to the fundamental. For the AD7840, total harmonic distortion (THD) is defined as

$$THD = 20 \log \frac{\sqrt{V_2^2+V_3^2+V_4^2+V_5^2+V_6^2}}{V_1}$$

where V_1 is the rms amplitude of the fundamental and V_2, V_3, V_4, V_5 and V_6 are the rms amplitudes of the second through the sixth harmonic. The THD is also derived from the 2048-point FFT plot.

Peak Harmonic or Spurious Noise

Peak harmonic or spurious noise is defined as the ratio of the rms value of the next largest component in the DAC output spectrum (up to fs/2 and excluding dc) to the rms value of the fundamental. Normally, the value of this specification will be determined by the largest harmonic in the spectrum, but for parts where the harmonics are buried in the noise floor the peak will be a noise peak.

Testing the AD7840

A simplified diagram of the method used to test the dynamic performance specifications is outlined in Figure 11. Data is loaded to the AD7840 under control of the microcontroller and associated logic at a 100kHz update rate. The output of the AD7840 is applied to a ninth order, 50kHz, low-pass filter. The output of the filter is in turn applied to a 16-bit accurate digitizer. This digitizes the signal and the microcontroller generates an FFT plot from which the dynamic performance of the AD7840 can be evaluated.

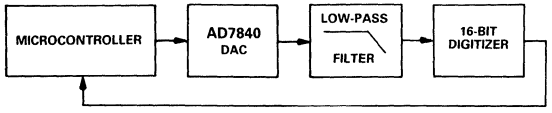

Figure 11. AD7840 Dynamic Performance Test Circuit

The digitizer sampling is synchronized with the AD7840 update rate to ease FFT calculations. The digitizer samples the AD7840 after the output has settled to its new value. Therefore, if the digitizer was to sample the output directly it would effectively be sampling a dc value each time. As a result, the dynamic performance of the AD7840 would not be measured correctly. Using the digitizer directly on the AD7840 output would give better results than the actual performance of the AD7840. Using a filter between the DAC and the digitizer means that the digitizer samples a continuously moving signal and the true dynamic performance of the AD7840 is measured.

Some applications will require improved performance versus frequency from the AD7840. In these applications, a simple sample-and-hold circuit such as that outlined in Figure 12 will extend the very good performance of the AD7840 to 20kHz.

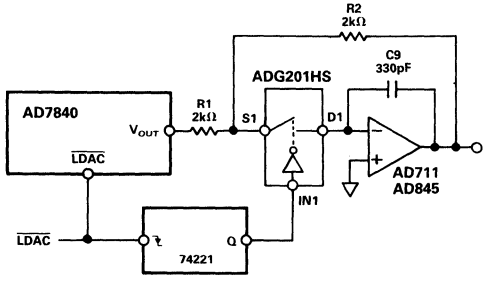

Figure 12. Sample-and-Hold Circuit

Other applications will already have an inherent sample-and-hold function following the AD7840. An example of this type of application is driving a switched-capacitor filter where the updating of the DAC is synchronized with the switched-capacitor filter. This inherent sample-and-hold function also extends the frequency range performance of the AD7840.

Performance versus Frequency

The typical performance plots of Figures 13 and 14 show the AD7840's performance over a wide range of input frequencies at an update rate of 100kHz. The plot of Figure 13 is without a sample-and-hold on the AD7840 output while the plot of Figure 14 is generated with the sample-and-hold circuit of Figure 12 on the output.

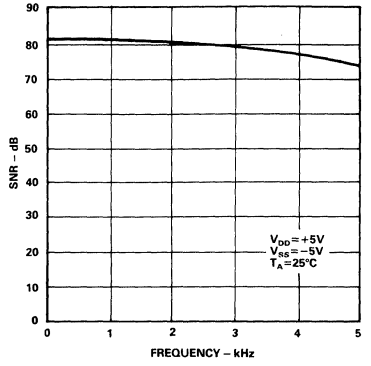

Figure 13. Performance vs. Frequency (No Sample-and-Hold)

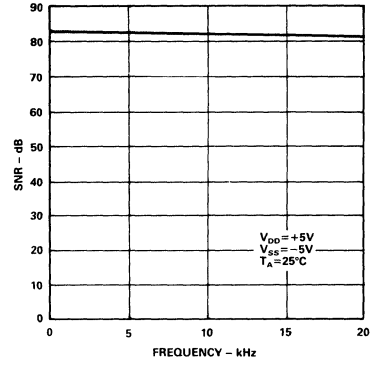

Figure 14. Performance vs. Frequency (with Sample-and-Hold)

MICROPROCESSOR INTERFACING

The AD7840 logic architecture allows two interfacing options for interfacing the part to microprocessor systems. It offers a 14-bit wide parallel format and a serial format. Fast pulse widths and data setup times allow the AD7840 to interface directly to most microprocessors including the DSP processors. Suitable interfaces to various microprocessors are shown in Figures 15 to 23.

Parallel Interfacing

Figures 15 to 17 show interfaces to the DSP processors, the ADSP-2100, the TMS32010 and TMS32020. An external timer controls the updating of the AD7840. Data is loaded to the AD7840 input latch using the following instructions:

ADSP-2100 : DM(DAC) = MR0
TMS32010 : OUT DAC,D
TMS32020 : OUT DAC,D
MR0 = ADSP-2100 MR0 Register
D = Data Memory Address
DAC = AD7840 Address

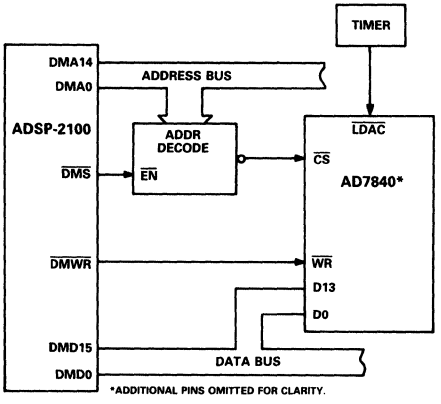

Figure 15 AD7840 – ADSP-2100 Parallel Interface

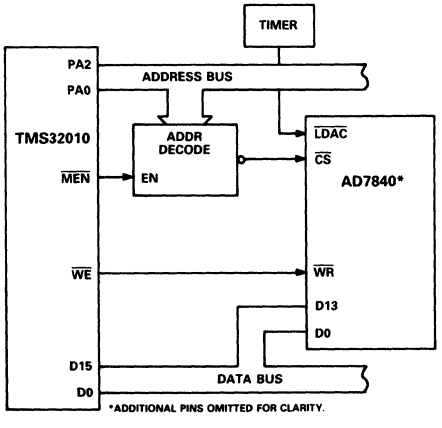

Figure 16. AD7840 – TM32010 Parallel Interface

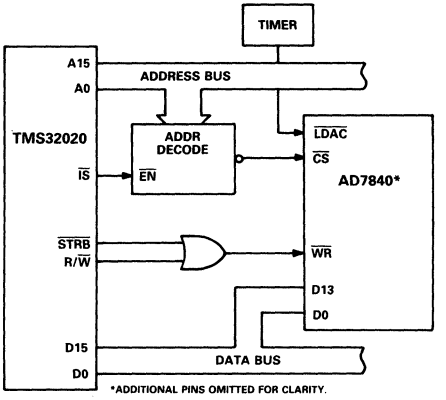

Figure 17. AD7840 – TMS32020 Parallel Interface

Some applications may require that the updating of the AD7840 DAC latch be controlled by the microprocessor rather than the external timer. One option (for double-buffered interfacing) is to decode the AD7840 $\overline{LDAC}$ from the address bus so that a write operation to the DAC latch (at a separate address than the input latch) updates the output. An example of this is shown in the 8086 interface of Figure 18. Note that connecting the $\overline{LDAC}$ input to the $\overline{CS}$ input will not load the DAC latch correctly since both latches cannot be transparent at the same time.

AD7840 – 8086 Interface

Figure 18 shows an interface between the AD7840 and the 8086 microprocessor. For this interface, the $\overline{LDAC}$ input is derived from a decoded address. If the least significant address line, A0, is decoded then the input latch and the DAC latch can reside at consecutive addresses. A move instruction loads the input latch while a second move instruction updates the DAC latch and the AD7840 output. The move instruction to load a data word WXYZ to the input latch is as follows:

MOV DAC,#YZWX
DAC = AD7840 Address

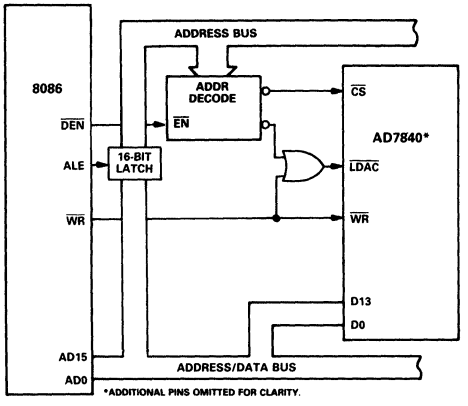

Figure 18. AD7840 – 8086 Parallel Interface

AD7840 – 68000 Interface
An interface between the AD7840 and the 68000 microprocessor is shown in Figure 19. In this interface example, the $\overline{LDAC}$ input is hardwired low. As a result the DAC latch and analog output are updated on the rising edge of $\overline{WR}$. A single move instruction, therefore, loads the input latch and updates the output.

MOVE.W D0,$DAC
D0 = 68000 D0 Register
DAC = AD7840 Address

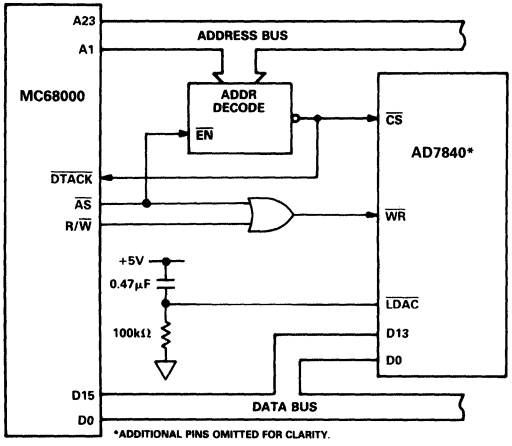

Figure 19. AD7840 – MC68000 Parallel Interface

Serial Interfacing
Figures 20 to 23 show the AD7840 configured for serial interfacing with the $\overline{CS}$ input hardwired to −5V. The parallel bus is not activated during serial communication with the AD7840.

AD7840 – ADSP-2101/ADSP-2102 Serial Interface
Figure 20 shows a serial interface between the AD7840 and the ADSP-2101/ADSP-2102 DSP processor. Also included in the interface is the AD7870, a 12-bit A/D converter. An interface such as this is suitable for modem and other applications which have a DAC and an ADC in serial communication with a microprocessor.

The interface uses just one of the two serial ports of the ADSP-2101/ADSP-2102. Conversion is initiated on the AD7870 at a fixed sample rate (e.g., 9.6kHz) which is provided by a timer or clock recovery circuitry. While communication takes place between the ADC and the ADSP-2101/ADSP-2102, the AD7870 $\overline{SSTRB}$ line is low. This $\overline{SSTRB}$ line is used to provide a frame synchronization pulse for the AD7840 $\overline{SYNC}$ and ADSP-2101/ADSP-2102 TFS lines. This means that communication between the processor and the AD7840 can only take place while the AD7870 is communicating with the processor. This arrangement is desirable in systems such as modems where the DAC and ADC communication should be synchronous.

The use of the AD7870 SCLK for the AD7840 SCLK and ADSP-2101/ADSP-2102 SCLK means that only one serial serial port of the processor is used. The serial clock for the AD7870 must be set for continuous clock for correct operation of this interface.

Data from the ADSP-2101/ADSP-2102 is valid on the falling edge of SCLK. The $\overline{LDAC}$ input of the AD7840 is permanently low so the update of the DAC latch and analog output takes place on the sixteenth falling edge of SCLK (with $\overline{SYNC}$ low). The FORMAT pin of the AD7840 must be tied to +5V and the JUSTIFY pin tied to DGND for this interface to operate correctly.

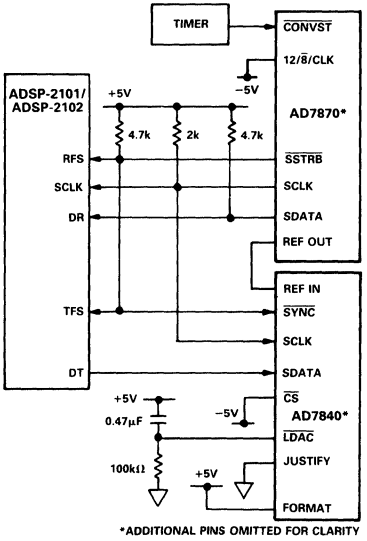

Figure 20. Complete DAC/ADC Serial Interface

AD7840 – DSP56000 Serial Interface
A serial interface between the AD7840 and the DSP56000 is shown in Figure 21. The DSP56000 is configured for normal mode synchronous operation with gated clock. It is also set up for a 16-bit word with SCK and SC2 as outputs and the FSL control bit set to a 0. SCK is internally generated on the DSP56000 and applied to the AD7840 SCLK input. Data from the DSP56000 is valid on the falling edge of SCK. The SC2 output provides the framing pulse for valid data. This line must be inverted before being applied to the $\overline{SYNC}$ input of the AD7840.

The $\overline{LDAC}$ input of the AD7840 is connected to DGND so the update of the DAC latch takes place on the sixteenth falling edge of SCLK. As with the previous interface, the FORMAT pin of the AD7840 must be tied to +5V and the JUSTIFY pin tied to DGND.

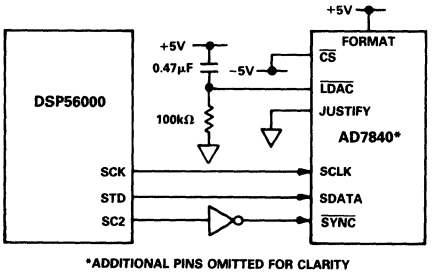

Figure 21. AD7840 – DSP56000 Serial Interface

AD7840 – TMS32020 Serial Interface

Figure 22 shows a serial interface between the AD7840 and the TMS32020 DSP processor. In this interface, the CLKX and FSX pin of the TMS32020 are generated from the clock/timer circuitry. The same clock/timer circuitry generates the $\overline{\text{LDAC}}$ signal of the AD7840 to synchronize the update of the output with the serial transmission. The FSX pin of the TMS32020 must be configured as an input.

Data from the TMS32020 is valid on the falling edge of CLKX. Once again, the FORMAT pin of the AD7840 must be tied to +5V while the JUSTIFY pin must be tied to DGND.

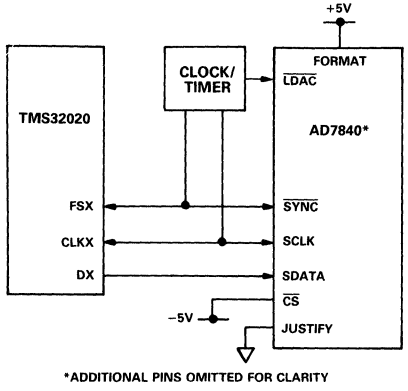

Figure 22. AD7840 – TMS32020 Serial Interface

AD7840 – NEC7720 Serial Interface

A serial interface between the AD7840 and the NEC7720 is shown in Figure 23. This clock must be inverted before being applied to the AD7840 SCLK input because data from the processor is valid on the rising edge of SCK.

The NEC7720 is programmed for the LSB to be the first bit in the serial data stream. Therefore, the AD7840 is set up with the FORMAT pin tied to DGND and the JUSTIFY pin tied to +5V.

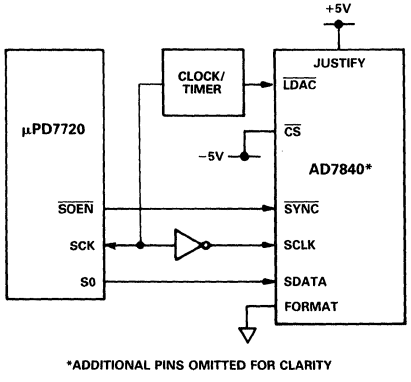

Figure 23. AD7840 – NEC7720 Serial Interface

APPLYING THE AD7840

Good printed circuit board layout is as important as the overall circuit design itself in achieving high speed converter performance. The AD7840 works on an LSB size of 366µV. Therefore, the designer must be conscious of minimizing noise in both the converter itself and in the surrounding circuitry. Switching mode power supplies are not recommended as the switching spikes can feed through to the on-chip amplifier. Other causes of concern are ground loops and digital feedthrough from microprocessors. These are factors which influence any high performance converter, and a proper PCB layout which minimizes these effects is essential for best performance.

LAYOUT HINTS

Ensure that the layout for the printed circuit board has the digital and analog lines separated as much as possible. Take care not to run any digital track alongside an analog signal track. Establish a single point analog ground (star ground) separate from the logic system ground. Place this star ground as close as possible to the AD7840 as shown in Figure 24. Connect all analog grounds to this star ground and also connect the AD7840 DGND pin to this ground. Do not connect any other digital grounds to this analog ground point.

Low impedance analog and digital power supply common returns are essential to low noise operation of high performance converters. Therefore, the foil width for these tracks should be kept as wide as possible. The use of ground planes minimizes impedance paths and also guards the analog circuitry from digital noise. The circuit layout of Figures 27 and 28 have both analog and digital ground planes which are kept separated and only joined at the star ground close to the AD7840.

NOISE

Keep the signal leads on the V_{OUT} signal and the signal return leads to AGND as short as possible to minimize noise coupling. In applications where this is not possible, use a shielded cable between the DAC output and its destination. Reduce the ground circuit impedance as much as possible since any potential difference in grounds between the DAC and its destination device appears as an error voltage in series with the DAC output.

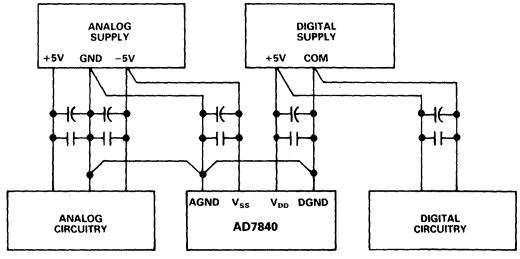

Figure 24. Power Supply Grounding Practice

DATA ACQUISITION BOARD

Figure 25 shows the AD7840 in a data acquisition circuit. The corresponding printed circuit board (PCB) layout and silkscreen are shown in Figures 26 to 28. The board layout has three interface ports: one serial and two parallel. One of the parallel ports is directly compatible with the ADSP-2100 evaluation board expansion connector.

Some systems will require the addition of a re-construction filter on the output of the AD7840 to complete the data acquisition system. There is a component grid provided near the analog output on the PCB which may be used for such a filter or any other output conditioning circuitry. To facilitate this option, there is a shorting plug (labeled LK1 on the PCB) on the analog output track. If this shorting plug is used, the analog output connects to the output of the AD7840; otherwise this shorting plug can be omitted and a wire link used to connect the analog output to the PCB component grid.

The board also contains a simple sample-and-hold circuit which can be used on the output of the AD7840 to extend the very good performance of the AD7840 over a wider frequency range. A second wire link (labelled LK2 on the PCB) connects V_{OUT} (SKT1) to either the output of this sample-and-hold circuit or directly to the output of the AD7840.

INTERFACE CONNECTIONS

There are two parallel connectors, labeled SKT4 and SKT6, and one serial connector, labeled SKT5. A shorting plug option (LK8 in Figure 25) on the AD7840 $\overline{CS}$/SERIAL input configures the DAC for the appropriate interface (see Pin Function Description).

SKT6 is a 96-contact (3-row) Eurocard connector which is directly compatible with the ADSP-2100 Evaluation Board Prototype Expansion Connector. The expansion connector on the ADSP-2100 has eight decoded chip enable outputs labeled $\overline{ECE1}$ to $\overline{ECE8}$. $\overline{ECE6}$ is used to drive the AD7840 $\overline{CS}$ input on the data acquisition board. To avoid selecting on-board sockets at the same time, LK6 on the ADSP-2100 board must be removed. The AD7840 and ADSP-2100 data lines are aligned for left justified data transfer.

SKT4 is a 26-way (2-row) IDC connector. This connector contains the same signal contacts as SKT6 and in addition contains decoded R/$\overline{W}$ and $\overline{STRB}$ inputs which are necessary for TMS32020 interfacing. This decoded $\overline{WR}$ can be selected via LK4. The pinout for this connector is shown in Figure 29.

SKT5 is a nine-way D-type connector which is meant for serial interfacing only. The evaluation board has the facility to invert $\overline{SYNC}$ line via LK7. This is necessary for serial interfacing between the AD7840 and DSP processors such as the DSP56000 The SKT5 pinout is shown in Figure 30.

SKT1, SKT2 and SKT3 are three BNC connectors which provide connections for the analog output, the $\overline{LDAC}$ input and an external reference input. The use of an external reference is optional; the shorting plug (LK3) connects the REF IN pin to either this external reference or to the AD7840's own internal reference.

Wire links LK5 and LK6 connect the D11 and D10 inputs to the data lines for parallel operation. In the serial mode, these links allow the user to select the required format and justification for serial data (see Table I).

POWER SUPPLY CONNECTIONS

The PCB requires two analog power supplies and one 5V digital supply. Connections to the analog supplies are made directly to the PCB as shown on the silkscreen in Figure 26. The connections are labelled V+ and V− and the range for both of these supplies is 12V to 15V. Connection to the 5V digital supply is made through any of the connectors (SKT4 to SKT6). The −5V analog supply required by the AD7840 is generated from a voltage regulator on the V− power supply input (IC5 in Figure 25).

SHORTING PLUG OPTIONS

There are eight shorting plug options which must be set before using the board. These are outlined below:

LK1	Connects the analog output to SKT1. The analog output may also be connected to a component grid for signal conditioning.
LK2	Selects either the AD7840 V_{OUT} or the sample-and-hold output.
LK3	Selects either the internal or external reference.
LK4	Selects the decoded R/$\overline{W}$ and $\overline{STRB}$ inputs for TMS32020 interfacing.
LK5	Configures the D11/FORMAT input.
LK6	Configures the D10/JUSTIFY input.
LK7	Selects either the inverted or noninverted $\overline{SYNC}$.
LK8	Selects either parallel or serial interfacing.

COMPONENT LIST

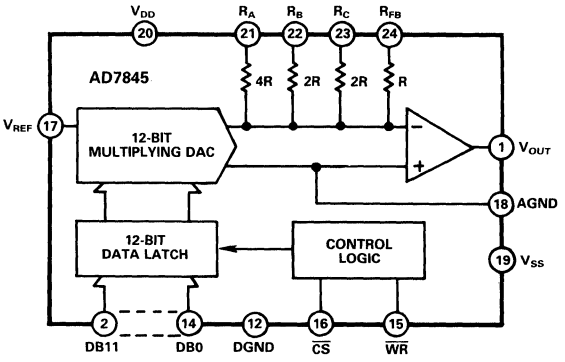
ANALOG DEVICES

LC²MOS
Complete 12-Bit Multiplying DAC
AD7845

FEATURES
- 12-Bit CMOS MDAC with Output Amplifier
- 4-Quadrant Multiplication
- Guaranteed Monotonic (T_{min} to T_{max})
- Space-Saving 0.3", 24-Pin DIPs and 28-Terminal Surface Mount Packages
- Application Resistors On Chip for Gain Ranging, etc.
- Low Power LC²MOS

APPLICATIONS
- Automatic Test Equipment
- Digital Attenuators
- Programmable Power Supplies
- Programmable Gain Amplifiers
- Digital-to-4-20mA Converters

AD7845 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7845 is the industry's first 4-quadrant multiplying D/A converter with an on-chip amplifier. It is fabricated on the LC²MOS process, which allows precision linear components and digital circuitry to be implemented on the same chip.

The 12 data inputs drive latches which are controlled by standard $\overline{CS}$ and $\overline{WR}$ signals, making microprocessor interfacing simple. For stand-alone operation, the $\overline{CS}$ and $\overline{WR}$ inputs can be tied to ground, making all latches transparent. All digital inputs are TTL and 5V CMOS compatible.

The output amplifier can supply ± 10V into a 2kΩ load. It is internally compensated, and its input offset voltage is low due to laser trimming at wafer level. For normal operation, R_{FB} is tied to V_{OUT}, but the user may alternatively choose R_A, R_B or R_C to scale the output voltage range.

PRODUCT HIGHLIGHTS

1. Voltage Output Multiplying DAC
   The AD7845 is the first DAC which has a full 4-quadrant multiplying capability and an output amplifier on-chip. All specifications include amplifier performance.
2. Matched Application Resistors
   Three application resistors provide an easy facility for gain ranging, voltage offsetting, etc.
3. Space Saving
   The AD7845 saves space in two ways. The integration of the output amplifier on-chip means that chip count is reduced. The part is housed in a skinny 24-pin, 0.3" DIP and 28-terminal surface mount package.

SPECIFICATIONS[1] (V_{DD} = +15V, ±5%, V_{SS} = −15V, ±5%, V_{REF} = +10V, AGND = DGND = 0V, V_{OUT} connected to R_{FB}. V_{OUT} load = 2kΩ, 100pF. All specifications T_{min} to T_{max} unless otherwise stated.)

NOTES

[1]Temperature Ranges are as follows: J, K Versions: 0 to +70°C
A, B Versions: −25°C to +85°C
S, T Versions: −55°C to +125°C

[2]Sample tested to ensure compliance.

[3]The metal lid on the ceramic D-24A package is connected to Pin 12 (DGND).

[4]The device is functional with a power supply of ±12V. See Figure 6.

[5]Minimum specified load resistance is 2kΩ.

Specifications subject to change without notice.

TIMING CHARACTERISTICS (V_{DD} = +15V, ±5%. V_{SS} = −15V, ±5%. V_{REF} = +10V. AGND = DGND = 0V.)

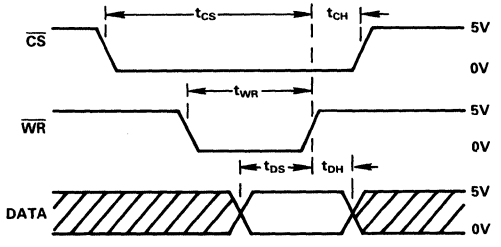
Lead Temperature (Soldering, 10sec) . . . . . +300°C

NOTE
[1]V_{OUT} may be shorted to AGND provided that the power dissipation of the package is not exceeded.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability. Only one Absolute Maximum Rating may be applied at any one time.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.



NOTES
1. All INPUT SIGNAL RISE AND FALL TIMES MEASURED FROM 10% to 90% of +5V. $t_R = t_F = 20$ns.
2. TIMING MEASUREMENT REFERENCE LEVEL IS $\frac{V_{IH} + V_{IL}}{2}$

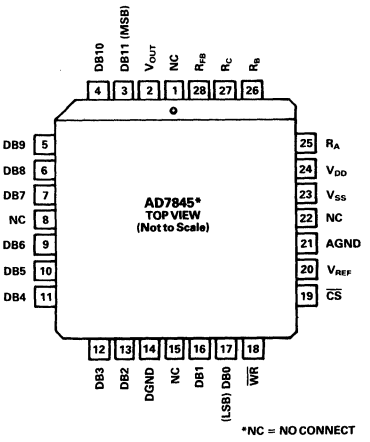
*NC = NO CONNECT

PLCC



*NC = NO CONNECT

TERMINOLOGY

LEAST SIGNIFICANT BIT
This is the analog weighting of 1 bit of the digital word in a DAC. For the AD7845, 1LSB = $\frac{V_{REF}}{2^{12}}$

RELATIVE ACCURACY
Relative accuracy or endpoint nonlinearity is a measure of the maximum deviation from a straight line passing through the endpoints of the DAC transfer function. It is measured after adjusting for both endpoints (i.e., offset and gain error are adjusted out) and is normally expressed in least significant bits or as a percentage of full-scale range.

DIFFERENTIAL NONLINEARITY
Differential nonlinearity is the difference between the measured change and the ideal 1LSB change between any two adjacent codes. A specified differential nonlinearity of +1LSB max over the operating temperature range ensures monotonicity.

GAIN ERROR
Gain error is a measure of the output error between an ideal DAC and the actual device output with all 1s loaded after offset error has been adjusted out. Gain error is adjustable to zero with an external potentiometer. See Figure 13.

ZERO CODE OFFSET ERROR
This is the error present at the device output with all 0s loaded in the DAC. It is due to the op amp input offset voltage and bias current and the DAC leakage current.

TOTAL HARMONIC DISTORTION
This is the ratio of the root-mean-square (rms) sum of the harmonics to the fundamental, expressed in dBs.

OUTPUT NOISE
This is the noise due to the white noise of the DAC and the input noise of the amplifier.

DIGITAL-TO-ANALOG GLITCH IMPULSE
This is the amount of charge injected from the digital inputs to the analog output when the inputs change state. This is normally specified as the area of the glitch in either pA-secs or nV-secs depending upon whether the glitch is measured as a current or voltage. The measurement takes place with V_{REF} = AGND.

DIGITAL FEEDTHROUGH
When the DAC is not selected (i.e., $\overline{CS}$ is high) high frequency logic activity on the device digital inputs is capacitively coupled through the device to show up as noise on the V_{OUT} pin. This noise is digital feedthrough.

MULTIPLYING FEEDTHROUGH ERROR
This is ac error due to capacitive feedthrough from the V_{REF} terminal to V_{OUT} when the DAC is loaded with all 0s.

OPEN LOOP GAIN
Open loop gain is defined as the ratio of a change of output voltage to the voltage applied at the V_{REF} pin with all 1s loaded in the DAC. It is specified at dc.

UNITY GAIN SMALL SIGNAL BANDWIDTH
This is the frequency at which the magnitude of the small signal voltage gain of the output amplifier is 3dB below unity. The device is operated as a closed loop unity gain inverter (i.e., DAC is loaded with all 1s).

OUTPUT RESISTANCE
This is the effective output source resistance.

FULL POWER BANDWIDTH
Full power bandwidth is specified as the maximum frequency, at unity closed loop gain, for which a sinusoidal input signal will produce full output at rated load without exceeding a distortion level of 3%.

PIN FUNCTION DESCRIPTION (DIP)

Pin	Mnemonic	Description
1	V_{OUT}	Voltage Output Terminal
2-11	DB11-DB2	Data Bit 11 (MSB) to Data Bit 2
12	DGND	Digital Ground. The metal lid on the ceramic package is connected to this pin
13-14	DB1-DB0	Data Bit 1 to Data Bit 0 (LSB)
15	$\overline{WR}$	Write Input. Active low
16	$\overline{CS}$	Chip Select Input. Active low
17	V_{REF}	Reference Input Voltage which can be an ac or dc signal
18	AGND	Analog Ground. This is the reference point for external analog circuitry
19	V_{SS}	Negative power supply for the output amplifier (nominal −12V to −15V)
20	V_{DD}	Positive power supply (nominal +12V to +15V)
21	R_A	Application resistor. $R_A = 4R_{FB}$
22	R_B	Application resistor. $R_B = 2R_{FB}$
23	R_C	Application resistor. $R_C = 2R_{FB}$
24	R_{FB}	Feedback resistor in the DAC. For normal operation this is connected to V_{OUT}

CIRCUIT INFORMATION

Digital Section

Figure 11 is a simplified circuit diagram of the AD7845 input control logic. When $\overline{CS}$ and $\overline{WR}$ are both low, the DAC latch is loaded with the data on the data inputs. All the digital inputs are TTL, HCMOS and +5V CMOS compatible, facilitating easy microprocessor interfacing. All digital inputs incorporate standard protection circuitry.

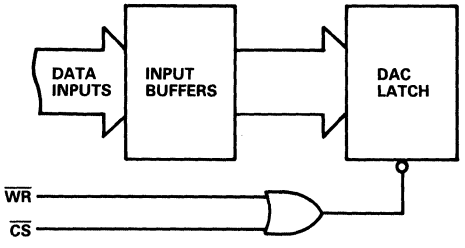

Figure 11. AD7845 Input Control Logic

D/A Section

Figure 12 shows a simplified circuit diagram for the AD7845 D/A section and output amplifier. The D/A converter is a standard R-2R ladder. Binarily weighted currents are switched between AGND and the inverting terminal of the on-chip output amplifier. The output amplifier and feedback resistor R_{FB} perform the current-to-voltage conversion. When connected in the standard configuration (i.e., R_{FB} connected to V_{OUT}),

$$V_{OUT} = -D \cdot V_{REF},$$

where D is the fractional representation of the digital input code. D can vary from 0 to 4095/4096.

The amplifier can maintain ±10V across a 2kΩ load. It is internally compensated and settles to 0.01% FSR (1/2LSB) in less than 5μs. The input offset voltage is laser trimmed at wafer level. The amplifier slew rate is typically 7V/μs, and the unity gain small signal bandwidth is 600kHz. There are three extra on-chip resistors (R_A, R_B, R_C) connected to the amplifier inverting terminal. These are useful in a number of applications including offset adjustment and gain ranging.

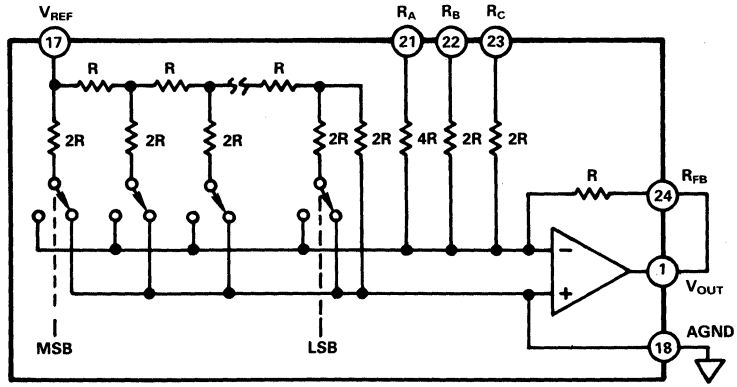

Figure 12. Simplified Circuit Diagram for the AD7845 D/A Section and Output Amplifier

UNIPOLAR BINARY OPERATION

Figure 13 shows the AD7845 connected for unipolar binary operation. When V_{IN} is an ac signal, the circuit performs 2-quadrant multiplication. The code table for Figure 13 is given in Table I.

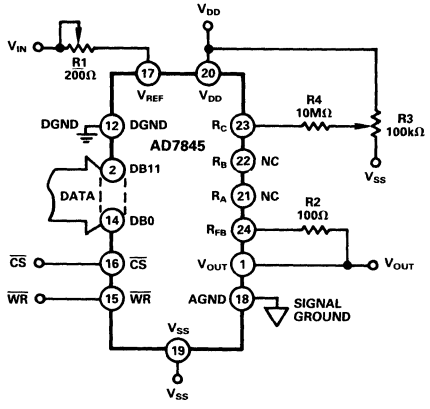

Figure 13. Unipolar Binary Operation

Binary Number In DAC Register			Analog Output, V_{OUT}
MSB		LSB	
1111	1111	1111	$-V_{IN}\left(\frac{4095}{4096}\right)$
1000	0000	0000	$-V_{IN}\left(\frac{2048}{4096}\right) = -1/2\,V_{IN}$
0000	0000	0001	$-V_{IN}\left(\frac{1}{4096}\right)$
0000	0000	0000	0V

Table I. Unipolar Binary Code Table for AD7845

OFFSET AND GAIN ADJUSTMENT FOR FIGURE 13

Zero Offset Adjustment

1. Load DAC with all 0s.
2. Trim R3 until V_{OUT} = 0V.

Gain Adjustment

1. Load DAC with all 1s.
2. Trim R1 so that $V_{OUT} = -V_{IN}\frac{4095}{4096}$

In fixed reference applications, full scale can also be adjusted by omitting R1 and R2 and trimming the reference voltage magnitude. For high temperature applications, resistors and potentiometers should have a low temperature coefficient.

BIPOLAR OPERATION (4-QUADRANT MULTIPLICATION)

The recommended circuit for bipolar operation is shown in Figure 14. Offset binary coding is used.

The offset specification of this circuit is determined by the matching of internal resistors R_B and R_C and by the zero code offset error of the device. Gain error may be adjusted by varying the ratio of R1 and R2.

To use this circuit without trimming and keep within the gain error specifications, resistors R1 and R2 should be ratio matched to 0.01%.

The code table for Figure 14 is given in Table II.

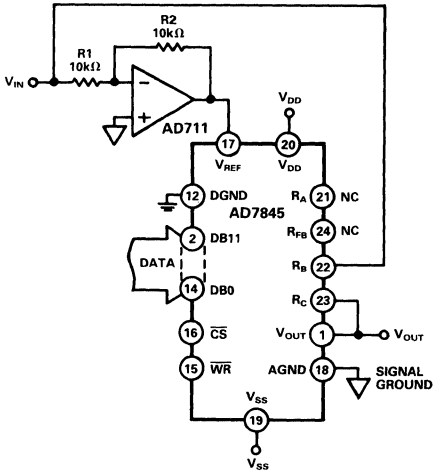

Figure 14. Bipolar Offset Binary Operation

Binary Number In DAC Register			Analog Output, V_{OUT}
MSB		LSB	
1111	1111	1111	$+V_{IN}\left(\frac{2047}{2048}\right)$
1000	0000	0001	$+V_{IN}\left(\frac{1}{2048}\right)$
1000	0000	0000	0V
0111	1111	1111	$-V_{IN}\left(\frac{1}{2048}\right)$
0000	0000	0000	$-V_{IN}\left(\frac{2048}{2048}\right) = -V_{IN}$

Table II. Bipolar Code Table for Offset Binary Circuit of Figure 14

PROGRAMMABLE GAIN AMPLIFIER (PGA)

The AD7845 performs a PGA function when connected as in Figure 15. In this configuration, the R-2R ladder is connected in the amplifier feedback loop. R_{FB} is the amplifier input resistor. As the code decreases, the R-2R ladder resistance increases and so the gain increases.

$$V_{OUT} = -V_{IN} \cdot \frac{R_{DAC}}{D} \cdot \frac{1}{R_{FB}}, \quad \left(D = 0 \text{ to } \frac{4095}{4096}\right)$$

$$= -V_{IN} \cdot \frac{R_{DAC}}{D} \cdot \frac{1}{R_{DAC}} = \frac{-V_{IN}}{D}, \text{ since } R_{FB} = R_{DAC}$$

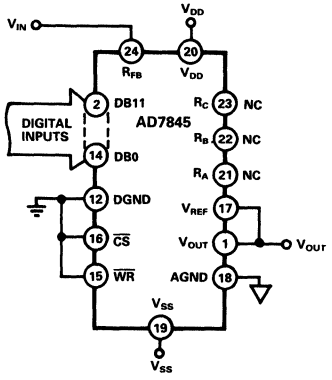

Figure 15. AD7845 Connected as PGA

As the programmed gain increases, the error and noise also increase. For this reason, the maximum gain should be limited to 256. Table III shows gain versus code.

Digital Inputs			Gain	Error (%)
1111	1111	1111	4096/4095 ≈1	0.04
1000	0000	0000	2	0.07
0100	0000	0000	4	0.13
0010	0000	0000	8	0.26
0001	0000	0000	16	0.51
0000	1000	0000	32	1.02
0000	0100	0000	64	2.0
0000	0010	0000	128	4.0
0000	0001	0000	256	8.0

Table III. Gain and Error vs. Input Code for Figure 15

Note that instead of using R_{FB} as the input resistor, it is also possible to use combinations of the other application resistors, R_A, R_B and R_C. For instance, if R_B is used instead of R_{FB}, the gain range for the same codes of Table II now goes from 1/2 to 128.

PROGRAMMABLE CURRENT SOURCES

The AD7845 is ideal for designing programmable current sources using a minimum of external components. Figures 16 and 17 are examples. The circuit of Figure 16 drives a programmable current I_L into a load referenced to a negative supply. Figure 17 shows the circuit for sinking a programmable current, I_L. The same set of circuit equations apply for both diagrams.

$$I_L = I_3 = I_2 + I_1$$

$$I_1 = \frac{D \cdot |V_{IN}|}{R_{DAC}}, \left(D = 0 \text{ to } \frac{4095}{4096}\right)$$

$$I_2 = \frac{1}{R1}\left(\frac{D \cdot |V_{IN}|}{R_{DAC}}\right) R_{FB} = \frac{D \cdot |V_{IN}|}{R1}, \text{ since } R_{FB} = R_{DAC}$$

$$I_L = \frac{D \cdot |V_{IN}|}{R1} + \frac{D \cdot |V_{IN}|}{R_{DAC}}$$

$$= \frac{D \cdot |V_{IN}|}{R1} \cdot \left(1 + \frac{R1}{R_{DAC}}\right)$$

Note that by making R1 much smaller than R_{DAC}, the circuit becomes insensitive to both the absolute value of R_{DAC} and its temperature variations. Now, the only resistor determining load current I_L is the sense resistor R1.

If $R_1 = 100\Omega$, then the programming range is 0 to 100mA, and the resolution is 0.024mA.

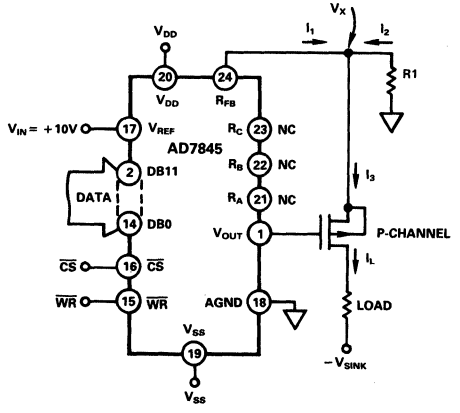

Figure 16. Programmable Current Source

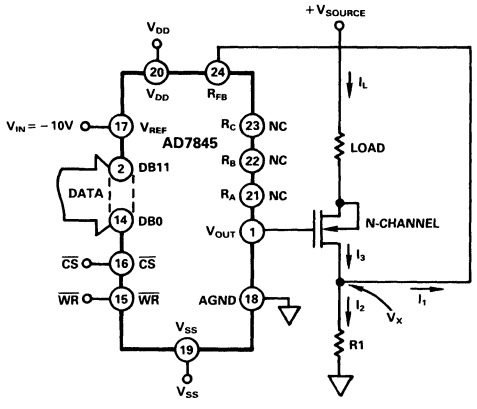

Figure 17. Programmable Current Sink

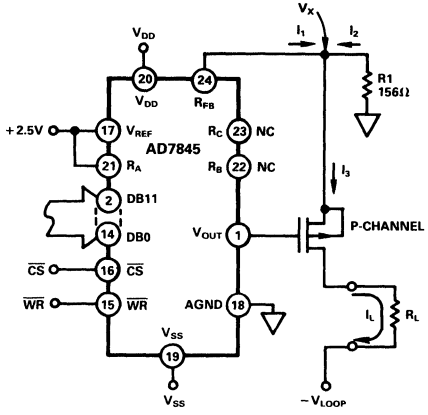

Figure 18. 4-20mA Current Loop

4-20mA CURRENT LOOP

The AD7845 provides an excellent way of making a 4-20mA current loop circuit. This is basically a variation of the circuits in Figures 16 and 17 and is shown in Figure 18. The application resistor R_A (Value 4R) produces the effective 4mA offset.

$$I_L = I_3 = I_2 + I_1$$

Since $I_2 >> I_1$,

$$I_L = -\frac{V_X}{156} = \left(\frac{2.5}{4R} \times R_{FB} + \frac{2.5}{R_{DAC}} \times D \times R_{FB}\right) \times \frac{1}{156}$$

and since $R_{DAC} = R_{FB} = R$

$$I_L = \left(\frac{2.5}{4} + D \times 2.5\right) \times \frac{1000}{156} \text{ mA}$$

$= [4 + (16 \times D)]$mA, where D goes from 0 to 1 with Digital Code

When D = 0 (Code of all 0s):
$I_L = 4$mA

When D = 1 (Code of all 1s):
$I_L = 20$mA

The above circuit succeeds in significantly reducing the circuit component count. Both the on-chip output amplifier and the application resistor R_A contribute to this.

APPLICATION HINTS

General Ground Management: AC or transient voltages between AGND and DGND can cause noise injection into the analog output. The simplest method of ensuring that voltages at AGND and DGND are equal is to tie AGND and DGND together at the AD7845. In more complex systems where the AGND and DGND intertie is on the backplane, it is recommended that two diodes be connected in inverse parallel between the AD7845 AGND and DGND pins (1N914 or equivalent).

Digital Glitches: When a new digital word is written into the DAC, it results in a change of voltage applied to some of the DAC switch gates. This voltage change is coupled across the switch stray capacitance and appears as an impulse on the current output bus of the DAC. In the AD7845, impulses on this bus are converted to a voltage by R_{FB} and the output amplifier. The output voltage glitch energy is specified as the area of the resulting spike in nV-seconds. It is measured with V_{REF} connected to analog ground and for a zero to full scale input code transition. Since microprocessor based systems generally have noisy grounds which couple into the power supplies, the AD7845 V_{DD} and V_{SS} terminals should be decoupled to signal ground.

Temperature Coefficients: The gain temperature coefficient of the AD7845 has a maximum value of 5ppm/°C. This corresponds to worst case gain shift of 2LSBs over a 100°C temperature range. When trim resistors R1 and R2 in Figure 13 are used to adjust full scale range, the temperature coefficient of R1 and R2 must also be taken into account. The offset temperature coefficient is 5ppm of FSR/°C maximum. This corresponds to a worst case offset shift of 2 LSBs over a 100°C temperature range.

The reader is referred to Analog Devices Application Note "Gain Error and Gain Temperature Coefficient of CMOS Multiplying DACs," Publication Number E630C-5-3/86.

MICROPROCESSOR INTERFACING

16-BIT MICROPROCESSOR SYSTEMS

Figures 19, 20 and 21 show how the AD7845 interfaces to three popular 16-bit microprocessor systems. These are the MC68000, 8086 and the TMS32010. The AD7845 is treated as a memory-mapped peripheral to the processors. In each case, a write instruction loads the AD7845 with the appropriate data. The particular instructions used are as follows:

MC68000: MOVE
8086: MOV
TMS32010: OUT

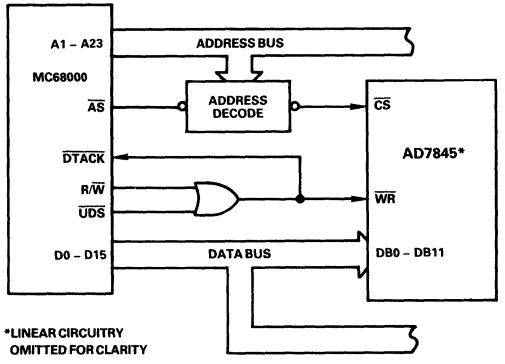

Figure 19. AD7845 to MC68000 Interface

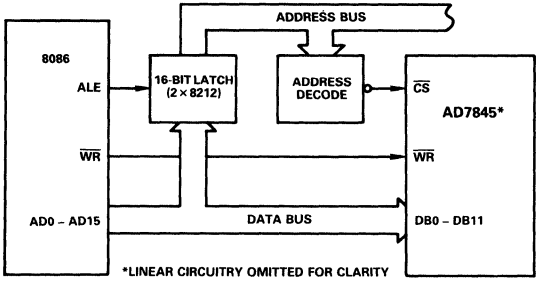

Figure 20. AD7845 to 8086 Interface

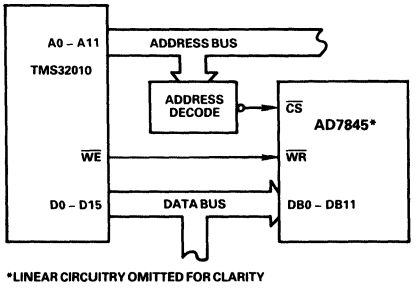

Figure 21. TMS32010 Interface

8-BIT MICROPROCESSOR SYSTEMS

Figure 22 shows an interface circuit for the AD7845 to the 8085A 8-bit microprocessor. The software routine to load data to the device is given in Table IV. Note that the transfer of the 12-bits of data requires two write operations. The first of these loads the 4 MSBs into the 7475 latch. The second write operation loads the 8 LSBs plus the 4 MSBs (which are held by the latch) into the DAC.

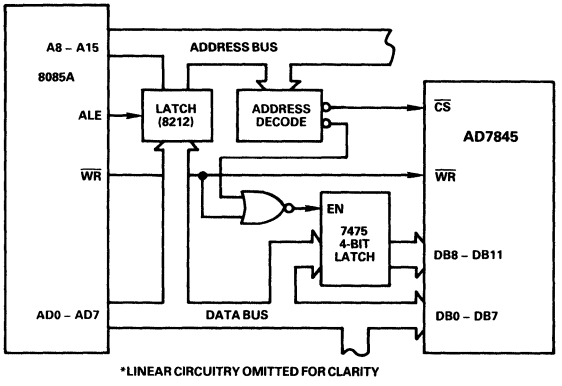

Figure 22. 8085A Interface

2000	LOAD DAC : LXI	H,#3000	The H,L register pair are loaded with latch address 3000.
	MVI	A,#"MS"	Load the 4 MSBs of data into accumulator.
	MOV	M,A	Transfer data from accumulator to latch.
	INR	L	Increment H,L pair to AD7845 address.
	MVI	A,#"LS"	Load the 8 LSBs of data into accumulator.
	MOV	M,A	Transfer data from accumulator to DAC.
	RET		End of routine.

Table IV. Subroutine Listing for Figure 22

Figures 23 and 24 are the interface circuits for the Z80 and MC6809 microprocessors. Again, these use the same basic format as the 8085A interface.

DIGITAL FEEDTHROUGH

In the preceding interface configurations, most digital inputs to the AD7845 are directly connected to the microprocessor bus. Even when the device is not selected, these inputs will be constantly changing. The high frequency logic activity on the bus can feed through the DAC package capacitance to show up as noise on the analog output. To minimize this digital feedthrough isolate the DAC from the noise source. Figure 25 shows an interface circuit which uses this technique. All data inputs are latched from the busy by the $\overline{CS}$ signal. One may also use other means, such as peripheral interface devices, to reduce the digital feedthrough.

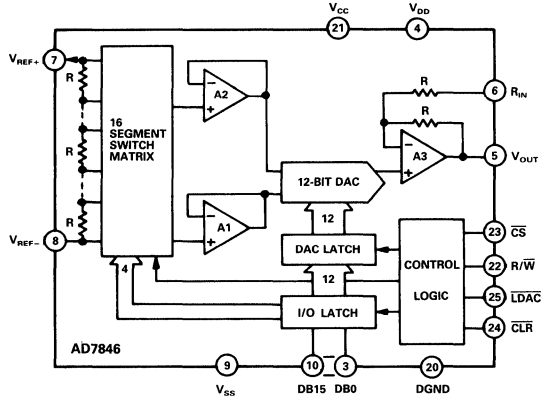
Unipolar or Bipolar Output
Multiplying Capability
Low Power (100mW typical)

AD7846 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7846 is a 16-bit DAC constructed with Analog Devices' LC²MOS process. It has V_{REF+} and V_{REF-} reference inputs and an on-chip output amplifier. These can be configured to give a unipolar output range (0 to +5V, 0 to +10V) or bipolar output ranges (±5V, ±10V).

The DAC uses a segmented architecture. The 4MSBs in the DAC latch select one of the segments in a 16-resistor string. Both taps of the segment are buffered by amplifiers and fed to a 12-bit DAC, which provides a further 12 bits of resolution. This architecture ensures 16-bit monotonicity. Excellent integral linearity results from tight matching between the input offset voltages of the two buffer amplifiers.

In addition to the excellent accuracy specifications, the AD7846 also offers a comprehensive microprocessor interface. There are 16 data I/O pins, plus control lines ($\overline{CS}$, R/$\overline{W}$, $\overline{LDAC}$ and $\overline{CLR}$). R/$\overline{W}$ and $\overline{CS}$ allow writing to and reading from the I/O latch. This is the readback function which is useful in ATE applications. $\overline{LDAC}$ allows simultaneous updating of DACs in a multi-DAC system and the $\overline{CLR}$ line will reset the contents the DAC latch to 00 . . . 000 or 10 . . . 000 depending on the state of R/$\overline{W}$. This means that the DAC output can be reset to 0V in both the unipolar and bipolar configurations.

The AD7846 is available in 28-pin plastic, ceramic and LCCC packages.

PRODUCT HIGHLIGHTS

1. 16-Bit Monotonicity
   The guaranteed 16-bit monotonicity over temperature makes the AD7846 ideal for closed-loop applications.
2. Readback
   The ability to read back the DAC register contents minimizes software routines when the AD7846 is used in ATE systems.
3. Power Dissipation
   Power dissipation of 100mW makes the AD7846 the lowest power, high accuracy DAC on the market.

SPECIFICATIONS[1]

(V_{DD} = +14.25V to +15.75V, V_{SS} = −14.25V to −15.75V, V_{CC} = +4.75V to +5.25V. V_{OUT} loaded with 2kΩ, 1000pF to 0V. V_{REF+} = +5V, R_{IN} connected to 0V. All specifications T_{min} to T_{max} unless otherwise stated.)

NOTES
[1]Timing specifications are sample tested at 25°C to ensure compliance. All input control signals are specified with t_R = t_F = 5 ns (10% to 90% of +5V) and timed from a voltage level of 1.6V.
[2]t_6 is measured with the load circuits of Figure 1 and defined as the time required for an output to cross 0.8V or 2.4V.
[3]t_7 is defined as the time required for an output to change 0.5V when loaded with the circuits of Figure 2.
Specifications subject to change without notice.

NOTES
[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods of time may affect device reliability. Only one Absolute Maximum Rating may be applied at any one time.
[2]V_{OUT} may be shorted to DGND, V_{DD}, V_{SS}, V_{CC} provided that the power dissipation of the package is not exceeded.

CAUTION:
ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however. permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

TERMINOLOGY

Least Significant Bit
This is the analog weighting of 1 bit of the digital word in a DAC. For the AD7846, 1LSB = $(V_{REF+} - V_{REF-})/2^{16}$.

Relative Accuracy
Relative accuracy or endpoint nonlinearity is a measure of the maximum deviation from a straight line passing through the end points of the DAC transfer function. It is measured after adjusting for both endpoints (i.e., offset and gain errors are adjusted out) and is normally expressed in least significant bits or as a percentage of full scale range.

Differential Nonlinearity
Differential nonlinearity is the difference between the measured change and the ideal change between any two adjacent codes. A specified differential nonlinearity of ±1LSB max over the operating temperature range ensures monotonicity.

Gain Error
Gain error is a measure of the output error between an ideal DAC and the actual device output with all 1s loaded after offset error has been adjusted out. Gain error is adjustable to zero with an external potentiometer.

Offset Error
This is the error present at the device output with all 0s loaded in the DAC. It is due to op amp input offset voltage and bias current and the DAC leakage current.

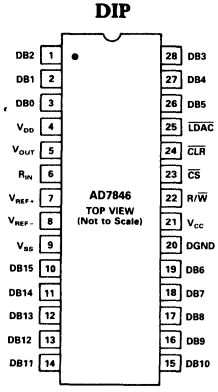
Bipolar Zero Error
When the AD7846 is connected for bipolar output and 10 . . . 000 is loaded to the DAC, the deviation of the analog output from the ideal midscale of 0V is called the bipolar zero error.

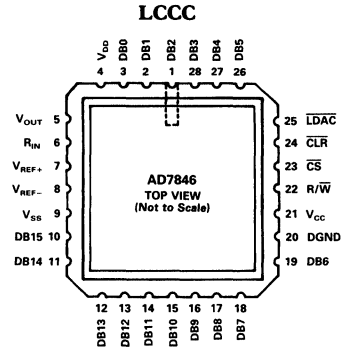
Digital-to-Analog Glitch Impulse
This is the amount of charge injected from the digital inputs to the analog output when the inputs change state. This is normally specified as the area of the glitch in either pA-secs or nV-secs depending upon whether the glitch is measured as a current or a voltage.

Multiplying Feedthrough Error
This is an ac error due to capacitive feedthrough from either of the V_{REF} terminals to V_{OUT} when the DAC is loaded with all 0s.

Digital Feedthrough
When the DAC is not selected (i.e., $\overline{CS}$ is held high), high frequency logic activity on the digital inputs in capacitively coupled through the device to show up as noise on the V_{OUT} pin. This noise is digital feedthrough.

PIN CONFIGURATIONS





PIN FUNCTION DESCRIPTION

Pin	Mnemonic	Description
1–3	DB2–DB0	Data I/O pins. DB0 is LSB.
4	V_{DD}	Positive supply for analog circuitry. This is +15V nominal.
5	V_{OUT}	DAC output voltage pin.
6	R_{IN}	Input to summing resistor of DAC output amplifier. This is used to select output voltage ranges. See Table I.
7	V_{REF+}	V_{REF+} input. The DAC is specified for V_{REF+} = +5V.
8	V_{REF-}	V_{REF-} input. For unipolar operation connect V_{REF-} to 0V and for bipolar operation connect it to −5V. The device is specified for both conditions.
9	V_{SS}	Negative supply for analog circuitry. This is −15V nominal.
10–19	DB15–DB6	Data I/O pins. DB15 is MSB.
20	DGND	Ground pin for digital circuitry.
21	V_{CC}	Positive supply for digital circuitry. This is +5V nominal.
22	R/$\overline{W}$	R/$\overline{W}$ input. This can be used to load data to the DAC or to read back the DAC latch contents.
23	$\overline{CS}$	Chip select input. This selects the device.
24	$\overline{CLR}$	Clear input. The DAC can be cleared to 000 . . . 000 or 100 . . . 000. See Table II.
25	$\overline{LDAC}$	Asynchronous load input to DAC.
26–28	DB5–DB3	Data I/O pins.

Output Range	V_{REF+}	V_{REF-}	R_{IN}
0V to +5V	+5V	0V	V_{OUT}
0V to +10V	+5V	0V	0V
+5V to −5V	+5V	−5V	V_{OUT}
+5V to −5V	+5V	0V	+5V
+10V to −10V	+5V	−5V	0V

CIRCUIT DESCRIPTION

Digital Section

Figure 15 shows the digital control logic and on-chip data latches in the AD7846. Table II is the associated truth table. The D/A converter had two latches which are controlled by four signals: $\overline{CS}$, R/$\overline{W}$, $\overline{LDAC}$ and $\overline{CLR}$. The input latch is connected to the data bus (DB15–DB0). A word is written to the input latch by bringing $\overline{CS}$ low and R/$\overline{W}$ low. The contents of the input latch may be read back by bringing $\overline{CS}$ low and R/$\overline{W}$ high. This feature is called "readback" and is used in system diagnostic and calibration routines.

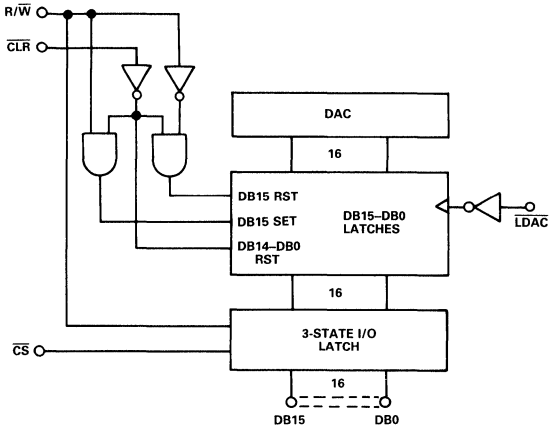

Figure 15. AD7846 Input Control Logic

$\overline{CS}$	R/$\overline{W}$	$\overline{LDAC}$	$\overline{CLR}$	Function
1	X	X	X	3-State DAC I/O Latch in High Z State
0	0	X	X	DAC I/O Latch Loaded with DB15–DB0
0	1	X	X	Contents of DAC I/O Latch Available on DB15–DB0
X	X	0	1	Contents of DAC I/O Latch Transferred to DAC Latch
X	0	X	0	DAC Latch Loaded with 000 . . . 000
X	1	X	0	DAC Latch Loaded with 100 . . . 000

Table II. AD7846 Control Logic Truth Table

Data is transferred from the input latch to the DAC latch with the $\overline{LDAC}$ strobe. The equivalent analog value of the DAC latch contents appears at the DAC output. The $\overline{CLR}$ pin resets the DAC latch contents to 000 . . . 000 or 100 . . . 000, depending on the state of R/$\overline{W}$. Writing a $\overline{CLR}$ loads 000 . . . 000 and reading a $\overline{CLR}$ loads 100 . . . 000. To reset a DAC to 0V in a unipolar system the user should exercise $\overline{CLR}$ while R/$\overline{W}$ is low; to reset to 0V in a bipolar system exercise the $\overline{CLR}$ while R/$\overline{W}$ is high.

D/A Conversion

Figure 16 shows the D/A section of the AD7846. There are three DACs, each of which have their own buffer amplifiers. DAC1 and DAC2 are 4-bit DACs. They share a 16-resistor string but have their own analog multiplexers. The voltage reference is applied to the resistor string. DAC3 is a 12-bit voltage mode DAC with its own output stage.

The 4MSBs of the 16-bit digital code drive DAC1 and DAC2 while the 12LSBs control DAC3. Using DAC1 and DAC2, the MSBs select a pair of adjacent nodes on the resistor string and present that voltage to the positive and negative inputs of DAC3. This DAC interpolates between these two voltages to produce the analog output voltage.

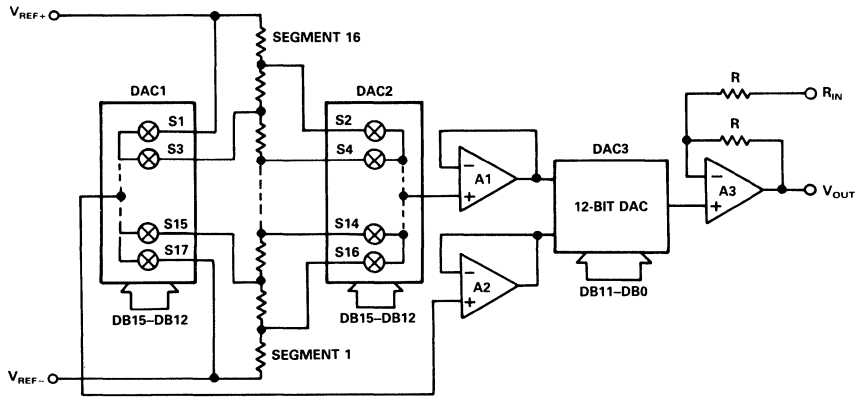

Figure 16. AD7846 D/A Conversion

To prevent non-monotonicity in the DAC due to amplifier offset voltages, DAC1 and DAC2 "leap-frog" along the resistor string. For example, when switching from Segment 1 to Segment 2, DAC1 switches from the bottom of Segment 1 to the top of Segment 2 while DAC2 stays connected to the top of Segment 1. The code driving DAC3 is automatically complemented to compensate for the inversion of its inputs. This means that any linearity effects due to amplifier offset voltages remain unchanged when switching from one segment to the next and 16-bit monotonicity is ensured if DAC3 is monotonic. So, 12-bit resistor matching in DAC3 guarantees overall 16-bit monotonicity. This is much more acheivable than the 16-bit matching which a conventional R-2R structure would have needed.

Output Stage

The output stage of the AD7846 is shown in Figure 17. It is capable of driving a 2kΩ/1000pF load. It also has a resistor feedback network which allows the user to configure it for gains of one or two. Table I shows the different output ranges that are possible.

An additional feature is that the output buffer is configured as a track-and-hold amplifier. Although normally tracking its input, this amplifier is placed in a hold mode for approximately 1μs after the leading edge of $\overline{\text{LDAC}}$. This short state keeps the DAC output at its previous voltage while the AD7846 is internally changing to its new value. So, any glitches that occur in the transition are not seen at the output. In systems where the $\overline{\text{LDAC}}$ is tied permanently low, the deglitching will not be in operation. Figures 8 and 9 show the outputs of the AD7846 with and without the deglitcher.

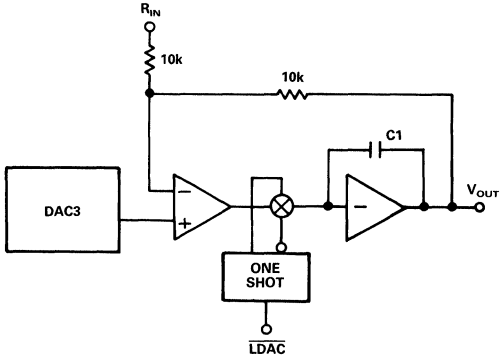

Figure 17. AD7846 Output Stage

UNIPOLAR BINARY OPERATION

Figure 18 shows the AD7846 in the unipolar binary circuit configuration. The DAC is driven by the AD586, +5V reference. Since R_{IN} is tied to 0V, the output amplifier has a gain of 2 and the output range is 0 to +10V. If a 0 to +5V range is required, R_{IN} should be tied to V_{OUT}, configuring the output stage for a gain of 1. Table III gives the code table for the circuit of Figure 18.

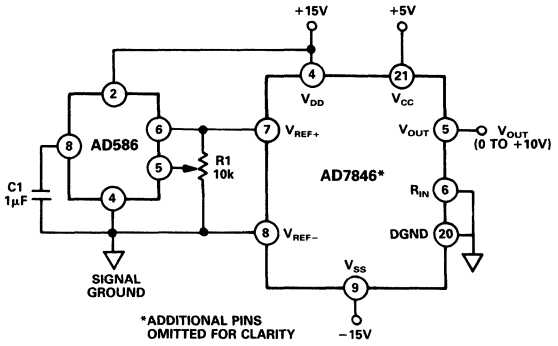

Figure 18. Unipolar Binary Operation

Binary Number in DAC Latch	Analog Output (V_{OUT})
MSB LSB	
1111 1111 1111 1111	+10 (65535/65536) V
1000 0000 0000 0000	+10 (32768/65536) V
0000 0000 0000 0001	+10 (1/65536) V
0000 0000 0000 0000	0V

NOTE
1LSB = $10V/2^{16}$ = 10V/65536 = 152μV.

Table III. Code Table for Figure 18

Offset and gain may be adjusted in Figure 18 as follows : To adjust offset, disconnect the V_{REF-} input from 0V, load the DAC with all 0s and adjust the V_{REF-} voltage until V_{OUT} = 0V. For gain adjustment, the AD7846 should be loaded with all 1s and R1 adjusted until V_{OUT} = 10(65535)/(65536) = 9.999847V. If a simple resistor divider is used to vary the V_{REF-} voltage, it is important that the temperature coefficients of these resistors match that of the DAC input resistance (−300ppm/°C). Otherwise, extra offset errors will be introduced over temperature. Many circuits will not require these offset and gain adjustments. In these circuits, R1, can be omitted. Pin 5 of the AD586 may be left open circuit and Pin 8 (V_{REF-}) of the AD7846 tied to 0V.

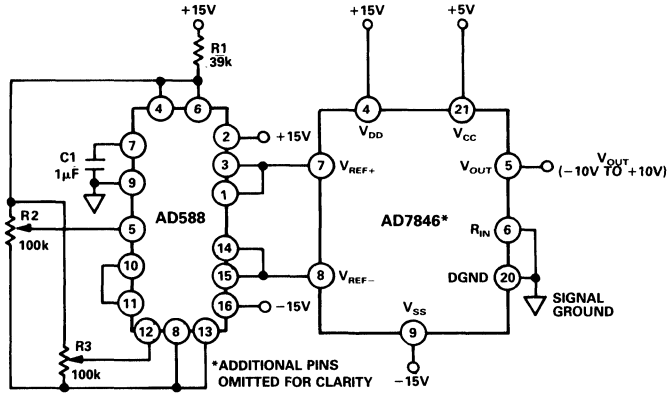

Figure 19. Bipolar ±10V Operation

BIPOLAR OPERATION

Figure 19 shows the AD7846 set up for ±10V bipolar operation. The AD588 provides precision ±5V tracking outputs which are fed to the V_{REF+} and V_{REF-} inputs of the AD7846. The code table for Figure 19 is shown in Table IV.

Binary Number in DAC Latch	Analog Output (V_{OUT})
MSB LSB	
1111 1111 1111 1111	+10 (32767/32768) V
1000 0000 0000 0001	+10 (1/32768) V
1000 0000 0000 0000	0V
0111 1111 1111 1111	−10 (1/32768) V
0000 0000 0000 0000	−10 (32768/32768) V

NOTE
1LSB = $10V/2^{15}$ = 10V/32768 = 305μV.

Table IV. Offset Binary Code Table for Figure 19

Full scale and bipolar zero adjustment are provided by varying the gain and balance on the AD588. R2 varies the gain on the AD588 while R3 adjusts the +5V and −5V outputs together with respect to ground.

For bipolar zero adjustment on the AD7846, load the DAC with 100 . . . 000 and adjust R3 until V_{OUT} = 0V. Full scale is adjusted by loading the DAC with all 1s and adjusting R2 until V_{OUT} = 9.999694V.

When bipolar zero and full scale adjustment are not needed, R2 and R3 can be omitted, Pin 12 on the AD588 should be connected to Pin 11 and Pin 5 should be left floating. If a user wants a ±5V output range, there are two choices. By tying Pin 6 (R_{IN}) of the AD7846 to V_{OUT} (Pin 5), the output stage gain is reduced to unity and the output range is ±5V. If only a positive +5V reference is available, bipolar ±5V operation is still possible. Tie V_{REF-} to 0V and connect R_{IN} to V_{REF+}. This will also give a ±5V output range. However, the linearity, gain, and offset error specifications will be the same as the unipolar 0 to +5V range.

Other Output Voltage Ranges

In some cases, users may require output voltage ranges other than those already mentioned. One example is systems which need the output voltage to be a whole number of millivolts (i.e. 1mV, 2mV, etc.). If the AD689 (8.192V reference) is used with the AD7846 as in Figure 20, then the LSB size is 125μV. This makes it possible to program whole millivolt values at the output. Table V shows the code table for Figure 20.

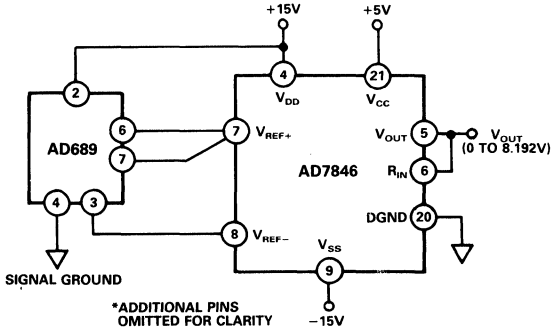

Figure 20. Unipolar Output with AD689

Binary Number in DAC Latch	Analog Output (V_{OUT})
MSB LSB	
1111 1111 1111 1111	8.192V (65535/65536) = 8.1919V
1000 0000 0000 0000	8.192V (32768/65536) = 4.096V
0000 0000 0000 1000	8.192V (8/65536) = 0.001V
0000 0000 0000 0100	8.192V (4/65536) = 0.0005V
0000 0000 0000 0010	8.192V (2/65536) = 0.00025V
0000 0000 0000 0001	8.192V (1/65536) = 0.000125V

NOTE
1LSB = 8.192V/2^{16} = 125μV.

Table V. Code Table for Figure 20

Multiplying Operation

The AD7846 is a full multiplying DAC. To get four-quadrant multiplication, tie V_{REF-} to 0V, apply the ac input to V_{REF+} and tie R_{IN} to V_{REF+}. Figure 6 shows the Large Signal Frequency Response when the DAC is used in this fashion.

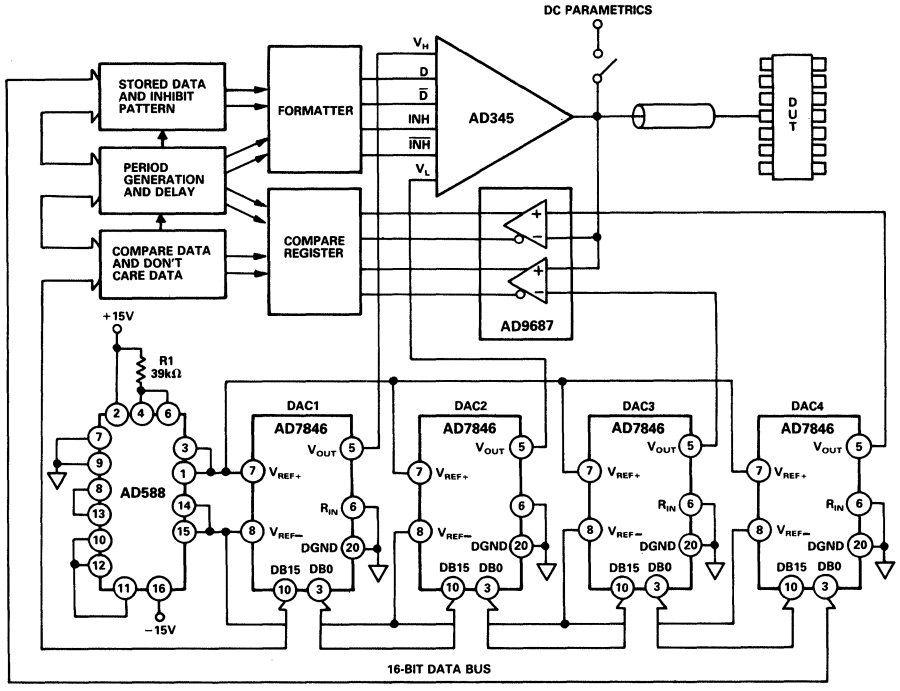

Figure 21. Digital Test System with 16-Bit Performance

TEST APPLICATION

Figure 21 shows the AD7846 in an Automatic Test Equipment application. The readback feature of the AD7846 is very useful in these systems. It allows the designer to eliminate phantom memory used for storing DAC contents and increases system reliability since the phantom memory is now effectively on chip with the DAC. The readback feature is used in the following manner to control a data transfer. First, write the desired 16-bit word to the DAC input latch using the $\overline{CS}$ and R/$\overline{W}$ inputs. Verify that correct data has been received by reading back the latch contents. Now, the data transfer can be completed by bringing the asynchronous $\overline{LDAC}$ control line low. The analog equivalent of the digital word now appears at the DAC output.

In Figure 21, each pin on the Device Under Test can be an input or output. The AD345 is the pin driver for the digital inputs, and the AD9687 is the receiver for the digital outputs. The digital control circuitry determines the signal timing and format.

DACs 1 and 2 set the pin driver voltage levels (V_H and V_L), and DACs 3 and 4 set the receiver voltage levels. The pin drivers used in ATE systems normally have a nonlinearity between input and output. The 16-bit resolution of the AD7846 allows compensation for these input/output nonlinearities. The dc parametrics shown in Figure 21 measure the voltage at the device pin and feed this back to the system processor. The pin voltage can thus be fine-tuned by incrementing or decrementing DACs 1 and 2 under system processor control.

POSITION MEASUREMENT APPLICATION

Figure 22 shows the AD7846 in a position measurement application using an LVDT (Linear Variable Displacement Transducer), an AD630 synchronous demodulator and a comparator to make a 16-bit LVDT-to-Digital Convertor. The LVDT is excited with a fixed frequency and fixed amplitude sine wave (usually 2.5kHz, 2V pk-pk). The outputs of the secondary coil are in anti-phase and their relative amplitudes depend on the position of the core in the LVDT. The AD7846 output interpolates between these two inputs in response to the DAC input code. The AD630 is set up so that it rectifies the DAC output signal. Thus, if the output of the DAC is in phase with the V_{REF+} input, the inverting input to the comparator will be positive, and if it is in phase with V_{REF-}, the output will be negative. By turning on each bit of the DAC in succession starting with the MSB, and deciding to leave it on or turn it off based on the comparator output, a 16-bit measurement of the core position is obtained.

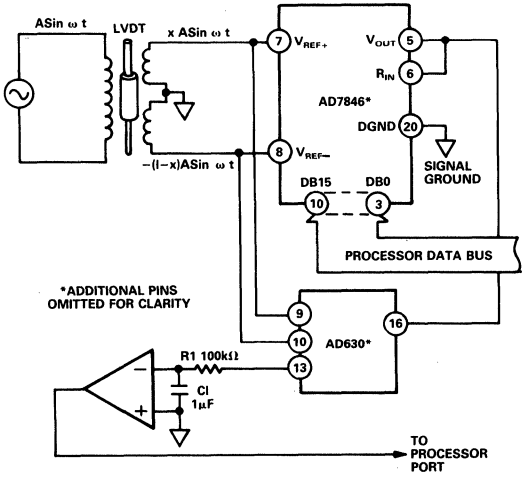

Figure 22. AD7846 in Position Measurement Application

MICROPROCESSOR INTERFACING

AD7846–8086 Interface

Figure 23 shows the 8086 16-bit processor interfacing to the AD7846. The double buffering feature of the DAC is not used in this circuit since $\overline{LDAC}$ is permanently tied to 0V. AD0–AD15 (the 16-bit data bus) are connected to the DAC data bus (DB0–DB15). The 16-bit word is written to the DAC in one MOV instruction and the analog output responds immediately. In this example, the DAC address is D000H.

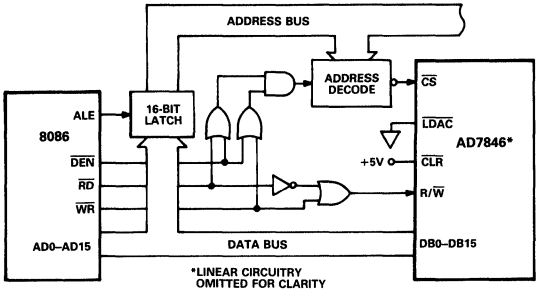

Figure 23. AD7846 to 8086 Interface Circuit

In a multiple DAC system, the double buffering of the AD7846 allows the user to simultaneously update all DACs. In Figure 24, a 16-bit word is loaded to the input latches of each of the DACs in sequence. Then, with one instruction to the appropriate address, $\overline{CS4}$ (i.e., $\overline{LDAC}$) is brought low, updating all the DACs simultaneously.

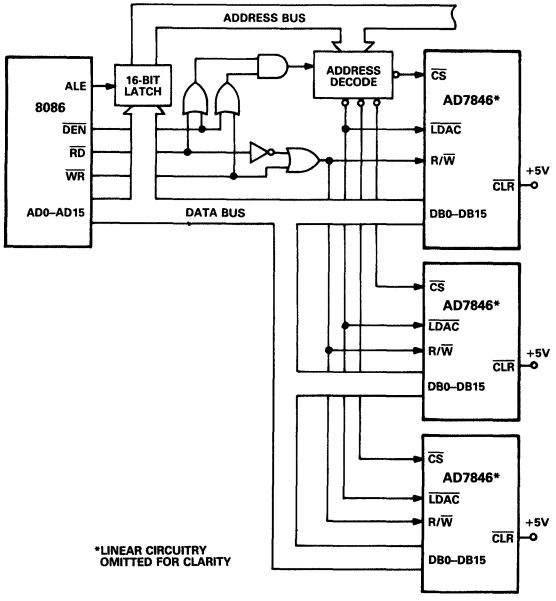

Figure 24. AD7846 to 8086 Interface: Multiple DAC System

AD7846 to MC68000 Interface

Interfacing between the AD7846 and MC68000 is accomplished using the circuit of Figure 25. The following routine writes data to the DAC latches and then outputs the data via the DAC latch.

1000	MOVE.W	#W, D0	The desired DAC data, W, is loaded into Data Register 0. W may be any value between 0 and 65535 (decimal) or 0 and FFFF (hexadecimal).
	MOVE.W	D0, $E000	The data, W, is transferred between D0 and the DAC register.
	MOVE.W	#228, D7	Control is returned to the System Monitor using these two instructions.
	TRAP	#14	

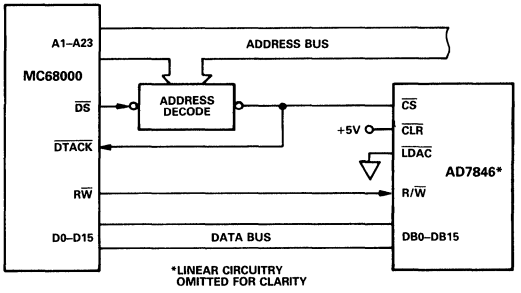

Figure 25. AD7846 to MC68000 Interface

DIGITAL FEEDTHROUGH

In the preceding interface configurations, most digital inputs to the AD7846 are directly connected to the microprocessor bus. Even when the device is not selected, these inputs will be constantly changing. The high frequency logic activity on the bus

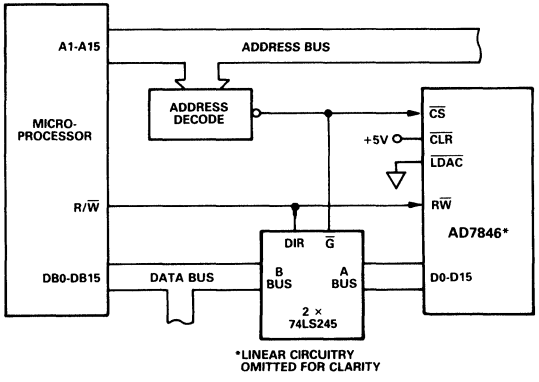

Figure 26. AD7846 Interface Circuit Using Latches to Minimize Digital Feedthrough

noise on the analog output. To minimize this Digital Feedthrough isolate the DAC from the noise source. Figure 26 shows an interface circuit which isolates the DAC from the bus. Note that to make use of the AD7846 readback feature using the isolation technique of Figure 26, the latch needs to be bidirectional.

