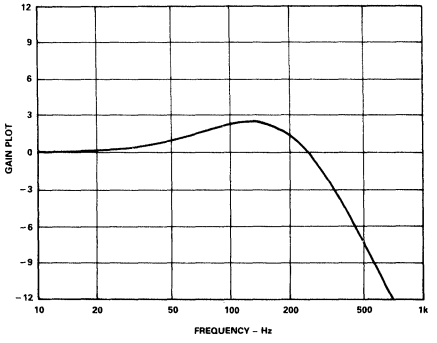

Figure 9

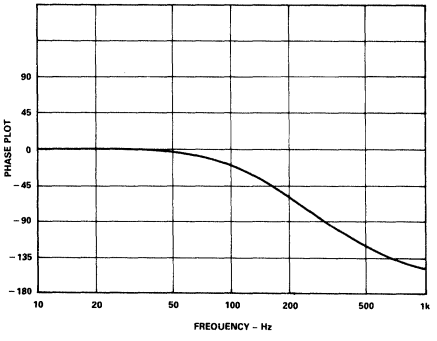

Figure 10

ACCELERATION ERROR

A tracking converter like the 1S20 employing a type 2 servo loop does not suffer any velocity lag, however, there is an additional error due to acceleration. This additional error can be defined using the acceleration constant K_a of the converter.

$$K_a = \frac{\text{Input acceleration}}{\text{Error in output angle}}$$

The numerator and denominator have the same units. K_a does not define maximum acceleration only the error due to acceleration, maximum acceleration is in the region of 10 times the K_a figure (deg/sec^2).

An example using the K_a of the 1S60/560

Acceleration of 33 revolutions sec^{-2} with K_a = 713,000

Additional error = 1 arc-min

DYNAMIC ACCURACY VS. RESOLVER PHASE SHIFT

Most resolvers, particularly those of the brushless type, exhibit a phase shift between the signal and the reference. This phase shift will give rise under dynamic conditions to an additional error defined by:

$$\frac{\text{Shaft Speed (RPS)} \times \text{Phase Shift (DEGS)}}{\text{Reference Frequency}}$$

For example, for a phase shift of 20°, a shaft rotation of 22rps and a reference frequency of 5kHz, the converter will exhibit an additional error of:

$$\frac{20 \times 22}{5000} = 0.088°$$

This effect can be eliminated by putting a phase shift in the reference to the converter equivalent to the phase shift in the resolver.

PROCESSING FOR HIGH RELIABILITY

STANDARD PROCESSING

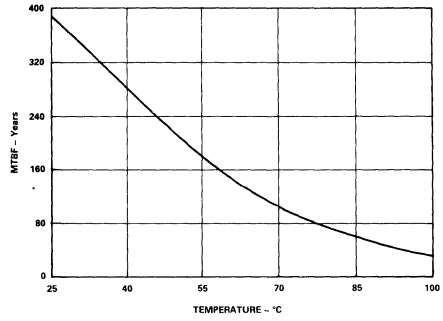
As part of the standard manufacturing procedure, all converters receive the following processing:

Process	Condition
1. Pre-Cap Visual Inspection	In-House Criteria
2. Burn-In	70°C
3. Constant Acceleration	5000G
4. Gross Leak Test	In-House Criteria
5. Final Electrical Test	Performed at 25°C

MEAN TIME BETWEEN FAILURES (MTBF)

The reliability of these products is very high due to the extensive use of custom chip circuitry. For details of MTBF figures under particular conditions please consult the factory.

The graph below shows the typical variation of MTBF with temperature for the 1S20, under ground benign environment.



5

ABSOLUTE MAXIMUM INPUTS (with respect to GND)

$+V_S$[1]	0V to +17V dc
$-V_S$[1]	0V to −17V dc
$+5V$[2]	0V to +7.0V dc
Reference	±17V dc
Sine	±17V dc
Cosine	±17V dc
Any Logical Input	−0.4V to +5.5V dc

CAUTION:

1. Correct polarity voltages must be maintained on the $+V_S$ and $-V_S$ pins.
2. The +5 volt power supply must *never* go below GND potential.

1S74

FEATURES
- **40-Pin Hybrid**
- **Tachogenerator Velocity Output**
- **User Selectable Resolution**
- **DC Error Output**
- **Sub LSB Output**
- **Angle Offset Input**
- **Reference Frequency of 2kHz to 10kHz**
- **Logic Outputs for Extension Pitch Counter**

APPLICATIONS
- **Numerical Control of Machine Tools**
- **Feed Forward Velocity Stabilizing Loops**
- **Robotics**
- **Closed Loop Motor Drives**
- **Brushless Tachometry**
- **Single Board Controllers**

GENERAL DESCRIPTION

The 1S74 is a hybrid device that converts standard resolver inputs to digital position and analog velocity outputs. All the essential features of multiturn or multipitch operation are included for numerically controlled machine tool and velocity feedback applications.

Typically, the input signal would be obtained from a brushless resolver and the resolver/converter combination gives a parallel absolute angular output word similar to that provided by an absolute encoder. The ratiometric conversion principle of the 1S74 ensures high noise immunity and tolerance of lead length when the converter is at a distance from the resolver.

In conjunction with the IPA1764 preamplifier, the 1S74 is also suitable for use with Inductosyns®.

The output word is in three-state digital logic form with a high and low byte enable input so that the converter can communicate with an 8- or 16-bit digital highway.

A unique feature of the converter is its internally generated tachogenerator velocity output offering a linear voltage-speed relationship. Only one external resistor is required to scale the velocity output to the user's chosen volts/rpm relationship.

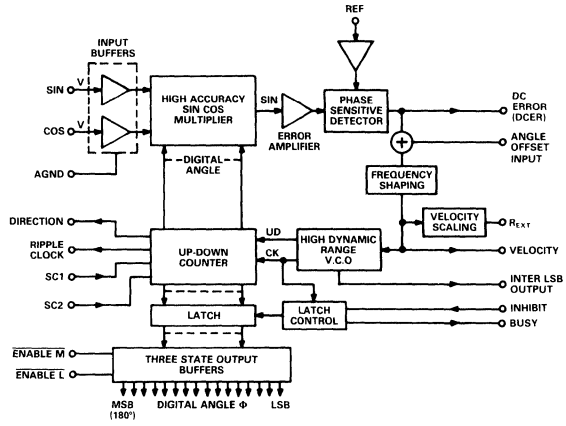
Repeatability is 1LSB under constant temperature conditions.

The resolution of the 1S74 converter is user selectable by means of applying a specific binary code to two of the converter's pins.

Four resolutions can be selected, all operating over a frequency range of 2kHz to 10kHz.

10 bit up to 40,800 revolutions per minute.
12 bit up to 10,200 revolutions per minute.
14 bit up to 2,550 revolutions per minute.
16 bit up to 630 revolutions per minute.

1S74 FUNCTIONAL BLOCK DIAGRAM



APPLICATIONS

The 1S74 has been designed for motor position control in the CNC, robotic and military fields. The use of a type 2 tracking servo loop circuit with high inherent noise immunity, makes the product ideally suited to these applications.

USER BENEFITS

Allows both velocity and position measurement from a single, low cost, standard, brushless resolver.

80dB dynamic range of velocity output.

0.5% ripple on velocity signal.

0.1% linearity of velocity signal.

Cost effective tachogenerator/encoder replacement.

Tracks at 5 to 10 times the rate of equivalent resolution encoders.

Analog output for interpolation between digital codes.

Direction and Ripple Clock (Datum) outputs facilitate revolution counting.

Hybrid construction offering small size and MTBF of >200 years at 50°C GB.

MIL operating temperature range and spec. options available.

Inductosyn® is a registered trademark of Farrand Industries, Inc.

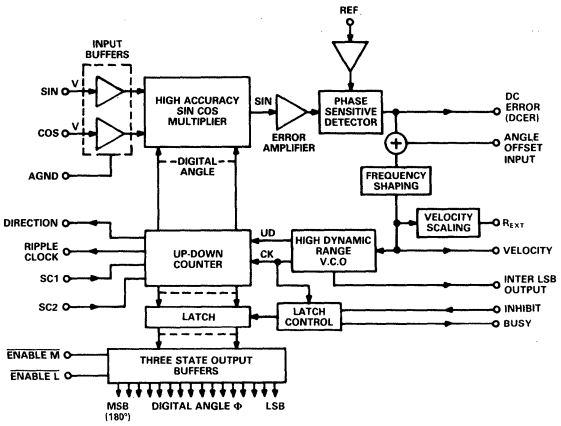
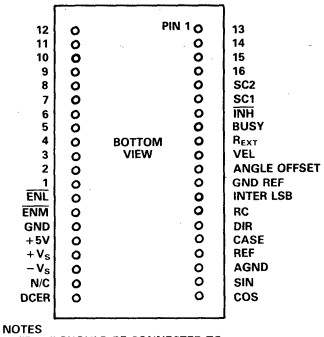
CAUTION:

1. Correct polarity voltages must be maintained on the $+V_S$ and $-V_S$ pins.
2. The +5 volt power supply must *never* go below GND potential.

FUNCTIONAL DIAGRAM



PIN CONNECTIONS



NOTES
1. "R_{EXT}" SHOULD BE CONNECTED TO "VEL" FOR UNITY GAIN.
2. CASE PIN CONNECTED ON 460 OPTION ONLY

OPERATION OF THE CONVERTER

The 1S74 is a tracking converter, this means that the output automatically follows the input for speeds up to the maximum tracking rate for the resolution option. No convert command is necessary as the conversion is initiated by each LSB increment of the input. Each LSB increment of the converter initiates a BUSY pulse.

POSITION OUTPUT

The resolver shaft position is represented at the converter output by a natural binary parallel digital word.

The static angular accuracy quoted for each converter type is the worst case error that can occur over the full operating temperature range with the following input conditions:

a) Signal input amplitudes within 5% of the nominal values.

b) Signal and reference frequency within the specified operating range.

c) Phase shift between signal and reference less than 10 degrees.

d) Signal and reference waveform harmonic distortion less than 10 percent.

These test conditions are selected primarily to establish a repeatable acceptance test procedure which can be traced to national standards. In practice, the converters can be used well outside these operating conditions providing the following points are observed.

SIGNAL AMPLITUDE (SINE AND COSINE INPUTS)

The amplitude of the signal inputs should be maintained within 5% of the nominal values if full performance is required from the analog outputs and inputs of the converter such as velocity, inter LSB position and angle offset.

The digital position output is relatively insensitive to amplitude variation. Increasing the input signal levels by more than 10% will result in a dramatic loss in accuracy due to internal overload. Reducing level will result in a steady decline in accuracy. With the signal levels at 50% of the correct value the angular error will increase by an amount equivalent to 1.3LSB. At this level the repeatability will also degrade to 2LSB and the dynamic response will also change, since the K_a is proportional to signal level.

SIGNAL AND REFERENCE FREQUENCY

Any frequency within the specified range of the converter may be used. It should be noted that the signal and reference input voltages must be in resolver format.

REFERENCE VOLTAGE LEVEL

The amplitude and waveform of the reference signal applied to the converter's input is not critical, however it is essential that the zero crossing points are maintained in the correct place to drive the converter's phase sensitive detector.

HARMONIC DISTORTION

The amount of harmonic distortion allowable on the signal and reference lines mainly depends on the type of transducer being used.

Square and triangle waveforms can be used but the input levels should be adjusted so that the average value after rectification is 1.9 volts. (For example – a square wave should be 1.9V peak.)

NOTE: The figure specified of 10% harmonic distortion is for calibration convenience only.

PHASE SHIFT (BETWEEN SIGNAL AND REFERENCE)

See Section on "Dynamic Accuracy vs. Resolver Phase Shift".

RESOLUTION PROGRAMMING

The 1S74 converter can be programmed for resolutions of 10, 12, 14, and 16 bit by applying a binary code to the pins "SC1" and "SC2".

The dc error output and maximum revolutions per minute for full scale are scaled internally according to the particular resolution selected.

Table I gives the binary code, dc error output and maximum tracking rate for the resolutions available.

Resolution	Binary Code SC1	SC2	DC Error (mV/Bit)	Tracking Rate for FS (±10V) rpm
10 Bit	0	0	160	40,800
12 Bit	0	1	40	10,200
14 Bit	1	0	10	2,550
16 Bit	1	1	2.5	630

Table I.

NOTE: When changing resolution under dynamic conditions, a period of uncertainty will exist before position and velocity data is valid.

For more information ask for the relevant application note.

DATA TRANSFER

BUSY Output:

The validity of the output data is indicated by the state of the BUSY output. When the input to the converter is changing, the signal appearing on the BUSY output is a series of pulses of TTL levels. A BUSY pulse is initiated each time the input moves by the analog equivalent of an LSB and the internal counter is incremented or decremented.

$\overline{\text{INHIBIT}}$ Input:

The $\overline{\text{INHIBIT}}$ logic input only inhibits the data transfer from the up-down counter to the output latches and therefore, does not interrupt the operation of the tracking loop. Releasing the $\overline{\text{INHIBIT}}$ automatically generates a BUSY pulse to refresh the output data.

NOTE: With the $\overline{\text{INHIBIT}}$ input pin in the "Hi" TTL state, data will be transferred automatically to the output latches.

$\overline{\text{ENABLE}}$ Inputs:

Two $\overline{\text{ENABLE}}$ inputs are provided, $\overline{\text{ENABLE M}}$ for the most significant 8-bits and $\overline{\text{ENABLE L}}$ for the least significant remainder. These $\overline{\text{ENABLES}}$ determine the state of the output data. A TTL logic "Hi" maintains the output data pins in a high impedance condition, the application of a logic "Lo" presents the data in the latches to the output pins. The operation of these $\overline{\text{ENABLES}}$ has no effect on the conversion process.

Two methods are available for transferring data, by using the inputs and outputs described.

One method is to transfer data when the BUSY is in a "Lo" state or clock the data out on the trailing edge of the BUSY pulse. Both the $\overline{\text{INHIBIT}}$ and the $\overline{\text{ENABLES}}$ must be in their correct state of "Hi" and "Lo's" respectively.

The alternative method is to use the $\overline{\text{INHIBIT}}$ input. Data will always be valid one microsecond after the application of a logic "Lo" to the $\overline{\text{INHIBIT}}$. This is regardless of the time when the $\overline{\text{INHIBIT}}$ is applied.

RIPPLE CLOCK (RC) AND DIRECTION (DIR) OUTPUTS:

As the digital output of the converter passes through the major carry, i.e., all "1's" to all "0's" or the converse, a RIPPLE CLOCK (RC) logic output is initiated indicating that a revolution or a pitch of the input has been completed.

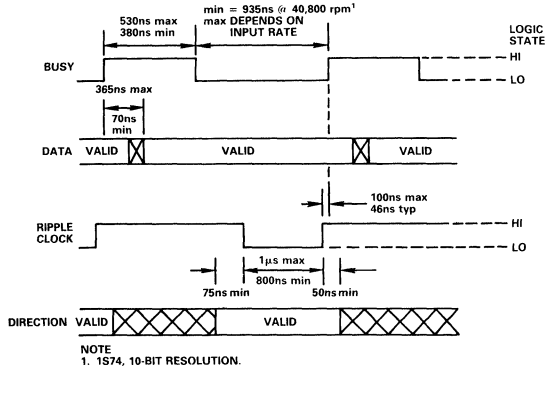


Figure 1. Timing Diagram

The DIRECTION (DIR) logic output indicates the direction of input rotation and this data is always valid in advance of the RIPPLE CLOCK pulse, and stays valid until the direction changes (see Timing Diagram).

These two logic outputs are provided so that the user can count the input revolutions or pitches. An external extension counter is required. Figure 2 shows the application circuit which should be used to perform this counting function.

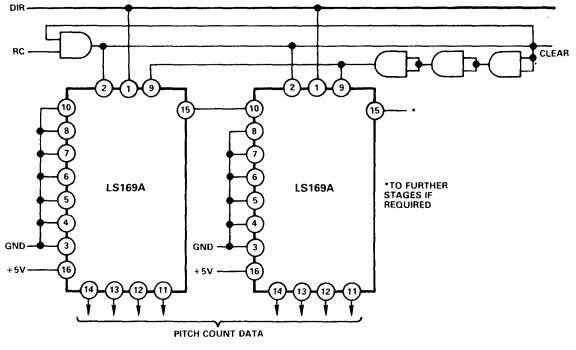

Figure 2. Connections for Use with LS Extension Counters

VELOCITY OUTPUT

The tracking conversion technique produces an internal signal at the input to the voltage controlled oscillator (VCO) that is proportional to the rate of the input angle. In the 1S74 additional circuitry is included to linearize this signal, which is closely characterized, producing a high quality tachogenerator velocity output at the VELOCITY (VEL) pin.

This analog tachogenerator velocity output is resistively scaled internally to give a full scale output of ±10V dc at the specified tracking rate for the converter.

However, a full scale output of ±10V dc can be obtained for lower speeds by changing the gain of the internal scaling amplifier using only an external resistor. The external resistor, R_{EXT}, should be connected between "R_{EXT}" pin and ground, and calculated using the following equation.

$$R_{EXT} = \frac{10 \times A}{B - A} \text{ k ohms}$$

Where A = required rpm to be represented by ±10V FS

B = specified rpm for the converter.

NOTE: A cannot be greater than B and for unity gain "VEL" and "R_{EXT}" pins should be linked.

Ripple and noise on the velocity signal consists of two components—steady state noise and dynamic noise.

Steady state noise—this is internally generated noise produced by the converter's circuitry and is the only noise signal present under static input conditions.

Dynamic noise—this is the noise produced, in addition to steady state noise, under dynamic operating conditions.

The two main components of the dynamic noise signal are due to the "non-zero" angular error of the resolver/converter combination. The figures given in the specification are typical for a size 11, 7 arc-minutes, brushless resolver.

It should be noted that when operating at low tracking rates it is critical to maintain the signal input voltage at its nominal value in order to keep the noise level on the velocity signal to an absolute minimum. The effect of variation in signal voltage at low tracking rates is to produce low energy spikes on the velocity output on the rising edge of the BUSY pulse. The amplitude of these spikes will be in the region of 30μV per percent variation in signal input voltage level.

NOTE: The velocity signal output and max tracking rate derates by 15% (max) for operation with ±12 volt power supplies.

SPECIAL FUNCTIONS

DC ERROR: The signal at the output of the phase sensitive detector is the input to the internal nulling loop and hence is proportional to the error between the input angle and the output digital angle. As the converters are a type 2 servo loop, this DC ERROR signal will increase if the output angle fails to track the input for any reason. It is therefore an indication that the input has exceeded the maximum tracking rate of the converter, or due to some internal malfunction, the converter is unable to reach a null. By the use of two external comparators this voltage can be used as a "built in test".

INTER LSB OUTPUT: In order to overcome the "free play" inherent in a servo system using digitized position feedback, an analog output voltage is available representing the resolver shaft position within the least significant bit of the digital angle output.

The output is therefore proportional to the inter LSB resolved position with a maximum output representing 1LSB.

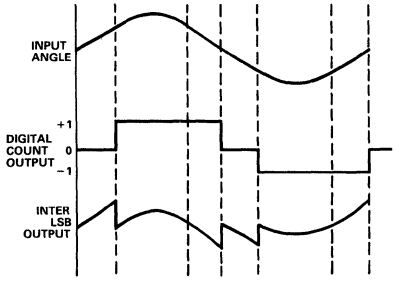

Figure 3.

Figure 3 illustrates how the INTER LSB output compensates for the instances where, due to hysteresis, there is no change in the digital count output for 1LSB change in input angle. The sum of the digital count output and INTER LSB output equals the actual input angle.

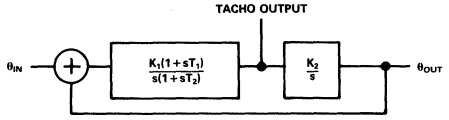
ANGLE OFFSET: A unique feature of the 1S74 converter is the angle offset input which allows the user to electrically "rotate" the input shaft of the resolver.

Injecting a current of 320nA into the angle offset input pin will offset the digital output of the converter by 1LSB relative to the angle defined by the resolver inputs. It is recommended that an offset equivalent to no greater than 30LSB's be applied to this input.

This input is a virtual ground, therefore a current source can be generated by a voltage source connected by a single resistor.

DYNAMIC PERFORMANCE

The transfer function of the converter is given below:



Positional Transfer Function:

$$\frac{\theta_{OUT}}{\theta_{IN}} = \frac{K_1 K_2}{s^2} \cdot \frac{1 + sT_1}{1 + sT_2} \text{ open loop}$$

$$\frac{\theta_{OUT}}{\theta_{IN}} = \frac{1 + sT_1}{1 + sT_1 + \frac{s^2}{K_1 K_2} + \frac{s^3 T_2}{K_1 K_2}} \text{ closed loop}$$

where $K_1K_2 = K_a$

Tachogenerator Transfer Function:

$$\frac{\text{Tachogenerator Output}}{\theta_{IN}} = \frac{K_1(1 + sT_1)}{s(1 + sT_2)} \text{ open loop}$$

$$\frac{\text{Tachogenerator Output}}{\theta_{IN}} = \frac{s(1 + sT_1)}{K_2(1 + sT_1) + \frac{s^2}{K_1} + \frac{s^3 T_2}{K_1}} \text{ closed loop}$$

Where: $K_1 = 3.23$
$K_2 = 68.2 \times 10^3$
$K_a = 220 \times 10^3$
$T_1 = 4.46\text{ms}$
$T_2 = 0.21\text{ms}$

Refer: Figures 4 and 5

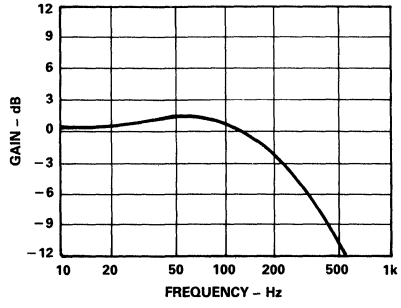


Figure 4. Gain Plot

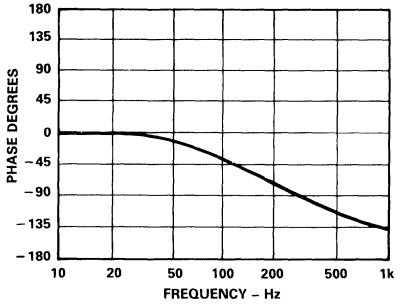

Figure 5. Phase Plot

DYNAMIC ACCURACY VS. RESOLVER PHASE SHIFT

Under static operating conditions phase shift between signal and reference lines theoretically does not affect the converter's static accuracy:

However, when rotating, most resolvers, particularly those of the brushless type, exhibit a phase shift between the signal and the reference. This phase shift will give rise under dynamic conditions, to an additional error defined by:

$$\frac{\text{SHAFT SPEED (RPS)} \times \text{Phase Shift (DEGS)}}{\text{Reference Frequency}}$$

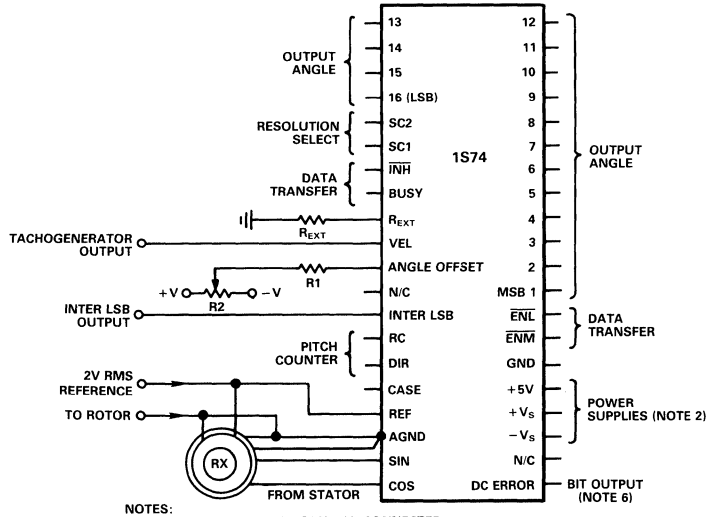
For example, for a phase shift of 20°, a shaft rotation of 22rps and a reference frequency of 5kHz, the converter will exhibit an additional error of:

$$\frac{20 \times 22}{5000} = 0.088°$$

This effect can be eliminated by putting a phase shift in the reference to the converter equivalent to the phase shift in the resolver.

NOTE: Capacitive and inductive crosstalk in the signal and reference leads and wiring can cause similar problems.

5



NOTES:
1. GND AND AGND ARE INTERNALLY CONNECTED.
2. EACH SUPPLY SHOULD BE DECOUPLED WITH 100nF CERAMIC CAPACITOR IN PARALLEL WITH A 6μF TANTALLUM CAPACITOR.
3. REXT IS EXTERNAL TACHOGENERATOR SENSITIVITY SCALING RESISTOR (IF REQUIRED) – SEE TEXT UNDER HEADING "VELOCITY OUTPUT".
4. R1 AND R2 ARE ANGLE OFFSET INPUT SCALING RESISTORS (IF REQUIRED) – SEE TEXT.
5. CASE PIN CONNECTED ON 460 OPTION ONLY.
6. POSSIBLE USE AS BUILT-IN TEST EQUIPMENT. (SEE HEADING "SPECIAL FUNCTIONS".)

Figure 6. Electrical Connections

CONNECTING THE CONVERTER

The electrical connection of the converter is straight-forward. The power supply voltages connected to $+V$, and $-V$, pins can be $\pm 12V$ to $\pm 15V$ but must not be reversed. The $+5V$ supply connects to the $+5V$ pin and should not be allowed to become negative with respect to the GND pin.

It is suggested that decoupling capacitors are connected in parallel between the power lines ($+V_s$, $-V_s$ and $+5V$) and GND adjacent to the converter.

When more than one converter is used on a card, then separate decoupling capacitors should be used for each converter.

The converter has some H/F decoupling provided internally, as well as input protection on the signal and reference inputs.

The resolver connections are made to the sine and cosine inputs, reference and analog ground as shown in the electrical connection diagram (Figure 6). The 2V rms reference supply, which can be provided by the OSC1758 oscillator, should be connected to the resolver rotor.

PROCESSING FOR HIGH RELIABILITY

STANDARD PROCESSING

As part of the standard manufacturing procedure, all converters receive the following processing:

Process	Condition
1. Pre-Cap Visual Inspection	In-House Criteria
2. Burn-In	70°C
3. Constant Acceleration	5000G
4. Gross Leak Test	In-House Criteria
5. Final Electrical Test	Performed at 25°C

HI-REL PROCESSING

All models ordered to high reliability requirements will be identified with a B suffix, and will have received the following processing:

1. Internal visual inspection
2. Stabilization bake, 24 hours at 150°C
3. Temperature cycling, −65°C to +150°C
4. Constant acceleration, 5000g
5. Powered burn-in, 160 hours at 125°C
6. Final electrical test at T_{min} and T_{max}
7. Seal test, fine and gross
8. External visual inspection

GENERAL DESCRIPTION

The 2S50 series converters translate the outputs from LVDT and RVDT transducers into digits directly. No signal conditioning, trims, preamplifiers, demodulators or filters are required. The 2S50 series can also be used as general purpose ratiometric A-to-D converters; very compatible with load cells, strain gauge bridges, some pressure transducers and interferometers.

The 2S50 linearly converts ac signals into an 11-bit parallel digital word. The digital output is an offset binary word which is the ratio of the signal and reference inputs. When used with LVDT and RVDT transducers, the digital output represents the linear or rotary displacements of the transducer. The converter is a continuous tracking type using a type 2 servo loop.

PRINCIPLE OF OPERATION

The 2S50 is a tracking converter. This means that the output automatically follows the input without the necessity of a convert command.

A conversion is initiated by a change of input signal equivalent to 1LSB of the output.

Each LSB increment of the output is indicated by a "Busy" pulse.

With an LVDT connected to give a null at center position, the output will track the input from digital "1 + all zeroes" to digital "all ones" for plus full scale, and digital "1 + all zeroes" to digital "all zeroes" for negative full scale.

The 2S50 operates only on the ratio of the two inputs for the conversion process. As such the whole system, consisting of excitation oscillator, LVDT and converter, is insensitive to change in excitation voltage, amplitude, frequency and waveshape.

Since a phase sensitive demodulator is included with the conversion loop of the 2S50, the system has a high rejection to signals that are not phase and frequency coherent with the excitation voltage. This feature, combined with ratiometric conversion gives a very high standard of integrity to digitized LVDT and RVDT systems.

PIN FUNCTION DESCRIPTION

$-V_S$	Main negative power supply -15V dc.
$+V_S$	Main positive power supply $+15$V dc.
$+5$V	Logic supply.
GND	Power supply ground. Digital ground. Reference voltage low.
Bit 1-11	Parallel output data bits.
Ref Hi	Analog reference input (Hi).
Diff Hi	Analog difference input (Hi).
Ref Lo	Analog reference input (Lo).
Diff Lo	Analog difference input (Lo).
$\overline{\text{INHIBIT}}$	Inhibit logic input. Taking this pin "Lo" inhibits data transfer from counter to output latches. The conversion loop continues to track.
BUSY	Converter BUSY. A "Hi" output indicates that the output latches are being updated. Data should not be transferred from the converter while BUSY is "Hi".
$\overline{\text{ENABLE}}$	The output data bits are set to a low impedance state by application of a logic "Lo".
CASE	This should normally be grounded. Case can be taken to any voltage with a low impedance up to ± 20V.
N/C	Pins designated N/C not connected internally.

High Resolution LVDT-to-Digital Converters

2S54/2S56/2S58

FEATURES

Direct Conversion of LVDT and RVDT Outputs into Digital Format
Ratiometric Conversion for Extremely High Stability
High Resolution (14-16 Bit) Parallel Digital Output
User Definable Input Gain
Quadrature Rejection
Operation Over 360 Hz to 11 kHz Frequency Range
Linearity Better than ±0.01%
Internal Bridge Completion Resistors
1 LSB Repeatability
75% Overrange Capability
Extended Temperature Range Versions

APPLICATIONS

Direct LVDT/RVDT-to-Digital Conversion
Industrial Measurement and Gauging
Valve and Actuator Control
Limit Sensing
Aircraft Control Systems
Semiconductor Wafer Profiling
AC-to-Digital Conversion

GENERAL DESCRIPTION

The 2S56 series of converters linearly converts the outputs of ac energized Linear and Rotary Variable Differential Transformers (LVDTs, RVDTs) directly into a high resolution digital format. For example, with a ±1 mm stroke LVDT, the least significant bit (LSB) of the 2S56 will represent 0.061 microns.

The 2S58, a high gain variant of the 2S56, can offer even higher positional resolution. Using the same ±1 mm stroke LVDT over a reduced range, the 2S58 can realize an LSB weighting of 1.22 nm.

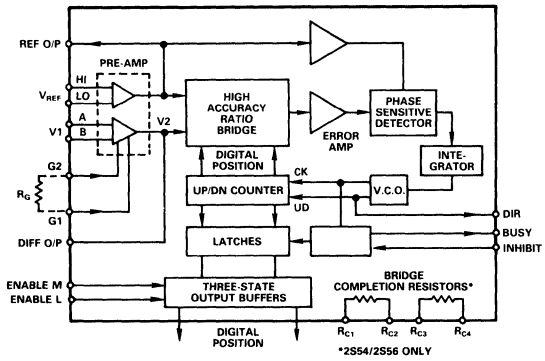
The ratiometric conversion technique employed by the converters obviates the need for high stability oscillators. The performance quoted for the devices can be achieved with as much as a ±10% variation in reference amplitude.

The converters are complete – no signal conditioning, preamplifiers or filters are required. The user need only supply a suitable reference oscillator.

The converters operate on a Type II, tracking, servo loop principle which means that the digital output continuously follows the transducer input without the need for external convert commands as in conventional A-to-D converters. The conversion technique also ensures that there is no lag between digital output and transducer input under constant velocity conditions.

To facilitate interfacing with various types of LVDTs and RVDTs, all inputs are fully differential. In addition, the converters have the flexibility of setting the input gain with a single

2S54, 2S56 AND 2S58 FUNCTIONAL BLOCK DIAGRAM



external resistor or link. In order to simplify the transducer interface, both the output of the gain stage as well as the reference voltage are brought out to enable simplified measurement.

The parallel digital output word is through tri-state drivers to enable direct connection to system data buses. Included is a High/Low byte enable which allows communication on both 8 and 16-bit busses. A separate line is provided to indicate the direction of transducer travel. A BUSY pulse is provided indicating that data is changing and not valid for transfer.

APPLICATIONS/USER BENEFITS

Because the 2S56 series of converters operates on the ratio of the transducer output signal to the excitation (reference) voltage, the entire measurement system is insensitive to changes in reference voltage, frequency and wave shape. The resulting stability makes conversion technique unrivaled, particularly in applications with poor voltage regulation.

The converters can also be connected in a mode which allows the 2S54/56/58 to be galvanically isolated from the excitation source. This configuration has the added benefit of minimizing the effect of phase shifts and signal input quadrature.

Because of the use of a phase sensitive demodulator in the tracking loop, the system has extremely high rejection of signals which are not phase and frequency coherent with the excitation voltage. The resulting noise immunity makes the converters an ideal choice for industrial and airborne applications.

The high precision of the conversion, together with the stability offered by ratiometric conversion, make the 2S56 series good candidates for applications previously beyond the capability of LVDTs. For example, the 2S58 can realize performance competitive with optical interferometric measurement systems.

NOTES

[1]Tested with nominal supply (±15 V dc, +5 V dc), reference/signal voltages and frequency.

[2]Guaranteed by design, test not required.

[3]V_1 is the signal input to the converter directly from the transducer. V_2 is the output of the internal gain stage. Because V_2 needs to be maintained at 2 V ±10% in order to meet the converter accuracy (see Note 5), the gain and the maximum value of V_1 should be carefully chosen. Furthermore, because the converter operates on the ratio of V_2 and V_{REF}, care should be taken to see these voltages are matched in order to achieve the full dynamic range of the converter.

[4]Maximum output current is 2.4 mA.

[5]Specified over the operating temperature range of the option and for:

a. ±10% difference in both V_{REF} and V_2 amplitudes

b. 10% harmonic distortion in V_{REF} and V_1.

c. The accuracy is specified for the preset gains of ×1, ×10, and ×50. For accuracy in the intermediate range, see Section "PHASE SHIFT AND QUADRATURE EFFECTS."

[6]Tested with input gains 1, 10 and 50 with V_1 attenuated by 1, 10 and 50, respectively.

[7]Full-Scale Range (FSR) is defined as $V_2 = +V_{REF}$ to $V_2 = -V_{REF}$. This would usually correspond to the utilized LVDT stroke.

[8]See Section 14 for package outline information.

*Specifications the same as the 2S54.

Specifications subject to change without notice.

MODELS AVAILABLE

The 2S56 series is available in three versions:

2S54	14-Bits	Input Gain	1–10
2S56	16-Bits	Input Gain	1–10
2S58	16-Bits	Input Gain	10–50

The 2S54 and 2S56 are available in two bandwidth options. The 50 Hz bandwidth option operates over the reference frequency range of 360 Hz to 5 kHz, while the 140 Hz bandwidth option operates over the range of 1 kHz to 5 kHz. The 2S58 is available only in a 300 Hz bandwidth version which operates with reference frequencies between 7 kHz and 11 kHz.

All three devices are available in both commercial (0 to +70°C) and military (−50°C to +125°C) operating temperature versions.

Full ordering information is given on the back page of this data sheet.

ABSOLUTE MAXIMUM RATINGS

$+V_S$ to GND	+17 V dc
$-V_S$ to GND	−17 V dc
V_{REF}	35 V p-p
$+V_L$ to GND	+7 V dc
V1	35 V p-p
Logical Input to GND (max)	+5.5 V dc
Logical Input to GND (min)	−0.4 V dc
Case to GND	±20 V dc
Power Dissipation	1.8 Watts
Junction Temperature	+150°C

CAUTION:

1. Absolute Maximum Ratings are the limits beyond which damage to the device may occur.
2. Correct polarity voltages must be maintained on the $+V_S$ and $-V_S$ pins.
3. The +5 V power supply must never go below GND.

PRINCIPLES OF OPERATION

The principle of operation is shown in Figure 1.

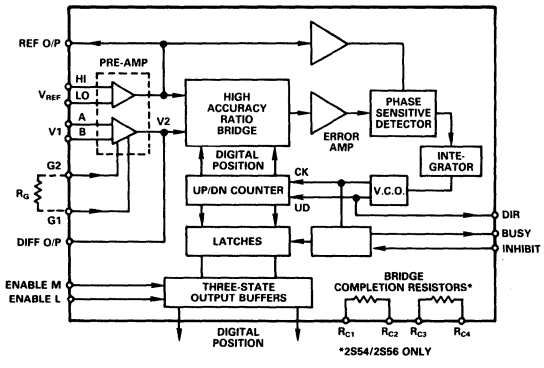

Figure 1. Principle of Operation of the 2S56 Series Converters

USING THE 2S56 SERIES CONVERTERS

The 2S56 series of converters operates on a tracking principle. This means that the output digital word always automatically represents the position of the LVDT or RVDT without the need for external convert commands and status wait loops. As the transducer moves through a position equivalent to 1 Least Significant Bit (LSB) on the output, the output digital word is automatically updated. Each LSB update initiates a BUSY pulse.

INPUT GAIN

Since the transformation ratio of an LVDT or RVDT from excitation voltage to signal voltage is typically in the order of 1:0.15, provision for gain scaling has been provided. The gain can, therefore, be selected to ensure that the full-scale output of the converter represents the maximum stroke position of the transducer.

The gain setting is accomplished by means of Pins 21 and 22 (G1 and G2). A link between the two pins gives a preset gain of ×10 (×50 on the 2S58) whereas no connections between them gives a preset gain of ×1 (×10 on the 2S58).

For intermediate gains a resistor should be connected between the pins (G1 and G2) according to the following equation:

$$G = \frac{R_1}{R_G + R_2} + G\infty$$

where R_G is the value of the external resistor in kΩ and G is the realized gain.

For the 2S54 and 2S56:

$R_1 = 27$ [kΩ]

$R_2 = 3$ [kΩ]

$G\infty = 1$

For the 2S58:

$R_1 = 108$ [kΩ]

$R_2 = 2.7$ [kΩ]

$G\infty = 10$

The internal resistors each have absolute accuracies of 0.02% at 25°C. Their absolute temperature coefficient is ±25 ppm/°C. Therefore, if the temperature coefficient and absolute accuracy of the external gain setting resistor, R_G, is known, the accuracy of the input gain stage can be calculated. This additional inaccuracy must be added to the gain error of the converter.

DIGITAL OUTPUT CODES

The 2S56 series of converters employs an offset binary output code, the null position of the LVDT being represented by the MSB being high and all other bits low. Representative digital output codes are shown in Figure 2. For the 2S54 (14-bit resolution), the two least significant bits are unused.

NOTE: A negative position is defined as being when the V1 and V_{REF} are out of phase. A positive position is when they are in phase.

OVERRANGE

The digital output code format shown in Figure 2 enables the user to determine if the LVDT has exceeded the negative or positive full-scale position and has gone into overrange. An indication of overrange can be obtained by performing an "exclusive OR" on Bits 1 and 2 (MSB and 2nd MSB). Alternatively this function can be performed in software.

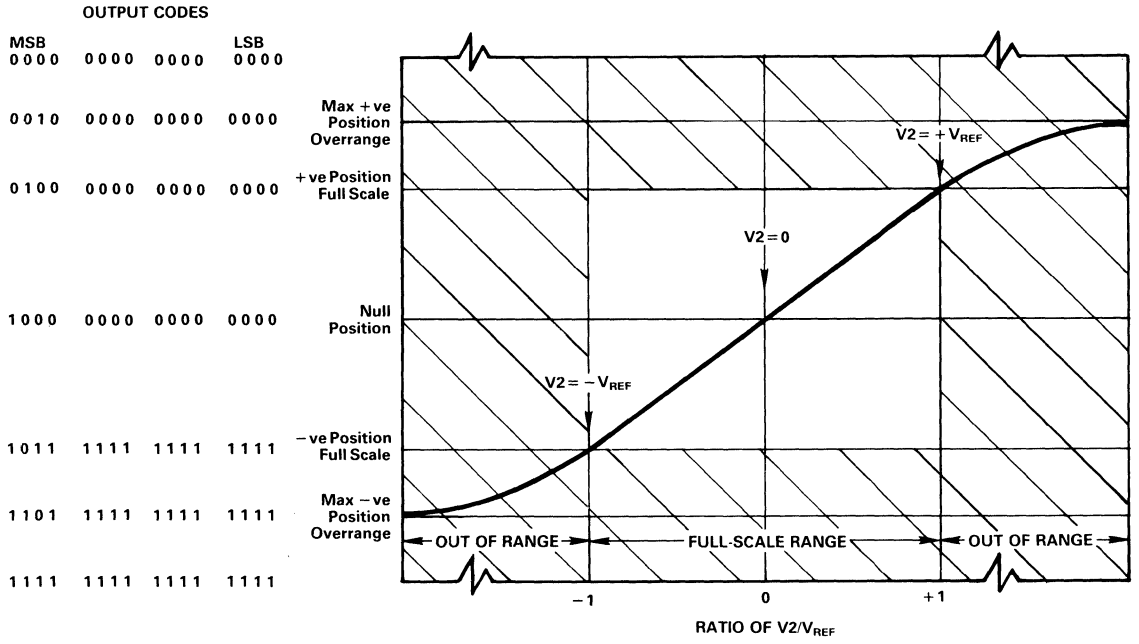

Figure 2. Output Code Format

PHASE SHIFT AND QUADRATURE EFFECTS

Reference to signal phase shift can be high in LVDTs, sometimes in the order of 70 degrees. If the converter is connected as in Figures 3 and 4, any effects due to this phase shift are minimized. This connection method, therefore, provides outstanding benefits.

The additional gain error caused by reference to signal phase shifts is given by:

$$(1 - \cos\theta) \times 100\% \text{ of } FSR$$

where

θ = phase shift between V_{REF} and V1.

When the phase shift between V_{REF} and V1 is zero, additional quadrature on the signal will have no effect on the converter. This is another benefit of the conversion method.

CONNECTING LVDTS

Since all input connections to 2S56 converters are truly differential, there is great flexibility in the input sensor connection configuration. Some of the various methods are shown in Figures 3, 4 and 5.

(It should be noted that a ground reference point should always be included and connected to either the V_{REF} or V1 inputs.)

It is suggested that decoupling capacitors be connected in parallel between the power supply lines ($+V_S$, $-V_S$, +5 V) and GND, adjacent to the converter. Suggested values are: 6.8 µF tantalum and 47 nF disc capacitors connected in parallel. When more than one converter is on a card, separate decoupling should be used for each converter, particularly the 47 nF capacitors.

The $+V_S$ and the $-V_S$ pins should be connected to dc power supplies of the appropriate polarity in the range of ±15 V ±5%. Care should be taken to ensure that the polarity can never become reversed. The +5 V pins should be connected to a +5 V ±5% dc supply. The +5 V supply must never be allowed to go negative with respect to ground.

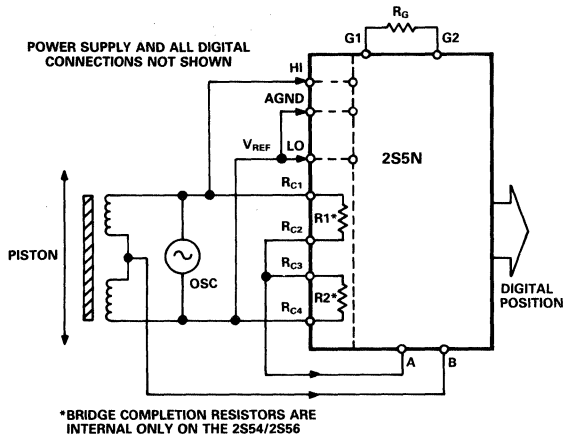

Figure 3. Half Bridge LVDT Connection

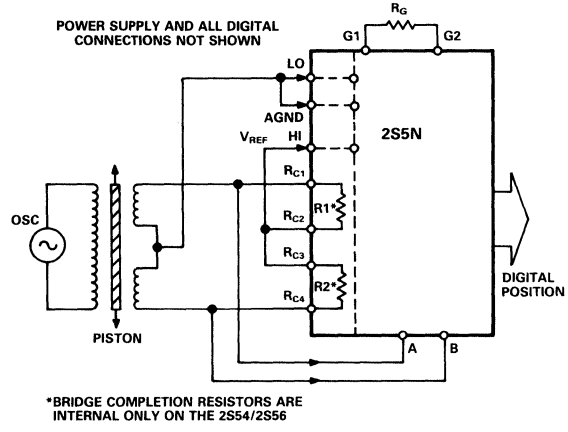

Figure 4. Three- or Four-Wire LVDT Connection

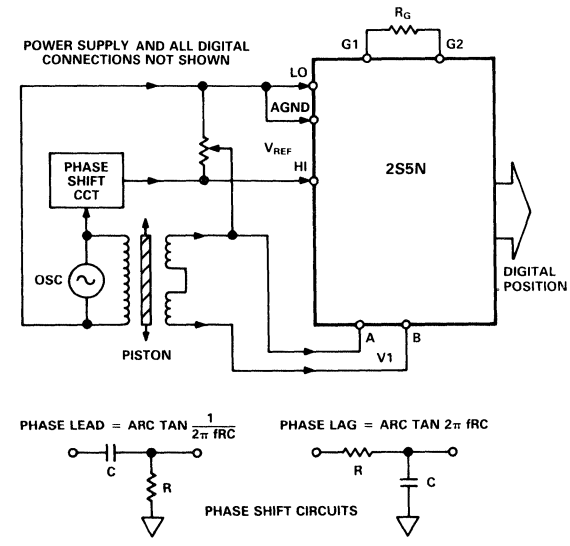

Figure 5. Two-Wire LVDT Connection

Half Bridge Type LVDT Connection

In this method of connection, shown in Figure 3, the internal bridge completion resistors, R1 and R2, in the 2S54 and 2S56 are used. If this configuration is used with the 2S58, external precision resistors must be employed. The "BRIDGE COMPLETION RESISTORS" in the SPECIFICATIONS section details the required precision. The internal resistors in the 2S54 and 2S56 have nominal values of 10 kΩ and are matched sufficiently to ensure that the null position of the LVDT is represented by the correct output code. The common connection between the two resistors (i.e., R_{C2} to R_{C3} on the 2S54, 2S56) can be replaced by a potentiometer if the null needs to be adjusted. For differential measurements, the resistors can be replaced by another LVDT. The system is nonisolated.

Three or Four Wire LVDT Connection

In this method of connection, shown in Figure 4, the converters digital output is proportional to the ratio:

$$\frac{(A-B)}{(A+B)/2}$$

where A and B are the individual LVDT secondary output voltages. Inspection of Figure 4 should demonstrate why this relationship is true. (A−B) is simply the voltage across the series connected secondaries of the LVDT and is applied to the V1 input to the converter. (A+B)/2 is effectively the average of the two secondary voltages as computed by the balanced bridge completion resistors and the grounding of the secondary center-tap.

Note: This method of connection is appropriate only for where (A+B) is a constant, independent of LVDT position. Any lack of constancy in (A+B) will be reflected as an additional non-linearity in the output. It is up to the user to determine if (A+B) is sufficiently constant over the particular stroke length employed. (A+B)/2 can be monitored on the "REF O/P" pin.

This method will usually restrict the usable LVDT range to half of its full range. The restriction can be eliminated, however, by attenuating V1 by a factor of 2 or increasing V_{REF} by a factor of 2.

This connection method has the tremendous advantage of being insensitive to temperature related phase shifts and excitation oscillator instabililty effects usually associated with more conventional LVDT conversion systems.

As in the case of the Half Bridge Type LVDT Connection, R1 and R2 are the bridge completion resistors (internal on the 2S54, 2S56; external on the 2S58) and are matched to a degree sufficient to ensure that the digital output representing the null position does not vary from the LVDT's natural null position. If null adjustment is required, a potentiometer can be used in place of the common connection between the two resistors.

Two-Wire LVDT Connection

This method should be used in cases where the sum of the LVDT secondary output voltages (A+B) is not constant with LVDT displacement over the desired stroke length. The method of connection, shown in Figure 5, still maintains the ratiometric operation and the insensitivity to variations in reference amplitude and frequency. However, the phase shift between V_{REF} and V1 should be minimized to maintain accuracy (see Section "PHASE SHIFT AND QUADRATURE EFFECTS"). Suggested phase compensation circuits are shown in Figure 5.

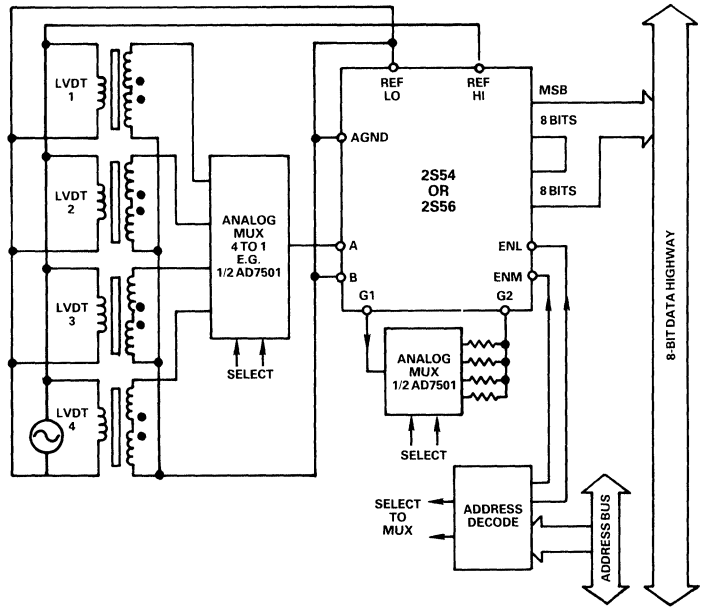

Figure 6. Multiplexing 4 LVDTs into the 2S54/2S56

MULTIPLEXING THE CONVERTERS

Although the 2S56 series of converters are primarily intended for use as single channel, continuous conversion devices, they can also be used in small multiplexed systems as shown in Figure 6. However, when switching between LVDT channels, ample time must be allowed for the converters to settle prior to transferring data.

Using the 2S54/X40 as in Figure 6 and allowing a time between samples of 70 ms, the maximum settling time of the converter can yield four 14-bit results from the 4 LVDTs in 280 ms. The gain can be programmed, as shown, to accommodate various transformation rations of dissimilar LVDTs. Note, however, that the finite "ON" resistance of the analog switch used with the gain setting resistor can introduce gain inaccuracies. This error is minimized for lower gains as the "ON" resistance of the switch will be negligible compared to the gain setting resistor. The error introduced can be calculated from the equation for the preamplifier gain in the "INPUT GAIN" section.

SCALING THE INPUTS

In cases where there is a requirement for a particular LVDT stroke length to correspond to full-scale on the digital output, the input gain must be chosen accordingly. It is important to remember that it is the relationship between V2 and V_{REF}, not V1 and V_{REF}, which determines the full-scale digital output. Furthermore, it should be ensured that these voltages are each 2 V rms ±10%, respectively. For monitoring purposes, V2 is brought to the "DIFF O/P" pin and V_{REF} is brought to the "REF O/P" pin.

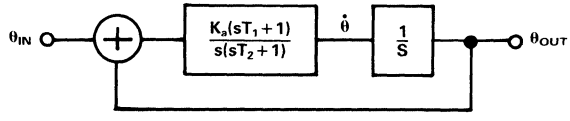

Figure 7. Transfer Function

DYNAMIC PERFORMANCE

The transfer function of the converters, shown in Figure 7 is given by:

Open Loop Gain:

$$\frac{\Delta_{OUT}}{\Delta_{IN}} = \frac{K_a}{S^2} \cdot \frac{1+sT_1}{1+sT_2}$$

Closed Loop Gain:

$$\frac{\Delta_{OUT}}{\Delta_{IN}} = \frac{1+sT_1}{1+sT_1+s^2/K_a+s^3T_2/K_a}$$

where:

	k_a	T1	T2
2S54/56 X10 options	12000 sec^{-2}	14.7 ms	2.3 ms
2S54/56 X40 options	93600 sec^{-2}	5.9 ms	1.0 ms
2S58	450000 sec^{-2}	2.4 ms	0.4 ms

The gain and phase response of each of the three options is shown in Figures 8, 9, 10, 11, 12 and 13.

ACCELERATION ERROR

Tracking converters such as the 2S56 series, employing a type 2 servo loop, do not suffer any velocity lag. However, there is an additional error when the LVDT is undergoing periods of acceleration.

The additional error can be defined using the K_a constant of the converter (see DYNAMIC PERFORMANCE section) as follows:

$$K_a = \frac{\textit{Input acceleration}}{\textit{Error in output position}}$$

where the numerator and the denominator are defined in the same units.

K_a does not define the maximum acceleration, only the error due to the acceleration.

DATA TRANSFER

The validity of the output data is indicated by the state of the BUSY output. When the input to the converter is changing, due to a change in displacement of the LVDT, the signal appearing on the converter's BUSY output pin is a series of pulses of TTL levels. A BUSY pulse is initiated each time the input moves by the equivalent of an LSB and the internal up-down counter is incremented or decremented.

With the INHIBIT input pin in the "Hi" state, data will be transferred automatically to the output latches.

The two three-state enable inputs, ENABLE L and ENABLE M, allow the digital input to be transferred on to a data bus in two separate bytes. ENABLE M enables the most significant 8 bits of the output word while ENABLE L enables the remaining least significant bits.

Figure 14 shows the timing diagram.

There are two methods of transferring the output data. The first is to detect the state of the "BUSY" which is 'Hi" for 1 μs max and then transfer the data when the BUSY is "Lo". Both INHIBIT, ENABLE M and ENABLE L must be in their correct state of "Hi" and "Lo" respectively, in order that the data is presented to the output.

The alternative method is to use the INHIBIT input. Taking this input to a "Lo" state prevents the internal monostable circuits being triggered and consequently the latches being updated. Data will always be valid 1 μs after the application of a logic "Lo" to the INHIBIT. However, if INHIBIT is applied while BUSY is in the "Lo" state (with ENABLE M and ENABLE L also "Lo"), data is valid instantaneously.

The internal tracking operation of the converter cannot in any way be affected by the logic state present on either the INHIBIT or the ENABLE pins.

OTHER INPUTS AND OUTPUTS

Differential Output (DIFF O/P)

This signal is in fact V2 and is brought out to a pin in order to simplify scaling of the V1 signal.

Direction (DIR)

This TTL output signal indicates the direction of the transducer. It is a logic "Hi" when counting up and a logic "Lo" when counting down.

Reference Output (REF O/P)

This is the reference signal after the input buffer stage. It can be used as a single ended measurement point for the V_{REF} input.

It can also be used as a BITE (Built in Test Equipment) signal to detect if the LVDT has become disconnected or the reference supply has failed.

SUPPORT OSCILLATOR

A power oscillator, OSC1758, is available for use as a reference generator for LVDT and RVDT transducers. It is capable of providing up to 7 volts rms at 1.4 VA.