APPLICATION HINTS

Noise

In high resolution systems, noise is often the limiting factor. With a 10 volt span, a 16-bit LSB is 152μV (−96dB). Thus, the noise floor must stay below −96dB in the frequency range of interest. Figure 7 shows the noise spectral density for the AD7846.

Grounding

As well as noise, the other prime consideration in high resolution DAC systems is grounding. With an LSB size of 152μV and a load current of 5mA, 1LSB of error can be introduced by series resistance of only 0.03Ω.

Figure 27 below shows recommended grounding for the AD7846 in a typical application.

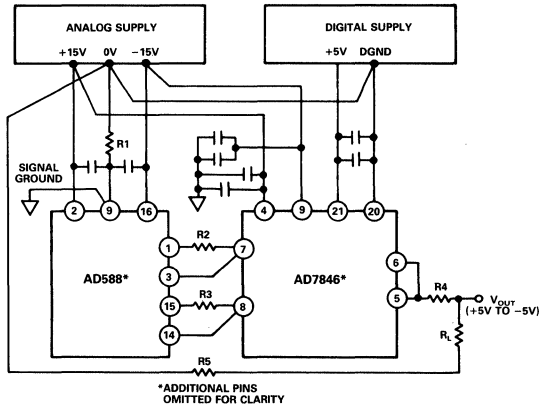

Figure 27. AD7846 Grounding

R1 to R5 represent lead and track resistances on the printed circuit board. R1 is the resistance between the Analog Power Supply ground and the Signal Ground. Since current flowing in R1 is very low (bias current of AD588 sense amplifier), the effect of R1 is negligible. R2 and R3 represent track resistance between the AD588 outputs and the AD7846 reference inputs. Because of the Force and Sense outputs on the AD588, these resistances will also have a negligible effect on accuracy.

R4 is the resistance between the DAC output and the load. If R_L is constant, then R4 will introduce a gain error only which can be trimmed out in the calibration cycle. R5 is the resistance between the load and the analog common. If the output voltage is sensed across the load, R5 will introduce a further gain error which can be trimmed out. If, on the other hand, the output voltage is sensed at the analog supply common, R5 appears as part of the load and therefore introduces no errors.

Printed Circuit Board Layout

Figure 28 shows the AD7846 in a typical application with the AD588 reference, producing an output analog voltage in the ±10 volts range. Full scale and bipolar zero adjustment are provided by potentiometers R2 and R3. Latches (2×74LS245) isolate the DAC digital inputs from the active microprocessor bus and minimize digital feedthrough.

The printed circuit board layout for Figure 28 is shown in Figures 29 and 30. Figure 29 is the component side layout while Figure 30 is the solder side layout. The component overlay is shown in Figure 31.

In the layout, the general grounding guidelines given in Figure 27 are followed. The AD588 and AD7846 are as close as possible, and the decoupling capacitors for these are also kept as close to the device pins as possible.

ANALOG DEVICES

LC²MOS Complete 12-BIT DAC with DSP Interface

AD7848

FEATURES

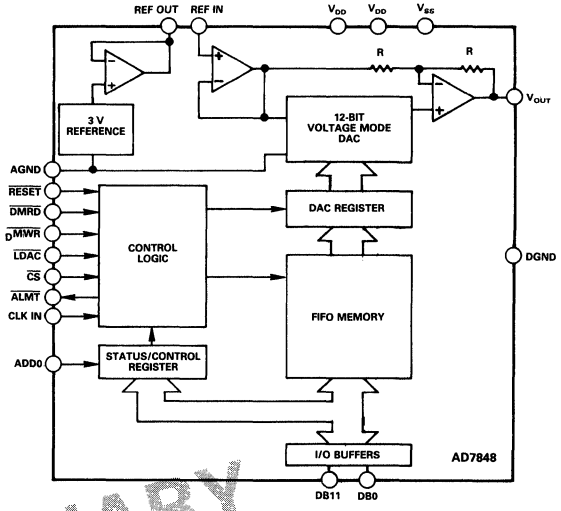
Complete DAC with DSP Interface, Comprising:
- **12-Bit Voltage Mode DAC**
- **3 V Zener Reference**
- **Output Buffer Amplifier with 4 μs Settling Time**
- **8-Word FIFO and Interface Logic**

72 dB Signal-to-Noise Ratio
Interfaces to High Speed DSP Processors, e.g., ADSP-2100, TMS32010, TMS32020
42 ns min $\overline{WR}$ Pulse Width
Low Power – 95 mW max

APPLICATIONS

Digital Signal Processing
Speech Synthesis
High Speed Modems
DSP Servo Control When Used with AD7878

AD7848 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD7848 is a fast, complete, 12-bit, voltage output D/A converter with a versatile DSP interface consisting of an 8-word, first-in, first-out (FIFO) memory and associated control logic.

The FIFO memory allows up to eight samples to be loaded to the AD7848 at full microprocessor speed. The samples are then loaded to the DAC register under control of an asynchronous $\overline{LDAC}$ signal. A fast data setup time of 21 ns allows direct interfacing to DSP processors and high speed 16-bit microprocessors.

An on-chip status/control register allows the user to program the effective length of the FIFO and contains FIFO empty, FIFO full and FIFO word count information.

The analog output from the AD7848 provides a bipolar output range of ±3 V. Full power output signals up to 20 kHz can be created, and the AD7848 is fully specified for dynamic performance parameters such as signal-to-noise ratio and harmonic distortion.

The AD7848 is fabricated in Linear Compatible CMOS (LC^2MOS), an advanced, mixed technology, process that combines precision bipolar circuits with low power CMOS logic. The part is available in a 28-pin plastic and hermetic dual-in-line package (DIP) and in a 28-terminal plastic leaded chip carrier (PLCC).

PRODUCT HIGHLIGHTS

1. Complete D/A Function with DSP Interface
   The AD7848 provides the complete function for creating ac signals to 12-bit accuracy. The part features an on-chip reference, an output buffer amplifier and 12-bit D/A converter. The additional feature of an 8-word FIFO reduces the high software overheads associated with servicing peripherals in DSP processors.
2. Dynamic Specifications for DSP Users
   The AD7848 is fully specified and tested for ac parameters, including signal-to-noise ratio and harmonic distortion. Key digital timing parameters are also tested and specified over the full operating temperature range.
3. Fast Microprocessor Interface
   Data setup times of 21 ns and write pulse widths of 42 ns make the AD7848 compatible with all modern 16-bit microprocessors and digital signal processors.

SPECIFICATIONS (V_{DD} = 5 V± 5%, V_{SS} = −5 V ±5%, AGND = DGND = 0V, REF IN = +3 V, R_L = 2 kΩ, C_L = 100 pF, f_{CLK} = 8 MHz. All Specifications T_{min} to T_{max} unless otherwise noted.)

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

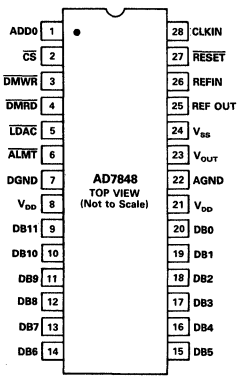
ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

PIN FUNCTION DESCRIPTION

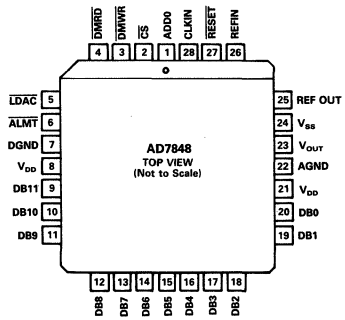
Pin No.	Pin Mnemonic	Function
1	ADD0	Address Input. This input determines whether the word on the data bus during a write operation is loaded to the FIFO RAM or to the status/control register. A logic low selects the FIFO memory, while a logic high selects the status/control register (see Status/Control Register section).
2	$\overline{CS}$	Chip Select. Active low logic input. The device is selected when this input is active.
3	$\overline{DMWR}$	Data Memory Write. Active low logic input. $\overline{DMWR}$ is used in conjunction with $\overline{CS}$ to write data to either the FIFO memory or the status/control register. Corresponds directly to $\overline{DMWR}$ (ADSP-2100), R/$\overline{W}$ (MC68000, TMS32020), $\overline{WE}$ (TMS32010).
4	$\overline{DMRD}$	Data Memory Read. Active low logic input. $\overline{DMRD}$ is used in conjunction with $\overline{CS}$ low to access data from the status/control register. Corresponds directly to $\overline{DMRD}$ (ADSP-2100), $\overline{DEN}$ (TMS32010).
5	$\overline{LDAC}$	Load DAC. Logic input. A new word is loaded to the DAC register from FIFO memory Location 0 on the falling edge of this signal. The $\overline{LDAC}$ input is asynchronous to CLK IN and is independent of $\overline{CS}$, $\overline{DMWR}$ and $\overline{DMRD}$.
6	$\overline{ALMT}$	FIFO Almost Empty. A logic low indicates that the word count (i.e., number of data words in the FIFO) has reached the programmed almost empty word count in the status/control register. $\overline{ALMT}$ is updated after every $\overline{LDAC}$ operation. The $\overline{ALMT}$ output can be disabled (i.e., set to a logic high) by writing a logic 1 to DB7 ($\overline{ENAL}$) of the status/control register.
7	DGND	Digital Ground. Ground reference for digital circuitry.
8	V_{DD}	Positive Supply Voltage, +5 V ± 5%.
9–20	DB11–DB0	Data Bit 11 (MSB) to DB0 (LSB). Three-state TTL input/outputs. Coding for data words is assumed to be 2s complement.
21	V_{DD}	Positive Supply Voltage, +5 V ±5%. Same as Pin 8.
22	AGND	Analog Ground. Ground reference for DAC, reference and output buffer amplifier.
23	V_{OUT}	Analog Output Voltage. This is the buffer amplifier output voltage. Bipolar output range (±3 V with REF IN = +3 V).
24	V_{SS}	Negative Supply Voltage, −5 V± 5%.
25	REF OUT	Voltage Reference Output. The internal 3 V analog reference is provided at this pin. To operate the AD7848 with internal reference, REF OUT should be connected to REF IN. The external load capability of the reference is 500 μA.
26	REF IN	Voltage Reference Input. The reference voltage for the DAC is applied to this pin. It is internally buffered before being applied to the DAC. The nominal reference voltage for correct operation of the AD7848 is 3 V.
27	RESET	Reset. Active low logic input. A logic low clears the words in the FIFO memory and the contents of the DAC register to 1000 0000 0000 and resets the status/control register and control logic.
28	CLK IN	Clock Input. TTL-compatible logic input. Used as the clock source for all internal dynamic logic and provides synchronization during bus transactions. The mark/space ratio of this clock can vary from 35/65 to 65/35.

PIN CONFIGURATIONS

DIP



PLCC



STATUS/CONTROL REGISTER

The status/control register serves the dual function of providing control and monitoring the status of the FIFO memory. This register is directly accessible through the data bus (DB11–DB0) with a read or a write operation when ADD0 is high. A write operation to the status/control register provides control for the $\overline{ALMT}$ output, DAC register updates and FIFO word count reset. This is normally done on power-up initialization. The FIFO memory address pointer is decremented after every DAC register update and this pointer is compared with a preprogrammed count in the status/control register. When this preprogrammed count is reached, the $\overline{ALMT}$ output is asserted if the $\overline{ENAL}$ control bit is set to zero. This $\overline{ALMT}$ can be used to interrupt the microprocessor after any predetermined number of DAC register updates (between 1 and 8). The status of the address pointer, along with FIFO underflow, FIFO empty and $\overline{ALMT}$ status can be accessed at any time by reading the status/control register. Note, reading from the status/control register does not cause any internal movement in the FIFO memory.

STATUS/CONTROL REGISTER FUNCTION DESCRIPTION

DB11 ($\overline{ALMT}$)
Almost Empty Flag. Read only. This is the same as the Pin 6 ($\overline{ALMT}$ output) status. A logic low indicates that the word count in the FIFO memory has reached the preprogrammed word count in bit locations DB10–DB8. $\overline{ALMT}$ is updated at the end of an $\overline{LDAC}$ operation. $\overline{ALMT}$ is active following a device reset because both the FIFO word count and the almost empty word count are 000.

DB10–DB8 (AEC2–AEC0)
Almost Empty Word Count. Read/Write. The count value determines the number of words in the FIFO memory which will cause $\overline{ALMT}$ to be set. When the FIFO word count equals the programmed count in these three bits then both the $\overline{ALMT}$ output and DB11 of the status/control register are set to a logic low. For example, when a code of 011 is written to these bits, $\overline{ALMT}$ is set when Location 0 through Location 3 of the FIFO memory contain valid data. AEC2 is the most significant bit of the word count. The count value can be read back if required.

DB7 ($\overline{ENAL}$)
Enable Almost Empty. Read/Write. Writing a 1 to this bit disables the $\overline{ALMT}$ output and status/control register bit DB11.

DB6 ($\overline{FFUL}$/RESET)
FIFO Full/Reset. Read/Write. Reading a 0 from this bit indicates that there are 8 words in the FIFO memory (i.e., the FIFO is full). Writing a 1 to this bit location will cause a system reset as per the $\overline{RESET}$ input (Pin 27).

DB5 ($\overline{LDAC}$)
Load DAC. Write only. Writing a 0 to this location causes the sample in Location 0 of the FIFO to be loaded into the DAC register. The function of this bit is the same as the $\overline{LDAC}$ input (Pin 5).

DB4 (FEMP)
FIFO Empty. Read only. Reading a 1 indicates that there are no words in FIFO memory. When the FIFO is empty, any further $\overline{LDAC}$ operations will continue to update the DAC register with the contents of Location 0 of the FIFO.

DB3 (FUND)
FIFO Underflow. Read only. If the FIFO memory is empty and further DAC register updates occur, then this bit is set to a 1. It will remain set until an $\overline{LDAC}$ operation occurs with valid data in FIFO Location 0.

DB2–DB0 (FCN2–FCN0)
FIFO Word Count. Read only. The value read from these bits indicates the number of words in FIFO memory. For example, reading 011 from these bits indicates that Location 0 through Location 3 contain valid data. Note, reading all 0s indicates that there is either one word or no word in the FIFO memory; in this case, the FIFO Empty bit determines if there is no word in memory. FCN2 is the most significant bit of the word count.

INTERNAL FIFO MEMORY

The internal FIFO memory of the AD7848 consists of eight memory locations, each memory location 12 bits wide. A block diagram of the AD7848 FIFO architecture is shown in Figure 3.

Data is loaded to the FIFO under control of $\overline{CS}$ and $\overline{DMWR}$. The FIFO Address Pointer always points to the top of memory, i.e., the uppermost location which contains valid data. This pointer is incremented when a new word is loaded to the FIFO from the data bus. Data is loaded from the FIFO to the DAC register under control of an asynchronous $\overline{LDAC}$ signal. When $\overline{LDAC}$ is asserted, the data contained in the bottom location of the FIFO (Location 0) is transferred to the DAC register. On completion of this transfer operation, each word in the FIFO moves down one location and the Address Pointer is decremented by one. Therefore, each data word enters at the top of memory, propagates down with successive $\overline{LDAC}$ operations until it reaches Location 0 from where it can be transferred to the DAC register.

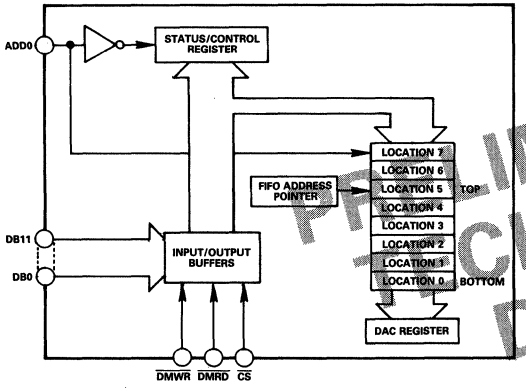

Figure 3. Internal FIFO Architecuture

The propagation of data words down the FIFO occurs in synchronization with the AD7848 input clock (CLK IN). As a result, a write operation to the FIFO memory must also be synchronous with CLK IN to avoid input/output conflicts in the FIFO (i.e., writing to the FIFO while the FIFO data words are rippling down after a DAC register update). This requires that the microprocessor clock and the AD7848 CLK IN are derived from the same source.

D/A SECTION

The AD7848 contains a 12-bit, voltage output D/A converter consisting of highly stable thin film resistors and high speed NMOS single pole, double throw switches. The simplified circuit diagram for the DAC section is shown in Figure 4. The three MSBs of the data word are decoded to drive the seven switches A–G. The 9 LSBs switch a 9-bit R-2R ladder structure. The output voltage from this converter has the same polarity as the reference voltage, REF IN.

The REF IN voltage is internally buffered by a unity gain amplifier before being applied to the D/A converter and the bipolar bias circuitry. The D/A converter is configured and scaled for a 3 V reference and the device is tested with 3 V applied to REF IN. Operating the AD7848 at reference voltages outside the ±5% tolerance range may result in degraded performance from the part.

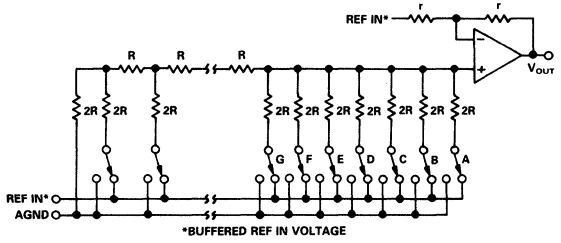

Figure 4. DAC Ladder Structure

INTERNAL REFERENCE

The AD7848 has an on-chip temperature compensated buried Zener reference (see Figure 5) which is factory trimmed to 3 V ± 10 mV. The reference voltage is provided at the REF OUT pin. This reference can be used to provide both the reference voltage for the D/A converter and the bipolar bias circuitry. This is achieved by connecting the REF OUT pin to the REF IN pin of the device.

The reference voltage can also be used as a reference for other components in the system and is capable of providing up to 500 μA to an external load. The maximum recommended capacitance on REF OUT for normal operation is 50 pF. If the reference is required for external use, it should be decoupled with a 200 Ω resistor in series with a parallel combination of a 10 μF tantalum capacitor and a 0.1 μF ceramic capacitor.

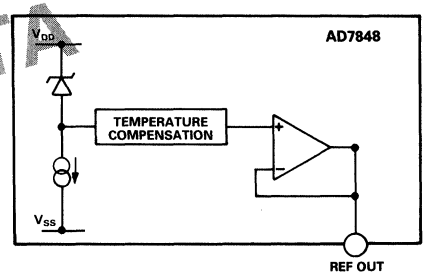

Figure 5. Internal Reference

EXTERNAL REFERENCE

In some applications, the user may require a system reference or some other external reference to drive the AD7848 reference input. Figure 6 shows how the AD586 5 V reference can be conditioned to provide the 3 V reference required by the AD7848 REF IN. An alternate source of reference voltage for the AD7848 in systems which use both a DAC and an ADC is to use the REF OUT voltage of an ADC such as the AD7878 or AD7870.

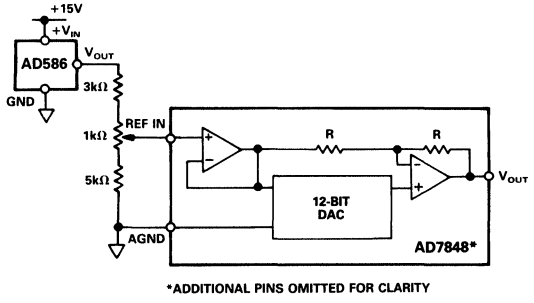

Figure 6. AD586 Driving AD7848 REF IN

OP AMP SECTION

The output from the converter is buffered by a noninverting amplifier. Internal scaling resistors on the AD7848 configure the output voltage for ±3 V from an input reference voltage of +3 V. Figure 4 shows the arrangement of these resistors around the output op amp. The buffer amplifier is capable of developing ± 3 V across a 2 kΩ and 100 pF load to ground and can produce 6 V peak-to-peak sine wave signals up to a frequency of 20 kHz.

The output is updated on the falling edge of the $\overline{LDAC}$ input. For a software DAC update, the output is updated on the next rising clock edge after receiving a software $\overline{LDAC}$. The amplifier settles to within 1/2 LSB of its final value in typically less than 2 μs.

TRANSFER FUNCTION

The basic circuit configuration for the AD7848 is shown in Figure 7. Table II shows the ideal input code to output voltage relationship for this configuration. Input coding to the DAC is 2s complement with 1 LSB=FS/4096=6 V/4096= 1.465 mV. The output voltage, V_{OUT}, can be expressed in terms of the input code, N, using the following relationship:

$$V_{OUT} = \frac{2 \cdot N \cdot REFIN}{4096} \quad -2048 \leq N \leq +2047$$

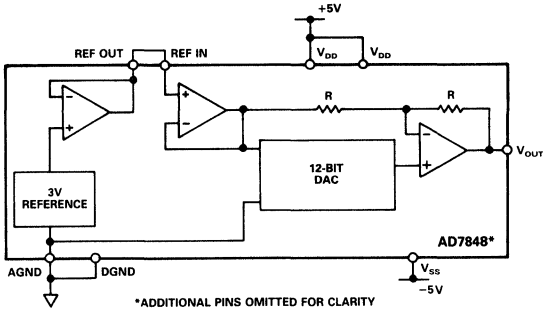

Figure 7. Basic Connection Diagram

DAC Latch Contents MSB LSB	Analog Output, V_{OUT}*
0111 1111 1111	+2.998535 V
0111 1111 1110	+2.99707 V

0000 0000 0000	0 V
1111 1111 1111	−0.001465 V
1000 0000 0001	−2.998535 V
1000 0000 0000	−3 V

*Assuming REF IN = +3 V.

Table II. Ideal Input/Output Code Table

READ/WRITE OPERATIONS

The AD7848 read/write operations consist of writing to the FIFO memory and status/control register and reading from the status/control register. These operations are controlled by the $\overline{CS}$, $\overline{DMWR}$, $\overline{DMRD}$ and ADD0 logic inputs.

Write Operation

A write operation to the AD7848 FIFO memory consists of bringing $\overline{CS}$ and $\overline{DMWR}$ low with ADD0 low. Internally, these signals are gated with CLK IN to provide an INTERNAL WRITE signal (see Figure 8). The pulse width of this INTERNAL WRITE signal is effectively the overlap between the CLK IN low time and the $\overline{CS}$ and $\overline{DMWR}$ pulses. This may result in shorter write pulse widths, setup times and data hold times than those given by a microprocessor. The timing on the AD7848 timing diagram of Figure 9 is therefore given with respect to the INTERNAL WRITE signal rather than the $\overline{DMWR}$ signal. A similar situation exists for writing information to the AD7848 status/control register. A write operation to the status/control register consists of bringing $\overline{CS}$ and $\overline{DMWR}$ low with ADD0 high.

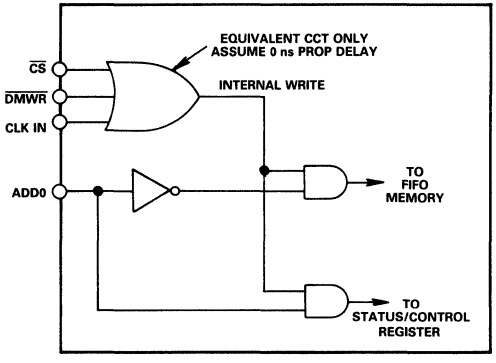

Figure 8. $\overline{DMWR}$ Internal Logic

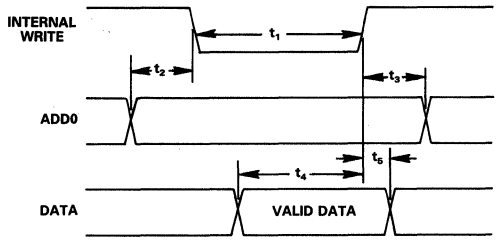

Figure 9. AD7848 Write Operation

Read Operation

Figure 10 shows the timing diagram for a read operation from the status/control register of the AD7848. $\overline{CS}$ and $\overline{DMRD}$ going low accesses data from the status/control register. Status information for a particular word should be read before the word is transferred to the DAC register.

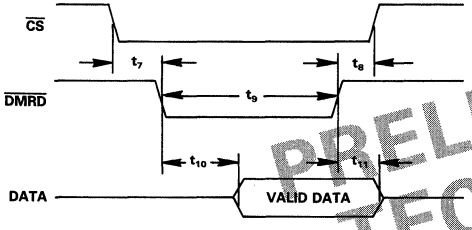

Figure 10. AD7848 Read Operation

UPDATING THE DAC OUTPUT

The DAC output on the AD7848 can be updated under software or hardware control. For hardware control, the output is updated by asserting the $\overline{LDAC}$ input; for software control, writing a 0 to DB5 of the status/control register updates the output.

The $\overline{LDAC}$ input is an asynchronous input which is independent of either the DAC or DSP clocks. This is essential for applications where precise sampling in time is important. In these applications, the signal update must occur at exactly equal intervals to minimize errors due to updating uncertainty or jitter. In these cases, the $\overline{LDAC}$ input is driven from a timer or some precise clock source.

In applications where precise sampling is not critical, the $\overline{LDAC}$ pulse can be generated from a microprocessor $\overline{WR}$ line gated with a decoded address (different to the AD7848 $\overline{CS}$ address). Note, the $\overline{LDAC}$ input must stay low for at least 1.5 CLK IN cycles.

The alternative method for updating the DAC output is a software update which is achieved by writing a 0 to DB5 of the status/control register. In this case, the DAC register is updated on the next rising clock edge of CLK IN. Continuous DAC register updates do not take place when there is a 0 in DB5. The update only occurs on the next falling CLK IN edge after the 0 is written to DB5. The $\overline{LDAC}$ input (Pin 5) should be tied high for software control of the DAC update.

Testing the AD7848

The method used to test the dynamic performance specifications is outlined in Figure 11. Data is loaded to the AD7848 under control of the microcontroller and associated logic. The output of the AD7848 is applied to a 9th order low pass filter. The output of the filter is in turn applied to a 14-bit accurate digitizer. This samples the signal and the microcontroller generates an FFT plot from which the dynamic performance of the AD7848 can be evaluated.

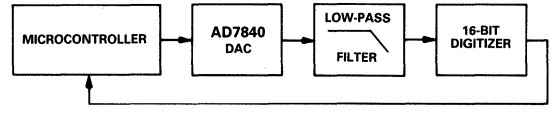

Figure 11. AD7848 Dynamic Performance Test Circuit

The digitizer's sampling is synchronized with the AD7848 update rate to ease FFT calculations. The digitizer samples the AD7848 after the output has settled to its new value. Therefore, if the digitizer was to sample the output directly, it would effectively be sampling a dc value each time. As a result, the dynamic performance of the AD7848 would not be measured correctly. Using the digitizer directly on the AD7848 output would give better results than the actual performance of the AD7848. Using a filter between the DAC and the digitizer means that the digitizer samples a continuously moving signal and the true dynamic performance of the AD7848 is measured.

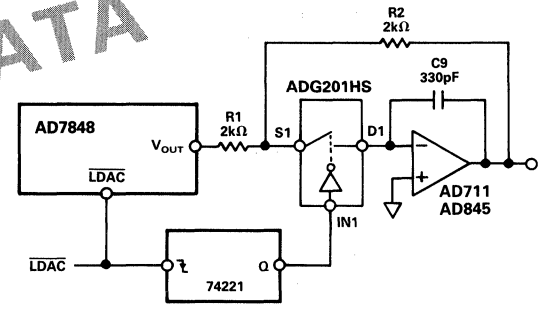

Figure 12. Sample-and-Hold Circuit

Some applications will require improved performance versus frequency from the AD7848. In these applications, a simple sample-and-hold circuit such as that outlined in Figure 12 will extend the very good performance of the AD7848 to 20 kHz. Other applications will already have an inherent sample-and-hold function following the AD7848. An example of this type of application is driving a switched-capacitor filter where the updating of the DAC is synchronized with the switched-capacitor filter. This inherent sample-and-hold function also extends the frequency range performancce of the AD7848.

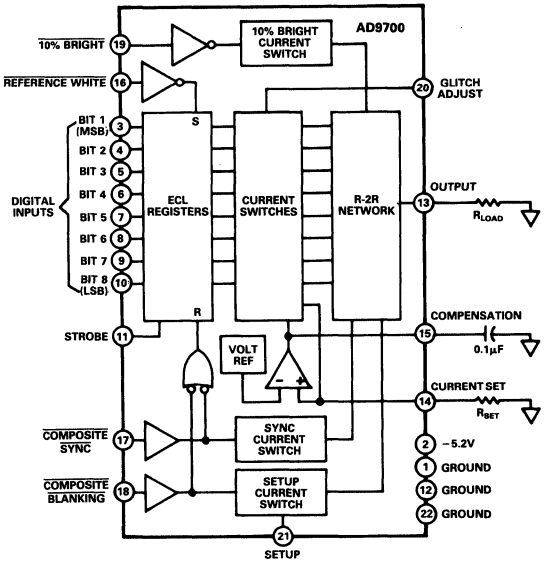
AD9700 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD9700 digital-to-analog converter is a monolithic device capable of accepting eight bits of digital data at update rates as high as 125MHz. On-chip registers on the data lines help minimize "glitches" in the output signal.

Incorporating the AD9700 into system designs is eased by its blanking, sync, 10% brightness, and reference white control signals. An on-board reference eliminates the need for external circuits, making it considerably easier to design the AD9700 into high-speed applications than it is for converters which do not have this feature.

The unit is housed in a 22-pin package; operates from a single −5.2V power supply; and dissipates only 650mW, making this the smallest, lowest power D/A converter available to design engineers who need true "graphics ready" converters for raster scan, color graphics, and other high-speed systems.

This device is a natural extension of the Analog Devices advanced technology that produced the first hybrid converters which included composite capabilities. Like the earlier HDG-Series D/A converters, the AD9700 is designed to have general output compatibility with EIA Standards RS-170 and RS-343.

Five versions of the AD9700 are available. The AD9700BW (non-hermetic) and AD9700BD (hermetic) are DIP units operating over a temperature range of −25°C to +85°C; the hermetic DIP AD9700SD is for use over a temperature range of −55°C to +125°C. The AD9700BE and AD9700SE are leadless chip carrier (LCC) devices for temperature ranges of −25°C to +85°C and −55°C to +125°C, respectively.

NOTES
[1]Electrical specifications for AD9700BE same as AD9700BD/BW.
[2]Electrical specifications for AD9700SE same as AD9700SD.
[3]Settling to GS percentage includes FS and MSB transitions. Inherent 3ns register delay (50% points) is not included.
[4]Minimum update rate limited by full-scale settling time for eight bits. Unit can be updated to 125MHz.
[5]Glitch can be reduced with glitch adjustment.
[6]See Figure 2 for operation with TTL logic.
[7]FS current = GS current + video functions = 30mA.
[8]LSB value of 2.5mV used for calibration. This causes Gray Scale output to to be 637.5mV rather than 643mV shown in idealized composite waveform elsewhere in this data sheet; both values are well within the output and EIA Standard RS-170 tolerances. $I_{OUT} = (1.26/R_{SET}) \times 4$ when $R_{SET} = 300\Omega$.
[9]Effect on analog output of logic "0" at Reference White input depends on signal at 10% Bright input (see Table I).
[10]10% Bright, Composite Sync, and Composite Blanking outputs shown add to Gray Scale analog output at Pin 13.
[11]Composite Sync or Composite Blanking control signals reset input registers. Composite Sync or Composite Blanking should not be operated simultaneously with Reference White.
[12]Maximums shown are at temperature extremes.
[13]Maximum junction temperature = +150°C.
[14]Calculated using MIL HNBK-217; Ground Fixed; +25°C Ambient.
[15]See Section 14 for package outline information.
*Specifications same as AD9700BD/BW.
Specifications subject to change without notice.

NOTES
[1]Setup (Pin 21) grounded (0 IRE units).
[2]Setup (Pin 21) open (7.5 IRE units).
[3]Setup (Pin 21) to −5.2V through 1k (10 IRE units).
[4]Setup (Pin 21) to −5.2V (20 IRE units).

Analog output values shown are based on LSB value of 2.5mV used for ease of calibration; this causes Gray Scale output to be 637.5mV rather than 643mV shown elsewhere in this data sheet in sketch of idealized composite output. Both values are well within the output and EIA Standard RS-170 tolerances.

Table I.

USING AD9700 AS RASTER SCAN D/A

Refer to the block diagram of the AD9700 D/A converter.

The digital input bits represent the Gray Scale value of the 256 (2^8) discrete levels between Reference Black and Reference White in a composite video signal, and are applied to Pins 3 through 10.

The output analog signal (at Pin 13) will be a function of these digital inputs. The output will also be affected by the ECL levels at the control inputs of 10% Bright, Reference White, Composite Sync, and Composite Blanking; and the level of the control signal (expressed in terms of IRE units) at the Setup input.

The total effect of these combined signals can be illustrated in a truth table format if arbitrary values are assigned for Gray scale inputs and various combinations of control inputs are selected.

Refer to Table I.

As the footnote to this figure points out, the full-scale (−637.5mV) output of the AD9700 is different from the −643mV output of the idealized composite waveform shown elsewhere in this data sheet. The reason for this discrepancy is Analog Devices' use of 2.5mV for the value of the LSB; that choice of LSB weighting eases calibration of the converter. The disparity does not cause any problems in using the device, since both values are well within the tolerances of the output and the RS-170 standard.

Referring again to the block diagram, the Strobe input applied to the AD9700 clocks the input registers when the strobe signal makes the transition from a logic "0" to a logic "1". The purpose of the registers is to remove time skew from the digital input bits and minimize pertubations or "glitches" in the analog output signal.

The signal applied to the Reference White input sets the input registers, thereby overriding the video input word. When this occurs, the analog output of the AD9700 goes to 0V or to −71mV, depending upon whether or not the 10% Bright signal is also operated.

A logic "0" applied to either the Composite Sync or Composite Blanking input will reset the input registers to 00000000. The analog output at Pin 13 will be −922.5mV (−637.5mV plus −285mV) if the Composite Sync input is operated; this is not affected by the value of IRE units at the setup input.

When Composite Blanking is operated, the analog output will go to its full-scale value of −637.5mV plus some additional amount, as determined by the voltage at setup. The −53.25mV example used in the specifications section of the data sheet is based on the setup input floating, which is equivalent to 7.5 IRE units. (For this example, the analog output would be 690.75mV.)

The internal voltage reference shown in the block diagram is a bandgap type. Including this reference within the converter eliminates the need for external circuits, making it markedly easier to design the AD9700 into various applications. The internal precision reference also provides superior power supply rejection and gain tempco.

Details on the connections for using the AD9700 in composite video applications are shown in Figure 1.

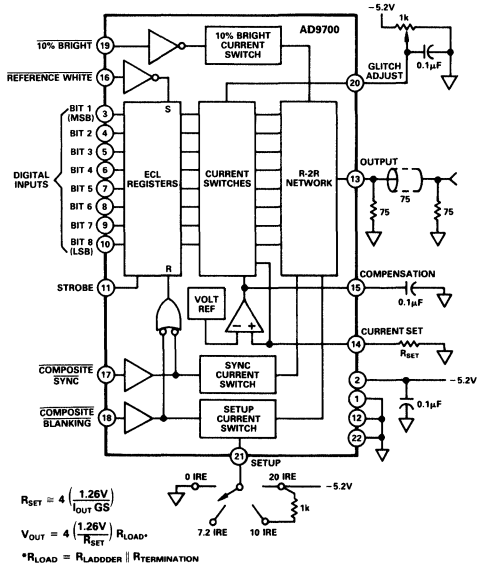

Figure 1. AD9700 D/A Connections

The value of R_{SET} can be established by using the first of the two equations which are part of the connection illustration; in the formula, the 1.26 volts is the reference voltage. When that voltage is divided by the desired Gray Scale current, the value which results is approximately one-fourth the resistance of R_{SET}.

The resistance of R_{SET}, in turn, can be used in the calculation of analog output voltage when the AD9700 is operating as a raster scan D/A converter. The full-scale current of the device is the Gray Scale current plus the video functions, and is specified at 30mA total. The user needs to keep that number in mind to assure that the AD9700 is utilized correctly in circuit designs.

In some instances, the user may be driving a lighter load than the coaxial cable shown in Figure 1 and prefers to operate with lower power dissipation than that in high speed raster scan use. For these situations, the value of R_{SET} can be doubled, which halves the output current while still maintaining a useable current drive from the converter. Power dissipation would be reduced approximately 75mW; the trade-off to obtain this is a decrease in the speed of the AD9700 and a lengthening of setting time.

Ground pins 1, 12, and 22 are shown connected together and to ground near the unit; this is the recommended procedure for obtaining optimum performance, especially in high-speed applications. Inside the AD9700, Pin 1 is register ground; Pin 12 is analog ground; and Pin 22 is digital ground.

For some applications, in addition to by-passing the $-5.2V$ supply with $0.01\mu F$ as shown, it may be desirable to by-pass it also with a tantalum capacitor of $3.3 - 10\mu F$. Although this is not generally necessary, it may enhance the converter's performance in some designs.

The circuit connected to Pin 21 setup is used for illustrative purposes to demonstrate the relationships of various IRE units; it is not intended to imply this is the preferred way to obtain these values. At Pin 20, the circuit used for adjusting the glitch can reduce the amount of glitch from its typical 50pV-s to a lesser value for those applications which require it.

USING AD9700 IN TTL MODE

Most applications using the AD9700 for composite video reconstruction will be in ECL systems, but there may be instances where its high-performance characteristics need to be applied in TTL designs.

A method of accomplishing this is illustrated in Figure 2.

Except as shown, all input pull-up resistors which are used are the same value: $2k\Omega$. If some of the input bit connections are not used because of operating with fewer than eight bits of resolution, the unused input pins should be resistively connected to $+5V$ to prevent undesirable side effects in the performance of the converter.

This same technique of resistively connecting unused inputs to $+5V$ also applies for the Reference White, Composite Sync, and Composite Blanking inputs. If 10% Bright is not used, Pin 19 should be either grounded or left open; no pull-up resistor should be used.

The table which is part of Figure 2 shows the required connections to Pin 21 for the various blanking levels when operating in the TTL mode.

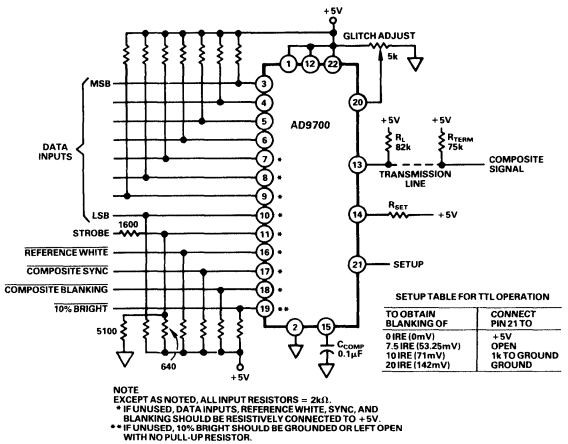

Figure 2. Using AD9700 in TTL Mode

USING AD9700 AS STANDARD D/A

Although designed for use in composite video applications, the AD9700 can also be utilized as a standard D/A converter with remarkable performance. The extremely low glitch energy of the unit makes it especially attractive, because video reconstruction can be accomplished with exceptional spectral purity.

Refer to Figure 3.

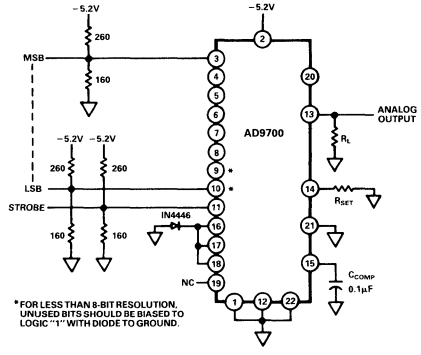

Figure 3. AD9700 as Standard D/A

When used as a standard D/A, the unused control inputs required for video applications are connected to ground; in most cases, this connection is made through a diode. Examples of that are shown on Pins 16, 17, and 18, the inputs for Reference White, Composite Sync, and Composite Blanking, respectively. The 10% Bright input (Pin 19) is left open, and setup (Pin 21) is tied directly to ground.

If fewer than eight bits of digital input will be applied, the unused input pins should be connected to ground via a diode with the same technique used at Pins 16, 17, and 18. If they are tied directly to ground, converter performance may be affected adversely.

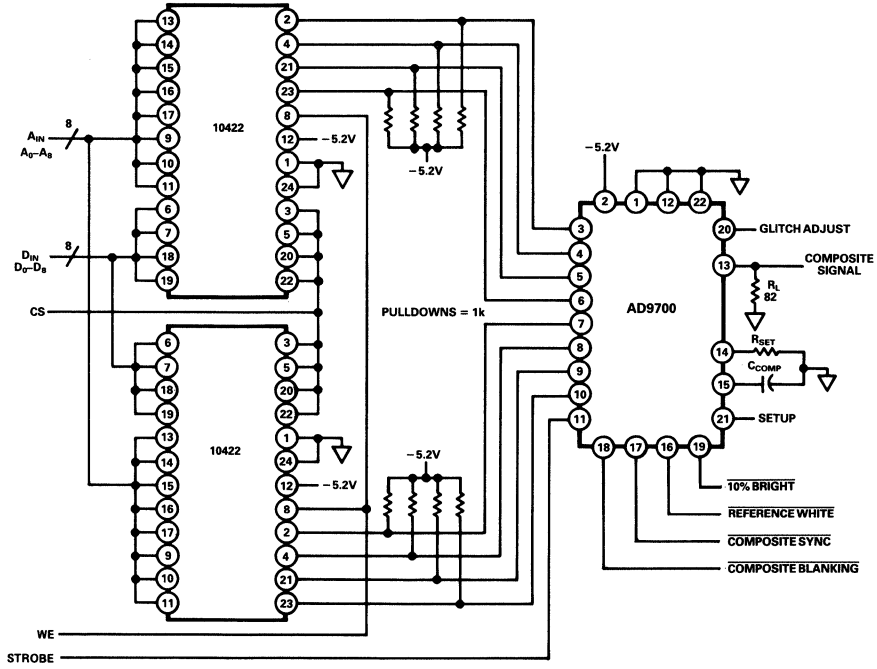

Figure 4. Using the AD9700 with Look-Up Table

USING AD9700 WITH RANDOM ACCESS MEMORY

In many applications, it may be necessary to operate the AD9700 D/A converter with look-up tables (LUT's) for raster scan display applications. One possible way to operate with fast random access memory (RAM) is shown in Figure 4.

If the user is interested in obtaining an RGB video subsystem, the circuit which is shown would be repeated three times. The Address Bus (A_{IN}), Data Bus (D_{IN}), Write enable (WE), and Strobe lines for the three would be connected in parallel. During write operations, the appropriate Chip Select (CS) line would be operated to control which RAM will receive data on the Data Bus.

Data are written into the RAM during an inactive portion of the scan cycle. The full tables can be written during the vertical retrace time; or small blocks of data can be written during the horizontal retrace. Write cycle timing requirements for the 10422 RAM which is illustrated are shown in Figure 5.

The major advantage of the configuration recommended here is realized during the read mode of the RGB system. In the method illustrated in Figure 4, all three D/A converter outputs are updated simply by changing the 8-bit address. Refer to Figure 6.

This illustrates the timing relationships and the intervals for the various operations which occur during the read cycle of the LUT.

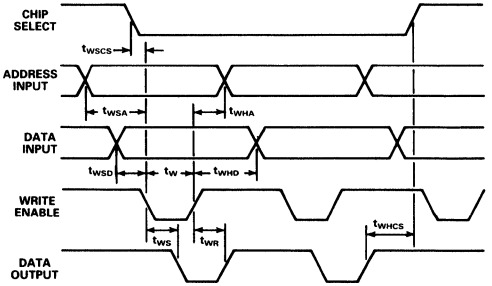

Figure 5. LUT Write Cycle Timing Diagram

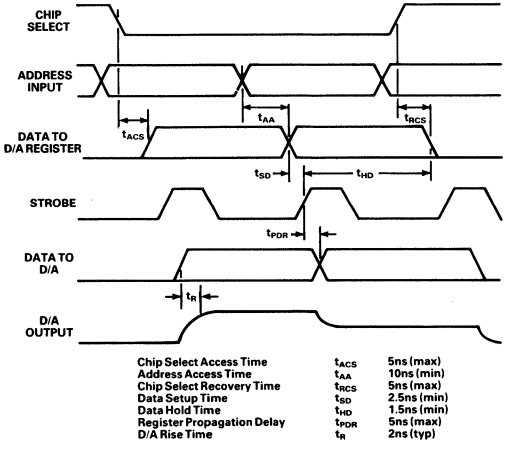

Figure 6. LUT Read Cycle Timing Diagram

ANALOG DEVICES

250MHz Video Digital-to-Analog Converter

AD9701

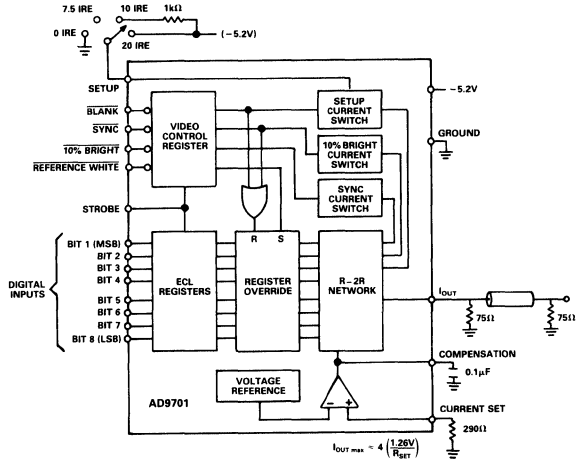
AD9701 FUNCTIONAL BLOCK DIAGRAM



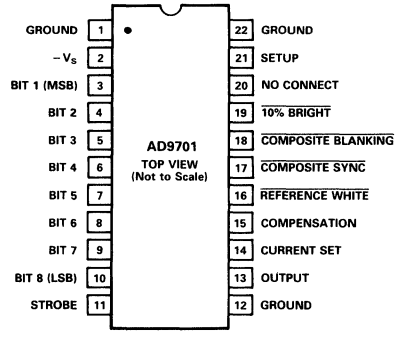
GENERAL DESCRIPTION

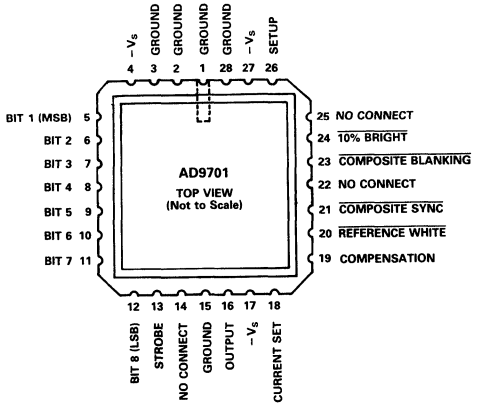
The AD9701 is a high-speed, 8-bit digital-to-analog converter with fully integrated composite video functions. High-speed ECL input registers provide synchronous operation of data and control functions up to 250MHz.

The AD9701 incorporates on-board control functions including horizontal sync, blanking, reference white level, and a 10% bright signal for highlighting. The setup level is also adjustable from 0 IRE units to 20 IRE units, through the control pin. An internal voltage reference allows the AD9701 to operate as a stand-alone video reconstruction DAC.

The AD9701 is available as an industrial temperature range device, −25°C to +85°C, and as an extended temperature range device, −55°C to +125°C. Both grades of the AD9701 are packaged in a 22-pin ceramic DIP, with the extended temperature device also available in a 28-pin LCC package.

PIN CONFIGURATIONS





ORDERING INFORMATION

Device	Temperature Range	Description	Package Options*
AD9701BQ	−25°C to +85°C	22-Pin DIP, Industrial Temperature	D-22
AD9701SE	−55°C to +125°C	28-Pin LCC, Extended Temperature	E-28A
AD9701SQ	−55°C to +125°C	22-Pin DIP, Extended Temperature	D-22

*See Section 14 for package outline information.

NOTES

[1]Absolute maximum ratings are limiting values, to be applied individually, and beyond which serviceability of the circuit may be impaired. Functional operability under any of these conditions is not necessarily implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

[2]Typical thermal impedance . . .
22-Pin Ceramic $\theta_{ja} = 64°C/W$; $\theta_{jc} = 16°C/W$
28-Pin Ceramic LCC $\theta_{ja} = 70°C/W$; $\theta_{jc} = 21°C/W$

[3]SYNC, BLANKING, and REFERENCE WHITE are inactive (Logic "1"). $I_{SET} \approx 1.26V/R_{SET}$.

[4]All bits at logic HIGH.

[5]All values are relative to full-scale output, after being normalized to nominal value. Typical variation in full-scale output from device to device can reach ± 10%, for a fixed R_{SET} resistor.

[6]The effect of 10% BRIGHT algebraically adds to the output waveform.

[7]The output level with BLANKING active (Logic "0"), is determined by the setup control level.

[8]In normal operation, the BLANKING input is activated (Logic "0") prior to or in conjunction with the SYNC input. The effect of the SYNC utput is relative to the setup level.

[9]Measured from edge of STROBE to 50% transition point of the output signal.

[10]Measured with full-scale change in output level, from the 10% transition level to within ± 0.2% of the final output value.

[11]Measured from 10% to 90% transition point for full-scale step output.

[12]An IRE unit is 1% of the Grey Scale (GS range) with a 0 IRE setup level.

[13]Supply Voltage should remain stable within ± 5% for normal operation.

[14]Measured at ± 5% of $-V_S$.

Specifications subject to change without notice.

NOTES
1. Setup (Pin 21) grounded (0 IRE units).
2. Setup (Pin 21) open (7.5 IRE units).
3. Setup (Pin 21) to −5.2V through 1k (0 IRE units).
4. Setup (Pin 21) to −5.2V (20 IRE units).

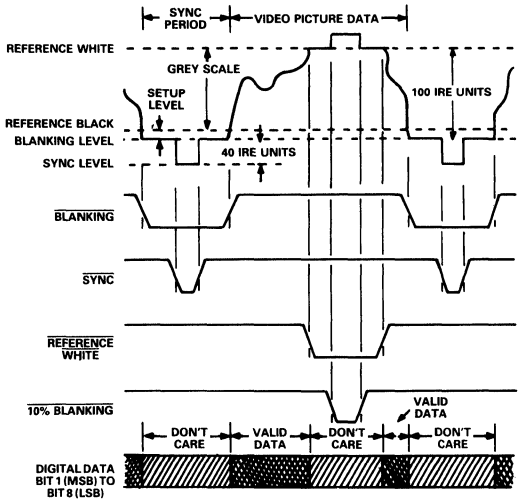
FUNCTIONAL DESCRIPTION

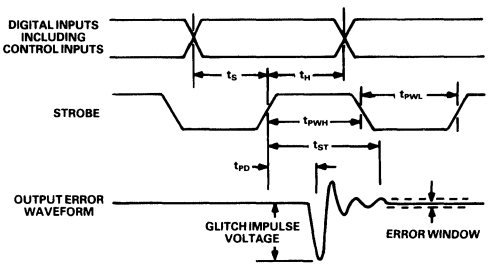
PIN NAME	DESCRIPTION
GROUND	– One of three ground returns. All grounds should be connected together near the AD9701.
$-V_S$	– Negative supply pin, nominally $-5.2V$.
BIT 1 (MSB)	– One of eight digital input bits. BIT 1 (MSB) is the most-significant-bit of the digital input word.
BIT 2 – BIT 7	– One of eight digital input bits.
BIT 8 (LSB)	– One of eight digital input bits. BIT 8 (LSB) is the least-significant-bit of the digital input word.
STROBE	– Data and control register strobe input. STROBE is leading edge triggered.
GROUND	– One of three ground returns. All grounds should be connected together near the AD9701.
SETUP	– The SETUP input determines the position of the blanking level relative to the "reference black" level (all data bits at logic "0"). The setup level is adjustable from 0 IRE units to 20 IRE units below the reference black level (an IRE unit is 1% of the "grey scale" range).

SETUP LEVEL	CONFIGURATION (PIN 21)
0 IRE Units	Ground
7.5 IRE Units	Open
10 IRE Units	Connection to $-5.2V$ through $1k\Omega$
20 IRE Units	Connection to $-5.2V$

$\overline{\text{10\% BRIGHT}}$	– $\overline{\text{10\% BRIGHT}}$ adds an additional current to the output level, equal to roughly 10% of the "grey scale" range. The $\overline{\text{10\% BRIGHT}}$ is active logic LOW, and operates independently of all other inputs.
$\overline{\text{COMPOSITE BLANKING}}$	– The $\overline{\text{COMPOSITE BLANKING}}$ input, active logic LOW, forces output to the blanking level set with the SETUP input.
$\overline{\text{COMPOSITE SYNC}}$	– The $\overline{\text{COMPOSITE SYNC}}$ input, active LOW, creates a negative going horizontal synchronization pulse relative to the blanking level. Under normal operating conditions the $\overline{\text{COMPOSITE BLANKING}}$ signal should precede and extend past the $\overline{\text{COMPOSITE SYNC}}$ signal. See SETUP for additional information.
$\overline{\text{REFERENCE WHITE}}$	– The $\overline{\text{REFERENCE WHITE}}$ input, active LOW, overrides the data inputs, and forces the output to the maximum "grey scale" level.
COMPENSATION	– The COMPENSATION input insures adequate gain stability for the internal reference amplifier. Under normal operating conditions, the COMPENSATION input is decoupled to ground through a $0.1\mu F$ capacitor.
CURRENT SET	– The CURRENT SET input determines the full-scale or "grey scale" range. The effects of the video control functions are in addition to the "grey scale" range. ($168\Omega \leq R_{SET} \leq 600\Omega$). $I_{OUTmax} \approx 4I_{SET} = 4(1.26V/R_{SET})$
OUTPUT	– Analog output.
GROUND	– One of three ground returns. All grounds should be connected together near the AD9701.

SYSTEM TIMING DIAGRAMS

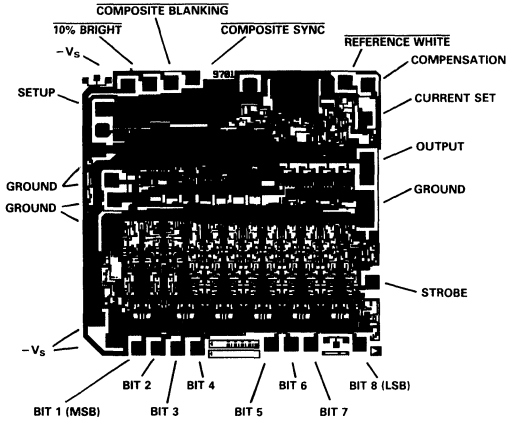




t_S	DIGITAL DATA SETUP TIME
t_H	DIGITAL DATA HOLD TIME
t_{PWH}	STROBE PULSE WIDTH HIGH
t_{PWL}	STROBE PULSE WIDTH LOW
t_{ST}	SETTLING TIME
t_{PD}	MINIMUM PROPAGATION DELAY

NOTES
1. ALL INPUTS, INCLUDING THE VIDEO CONTROL FUNCTIONS, ARE SYNCHRONIZED TO THE STROBE INPUT.
2. THE 10% BRIGHT CONTROL WILL INCREASE THE OUTPUT LEVEL BY APPROXIMATELY 10 IRE UNITS OVER THE PRESENT OUTPUT LEVEL.
3. AN IRE UNIT IS IDEALLY 7.14mV.

DIE LAYOUT AND MECHANICAL INFORMATION



Die Dimensions	107 × 104 × 15 (± 2) mils
Pad Dimensions	4 × 4 mils
Metalization	Aluminum
Backing	None
Substrate Potential	$-V_S$
Passivation	Oxynitride
Die Attach	Gold Eutectic
Bond Wire	1.25 mil Aluminum; Ultrasonic Bonding or 1mil Gold; Gold Ball Bonding

APPLICATIONS INFORMATION

Raster scan video displays image data on a line by line basis, with timing and control signals inserted between the lines. The control signals include the horizontal synchronization pulses which are used to align the display circuitry at the beginning of each line. After the complete video image is displayed on the monitor, the process begins again with the next image. The vertical reset pulse(s) that initiate this timing sequence are located between each video image.

The image data is distinguished from the timing information by its location relative to the blanking level. The blanking reference level is at the blackest extreme of the image data, and all timing signals are designed to fall below the blanking level so as not to be seen on the monitor. The actual image data is located above the blanking level, and it may be further separated from the timing signal by the setup level. The setup level is simply a buffer zone between the timing and image data.

Generation of the timing signals for the AD9701 is controlled by the $\overline{\text{COMPOSITE BLANKING}}$ and the $\overline{\text{COMPOSITE SYNC}}$ inputs. In normal operation the output level of the AD9701 is forced to the blanking level (black) with the $\overline{\text{COMPOSITE BLANKING}}$ control so that when the synchronization occurs, it will not interfere (be seen) with the monitor image. The $\overline{\text{COMPOSITE SYNC}}$ control forces the output level below the blanking level, generating the synchronization pulse.

The "grey scale" is the image intensity range, located above the blanking level by the amount of the setup level. The setup level is "reference black," the darkest displayable picture intensity. The top of the "grey scale" is "reference white," or the brightest picture intensity. As an 8-bit device, the AD9701 divides the "grey scale" into 256 individual levels.

Normal raster scan waveforms divide the region between the blanking level and reference white into 100 IRE units (International Radio Engineers). The setup level can range from 0 to 20 IRE units, but typically is around 10 IRE units, and the synchronization pulse level typically falls 40 IRE units below the blanking level. For the AD9701, the reference white level is 10 IRE units below the full-scale output range ($0mA_{OUT}$).

In terms of priority, the $\overline{\text{REFERENCE WHITE}}$ control overrides the data inputs, but both $\overline{\text{COMPOSITE SYNC}}$ and $\overline{\text{COMPOSITE BLANKING}}$ override the data inputs and the $\overline{\text{REFERENCE WHITE}}$ control. A fourth control is active at all times, $\overline{\text{10\% BRIGHT}}$, which adds approximately 10 IRE units to the output level no matter what the input state of the AD9701. The $\overline{\text{10\% BRIGHT}}$ control is primarily used to highlight areas of the video image.

As with any high-speed device, the AD9701 requires a substantial low impedance ground plane and high quality ground connections to achieve the best performance. Performance can also be improved with adequate power supply decoupling near the supply pins of the AD9701. In ECL mode, the output of the AD9701 is designed to drive 75Ω cable directly, with 75Ω terminations to ground at both ends of the cable. For TTL configurations the output should be terminated to +5.0V through an 82Ω resistor (see circuit below).

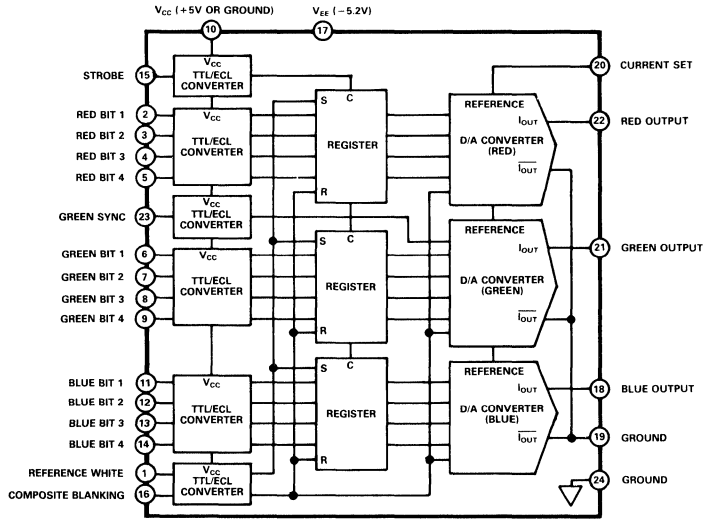
AD9702 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD9702 D/A Converter is a single monolithic IC containing three separate 4-bit digital-to-analog (D/A) converters for red, green, blue (RGB) graphics display applications; 4,096 colors are available to the user. Composite blanking, green sync, and reference white digital control inputs are also included. On-chip data registers and a capability for varying output drive make this a *total* functional solution for graphics displays.

A unique TTL/ECL interface allows the designer a choice of logic compatibility for all inputs; this can be accomplished by applying either +5V or ground to the V_{CC} pin. Internally, the registers and control switching signals operate at ECL logic levels to help assure low glitch impulse at the DAC outputs.

The unit is housed in a 24-pin ceramic package and operates with −5.2V applied for the ECL mode; and −5.2V and +5V for TTL mode. Power dissipation is 1.3 watts for ECL operation and 1.5 watts for TTL.

Monolithic devices are inherently less expensive and more reliable than hybrids. When combined with its small size and outstanding electrical characteristics, these attributes make the AD9702 D/A Converter the first choice for designers of next-generation, medium-resolution displays.

NOTES
[1]Settling to GS percentage includes FS and MSB transitions. Inherent 3ns register delay (50% points) is not included.
[2]Digital "0" at Reference White control input (Pin 1) sets registers; red, green, and blue outputs go to zero.
[3]In "normal operation," GS current or GS voltage outputs for red, green, and/or blue are established by RGB digital inputs.
[4]Digital "0" at Composite Blanking control input (Pin 16) resets registers; value shown is added to full-scale outputs at red, green, and blue outputs. Reference White and Composite Blanking should not be operated simultaneously.
[5]Green Sync control signal (@ Pin 23) affects only Green Output (@ Pin 21); value shown is added to Green Output established by Green digital inputs (and by Composite Blanking if digital "0" is simultaneously applied to Pin 16).
[6]Logic "0" digital inputs applied to D/A under test; full scale step function "toggling" applied to active D/A.
[7]Power supplies should have less than 10mV p-p ripple.
[8]Maximum junction temperature = 150°C.
[9]See Section 14 for package outline information.
Specifications subject to change without notice.

2

THEORY OF OPERATION

Refer to the Block Diagram of the AD9702 D/A Converter.

The digital inputs are applied through TTL/ECL converters to registers within the AD9702; the purpose of the registers is to eliminate time skew from the inputs and help reduce glitch impulse in the output signals. The switching of the inputs through the registers to the three internal D/A converters is controlled by the Strobe, Green Sync, Reference White, and Composite Blanking signals.

When operating with ECL-compatible logic, V_{EE} (−5.2V) is applied to Pin 17 and Pin 10 is connected to ground. Under these conditions, the TTL/ECL converters at the input are transparent to incoming signals and the signals are applied directly to the registers. Regardless of the logic levels of the digital inputs, the registers and control logic internal to the AD9702 are operated at ECL levels to help assure maximum switching speed and minimum glitch on the analog outputs.

For TTL logic, V_{CC} (+5V) is applied to Pin 10 and −5.2V is applied to Pin 17. The positive voltage is used only on the TTL/ECL converters, and adds to the flexibility of the AD9702 by allowing it to be compatible with both forms of logic generally encountered in graphics displays.

There is an alternate method of operating with TTL logic without a need for −5.2V supplies. In this arrangement, Pins 10, 19, and 24 are connected to +5V; and Pin 17 is grounded. In addition, digital inputs (RGB Bits 1 – 4) are connected to +5V through 2k resistors on each input line.

The disadvantage of this technique is that the output is referenced to the +5V supply instead of ground. When this happens, the dc component of the output may exceed the general requirements of RS-170 and RS-343. In addition, any noise which is on the power supply can be coupled directly onto the video signal.

One method of overcoming these potential problems is illustrated in Figure 1, Using AD9702 in TTL Mode.

In this arrangement, the strobe signal is attenuated and shifted positively by a resistor network to minimize feedthrough of the clock signal. The digital input signals do not require the same kind of attenuation because their larger TTL swings do not present any problems.

The pull-up resistors which are used on the inputs help assure proper digital "1" logic levels regardless of which TTL logic family is used.

The PNP level shifter shown at the analog output in Figure 1 eliminates the possible problems of TTL operation cited above. Most of the noise which might be present on the +5V supply is cancelled by common mode rejection in this circuit; and level shifting helps insure the dc component of the output meets video standards.

Minor linearity degradation and temperature drift which might be introduced by the level shifter are not discernible on most video displays. The level shifter circuit is repeated three times for the Red, Green, and Blue analog outputs of the AD9702.

As shown in the block diagram and discussed in the Specifications section, a digital "0" level of the Reference White signal (at Pin 1) is used to set the registers within the converter. This action causes the three (RGB) analog outputs to go to zero output.

The Composite Blanking signal is applied to Pin 16; when a digital "0" level is used, it resets the registers and causes the three analog outputs to be −17.4mA or −653mV because of the amount added to the normal full-scale outputs.

The Green Sync signal at Pin 23 has an effect only on the Green Output of the AD9702 (at Pin 21). When this control and Composite Blanking are at a digital "0" level, the value of the Green analog output will be −25mA or −938mV.

When control inputs Reference White, Composite Blanking, and Green Sync are at digital "1" levels, the RGB analog outputs at Pins 22, 21, and 18 will be a function of their corresponding

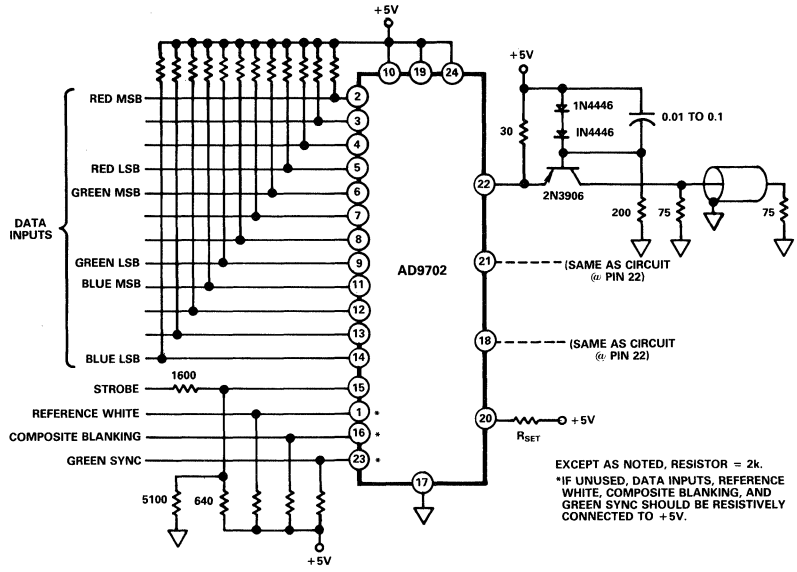

Figure 1. Using AD9702 in TTL Mode (Single Supply)

digital inputs. This is the "normal operation" referred to in the Specifications Table.

Resistor R_{SET} is connected between Pin 20, Current Set, and ground to establish the Gray Scale (GS) value of the RGB outputs. The value to be used is based on the desired full-scale GS output and the following equations:

$$I_{GS} = 5 \times I_{SET}$$

$$R_{SET} = \frac{4.4}{I_{SET}}$$

$$V_{OUT} = \frac{22 \times R_{LOAD}}{R_{SET}}$$

When using these equations, typical values of I_{SET} and V_{OUT} (Gray Scale output) will be within ±5%.

The idealized green analog output is illustrated in Figure 1.

The red and blue analog outputs are similar to the waveform shown in Figure 1, with the exception no sync portion is present on the Red and Blue outputs.

Sync control inputs are not required for Red and Blue outputs because of the RGB signals being synchronized within the AD9702. The majority of applications for the AD9702 in graphics displays use the green sync as the synchronizing signal for the monitor.

ORDERING INFORMATION

The standard AD9702 triple four-bit D/A converter is supplied in hermetic and non-hermetic units. Both versions operate over a case temperature range of −25°C to +85°C. The hermetically-sealed ceramic DIP configuration is model number AD9702BD; the non-hermetic unit is AD9702BW. For special applications or units for military applications, contact the factory for details.

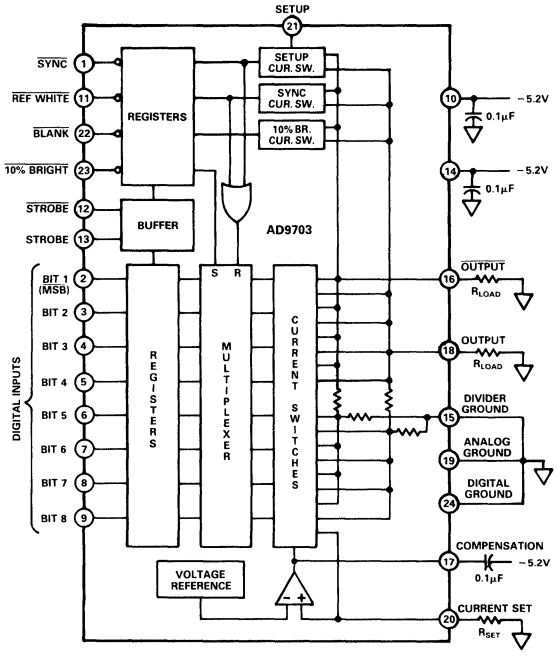
AD9703 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD9703 D/A Converter is a state-of-the-art monolithic digital-to-analog converter capable of accepting 8 bits of digital data at update rates of 300MHz. It is designed specifically for ultra-high-performance, high-resolution raster graphics systems but can also be used for other applications which require low glitch, such as waveform generation.

It comes complete with synchronized composite functions including sync, blank, reference white, and 10% bright. The reference white input forces the analog output to the reference white level regardless of the data inputs. The 10% bright input can be used to generate a white cursor on a white background.

Synchronization of the inputs prevents short or missing pixels. Multiplexing video functions from synchronized inputs eliminates recovery times and the need to reset registers. This unique feature is different from most data input register designs and materially enhances the performance of the AD9703.

An on-board reference eases design effort by eliminating the need for external circuits. Input registers and a differential clock input minimize glitch impulse and clock feedthrough. The unit is housed in a 24-pin DIP and will operate in both 10KH and 100K ECL systems. The AD9703 dissipates 1.1 watts and is truly a "graphics ready" device.

Analog Devices' advanced technology produced the first hybrid converters which included composite capabilities; the AD9703 is one of a series of monolithic graphics DACs made by the company. (The AD9701 is an 8-bit 250MHz device; the AD9702 is a triple 4-bit 125MHz converter.)

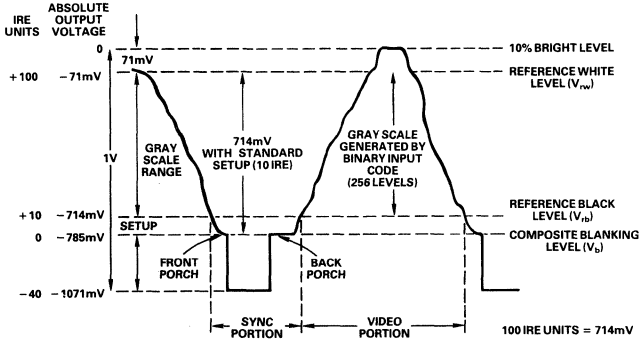
NOTE: CONNECT PINS 15, 19, AND 24 TOGETHER AND TO GROUND AS CLOSE TO CASE AS POSSIBLE.

NOTES
[1]Inherent register delay (50% points) is not included.
[2]Maximum update rate limited by input registers.
[3]FS Current = GS Current + Video Functions = 30mA maximum.
[4]LSB value of 2.5mV used for calibration. This causes Gray Scale output to be 637.5mV, rather than 643mV of idealized composite waveform shown elsewhere. $I_{OUT} = 4(1.26/R_{SET})$ when $R_{SET} = 300\Omega$.
[5]Output voltages based on $R_{LOAD} = 75\Omega \| R_{TERMINATION} = 75\Omega$.
[6]Divider Ground (Pin 15) must be at +3V for +3V compliance. (See text.)
[7]The effect on the analog output of logic "0" at Reference White input (Pin 11) depends on signal at 10% Bright input (Pin 23).
[8]10% Bright, Composite Sync, and Composite Blanking outputs add to analog output.
[9]Composite Sync and/or Composite Blanking signals override input registers. Neither of these signals should be operated simultaneously with Reference White.
[10]Maximum junction temperature is +175°C.
[11]Calculated using MIL HNBK-217; Ground; Fixed; +25°C Ambient.
[12]See Section 14 for package outline information.
Specifications subject to change without notice.



Idealized Composite Output Waveform

USING AD9703 AS RASTER SCAN D/A

Refer to the block diagram of the AD9703. The digital input bits applied to Pins 2 through 9 represent the Gray Scale value of the 256 (2^8) discrete levels between Reference Black and Reference White in a composite video signal.

The (true and complementary) analog outputs are also affected by the 100K or 10KH ECL levels at the control inputs, and the level (in IRE units) of the control signal at SETUP, Pin 21.

STROBE and $\overline{\text{STROBE}}$ signal pulses clock the input registers to remove time skew from the digital input bits and minimize discontinuities or "glitches" in the analog output.

In the idealized waveform, the full-scale output is −643mV. Normal fullscale output of the AD9703, however, is −637.5mV because of using 2.5mV for the weight of the LSB during calibration of the unit. Both values are well within the tolerances of the output and the RS-170 standard.

The internal voltage reference shown in the block diagram is a bandgap type and eliminates the need for external circuits. Other benefits of the internal precision reference include superior power supply rejection and gain tempco.

The value of the internal reference is 1.26 volts (±20mV; ±60mV max), and that knowledge can be combined with information on Gray Scale output current to determine the value of the R_{SET} resistor. R_{SET} is approximately four times the value of the number which results when the reference voltage is divided by the Gray Scale current. Expressed mathematically:

$$R_{SET} \approx 4\left(\frac{1.26V}{I_{OUT}GS}\right)$$

Assume the user's desired Gray Scale voltage is 637.5mV; and the external load is 37.5 ohms. Dividing 637.5mV by 37.5 ohms sets Gray Scale current at 17mA. The reference voltage of 1.26 volts divided by 17mA, and multiplied by four, determines a (rounded) R_{SET} value of 296 ohms.

Full-scale current is Gray Scale current **plus** the video functions and is specified for a **total** of 30mA.

Using the value of R_{SET}, the user can calculate Gray Scale output voltage within 15% with the equation:

$$V_{OUT} = 4\left(\frac{1.26V}{R_{SET}}\right)\left(R_{LOAD} \parallel R_{INTERNAL}\right)$$

The resistance of the internal ladder is 800 ohms in parallel with the load resistor and is included in the above example.

APPLICATION HINTS

In the Specifications, data on $\overline{\text{COMPOSITE BLANKING}}$ assume the SETUP connection is open, equivalent to 7.5 IRE Units. Pin 20 connected to ground is equivalent to 0 IRE Units. Connecting to −5.2V through a 1kΩ resistor is 10 units; connecting to −5.2V directly is 20 units.

For some applications, additional by-pass capacitors for the −5.2V supply lines may be desirable. In addition to the ceramic 0.1μF capacitors shown on the block diagram, tantalum capacitors of 3.3 − 10μF may enhance the converter's performance in some designs. All by-pass capacitors should be connected as closely as possible to the supply pins of the converter.

If the user is driving a lighter load than a coaxial cable and needs lower power dissipation, doubling the value of R_{SET} halves the output current but still maintains useable drive.

Ground pins 15, 19, and 24 are normally connected together and to ground; these connections should also be made close to the unit. Divider Ground must be referenced to +3V to obtain +3V compliance. Figure 1 shows a method of doing this.

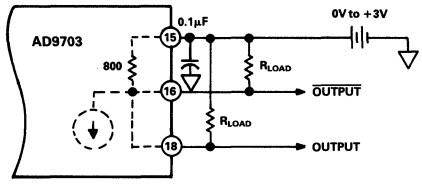


Figure 1. Connection for Positive Voltage Compliance

Values of up to +3V might be applied. Assume R_{LOAD} is 75 ohms. With +1V applied, the output would be ±1V; at +3V, the output would be +1V to +3V.

USING AD9703 AS STANDARD D/A

The AD9703 can also be used as a standard D/A converter capable of remarkable performance; it is attractive for that application because of the low value of glitch impulse.

Refer to Figure 2.

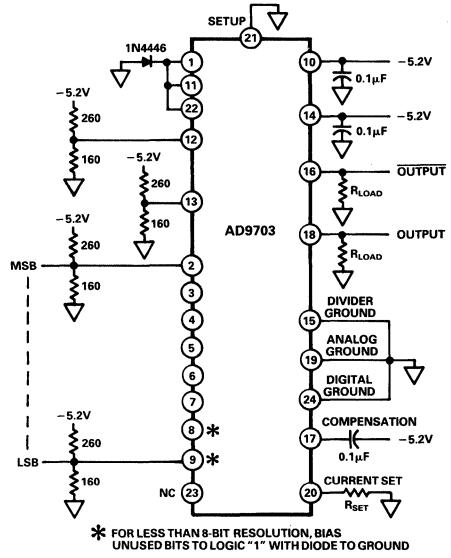

Figure 2. AD9703 as Standard D/A

As a standard D/A, unused control inputs are tied to ground via a diode as shown on Pins 1, 11, and 22. The $\overline{\text{10\% Bright}}$ input (Pin 23) is left open; and Setup (Pin 21) is tied directly to ground. For less than eight bits of data, unused input pins are also grounded via diodes.

ORDERING INFORMATION

Three versions of the AD9703 are available, all in ceramic DIP packages. The non-hermetic AD9703BW and hermetic AD9703BD operate over a temperature range of −25°C to +85°C. The hermetic AD9703TD and mil-processed AD9703TDB are for −55°C to +125°C.

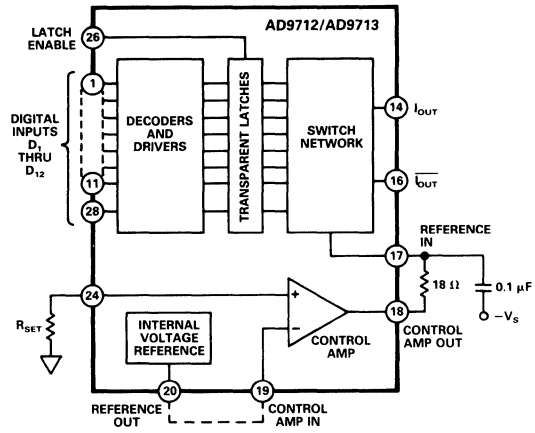
12-Bit, 100 MSPS D/A Converters

AD9712/AD9713

FEATURES
100 MSPS Update Rate
ECL/TTL Compatibility
Low Glitch Impulse: 100 pV–s
Fast Settling: 30 ns to ±1 LSB
Low Power: 700 mW

APPLICATIONS
ATE
Signal Reconstruction
Arbitrary Waveform Generators
Digital Synthesizers
Signal Generators

AD9712/AD9713 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD9712 and AD9713 are 12-bit, high speed digital-to-analog converters constructed in an advanced oxide isolated bipolar process. The AD9712 is an ECL-compatible device featuring update rates of 100 MSPS minimum; the TTL-compatible AD9713 will update at 80 MSPS minimum.

Designed for direct digital synthesis, waveform reconstruction, and high resolution imaging applications, both devices feature low glitch impulse of 100 pV-s; and fast settling times of 30 ns to ±1 LSB. Both units are characterized for dynamic performance, and have excellent harmonic suppression.

The AD9712 and AD9713 are available in 28-pin plastic DIPs and PLCCs, with an operating temperature range of 0 to +70°C. Contact the factory for availability of military-grade devices.

NOTES

[1]Absolute maximum ratings are limiting values to be applied individually, and beyond which the serviceability of the circuit may be impaired. Functional operability is not necessarily implied. Exposure to absolute maximum rating conditions for an extended period of time may affect device reliability.