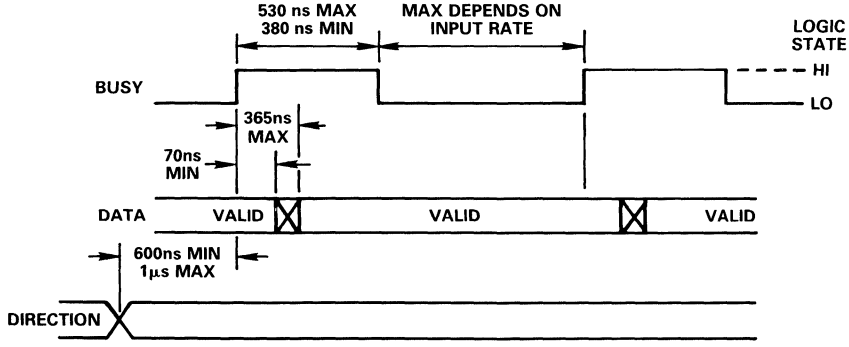

Figure 14. 2S56 Data Transfer Timing Diagram

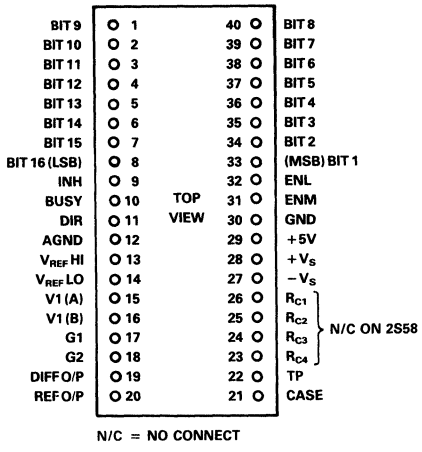
PIN CONFIGURATIONS



N/C = NO CONNECT

MEAN TIME BETWEEN FAILURES (MTBF)

The predicted reliability of these converters is exceptionally high due to the extensive uses of LSI custom circuitry. Figure 15 shows the MTBF of the 4YZ options as calculated according to MIL HDBK 217D at various temperatures under ground benign environment. For MTBF calculations under other environments, please consult the factory.

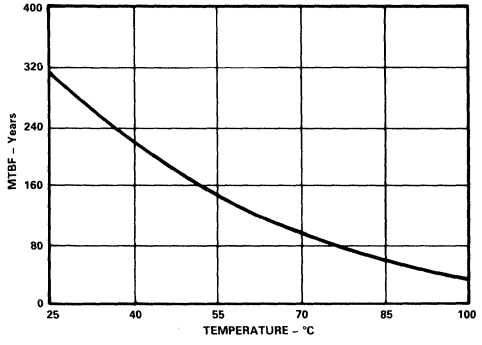


Figure 15.

PIN FUNCTION DESCRIPTION

$-V_S$	Main negative power supply.
$+V_S$	Main positive power supply.
+5 V	Logic power supply.
GND	Power supply ground. Digital ground.
Bit 1–14 (2S54) Bit 1–16 (2S56, 2S58))	Parallel output data bits.
$\overline{\text{INHIBIT}}$	Inhibit logic input. Taking this pin "Lo" inhibits data transfer from counter to output latches. The conversion loop continues to track.
BUSY	Converter BUSY. A "Hi" output indicates that the output latches are being updated. Data should not be transferred from the converter while BUSY is "Hi."
$\overline{\text{ENABLE M}}$	The 8 most significant output data bits are set to a high impedance state by application of a logic "Hi."
$\overline{\text{ENABLE L}}$	The 6 least significant bits of a 2S54, or the 8 least significant bits of a 2S56 "and 2S58," are set to a high impedance state by application of a logic "Hi."
R_{C1} R_{C2}	Connections to R1, internal bridge completion resistor (2S54/2S56 only).
R_{C3} R_{C4}	Connections to R2, internal bridge completion resistor (2S54/2S56 only).
DIR	TTL output indicating the direction of movement of the transducer.
AGND	Analog ground.
V_{REF} HI V_{REF} LO	Input pins for the Reference signal.
V1 (A) V1 (B)	Input pins for the Signal.
G1 G2	A gain setting resistor, or a link, can be connected between these pins.
DIFF O/P	This is a V1 after scaling (V2).
REF O/P	This is the reference signal after the input buffer stage.
CASE	This should normally be grounded. Case can be taken to any voltage with a low impedance up to ±20 V.
TP	Test Point. Do not make connections to this pin.

STANDARD PROCESSING

As part of the standard manufacturing procedure, all converters receive the following processing:

Process	Condition
1. Preseal Burn In	64 Hours at +125°C
2. Precap Visual Inspection	In-House Criteria
3. Seal Test, Fine and Gross	In-House Criteria
4. Final Electrical Test	

Extended temperature range versions receive additional processing as follows:

4. Final Electrical Test	Performed at Maximum and Minimum Operating Temperatures

PROCESSING FOR HIGH RELIABILITY

All extended temperature range models are available with high reliability screening. The parts are identified with a B suffix, and will receive the following processing.

Process	Conditions
1. Preseal Burn In	64 Hours at +125°C
2. Precap Visual Inspection	MIL-STD-883, Method 2017
3. Temperature Cycling	10 Cycles, −65°C to +150°C
4. Constant Acceleration	5000G, Y1 Plane
5. Interim Electrical Tests	
6. Operating Burn In	96 Hours at +125°C
7. Seal Test, Fine and Gross	MIL-STD-883, Method 1014
8. Final Electrical Testing (Group A)	Performed at T_{min}, T_{AMB}, and T_{max}
9. External Visual Inspection	MIL-STD-883, Method 2009

NOTE: Test and screening data can be supplied. Further information on request.

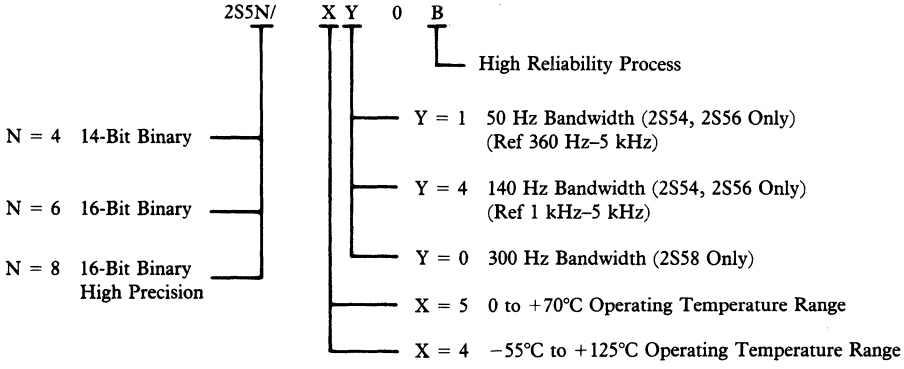
ORDERING INFORMATION



Variable Resolution, Monolithic Resolver-to-Digital Converter

2S80

FEATURES

Monolithic (BiMOS II) Tracking R/D Converter
40-Pin DIL Package
10-, 12-, 14- and 16-Bit Resolution Set by User
Ratiometric Conversion
Low-Power Consumption – 300mW typ
Dynamic Performance Set by User
High Max Tracking Rate 1040 rps (10 Bits)
Velocity Output
Military Temperature Range Version

APPLICATIONS

Brushless Motor Control
Process Control
Numerical Control of Machine Tools
Robotics
Axis Control
Military Servo Control

GENERAL DESCRIPTION

The 2S80 is a monolithic 10-, 12-, 14- or 16-bit tracking resolver-to-digital converter contained in a 40-pin, dual-in-line ceramic package. It is manufactured on a BiMOS II process that combines the advantages of CMOS logic and Bipolar high-accuracy linear circuits on the same chip.

The converter allows users **to select their own resolution and dynamic performance with external components.** This allows the users great flexibility in defining the converter that best suits their system requirements. The converter allows users to select the resolution to be 10, 12, 14 or 16 bits and to track resolver signals rotating at up to 1040 revs per second (62,400 rpm) when set to 10-bit resolution.

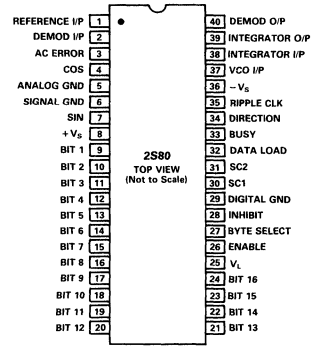
The 2S80 converts resolver format input signals into a parallel natural binary digital word using a ratiometric tracking conversion method. This ensures high-noise immunity and tolerance of lead length when the converter is remote from the resolver.

The 10-, 12-, 14- or 16-bit output word is in a three-state digital logic form available in 2 bytes on the 16 output data lines. BYTE SELECT, ENABLE and INHIBIT pins ensure easy data transfer to 8- and 16-bit data buses, and outputs are provided to allow for cycle or pitch counting in external counters.

An analog signal proportional to velocity is also available.

The 2S80 operates over 50 to 20,000 Hertz reference frequency.

2S80 PIN CONFIGURATION



PRODUCT HIGHLIGHTS

Monolithic. A one-chip solution reduces the package size required and increases the reliability.

Resolution Set by User. Two control pins are used to select the resolution of the 2S80 to be 10, 12, 14 or 16 bits allowing the user to use the 2S80 with the optimum resolution for each application.

Ratiometric Tracking Conversion. Conversion technique provides continuous output position data without conversion delay and is insensitive to absolute signal levels. It also provides good noise immunity and a tolerance to harmonic distortion on the reference and input signals.

Dynamic Performance Set by the User. By selecting external resistor and capacitor values the user can determine bandwidth, maximum tracking rate and velocity scaling of the converter to match the system requirements. The external components required are all low-cost preferred value resistors and capacitors and the component values are easy to select using the simple instructions given.

Velocity Output. An analog signal proportional to velocity is available and is linear to typically one percent. This can be used in place of a velocity transducer in many applications to provide loop stabilization and velocity feedback data.

Low-Power Consumption. Typically only 300mW.

MODELS AVAILABLE

Information on the models available is given in the section "Ordering Information."

SPECIFICATIONS (typical at 25°C unless otherwise specified)

Model	2S80	Units	Notes
TYPICAL CONVERTER PERFORMANCE (Connected as shown in Figure 1)			
Resolution	10, 12, 14 or 16	bits	
Accuracy JD, SD Options	±8 + 1LSB	arc mins	Accuracy will be affected by the offset at the
KD, TD Options	±4 + 1LSB	arc mins	INTEGRATOR I/P.
LD, UD Options	±2 + 1LSB	arc mins	
Tracking Rate Range			
10-Bit Resolution	0 to 1040	rps	User Selected, max rate limited to 1/16 of the
12-Bit Resolution	0 to 260	rps	reference frequency.
14-Bit Resolution	0 to 65	rps	
16-Bit Resolution	0 to 16.25	rps	
Operating Frequency Range	50 to 20,000	Hz	
Repeatability of Position Output	1	LSB	
Bandwidth	User Selectable		
Velocity Signal			See "Using the Velocity Signal."
Linearity			
Over Full Range	±1	% of output	See VCO spec.
Reversion Error	±1	%	With power supplies adjusted for best performance.
Zero Offset	+6	mV	For max tracking rate range. Depends on VCO I/P resistor (R6).
Zero Offset Tempco	−22	µV/°C	For max tracking rate range. Depends on VCO I/P resistor (R6).
Gain Scaling Accuracy	±10	% FSD	
Output Voltage	±8	V dc	
Noise and Ripple			
at LSB Rate	2	mV	See section "Using the Velocity Output."
Dynamic Ripple (Peak)	1.5	% of mean output	
ANALOG INPUTS			
Protection	All analog inputs are diode protected against overvoltage at ±8V.		
REFERENCE INPUT			
Frequency	50–20,000	Hz	
Voltage Level Nominal	2	V rms	
Max	11	V peak	
Input Bias Current	60 (typ), 150 (max)	nA	
Input Impedance	>1	MΩ	
SIGNAL INPUTS (SIN, COS)			
Frequency	50–20,000	Hz	
Allowable Phase Shift			
(Signal to Reference)	10	Degrees	
Voltage Level	2, ±10%	V rms	
Input Bias Current	60 (typ), 150 (max)	nA	
Input Impedance	>1	MΩ	
Maximum Voltage Nominal	±8	V	
DIGITAL INPUTS	TTL Compatible		Except DATA LOAD and SHORT CYCLE INPUTS.
INHIBIT			
Sense	Logic LO to inhibit		
Time to Data Stable (After Negative Going Edge of INHIBIT)	600	ns	
DATA LOAD			
Sense	Internally pulled up to +12V. Unconnected for normal operation. Logic LO allows data to be loaded into the counters from the data lines.		Connect when multiplexing the 2S80 or when using as a control transformer. Ensure data lines are in high impedance state when loading data.
SHORT CYCLE INPUTS (SC1, SC2)			
			Internally pulled up to $+V_S$.
	SC1	SC2	Used to select the resolution of the converter.
For 10-Bit Resolution	0	0	0 = Digital Ground. Drive low with open collector TTL.
For 12-Bit Resolution	0	1	1 = Open Circuit (internally pulled up through 100kΩ).
For 14-Bit Resolution	1	0	
For 16-Bit Resolution	1	1	
BYTE SELECT			
Sense Logic HI	8 MSBs selected on data lines 1 to 8. LS Byte selected on data lines 9 to 16.		The size of the LS Byte will be between 2 and 8 bits depending on the resolution selected.
Logic LO	LS Byte selected on data lines 1 to 8 and 9 to 16.		
Time to Data Available (After Change in State)	150 (typ), 450 (max)		ns

Model	2S80	Units	Notes
ENABLE			
Sense	Logic LO to enable position outputs. Logic HI position outputs in high impedance state.		
Enable and Disable Times	200 (typ), 550 (max)	ns	
ANALOG OUTPUTS			
Protection	Short-circuit output current limited to ± 8mA, ± 30%.		
Output Voltage Range, typ	+ 9 to − 9	V	With 1mA load.
max	+ 10.5 to − 10.5	V	
min	+ 8 to − 8	V	
DIGITAL OUTPUTS			
Format	V_L = + 5V	TTL Compatible	Voltage on V_L sets the voltage level of the digital outputs.
	V_L = + 12V	CMOS Compatible	
POSITION OUTPUTS			
Format	Three-state natural binary		
Resolution	10, 12, 14 or 16	bits	
Number of Data Lines	16		
Max Load	3	LSTTL	
Monotonicity			
JD, KD, SD, TD Options	Guaranteed to 14 bits		
LD and UD Options	Guaranteed to 16 bits		
DIRECTION			
Sense	Logic HI when counting up. Logic LO when counting down.		
Timing	Only changes, if required, at start of output position data cycle.		
Max Load	3	LSTTL	
RIPPLE CLOCK			
Sense	Positive going edge when counting up from all "1s" and when counting down from all "0s" as data changes.		
Timing	Edge occurs at least 300ns before change in DIR can occur.		
Width	300 (min)	ns	
Reset	By start of next data update.		
Max Load	3	LSTTL	
BUSY			
Sense	Logic HI when converter position output changing.		
Timing	Positive going edge 50ns before change in position output.		
Width typ	300	ns	
min	200	ns	
max	600	ns	
Max Load	3	LSTTL	
POWER SUPPLIES			The 2S80 may latch up if $+V_S$ is applied without $-V_S$.
Voltage Levels			
$+V_S$	+ 12 ± 10%	V	
$-V_S$	− 12 ± 10%	V	
$+V_L$	+ 5 to + 14	V	
Current			Over operating temperature range.
$+V_S$, $-V_S$ at 12V	12 (typ), 23 (max)	mA	
$+V_S$, $-V_S$ at 13.2V	19 (typ), 30 (max)	mA	
$+V_L$	0.5 (typ), 1.5 (max)	mA	
GENERAL			
Operating Temperature Range			
JD, KD, LD Options	0 to + 70	°C

Input Bias Current	120 (typ), 300 (max)	nA	
Input Bias Current Tempco	−0.55	nA/°C	
Input Voltage Range	−8 to +8	V	
Linearity of Absolute Rate			
Over Full Range	±1 (typ), ±3 (max)	%	
Over 0 to 50% of Max Range	+1 (max)	%	
Reversion Error	<3 (max)	%	Symmetrical power supplies.
Sensitivity of Reversion Error to Symmetry of Power Supplies	8	%/V of Asymmetry	See section "Using the Velocity Output."

Specifications subject to change without notice.

ABSOLUTE MAXIMUM INPUTS (with respect to GND)

$+V_S$[1] . . . . . 0V to +14V dc
$-V_S$ . . . . . 0V to −14V dc
$+V_L$ . . . . . 0V to $+V_S$
Reference . . . . . +14V to $-V_S$
Sin . . . . . +14V to $-V_S$
Cos . . . . . +14V to $-V_S$
Any Logical Input . . . . . −0.4V to $+V_L$ dc
Demodulator Input . . . . . +14V to $-V_S$
Integrator Input . . . . . +14V to $-V_S$
VCO Input . . . . . +14V to $-V_S$

CAUTION:

1. Correct polarity voltages must be maintained on the $+V_S$ and $-V_S$ pins.

OPERATION OF THE CONVERTER

When connected in a circuit such as is shown in Figure 1 the 2S80 operates as a tracking resolver-to-digital converter and forms a type 2 closed loop system. This means that the output will automatically follow the input for speeds up to the selected maximum tracking rate. No convert command is necessary as the conversion is initiated by each LSB increment of the input. Each LSB increment of the converter initiates a BUSY pulse.

Because the conversion depends on the ratio of the input signals the 2S80 is remarkably tolerant of input amplitude and frequency (there is no need of an accurate, stable oscillator to produce the reference signal). The inclusion of a phase sensitive detector in the conversion loop ensures a high immunity to signals that are not coherent or are in quadrature with the reference signal.

Two major areas of the 2S80 specification can be selected by the user to optimize the total system performance. The resolution of the digital output is set by the state of the inputs SC1 and SC2 to be 10, 12, 14 or 16 bits and the dynamic characteristics of bandwidth and tracking rate are selected by the choice of external components.

Position Output

The resolver shaft position is represented at the converter output by a natural binary parallel digital word.

As the digital output of the converter passes through the major carries, i.e., all "1s" to all "0s" or the converse, a RIPPLE CLOCK (RC) logic output is initiated indicating that a revolution or a pitch of the input has been completed.

The direction of input rotation is indicated by the DIRECTION (DIR) logic output. This direction data is always valid in advance of a RIPPLE CLOCK pulse and, as it is internally latched, only changes with a change in direction.

Both the RIPPLE CLOCK pulse and the DIRECTION data are unaffected by the application of the INHIBIT.

The static accuracy quoted is the worst case error that can occur over the full operating temperature excluding the effect of offset signals at the INTEGRATOR INPUT (which can be trimmed out) and with the following conditions: input signal amplitudes are within 5% of the nominal values; signal and reference frequency is within the specified operating range; phase shift between signal and reference is less than 10 degrees; signal and reference waveform harmonic distortion is less than 10%.

These test conditions are selected primarily to establish a repeatable acceptance test procedure which can be traced to national standards. In practice, the 2S80 can be used well outside these operating conditions providing the following points are observed.

Signal Amplitude (Sine and Cosine Inputs)

The amplitude of the signal inputs should be maintained within 5% of the nominal values if full performance is required from the velocity signal.

The digital position output is relatively insensitive to amplitude variation. Increasing the input signal levels by more than 10% will result in a dramatic loss in accuracy due to internal overload. Reducing level will result in a steady decline in accuracy. With the signal levels at 50% of the correct value, the angular error will increase to an amount equivalent to 1.3LSB. At this level the repeatability will also degrade to 2LSB and the dynamic response will also change, since the dynamic characteristics are proportional to the signal level.

The 2S80 will not be damaged if the signal inputs are applied to the converter without the power supplies and/or the reference.

Reference Voltage Level

The amplitude of the reference signal applied to the converter's input is not critical, but care should be taken to ensure it is kept below the absolute maximum voltage.

The 2S80 will not be damaged if the reference is supplied to the converter without the power supplies and/or the signal inputs.

Harmonic Distortion

The amount of harmonic distortion allowable on the signal and reference lines mainly depends on the type of transducer being used.

Square waveforms can be used but the input levels should be adjusted so that the average value is 1.9V rms. (For example, a square wave should be 1.9V peak.)

Note: The figure specified of 10% harmonic distortion is for calibration convenience only.

Velocity Signal

The tracking converter technique generates an internal signal at the output of the integrator (the INTEGRATOR OUTPUT Pin) that is proportional to the rate of change of the input angle. This is a dc analog output referred to as the VELOCITY signal.

DC Error Signal

The signal at the output of the phase sensitive detector (DEMODULATOR OUTPUT) is the signal to be nulled by the tracking loop and is therefore proportional to the error between the input angle and the output digital angle. This is the DC ERROR of the converter; and as the converter is a type 2 servo loop, it will increase if the output fails to track the input for any reason. It is an indication that the input has exceeded the maximum tracking rate of the converter or, due to some internal malfunction, the converter is unable to reach a null. By connecting two external comparators, this voltage can be used as a "built-in test".

CONNECTING THE CONVERTER

The power supply voltages connected to $+V_S$ and $-V_S$ pins should be $\pm$ 12V and must not be reversed. If one rail is connected without the other, the converter will not operate and may "latch up". In this case, the removal of both rails is necessary in order for the converter to function correctly again. The voltage applied to V_L can be $+5V$ to $+V_S$.

It is suggested that decoupling capacitors are connected in parallel between the power lines $+V_S$, $-V_S$ and ANALOG GROUND adjacent to the converter. Suggested values of 100nF (ceramic) and 10μF (tantalum). Decoupling capacitors of 100nF and 10μF should also be connected between $+V_L$ and DIGITAL GROUND adjacent to the converter.

When more than one converter is used on a card, then separate decoupling capacitors should be used for each converter.

The resolver connections should be made to the SIN and COS inputs, REFERENCE INPUT and SIGNAL GROUND as shown in Figure 7 and described in section "CONNECTING THE RESOLVER". The two signal ground wires from the resolver should be joined at the SIGNAL GROUND pin of the converter to minimize the coupling between the sine and cosine signals. For this reason it is also recommended that the resolver is connected using twisted pair cables with the sine, cosine and reference signals twisted separately.

SIGNAL GROUND and ANALOG GROUND are connected

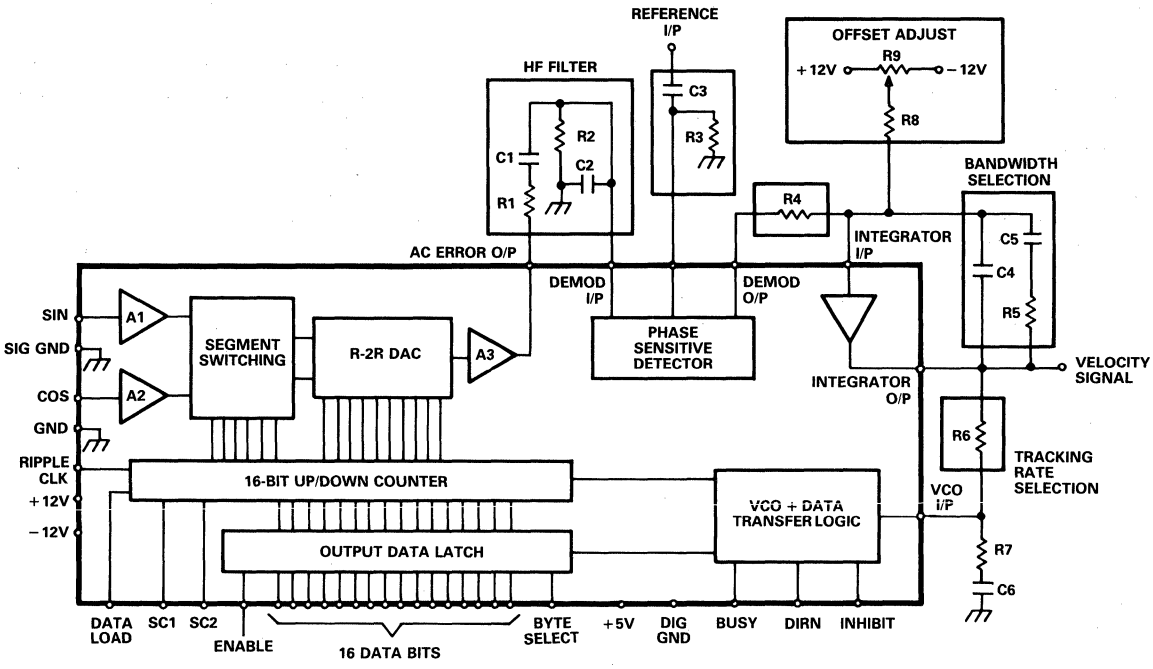

Figure 1. 2S80 Connection Diagram

internally. ANALOG GROUND and DIGITAL GROUND must be connected externally.

The external components required should be connected as shown in Figure 1.

SELECTING THE RESOLUTION

The resolution of the 2S80 can be selected to be 10, 12, 14 or 16 bits by use of the short cycling inputs SC1 and SC2. The required resolution can be selected as shown in the specification section.

The choice of resolution will affect the values of R4 and R6 which scale the inputs to the integrator and the VCO respectively (see section "COMPONENT SELECTION"). If the resolution is changed, then new values of R4 and R6 must be switched into the circuit.

Note: When changing resolution under dynamic conditions, a period of uncertainty will exist before position and velocity data is valid.

COMPONENT SELECTION

The following instructions describe how to select the external components to the converter in order to achieve the required bandwidth and tracking rate. In all cases the nearest "preferred value" component should be used and a 5% tolerance will not degrade the overall performance of the converter. Care should be taken that the resistors and capacitors will function over the required operating temperature range. The components should be connected as shown in Figure 1.

For more detailed information and explanation, see section "CIRCUIT FUNCTIONS AND DYNAMIC PERFORMANCE".

1. HF Filter (R1, R2, C1, C2)

The function of the HF filter is to reduce the amount of noise present on the signal inputs to the 2S80, reaching the Phase Sensitive Detector and affecting the outputs. R1 and C2 may be omitted – in which case R2 = R3 and C1 = C3, calculated below – but their use is particularly recommended if noise from a switch mode motor drive is present.

Values should be chosen so that

$$R1 = R2 \leq 56k\Omega$$

$$C1 = C2 = \frac{1}{2\pi\, R1\, f_{REF}}$$

and f_{REF} = Reference frequency (Hz)

This filter gives an attenuation of 3 times at the input to the phase sensitive detector.

2. Gain Scaling Resistor (R4)
If R1, C2 are fitted then:

$$R4 = \frac{E_{DC}}{100 \times 10^{-9}} \times \frac{1}{3}\,\Omega$$

If R1, C2 are not fitted then:

$$R4 = \frac{E_{DC}}{100 \times 10^{-9}}\,\Omega$$

where E_{DC} = 160×10^{-3} for 10 bits resolution
= 40×10^{-3} for 12 bits
= 10×10^{-3} for 14 bits
= 2.5×10^{-3} for 16 bits
= Scaling at the DC ERROR in volts

3. AC Coupling of Reference Input (R3, C3)
Select R3 and C3 so that there is no significant phase shift at the reference frequency. That is,

$R3 = 100k\Omega$

$$C3 > \frac{1}{10^5 \times f_{REF}}$$

4. Maximum Tracking Rate (R6)
   The VCO input resistor R6 sets the maximum tracking rate of the converter and hence the velocity scaling as at the max tracking rate the velocity output will be 8V.

   Decide on your required maximum tracking rate, "T", in revolutions per second. Note that "T" must not exceed the specified maximum tracking rate or 1/16 of the reference frequency.

$$R6 = \frac{5.92 \times 10^7}{T \times p}\ k\Omega$$

   where p = bit per rev
   = 1,024 for 10 bits resolution
   = 4,096 for 12 bits
   = 16,384 for 14 bits
   = 65,536 for 16 bits

5. Closed Loop Bandwidth Selection (C4, C5, R5)
   a. Choose the Closed Loop 3dB Bandwidth (f_{BW}) required ensuring that

$$f_{REF} > 2.5 \times f_{BW}$$

   Typical values may be 100Hz for 400Hz reference frequency and 500 to 1000Hz for 5kHz reference frequency.

   b. Select C4 so that

$$C4 = \frac{20.2 \times 10^{-3}}{R6 \times f_{BW}^2}$$

   with R6 in kΩ and f_{BW} in Hz selected above.

   c. C5 is given by

$$C5 = 5 \times C4$$

   d. R5 is given by

$$R5 = \frac{4}{2 \times \pi \times f_{BW} \times C5}\ \Omega$$

6. VCO Phase Compensation
   The following values of C6 and R7 should be fitted.

   C6 = 470pF R7 = 68Ω

7. Offset Adjust
   Offset and bias current at the integrator input can cause an additional positional offset at the output of the converter of 1 arc min typical, 5.3 arc mins maximum. If this can be tolerated, then R8 and R9 can be omitted from the circuit.

   If fitted, the following values of R8 and R9 should be used: R8 = 4.7MΩ, R9 = 1MΩ potentiometer.

   To adjust for zero offset, ensure the resolver is disconnected and all the other external components are fitted. Connect the COS pin to the REFERENCE INPUT and the SIN pin to the SIGNAL GROUND and with the power and reference applied, adjust the potentiometer to give all "0s" on the digital output bits.

   The potentiometer may be replaced by select on test resistors if preferred.

PIN FUNCTIONS

REFERENCE I/P	Input pin for the Reference Signal.
DEMOD I/P	Demodulator input pin.
AC ERROR O/P	Output of Ratio Multiplier.
COS	Input pin for Cosine signal from resolver.
ANALOG GROUND	Power ground.
SIGNAL GROUND	Ground pin for signals from resolver.
SIN	Input pin for Sine signal from resolver.
$+V_S$	Main positive power supply.
BIT 1 – BIT 16	Parallel output data bits.
V_L	Logic power supply.
ENABLE	Logic "HI" sets the output data bits to a high impedance state, a logic "LO" presents the data in the latches to the output pins.
BYTE SELECT	Selects the data output bits presented on data bits 1 to 8. Logic "HI" will present the 8 most significant bits; a logic "LO" will present the least significant byte.
INHIBIT	Logic "LO" inhibits the data transfer from the counter to the output latches.
DIGITAL GROUND	Ground pin for digital circuitry.
SC1, SC2	Logic inputs used for selecting the resolution of the converter.
DATA LOAD	Logic "LO" allows data to be loaded into the counters.
BUSY	Converter BUSY. A logic "HI" indicates that the output latches are being updated and data should not be transferred.
DIRECTION	Logic output indicating the direction of rotation of the input signals.
RIPPLE CLOCK	A negative going pulse whenever the output of the converter changes from all "1s" top all "0s" or the converse.
$-V_S$	Main negative power supply.
VCO I/P	Input pin to VCO.
INTEGRATOR I/P	Input pin of Integrator.
INTEGRATOR O/P	Output pin of Integrator.
DEMOD O/P	Output pin of Demodulator.

DATA TRANSFER

To transfer data the INHIBIT input should be used. The data will be valid 600ns after the application of a logic "Lo" to the INHIBIT. This is regardless of the time when the INHIBIT is applied and allows time for an active BUSY to clear. By using the ENABLE input the two bytes of data can be transferred after which the INHIBIT should be returned to a logic "Hi" state to enable the output latches to be updated.

BUSY Output:

The validity of the output data is indicated by the state of the BUSY output. When the input to the converter is changing, the signal appearing on the BUSY output is a series of pulses at TTL levels. A BUSY pulse is initiated each time the input moves by the analog equivalent of an LSB and the internal counter is incremented or decremented.

INHIBIT Input:
The INHIBIT logic input only inhibits the data transfer from the up-down counter to the output latches and, therefore, does not interrupt the operation of the tracking loop. Releasing the INHIBIT automatically generates a BUSY pulse to refresh the output data.

ENABLE Input:
The ENABLE input determines the state of the output data. A logic "Hi" maintains the output data pins in the high impedance condition, and application of a logic "Lo" presents the data in the latches to the output pins. The operation of the ENABLE has no effect on the conversion process.

BYTE SELECT Input:
The BYTE SELECT input selects the byte of position data to be presented at the data output bits 1 to 8. The least significant byte will be presented on data output bits 9 to 16 (with the ENABLE input taken to a logic "Lo") regardless of the state of the BYTE SELECT pin. Note that when the 2S80 is used with a resolution less than 16 bits the unused data lines are pulled to a logic "Lo". A logic "Hi" on the BYTE SELECT input will present the eight most significant data bits on data output Bits 1 and 8. A logic "Lo" will present the least significant byte on data outputs 1 to 8, i.e., data outputs 1 to 8 will duplicate data outputs 9 to 16.

The operation of the BYTE SELECT has no effect on the conversion process of the converter.

RIPPLE CLOCK Output:
As the output of the converter passes through the major carry, i.e., all "1s" to all "0s" or the converse, a positive going edge on the RIPPLE CLOCK (RC) output is initiated indicating that a revolution, or a pitch, of the input has been completed. The pulse has a minimum width of 300ns and is reset by the start of the next data update cycle.

DIRECTION Output:
The DIRECTION (DIR) logic output indicates the direction of the input rotation, and this data is valid in advance of the RIPPLE CLOCK pulse and stays valid until the direction changes. This is the start of the next data update cycle – if the direction of rotation of the inputs has changed – and will be at least 300ns after the rising edge of the RIPPLE clock (see Figure 2).

The DIR and RC outputs are unaffected by the state of the INHIBIT input.

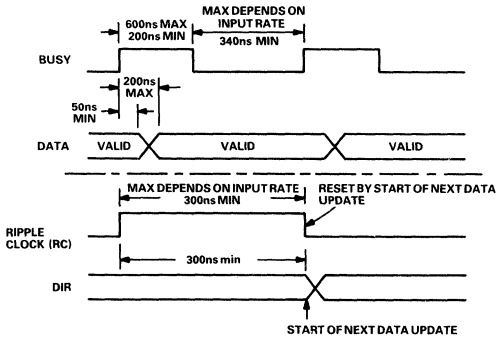

Figure 2. Timing Diagram

CIRCUIT FUNCTIONS AND DYNAMIC PERFORMANCE

The 2S80 allows the user great flexibility in choosing the dynamic characteristics of the resolver-to-digital conversion to ensure the optimum system performance. The characteristics are set by the external components shown in Figure 1, and the section "COMPONENT SELECTION" explains how to select desired maximum tracking rate and bandwidth values. The following paragraphs explain in greater detail the circuit of the 2S80 and the variations in the dynamic performance available to the user.

Loop Compensation
The 2S80 (connected as shown in Figure 1) behaves as a type 2 tracking servo loop where the VCO/counter combination and the Integrator perform the two integration functions inherent in a type 2 loop.

Additional compensation in the form of a pole/zero pair is required to stabilize any type 2 loop to avoid the loop gain characteristic crossing the 0dB axis with 180° of additional phase lag, as shown in Figure 4. This compensation is implemented by the integrator components (R4, C4, R5, C5).

The overall response of such a system is that of a unity gain second order low pass filter, with the angle of the resolver as the input and the digital position data as the output.

The 2S80 does not have to be connected as tracking converter, parts of the circuit can be used independently. This is particularly true of the Ratio Multiplier which can be used as a control transformer.

A block diagram of the 2S80 is given in Figure 3.

Ratio Multiplier
The Ratio Multiplier is the input section of the 2S80 and compares the signal from the resolver inputs, θ, to the digital angle, ϕ, held in the counter. Any difference between these two angles results in an analog voltage at the AC ERROR OUTPUT. This circuit function has historically been called a "Control Transformer" as it was originally performed by a mechanical device known by that name.

The AC ERROR signal is given by

$$A1 \sin(\theta - \phi) \sin\omega t.$$

where $\omega = 2\pi f_{REF}$

f_{REF} = reference frequency

A1, the gain of the ratio multiplier stage is 14.5 times

So for 2V rms inputs signals
AC ERROR output in volts/(bit of error)

$$= 2 \times \sin\left(\frac{360}{p}\right) \times A1$$

where p = bits per rev
= 1,024 for 10 bits resolution
= 4,096 for 12 bits
= 16,384 for 14 bits
= 65,536 for 16 bits

Giving AC ERROR output
= 178mV rms/bit @ 10 bits resolution
= 44.5mV rms/bit @ 12 bits
= 11.125mV rms/bit @ 14 bits
= 2.78mV rms/bit @ 16 bits

The Ratio Multiplier will operate in exactly the same way whether the 2S80 is connected as a tracking converter or as a control transformer, where data is preset into the counters using the DATA LOAD pin.

HF Filter

The AC ERROR OUTPUT may be fed to the PSD via a simple ac coupling network (R2, C1) to remove any DC offset at this point. Note, however, that the PSD of the 2S80 is a wideband demodulator and is capable of aliasing HF noise down to within the loop bandwidth. This is most likely to happen where the resolver is situated in particularly noisy environments, and the user is advised to fit a simple HF filter R1, C2 prior to the phase sensitive demodulator.

The attenuation and frequency response of a filter will affect the loop gain and must be taken into account in deriving the loop transfer function. The suggested filter (R1, C1, R2, C2) is shown in Figure 1 and gives an attenuation at the reference frequency (f_{REF}) of 3 times at the input to the phase sensitive demodulator.

Values of the components used in the filter must be chosen to ensure that the phase shift at f_{REF} is within the allowable signal to reference phase shift of the converter.

Phase Sensitive Demodulator

The Phase Sensitive Demodulator is effectively ideal and develops a mean dc output at the DEMODULATOR OUTPUT pin of

$$\frac{\pm 2\sqrt{2}}{\pi} \times \text{(DEMODULATOR INPUT rms voltage)}$$

for sinusoidal signals in phase or antiphase with the reference (for a square wave the DEMODULATOR OUTPUT voltage will equal the DEMODULATOR INPUT). This provides a signal at the DEMODULATOR OUTPUT which is a dc level proportional to the positional error of the converter.

DC Error Scaling = 160mV/bit (10 bits resolution)
= 40mV/bit (12 bits resolution)
= 10mV/bit (14 bits resolution)
= 2.5mV/bit (16 bits resolution)

When the tracking loop is closed, this error is nulled to zero unless the converter input angle is accelerating.

Integrator

The integrator components (R4, C4, R5, C5) are external to the 2S80 to allow the user to determine the optimum dynamic characteristics for any given application. The section "COMPONENT SELECTION" explains how to select components for a chosen bandwidth.

Since the output from the integrator is fed to the VCO INPUT, it is proportional to velocity (rate of change of output angle) and can be scaled by selection of R6, the VCO input resistor. This is explained in the section "VOLTAGE CONTROLLED OSCILLATOR (VCO)" below.

To prevent the converter from "flickering" (i.e., continually toggling by ±1 bit when the quantized digital angle, ϕ, is not an exact representation of the input angle, θ) feedback is internally applied from the VCO to the integrator input to ensure that the VCO will only update the counter when the error is greater than or equal to 1 bit. In order to ensure that this feedback "hysteresis" is set to 1LSB the input current to the integrator must be scaled to be 100nA/bit. So,

$$R4 = \frac{\text{DC Error Scaling (mV/bit)}}{100\ (\text{nA/bit})}\ \text{M}\Omega$$

Any offset at the input of the integrator will affect the accuracy of the conversion as it will be treated as an error signal and offset the digital output. One LSB of extra error will be added for each 100nA of input bias current. The method of adjusting out this offset is given in the section "COMPONENT SELECTION".

Voltage Controlled Oscillator (VCO)

The VCO is essentially a simple integrator feeding a pair of dc level comparators. Whenever the integrator output reaches one of the comparator threshold voltages, a fixed charge is injected into the integrator input to balance the input current. At the same time the counter is clocked either up or down, dependent on the polarity of the input current. In this way the counter is clocked at a rate proportional to the magnitude of the input current of the VCO.

During the reset period the input continues to be integrated although the reset period is constant at 400ns.

The VCO rate is fixed for a given input current by the VCO scaling factor,

$= 7.4\text{kHz}/\mu\text{A}$

The tracking rate in rps per μA of VCO input current can be found by dividing the VCO scaling factor by the number of LSB changes per rev (i.e., 4096 for 12-bit resolution).

The input resistor R6 determines the scaling between the converter velocity signal voltage at the INTEGRATOR OUTPUT pin and the VCO input current. Thus to achieve a 5V output at 100 rps (6000 rpm) and 12-bit resolution the VCO input current must be:

$(100 \times 4096)/(7400) = 55.3\mu\text{A}$

Thus, R6 would be set to: $5/(55.3 \times 10^{-6}) = 90\text{k}\Omega$

The velocity offset voltage depends on the VCO input resistor, R6, and the VCO bias current and is given by

Velocity Offset Voltage = R6 × (VCO bias current)

The temperature coefficient of this offset is given by

Velocity Offset Tempco = R6 × (VCO bias current tempco)

where the VCO bias current tempco is typically −0.55nA/°C.

The maximum recommended rate for the VCO is 1.1MHz which sets the maximum possible tracking rate.

Since the maximum voltage swing available at the integrator output is ±8V, this implies that the minimum value for R6 is 54kΩ. As

$$\text{Max Current} = \frac{1.1 \times 10^6}{7.4 \times 10^3} = 149\mu\text{A}$$

$$\text{Min Value } R_6 = \frac{8}{149 \times 10^{-6}} = 54\text{k}\Omega$$

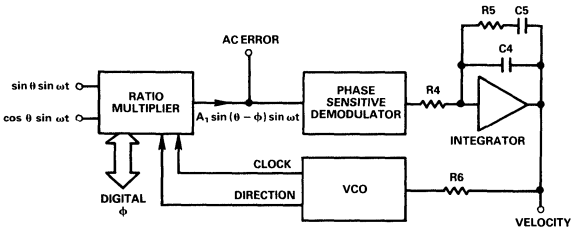

Figure 3. 2S80 Functional Diagram

Transfer Function

By selecting components using the method outlined in the section "Component Selection" the converter will have a critically damped time response and maximum phase margin. The Closed-Loop Transfer Function is given by:

$$\frac{\theta_{OUT}}{\theta_{IN}} = \frac{14\,(1 + s_N)}{(s_N + 2.4)\,(s_N^2 + 3.4\,s_N + 5.8)}$$

where, s_N, the normalized frequency variable is

$$s_N = \frac{2}{\pi}\,\frac{s}{f_{BW}}$$

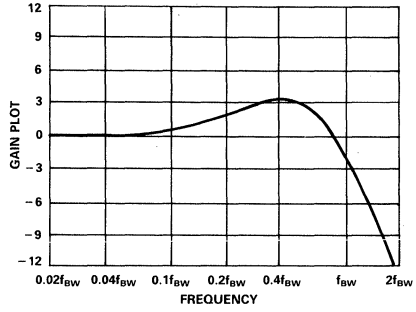

Figure 4. 2S80 Gain Plot

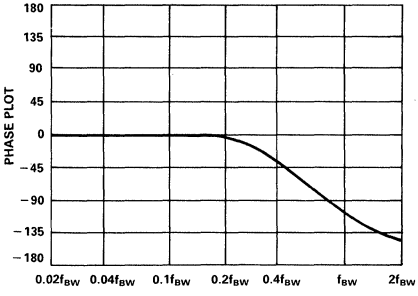

Figure 5. 2S80 Phase Plot

and f_{BW} is the closed-loop 3dB bandwidth (selected by the choice of external components).

The acceleration constant, K_A, is given approximately by

$$K_A = 6 \times (f_{BW})^2 \quad sec^{-2}$$

The normalized gain and phase diagrams are given in Figures 4 and 5.

The small signal step response is shown in Figure 6. The time from the step to the first peak is t_1 and the t_2 is the time from the step until the converter as settled to 1LSB. The times t_1 and t_2 are given approximately by

$$t_1 = \frac{1}{f_{BW}}$$

$$t_2 = \frac{5}{f_{BW}} \times \frac{R}{12}$$

where R = resolution, i.e., 10, 12, 14 or 16.

The large signal step response (for steps greater than 10 degrees) applies when the error voltage will exceed the linear range of the converter. Typically the converter will take 3 times longer to reach the first peak for a 179 degrees step.

The response to a velocity step, the velocity output will exhibit the same time response characteristics as outlined above for the position output.

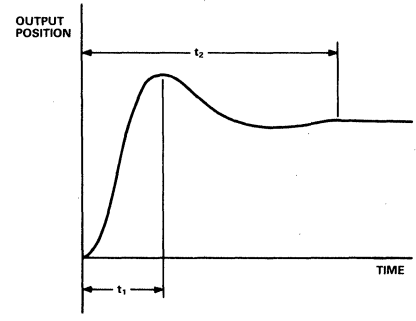

Figure 6. 2S80 Small Step Response

APPLICATIONS

USING THE 2S80 AS A CONTROL TRANSFORMER

The ratio multiplier section of the 2S80 can be used independently to the rest of the converter to perform the function of Control Transformer. In this mode the signal from the resolver inputs, θ, is compared to a digital angle, ϕ, loaded into the counters. Any difference between these two angles results in an analog voltage at the AC ERROR OUTPUT. To use the device in this way the DATA LOAD pin is used.

Applying a logic "Lo" to the DATA LOAD pin will allow data to be loaded into the counters of the converter from the data lines. It is important that the data lines are placed in the high impedance state before loading data.

To operate the 2S80 as a tracking resolver-to-digital converter the DATA LOAD pin should be left unconnected as it is pulled high internally to +12V.

CAUSES OF ADDITIONAL ERROR

Integrator Offset

Additional inaccuracies in the conversion of the resolver signals will result from an offset at the input to the integrator as it will be treated as an error signal. This error will be typically 1 arc minute over the operating temperature range.

A description of how to adjust for zero offset is given in the section "COMPONENT SELECTION" and the circuit required is shown in Figure 1.

Differential Phase Shift

Phase shift between the sine and the cosine signals from the resolver is known as differential phase shift and can cause static error. Some differential phase shift will be present on all resolvers as a result of coupling. A small resolver residual voltage (quadrature voltage) indicates a small differential phase shift. Additional phase shift can be introduced if the sine channel wires and the cosine channel wires are treated differently. For instance, different cable lengths or different loads could cause differential phase shift.

The additional error caused by differential phase shift on the input signals approximates to

$$\text{Error} = 0.53\ a.b \text{ arc minutes}$$

where a = differential phase shift in degrees
and b = signal to reference phase shift in degrees.

This error can be minimized by choosing a resolver with a small residual voltge, ensuring that the sine and cosine signals are handled identically and removing the reference phase shift (see section "CONNECTING THE RESOLVER"). By taking these precautions, the extra error can be made insignificant.

Resolver Phase Shift

Under static operating conditions phase shift between the reference and the signal lines alone will not theoretically affect the converter's static accuracy.

However, most resolvers exhibit a phase shift between the signal and the reference. This phase shift will give rise under dynamic conditions to an additional error defined by:

$$\frac{\text{Shaft Speed (rps)} \times \text{Phase Shift (Degs)}}{\text{Reference Frequency}}$$

For example, for a phase shift of 20 degrees, a shaft rotation of 22rps and a reference frequency of 5kHz, the converter will exhibit an additional error of:

$$\frac{22 \times 20}{5000} = 0.088 \text{ degrees}$$

This effect can be eliminated by putting a phase shift in the reference to the converter equivalent to the phase shift in the resolver (see section "CONNECTING THE RESOLVER").

NOTE: Capacitive and inductive crosstalk in the signal and reference leads and wiring can cause similar problems.

USING THE VELOCITY SIGNAL

The signal at the INTEGRATOR OUTPUT pin relative to the ANALOG GROUND pin is an analog voltage proportional to the rate of change of the input angle. This signal can be used to stabilize servo loops or in place of a velocity transducer. Although the conversion loop of the 2S80 includes a digital section there is an additional totally analog feedback loop around the velocity signal. This ensures that there is no digital effects on the output signal and that the loop is closed even when the input signals are such that the digital output does not change.

A better quality velocity signal will be achieved if the following points are considered.

1. Protection.
   The velocity signal should be buffered before use.
2. Reversion Error.
   If necessary, the reversion error can be reduced by a simple trimming circuit. Reversion error, or side-to-side nonlinearity, is a result of differences in the up and down rates of the VCO. The reversion error can be nulled by varying one supply rail relative to the other.
3. Ripple and Noise.
   Noise on the input signals to the converter is the major cause of noise on the velocity signal. This can be reduced to a minimum if the following precautions are taken:

   The resolver is connected to the converter using separate screened twisted pair cable for the sine, cosine and reference signals.

   Care is taken to reduce the external noise wherever possible.

   An HF filter is fitted before the Phase Sensitive Demodulator (as described in the section HF FILTER).

   A resolver is chosen that has a low residual voltage, i.e., a small signal in quadrature with the reference.

   Components are selected to operate the 2S80 with the lowest acceptable bandwidth.

   Feedthrough of the reference frequency should be removed by a filter on the velocity signal.

   The signal voltages are 2V rms to prevent a ripple at the LSB switching rate. This is because the 1LSB of analog feedback that prevents the output from flickering will be incorrectly scaled (see section "INTEGRATOR").

   If the above precautions are taken, a very good noise and ripple performance is obtainable making the 2S80 velocity signal usable in very noisy environments, for instance in motor drive applications with PWM switching noise.

   The positional error curve of the converter and the resolver will result in an apparent acceleration when the resolver is rotating at a constant velocity. The main result of this will be a ripple on the velocity signal twice per revolution.

CONNECTING THE RESOLVER

The recommended connection circuit is shown in Figure 7.

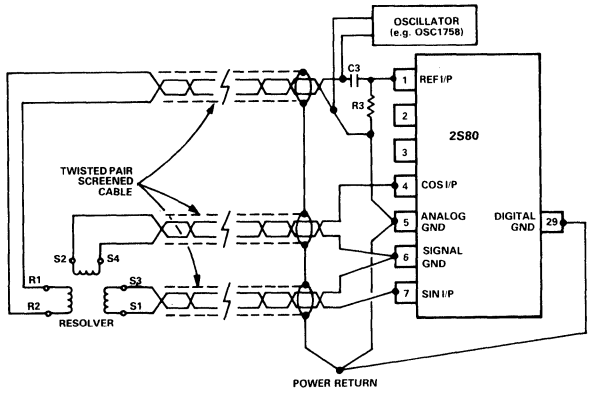

Figure 7. Connecting the 2S80 to a Resolver

In cases where the reference phase relative to the input signals from the resolver requires adjustment, this can be easily achieved by varying the value of the resistor R2 of the HF filter (see Figure 1).

Assuming that R1 = R2 = R and C1 = C2 = C

and Reference Frequency $= \frac{1}{2\pi R C}$

By altering the value of R2 the phase of the reference relative to the input signals will change in an approximately linear manner for phase shifts of up to 10 degrees.

Increasing R2 by 10% introduces a phase lag of 2 degrees. Decreasing R2 by 10% introduces a phase lead of 2 degrees.

For signal and reference voltages greater than 2V rms a simple voltage divider circuit of resistors can be used to generate the correct signal level at the converter. Care should be taken to ensure that the ratios of the resistors between the sine signal line and ground and the cosine signal line and ground are the same. Any difference will result in an additional position error.

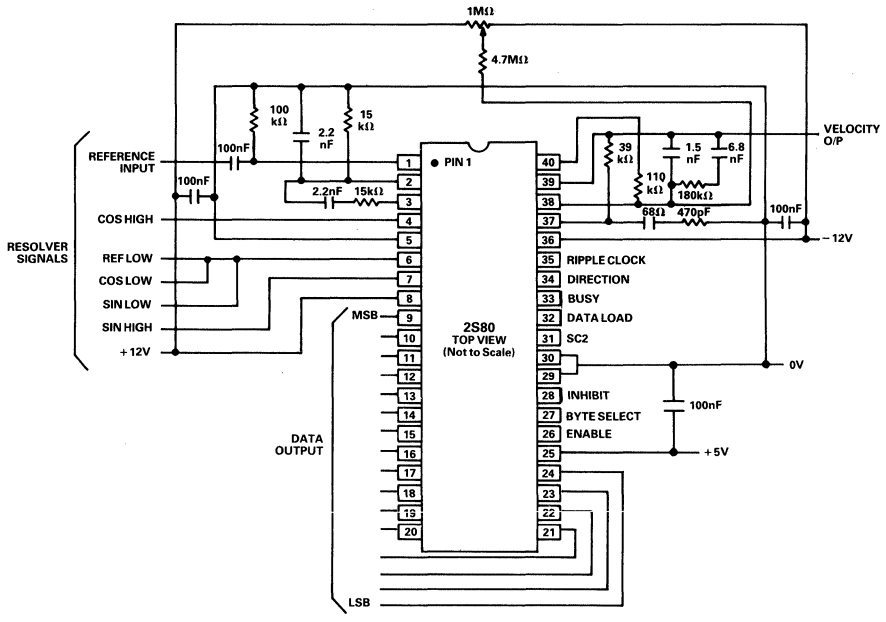

Figure 8.

TYPICAL CIRCUIT CONFIGURATION

Figure 8 shows a typical circuit configuration for the 2S80 in a 12-bit resolution mode. Values of the external components have been chosen for a reference frequency of 5kHz and to give a maximum tracking rate of 260 rps and a bandwidth of 520Hz. The resistors are 0.125W, 5% tolerance preferred values. The capacitors are 100V ceramic, 10% tolerance components.

An offset adjustment potentiometer is included at the integrator input to remove the offset error. Obviously this can be left out of the circuit if the extra inaccuracy can be tolerated.

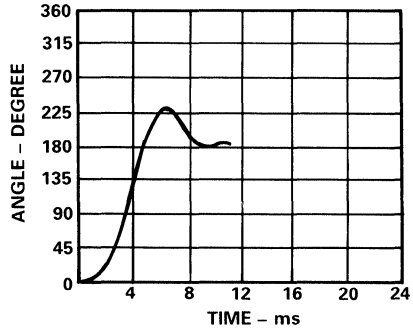

Figure 9. Large Step Response Curves for Typical Circuit Shown in Figure 8

ORDERING INFORMATION

Model	Accuracy (Arc mins)	Operating Temperature Range (°C)	Package Option*
2S80JD	8	0 to +70	D-40

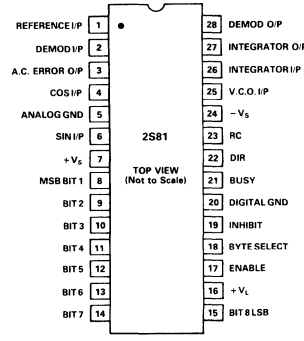
2S81 PIN CONFIGURATION



5

GENERAL DESCRIPTION

The 2S81 is a monolithic 12-bit tracking resolver-to-digital converter packaged in a 28-pin DIP. It is manufactured in Analog Devices' proprietary BiMOS II process which combines high-density and low-power CMOS logic with high-accuracy bipolar linear circuitry.

The converter can track resolver signals at rates up to 260 revolutions per second (15,600 rpm). Users can set the converter's dynamic performance with external components, providing greater flexibility in tailoring the converter to suit system requirements.

The 2S81 converts resolver format input signals into a 12-bit natural binary digital word using a ratiometric tracking conversion method. This ensures high noise immunity and tolerance of long lead lengths when the converter is located remotely from the resolver. The 12-bit output word is in a three-state digital logic form, available in 2 bytes on the 8 output data lines. BYTE SELECT and INHIBIT pins ensure easy data transfer. In addition, output pins are available to permit the use of external counters to count cycle or pitch. An analog signal proportional to velocity is also available.

PRODUCT HIGHLIGHTS

Monolithic: The single-chip construction reduces package size and increases inherent reliability.

Low Cost: The use of a single integrated circuit to perform the conversion ensures low cost.

Ratiometric Tracking Conversion: Conversion technique provides continuous output position data without conversion delay and is insensitive to absolute signal levels. It also provides good noise immunity and tolerates harmonic distortion in the reference and input signals.

Dynamic Performance Set by User: By selecting external resistor and capacitor values, the user can determine bandwidth, maximum tracking rate and velocity scaling of the converter to match the system requirements. The external components required are all low-cost preferred value resistors and capacitors.

Velocity Output: An analog signal proportional to velocity is linear to 1% (typical). This can be used in place of a velocity transducer in many applications to provide loop stabilization and velocity feedback data.