[2]Typical thermal impedances: 28-pin plastic DIP θ_{JA} = 42°C/W; θ_{JC} = 7°C/W; 28-pin PLCC θ_{JA} = 48°C/W; θ_{JC} = 10°C/W.

[3]Measured as error of the ratio of full-scale current to current through R_{SET} (160 μA nominal); ratio is nominally 128.

[4]Full-scale variations among devices are more severe when driving REFERENCE IN directly.

[5]Frequency at which a 3 dB reduction in output of DAC is observed; R_L = 50 Ω; 50% modulation at midscale.

[6]Based on $I_{FS} = 128 (V_{REF}/R_{SET})$ when using internal amplifier.

[7]Output settling to 0.1%.

[8]Measured at midscale transition, to ±0.024%.

[9]Measured from falling edge of LATCH ENABLE signal to 50% point of full-scale transition.

[10]Glitch impulse combines the absolute value of positive and negative transitions operating in latched mode.

[11]Measured with R_L = 50 Ω and DAC operating in latched mode.

[12]Data must remain stable prior to falling edge of LATCH ENABLE signal for specified time.

[13]Data must remain stable after rising edge of LATCH ENABLE signal for specified time.

[14]Update rate ≤50 MSPS; output frequency = 5 MHz.

[15]Supply voltages should remain stable within ±5% for normal operation.

[16]Measured at ±5% of $+V_S$ (AD9713 only) and $-V_S$ (AD9712 or AD9713) using external reference.

Specifications subject to change without notice.

EXPLANATION OF TEST LEVELS

Level

I – 100% production tested.

II – 100% production tested at +25°C, and sample tested at specified temperatures.

III – Sample tested only.

IV – Parameter is guaranteed by design and characterization testing.

V – Parameter is a typical value only.

VI – All devices are 100% production tested at +25°C. 100% production tested at temperature extremes for extended temperature devices; sample tested at temperature extremes for commercial/industrial devices.

AD9712/AD9713 PIN DESCRIPTIONS

Pin No.	Name	Function
1–10	D_2–D_{11}	Ten of twelve digital input bits.
11	D_{12} (LSB)	Least Significant Bit (LSB) of digital input word.
12	DIGITAL $-V_S$	One of two negative digital supply pins; nominally −5.2 V.
13	ANALOG RETURN	Analog ground return. This point and the reference side of the DAC load resistors should be connected to the same potential (nominally ground).
14	I_{OUT}	Analog current output; full-scale output occurs with digital inputs at all "1."
15	ANALOG $-V_S$	One of two negative analog supply pins; nominally −5.2 V.
16	$\overline{I_{OUT}}$	Complementary analog current output; zero scale output occurs with digital inputs at all "1."
17	REFERENCE IN	Normally connected to CONTROL AMP OUT (Pin 18). Direct line to DAC current switch network. Voltage changes at this point have a direct effect on the full-scale output. Full-scale current output = 128 (Reference voltage/R_{SET}) when using internal amplifier.
18	CONTROL AMP OUT	Normally connected to REFERENCE IN (Pin 17). Output of internal control amplifier, which provides a temperature compensated drive level to the current switch network.
19	CONTROL AMP IN	Normally connected to REFERENCE OUT (Pin 20) if not connected to external reference. Full-scale current out = 128 (Reference voltage/R_{SET}) when using internal amplifier.
20	REFERENCE OUT	Normally connected to CONTROL AMP IN (Pin 19). Internal voltage reference, nominally −1.26 V.
21	DIGITAL $-V_S$	One of two negative digital supply pins; nominally −5.2 V.
22	REFERENCE GROUND	Ground return for the internal voltage reference and amplifier.
23	DIGITAL $+V_S$	Positive digital supply pin; used only on the AD9713; nominally +5 V.
24	R_{SET}	Connection for external resistance reference. Full-scale current out = 128 (Reference voltage/R_{SET}) when using internal amplifier.
25	ANALOG $-V_S$	One of two negative analog supply pins; nominally −5.2 V.
26	LATCH ENABLE	Transparent latch control line.
27	DIGITAL GROUND	Digital ground return.
28	D_1 (MSB)	Most Significant Bit (MSB) of digital input word.

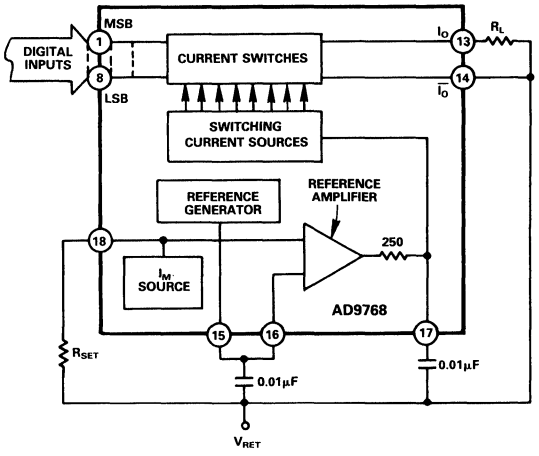
ECL-Compatible
40MHz Multiplying Mode

APPLICATIONS
Raster Scan & Vector Graphic Displays
High Speed Waveform Generation
Digital VCOs
Ultra-Fast Digital Attenuators

AD9768 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The Analog Devices AD9768SD D/A converter is a monolithic current-output converter which can accept 8 bits of ECL-level digital input voltages and convert them into analog signals at update rates as high as 100MHz. In addition to its use as a standard D/A converter, it can also be utilized as a two-quadrant multiplying D/A at multiplying bandwidths as high as 40MHz.

An inherently low glitch design is used, and the complementary current outputs are suitable for driving transmission lines directly. Nominal full-scale output is 20mA, which corresponds to a 1-volt drop across a 50Ω load, or ±1 volt across 100Ω returned to +1 volt. The actual output current is determined by the on-chip reference voltage ($V_{REF} \approx -1.26V$) and an external current setting resistor, R_{SET}.

Full-scale output current I_{OUT} with digital "1" at all inputs is calculated with the equation:

$$I_{OUT} = 4 \times \frac{V_{RET} - V_{REF}}{R_{SET}}$$

The setting resistor R_{SET} and the output load resistor should both have low temperature coefficients. A complementary $\overline{I_{OUT}}$ is also provided.

The reference voltage source is a modified bandgap type and is nominally −1.26 volts. This reference supply requires no external regulation. To reduce the possibility of noise generation and/or instability, pin 15 (REFERENCE OUT) can be decoupled using a high-quality ceramic chip capacitor. Stabilization of the internal loop amplifier is by a single capacitor connected from pin 17 (COMPENSATION) to ground. The minimum value for this capacitor is 3900pF, although a 0.01μF ceramic chip capacitor is recommended.

The incredible speed characteristics of the AD9768SD D/A converter make it attractive for a wide range of high speed applications. The ability of the unit to operate as a two-quadrant multiplying D/A converter adds another dimension to its usefulness and makes the AD9768SD a truly versatile device.

AD9768SD D/A Schematic

THEORY OF OPERATION

Refer to the AD9768SD schematic.

The transistors pictured on the bottom of the diagram, connected to paired transistors in the middle of the schematic, are current sources which are always "on". The paired transistors are differential current switches, designed to steer current from the current sources to either pin 13 (I_O) or pin 14 ($\overline{I_O}$).

Digital inputs applied to pins 1-8 determine which transistors will be operating in each pair and establish what current will flow at pins 13 and 14.

The transistor on the extreme left of the schematic is a base reference for the paired current switches and is used to assure the switches will be centered around an ECL voltage swing. The diodes connected to the base of this transistor are temperature compensation devices for the base reference circuit.

There are three different current sources in the AD9768 D/A. The eight transistors shown on the bottom of the schematic are structured as two identical groups of four current sources, each of which is binarily weighted. The MSB group, comprised of the four on the right, is connected to the LSB group through a 15:1 current divider made up of two 50Ω and two 750Ω resistor networks. The geometry of the AD9768 guarantees the binary weighing ratios among the 100, 200, 400 and 800 resistors in each emitter circuit are correct.

The resistor values which are shown indicate the ratios among the resistors, and not their nominal values.

The third current source is a single transistor, pictured in the lower left portion of the schematic with its collector connected to pin 18 R_{SET}. Its function is to help establish the base voltage on the eight current sources; it works in conjunction with the external R_{SET} resistor selected by the user of the AD9768, and the reference amplifier. Current flowing through this transistor is referred to as I_M in the figures and test.

When the AD9768 is operating as a conventional current-output D/A converter, I_M develops a voltage across R_{SET} which is one of the inputs to the on-board reference amplifier shown in the schematic. The other input to this amplifier is the on-chip reference voltage of −1.26 volts.

The output of the reference amplifier adjusts the current-source base reference voltage at pin 17; this, in turn, adjusts the value of I_M in the single-transistor current source and causes it to develop a voltage across R_{SET} which maintains pin 18 at the −1.26 volts of the on-chip reference supply.

To maintain good stability in the internal loop reference amplifier, a ceramic chip capacitor with a nominal value of 0.01μF should be connected to pin 17 COMPENSATION; minimum recommended value for this capacitor is 3900pF.

The temperature coefficient of the load resistor (R_L) can affect the performance of the AD9768 D/A converter, as it can with any current-output converter. The design and use of the AD9768 and its dependence on an external R_{SET} resistor, however, make it sensitive also to the tempco of R_{SET}. The user is cautioned to select R_L and R_{SET} resistors which have low temperature coefficients.

DIGITAL GROUND (pin 11) and ANALOG RETURN (pin 12) are normally connected together; this connection should be made as close as possible to the device case to minimize possible noise problems. The AD9768 D/A is similar to any other high-speed, high performance device: optimum use requires careful attention to all design details, including the layout of the circuit in which the converter is used.

CONVENTIONAL AD9768

Refer to Figure 1, Conventional AD9768SD.

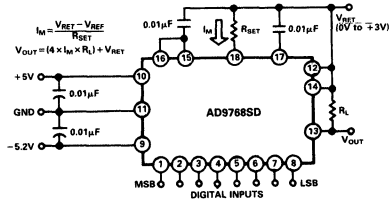

Figure 1. Conventional AD9768SD

The output current of the AD9768 appears at pin 13 (I_O) and develops a voltage across the load resistor R_L which is based on:

A. I_M (the current flowing through the single-transistor source discussed above)
B. Value of R_L

I_M is a function of the return voltage (V_{RET}), the reference voltage (V_{REF}), and the value of R_{SET}; all of these are selected by the user for his application. The necessary equations for calculating precise values for each are part of Figure 1. As indicated,

the voltage drop across R_L is added to the return voltage; the resulting voltage is the total V_{OUT} of the converter.

VOLTAGE MULTIPLYING MODE

In addition to its use as an ultra-high speed current output D/A converter, the AD9768 can also be used as a two-quadrant multiplying D/A in either a voltage mode or a current mode.

Refer to Figure 2, Multiplying AD9768 (Voltage Mode).

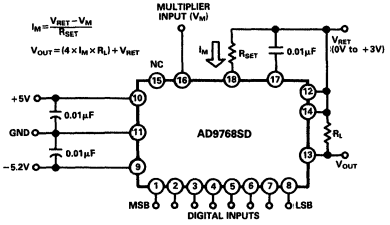

Figure 2. Multiplying AD9768 (Voltage Mode)

When operating in this mode, the analog output of the AD9768 is influenced by the digital inputs and an external multiplying voltage (V_M) applied to pin 16 REFERENCE IN, which takes the place of the internal reference used when the D/A is operating in a conventional manner.

The value of I_M flowing through R_{SET} is set by the voltage of V_{RET} minus the multiplying voltage (V_M), divided by R_{SET}; the amount of this current is part of the equation which establishes the analog output (V_{OUT}) of the AD9768 and is chosen by the user for his application. As it is when operating the D/A in a conventional fashion, V_{RET} can be any value between 0 volts and +3 volts. V_M (for purposes of discussion here) is some negative voltage and can be varied over a range which is approximately 1 volt peak-to-peak.

If the load resistor (R_L) has a value of 50 ohms, if R_{SET} has a value of 220 ohms, and if V_{RET} is 0V, the center of the V_M voltage will be −0.6V; and it can vary from −0.1V to −1.1V. Typically, the frequency of these variations has an upper limit of 250kHz when operating in the voltage multiplying mode; that frequency is the 3dB point of the bandwidth of the internal reference amplifier.

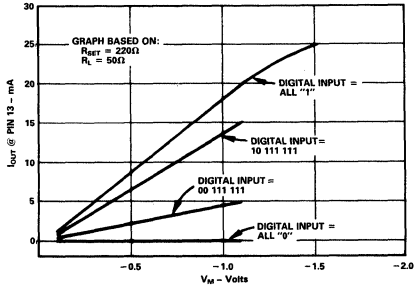

Figure 3. I_{OUT} vs. Multiplying Voltage

The combined effects of variations in V_M and changes in digital input values are shown in Figure 3, I_{OUT} vs. Multiplying Voltage. In this illustration, the ordinate of the graph is expressed in terms of milliamps of I_{OUT} current at pin 13. V_{OUT}, of course, will be a function of the value of R_L chosen by the user.

The negative value of V_M on the horizontal axis is shown starting at approximately −0.1V, rather than 0V, because the AD9768 must have some small value of voltage applied to perform a multiplying function. For the conditions shown in the figure, output current starts to become nonlinear at approximately 20mA because of the maximum 30mA output drive capabilities of the device. Different values for R_{SET} and R_L would alter the point where limiting first appears.

CURRENT MULTIPLYING MODE

The AD9768 D/A converter can be operated at markedly higher multiplying rates when operated in a current-multiplying mode, as contrasted with the voltage-multiplying mode. Refer to Figure 4, Multiplying AD9768SD (Current Mode).

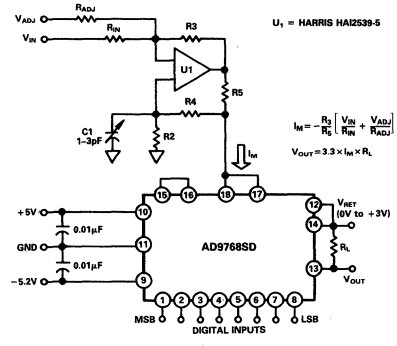

Figure 4. Multiplying AD9768SD (Current Mode)

In this mode, the internal reference amplifier and its inherent frequency limitations are replaced by a current source comprised of U1 and associated circuits. These circuits supply a unipolar current I_M which is one-fourth the full-scale output current (with digital "1" applied to all inputs) and set current flow through the load resistor.

V_{IN} is some voltage chosen by the user for his particular application; the value of this voltage is based in part on the size of the load resistor and the 0mA to 5mA range of I_M. V_{IN} can have frequency components as high as 40MHz. V_{ADJ} and R_{ADJ} provide an offset adjustment to compensate for the dc component of V_{IN} to assure I_M is always a unipolar current between 0mA and 5mA. The values of the required voltages and resistors can be calculated using the equations which are part of Figure 4.

Refer to Figure 5, I_{OUT} vs. Multiplying Current.

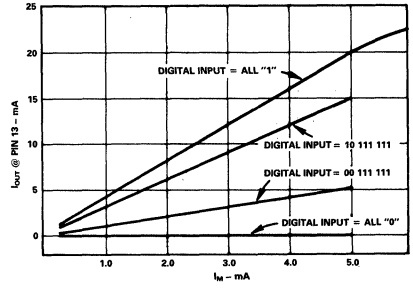

Figure 5. I_{OUT} vs. Multiplying Current

As shown, I_M can vary over the range of 0mA to 5mA; a value of approximately 0.3mA may be the practical lower limit because of nonlinearities at extremely small current levels. These changes in I_M are combined with variations in digital inputs, producing complex changes in the output current (at pin 13) and in V_{OUT}. The "rounding" of the current curve in the graph is the result of I_{OUT} approaching the 30mA maximum drive capabilities of the AD9768 and needs to be taken into account to assure optimum performance in the selected application.

ANALOG DEVICES

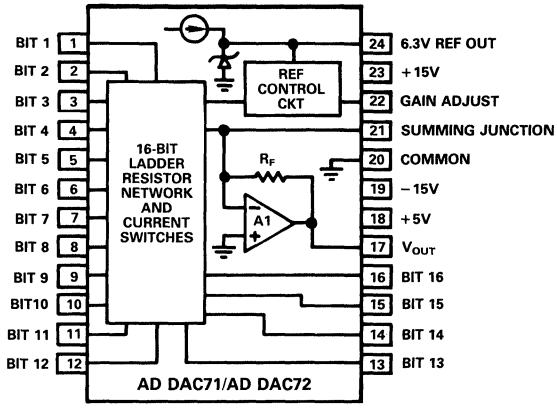
High Resolution 16-Bit D/A Converters

AD DAC71/AD DAC72*

FEATURES

16-Bit Resolution
±0.003% Maximum Nonlinearity
Low Gain Drift ±7ppm/°C
0 to +70°C Operation (AD DAC71, AD DAC71H, AD DAC72C)
−25°C to +85°C Operation (AD DAC72)
Current and Voltage Models Available
Improved Second-Source
Low Cost

AD DAC71/AD DAC72 FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD DAC71 and AD DAC72 are high resolution 16-bit hybrid IC digital-to-analog converters including reference, scaling resistors and output amplifier (V models).

The devices offer outstanding accuracy, including maximum linearity error of 0.003% at room temperature and maximum gain drifts of 15ppm/°C (AD DAC71, AD DAC71H, AD DAC72C) and 7ppm/°C (AD DAC72). This performance is possible due to the innovative design, using proprietary monolithic D/A converter chips. Laser-trimmed thin film resistors provide the linearity and wide temperature range for guaranteed monotonicity.

The AD DAC71 and AD DAC72 digital inputs are TTL-compatible. Coding is complementary straight binary (CSB) for unipolar output versions and complementary offset binary (COB) for bipolar output versions.

All versions are packaged in a 24-pin metal DIP. The AD DAC71, AD DAC71H and AD DAC72C are specified for operation from 0 to +70°C, and the AD DAC72 is specified from −25°C to +85°C. The AD DAC71H, AD DAC72 and AD DAC72C are supplied in hermetically-sealed packages.

The AD DAC71 and AD DAC72 are intended to serve as improved second sources to DAC71 and DAC72 devices from other manufacturers.

PRODUCT HIGHLIGHTS

1. The AD DAC71 and AD DAC72 provide 16-bit resolution with 0.003% linearity error.
2. The proprietary chips used in the hybrid design provide excellent stability over temperature and improved reliability.
3. Unipolar and bipolar current and voltage output versions are available to fill a wide range of system requirements.
4. The AD DAC71 and AD DAC72 are improved second source replacements for DAC71 and DAC72 devices from other manufacturers.

NOTES
[1]Adding external CMOS hex buffers CD4009A will provide 15V dc CMOS input compatibility.
[2]Accuracy is specified when using internal feedback resistors. Current output specifications are guaranteed at the voltage output of an external op amp using the internal feedback resistor.
[3]FSR means Full Scale Range and is 20V for ±10V range.
[4]Adjustable to zero with external trim potentiometer.
[5]With gain and offset errors adjusted to zero at 25°C.
[6]LSB is for 14-bit resolution.
[7]Parameter guaranteed, not tested.
[8]Maximum with no degradation of specification.

Specifications subject to change without notice.

*See Section 14 for package outline information.

PRESERVING THE ACCURACY OF THE AD DAC71 AND AD DAC72

A great deal of care must be exercised when using high resolution converters such as the AD DAC71 and AD DAC72. Since one least significant bit of a 16-bit converter (LSB) represents an analog voltage of only 153 microvolts out of a 10V scale, normally negligible error sources become significant. Series resistances of connectors and wiring can be major contributors, as can thermocouple effects. Figure 3 illustrates the connections for voltage output versions of the AD DAC71 and AD DAC72.

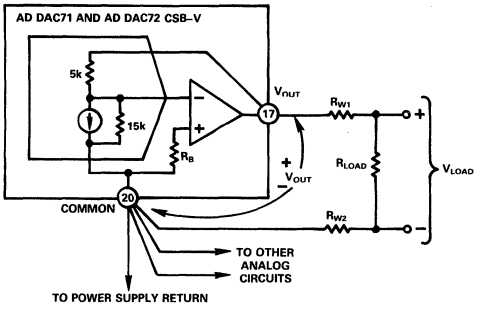

Figure 3. AD DAC71 and AD DAC72 Connection Diagram (Voltage Models)

In this circuit, the analog output voltage is accurately developed between pin 17 and pin 20 of the DAC. The voltage measured at the load will be inaccurate if there is significant resistance in the wiring (and any connectors) between the DAC and the load. If the load resistance is constant, the effects of R_{W1} and R_{W2} can be treated as a simple gain error, and can be trimmed out. However, if R_L is variable, then R_{W1} and R_{W2} should be reduced to a value less than $\frac{R_{L\ MIN}}{2^{16}}$. This will reduce the effect of the wiring resistances to a gain error of less than 1LSB. The AD DAC71 and AD DAC72 are rated at an output current of 5mA which translates to a minimum load resistance of 2kΩ. Thus wiring resistances should be held to a maximum of 30 milliohms. This corresponds to approximately six inches of #28 wire or a six inch long printed circuit track 0.050 inches wide.

The current output versions of the AD DAC71 and AD DAC72 use an external operational amplifier to convert the output current to an output voltage. The recommended configuration is shown in Figure 4. Notice that this configuration permits the voltage at the load to the sensed remotely. The resistance (R_{W1}) of the lead connecting the load to the internal feedback resistor introduces a gain error equal to $\frac{R_{W1}}{R_{LOAD}}$, independent of R_{LOAD} and R_{W2}. The error contributed by R_{W3} depends upon where the output is measured. If the output is measured between the top of R_{LOAD} and pin 20 of the DAC, no error results since R_{W3} effectively becomes part of the load resistance.

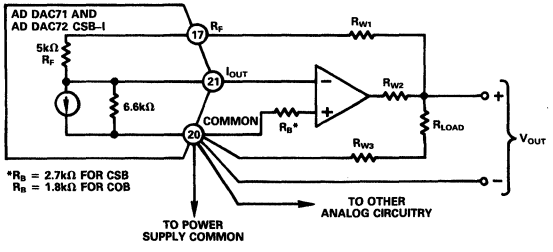

Figure 4. Connections for AD DAC71 and AD DAC72 Current Output Versions

In applications where R_{W3} is large or large currents flow in R_{W3}, it is necessary to use remote sensing as shown in Figure 5.

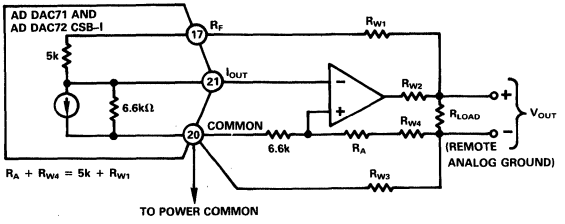

Figure 5. Use of Output Amplifier as Subtractor for Remote Ground Sensing

This circuit uses the output amplifier as a subtractor stage. Any spurious voltage developed across R_{W3} becomes a common mode voltage and its error contribution is reduced by the common mode rejection of the op amp.

In the circuits of both Figure 4 and Figure 5, R_{W2}'s effect is negligible since it is inside the loop of the amplifier. If current boosting is required in order to drive heavy loads, a suitable booster stage can be inserted between the amplifier's output and the load. Since the loop is closed from the load end, offsets and other errors induced by the booster are eliminated.

It is also important to minimize thermocouple effects in circuitry using the AD DAC71 and AD DAC72. Recalling that 1LSB of a 16 bit, 10 volt scale converter is only 153 microvolts, a stray uncompensated thermocouple can introduce several LSBs of offset in response to minor changes in ambient temperature. Any part of a circuit which includes a junction between two dissimilar metals forms a thermocouple. Such junctions include connectors, sockets, and any soldered connections. The solution to thermocouple errors is to insure that every junction is cancelled by an identical, but opposite, junction at the same temperature. While this is often automatically accomplished (for example, in a connector carrying both signal and return leads), careful attention should be given to the physical layout of circuits using the AD DAC71 and AD DAC72.

Another source of signal degradation in high-resolution converter circuits is magnetically-coupled interference from stray fields. Signal and return leads should be arranged in a way which minimizes both length and the total cross-section area of the loop. Of course, high resolution circuits should be located as far as possible from any sources of electromagnetic interference, including power transformers, digital logic and electromechanical devices.

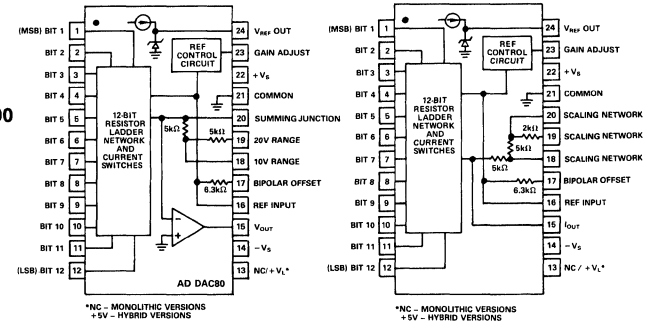
Complete Low Cost 12-Bit D/A Converters

AD DAC80/AD DAC85/AD DAC87

FEATURES

- Single Chip Construction
- On-Board Output Amplifier
- Low Power Dissipation: 300mW
- Monotonicity Guaranteed over Temperature
- Guaranteed for Operation with ±12V Supplies
- Improved Replacement for Standard DAC80, DAC800 HI-5680
- High Stability, High Current Output Buried Zener Reference
- Laser Trimmed to High Accuracy: ±1/2LSB max Nonlinearity
- Low Cost Plastic Packaging

AD DAC80 SERIES FUNCTIONAL BLOCK DIAGRAMS



PRODUCT DESCRIPTION

The AD DAC80 Series is a family of low cost 12-bit digital-to-analog converters with both a high stability voltage reference and output amplifier combined on a single monolithic chip. The AD DAC80 Series is recommended for all low cost 12-bit D/A converter applications where reliability and cost are of paramount importance.

Advanced circuit design and precision processing techniques result in significant performance advantages over conventional DAC80 devices. Innovative circuit design reduces the total power consumption to 300mW which not only improves reliability but also improves long term stability.

The AD DAC80 incorporates a fully differential, non-saturating precision current switching cell structure which provides greatly increased immunity to supply voltage variation. This same structure also reduces nonlinearities due to thermal transients as the various bits are switched; nearly all critical components operate at constant power dissipation. High stability, SiCr thin film resistors are trimmed with a fine resolution laser, resulting in lower differential nonlinearity errors. A low noise, high stability, subsurface Zener diode is used to produce a reference voltage with excellent long term stability, high external current capability and temperature drift characteristics which challenge the best discrete Zener references.

The AD DAC80 Series is available in three performance grades and two package types. The AD DAC80 is specified for use over the 0 to +70°C temperature range and is available in both plastic and ceramic DIP packages. The AD DAC85 and AD DAC87 are available in hermetically sealed ceramic packages and are specified for the −25°C to +85°C and −55°C to +125°C temperature ranges.

PRODUCT HIGHLIGHTS

1. The AD DAC80 series of D/A converters directly replaces all other devices of this type with significant increases in performance.
2. Single chip construction and low power consumption provides the optimum choice for applications where low cost and high reliability are major considerations.
3. The high speed output amplifier has been designed to settle within 1/2LSB for a 10V full scale transition in 2.0μs, when properly compensated.
4. The precision buried Zener reference can supply up to 2.5mA for use elsewhere in the application.
5. The low TC binary ladder guarantees that all units are monotonic over the specified temperature range.
6. System performance upgrading is possible without redesign.

PRODUCT OFFERING

Analog Devices has developed a number of technologies to support products within the data acquisition market. In serving the market new products are implemented with the technology best suited to the application. The DAC80 series of products was first implemented in hybrid form and now it is available in a single monolithic chip. We will provide both the hybrid and monolithic versions of the family so that in existing designs changes to documentation or product qualification will not have to be done. Specifications and ordering information for both versions are delineated in this data sheet.

NOTES

[1]Least Significant Bit.

[2]Adjustable to zero with external trim potentiometer.

[3] FSR means "Full Scale Range" and is 20V for the ±10V range and 10V for the ±5V Range.

[4]Gain and offset errors adjusted to zero at +25°C.

[5]C_F = 0, see Figure 1a.

[6]Maximum with no degradation of specification, must be a constant load.

[7]A minimum of ±12.3V is required for a ±10V full scale output and ±11.4V is required for all other voltage ranges.

Specifications subject to change without notice.

Specifications shown in boldface are tested on all production units at final electrical test. Results from those tests are used to calculate outgoing quality levels. All min and max specifications are guaranteed, although only those shown in boldface are tested on all production units.

DIGITAL INPUT CODES

The AD DAC80 Series accepts complementary digital input code in binary (CBI) format. The CBI model may be connected by the user for anyone of three complementary codes: CSB, COB or CTC.

Digital Input		Analog Output		
MSB	LSB	CSB Compl. Straight Binary	COB Compl. Offset Binary	CTC* Compl. Two's Compl.
0 0 0 0 0 0 0 0 0 0 0 0		+ Full Scale	+ Full Scale	− 1LSB
0 1 1 1 1 1 1 1 1 1 1 1		+ 1/2 Full Scale	Zero	− Full Scale
1 0 0 0 0 0 0 0 0 0 0 0		Mid-Scale	− 1LSB	+ Full Scale
1 1 1 1 1 1 1 1 1 1 1 1		Zero	− Full Scale	Zero

*Invert the MSB of the COB code with an external inverter to obtain CTC code.

Table I. Digital Input Codes

ACCURACY

Accuracy error of a D/A converter is the difference between the analog output that is expected when a given digital code is applied and the output that is actually measured with that code applied to the converter. Accuracy error can be caused by gain error, zero error, linearity error, or any combination of the three. Of these three specifications, the linearity error specification is the most important since it cannot be corrected. Linearity error is specified over its entire temperature range. This means that the analog output will not vary by more than its maximum specification, from an ideal straight line drawn between the end points (inputs all "1"s and all "0"s) over the specified temperature range.

Differential linearity error of a D/A converter is the deviation from an ideal 1LSB voltage change from one adjacent output state to the next. A differential linearity error specification of ± 1/2LSB means that the output voltage step sizes can range from 1/2LSB to 1 1/2LSB when the input changes from one adjacent input state to the next.

DRIFT

Gain Drift is a measure of the change in the full scale range output over temperature expressed in parts per million of full scale range per °C (ppm of FSR/°C). Gain drift is established by: 1) testing the end point differences for each AD DAC80 model at the lowest operating temperature, + 25°C and the highest operating temperature; 2) calculating the gain error with respect to the + 25°C value and; 3) dividing by the temperature change.

Offset Drift is a measure of the actual change in output with all "1"s on the input over the specified temperature range. The maximum change in offset is referenced to the offset at + 25°C and is divided by the temperature range. This drift is expressed in parts per million of full scale range per °C (ppm of FSR/°C).

SETTLING TIME

Settling time for each model is the total time (including slew time) required for the output to settle within an error band around its final value after a change in input.

Voltage Output Models. Three settling times are specified to ± 0.01% of full scale range (FSR); two for maximum full scale range changes of 20V, 10V and one for a 1LSB change. The 1LSB change is measured at the major carry (0 1 1 1 . . . 1 1 to 1 0 0 0 . . . 0 0), the point at which the worst case settling time occurs. The settling time characteristic depends on the compensation capacitor selected, the optimum value is 25pF as shown in Figure 1a.

Current Output Models. Two settling times are specified to ± 0.01% of FSR. Each is given for current models connected with two different resistive loads: 10 to 100 ohms and 1000 to 1875 ohms. Internal resistors are provided for connecting nominal load resistances of approximately 1000 to 1800 ohms for output voltage ranges of ± 1V and 0 to − 2V.

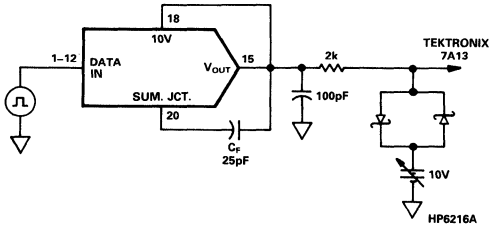

Figure 1a. Voltage Model Settling Time Circuit

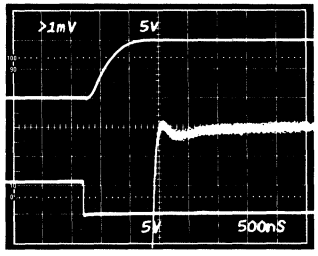

Figure 1b. Voltage Model Settling Time C_F = 25pF

POWER SUPPLY SENSITIVITY

Power supply sensitivity is a measure of the effect of a power supply change on the D/A converter output. It is defined as a per cent of FSR per per cent of change in either the positive or negative supplies about the nominal power supply voltages.

REFERENCE SUPPLY

All models are supplied with an internal 6.3 volt reference voltage supply. This voltage (pin 24) is accurate to ± 1% and must be connected to the Reference Input (pin 16) for specified operation. This reference may also be used externally with external current drain limited to 2.5mA. An external buffer amplifier is recommended if this reference is to be used to drive other system components. Otherwise, variations in the load driven by the reference will result in gain variations. All gain adjustments should be made under constant load conditions.

ANALYZING DEVICE ACCURACY OVER THE TEMPERATURE RANGE

For the purposes of temperature drift analysis, the major device components are shown in Figure 2. The reference element and buffer amplifier drifts are combined to give the total reference temperature coefficient. The input reference current to the DAC, I_{REF}, is developed from the internal reference and will show the same drift rate as the reference voltage. The DAC output current, I_{DAC}, which is a function of the digital input codes, is designed to track I_{REF}; if there is a slight mismatch in these currents over temperature, it will contribute to the gain T.C. The bipolar offset resistor, R_{BP}, and gain setting resistor, R_{GAIN}, also have temperature coefficients which contribute to system drift errors. The input offset voltage drift of the output amplifier, OA, also contributes a small error.

There are three types of drift errors over temperature: offset, gain, and linearity. Offset drift causes a vertical translation of the entire transfer curve; gain drift is a change in the slope of the curve; and linearity drift represents a change in the shape of the curve. The combination of these three drifts results in the complete specification for total error over temperature.

Total error is defined as the deviation from a true straight line transfer characteristic from exactly zero at a digital input which calls for zero output to a point which is defined as full scale. A specification for total error over temperature assumes that both the zero and full scale points have been trimmed for zero error at +25°C. Total error is normally expressed a percentage of the full scale range. In the bipolar situation, this means the total range from $-V_{FS}$ to $+V_{FS}$.

Several new design concepts not previously used in DAC80-type devices contribute to a reduction in all the error factors over temperature. The incorporation of low temperature coefficient silicon-chromium thin-film resistors deposited on a single chip, a patented, fully differential, emitter weighted, precision current steering cell structure, and a T.C. trimmed buried zener diode reference element results in superior wide temperature range performance. The gain setting resistors and bipolar offset resistor are also fabricated on the chip with the same SiCr material as the ladder network, resulting in low gain and offset drift.

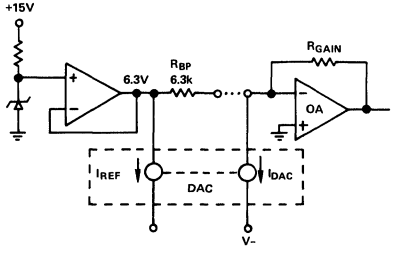

Figure 2. Bipolar Configuration

MONOTONICITY AND LINEARITY

The initial linearity error of ± 1/2LSB max and the differential linearity error of ± 3/4LSB max guarantee monotonic performance over the specified range. It can, therefore, be assumed that linearity errors are insignificant in computation of total temperature errors.

UNIPOLAR ERRORS

Temperature error analysis in the unipolar mode is straightforward: there is an offset drift and a gain drift. The offset drift (which comes from leakage currents and drift in the output amplifier (OA)) causes a linear shift in the transfer curve as shown in Figure 3. The gain drift causes a change in the slope of the curve and results from reference drift, DAC drift, and drift in R_{GAIN} relative to the DAC resistors.

BIPOLAR RANGE ERRORS

The analysis is slightly more complex in the bipolar mode. In this mode R_{BP} is connected to the summing node of the output amplifier (see Figure 2) to generate a current which, exactly balances the current of the MSB so that the output voltage is zero with only the MSB on.

Note that if the DAC and application resistors track perfectly, the bipolar offset drift will be zero even if the reference drifts. A change in the reference voltage, which causes a shift in the bipolar offset, will also cause an equivalent change in I_{REF} and thus I_{DAC}, so that I_{DAC} will always be exactly balanced by I_{BP} with the MSB turned on. This effect is shown in Figure 3. The net effect of the reference drift then is simply to cause a rotation in the transfer around bipolar zero. However, consideration of second order effects (which are often overlooked) reveals the errors in the bipolar mode. The unipolar offset drifts discussed before will have the same effect on the bipolar offset. A mismatch of R_{BP} to the DAC resistors is usually the largest component of bipolar drift, but in the AD DAC80 this error is held to 10ppm/°C max. Gain drift in the DAC also contributes to bipolar offset drift, as well as full scale drift, but again is held to 10ppm/°C max.

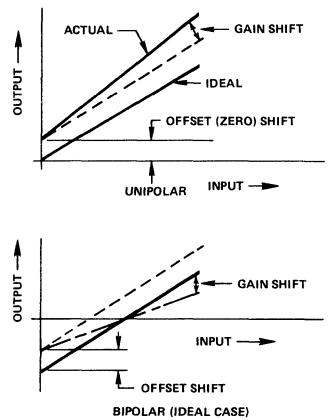

Figure 3. Unipolar and Bipolar Drifts

Using the AD DAC80 Series

POWER SUPPLY CONNECTIONS

For optimum performance power supply decoupling capacitors should be added as shown in the connection diagrams. These capacitors (1μF electrolytic recommended) should be located close to the AD DAC80. Electrolytic capacitors, if used, should be paralleled with 0.01μF ceramic capacitors for optimum high frequency performance.

EXTERNAL OFFSET AND GAIN ADJUSTMENT

Offset and gain may be trimmed by installing external OFFSET and GAIN potentiometers. These potentiometers should be connected as shown in the block diagrams and adjusted as described below. TCR of the potentiometers should be 100ppm/°C or less. The 3.9MΩ and 10MΩ resistors (20% carbon or better) should be located close to the AD DAC80 to prevent noise pickup. If it is not convenient to use these high-value resistors, a functionally equivalent "T" network, as shown in Figure 6 may be substituted in each case. The gain adjust (pin 23) is a high impedance point and a 0.01μF ceramic capacitor should be connected from this pin to common to prevent noise pickup.

Offset Adjustment. For unipolar (CSB) configurations, apply the digital input code that should produce zero potential output and adjust the OFFSET potentiometer for zero output. For bipolar (COB, CTC) configurations, apply the digital input code that should produce the maximum negative output voltage. Example: If the FULL SCALE RANGE is connected for 20 volts, the maximum negative output voltage is −10V. See Table II for corresponding codes.

Gain Adjustment. For either unipolar or bipolar configurations, apply the digital input that should give the maximum positive voltage output. Adjust the GAIN potentiometer for this positive full scale voltage. See Table II for positive full scale voltages.

*To obtain values for other binary ranges 0 to +5V range: divide 0 to +10 values by 2; ±5V range: divide ±10V range values by 2; ±2.5V range: divide ±10V range values by 4.

Table II. Digital Input/Analog Output

VOLTAGE OUTPUT MODELS

Internal scaling resistors provided in the AD DAC80 may be connected to produce bipolar output voltage ranges of ±10, ±5 or ±2.5V or unipolar output voltage ranges of 0 to +5 or 0 to +10V (see Figure 7).

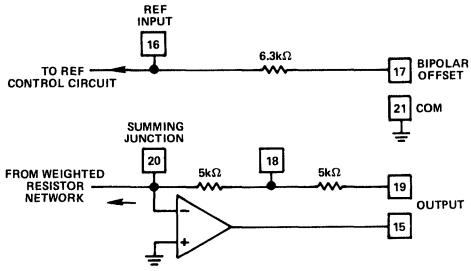

Figure 7. Output Amplifier Voltage Range Scaling Circuit

Gain and offset drift are minimized in the AD DAC80 because of the thermal tracking of the scaling resistors with other device components. Connections for various output voltage ranges are shown in Table III. Settling time is specified for a full scale range change: 4 microseconds for a 10kΩ feedback resistor; 3 microseconds for a 5kΩ feedback resistor when using the compensation capacitor shown in Figure 1.

The equivalent resistive scaling network and output circuit of the current model are shown in Figures 8 and 9. External R_{LS} resistors are required to produce exactly 0 to −2V or ±1V output. TCR of these resistors should be ±100ppm/°C or less to maintain the AD DAC80 output specifications. If exact output ranges are not required, the external resistors are not needed.

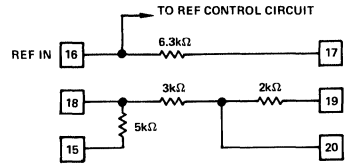

Figure 8. Internal Scaling Resistors

Internal resistors are provided to scale an external op amp or to configure a resistive load to offer two output voltage ranges of ±1V or 0 to −2V. These resistors (R_{LI}: TCR = 20ppm/°C) are an integral part of the AD DAC80 and maintain gain and bipolar offset drift specifications. If the internal resistors are not used, external R_L (or R_F) resistors should have a TCR of ±25ppm/°C or less to minimize drift. This will typically add ±50ppm/°C + the TCR of R_L (or R_F) to the total drift.

Table IV. Current Model/Resistive Load Connections

DRIVING A RESISTIVE LOAD UNIPOLAR

A load resistance, $R_L = R_{LI} + R_{LS}$, connected as shown in Figure 10 will generate a voltage range, V_{OUT}, determined by:

$$V_{OUT} = -2mA \left(\frac{6.6k \times R_L}{6.6k + R_L}\right)$$

Where R_L max = 1.54kΩ

and V_{OUT} max = −2.5V

To achieve specified drift, connect the internal scaling resistor (R_{LI}) as shown in Table IV to an external metal film trim resistor (R_{LS}) to provide full scale output voltage range of 0 to −2V. With $R_{LS} = 0$, $V_{OUT} = -1.69V$.

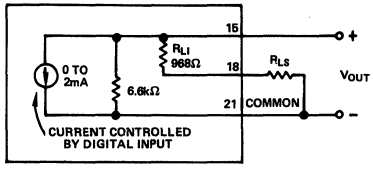

Figure 10. Equivalent Circuit AD DAC80-CBI-I Connected for Unipolar Voltage Output with Resistive Load

DRIVING A RESISTOR LOAD BIPOLAR

The equivalent output circuit for a bipolar output voltage range is shown in Figure 11, $R_L = R_{LI} + R_{LS}$. V_{OUT} is determined by:

$$V_{OUT} = \pm 1mA \left(\frac{R_L \times 3.22k}{R_L + 3.22k}\right)$$

Where R_L max = 11.18kΩ

and V_{OUT} max = ±2.5V

To achieve specified drift, connect the internal scaling resistors (R_{LI}) as shown in Table IV for the COB or CTC codes and add an external metal film resistor (R_{LS}) in series to obtain a full scale output range of ±1V. In this configuration, with R_{LS} equal to zero, the full scale range will be ±0.874V.

DRIVING AN EXTERNAL OP AMP

The current model AD DAC80 will drive the summing junction of an op amp used as a current to voltage converter to produce an output voltage. As seen in Figure 12,

$$V_{OUT} = I_{OUT} \times R_F$$

where I_{OUT} is the AD DAC80 output current and R_F is the feedback resistor. Using the internal feedback resistors of the current model AD DAC80 provides output voltage ranges the

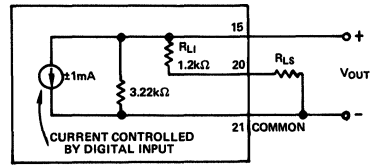

Figure 11. AD DAC80-CBI-I Connected for Bipolar Output Voltage with Resistive Load

same as the voltage model AD DAC80. To obtain the desired output voltage range when connecting an external op amp, refer to Table V and Figure 12.

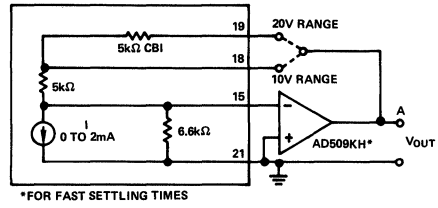

Figure 12. External Op Amp–Using Internal Feedback Resistors

OUTPUT LARGER THAN 20V RANGE

For output voltage ranges larger than ±10 volts, a high voltage op amp may be employed with an external feedback resistor. Use I_{OUT} values of ±1mA for bipolar voltage ranges and −2mA for unipolar voltage ranges (see Figure 13). Use protection diodes when a high voltage op amp is used.

The feedback resistor, R_F, should have a temperature coefficient as low as possible. Using an external feedback resistor, overall drift of the circuit increases due to the lack of temperature tracking between R_F and the internal scaling resistor network. This will typically add 50ppm/°C + R_F drift to total drift.

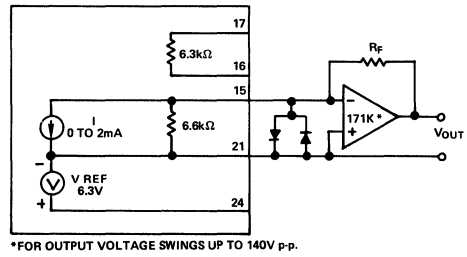

Figure 13. External Op Amp–Using External Feedback Resistors

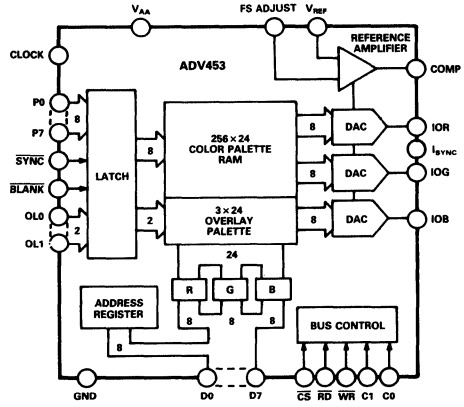
ADV453 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The ADV453 is a complete analog video output RAM-DAC on a single monolithic chip. It is specifically designed for high resolution color graphics systems. The part contains a 256×24 color lookup table, a 3×24 overlay palette as well as triple 8-bit video D/A converters. The ADV453 is capable of simultaneously displaying up to 259 colors, 256 from the lookup table and three from the overlay registers, out of a total color palette of 16.8 million addressable colors.

The three overlay registers allow for the implementation of overlaying cursors, pull down menus and grids. There is an independent, asynchronous MPU bus which allows access to the color lookup table without affecting the input of video data via the pixel port. The ADV453 is capable of generating RGB video output signals which are compatible with RS-343A and RS-170 video standards, without requiring external buffering.

The ADV453 is fabricated in a +5V CMOS process. Its monolithic CMOS construction ensures greater functionality with low power dissipation. The part is packaged in both a 0.6", 40-pin DIP and a 44-pin plastic leaded (J-lead) chip carrier, PLCC.

PRODUCT HIGHLIGHTS

1. Fast video refresh rate, 66MHz.
2. Compatible with a wide variety of high resolution color graphics systems including VGA* and Macintosh II**.
3. Three overlay registers allow for implementation of overlaying cursors, pull down menus and grids.
4. Guaranteed monotonic. Integral and differential nonlinearities guaranteed to be a maximum of ±1LSB.
5. Low glitch energy, 50pV secs.

*VGA is a trademark of International Business Machines Corp.
**Macintosh II is a registered trademark of Apple Computer Inc.

SPECIFICATIONS (V_{AA} = +5V ±5%, V_{REF} = +1.235V, R_{SET} = 280Ω. I_{SYNC} connected to IOG. All specifications T_{min} to T_{max}[1] unless otherwise noted.)

Parameter	All Versions	Units	Test Conditions/Comments
STATIC PERFORMANCE

RECOMMENDED OPERATING CONDITIONS

Parameter	Symbol	Min	Typ	Max	Units
Power Supply	V_{AA}	4.75	5.00	5.25	Volts
Ambient Operating Temperature	T_A	0		+70	°C
Output Load	R_L		37.5		Ω
Reference Voltage	V_{REF}	1.14	1.235	1.26	Volts

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

ABSOLUTE MAXIMUM RATINGS*

V_{AA} to GND . . . . . +7V
Voltage on Any Digital Pin . . . . . .GND–0.5V to V_{AA} +0.5V
Ambient Operating Temperature (T_A) . . . . . .0 to +70°C
Storage Temperature (T_S) . . . . . .–65°C to +150°C
Junction Temperature (T_J) . . . . . .+175°C
Soldering Temperature (5secs) . . . . . .260°C
IOR, IOB, IOG to GND[1] . . . . . .0V to V_{AA}

NOTES
*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
[1]Analog Output Short Circuit to any Power Supply or Common can be of an indefinite duration.

PIN FUNCTION DESCRIPTION

Pin Mnemonic	Function
$\overline{\text{BLANK}}$	Composite blank control input (TTL compatible). A logic zero on this control input drives the analog outputs to the blanking level, as shown in Table V. The $\overline{\text{BLANK}}$ signal is latched on the rising edge of CLOCK. While $\overline{\text{BLANK}}$ is at logical zero, the pixel and overlay inputs are ignored.
$\overline{\text{SYNC}}$	Composite sync control input (TTL compatible). A logical zero on the $\overline{\text{SYNC}}$ input switches off a 40 IRE current source on the I_{SYNC} output (see Figure 5). $\overline{\text{SYNC}}$ does not override any other control or data input, as shown in Table V; therefore, it should only be asserted during the blanking interval. $\overline{\text{SYNC}}$ is latched on the rising edge of CLOCK.
CLOCK	Clock input (TTL compatible). The rising edge of CLOCK latches the P0–P7 and OL0–OL1 data inputs as well as the $\overline{\text{SYNC}}$ and $\overline{\text{BLANK}}$ control inputs. It is typically the pixel clock rate of the video system. CLOCK should be driven by a dedicated TTL buffer.
P0–P7	Pixel select inputs (TTL compatible). These inputs specify, on a pixel basis, which one of the 256 entries in the color palette RAM is to be used to provide color information. P0–P7 pixel select inputs are latched on the rising edge of CLOCK. P0 is the LSB. Unused pixel select inputs should be connected to GND.
OL0–OL1	Overlay select inputs (TTL compatible). These inputs specify which palette is to be used to provide color information (see Table IV), i.e., the 256×24 color palette or the 3×24 overlay palette. When accessing the overlay palette, the P0–P7 inputs are ignored. OL0–OL1 are latched on the rising edge of CLOCK. OL0 is the LSB. Unused inputs should be connected to GND.
IOR, IOG, IOB	Red, green, and blue current outputs. These high impedance current sources are capable of directly driving a doubly terminated 75Ω coaxial cable, as shown in Figure 4a. All three current outputs should have similar output loads whether or not they are all being used.
I_{SYNC}	Sync current output. This high impedance current source can be directly connected to the IOG output (see Figure 3). This allows sync information to be encoded onto the green channel. I_{SYNC} does not output any current while $\overline{\text{SYNC}}$ is at logical zero. The amount of current output at I_{SYNC} while $\overline{\text{SYNC}}$ is at logical one is given by: I_{SYNC} (mA) = 1,728 * V_{REF}(V)/ R_{SET} (Ω). If sync information is not required on the green channel, I_{SYNC} should be connected to GND.
FS ADJUST	Full scale adjust control. A resistor (R_{SET}) connected between this pin and GND (see Figure 6) controls the magnitude of the full scale video signal. Note that the IRE relationships in Figure 5 are maintained, regardless of the full scale output current. The relationship between R_{SET} and the full scale output current on IOG (assuming I_{SYNC} is connected to IOG) is given by: IOG (mA) = (K + 326 + 1,728) * V_{REF}(V)/R_{SET} (Ω) The relationship between R_{SET} and the full scale output current on IOR and IOB is given by: IOR, IOB (mA) = (K + 326)* V_{REF}(V)/R_{SET}(Ω) where K = 3,993
COMP	Compensation pin. This is a compensation pin for the internal reference amplifier. A 0.1μF ceramic capacitor must be connected between COMP and V_{AA} (Figure 6).
V_{REF}	Voltage reference input. An external 1.235V voltage reference must be connected to this pin. The use of an external resistor divider network is not recommended. A 0.1μF decoupling ceramic capacitor should be connected between V_{REF} and V_{AA} (Figure 6.)
V_{AA}	Analog power supply (5V±5%). All V_{AA} pins on the ADV453 must be connected.
GND	Analog ground. All GND pins must be connected.
$\overline{\text{CS}}$	Chip select control input (TTL compatible). $\overline{\text{CS}}$ must be at logical zero to enable the reading and writing of data to and from the device. The IOR, IOG and IOB outputs are forced to the black level while $\overline{\text{CS}}$ is at logical zero. Note that the ADV453 will not operate properly if $\overline{\text{CS}}$, $\overline{\text{RD}}$ and $\overline{\text{WR}}$ are simultaneously at logical zero.
$\overline{\text{WR}}$	Write control input (TTL compatible). $\overline{\text{CS}}$ and $\overline{\text{WR}}$ must both be at logical zero when writing data to the device. D0–D7 data is latched on the rising edge of $\overline{\text{WR}}$ or $\overline{\text{CS}}$. See Figure 1.
$\overline{\text{RD}}$	Read control input (TTL compatible). $\overline{\text{CS}}$ and $\overline{\text{RD}}$ must both be at logical zero when reading data from the device. See Figure 1.
C0, C1	Command control inputs (TTL compatible). C0 and C1 specify the type of read or write operation being carried out, i.e., address register, color palette RAM or overlay registers read or write operations. See Tables I, II, III.
D0–D7	Data bus (TTL compatible). Data is transferred to and from the address register, the color palette RAM and the overlay registers over this 8-bit bidirectional data bus. D0 is the least significant bit.

TERMINOLOGY

Blanking Level
The level separating the SYNC portion from the video portion of the waveform. Usually referred to as the front porch or back porch. At 0 IRE units, it is the level which will shut off the picture tube, resulting in the blackest possible picture.

Color Video (RGB)
This usually refers to the technique of combining the three primary colors of red, green and blue to produce color pictures within the usual spectrum. In RGB monitors, three DACs are required, one for each color.

Sync Signal (SYNC)
The position of the composite video signal which synchronizes the scanning process.

Gray Scale
The discrete levels of video signal between reference black and reference white levels. An 8-bit DAC contains 256 different levels while a 6-bit DAC contains 64.

Raster Scan
The most basic method of sweeping a CRT one line at a time to generate and display images.

Reference Black Level
The maximum negative polarity amplitude of the video signal.

Reference White Level
The maximum positive polarity amplitude of the video signal.

Sync Level
The peak level of the SYNC signal.

Video Signal
That portion of the composite video signal which varies in gray scale levels between reference white and reference black. Also referred to as the picture signal, this is the portion which may be visually observed.

ADV453 CIRCUIT DESCRIPTION

MPU Interface
As illustrated in the functional block diagram, the ADV453 supports a standard MPU bus interface, allowing the MPU direct access to the color palette RAM and overlay color registers. The color palette RAM and overlay color registers can be accessed only when $\overline{CS}$ is low. The Pixel and Overlay Select inputs are disabled while $\overline{CS}$ is low.

The C0 and C1 control inputs specify whether the MPU is accessing the address register, color palette RAM or the overlay registers, as shown in Table I. The 8-bit address register is used to address the color palette RAM and overlay registers, eliminating the requirement for external address multiplexers.

$\overline{CS}$	C1	C0	Addressed by MPU
0	X	0	Address Register
0	0	1	Color Palette RAM
0	1	1	Overlay Register

Table I. Control Input Truth Table

To write color data, the MPU writes to the address register with either the address of the color palette RAM location or the address of the overlay register which is to be modified. The MPU performs three successive write cycles (8 bits of red data, 8 bits of green data and 8 bits of blue data). This color data is diverted to either the color palette RAM or the overlay registers, as determined by C0 and C1. During the blue write cycle, the three bytes of color information are concatenated into a 24-bit word and written to the location specified by the address register. The address register then automatically increments to the next location which the MPU may modify by simply writing another sequence of red, green and blue data.

To read back color data, the MPU loads the address register (selecting RAM or overlay read mode) with the address of the color palette RAM location or overlay register to be read. The MPU performs three successive read cycles (8 bits each of red, green and blue data), using C0 and C1 to select either the color palette RAM or the overlay registers. Following the blue read cycle, the address register increments to the next location which the MPU may read by simply reading another sequence of red, green and blue data.

When $\overline{CS}$ is low, i.e., during MPU read/write cycles, the video outputs are forced to the black level. During color palette RAM access, the address register resets to 00H following a blue read or write operation to RAM location FFH.

The three overlay registers can be accessed in the same way as the color palette RAM. The overlays are selected using C0 and C1 according to Table I. When accessing the overlay color registers, the address register increments following a blue read or write cycle. However, while accessing the overlay color registers, the six most significant bits of the address register (ADDR2–7) are ignored.

The MPU interface operates asynchronously to the pixel clock. Data transfers between the color palette RAM/overlay registers and the color registers (R, G and B in the block diagram) are synchronized by internal logic and occur in the period between MPU accesses. Color (RGB) data is normally loaded to the color palette RAM/overlay registers during video screen retrace, i.e. during the video waveform blanking period (see Figure 5).

To keep track of the red, green and blue read/write cycles, the address register has two additional bits (ADDRa, ADDRb) that count modulo three, as shown in Table II. They are reset to zero when the MPU writes to the address register and are not reset to zero when the MPU reads the address register. The MPU does not have access to these bits. The other eight bits of the address register, incremented following a blue read or write cycle, (ADDR0–7) are accessible to the MPU and are used to address color palette RAM locations and overlay registers, as shown in Table III. ADDR0 is the LSB when the MPU is accessing the RAM or overlay registers. The MPU may read the address register at any time without modifying its contents or the existing read/write mode.

Figure 1 illustrates the MPU read/write timing and Table III shows the associated functional instructions.

	Value	C1	C0	Addressed by MPU
ADDRa,b (Counts Modulo 3)	00	X	1	Red Value
	01	X	1	Green Value
	10	X	1	Blue Value
ADDR0–7 (Counts Binary)	00H–FFH	0	1	Color Palette RAM
	XXXX XX00	1	1	Reserved
	XXXX XX01	1	1	Overlay Color 1
	XXXX XX10	1	1	Overlay Color 2
	XXXX XX11	1	1	Overlay Color 3

Note: Control input C1 determines whether a read/write operation is performed on the color palette RAM or the overlay registers.

Table II. Address Register (ADDR) Operation

$\overline{CS}$	$\overline{RD}$	$\overline{WR}$	C0	C1	ADDRb	ADDRa	Operation Performed	
0	1	0	0	X	X	X	Write Address Register;	D0–D7→ADDR0–7 0→ADDRa,b
0	1	0	1	X	0	0	Write Red Value;	Increment ADDRa-b
0	1	0	1	X	0	1	Write Green Value;	Increment ADDRa-b
0	1	0	1	X	1	0	Write Blue Value;	Modify RAM/Overlay Location Increment ADDR0–7 Increment ADDRa-b
0	0	1	0	X	X	X	Read Address Register;	ADDR0–7→D0–D7
0	0	1	1	X	0	0	Read Red Value;	Increment ADDRa-b
0	0	1	1	X	0	1	Read Green Value;	Increment ADDRa-b
0	0	1	1	X	1	0	Read Blue Value; Increment ADDRa-b	Increment ADDR0–7
0	0	0	X	X	X	X	Invalid Operation	

Note: Control input C1 determines whether a read/write operation is performed on the color palette RAM or the overlay registers.

Table III. Truth Table for Read/Write Operations

Frame Buffer Interface

The P0–P7, OL0 and OL1 inputs are used to address the color palette RAM and overlay registers, as shown in Table IV. These inputs are latched on the rising edge of CLOCK and address any of the 256 locations in the color palette RAM or the three overlay registers. The addressed location contains 24 bits of color (8 bits of red, 8 bits of green and 8 bits of blue) information.This data is transferred to the three DACs and is then converted to an analog output (IOR, IOG and IOB), these outputs then control the red green and blue electron guns in the monitor.

The $\overline{\text{SYNC}}$ and $\overline{\text{BLANK}}$ inputs are also latched on the rising edge of CLOCK. This is to maintain synchronization with the color data.

OL1	OL0	P0–P7	Addressed by Frame Buffer
0	0	00H	Color Palette RAM Location 00H
0	0	01H	Color Palette RAM Location 01H
.	.	.	.
.	.	.	.
0	0	FFH	Color Palette RAM Location FFH
0	1	XXH	Overlay Color 1
1	0	XXH	Overlay Color 2
1	1	XXH	Overlay Color 3

Table IV. Pixel and Overlay Control Truth Table

Analog Interface

The ADV453 has three analog outputs, corresponding to the red, green and blue video signals. A fourth analog output (I_{SYNC}) can be used if it is required to encode video synchronization information onto the green signal. In this case, I_{SYNC} is connected to IOG as shown in Figure 3. If it is not required to encode sync information onto the green signal (as would be the case if a separate synchronization circuit was used), I_{SYNC} should be connected to GND and the digital $\overline{\text{SYNC}}$ input pin should be tied low.

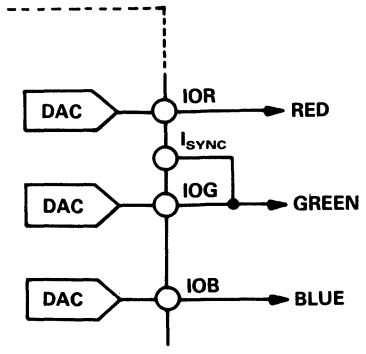

Figure 3. Encoding SYNC onto Green Signal

The red, green and blue analog outputs of the ADV453 are high impedance current sources. Each one of these three RGB current outputs is capable of directly driving a 37.5Ω load, such as a doubly terminated 75Ω coaxial cable. Figure 4a shows the required configuration for each of the three RGB outputs connected into a doubly terminated 75Ω load. This arrangement will develop RS-343A video output voltage levels across a 75Ω monitor. A simple method of driving RS-170 video levels into a 75Ω monitor is shown in Figure 4b. The output current levels of the DACs remain unchanged, but the source termination resistance, Z_S, on each of the three DACs is increased from 75Ω to 150Ω.

More detailed information regarding load terminations for various output configurations, including RS-343A and RS-170, is available in an application note entitled "Video Formats & Required Load Terminations" available from Analog Devices.

Figure 5 shows the video waveforms associated with the three RGB outputs driving the doubly terminated 75Ω load of Figure 4a. As well as the grey scale levels, Black Level to White Level, the diagram also shows the contributions of $\overline{\text{SYNC}}$ and $\overline{\text{BLANK}}$. These control inputs add appropriately weighted currents to the analog outputs producing the specific output level requirements for video applications. Table V details how the $\overline{\text{SYNC}}$ and $\overline{\text{BLANK}}$ inputs modify the output levels.

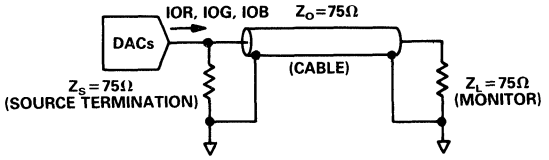

Figure 4a. Recommended Analog OutputTermination for RS-343A

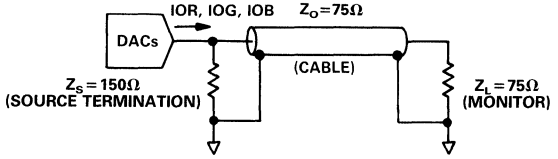

Figure 4b. Recommended Analog Output Termination for RS-170

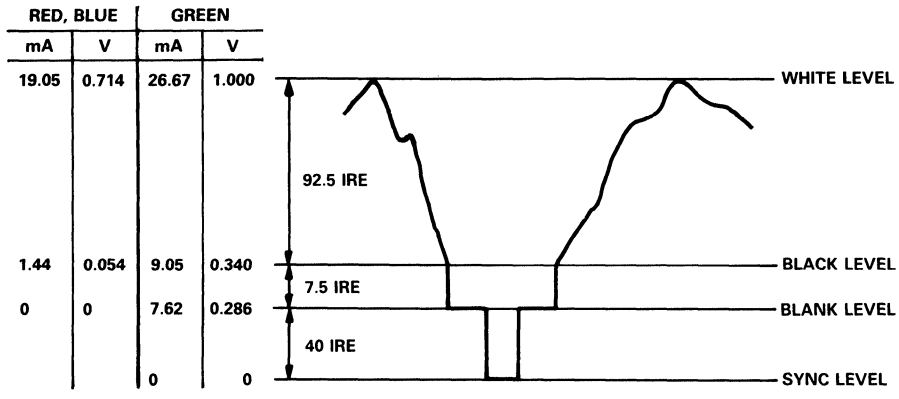


NOTES
1. OUTPUTS CONNECTED TO A DOUBLY TERMINATED 75Ω LOAD.
2. V_{REF} = 1.235V, R_{SET} = 280Ω, I_{SYNC} CONNECTED TO IOG.
3. RS-343A LEVELS AND TOLERANCES ASSUMED ON ALL LEVELS.

Figure 5. RGB Video Output Waveform

Description	IOG mA[1]	IOR, IOB mA	$\overline{SYNC}$	$\overline{BLANK}$	DAC Input Data
White Level	26.67	19.05	1	1	FFH
Video	Video + 9.05	Video + 1.44	1	1	Data
Video to Blank	Video + 1.44	Video + 1.44	0	1	Data
Black Level	9.05	1.44	1	1	00H
Black to Blank	1.44	1.44	0	1	00H
Blank Level	7.62	0	1	0	XXH
SYNC Level	0	0	0	0	XXH

NOTES
[1]Typical with full scale IOG = 26.67mA.
V_{REF} = 1.235V, R_{SET} = 280Ω, I_{SYNC} connected to IOG.

Table V. Video Output Truth Table

PC BOARD LAYOUT CONSIDERATIONS

The ADV453 is optimally designed for lowest noise performance, both radiated and conducted noise. To complement the excellent noise performance of the ADV453, it is imperative that great care be given to the PC board layout. The layout should be optimized for lowest noise on the ADV453 power and ground lines. This can be achieved by shielding the digital inputs and providing good decoupling. The lead length between groups of V_{AA} and GND pins should by minimized so as to minimize inductive ringing.

Ground Planes

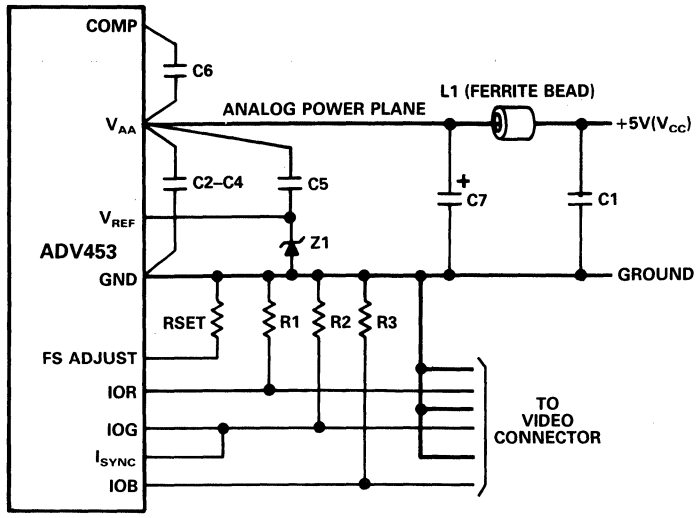
The ground plane should encompass all ADV453 ground pins, voltage reference circuitry, power supply bypass circuitry, the analog output traces and all the digital signal traces leading up to the ADV453.

Power Planes

The PC board layout should have two distinct power planes, one for analog circuitry and one for digital circuitry. The analog power plane should encompass the ADV453 (V_{AA}) and all associated analog circuitry. This power plane should be connected to the regular PCB power plane (V_{CC}) at a single point through a ferrite bead, as illustrated in Figure 6. This bead should be located within three inches of the ADV453.

The PCB power plane should provide power to all digital logic on the PC board, and the analog power plane should provide power to all ADV453 power pins, voltage reference circuitry and any output amplifiers.

The PCB power and ground planes should not overlay portions of the analog power plane. Keeping the PCB power and ground planes from overlaying the analog power plane will contribute to a reduction in plane-to-plane noise coupling.



COMPONENT	DESCRIPTION	VENDOR PART NUMBER
C1–C6	0.1μF CERAMIC CAPACITOR	
C7	10μF TANTALUM CAPACITOR

R_{SET}	280Ω 1% METAL FILM RESISTOR	DALE CMF-55C
Z1	1.235V VOLTAGE REFERENCE	ANALOG DEVICES AD589KH

Figure 6. ADV453 Typical Connection Diagram and Component List

Supply Decoupling

Noise on the analog power plane can be further reduced by the use of multiple decoupling capacitors (see Figure 6).

Optimum performance is achieved by the use of 0.1μF ceramic capacitors. Each of the three groups of V_{AA} should be individually decoupled to ground. This should be done by placing the capacitors as close as possible to the device with the capacitor leads as short as possible, thus minimizing lead inductance.

It is important to note that while the ADV453 contains circuitry to reject power supply noise; this rejection decreases with frequency. If a high frequency switching power supply is used, the designer should pay close attention to reducing power supply noise. A dc power supply filter (Murata BNX002) will provide EMI supression between the switching power supply and the main PCB. Alternatively, consideration could be given to using a three-terminal voltage regulator.

Digital Signal Interconnect

The digital signal lines to the ADV453 should be isolated as much as possible from the analog outputs and other analog circuitry. Digital signal lines should not overlay the analog power plane.

Due to the high clock rates used, long clock lines to the ADV453 should be avoided so as to minimize noise pickup.

Any active pull-up termination resistors for the digital inputs should be connected to the regular PCB power plane (V_{CC}), and not the analog power plane.

Analog Signal Interconnect

The ADV453 should be located as close as possible to the output connectors thus minimizing noise pickup and reflections due to impedance mismatch.

The video output signals should overlay the ground plane, and not the analog power plane, thereby maximizing the high frequency power supply rejection.

For optimum performance, the analog outputs should each have a source termination resistance to ground of 75Ω. This termination resistance should be as close as possible to the ADV453 to minimize reflections.

Monolithic 256×18 CMOS Color Palette RAM-DAC

ADV476

FEATURES
Personal System/2* and VGA* Compatible
Plug-in Replacement for INMOS 171/176
66MHz Pipelined Operation
Three 6-Bit D/A Converters
256×18 Color Palette RAM
RS-343A/RS-170 Compatible Outputs
Blank on All Three Channels
Standard MPU Interface
Asynchronous Access to All Internal Registers
+5V CMOS Monolithic Construction
Low Power Dissipation
Standard 28-Pin, 0.6" DIP

APPLICATIONS
High Resolution Color Graphics
CAE/CAD/CAM Applications
Image Processing
Instrumentation
Desktop Publishing

AVAILABLE CLOCK RATES
66MHz
50MHz
35MHz

GENERAL DESCRIPTION

The ADV476 is a pin compatible and software compatible RAM-DAC designed specifically for VGA and Personal System/2 color graphics.

The ADV476 is a complete analog output RAM-DAC on a single monolithic chip. The part contains a 256×18 color lookup table, a pixel mask register as well as a triple 6-bit video D/A converter. The ADV476 is capable of simultaneously displaying up to 256 colors, from a total color palette of 262,144 addressable colors.

The on-chip asynchronous MPU bus allows access to the color lookup table without affecting the input video data via the pixel port. The pixel read mask register provides a convenient way of altering the displayed colors without updating the color lookup table. The ADV476 is capable of generating RGB video output signals which are compatible with RS-343A and RS-170 video standards, without requiring external buffering.

The ADV476 is fabricated in a +5V CMOS process. Its monolithic CMOS construction ensures greater functionality with low power dissipation and small board area. The part is packaged in a 0.6", 28-pin DIP.

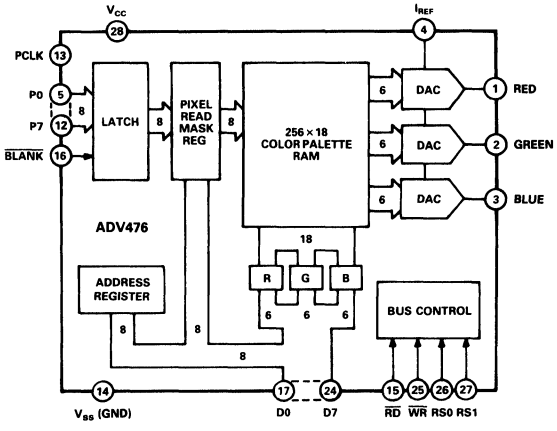
ADV476 FUNCTIONAL BLOCK DIAGRAM



PRODUCT HIGHLIGHTS

1. Standard video refresh rates, 35MHz, 50MHz and 66MHz.
2. Fully compatible with VGA and Personal System/2 color graphics.
3. Guaranteed monotonic. Integral and differential linearity guaranteed to be a maximum of ±1LSB.
4. Low glitch energy, 75pV secs.

SPECIFICATIONS

(V_{CC} = +5V ±10%, I_{REF} = 8.88mA. All Specifications T_{min} to T_{max}[1] unless otherwise noted.)

Parameter	All Versions	Units	Test Conditions/Comments
STATIC PERFORMANCE			
Resolution (Each DAC)	6	Bits	
Accuracy (Each DAC)			
Integral Nonlinearity	±0.5	LSB max	Guaranteed Monotonic
Full Scale Error	±5	% max	Full Scale = $2.15 \times I_{REF} \times R_L$, I_{REF} = 8.39mA
Blank Level	±0.5	LSB max	$\overline{BLANK}$ = Logic Low
Offset Error	±0.5	LSB max	$\overline{BLANK}$ = Logic High
DIGITAL INPUTS			
Input High Voltage, V_{INH}	2	V min	
Input Low Voltage, V_{INL}	0.8	V max	
Input Current, I_{IN}	±10	µA max	V_{CC} = 5.5V, V_{IN} = 0.4V to V_{CC}
Input Current ($\overline{RD}$ Input Only)	±100	µA max	V_{CC} = 5.5V, V_{IN} = 0.4V to V_{CC}
Input Capacitance, C_{IN}	7	pF typ

NOTES

[1]Temperature range (T_{min} to T_{max}); 0 to +70°C.

[2]Relative to the midpoint of the distribution of the three DACs measured at full scale.

[3]TTL input values are 0 to 3 volts, with input rise/fall times ≤3ns, measured between the 10% and 90% points. Timing reference points at 50% for inputs and outputs. Analog output load ≤10pF, 37.5Ω. D0–D7 output load ≤50pF. See timing notes in Figure 2.

[4]Clock and data feedthrough is a function of the amount of overshoot and undershoot on the digital inputs. For this test, the digital inputs have a 1kΩ resistor to ground and are driven by 74HC logic. Glitch impulse includes clock and data feedthrough, −3dB test bandwidth = 2×clock rate.

Specifications subject to change without notice.

TIMING CHARACTERISTICS[1] (V_{CC} = +5V±10%. All Specifications T_{min} to T_{max}[2])

Parameter	66MHz Version	50MHz Version	35MHz Version	Units	Conditions/Comments

NOTES
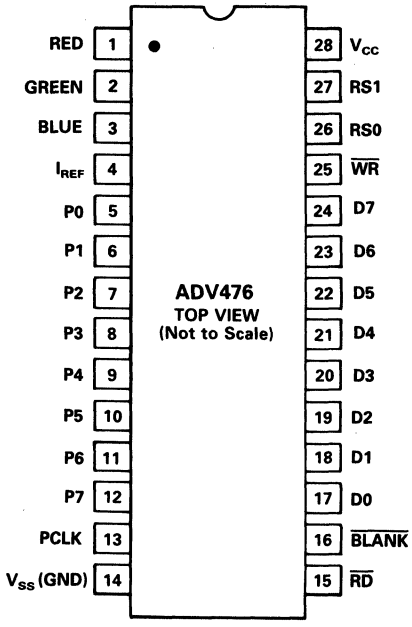
*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
[1]Analog output short circuit to any power supply or common can be of an indefinite duration.

DIP PIN CONFIGURATIONS



RECOMMENDED OPERATING CONDITIONS

Parameter	Symbol	Min	Typ	Max	Units
Power Supply	V_{CC}	4.5	5.00	5.5	Volts
Ambient Operating Temperature	T_A	0		+70	°C
Output Load	R_L		37.5		Ω
Reference Current	I_{REF}	−3		−10	mA

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

ORDERING INFORMATION[1]

Model	Speed	Package Options[2, 3]
ADV476KN35	35MHz	N-28
ADV476KN50	50MHz	N-28
ADV476KN66	66MHz	N-28

NOTES
[1]All devices are specified for 0 to +70°C operation.
[2]All devices are packaged in 0.6" 28-pin plastic DIPs (N-28).
[3]See Section 14 for package outline information.

PIN FUNCTION DESCRIPTION

Pin Mnemonic	Function
$\overline{\text{BLANK}}$	Composite blank control input (TTL compatible). A logic zero on this control input drives the analog outputs to the blanking level, as shown in Table V. The $\overline{\text{BLANK}}$ signal is latched on the rising edge of PCLK. While $\overline{\text{BLANK}}$ is a logical zero, the pixel inputs are ignored.
PCLK	Clock input (TTL compatible). The rising edge of PCLK latches the P0–P7 data inputs and the $\overline{\text{BLANK}}$ control input. It is typically the pixel clock rate of the video system. PCLK should be driven by a dedicated TTL buffer.
P0–P7	Pixel select inputs (TTL compatible). These inputs specify, on a pixel basis, which one of the 256 entries in the color palette RAM is to be used to provide color information. P0–P7 pixel select inputs are latched on the rising edge of PCLK. P0 is the LSB. Unused pixel select inputs should be connected to GND.
RED, GREEN, BLUE	Red, green and blue current outputs. These high impedance current sources are capable of directly driving a doubly terminated 75Ω coaxial cable, as shown in Figure 4a. All three current outputs should have similar output loads whether or not they are all being used.
V_{CC}	Analog power supply (5V ±10%).
GND	Analog ground.
I_{REF}	Current reference input. The relationship between the current input and the full scale output voltage of the DACs is given by the following expression: I_{REF} = VO (Full Scale)/2.15 × R_L R_L = Load Resistance
$\overline{\text{WR}}$	Write control input (TTL compatible). $\overline{\text{WR}}$ must be at logical zero when writing data to the device. D0–D7 data is latched on the rising edge of $\overline{\text{WR}}$. See Figure 1.
$\overline{\text{RD}}$	Read control input (TTL compatible). $\overline{\text{RD}}$ must both be at logical zero when reading data from the device. See Figure 1.
RS0, RS1	Command control inputs (TTL compatible). RS0 and RS1 specify the type of read or write operation being carried out, i.e., address register or color palette RAM read or write operations. See Tables I, II, III.
D0–D7	Data bus (TTL compatible). Data is transferred to and from the address register and the color palette RAM over this 8-bit bidirectional data bus. D0 is the least significant bit.

TERMINOLOGY

Blanking Level
The level separating the SYNC portion from the Video portion of the waveform. Usually referred to as the Front Porch or Back Porch. At 0 IRE Units, it is the level which will shut off the picture tube, resulting in the blackest possible picture.

Color Video (RGB)
This usually refers to the technique of combining the three primary colors of Red, Green and Blue to produce color pictures within the usual spectrum. In RGB monitors, three DACs are required, one for each color.

Gray Scale
The discrete levels of video signal between Reference Black and Reference White levels. An 8-bit DAC contains 256 different levels while a 6-bit DAC contains 64.

Raster Scan
The most basic method of sweeping a CRT one line at a time to generate and display images.

Reference Black Level
The maximum negative polarity amplitude of the video signal.

Reference White Level
The maximum positive polarity amplitude of the video signal.

Video Signal
That portion of the composite video signal which varies in gray scale levels between Reference White and Reference Black. Also referred to as the picture signal, this is the portion which may be visually observed.

MPU Interface

As illustrated in the functional block diagram, the ADV476 supports a standard MPU bus interface, allowing the MPU direct access to the color palette RAM .

The RS0 and RS1 control inputs specify whether the MPU is accessing the address register or the color palette RAM, as shown in Table I. The 8-bit address register is used to address the color palette RAM, eliminating the requirement for external address multiplexers.

RS1	RS0	Addressed by MPU
0	0	Pixel Address Register (RAM Write Mode)
1	1	Pixel Address Register (RAM Read Mode)
0	1	Color Palette RAM
1	0	Pixel Read Mask Register

Table I. Control Input Truth Table

To write color data, the MPU writes to the address register with the 8-bit address of the color palette RAM location which is to be modified. The MPU performs three successive write cycles (six bits of red data, six bits of green data and six bits of blue data). During the blue write cycle, the three bytes of color information are concatenated into an 18-bit word and written to the location specified by the address register. The address register then automatically increments to the next location which the MPU may modify by simply writing another sequence of red, green and blue data.

To read back color data, the MPU loads the address register with the address of the color palette RAM location to be read. The MPU performs three successive read cycles (6 bits each of red, green and blue data). Following the blue read cycle, the address register increments to the next location which the MPU may read by simply reading another sequence of red, green and blue data.

This 6-bit color data is right justified, i.e., the lower six bits of the data bus with D0 being the LSB and D5 the MSB. D6 and D7 are ignored during a color write cycle and are set to zero during a color read cycle.

During color palette RAM access, the address register resets to 00H following a blue read or write operation to RAM location FFH.

The MPU interface operates asynchronously to the pixel clock. Data transfers between the color palette RAM and the color registers (R, G, and B in the block diagram) are synchronized by internal logic, and occur in the period between MPU accesses. Color (RGB) data is normally loaded to the color palette RAM during video screen retrace, i.e., during the video waveform blanking period, see Figure 5.

To keep track of the red, green and blue read/write cycles, the address register has two additional bits (ADDRa, ADDRb) that count modulo three, as shown in Table II. They are reset to zero when the MPU writes to the address register, and are not reset to zero when the MPU reads the address register. The MPU does not have access to these bits. The other eight bits of the address register, incremented following a blue read or write cycle, (ADDR0–7) are accessible to the MPU, and are used to address color palette RAM locations, as shown in Table III. ADDR0 is the LSB when the MPU is accessing the RAM. The MPU may read the address register at any time without modifying its contents or the existing read/write mode.

Figure 1 illustrates the MPU read/write timing and Table III shows the associated functional instructions.

	Value	RS1	RS0	Addressed by MPU
ADDRa,b (Counts Modulo 3)	00			Red Value
	01			Green Value
	10			Blue Value
ADDR0–7 (Counts Binary)	00H–FFH	0	1	Color Palette RAM

Table II. Address Register (ADDR) Operation

$\overline{RD}$	$\overline{WR}$	RS0	RS1	ADDRa	ADDRb	Operation Performed	
1	0	0	0	X	X	Write Address Register;	D0–D7 → ADDR0–7 0 → ADDRa,b
1	0	1	0	0	0	Write Red Value;	Increment ADDRa–b
1	0	1	0	0	1	Write Green Value;	Increment ADDRa–b
1	0	1	0	1	0	Write Blue Value;	Modify RAM Location Increment ADDR0–7 Increment ADDRa–b
0	1	1	1	X	X	Read Address Register;	ADDR0–7 → D0–D7
0	1	1	0	0	0	Read Red Value;	Increment ADDRa–b
0	1	1	0	0	1	Read Green Value;	Increment ADDRa–b
0	1	1	0	1	0	Read Blue Value;	Increment ADDR0–7 Increment ADDRa–b
0	0	X	X	X	X	Invalid Operation	

Table III. Truth Table for Read/Write Operations

Frame Buffer Interface

The P0–P7 inputs are used to address the color palette RAM, as shown in Table IV. These inputs are latched on the rising edge of PCLK and address any of the 256 locations in the color palette RAM. The addressed location contains 18 bits of color (6 bits of red, 6 bits of green and 6 bits of blue) information. This data is transferred to the three DACs and is then converted to an analog output (RED, GREEN, BLUE), these outputs then control the red, green and blue electron guns in the monitor.

The $\overline{\text{BLANK}}$ input is also latched on the rising edge of PCLK. This is to maintain synchronization with the color data.

P0–P7	Addressed by Frame Buffer
00H	Color Palette RAM Location 00H
01H	Color Palette RAM Location 01H
•	• •
•	• •
FFH	Color Palette RAM Location FFH

Table IV. Pixel Select/Color Palette Control Truth Table

Pixel Read Mask Register

The Pixel Read Mask Register in the ADV476 can be used to implement register level pixel processing, thereby cutting down on software overhead. This is achieved by gating the input pixel stream (P0–P7) with the contents of the pixel read mask register. The operation is a bitwise logical ANDing of the pixel data. The contents of this register can be accessed and altered at any time by the MPU (D0–D7). Table I shows the relevant control signals.

This pixel masking operation can be used to alter the displayed colors without changing the contents of either the video frame buffer or the color palette RAM. The effect of this operation is to partition the color palette into a user determined number of color planes. This process can be used for special effects including animation, overlays and flashing objects.

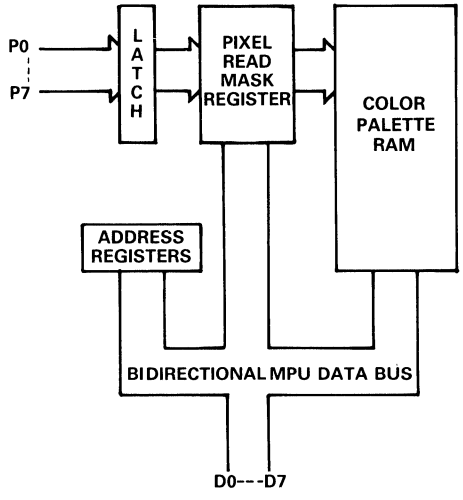


Figure 3. Block Diagram Showing Pixel Read Mask Register

Analog Interface

The ADV476 has three analog outputs, corresponding to the Red, Green and Blue video signals.

The Red, Green and Blue analog outputs of the ADV476 are high impedance current sources. Each one of these three RGB current outputs is capable of directly driving a 37.5Ω load, such as a doubly-terminated 75Ω coaxial cable. Figure 4a shows the required configuration for each of the three RGB outputs connected into a doubly-terminated 75Ω load. This arrangement will develop RS-343A video output voltage levels across a 75Ω monitor. A simple method of driving RS-170 video levels into a 75Ω monitor is shown in Figure 4b. The output current levels of the DACs remain unchanged but the source termination resistance, Z_S, on each of the three DACs is increased from 75Ω to 150Ω.

More detailed information regarding load terminations for various output configurations, including RS-343A and RS-170, is available in an application note entitled "Video Formats & Required Load Terminations" available from Analog Devices.

Figure 5 shows the video waveforms associated with the three RGB outputs, driving the doubly terminated 75Ω load of Figure 4a. The $\overline{\text{BLANK}}$ control input drives the analog outputs to the Black Level. $\overline{\text{BLANK}}$ is asserted prior to horizontal and vertical screen retrace. Table V details how the $\overline{\text{BLANK}}$ input modifies the output levels.

Figure 5. RGB Video Output Waveform

Description	RED, GREEN, BLUE, (mA)[1]	$\overline{\text{BLANK}}$	DAC Input Data
WHITE LEVEL	19.05	1	FFH
VIDEO	Video	1	DATA
BLACK LEVEL	0	1	00H
BLANK LEVEL	0	0	xxH

NOTE
[1]Typical with full scale RED, GREEN, BLUE = 19.05mA. I_{REF} = 8.88mA.

Table V. Video Output Truth Table

Reference Input
The ADV476 requires an active current reference to enable the DACs provide stable and accurate video output levels. The relationship between the output voltage and the required input reference current is given by:

$$I_{REF}=\frac{VO\ (FULL\ SCALE)}{2.15\times R_L}$$

where R_L = 37.5Ω (for doubly terminated 75Ω load)
= 75Ω (for singly terminated 75Ω load)

and VO = 0.714V (RS-343A video levels)
= 1.0V (RS-170 video levels).

In a standard application which requires RS-343A video levels to be driven into a doubly terminated 75Ω load (R_L = 37.5Ω), the necessary reference input current is:

I_{REF} = 8.88mA.

To drive the same levels into a singly terminated 75Ω load (R_L = 75Ω), the reference current is:

I_{REF} = 4.44mA.

A suggested current reference design for the doubly terminated case, with RS-343A video levels and based on the LM334, a three-terminal adjustable current source, is shown in Figure 6.

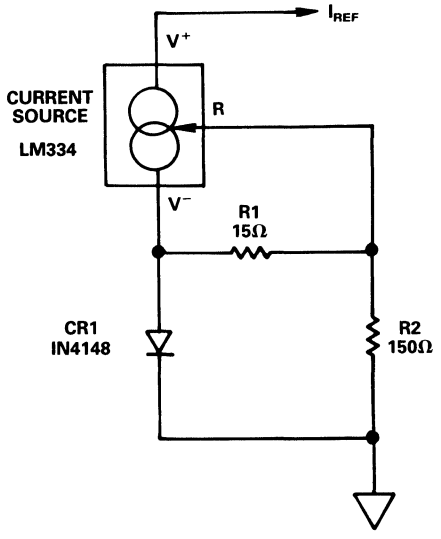

Figure 6. Current Reference Design Using an LM334 Current Source

PC BOARD LAYOUT CONSIDERATIONS

The ADV476 is optimally designed for lowest noise performance, both radiated and conducted noise. For optimum system noise performance, it is imperative that great care be given to the PC board layout. The layout should be optimized for lowest noise on the ADV476 power and ground lines. This can be achieved by shielding the digital inputs and providing good decoupling. The lead length between groups of V_{CC} and GND pins should by minimized so as to minimize inductive ringing.

Ground Planes

The ground plane should encompass all ADV476 ground pins, voltage reference circuitry, power supply bypass circuitry, the analog output traces and all the digital signal traces leading up to the ADV476.

Power Planes

The PC board layout should have two distinct power planes, one for analog circuitry and one for digital circuitry. The analog power plane (V_{CC}) should encompass the ADV476 and all associated analog circuitry. This power plane should be connected to the regular PCB power plane at a single point through a ferrite bead, as illustrated in Figure 7. This bead should be located within three inches of the ADV476.

The PCB power plane should provide power to all digital logic on the PC board, and the analog power plane should provide power to all ADV476 power pins, current reference circuitry and any output amplifiers.

The PCB power and ground planes should not overlay portions of the analog power plane. Keeping the PCB power and ground planes from overlaying the analog power plane will contribute to a reduction in plane-to-plane noise coupling.

Supply Decoupling

Noise on the analog power plane can be further reduced by the use of multiple decoupling capacitors, see Figure 7.

Optimum performance is achieved by the use of 0.1μF ceramic capacitors. This should be done by placing the capacitors as close as possible to the device with the capacitor leads as short as possible, thus minimizing lead inductance.

It is important to note that while the ADV476 contains circuitry to reject power supply noise, this rejection decreases with frequency. If a high frequency switching power supply is used, the designer should pay close attention to reducing power supply noise. A dc power supply filter (Murata BNX002) will provide EMI suppression between the switching power supply and the main PCB. Alternatively, consideration could be given to using a three terminal voltage regulator.

Digital Signal Interconnect

The digital signal lines to the ADV476 should be isolated as much as possible from the analog outputs and other analog circuitry. Digital signal lines should not overlay the analog power plane.

Due to the high clock rates used, long clock lines to the ADV476 should be avoided so as to minimize noise pickup.

Any active pull-up termination resistors for the digital inputs should be connected to the regular PCB power plane and not the analog power plane.

Analog Signal Interconnect

The ADV476 should be located as close as possible to the output connectors thus minimizing noise pickup and reflections due to impedance mismatch.

The video output signals should overlay the ground plane, and not the analog power plane, thereby maximizing the high frequency power supply rejection.

For optimum performance, the analog outputs should each have a source termination resistance to ground of 75Ω. This termination resistance should be as close as possible to the ADV476 to minimize reflections.

CMOS 80MHz Monolithic 256 × 24(18) Color Palette RAM-DAC

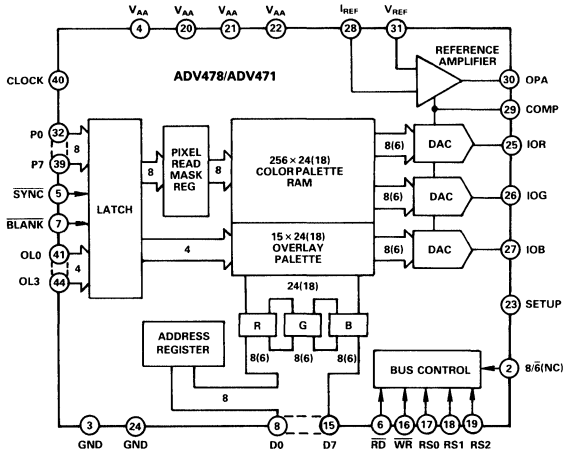
ADV478/ADV471

FEATURES
Personal System/2* Compatible
80MHz Pipelined Operation
Triple 8-Bit (6-Bit) D/A Converters
256 × 24(18) Color Palette RAM
15 × 24(18) Overlay Registers
RS-343A/RS-170 Compatible Outputs
Sync on All Three Channels
Programmable Pedestal (0 or 7.5 IRE)
External Voltage or Current Reference
Standard MPU Interface
+5V CMOS Monolithic Construction
44-Pin PLCC Package
Power Dissipation: 800mW

APPLICATIONS
High Resolution Color Graphics
CAE/CAD/CAM Applications
Image Processing
Instrumentation
Desktop Publishing

AVAILABLE CLOCK RATES
80MHz
66MHz
50MHz
35MHz

ADV478/ADV471 FUNCTIONAL BLOCK DIAGRAM



NOTES

2. NC = NO CONNECT

GENERAL DESCRIPTION

The ADV478 and ADV471 are pin compatible and software compatible RAM-DACs designed specifically for Personal System/2 compatible color graphics.

The ADV478 has a 256 × 24 color lookup table with triple 8-bit video D/A converters. It may be configured for either 6 bits or 8 bits per color operation. The ADV471 has a 256 × 18 color lookup table with triple 6-bit video D/A converters.

Options on both parts include a programmable pedestal (0 or 7.5 IRE) and use of an external voltage or current reference. Fifteen overlay registers provide for overlaying cursors, grids, menus, EGA emulation, etc. Also supported is a pixel read mask register and sync generation on all three channels.

The ADV478 and ADV471 generate RS-343A compatible video signals into a doubly terminated 75Ω load, and RS-170 compatible video signals into a singly terminated 75Ω load, without requiring external buffering. Differential and integral linearity errors are guaranteed to be a maximum of ±1LSB for the ADV478 and ±1/4LSB for the ADV471 over the full temperature range.

NOTES

[1] ±5% for 80MHz parts; ±10% for 66MHz, 50MHz and 35MHz parts.

[2] Temperature Range (T_{min} to T_{max}); 0 to +70°C.

[3] Numbers in parentheses indicate ADV471 parameter value.

[4] Clock and data feedthrough is a function of the amount of overshoot and undershoot on the digital inputs. For this test, the digital inputs have a 1kΩ resistor to ground and are driven by 74HC logic. Glitch impulse includes clock and data feedthrough, −3dB test bandwidth = 2 × clock rate.

[5] TTL input values are 0 to 3 volts, with input rise/fall times ≤3ns, measured between the 10% and 90% points. Timing reference points at 50% for inputs and outputs. Analog output load ≤10pF, D0 – D7 output load ≤50pF. See timing notes in Figure 2.

[6] DAC to DAC crosstalk is measured by holding one DAC high while the other two are making low to high and high to low transitions.

Specifications subject to change without notice.

TIMING CHARACTERISTICS[1] (V_{AA}[2] = +5V, SETUP = 8/$\overline{6}$ = V_{AA}, V_{REF} = 1.235V. R_{SET} = 147Ω. All Specifications T_{min} to T_{max}[3].)

RECOMMENDED OPERATING CONDITIONS

Parameter	Symbol	Min	Typ	Max	Units
Power Supply	V_{AA}				
80MHz Parts		4.75	5.00	5.25	Volts
50, 35MHz Parts		4.5	5.00	5.5	Volts
Ambient Operating Temperature	T_A	0		+70	°C
Output Load	R_L		37.5		Ω
Voltage Reference Configuration					
Reference Voltage	V_{REF}	1.14	1.235	1.26	Volts
Current Reference Configuration					
Reference Current	I_{REF}	−3		−10	mA

CAUTION

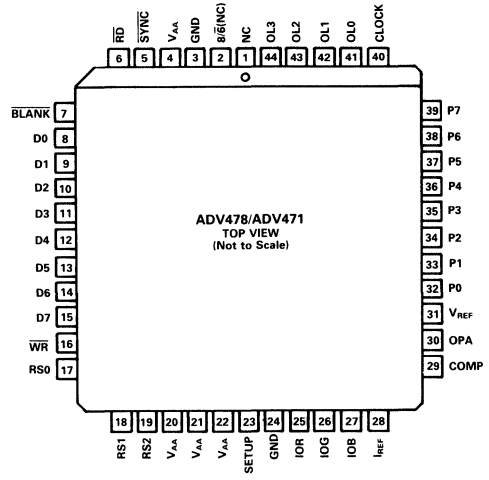
ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

ABSOLUTE MAXIMUM RATINGS*

V_{AA} to GND . . . . . +7V
Voltage on Any Digital Pin . . . GND −0.5V to V_{AA} +0.5V
Ambient Operating Temperature (T_A) . . . −55°C to +125°C
Storage Temperature (T_S) . . . . . −65°C to +150°C
Junction Temperature (T_J) . . . . . +175°C
Vapor Phase Soldering (2 minutes) . . . . . TBD
IOR, IOB, IOG to GND[1] . . . . . 0V to V_{AA}

NOTES
*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
[1]Analog output short circuit to any power supply or common can be of an indefinite duration.

PLCC PIN CONFIGURATION



NOTES
[1]All devices are packaged in a 44-pin plastic leaded (J-lead) chip carrier, PLCC.
[2]All devices are specified for 0 to +70°C operation.
[3]See Section 14 for package outline information.

PIN FUNCTION DESCRIPTION

Pin Mnemonic	Function
$\overline{\text{BLANK}}$	Composite blank control input (TTL compatible). A logic zero drives the analog outputs to the blanking level as illustrated in Tables IV and V. It is latched on the rising edge of CLOCK. When $\overline{\text{BLANK}}$ is a logical zero, the pixel and overlay inputs are ignored
SETUP	Setup control input. Used to specify either a 0 IRE (SETUP = GND) or 7.5 IRE (SETUP = V_{AA}) blanking pedestal.
$\overline{\text{SYNC}}$	Composite sync control input (TTL compatible). A logical zero on this input switches off a 40 IRE current source on the analog outputs (see Figures 3 and 4). $\overline{\text{SYNC}}$ does not override any other control or data input, as shown in Tables IV and V; therefore, it should be asserted only during the blanking interval. It is latched on the rising edge of CLOCK.
CLOCK	Clock input (TTL compatible). The rising edge of CLOCK latches the P0 – P7, OL0 – OL3, $\overline{\text{SYNC}}$, and $\overline{\text{BLANK}}$ inputs. It is typically the pixel clock rate of the video system. It is recommended that CLOCK be driven by a dedicated TTL buffer.
P0 – P7	Pixel select inputs (TTL compatible). These inputs specify, on a pixel basis, which one of the 256 entries in the color palette RAM is to be used to provide color information. They are latched on the rising edge of CLOCK. P0 is the LSB. Unused inputs should be connected to GND.
OL0 – OL3	Overlay select inputs (TTL compatible). These inputs specify which palette is to be used to provide color information, as illustrated in Table III. When accessing the overlay palette, the P0 – P7 inputs are ignored. They are latched on the rising edge of CLOCK. OL0 is the LSB. Unused inputs should be connected to GND.
IOR, IOG, IOB	Red, green, and blue current outputs. These high impedance current sources are capable of directly driving a doubly terminated 75Ω coaxial cable (Figures 5 and 6).
I_{REF}	Full-scale adjust control. Note that the IRE relationships in Figures 3 and 4 are maintained, regardless of the full-scale output current. When using an external voltage reference (Figure 5), a resistor (R_{SET}) connected between this pin and GND controls the magnitude of the full-scale video signal. The relationship between R_{SET} and the full-scale output current on each output is: $R_{SET}\ (\Omega) = K * 1{,}000 * V_{REF}\ (V)/I_{OUT}\ (mA)$ K is defined in the table below, along with corresponding R_{SET} values for doubly terminated 75Ω loads. When using an external current reference (Figure 6), the relationship between I_{REF} and the full-scale output current on each output is: $I_{REF}\ (mA) = I_{OUT}\ (mA)/K$

Mode	Pedestal	K	R_{SET} (Ω)
6-Bit	7.5 IRE	3.170	147
8-Bit	7.5 IRE	3.195	147
6-Bit	0 IRE	3.000	147
8-Bit	0 IRE	3.025	147

COMP	Compensation pin. If an external voltage reference is used (Figure 5), this pin should be connected to OPA. If an external current reference is used, this pin should be connected to I_{REF}. A 0.1μF ceramic capacitor must always be used to bypass this pin to V_{AA}.
V_{REF}	Voltage reference input. If an external voltage reference is used (Figure 5), it must supply this input with a 1.2V (typical) reference. If an external current reference is used (Figure 6), this pin should be left floating, except for the bypass capacitor. A 0.1μF ceramic capacitor must always be used to decouple this input to V_{AA} as shown in Figures 5 and 6.
OPA	Reference amplifier output. If an external voltage reference is used (Figure 5), this pin must be connected to COMP. When using an external current reference (Figure 6), this pin should be left floating.
V_{AA}	Analog power. All V_{AA} pins must be connected to the Analog Power Plane.
GND	Analog ground. All GND pins must be connected to the Ground Plane.
$\overline{\text{WR}}$	Write control input (TTL compatible). D0 – D7 data is latched on the rising edge of $\overline{\text{WR}}$, and RS0 – RS2 are latched on the falling edge of $\overline{\text{WR}}$ during MPU write operations. See Figure 1.

Pin Mnemonic	Function
$\overline{RD}$	Read control input (TTL compatible). To read data from the device, $\overline{RD}$ must be a logical zero. RS0 – RS2 are latched on the falling edge of $\overline{RD}$ during MPU read operations.
RS0, RS1, RS2	Register select inputs (TTL compatible). RS0 – RS2 specify the type of read or write operation being performed as illustrated in Tables I and II.
D0 – D7	Data bus (TTL compatible). Data is transferred into and out of the device over this 8-bit bidirectional data bus. D0 is the least significant bit.
8/$\overline{6}$	8-bit/6-bit select input (TTL compatible). This control input specifies whether the MPU is reading and writing 8-bits (logical one) or 6-bits (logical zero) of color information each cycle. For 8-bit operation, D7 is the most significant data bit during color read/write cycles. For 6-bit operation, D5 is the most significant data bit during color read/write cycles (D6 and D7 are ignored during color write cycles and are logical zero during color read cycles). This control input is implemented only on the ADV478.

TERMINOLOGY

Blanking Level
The level seperating the SYNC portion from the video portion of the waveform. Usually referred to as the front porch or back porch. At 0 IRE units, it is the level which will shut off the picture tube, resulting in the blackest possible picture.

Color Video (RGB)
This usually refers to the technique of combining the three primary colors of red, green and blue to produce color pictures within the usual spectrum. In RGB monitors, three DACs would be required, one for each color.

Composite SYNC Signal (SYNC)
The position of the composite video signal which synchronizes the scanning process.

Composite Video Signal
The video signal with or without setup, plus the composite SYNC signal.

Gray Scale
The discrete levels of video signal between reference black and reference white levels. An 8-bit DAC contains 256 different levels while a 6-bit DAC contains 64.

Raster Scan
The most basic method of sweeping a CRT one line at a time to generate and display images.

Reference Black Level
The maximum negative polarity amplitude of the video signal.

Reference White Level
The maximum positive polarity amplitude of the video signal.

Setup
The difference between the reference black level and the blanking level.

SYNC Level
The peak level of the composite SYNC signal.

Video Signal
That portion of the composite video signal which varies in gray scale levels between reference white and reference black. Also referred to as the picture signal, this is the portion which may be visually observed.

CIRCUIT DESCRIPTION

MPU Interface

As illustrated in the functional block diagram, the ADV478 and ADV471 support a standard MPU bus interface, allowing the MPU direct access to the color palette RAM and overlay color registers.

The RS0 – RS2 select inputs specify whether the MPU is accessing the address register, color palette RAM, overlay registers or read mask register, as shown in Table I. The 8-bit address register is used to address the color palette RAM and overlay registers, eliminating the requirement for external address multiplexers.

To write color data, the MPU writes to the address register (selecting RAM or overlay write mode) with the address of the color palette RAM location or overlay register to be modified. The MPU performs three successive write cycles (8 or 6 bits each of red, green and blue), using RS0 – RS2 to select either the color palette RAM or overlay registers. During the blue write cycle, the three bytes of color information are concatenated into a 24-bit word (18-bit word for the ADV471) and written to the location specified by the address register. The address register then increments to the next location which the MPU may modify by simply writing another sequence of red, green and blue data.

RS2	RS1	RS0	Addressed by MPU
0	0	0	Address Register (RAM Write Mode)
0	1	1	Address Register (RAM Read Mode)
0	0	1	Color Palette RAM
0	1	0	Pixel Read Mask Register
1	0	0	Address Register (Overlay Write Mode)
1	1	1	Address Register (Overlay Read Mode)
1	0	1	Overlay Registers
1	1	0	Reserved

Table I. Control Input Truth Table

To read color data, the MPU loads the address register (selecting RAM or overlay read mode) with the address of the color palette RAM location or overlay register to be read. The MPU performs three successive read cycles (8 or 6 bits each of red, green and blue), using RS0 – RS2 to select either the color palette RAM or overlay registers. Following the blue read cycle, the address register increments to the next location which the MPU may read by simply reading another sequence of red, green and blue data.

When accessing the color palette RAM, the address register resets to 00H following a blue read or write cycle to RAM location FFH. When accessing the overlay color registers, the address register increments following a blue read or write cycle. However, while accessing the overlay color registers, the four most significant bits of the address register (ADDR4 – 7) are ignored.

The MPU interface operates asynchronously to the pixel clock. Data transfers between the color palette RAM/overlay registers and the color registers (R, G and B in the block diagram) are synchronized by internal logic and occur in the period between MPU accesses. As only one pixel clock cycle is required to complete the transfer, the color palette RAM and overlay registers may be accessed at any time with no noticeable disturbance on the display screen.

To keep track of the red, green and blue read/write cycles, the address register has two additional bits (ADDRa, ADDRb) that count modulo three, as shown in Table II. They are reset to zero when the MPU writes to the address register and are not reset to zero when the MPU reads the address register. The MPU does not have access to these bits. The other eight bits of the address register, incremented following a blue read or write cycle (ADDR0 – 7), are accessible to the MPU and are used to address color palette RAM locations and overlay registers, as shown in Table II. ADDR0 is the LSB when the MPU is accessing the RAM or overlay registers. The MPU may read the address register at any time without modifying its contents or the existing read/write mode.

Figure 1 illustrates the MPU read/write timing.

	Value	RS2	RS1	RS0	Addressed By MPU
ADDRa,b (Counts Modulo 3)	00				Red Value
	01				Green Value
	10				Blue Value
ADDR0 – 7 (Counts Binary)	00H – FFH	0	0	1	Color Palette RAM
	XXXX 0000	1	0	1	Reserved
	XXXX 0001	1	0	1	Overlay Color 1
	XXXX 0010	1	0	1	Overlay Color 2
	•	•	•	•	•
	•	•	•	•	•
	XXXX 1111	1	0	1	Overlay Color 15

Table II. Address Register (ADDR) Operation

ADV478 Data Bus Interface

On the ADV478, the 8/$\overline{6}$ control input is used to specify whether the MPU is reading and writing 8 bits (8/$\overline{6}$ = logical one) or 6 bits (8/$\overline{6}$ = logical zero) of color information each cycle.

For 8-bit operation, D0 is the LSB and D7 is the MSB of color data.

For 6-bit operation (and also when using the ADV471), color data is contained on the lower six bits of the data bus, with D0 being the LSB and D5 the MSB of color data. When writing color data, D6 and D7 are ignored. During color read cycles, D6 and D7 will be a logical zero.

ADV471 Data Bus Interface

Color data is contained on the lower six bits of the data bus, with D0 being the LSB and D5 the MSB of color data. When writing color data, D6 and D7 are ignored. During color read cycles, D6 and D7 will be a logical zero.

Frame Buffer Interface

The P0 – P7 and OL0 – OL3 inputs are used to address the color palette RAM and overlay registers, as shown in Table III.

OL0 – OL3	P0 – P7	Addressed by Frame Buffer
0H	00H	Color Palette RAM Location 00H
0H	01H	Color Palette RAM Location 01H
•	•	•
•	•	•
0H	FFH	Color Palette RAM Location FFH
1H	XXH	Overlay Color 1
2H	XXH	Overlay Color 2
•	•	•
•	•	•
FH	XXH	Overlay Color 15

External voltage or current reference adjusted for 26.67mA full-scale output.

Table IV. Video Output Truth Table (SETUP = V_{AA})

The contents of the pixel read mask register, which may be accessed by the MPU at any time, are bit-wise logically ANDed with the P0 – P7 inputs. Bit D0 of the pixel read mask register corresponds to pixel input P0. The addressed location provides 24 bits (18 bits for the ADV471) of color information to the three D/A converters.

The $\overline{SYNC}$ and $\overline{BLANK}$ inputs, also latched on the rising edge of CLOCK to maintain synchronization with the color data, add appropriately weighted currents to the analog outputs, producing the specific output levels required for video applications, as illustrated in Figures 3 and 4. Tables IV and V detail how the $\overline{SYNC}$ and $\overline{BLANK}$ inputs modify the output levels.

The SETUP input is used to specify whether a 0 IRE (SETUP = GND) or 7.5 IRE (SETUP = V_{AA}) blanking pedestal is to be used.

The analog outputs of the ADV478 and ADV471 are capable of directly driving a 37.5Ω load, such as a doubly terminated 75Ω coaxial cable.

PC BOARD LAYOUT CONSIDERATIONS

PC Board Considerations

The layout should be optimized for lowest noise on the ADV478/ADV471 power and ground lines by shielding the digital inputs and providing good decoupling. The lead length between groups of V_{AA} and GND pins should by minimized so as to minimize inductive ringing.

Ground Planes

The ground plane should encompass all ADV478/ADV471 ground pins, current/voltage reference circuitry, power supply bypass circuitry for the ADV478/ADV471, the analog output traces and all the digital signal traces leading up to the ADV478/ADV471.

Power Planes

The ADV478/ADV471 and any associated analog circuitry should have its own power plane, referred to as the analog power plane. This power plane should be connected to the regular PCB power plane (V_{CC}) at a single point through a ferrite bead, as illustrated in Figures 5 and 6. This bead should be located within three inches of the ADV478/ADV471.

The PCB power plane should provide power to all digital logic on the PC board, and the analog power plane should provide power to all ADV478/ADV471 power pins and current/voltage reference circuitry.

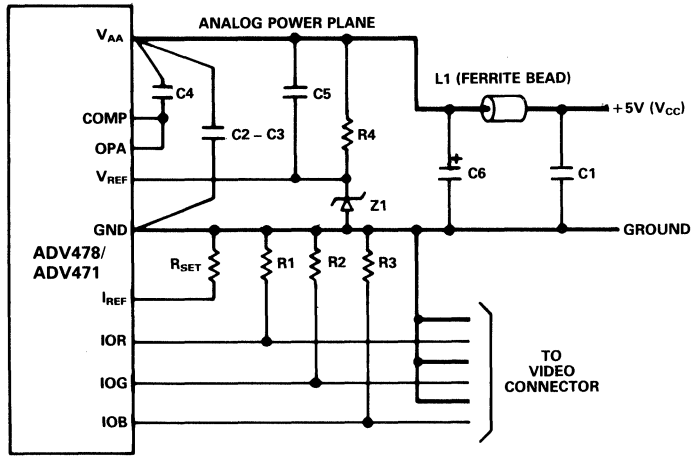
Plane-to-plane noise coupling can be reduced by ensuring that portions of the regular PCB power and ground planes do not overlay portions of the analog power plane, unless they can be arranged such that the plane-to-plane noise is common mode.

Supply Decoupling

For optimum performance, bypass capacitors should be installed using the shortest leads possible, consistent with reliable operation, to reduce the lead inductance.

Best performance is obtained with a 0.1μF ceramic capacitor decoupling each of the two groups of V_{AA} pins to GND. These capacitors should be placed as close as possible to the device.

It is important to note that while the ADV478 and ADV471 contain circuitry to reject power supply noise, this rejection decreases with frequency. If a high frequency switching power supply is used, the designer should pay close attention to reducing power supply noise and consider using a three terminal voltage regulator for supplying power to the analog power plane.



COMPONENT	DESCRIPTION	VENDOR PART NUMBER

R_{SET}	1% Metal Film Resistor	Dale CMF-55C
Z1	1.2V Voltage Reference	Analog Devices AD589KH

Figure 5. Typical Connection Diagram and Component List (External Voltage Reference)

Digital Signal Interconnect

The digital inputs to the ADV478/ADV471 should be isolated as much as possible from the analog outputs and other analog circuitry. Also, these input signals should not overlay the analog power plane.

Due to the high clock rates involved, long clock lines to the ADV478/ADV471 should be avoided to reduce noise pickup.

Any active termination resistors for the digital inputs should be connected to the regular PCB power plane (V_{CC}), and not the analog power plane.

Analog Signal Interconnect

The ADV478/ADV471 should be located as close as possible to the output connectors to minimize noise pickup and reflections due to impedance mismatch.

The video output signals should overlay the ground plane, and not the analog power plane, to maximize the high frequency power supply rejection.

For maximum performance, the analog outputs should each have a 75Ω load resistor connected to GND. The connection between the current output and GND should be as close as possible to the ADV478/ADV471 to minimize reflections.

Figure 6. Typical Connection Diagram and Component List (External Current Reference)

APPLICATION INFORMATION

External Voltage vs. Current Reference

The ADV478/ADV471 is designed to have excellent performance using either an external voltage or current reference. The voltage reference design (Figure 5) has the advantages of temperature compensation, simplicity, lower cost and provides excellent power supply rejection. The current reference design (Figure 6) requires more components to provide adequate power supply rejection and temperature compensation (two transistors, three resistors and additional capacitors).

RS-170 Video Generation

For generation of RS-170 compatible video, it is recommended that the DAC outputs be connected to a singly terminated 75Ωload. If the ADV478/ADV471 is not driving a large capacitive load, there will be negligible difference in video quality between doubly terminated 75Ω and singly terminated 75Ω loads.

If driving a large capacitive load (load RC> $1/(2\pi f_C)$), it is recommended that an output buffer (such as a MC1378 with an unloaded gain>2) be used to drive a doubly terminated 75Ω load.

ANALOG DEVICES

High Resolution 16- and 18-Bit Digital-to-Analog Converters

DAC1136/DAC1138

FEATURES

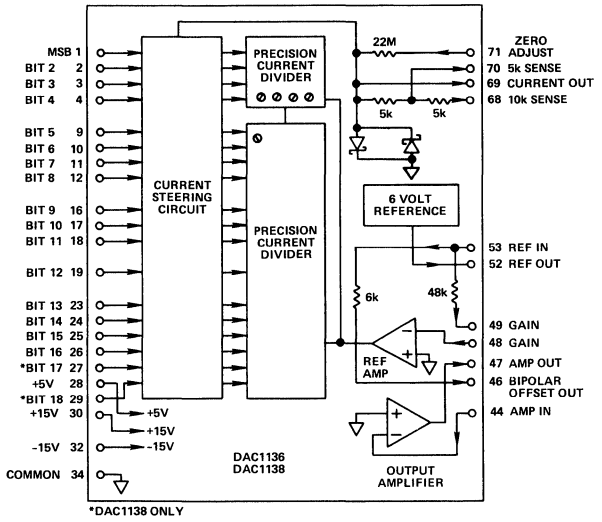
DAC1138

18-Bit Resolution and Accuracy (38μV, 1 Part in 262,144)
Nonlinearity 1/2LSB max (DAC1138K)
Excellent Stability
Settling to 1/2LSB (0.0002%) in 10μs
Hermetically-Sealed Semiconductors

DAC1136

16-Bit Resolution and Accuracy (152μV, 1 Part in 65,536)
Low Cost
Nonlinearity 1/2LSB max (DAC1136K, L)
Settling to 1/2LSB max (0.0008%) in 6μs

DAC1136/DAC1138 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The DAC1136/1138 are complete self-contained current or voltage output modular digital-to-analog converters with resolutions and accuracies of 16 and 18 bits.

The DAC1136/1138 combine precision current sources with state-of-the-art steering switches to produce a very linear output. Inputs to these converters are compatible with TTL levels. The converters have a current output of -2mA full scale. A voltage output can be obtained by connecting the internal amplifier to the current output by means of jumpers. By using additional jumpers, the user can select any one of the following output ranges: 0 to +5V, 0 to +10V, ±5V, or ±10V.

WHERE TO USE HIGH RESOLUTION DACS

The DAC1136/1138 deliver exceptional accuracy for a broad range of display, test and instrumentation applications. The DAC1136, with a resolution of 16 bits or 1 part in 65,536, and the DAC1138 with a resolution of 18 bits or 1 part in 262,144 are ideally suited for applications requiring wide dynamic range measurement and control. Applications include data acquisition systems, high resolution CRT displays, automatic semiconductor testing, photo-typesetting, frequency synthesis and nuclear reactor control.

CERTIFICATE OF CALIBRATION

Each DAC1138 has been calibrated with equipment and methods that are traceable to the National Bureau of Standards (NBS). A Certificate of Performance is sent with each unit, which includes linearity test data.

SPECIFICATIONS (typical @ +25°C, rated power supplies unless otherwise noted)

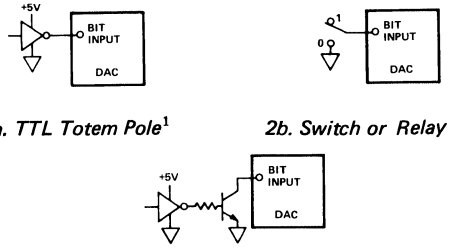
INPUT CONSIDERATIONS

The DAC1136/1138 may be driven by TTL or CMOS as shown in Figure 2. Note that the TTL input is shown with inputs for both a direct "totem pole" TTL gate and open collector (or "pull-up") configurations.



2a. TTL Totem Pole[1] *2b. Switch or Relay Input[2]*

2c. CMOS Input

1. FOR TTL WITH OPEN COLLECTOR, DO NOT USE EXTERNAL PULL-UP. CONVERTERS HAVE INTERNAL 10kΩ PULL-UP ON EACH INPUT TO 3.8V.
2. USE SPST SWITCH OR RELAY TO GROUND. WHEN SWITCH IS OPEN, THE INTERNAL 10kΩ WILL PULL INPUT UP TO 3.8V.

Figure 2. Input Connections

OUTPUT CONNECTIONS AND GUARDING

The DAC1136/1138 output connections for various voltage ranges are shown in Figure 3.

Since an LSB is only 38µV (at 10 volts full scale for the DAC1138), care must be exercised to properly guard the current output of the converter from leakage current. Any connection made to the DAC's current output (pin 69) should be guarded. Suggested printed circuit board guarding is shown in Figure 3

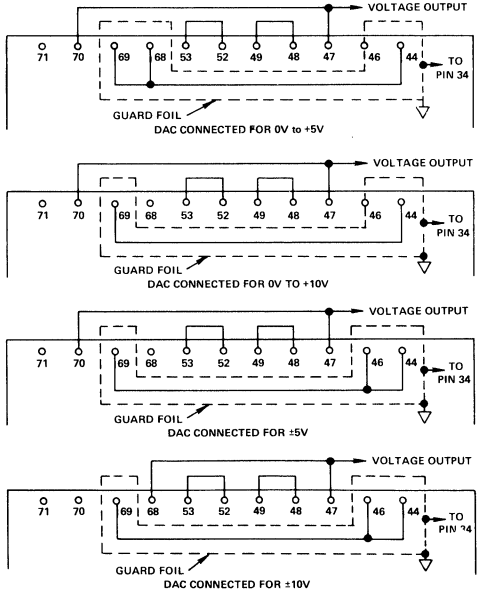


Figure 3. Output Voltage Connections and Suggested PCB Guarding (Unipolar and Bipolar)

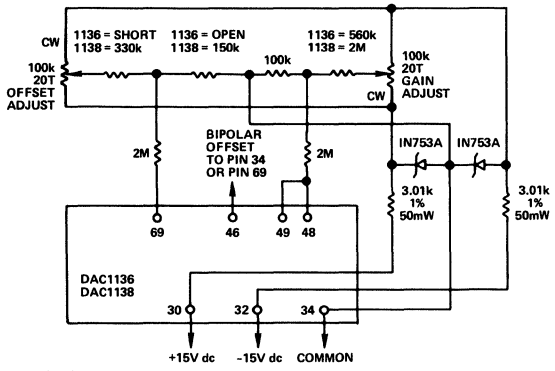
GAIN AND OFFSET ADJUSTMENTS

The gain and offset adjustments are made with external potentiometers which the user supplies. With the appropriate digital inputs applied, these potentiometers are adjusted until the desired output voltage is obtained. The proper connections for offset and gain are shown in Figure 4. The voltmeter used to measure the output should be capable of stable resolution of 1/4LSB in the region of zero and full scale. Because of the interaction between offset and gain adjustments, the adjustment procedure described below should be carefully followed. Offset adjustment affects gain, but gain adjustment does not affect offset.



NOTES:
1. ALL FIXED RESISTORS ARE 5% CARBON COMP, UNLESS OTHERWISE NOTED.
2. ALL POTENTIOMETERS ARE 20-TURN INFINITE RESOLUTION TYPE.

Figure 4. Gain and Offset Adjustments

For unipolar mode, apply a digital input of all "1's" (complementary binary code for zero output) and adjust the offset potentiometer until a 0.00000V output is obtained (see Table I). Once the appropriate offset adjustment has been made, apply a digital input of all "0's". Adjust the gain potentiometer until the plus full scale output is obtained (see Table I).

For bipolar mode, apply a digital input of all "1's" (complementary offset binary code for minus full scale) and adjust the offset potentiometer for the proper minus full scale output voltage (see Table I). Once the appropriate minus full scale adjustment has been made, apply a digital input of all "0's". Adjust the gain potentiometer until the plus full scale output shown below is obtained.

RANGE	IDEAL OUTPUT		
		DAC1138	DAC1136
Unipolar:	All 11...1	All 00...0	
0V→+10V	0.00000V	+9.999962V	+9.999848V
0V→+5V	0.00000V	+4.999981V	+4.999924V
Bipolar:			
-10V→+10V	-10.00000V	+9.999934V	+9.999695V
-5V → +5V	-5.00000V	+4.999962V	+4.999848V
To adjust:	Adjust ZERO pot	Adjust GAIN pot	

Table I. Full Scale Output

DIFFERENTIAL LINEARITY ADJUSTMENT

Each DAC1136/1138 has been factory calibrated and tested to achieve the performance indicated in the electrical specifications. Before attempting recalibration, it is imperative that the circuit be checked to confirm that all previously described precautions have been taken to insure proper application at the 16- or 18-bit level. Basically, the DAC is trimmed by comparing a bit to the sum of all lower bits, and adjusting, if necessary, for a one LSB positive difference. The top 4 major carries, i.e., MSB minus the sum of bits 2-through-the-LSB, down through bit 4 minus the sum of bits 5-through-the-LSB, can be trimmed using the procedure outlined below. A differential voltmeter capable of 100μV Full Scale should be connected to V_{OUT} of the DAC. This will resolve an LSB which at 18 bits is 38μV (10V range). A Fluke 895A or equivalent is recommended.

1. Bit 4 Trim
   a. Set bit inputs to 11110 . . . . 0.
   b. Read the output voltage by nulling the voltmeter.
   c. Set bit inputs to 11101 . . . . 1.
   d. Read voltage by nulling voltmeter. This reading should be equal to that of step 1b plus 1LSB. Adjust bit 4 if required (see B4, Figure 6).

2. Bit 3 Trim
   a. Set bit inputs to 1110 . . . . 0.
   b. Read output voltage by nulling the voltmeter.
   c. Set inputs to 1101 . . . . 1.
   d. Read voltage by nulling the voltmeter. This reading should be equal to that of step 2b plus 1LSB. Adjust bit 3 if required (see B3, Figure 6).

3. Bit 2 Trim
   a. Set bit inputs to 110 . . . . 0.
   b. Read output voltage by nulling the voltmeter.
   c. Set bit inputs to 101 . . . . 1.
   d. Read voltage by nulling voltmeter. This reading should be equal to that of step 3b plus 1LSB. Adjust bit 2 if required (see B2, Figure 6),

4. Bit 1 (MSB) Trim
   a. Set bit switches to 100 . . . . 0.
   b. Read output voltage by nulling the voltmeter.
   c. Set bit switches to 011 . . . . 1.
   d. Read voltage by nulling voltmeter. This reading should be equal to that of step 4b plus 1LSB. Adjust bit 1 (MSB) if required (see MSB, Figure 6).

If insufficient range exists on any adjustment, then a separate adjustment for the weight of bits 5-through-the-LSB (see Sum B5 → LSB, Figure 6) should be performed. This condition will probably not occur on bit 2, 3 and 4 but might occur on the MSB. If adjustment of the sum of bits 5-through-the-LSB is made, the trim procedure for all bits should be repeated. Obviously, since the procedure affects the weight of individual bits, it affects the overall gain of the DAC. The final step should be adjustment of gain (user supplied adjustment external to module).

USING AN EXTERNAL 6V REFERENCE

The DAC1136/1138 can be operated with an external reference connected to pin 53 of the module. The current drain on the external reference will be 1.125mA in bipolar mode or 0.125mA in unipolar mode (pin 46 should be left open and not grounded when using an external reference in the unipolar mode). When an external reference is used, pin 52, (the output of the internal reference) is left open.

Codi Semiconductor manufactures a reference module called Certavolt[1] with a 10 volt output accurate to 0.001%. This output is temperature compensated to within 1ppm/°C from +15°C to +55°C. The Certavolt requires a power supply of +28V dc @ 20mA. To convert the +10 volt output of the Certavolt to the +6 volt reguired by the DAC, the circuit shown in Figure 5 is recommended.

[1] Certavolt is a registered trade name by Codi Semiconductor.

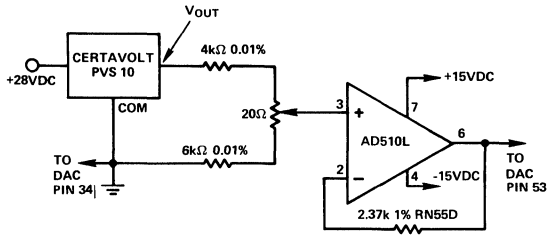


Figure 5. DAC1136/1138 with External Precision Reference

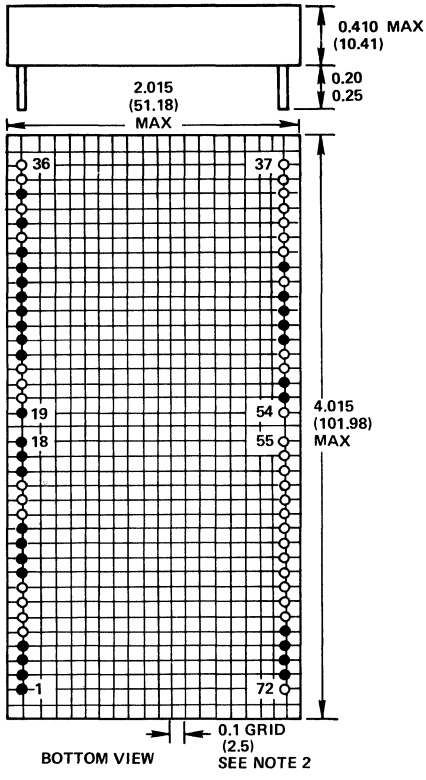
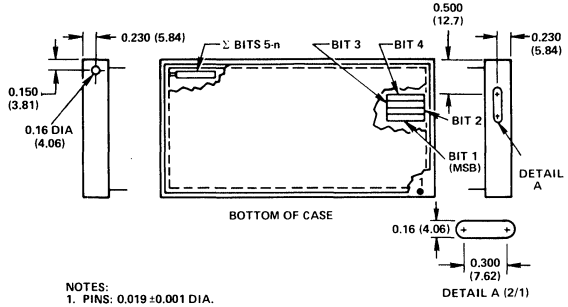
OUTLINE DIMENSIONS AND PIN DESIGNATIONS

Dimensions shown in inches and (mm).





NOTES:
1. PINS: 0.019 ±0.001 DIA.
2. GRID AND MARKINGS NEXT TO PINS ARE FOR REFERENCE ONLY AND DO NOT APPEAR ON UNIT.
3. PINS 27 AND 29 ARE NOT PRESENT ON DAC1136.

ASSEMBLY INSTRUCTIONS

CAUTION: This module is not an embedded assembly and is not hermetically sealed. Do not subject to a solvent or water-wash process that would allow direct contact with free liquids or vapors. Entrapment of contaminants may occur, causing performance degradation and permanent damage. Install after any clean/wash process and then only spot clean by hand.

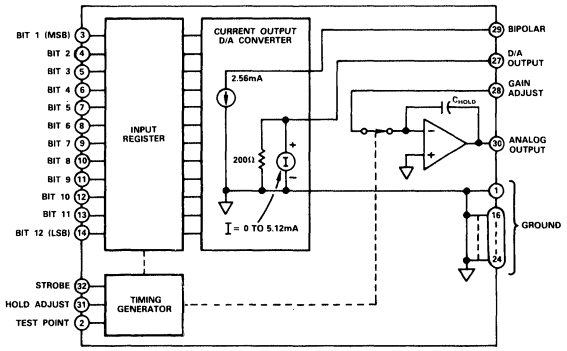
HDD-1206 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The Analog Devices HDD-1206 D/A converter combines innovative design techniques with remarkable hybrid construction to achieve deglitched voltage outputs at digital update rates as high as 6MHz.

Despite its small size and low power, the HDD-1206 provides the user with a complete solution to demanding applications which require the conversion of high-speed digital inputs into deglitched analog output voltages.

The unit is housed in an industry standard 32-pin hybrid and contains all the necessary circuit components to provide analog outputs at high update rates without the need for designing external circuits. Input registers, current-output D/A, deglitching circuits, and an output amplifier are all included inside the HDD-1206.

With the deglitching problem solved in a single package, the user of the HDD-1206 is able to incorporate the solution into his system with a minimum of design effort. User involvement is limited to the simple task of establishing the "hold" time for an optimum value by selecting the correct resistor value.

After that step is accomplished, the addition of a low-pass filter at the output of the D/A assures a "clean" voltage representation of the 12 bits of digital information applied to the inputs at video update rates.

The HDD-1206 is available in 32-pin dual in-line ceramic packages.

THEORY OF OPERATION

The equivalent circuit for the for the HDD-1206 D/A converter is shown in functional block diagram.

The unit consists of input registers, fast-settling current output D/A, output amplifier, timing generator, and associated circuits.

The purpose of the input register circuits is to de-skew the input bits and assure their simultaneous arrival at the input of the current D/A. This is critical because time skew on the input data bits is a major contributor to discontinuities, or "glitches," in the analog output of a D/A.

The Timing Generator includes a Track & Hold circuit and generates the required internal pulses for operation whenever it receives a Strobe input pulse. See Figure 1, the HDD-1206 timing diagram.

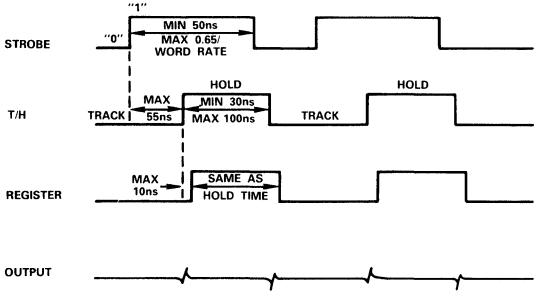

Figure 1. HDD-1206 Timing Diagram (Digital Inputs not Changing)

As shown, the Strobe pulse is a positive-going TTL pulse supplied by the user of the HDD-1206. Internal timing circuits establish the maximum 55ns delay from the leading edge of the Strobe pulse to the leading edge of the T/H (Track/Hold) pulse; and the maximum 10ns delay from the leading edge of the T/H pulse to the leading edge of the Register pulse. The data from the input registers are strobed into the current D/A at the end of this 65ns interval, so they must be valid by that time.

The user determines the width of the T/H pulse (and the Register pulse) by selecting the value of the R_{HOLD} resistor. See Figures 1 and 2. As shown, the width of the Hold pulse can vary from approximately 30ns to approximately 100ns by using resistor values from 1k to 5k, respectively.

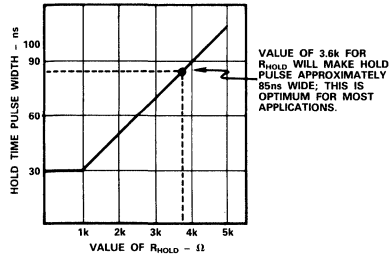

Figure 2. Hold Time vs. R_{HOLD}

For most applications, a value of 3.6kΩ and a pulse width of approximately 85ns is the optimum choice. This pulse width will "hold" the analog output of the HDD-1206 D/A until the "glitch" resulting from the most recent update has passed, without infringing on the word rate capabilities of the HDD-1206.

CURRENT-OUTPUT D/A CONVERTERS

A brief review of the salient characteristics of current D/A converters may be a useful approach to understanding the operation of the HDD-1206 unit.

Current-switching D/A converters are inherently faster than voltage-output types because of the absence of an output amplifier. This means current-switching converters have no slew rate limitation which can slow settling; nor are they subject to the overshoot and ringing problems often associated with feedback amplifiers.

Both current-switching and voltage-output converters display a discontinuity, or "glitch," in their analog outputs because of the basic characteristic of saturated logic (TTL is an example) which causes the propagation delay to be less for negative-going inputs than it is for positive-going inputs.

This difference in propagation delay manifests itself as a "worst case glitch" at the major carry point, or mid-scale, of the output range of the current converter. This is the point at which nearly equal and opposite currents are being switched within the converter.

The "glitch" at mid-scale, the switching point of the Most Significant Bit (MSB), will be halved at the ¼ and ¾ points; halved again at the ⅛ and ⅞ points, etc. The amplitude of the "glitch," therefore, is a function of signal dynamics and cannot be eliminated with filtering.

The variations in glitch amplitude caused by signal dynamics create a multitude of intermodulation (IM) products, some of which fall into the video pass-band as spurious signals, and increased noise level. These IM products are also relatively immune to elimination by filtering.

The amplitude of the glitch can be reduced by de-skewing the input bits; but no amount of de-skewing or filtering can negate the physics of saturated logic which cause the glitch to be generated initially.

The best solution, then, is to cause the glitch to remain a constant across the entire output range of the converter. The efficiencies of the circuit will be enhanced if the solution can also permit using the full drive capabilities of the current-output D/A in either unipolar or bipolar modes of operation.

The design approach used in the Analog Devices HDD-1206 D/A converter accomplishes these desired goals and provides voltage outputs at high update rates.

NOTES ON DEGLITCHING

Refer again to the equivalent circuit for the HDD-1206. The data bits are applied through the input register to the current-output D/A converter, which is capable of supplying up to 5.12mA of output current.

The output of the current D/A, in turn, is applied to the input of the output amplifier via strapping external to the HDD-1206. The Timing Generator supplies the necessary pulses and timing to apply signals to the current D/A and output amplifier after the initial glitch caused by the digital inputs has subsided.

The digital "1" (Hold) level of the T/H pulse causes the switch at the input of the amplifier to open, holding the last value of the current D/A converter. During this hold interval, the switching transients caused by updating digital inputs are masked from the amplifier, thereby avoiding HDD-1206 output discontinuities whose amplitude would be a function of signal dynamics.

Ten nanoseconds after the T/H pulse goes to the digital "1" level, the register pulse also changes state from "0" to "1".

This transition moves the output of the current D/A to the new value established by the most recent digital inputs applied to the HDD-1206.

Any change in the current D/A output has stablized by the time the T/H pulse returns to the digital "0" (Track) level. Re-establishing the track mode closes the switch at the input of the amplifier and the output of the HDD-1206 moves to the new analog value dictated by the digital input word.

As shown in Figure 1, the output of the HDD-1206 will contain switching transients associated with the T/H pulse. But these "glitches" will be constant in amplitude and duration and will occur at the update rate, since they are a function of the strobe pulse applied by the user.

These switching transients will settle out in approximately 500ns, and will have uniform amplitude over the complete analog output range of the D/A. For strobe rates of 2MHz and above, the settling interval switching from "hold" to "track", and vice versa, will produce a constant dc offset on the output. The HDD-1206 is not intended to get rid of all glitches per se; it is designed to provide a constant-amplitude glitch.

When the area under the transient curve is held constant, the frequency spectrum of the glitch is a fine line, i.e., a single-line spectrum at the sample rate frequencies, and harmonics of the sample frequency.

The HDD–1206 effectively eliminates the IM products discussed above. When it does, the signal-to-noise (S/N) ratio approaches that of an ideally-quantized signal, where the rms noise is $q/\sqrt{12}$, when frequencies above Nyquist are filtered out.

GLITCH VS. PEDESTAL

In addition to the "glitch" which is a characteristic of current D/As, the track & hold used in the HDD-1206 also contributes an anomaly to the output signal.

Refer to Figure 3. This diagram compares the "glitch" created by the HDD-1206 to the pedestal created by the internal T/H circuits.

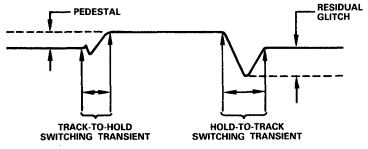

Figure 3. Pedestal/Glitch Relationship

As shown, the "glitch" is a transient signal which remains constant in width and amplitude over the entire output range, at all update rates. The pedestal, on the other hand, is an offset signal whose amplitude can vary (because of switching transient settling) as a function of hold time and word rate.

This pedestal is caused by charge transfer associated with the hold capacitor; the transfer occurs when the HDD-1206 circuits are switched from a "track" to "hold" condition. The pedestal is basically an offset error in the HDD-1206 output and can be compensated with the Offset Adjust when the unit is installed in the user's system.

Figure 3 is not drawn to scale; there is no attempt to imply the identified elements have precisely that relationship to one another. They are exaggerated for illustrative purposes.

Applications

Bipolar connections for the HDD-1206 D/A converter are shown in Figure 4. As indicated, a unipolar negative output is accomplished by connecting Bipolar Pin 29 to ground, instead of to Pins 27 and 28.

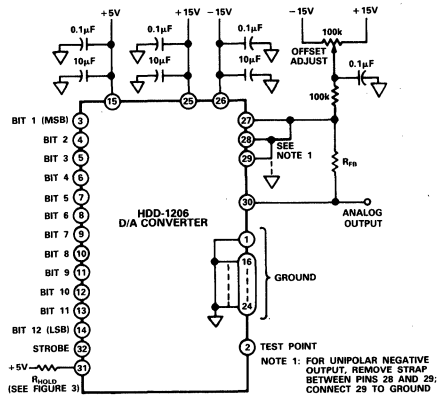

Figure 4. HDD-1206 Bipolar Connections

The output voltage swing is established by the value of feedback resistor R_{FB}. The table below indicates output levels for both unipolar and bipolar operation, with feedback resistors of either 1,000Ω or 2,000Ω.

Hold resistor R_{HOLD} connected between the +5V supply and Pin 31 sets the width of the Hold mode of the T/H pulse. Test Point Pin 2 is used for observing the pulse.

The Offset Adjust potentiometer is used to set the desired analog output of the HDD-1206 and can be used to help assure correct voltages are present when the D/A is installed in the system.

When operated in a unipolar mode with digital "0" applied to all inputs but no continuous strobe pulses applied, the Offset Adjust is set for an analog output of −5.12V or less 1LSB, with 1k for the value of R_{FB}. (NOTE: At least one strobe pulse needs to be applied to latch the input data into the registers.)

If the HDD-1206 is installed in a system and the strobe pulse is applied continuously, the Offset Adjust is calibrated for the desired output value with a digital "0" applied to all input pins.

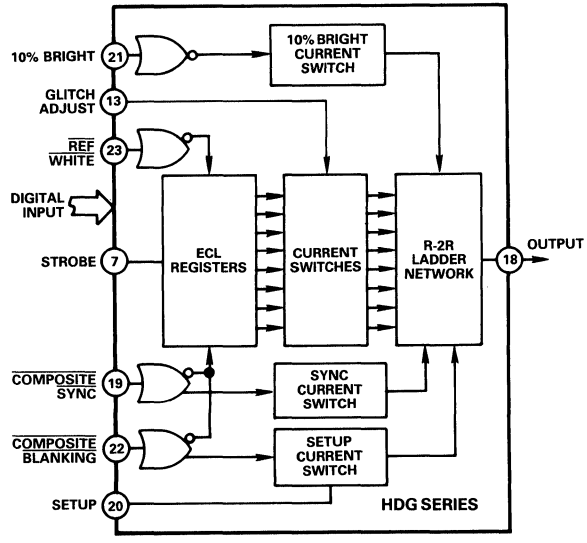
HDG SERIES FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The HDG-Series D/A Converters have become the standard of comparison for fast-settling D/As with complete composite inputs. The HDG-0805 is an eight-bit (256 Gray levels) device.

All versions have complete composite controls, including self-contained, digitally-controlled sync and blanking; and a reference white control input to help assure compatibility with EIA Standards RS-170, RS-330, and RS-343-A. Their performance is enhanced even more with a 10% bright input capability.

Output inpedance is 75 ohms and their full-scale output current is capable of developing standard video levels across video loads. In addition to all of these characteristics which make them easy to incorporate into circuits, the need for a single −5.2V power supply also adds to their attractiveness.

The model number without a suffix designates the "original" HDG Series D/A Converter and is housed in 24-pin metal packages. The model numbers with suffixes make use internally of the Analog Devices Model AD9700 to obtain better performance; these devices are housed in ceramic DIP packages.

The "BD" and "BW" versions in the newer (suffixed) units are close equivalents to the original design, but a number of advantages accrue by using the newer units. Note particularly the parameters for linearity tempco; strobe input loading; Composite Sync and Composite Blanking outputs; Power Supply Rejection Ratio (PSRR); supply current; and power dissipation. Conversely, the original design is slightly better in terms of voltage settling time, glitch energy, and output compliance.

NOTES
[1]Settling to GS percentage includes FS and MSB transitions. Inherent 3ns register delay (50%) points) is not included.
[2]Minimum update rates limited by full-scale settling time for useable number of bits.
Units can be updated to 150MHz with settling degradation.
[3]Glitch can be reduced with glitch adjustment.
[4]LSB value used for calibration causes Gray Scale output to be 637.5mV rather than 643mV shown in idealized composite waveform; both values are well within the output and EIA Standard RS-170 tolerances.
[5]Effect on analog output of logic "0" at $\overline{\text{Reference White}}$ input depends on 10% Bright signal input (See Table I).
[6]10% Bright, $\overline{\text{Composite Sync}}$, and $\overline{\text{Composite Blanking}}$ outputs shown add to Gray scale analog output at Pin 18 (See Table I).
[7]$\overline{\text{Composite Sync}}$ or $\overline{\text{Composite Blanking}}$ control signals reset input registers. $\overline{\text{Composite Sync}}$ or $\overline{\text{Composite Blanking}}$ should not be operated simultaneously with $\overline{\text{Reference White}}$.
[8]Power supply must have less than 5mV p-p ripple.
[9]Operating temperature −55°C to +125°C on "SD" units.
[10]Maximum junction temperature = 150°C.
[11]Calculated for HDG-0805SDB using MIL HNBK-217; Ground Fixed; +25°C Ambient.
[12]See Section 14 for package outline information.

USING HDG-SERIES UNIT FOR RASTER SCAN

Refer to the block diagram of the HDG-Series D/A Converter and the idealized composite output waveform.

The digital input bits represent the Gray Scale values (the discrete levels between Reference Black and Reference White) in a composite video signal. There are 256 (2^8) of these levels.

The input bits are applied to Pins 3–6 or Pins 8–11 of the HDG-0805.

The output analog signal (at Pin 18) will be a function of these digital inputs. The output will also be affected by the ECL levels at the control inputs of 10% Bright, Reference White, Composite Sync, and Composite Blanking; and the level of the control signal (expressed in terms of IRE units) at the Setup input.

The total effect of these combined signals can be illustrated in a truth table format if arbitrary values are assigned for Gray scale inputs, and various combinations of control inputs are selected.

Refer to Table I.

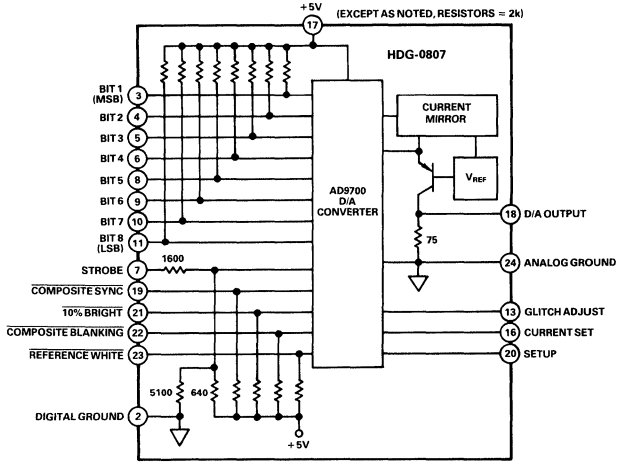
Hybrid Video Digital-to-Analog Converter

HDG-0807

FEATURES
- Update Rates to 50MHz
- Low Glitch
- Complete Composite Inputs
- Single +5V Power Supply
- TTL-Compatible Inputs
- Directly Drives 75Ω to Ground

APPLICATIONS
- Raster Scan Displays
- Color Graphics
- Analytical Instrumentation
- TV Video Reconstruction

HDG-0807 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The HDG-0807 D/A Converters are extensions of the technology and capabilities of the HDG-Series high-speed raster scan D/A converters. They offer the user increased flexibility because of their ability to operate on a single +5V power supply, and their compatibility with TTL signals.

The HDG-0807 is an eight-bit (256 levels) device.

Both versions have complete composite controls, including self-contained, digitally-controlled sync and blanking; and a reference white control input to help assure compatibility with EIA Standards RS-170, RS-330, and RS-343-A. Performance is enhanced even more with a 10% bright input capability.

Output impedance is 75Ω and the full-scale output current is capable of developing standard video levels across video loads. An output current mirror shifts the output to ground reference while attenuating power supply noise by means of common-mode rejection.

Model numbers with "BW" suffixes are housed in 24-pin non-hermetic ceramic dual-in-line packages. Versions with "BD" suffixes are housed in hermetically-sealed ceramic DIP packages.

NOTES
[1]Settling to GS percentage includes FS and MSB transitions. Inherent 3ns register delay (50%) points) is not included.
[2]Glitch can be reduced with glitch adjustment.
[3]Internal 2k pull-up resistors help assure compatibility with logic levels of multiple TTL families.
[4]LSB value used for calibration causes Gray Scale output to be 637.5mV rather than 643mV shown in idealized composite waveform; both values are well within the output and EIA Standard RS-170 tolerances.
[5]Effect on analog output of logic "0" at Reference White input depends on 10% Bright signal input.
[6]10% Bright, Composite Sync, and Composite Blanking outputs shown add to Gray scale analog output at Pin 18 and are measured with respect to sync level (V_S) shown in waveform.
[7]Composite Sync or Composite Blanking control signals reset input registers. Composite Sync or Composite Blanking should not be operated simultaneously with Reference White, which sets input registers.
[8]Maximum junction temperature = 150°C.
[9]See Section 14 for package outline information.

Specifications subject to change without notice.

14	+5V	11	BIT 8 (LSB)
13	GLITCH ADJUST	12	+5V

NOTES: Connect Pins 2 and 24 together and to low-impedance ground plane as close to case as possible.
+5V must be applied to all designated pins.

THEORY OF OPERATION

Refer to the block diagram of the HDG-0807 D/A Converter and the HDG-0807 composite output waveform.

The digital input bits represent the Gray Scale values (the discrete levels between Reference Black and Reference White) in a composite video signal. For HDG-0807 units, there are 256 (2^8) levels.

Input bits are applied to Pins 3-6 and Pins 8-11 for the HDG-0807.

The output analog signal (at Pin 18) will be a function of these digital inputs. The output will also be affected by the TTL levels at the control inputs of $\overline{\text{10\% Bright}}$, $\overline{\text{Reference White}}$, $\overline{\text{Composite Sync}}$, and $\overline{\text{Composite Blanking}}$; and the level of the control signal (expressed in terms of IRE units) at the Setup input.

The total effect of these combined signals can be illustrated in a truth table format if arbitrary values are assigned for Gray scale inputs, and various combinations of control inputs are selected.

Refer to Table I.

Analog Devices uses 2.5mV for weighting the LSB during calibration of the converter, which causes the full-scale 637.5mV output of the HDG-0807 to be different from the ideal 643mV output shown in the composite waveform in the RS-170 standard.

This disparity does not cause any problems in using the device, since both the ideal value and the actual value are well within the tolerances of the output and the RS-170 standard.

Referring again to the block diagram, the Strobe input applied to the HDG D/A clocks the input registers when the strobe signal makes the transition from a logic "0" to a logic "1". The purpose of the registers is to remove time skew from the digital input bits and minimize perturbations or "glitches" in the analog output signal.

A logic "0" applied to either the $\overline{\text{Composite Sync}}$ or $\overline{\text{Composite Blanking}}$ input resets the input registers to 00 000 000. A logic "0" signal applied to the $\overline{\text{Reference White}}$ input sets the input registers, thereby overriding the video input word. When this occurs, the analog output of the converter goes to 1046.75mV or to 975.75mV, depending upon whether or not the $\overline{\text{10\% Bright}}$ signal is also operated.

When $\overline{\text{Composite Blanking}}$ is operated, the analog output will go to a Reference Black value of 338.25mV less some amount, as determined by the voltage at Setup. The 53.25mV example used in the Specifications section of the data sheet is based on the Setup input floating, which is equivalent to 7.5 IRE units. (For this example, the analog output would be 285mV.)

APPLICATIONS

The HDG-0807 is specifically designed for operation in raster scan graphics applications, in which digital input data are being changed at a relatively high rate.

The D/A output is generally ac-coupled to the monitor, which eliminates the changing dc offset associated with the thermal drift of the level shift circuits. This offset drift, which is a function of output level, is held to a maximum of 50mV and will not affect dynamic video levels.

For optimum performance, ground pins 2 and 24 should be connected together and to a large ground plane near the unit. As indicated in the footnotes on the pin designations table, +5V must be applied to all pins which are called out to receive it.

The performance of the HDG devices can be enhanced with external bypass capacitors which will supplement the internal components. Low-frequency bypassing should be provided with 1μF (or larger) tantalum capacitors between the +5V supply pins and ground. High-frequency bypassing can be provided with ceramic capacitors of 0.1μF or larger. All bypass capacitors should be tied as closely as possible to the hybrid power supply pins.

A 200Ω potentiometer between +5V and ground with the center arm connected to Pin 13 changes the threshold of the internal current switches; this can reduce the amount of glitch from the typical 50pV-s to a lesser value when required.

For best performance, standard 24-pin hybrid sockets should be avoided. Individual pin sockets are preferable for evaluating devices and are available from Analog Devices; in final designs, the D/A should be soldered directly into the printed circuit board without sockets.

If it is necessary to route digital signals and/or strobe signals for distances greater than one inch (2.54cm), microstrip techniques should be used. Otherwise, the performance of the D/A converter may be affected adversely.

ORDERING INFORMATION

There are two versions of the 8-bit converter; both units operate over a temperature range of −25°C to +85°C. The model numbers are HDG-0807BD or HDG-0807BW. In these model numbers, the "D" in the suffix indicates a ceramic, hermetically-sealed DIP; and the "W" indicates a non-hermetic ceramic DIP.

Versions are available screened to military requirements; contact the factory for details. It is also possible to order units with synchronous functions on a "special order" basis; detailed information is available from the factory.

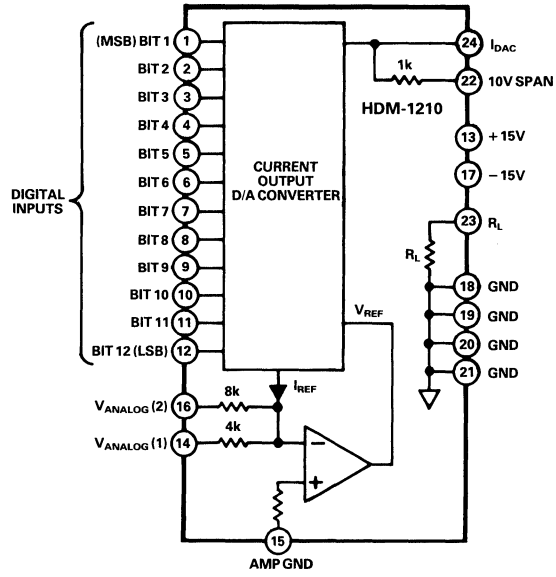
APPLICATIONS
CRT Displays
Waveform Generation
Vector Generation
MHz-Rate Digital or Analog Attenuators

HDM-1210 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The HDM-1210 D/A converter is an ultrahigh-speed current output multiplying converter which offers circuit designers a chance to obtain high speed, good drive, and flexible design parameters in a DIP package. Its output is the product of 12 bits of digital input data and the analog input(s), providing flexibility for a wide variety of applications.

Typical analog settling time to 1% is only 85ns; and 3dB analog bandwidth is 10MHz. Digital settling time to 0.1% accuracy at the major carry transition is an incredible 80ns, making the HDM-1210 D/A extremely attractive for a range of high-speed multiplying functions.

In one mode of operation, its output current is precisely proportional to the analog input signal, multiplied by the digital input code. The analog signal being multiplied can be a sine wave, triangle wave, sawtooth, or any one of a variety of complex waveforms. The output is an accurate scaled version of the input, with the digital input used as the scale factor.

In another mode of operation, the analog input voltage can be used as the scale factor for the digital input code. In addition to this kind of flexibility, the HDM-1210 also has various offsetting capabilities which allow the analog input, digital input, analog output, and/or an external amplifier to be combined. With these features, the HDM-1210 can be used to accommodate unipolar or bipolar operation; and provide either one-quadrant or two-quadrant multiplication.

THEORY OF OPERATION

Refer to the block diagram of the HDM-1210 D/A Converter.

The HDM-1210 uses the analog input voltages to set the reference current, designated as I_{REF} in the block diagram. Since this reference current is limited to 1.25mA, maximum inputs applied to V_{ANALOG} (1) (Pin 14) and V_{ANALOG} (2) (Pin 16) are also limited. When V_{ANALOG} (2) is open or grounded, the maximum input at V_{ANALOG} (1) is −5V; when V_{ANALOG} (1) is open or grounded, maximum input at V_{ANALOG} (2) is −10V.

If some combination of voltages in excess of those cited above is applied to the analog inputs, the analog output becomes limited to zero and remains at that value until the excessive analog input(s) is removed.

The output of the unit will not be limited if:

$$-1.25\text{mA} \leq \frac{V_{ANALOG\ (1)}}{4k} + \frac{V_{ANALOG\ (2)}}{8k} \leq 0\text{mA}$$

Permanent damage to the HDM-1210 may take place if the input at V_{ANALOG} (1) exceeds +1V with V_{ANALOG} (2) open or grounded; with V_{ANALOG} (1) open or grounded, voltage at V_{ANALOG} (2) should not exceed +2V.

The amount of overvoltage (up to the levels which may cause damage) will have an effect on the interval required for the converter to recover; the larger the overvoltage, the longer the interval. As shown in the SPECIFICATIONS section, a voltage of +0.5V overdrive is applied to V_{ANALOG} (1) when specifying recovery time.

Maximum output at I_{DAC} (Pin 24) is a function of the reference current established by the inputs; with all digital inputs at logic "1", the output current is based on the equation:

$$I_{OUT}\ (\text{max}) = I_{REF}\ (8.192)$$

where

$$I_{REF} = \frac{-V_{ANALOG\ (1)}}{4k\Omega} + \frac{-V_{ANALOG\ (2)}}{8k\Omega}$$

I_{REF} (max) is 1.25mA; therefore, maximum output current is 10.24mA.

This characteristic of the HDM-1210 means output current can be digitally adjusted, just as it is in a conventional D/A which has a variable maximum output current.

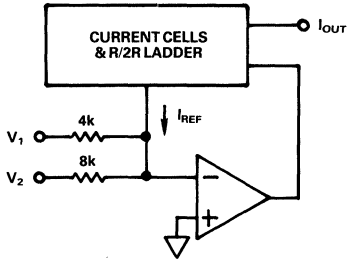

Figure 1. HDM-1210 Functional Block Diagram

There are 4,096 digital steps from zero to full-scale output for the HDM-1210, calculated with the equation:

$$I_{OUT} = (D)\ (8.192)\ (I_{REF})$$

where

D = 0 to 1 digital word in 4,096 steps (0.024%/step)

The two analog inputs at Pins 14 and 16 provide various offsetting capabilities which allow the HDM-1210 to accommodate either unipolar or bipolar input operation. When one of these inputs is properly offset to a negative voltage, the other input can be used for both negative and positive inputs. I_{REF} is still limited to 1.25mA, which limits the total output to the range from 0 to 10.24mA. Examples of outputs versus various inputs are shown in Table I.

Voltage @ V_{ANALOG} (1) (Pin 14)	Voltage @ V_{ANALOG} (2) (Pin 16)	D/A Output @ Pin 24	
		All "1" Digital Input	All "0" Digital Input
0V	Ground	0mA	0mA
−5V		+10.24mA	0mA
+2.5V	−5V	0mA	0mA
−2.5V		+1.024mA	0mA
+5V	−10V	0mA	0mA
0V		+10.24mA	0mA
Ground	0V	0mA	0mA
	−10V	+10.24mA	0mA
−2.5V	+5V	0mA	0mA
	−5V	+10.24mA	0mA
−5V	+10V	0mA	0mA
	0V	+10.24mA	0mA

Table I. Output vs. Inputs

There are two methods of obtaining a voltage output from the current output HDM-1210. The first method simply requires connecting a load resistor from Pin 24 to ground, as shown in Figure 2.

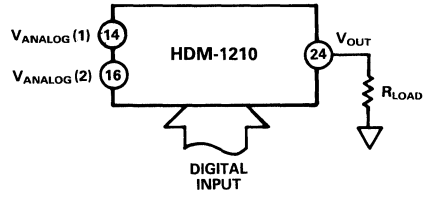

Figure 2. Passive I-to-V Converter (External Load)

The output voltage for this circuit is established by the equation $V_{OUT} = (R_{LOAD} \| R_{LADDER})\ (I_{OUT})$. R_{LADDER} is approximately 200Ω. The user must exercise care to avoid exceeding the compliance of the HDM-1210.

Alternatively, the output of the HDM-1210 can be connected to an internal load, as shown in Figure 3. This connection provides output resistance of 100Ω (±2%) and an output voltage swing of 0V to 1.024V.

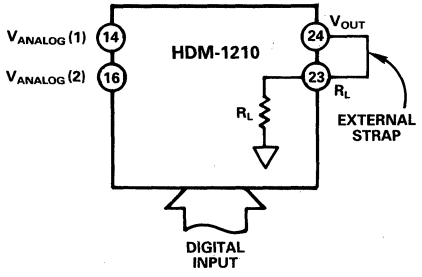

Figure 3. Passive I-to-V Converter (Internal Load)

The second method of obtaining a voltage output from the HDM-1210 D/A converter requires an external operational amplifier and a feedback resistor, as shown in Figure 4.

When the correct op amp is chosen, the output voltage from the combination shown in Figure 4 can be considerably greater than the output of an HDM-1210 operating as a passive I-to-V converter.

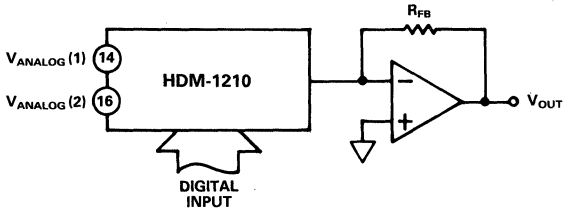

Figure 4. Active I-to-V Converter

If the Analog Devices' HOS-050A or HOS-060 operational amplifier is selected, the user will have wide output range, good drive, and easy compensation.

An internal feedback resistor of 1,000Ω in the HDM-1210 makes the circuit shown in Figure 4 capable of providing an output voltage of 0V to −10.24V.