MODELS AVAILABLE

The 2S81 operates over 0 to +70°C temperature range. The reference frequency can range from 400 to 20,000Hz.

SPECIFICATIONS (typical at 25°C unless otherwise specified)

Model	2S81JD	Units	Notes
OVERALL CONVERTER SPECIFICATIONS (CONNECTED AS SHOWN IN FIGURE 1)			
Resolution	12	Bits	
Accuracy	± 30 + 1LSB	Arc Minutes	Accuracy will be Affected by the Offset at the INTEGRATOR I/P.
Tracking Rate Range	0 to 260 (max)	rps	User Selected, Max Rate Limited at Lower Operating Frequencies.
Operating Frequency Range	400 to 20,000	Hz	
Repeatability of Position Output	1	LSB	
Bandwidth	User Selectable		
Velocity Signal			See "Using the Velocity Signal"
Linearity Over Full Range	± 1 (typ), ± 3 (max)	%	
Over 0 to 6000 rpm	± 1 (max)	%	
Reversion Error	± 5 (max)	%	Symmetry of $-V_S$ and $+V_S$ Power Supplies to be within ± 5%.
	± 2 (max)	%	With $-V_S$ Adjusted for Best Performance.
Zero Offset (for 260 rps Max Tracking Rate)	± 6 (typ) + 16 (max)	mV	Depends on VCO I/P Resistor (R6).
Zero Offset Tempco (for 260 rps Max Tracking Rate)	− 22	μV/°C	Depends on VCO I/PResistor (R6).
Gain Scaling Accuracy	± 10	% FSD	
Output Voltage	± 8	V dc	
Noise and Ripple (av-pk)	1.5	%	See Section "Using the Velocity Signal"
ANALOG INPUTS			
Protection	All Analog Inputs Are Diode Protected Against Overvoltage at ± 8V		
REFERENCE INPUT			
Frequency	400 – 20,000	Hz	
Voltage Level Nominal	2	V rms	
max	11	V peak	
Input Bias Current	60 (typ), 150 (max)	nA	
Input Impedance	>1	MΩ	
SIGNAL INPUTS (SIN, COS)			
Frequency	400 – 20,000	Hz	
Allowable Phase Shift (Signal to Reference)	10	Degrees	
Voltage Level	2, ± 10%	V rms	
Input Bias Current	60 (typ), 150 (max)	nA	
Input Impedance	>1	MΩ	
Maximum Voltage Nominal	± 8	V	
DIGITAL INPUTS	TTL-Compatible		
INHIBIT			
Sense	Logic LO to Inhibit		
Time to Data Stable (After Negative Going Edge of INHIBIT)	1	μs	
BYTE SELECT			
Sense	Logic HI Selects 8MSBs on Pins 8-15 Logic LO Selects 4LSBs on Pins 8-11; Pins 12-15 Are Logic LO		
Data Available (After Change in State)	150 (typ), 450 (max)	ns	
ENABLE			
Sense	Logic LO to Enable Position Outputs Logic HI Position Outputs in High Impedance State		
Enable and Disable Times	200 (typ), 550 (max)	ns	
ANALOG OUTPUTS			
Protection	Short Circuit Output Current Limited to ± 8mA, ± 30% Output Voltage Range Will Be Degraded for Currents >3mA		
Output Voltage Range (typ)	+ 9 to − 9	V	
(max)	+ 10.5 to − 10.5	V	
(min)	+ 8 to − 8	V	
DIGITAL OUTPUTS			
Format	V_L = + 5V TTL Compatible V_L = + 12V CMOS Compatible		Voltage on V_L Sets the Voltage Level of Digital Outputs.

Model	2S81JD	Units	Notes
POSITION OUTPUTS			
Format	Three-State Natural Binary		
Resolution	12	Bits	
Number of Data Lines	8		Pins 8 to 15
Max Load	3	LSTTL	
Monotonicity	Guaranteed		
DIRECTION (DIR)			
Sense	Logic "HI" When Counting Up Logic "LO" When Counting Down

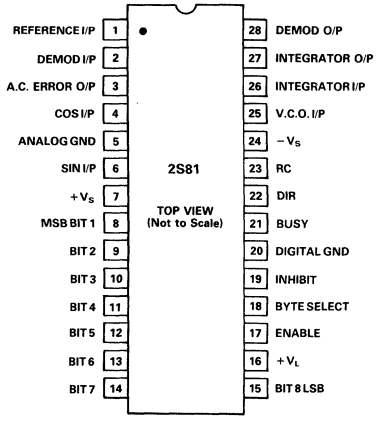
PIN CONFIGURATION



OPERATION OF THE CONVERTER

When connected in a circuit such as is shown in Figure 1 the 2S81 operates as a tracking resolver-to-digital converter and forms a type 2 closed loop system. This means that the digital output will automatically follow the input for speeds up to the maximum tracking rate, set by the choice of external components. No convert command is necessary as the conversion is initiated by each LSB increment of the input. Each LSB increment of the converter initiates a BUSY pulse.

As the digital output of the converter passes through the major carry, i.e., all "1s" to all "0s" or the converse, a RIPPLE CLOCK (RC) logic output is initiated indicating that a revolution or a pitch of the input has been completed.

The direction of input rotation is indicated by the DIRECTION (DIR) logic output. This direction data is *always* valid in advance of a RIPPLE CLOCK pulse and, as it is internally latched, only changes with a change in direction.

Both the RIPPLE clock pulse and DIRECTION data are unaffected by the application of the $\overline{\text{INHIBIT}}$.

Position Output

The resolver shaft position is represented at the converter output by a natural binary digital word.

The static angular accuracy quoted is the worst case error that can occur over the full operating temperature range with the following input conditions:

a) Signal input amplitudes within 5% of the nominal values.

b) Signal and reference frequency within the specified operating range.

c) Phase shift between signal and reference less than 10 degrees.

d) Signal and reference waveform harmonic distortion less than 10 percent.

These test conditions are selected primarily to establish a repeatable acceptance test procedure which can be traced to national standards. In practice, the converters can be used well outside these operating conditions providing the following points are observed.

Signal Amplitude (Sine and Cosine Inputs)

The amplitude of the signal inputs should be maintained within 5% of the nominal values if full performance is required from the velocity signal.

The digital position output is relatively insensitive to amplitude variation. Increasing the input signal levels by more than 10% will result in a dramatic loss in accuracy due to internal overload. Reducing level will result in a steady decline in accuracy. With the signal levels at 50% of the correct value, the angular error will increase to an amount equivalent to 1.3LSB. At this level the repeatability will also degrade to 2LSB and the dynamic response will also change, since the dynamic characteristics are proportional to the signal level.

The 2S81 will not be damaged if the signal inputs are applied to the converter without the power supplies and/or the reference.

Reference Voltage Level

The amplitude of the reference signal applied to the converter's input is noncritical; however, it is essential that the zero crossing points are maintained in the correct place to drive the converter's phase sensitive detector.

The 2S81 will not be damaged if the reference is supplied to the converter without the power supplies and/or the signal inputs.

Harmonic Distortion

The amount of harmonic distortion allowable on the signal and reference lines mainly depends on the type of transducer being used.

Square waveforms can be used but the input levels should be adjusted so that the average value is 1.9 volts rms. (For example – a square wave should be 1.9V peak.)

Note: The figure specified of 10% harmonic distortion is for calibration convenience only.

Velocity Signal

The tracking converter technique generates an internal signal at the output of the integrator (the INTEGRATOR OUTPUT pin) that is proportional to the rate of change of the input angle. This is a dc analog output referred to as the VELOCITY signal.

DC Error Signal

The signal at the output of the phase sensitive detector (DEMODULATOR OUTPUT) is the signal to be nulled by the tracking loop and is therefore proportional to the error between the input angle and the output digital angle. This is the DC ERROR of the converter; and as the converter is a type 2 servo loop, it will increase if the output fails to track the input for any reason. It is an indication that the input has exceeded the maximum tracking rate of the converter or, due to some internal malfunction, the converter is unable to reach a null. By connecting two external comparators this voltage can be used as a "built-in test".

CONNECTING THE CONVERTER

The power supply voltages connected to $+V_S$ and $-V_S$ pins should be $\pm$ 12V and must not be reversed. If one rail is connected without the other, the converter will not operate and may "latch up". In this case the removal of both rails is necessary in order for the converter to function correctly again. The voltage applied to V_L can be +5V to $+V_S$.

It is suggested that decoupling capacitors are connected in parallel between the power lines $+V_S$, $-V_S$ and ANALOG GROUND adjacent to the converter. Suggested values are 100nF (ceramic) and 10μF (tantalum). Decoupling capacitors of 100nF and 10μF should also be connected between $+V_L$ and DIGITAL GROUND adjacent to the converter.

When more than one converter is used on a card, then separate decoupling capacitors should be used for each converter.

The resolver connections should be made to the SIN and COS inputs, REFERENCE INPUT and ANALOG GROUND as shown in Figure 7 and described in section "CONNECTING THE RESOLVER". The two signal ground wires from the resolver should be joined at the ANALOG GROUND pin of the converter to minimize the coupling between the sine and cosine signals. For this reason it is also recommended that the resolver is connected using twisted pair cables with the sine, cosine and reference signals twisted separately.

The external components required should be connected as shown in Figure 1.

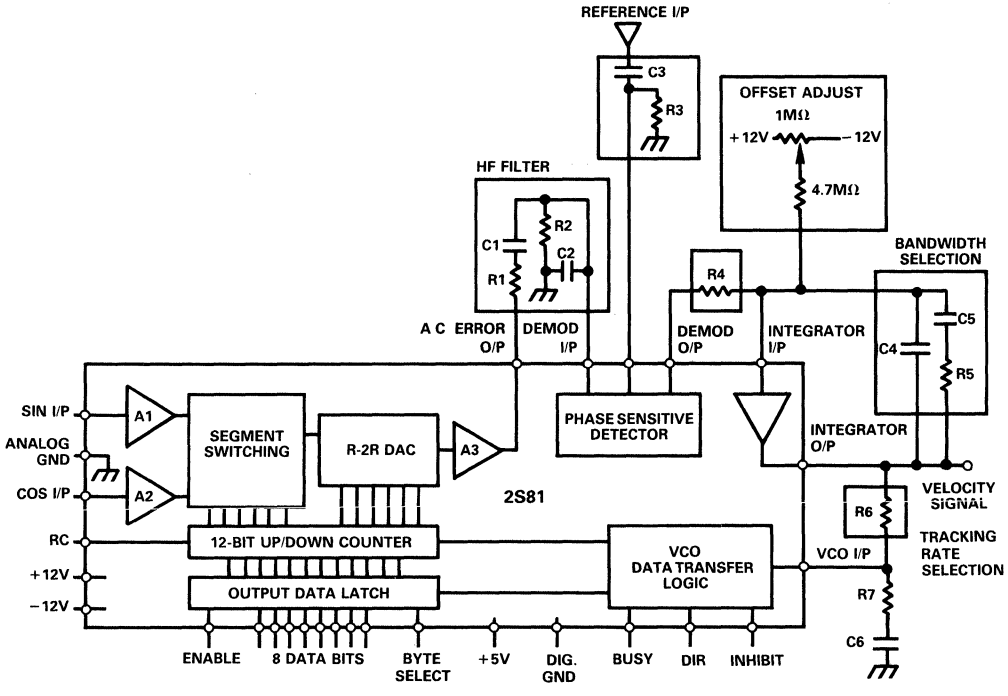


Figure 1. 2S81 Connection Diagram

COMPONENT SELECTION

The following instructions describe how to select the external components to the converter in order to achieve the required bandwidth and tracking rate. In all cases the nearest "preferred value" component should be used and a 5 percent tolerance will not degrade the overall performance of the converter. Care should be taken that the resistors and capacitors will function over the required operating temperature range. The components should be connected as shown in Figure 1.

For more detailed information and explanation, see section "CIRCUIT FUNCTIONS AND DYNAMIC PERFORMANCE".

1. HF Filter (R1, R2, C1, C2)
   The function of the HF filter is to reduce the amount of noise present on the signal inputs to the 2S81 reaching the Phase Sensitive Detector and affecting the outputs. R1 and C2 may be omitted – in which case R2 = R3 and C1 = C3, calculated below – but their use is particularly recommended if noise from a switch mode motor drive is present.

   Values should be chosen so that

   $R1 = R2 = 50k\Omega$ (max)

   $$C1 = C2 = \frac{1}{2\pi f_{REF} R1}$$

   and f_{REF} = Reference frequency (Hz)

   This filter gives an attenuation of 3 times at the input to the phase sensitive detector.

2. Gain Scaling Resistor (R4)
   If R1, C2 are fitted then: $R4 = 120k\Omega$

   If R1, C2 are not fitted then: $R4 = 390k\Omega$

3. AC Coupling of Reference Input (R3, C3)
   Select R3 and C3 so that there is no significant phase shift at the reference frequency. That is,

   $R3 = 100k\Omega$

   $$C3 > \frac{1}{10^5 \times f_{REF}}$$

4. Maximum Tracking Rate (R6)
   The VCO input resistor R6 sets the maximum tracking rate of the converter and hence the velocity scaling as at the max tracking rate the velocity output will be 8 volts.

   Decide on your required maximum tracking rate, "T" in revolutions per second. Note that "T" must not exceed 260 rps and 1/8 of the reference frequency.

   $$R6 = \frac{14.5 \times 10^3}{T} \ k\Omega$$

   This gives a scale factor of $\frac{T}{8}$ rps/volt

5. Closed-Loop Bandwidth Selection (C4, C5, R5)
   a. Choose the Closed-Loop 3dB Bandwidth (B_{CL}) required ensuring that

      $f_{REF} > 2.5 \times B_{CL}$

      Typical values may be 100Hz for 400Hz reference frequency and 500 to 1000Hz for 5kHz reference frequency.

   b. Select C4 so that

      $$C4 = \frac{20.4 \times 10^{-3}}{R6 \times B_{CL}^{2}}$$

      with R6 in kΩ and B_{CL} in Hz selected above.

   c. C5 is given by

      $C5 = 5 \times C4$

   d. R5 is given by

      $$R5 = \frac{4}{2 \times \pi \times B_{CL} \times C5} \ \Omega$$

6. VCO Phase Compensation
   The following values of C6 and R7 should be fitted.

   C6 = 470pF R7 = 68Ω.

7. Offset Adjust
   Input bias current at the integrator input can cause an additional positional offset at the output of the converter of 4 arc mins typical, 10 arc mins maximum. If this can be tolerated then the 4.7MΩ resistor and the 1MΩ potentiometer can be omitted from the circuit.

   To adjust for zero offset, ensure the resolver is disconnected and all the other external components are fitted. Connect COS to the REFERENCE INPUT and SIN to the ANALOG GROUND and with the power and reference applied, adjust the potentiometer to give all "0s" on the digital output bits.

   The potentiometer may be replaced by select on test resistors if preferred.

DATA TRANSFER

BUSY Output:
The validity of the output data is indicated by the state of the BUSY output. When the input to the converter is changing, the signal appearing on the BUSY output is a series of pulses of TTL levels. A BUSY pulse is initiated each time the input moves by the analog equivalent of an LSB and the internal counter is incremented or decremented.

$\overline{\text{INHIBIT}}$ Input:
The $\overline{\text{INHIBIT}}$ logic input only inhibits the data transfer from the up-down counter to the output latches and therefore, does not interrupt the operation of the tracking loop. Releasing the $\overline{\text{INHIBIT}}$ automatically generates a BUSY pulse to refresh the output data.

NOTE: With the $\overline{\text{INHIBIT}}$ input pin in the "Hi" TTL state, data will be transferred automatically to the output latches.

ENABLE Input:
The ENABLE input determines the state of the output data. A logic "HI" maintains the output data pins in the high impedance condition, and application of a logic "LO" presents the data in the latches to the output pins. The operation of the ENABLE has no effect on the conversion process.

BYTE SELECT Input:
The BYTE SELECT input selects the byte of position data to be presented at the data output pins. A logic "HI" on the BYTE SELECT input will present the 8 most significant data bits on pins 8 to 15 when the ENABLE input is taken to a logic "LO". A logic "LO" will present the 4 least significant data bits on pins 8 to 11 and place a logic "LO" on pins 12 to 15 (with the ENABLE input taken to a logic "LO").

The operation of the BYTE SELECT has no effect on the conversion process of the converter.

To transfer data the INHIBIT input should be used. The data will be valid 600ns after the application of a logic "LO" to the INHIBIT. This is regardless of the time when the INHIBIT is applied and allows time for an active BUSY to clear. By using the BYTE SELECT input the two bytes of data can be transferred after which the INHIBIT should be returned to a logic "HI" state to enable the output latches to be updated.

RIPPLE CLOCK (RC) and DIRECTION (DIR) Outputs: As the output of the converter passes through the major carry, i.e., all "1s" to all "0s" or the converse, a positive going edge on the RIPPLE CLOCK (RC) output is initiated indicating that a revolution or a pitch of the input has been completed. The pulse has a minimum width of 300ns and is reset by the start of the next data update cycle.

The DIRECTION (DIR) logic output indicates the direction of the input rotation, and this data is valid in advance of the RIPPLE CLOCK pulse and stays valid until the direction changes. This is the start of the next data update cycle – if the direction of rotation of the inputs has changed – and will be at least 300ns after the rising edge of the RIPPLE CLOCK (see Figure 2).

The DIR and RC outputs are unaffected by the state of the INHIBIT input.

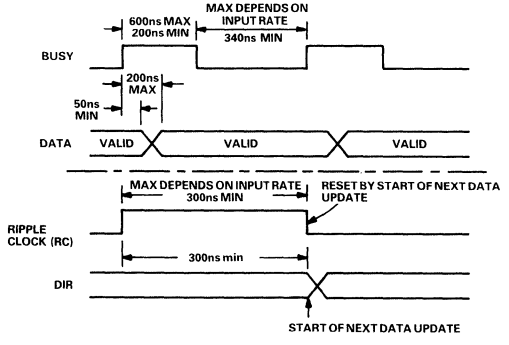

Figure 2. Timing Diagram

CIRCUIT FUNCTIONS AND DYNAMIC PERFORMANCE

The 2S81 allows the user great flexibility in choosing the dynamic characteristics of the resolver-to-digital conversion to ensure the optimum system performance. The characteristics are set by the exernal components shown in Figure 1, and the section "COMPONENT SELECTION" explains how to select desired maximum tracking rate and bandwidth values. The following paragraphs explain in greater detail the circuit of the 2S81 and the variations in the dynamic performance available to the user.

Loop Compensation

The 2S81 (connected as shown in Figure 1) behaves as a type 2 tracking servo loop where the VCO/counter combination and the Integrator perform the 2 integration functions inherent in a type 2 loop.

Additional compensation in the form of a pole/zero pair is required to stabilize any type 2 loop to avoid the loop gain characteristic crossing the 0dB axis with 180 degrees of additional phase lag, as shown in Figure 4. This compensation is implemented by the integrator components (R4, C4, R5, C5).

The overall response of such a system is that of a unity gain second order low pass filter, with the angle of the resolver as the input and the digital position data as the output.

A block diagram of the 2S81 is given in Figure 3.

Ratio Multiplier

The Ratio Multiplier is the input section of the 2S81 and compares the signal from the resolver inputs, θ, to the output digital angle, ϕ, held in the counter. Any difference between these two angles results in an analog voltage at the AC ERROR OUTPUT. This circuit function has historically been called a "Control Transformer" as it was originally performed by a mechanical device known by that name.

The AC ERROR signal is given by

AC ERROR OUTPUT = A1 sin $(\theta - \phi)$ sinωt.

where $\omega = 2\pi f_{REF}$

f_{REF} = reference frequency

A1, the gain of the ratio multiplier stage, is 14.5 times

So for 2V rms input signals

AC ERROR output in volts/(bit of error)

$$= 2 \times \sin\left(\frac{360}{4096}\right) \times A1$$

$$= 44.5\text{mV/rms/bit}$$

HF Filter

The AC ERROR OUTPUT may be fed to the PSD via a simple ac coupling network (R2, C1) to remove any DC offset at this point. Note, however, that the PSD of the 2S81 is a wideband demodulator and is capable of aliasing HF noise down to within the loop bandwidth. This is most likely to happen where the resolver is situated in particularly noise environments, and the user is advised to fit a simple HF filter (R1, C2) prior to the phase sensitive demodulator.

The attenuation and frequency response of a filter will affect the loop gain and must be taken into account in deriving the loop transfer function. The suggested filter (R1, C1, R2, C2) is shown in Figure 1 and gives an attenuation at the reference frequency (f_{REF}) of 3 times at the input to the phase sensitive demodulator.

Values of the components used in the filter must be chosen to ensure that the phase shift at f_{REF} is within the allowable signal to reference phase shift of the converter.

Phase Sensitive Demodulator

The Phase Sensitive Demodulator is effectively ideal and develops a mean dc output at the DEMODULATOR OUTPUT pin of

$$\frac{\pm 2\sqrt{2}}{\pi} \times (\text{DEMODULATOR INPUT rms voltage})$$

for sinusoidal signals in phase or antiphase with the reference (for a square wave the DEMODULATOR OUTPUT voltage will equal the DEMODULATOR INPUT). This provides a signal at the DEMODULATOR OUTPUT which is a dc level proportional to the positional error of the converter.

DC Error = 40mV/bit

When the tracking loop is closed, this error is nulled to zero unless the converter input angle is accelerating.

Integrator

The integrator components (R4, C4, R5, C5) are external to the 2S81 to allow the user to determine the optimum dynamic characteristics for any given application. The section "COMPONENT SELECTION" explains how to select components for a chosen bandwidth.

Since the output from the integrator is fed to the VCO INPUT, it is proportional to velocity (rate of change of output angle) and can be scaled by selection of R6, the VCO input resistor. This is explained in the section "VOLTAGE CONTROLLED OSCILLATOR (VCO)" below.

To prevent the converter from 'flickering' (i.e., continually toggling by ± 1 bit when the quantized digital angle, ϕ, is not an exact representation of the input angle, θ) feedback is internally applied from the VCO to the integrator input to ensure that the VCO will only update the counter when the error is greater than or equal to 1 bit. In order to ensure that this feedback "hysteresis" is set to 1LSB the input current to the integrator must be scaled to be 100nA/bit. So

$$R4 = \frac{40\text{mV/bit}}{100\text{nA/bit}} = 400\text{k}\Omega$$ (390kΩ is the nearest preferred value).

Any offset at the input of the integrator will affect the accuracy of the conversion as it will be treated as an error signal and offset the digital output. One LSB (5.3 arc mins) of extra error will be added for each 100nA of input bias current. The method of adjusting out this offset is given in the section "COMPONENT SELECTION".

Voltage Controlled Oscillator (VCO)

The VCO is essentially a simple integrator feeding a pair of dc level comparators. Whenever the integrator output reaches one of the comparator threshold voltages, a fixed charge is injected into the integrator input to balance the input current. At the same time the counter is clocked either up or down, dependent on the polarity of the input current. In this way the counter is clocked at a rate proportional to the magnitude of the input current of the VCO.

During the reset period the input continues to be integrated although the reset period is constant at 400ns.

The VCO rate is fixed for a given input current by the VCO scaling factor,

$= 7.4\text{kHz}/\mu\text{A}$

This is equivalent to a tracking rate of 7400/4096 = 1.807 rps per μA of VCO input current.

The input resistor R6 determines the scaling between the converter velocity signal voltage at the INTEGRATOR OUTPUT pin and the VCO input current. Thus to achieve a 5 volt output at 100 rps (6000 rpm) the VCO input current must be:

$(100 \times 4096)/(7400) = 55.4\mu\text{A}$

Thus R6 would be set to: $5/(55.4 \times 10^{-6}) = 90\text{k}\Omega$

The velocity offset voltage depends on the VCO input resistor, R6, and the VCO bias current and is given by

Velocity Offset Voltage = R6 × (VCO bias current)

The temperature coefficient of this offset is given by

Velocity Offset Tempco = R6 × (VCO bias current tempco)

where the VCO bias current tempco is typically −0.55nA/°C.

The maximum recommended rate for the VCO is 1.1MHz which sets the maximum possible tracking rate at

$$1.1 \times \frac{10^6}{4096} \text{ revs/second}$$

Since the maximum voltage swing available at the integrator output is ±8 volts, this implies that the minimum value for R6 is 54kΩ. As

$$\text{Max Current} = \frac{1.1\ 10^6}{7.4 \times 10^3} = 149\mu\text{A}$$

$$\text{Min Value } R_6 = \frac{8}{149 \times 10^{-6}} = 54\text{k}\Omega$$

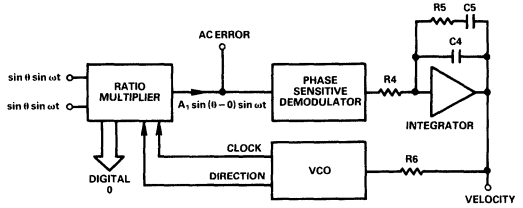

Figure 3. 2S81 Functional Diagram

Transfer Function

By selecting components using the method outlined in the section "Component Selection" the converter will have a critically damped time response and maximum phase margin. The Closed-Loop Transfer Function is given by:

$$\frac{\theta_{OUT}}{\theta_{IN}} = \frac{14\ (1+s_N)}{(s_N+2.4)\ (s_N^2+3.4\ s_N+5.8)}$$

where, s_N, the normalized frequency variable is

$$s_N = \frac{2}{\pi}\ \frac{s}{f_{BW}}$$

and f_{BW} is the closed-loop 3dB bandwidth (selected by the choice of external components).

The acceleration constant, K_A is given approximately by

$$K_A = 6 \times (f_{BW})^2 \quad \text{sec}^{-2}$$

The normalized gain and phase diagrams are given in Figures 4 and 5.

The small signal step response is shown in Figure 6. The time from the step to the first peak is t_1 and the t_2 is the time from the step until the converter has settled to 1LSB. The times t_1 and t_2 are given approximately by

$$t_1 = \frac{1}{f_{BW}}$$

$$t_2 = \frac{5}{f_{BW}}$$

The large signal step response (for steps greater than 10 degrees) applies when the error voltage will exceed the linear range of the converter. Typically the converter will take 3 times longer to reach the first peak for a 179° step.

In response to a velocity step the velocity output will exhibit the same time response characteristics as outlined above for the position output.

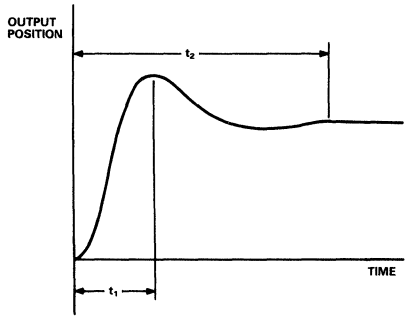

Figure 6. 2S81 Small Step Response

APPLICATIONS

Causes of Additional Error

Integrator Offset

Additional inaccuracies in the conversion of the resolver signals will result from an offset at the input to the integrator as it will be treated as an error signal. This error will be a maximum of 10 arc minutes over the operating temperature range, and if it can be tolerated in the performance of the converter, then the 4.7MΩ resistor and the 1MΩ potentiometer shown in Figure 1 can be omitted. (An offset of 40mV at the input to the integrator will cause an additional error of 1LSB in the accuracy of the converter.)

A description of how to adjust for zero offset is given in the section "COMPONENT SELECTION" and the circuit required is shown in Figure 1.

Differential Phase Shift

Phase shift between the sine and the cosine signals from the resolver is known as differential phase shift and will cause static error. Some differential phase shift will be present on all resolvers as a result of coupling. A small resolver residual voltage (quadrature voltage) indicates a small differential phase shift. Additional phase shift can be introduced if the sine channel wires and the cosine channel wires are treated differently. For instance, different cable lengths or different loads could cause differential phase shift.

The additional error caused by differential phase shift on the input signals approximates to

$$\text{Error} = 0.53\ a.b \text{ arc minutes}$$

where a = differential phase shift in degrees
and b = signal to reference phase shift in degrees.