TWO-QUADRANT ANALOG MULTIPLYING

Two HDM-1210 D/A converters can be used in combination with op amps to provide two-quadrant analog multiplying, as illustrated in Figure 5. The circuit uses standard binary coding; it will accept a bipolar input and provide a bipolar output.

The offset at the V_{ANALOG} (1) input (Pin 14) of each D/A converter allows maximum analog speed over the entire analog input range. The signal is inverted after the D/A in the lower channel, so effects of any offset are cancelled at the output of the circuit. The overall analog output range can be adjusted by changing the value of feedback resistor R_{FB} in the output driver circuit changing the value of this resistor will not affect the linearity of the circuit.

Any gain errors which may exist between the HDM-1210 D/As can be compensated by adjusting the values of R_A and R_B to match the gain of the lower channel to the gain of the upper channel.

The output voltage of the two-quadrant multiplier is calculated with the equation:

$$V_{OUT} = (D)\,(16.384)\left(\frac{V_{IN}}{8k}\right)(R_{FB})$$

where D is a digital word which varies from 0 to 1.

FOUR-QUADRANT ANALOG MULTIPLYING

Adding a feed-forward resistor, as shown in Figure 6, expands the circuit in Figure 5 to a four-quadrant multiplier whose output voltage is based on the equation:

$$V_{OUT} = \left(-\frac{R_{FB}}{R_{FF}}\right)V_{IN} + (D)\,(16.384)\left(\frac{V_{IN}}{8k}\right)(R_{FB})$$

where D is a digital word which varies from 0 to 1.

Overall, the circuit in Figure 6 uses offset binary coding; individually, the HDM-1210 D/A converters continues to use standard binary coding.

Gain error between the two channels can be adjusted by varing the values of R_A and R_B, as explained earlier. After their gains have been matched, the feed-forward resistor R_{FF} must be adjusted to match the gain of the two converters. To accomplish this, set the digital input code to 1000 000 000 000 and vary the value of R_{FF} to obtain an analog output V_{OUT} of zero volts.

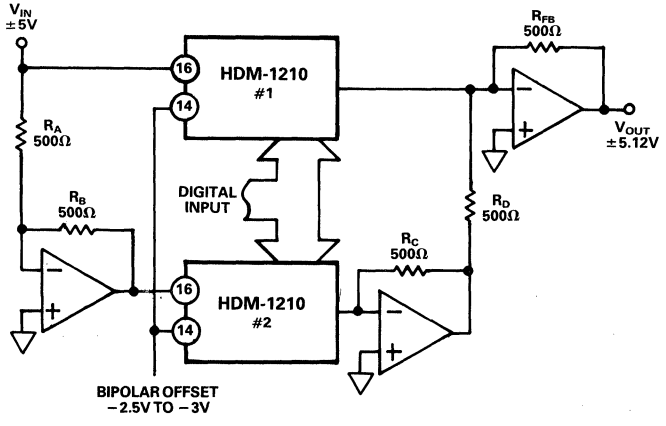

Figure 5. Two-Quadrant Analog Multiplier

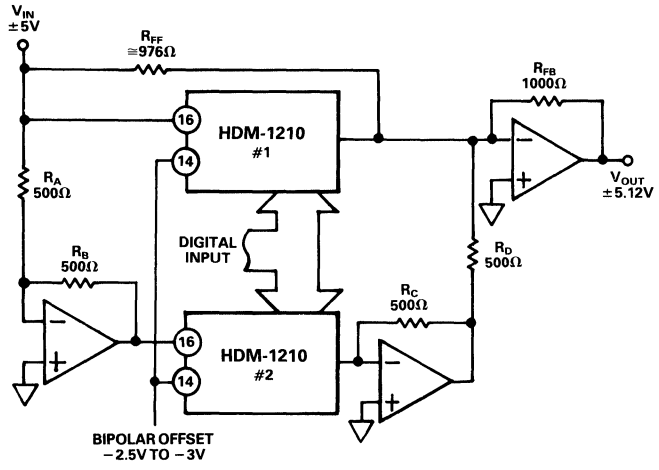

Figure 6. Four-Quadrant Analog Multiplier

The overall offset of the input signal should be fixed at zero in the four-quadrant multiplier because it cannot be cancelled out as it is in the two-quadrant version. The value of R_{FF} will be approximately 976Ω, as shown in Figure 6. The value is based on the equation:

$$R_{FF} = \frac{V\ max}{I\ max/2}$$

where V max = maximum input voltage (5V)

I max = maximum HDM-1210 output (10.24mA)

In the circuits shown in Figures 5 and 6, the recommended op amp is the Analog Devices' HOD-050A or HOS-060 operational amplifier, just as it is in Figure 4.

OUTPUT VERSUS INPUTS

Table I above lists various output currents versus several combinations of input voltages a V_{ANALOG} (1) and V_{ANALOG} (2). Additional information regarding outputs with various inputs is shown in Figure 7 through Figure 11.

In Figures 8, 10, and 11, varying outputs which are the result of changes in digital inputs are designated as follows:

Digital Input Code	BIN	OBN	Output
111 111 111 111	Full Scale	Max Positive	A
110 000 000 000	3/4 Scale	1/2 Scale Positive	B
100 000 000 000	Half Scale	Zero	C
010 000 000 000	1/4 Scale	1/2 Scale Negative	D
000 000 000 000	Zero	Max Negative	E

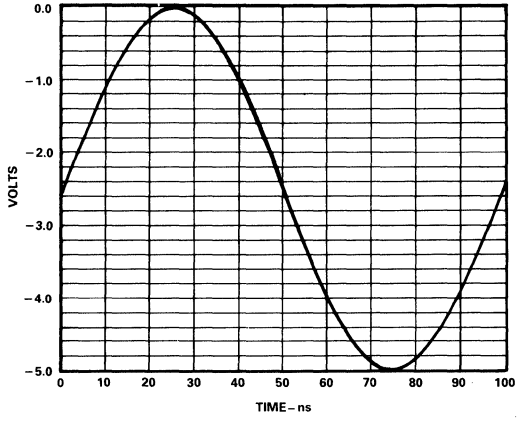

Figure 7. Input for Circuit in Figure 3

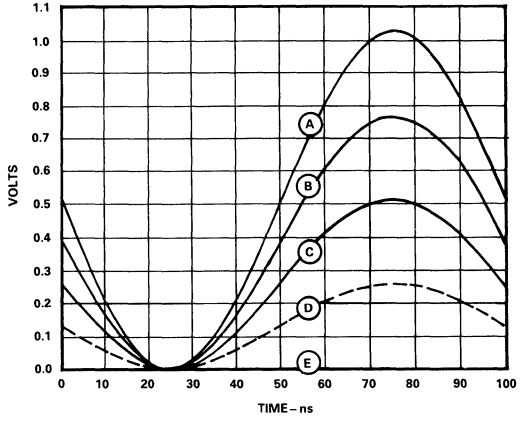

Figure 8. Outputs of Circuit in Figure 3

The input signal at V_{IN} in Figures 5 and 6 is shown in Figure 9.

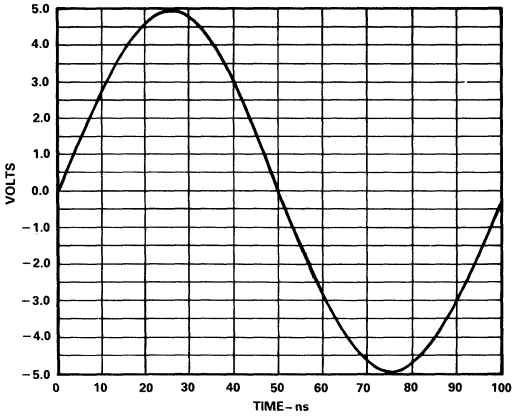

Figure 9. Inputs for Circuits In Figures 5 and 6

The outputs of the two-quadrant multiplying circuits of Figure 5 are shown in Figure 10, with the outputs labeled for various digital multiplying inputs.

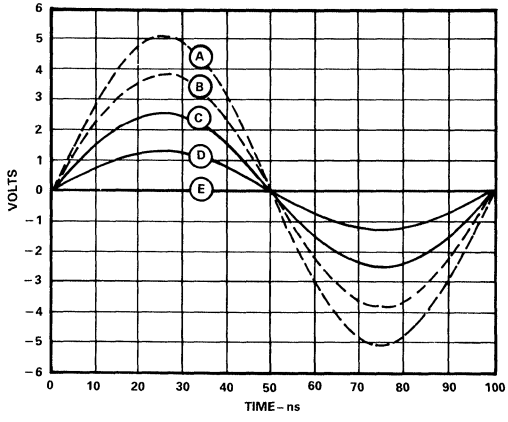

Figure 10. Outputs of Circuit in Figure 5

Refer to Figure 11.

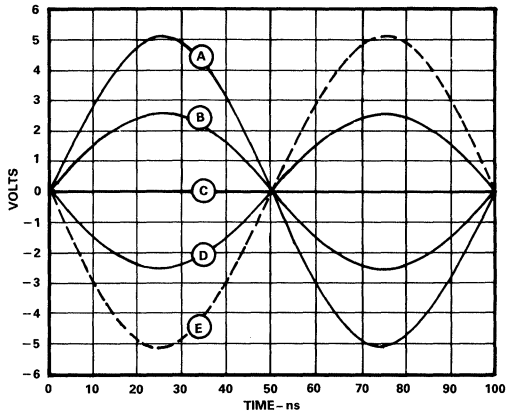

Figure 11. Outputs of Circuit in Figure 6

Four-quadrant multiplying of an analog input is shown in this illustration. The changes in output which result from variations in the digital inputs are labeled as described earlier.

SETTLING VERSUS INPUT

The SPECIFICATIONS table and footnote 5 point out digital settling time is affected by the level of the analog input signal. This characteristic of the HDM-1210 is shown in Figure 12.

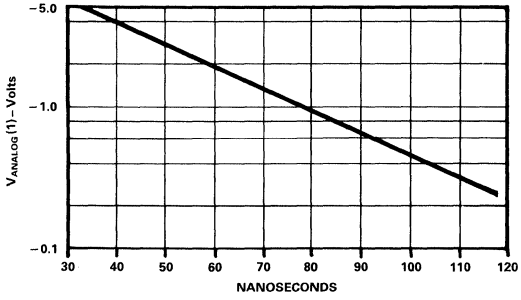

Figure 12. Digital Settling Time to ± 1%

Settling is fastest with high levels of analog input; settling time increases as levels decrease, but there is no direct ratio between the two variables.

ORDERING INFORMATION

There are three versions of the HDM-1210 D/A converter, all in hermetic ceramic DIP housings; with the exception of temperature ranges, all models meet the same electrical specifications.

The HDM-1210BD operates over a temperature range of −25°C to +85°C; the HDM-1210SD operates over a range of −55°C to +100°C. For this latter temperature range and military screening of components, order part number HDM-1210SDB; contact the factory for details.

Ultrahigh-Speed 12-Bit D/A Converter

HDS-1250

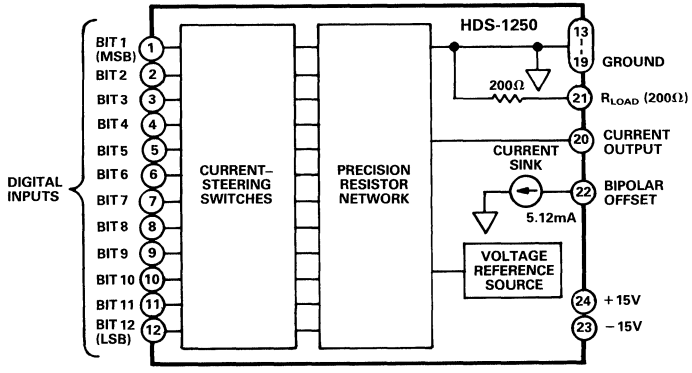
HDS-1250 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The HDS-1250 D/A Converter is an ultrahigh-speed current output digital-to-analog converter using reliable thin film construction in a 24-pin hermetically sealed hybrid package.

Active laser trimming assures precise 12-bit operation over a wide temperature range, and the device is guaranteed to be monotonic over its entire operating range. These characteristics and the assembly and testing in a MIL-STD-1772-certified facility make the HDS-1250 attractive for a variety of military and high-reliability applications.

Full-scale output is 10.24mA, making the converter useful for directly driving capacitive loads and transmission lines. An internal precision reference eliminates the need for external circuits for most applications.

NOTES
[1]HDS-1250KD specifications preceded by a check (√) are tested at +25°C ambient temperature; performance is guaranteed over case temperature range of 0 to 70°C.
[2]HDS-1250TM and HDS-1250TM/883B specifications preceded by a check (√) are tested at −55°C case, +25°C ambient, and +125°C case temperatures unless otherwise indicated (See Subgroups).
[3]With internal 200Ω load resistor. Other voltages within the compliance range may be obtained with an external load resistor using following:

$$V_{OUT} = I_{OUT} \times R_{EQUIVALENT}$$

Where: $R_{EQUIVALENT}$ = 200Ω internal impedance in parallel with external load resistance.
[4]The relationship between the device package and outside environment (θ_{ca}) varies with the application. Value shown is based on measuring case temperature with supply voltages applied to a device in a ZIF socket mounted on a standard "EJ" burn-in board.
[5]MTBF calculated for HDS-1250TM/883B using MIL-HNBK 217D; Ground Fixed; Temperature (ambient) = 25°C.
[6]See Section 14 for package outline information.
Specifications subject to change without notice.

EXPLANATION OF SUBGROUPS

Subgroup 1 – Static tests at +25°C.
(10% PDA calculated against Subgroup 1 for high-rel versions)
Subgroup 2 – Static tests at maximum rated temperature.
Subgroup 3 – Static tests at minimum rated temperature.
Subgroup 4 – Dynamic tests at +25°C.
Subgroup 5 – Dynamic tests at maximum rated temperature.
Subgroup 6 – Dynamic tests at minimum rated temperature.
Subgroup 7 – Functional tests at +25°C.
Subgroup 8 – Functional tests at maximum and minimum rated temperatures.
Subgroup 9 – Switching tests at +25°C.
Subgroup 10 – Switching tests at maximum rated temperature.
Subgroup 11 – Switching tests at minimum rated temperature.
Subgroup 12 – Periodically sample tested.

ABSOLUTE MAXIMUM RATINGS

Supply Voltage (+V_S) . . . . . +17V
Supply Voltage (−V_S) . . . . . −17V
Digital Inputs . . . . . 0 to +8V
Storage Temperature . . . . . −55°C to +125°C
Lead Soldering (10sec) . . . . . +300°C
Junction Temperature . . . . . +165°C

13	GROUND	12	BIT 12 (LSB)

THEORY OF OPERATION

Refer to the HDS-1250 Block Diagram.

The HDS-1250 consists of an array of high-speed, current-steering switches and a precision R2R resistor network. An internal voltage reference provides current which is switched between the digital input and the resistor network, depending on digital input level. Full-scale output current is 10.24mA, scaled by the binary digital input word.

The parallel combination of the R2R network and the internal load resistor (R_L) causes the HDS-1250 D/A Converter to have a unipolar output voltage of +1.024V. A 5.12mA current sink contained within the device provides a bipolar function (Pin 22) when it is connected to the output pin.

ANALOG OUTPUT CIRCUITS

The HDS-1250 is primarily a current-output DAC which can be operated in either a unipolar or bipolar mode. The connections for unipolar operation are shown in Figure 1.

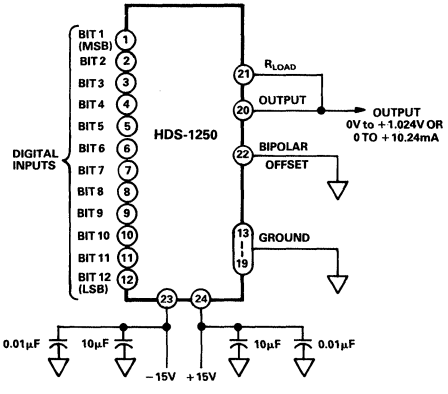

Figure 1.

When a load resistor is connected between the output (Pin 20) and ground, the HDS-1250 can also function as a voltage DAC. Its output voltage must remain within a certain tolerance or the linearity of the device will be affected adversely. This "compliance" voltage range for the HDS-1250 is −2.0V to +1.5V. The voltage output of 0V to +1.024V provided by the internal 200Ω load is well within the compliance range of the device.

Bipolar use of the HDS-1250 is illustrated in Figure 2.

An alternate way of achieving a voltage output with the HDS-1250 is to use an operational amplifier as a current-to-voltage converter on the output as shown in Figure 3.

The DAC output is connected directly to the summing node of the amplifier; the output impedance of the R2R network serves as the Thevenin equivalent feed forward resistance in the circuit.

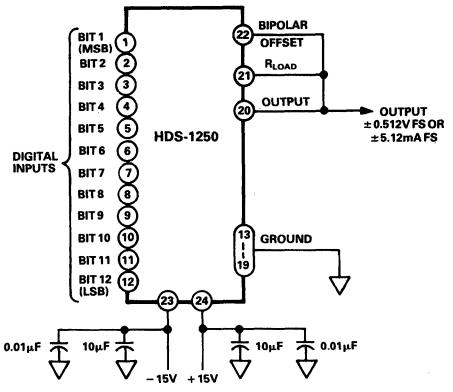

Figure 2.

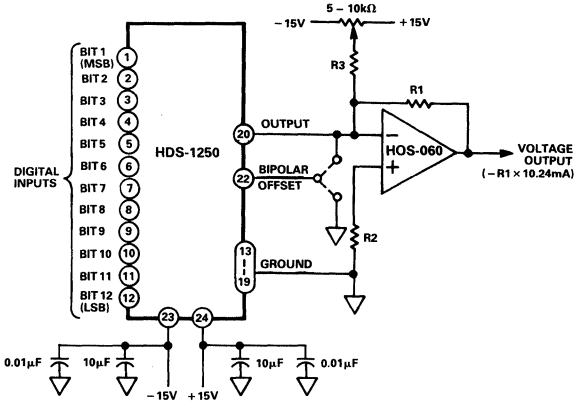

Figure 3.

This technique allows the fastest possible settling of the combination, which is approximated by:

$$T_S = \sqrt{(T_D)^2 + (T_A)^2}$$

Where: T_S = Total settling time
T_D = DAC settling time
T_A = Op Amp settling time

The gain of the amplifier can be controlled most accurately by varying the ratio between current flow through the feedback resistor (R1) and the 10.24mA current output of the DAC. The amplifier's output offset can be adjusted by sinking current from or sourcing current to the summing node through a potentiometer connected to the positive and negative supply voltages. The value of R3 in Figure 2 will be based on the desired range of adjustment.

DESIGN RULES

There are certain circuit layout rules that must be observed to obtain successful high-speed data conversion. Heavy ground currents and fast switching speeds can combine to present a formidable challenge to noise-free performance unless precautions are taken.

The foundation for a good high-speed design lies in the ground plane. The HDS-1250 should be mounted on a PC board that has one side (or layer) dedicated as a large, low-impedance ground plane. This helps ensure that ground loops and differences in ground potential do not develop in the vicinity of the DAC and erode its effective linearity.

To avoid loss of resolution due to noise, it is imperative to decouple the power supply pins of the HDS-1250 directly to the ground plane as physically close to the package as possible. Minimum decoupling should consist of a 10μF tantalum capacitor and a 0.01μF ceramic capacitor in parallel at each supply voltage pin. This will help suppress both high- and low-frequency noise components in the supply voltage.

If a voltage output op amp is used, locate it as close as practical to the DAC output to minimize the length of the summing node circuit trace. At high switching speeds, parasitic capacitance and inductance become critical factors in determining settling characteristics, and precautions must be observed to limit their effects. Any offset control functions connected to the summing node must also be as short as possible to minimize output ringing.

When selecting resistors to use as the output load or as feedback for the op amp, the designer should bear in mind that the temperature coefficient of these resistors will materially affect the overall temperature stability of the data conversion design. Resistor grades should be selected to support the allotted error budget of the system.

Output "glitches" are another anomaly that plague the success of high-speed DAC designs. These aberrations in the output are generally caused by skewing in the transition points of the parallel bit inputs. Small differences in the start of switching among the input bits cause the DAC output to try to respond with each change.

The glitches appear in the output as small triangular waveforms at the bit transitions, and are measured in terms of area as a function of voltage and time. Bit-weighting causes glitch impulse to be most significant at the Bit 1 transition, and it diminishes by half at each successive bit. This causes the amplitudes of the glitches to be code-dependent, making it virtually impossible to eliminate them with a filter.

Glitches of 100-500 pico-volt seconds are common for high-speed TTL DACs and can have an undesirable effect on the reconstructed signal purity in some applications.

There are two methods for minimizing glitch impulse in applications using the HDS-1250. In one, a set of high-speed registers in front of the bit inputs will reduce the amount of skew in the input data. These registers should be mounted physically close to the HDS-1250 package, and Bits 1-4 should be located in a single quad package.

The second method is to utilize a deglitching amplifier on the output of the DAC. See Figure 4.

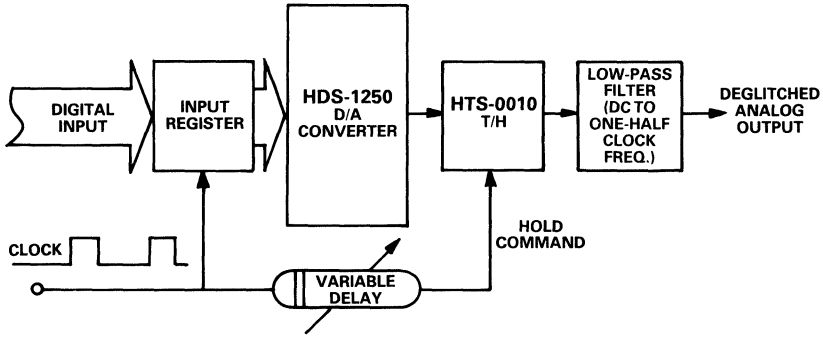

Figure 4.

This deglitching circuit includes the input registers mentioned above and a high-speed track-and-hold (T/H) amplifier. The HTS-0010 shown is timed to "hold" a constant output during the time of the glitch activity; and update the output after DAC settling has occurred.

The deglitching amplifier introduces its own switching anomalies, but they occur at the update rate of the input data and are beyond the reconstructed bandwidth of interest.

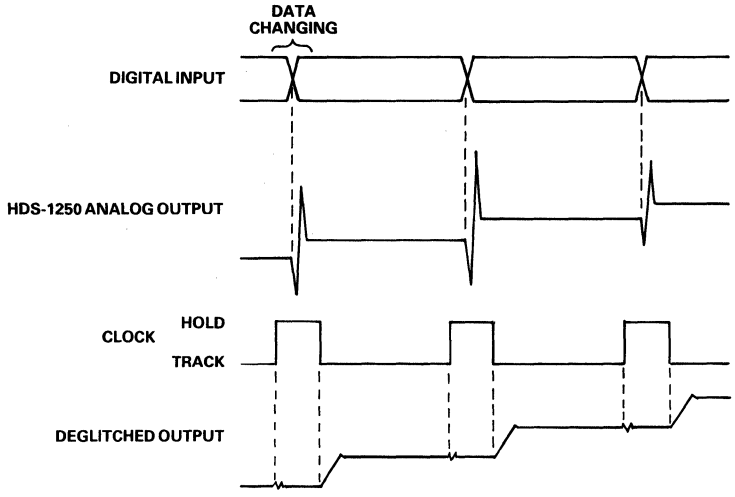

Figure 5.

These aberrations can be filtered with a bandpass filter at the output of the (T/H) deglitching amplifier. The filter should be selected to pass a frequency range from dc to one-half the DAC's update rate.

For a better insight into the timing involved, refer to Figure 5.

As shown, the analog output of the HDS-1250 will attempt to follow the switching of the digital inputs as they change; if time skew exists among the input bits, the glitches which result will be pronounced. The clock signal shown in Figure 5 serves as a strobe for the input register and also causes the T/H to switch from a "track" to "hold" mode of operation. After the glitch on the output of the HDS-1250 has subsided, the T/H will return to the track condition and slew to the new value established by the most recent digital input changes.

Minor switching transients introduced by the action of the T/H occur at the input data rates and are outside the passband of interest. Their effects can be eliminated with a bandpass filter at the output of the HTS-0010.

ORDERING INFORMATION

Three models of the HDS-1250 D/A Converter are available; all are manufactured in a MIL-STD-1772-certified facility.

Model HDS-1250KD operates over a case temperature range of 0 to +70°C; the KD suffix indicates a 24-pin hermetic ceramic DIP package.

For operating case temperatures of −55°C to +125°C, order either the HDS-1250TM or the HDS-1250TM/883B; both units are housed in hermetic 24-pin metal packages. The 883B designation indicates units which are intended for military or other high-reliability applications; these devices are manufactured and screened per the requirements of MIL-STD-883.

[1]X indicates that the internal SHA bandwidth is not specified in kHz.
[2]Ext indicates external reference with the range of voltages listed where applicable. Ext (M) indicates external reference with multiplying capability. Int indicates reference is internal. A voltage value is given if the reference is pinned out.
[3]This column lists the data format for the bus with "µP" indicating microprocessor capability—i.e., for a 12-bit converter 8/12, µP indicates that the data can be formatted for an 8-bit bus or can be in parallel (12 bits) and is microprocessor compatible.
[4]Package Options: D–Side-Brazed Dual-In-Line Ceramic; E–Leadless Chip Carrier; M–Metal Hermetic Dual-In-Line; N–Plastic Molded Dual-In-Line; P–Plastic Leaded Chip Carrier (PLCC); Q–Cerdip; R–Small Outline Plastic (SOIC).
[5]Temperature Ranges: C–Commercial, 0 to +70°C; I–Industrial, −40°C to +85°C (Some older products −25°C to +85°C); M–Military, −55°C to +125°C.
Boldface Type: Product recommended for new design.
*New product since the publication of the 1987/1988 Databooks.

[1]X indicates that the internal SHA bandwidth is not specified in kHz.
[2]Ext indicates external reference with the range of voltages listed where applicable. Ext (M) indicates external reference with multiplying capability. Int indicates reference is internal. A voltage value is given if the reference is pinned out.
[3]This column lists the data format for the bus with "µP" indicating microprocessor capability—i.e., for a 12-bit converter 8/12, µP indicates that the data can be formatted for an 8-bit bus or can be in parallel (12 bits) and is microprocessor compatible.
[4]Package Options: D–Side-Brazed Dual-In-Line Ceramic; E–Leadless Chip Carrier; M–Metal Hermetic Dual-In-Line; N–Plastic Molded Dual-In-Line; P–Plastic Leaded Chip Carrier (PLCC); Q–Cerdip; V–Pin-Stake; Z–Ceramic Leaded Chip Carrier.
[5]Temperature Ranges: C–Commercial, 0 to +70°C; I–Industrial, −40°C to +85°C (Some older products −25°C to +85°C); M–Military, −55°C to +125°C.
Boldface Type: Product recommended for new design.
*New product since the publication of the 1987/1988 Databooks.

FACTORS IN CHOOSING AN A/D CONVERTER

In this catalog, there are listed approximately 50 different families of analog-to-digital converters (ADCs). If one were to consider all the variations, there would be considerably more than 100 different types to choose among. The reason for so many different types is the number of degrees of freedom in selection-technological, functional, performance and package. Complete information on converters may be found in the 700-page book, *Analog-Digital Conversion Handbook*, published by Prentice-Hall, Inc.

FUNCTIONAL CHARACTERISTICS

Block diagrams illustrating the various conversion techniques appear on individual data sheets.

The moderate-speed converters described in this catalog (<1MHz) employ two fundamental techniques – *successive approximations* for moderate-to-high resolution at moderate-to-high speed, and *integration* for high resolution at modest speeds. The AD574A and ADC1130/1131 are examples of the former, the AD1175 the latter.

Like a chemist's balance with binary weights (1/2, 1/4, 1/8, etc.), the *successive approximation* converter compares the unknown input with sums of accurately-known binary fractions of full scale starting with the largest (2^{-1}) and rejecting any that change the comparator's state ("tip the scale"). At the end of conversion (EOC), the output of the converter is a digital word representing the ratio of the input to full scale by a fractional-binary code.

Integrating types count pulses for a period proportional to the input. The charge balancing integrating converter (essentially a voltage-to-frequency converter) measures the input signal by balancing a proportional current against a train of precisely controlled reference pulses using an integrator (AD1170). During the integration phase, the input signal is measured; during the computation phase, the data from the first phase is processed and calibration factors applied. This type of converter can provide very high resolution and accuracy.

The video converters described here (AD9002, CAV-1205, etc.) employ two basic encoding techniques: simultaneous, or *flash* conversion, and serial-Gray-Code conversion. High resolution and high speed are obtained by *subranging* i.e., by performing an n-bit conversion in two steps; Analog Devices has perfected a form of subranging known as DCS – *digitally corrected subranging* – which permits accurate resolutions of 12 bits and more.*

In *flash* conversion, the analog signal is compared against $2^n - 1$ graded voltage levels using as many comparators, and the comparator output logic levels are processed by a priority encoder which converts the "thermometer" output to a binary (or Gray) code. Since the whole conversion occurs essentially simultaneously, it is the fastest means of conversion, but it requires many accurate comparators and large numbers of gates.

In *serial* analog-parallel-digital conversion, there are a number of cascaded stages, each having a gain of +2 for signals less than one-half the reference, and a gain of −2 for signals between one-half the reference and full scale. At each stage, a decision is made as to whether the signal is larger (1) or smaller (0) than one-half the reference; the stage's analog output becomes the input to the next stage. The complete time for one conversion is determined by the propagation delay of the analog signal through all stages; however, since the decision of each stage can be latched as soon as the stage has settled (and a new conversion can, in principle, be started as soon as the first bit has been latched), the rate at which conversions come out of the pipeline is considerably faster than the time for one sample to go through the conversion process. Though fast, this process is difficult to implement accurately for more than a few bits because of the compounding of gain (hence errors).

A *subranging* converter digitizes to a group of more-significant bits and stores them in a latch. A fast, very high-accuracy D/A converter converts them to an analog signal which is then subtracted from the input. The difference, or residue, is amplified and digitized, and (in DCS) the result is combined digitally in such a way as to correct for midscale conversion errors.

Whatever the technique, these A/D converters comprise several essential functions: an analog section, a digital data-generating section, data outputs and digital controls.

Analog Section

This section requires a reference, one or more high-gain comparators, and either a D/A converter (successive approximations) or a controllable integrator. The reference may be internal or external, fixed or variable, and of a specified polarity/sense in relation to the analog input. In ratiometric conversion, the reference is usually external and variable.

In successive approximation converters, the comparator is generally used in the *current-summing* mode; that is, the current output of the DAC is summed with the current developed in the DAC's "feedback resistor" by the input voltage (of opposite polarity), and the balancing action of the converter tends to bring the summing junction towards a voltage null (much like that of an op amp) at the end of conversion. The typical DAC feedback options, when applied in an ADC, provide input-scaling choices. When the bipolar-offset connection is jumpered to the summing point, input signals of both polarities can be handled. The current-switching action of the DAC, at the typically fast clock rates used in successive approximation converters, can disturb the output of the analog signal source, especially if it is a slow high-precision op amp. In such cases, buffering may be necessary.

Sample and Hold

When an ADC without a sample and hold is used, the analog input must not change by more than 1/2 LSB during the conversion. For some applications this constraint is not a concern, but it limits the bandwidth of the signal that can be applied to the converter. A sample-and-hold circuit must be used in front of the ADC if increased bandwidth is required. This sample and hold can be external, or an integral part of the converter (e.g., AD7579/AD7580).

***A considerable amount of useful information about the differences between video conversion and moderate-speed conversion can be found in the article "Very High Speed Data Acquisition," by Ed Graves in *Analog Dialogue* 13–2, available upon request.**

Digital Data-Generating Section
In successive-approximation types, this section consists of a discrete or integrated successive-approximations register (SAR), its controls and inputs from the comparator and clock (which is on-board, but in many cases permits external clock pulses, frequency adjustment and/or control). In integrating types, this section consists of the clock-pulse generator, the counter(s), the input from the comparator and the associated controls. Often, provisions are made for the pulse train to be jumpered to the counter externally so that the pulse train can be operated on externally, or can transmit its train of pulses to a remote counter. In a few types there are no on-board counters or registers; the pulse train, magnitude, overrange and control terminals are intended to communicate with external counters and registers.

Data Outputs
Factors to consider here include coding, resolution, overrange information, levels, format, validity and timing. *Coding* is usually binary including jumper-connected offset-binary and/or twos complement for bipolar input signals. For some types, BCD is available with sign-magnitude for bipolar inputs. Output coding specs should always be checked for digital polarity (positive- or negative-true) of both magnitude and sign information. The *resolution* (number of output bits) must be sufficient for the application; in addition, the specifications must be checked to ascertain that not only will all 2^n (binary) output codes be present (no missing codes), but they must all be present at any temperature in the operating range and related to the input with sufficient accuracy. Integrating types generally have no problems with missing codes (except sometimes at zero, with sign-magnitude coding); nevertheless, nonlinear integration can cause the conversion relationship to become nonlinear. Successive-approximation types have no way of determining *overrange*; they simply fill up. However, counter types roll over and put out a carry flag to signal overrange. Analog Devices offers ADCs, with 4- through 22-bit resolution, with a span of conversion times from milliseconds to nanoseconds.

The *data levels* available at the converter output must be checked (TTL, low-voltage CMOS, high-voltage CMOS, ECL), as must the load-driving capability and fanout, and the supply conditions under which appropriate output levels will be furnished. The available choice of output *formats* must also be as desired – parallel, serial, byte-serial, and/or pulse-train. If the converter is intended to communicate directly with an 8-bit data bus, the output should have three-state capability, and parallel outputs must be enabled in bytes of eight or fewer lines (AD573, AD574A). If the output is serial, it is usually NRZ (non-return-to-zero) and should be accompanied by a set of synchronized clock-pulses.

A *status* (or *busy* or EOC) output changes state to indicate when the data becomes *valid*. The exact nature of this transition should be specified – polarity, timing, levels, etc. For serial data, the exact relationship between the data and the synchronizing clock should be specified to indicate when each bit becomes valid, and for how long. In general, the *timing* of the whole conversion process must be clearly understood, especially if high speeds are necessary, either for conversion or for communication with a processor (or both). The timing diagrams on specification sheets are usually accompanied by adequate descriptions of the conversion process and specifications of the critical interface parameters.

Controls
The functions, action (levels or edges), polarity and timing of all control inputs and outputs should be clearly understood, as well as their loading characteristics and dependence on the supply. In addition to the essential *start-conversion-command* input and a *status* output, various control commands may be available, such as *clock inhibit, high- (low-) byte enable, status enable* and – for speeding up conversion at the cost of resolution in successive-approximation converters – *short-cycle*.

Many ADCs are designed to interface directly to the bus of a computer or microprocessor. These ADCs provide the necessary control and handshake lines, as well as data bit registers, to minimize and often eliminate the required interface circuitry. The bus timing should be studied with respect to the timing provided by the ADC interface, especially as the processor executes a data read cycle to the ADC to retrieve the conversion results. Systems with higher speed clocks require either shorter minimum write pulse widths (such as 50ns for the AD7579/AD7580) or the use of processor-wait states when the ADC is addressed.

STATIC AND DYNAMIC PERFORMANCE SPECIFICATIONS

All ADCs are specified using terms such as accuracy, linearity, offset, defined and explained below. These static, or "dc," parameters are necessary and sufficient for many applications; they may not be sufficient for others, such as those in digital signal processing, adaptive filtering or waveform generation. Dynamic ac specifications define how the ADC performs using parameters such as signal-to-noise ratio (SNR), intermodulation distortion (IMD) and total harmonic distortion (THD). These specifications characterize the performance of the ADC output in applications where the envelope of output changes and output timing errors are critical.

POWER SUPPLIES

Appropriate power supplies should be made available considering the logic levels and analog input signals to be employed in the system. The appropriate degree of power-supply stability to meet the accuracy specifications should be provided. Any recommended external protection circuitry should be planned for. In many cases, separate analog and digital grounds are required; ground wiring should follow best practice to minimize digital interference with high-accuracy analog signals while ensuring that a connection between grounds can always exist at one point, even if the "mecca" point is inadvertently unplugged from the system.

APPLICATION CHECKLIST

The designer will generally require specific information in the following categories before proceeding to the selection process:

- Accurate description of input and output
  1. Analog signal range and source or load impedance
  2. Digital code needed – binary, offset binary, twos complement, BCD, etc.
  3. Logic level system, i.e., TTL/DTL compatible

- What is the needed data throughput rate?
- What are the control interface details?
- What does the system error budget allow for the converter?
- What are environmental conditions – temperature range, time, supply voltage – over which the converter should operate to the desired accuracy?

For A/D converters, the following considerations are typical.

- What is the analog input voltage range, and to what resolution must the signal be measured?
- What is the requirement for linearity error (or relative accuracy error)?
- To what extent must the various sources of error be minimized as environmental temperature changes?
- How much time can be allowed in the system for each complete conversion? What aperture uncertainty and acquisition time are needed for the sample-hold?
- How stable is the system power supply? What errors will result from power supply terminal voltage variations of this order?
- Can the system tolerate missed codes under any conditions?
- What is the character of the input signal? Is it noisy, sampled, filtered, rapidly varying, slowly varying? What kind of pre processing is to be (or can be) done that will affect the choice (and cost) of the converter? Is aliasing a potential problem?

SPECIFICATIONS AND TERMS

Definitions of performance specifications and related information are to be found on the following pages in alphabetical order.*

Accuracy, Absolute

The error of an A/D converter at a given output code is the difference between the theoretical and the actual analog input voltages required to produce that code. Since the code can be produced by any analog voltage in a finite band (see Quantizing Uncertainty), the "input required to produce that code" is defined as the midpoint of the band of inputs that will produce the code. For example, if 5 volts ($\pm$ 1.2mV) will theoretically produce a 12-bit half-scale code of 100000000000, then a converter for which any voltage from 4.997V to 4.999V will produce that code will have absolute error of 1/2 (4.997 + 4.999) $-$5 volts = $-$2mV.

Absolute error comprises gain error, zero error and nonlinearity, together with noise. Absolute-accuracy measurements should be made under a set of standard conditions with sources and meters traceable to an internationally accepted standard.

***For video converters, there are a number of additional application-oriented specifications pertaining to the device's use in a system (e.g., *noise power ratio, differential phase, differential gain, signal-to-noise ratio*). Some useful references for understanding such specifications can be found in the following publications available from Analog Devices, Computer Labs Division, 7910 Triad Center Drive, Greensboro, NC 27409.**

Pratt, W.J., "Test A/D Converters Digitally," *Electronic Design*, December 6, 1975.

Smith, B.F. and Pratt, W.J., "Understanding High-Speed A/D Converter Specifications," Computer Labs, 1974.

Accuracy, Relative

Relative accuracy error, expressed in %, ppm or fractions of an LSB, is the deviation of the analog value at any code (relative to the full analog range of the device transfer characteristic) from its theoretical value (relative to the same range) after the full-scale range (FSR) has been calibrated.

Since the discrete points on the theoretical transfer characteristic lie on a straight line, this deviation can also be interpreted as a measure of nonlinearity (see Linearity).

The "discrete points" of an A/D transfer characteristic are the midpoints of the quantization bands at each code (see Accuracy, Absolute).

Aperture Time

This is the interval between the application of the *hold* command to a sample/track-hold and the actual opening of the switch. The aperture time consists of a delay (which depends on the logic and the switching device – 5ns for HTS-0025) and an uncertainty (due to jitter – 20ps max rms for HTS-0025). When a sample-hold is used in an application where timing is critical, the timing of the hold command can be advanced to compensate for the known component of aperture delay. The jitter, however, imposes the ultimate limitation on timing accuracy. When a sample-hold is used with an ADC, the timing uncertainty of the conversion process is reduced by the ratio of aperture jitter to the conversion time, i.e., the maximum frequency which can be handled with less than 1LSB error due to timing is $2^{-n}/(\pi\ \tau_{au})$ instead of $2^{-n}/(\pi\ \tau_c)$, where τ_{au} is the aperture uncertainty and τ_c is the conversion time.

Common-Mode Rejection (CMR)

The ability of a device to reject the effect of voltage applied to both input terminals simultaneously. Usually expressed as the log of a "common-mode rejection ratio," e.g., 1,000,000:1 (CMRR) or 120dB (CMR). A CMRR of 1,000,000 to 1 means that a 1V common-mode voltage passes through the amplifier as though it were a differential signal of one microvolt at the input.

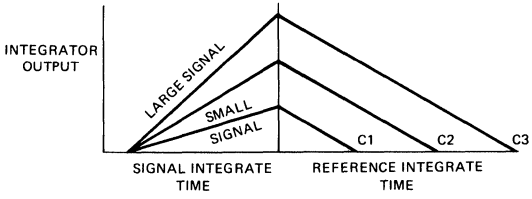
Conformance, Straight-Line

This indicates how closely the ADC transfer characteristic conforms to a reference straight line. This straight-line conformance is critical in DSP applications where deviations from a straight line are seen as distortion, while gain and offset errors are not as serious. The straight-line conformance error is measured from the center of each code to the best-fit straight line.

Conversion Time and Conversion Rate

The time required for a complete measurement by an ADC is called *conversion time*. For most converters (assuming no significant additional systemic delays), this is identical to the inverse of *conversion rate*. However, in some high-speed converters, because of pipelining, new conversions are initiated before the results of prior conversions have been determined; thus, for example, the CAV-1250 can provide 12-bit output data at a 3.85MHz word rate (260ns/conversion), even though the time for any one conversion, from start to finish, is two 280ns encode periods plus 195ns, or 755ns at 3.85MHz.

Dual-Slope Converter
An integrating analog-to-digital converter in which the unknown signal is converted to a proportional time interval, which is then measured digitally. This is done by integrating the unknown for a predetermined time. Then a reference input is switched to the integrator and integrates "down" from the level determined by the unknown until a "zero" level is reached. The time for the second integration process is proportional to the average of the unknown signal level over the predetermined integrating period. A digital time-interval meter (i.e., counter) is generally used as the output indicator.



Feedthrough
Undesirable signal coupling around switches or other devices that are supposed to be turned off or provide isolation, e.g., *feedthrough error* in a multiplexer. It is variously specified in %, ppm, fractions of 1LSB, or fractions of 1 volt, with a given set of inputs at a specified frequency.

"Flash" Converter
A converter in which all the bit choices are made at the same time. It requires $2^n - 1$ voltage-divider taps and comparators, and a comparable amount of priority encoding logic. An extremely fast scheme, it requires large numbers of precision components. Flash converters are often used for partial conversions in *subranging converters*.

Full-Scale Error
The ideal difference between the first transition voltage and last transition voltage for an ADC is (F.S. -2LSB). Full-Scale Error is defined as the deviation between this ideal difference and the measured difference.

Gain Adjustment
The "gain" of a converter is that analog scale factor setting that provides the nominal conversion relationship, e.g., 10V full scale in a fixed-reference converter, or 100% of full scale in a ratiometric converter. Gain- and zero-adjustment principles are discussed under *zero*.

Harmonic Distortion (and Total Harmonic Distortion)
The ADC is driven by a spectrally pure, analog sine wave from a signal generator. The ADC outputs are analyzed via FFT and the ratio of the rms sum of the harmonics of the ADC output to the fundamental value is the THD. Usually, only the lower order harmonics are included, such as second through fifth:

$$\text{THD} = 20 \log \frac{(V_2^2 + V_3^2 + V_4^2 + V_5^2)^{1/2}}{V_1}$$

where V_1 is the rms amplitude of the fundamental and V_2, V_3, V_4 and V_5 are the rms amplitudes of the individual harmonics.

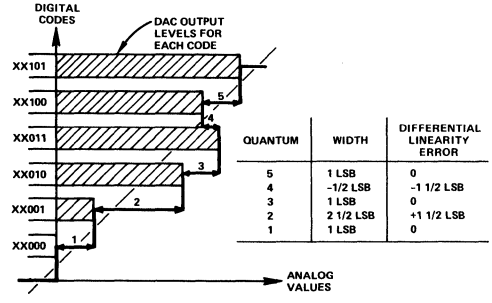
Intermodulation Distortion
The ADC is driven by an analog signal source producing two combined sine waves of frequencies f_a and f_b. As with any imperfectly linear device, distortion products (of order $m+n$) are produced at sum and difference frequencies of $mf_a \pm nf_b$ where m, n = 0, 1, 2, 3 . . . by the ADC. Intermodulation terms are those for which m or n is not equal to zero. The second order terms include $(f_a + f_b)$, and $f_a - f_b)$, and the third order terms are $(2f_a + f_b)$, $(2f_a - f_b)$, $(f_a + 2f_b)$ and $(f_a - 2f_b)$. The ADC outputs are analyzed by FFT. IMD is defined as:

$$\text{IMD} = 20 \log \frac{\text{(rms sum of the sum and difference distortion products)}}{\text{rms amplitude of the fundamental}}$$

Least Significant Bit (LSB)
In a system in which a numerical magnitude is represented by a series of binary (i.e., two-valued) digits, the "least significant bit" is that digit (or "bit") that carries the smallest value or weight. For example, in the natural binary number 1101 (decimal 13, or $2^3 + 2^2 + 0 + 2^0$), the rightmost "1" is the LSB. Its analog weight, relative to full scale, is 2^{-n}, where n is the number of binary digits. It represents the smallest change that can be resolved by an n-bit converter.

Linearity Error
Linearity error of a converter, expressed in percent or parts-per-million of full-scale range, or fractions of a least-significant bit, is the deviation of the analog values from a straight line, in a plot of the measured conversion relationship. The straight line can be either a "best straight line," determined empirically by manipulation of the gain and/or offset to equalize maximum positive and negative deviations of the actual transfer characteristic from this straight line; or it can be a straight line passing through the end points of the transfer characteristic after they have been calibrated. Sometimes referred to as "end-point" nonlinearity, the latter is both a more conservative measure and is much easier to verify in actual practice. "End-point" nonlinearity is similar to relative accuracy error (see Accuracy, Relative). Linearity has two components – *differential* and *integral* nonlinearity.

Linearity, Differential and Integral
A digital output code should correspond to a quantum of analog input values exactly 1LSB in width (2^{-n} of full scale, for an n-bit converter). Any deviation of the measured "step" from the ideal width is called Differential Nonlinearity. It is an important specification, because a differential nonlinearity error greater than 1LSB can lead to nonmonotonic behavior of a D/A converter and missed codes in an A/D converter employing such a DAC. A flagrant example of differential nonlinearity is shown here.



QUANTUM	WIDTH	DIFFERENTIAL LINEARITY ERROR
5	1 LSB	0
4	-1/2 LSB	-1 1/2 LSB
3	1 LSB	0
2	2 1/2 LSB	+1 1/2 LSB
1	1 LSB	0

In the illustration, the horizontal bars represent the measured DAC output values corresponding to six adjacent digital codes. The DAC is nonlinear in that the next least-significant bit (XX010) is 1 1/2LSB too large. Thus, instead of the five quanta, or steps, being all equal (=1LSB), quantum 2 is 2 1/2LSB and quantum 4 is −1/2LSB. The differential linearity error, the difference between the actual quantum width and the ideal 1LSB, is 1 1/2LSB for quantum 2 and −1 1/2LSB for quantum 4.

When this DAC is used in successive-approximations conversion, it will lead to a missed code. Analog inputs slightly larger than the value of XX100 will be converted to XX100, and analog inputs slightly less than the value of XX100 will be converted to XX010. The code XX011 will not exist; it will be a *missed code.*

Often, instead of a maximum differential nonlinearity specification, there will be a simple specification of "no missed codes" which implies a differential nonlinearity less than 1LSB.

While differential nonlinearity deals with errors in step size, *integral nonlinearity* has to do with deviations of the overall shape of the conversion response. Even converters that are not subject to differential linearity errors (e.g., integrating types) have integral linearity (sometimes just "linearity") errors.

Power-Supply Sensitivity
The sensitivity of a converter to dc changes in power-supply voltages is normally expressed in terms of percentage change in analog input value (or fractions of the analog equivalent of 1LSB), corresponding to a given code for a 1% dc change in the power supply, e.g., $0.05\%/\%\Delta V_S$. Power-supply sensitivity may also be expressed in relation to a specified dc shift of the supply voltage. High-accuracy ADCs intended for battery operation require excellent rejection of large supply variations.

Quad-Slope Converter
This is an integrating analog-to-digital converter that goes through two cycles of *dual-slope* conversion, once with zero input and once with the analog input being measured. The errors determined during the first cycle are subtracted digitally from the result in the second cycle. The scheme results in an extremely accurate converter.

Quantizing Uncertainty (or "Error")
The analog continuum is partitioned into 2^n discrete ranges for n-bit conversion. All analog values within a given range are represented by the same digital code usually assigned to the nominal midrange value. There is, therefore, an inherent quantization uncertainty of ± 1/2LSB, in addition to the actual conversion errors. In integrating converters, this "error" is often expressed as "± 1 count."

Ratiometric Converter
The output of an A/D converter is a digital number proportional to the ratio of (some measure of) the input to a reference. Most requirements for conversions call for an absolute measurement, i.e., against a fixed reference. In some cases, where the measurement is affected by a changing reference voltage (e.g., the voltage applied to a bridge), it is advantageous to use that same reference as the reference for the conversion, to eliminate the effect of variation. Ratiometric conversion can also serve as a substitute for analog signal division (where the denominator changes but little during the conversion).

Signal-to-Noise Ratio
Signal-to-Noise Ratio (SNR) is measured signal to noise at the output of the ADC. The signal is the rms magnitude of the fundamental. Noise is the rms sum of all nonfundamental signals up to half the sampling frequency. SNR is dependent on the number of quantization levels used in the digitization process; the more levels, the smaller the quantization noise. The theoretical SNR for a sine-wave input is given by:

$$SNR = (6.02N + 1.76)\ dB,$$

where N is the number of bits in the ADC. Thus for an ideal 10-bit ADC, SNR = 62dB.

Slew Rate
Slew rate is the maximum allowable rate of change of input signal such that the digital sample values are not in error.

Stability
Stability of a converter usually applies to the insensitivity of its characteristics with time, temperature, etc. All measurements of stability are difficult and time consuming, but stability vs. temperature is sufficiently critical in most applications to warrant universal inclusion in tables of specifications (see "Temperature Coefficients").

Subranging Converters
In this type of converter, an extremely fast conversion produces the most significant portion of the output word. This portion is converted back to analog with a fast high-accuracy D/A converter and subtracted from the input. The resulting residue is converted to digital at high speed and combined with the results of the earlier conversion to form the output word. In *digitally corrected subranging* (DCS), the two bytes are combined in a manner that corrects for the error of the LSB of the most significant byte. For example, using 8-bit and 5-bit conversion, and this proprietary technique, a full-accuracy high-speed 12-bit converter can be built.

Successive Approximations
Successive approximations is a high-speed method of comparing an unknown against a group of weighted references. The operation of a successive approximations A/D converter is generally similar to the orderly weighing of an unknown quantity on a precision chemical balance using a set of weights such as: 1 gram, 1/2 gram, 1/4 gram, 1/8 gram, 1/16 gram, etc. The weights are tried in order, starting with the largest. Any weight that tips the scale is removed. At the end of the process, the sum of the weights remaining on the scale will be within 1LSB of the actual weight (± 1/2LSB, if the scale is properly biased – see *zero*).

Temperature Coefficients
In general, temperature instabilities are expressed in %/°C, ppm/°C, as fractions of 1LSB/°C, or as a change in a parameter over a specified temperature range. Measurements are usually made at room temperature and at the extremes of the specified range, and the temperature coefficient (tempco, T.C.) is defined as the change in the parameter divided by the corresponding temperature change. Parameters of interest include, *gain, linearity, offset* (bipolar) and *zero*. The last three are expressed in % or ppm of full-scale range per Celsius degree.

Gain Tempco: Two factors principally affect converter gain instability with temperature:

1. In fixed-reference converters, the reference source will vary with temperature. For example, the tempco of an AD581L is typically 5ppm/°C.
2. The ratiometric circuitry has a sensitivity to temperature.

Linearity Tempco: Sensitivity of linearity to temperature over the specified range. To avoid missed codes, it is sufficient that the differential nonlinearity error be less than 1LSB at any temperature in the range of interest. The *differential nonlinearity temperature coefficient* may be expressed as a ratio, as a maximum change over a specified temperature range, and/or implied by a statement that there are no missed codes when operating within a specified temperature range.

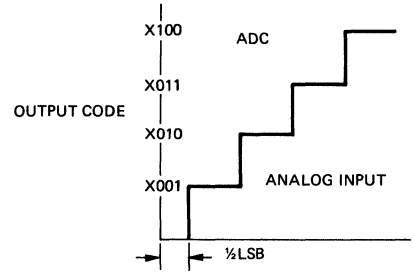
Offset Tempco: The temperature coefficient of the all-DAC-switches-off (minus full-scale) point, of a bipolar successive-approximations converter, is dependent on three variables:

1. The tempco of the reference source
2. The voltage stability of the input buffer and the comparator
3. The tracking capability of the bipolar-offset resistors and the gain resistors.

Unipolar Zero: The zero tempco of an ADC is dependent only on the zero stability of the integrator and/or the input buffer and the comparator. It may be expressed in μV/°C, or in percent or ppm of full-scale per degree C.

Zero- and Gain-Adjustment Principles

The zero adjustment of a unipolar ADC is set so that the transition from all-bits-off to LSB-on occurs at $1/2 \times 2^{-n}$ of nominal full scale. The gain is set for the final transition to all-bits-on to occur at F.S. $(1 - 3/2 \times 2^{-n})$. The "zero" of an offset-binary bipolar ADC is set so that the first transition occurs at $-$F.S. $(1-2^{-n})$ and the last transition at $+$F.S. $(1-3\times2^{-n})$. The data sheet instructions should be followed.



Zero Code Error

This is a measure of the difference between the ideal (0.5LSB) and the actual differential analog input level required to produce the first positive LSB code to transition (00 . . . 00 to 00 . . . 01).

ANALOG DEVICES

8- and 10-Bit Analog-to-Digital Converters

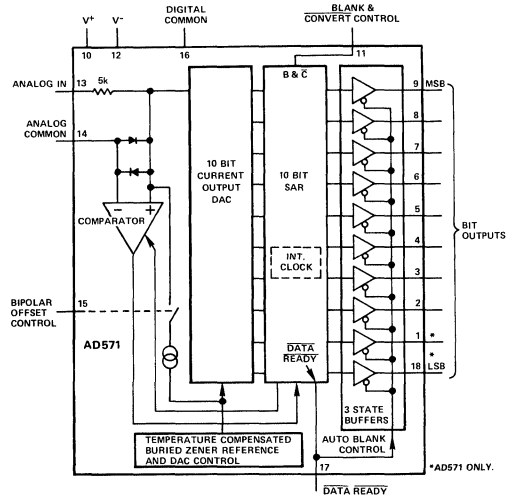
AD570/AD571 FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTIONS

The AD570/AD571 are successive approximation A/D converters consisting of a DAC, voltage reference, clock, comparator, successive approximation register and output buffers – all fabricated on a single chip. No external components are required to perform full accuracy conversions in 25μs.

The AD570/AD571 incorporate advanced integrated circuit design and processing technologies. They employ I^2L (integrated logic) processing in the fabrication of the SAR function. Laser trimming of the high stability SiCr thin-film resistor ladder network insures high accuracy, which is maintained with a temperature compensated, subsurface Zener reference.

Operating on supplies of +5V to +15V and −15V, the AD570/AD571 will accept analog inputs of 0 to +10V, unipolar or ±5V bipolar, externally selectable. As the BLANK and $\overline{\text{CONVERT}}$ input is driven low, the three-state outputs will be open and a conversion will commence. Upon completion of the conversion, the $\overline{\text{DATA READY}}$ line will go low and the data will appear at the output. Pulling the BLANK and $\overline{\text{CONVERT}}$ high blanks the outputs and readies the device for the next conversion.

The devices are available in two versions: the "J" and "K" specified for the 0 to +70°C temperature range. The "S" guarantees the specified accuracy and no missing codes from −55°C to +125°C.

*Covered by Patent Nos. 3,940,760; 4,213,806; 4,136,349.

PRODUCT HIGHLIGHTS

1. The AD571 is a complete 10-bit A/D converter. The AD570 is an 8-bit version which employs the same architecture. No external components are required to perform a conversion.
2. The AD570/AD571 are single chip devices employing advanced IC processing techniques. Thus, the user has at his disposal a truly precision component with the reliability and low cost inherent in monolithic construction.
3. The converters accept either unipolar (0 to +10V) or bipolar (−5V to +5V) analog inputs by simply grounding or opening a single pin.
4. Each device offers the specified accuracy with no missing codes over its entire operating temperature range.
5. Operation is guaranteed with −15V and +5V to +15V supplies. The devices will also operate with a −12V supply.

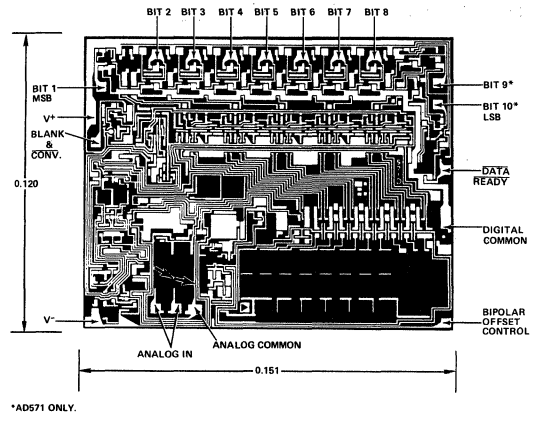
CHIP BONDING DIAGRAM



CIRCUIT DESCRIPTION

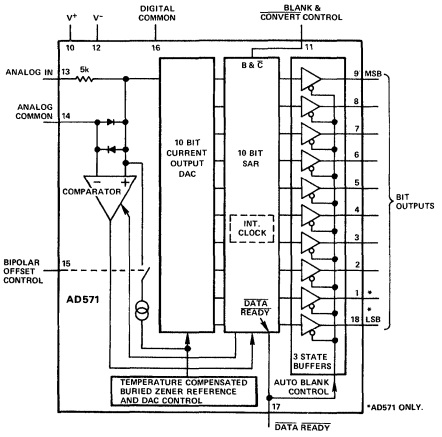
The AD571 is a complete 10-bit A/D converter which requires no external components to provide the complete successive approximation analog-to-digital conversion function. The AD570 is an 8-bit version. A functional block diagram of the AD570/AD571 is shown below. Upon receipt of the $\overline{\text{CONVERT}}$ command, the internal 10-bit (AD571) current output DAC is sequenced by the I^2L successive approximation register (SAR) from its most-significant bit (MSB) to least-significiant bit (LSB) to provide an output current which accurately balances the input signal current through the 5kΩ input resistor. The comparator determines whether the addition of each successively weighted bit current causes the DAC current sum to be greater or less than the input current. If the sum is less, the bit is left on; if more, the bit is turned off. After testing all the bits, the SAR contains a 10-bit binary code which accurately represents the input signal to within ±1/2LSB (0.05%).

Upon completion of the sequences, the SAR sends out a $\overline{\text{DATA READY}}$ signal (active low), which also brings the three-state buffers out of their "open" state, making the bit output lines become active high or low, depending on the code in the SAR. When the BLANK and $\overline{\text{CONVERT}}$ line is brought high, the output buffers again go "open", and the SAR is prepared for another conversion cycle. Details of the timing are given further on.

The temperature compensated buried Zener reference provides the primary voltage reference to the DAC and guarantees excellent stability with both time and temperature. The bipolar offset input controls a switch which allows a positive bipolar offset current to be injected into the summing (+) node of the comparator to offset the DAC output. The nominal 0 to +10V unipolar input range now becomes a −5V to +5V range. The 5kΩ thin-film input resistor is trimmed so that with a full-scale input signal, an input current will be generated which exactly matches the DAC output with all bits on. (The input resistor is trimmed slightly low to facilitate user trimming, as discussed on the next page.)

POWER SUPPLY SELECTION

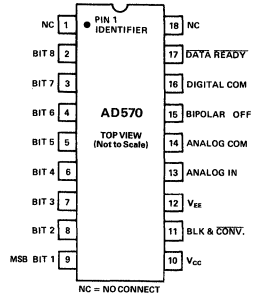
The AD570/AD571 are designed for optimum performance using a +5V and −15V supply, for which the J and S grades are specified. AD571K will also operate with up to a +15V supply, which allows direct interface to CMOS logic.



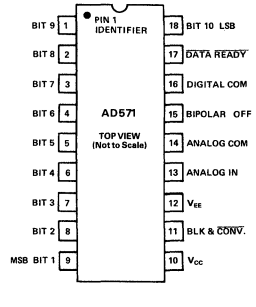
AD570/AD571 Functional Block Diagram

CONNECTING THE AD570/AD571 FOR STANDARD OPERATION

The AD570/AD571 contain all the active components required to perform a complete A/D conversion. Thus, for most situations, all that is necessary is connection of the power supply (+5 and −15), the analog input, and the conversion start pulse. The functional pin outs are shown below.



AD570 Pin Connections



AD571 Pin Connections

FULL-SCALE CALIBRATION

The 5kΩ thin-film input resistor is laser trimmed to produce a current which matches the full-scale current of the internal DAC when a full-scale analog input voltage of 10 volts – 1LSB is applied at the input. The input resistor is trimmed in this way so that if a fine-trimming potentiometer is inserted in series with the input signal, the input current at the full-scale input voltage can be trimmed down to match the DAC full-scale current as precisely as desired. However, for many applications the nominal 9.990 (9.961 for the AD570) volt full scale can be achieved to sufficient accuracy by simply inserting a 15Ω resistor in series with the analog input to Pin 13. Typical full-scale calibration error will then be about ±2LSB. If the more precise calibration is desired, a trimmer should be used instead. A 50Ω potentiometer should be used with the AD571 and a 200Ω with the AD570. Set the analog input at full scale and set the trimmer so that the output code is just at the transition between 1111111110 and 1111111111. Each LSB will then have a weight of $10V/2^N$ (where N = number of bits).

BIPOLAR OPERATION

The standard unipolar 0 to +10V range is obtained by shorting the bipolar offset control pin to digital common. If the pin is left open, the bipolar offset current will be switched into the comparator summing node, giving a −5V to +5V range with an offset binary code. The bipolar offset control input is not directly TTL compatible, but a TTL interface for logic control can be constructed as shown in Figure 1.

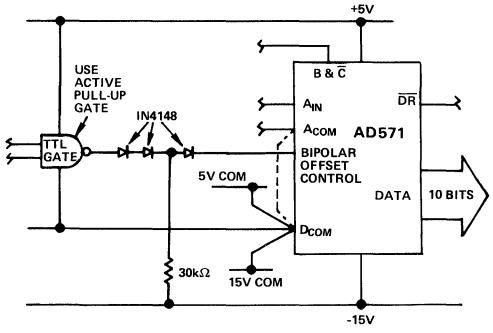


Figure 1. Bipolar Offset Controlled by Logic Gate
Gate Output = 1 Unipolar 0 – 10V Input Range
Gate Output = 0 Bipolar ±5V Input Range

COMMON-MODE RANGE

The AD570/AD571 provide separate analog and digital common connections. The circuit will operate properly with as much as ±200mV of common-mode range between the two commons. This permits more flexible control of system common bussing and digital and analog return.

In normal operation the analog common terminal may generate transient currents of up to 2mA during a conversion. In addition, a static current of about 2mA will flow into analog common in the unipolar mode after a conversion is complete. An additional 1mA will flow in during a blank interval with zero analog input. The analog common current will be modulated by the variations in input signal.

The absolute maximum voltage rating between the two commons is ±1 volt. We recommend the connection of a parallel pair of back-to-back protection diodes between the commons if they are not connected locally.

ZERO OFFSET

The apparent zero point of the AD570/AD571 can be adjusted by inserting an offset voltage between the analog common of the device and the actual signal return or signal common. Figure 2 illustrates two methods of providing this offset for the AD571. Figure 2a shows how the converter zero may be offset by up to ±3 bits to correct the device initial offset and/or input signal offsets. As shown, the circuit gives approximately symmetrical adjustment in unipolar mode. In bipolar mode R2 should be omitted to obtain a symmetrical range.

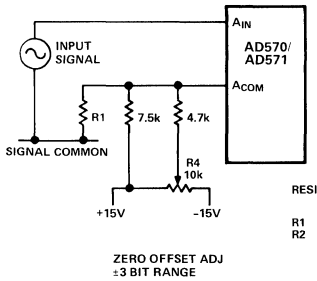

Figure 2a.

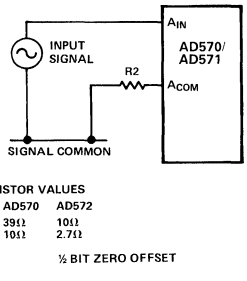

Figure 2b.

Figure 3 shows the nominal transfer curve near zero for an AD571 in unipolar mode. The code transitions are at the edges of the nominal bit weights. In some applications it will be preferable to offset the code transitions so that they fall between the nominal bit weights, as shown in the offset characteristics. This offset can easily be accomplished as shown in Figure 2b. At balance (after a conversion) approximately 2mA flows into the analog common terminal. A 2.7Ω resistor in series with this terminal will result in approximately the desired 1/2 bit offset of the transfer characteristics. The nominal 2mA analog common current is not closely controlled in manufacture. If high accuracy is required, a 5Ω potentiometer (connected as a rheostat) can be used as R1. Additional negative offset range may be obtained by using larger values of R1. Of course, if the zero transition point is changed, the full-scale transition point will also move. Thus, if an offset of 1/2LSB is introduced, full-scale trimming as previously described should be done with an analog input of 9.985 volts.

NOTE: During a conversion transient currents from the analog common terminal will disturb the offset voltage. Capacitive decoupling should not be used around the offset network. These transients will settle as appropriate during a conversion. Capacitive decoupling will "pump up" and fail to settle resulting in conversion errors. Power supply decoupling, which returns to analog signal common, should go to the signal input side of the resistive offset network.

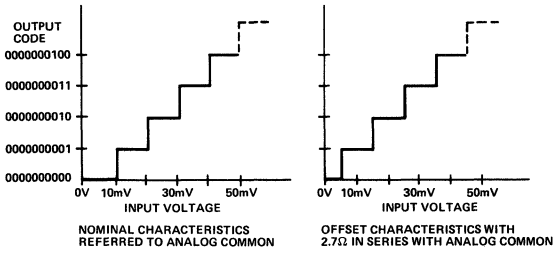

Figure 3. AD571 Transfer Curve – Unipolar Operation (Approximate Bit Weights Shown for Illustration, Nominal Bit Weights~9.755mV)

BIPOLAR CONNECTION

To obtain the bipolar −5V to +5V range with an offset binary output code the bipolar offset control pin is left open.

A −5.0 volt signal will give a 10-bit code of 00000000 00; an input of 0.00 volts results in an output code of 10000000 00 and +4.99 volts at the input yields the 11111111 11 code. The nominal transfer curve for the AD571 is shown in Figure 4. The MSB transition for both the AD570 and the AD571 occurs at a −4.88mV input.

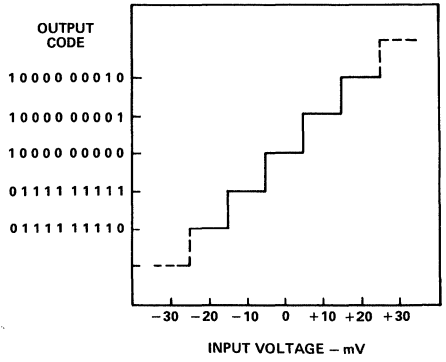

Figure 4. AD571 Transfer Curve – Bipolar Operation

CONTROL AND TIMING OF THE AD570/AD571

There are several important timing and control features on the AD570/AD571 which must be understood precisely to allow optimal interfacing to microprocessor or other types of control systems. All of these features are shown in the timing diagram in Figure 5.

The normal standby situation is shown at the left end of the drawing. The BLANK and $\overline{\text{CONVERT}}$ (B & $\overline{\text{C}}$) line is held high, the output lines will be "open", and the $\overline{\text{DATA READY}}$ ($\overline{\text{DR}}$) line will be high. This mode is the lowest power state of the device (typically 150mW). When the (B & $\overline{\text{C}}$) line is brought low, the conversion cycle is initiated; but the $\overline{\text{DR}}$ and data lines do not change state. When the conversion cycle is complete (typically 25μs), the $\overline{\text{DR}}$ line goes low, and within 500ns, the data lines become active with the new data.

About 1.5μs after the B & $\overline{\text{C}}$ line is again brought high, the $\overline{\text{DR}}$ will go high and the data lines will go open. When the B & $\overline{\text{C}}$ line is again brought low, a new conversion will begin. The minimum pulse width for the B & $\overline{\text{C}}$ line to blank previous data and start a new conversion is 2μs. If the the B & $\overline{\text{C}}$ line is brought high during a conversion, the conversion will stop, and the $\overline{\text{DR}}$ and data lines will not change. If a 2μs or longer pulse is applied to the B & $\overline{\text{C}}$ line during a conversion, the converter will clear and start a new conversion cycle.

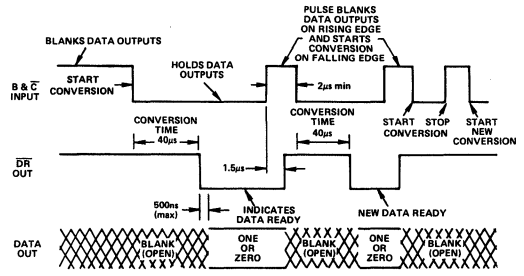

Figure 5. AD570/AD571 Timing and Control Sequences

CONTROL MODES WITH BLANK AND $\overline{\text{CONVERT}}$

The timing sequence of the AD570/AD571 discussed above allows the devices to be easily operated in a variety of systems with differing control modes. The two most common control modes, the convert pulse mode and the multiplex mode, are illustrated here.

Convert Pulse Mode – In this mode, data is present at the output of the converter at all times except when conversion is taking place. Figure 6 illustrates the timing of this mode. The BLANK and $\overline{\text{CONVERT}}$ line is normally low and conversions are triggered by a positive pulse.

Multiplex Mode – In this mode the outputs are blanked except when the device is selected for conversion and readout; this timing is shown in Figure 7.

This operating mode allows multiple converters to drive common data lines. All BLANK and $\overline{\text{CONVERT}}$ lines are held high to keep the outputs blanked. A single AD571 is selected, its BLANK and $\overline{\text{CONVERT}}$ line is driven low and at the end of conversion, which is indicated by $\overline{\text{DATA READY}}$ going low, the conversion result will be present at the outputs. When this data has been read from the 10-bit bus, BLANK and $\overline{\text{CONVERT}}$ is restored to the blank mode to clear the data bus for other converters. When several converters are multiplexed in sequence, a new conversion may be started in one AD570/AD571 while data is being read from another. As long as the data is read and the first AD570/AD571 is cleared within 15μs after the start of conversion of the second AD570/AD571, no data overlap will occur.

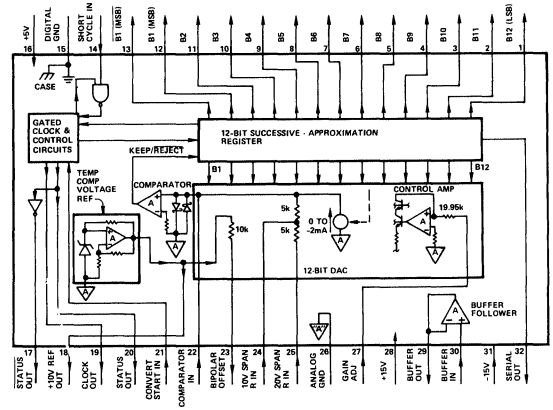
AD572 FUNCTIONAL BLOCK DIAGRAM



32-PIN DIP

GENERAL DESCRIPTION

The AD572 is a complete 12-bit successive approximation analog-to-digital converter that includes an internal clock, reference, comparator, and buffer amplifier. Its hybrid IC design utilizes MSI digital and linear monolithic chips and active laser trimming of high-stability thin-film resistors to provide superior performance, flexibility and ease of use, combined with IC size, price, and reliability.

Important performance characteristics of the AD572 include a maximum linearity error at 25°C of ±0.012%, gain T.C. below 15ppm/°C, typical power dissipation of 900mW, and conversion time of less than 25μs. Of considerable significance in aerospace applications is the guaranteed performance from -55°C to +125°C of the AD572S. Monotonic operation of the feedback D/A converter guarantees no missing output codes over temperature ranges of 0 to +70°C, -25°C to +85°C, and -55°C to +125°C.

The design of the AD572 includes scaling resistors that provide analog input signal ranges of ±2.5, ±5.0, ±10, 0 to +5, or 0 to +10 volts. Adding flexibility and value are the +10V precision reference, which also can be used for external applications, and the input buffer amplifier. All digital signals are fully DTL and TTL compatible, and the data output is positive-true and available in either serial or parallel form.

The AD572 is available in three versions with differing guaranteed performance characteristics and operating temperature ranges; the "A" and "B" are specified from -25°C to +85°C, and the "S" from -55°C to +125°C.

PRODUCT DESCRIPTION

The AD572 functional diagram and pin-out are shown in Figure 1. The device consists of the following monolithic bipolar circuit elements:

1. 12-bit successive-approximation register
2. 12-bit DAC
3. low-drift comparator
4. temperature-compensated precision +10V reference
5. high-impedance buffer follower
6. gated clock and digital control circuits

NOTES
*Same specification as AD572AD.
**Same specification as AD572BD.

Specifications subject to change without notice.

Note 1 Positive pulse 200ns wide (min). Leading edge ("0" to "1") resets registers. Trailing edge ("1" to "0") initiates conversion.

Note 2 With 50Ω, 1% fixed resistor in place of Gain Adjust pot; see Figures 4 and 5.

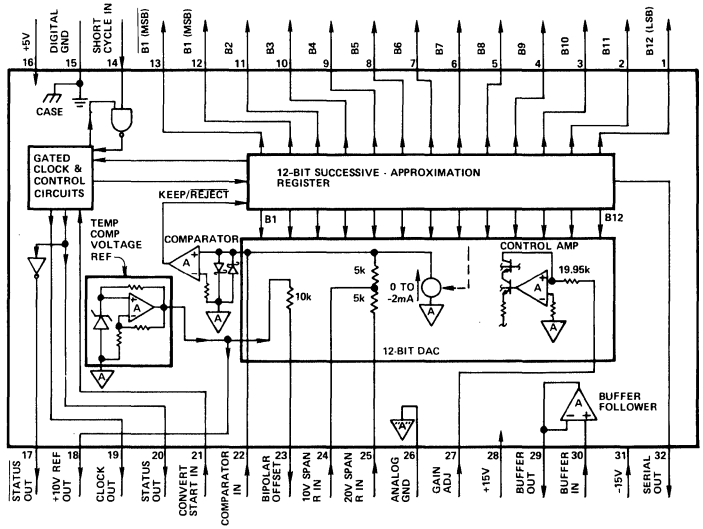

Figure 1. AD572 Functional Diagram & Pinout

The +10V reference is derived from a low T.C. zener reference diode which has its zener voltage amplified and buffered by an op amp. The reference voltage is calibrated to +10V, ±10mV by active laser trimming of the thin-film resistors which determine the closed-loop gain of this op amp.

The DAC chip uses 12 precision, high speed bipolar current steering switches, a control amplifier and a laser-trimmed thin film resistor network to produce a very fast, high accuracy analog output current. The DAC is laser-trimmed to calibrate all bit ratio scale factors to a precision of 0.0005% of FSR (full-scale range) to guarantee no missing codes over the appropriate temperature ranges specified for the AD572A, AD572B, and AD572S versions.

Different unipolar and bipolar analog input ranges can be selected by changing connections at the device terminal pins. The analog voltage input can be applied to either of the span (direct input) resistors. Alternatively, the unity buffer follower can be connected between the analog signal and either direct input terminal when a high impedance input is required.

THEORY OF OPERATION

On receipt of a CONVERT START command, the AD572 converts the voltage at its analog input into an equivalent 12-bit binary number. This conversion is accomplished as follows:

The 12-bit successive-approximation register (SAR) has its 12-bit outputs connected both to the respective device bit output pins and to the corresponding bit inputs of the feedback DAC.

The analog input is successively compared to the feedback DAC output, one bit at a time (MSB first, LSB last). The decision to keep or reject each bit is then made at the completion of each bit comparison period, depending on the state of the comparator at that time.

TIMING

The timing diagram is shown in Figure 2. Receipt of a CONVERT START signal sets the STATUS flag, indicating conversion in progress. This, in turn, removes the inhibit applied to the gated clock, permitting it to run through

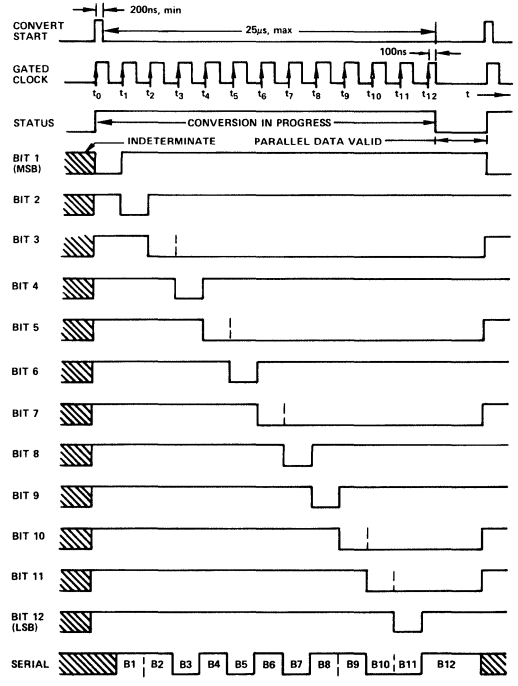

Figure 2. Timing Diagram (Binary Code 110101011001)

13 cycles. All SAR parallel bit and STATUS flip-flops are initialized on the leading edge, and the gated clock inhibit signal removed on the trailing edge of the CONVERT START signal. At time t_0, B_1 is reset and B_2 -B_{12} are set unconditionally. At t_1 the Bit 1 decision is made (keep) and Bit 2 is unconditionally reset. At t_2, the Bit 2 decision is made (keep) and Bit 3 is reset unconditionally. This sequence continues until the Bit 12 (LSB) decision (keep) is made at t_{12}. After a 100ns delay period, the STATUS flag is reset, indicating that the conversion is complete and that the parallel output data is valid. Resetting the STATUS flag restores the gated clock inhibit signal, forcing the clock output to the logic "0" state.

Corresponding serial and parallel data bits become valid on the same positive-going clock edge. Serial data does not change and is guaranteed valid on negative-going clock edges, however; serial data can be transferred quite simply by clocking it into a receiving shift register on these edges (see Figure 8).

Incorporation of this 100ns delay period guarantees that the parallel (and serial) data are valid at the Logic "1" to "0" transition of the STATUS flag, permitting parallel data transfer to be initiated by the trailing edge of the STATUS signal.

BINARY CODING

The AD572 binary output number $N_o = B_1\ B_2\ B_3 \ldots B_{12}$ is related to the analog input voltage E_{in} for all unipolar ranges by the expression:

$$\frac{B_1\ 2^{11} + B_2\ 2^{10} + B_3\ 2^9 + \ldots + B_{12}\ 2^0}{2^{12}} = \frac{E_{in}}{FSR} \qquad (1)$$

. . .where B_1 = MSB, B_{12} = LSB, and FSR = full-scale range. For all bipolar ranges a fixed bipolar offset equal to $\frac{+FSR}{2}$ is internally summed with E_{in} so that the sum of E_{in} plus this offset will be positive over the rated operating range. For bipolar ranges, expression (1) becomes:

$$\frac{B_1\ 2^{11} + B_2\ 2^{10} + B_3 2^9 + \ldots + B_{12}\ 2^0}{2^{12}} = \frac{E_{in} + \frac{FSR}{2}}{FSR} \qquad (2)$$

Expressions (1) and (2) can be put in an alternate form:

$$\left(\frac{B_1}{2} + \frac{B_2}{4} + \frac{B_3}{8} + \ldots + \frac{B_{12}}{4096}\right) FSR = E_{in} \qquad (3)$$

Unipolar (Binary Coding)

...and...

$$\left(\frac{B_1}{2} + \frac{B_2}{4} + \frac{B_3}{8} + \ldots + \frac{B_{12}}{4096}\right) FSR - \frac{FSR}{2} = E_{in} \qquad (4)$$

Bipolar (Offset Binary Coding)

Several examples will illustrate how this binary coding works.

0 TO +10V INPUT RANGE

Assume FSR = 10V and $B_1\ B_2\ B_3\ .\ .B_{12}$ = 110001000001, then from (3), E_{in} = +5V +2.5V +0.1563V + 0.0024V = +7.6587V.

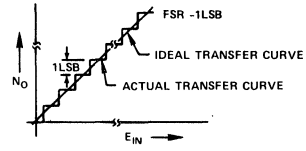
-5V TO +5V INPUT RANGE

Assume FSR = 10V as above, but that the bipolar offset is connected and $B_1\ B_2\ B_3\ .\ .B_{12}$ = 0110000000001. Then from (4), E_{in} = (+2.5V + 1.25V + 0.0024V) - 5V = -1.2476V.

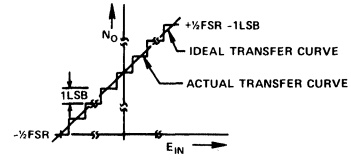
-10V TO +10V INPUT RANGE

Assume the bipolar offset is connected as above, but that the input span is now 20V. Assuming the same digital output code as in the -5V to +5V input range example, from (4), E_{in} = (+5V +2.5V +0.0049V) -10V = -2.4951V, or twice the value of the previous example (neglecting round-off errors).

The encoding process defined by the previous relations (1) and (2) or (3) and (4) determines that the analog input lies within one of the 2^{12} = 4096 quantization levels between 0 and FSR (or -FSR/2 and +FSR/2). Figures 3 (A) and 3 (B) show the actual device transfer curves for unipolar and bipolar ranges (offset binary coding). They also show the ideal straight-line transfer curves which pass through the center of each quantization level. As can be seen from these figures, the actual and ideal transfer curves differ by exactly ±½LSB at the end of each quantization interval, giving rise to the fundamental ±½LSB quantization error inherent in the digitizing process.



(A) Unipolar Range (Binary Coding)



(B) Bipolar Range (Offset Binary Coding)

Figure 3. Unipolar and Bipolar Range Transfer Curves

ANALOG INPUT AND POWER CONNECTIONS

Offset Adjust: Analog and power connections for 0 to +10V unipolar and -10V to +10V bipolar input ranges are shown in Figures 4 and 5, respectively. The Bipolar Offset pin 23 is open-circuited for all unipolar input ranges, and connected to Comparator Input pin 22 for all bipolar input ranges. The zero adjust circuit consists of a potentiometer connected across $\pm V_S$ with its slider connected through a 3.9MΩ resistor to Comparator Input pin 22 for all ranges. The tolerance of this fixed resistor is not critical, and a carbon composition type is generally adequate. Using a carbon composition resistor having a -1200ppm/°C tempco contributes a worst-case offset tempco of 8 x 244 x 10^{-6} x 1200ppm/°C = 2.3ppm/°C of FSR, if the OFFSET ADJ potentiometer is set at either end of its adjustment range. Since the maximum offset adjustment required is typically no more than ±4LSB, use of a carbon composition offset summing resistor typically contributes no more than 1ppm/°C of FSR offset tempco.

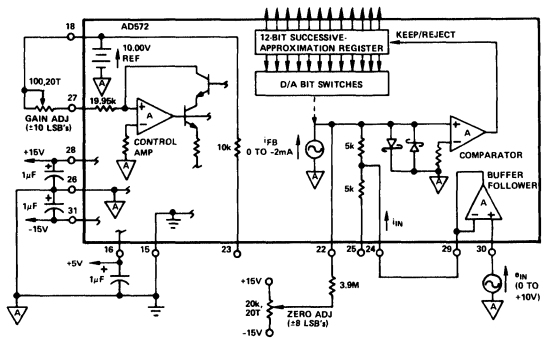


Figure 4. Analog and Power Connections for Unipolar 0 to +10V Input Range with Buffer Follower

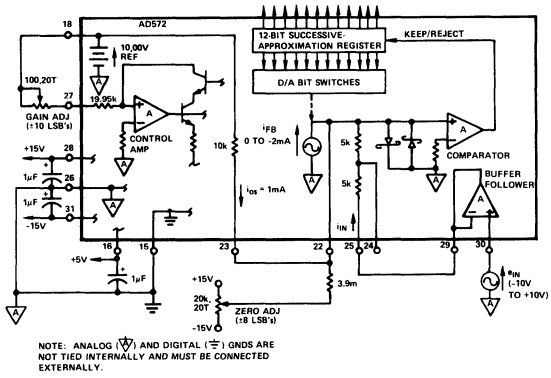

Figure 5. Analog and Power Connections for Bipolar -10V to +10V Input Range with Buffer Follower

An alternate offset adjust circuit, which contributes negligible offset tempco if metal film resistors (tempco < 100 ppm/°C) are used, is shown in Figure 6.

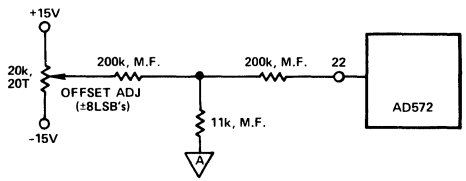

Figure 6. Low Tempco Zero Adj Circuit

In either zero adjust circuit, the fixed resistor connected to pin 22 should be located close to this pin to keep the pin 22 connection runs short, since the Comparator Input pin 22 is quite sensitive to external noise pick-up.

Gain Adjust: The gain adjust circuit consists of a 100Ω potentiometer connected between +10V Reference Output pin 18 and Gain Adjust Input pin 27 for all ranges. Both GAIN and ZERO ADJ potentiometers should be multi-turn, low tempco types; 20T cermet (tempco = 100ppm/°C max) types are recommended. If the 100Ω GAIN ADJ potentiometer is replaced by a fixed 50Ω resistor, absolute gain calibration to ±0.1% of FSR is guaranteed.

Grounding: Analog and digital power supply grounds should be kept separate where possible to prevent digital signals from flowing in the analog ground circuit and inducing spurious analog signal noise. Analog Ground pin 26 and Digital Ground pin 15 are not connected internally; these two pins must be connected externally for the device to operate properly. Preferably, this connection is made at only one point, and as close to the device as possible.

Power Supply Bypassing: The ±15V and +5V power leads should be capacitively bypassed for optimum device performance. 1μF tantalum types are recommended; these capacitors should be located close to the device. It is not necessary to shunt these capacitors with disc capacitors to provide additional high frequency power supply decoupling (as is required with some competitive products), since each power lead is bypassed internally with a 0.039μF ceramic capacitor.

CALIBRATION

External ZERO ADJ and GAIN ADJ potentiometers, connected as shown in Figures 3 and 4, are used for device calibration. To prevent interaction of these two adjustments, Zero is always adjusted first and then Gain. Zero is adjusted with the analog input near the most negative end of the analog range (0 for unipolar and -½FSR for bipolar input ranges). Gain is adjusted with the analog input near the most positive end of the analog range.

0 to +10V Range: Set analog input to +1LSB = +0.0024V. Adjust Zero for digital output = 000000000001; Zero is now calibrated. Set analog input to +FSR -2LSB = +9.9952V. Adjust Gain for 111111111110 digital output code; full-scale (Gain) is now calibrated. Half-scale calibration check: set analog input to +5.0000V; digital output code should be 100000000000.

-10V to +10V Range: Set analog input to -9.9951V; adjust Zero for 000000000001 digital output (offset binary) code. Set analog input to +9.9902V; adjust Gain for 111111111110 digital output (offset binary) code. Half-scale calibration check: set analog input to 0.0000V; digital output (offset binary) code should be 100000000000.

Other Ranges: Representative digital coding for 0 to +10V, -5V to +5V, and -10V to +10V ranges is shown in Table I. Coding relationships and calibration points for 0 to +5V and -2.5V to +2.5V ranges can be found by halving the corresponding code equivalents listed for the 0 to +10V and -5V to +5V ranges, respectively.

Zero and full-scale calibration can be accomplished to a precision of approximately ±¼LSB using the static adjustment procedure described above. By summing a small sine or triangular-wave voltage with the signal applied to the analog input, the output can be cycled through each of the calibration codes of interest to more accurately determine the center (or end points) of each discrete quantization level. A detailed description of this dynamic calibration technique is presented in "A/D Conversion Notes", D. Sheingold, Analog Devices, Inc., 1977, Part II, Chapter 4.

Analog Input - Volts (Center of Quantization Interval)			Input Normalized to FSR		Digital Output Code (Binary for Unipolar Ranges; Offset Binary for Bipolar Ranges)	
0 to +10V Range	-5V to +5V Range	-10V to +10V Range	Unipolar Ranges	Bipolar Ranges	B1 (MSB)	B12 (LSB)

Table I. Digital Output Codes vs Analog Input For Unipolar and Bipolar Ranges

RANGE AND BUFFER FOLLOWER PIN CONNECTIONS

Analog pin connections for each of the ranges, with and without the buffer follower being used, are shown in Table II.

Range	Buffer Follower	Connect Analog Input To Pin:	Connect Span Pin:	Connect Bipolar Pin 23 To:
0 to +5V	Used	30, and 29 to 24	25 to 22	—
	Not Used	24		
0 to +10V	Used	30, and 29 to 24	—	
	Not Used	24		
-2.5 to +2.5V	Used	30, and 29 to 24	25 to 22	22
	Not Used	24		
-5 to +5V	Used	30, and 29 to 24	—	
	Not Used	24		
-10 to +10V	Used	30, and 29 to 25	—	
	Not Used	25		

Table II. Range and Buffer Follower Pin Connections

When the analog signal source has a low impedance (as would be the case if it were the output of the sample-hold amplifier of Figure 9), it can be connected to either of the direct input pins 24 or 25. The buffer follower is used in the application as shown in Figure 6, in which the analog input to the converter comes directly from the output of a FET analog multiplexer. The selected channel has a typical r_{on} = 200Ω which has a 3000ppm/°C tempco. If the multiplexer output were connected to the 0 to +10V direct input pin 24 (5kΩ input impedance, nominal), this r_{on} would introduce a 4% gain scale-factor loading error, which is well beyond the normal ±0.25% FSR external gain adjustment range, and a tempco of approximately 3000ppm/°C x 4% = 120ppm/°C. By connecting the buffer between the multiplexer output and direct input, these errors are eliminated. The buffer amplifier input bias current (50nA typical) must flow through the analog signal source, however. This limits the upper practical source impedance to several kilohms so that the offset voltage I_{BIAS} R_{SOURCE} can be kept negligible, even though the buffer amplifier dynamic input impedance ⩾ 100MΩ. The buffer amplifier has a 2μs settling time to 0.01% FSR for a 20V input step. This must be added to the conversion time when the input voltage can change significantly between successive conversions (as could be the case in the circuit of Figure 7).

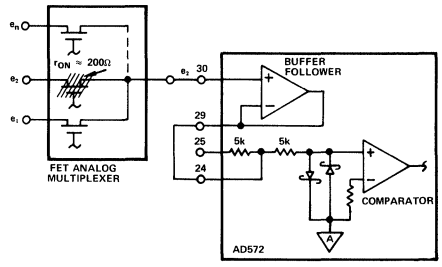

Figure 7. Using Buffer Follower With Multiplexed Analog Input

Short Cycle Input: A Short Cycle Input pin 14 permits the timing cycle shown in Figure 2 to be terminated after any number of desired bits has been converted, permitting somewhat shorter conversion times in applications not requiring full 12-bit resolution. When 12-bit resolution is required, pin 14 is connected to +5V (pin 16). When 10-bit resolution is desired, pin 14 is connected to Bit 11 output pin 2. The conversion cycle then terminates, and the STATUS flag resets after the Bit 10 decision (t_{10} +100ns in timing diagram of Figure 2). Short Cycle pin connections and associated maximum 12-, 10- and 8-bit conversion times are summarized in Table III.

Connect Short Cycle Pin 14 to Pin:	Bits	Resolution (% FSR)	Maximum Conversion Time (μs)	Status Flag Reset at: (Figure 2)
16	12	0.024	25	t_{12} + 100ns
2	10	0.10	21	t_{10} + 100ns
4	8	0.39	17	t_8 + 100ns

Table III. Short Cycle Connections

(One should note that the calibration voltages listed in Table I are for 12-bit resolution only, and are not those corresponding to the center of each discrete quantization interval at reduced bit resolutions.)

DIGITAL OUTPUT DATA

Both parallel and serial data are in positive-true form and outputted from TTL storage registers. Parallel data output coding is binary for unipolar ranges and either offset binary

or two's complement binary, depending on whether Bit 1 (pin 12) or its logical inverse $\overline{\text{BIT 1}}$ (pin 13) is used as the MSB. Parallel data becomes valid approximately 200ns before the STATUS flag returns to Logic "0", permitting parallel data transfer to be clocked on the "1" to "0" transition of the STATUS flag.

Serial data coding is binary for unipolar input ranges and offset binary for bipolar input ranges. Serial output is by bit (MSB first, LSB last) in NRZ (non-return-to-zero) format. Serial and parallel data outputs change state on positive-going clock edges. Serial data is guaranteed valid on all negative-going clock edges, permitting serial data to be clocked directly into a receiving register on these edges as shown in Figure 8. There are 13 negative-going clock edges in the complete 12-bit conversion cycle, as shown in Figure 2. The first edge shifts an invalid bit into the register, which is shifted out on the 13th negative-going clock edge. All serial data bits will have been correctly transferred and be in the receiving shift register locations shown at the completion of the conversion period.

APPLICATIONS

Sample-Hold Amplifier: A sample-hold amplifier (SHA) is normally connected between the analog signal source and AD572 analog input when the analog signal can change by more than ½LSB during conversion. Typical SHA-AD572 interconnections are shown in Figure 9. The $\overline{\text{STATUS}}$ output drives the SHA SAMPLE/HOLD input directly. On receipt of a CONVERT START pulse, the $\overline{\text{STATUS}}$ flag changes from "1" to "0" causing SHA mode to change from SAMPLE to HOLD. The SHA output voltage $e_{o\ S\text{-}H}$ is then held constant at the value existing just prior to application of the HOLD command for the complete conversion period. At the end of conversion, the $\overline{\text{STATUS}}$ flag returns to "1", restoring the SHA mode to SAMPLE, and $e_{o\ S\text{-}H}$ again tracks the analog signal voltage $e_{in\ S\text{-}H}$ (after the signal acquisition transient has subsided).

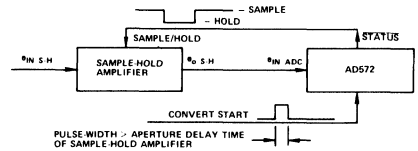

Figure 9. Sample-Hold Amplifier – AD572 Interconnections

Note that the internal (gated) clock is inhibited for the duration of the CONVERT START pulse and does not start running until the termination of this pulse (see timing). This can be used to simplify control signal timing requirements. In the circuit of Figure 9, for example, the CONVERT START signal pulse-width can be extended beyond the aperture delay time of the SHA to assure that $e_{o\ S\text{-}H}$ is in steady-state before conversion is initiated. This assures accurate conversion without requiring additional delay timing circuitry. The effect of varying the CONVERT START pulse-width on the conversion timing cycle is shown in Figure 10.

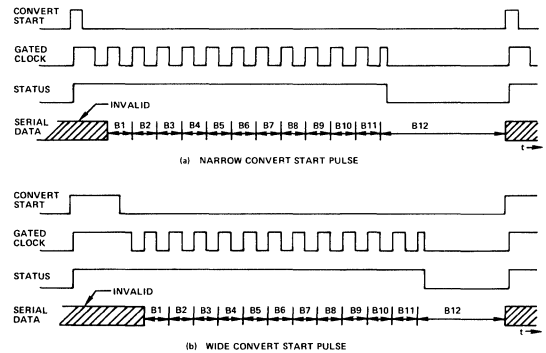

Figure 10. Effect of Convert Start Pulse-Width on Timing

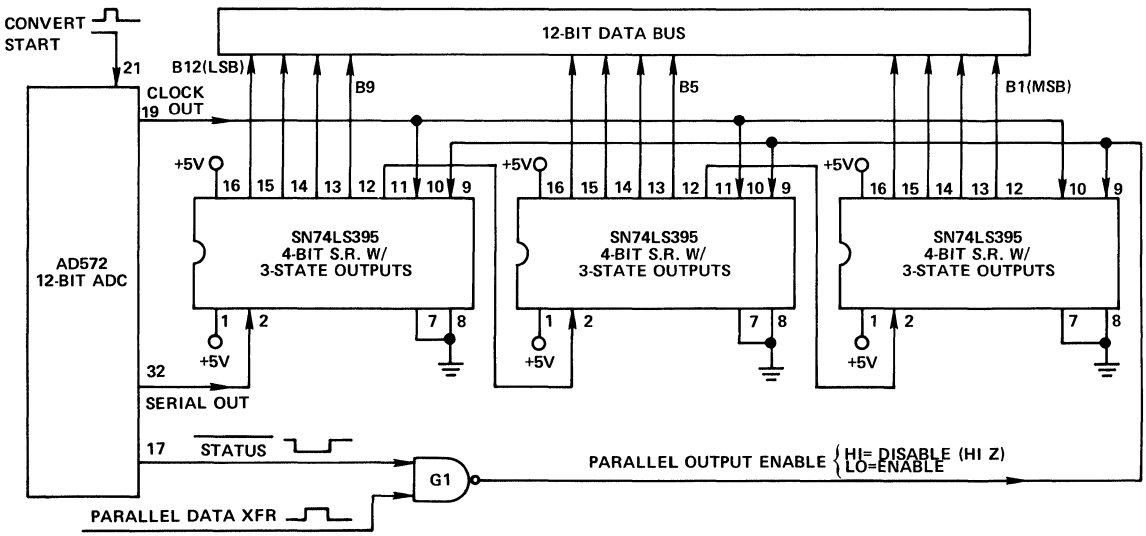

Figure 8. Serial Data Transfer Into Shift Register With Parallel Output to Data Bus

Digital Gain Control: Figure 11 shows a method of varying the AD572 gain digitally, using an 8-bit DAC. The 100Ω GAIN ADJ potentiometer is replaced by a 15Ω fixed resistor. This biases full-scale high by approximately 35Ω/20,000Ω = +0.18% of FSR. The AD559 has a large positive compliance voltage which permits its Current Output pin 4 to be connected directly to the AD572 Reference Input pin 27. The AD559 2.5mA output current is established by the AD580 +2.5V voltage reference connected through a 1kΩ resistor to Reference Current Input pin 14. The 2.5mA DAC full-scale output current removed from the AD572 pin 27 node changes the pin 27 input current -2.5mA x 15Ω/20kΩ = -1.88μA, or -1.88μA/500μA = -0.38% of FSR; this permits a digital gain adjustment range of approximately ±0.2% FSR from nominal.

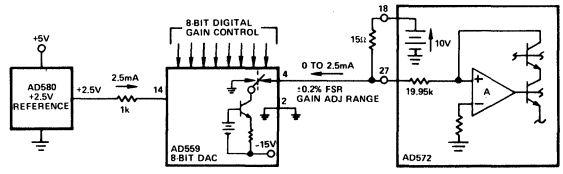

Figure 11. Digital Gain Control Using 8-Bit DAC

ANALOG DEVICES

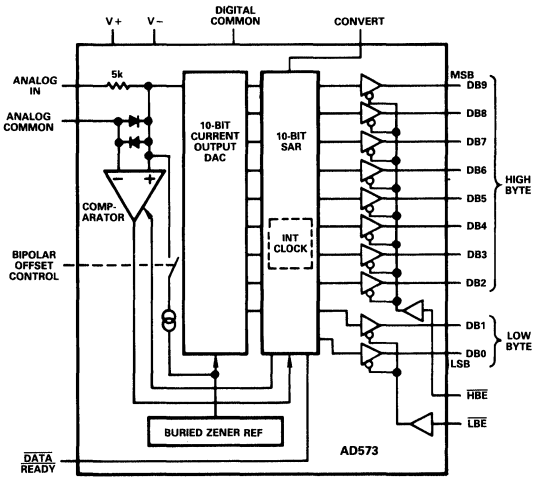
10-Bit A/D Converter

AD573*

FEATURES

Complete 10-Bit A/D Converter with Reference, Clock and Comparator
Full 8- or 16-Bit Microprocessor Bus Interface
Fast Successive Approximation Conversion – 20μs typ
No Missing Codes Over Temperature
Operates on +5V and −12V to −15V Supplies
Low Cost Monolithic Construction

AD573 FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD573 is a complete 10-bit successive approximation analog to digital converter consisting of a DAC, voltage reference, clock, comparator, successive approximation register (SAR) and 3 state output buffers–all fabricated on a single chip. No external components are required to perform a full accuracy 10-bit conversion in 20μs.

The AD573 incorporates advanced integrated circuit design and processing technologies. The successive approximation function is implemented with I^2L (integrated injection logic). Laser trimming of the high stability SiCr thin film resistor ladder network insures high accuracy, which is maintained with a temperature compensated sub-surface Zener reference.

Operating on supplies of +5V and −12V to −15V, the AD573 will accept analog inputs of 0 to +10V or −5V to +5V. The trailing edge of a positive pulse on the CONVERT line initiates the 20μs conversion cycle. $\overline{\text{DATA READY}}$ indicates completion of the conversion. $\overline{\text{HIGH BYTE ENABLE}}$ ($\overline{\text{HBE}}$) and $\overline{\text{LOW BYTE ENABLE}}$ ($\overline{\text{LBE}}$) control the 8-bit and 2-bit three state output buffers.

The AD573 is available in two versions for the 0 to +70°C temperature range, the AD573J and AD573K. The AD573S guarantees ±1LSB relative accuracy and no missing codes from −55°C to +125°C.

Two package configurations are offered. All versions are also offered in a 20-pin hermetically sealed ceramic DIP. The AD573J and AD573K are also available in a 20-pin plastic DIP.

***Protected by U.S. Patent Nos. 3,940,760; 4,213,806; 4,136,349; 4,400,689; and 4,400,690**

PRODUCT HIGHLIGHTS

1. The AD573 is a complete 10-bit A/D converter. No external components are required to perform a conversion.
2. The AD573 interfaces to many popular microprocessors without external buffers or peripheral interface adapters. The 10 bits of output data can be read as a 10-bit word or as 8- and 2-bit words.
3. The device offers true 10-bit accuracy and exhibits no missing codes over its entire operating temperature range.
4. The AD573 adapts to either unipolar (0 to +10V) or bipolar (−5V to +5V) analog inputs by simply grounding or opening a single pin.
5. Performance is guaranteed with +5V and −12V or −15V supplies.

NOTES

[1]Relative accuracy is defined as the deviation of the code transition points from the ideal transfer point on a straight line from the zero to the full scale of the device.

[2]Full-scale calibration is guaranteed trimmable to zero with an external 50Ω potentiometer in place of the 15Ω fixed resistor. Full scale is defined as 10 volts minus 1LSB, or 9.990 volts.

[3]Defined as the resolution for which no missing codes will occur.

[4]Change from +25°C value from +25°C to T_{min} or T_{max}.

[5]The data output lines have active pull-ups to source 0.5mA. The $\overline{\text{DATA READY}}$ line is open collector with a nominal 6kΩ internal pull-up resistor.

Specifications subject to change without notice.

Specifications shown in boldface are tested on all production units at final electrical test. Results from those tests are used to calculate outgoing quality levels. All min and max specifications are guaranteed, although only those shown in boldface are tested on all production units.

FUNCTIONAL DESCRIPTION

A block diagram of the AD573 is shown in Figure 1. The positive CONVERT pulse must be at least 500ns wide. $\overline{DR}$ goes high within 1.5μs after the leading edge of the convert pulse indicating that the internal logic has been reset. The negative edge of the CONVERT pulse initiates the conversion. The internal 10-bit current output DAC is sequenced by the integrated injection logic (I^2L) successive approximation register (SAR) from its most significant bit to least significant bit to provide an output current which accurately balances the input signal current through the 5kΩ resistor. The comparator determines whether the addition of each successively weighted bit current causes the DAC current sum to be greater or less than the input current; if the sum is more, the bit is turned off. After testing all bits, the SAR contains a 10-bit binary code which accurately represents the input signal to within ½LSB (0.05% of full scale).

The SAR drives $\overline{DR}$ low to indicate that the conversion is complete and that the data is available to the output buffers. $\overline{HBE}$ and $\overline{LBE}$ can then be activated to enable the upper 8-bit and lower 2-bit buffers as desired. $\overline{HBE}$ and $\overline{LBE}$ should be brought high prior to the next conversion to place the output buffers in the high impedance state.

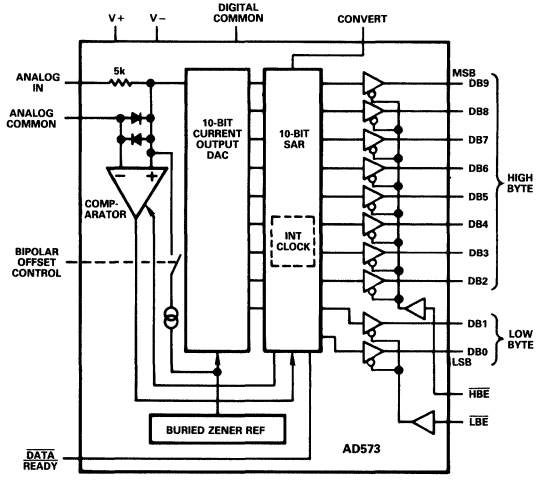

Figure 1. AD573 Functional Block Diagram

The temperature compensated buried Zener reference provides the primary voltage reference to the DAC and ensures excellent stability with both time and temperature. The bipolar offset input controls a switch which allows the positive bipolar offset current (exactly equal to the value of the MSB less ½LSB) to be injected into the summing (+) node of the comparator to offset the DAC output. Thus the nominal 0 to +10V unipolar input range becomes a −5V to +5V range. The 5kΩ thin film input resistor is trimmed so that with a full scale input signal, an input current will be generated which exactly matches the DAC output with all bits on.

UNIPOLAR CONNECTION

The AD573 contains all the active components required to perform a complete A/D conversion. Thus, for many applications, all that is necessary is connection of the power supplies (+5V and −12V to −15V), the analog input and the convert pulse. However, there are some features and special connections which should be considered for achieving optimum performance. The functional pin-out is shown in Figure 2.

The standard unipolar 0 to +10V range is obtained by shorting the bipolar offset control pin (pin 16) to digital common (pin 17).

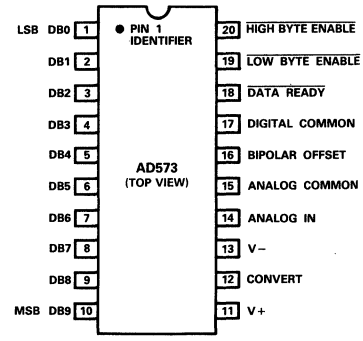

Figure 2. AD573 Pin Connections

Full Scale Calibration

The 5kΩ thin film input resistor is laser trimmed to produce a current which matches the full scale current of the internal DAC–plus about 0.3%–when an analog input voltage of 9.990 volts (10 volts – 1LSB) is applied at the input. The input resistor is trimmed in this way so that if a fine trimming potentiometer is inserted in series with the input signal, the input current at the full scale input voltage can be trimmed down to match the DAC full scale current as precisely as desired. However, for many applications the nominal 9.99 volt full scale can be achieved to sufficient accuracy by simply inserting a 15Ω resistor in series with the analog input to pin 14. Typical full scale calibration error will then be within ±2LSB or ±0.2%. If more precise calibration is desired, a 50Ω trimmer should be used instead. Set the analog input at 9.990 volts, and set the trimmer so that the output code is just at the transition between 11111111 10 and 11111111 11. Each LSB will then have a weight of 9.766mV. If a nominal full scale of 10.24 volts is desired (which makes the LSB have a weight of exactly 10.00mV), a 100Ω resistor and a 100Ω trimmer (or a 200Ω trimmer with good resolution) should be used. Of course, larger full scale ranges can be arranged by using a larger input resistor, but linearity and full scale temperature coefficient may be compromised if the external resistor becomes a sizeable percentage of 5kΩ. Figure 3 illustrates the connections required for full scale calibration.

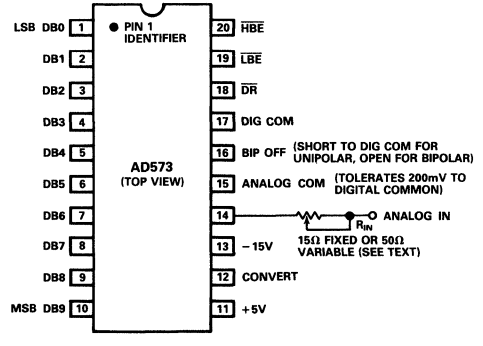

Figure 3. Standard AD573 Connections

Unipolar Offset Calibration

Since the Unipolar Offset is less than ±1LSB for all versions of the AD573, most applications will not require trimming. Figure 4 illustrates two trimming methods which can be used if greater accuracy is necessary.

Figure 4a shows how the converter zero may be offset by up to ±3 bits to correct the device initial offset and/or input signal offsets. As shown, the circuit gives approximately symmetrical adjustment in unipolar mode.

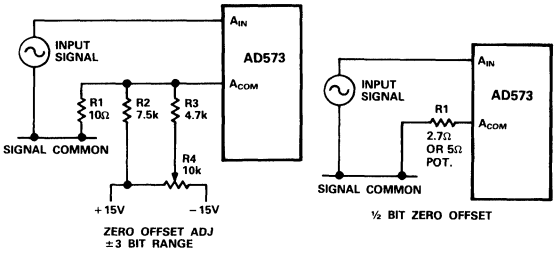

Figure 4a. *Figure 4b.*

Figure 4. Offset Trims

Figure 5 shows the nominal transfer curve near zero for an AD573 in unipolar mode. The code transitions are at the edges of the nominal bit weights. In some applications it will be preferable to offset the code transitions so that they fall between the nominal bit weights, as shown in the offset characteristics.

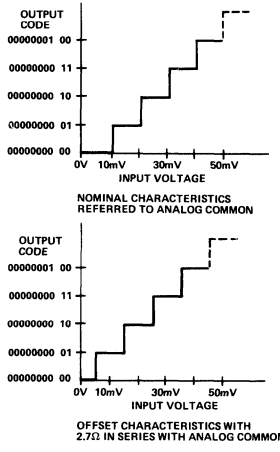

Figure 5. AD573 Transfer Curve – Unipolar Operation (Approximate Bit Weights Shown for Illustration, Nominal Bit Weights ~ 9.766mV)

This offset can easily be accomplished as shown in Figure 4b. At balance (after a conversion) approximately 2mA flows into the Analog Common terminal. A 2.7Ω resistor in series with this terminal will result in approximately the desired ½ bit offset of the transfer characteristics. The nominal 2mA Analog Common current is not closely controlled in manufacture. If high accuracy is required, a 5Ω potentiometer (connected as a rheostat) can be used as R1. Additional negative offset range may be obtained by using larger values of R1. Of course, if the zero transition point is changed, the full scale transition point will also move. Thus, if an offset of ½LSB is introduced, full scale trimming as described on the previous page should be done with an analog input of 9.985 volts.

NOTE: During a conversion, transient currents from the Analog Common terminal will disturb the offset voltage. Capacitive decoupling should not be used around the offset network. These transients will settle appropriately during a conversion. Capacitive decoupling will "pump up" and fail to settle resulting in conversion errors. Power supply decoupling, which returns to analog signal common, should go to the signal input side of the resistive offset network.

BIPOLAR CONNECTION

To obtain the bipolar −5V to +5V range with an offset binary output code, the bipolar offset control pin is left open.

A −5.000 volt signal will give a 10-bit code of 00000000 00; an input of 0.000 volts results in an output code of 10000000 00 and +4.99 volts at the input yields the 11111111 11 code. The nominal transfer curve is shown in Figure 6.

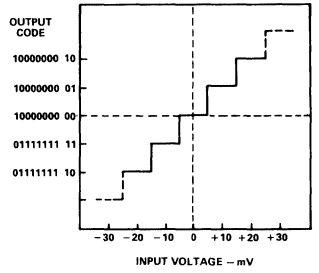

Figure 6. AD573 Transfer Curve – Bipolar Operation

Note that in the bipolar mode, the code transitions are offset ½LSB such that an input voltage of 0 volts ±5mV yields the code representing zero (10000000 00). Each output code is then *centered* on its nominal input voltage.

Full Scale Calibration

Full Scale Calibration is accomplished in the same manner as in Unipolar operation except the full scale input voltage is +4.985 volts.

Negative Full Scale Calibration

The circuit in Figure 4a can also be used in Bipolar operation to offset the input voltage (nominally −5V) which results in the 00000000 00 code. R2 should be omitted to obtain a symmetrical range.

The bipolar offset control input is not directly TTL compatible but a TTL interface for logic control can be constructed as shown in Figure 7.

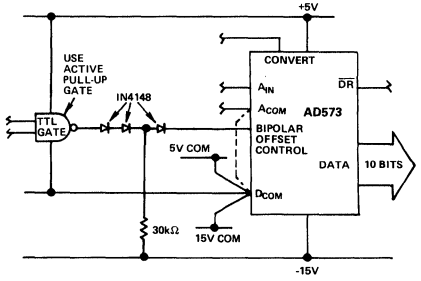

Figure 7. Bipolar Offset Controlled by Logic Gate
Gate Output = 1 Unipolar 0 – 10V Input Range
Gate Output = 0 Bipolar ±5V Input Range

SAMPLE-HOLD AMPLIFIER CONNECTION TO THE AD573

Many situations in high-speed acquisition systems or digitizing rapidly changing signals require a sample-hold amplifier (SHA) in front of the A-D converter. The SHA can acquire and hold a

signal faster than the converter can perform a conversion. A SHA can also be used to accurately define the exact point in time at which the signal is sampled. For the AD573, a SHA can also serve as a high input impedance buffer.

Figure 8 shows the AD573 connected to the AD582 monolithic SHA for high speed signal acquisition. In this configuration, the AD582 will acquire a 10 volt signal in less than 10μs with a droop rate less than 100μV/ms.

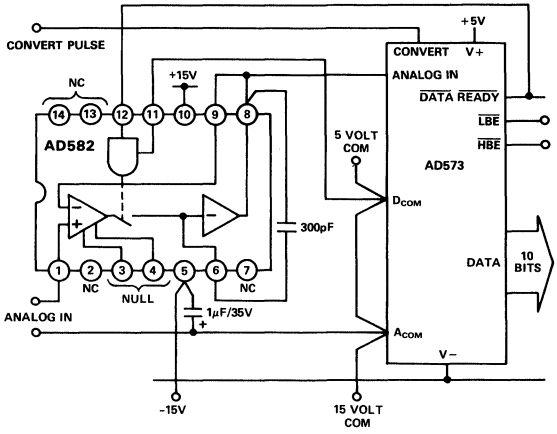

Figure 8. Sample-Hold Interface to the AD573

$\overline{DR}$ goes high after the conversion is initiated to indicate that reset of the SAR is complete. In Figure 8 it is also used to put the AD582 into the hold mode while the AD573 begins its conversion cycle. (The AD582 settles to final value well in advance of the first comparator decision inside the AD573).

$\overline{DR}$ goes low when the conversion is complete placing the AD582 back in the sample mode. Configured as shown in Figure 8, the next conversion can be initiated after a 10μs delay to allow for signal acquisition by the AD582.

Observe carefully the ground, supply, and bypass capacitor connections between the two devices. This will minimize ground noise and interference during the conversion cycle.

GROUNDING CONSIDERATIONS

The AD573 provides separate Analog and Digital Common connections. The circuit will operate properly with as much as ±200mV of common mode voltage between the two commons. This permits more flexible control of system common bussing and digital and analog returns.

In normal operation, the Analog Common terminal may generate transient currents of up to 2mA during a conversion. In addition a static current of about 2mA will flow into Analog Common in the unipolar mode after a conversion is complete. The Analog Common current will be modulated by the variations in input signal.

The absolute maximum voltage rating between the two commons is ±1 volt. It is recommended that a parallel pair of back-to-back protection diodes be connected between the commons if they are not connected locally.

CONTROL AND TIMING OF THE AD573

The operation of the AD573 is controlled by three inputs: CONVERT, $\overline{HBE}$ and $\overline{LBE}$.

Starting a Conversion

The conversion cycle is initiated by a positive-going CONVERT pulse at least 500ns wide. The rising edge of this pulse resets the internal logic, clears the result of the previous conversion, and sets $\overline{DR}$ high. The falling edge of CONVERT begins the conversion cycle. When conversion is completed $\overline{DR}$ returns low. During the conversion cycle, $\overline{HBE}$ and $\overline{LBE}$ should be held high. If $\overline{HBE}$ or $\overline{LBE}$ goes low during a conversion, the data output buffers will be enabled and intermediate conversion results will be present on the data output pins. This may cause bus conflicts if other devices in a system are trying to use the bus.

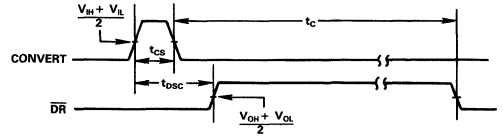

Figure 9. Convert Timing

Reading the Data

The three-state data output buffers are enabled by $\overline{HBE}$ and $\overline{LBE}$. Access time of these buffers is typically 150ns (250 maximum). The Data outputs remain valid until 50ns after the enable signal returns high, and are completely into the high-impedance state 100ns later.

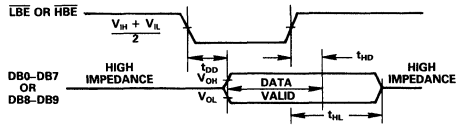

Figure 10. Read Timing

TIMING SPECIFICATIONS (All grades, $T_A = T_{min} - T_{max}$)

Parameter	Symbol	Min	Typ	Max	Units
CONVERT Pulse Width	t_{CS}	500	–	–	ns
$\overline{DR}$ Delay from CONVERT	t_{DSC}	–	1	1.5	μs
Conversion Time	t_C	10	20	30	μs
Data Access Time	t_{DD}	0	150	250	ns
Data Valid after $\overline{HBE}$/$\overline{LBE}$ High	t_{HD}	50	–	–	ns
Output Float Delay	t_{HL}	–	100	200	ns

MICROPROCESSOR INTERFACE CONSIDERATIONS – GENERAL

When an analog-to-digital converter like the AD573 is interfaced to a microprocessor, several details of the interface must be considered. First, a signal to start the converter must be generated; then an appropriate delay period must be allowed to pass before valid conversion data may be read. In most applications, the AD573 can interface to a microprocessor system with little or no external logic.

The most popular control signal configuration consists of decoding the address assigned to the AD573, then gating this signal with the system's WR signal to generate the CONVERT pulse, and gating it with RD to enable the output buffers. The use of a memory address and memory WR and RD signals denotes "memory-mapped" I/O interfacing, while the use of a separate I/O address space denotes "isolated I/O" interfacing. In 8-bit bus systems, the 10-bit AD573 will occupy two locations when data is to be read; therefore, two (usually consecutive) addresses must be decoded. One of the addresses can also be used as the address which produces the CONVERT signal during WR operations.

Figure 11 shows a generalized diagram of the control logic for

an AD573 interfaced to an 8-bit data bus, where two addresses (ADC ADDR and ADC ADDR + 1) have been decoded. ADC ADDR starts the converter when written to (the actual data being written to the converter does not matter) and contains the high byte data during read operations. ADC ADDR + 1 performs no function during write operations, but contains the low byte data during read operations.

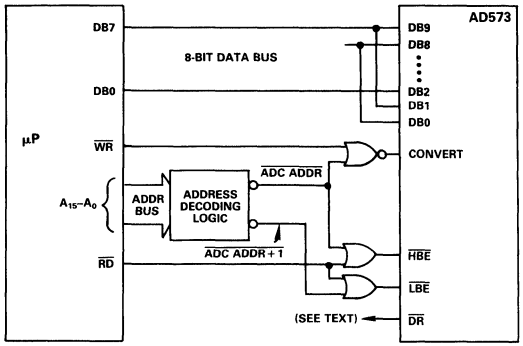

Figure 11. General AD573 Interface to 8-Bit Microprocessor

In systems where this read-write interface is used, at least 30 microseconds (the maximum conversion time) must be allowed to pass between starting a conversion and reading the results. This delay or "timeout" period can be implemented in a short software routine such as a countdown loop, enough dummy instructions to consume 30 microseconds, or enough actual useful instructions to consume the required time. In tightly-timed systems, the $\overline{DR}$ line may be read through an external three-state buffer to determine precisely when a conversion is complete. Higher-speed systems may choose to use $\overline{DR}$ to signal an interrupt to the processor at the end of a conversion.

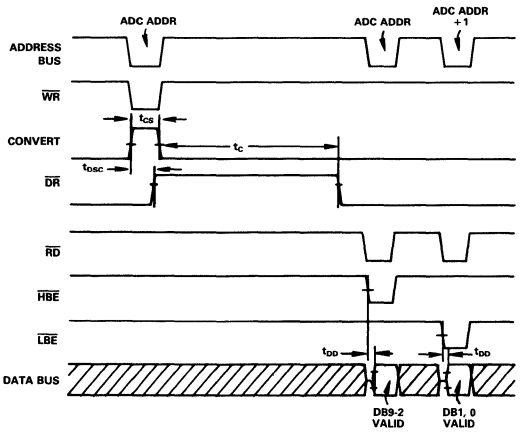

Figure 12. Typical AD573 Interface Timing Diagram

CONVERT Pulse Generation

The AD573 is tested with a CONVERT pulse width of 500ns and will typically operate with a pulse as short as 300ns. However, some microprocessors produce active WR pulses which are shorter than this. Either of the circuits shown in Figure 13 can be used to generate an adequate CONVERT pulse for the AD573.

In both circuits, the short low-going WR pulse sets the CONVERT line high through a flip-flop. The rising edge of $\overline{DR}$ (which signifies that the internal logic has been reset) resets the flip-flop and brings CONVERT low, which starts the conversion.

Note that t_{DSC} is slightly longer when the result of the previous conversion contains a logic 1 on the LSB. This means that the actual CONVERT pulse generated by the circuits in Figure 13 will vary slightly in width.

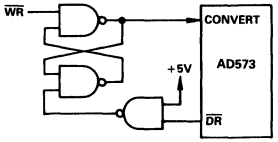

Figure 13a. Using 74LS00

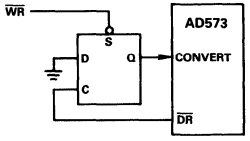

Figure 13b. Using 1/2 74LS74

Output Data Format

The AD573 output data is presented in a left-justified format. The 8 MSBs (DB9–DB2, pins 10 through 3) are enabled by $\overline{HBE}$ (pin 20) and the 2 LSBs (DB1, DB0 – pins 2 and 1) are enabled by $\overline{LBE}$ (pin 19). This allows simple interface to 8-bit system buses by overlapping the 2 MSBs and the 2 LSBs. The organization of the data is shown in Figure 14.

When the least significant bits are read ($\overline{LBE}$ brought low), the six remaining bits of the byte will contain meaningless data. These unwanted bits can be masked by logically ANDing the byte with 11000000 (C0 hex), which forces the 6 lower bits to logic 0 while preserving the two most significant bits of the byte.

Note that it is not possible to reconfigure the AD573 for right justified data.

$\overline{HBE}$	DB9	DB8	DB7	DB6	DB5	DB4	DB3	DB2
$\overline{LBE}$	DB1	DB0	X	X	X	X	X	X

Figure 14. AD573 Output Data Format

In systems where all 10 bits are desired at the same time, $\overline{HBE}$ and $\overline{LBE}$ may be tied together. This is useful in interfacing to 16-bit bus systems. The resulting 10-bit word can then be placed at the high end of the 16-bit bus for left justification or at the low end for right justification.

It is also possible to use the AD573 in a "stand-alone" mode, where the output data buffers are automatically enabled at the end of a conversion cycle. In this mode, the $\overline{DR}$ output is wired to the $\overline{HBE}$ and $\overline{LBE}$ inputs. The outputs thus are forced into the high-impedance state during the conversion period, and valid data becomes available approximately 500ns after the $\overline{DR}$ signal goes low at the end of the conversion. The 500ns delay allows propagation of the least significant bit through the internal logic.

This mode is particularly useful for bench-testing of the AD573, and in applications where dedicated I/O ports of peripheral interface adapter chips are available.

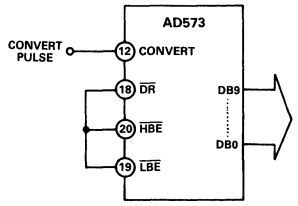

Figure 15. AD573 in "Stand-Alone" Mode (Output Data Valid 500ns After DR Goes Low)

Apple II Microcomputer Interface

The AD573 can provide a flexible, low-cost analog interface for the popular Apple II microcomputer. The Apple II, based on a 1MHz 6502 microprocessor, meets all timing requirements for the AD573. Only a few TTL gates are required to decode the signals available on the Apple II's peripheral connector. The recommended connections are shown in Figure 16.

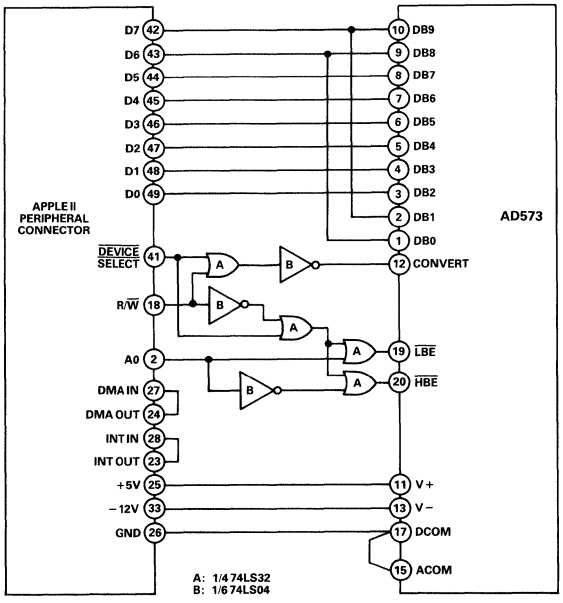

Figure 16. AD573 Interface to Apple II

The BASIC routine listed here will operate the AD573 circuit shown in Figure 16. The conversion is started by POKEing to the location which contains the AD573. The relatively slow execution speed of BASIC eliminates the need for a delay routine between starting and reading the converter. This routine assumes that the AD573 is connected for a ±5 volt input range. Variable I represents the integer value (from 0 to 1023) read from the AD573. Variable V represents the actual value of the input signal (in volts).

```
100 PRINT "WHICH SLOT IS THE A/D IN";:INPUT S
110 A= 49280+16*S
120 POKE A,0
130 L=PEEK(A) :H=PEEK(A+1)
140 I=(4*H)+INT(L/64)
150 V=(I/1024)*10-5
160 PRINT "THE INPUT SIGNAL IS ";V;"VOLTS."
```

It is also possible to write a faster-executing assembly-language routine to control the AD573. Such a routine will require a delay between starting and reading the converter. This can be easily implemented by calling the Apple's WAIT subroutine (which resides at location $FCA8) after loading the accumulator with a number greater than or equal to two.

8085-Series Microprocessor Interface

The AD573 can also be used with 8085-series microprocessors. These processors use separate control signals for RD and WR, as opposed to the single R/$\overline{W}$ control signal used in the 6800/6500 series processors.

There are two constraints related to operation of the AD573 with 8085-series processors. The first problem is the width of the CONVERT pulse. The circuit shown in Figure 17 (essentially the same as that shown in Figure 13) will produce a wide enough CONVERT pulse when the 8085 is running at 5MHz. For 8085 systems running at slower clock rates (3MHz), the flip-flop-based circuit can be eliminated since the $\overline{WR}$ pulse will be approximately 500ns wide.

The other consideration is the access time of the AD573's three-state output data buffers, which is 250ns maximum. It may be necessary to insert wait states during RD operations from the AD573. This will not be a problem in systems using memories with comparable access times, since wait states will have already been provided in the basic system design.

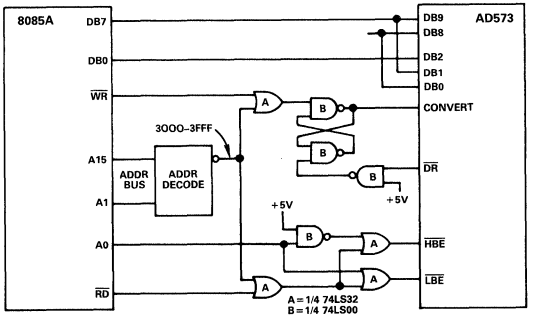

Figure 17. AD573–8085A Interface Connections

The following assembly-language subroutine can be used to control an AD573 residing at memory locations 3000_H and 3001_H. The 10 bits of data are returned (left-justified) in the DE register pair.

```
ADC:  LXI  H,3000  ;LOAD HL WITH AD573 ADDRESS
      MOV  M,A     ;START CONVERSION
      MVI  B,06    ;LOAD DELAY PERIOD
LOOP: DCR  B       ;DELAY LOOP
      JNZ  LOOP    ;
      MOV  A,M     ;READ LOW BYTE
      ANI  C0      ;MASK LOWER 6 BITS
      MOV  E,A     ;STORE CLEAN LOW BYTE IN E
      INR  L       ;LOAD HIGH BYTE ADDRESS
      MOV  D,M     ;MOVE HIGH BYTE TO D
      RET          ;EXIT
```

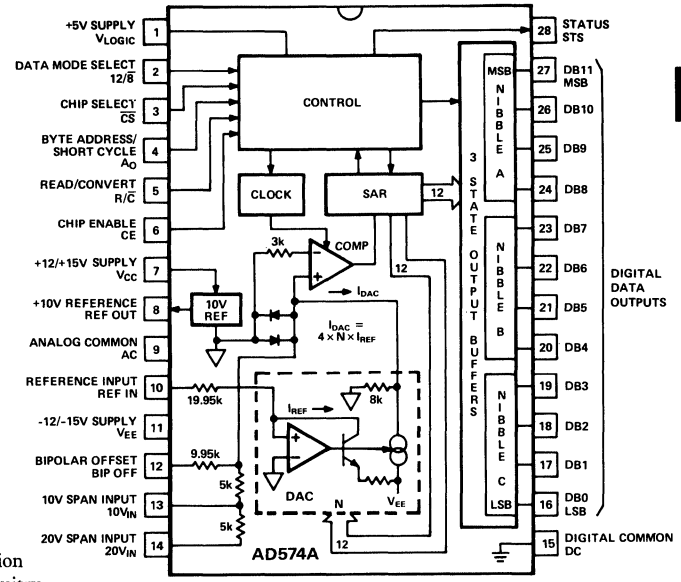
AD574A BLOCK DIAGRAM AND PIN CONFIGURATION



PRODUCT DESCRIPTION

The AD574A is a complete 12-bit successive-approximation analog-to-digital converter with 3-state output buffer circuitry for direct interface to an 8- or 16-bit microprocessor bus. A high-precision voltage reference and clock are included on-chip, and the circuit guarantees full-rated performance without external circuitry or clock signals.

The AD574A design is implemented using Analog Devices' Bipolar/I^2L process, and integrates all analog and digital functions on one chip. Offset, linearity and scaling errors are minimized by active laser-trimming of thin-film resistors at the wafer stage. The voltage reference uses an implanted buried Zener for low noise and low drift. On the digital side, I^2L logic is used for the successive-approximation register, control circuitry and 3-state output buffers.

The AD574A is available in six different grades. The AD574AJ, K, and L grades are specified for operation over the 0 to +70°C temperature range. The AD574AS, T, and U are specified for the −55°C to +125°C range. All grades are available in a 28-pin hermetically-sealed ceramic DIP. The J, K, and L grades are also available in a 28-pin plastic DIP and PLCC.

The S, T, and U grades are available with optional processing to MIL-STD-883C Class B. The Analog Devices' Military Products Databook should be consulted for details on /883B testing of the AD574A.

PRODUCT HIGHLIGHTS

1. The AD574A interfaces to most 8- or 16-bit microprocessors. Multiple-mode three-state output buffers connect directly to the data bus while the read and convert commands are taken from the control bus. The 12 bits of output data can be read either as one 12-bit word or as two 8-bit bytes (one with 8 data bits, the other with 4 data bits and 4 trailing zeros).
2. The precision, laser-trimmed scaling and bipolar offset resistors provide four calibrated ranges: 0 to +10 and 0 to +20 volts unipolar, −5 to +5 and −10 to +10 volts bipolar. Typical bipolar offset and full-scale calibration errors of ±0.1% can be trimmed to zero with one external component each.
3. The internal buried Zener reference is trimmed to 10.00 volts with 0.2% maximum error and 15ppm/°C typical T.C. The reference is available externally and can drive up to 1.5mA beyond the requirements of the reference and bipolar offset resistors.

ABSOLUTE MAXIMUM RATINGS*

(Specifications apply to all grades, except where noted)

V_{CC} to Digital Common . . . . . 0 to +16.5V
V_{EE} to Digital Common . . . . . 0 to −16.5V
V_{LOGIC} to Digital Common . . . . . 0 to +7V
Analog Common to Digital Common . . . . . ±1V
Control Inputs (CE, $\overline{CS}$, A_0, 12/$\overline{8}$, R/$\overline{C}$) to
Digital Common . . −0.5V to V_{LOGIC} +0.5V
Analog Inputs (REF IN, BIP OFF, $10V_{IN}$) to
Analog Common . . . . . V_{EE} to V_{CC}
$20V_{IN}$ to Analog Common . . . . . ±24V
REF OUT . . . . . Indefinite short to common
Momentary short to V_{CC}

Chip Temperature . . . . . 175°C
Power Dissipation 825mW
Lead Temperature, Soldering . . . . . +300°C, 10 sec.
Storage Temperature (Ceramic) . . . . . −65°C to +150°C
(Plastic) . . . . . −25°C to +100°C

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

AD574A ORDERING GUIDE

Model*	Temp. Range	Linearity Error Max (T_{min} to T_{max})	Resolution No Missing Codes (T_{min} to T_{max})	Max Full Scale T.C. (ppm/°C)
AD574AJ(X)	0 to +70°C	±1LSB	11 Bits	50.0
AD574AK(X)	0 to +70°C	±1/2LSB	12 Bits	27.0
AD574AL(X)	0 to +70°C	±1/2LSB	12 Bits	10.0
AD574AS(X)	−55°C to +125°C	±1LSB	11 Bits	50.0
AD574AT(X)	−55°C to +125°C	±1LSB	12 Bits	25.0
AD574AU(X)	−55°C to +125°C	±1LSB	12 Bits	12.5

NOTES
*X = Package designator. Available packages are:
D (D-28) for all grades.
E (E-28) for J, K, S, T, U grades.
N (N-28) for J, K, and L grades.
P for PLCC in J, K grades.
Example: AD574AKN is K grade in plastic DIP.

THE AD574A OFFERS GUARANTEED MAXIMUM LINEARITY ERROR OVER THE FULL OPERATING TEMPERATURE RANGE

DEFINITIONS OF SPECIFICATIONS

LINEARITY ERROR
Linearity error refers to the deviation of each individual code from a line drawn from "zero" through "full scale". The point used as "zero" occurs 1/2LSB (1.22mV for 10 volt span) before the first code transition (all zeros to only the LSB "on"). "Full scale" is defined as a level 1 1/2LSB beyond the last code transition (to all ones). The deviation of a code from the true straight line is measured from the middle of each particular code.

The AD574AK, L, T, and U grades are guaranteed for maximum nonlinearity of ± 1/2LSB. For these grades, this means that an analog value which falls exactly in the center of a given code width will result in the correct digital output code. Values nearer the upper or lower transition of the code width may produce the next upper or lower digital output code. The AD574AJ and S grades are guaranteed to ± 1LSB max error. For these grades, an analog value which falls within a given code width will result in either the correct code for that region or either adjacent one.

Note that the linearity error is not user-adjustable.

DIFFERENTIAL LINEARITY ERROR (NO MISSING CODES)
A specification which guarantees no missing codes requires that every code combination appear in a monotonic increasing sequence as the analog input level is increased. Thus every code must have a finite width. For the AD574AK, L, T, and U grades, which guarantee no missing codes to 12-bit resolution, all 4096 codes must be present over the entire operating temperature ranges. The AD574AJ and S grades guarantee no missing codes to 11-bit resolution over temperature; this means that all code combinations of the upper 11 bits must be present; in practice very few of the 12-bit codes are missing.

UNIPOLAR OFFSET
The first transition should occur at a level 1/2LSB above analog common. Unipolar offset is defined as the deviation of the actual transition from that point. This offset can be adjusted as discussed on the following two pages. The unipolar offset temperature coefficient specifies the maximum change of the transition point over temperature, with or without external adjustment.

BIPOLAR OFFSET
In the bipolar mode the major carry transition (0111 1111 1111 to 1000 0000 0000) should occur for an analog value 1/2LSB below analog common. The bipolar offset error and temperature coefficient specify the initial deviation and maximum change in the error over temperature.

QUANTIZATION UNCERTAINTY
Analog-to-digital converters exhibit an inherent quantization uncertainty of ± 1/2LSB. This uncertainty is a fundamental characteristic of the quantization process and cannot be reduced for a converter of given resolution.

LEFT-JUSTIFIED DATA
The data format used in the AD574A is left-justified. This means that the data represents the analog input as a fraction of full-scale, ranging from 0 to $\frac{4095}{4096}$. This implies a binary point to the left of the MSB.

FULL-SCALE CALIBRATION ERROR
The last transition (from 1111 1111 1110 to 1111 1111 1111) should occur for an analog value 1 1/2LSB below the nominal full scale (9.9963 volts for 10.000 volts full scale). The full-scale calibration error is the deviation of the actual level at the last transition from the ideal level. This error, which is typically 0.05 to 0.1% of full scale, can be trimmed out as shown in Figures 3 and 4.

TEMPERATURE COEFFICIENTS
The temperature coefficients for full-scale calibration, unipolar offset, and bipolar offset specify the maximum change from the initial (25°C) value to the value at T_{min} or T_{max}.

POWER SUPPLY REJECTION
The standard specifications for the AD574A assume use of +5.00 and ± 15.00 or ± 12.00V supplies. The only effect of power supply error on the performance of the device will be a small change in the full-scale calibration. This will result in a linear change in all lower-order codes. The specifications show the maximum full-scale change from the initial value with the supplies at the various limits.

CODE WIDTH
A fundamental quantity for A/D converter specifications is the code width. This is defined as the range of analog input values for which a given digital output code will occur. The nominal value of a code width is equivalent to 1 least significant bit (LSB) of the full-scale range or 2.44mV out of 10 volts for a 12-bit ADC.

CIRCUIT OPERATION

The AD574A is a complete 12-bit A/D converter which requires no external components to provide the complete successive-approximation analog-to-digital conversion function. A block diagram of the AD574A is shown in Figure 1.

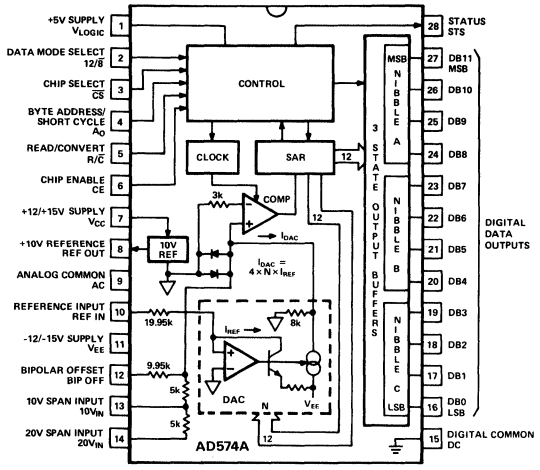

Figure 1. Block Diagram of AD574A 12-Bit A-to-D Converter

When the control section is commanded to initiate a conversion (as described later), it enables the clock and resets the successive-approximation register (SAR) to all zeros. Once a conversion cycle has begun, it cannot be stopped or re-started and data is not available from the output buffers. The SAR, timed by the clock, will sequence through the conversion cycle and return an end-of-convert flag to the control section. The control section will then disable the clock, bring the output status flag low, and enable control functions to allow data read functions by external command.

During the conversion cycle, the internal 12-bit current output DAC is sequenced by the SAR from the most significant bit (MSB) to least significant bit (LSB) to provide an output current which accurately balances the input signal current through the 5kΩ (or 10kΩ) input resistor. The comparator determines whether the addition of each successively-weighted bit current causes the DAC current sum to be greater or less than the input current; if the sum is less, the bit is left on; if more, the bit is turned off. After testing all the bits, the SAR contains a 12-bit binary code which accurately represents the input signal to within ±1/2LSB.

The temperature-compensated buried zener reference provides the primary voltage reference to the DAC and guarantees excellent stability with both time and temperature. The reference is trimmed to 10.00 volts ±0.2%; it can supply up to 1.5mA to an external load in addition to the requirements of the reference input resistor (0.5mA) and bipolar offset resistor (1mA) when the AD574A is powered from ±15V supplies. If the AD574A is used with ±12V supplies, or if external current must be supplied over the full temperature range, an external buffer amplifier is recommended. Any external load on the AD574A reference must remain constant during conversion. The thin-film application resistors are trimmed to match the full-scale output current of the DAC. There are two 5kΩ input scaling resistors to allow either a 10 volt or 20 volt span. The 10kΩ bipolar offset resistor is grounded for unipolar operation and connected to the 10 volt reference for bipolar operation.

DRIVING THE AD574 ANALOG INPUT

The internal circuitry of the AD574 dictates that its analog input be driven by a low source impedance. Voltage changes at the current summing node of the internal comparator result in abrupt modulations of the current at the analog input. For accurate 12-bit conversions the driving source must be capable of holding a constant output voltage under these dynamically changing load conditions.

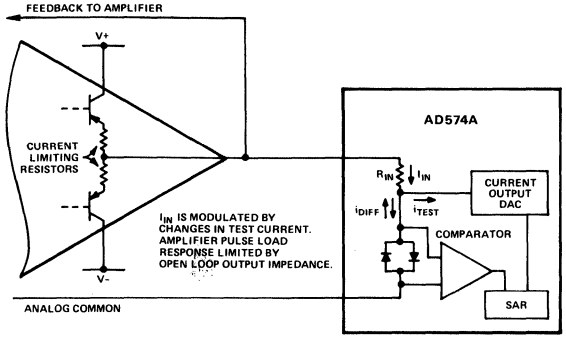

Figure 2. Op Amp – AD574A Interface

The output impedance of an op amp has an open-loop value which, in a closed loop, is divided by the loop gain available at the frequency of interest. The amplifier should have acceptable loop gain at 500kHz for use with the AD574A. To check whether the output properties of a signal source are suitable, monitor the AD574's input with an oscilloscope while a conversion is in progress. Each of the 12 disturbances should subside in 1μs or less.

For applications involving the use of a sample-and-hold amplifier, the AD585 is recommended. The AD711 or AD544 op amps are recommended for dc applications.

SAMPLE-AND-HOLD AMPLIFIERS

Although the conversion time of the AD574A is a maximum of 35μs, to achieve accurate 12-bit conversions of frequencies greater than a few Hz requires the use of a sample-and-hold amplifier (SHA). If the voltage of the analog input signal driving the AD574A changes by more than 1/2LSB over the time interval needed to make a conversion, then the input requires a SHA.

The AD585 is a high-linearity SHA capable of directly driving the analog input of the AD574A. The AD585's fast acquisition time, low aperture and low aperture jitter are ideally suited for high-speed data acquisition systems. Consider the AD574A converter with a 35μs conversion time and an input signal of 10V p-p: the maximum frequency which may be applied to achieve rated accuracy is 1.5Hz. However, with the addition of an AD585, as shown in Figure 3, the maximum frequency increases to 26kHz.

The AD585's low output impedance, fast-loop response, and low droop maintain 12-bits of accuracy under the changing load conditions that occur during a conversion, making it suitable for use in high-accuracy conversion systems. Many other SHAs cannot achieve 12-bits of accuracy and can thus compromise a system. The AD585 is recommended for AD574A applications requiring a sample and hold.

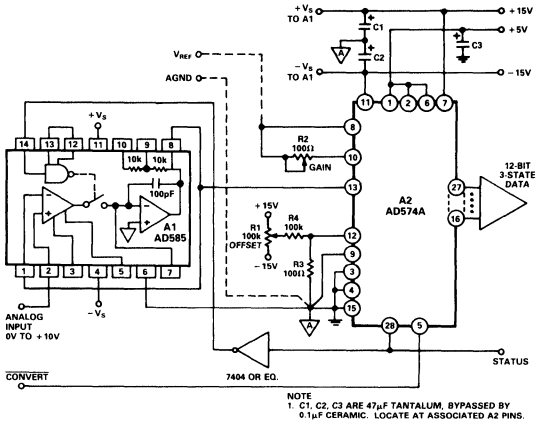

Figure 3. AD574A with AD585 Sample and Hold

SUPPLY DECOUPLING AND LAYOUT CONSIDERATIONS

It is critically important that the AD574A power supplies be filtered, well regulated, and free from high-frequency noise. Use of noisy supplies will cause unstable output codes. Switching power supplies are not recommended for circuits attempting to achieve 12-bit accuracy unless great care is used in filtering any switching spikes present in the output. Remember that a few millivolts of noise represents several counts of error in a 12-bit ADC.

Decoupling capacitors should be used on all power supply pins; the +5V supply decoupling capacitor should be connected directly from pin 1 to pin 15 (digital common) and the $+V_{CC}$ and $-V_{EE}$ pins should be decoupled directly to analog common (pin 9). A suitable decoupling capacitor is a 4.7μF tantalum type in parallel with a 0.1μF disc ceramic type.

Circuit layout should attempt to locate the AD574A, associated analog input circuitry, and interconnections as far as possible from logic circuitry. For this reason, the use of wire-wrap circuit construction is not recommended. Careful printed-circuit construction is preferred.

GROUNDING CONSIDERATIONS

The analog common at pin 9 is the ground reference point for the internal reference and is thus the "high quality" ground for the AD574A; it should be connected directly to the analog reference point of the system. In order to achieve all of the high-accuracy performance available from the AD574A in an environment of high digital noise content, the analog and digital commons should be connected together at the package. In some situations, the digital common at pin 15 can be connected to the most convenient ground reference point; analog power return is preferred.

UNIPOLAR RANGE CONNECTIONS FOR THE AD574A

The AD574A contains all the active components required to perform a complete 12-bit A/D conversion. Thus, for most situations, all that is necessary is connection of the power supplies (+5, +12/+15 and −12/−15 volts), the analog input, and the conversion initiation command, as discussed on the next page. Analog input connections and calibration are easily accomplished; the unipolar operating mode is shown in Figure 4.

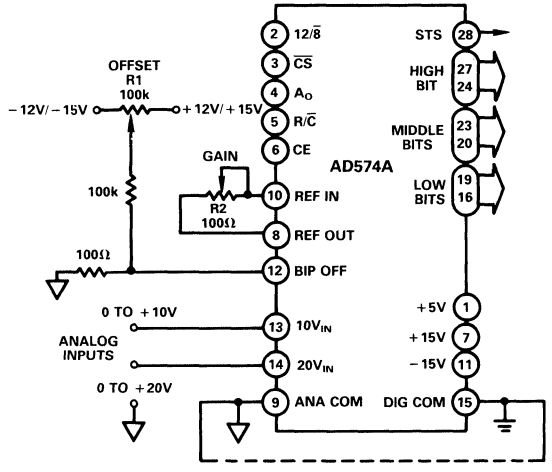

Figure 4. Unipolar Input Connections

All of the thin-film application resistors of the AD574A are trimmed for absolute calibration. Therefore, in many applications, no calibration trimming will be required. The absolute accuracy for each grade is given in the specification tables. For example, if no trims are used, the AD574AK guarantees ±1LSB max zero offset error and ±0.25% (10LSB) max full-scale error. (Typical full-scale error is ±2LSB.) If the offset trim is not required, pin 12 can be connected directly to pin 9; the two resistors and trimmer for pin 12 are then not needed. If the full-scale trim is not needed, a 50Ω ±1% metal film resistor should be connected between pin 8 and pin 10.

The analog input is connected between pin 13 and pin 9 for a 0 to +10V input range, between 14 and pin 9 for a 0 to +20V input range. The AD574A easily accommodates an input signal beyond the supplies. For the 10 volt span input, the LSB has a nominal value of 2.44mV; for the 20 volt span, 4.88mV. If a 10.24V range is desired (nominal 2.5mV/bit), the gain trimmer (R2) should be replaced by a 50Ω resistor, and a 200Ω trimmer inserted in series with the analog input to pin 13 for a full-scale range of 20.48V (5mV/bit), use a 500Ω trimmer into pin 14. The gain trim described below is now done with these trimmers. The nominal input impedance into pin 13 is 5kΩ, and 10kΩ into pin 14.

UNIPOLAR CALIBRATION

The AD574A is intended to have a nominal 1/2LSB offset so that the exact analog input for a given code will be in the middle of that code (halfway between the transitions to the codes above and below it). Thus, the first transition (from 0000 0000 0000 to 0000 0000 0001) will occur for an input level of + 1/2LSB (1.22mV for 10V range).

If pin 12 is connected to pin 9, the unit will behave in this manner, within specifications. If the offset trim (R1) is used, it should be trimmed as above, although a different offset can be set for a particular system requirement. This circuit will give approximately ± 15mV of offset trim range.

The full-scale trim is done by applying a signal 1 1/2LSB below the nominal full scale (9.9963 for a 10V range). Trim R2 to give the last transition (1111 1111 1110 to 1111 1111 1111).

BIPOLAR OPERATION

The connections for bipolar ranges are shown in Figure 5. Again, as for the unipolar ranges, if the offset and gain specifications are sufficient, one or both of the trimmers shown can be replaced by a 50Ω ± 1% fixed resistor. Bipolar calibration is similar to unipolar calibration. First, a signal ½LSB above negative full scale (−4.9988V for the ±5V range) is applied and R1 is trimmed to give the first transition (0000 0000 0000 to 0000 0000 0001). Then a signal 1½LSB below positive full scale (+4.9963V for the ±5V range) is applied and R2 trimmed to give the last transition (1111 1111 1110 to 1111 1111 1111).

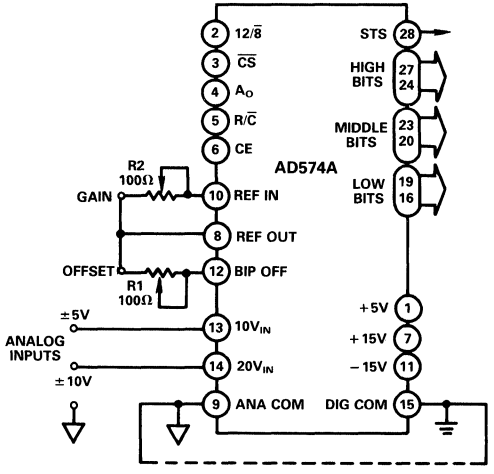

Figure 5. Bipolar Input Connections

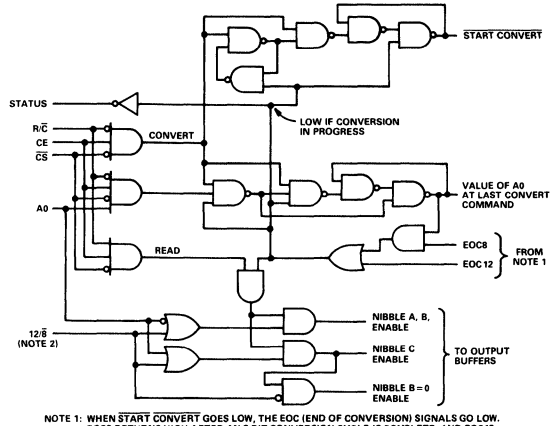
CONTROL LOGIC

The AD574A contains on-chip logic to provide conversion initiation and data read operations from signals commonly available in microprocessor systems. Figure 6 shows the internal logic circuitry of the AD574A.

The control signals CE, $\overline{CS}$, and R/$\overline{C}$ control the operation of the converter. The state of R/$\overline{C}$ when CE and $\overline{CS}$ are both asserted determines whether a data read (R/$\overline{C}$ = 1) or a convert (R/$\overline{C}$ = 0) is in progress. The register control inputs A_0 and 12/$\overline{8}$ control conversion length and data format. The A_0 line is usually tied to the least significant bit of the address bus. If a conversion is started with A_0 low, a full 12-bit conversion cycle is initiated. If



NOTE 1: WHEN $\overline{START\ CONVERT}$ GOES LOW, THE EOC (END OF CONVERSION) SIGNALS GO LOW. EOC8 RETURNS HIGH AFTER AN 8-BIT CONVERSION CYCLE IS COMPLETE, AND EOC12 RETURNS HIGH WHEN ALL 12 BITS HAVE BEEN CONVERTED. THE EOC SIGNALS PREVENT DATA FROM BEING READ DURING CONVERSIONS.

NOTE 2: 12/$\overline{8}$ IS NOT A TTL-COMPATIBLE INPUT AND SHOULD ALWAYS BE WIRED DIRECTLY TO V_{LOGIC} OR DIGITAL COMMON.

Figure 6. AD574A Control Logic

A_0 is high during a convert start, a shorter 8-bit conversion cycle results. During data read operations, A_0 determines whether the three-state buffers containing the 8 MSBs of the conversion result (A_0 = 0) or the 4 LSBs (A_0 = 1) are enabled. The 12/$\overline{8}$ pin determines whether the output data is to be organized as two 8-bit words (12/$\overline{8}$ tied to DIGITAL COMMON) or a single 12-bit word (12/$\overline{8}$ tied to V_{LOGIC}). The 12/$\overline{8}$ pin is not TTL-compatible and must be hard-wired to either V_{LOGIC} or DIGITAL COMMON. In the 8-bit mode, the byte addressed when A_0 is high contains the 4 LSBs from the conversion followed by four trailing zeroes. This organization allows the data lines to be overlapped for direct interface to 8-bit buses without the need for external three-state buffers.

It is not recommended that A_0 change state during a data read operation. Asymmetrical enable and disable times of the three-state buffers could cause internal bus contention resulting in potential damage to the AD574A.

An output signal, STS, indicates the status of the converter. STS goes high at the beginning of a conversion and returns low when the conversion cycle is complete.

CE	$\overline{CS}$	R/$\overline{C}$	12/$\overline{8}$	A_0	Operation
0	X	X	X	X	None
X	1	X	X	X	None
1	0	0	X	0	Initiate 12-Bit Conversion
1	0	0	X	1	Initiate 8-Bit Conversion
1	0	1	Pin 1	X	Enable 12-Bit Parallel Output
1	0	1	Pin 15	0	Enable 8 Most Significant Bits
1	0	1	Pin 15	1	Enable 4LSBs + 4 Trailing Zeroes

Table I. AD574A Truth Table

TIMING

The AD574A is easily interfaced to a wide variety of microprocessors and other digital systems. The following discussion of the timing requirements of the AD574A control signals should provide the system designer with useful insight into the operation of the device.

CONVERT START TIMING – FULL CONTROL MODE

Symbol	Parameter	Min	Typ	Max	Units
t_{DSC}	STS Delay from CE			400	ns
t_{HEC}	CE Pulse Width	300			ns
t_{SSC}	$\overline{CS}$ to CE Setup	300			ns
t_{HSC}	$\overline{CS}$ Low During CE High	200			ns
t_{SRC}	R/$\overline{C}$ to CE Setup	250			ns
t_{HRC}	R/$\overline{C}$ Low During CE High	200			ns
t_{SAC}	A_0 to CE Setup	0			ns
t_{HAC}	A_0 Valid During CE High	300			ns
t_C	Conversion Time				
	8-Bit Cycle	10		24	µs
	12-Bit Cycle	15		35	µs

Figure 7 shows a complete timing diagram for the AD574A convert start operation. R/$\overline{C}$ should be low before both CE and $\overline{CS}$ are asserted; if R/$\overline{C}$ is high, a read operation will momentarily occur, possibly resulting in system bus contention. Either CE or $\overline{CS}$ may be used to initiate a conversion; however, use of CE is recommended since it includes one less propagation delay than $\overline{CS}$ and is the faster input. In Figure 7, CE is used to initiate the conversion.

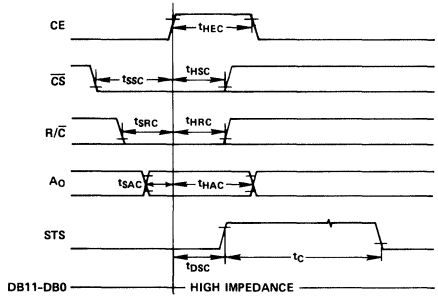


Figure 7. Convert Start Timing

Once a conversion is started and the STS line goes high, convert start commands will be ignored until the conversion cycle is complete. The output data buffers cannot be enabled during conversion.

Figure 8 shows the timing for data read operations. During data read operations, access time is measured from the point where CE and R/$\overline{C}$ both are high (assuming $\overline{CS}$ is already low). If $\overline{CS}$ is used to enable the device, access time is extended by 100ns.

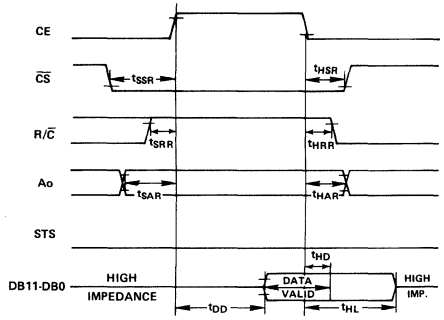

Figure 8. Read Cycle Timing

In the 8-bit bus interface mode (12/$\overline{8}$ input wired to DIGITAL COMMON), the address bit, A_0, must be stable at least 150ns prior to $\overline{CE}$ going high and must remain stable during the entire read cycle. If A_0 is allowed to change, damage to the AD574A output buffers may result.

READ TIMING – FULL CONTROL MODE

Symbol	Parameter	Min	Typ	Max	Units
t_{DD}[1]	Access Time (from CE)			200	ns
t_{HD}	Data Valid after CE Low	25			ns
t_{HL}[2]	Output Float Delay			100	ns
t_{SSR}	$\overline{CS}$ to CE Setup	150			ns
t_{SRR}	R/$\overline{C}$ to CE Setup	0			ns
t_{SAR}	A_0 to CE Setup	150			ns
t_{HSR}	$\overline{CS}$ Valid After CE Low	50			ns
t_{HRR}	R/$\overline{C}$ High After CE Low	0			ns
t_{HAR}	A_0 Valid After CE low	50			ns

[1] t_{DD} is measured with the load circuit of Figure 9 and defined as the time required for an output to cross 0.4V or 2.4V.
[2] t_{HL} is defined as the time required for the data lines to change 0.5V when loaded with the circuit of Figure 10.

Figure 10. Load Circuit for Output Float Delay Test

"STAND-ALONE" OPERATION

The AD574A can be used in a "stand-alone" mode, which is useful in systems with dedicated input ports available and thus not requiring full bus interface capability.

In this mode, CE and 12/$\overline{8}$ are wired high, $\overline{CS}$ and A_0 are wired low, and conversion is controlled by R/$\overline{C}$. The three-state buffers are enabled when R/$\overline{C}$ is high and a conversion starts when R/$\overline{C}$ goes low. This allows two possible control signals – a high pulse or a low pulse. Operation with a low pulse is shown in Figure 11. In this case, the outputs are forced into the high-impedance state in response to the falling edge of R/$\overline{C}$ and return

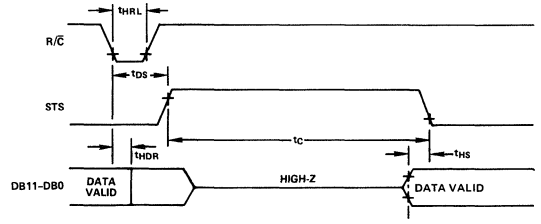

Figure 11. Low Pulse for R/$\overline{C}$ – Outputs Enabled After Conversion

to valid logic levels after the conversion cycle is completed. The STS line goes high 600ns after R/$\overline{C}$ goes low and returns low 300ns after data is valid.

If conversion is initiated by a high pulse as shown in Figure 12, the data lines are enabled during the time when R/$\overline{C}$ is high. The falling edge of R/$\overline{C}$ starts the next conversion, and the data lines return to three-state (and remain three-state) until the next high pulse of R/$\overline{C}$.