This error can be minimized by choosing a resolver with a small residual voltage, ensuring that the sine and cosine signals are handled identically and removing the reference phase shift (see section "CONNECTING THE RESOLVER"). By taking these precautions, the extra error can be made insignificant.

Resolver Phase Shift

Under static operating conditions phase shift between the reference and the signal lines alone will not theoretically effect the converter's static accuracy.

However, when rotating, most resolvers, particularly those of the brushless type, exhibit a phase shift between the signal and the reference. This phase shift will give rise under dynamic conditions to an additional error defined by:

$$\frac{\text{Shaft Speed (RPS)} \times \text{Phase Shift (DEGS)}}{\text{Reference Frequency}}$$

For example, for a phase shift of 20°, a shaft rotation of 22rps and a reference frequency of 5kHz, the converter will exhibit an additional error of:

$$\frac{22 \times 20}{5000} = 0.088°$$

This effect can be eliminated by putting a phase shift in the reference to the converter equivalent to the phase shift in the resolver (see section "CONNECTING THE RESOLVER").

NOTE: Capacitive and inductive crosstalk in the signal and reference leads and wiring can cause similar problems.

Using the Velocity Signal

The signal at the INTEGRATOR OUTPUT pin relative to the ANALOG GROUND pin is an analog voltage proportional to the rate of change of the input angle. This signal can be used to stabilize servo loops or in place of a velocity transducer. Although the conversion loop of the 2S81 includes a digital section there is an additional totally analog feedback loop around the velocity signal. This ensures that there is no digital effects on the output signal and that the loop is closed even when the input signals are such that the digital output does not change.

A better quality velocity signal will be achieved if the following points are considered.

1. Protection.
   The velocity signal should be buffered before use.
2. Reversion Error.
   If necessary, the reversion error can be reduced by a simple trimming circuit. Reversion error, or side-to-side nonlinearity, is a result of differences in the up and down rates of the VCO. Because the sensitivity of the VCO rate to $-V_S$ depends on the direction of rotation, the reversion error can be reduced by varying the magnitude of $-V_S$. By trimming a reversion error of less than 1% is achievable.
3. Ripple and Noise.
   Noise on the input signals to the converter is the major cause of noise on the velocity signal. This can be reduced to a minimum if the following precautions are taken:

   The resolver is connected to the converter using screened separate twisted pair cables for the sine, cosine and reference signals.

   Care is taken to reduce the external noise wherever possible.

   An HF filter is fitted before the Phase Sensitive Demodulator (as described in the section HF FILTER).

   A resolver is chosen that has a low residual voltage, i.e., a small signal in quadrature with the reference.

   Components are selected to operate the 2S81 with the lowest acceptable bandwidth.

   Feedthrough of the reference frequency should be removed by a filter on the velocity signal.

   The signal voltages are 2V rms to prevent a ripple at the LSB switching rate. This is because the 1LSB of analog feedback that prevents the output from flickering will be incorrectly scaled (see section "INTEGRATOR").

   If the above precautions are taken, a very good noise and ripple performance is obtainable making the 2S81 velocity signal usable in very noisy environments, for instance in motor drive applications with PWM switching noise.

   The positional error curve of the converter and the resolver will result in an apparent acceleration when the resolver is rotating at a constant velocity. The main result of this will be a ripple on the velocity signal twice per revolution.

Connecting the Resolver

The recommended connection circuit is shown in Figure 7.

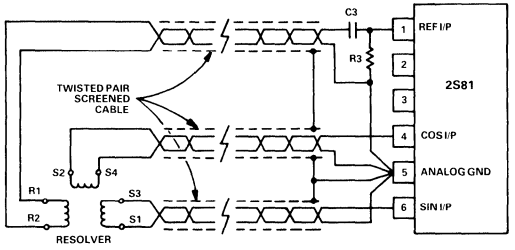

Figure 7. Connecting the 2S81 to a Resolver

In cases where the reference phase relative to the input signals from the resolver requires adjustment this can be easily achieved by varying the value of the resistor R2 of the HF filter (see Figure 1).

Assuming that R1 = R2 = R and C1 = C2 = C

and Reference Frequency $= \frac{1}{2\pi R C}$

By altering the value of R2 the phase of the reference relative to the input signals will change in an approximately linear manner for phase shifts of up to 10 degrees.

Increasing R2 by 10% introduces a phase lag of 2 degrees. Decreasing R2 by 10% introduces a phase lead of 2 degrees.

For signal and reference voltages greater than 2V rms a simple voltage divider circuit of resistors can be used to generate the correct signal level at the converter. Care should be taken to ensure that the ratios of the resistors between the sine signal line and ground and the cosine signal line and ground are the same. Any difference will result in an additional position error.

Typical Circuit Configuration

Figure 8 shows a typical circuit configuration for the 2S81. Values of the external components have been chosen for a reference frequency of 5kHz and to give a maximum tracking rate of 260 rps and a bandwidth of 520Hz. The resistors are 0.25W (except for the 4.7MΩ which is 0.5W) 5 percent tolerance preferred values. The capacitors are 100V ceramic 5 percent tolerance components.

An offset adjustment potentiometer is included at the integrator input to remove the offset error. Obviously this can be left out of the circuit if the extra inaccuracy can be tolerated.

ANALOG DEVICES

Variable Resolution, Monolithic Resolver-to-Digital Converter

2S82

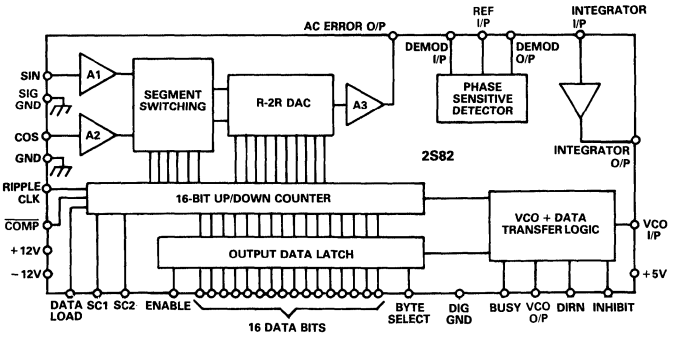
FEATURES

Monolithic (BiMOS II) Tracking R/D Converter
44-Pin J Leaded Chip Carrier (LCC)
10-, 12-, 14- and 16-Bit Resolution Set by User
Ratiometric Conversion
Low Power Consumption – 300mW typ
Dynamic Performance Set by User
High max Tracking Rate 1040 rps (10 Bits)
Velocity Output
VCO Output (Inter LSB Output)
Data Complement Facility
Military Temperature Range Version

APPLICATIONS

Brushless Motor Control
Process Control
Numerical Control of Machine Tools
Robotics
Axis Control

2S82 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The 2S82 is a monolithic 10-, 12-, 14- or 16-bit tracking resolver-to-digital converter contained in a 44-pin J leaded chip carrier package. Two extra functions are provided in the new surface mount package – COMPLEMENT and VCO OUTPUT. All other functions are identical to the 2S80.

The converter allows users to select their own resolution and dynamic performance with external components. This allows the users great flexibility in defining the converter that best suits their system requirements. The converter allows users to select the resolution to be 10, 12, 14 or 16 bits and to track resolver signals rotating at up to 1040 revs per second (62,400 rpm) when set to 10-bit resolution.

The 2S82 converts resolver format input signals into a parallel natural binary digital word using a ratiometric tracking conversion method. This ensures high noise immunity and tolerance of lead length when the converter is remote from the resolver.

The 10-, 12-, 14- or 16-bit output word is tristate available in two bytes on the 16 output data lines. BYTE SELECT, ENABLE and INHIBIT pins ensure easy data transfer to 8- and 16-bit data buses, and outputs are provided to allow for cycle or pitch counting in external counters.

An analog signal proportional to velocity is also available.

Reference frequency operating range for the 2S82 is 50Hz to 20,000Hz.

PRODUCT HIGHLIGHTS

Monolithic. A one-chip surface mount package solution reduces the package size required and increases reliability.

Resolution Set by User. Two control pins are used to select the resolution of the 2S82 to be 10, 12, 14 or 16 bits allowing the user to use the 2S82 with optimum resolution for each application.

Ratiometric Tracking Conversion. Conversion technique provides continuous output position data without conversion delay and is insensitive to absolute signal levels. It also provides good noise immunity and a tolerance to harmonic distortion on the reference and input signals.

Dynamic Performance Set by the User. By selecting external resistor and capacitor values, the user can determine bandwidth, maximum tracking rate and velocity scaling of the converter to match the system requirements. The external components required are all low cost, preferred value resistors and capacitors, and the component values are easy to select using the simple instructions given.

Velocity Output. An analog signal proportional to velocity is available and is linear to typically one percent. This can be used in place of a velocity transducer in many applications to provide loop stabilization and velocity feedback data.

Low Power Consumption. Typically only 300mW.

ORDERING INFORMATION

Model	Accuracy (Arc mins)	Operating Temperature Range	Package Options
2S82HP	22 + 1LSB	0 to +70°C	Plastic LCC
2S82JP	8 + 1LSB	0 to +70°C	Plastic LCC
2S82KP	4 + 1LSB	0 to +70°C	Plastic LCC
2S82LP	2 + 1LSB	0 to +70°C	Plastic LCC

SPECIFICATIONS (typical at 25°C unless otherwise specified)

Model	2S82	Units	Notes
TYPICAL CONVERTER PERFORMANCE (Connected as shown in Figure 1)			
Resolution	10, 12, 14 or 16	bits	
Accuracy HP Option	±22 + 1LSB	arc mins	Accuracy will be affected by the offset at the INTEGRATOR I/P.
JP Option	±8 + 1LSB	arc mins	
KP Option	±4 + 1LSB	arc mins	
LP Option	±2 + 1LSB	arc mins	
Tracking Rate Range			
10-Bit Resolution	0 to 1040	rps	User Selected, max rate limited to 1/16 of the reference frequency.
12-Bit Resolution	0 to 260	rps	
14-Bit Resolution	0 to 65	rps	
16-Bit Resolution	0 to 16.25	rps	
Operating Frequency Range	50 to 20,000	Hz	
Repeatability of Position Output	1	LSB	
Bandwidth	User Selectable		
Velocity Signal			See "Using the Velocity Signal."
Linearity			
Over Full Range	±1	% of output	See VCO spec.
Reversion Error	±1	%	With power supplies adjusted for best performance.
Zero Offset	+6	mV	For max tracking rate range. Depends on VCO I/P resistor (R6).
Zero Offset Tempco	−22	μV/°C	For max tracking rate range. Depends on VCO I/P resistor (R6).
Gain Scaling Accuracy	±10	% FSD	
Output Voltage	±8	V dc	
Noise and Ripple			
at LSB Rate	2	mV	See section "Using the Velocity Output."
Dynamic Ripple (Peak)	1.5	% of mean output	
ANALOG INPUTS			
Protection	All analog inputs are diode protected against overvoltage at ±8V.		
REFERENCE INPUT			
Frequency	50–20,000	Hz	
Voltage Level Nominal	2	V rms	
Max	11	V peak	
Input Bias Current	60 (typ), 150 (max)	nA	
Input Impedance	>1	MΩ	
SIGNAL INPUTS (SIN, COS)			
Frequency	50–20,000	Hz	
Allowable Phase Shift (Signal to Reference)	10	Degrees	
Voltage Level	2, ±10%	V rms	
Input Bias Current	60 (typ), 150 (max)	nA	
Input Impedance	>1	MΩ	
Maximum Voltage Nominal	±8	V	
DIGITAL INPUTS	TTL Compatible		Except DATA LOAD and SHORT CYCLE INPUTS.
INHIBIT			
Sense	Logic LO to inhibit		See section "INHIBIT Input."
Time to Data Stable (After Negative Going Edge of INHIBIT)	600	ns	
DATA LOAD			
Sense	Internally pulled up to +12V. Unconnected for normal operation. Logic LO allows data to be loaded into the counters from the data lines.		Connect when multiplexing the 2S82 or when using as a control transformer. Ensure data lines are in high impedance state when loading data.
SHORT CYCLE INPUTS (SC1, SC2)			Internally pulled up to $+V_S$.
	SC1	SC2	Used to select the resolution of the converter.
For 10-Bit Resolution	0	0	0 = Digital Ground. Drive low with open collector TTL.
For 12-Bit Resolution	0	1	1 = Open Circuit (internally pulled up through 100kΩ).
For 14-Bit Resolution	1	0	
For 16-Bit Resolution	1	1	
BYTE SELECT			
Sense Logic HI	8 MSBs selected on data lines 1 to 8. LS Byte selected on data lines 9 to 16.		The size of the LS Byte will be between 2 and 8 bits depending on the resolution selected.
Logic LO	LS Byte selected on data lines 1 to 8 and 9 to 16.		
Time to Data Available (After Change in State)	150 (typ), 450 (max)		ns

Model	2S82	Units	Notes
$\overline{\text{COMPLEMENT}}$	Internally pulled up to +12V. Unconnected for normal operation. Logic LO to activate.		
$\overline{\text{ENABLE}}$			
Sense	Logic LO to enable position outputs. Logic HI position outputs in high impedance state.		
Enable and Disable Times	200 (typ), 550 (max)	ns	
ANALOG OUTPUTS			
Protection	Short-circuit output current limited to ±8mA, ±30%.		
Output Voltage Range, typ	+9 to −9	V	With 1mA load.
max	+10.5 to −10.5	V	
min	+8 to −8	V	
DIGITAL OUTPUTS			
Format	V_L = +5V	TTL Compatible	Voltage on V_L sets the voltage level of the digital outputs.
	V_L = +12V	CMOS Compatible	
POSITION OUTPUTS			
Format	Three-state natural binary		
Resolution	10, 12, 14 or 16	bits	
Number of Data Lines	16		
Max Load	3	LSTTL	
Monotonicity			
HP, JP, KP Options	Guaranteed to 14 bits		
LP Option	Guaranteed to 16 bits		
DIRECTION			
Sense	Logic HI when counting up. Logic LO when counting down.		
Timing	Only changes, if required, at start of output position data cycle.		
Max Load	3	LSTTL	
RIPPLE CLOCK			
Sense	Positive going edge when counting up from all "1s" and when counting down from all "0s" as data changes.		
Timing	Edge occurs at least 300ns before change in DIR can occur.		
Width	300 (min)	ns	
Reset	By start of next data update.		
Max Load	3	LSTTL	
BUSY			
Sense	Logic HI when converter position output changing.		
Timing	Positive going edge 50ns before change in position output.		
Width typ	300	ns	
min	200	ns	
max	600	ns	
Max Load	3	LSTTL	See Section "BUSY Output."
POWER SUPPLIES			The 2S82 may latch up if $+V_S$ is applied without $-V_S$.
Voltage Levels			
$+V_S$	+12 ±10%	V	
$-V_S$	−12 ±10%	V	
$+V_L$	+5 to +14	V	
Current			Over operating temperature range.
$+V_S$, $-V_S$ at 12V	12 (typ), 23 (max)	mA	
$+V_S$, $-V_S$ at 13.2V	19 (typ), 30 (max)	mA	
$+V_L$	0.5 (typ), 1.5 (max)	mA	
GENERAL			
Operating Temperature Range

Specifications subject to change without notice.

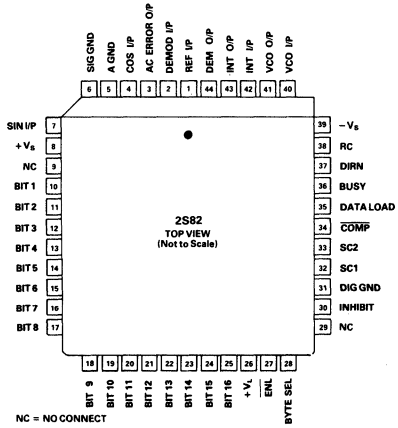
ABSOLUTE MAXIMUM INPUTS (with respect to GND)

$+V_S$[1]	0V to +14V dc
$-V_S$	0V to −14V dc
$+V_L$	0V to $+V_S$
Reference	+14V to $-V_S$
Sin	+14V to $-V_S$
Cos	+14V to $-V_S$
Any Logical Input	−0.4V to $+V_L$ dc
Demodulator Input	+14V to $-V_S$
Integrator Input	+14V to $-V_S$
VCO Input	+14V to $-V_S$

NOTE

[1]**CAUTION** – Correct polarity voltages must be maintained on the $+V_S$ and $-V_S$ pins.

PIN CONFIGURATION



OPERATION OF THE CONVERTER

When connected in a circuit such as is shown in Figure 1, the 2S82 operates as a tracking resolver-to-digital converter and forms a type 2 closed loop system. This means that the output will automatically follow the input for speeds up to the selected maximum tracking rate. No convert command is necessary as the conversion is initiated by each LSB increment of the input. Each LSB increment of the converter initiates a BUSY pulse.

Because the conversion depends on the ratio of the input signals, the 2S82 is remarkably tolerant of input amplitude and frequency (there is no need of an accurate, stable oscillator to produce the reference signal). The inclusion of a phase sensitive detector in the conversion loop ensures a high immunity to signals that are not coherent or are in quadrature with the reference signal.

Two major areas of the 2S82 specification can be selected by the user to optimize the total system performance. The resolution of the digital output is set by the state of the inputs SC1 and SC2 to be 10, 12, 14 or 16 bits, and the dynamic characteristics of bandwidth and tracking rate are selected by the choice of external components.

Position Output

The resolver shaft position is represented at the converter output by a natural binary parallel digital word.

As the digital output of the converter passes through the major carries, i.e., all "1s" to all "0s" or the converse, a RIPPLE CLOCK (RC) logic output is initiated indicating that a revolution or a pitch of the input has been completed.

The direction of input rotation is indicated by the DIRECTION (DIR) logic output. This direction data is always valid in advance of a RIPPLE CLOCK pulse and, as it is internally latched, only changes with a change in direction.

Both the RIPPLE CLOCK pulse and the DIRECTION data are unaffected by the application of the INHIBIT.

The static accuracy quoted is the worst case error that can occur over the full operating temperature excluding the effect of offset signals at the INTEGRATOR INPUT (which can be trimmed out) and with the following conditions: input signal amplitudes are within 5% of the nominal values; signal and reference frequency is within the specified operating range; phase shift between signal and reference is less than 10 degrees; signal and reference waveform harmonic distortion is less than 10%.

These test conditions are selected primarily to establish a repeatable acceptance test procedure which can be traced to national standards. In practice, the 2S82 can be used well outside these operating conditions providing the following points are observed.

Signal Amplitude (Sine and Cosine Inputs)

The amplitude of the signal inputs should be maintained within 5% of the nominal values if full performance is required from the velocity signal.

The digital position output is relatively insensitive to amplitude variation. Increasing the input signal levels by more than 10% will result in a dramatic loss in accuracy due to internal overload. Reducing level will result in a steady decline in accuracy. With the signal levels at 50% of the correct value, the angular error will increase to an amount equivalent to 1.3LSB. At this level the repeatability will also degrade to 2LSB and the dynamic response will also change, since the dynamic characteristics are proportional to the signal level.

The 2S82 will not be damaged if the signal inputs are applied to the converter without the power supplies and/or the reference.

Reference Voltage Level

The amplitude of the reference signal applied to the converter's input is not critical, but care should be taken to ensure it is kept below the absolute maximum voltage.

The 2S82 will not be damaged if the reference is supplied to the converter without the power supplies and/or the signal inputs.

Harmonic Distortion

The amount of harmonic distortion allowable on the signal and reference lines mainly depends on the type of transducer being used.

Square waveforms can be used but the input levels should be adjusted so that the average value is 1.9V rms. (For example, a square wave should be 1.9V peak.)

Note: The figure specified of 10% harmonic distortion is for calibration convenience only.

Velocity Signal

The tracking converter technique generates an internal signal at the output of the integrator (the INTEGRATOR OUTPUT pin) that is proportional to the rate of change of the input angle. This is a dc analog output referred to as the VELOCITY signal.

DC Error Signal

The signal at the output of the phase sensitive detector (DEMODULATOR OUTPUT) is the signal to be nulled by the tracking loop and is therefore proportional to the error between the input angle and the output digital angle. This is the DC ERROR of the converter; and as the converter is a type 2 servo loop, it will increase if the output fails to track the input for any reason. It is an indication that the input has exceeded the maximum tracking rate of the converter or, due to some internal malfunction, the converter is unable to reach a null. By connecting two external comparators, this voltage can be used as a "built-in test."

CONNECTING THE CONVERTER

The power supply voltages connected to $+V_S$ and $-V_S$ pins should be $\pm$ 12V and must not be reversed. If one rail is connected without the other, the converter will not operate and may "latch up." In this case, the removal of both rails is necessary in order for the converter to function correctly again. The voltage applied to V_L can be $+5V$ to $+V_S$.

It is suggested that decoupling capacitors are connected in parallel between the power lines $+V_S$, $-V_S$ and ANALOG GROUND adjacent to the converter. Suggested values of 100nF (ceramic) and 10μF (tantalum). Decoupling capacitors of 100nF and 10μF should also be connected between $+V_L$ and DIGITAL GROUND adjacent to the converter.

When more than one converter is used on a card, then separate decoupling capacitors should be used for each converter.

The resolver connections should be made to the SIN and COS inputs, REFERENCE INPUT and SIGNAL GROUND as shown in Figure 7 and described in section "CONNECTING THE RESOLVER". The two signal ground wires from the

resolver should be joined at the SIGNAL GROUND pin of the converter to minimize the coupling between the sine and cosine signals. For this reason it is also recommended that the resolver is connected using twisted pair cables with the sine, cosine and reference signals twisted separately.

SIGNAL GROUND and ANALOG GROUND are connected internally. ANALOG GROUND and DIGITAL GROUND must be connected externally.

The external components required should be connected as shown in Figure 1.

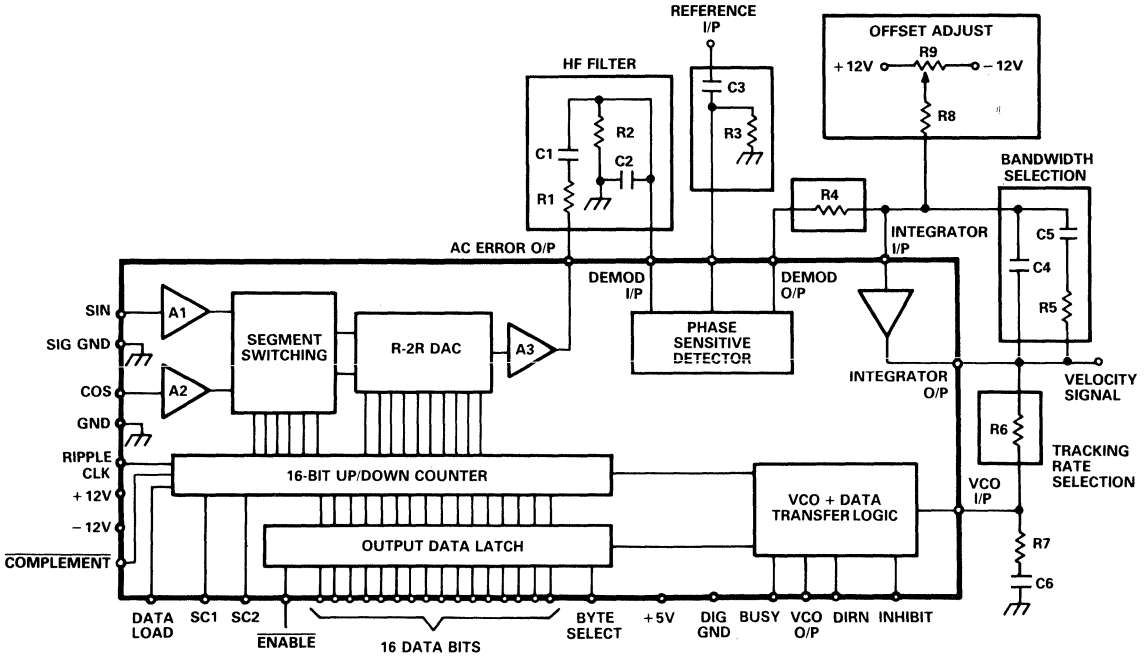


Figure 1. 2S82 Connection Diagram

SELECTING THE RESOLUTION

The resolution of the 2S82 can be selected to be 10, 12, 14 or 16 bits by use of the short cycling inputs SC1 and SC2. The required resolution can be selected as shown in the specification section.

The choice of resolution will affect the values of R4 and R6 which scale the inputs to the integrator and the VCO respectively (see section "COMPONENT SELECTION"). If the resolution is changed, then new values of R4 and R6 must be switched into the circuit.

Note: When changing resolution under dynamic conditions, a period of uncertainty will exist before position and velocity data is valid.

COMPONENT SELECTION

The following instructions describe how to select the external components to the converter in order to achieve the required bandwidth and tracking rate. In all cases the nearest "preferred value" component should be used and a 5% tolerance will not degrade the overall performance of the converter. Care should be taken that the resistors and capacitors will function over the required operating temperature range. The components should be connected as shown in Figure 1.

For more detailed information and explanation, see section "CIRCUIT FUNCTIONS AND DYNAMIC PERFORMANCE."

1. HF Filter (R1, R2, C1, C2)
   The function of the HF filter is to reduce the amount of noise present on the signal inputs to the 2S82, reaching the Phase Sensitive Detector and affecting the outputs. R1 and C2 may be omitted – in which case R2 = R3 and C1 = C3, calculated below – but their use is particularly recommended if noise from a switch mode motor drive is present.

   Values should be chosen so that

   $$R1 = R2 \leq 56k\Omega$$

   $$C1 = C2 = \frac{1}{2\pi\, R1\, f_{REF}}$$

   and f_{REF} = reference frequency. (Hz)

   This filter gives an attenuation of 3 times at the input to the phase sensitive detector.

2. Gain Scaling Resistor (R4)
   If R1, C2 are fitted then:

   $$R4 = \frac{E_{DC}}{100 \times 10^{-9}} \times \frac{1}{3}\,\Omega$$

   If R1, C2 are not fitted then:

   $$R4 = \frac{E_{DC}}{100 \times 10^{-9}}\,\Omega$$

   where E_{DC} = 160×10^{-3} for 10 bits resolution
   = 40×10^{-3} for 12 bits
   = 10×10^{-3} for 14 bits
   = 2.5×10^{-3} for 16 bits
   = Scaling at the DC ERROR in volts

3. AC Coupling of Reference Input (R3, C3)
Select R3 and C3 so that there is no significant phase shift at the reference frequency. That is,

$$R3 = 100k\Omega$$

$$C3 > \frac{1}{10^5 \times f_{REF}}$$

4. Maximum Tracking Rate (R6)
The VCO input resistor R6 sets the maximum tracking rate of the converter and hence the velocity scaling as at the max tracking rate the velocity output will be 8V.

Decide on your required maximum tracking rate, "T," in revolutions per second. Note that "T" must not exceed the specified maximum tracking rate or 1/16 of the reference frequency.

$$R6 = \frac{5.92 \times 10^7}{T \times p}\ k\Omega$$

where p = bit per rev
= 1,024 for 10 bits resolution
= 4,096 for 12 bits
= 16,384 for 14 bits
= 65,536 for 16 bits

5. Closed Loop Bandwidth Selection (C4, C5, R5)
a. Choose the Closed Loop 3dB Bandwidth (f_{BW}) required ensuring that

$$f_{REF} > 2.5 \times f_{BW}$$

Typical values may be 100Hz for 400Hz reference frequency and 500 to 1000Hz for 5kHz reference frequency.

b. Select C4 so that

$$C4 = \frac{20.2 \times 10^{-3}}{R6 \times f_{BW}^2}$$

with R6 in kΩ and f_{BW} in Hz selected above.

c. C5 is given by

$$C5 = 5 \times C4$$

d. R5 is given by

$$R5 = \frac{4}{2 \times \pi \times f_{BW} \times C5}\ \Omega$$

6. VCO Phase Compensation
The following values of C6 and R7 should be fitted.

C6 = 470pF R7 = 68Ω

7. Offset Adjust
Offset and bias current at the integrator input can cause an additional positional offset at the output of the converter of 1 arc min typical, 5.3 arc mins maximum. If this can be tolerated, then R8 and R9 can be omitted from the circuit.