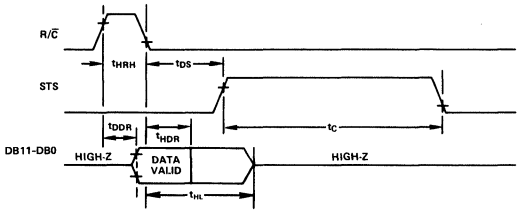

Figure 12. High Pulse for R/$\overline{C}$ – Outputs Enabled While R/$\overline{C}$ High, Otherwise High-Z

STAND-ALONE MODE TIMING

Symbol	Parameter	Min	Typ	Max	Units
t_{HRL}	Low R/$\overline{C}$ Pulse Width	250			ns
t_{DS}	STS Delay from R/$\overline{C}$			600	ns
t_{HDR}	Data Valid After R/$\overline{C}$ Low	25			ns
t_{HL}	Output Float Delay			150	ns
t_{HS}	STS Delay After Data Valid	300		1000	ns
t_{HRH}	High R/$\overline{C}$ Pulse Width	300			ns
t_{DDR}	Data Access Time			250	ns

Usually the low pulse for R/$\overline{C}$ stand-alone mode will be used. Figure 13 illustrates a typical stand-alone confirguration for 8086 type processors. The addition of the 74F/S374 latches improves bus access/release times and helps minimize digital feedthrough to the analog portion of the converter.

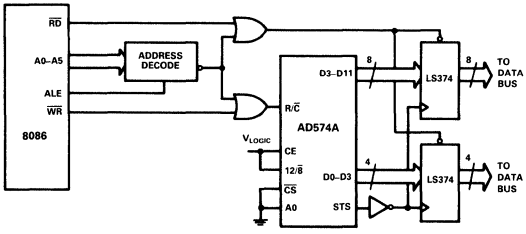

Figure 13. 8086 Stand-Alone Configuration

INTERFACING THE AD574A TO MICROPROCESSORS

The control logic of the AD574A makes direct connection to most microprocessor system buses possible. While it is impossible to describe the details of the interface connections for every microprocessor type, several representative examples will be described here.

GENERAL A/D CONVERTER INTERFACE CONSIDERATIONS

A typical A/D converter interface routine involves several operations. First, a write to the ADC address initiates a conversion. The processor must then wait for the conversion cycle to complete, since most ADCs take longer than one instruction cycle to complete a conversion. Valid data can, of course, only be read after the conversion is complete. The AD574A provides an output signal (STS) which indicates when a conversion is in progress. This signal can be polled by the processor by reading it through an external three-state buffer (or other input port). The STS signal can also be used to generate an interrupt upon completion of conversion, if the system timing requirements are critical (bear in mind that the maximum conversion time of the AD574A is only 35 microseconds) and the processor has other tasks to perform during the ADC conversion cycle. Another possible time-out method is to assume that the ADC will take 35 microseconds to convert, and insert a sufficient number of "do-nothing" instructions to ensure that 35 microseconds of processor time is consumed.

Once it is established that the conversion is finished, the data can be read. In the case of an ADC of 8-bit resolution (or less), a single data read operation is sufficient. In the case of converters with more data bits than are available on the bus, a choice of data formats is required, and multiple read operations are needed. The AD574A includes internal logic to permit direct interface to 8-bit or 16-bit data buses, selected by connection of the 12/$\overline{8}$ input. In 16-bit bus applications (12/$\overline{8}$ high) the data lines (DB11 through DB0) may be connected to either the 12 most significant or 12 least significant bits of the data bus. The remaining four bits should be masked in software. The interface to an 8-bit data bus (12/$\overline{8}$ low) is done in a left-justified format. The even address (A0 low) contains the 8MSBs (DB11 through DB4). The odd address (A0 high) contains the 4LSBs (DB3 through DB0) in the upper half of the byte, followed by four trailing zeroes, thus eliminating bit masking instructions.

It is not possible to rearrange the AD574A data lines for right-justified 8-bit bus interface.

	D7							D0
XXX0 (EVEN ADDR):	DB11 (MSB)	DB10	DB9	DB8	DB7	DB6	DB5	DB4

SPECIFIC PROCESSOR INTERFACE EXAMPLES

Z-80 System Interface

The AD574A may be interfaced to the Z-80 processor in an I/O or memory mapped configuration. Figure 15 illustrates an I/O mapped configuration. The Z-80 uses address lines A0-A7 to decode the I/O port address.

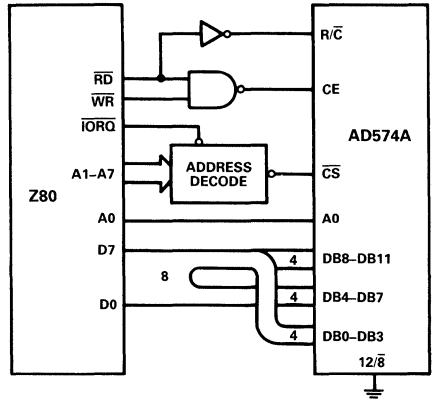

Figure 15. Z80–AD574A Interface

An interesting feature of the Z-80 is that during I/O operations a single wait state is automatically inserted, allowing the AD574A to be used with Z-80 processors having clock speeds up to 4MHz. For applications faster than 4MHz use the wait state generator in Figure 16. In a memory mapped configuration the AD574A may be interfaced to Z-80 processors with clock speeds of up to 2.5MHz.

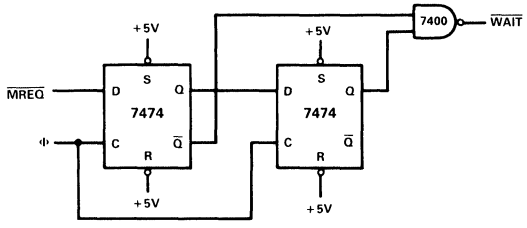

Figure 16. Wait State Generator

IBM PC Interface

The AD574A appears in Figure 17 interfaced to the 4MHz 8088 processor of an IBM PC. Since the device resides in I/O space, its address is decoded from only the lower ten address lines and must be gated with AEN (active low) to mask out internal DMA cycles which use the same I/O address space. This active low signal is applied to $\overline{CS}$. $\overline{IOR}$ and $\overline{IOW}$ are used to initiate the conversion and read, and are gated together to drive the chip enable, CE. Because the data bus width is limited to 8 bits, the AD574A data resides in two adjacent addresses selected by A0.

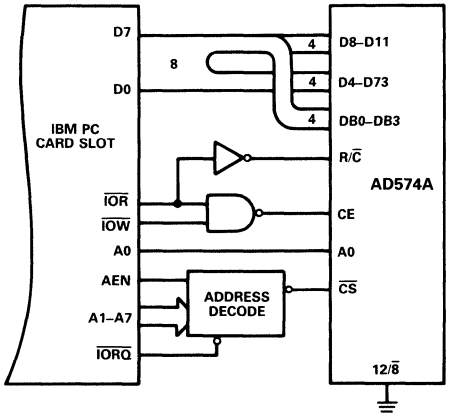

Figure 17. IBM PC – AD574A Interface

Note: Due to the large number of of options that may be installed in the PC, the I/O bus loading should be limited to one Schottky TTL load. Therefore, a buffer/driver should be used when interfacing more than two AD574As to the I/O bus.

8086 Interface

The data mode select pin (12/$\overline{8}$) of the AD574A should be connected to V_{LOGIC} to provide a 12-bit data output. To prevent possible bus contention, a demultiplexed and buffered address/data bus is recommended. In the cases where the 8-bit short conversion cycle is not used, A0 should be tied to digital common. Figure 18 shows a typical 8086 configuration.

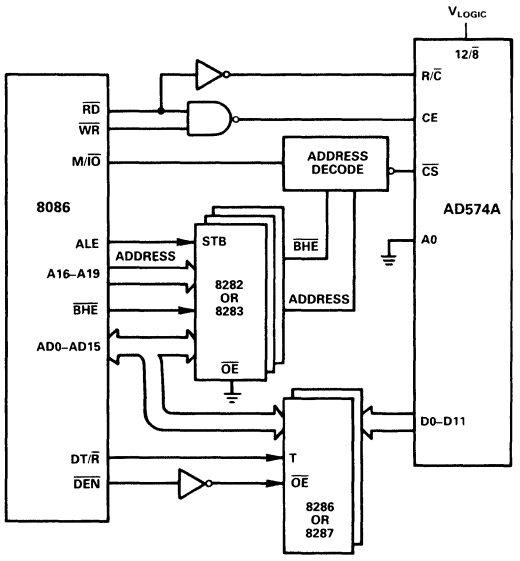

Figure 18. 8086 – AD574A with Buffered Bus Interface

For clock speeds greater than 4MHz wait state insertion similar to Figure 16 is recommended to ensure sufficient CE and R/$\overline{C}$ pulse duration.

The AD574A can also be interfaced in a stand-alone mode (see Figure 13). A low-going pulse derived from the 8086's $\overline{WR}$ signal logically ORed with a low address decode starts the conversion. At the end of the conversion, STS clocks the data into the three-state latches.

68000 Interface

The AD574, when configured in the stand-alone mode, will easily interface to the 4MHz version of the 68000 microprocessor. The 68000 R/$\overline{W}$ signal combined with a low address decode initiates conversion. The $\overline{UDS}$ or $\overline{LDS}$ signal, with the decoded address, generates the $\overline{DTACK}$ input to the processor, latching in the AD574A's data. Figure 19 illustrates this configuration.

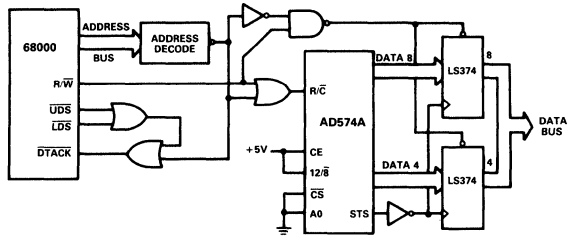

Figure 19. 68000 – AD574A Interface

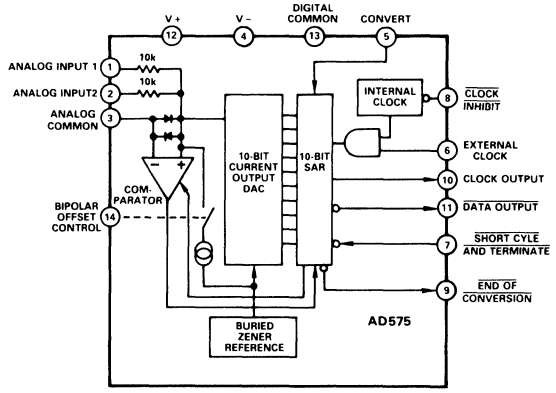
Complete 10-Bit A/D Converter with Serial Output

AD575*

FEATURES

Complete Serial Output 10-Bit A/D Converter with Reference, Clock and Comparator
30μs Conversion
No Missing Codes Over Temperature
Operates on +5V and −12V to −15V Supplies
Low Cost Monolithic Construction
Internal or External Clock
Triggered or Continuous Conversions
Short Cycle Capability

AD575 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD575 is a complete 10-bit successive-approximation analog-to-digital converter consisting of a DAC, voltage reference, clock, comparator, successive approximation register (SAR) and serial interface on a single chip. No additional components are required to perform a full-accuracy 10-bit conversion in 30μs.

The AD575 incorporates the most advanced integrated circuit design and processing technology available. The successive approximation function is implemented with I^2L (integrated injection logic). Laser trimming of the SiCr thin-film resistor ladder network at the wafer stage insures high accuracy, which is maintained with a temperature-compensated sub-surface zener reference.

Operating on supplies of +5V and −12V to −15V, the AD575 will accept full scale analog inputs of 0V to +10V, 0V to +20V, −5V to +5V or −10V to +10V. The rising edge of a positive pulse on the CONVERT line initiates the conversion cycle. Eleven pulses will appear at the CLOCK OUTPUT pin with data valid on the falling edges of the clock waveform. The data is presented serially beginning with the MSB which is valid on the falling edge of the second clock pulse. The part may be programmed to perform 8-bit conversions or short cycled to 2-, 4-, 6- or 8-bit word lengths. $\overline{EOC}$ indicates that conversion is complete. The AD575 may be synchronized to an external clock if desired.

The AD575 is available in two versions for the 0 to +70°C temperature range, the AD575J and AD575K. The AD575S guarantees ±1LSB relative accuracy and no missing codes from −55°C to +125°C.

***Protected by U.S. Patent Nos. 3,940,760; 4,400,689; and 4,400,690.**

Two package types are available. All versions are offered in a 14-pin hermetically-sealed ceramic DIP. The AD575J and AD575K are also available in a 14-pin plastic DIP.

PRODUCT HIGHLIGHTS

1. The AD575 is a complete 10-bit A/D converter. No external active components or control signals are required to perform a conversion.
2. The serial output of the AD575 allows a wide range of microprocessor interfacing and data transmission possibilities.
3. The device offers true 10-bit relative accuracy and exhibits no missing codes over its entire operating temperature range.
4. The AD575 adapts to unipolar or bipolar analog inputs by grounding or opening a single pin.
5. Performance is guaranteed with +5V and −12V or −15V supplies.
6. The AD575 can be synchronized to an external clock.
7. Conversions can be initiated externally or internally.
8. The AD575 can be short-cycled to 8 bits by pin programming.
9. The Short Cycle and Terminate feature allows the user to program conversions of 2, 4, 6 or 8 bits.

NOTES

[1]Gain Error is specified with a 15Ω resistor in series with the 10V input (Pins 1 and 2 tied together) or a 30Ω resistor in series with the 20V input (Pin 1 with Pin 2 tied to analog common). Gain Error is guaranteed trimmable to zero (see text).

[2]The gain drift is calculated from gain measurements at the extremes of the temperature range under consideration.

[3]Relative Accuracy, also referred to as Integral Linearity, is defined as the deviation of the code transition points from the ideal transfer points on a straight line from zero to full-scale. It is also a measure of the error which remains when offset and full scale errors are trimmed to zero in an application.

[4]Measured at full scale.

[5]These specifications apply to the CONV, XCL, and $\overline{SCAT}$ inputs. $\overline{CLI}$ is hardwired to DGND or $+V_S$ in most applications. Typically I_{INH} = +350μA and I_{INL} = 120μA for the $\overline{CLI}$ input.

Specifications shown in boldface are tested on all production units at final electrical test. Results from those tests are used to calculate outgoing quality levels. All min and max specifications are guaranteed, although only those shown in boldface are tested on all production units.

Specifications subject to change without notice.

FUNCTIONAL DESCRIPTION

A block diagram of the AD575 is shown in Figure 1. A conversion is initiated by a positive pulse on the CONVERT line. $\overline{EOC}$ goes high within 150ns indicating that a conversion has started. The internal 10-bit current-output DAC is sequenced by the successive approximation register (SAR) from most significant bit to least significant bit to provide an output current which accurately balances the input signal current through the 10kΩ input resistor(s). The comparator determines whether the addition of each successively-weighted bit current causes the DAC current to be higher or lower than the input current. If the sum is less the bit is left on ($\overline{DO}$ set low). If the sum is more, the bit is turned off ($\overline{DO}$ set high). The result of each bit decision is passed to $\overline{DO}$ on the rising edge of CO.

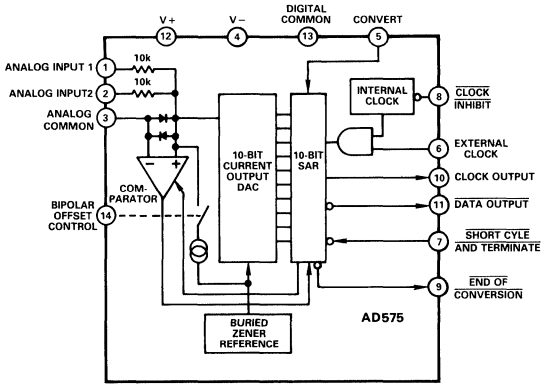

Figure 1. AD575 Functional Block Diagram

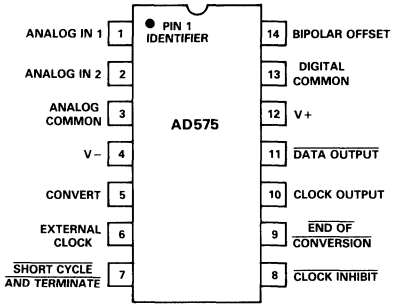

Figure 2. AD575 Pin Connections

After all bits have been tested, the DAC output current will match the input signal current to within 0.05% (1/2LSB). $\overline{EOC}$ returns low after the final bit decision to indicate that the AD575 has been reset and is ready to perform a new conversion. The output data stream can be synchronized to an external clock using the XCL input and short cycled to any desired word length using the $\overline{SCAT}$ line.

The AD575 contains all the active components required to perform a complete A/D conversion. Thus, for many applications, all that is necessary is to connect the power supplies (+5V and −12V or −15V), and the analog input. The pinout is shown in Figure 2.

ANALOG INPUT CONNECTIONS

The AD575 can be configured for unipolar or bipolar operation on 10V span or 20V span input signals. The appropriate input range is selected by connecting pins 2 and 14 according to the table of Figure 3.

The AD575's low offset and gain errors (shown in the Specifications) are adequate for most applications. For these cases, a fixed gain resistor (R2 in Figure 3) is the only external component, in addition to any power supply decoupling that may be required. Pins 3 and 13 should be connected directly together.

Figure 3 shows a trimming circuit that can be used to adjust the offset to zero, using the appropriate value of the R1 potentiometer as shown in the table. If gain trim is required, R2 should also be replaced by the appropriate potentiometer as shown in the table.

ANALOG INPUT RANGE	CONNECTIONS PIN 2	PIN 14	COMPONENTS R1 (OFFSET)	R2 (GAIN)
0V TO +10V	PIN 1	PIN 13	10Ω	15Ω FIXED OR 50Ω POT
0V TO +20V	PIN 3	PIN 13	20Ω	30Ω FIXED OR 100Ω POT
−5V TO +5V	PIN 1	OPEN	10Ω	15Ω FIXED OR 50Ω POT
−10V TO +10V	PIN 3	OPEN	20Ω	30Ω FIXED OR 100Ω POT

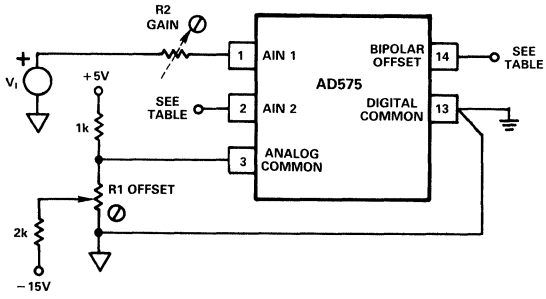

Figure 3. AD575 Input Circuit Showing Offset and Gain Adjustment

UNIPOLAR MODE OPERATION

In unipolar mode, the nominal location of the low side transition of the first code (1111111110) occurs at an input voltage of +1LSB (10mV for the 10V span, 20mV for the 20V span). The offset error of the AD575 can be trimmed out, if required, by applying an input voltage of +1LSB to the analog input and adjusting R1 until the low side transition of the first code occurs.

If the Gain Error needs to be trimmed, the gain resistor should be replaced with a potentiometer according to Figure 3. The nominal location of the low side transition of the full scale code (0000000000) in unipolar mode is full scale minus 1LSB (9.99V for 10V span, 19.98V for 20V span). Once the offset has been adjusted, the full scale range can be set by adjusting the gain potentiometer.

BIPOLAR CONNECTION

If the bipolar offset control (pin 14) is left open, the AD575 will accept bipolar input voltages with 0V as the nominal bipolar zero point. The input voltage corresponding to the low side transition of the mid-scale code (0111111111) is −1/2LSB (−5mV for 10V spans and −10mV for 20V spans). The nominal location of the code transitions are therefore offset by 1/2LSB as shown in Figure 4. This offset may be adjusted using the trim scheme shown in Figure 3 with a 1.2kΩ resistor in place of the 1kΩ resistor shown.

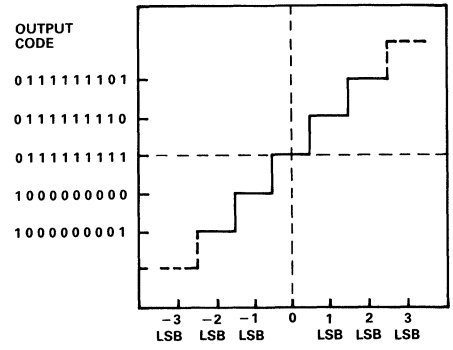

Figure 4. AD575 Transfer Characteristic (Bipolar Operation)

The gain error should be adjusted after any offset adjustment. An input voltage of full scale minus 1 1/2LSBs is applied (4.985V for −5V to +5V range, 9.971V for −10V to +10V range) and R2 is adjusted until the low-side transition of the full scale code (0000000000) occurs.

The bipolar offset control input is not directly TTL compatible, but a TTL interface for logic control can be constructed as shown in Figure 5.

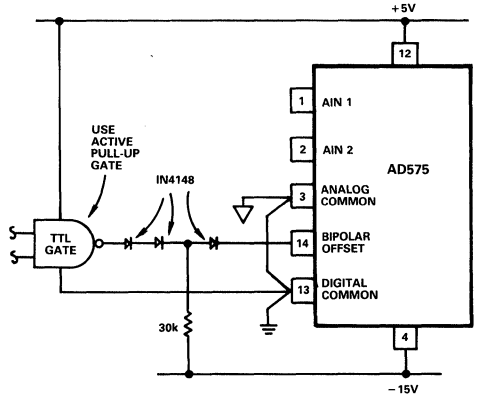

Figure 5. Bipolar Offset Controlled by Logic Gate

CONTROL AND TIMING OF THE AD575

The AD575 has a flexible control architecture which supports several operating modes. It can provide its own clock or it can be synchronized to an external clock. Conversions can be initiated externally, or the part can perform continuous conversions yielding a stream of output data. In addition, the AD575 can be short-cycled to any of several convenient data word lengths to tailor the output to the specific input requirements of the system. Figure 6 shows the control logic diagram of the AD575. The four inputs which control the operation of the AD575 are CONV (convert), $\overline{CLI}$ (clock inhibit), XCL (external clock), and $\overline{SCAT}$ (short cycle and terminate). Three outputs are provided: $\overline{DO}$ (Data Out), CO (Clock Out), and $\overline{EOC}$ (End of Conversion).

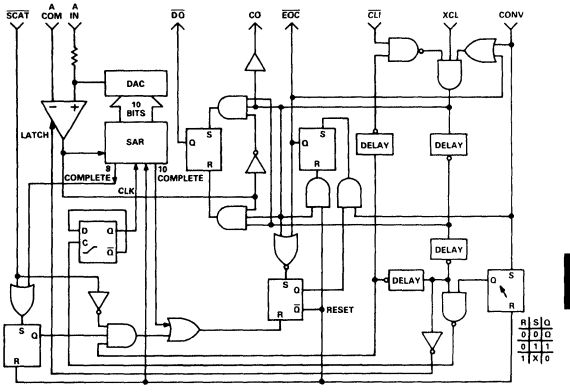

Figure 6. AD575 Control Logic Diagram

EXTERNALLY INITIATED CONVERSIONS

Figure 7 is the timing diagram which illustrates the operation of the AD575 with an externally applied convert signal. Conversions are initiated by a positive-going pulse applied to the CONV (convert) input. This pulse should be at least 250ns wide and should return low before $\overline{EOC}$ returns low to prevent the initiation of a second conversion. If the internal clock is used, the clock will start on the rising edge of the convert start pulse. If an external clock is used, the falling edge of the clock must occur no earlier than 900ns following the rising edge of the convert command.

INTERNAL CLOCK MODE

The AD575 can be configured for internal clock operation by tying $\overline{CLI}$ and XCL to +5V. CO (clock output) provides the necessary synchronizing information in this mode. Data is transferred to $\overline{DO}$ on the rising clock edge and is stable on the falling edge. The duty cycle of the CO waveform in this mode will be in the range of 30% to 70%.

EXTERNAL CLOCK MODE

When $\overline{CLI}$ is connected to digital common, an external clock can be applied to XCL. The external clock should have a maximum frequency of 450kHz with a minimum of 900ns in the high or low phase. Arbitrarily slow clocks may be used as long as these minimum high and low periods are observed. Conversion time will increase as clock frequency decreases. Each data bit will be stable within 150ns of the rising edge of the associated external clock pulse and will remain stable until the rising edge of the subsequent clock pulse. Data is guaranteed to be stable on the falling edge of the clock pulse.

The state of the $\overline{DO}$ output during the first clock period is undefined but it is stable until the rising edge of the second clock period. The MSB appears at $\overline{DO}$ during the second clock period. The subsequent data bits are then clocked out until the N^{th} bit or LSB is clocked out on the $(N+1)^{th}$ clock pulse. $\overline{EOC}$ returns low within 150ns of the rising edge of this final clock pulse. In internal clock mode, the output clock pulse associated with the LSB is shorter than the others but the LSB is guaranteed to be stable on the falling edge of this pulse. The LSB will remain stable until a new conversion is initiated. The value of N will be 10 unless the conversion has been short cycled (see "short cycle and terminate" text).

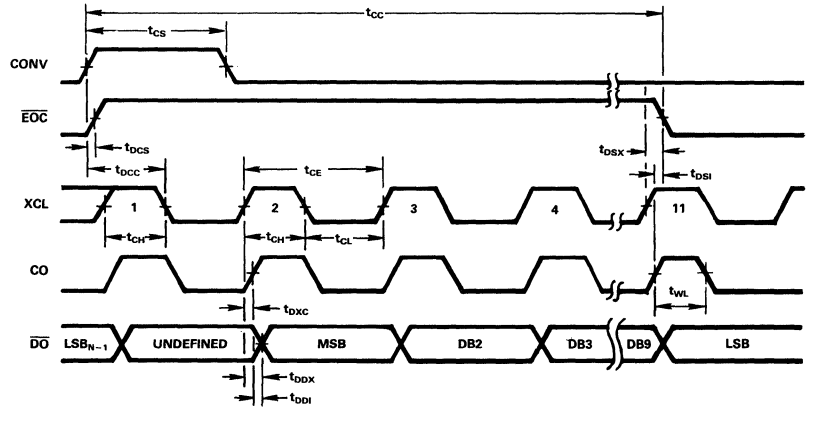

Figure 7. Externally Initiated Conversions

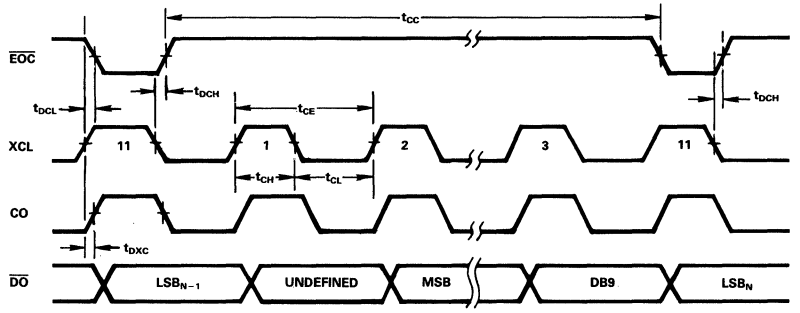

Figure 8. Continuous Conversion Mode (CONV. Held High)

CONTINUOUS CONVERSIONS

Figure 8 is the timing diagram associated with the continuous conversion mode of operation. If CONV is high when $\overline{EOC}$ goes low, another conversion will begin immediately. $\overline{EOC}$ will be set (high) following the falling edge of the $(N+1)^{st}$ CO pulse and conversion commences with the rising edge of the next CO pulse. The $(N+1)^{st}$ CO pulse is not shortened in this mode. If CONVERT is held high the AD575 will put out a continuous stream of conversions, punctuated by $\overline{EOC}$ which will mark the last clock pulse of a conversion. $\overline{EOC}$ will remain low until the falling edge of CO, the output clock, in this mode. Therefore, the rising edge of $\overline{EOC}$ may be used to signal that conversion is complete and that data is transferred. This sequence is useful for initiating parallel dumps from a serially loaded shift register.

SHORT CYCLE AND TERMINATE

For normal 10-bit operation, the Short Cycle and Terminate ($\overline{SCAT}$) line should be tied high. If 8-bit conversions are required, $\overline{SCAT}$ should be tied low. In this mode, $\overline{EOC}$ will go low after the rising edge of the ninth clock pulse to indicate that the eighth and final data bit is valid. This mode is useful when parallel loads to 8-bit data buses are desired since it avoids the complication of suppressing the 9th and 10th data bits.

Conversions of 2, 4, 6 or 8 bits can be performed by pulling $\overline{SCAT}$ low during the negative clock phase prior to the positive clock associated with the desired LSB. Figure 9 illustrates the timing associated with this mode of operation. For example, to terminate the conversion after six data bits, $\overline{SCAT}$ should be driven low during the negative clock phase following the sixth clock pulse. $\overline{EOC}$ will then go low following the rising edge of the seventh clock pulse to indicate that the sixth and final data bit is valid.

This terminate feature can also be used to program conversions of 1, 3, 5, 7 or 9 bits. However, the conversion immediately following a conversion of an odd number of data bits will be spurious. All subsequent conversions will be normal until the conversion following another odd data word length conversion.

The negative edge of the $\overline{SCAT}$ signal should always occur during the negative phase of a clock cycle and it should be held low for a minimum of 900ns. $\overline{SCAT}$ may be held low into the next conversion but it must be restored high at least one clock cycle prior to being used to terminate a conversion. If $\overline{SCAT}$ is not restored high prior to the eighth clock pulse, $\overline{EOC}$ will go low and an 8-bit short cycle will occur. Care should be taken not to pulse $\overline{SCAT}$ from high to low between conversions (when $\overline{EOC}$ is low). This would initiate a terminate sequence which will execute on the rising edge of the first clock pulse following the next Convert command.

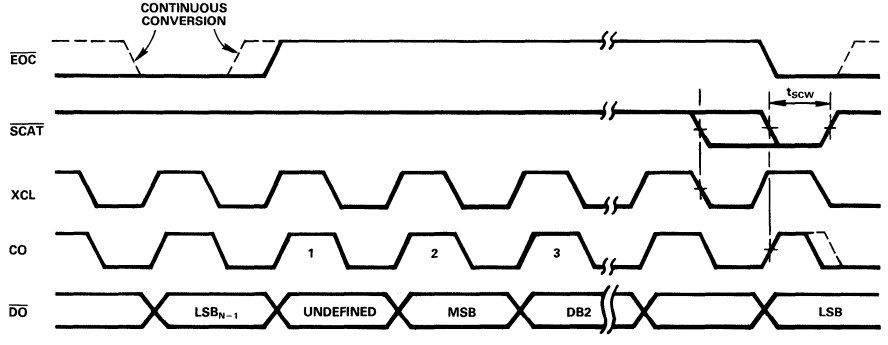

Figure 9. Short Cycle and Terminate Operation

Table I. AD575 Timing Specifications

SAMPLE-HOLD AMPLIFIER CONNECTION TO THE AD575

Many data acquisition systems for digitizing rapidly changing signals require a sample-hold amplifier (SHA) in front of the A/D converter. A SHA can be used to accurately define the exact point in time at which the signal is sampled. A SHA can also serve as a high input-impedance buffer for the AD575.

Figure 10 shows the AD575 connected to the AD585 monolithic SHA. In this configuration, the AD585 will acquire a 10V signal in less than 2μs and droop less than 1mV/ms using the on-chip hold capacitor.

$\overline{EOC}$ goes high after the conversion is initiated to indicate that a conversion is underway. In Figure 10 it is also used to put the AD585 into the hold mode while the AD575 begins its conversion cycle. (The AD585 output settles to final value well in advance of the first comparator decision within the AD575.) $\overline{EOC}$ goes low when the conversion is complete placing the AD585 back in the sample mode.

Configured as shown in Figure 10, the next conversion can be initiated after a 2μs delay to allow for signal acquisition by the AD585.

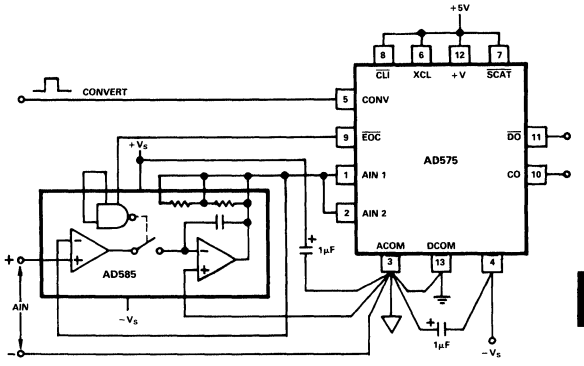

Figure 10. AD575 to AD585 Sample and Hold Interface

SUPPLY DECOUPLING AND LAYOUT

For proper operation, the AD575's power supplies should be free from high-frequency noise. The stability of the transfer function is especially sensitive to noise on the V− supply. Noise on the V+ supply can also propagate to the digital outputs.

If decoupling is required, tantalum capacitors are suggested. Best results will be obtained if the capacitors are connected directly to the appropriate pins of the AD575. Decoupling capacitors for V− should be connected between pin 4 and Analog Common (pin 3). Decoupling capacitors for V+ should be connected between pin 12 and Digital Common (pin 13).

Good circuit layout practice suggests that the AD575 and its associated analog input circuitry be kept separate from system logic circuitry to avoid unwanted interactions.

GROUNDING CONSIDERATIONS

The AD575 provides separate Analog and Digital Common connections. The circuit will operate properly with as much as ±200mV of common-mode voltage between the two commons. The absolute maximum voltage rating between the two commons is ±1V. A parallel pair of back-to-back protection diodes should be connected between the commons if they are not connected locally.

In normal operation, the Analog Common terminal may generate transient currents of up to 2mA during a conversion. In addition, a static current of about 2mA will flow into Analog Common in the unipolar mode after a conversion is complete. The Analog Common current will be modulated by the variations in input signal.

AD575 TO 8085 INTERFACE

The 8085 has both serial output (SOD) and serial input (SID) capability. A simple 3 hardware line interface can be constructed between the AD575 and 8085. These leads can be opto-coupled in order to establish galvanic isolation between the two devices as shown in Figure 11.

The software routine in Table II will read a complete 10-bit data word from the AD575 in 180μs (3MHz 8085). The software generates the clock for the AD575 in order to synchronize the data output with the 8085 serial read operation.

The DATA procedure loads appropriate constants into the 8085 registers and initiates the conversion. The CONV procedure assumes that the AD575 clock was in the high state when the CONVERT pulse was generated (upon completion, this sample routine leaves the SOD line in the appropriate state to insure this). A low clock pulse is generated, and the data bit is read into the MSB of the accumulator. The data bit is then shifted into the LSB of the temporary register (L), the clock is set high, and the procedure is repeated.

After the loop has executed three times, a logical AND is performed to set the first bit (the undefined bit) to zero, and the result is placed into the high byte (H) register. The loop counter is then reset, and the CONV procedure is executed 8 more times. Upon completion of the sample routine, 10 bits of right-justified data will reside in the HL register pair.

Note that the opto-isolators invert the clock and data lines. If these are not used (no inversion present), the constants in the D and E registers should be swapped, a CMA instruction should be inserted after the RIM instruction, and an inverter should be connected between the address decoder and the CONVERT pin. Also, the results of the first pass through the routine should be ignored following power up and reset cycles to insure that the AD575 has been reset.

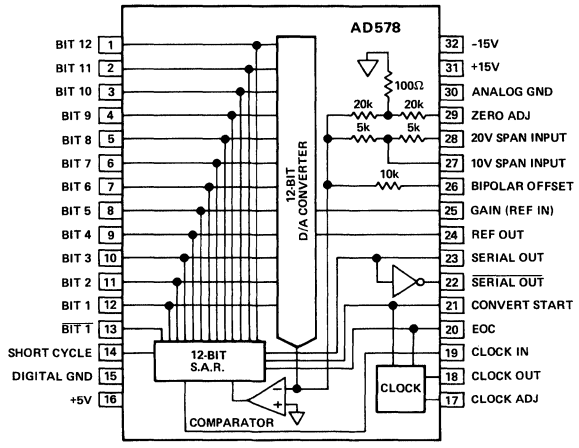
AD578 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The AD578 is a high speed 12-bit successive approximation analog-to-digital converter that includes an internal clock, reference and comparator. Its hybrid IC design utilizes MSI digital and linear monolithic chips in conjunction with a 12-bit monolithic DAC to provide superior performance and versatility with IC size, price and reliability.

Important performance characteristics of the AD578 include a maximum linearity error at +25°C of ±0.012%, maximum gain temperature coefficient of ±30ppm/°C, typical power dissipation of 875mW and maximum conversion time of 3μs.

The fast conversion speeds of 3μs (L grade) 4.5μs (K, T grades) and 6μs (J, S grades) make the AD578 an excellent choice in a variety of applications where system throughput rates from 166kHz to 333kHz are required. In addition, it may be short cycled to obtain faster conversion speeds at lower resolutions.

The design of the AD578 includes scaling resistors that provide analog input signal ranges of ±5V, ±10V, 0 to +10V or 0 to +20V. Adding flexibility and value is the +10V precision reference which can be used for external applications.

The AD578 is available with either the polymer seal (N) for use in benign environmental applications or hermetic solder-seal (D) for more harsh or rigorous surroundings. Both are contained in a 32-pin side-brazed, ceramic DIP.

The AD578S, T are available processed to MIL-STD-883 Level B, Method 5008.

PRODUCT HIGHLIGHTS

1. The AD578 is a complete 12-bit A/D converter. No external components are required to perform a conversion.
2. The fast conversion rate of the AD578 makes it an excellent choice for high speed data acquisition and digital signal processing applications.
3. The internal buried zener reference is laser trimmed to 10.00V ±1.0% and ±15ppm/°C typical T.C. The reference is available for external use and can provide up to 1mA.
4. The scaling resistors are included on the monolithic DAC for exceptional thermal tracking.
5. The component count is minimized, resulting in low bond wire and chip count and high MTBF.
6. Short cycle and external clock capabilities are provided for applications requiring faster conversion speeds and/or lower resolutions.
7. The integrated package construction provides high quality and reliability with small size and weight.

NOTES
[1]Available to MIL-STD-883, Level B. See ADI Military Products Databook for detail specifications.
[2]Positive pulse 200ns wide (min) leading edge (0 to 1) resets outputs. Trailing edge initiates conversion.
[3]With 50Ω, 1% fixed resistor in place of gain adjust potentiometer.
[4]Adjustable to zero.
[5]With 50Ω, 1% resistor between Ref Out and Bipolar Offset (Pins 24 & 26).
[6]Conversion time is defined as the time between the falling edge of convert start and the falling edge of the EOC.
[7]Each grade is specified at the conversion speed shown.
[8]Externally adjustable by a resistor or capacitor (see Figure 7).
[9]For "Z" models order AD578ZJ, ZK, ZL (±11.6V to ±16.5V).
*Specifications same as AD578J.
Specifications subject to change without notice.

THEORY OF OPERATION

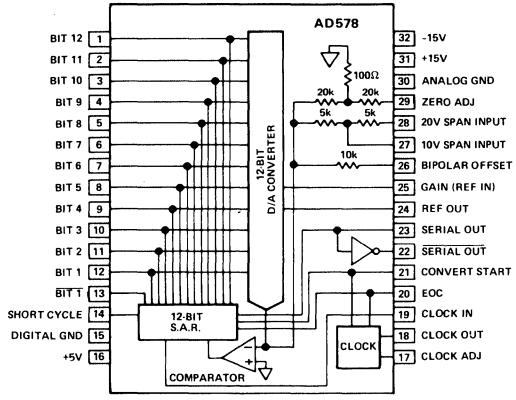

Figure 1. AD578 Functional Diagram and Pinout

The AD578 is a complete pretrimmed 12-bit A/D converter which requires no external components to provide the successive-approximation analog-to-digital conversion function. A block diagram of the AD578 is shown in Figure 1.

When the control section is commanded to initiate a conversion it enables the clock and resets the successive-approximation register (SAR). The SAR, timed by the clock, sequences through the conversion cycle and returns an end-of-convert flag to the control section. The control section disables the clock and brings the output status flag low. The parallel data bits become valid on the rising edge of the clock pulse starting with t_1 and ending with t_{12} (Figure 2), and accurately represent the input signal to within ±1/2LSB.

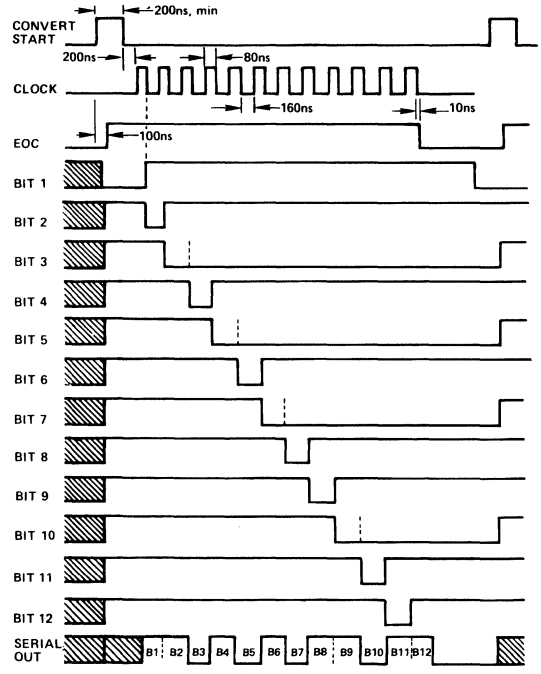
The temperature-compensated buried Zener reference provides the primary voltage reference to the DAC and guarantees excellent stability with both time and temperature. The reference is trimmed to 10.00 volts ±1.0%, it is buffered and can supply up to 1.0mA to an external load in addition to the current required to drive the reference input resistor (0.5mA) and bipolar offset resistor (1mA). The thin-film application resistors are trimmed to match the full scale output current of the DAC. There are two 5kΩ input scaling resistors to allow either a 10 volt or 20 volt span. The 10kΩ bipolar offset resistor is grounded for unipolar operation or connected to the 10 volt reference for bipolar operation.

UNIPOLAR CALIBRATION

The AD578 is intended to have a nominal 1/2LSB offset so that the exact analog input for a given code will be in the middle of that code (halfway between the transitions to the codes above and below it). Thus, when properly calibrated, the first transition (from 0000 0000 0000 to 0000 0000 0001) will occur for an input level of +1/2LSB (1.22mV for 10V range).

If pin 26 is connected to pin 30, the unit will behave in this manner, within specifications. Refer to Table I and Figure 3 for further clarification. If the offset trim (R1) is used, it should be trimmed as above, although a different offset can be set for a particular system requirement. This circuit will give approximately ±25mV of offset trim range.

The full scale trim is done by applying a signal 1 1/2LSB below the nominal full scale (9.9963V for a 10V range). Trim R2 to give the last transition (1111 1111 1110 to 1111 1111 1111).



CLOCK
INTERNAL: CONNECT CLOCK OUT (18) TO CLOCK IN (19)
EXTERNAL: CONNECT EXTERNAL CLOCK TO CLOCK IN (19)
CLOCK SHOULD BE AT LEAST 30% DUTY CYCLE WITH MINIMUM PERIOD, T_{MIN} OF 100ns.

NOTE
[1]THE RISING EDGE OF CONVERT START PULSE RESETS THE MSB TO ZERO, AND THE LSBs TO ONE. THE TRAILING EDGE INITIATES CONVERSION.

Figure 2. AD578 3µs Timing Diagram

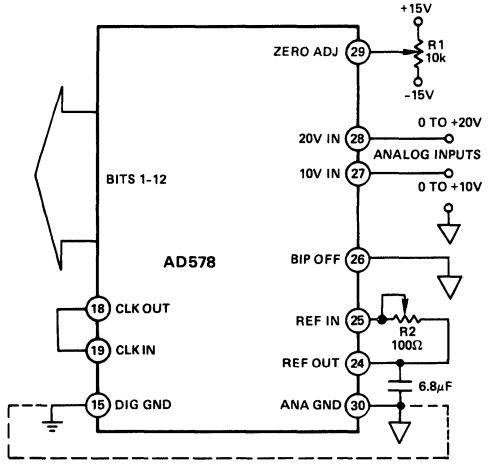


Figure 3. Unipolar Input Connections

BIPOLAR OPERATION

The connections for bipolar ranges are shown in Figure 4. Again, as for the unipolar ranges, if the offset and gain specifications are sufficient the 100Ω trimmer shown can be replaced by a 50Ω ±1% fixed resistor. The analog input is applied as for the unipolar ranges. Bipolar calibration is similar to unipolar calibration. First, a signal 1/2LSB above negative full scale (−4.9988V for the ±5V range) is applied, and R1 is trimmed to give the first transition (0000 0000 0000 to 0000 0000 0001). Then a signal 1 1/2LSB below positive full scale (+4.9963V for the ±5V range) is applied and R2 trimmed to give the last transition (1111 1111 1110 to 1111 1111 1111).

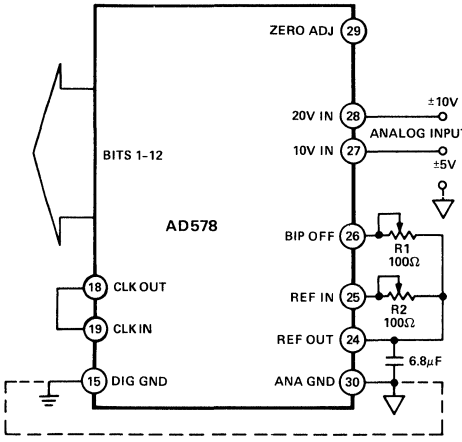

Figure 4. Bipolar Input Connections

LAYOUT CONSIDERATION

Many data-acquisition components have two or more ground pins which are not connected together within the device. These "grounds" are usually referred to as the Logic Power Return, Analog Common (Analog Power Return), and Analog Signal Ground. These grounds must be tied together at one point, usually at the system power-supply ground. Ideally, a single solid ground would be desirable. However, since current flows through the ground wires and etch stripes of the circuit cards, and since these paths have resistance and inductance, hundreds of millivolts can be generated between the system ground point and the ground pin of the AD578. Separate ground returns should be provided to minimize the current flow in the path from sensitive points to the system ground point. In this way supply currents and logic-gate return currents are not summed into the same return path as analog signals where they would cause measurement errors.

Each of the AD578's supply terminals should be capacitively decoupled as close to the AD578 as possible. A large value capacitor such as 10μF in parallel with a 0.1μF capacitor is usually sufficient. Analog supplies are bypassed to the Analog Power Return pin and the logic supply is bypassed to the Digital GND pin.

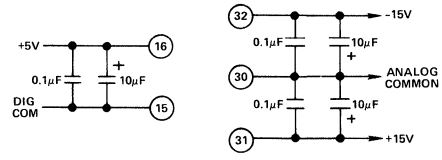

Figure 5. Basic Grounding Practice

To minimize noise the reference output (pin 24) should be decoupled by a 6.8μF capacitor to pin 30.

CLOCK RATE CONTROL

The internal clock is preset to a nominal conversion time of 5.6μs. It can be adjusted for either faster or slower conversions. For faster conversion connect the appropriate 1% resistor between pin 17 and pin 18 and short pin 18 to pin 19.

For slower conversions connect a capacitor between pin 15 and pin 17.

The curves in Figure 6 characterize the conversion time for a given resistor or capacitor connection.

Note: 12-bit operation with no missing codes is not guaranteed when operating in this mode if a particular grade's conversion speed specification has been exceeded.

Short Cycle Input – A Short Cycle Input, pin 14, permits the timing cycle shown in Figure 2 to be terminated after any number of desired bits has been converted, allowing somewhat shorter conversion times in applications not requiring full 12-bit resolution. Short cycle pin connections and associated maximum 12-, 10-, and 8-bit conversion times are summarized in Table II.

Analog Input – Volts (Center of Quantization Interval)				Digital Output Code (Binary For Unipolar Ranges; Offset Binary for Bipolar Ranges)

Conversion Speed (μs)	3	2.5	2

Table II. Short Cycle Connections

External Clock – An external clock may be connected directly to the clock input, pin 19. When operating in this mode, the convert start should be held high for a minimum of one clock period in order to reset the SAR and synchronize the conversion cycle. A positive going pulse width of 100 to 200 nanoseconds will provide a continuous string of conversions that start on the first rising edge of the external clock after the EOC output has gone low.

External Buffer Amplifier – In applications where the AD578 is to be driven from high impedance sources or directly from an analog multiplexer a fast slewing, wideband op amp like the AD711 should be used.

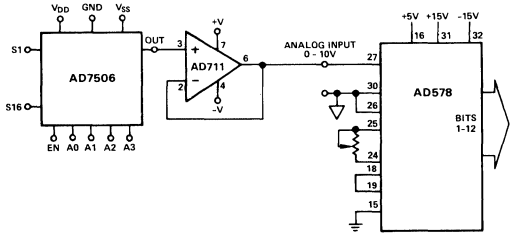

Figure 7. Input Buffer

MICROPROCESSOR INTERFACING

The 3μs conversion times of the AD578 suggests several different methods of interface to microprocessors. In systems where the AD578 is used for high sampling rates on a single signal which is to be digitally processed, CPU-controlled conversion may be inefficient due to the slow cycle times of most microprocessors. It is generally preferable to perform conversions independently, inserting the resultant digital data directly into memory. This can be done using direct memory access (DMA) which is totally transparent to the CPU. Interface to user-designed DMA hardware is facilitated by the guaranteed data validity on the falling edge of the EOC signal.

In many multichannel data acquisition systems, the processor spends a good deal of time waiting for the ADC to complete its cycle. Converters with total conversion times of 25μs to 100μs are not slow enough to justify use of interrupts, nor fast enough to finish converting during one instruction and are usually timed out with loops, or continuously polled for status. The AD578 allows the microprocessor to time out the converter with just a few dummy instructions. For example, an 8085 system running at a 5MHz clock rate will time out an AD578 by pushing a register pair onto the stack and popping the same pair back off the stack. Such a time-out routine only occupies two bytes of program memory but requires 22 clock cyles (4.4μs). The time saved by not having to wait for the converter allows the processor to run much more efficiently particularly in multichannel systems.

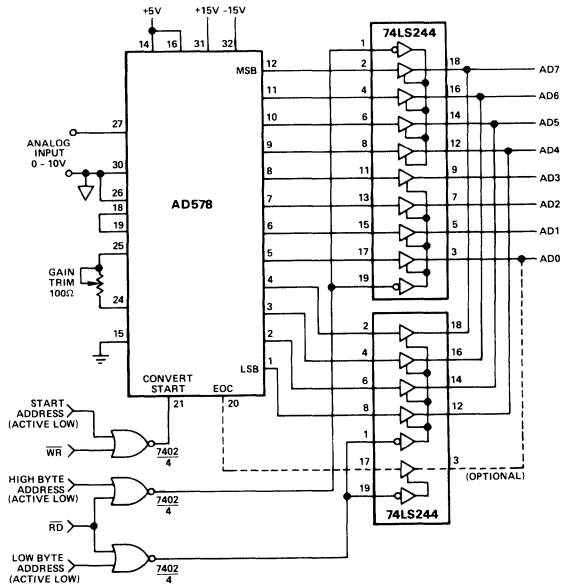

Figure 8. AD578–8085A Interface Connections

Clearly, 12 bits of data must be broken up for interface to an 8-bit wide data bus. There are two possible formats: right-justified and left-justified. In a right-justified system, the least-significant 8 bits occupy one byte and the four MSBs reside in the low nybble of another byte. This format is useful when the data from the ADC is being treated as a binary number between 0 and 4095. The left-justified format supplies the eight most-significant bits in one byte and the 4LSBs in the high nybble of another byte. The data now represents the fractional binary number relating the analog signal to the full-scale voltage. An advantage to this organization is that the most-significant eight bits can be read by the processor as a coarse indication of the true signal value. The full 12-bit word can then be read only when all 12 bits are needed. This allows faster and more efficient control of a process.

Figure 8 shows a typical connection to an 8085-type bus, using left-justified data format for unipolar inputs. Status polling is

optional, and can be read simultaneously with the 4LSBs. If it is desired to right-justify the data, pins 1 through 12 of the AD578 should be reversed, as well as the connections to the data bus and high and low byte address signals.

When dealing with bipolar inputs (±5V, ±10V ranges), using the MSB directly yields an offset binary-coded output. If two's complement coding is desired, it can be produced by substituting $\overline{MSB}$ (pin 13) for the MSB. This facilitates arithmetic operations which are subsequently performed on the ADC output data.

SAMPLED DATA SYSTEMS

The conversion speed of the AD578 allows accurate digitization of high frequency signals and high throughput rates in multi-channel data acquisition systems. The AD578LD, for example, is capable of a full accuracy conversion in 3μs. In order to benefit from this high speed, a fast sample-hold amplifier (SHA) such as the HTC-0300 is required. This SHA has an acquisition time to 0.01% of approximately 300ns, so that a complete sample-convert-acquire cycle can be accomplished in approximately 4μs. This means a sample rate of 250kHz can be realized, allowing a signal with no frequency components above 125kHz to be sampled with no loss of information. Note that the EOC signal from the AD578 places the SHA in the hold mode in advance of the actual start of the conversion cycle, and releases the SHA from the HOLD mode only after completion of the conversion. After allowing at least 300ns for the SHA to acquire the next analog value, the converter can again be started.

AD578 ORDERING GUIDE*

	Conversion Speed	Temperature Range	Package Option[1]
AD578JN(JD)	6.0μs	0 to +70°C	Solder Seal (DH-32B)
AD578KN(KD)	4.5μs	0 to +70°C	Solder Seal (DH-32B)

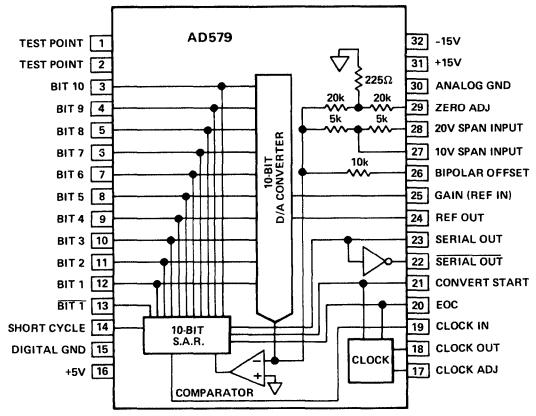
AD579 FUNCTIONAL BLOCK DIAGRAM



32-PIN DIP

PRODUCT DESCRIPTION

The AD579 is a high speed low cost 10-bit successive approximation analog-to-digital converter that includes an internal clock, reference and comparator. Its hybrid IC design utilizes MSI digital and linear monolithic chips in conjunction with a 10-bit monolithic DAC to provide superior performance and versatility with IC size, price and reliability.

Important performance characteristics of the AD579 include a maximum linearity error at +25°C of ±0.048%, maximum gain temperature coefficient of ±40ppm/°C, typical power dissipation of 775mW and maximum conversion time of 1.8μs.

The fast conversion speeds of 1.8μs (K and T grades) and 2.2μs (J grade) make the AD579 an excellent choice in a variety of applications where system throughput rates from 454kHz to 555kHz are required. In addition, it may be short cycled to obtain faster conversion speeds at lower resolutions.

The design of the AD579 includes scaling resistors that provide analog input signal ranges of ±5V, ±10V, 0 to +10V or 0 to +20V. Adding flexibility and value is the +10V precision reference which can be used for external applications.

The AD579 is available with solder-seal (D) for harsh or rigorous surroundings and is contained in a 32-pin side-brazed, ceramic DIP.

PRODUCT HIGHLIGHTS

1. The AD579 is a complete 10-bit A/D converter. No external components are required to perform a conversion.
2. The fast conversion rate of the AD579 makes it an excellent choice for high speed data acquisition on systems requiring high throughput rate.
3. The internal buried Zener reference is laser trimmed to 10.00V ±0.1% and ±15ppm/°C typ T.C. The reference is available externally and can provide up to 1mA.
4. The scaling resistors are included on the monolithic DAC for exceptional thermal tracking.
5. Short cycle and external clock capabilities are provided for applications requiring faster conversion speeds and/or lower resolutions.
6. The integrated package construction provides high quality and reliability with small size and weight.

AD579 ORDERING GUIDE

Model	Conversion Speed	Package	Temperature Range	Power Supply Range	Package Outline*
AD579JN	2.2μs	Hermetic-Seal	0 to +70°C	±15V ±10%	DH-32B

NOTES

[1] Positive pulse 200ns wide (min) leading edge (0 to 1) resets outputs. Trailing edge initiates conversion.

[2] With 50Ω, 1% fixed resistor in place of gain adjust potentiometer.

[3] Adjustable to zero.

[4] With 50Ω, 1% resistor between Ref Out and Bipolar Offset (Pins 24 & 26).

[5] Conversion time is defined as the time between the falling edge of convert start and the falling edge of the EOC.

[6] Each grade is specified at the conversion speed shown. See Figure 7 for appropriate connections.

[7] Externally adjustable by a resistor or capacitor.

[8] For "Z" models order AD579ZJN, AD579ZKN or AD579ZTD.

*Specifications same as AD579JN.

**Specifications same as AD579KN.

Specifications subject to change without notice.

THEORY OF OPERATION

The AD579 is a complete 10-bit A/D converter which requires no external components to provide the successive-approximation analog-to-digital conversion function. A block diagram of the AD579 is shown in Figure 1.

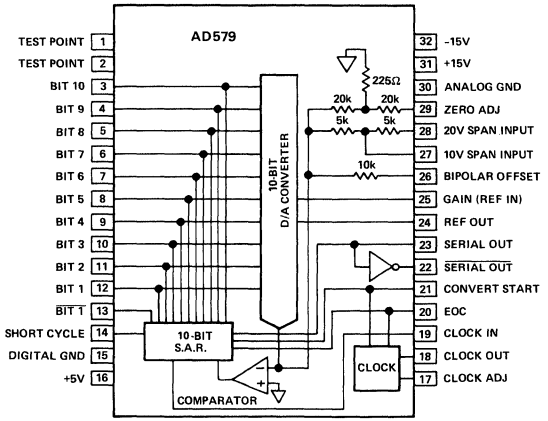

Figure 1. AD579 Functional Diagram and Pinout

On receipt of a CONVERT START command, the AD579 converts the voltage at its analog input into an equivalent bit binary number. This conversion is accomplished as follows: the 10-bit successive-approximation register (SAR) has its 10-bit outputs connected both to the device bit output pins and to the corresponding bit inputs of the feedback DAC. The analog input is successively compared to the feedback DAC output, one bit at a time (MSB first, LSB last). The decision to keep or reject each bit is then made at the completion of each bit comparison period, depending on the state of the comparator at that time.

The temperature-compensated buried Zener reference provides the primary voltage reference to the DAC and guarantees excellent stability with both time and temperature. The reference is trimmed to 10.00 volts ±0.1%; it is buffered and can supply up to 1.0mA to an external load in addition to the current required to drive the reference input resistor (0.5mA) and bipolar offset resistor (1mA). The thin film application resistors are trimmed to match the full scale output current of the DAC. There are two 5kΩ input scaling resistors to allow either a 10 volt or 20 volt span. The 10kΩ bipolar offset resistor is grounded for unipolar operation or connected to the 10 volt reference for bipolar operation.

TIMING

The timing diagram is shown in Figure 2. Receipt of a CONVERT START signal sets the STATUS flag, indicating conversion in progress. This, in turn, removes the inhibit applied to the gated clock, permitting it to run through 10 cycles. All SAR parallel bit and STATUS flip-flops are initialized on the leading edge, and the gated clock inhibit signal is removed on the trailing edge of the CONVERT START signal. At time t_0, B_1 is reset and B_2 -B_{10} are set unconditionally. At t_1 the Bit 1 decision is made (keep) and Bit 2 is unconditionally reset. At t_2, the Bit 2 decision is made (keep) and Bit 3 is reset unconditionally. This sequence continues until Bit 10 (LSB) decision (keep) is made at t_{10}. After a 15ns delay period, the STATUS flag is reset, indicating that the conversion is complete and that the parallel output data is valid. Resetting the STATUS flag restores the gated clock inhibit signal, forcing the clock output to Logic "0" state.

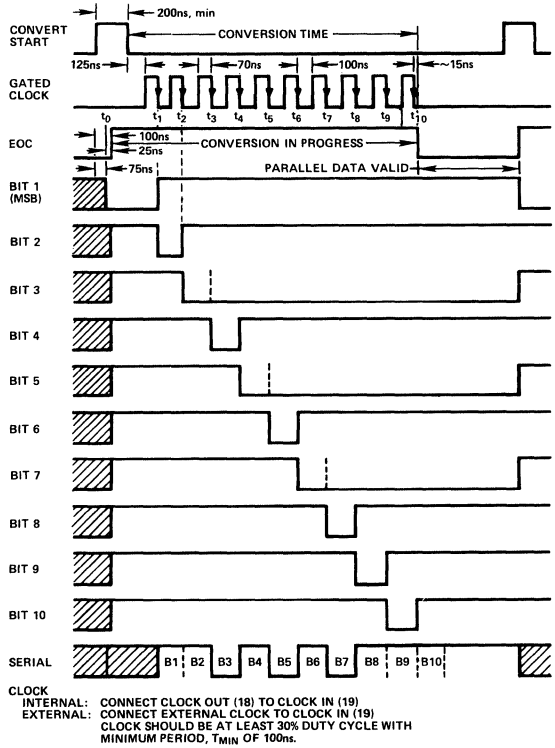

Figure 2. AD579 Timing Diagram

Serial data does not change and is guaranteed valid on negative-going clock edges, therefore; serial data can be transferred quite simply by clocking it into a receiving shift register on these edges (see Figure 2).

Incorporation of this 15ns delay guarantees that the parallel (and serial) data are valid at the Logic "1" to "0" transition of the STATUS flag, permitting parallel data transfer to be initiated by the trailing edge of the STATUS signal.

UNIPOLAR CALIBRATION

The AD579 is intended to have a nominal 1/2LSB offset so that the exact analog input for a given code will be in the middle of that code (halfway between the transitions to the codes above and below it). Thus, when properly calibrated, the first transition (from 0000 0000 00 to 0000 0000 01) will occur for an input level of +1/2LSB (4.88mV for 10V range).

If pin 26 is connected to pin 30, the unit will behave in this manner, within specifications. Refer to Table I and Figure 3 for further clarification. If the offset trim (R1) is used, it should be trimmed as above, although a different offset can be set for a particular system requirement. This circuit will give approximately ±50mV of offset trim range.

The full scale trim is done by applying a signal 1 1/2LSB below the nominal full scale (9.985V for a 10V range). Trim R2 to give the last transition (1111 1111 10 to 1111 1111 11).

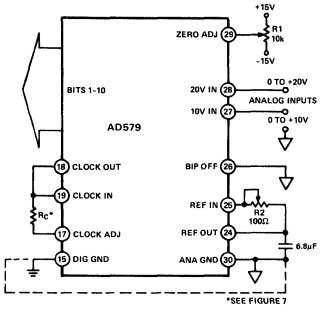

Figure 3. Unipolar Input Connections

BIPOLAR OPERATION

The connections for bipolar ranges are shown in Figure 4. Again, as for the unipolar ranges, if the offset and gain specifications are sufficient, the 100Ω trimmer shown can be replaced by a 50Ω ±1% fixed resistor. The analog input is applied as for the unipolar ranges. Bipolar calibration is similar to unipolar calibration. First, a signal 1/2LSB above negative full scale (-4.9957V for the ±5V range) is applied, and R1 is trimmed to give the first transition (0000 0000 00 to 0000 0000 01). Then, a signel 1 1/2LSB below positive full scale (+4.9853V for the ±5V range) is applied and R2 trimmed to give the last transition (1111 1111 10 to 1111 1111 11).

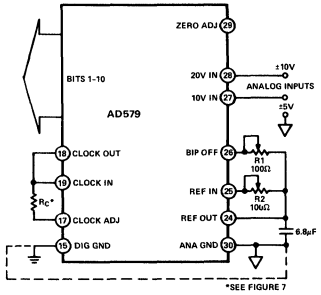

Figure 4. Bipolar Input Connections

ERROR SOURCES

The analog continuum is partitioned into 2^{10} discrete ranges for 10-bit conversion. All analog values within a given quantum are represented by the same digital code, usually assigned to the nominal midrange value. There is an inherent quantization uncertainty of ±1/2LSB, associated with the resolution, in addition to the actual conversion errors.

The actual conversion errors that are associated with A/D converters are combinations of analog errors due to the linear circuitry, matching and tracking properties of the ladder and scaling networks, reference error and power supply rejection.

The matching and tracking errors in the AD579 have been minimized by the use of a monolithic DAC that includes the scaling network. The initial gain and offset errors are specified at ±0.1% FSR typical. These errors may be trimmed to zero by the use of the external trim circuits as shown in Figures 3 and 4. Linearity error is defined as the deviation from a true straight line transfer characteristic from a zero analog input which calls for a zero digital output to a point which is defined as full scale. The linearity error is unadjustable and is the most meaningful indication of A/D converter accuracy. Differential nonlinearity is a measure of the deviation in staircase step width between codes from the ideal least significant bit step size (Figure 5).

Monotonic behavior requires that the differential linearity error be less than 1LSB, however a monotonic converter can having missing codes; the AD579TD is specified as having no missing codes from -55°C to +125°C and thus is monotonic.

There are three types of drift error over temperature: offset, gain and linearity. Offset drift causes a shift of the transfer characteristic left or right over the operating temperature range. Gain drift causes a rotation of the transfer characteristic about the zero or minus full scale point. The worst case accuracy drift is the summation of all three drift errors over temperature. Statistically, however, the drift error behaves as the root-sum-squared (RSS) and can be shown as:

$$RSS = \sqrt{\epsilon_G{}^2 + \epsilon_O{}^2 + \epsilon_L{}^2}$$

ϵ_G = Gain Drift Error (ppm/°C)
ϵ_O = Offset Drift Error (ppm of FSR/°C)
ϵ_L = Linearity Error (ppm of FSR/°C)

LAYOUT CONSIDERATIONS

Many data acquisition components have two or more ground pins which are not connected together within the device. These "grounds" are usually referred to as the Logic Power Return, Analog Common (Analog Power Return), and Analog Signal Ground. These grounds must be tied together at one point, usually at the system power-supply ground. Ideally, a single solid ground would be desirable. However, since current flows through the ground wires and etch stripes of the circuit cards, and since these paths have resistance and inductance, hundreds of millivolts can be generated between the system ground point and the ground pin of the AD579. Separate ground returns should be provided to minimize the current flow in the path from sensitive points to the system ground point. In this way supply currents and logic-gate return currents are not summed into the same return path as analog signals where they would cause measurement errors.

Each of the AD579's supply terminals should be capacitively decoupled as close to the AD579 as possible. A large value capacitor such as 10μF in parallel with a 0.1μF capacitor is usually sufficient. Analog supplies are bypassed to the Analog Power Return pin and the logic supply is bypassed to the Digital GND pin.

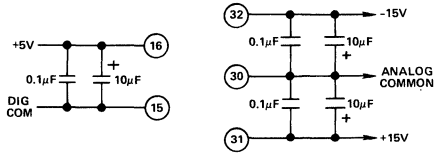

Figure 6. Basic Grounding Practice

To minimize noise the reference output (Pin 24) should be decoupled by a 6.8μF capacitor to pin 30.

CLOCK RATE CONTROL

The internal clock is preset to a nominal conversion time of 4.8μs. It can be adjusted for either faster or slower conversions. For faster conversion connect the appropriate 1% resistor between pin 17 and pin 18 and short pin 18 to pin 19.

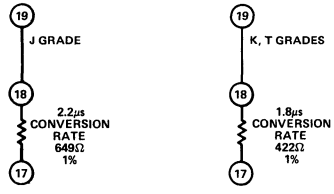

Figure 7. Clock Rate Control Connection

Short Cycle Input – A Short Cycle Input, pin 14, permits the timing cycle shown in Figure 2 to be terminated after any number of desired bits has been converted, allowing somewhat shorter conversion times in applications not requiring full 10-bit resolution. Short cycle pin connections and associated maximum 10- and 8-bit conversion times are summarized in Table II.

Resolution (Bits)	10	8
Connect Pin 14 to Pin	2	4
Conversion Speed (μs)	1.8	1.5

Table II. Short Cycle Connections

External Clock – An external clock may be connected directly to the clock input, pin 19. When operating in this mode the convert start should be held high for a minimum of one clock period in order to reset the SAR and synchronize the conversion cycle.

External Buffer Amplifier – In applications where the AD579 is to be driven from high impedance sources or directly from an analog multiplexer a fast slewing, wideband op amp like the AD841 should be used.

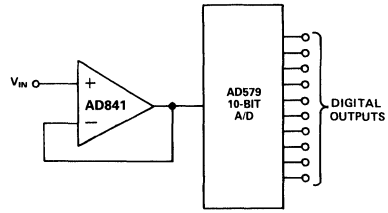

Figure 8. Input Buffer

SAMPLED DATA SYSTEMS

The conversion speed of the AD579 allows accurate digitization of high frequency signals and high throughput rates in multichannel data acquisition systems. The AD579TD, for example, is capable of a full accuracy conversion in 1.8μs. In order to benefit from this high speed, a fast sample-hold amplifier (SHA) such as the HTC-0300 is required. This SHA has an acquisition time to 0.01% of approximately 300ns, so that a complete sample-convert-acquire cycle can be accomplished in approximately 2.5μs. This means a sample rate of 400kHz can be realized, allowing a signal with no frequency components above 200kHz to be sampled with no loss of information. Note that the EOC signal from the AD579 places the SHA in the hold mode in advance of the actual start of the conversion cycle, and releases the SHA from the HOLD mode only after completion of the conversion. After allowing at least 300ns for the SHA to acquire the next analog value, the converter can again be started.

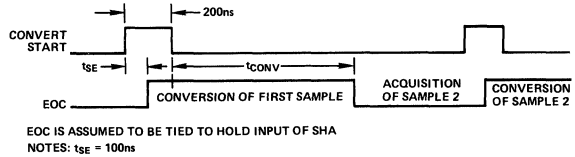

Figure 9. Start/EOC Timing for Sampled Data System

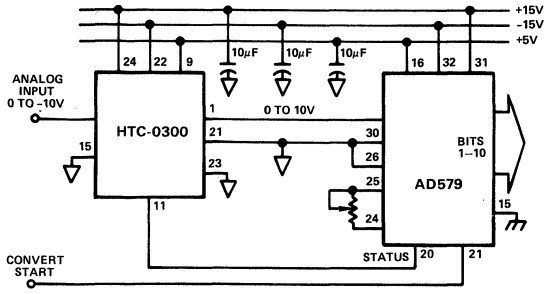

Figure 10. 400kHz – 10-Bit, A/D Conversion System

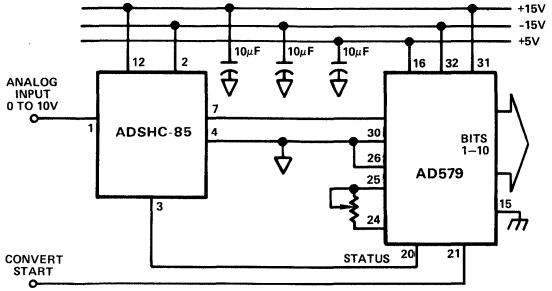

Figure 11. 154kHz – 10-Bit, A/D Conversion System

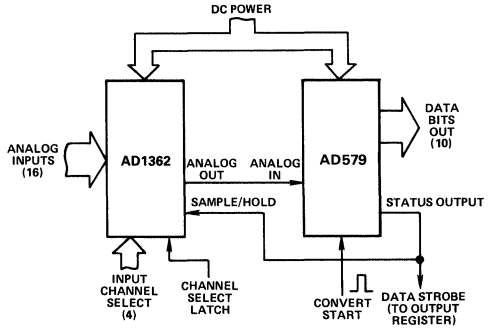

Figure 12. High Speed 10-Bit DAS

A fast (85kHz) 10-bit DAS can be configured using the AD1362 and the AD579. The AD1362 contains two 8-channel multiplexers, a differential amplifier, a sample-and-hold with high-speed output amplifier, a channel address latch and control logic. The multiplexers may be connected to the differential amplifier in either an 8-channel differential or 16-channel single-ended configuration. A feature of the AD1362 is an internal user-controllable analog switch that connects the multiplexers in either a single-ended or differential mode. This allows a single device to perform in either mode without hard-wire programming and permits a mixture of single-ended and differential sources to be interfaced by dynamically switching the input mode control.

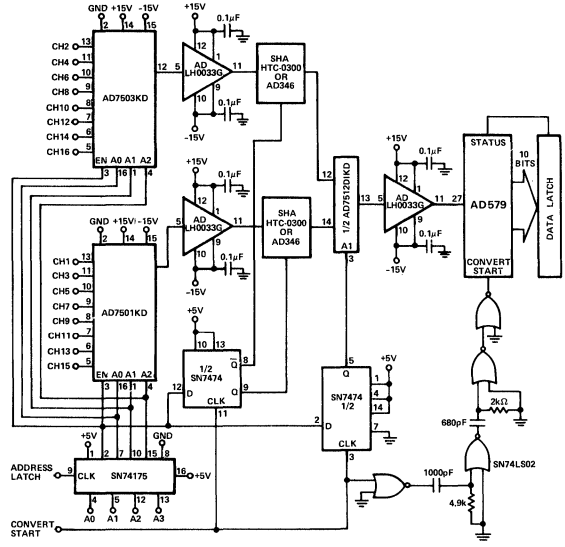

Figure 13. High Speed–165kHz–10-Bit DAS

A high speed 10-bit DAS with a throughput rate of 165kHz can be built around an AD579. The DAS of Figure 13 "Ping Pongs" two sample and hold amplifiers to eliminate the effects of the acquisition time of the sample and hold amplifiers. By applying sequential channel address the A0 of the address enables one of the two multiplexers. The incorporation of the flip-flops on the SHA mode controls and the switch address allows a new channel address to be latched in while a conversion is in progress.

ANALOG DEVICES

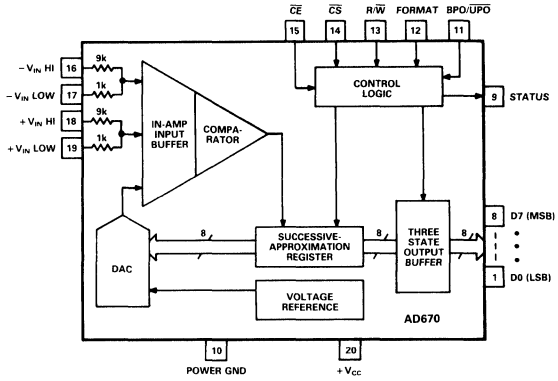
Low Cost Signal Conditioning 8-Bit ADC

AD670

FEATURES

Complete 8-Bit Signal Conditioning A/D Converter Including Instrumentation Amp and Reference
Microprocessor Bus Interface
10μs Conversion Speed
Flexible Input Stage: Instrumentation Amp Front End Provides Differential Inputs and High Common-Mode Rejection
No User Trims Required
No Missing Codes Over Temperature
Single +5V Supply Operation
Convenient Input Ranges
20-Pin DIP or Surface-Mount Package
Low Cost Monolithic Construction

AD670 BLOCK DIAGRAM AND TERMINAL CONFIGURATION (ALL PACKAGES)



GENERAL DESCRIPTION

The AD670 is a complete 8-bit signal conditioning analog-to-digital converter. It consists of an instrumentation amplifier front end along with a DAC, comparator, successive approximation register (SAR), precision voltage reference, and a three-state output buffer on a single monolithic chip. No external components or user trims are required to interface, with full accuracy, an analog system to an 8-bit data bus. The AD670 will operate on the +5V system supply. The input stage provides differential inputs with excellent common-mode rejection and allows direct interface to a variety of transducers.

The device is configured with input scaling resistors to permit two input ranges: 0 to 255mV (1mV/LSB) and 0 to 2.55V (10mV/LSB). The AD670 can be configured for both unipolar and bipolar inputs over these ranges. The differential inputs and common-mode rejection of this front end are useful in applications such as conversion of transducer signals superimposed on common-mode voltages.

The AD670 incorporates advanced circuit design and proven processing technology. The successive approximation function is implemented with I^2L (integrated injection logic). Thin-film SiCr resistors provide the stability required to prevent missing codes over the entire operating temperature range while laser wafer trimming of the resistor ladder permits calibration of the device to within ±1LSB. Thus, no user trims for gain or offset are required. Conversion time of the device is 10μs.

The AD670 is available in four package types and five grades. The J and K grades are specified over 0 to +70°C and come in 20-pin plastic DIP packages or 20-terminal PLCC packages. The A and B grades (−40°C to +85°C) and the S grade (−55°C to +125°C) come in 20-pin ceramic DIP packages.

The S grade is also available with optional processing to MIL-STD-883 in 20-pin ceramic DIP or 20-terminal LCC packages. The Analog Devices Military Products Databook should be consulted for details on these configurations.

PRODUCT HIGHLIGHTS

1. The AD670 is a complete 8-bit A/D including three-state outputs and microprocessor control for direct connection to 8-bit data buses. No external components are required to perform a conversion.
2. The flexible input stage features a differential instrumentation amp input with excellent common-mode rejection. This allows direct interface to a variety of transducers without preamplification.
3. No user trims are required for 8-bit accurate performance.
4. Operation from a single +5V supply allows the AD670 to run off of the microprocessor's supply.
5. Four convenient input ranges (two unipolar and two bipolar) are available through internal scaling resistors: 0 to 255mV (1mV/LSB) and 0 to 2.55V (10mV/LSB).
6. Software control of the output mode is provided. The user can easily select unipolar or bipolar inputs and binary or 2's complement output codes.

CIRCUIT OPERATION/FUNCTIONAL DESCRIPTION

The AD670 is a functionally complete 8-bit signal conditioning A/D converter with microprocessor compatibility. The input section uses an instrumentation amplifier to accomplish the voltage to current conversion. This front end provides a high impedance, low bias current differential amplifier. The common-mode range allows the user to directly interface the device to a variety of transducers.

The A/D conversions are controlled by R/$\overline{W}$, $\overline{CS}$, and $\overline{CE}$. The R/$\overline{W}$ line directs the converter to read or start a conversion. A minimum write/start pulse of 300ns is required on either $\overline{CE}$ or $\overline{CS}$. The STATUS line goes high, indicating that a conversion is in process. The conversion thus begun, the internal 8-bit DAC is sequenced from MSB to LSB using a novel successive approximation technique. In conventional designs, the DAC is stepped through the bits by a clock. This can be thought of as a static design since the speed at which the DAC is sequenced is determined solely by the clock. No clock is used in the AD670. Instead, a "dynamic SAR" is created consisting of a string of inverters with taps along the delay line. Sections of the delay line between taps act as one shots. The pulses are used to set and reset the DAC's bits and strobe the comparator. When strobed, the comparator then determines whether the addition of each successively weighted bit current causes the DAC current sum to be greater or less than the input current. If the sum is less, the bit is turned off. After all bits are tested, the SAR holds an 8-bit code representing the input signal to within 1/2LSB accuracy. Ease of implementation and reduced dependence on process related variables make this an attractive approach to a successive approximation design.

The SAR provides an end-of-conversion signal to the control logic which then brings the STATUS line low. Data outputs remain in a high impedance state until R/$\overline{W}$ is brought high with $\overline{CE}$ and $\overline{CS}$ low and allows the converter to be read. Bringing $\overline{CE}$ or $\overline{CS}$ high during the valid data period ends the read cycle. The output buffers cannot be enabled during a conversion. Any convert start commands will be ignored until the conversion cycle is completed; once a conversion cycle has been started it cannot be stopped or restarted.

The AD670 provides the user with a great deal of flexibility by offering two input spans and formats and a choice of output codes. Input format and input range can each be selected. The BPO/$\overline{UPO}$ pin controls a switch which injects a bipolar offset current of a value equal to the MSB less 1/2LSB into the summing node of the comparator to offset the DAC output. Two precision 10 to 1 attenuators are included on board to provide input range selection of 0 to 2.55V or 0 to 255mV. Additional ranges of

– 1.28 to 1.27V and – 128 to 127mV are possible if the BPO/$\overline{\text{UPO}}$ switch is high when the conversion is started. Finally, output coding can be chosen using the FORMAT pin when the conversion is started. In the bipolar mode and with a logic 1 on FORMAT, the output is in two's complement; with a logic 0, the output is offset binary.

CONNECTING THE AD670

The AD670 has been designed for ease of use. All active components required to perform a complete A/D conversion are on board and are connected internally. In addition, all calibration trims are performed at the factory, assuring specified accuracy without user trims. There are, however, a number of options and connections that should be considered to obtain maximum flexibility from the part.

INPUT CONNECTIONS

Standard connections are shown in the figures that follow. An input range of 0 to 2.55V may be configured as shown in Figure 2a. This will provide a one LSB change for each 10mV of input change. The input range of 0 to 255mV is configured as shown in Figure 2b. In this case, each LSB represents 1mV of input change. When unipolar input signals are used, Pin 11, BPO/$\overline{\text{UPO}}$, should be grounded. Pin 11 selects the input format for either unipolar or bipolar signals. Figures 3a and 3b show the input connections for bipolar signals. Pin 11 should be tied to $+V_{CC}$ for bipolar inputs.

Although the instrumentation amplifier has a differential input, there must be a return path to ground for the bias currents. If it is not provided, these currents will charge stray capacitances and cause internal circuit nodes to drift uncontrollably causing the digital output to change. Such a return path is provided in Figures 2a and 3a (larger input ranges) since the 1k resistor leg

NOTE: PIN 11, BPO/$\overline{\text{UPO}}$ SHOULD BE HIGH WHEN CONVERSION IS STARTED.

Figure 3. Bipolar Input Connections

is tied to ground. This is not the case for Figures 2b and 3b (the lower input ranges). When connecting the AD670 inputs to floating sources, such as transformers and ac-coupled sources, there must still be a dc path from each input to common. This can be accomplished by connecting a 10kΩ resistor from each input to ground.

Bipolar Operation

Through special design of the instrumentation amplifier, the AD670 accommodates input signal excursions below ground, even though it operates from a single 5V supply. To the user, this means that true bipolar input signals can be used without the need for any additional external components. Bipolar signals can be applied differentially across both inputs, or one of the inputs can be grounded and a bipolar signal applied to the other.

Common-Mode Performance

The AD670 is designed to reject dc and ac common-mode voltages. In some applications it is useful to apply a differential input signal V_{IN} in the presence of a dc common-mode voltage V_{CM}. The user must observe the absolute input signal limits listed in the specifications, which represent the maximum voltage V_{IN} + V_{CM} that can be applied to either input without affecting proper operation. Exceeding these limits (within the range of absolute maximum ratings), however, will not cause permanent damage.

The excellent common-mode rejection of the AD670 is due to the instrumentation amplifier front end, which maintains the differential signal until it reaches the output of the comparator. In contrast to a standard operational amplifier, the instrumentation amplifier front end provides significantly improved CMRR over a wide frequency range (Figure 4a).

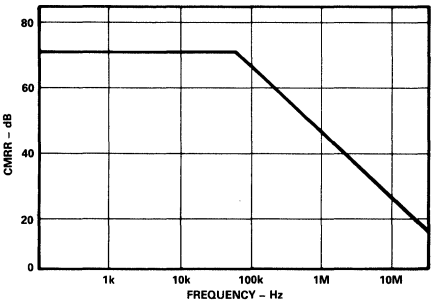

Figure 4a. CMRR over Frequency

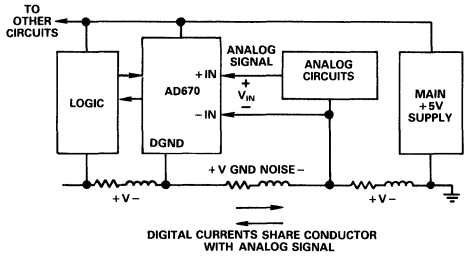

Figure 4b. AD670 Input Rejects Common-Mode Ground Noise

Good common-mode performance is useful in a number of situations. In bridge-type transducer applications, such performance facilitates the recovery of differential analog signals in the presence of a dc common-mode or a noisy electrical environment. High-frequency CMRR also becomes important when the analog signal is referred to a noisy, remote digital ground. In each case, the CMRR specification of the AD670 allows the integrity of the input signal to be preserved.

The AD670's common-mode voltage tolerance allows great flexibility in circuit layout. Most other A/D converters require the establishment of one point as the analog reference point. This is necessary in order to minimize the effects of parasitic voltages. The AD670, however, eliminates the need to make the analog ground reference point and A/D analog ground one and the same. Instead, a system such as that shown in Figure 4b is possible as a result of the AD670's common-mode performance. The resistors and inductors in the ground return represent unavoidable system parasitic impedances.

Input/Output Options

Data output coding (2's complement vs. straight binary) is selected using Pin 12, the FORMAT pin. The selection of input format (bipolar vs. unipolar) is controlled using Pin 11, BPO/$\overline{\text{UPO}}$. Prior to a write/convert, the state of FORMAT and BPO/$\overline{\text{UPO}}$ should be available to the converter. These lines may be tied to the data bus and may be changed with each conversion if desired. The configurations are shown in Table I. Output coding for representative signals in each of these configurations is shown in Figure 5.

An output signal, STATUS, indicates the status of the conversion. STATUS goes high at the beginning of the conversion and returns low when the conversion cycle has been completed.

BPO/$\overline{\text{UPO}}$	FORMAT	INPUT RANGE/OUTPUT FORMAT
0	0	Unipolar/Straight Binary
1	0	Bipolar/Offset Binary

Calibration

Because of its precise factory calibration, the AD670 is intended to be operated without user trims for gain and offset; therefore, no provisions have been made for such user trims. Figures 6a, 6b, and 6c show the transfer curves at zero and full scale for the unipolar and bipolar modes. The code transitions are positioned so that the desired value is centered at that code. The first LSB transition for the unipolar mode occurs for an input of +1/2LSB (5mV or 0.5mV). Similarly, the MSB transition for the bipolar mode is set at –1/2LSB (–5mV or –0.5mV). The full scale transition is located at the full scale value –1 1/2LSB. These values are 2.545V and 254.5mV.

CONTROL AND TIMING OF THE AD670

Control Logic

The AD670 contains on-chip logic to provide conversion and data read operations from signals commonly available in microprocessor systems. Figure 7 shows the internal logic circuitry of the AD670. The control signals, $\overline{CE}$, $\overline{CS}$, and R/$\overline{W}$ control the operation of the converter. The read or write function is determined by R/$\overline{W}$ when both $\overline{CS}$ and $\overline{CE}$ are low as shown in Table II. If all three control inputs are held low longer than the conversion time, the device will continuously convert until one input, $\overline{CE}$, $\overline{CS}$, or R/$\overline{W}$ is brought high. The relative timing of these signals is discussed later in this section.

Timing

The AD670 is easily interfaced to a variety of microprocessors and other digital systems. The following discussion of the timing requirements of the AD670 control signals will provide the designer with useful insight into the operation of the device.

Write/Convert Start Cycle

Figure 8 shows a complete timing diagram for the write/convert start cycle. $\overline{CS}$ (chip select) and $\overline{CE}$ (chip enable) are active low and are interchangeable signals. Both $\overline{CS}$ and $\overline{CE}$ must be low for the converter to read or start a conversion. The minimum pulse width, t_W, on either $\overline{CS}$ or $\overline{CE}$ is 300ns to start a conversion.

Table III. AD670 TIMING SPECIFICATIONS

Boldface indicates parameters tested 100% unless otherwise noted. See Specifications page for explanation.

		@ +25°C			
Symbol	**Parameter**	**Min**	**Typ**	**Max**	**Units**
WRITE/CONVERT START MODE					
t_W	Write/Start Pulse Width	300			ns
t_{DS}	Input Data Setup Time	200			ns
t_{DH}	Input Data Hold	10			ns
t_{RWC}	Read/Write Setup Before Control	0			ns
t_{DC}	Delay to Convert Start			700	ns
t_C	**Conversion Time**			**10**	µs
READ MODE					
t_R	Read Time	250			ns
t_{SD}	Delay from Status Low to Data Read			250	ns
t_{TD}	**Bus Access Time**		200	**250**	ns
t_{DH}	Data Hold Time	25			ns
t_{DT}	**Output Float Delay**			**150**	ns
t_{RT}	R/$\overline{W}$ before $\overline{CE}$ or $\overline{CS}$ low	0			ns

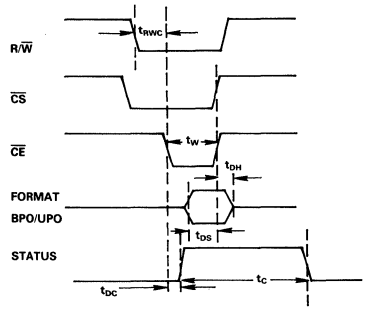

Figure 8. Write/Convert Start Timing

The R/$\overline{W}$ line is used to direct the converter to start a conversion (R/$\overline{W}$ low) or read data (R/$\overline{W}$ high). The relative sequencing of the three control signals (R/$\overline{W}$, $\overline{CE}$, $\overline{CS}$) is unimportant. However, when all three signals remain low for at least 300ns (t_W), STATUS will go high to signal that a conversion is taking place.

Once a conversion is started and the STATUS line goes high, convert start commands will be ignored until the conversion cycle is complete. The output data buffer cannot be enabled during a conversion.

Read Cycle

Figure 9 shows the timing for the data read operation. The data outputs are in a high impedance state until a read cycle is initiated. To begin the read cycle, R/$\overline{W}$ is brought high. During a read cycle, the minimum pulse length for $\overline{CE}$ and $\overline{CS}$ is a function of the length of time required for the output data to be valid. The data becomes valid and is available to the data bus in a maximum of 250ns. This delay between the high impedance state and valid data is the maximum bus access time or t_{TD}. Bringing $\overline{CE}$ or $\overline{CS}$ high during valid data ends the read cycle. The outputs remain valid for a minimum of 25ns (t_{DH}) and return to the high impedance state after a delay, t_{DT}, of 150ns maximum.

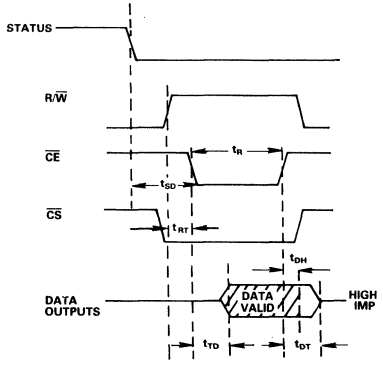

Figure 9. Read Cycle Timing

STAND-ALONE OPERATION

The AD670 can be used in a "stand-alone" mode, which is useful in systems with dedicated input ports available. Two typical conditions are described and illustrated by the timing diagrams which follow.

Single Conversion, Single Read

When the AD670 is used in a stand-alone mode, $\overline{CS}$ and $\overline{CE}$ should be tied together. Conversion will be initiated by bringing R/$\overline{W}$ low. Within 700ns, a conversion will begin. The R/$\overline{W}$ pulse should be brought high again once the conversion has started so that the data will be valid upon completion of the conversion. Data will remain valid until $\overline{CE}$ and $\overline{CS}$ are brought high to indicate the end of the read cycle or R/$\overline{W}$goes low. The timing diagram is shown in Figure 10.

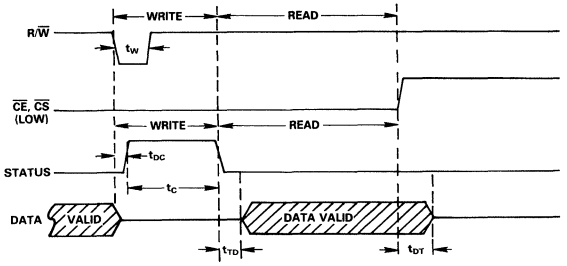

Figure 10. Stand-Alone Mode Single Conversion/ Single Read

Continuous Conversion, Single Read

A variety of applications may call for the A/D to be read after several conversions. In process control systems, this is often the case since a reading from a sensor may only need to be updated every few conversions. Figure 11 shows the timing relationships.

Once again, $\overline{CE}$ and $\overline{CS}$ should be tied together. Conversion will begin when the R/$\overline{W}$ signal is brought low. The device will convert repeatedly as indicated by the status line. A final conversion will take place once the R/$\overline{W}$ line has been brought high. The rising edge of R/$\overline{W}$ must occur while STATUS is high. R/$\overline{W}$ should not return high while STATUS is low since the circuit is in a reset state prior to the next conversion. Since the rising edge of R/$\overline{W}$ must occur while STATUS is high, R/$\overline{W}$'s length must be a minimum of 10.25μs (t_C + t_{TD}). Data becomes valid upon completion of the conversion and will remain so until the $\overline{CE}$ and $\overline{CS}$ lines are brought high indicating the end of the read cycle or R/$\overline{W}$ goes low initiating a new series of conversions.

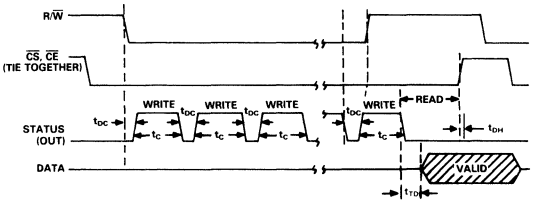

Figure 11. Stand-Alone Mode Continuous Conversion/ Single Read

APPLYING THE AD670

The AD670 has been designed for ease of use, system compatibility, and minimization of external components. Transducer interfaces generally require signal conditioning and preamplification before the signal can be converted. The AD670 will reduce and even eliminate this excess circuitry in many cases. To illustrate the flexibility and superior solution that the AD670 can bring to a transducer interface problem, the following discussions are offered.

Temperature Measurements

Temperature transducers are one of the most common sources of analog signals in data acquisition systems. These sensors require circuitry for excitation and preamplification/buffering. The instrumentation amplifier input of the AD670 eliminates the need for this signal conditioning. The output signals from temperature transducers are generally sufficiently slow that a sample/hold amplifier is not required. Figure 12 shows the AD590 IC temperature transducer interfaced to the AD670. The AD580 voltage reference is used to offset the input for 0°C calibration. The current output of the AD590 is converted into a voltage by R1. The high impedance unbuffered voltage is applied directly to the AD670 configured in the −128mV to 127mV bipolar range. The digital output will have a resolution of 1°C.

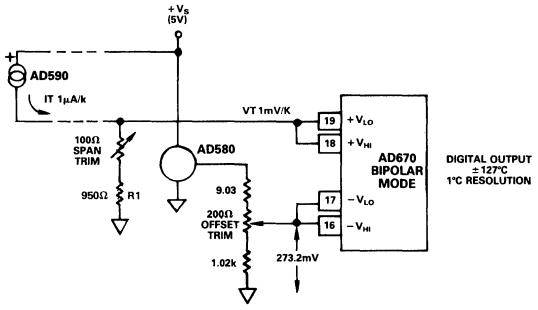

Figure 12. AD670 Temperature Transducer Interface

Platinum RTDs are also a popular, temperature transducer. Typical RTDs have a resistance of 100Ω at 0°C and change resistance 0.4Ω per °C. If a constant excitation current is caused to flow in the RTD, the change in voltage drop will be a measure of the change in temperature. Figure 13 shows such a method and the required connections to the AD670. The AD580 2.5V reference provides the accurate voltage for the excitation current and range offsetting for the RTD. The op-amp is configured to force a constant 2.5mA current through the RTD. The differential inputs of the AD670 measure the difference between a fixed offset voltage and the temperature dependent output of the op-amp which varies with the resistance of the RTD. The RTD change of approximately 0.4Ω/°C results in a 1mV/°C voltage change. With the AD670 in the 1mV/LSB range, temperatures from 0 to 255°C can be measured.

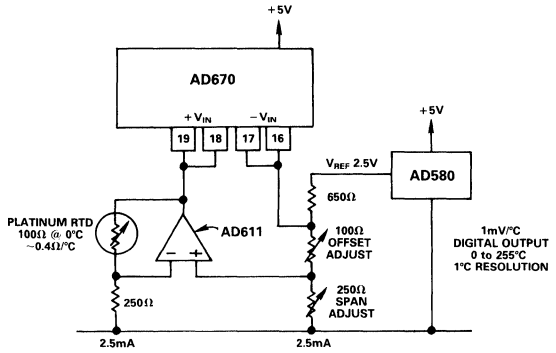

Figure 13. Low Cost RTD Interface

Differential temperature measurements can be made using an AD590 connected to each of the inputs as shown in Figure 14. This configuration will allow the user to measure the relative temperature difference between two points with a 1°C resolution. Although the internal 1k and 9k resistors on the inputs have ±20% tolerance, trimming the AD590 is unnecessary as most differential temperature applications are concerned with the relative differences between the two. However, the user may see up to a 20% scale factor error in the differential temperature to digital output transfer curve.

This scale factor error can be eliminated through a software correction. Offset corrections can be made by adjusting for any difference that results when both sensors are held at the same temperature. A span adjustment can then be made by immersing one AD590 in an ice bath and one in boiling water and eliminating any deviation from 100°C. For a low cost version of this setup, the plastic AD592 can be substituted for the AD590.

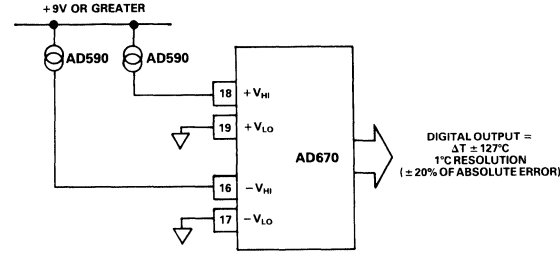

Figure 14. Differential Temperature Measurement Using the AD590

STRAIN GAUGE MEASUREMENTS

Many semiconductor-type strain gauges, pressure transducers, and load cells may also be connected directly to the AD670. These types of transducers typically produce 30 millivolts full-scale per volt of excitation. In the circuit shown in Figure 15, the AD670 is connected directly to a Data Instruments model JP-20 load cell. The AD584 programmable voltage reference is used along with an AD741 op-amp to provide the ±2.5V excitation for the load cell. The output of the transducer will be ±150mV for a force of ±20 pounds. The AD670 is configured for the ±128 millivolt range. The resolution is then approximately 2.1 ounces per LSB over a range of ±17 pounds. Scaling to exactly 2 ounces per LSB can be accomplished by trimming the reference voltage which excites the load cell.

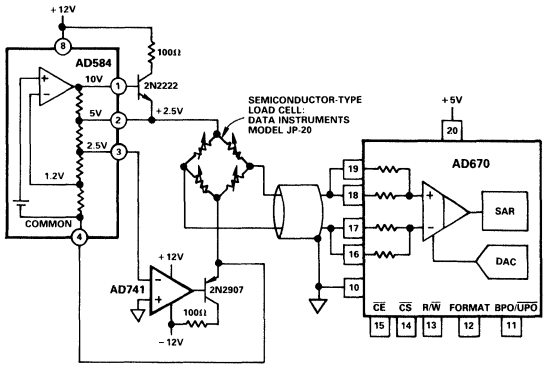

Figure 15. AD670 Load Cell Interface

MULTIPLEXED INPUTS

Most data acquisition systems require the measurement of several analog signals. Multiple A/D converters are often used to digitize these inputs, requiring additional preamplification and buffer stages per channel. Since these signals vary slowly, a differential MUX can multiplex inputs from several transducers into a single AD670. And since the AD670's signal-conditioning capability is preserved, the cost of several ADCs, differential amplifiers, and other support components can be reduced to that of a single AD670, a MUX, and a few digital logic gates.

An AD7502 dual 4-channel MUX appears in Figure 16 multiplexing four differential signals to the AD670. The AD7502's decoded address is gated with the microprocessor's write signal to provice a latching strobe at the flip-flops. A write cycle to the AD7502's address then latches the two LSBs of the data word thereby selecting the input channel for subsequent conversions.

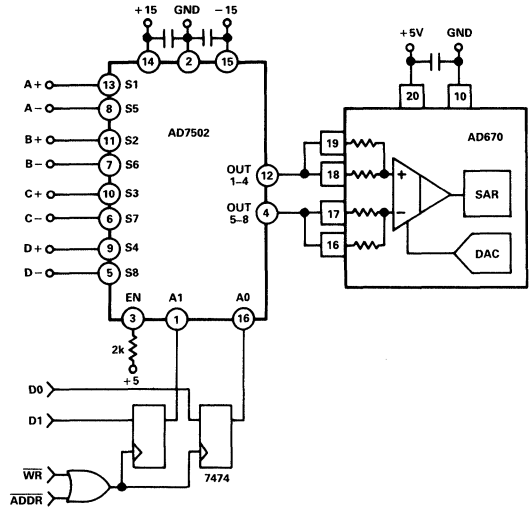

Figure 16. Multiplexed Analog Inputs to AD670

SAMPLED INPUTS

For those applications where the input signal is capable of slewing more than 1/2LSB during the AD670's 10μs conversion cycle, the input should be held constant for the cycle's duration. The circuit shown in Figure 17 uses a CMOS switch and two capacitors to sample/hold the input. The AD670's STATUS output, once inverted, supplies the sample/hold ($S/\overline{H}$) signal.

A convert command applied on the $\overline{CE}$, $\overline{CS}$ OR $R/\overline{W}$ lines will initiate the conversion. The AD670's STATUS output, once inverted, supplies the sample/hold signal to the CD4066. The CD4066 CMOS switch shown in Figure 17 was chosen for its fast transition times, low on-resistance and low cost. The control input's propagation delay for switch-closed to switch-open should remain less than 150ns to ensure that the sample-to-hold transition occurs before the first bit decision in the AD670.

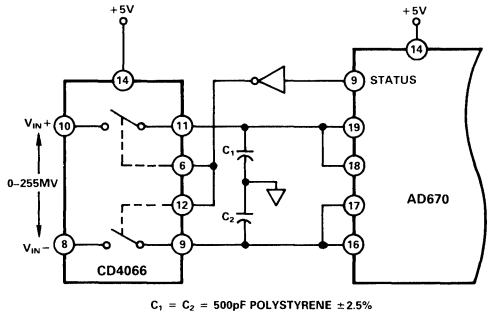

Figure 17. Low Cost Sample-and-Hold Circuit for AD670

Since settling to 1/2LSB at 8-bits of resolution requires 6.2 RC time constants, the 500pF hold capacitors and CD4066's 300Ω on-resistance yield an acquisition time of under 1μs, assuming a low impedance source.

This sample/hold approach makes use of the differential capabilities of the AD670. Because 500pF hold capacitors are used on both $V_{IN}+$ and $V_{IN}-$ inputs, the droop rate depends only on the offset current of the AD670, typically 20nA. With the matched 500pF capacitors, the droop rate is 40μV/μs. The input will then droop only 0.4mV (0.4LSB) during the AD670's 10μs conversion time. The differential approach also minimizes pedestal error since only the difference in charge injection between the two switches results in errors at the A/D.

The fast conversion time and differential and common-mode capabilities of the AD670 permit this simple sample-hold design to perform well with low sample-to-hold offset, droop rate of about 40μV/μs and acquisition time under 1μs. The effective aperture time of the AD670 is reduced by about 2 orders of magnitude with this circuit, allowing frequencies to be converted up to several kilohertz.

While no input anti-aliasing filter is shown, filtering will be necessary to prevent output errors if higher frequencies are present in the input signal. Many practical variations are possible with this circuit, including input MUX control, for digitizing a number of AC channels.

IBM PC INTERFACE

The AD670 appears in Figure 18 interfaced to the IBM PC. Since the device resides in I/O space, its address is decoded from only the lower ten address lines and must be gated with AEN (active low) to mask out internal (DMA) cycles which use the same I/O address space. This active low signal is applied to $\overline{CS}$. AO, meanwhile, is reserved for the R/$\overline{W}$ input. This places

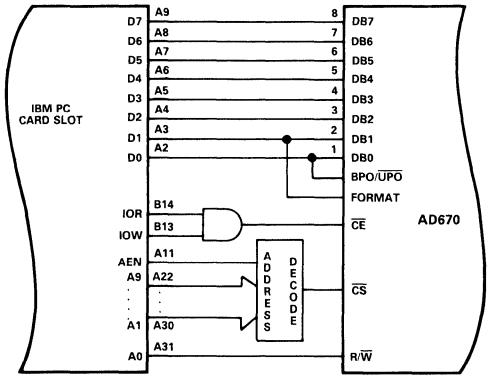

Figure 18. IBM PC Interface to AD670

the AD670 in two adjacent addresses; one for starting the conversion and the other for reading the result. The $\overline{IOR}$ and $\overline{IOW}$ signals are then gated and applied to $\overline{CE}$, while the lower two data lines are applied to FORMAT and BPO/$\overline{UPO}$ inputs to provide software programmable input formats and output coding.

In BASIC, a simple OUT ADDR, WORD command initiates a conversion. While the upper six bits of the data WORD are meaningless, the lower two bits define the analog input format and digital output coding according to Table IV. The data is available ten microseconds later (which is negligible in BASIC) and can be read using INP (ADDR + 1). The 3-line subroutine in Figure 19, used in conjunction with the interface of Figure 18, converts an analog input within a bipolar range to an offset binary coded digital word.

NOTE: Due to the large number of options that may be installed in the PC, the I/O bus loading should be limited to one Schottky TTL load. Therefore, a buffer/driver should be used when interfacing more than two AD670's to the I/O bus.

DATA	INPUT FORMAT	OUTPUT CODING
0	Unipolar	Straight Binary

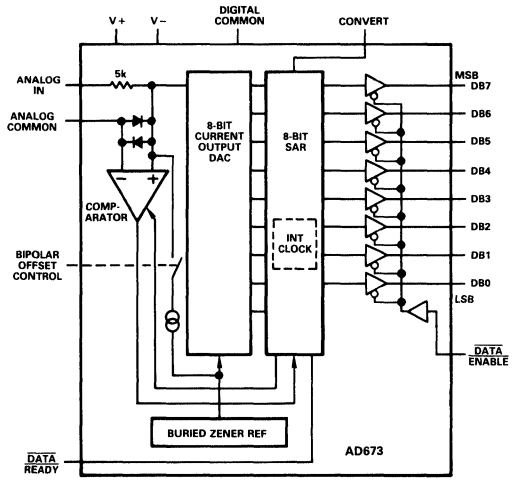
FEATURES

Complete 8-Bit A/D Converter with Reference, Clock and Comparator
30μs Maximum Conversion Time
Full 8- or 16-Bit Microprocessor Bus Interface
Unipolar and Bipolar Inputs
No Missing Codes Over Temperature
Operates on +5V and −12V to −15V Supplies

AD673 FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD673 is a complete 8-bit successive approximation analog-to-digital converter consisting of a DAC, voltage reference, clock, comparator, successive approximation register (SAR) and 3 state output buffers–all fabricated on a single chip. No external components are required to perform a full accuracy 8-bit conversion in 20μs.

The AD673 incorporates advanced integrated circuit design and processing technologies. The successive approximation function is implemented with I^2L (integrated injection logic). Laser trimming of the high stability SiCr thin film resistor ladder network insures high accuracy, which is maintained with a temperature compensated sub-surface Zener reference.

Operating on supplies of +5V and −12V to −15V, the AD673 will accept analog inputs of 0 to +10V or −5V to +5V. The trailing edge of a positive pulse on the CONVERT line initiates the 20μs conversion cycle. $\overline{\text{DATA READY}}$ indicates completion of the conversion.

The AD673 is available in two versions. The AD673J as specified over the 0 to +70°C temperature range and the AD673S guarantees ±½LSB relative accuracy and no missing codes from −55°C to +125°C.

Two package configurations are offered. All versions are also offered in a 20-pin hermetically sealed ceramic DIP. The AD673J is also available in a 20-pin plastic DIP.

***Protected by U.S. Patent Nos. 3,940,760; 4,213,806; 4,136,349; 4,400,689; and 4,400,690**

PRODUCT HIGHLIGHTS

1. The AD673 is a complete 8-bit A/D converter. No external components are required to perform a conversion.
2. The AD673 interfaces to many popular microprocessors without external buffers or peripheral interface adapters.
3. The device offers true 8-bit accuracy and exhibits no missing codes over its entire operating temperature range.
4. The AD673 adapts to either unipolar (0 to +10V) or bipolar (−5V to +5V) analog inputs by simply grounding or opening a single pin.
5. Performance is guaranteed with +5V and −12V or −15V supplies.

NOTES

[1]Relative accuracy is defined as the deviation of the code transition points from the ideal transfer point on a straight line from the zero to the full scale of the device.

[2]Full scale calibration is guaranteed trimmable to zero with an external 200Ω potentiometer in place of the 15Ω fixed resistor.

Full scale is defined as 10 volts minus 1LSB, or 9.961 volts.

[3]Defined as the resolution for which no missing codes will occur.

[4]The data output lines have active pull-ups to source 0.5mA. The DATA READY line is open collector with a nominal 6kΩ internal pull-up resistor.

Specifications subject to change without notice.

Specifications shown in boldface are tested on all production units at final electrical test. Results from those tests are used to calculate outgoing quality levels. All min and max specifications are guaranteed, although only those shown in boldface are tested on all production units.

FUNCTIONAL DESCRIPTION

A block diagram of the AD673 is shown in Figure 1. The positive CONVERT pulse must be at least 500ns wide. $\overline{DR}$ goes high within 1.5μs after the leading edge of the convert pulse indicating that the internal logic has been reset. The negative edge of the CONVERT pulse initiates the conversion. The internal 8-bit current output DAC is sequenced by the integrated injection logic (I^2L) successive approximation register (SAR) from its most significant bit to least significant bit to provide an output current which accurately balances the input signal current through the 5kΩ resistor. The comparator determines whether the addition of each successively weighted bit current causes the DAC current sum to be greater or less than the input current; if the sum is more, the bit is turned off. After testing all bits, the SAR contains a 8-bit binary code which accurately represents the input signal to within (0.05% of full scale).

The SAR drives $\overline{DR}$ low to indicate that the conversion is complete and that the data is available to the output buffers. $\overline{DATA\ ENABLE}$ can then be activated to enable the 8-bits of data desired. $\overline{DATA\ ENABLE}$ should be brought high prior to the next conversion to place the output buffers in the high impedance state.

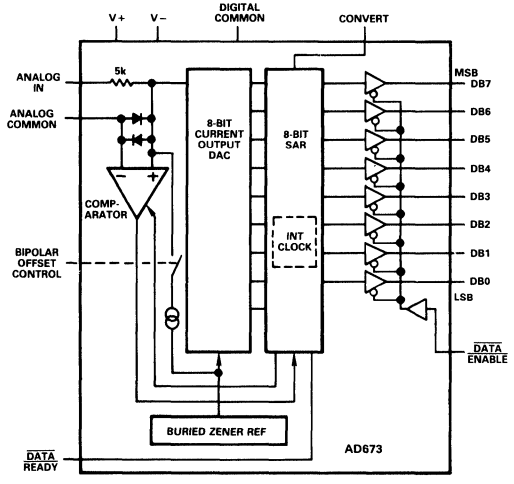

Figure 1. AD673 Functional Block Diagram

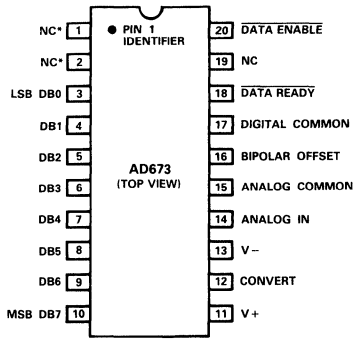
The temperature compensated buried Zener reference provides the primary voltage reference to the DAC and ensures excellent stability with both time and temperature. The bipolar offset input controls a switch which allows the positive bipolar offset current (exactly equal to the value of the MSB less ½LSB) to be injected into the summing (+) node of the comparator to offset the DAC output. Thus the nominal 0 to +10V unipolar input range becomes a −5V to +5V range. The 5kΩ thin film input resistor is trimmed so that with a full scale input signal, an input current will be generated which exactly matches the DAC output with all bits on.

UNIPOLAR CONNECTION

The AD673 contains all the active components required to perform a complete A/D conversion. Thus, for many applications, all that is necessary is connection of the power supplies (+5V and −12V to −15V), the analog input and the convert pulse. However, there are some features and special connections which should be considered for achieving optimum performance. The functional pin-out is shown in Figure 2.

The standard unipolar 0 to +10V range is obtained by shorting the bipolar offset control pin (pin 16) to digital common (pin 17).



*PINS 1 & 2 ARE INTERNALLY CONNECTED TO TEST POINTS AND SHOULD BE LEFT FLOATING

Figure 2. AD673 Pin Connections

Full Scale Calibration

The 5kΩ thin film input resistor is laser trimmed to produce a current which matches the full scale current of the internal DAC–plus about 0.3%–when an analog input voltage of 9.961 volts (10 volts – 1LSB) is applied at the input. The input resistor is trimmed in this way so that if a fine trimming potentiometer is inserted in series with the input signal, the input current at the full scale input voltage can be trimmed down to match the DAC full scale current as precisely as desired. However, for many applications the nominal 9.961 volt full scale can be achieved to sufficient accuracy by simply inserting a 15Ω resistor in series with the analog input to pin 14. Typical full scale calibration error will then be within ±2LSB or ±0.8%. If more precise calibration is desired, a 200Ω trimmer should be used instead. Set the analog input at 9.961 volts, and set the trimmer so that the output code is just at the transition between 111111 10 and 11111111. Each LSB will then have a weight of 39.06mV. If a nominal full scale of 10.24 volts is desired (which makes the LSB have a weight of exactly 40.0mV), a 100Ω resistor and a 100Ω trimmer (or a 200Ω trimmer with good resolution) should be used. Of course, larger full scale ranges can be arranged by using a larger input resistor, but linearity and full scale temperature coefficient may be compromised if the external resistor becomes a sizeable percentage of 5kΩ. Figure 3 illustrates the connections required for full scale calibration.

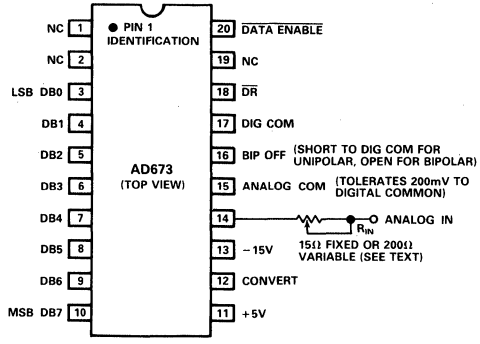


Figure 3. Standard AD673 Connections

Unipolar Offset Calibration

Since the Unipolar Offset is less than ±½LSB for all versions of the AD673, most applications will not require trimming. Figure 4 illustrates two trimming methods which can be used if greater accuracy is necessary.

Figure 4a shows how the converter zero may be offset to correct for initial offset and/or input signal offsets. As shown, the circuit gives approximately symmetrical adjustment in unipolar mode.

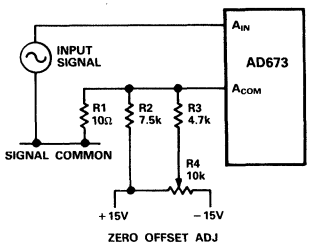

Figure 4a.

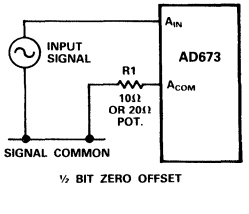

Figure 4b.

Figure 4. Unipolar Offset Trimming

Figure 5 shows the nominal transfer curve near zero for an AD673 in unipolar mode. The code transitions are at the edges of the nominal bit weights. In some applications it will be preferable to offset the code transitions so that they fall between the nominal bit weights, as shown in the offset characteristics.

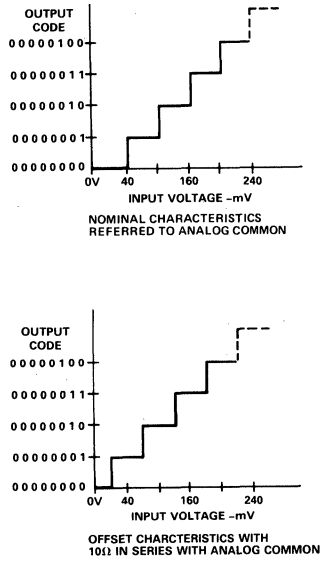

Figure 5. AD673 Transfer Curve – Unipolar Operation (Approximate Bit Weights Shown for Illustration, Nominal Bit Weights % 39.06mV)

This offset can easily be accomplished as shown in Figure 4b. At balance (after a conversion) approximately 2mA flows into the Analog Common terminal. A 10Ω resistor in series with this terminal will result in approximately the desired ½ bit offset of the transfer characteristics. The nominal 2mA Analog Common current is not closely controlled in manufacture. If high accuracy is required, a 20Ω potentiometer (connected as a rheostat) can be used as R1. Additional negative offset range may be obtained by using larger values of R1. Of course, if the zero transition point is changed, the full scale transition point will also move. Thus, if an offset of ½LSB is introduced, full scale trimming as described on the previous page should be done with an analog input of 9.941 volts.

NOTE: During a conversion, transient currents from the Analog Common terminal will disturb the offset voltage. Capacitive decoupling should not be used around the offset network. These transients will settle appropriately during a conversion. Capacitive decoupling will "pump up" and fail to settle resulting in conversion errors. Power supply decoupling, which returns to analog signal common, should go to the signal input side of the resistive offset network.

BIPOLAR CONNECTION

To obtain the bipolar −5V to +5V range with an offset binary output code, the bipolar offset control pin is left open.

A −5.00 volt signal will give a 8-bit code of 00000000; an input of 0.00 volts results in an output code of 10000000 and +4.961 volts at the input yields the 11111111 code. The nominal transfer curve is shown in Figure 6.

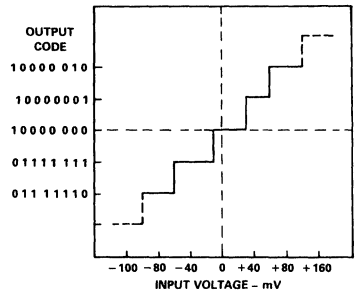

Figure 6. AD673 Transfer Curve–Bipolar Operation

Note that in the bipolar mode, the code transitions are offset ¼LSB such that an input voltage of 0 volts −5mV to +35mV yields the code representing zero (10000000). Each output code is then *centered* on its nominal input voltage.

Full Scale Calibration

Full Scale Calibration is accomplished in the same manner as in Unipolar operation except the full scale input voltage is +4.61 volts.

Negative Full Scale Calibration

The circuit in Figure 4a can also be used in Bipolar operation to offset the input voltage (nominally −5V) which results in the 000000 00 code. R2 should be omitted to obtain a symmetrical range.

The bipolar offset control input is not directly TTL compatible but a TTL interface for logic control can be constructed as shown in Figure 7.

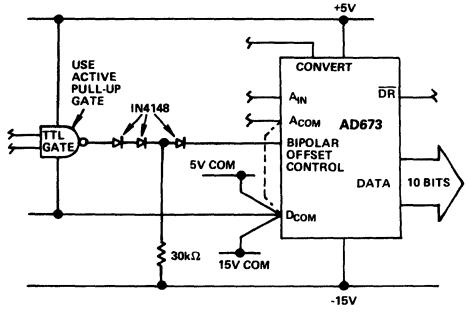

Figure 7. Bipolar Offset Controlled by Logic Gate
Gate Output = 1 Unipolar 0–10V Input Range
Gate Output = 0 Bipolar ±5V Input Range

SAMPLE-HOLD AMPLIFIER CONNECTION TO THE AD673

Many situations in high-speed acquisition systems or digitizing rapidly changing signals require a sample-hold amplifier (SHA) in front of the A-D converter. The SHA can acquire and hold a signal faster than the converter can perform a conversion. A SHA can also be used to accurately define the exact point in time at which the signal is sampled. For the AD673, a SHA can also serve as a high input impedance buffer.

Figure 8 shows the AD673 connected to the AD582 monolithic SHA for high speed signal acquisition. In this configuration, the AD582 will acquire a 10 volt signal in less than 10μs with a droop rate less than 100μV/ms.

$\overline{DR}$ goes high after the conversion is initiated to indicate that reset of the SAR is complete. In Figure 8 it is also used to put the AD582 into the hold mode while the AD673 begins its conversion cycle. (The AD582 settles to final value well in advance of the first comparator decision inside the AD673).

$\overline{DR}$ goes low when the conversion is complete placing the AD582 back in the sample mode. Configured as shown in Figure 8, the next conversion can be initiated after a 10μs delay to allow for signal acquisition by the AD582.

Observe carefully the ground, supply, and bypass capacitor connections between the two devices. This will minimize ground noise and interference during the conversion cycle.

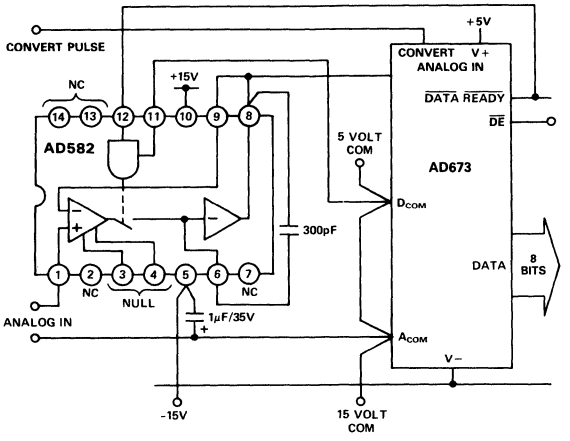

Figure 8. Sample-Hold Interface to the AD673

GROUNDING CONSIDERATIONS

The AD673 provides separate Analog and Digital Common connections. The circuit will operate properly with as much as ±200mV of common mode voltage between the two commons. This permits more flexible control of system common bussing and digital and analog returns.

In normal operation, the Analog Common terminal may generate transient currents of up to 2mA during a conversion. In addition a static current of about 2mA will flow into Analog Common in the unipolar mode after a conversion is complete. The Analog Common current will be modulated by the variations in input signal.

The absolute maximum voltage rating between the two commons is ±1 volt. It is recommended that a parallel pair of back-to-back protection diodes be connected between the commons if they are not connected locally.

CONTROL AND TIMING OF THE AD673

The operation of the AD673 is controlled by two inputs: CONVERT and $\overline{\text{DATA ENABLE}}$.

Starting a Conversion

The conversion cycle is initiated by a positive-going CONVERT pulse at least 500ns wide. The rising edge of this pulse resets the internal logic, clears the result of the previous conversion, and sets $\overline{\text{DR}}$ high. The falling edge of CONVERT begins the conversion cycle. When conversion is completed $\overline{\text{DR}}$ returns low. During the conversion cycle, $\overline{\text{DE}}$ should be held high. If $\overline{\text{DE}}$ goes low during a conversion, the data output buffers will be enabled and intermediate conversion results will be present on the data output pins. This may cause bus conflicts if other devices in a system are trying to use the bus.

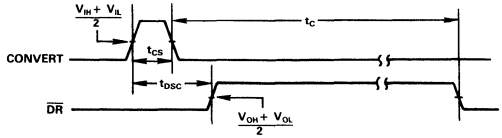

Figure 9. Convert Timing

Reading the Data

The three-state data output buffers is enabled by $\overline{\text{DE}}$. Access time of these buffers is typically 150ns (250 maximum). The Data outputs remain valid until 50ns after the enable signal returns high, and are completely into the high-impedance state 100ns later.

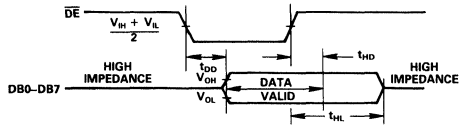

Figure 10. Read Timing

TIMING SPECIFICATIONS

Parameter	Symbol	Min	Typ	Max	Units
CONVERT Pulse Width	t_{CS}	500	–	–	ns
$\overline{\text{DR}}$ Delay from CONVERT	t_{DSC}	–	1	1.5	µs
Conversion Time	t_C	10	20	30	µs
Data Access Time	t_{DD}	0	150	250	ns
Data Valid after $\overline{\text{DE}}$ High	t_{HD}	50	–	–	ns
Output Float Delay	t_{HL}	–	100	200	ns

MICROPROCESSOR INTERFACE CONSIDERATIONS – GENERAL

When an analog-to-digital converter like the AD673 is interfaced to a microprocessor, several details of the interface must be considered. First, a signal to start the converter must be generated; then an appropriate delay period must be allowed to pass before valid conversion data may be read. In most applications, the AD673 can interface to a microprocessor system with little or no external logic.

The most popular control signal configuration consists of decoding the address assigned to the AD673, then gating this signal with the system's WR signal to generate the CONVERT pulse, and gating it with RD to enable the output buffers. The use of a memory address and memory WR and RD signals denotes "memory-mapped" I/O interfacing, while the use of a separate I/O address space denotes "isolated I/O" interfacing.

Figure 11 shows a generalized diagram of the control logic for an AD673 interfaced to an 8-bit data bus, where an address ADC ADDR has been decoded. ADC ADDR starts the converter when written to (the actual data being written to the converter does not matter) and contains the high byte data during read operations.

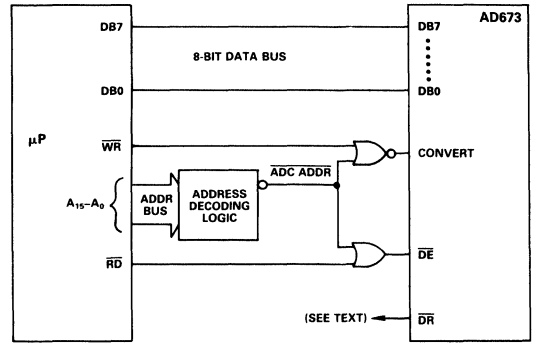

Figure 11. General AD673 Interface to 8-Bit Microprocessor

In systems where this read-write interface is used, at least 30 microseconds (the maximum conversion time) must be allowed to pass between starting a conversion and reading the results. This delay or "timeout" period can be implemented in a short software routine such as a countdown loop, enough dummy instructions to consume 30 microseconds, or enough actual useful instructions to consume the required time. In tightly-timed systems, the $\overline{DR}$ line may be read through an external three-state buffer to determine precisely when a conversion is complete. Higher-speed systems may choose to use $\overline{DR}$ to signal an interrupt to the processor at the end of a conversion.

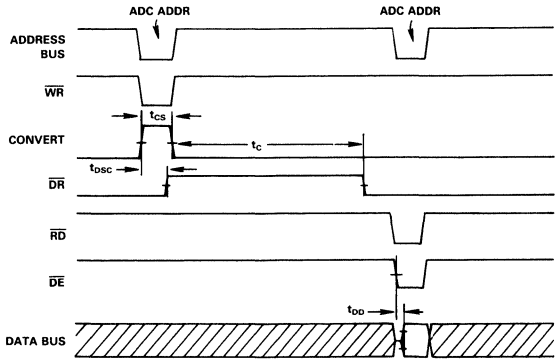

Figure 12. Typical AD673 Timing Diagram

CONVERT Pulse Generation

The AD673 is tested with a CONVERT pulse width of 500ns and will typically operate with a pulse as short as 300ns. However, some microprocessors produce active WR pulses which are shorter than this. Either of the circuits shown in Figure 13 can be used to generate an adequate CONVERT pulse for the AD673. In both circuits, the short low-going WR pulse sets the CONVERT line high through a flip-flop. The rising edge of $\overline{DR}$ (which signifies that the internal logic has been reset) resets the flip-flop and brings CONVERT low, which starts the conversion.

Note that t_{DSC} is slightly longer when the result of the previous conversion contains a logic 1 on the LSB. This means that the actual CONVERT pulse generated by the circuits in Figure 13 will vary slightly in width.

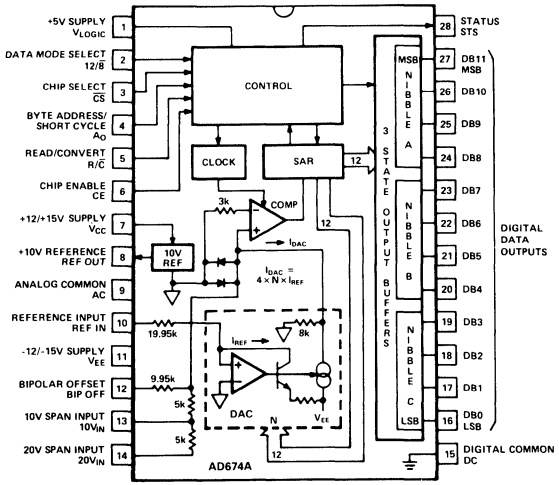
AD674A FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD674A is a complete 12-bit successive-approximation analog-to-digital converter with three-state output buffer circuitry for direct interface to an 8- and 16-bit microprocessor bus. A high-precision voltage reference and clock are included on-chip, and the circuit requires only power supplies and control signals for operation.

The AD674A is pin compatible with the industry-standard AD574A but offers faster conversion time and bus-access speed.

The AD674A design is implemented with two LSI chips each containing both analog and digital circuitry, resulting in the maximum performance and flexibility at the lowest cost. The chips are laser trimmed at the wafer stage to obtain full rated performance without external trims.

The AD674A is available in six different grades. The AD674AJ, K, and L grades are specified for operation over the 0 to +70°C temperature range. The AD674AS, T, and U are specified for the −55°C to +125°C range. All grades are available in a 28-pin hermetically sealed ceramic DIP.

The S, T, and U grades are also available with optional processing to MIL-STD-883C Class B in 28-pin DIP. The Analog Devices Military Products Databook should be consulted for details on /883B testing of the AD674A.

***Protected by U.S. Patent Nos. 3,803,590; 4,213,806; 4,511,413; RE 28,633.**

PRODUCT HIGHLIGHTS

1. The AD674A interfaces to most 8- or 16-bit microprocessors. Multiple-mode three-state output buffers connect directly to the data bus while the read and convert commands are taken from the control bus. The 12 bits of output data can be read either as one 12-bit word or as two 8-bit bytes (one with 8 data bits, the other with 4 data bits and 4 trailing zeros).
2. The precision, laser-trimmed scaling and bipolar offset resistors provide four calibrated ranges: 0 to +10 and 0 to +20 volts unipolar, −5 to +5 and −10 to +10 volts bipolar. Typical bipolar offset and full-scale calibration errors of ±0.1% can be trimmed to zero with one external component each.
3. The internal buried zener reference is trimmed to 10.00 volts with 1% maximum error and 15ppm/°C typical T.C. The reference is available externally and can drive up to 2.0mA beyond the requirements of the reference and bipolar offset resistors.

DEFINITIONS OF SPECIFICATIONS

LINEARITY ERROR

Linearity error refers to the deviation of each individual code from a line drawn from "zero" through "full scale". The point used as "zero" occurs 1/2LSB (1.22mV for 10 volt span) before the first code transition (all zeros to only the LSB "on"). "Full scale" is defined as a level 1 1/2LSB beyond the last code transition (to all ones). The deviation of a code from the true straight line is measured from the middle of each particular code.

The AD674AK, L, T, and U grades are guaranteed for maximum nonlinearity of ±1/2LSB. For these grades, this means that an analog value which falls exactly in the center of a given code width will result in the correct digital output code. Values nearer the upper or lower transition of the code width may produce the next upper or lower digital output code. The AD674AJ and S grades are guaranteed to ±1LSB max error. For these grades, an analog value which falls within a given code width will result in either the correct code for that region or either adjacent one.

Note that the linearity error is not user adjustable.

DIFFERENTIAL LINEARITY ERROR (NO MISSING CODES)

A specification which guarantees no missing codes requires that every code combination appear in a monotonic increasing sequence as the analog input level is increased. Thus every code must have a finite width. For the AD674AK, L, T, and U grades, which guarantee no missing codes to 12-bit resolution, all 4096 codes must be present over the entire operating temperature ranges. The AD674AJ and S grades guarantee no missing codes to 11-bit resolution over temperature; this means that all code combinations of the upper 11 bits must be present; in practice very few of the 12-bit codes are missing.

UNIPOLAR OFFSET

The first transition should occur at a level 1/2LSB above analog common. Unipolar offset is defined as the deviation of the actual transition from that point. This offset can be adjusted as discussed later. The unipolar offset temperature coefficient specifies the maximum change of the transition point over temperature, with or without external adjustment.

BIPOLAR OFFSET

In the bipolar mode the major carry transition (0111 1111 1111 to 1000 0000 0000) should occur for an analog value 1/2LSB below analog common. The bipolar offset error and temperature coefficient specify the initial deviation and maximum change in the error over temperature.

QUANTIZATION UNCERTAINTY

Analog-to-digital converters exhibit an inherent quantization uncertainty of ±1/2LSB. This uncertainty is a fundamental characteristic of the quantization process and cannot be reduced for a converter of given resolution.

LEFT-JUSTIFIED DATA

The data format used in the AD674A is left-justified. This means that the data represents the analog input as a fraction of full scale, ranging from 0 to $\frac{4095}{4096}$. This implies a binary point to the left of the MSB.

FULL-SCALE CALIBRATION ERROR

The last transition (from 1111 1111 1110 to 1111 1111 1111) should occur for an analog value 1 1/2LSB below the nominal full scale (9.9963 volts for 10.000 volts full scale). The full-scale calibration error is the deviation of the actual level at the last transition from the ideal level. This error, which is typically 0.05 to 0.1% of full scale, can be trimmed out as shown in Figures 3 and 4. The full-scale calibration error over temperature is given with and without the initial error trimmed out. The temperature coefficients for each grade indicate the maximum change in the full-scale gain from the initial value using the internal 10V reference.

TEMPERATURE COEFFICIENTS

The temperature coefficients for full-scale calibration, unipolar offset, and bipolar offset specify the maximum change from the initial (25°C) value to the value at T_{min} or T_{max}.

POWER SUPPLY REJECTION

The standard specifications for the AD674A assume use of +5.00 and ±15.00 or ±12.00V supplies. The only effect of power supply error on the performance of the device will be a small change in the full-scale calibration. This will result in a linear change in all lower-order codes. The specifications show the maximum full-scale change from the initial value with the supplies at the various limits.

CODE WIDTH

A fundamental quantity for A/D converter specifications is the code width. This is defined as the range of analog input values for which a given digital output code will occur. The nominal value of a code width is equivalent to 1 least significant bit (LSB) of the full-scale range or 2.44mV out of 10 volts for a 12-bit ADC.

CIRCUIT OPERATION

The AD674A is a complete 12-bit A/D converter which requires no external components to provide the complete successive-approximation analog-to-digital conversion function. A block diagram of the AD674A is shown in Figure 1.

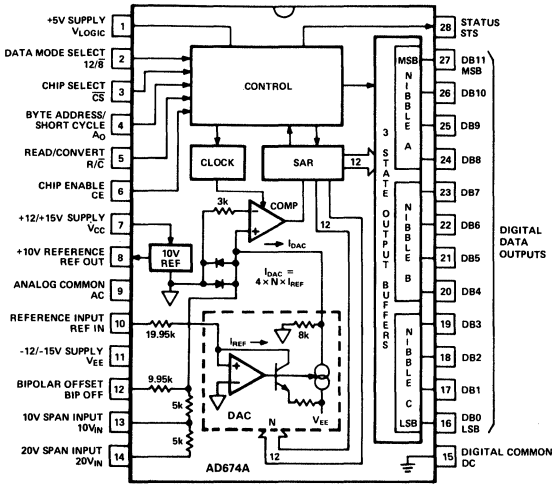

Figure 1. Block Diagram of AD674A 12-Bit A-to-D Converter

When the control section is commanded to initiate a conversion (as described later), it enables the clock and resets the successive-approximation register (SAR) to all zeros. Once a conversion cycle has begun, it cannot be stopped or re-started and data is not available from the output buffers. The SAR, timed by the clock, will sequence through the conversion cycle and return an end-of-convert flag to the control section. The control section will then disable the clock, bring the output status flag low, and enable control functions to allow data read functions by external command.

During the conversion cycle, the internal 12-bit current output DAC is sequenced by the SAR from the most-significant-bit (MSB) to least-significant-bit (LSB) to provide an output current which accurately balances the input signal current through the 5kΩ (or 10kΩ) input resistor. The comparator determines whether the addition of each successively-weighted bit current causes the DAC current sum to be greater or less than the input current; if the sum is less, the bit is left on; if more, the bit is turned off. After testing all the bits, the SAR contains a 12-bit binary code which accurately represents the input signal to within ±1/2LSB.

The temperature-compensated buried zener reference provides the primary voltage reference to the DAC and guarantees excellent stability with both time and temperature. The reference is trimmed to 10.00 volts ±1%; it can supply up to 1.5mA to an external load in addition to the requirements of the reference input resistor (0.5mA) and bipolar offset resistor (1mA) when the AD674A is powered from ±15V supplies. If the AD674A is used with ±12V supplies, or if external current must be supplied over the full temperature range, an external buffer amplifier is recommended. Any external load on the AD674A reference must remain constant during conversion. The thin film application resistors are trimmed to match the full-scale output current of the DAC. There are two 5kΩ input scaling resistors to allow either a 10 volt or 20 volt span. The 10kΩ bipolar offset resistor is grounded for unipolar operation and connected to the 10 volt reference for bipolar operation.

DRIVING THE AD674A ANALOG INPUT

The AD674A is a successive-approximation analog-to-digital converter. During the conversion cycle, the ADC input current is modulated by the DAC test current at approximately a 1MHz rate. Thus it is important to recognize that the signal source driving the AD674A must be capable of holding a constant output voltage under dynamically-changing load conditions.

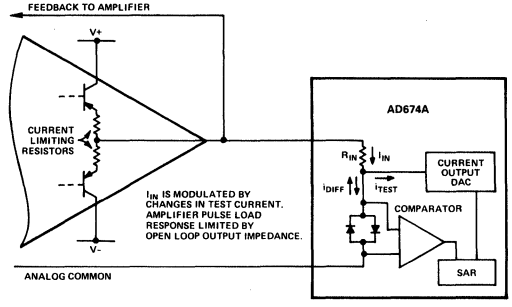

Figure 2. Op Amp – AD674A Interface

The closed-loop output impedance of an op amp is equal to the open-loop output impedance (usually a few hundred ohms) divided by the loop gain at the frequency of interest. It is often assumed that the loop gain of a follower-connected op amp is sufficiently high to reduce the closed-loop output impedance to a negligibly small value, particularly if the signal is low frequency. However, the amplifier driving an AD674A must either have sufficient loop gain at 1MHz to reduce the closed-loop output impedance to a low value or have low open-loop output impedance. This can be accomplished by using a wideband op amp, such as the AD711.

If a sample-hold amplifier is required, the monolithic AD585 is recommended. Its output buffer will drive the AD674A input directly.

SUPPLY DECOUPLING AND LAYOUT CONSIDERATIONS

It is critically important that the AD674A power supplies be filtered, well regulated, and free from high frequency noise. Use of noisy supplies will cause unstable output codes. Switching power supplies are not recommended for circuits attempting to achieve 12-bit accuracy unless great care is used in filtering any switching spikes present in the output. Remember that a few millivolts of noise represents several counts of error in a 12-bit ADC.

Decoupling capacitors should be used on all power supply pins; the +5V supply decoupling capacitor should be connected directly from Pin 1 to Pin 15 (digital common) and the $+V_{CC}$ and $-V_{EE}$ pins should be decoupled directly to analog common (Pin 9). A suitable decoupling capacitor is a 4.7μF tantalum type in parallel with a 0.1μF disc ceramic type.

Circuit layout should attempt to locate the AD674A, associated analog input circuitry, and interconnections as far as possible from logic circuitry. For this reason, the use of wire-wrap circuit construction is not recommended. Careful printed-circuit construction is preferred.

UNIPOLAR RANGE CONNECTIONS FOR THE AD674A

The AD674A contains all the active components required to perform a complete 12-bit A/D conversion. Thus, for most situations, all that is necessary is connection of the power supplies (+5, +12/+15 and −12/−15 volts), the analog input, and the conversion initiation command, as discussed on the next page.

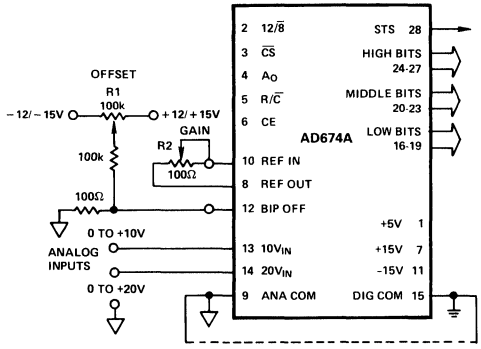

Figure 3. Unipolar Input Connections

All of the thin-film application resistors of the AD674A are trimmed for absolute calibration. Therefore, in many applications, no calibration trimming will be required. The absolute accuracy for each grade is given in the specification tables. For example, if no trims are used, the AD674A guarantees ±2LSB max zero offset error and ±0.25% (10LSB) max full scale error. If the offset trim is not required, Pin 12 can be connected directly to Pin 9; the two resistors and trimmer for Pin 12 are then not needed. If the full-scale trim is not required, a 50Ω ±1% metal film resistor should be connected between Pin 8 and Pin 10.

The analog input is connected between Pins 13 and 9 for a 0 to +10V input range, between Pins 14 and 9 for a 0 to +20V input range. The AD674A easily accommodates input signals beyond the supplies. For the 10 volt span input, the LSB has a nominal value of 2.44mV; for the 20 volt span, 4.88mV. If a 10.24V range is desired (nominal 2.5mV/bit), the gain trimmer (R2) should be replaced by a 50Ω resistor, and a 200Ω trimmer inserted in series with the analog input to Pin 13 (for a full-scale range of 20.48V (5mV/bit), use a 500Ω trimmer into Pin 14). The gain trim described below is now done with these trimmers. The nominal input impedance into Pin 13 is 5kΩ, and 10kΩ into Pin 14.

UNIPOLAR CALIBRATION

The connections for unipolar ranges are shown in Figure 3. The AD674A is trimmed to a nominal 1/2LSB offset so that the exact analog input for a given code will be in the middle of that code (halfway between the transitions to the codes above and below it). Thus, when properly calibrated, the first transition (from 0000 0000 0000 to 0000 0000 0001) will occur for an input level of +1/2LSB (1.22mV for 10V range).

If Pin 12 is connected to Pin 9, the unit will behave in this manner, within specifications. If the offset trim (R1) is used, it should be trimmed as above, although a different offset can be set for a particular system requirement. This circuit will give approximately ±15mV of offset trim range.

The full-scale trim is done by applying a signal 1 1/2LSB below the nominal full scale (9.9963 for a 10V range). Trim R2 to give the last transition (1111 1111 1110 to 1111 1111 1111).

BIPOLAR OPERATION

The connections for bipolar ranges are shown in Figure 4. Again, as for the unipolar ranges, if the offset and gain specifications are sufficient, one or both of the trimmers shown can be replaced by a 50Ω ±1% fixed resistor. The analog input is applied as for the unipolar ranges. Bipolar calibration is similar to unipolar calibration. First, a signal ½LSB above negative full scale (−4.9988V for the ±5V range) is applied and R1 is trimmed to give the first transition (0000 0000 0000 to 0000 0000 0001). Then a signal 1½LSB below positive full scale (+4.9963V for the ±5V range) is applied and R2 trimmed to give the last transition (1111 1111 1110 to 1111 1111 1111).

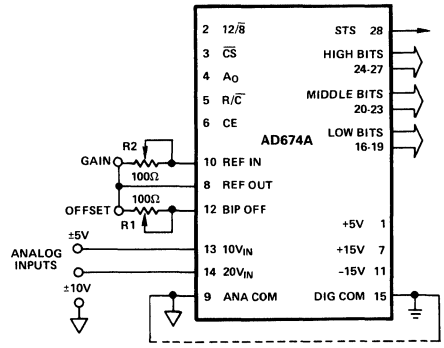

Figure 4. Bipolar Input Connections

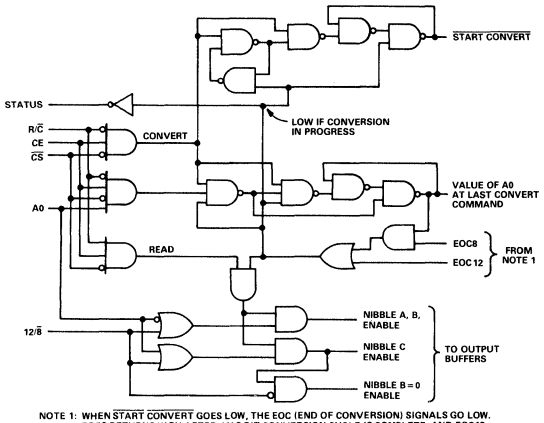
GROUNDING CONSIDERATIONS

The analog common at Pin 9 is the ground reference point for the internal reference and is thus the "high quality" ground for the AD674A; it should be connected directly to the analog reference point of the system. In order to achieve all of the high accuracy performance available from the AD674A in an environment of high digital noise content, it is required that the analog and digital commons be connected together at the package. In some situations, the digital common at Pin 15 can be connected to the most convenient ground reference point; digital power return is preferred.

CONTROL LOGIC

The AD674A contains on-chip logic to provide conversion initiation and data read operations from signals commonly available in microprocessor systems. Figure 5 shows the internal logic circuitry of the AD674A.



NOTE 1: WHEN START CONVERT GOES LOW, THE EOC (END OF CONVERSION) SIGNALS GO LOW. EOC8 RETURNS HIGH AFTER AN 8-BIT CONVERSION CYCLE IS COMPLETE, AND EOC12 RETURNS HIGH WHEN ALL 12 BITS HAVE BEEN CONVERTED. THE EOC SIGNALS PREVENT DATA FROM BEING READ DURING CONVERSIONS.

Figure 5. AD674A Control Logic

The control signals CE, $\overline{CS}$, and R/$\overline{C}$ control the operation of the converter. The state of R/$\overline{C}$ when CE and $\overline{CS}$ are both asserted determines whether a data read (R/$\overline{C}$ = 1) or a convert (R/$\overline{C}$ = 0) is in progress. The register control inputs A_0 and 12/$\overline{8}$ control conversion length and data format. If a conversion is started with A_0 low, a full 12-bit conversion cycle is initiated. If A_0 is high during a convert start, a shorter 8-bit conversion cycle results. During data read operations, A_0 determines whether the three-state buffers containing the 8 MSBs of the conversion result (A_0 = 0) or the 4 LSBs (A_0 = 1) are enabled. The 12/$\overline{8}$ pin determines whether the output data is to be organized as two 8-bit words (12/$\overline{8}$ tied to DIGITAL COMMON) or a single 12-bit word (12/$\overline{8}$ tied to V_{LOGIC}). In the 8-bit mode, the byte addressed when A_0 is high contains the 4 LSBs from the conversion followed by four trailing zeroes. This organization allows the data lines to be overlapped for direct interface to 8-bit buses without the need for external three-state buffers.

An output signal, STS, indicates the status of the converter. STS goes high at the beginning of a conversion and returns low when the conversion cycle is complete.

CE	$\overline{CS}$	R/$\overline{C}$	12/$\overline{8}$	A_0	Operation
0	X	X	X	X	None
X	1	X	X	X	None
1	0	0	X	0	Initiate 12-Bit Conversion
1	0	0	X	1	Initiate 8-Bit Conversion
1	0	1	1	X	Enable 12-Bit Parallel Output
1	0	1	0	0	Enable 8 Most Significant Bits
1	0	1	0	1	Enable 4LSBs + 4 Trailing Zeroes

Table I. AD674A Truth Table

TIMING

The AD674A is easily interfaced to a wide variety of microprocessors and other digital systems. Discussion of the timing requirements of the AD674A control signals will provide the system designer with useful insight into the operation of the device.

Figure 6 shows a complete timing diagram for the AD674A convert start operation. R/$\overline{C}$ should be low before both CE and $\overline{CS}$ are asserted; if R/$\overline{C}$ is high, a read operation will momentarily occur, possibly resulting in system bus contention. Either CE or $\overline{CS}$ may be used to initiate a conversion. As shown in Figure 6, CE is used. Note that CE includes one less propagation delay than $\overline{CS}$ and is therefore the faster input.

Once a conversion is started and the STS line goes high, convert start commands will be ignored until the conversion cycle is complete. The output data buffers cannot be enabled during conversion.

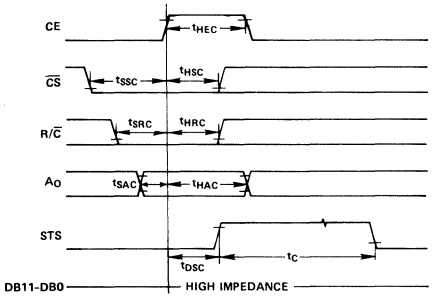


Figure 6. Convert Start Timing

CONVERT START TIMING – FULL CONTROL MODE

Symbol	Parameter	Min	Typ	Max	Units
t_{DSC}	STS Delay from CE			200	ns
t_{HEC}	CE Pulse Width	50			ns
t_{SSC}	$\overline{CS}$ to CE Setup	50			ns
t_{HSC}	$\overline{CS}$ Low During CE High	50			ns
t_{SRC}	R/$\overline{C}$ to CE Setup	50			ns

"STAND-ALONE" OPERATION

The AD674A can be used in a "stand-alone" mode, which is useful in systems with dedicated input ports available and thus not requiring full bus interface capability.

In this mode, CE and 12/$\overline{8}$ are wired high, $\overline{CS}$ and A_0 are wired low, and conversion is controlled by R/$\overline{C}$. The three-state buffers are enabled when R/$\overline{C}$ is high and a conversion starts when R/$\overline{C}$ goes low. This gives rise to two possible control signals–a high pulse or a low pulse. Operation with a low pulse is shown in Figure 10. In this case, the outputs are forced into the high-impedance state in response to the falling edge of R/$\overline{C}$ and return to valid logic levels after the conversion cycle is completed. The STS line goes high 200ns after R/$\overline{C}$ goes low and returns low 600ns after data is valid.

If conversion is initiated by a high pulse as shown in Figure 11, the data lines are enabled during the time when R/$\overline{C}$ is high. The falling edge of R/$\overline{C}$ starts the next conversion and the data lines return to three-state (and remain three-state) until the next high pulse of R/$\overline{C}$.

t_{DDR}	Data Access Time			150	ns

GENERAL A/D CONVERTER INTERFACE CONSIDERATIONS

A typical A/D converter interface routine involves several operations. First, a write to the ADC address initiates a conversion. The processor must then wait for the conversion cycle to complete, since most integrated circuit ADCs take longer than one instruction cycle to complete a conversion. Valid data can, of course, only be read after the conversion is complete. The AD674A provides an output signal (STS) which indicates when a conversion is in progress. This signal can be polled by the processor by reading it through an external three-state buffer (or other input port). The STS signal can also be used to generate an interrupt upon completion of conversion, if the system timing requirements are critical (bear in mind that the maximum conversion time of the AD674A is only 15 microseconds) and the processor has other tasks to perform during the ADC conversion cycle. Another possible time-out method is to assume that the ADC will take 15 microseconds to convert, and insert a sufficient number of "no-op" instructions to ensure that 15 microseconds of processor time is consumed.

Once conversion is complete, the data can be read. For converters with more data bits than are available on the bus, a choice of data formats is required, and multiple read operations are needed. The AD674A includes internal logic to permit direct interface to 8-bit and 16-bit data buses, selected by the state of the 12/$\overline{8}$ input. In 16-bit bus applications (12/$\overline{8}$ high) the data lines (DB11 through DB0) may be connected to either the 12 most significant or 12 least significant bits of the data bus. The remaining four bits should be masked in software. The interface to an 8-bit data bus (12/$\overline{8}$ low) is done in a left-justified format. The even address (A0 low) contains the 8MSBs (DB11 through DB4). The odd address (A0 high) contains the 4LSBs (DB3 through DB0) in the upper half of the byte, followed by four trailing zeroes, thus eliminating bit masking instructions.

It is not possible to rearrange the AD674A data lines for right-justified 8-bit bus interface.

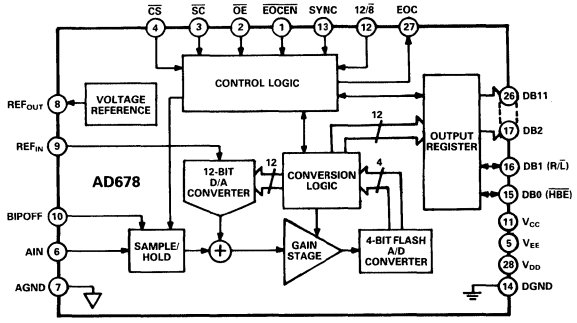
12-Bit 200 KSPS Complete Sampling ADC

AD678

FEATURES
AC and DC Characterized and Specified
200k Conversions per Second
1 MHz Full Power Bandwidth
500 kHz Full Linear Bandwidth
72 dB S/N+D (K Grade)
Twos Complement Data Format (Bipolar Mode)
Straight Binary Data Format (Unipolar Mode)
10 MΩ Input Impedance
8-Bit or 16-Bit Bus Interface
On-Board Reference and Clock
10 V Unipolar or Bipolar Input Range

AD678 FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD678 is a complete, multipurpose 12-bit monolithic analog-to-digital converter, consisting of a sample-hold amplifier (SHA), a microprocessor compatible bus interface, a voltage reference and clock generation circuitry.

The AD678 is similar to the AD1678 in that it is specified for ac (or "dynamic") parameters such as S/N+D ratio, THD and IMD which are important in signal processing applications. In addition, the AD678 is fully specified for dc parameters which are important in measurement applications.

The AD678 offers a choice of digital interface formats; the 12 data bits can be accessed by a 16-bit bus in a single read operation or by an 8-bit bus in two read operations (8+4), with right or left justification. Data format is straight binary for unipolar mode and twos complement binary for bipolar mode. The input has a full-scale range of 10 V with a full power bandwidth of 1 MHz and a full linear bandwidth of 500 kHz. High input impedance (10 MΩ) allows direct connection to unbuffered sources without signal degradation.

This product is fabricated on Analog Devices' BiMOS process, combining low power CMOS logic with high precision, low noise bipolar circuits; laser-trimmed thin-film resistors provide high accuracy. The converter utilizes a recursive subranging algorithm which includes error correction and flash converter circuitry to achieve high speed and resolution.

The AD678 operates from +5 V and ±12 V supplies and dissipates 745 mW. A 28-pin plastic DIP and a 0.6″ wide ceramic DIP are available. Contact factory for surface-mount package options.

Screening to MIL-STD-883C Class B is also available.

PRODUCT HIGHLIGHTS

1. COMPLETE INTEGRATION: The AD678 minimizes external component requirements by combining a high speed sample-hold amplifier (SHA), ADC, 5 V reference, clock and digital interface on a single chip. This provides a fully specified sampling A/D function unattainable with discrete designs.
2. SPECIFICATIONS: The AD678 is specified for both dc and ac parameters. DC specifications (such as INL, gain and offset) are important in control and measurement applications. AC specifications (such as S/N+D ratio, THD and IMD) are of value in signal processing applications.
3. EASE OF USE: The pinout is designed for easy board layout, and the choice of single or two read cycle output provides compatibility with 16- or 8-bit buses. Factory trimming eliminates the need for calibration modes or external trimming to achieve rated performance.
4. RELIABILITY: The AD678 utilizes Analog Devices' monolithic BiMOS technology. This ensures long term reliability compared to multichip and hybrid designs.

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

CONVERSION CONTROL

In synchronous mode (SYNC = HIGH), both Chip Select ($\overline{CS}$) and Start Convert ($\overline{SC}$) must be brought LOW to start a conversion. $\overline{CS}$ should be LOW t_{SC} before $\overline{SC}$ is brought LOW. In asynchronous mode (SYNC = LOW), a conversion is started by bringing $\overline{SC}$ low, regardless of the state of $\overline{CS}$.

Before a conversion is started, End-of-Convert (EOC) is HIGH, and the sample-hold is in track mode. After a conversion is started, the sample-hold goes into hold mode and EOC goes LOW, signifying that a conversion is in progress. During the conversion, the sample-hold will go back into track mode and start acquiring the next sample. EOC goes HIGH when the conversion is finished.

In track mode, the sample-hold will settle to ±0.01% (12 bits) in 1 μs maximum. The acquisition time does not affect the throughput rate as the AD678 goes back into track mode more than 1 μs before the next conversion. In multichannel systems, the input channel can be switched as soon as EOC goes LOW if the maximum throughput rate is needed.

END-OF-CONVERT

In asynchronous mode, End-of-Convert (EOC) is an open drain output (requiring a minimum 3 kΩ pull-up resistor) enabled by End-of-Convert ENable ($\overline{EOCEN}$). In synchronous mode, EOC is a three-state output which is enabled by $\overline{EOCEN}$ and $\overline{CS}$. See the Conversion Status Truth Table for details. Access (t_{BA}) and float (t_{FD}) timing specifications do not apply in asynchronous mode where they are a function of the time constant formed by the 10 pF output capacitance and the pull-up resistor.

12-BIT MODE CODING FORMAT (1 LSB = 2.44 mV)

Unipolar Coding (Straight Binary)		Bipolar Coding (Twos Complement)	
V_{IN}	Output Code	V_{IN}	Output Code
0	000 . . . 0	−5.000 V	100 . . . 0
5.000 V	100 . . . 0	−0.002 V	111 . . . 1
9.9964 V	111 . . . 1	0	000 . . . 0
		+2.500 V	010 . . . 0
		+4.9964 V	011 . . . 1

0 = LOW voltage level.
X = Don't care.
↓ = HIGH to LOW transition. Must stay low for t = t_{CP}.

CONVERSION STATUS TRUTH TABLE

	INPUTS			OUTPUT	
	SYNC	$\overline{CS}$	$\overline{EOCEN}$	EOC	STATUS
Synchronous Mode	1	0	0	0	Converting
	1	0	0	1	Not Converting
	1	1	X	High Z	Either
	1	X	1	High Z	Either
Asynchronous Mode*	0	X	0	0	Converting
	0	X	0	High Z	Not Converting
	0	X	1	High Z	Either

NOTES
1 = HIGH voltage level.
0 = LOW voltage level.
X = Don't care.
*EOC requires a pull-up resistor in asynchronous mode.

OUTPUT ENABLE OPERATION

The data bits (DB11–DB0) are three-state outputs enabled by Chip Select ($\overline{CS}$) and Output Enable ($\overline{OE}$). $\overline{CS}$ should be LOW t_{OE} before $\overline{OE}$ is brought LOW. Bits DB1 (R/$\overline{L}$) and DB0 ($\overline{HBE}$) are bidirectional. In 12-bit mode they are data output bits. In 8-bit mode they are inputs which define the format of the output register.

In unipolar mode (BIPOFF tied to AGND), the output coding is straight binary. In bipolar mode (BIPOFF tied to REF_{OUT}), output coding is twos complement binary.

When EOC goes HIGH, the output register contains the results of the previous conversion. A period of time t_{UD} is required for the present conversion results to be loaded into the output register. Bringing $\overline{OE}$ LOW t_{OE} after $\overline{CS}$ goes LOW makes the output register contents available on the data bits. A period of time t_{CD} is required after $\overline{OE}$ is brought HIGH before the next $\overline{SC}$ instruction is issued. This allows internal logic states to reset and guarantees minimum aperture jitter for the next conversion.

Output Enable ($\overline{OE}$) must be toggled to update the output register in both 8- and 12-bit read modes.

Figure 4 illustrates the 8-bit read mode (12/$\overline{8}$ = LOW), where only DB11–DB4 are used as output lines onto an 8-bit bus. The output is read in two steps, with the high byte read first, followed by the low byte. High Byte Enable ($\overline{HBE}$) controls the output sequence. The 12-bit result can be right or left justified depending on the state of R/$\overline{L}$. Note that for S and T grades, the 8-bit read mode results in a conversion rate of 5.23 µs.

In 12-bit read mode (12/$\overline{8}$ = HIGH), a single READ operation accesses all 12 output bits on DB11–DB0 for interface to a 16-bit bus. Figure 5 provides the output timing relationships. Note that t_{CR} must be ovserved, in that $\overline{SC}$ pulses should not be issued at intervals closer than 5 µs. If $\overline{SC}$ is asserted sooner than 5 µs, conversion accuracy may deteriorate. For this reason, $\overline{SC}$ should not be held LOW in an attempt to operate in a continuous convert mode.

POWER-UP

A conversion sequence, consisting of one $\overline{SC}$ instruction, is required after power-up to reset internal logic.

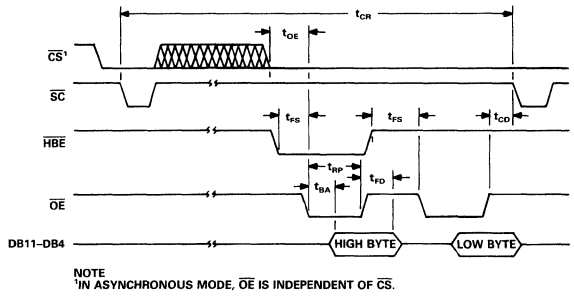

Figure 4. Output Timing, 8-Bit Read Mode