If fitted, the following values of R8 and R9 should be used: R8 = 4.7MΩ, R9 = 1MΩ potentiometer.

To adjust for zero offset, ensure the resolver is disconnected and all the other external components are fitted. Connect the COS pin to the REFERENCE INPUT and the SIN pin to the SIGNAL GROUND and with the power and reference applied, adjust the potentiometer to give all "0s" on the digital output bits.

The potentiometer may be replaced by select on test resistors if preferred.

PIN FUNCTIONS

REFERENCE I/P	Input pin for the reference signal.
DEMOD I/P	Demodulator input pin.
AC ERROR O/P	Output of ratio multiplier.
COS	Input pin for cosine signal from resolver.
ANALOG GROUND	Power ground.
SIGNAL GROUND	Ground pin for signals from resolver.
SIN	Input pin for sine signal from resolver.
$+V_S$	Main positive power supply.
BIT 1 – BIT 16	Parallel output data bits.
V_L	Logic power supply.
$\overline{\text{ENABLE}}$	Logic "HI" sets the output data bits to a high impedance state, a logic "LO" presents the data in the latches to the output pins.
BYTE SELECT	Selects the data output bits presented on data bits 1 to 8. Logic "HI" will present the 8 most significant bits; a logic "LO" will present the least significant byte.
INHIBIT	Logic "LO" inhibits the data transfer from the counter to the output latches.
DIGITAL GROUND	Ground pin for digital circuitry.
SC1, SC2	Logic inputs used for selecting the resolution of the converter.
DATA LOAD	Logic "LO" allows data to be loaded into the counters.
BUSY	Converter BUSY. A logic "HI" indicates that the output latches are being updated and data should not be transferred.
DIRECTION	Logic output indicating the direction of rotation of the input signals.
RIPPLE CLOCK	A negative going pulse whenever the output of the converter changes from all "1s" top all "0s" or the converse.
$-V_S$	Main negative power supply.
VCO I/P	Input pin to VCO.
INTEGRATOR I/P	Input pin of integrator.
INTEGRATOR O/P	Output pin of integrator.
DEMOD O/P	Output pin of demodulator.
$\overline{\text{COMPLEMENT}}$	Logic "LO" to activate
VCO O/P	Output pin of VCO.

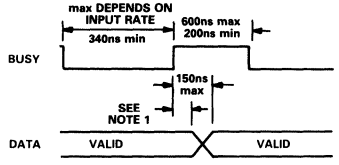
DATA TRANSFER
Data transfer can be accomplished using either the INHIBIT input or the trailing edge of the BUSY pulse output.

INHIBIT Input:
The INHIBIT logic input only inhibits the data transfer from the internal up-down counter to the output latches and, therefore, does not interrupt the operation of the tracking loop. Releasing the INHIBIT automatically generates a BUSY pulse to refresh the output data.

The output data is valid 350ns after the application of a logic "Lo" to the INHIBIT but the INHIBIT input must remain "Lo" for at least 600ns; otherwise the BUSY pulse generated by the logic "Lo" to "Hi" transition of the INHIBIT input may overlap the BUSY pulse that may have occurred at the time the INHIBIT is applied. The time required to assert the INHIBIT is 100ns.

BUSY Output:
The validity of the output data is indicated by the state of the BUSY output. When the input to the converter is changing, the signal appearing on the BUSY output is a series of pulses at TTL levels. A BUSY pulse is initiated each time the input moves by an analog equivalent of an LSB and the internal counter is incremented or decremented or the INHIBIT input is released.

Typically the width of the BUSY pulse is 350ns during the position data output updates. The trailing edge of the BUSY pulse indicates that the position data output has been updated and is ready for transfer. The maximum load on the BUSY output using the trailing edge of the BUSY pulse is 3 LSTTL loads.



NOTE 1
THE USE OF THE LEADING EDGE OF THE BUSY TO PREDICT DATA UPDATES IS ADVERSELY AFFECTED BY THE CAPACITIVE LOADING ON THE BUSY PULSE. TO ENSURE THAT THE LEADING EDGE OF THE BUSY PULSE OVERLAPS DATA TRANSITIONS, THE MAXIMUM LOAD ON BUSY OUTPUT SHOULD BE 15pF AND IT SHOULD BE PULLED UP TO +5 VOLT SUPPLY VIA A 5kΩ. THIS WILL RESTRICT THE MAXIMUM LOAD ON THE BUSY OUTPUT TO 1 LSTTL LOAD.

Figure 2. Timing Diagram

$\overline{\text{ENABLE}}$ Input:
The ENABLE input determines the state of the output data. A logic "Hi" maintains the output data pins in the high impedance condition, and application of a logic "Lo" presents the data in the latches to the output pins. The operation of the ENABLE has no effect on the conversion process.

BYTE SELECT Input:
The BYTE SELECT input selects the byte of position data to be presented at the data output Bits 1 to 8. The least significant byte will be presented on data output Bits 9 to 16 (with the ENABLE input taken to a logic "Lo") regardless of the state of the BYTE SELECT pin. Note that when the 2S82 is used with a resolution less than 16 bits the unused data lines are pulled to a logic "Lo." A logic "Hi" on the BYTE SELECT input will present the eight most significant data bits on data output Bits 1 and 8. A logic "Lo" will present the least significant byte on data outputs 1 to 8, i.e., data outputs 1 to 8 will duplicate data outputs 9 to 16.

The operation of the BYTE SELECT has no effect on the conversion process of the converter.

RIPPLE CLOCK Output:
As the output of the converter passes through the major carry, i.e., all "1s" to all "0s" or the converse, a positive going edge on the RIPPLE CLOCK (RC) output is initiated indicating that a revolution, or a pitch, of the input has been completed. The pulse has a minimum width of 300ns and is reset by the start of the next data update cycle.

DIRECTION Output:
The DIRECTION (DIR) logic output indicates the direction of the input rotation, and this data is valid in advance of the RIPPLE CLOCK pulse and stays valid until the direction changes. This is the start of the next data update cycle – if the direction of rotation of the inputs has changed – and will be at least 300ns after the rising edge of the RIPPLE clock.

The DIR and RC outputs are unaffected by the state of the INHIBIT input.

$\overline{\text{COMPLEMENT}}$
The $\overline{\text{COMPLEMENT}}$ pin is internally pulled up to +12V in the INACTIVATE STATE. It is pulled down to DIGITAL GROUND (~100μA) to ACTIVATE.

When used in conjunction with the DATA LOAD pin, Strobing Data Load and $\overline{\text{COMPLEMENT}}$ pins "LOW" will set the logic "HIGH" bits of the 2S82 counter to a "LOW" state. Those bits of the applied data which are logic "LOW" will not change the corresponding bits in the 2S82 counter.

For example:

Initial Counter State	– – – 1 0 1 0 1 – – –
Applied Data Word	– – – 1 1 0 0 0 – – –
Counter State after Data Load Only	– – – 1 1 0 0 0 – – –
Initial Counter State	– – – 1 0 1 0 1 – – –
Applied Data Word	– – – 1 1 0 0 0 – – –
Counter State after Data Load and Complement	– – – 0 0 1 0 1 – – –

In order to read the output the following procedure should be followed:
1. Place outputs in high impedance state (ENABLE – "HIGH").
2. Present data to pins.
3. Pull DATA LOAD and COMPLEMENT pins to ground.
4. Wait 100ns.
5. Remove data from pins.
6. Remove outputs from high impedance state (ENABLE – "LOW").
7. Read Outputs.

CIRCUIT FUNCTIONS AND DYNAMIC PERFORMANCE

The 2S82 allows the user great flexibility in choosing the dynamic characteristics of the resolver-to-digital conversion to ensure the optimum system performance. The characteristics are set by the external components shown in Figure 1, and the section "COMPONENT SELECTION" explains how to select desired maximum tracking rate and bandwidth values. The following paragraphs explain in greater detail the circuit of the 2S82 and the variations in the dynamic performance available to the user.

Loop Compensation
The 2S82 (connected as shown in Figure 1) behaves as a type 2 tracking servo loop where the VCO/counter combination and the integrator perform the two integration functions inherent in a type 2 loop.

Additional compensation in the form of a pole/zero pair is required to stabilize any type 2 loop to avoid the loop gain characteristic crossing the 0dB axis with 180° of additional phase lag, as shown in Figure 4. This compensation is implemented by the integrator components (R4, C4, R5, C5).

The overall response of such a system is that of a unity gain second order low pass filter, with the angle of the resolver as the input and the digital position data as the output.

The 2S82 does not have to be connected as tracking converter; parts of the circuit can be used independently. This is particularly true of the ratio multiplier which can be used as a control transformer.

A block diagram of the 2S82 is given in Figure 3.

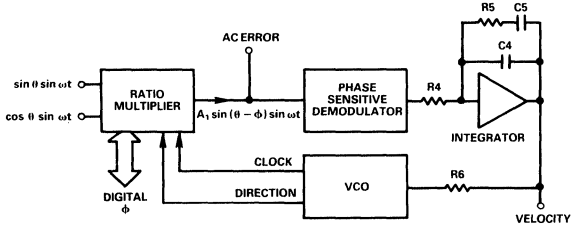


Figure 3. 2S82 Functional Diagram

Ratio Multiplier

The ratio multiplier is the input section of the 2S82 and compares the signal from the resolver inputs, θ, to the digital angle, ϕ, held in the counter. Any difference between these two angles results in an analog voltage at the AC ERROR OUTPUT. This circuit function has historically been called a "Control Transformer" as it was originally performed by a mechanical device known by that name.

The AC ERROR signal is given by

$A1 \sin(\theta - \phi) \sin\omega t$.

where $\omega = 2\pi f_{REF}$

f_{REF} = reference frequency

A1, the gain of the ratio multiplier stage is 14.5 times.

So for 2V rms inputs signals

AC ERROR output in volts/(bit of error)

$$= 2 \times \sin\left(\frac{360}{p}\right) \times A1$$

where p = bits per rev

= 1,024 for 10 bits resolution

= 4,096 for 12 bits

= 16,384 for 14 bits

= 65,536 for 16 bits

Giving AC ERROR output

= 178mV rms/bit @ 10 bits resolution

= 44.5mV rms/bit @ 12 bits

= 11.125mV rms/bit @ 14 bits

= 2.78mV rms/bit @ 16 bits.

The ratio multiplier will operate in exactly the same way whether the 2S82 is connected as a tracking converter or as a control transformer, where data is preset into the counters using the DATA LOAD pin.

HF Filter

The AC ERROR OUTPUT may be fed to the PSD via a simple ac coupling network (R2, C1) to remove any dc offset at this point. Note, however, that the PSD of the 2S82 is a wideband demodulator and is capable of aliasing HF noise down to within the loop bandwidth. This is most likely to happen where the resolver is situated in particularly noisy environments, and the user is advised to fit a simple HF filter R1, C2 prior to the phase sensitive demodulator.

The attenuation and frequency response of a filter will affect the loop gain and must be taken into account in deriving the loop transfer function. The suggested filter (R1, C1, R2, C2) is shown in Figure 1 and gives an attenuation at the reference frequency (f_{REF}) of 3 times at the input to the phase sensitive demodulator.

Values of the components used in the filter must be chosen to ensure that the phase shift at f_{REF} is within the allowable signal to reference phase shift of the converter.

Phase Sensitive Demodulator

The phase sensitive demodulator is effectively ideal and develops a mean dc output at the DEMODULATOR OUTPUT pin of

$$\frac{\pm 2\sqrt{2}}{\pi} \times \text{(DEMODULATOR INPUT rms voltage)}$$

for sinusoidal signals in phase or antiphase with the reference (for a square wave the DEMODULATOR OUTPUT voltage will equal the DEMODULATOR INPUT). This provides a signal at the DEMODULATOR OUTPUT which is a dc level proportional to the positional error of the converter.

DC Error Scaling = 160mV/bit (10 bits resolution)

= 40mV/bit (12 bits resolution)

= 10mV/bit (14 bits resolution)

= 2.5mV/bit (16 bits resolution)

When the tracking loop is closed, this error is nulled to zero unless the converter input angle is accelerating.

Integrator

The integrator components (R4, C4, R5, C5) are external to the 2S82 to allow the user to determine the optimum dynamic characteristics for any given application. The section "COMPONENT SELECTION" explains how to select components for a chosen bandwidth.

Since the output from the integrator is fed to the VCO INPUT, it is proportional to velocity (rate of change of output angle) and can be scaled by selection of R6, the VCO input resistor. This is explained in the section "VOLTAGE CONTROLLED OSCILLATOR (VCO)" below.

To prevent the converter from "flickering" (i.e., continually toggling by ±1 bit when the quantized digital angle, ϕ, is not an exact representation of the input angle, θ) feedback is internally applied from the VCO to the integrator input to ensure that the VCO will only update the counter when the error is greater than or equal to 1 bit. In order to ensure that this feedback "hysteresis" is set to 1LSB the input current to the integrator must be scaled to be 100nA/bit. So,

$$R4 = \frac{\text{DC Error Scaling (mV/bit)}}{100\ \text{(nA/bit)}}\ \text{MΩ}$$

Any offset at the input of the integrator will affect the accuracy of the conversion as it will be treated as an error signal and offset the digital output. One LSB of extra error will be added for each 100nA of input bias current. The method of adjusting out this offset is given in the section "COMPONENT SELECTION."

Voltage Controlled Oscillator (VCO)

The VCO is essentially a simple integrator feeding a pair of dc level comparators. Whenever the integrator output reaches one of the comparator threshold voltages, a fixed charge is injected into the integrator input to balance the input current. At the same time the counter is clocked either up or down, dependent on the polarity of the input current. In this way the counter is clocked at a rate proportional to the magnitude of the input current of the VCO.

During the reset period the input continues to be integrated although the reset period is constant at 400ns.

The VCO rate is fixed for a given input current by the VCO scaling factor,

$= 7.4\text{kHz}/\mu\text{A}$

The tracking rate in rps per μA of VCO input current can be found by dividing the VCO scaling factor by the number of LSB changes per rev (i.e., 4096 for 12-bit resolution).

The input resistor R6 determines the scaling between the converter velocity signal voltage at the INTEGRATOR OUTPUT pin and the VCO input current. Thus to achieve a 5V output at 100 rps (6000 rpm) and 12-bit resolution the VCO input current must be:

$(100 \times 4096)/(7400) = 55.3\mu\text{A}$

Thus, R6 would be set to: $5/(55.3 \times 10^{-6}) = 90\text{k}\Omega$

The velocity offset voltage depends on the VCO input resistor, R6, and the VCO bias current and is given by

Velocity Offset Voltage = R6 × (VCO bias current)

The temperature coefficient of this offset is given by

Velocity Offset Tempco = R6 × (VCO bias current tempco)

where the VCO bias current tempco is typically −0.55nA/°C.

The maximum recommended rate for the VCO is 1.1MHz which sets the maximum possible tracking rate.

Since the maximum voltage swing available at the integrator output is ±8V, this implies that the minimum value for R6 is 54kΩ. As

$$\text{Max Current} = \frac{1.1 \times 10^6}{7.4 \times 10^3} = 149\mu\text{A}$$

$$\text{Min Value } R_6 = \frac{8}{149 \times 10^{-6}} = 54\text{k}\Omega$$

VCO OUTPUT

VCO OUTPUT: In order to overcome the "free play" inherent in a servo system using digitized position feedback, an analog output voltage is available representing the resolver shaft position within the least significant bit of the digital angle output.

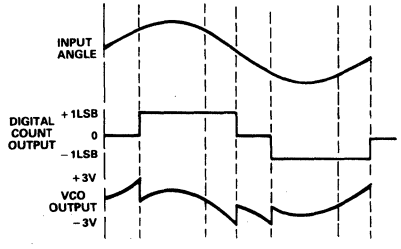

Figure 4.

The converter updates the output if the error is an LSB or greater and the VCO output gives the positional error smaller than 1LSB.

Figure 4 illustrates how the VCO output compensates for the instances where, due to hysteresis, there is no change in the digital count output for 1LSB change in input angle. The sum of the digital count output and VCO output equals the actual input angle.

Transfer Function

By selecting components using the method outlined in the section "Component Selection" the converter will have a critically damped time response and maximum phase margin. The closed-loop transfer function is given by:

$$\frac{\theta_{OUT}}{\theta_{IN}} = \frac{14\,(1 + s_N)}{(s_N + 2.4)\,(s_N^2 + 3.4\,s_N + 5.8)}$$

where, s_N, the normalized frequency variable is

$$s_N = \frac{2}{\pi}\,\frac{s}{f_{BW}}$$

and f_{BW} is the closed-loop 3dB bandwidth (selected by the choice of external components).

The acceleration constant, K_A, is given approximately by

$$K_A = 6 \times (f_{BW})^2 \quad \text{sec}^{-2}$$

The normalized gain and phase diagrams are given in Figures 5 and 6.

The small signal step response is shown in Figure 6. The time from the step to the first peak is t_1, and the t_2 is the time from

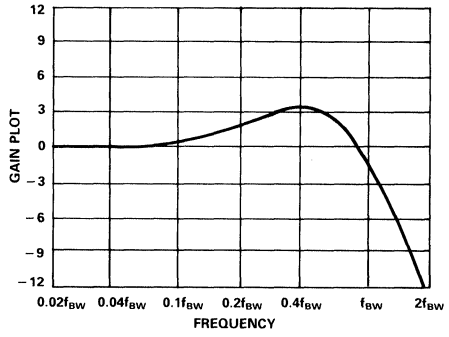

Figure 5. 2S82 Gain Plot

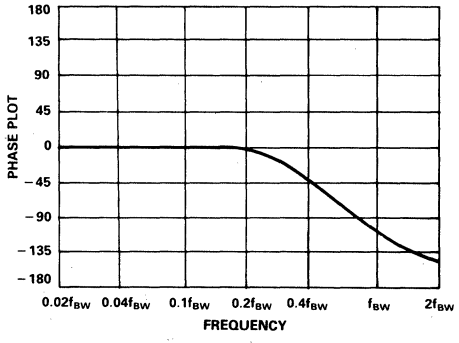

Figure 6. 2S82 Phase Plot

the step until the converter as settled to 1LSB. The times t_1 and t_2 are given approximately by

$$t_1 = \frac{1}{f_{BW}}$$

$$t_2 = \frac{5}{f_{BW}} \times \frac{R}{12}$$

where R = resolution, i.e., 10, 12, 14 or 16.

The large signal step response (for steps greater than 10 degrees) applies when the error voltage will exceed the linear range of the converter. Typically the converter will take 3 times longer to reach the first peak for a 179 degrees step.

The response to a velocity step, the velocity output will exhibit the same time response characteristics as outlined above for the position output.

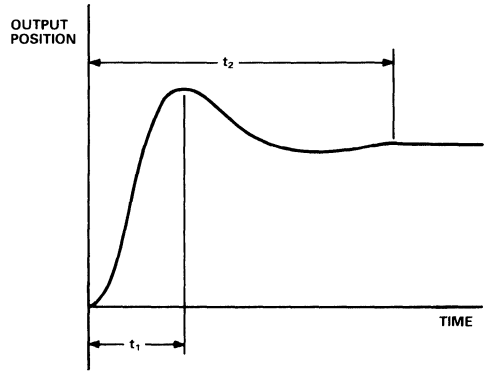

Figure 7. 2S82 Small Step Response

APPLICATIONS

USING THE 2S82 AS A CONTROL TRANSFORMER

The ratio multiplier section of the 2S82 can be used independently to the rest of the converter to perform the function of control transformer. In this mode the signal from the resolver inputs, θ, is compared to a digital angle, ϕ, loaded into the counters. Any difference between these two angles results in an analog voltage at the AC ERROR OUTPUT. To use the device in this way the DATA LOAD pin is used.

Applying a logic "Lo" to the DATA LOAD pin will allow data to be loaded into the counters of the converter from the data lines. It is important that the data lines are placed in the high impedance state before loading data.

To operate the 2S82 as a tracking resolver-to-digital converter the DATA LOAD pin should be left unconnected as it is pulled high internally to +12V.

CAUSES OF ADDITIONAL ERROR

Integrator Offset

Additional inaccuracies in the conversion of the resolver signals will result from an offset at the input to the integrator as it will be treated as an error signal. This error will be typically 1 arc minute over the operating temperature range.

A description of how to adjust for zero offset is given in the section "COMPONENT SELECTION" and the circuit required is shown in Figure 1.

Differential Phase Shift

Phase shift between the sine and the cosine signals from the resolver is known as differential phase shift and can cause static error. Some differential phase shift will be present on all resolvers as a result of coupling. A small resolver residual voltage (quadrature voltage) indicates a small differential phase shift. Additional phase shift can be introduced if the sine channel wires and the cosine channel wires are treated differently. For instance, different cable lengths or different loads could cause differential phase shift.

The additional error caused by differential phase shift on the input signals approximates to

Error = 0.53 a·b arc minutes

where a = differential phase shift in degrees
and b = signal to reference phase shift in degrees.

This error can be minimized by choosing a resolver with a small residual voltage, ensuring that the sine and cosine signals are handled identically and removing the reference phase shift (see section "CONNECTING THE RESOLVER"). By taking these precautions, the extra error can be made insignificant.

Resolver Phase Shift

Under static operating conditions phase shift between the reference and the signal lines alone will not theoretically affect the converter's static accuracy.

However, most resolvers exhibit a phase shift between the signal and the reference. This phase shift will give rise under dynamic conditions to an additional error defined by:

$$\frac{\text{Shaft Speed (rps)} \times \text{Phase Shift (Degs)}}{\text{Reference Frequency}}$$

For example, for a phase shift of 20 degrees, a shaft rotation of 22 rps and a reference frequency of 5kHz, the converter will exhibit an additional error of:

$$\frac{22 \times 20}{5000} = 0.088 \text{ degrees}$$

This effect can be eliminated by putting a phase shift in the reference to the converter equivalent to the phase shift in the resolver (see section "CONNECTING THE RESOLVER").

NOTE: Capacitive and inductive crosstalk in the signal and reference leads and wiring can cause similar problems.

USING THE VELOCITY SIGNAL

The signal at the INTEGRATOR OUTPUT pin relative to the ANALOG GROUND pin is an analog voltage proportional to the rate of change of the input angle. This signal can be used to stabilize servo loops or in place of a velocity transducer. Although the conversion loop of the 2S82 includes a digital section there is an additional totally analog feedback loop around the velocity signal. This ensures that there is no digital effects on the output signal and that the loop is closed even when the input signals are such that the digital output does not change.

A better quality velocity signal will be achieved if the following points are considered.

1. Protection.
   The velocity signal should be buffered before use.
2. Reversion Error.
   If necessary, the reversion error can be reduced by a simple trimming circuit. Reversion error, or side-to-side nonlinearity, is a result of differences in the up and down rates of the VCO. The reversion error can be nulled by varying one supply rail relative to the other.
3. Ripple and Noise.
   Noise on the input signals to the converter is the major cause of noise on the velocity signal. This can be reduced to a minimum if the following precautions are taken:

   The resolver is connected to the converter using separate screened twisted pair cable for the sine, cosine and reference signals.

   Care is taken to reduce the external noise wherever possible.

   An HF filter is fitted before the Phase Sensitive Demodulator (as described in the section HF FILTER).

   A resolver is chosen that has a low residual voltage, i.e., a small signal in quadrature with the reference.

   Components are selected to operate the 2S82 with the lowest acceptable bandwidth.

   Feedthrough of the reference frequency should be removed by a filter on the velocity signal.

   The signal voltages are 2V rms to prevent a ripple at the LSB switching rate. This is because the 1LSB of analog feedback that prevents the output from flickering will be incorrectly scaled (see section "INTEGRATOR").

If the above precautions are taken, a very good noise and ripple performance is obtainable making the 2S82 velocity signal usable in very noisy environments, for instance in motor drive applications with PWM switching noise.

The positional error curve of the converter and the resolver will result in an apparent acceleration when the resolver is rotating at a constant velocity. The main result of this will be a ripple on the velocity signal twice per revolution.

CONNECTING THE RESOLVER

The recommended connection circuit is shown in Figure 8.

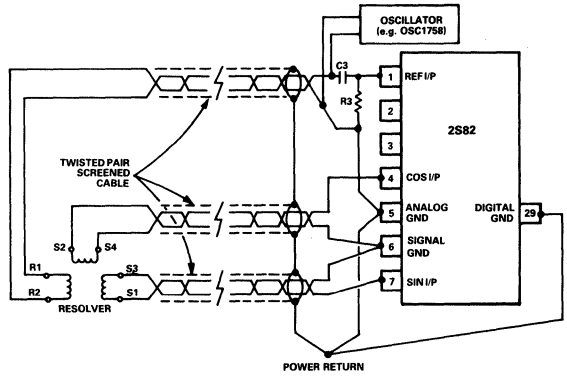

Figure 8. Connecting the 2S82 to a Resolver

In cases where the reference phase relative to the input signals from the resolver requires adjustment, this can be easily achieved by varying the value of the resistor R2 of the HF filter (see Figure 1).

Assuming that R1 = R2 = R and C1 = C2 = C

and Reference Frequency $= \frac{1}{2\pi R C}$

By altering the value of R2 the phase of the reference relative to the input signals will change in an approximately linear manner for phase shifts of up to 10 degrees.

Increasing R2 by 10% introduces a phase lag of 2 degrees. Decreasing R2 by 10% introduces a phase lead of 2 degrees.

For signal and reference voltages greater than 2V rms a simple voltage divider circuit of resistors can be used to generate the correct signal level at the converter. Care should be taken to ensure that the ratios of the resistors between the sine signal line and ground and the cosine signal line and ground are the same. Any difference will result in an additional position error.

5

GENERAL DESCRIPTION

The 5S70 series of miniature transformers provide Resolver-to-Resolver and/or Synchro-to-Resolver format transformations and input isolation for the 1S series of Resolver-to-Digital converters (e.g., 1S10/20/40/60/61, 1S14/24/44/64 and 1S74).

The 5S70 series accept all the standard synchro and resolver signal voltages and give the 2V rms required by the 1S series of converters.

The additional error introduced by the 5S70 is ±1.5 Arc Minute maximum.

The 5S72 transformers enable the reference input of the 1S series converters to be isolated and to accept voltages higher than the standard 2V rms.

All transformers operate over the 360Hz to 3kHz frequency range and have an operating temperature range of −55°C to +125°C.

The units are fitted with ruggedly secured threaded inserts to assist with PCB mounting.

The dc isolation is 1kV from primary to secondary and 5kV between any winding and the threaded insert.

The 5S70 transformers measure only 2.25" × 1.12" × 0.4" (57.0 × 28.5 × 10.2) and the 5S72 transformers 1.12" × 1.12" × 0.4" (28.5 × 28.5 × 10.2).

APPLICATIONS/USER BENEFITS

Apart from providing signal and reference isolation and allowing synchro inputs to be used with the 1S series of converters, high voltages can also be eliminated from the PCB by mounting the transformers externally.

In addition, by using a number of transformers on a PCB with a single converter, it is possible to cater for a number of different synchro and resolver configurations.

MODELS AVAILABLE

The 5S70 and 5S72 transformers are available with a variety of input voltage and format configurations. The transformers operate over the −55°C to +125°C temperature range and accept reference frequencies in the range 360Hz to 3kHz.

ORDERING INFORMATION

The transformers should be ordered by reference to the part numbers shown in the Specifications above.

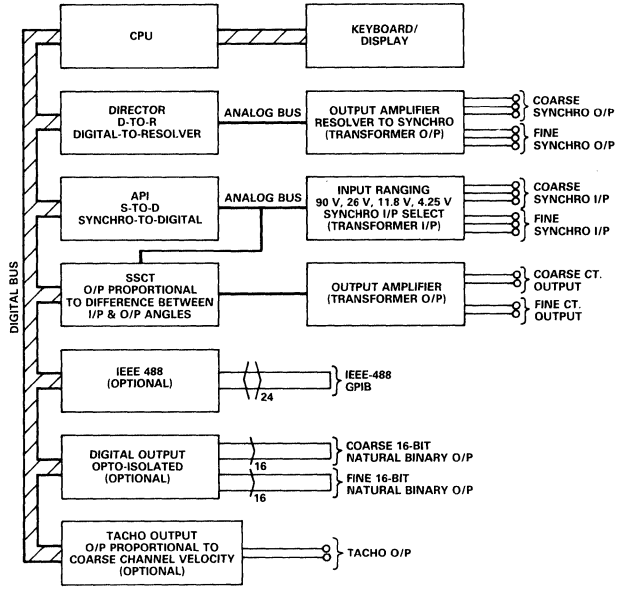
6S04 FUNCTIONAL BLOCK DIAGRAM



5

GENERAL DESCRIPTION

The 6S04 Digital Director is a microprocessor based **Universal Synchro Simulator and Test Instrument**.

It is designed as a portable Test Instrument and Synchro Simulator (Dummy Director) and its uses are the synchro transmitter electrical output simulation and testing of equipment with synchro inputs such as gun mounting sensors, radar processing and equipment and naval retransmission systems.

The 6S04 can be considered as three autonomous units.

The Director simulates the electrical outputs of a synchro coarse/fine transmitter. An operator can set the output of the director at any fixed angle and also select from a suite of predefined patterns of motion, referred to as "output functions."

The Angle Position Indicator measures and displays synchro format signals from either the director or an external synchro transmitter. The angular position of the selected source is displayed on the front panel of the instrument.

The Solid State Control Transformer simulates the action of a conventional control transformer by generating an analog signal proportional to the angular difference between the director output and the input from an external synchro transmitter.

SPECIFICATIONS (typical at +25°C unless otherwise specified)

Electrical Specification

MAINS POWER SUPPLY (Single Phase)

Voltage Range	115 V ac (90 V ac–132 V ac)
	220 V ac/240 V ac (180 V ac–265 V ac)
Supply Current	
1.4 A (typ)	2 A (max) (115 V ac)
0.7 A (typ)	1 A (max) (230 V ac)
Dissipation 160W (typ)	200 Watts (max)
Supply Frequency	47 Hz to 63 Hz
Fuse	2.5 A Anti-Surge (115 V ac)
	1.25 A Anti-Surge (230 V ac)
	Both 5 mm × 20 mm
Isolation	1000 V dc Input to Output
	1000 V dc Input to Case

DUMMY DIRECTOR

COARSE AND FINE REFERENCE INPUT (User Provided)

Voltage	115 V rms ±10% for Rated O/P
	3 V to 120 V rms for API Function
Frequency	60 Hz ±10% or 400 Hz ±10%
Input Impedance	220 kΩ (Nominal)
Isolation	500 V dc Galvanic Isolation

INTERNAL COARSE OUTPUT

Voltage	(Synchro) 90 V ±2% Line-to-Line at Nominal Reference and 100% Output Level
	(SLAB) 4.25 V ±2% Line-to-Line at Nominal Reference and 100% Output Level
Transformation Ratio	0.782 ±2% (Synchro)
	0.037 ±2% (SLAB)
Voltage Range	50% to 110% of Nominal,
	Resolution 1%, Accuracy ±0.5%
Resolution	0.01% of Output
Angular Accuracy	±0.1° @ 5 VA
	±0.15° @ 15 VA
Radius Vector Error	±0.1%
Energizing Power	15 VA @ 400 Hz Reference
	5 VA @ 60 Hz Reference
Energizing Current	200 mA (max)
Regulation	Better than 5% at 5 VA
	Better than 10% at 15 VA
Protection	Protected Against Open and Short Circuits, and Thermal Overload with Automatic Reset
Isolation	500 V dc Galvanic Isolation
Update Interval	0.977 ms
Effective Stator dc Resistance	20 Ω for 90 V Synchro Output
	1 Ω for SLAB Output

INTERNAL FINE OUTPUT

As Above Except:	
Voltage	(Synchro) 90 V ±2% Line-to-Line at Nominal Reference and 100% Ouput Level
	(SLAB) 11.8 V ±2% Line-to-Line at Nominal Reference and 100% Output Level
Transformation Ratio	0.782 ±2% (Synchro)
	0.037 ±2% (SLAB)
Effective Stator dc Resistance	20 Ω for 90 V Synchro Output
	2.4 Ω for SLAB Output

EXTERNAL COARSE AND FINE INPUT (for API)

Voltage	(a) 90 V ±20%

DIRECTOR FUNCTIONAL DESCRIPTION

The director consists of two electronically geared transmitters, each capable of providing a synchro transmitter output to an accuracy of ±0.1° under full load conditions. The combined accuracy of the two signals is determined by the gearing employed.

The signals may be selected to be either Synchro 90 V rms on both coarse and fine, or SLAB format, 4.25 V rms on coarse and 11.8V rms on fine.

OUTPUT FUNCTIONS

The user may select from the output functions below.

1. Datum Angle
   The combined coarse/fine output angle may be set at any angle between 0.00° to 359.99° to accuracy of ±0.1° and resolution of 0.01°.
2. Constant Velocity
   The synchro output can be made to rotate at constant rates in either direction at velocities from ±0.01° per second to ±359.99° per second.
3. Square Wave
   The output can be made to oscillate with a square waveform with a period selectable to any integer between 1 and 100 second and a peak-to-peak amplitude of between 0.00° and ±179.99°. The starting datum angle may be set at any angle in the range 0.00° to ±359.99°.
4. Sine Wave
   The output can be made to oscillate sinusoidally with a period selectable to any integer between 1 and 100 second and a peak amplitude of between 0.00° to ±179.99°. The center of oscillation may be set to any angle within the range 0.00° to ±359.99°.
5. Velocity + Square Wave
   This function superimposes the velocity and square wave functions as described above.
6. Manual Control
   Using the control knob, the velocity of the output angle can be varied mannually between 0° and ±90° per second on a logarithimic scale. In this mode, two push buttons are also enabled which allow the output angle to be stepped, either forwards or backwards by a fixed preselected amount between 0.00° to ±179.99°. These "INCH" keys are also enabled with the velocity function thus allowing manual steps to be superimposed on constant velocity.

ANGLE POSITION INDICATOR (API)

The API may be set to measure either the angle output from the Director or the angle input to the to the instrument from an external synchro transmitter. Either the coarse, the fine or the combined coarse and fine angle may be displayed. The display will normally be updated at a rate of approximately three times a second.

SOLID STATE CONTROL TRANSFORMER (SSCT)

The Solid State Control Transformer provides signals from both the coarse and fine channels, which are an indication of the angular difference between the director output, and the input from an external synchro transmitter. When used with 90 V, 26 V, 11.8 V and 4.25 V an error signal is produced which is scaled to give a 1 volt per degree of error. The null voltage is 150 mV maximum, which corresponds to an angular accuracy of 0.15°.

IEEE INTERFACE (Option 009)

The instrument can be provided with an IEEE 488 standard 24 wire General Purpose Interface Bus, which allows any standard IEEE controller to remotely operate the unit.

The IEEE standard 488 is a byte serial bit parallel interface system structured with 16 transmission lines of which 8 are data bus lines, 3 are data byte transfer control lines (handshake) and the remaining 5 are interface management lines.

The controller can set the unit to either Talk or Listen mode. In the Listen mode the controller can operate the various key functions, and in the Talk mode it can read the instruments API display. Please refer to operating manual for operator setup procedure for the IEEE Bus.

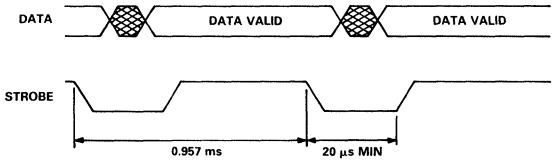
Interconnections

Refer to an IEEE handbook for detailed information and specifications.

DIGITAL OUTPUT (Option 090)

The digital output consists of two 16-bit parallel data channels carrying digital representations of the coarse and fine output angles. These are automatically updated with the coarse and fine output angles. Data is in the form of an unsigned 16-bit binary integer with the most significant bit representing 180 degrees.

BIT NO.	BIT WEIGHT (°)
1 (MSB)	180
2	90
3	45
4	22.5
5	11.25
6	5.625
7	2.812
8	1.406
9	0.703
10	0.352
11	0.176
12	0.088
13	0.044
14	0.022
15	0.011
16 (LSB)	0.005



Digital Output Timing

TACHO OUTPUT (Option 900)

The tacho output provides an analogue voltage signal via a BNC output socket which is proportional to the angular velocity of the coarse channel outputs.

[1] Package Options: D–Side-Brazed Dual-In-Line Ceramic; E–Leadless Chip Carrier; H–Round Hermetic Metal Can (Header); P–Plastic Leaded Chip Carrier (PLCC); Q–Cerdip.
[2]Temperature Ranges: C–Commercial, 0 to +70°C; I–Industrial, −40°C to +85°C (Some older products −25°C to +85°C); M–Military, −55°C to +125°C.
Boldface Type: Product recommended for new design.
*New product since the publication of the 1987/1988 Databooks.

Orientation
Sample/Track-Hold Amplifiers

The technical data in this volume embrace high-performance (high-resolution and high-speed) sample/track-holds in the form of monolithic and hybrid ICs. Besides the products in this section (stand-alone devices for performing the sample/track-hold function) similar functions can be found integrated into a variety of component and subsystem products. Component examples: a number of video A/D converters have on-board track-holds (MOD-1205); the monolithic AD7579/7580 A/D converters have integral sample-hold functions; and high-resolution D/A converters have deglitcher options (Deglitcher IV for the DAC1138). Besides these, sample-hold functions are inherent in data-acquisition subsystems and microcomputer analog I/O boards.

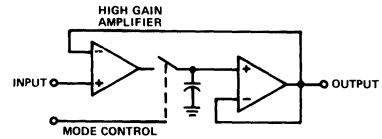
The principal application for sample/track-hold amplifiers is to maintain an analog-to-digital converter's input constant during conversion at a value representing the analog input as of a certain precisely known time. The characteristics of the SHA are crucial to system accuracy and the reliability of the digital data, especially in ≥12-bit and/or high-throughput-rate applications.

A sample/track-hold amplifier (s/h or SHA), as its name indicates, has two modes of operation, programmed by a digital control input. In the *track* or *sample* mode, the output follows the input, usually with a gain of +1. When the mode input switches to *hold*, the output of the SHA ideally retains the last value it had when the command to hold was given, and it retains that value until the logic input dictates *track (sample)*, at which time the output ideally jumps to the input value and follows the input until the next *hold* command is given.

Analog Devices' *track-holds* and *sample-holds* are functionally identical; they are designed to acquire input signals for either immediate hold or for a possibly extended period of tracking. They should not be confused with ac devices termed "sample-hold" that can *only* obtain quick samples and cannot track the input continuously.

SHA CIRCUITRY AND HARDWARE

A sample-hold amplifier usually consists of a storage capacitor, input- and output-buffer amplifiers and a switch and its drive circuitry. During *sample*, the circuit is connected to promote rapid charging of the capacitor. During *hold*, the capacitor is disconnected from its charging source and ideally retains its charge. The following figure shows a typical feedback configuration: the input buffer is a high-gain differential amplifier with a current output that charges the capacitor through the logic-controlled switch. The capacitor is unloaded by a unity-gain buffer-follower. The output is fed back to the negative input (as in an op amp follower configuration), and thus, in *sample* the charge on the capacitor is compelled to follow the input. In *hold*, the input amplifier no longer drives the capacitor; it retains its charge, unloaded by the output follower. In another popular configuration, the capacitor is used as the feedback element of an inside-the-loop integrator (AD346). The highest-speed devices usually run open-loop.

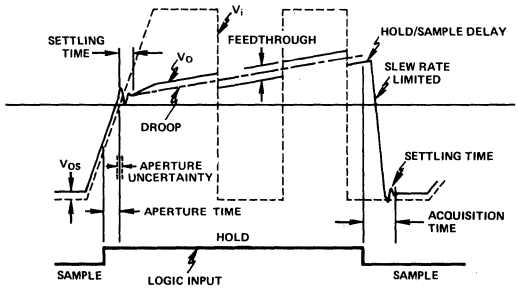


Since drive current is finite and leakage current in *hold* is not zero, the capacitance, if large, limits the slewing rate in *sample* and, if small, converts leakage current to "droop" in *hold*. In s/h *modules*, the capacitance is usually fixed, and the properties of the complete device are optimized for one condition, and so specified. In s/h *monolithic ICs*, the capacitor may be omitted and furnished by the user (both for flexibility and because good capacitors for this purpose are hard to integrate); the AD346 and AD585 have internal hold capacitors. The optimum capacitance can be selected for the specific application.

PERFORMANCE

In the *sample* mode, it is useful to consider that a SHA's performance can be characterized by specifications similar to those of a closed-loop operational amplifier (offset, drift, nonlinearity, gain error, bias current, etc.), but with somewhat slower response (gain-bandwidth, slewing rate, settling time) because of the need to charge the storage capacitor.

However, during the *sample-to-hold*, *hold* and *hold-to-sample* states, the dynamic nature of the mode-switching introduces a number of specifications that are peculiar to SHAs. The most important of these are defined below and illustrated in the adjoining figure. They include the *aperture time* and its *uncertainty*, the *sample-to-hold step*, *feedthrough* and *droop* (in hold) and *acquisition time*.



DEFINITIONS

Acquisition Time is the time required by the output of the device to reach its final value, within a specified error band, after the *sample* command has been given. Included are switch-delay time, the slewing interval and settling time for a specified output-voltage change.

Aperture (Delay) Time is the time required after the *hold* command for the switch to open fully. The sample is, in effect, delayed by this interval, and the *hold* command would have to be advanced by this amount for precise timing.

Aperture Uncertainty – or Aperture (Delay) Jitter – is the range of variation in the *aperture time*. If the *aperture time* is "tuned out" by advancing the *hold* command a suitable amount, this spec establishes the ultimate timing error, hence, the maximum sampling frequency to a given resolution. For example, the HTC-0300A specs are 8ns aperture time and 100ps aperture jitter.

Charge Transfer (or *offset step*), the principal component of *sample-to-hold* offset (or *pedestal*), is the charge transferred to the storage capacitor via stray capacitance when switching to the *hold* mode. It can sometimes be reduced by lightly coupling an appropriate polarity version of the *hold* signal to the capacitor for cancellation. The associated voltage error (ΔQ/C) can be reduced by using greater capacitance for storage, but this increases response time.

Droop is the change of the output voltage during *hold* as a result of leakage or bias currents flowing through the storage capacitor. Its polarity depends on the sources of leakage current within a given device. In ICs, it is specified as a (*droop* or *drift*) current, in modules, a dV/dt. [Note: I = C(dV/dt).]

Feedthrough is the fraction of the input signal variation or ac input waveform that appears at the output in *hold*. It is caused by stray capacitive coupling from the input to the storage capacitor, principally across the open switch.

Sample-to-Hold Offset, a shift in level between the last value in *sample* and the value settled-to in *hold*, is the residual step error after the *charge transfer* is accounted for and/or cancelled. Since it is unpredictable in magnitude and may be a function of the signal, it is also known as *offset nonlinearity*.

ANALOG DEVICES

High Speed Sample-and-Hold Amplifier

AD346

FEATURES

Fast 2.0μs Acquisition Time to ±0.01%
Low Droop Rate: 0.5mV/ms
Low Offset
Low Glitch: <40mV

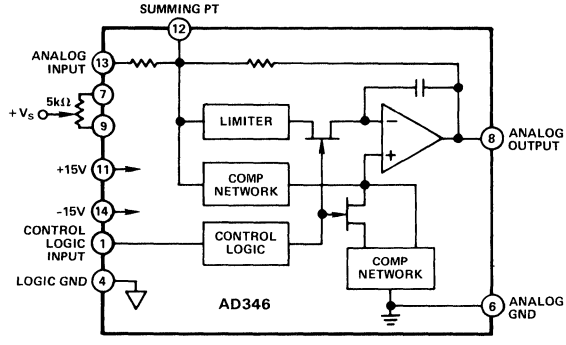
MIL-STD-883B Processing Available

AD346 FUNCTIONAL BLOCK DIAGRAM



6

PRODUCT DESCRIPTION

The AD346 is a high speed (2μs to 0.01%), adjustment free sample-and-hold amplifier designed for high throughput rate data acquisition applications. The fast acquisition time (2μs to 0.01%) and low aperture jitter (400ps) make it suitable for use with fast A/D converters to digitize signals up to 97kHz.

The AD346 is complete with an internal hold capacitor and it incorporates a compensation network which minimizes the sample to hold charge offset. The AD346 is also laser trimmed to eliminate the need for external trimming potentiometers.

Typical applications for the AD346 include sampled data systems, D/A deglitchers, peak hold functions, strobed measurement systems and simultaneous sampling converter systems.

The device is available in two versions: the "J" specified for operation over the 0 to +70°C commercial temperature range and the "S" specified over the extended temperature range, −55°C to +125°C.

ORDERING GUIDE

Model	Temperature Range	Package Option*
AD346JD	0 to +70°C	DH-14A
AD346SD	−55°C to +125°C	DH-14A
AD346SD/883B	−55°C to +125°C	DH-14A

*See Section 14 for package outline information.

PRODUCT HIGHLIGHTS

1. The AD346 is an improved second source for other sample and holds of the same pin configuration.
2. The AD346 provides separate analog and digital grounds, thus improving the device's immunity to ground and switching transients.
3. The droop rate is only 0.5mV/ms so that it may be used in slower high accuracy systems without the loss of accuracy.
4. The fast acquisition time and low aperture make it suitable for very high speed data acquisition systems.

TERMINOLOGY

Aperture Time is the time required after the "hold" command until the switch is fully open and produces a delay in the effective sampling timing.

Aperture Jitter is the uncertainty in Aperture Time. If the Aperture Time is "tuned out" by advancing the sample-to-hold command with respect to the input signal, the Aperture Jitter now determines the maximum sampling frequency.

Acquisition Time is the time required by the device to reach its final value within a given error band after the sample command has been given. This includes switch delay time, slewing time and settling time for a given output voltage change.

Droop is the change in the output voltage from the "held" value as a result of device leakage.

Feedthrough is that component of the output which follows the input signal *after* the switch is open. As a percentage of the input, feedthrough is determined as the ratio of the feedthrough capacitance to the hold capacitance (C_F/C_H).

Pedestal during hold is a sample-to-hold offset. This is an offset that occurs from such phenomena as charge dumps when switches are opened, coupling of the logic signal transients.

Transients are the spikes or glitches that occur on the output at the start and end of hold time.

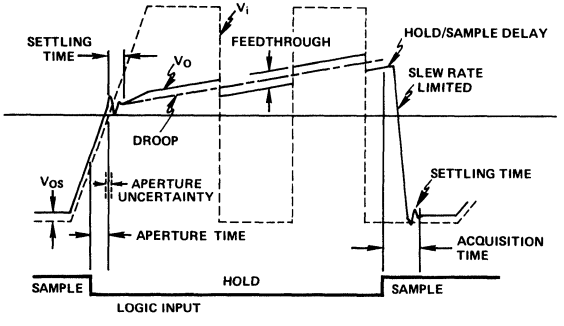

Figure 6. Pictorial Showing Various S/H Characteristics

GROUNDING

Many data-acquisition components have two or more ground pins which are not connected together within the device. These "grounds" are usually referred to as the Logic Power Return, Analog Common (Analog Power Return), and Analog Signal Ground. These grounds must be tied together at one point, usually at the system power-supply ground. Ideally, a single solid ground would be desirable. However, since current flows through the ground wires and etch stripes of the circuit cards, and since these paths have resistance and inductance, hundreds of millivolts can be generated between the system ground point and the ground pins of the AD346. Separate ground returns should be provided to minimize the current flow in the path from sensitive points to the system ground point. In this way supply currents and logic-gate return currents are not summed into the same return path as analog signals where they would cause measurement errors.

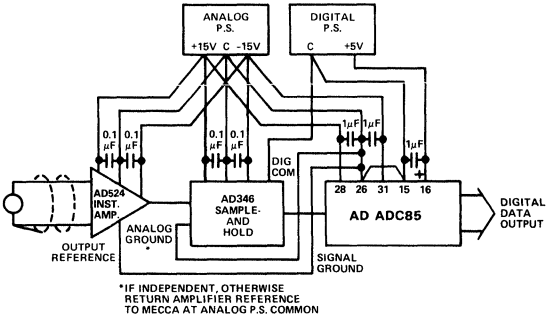

Figure 7. Basic Grounding Practice

SAMPLED DATA SYSTEMS

The fast acquisition time of the AD346 when used with a high speed A/D converter allows accurate digitization of high frequency signals and high throughput rates in multichannel data acqusition systems. The AD346 can be used with a number of different A/D converters to achieve high throughput rates. Figures 8, 9 and 10 show the use of an AD346 with the AD578, AD5240 and AD ADC85.

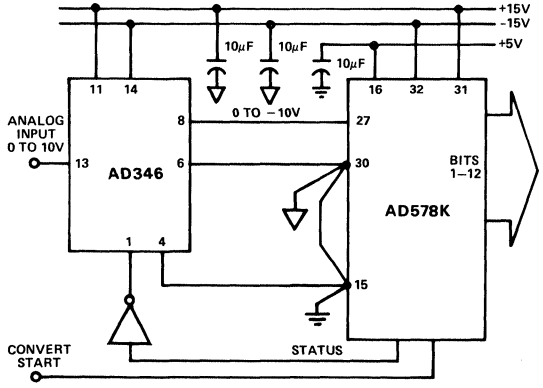

Figure 8. 153kHz–12-Bit, A/D Conversion System

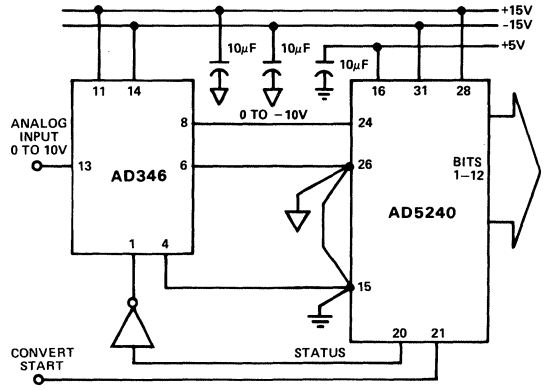

Figure 9. 142.8kHz–12-Bit, A/D Conversion System

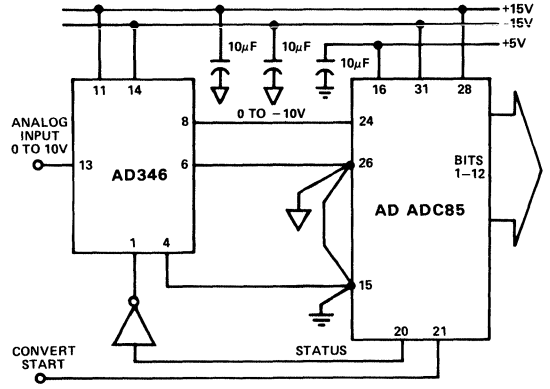

Figure 10. 83.3kHz–12-Bit, A/D Conversion System

In sampled data systems there are two limiting factors in digitizing high frequency signals. The first limitation is the bandwidth and aperture uncertainty of the sample-and-hold amplifier. The second limitation is the maximum update rate for the SHA and A/D converter combination. For high throughput rate data acquisition systems all factors must be understood.

The aperture time is the time required for the sample and hold amplifier to switch from sample to hold. Since this is a constant it can be tuned out by advancing the sample-to-hold command by 60ns with respect to the input signal and, therefore, can be eliminated as an error source. Once the aperture time has been eliminated the aperture jitter which is the variation aperture time from sample-to-sample, remains. The aperture jitter is a true error source and must be considered. The aperture jitter is a result of noise within the switching network which modulates the phase of the hold command and is manifested in the variations in the value of the analog input that has been held. The aperture error which results from this jitter is directly related to the dV/dt of the analog input.

The error due to aperture jitter is easily calculated as shown below. The error calculation takes into account the desired accuracy corresponding to the resolution of the A/D converter.

$$F_{max} = \frac{(\text{Full Scale Voltage})\ (2^{-N})}{(2)\ (\text{Full Scale Voltage})\ \pi\ (\text{Aperture Jitter})}$$

For an application with a 10-bit A/D converter with a 10V full scale:

$$F_{max} = \frac{(10)\ 2^{-10}}{(2)\ (10)\ \pi\ (4 \times 10^{-10}\ \text{sec})}$$

F_{max} = 388.6kHz.

For an application with a 12-bit A/D converter with a 10V full scale:

$$F_{max} = \frac{(10)\ 2^{-12}}{2\ (10)\ \pi\ (4 \times 10^{-10}\ \text{sec})}$$

F_{max} = 97.1kHz.

The maximum throughput rate is the sum of the sample-and-hold acquisition time, settling time and the A/D conversion time as shown in Figure 11.

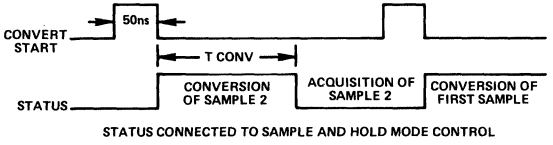

Figure 11. Start/Status Timing for Sampled Data System

The maximum input frequency is constrained by the Nyquist sampling theorem to be half of the maximum throughput rate. Input frequencies higher than half the maximum throughput rate result in "under sampling" or aliasing errors of the input signal. In the following table the maximum input frequency is reported as half of the throughput rate, what has been assumed is that an ideal brickwall filter has been placed in the signal path prior to the AD346 and A/D converter.

AD346 in Combination With an	Throughput Rate	Input Frequency Range
AD578K	153kHz	dc to 76.5kHz
AD5240	143kHz	dc to 71.5kHz
AD ADC85	83.3kHz	dc to 41.6kHz
AD579	263kHz	dc to 131kHz
HAS1202	250kHz	dc to 125kHz

Table I. SHA & ADC Combinations and Maximum Throughput Rate

MULTICHANNEL CONVERSION

In multichannel conversion systems, elements of the acquisition chain may be shared by two or more input sources. This sharing may occur in a number of ways, depending on the desired properties of the multiplexed system.

The data acquisition system shown in Figure 12 is one solution to digitizing data from many analog channels. For most efficient use of time, the multiplexer is acquiring the next channel to be converted while the sample-hold is holding the previous output level for conversion. When conversion is complete, the status line from the converter causes the S/H to return to the sample mode and acquire the new data. After the acquisition time is completed, the sample hold can be switched to hold. A conversion can then begin and the multiplexer can be switched to the next channel.

In applications where the AD346 is to be driven from high impedance sources or directly from an analog multiplexer, a fast slewing, fast settling wideband op amp like the ADLH0032 should be used as an input buffer.

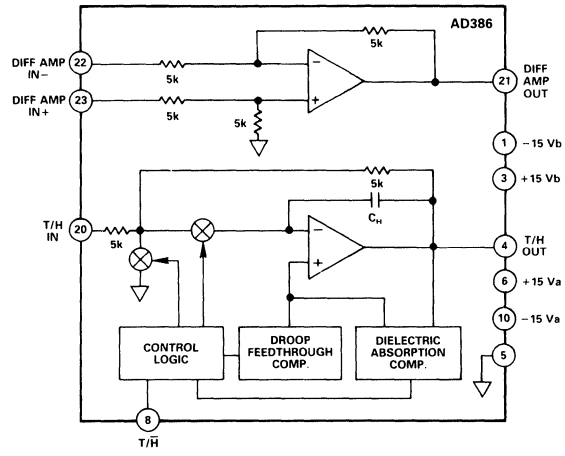
AD386 FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD386 is a high accuracy, adjustment free track-and-hold amplifier designed for high resolution data acquisition applications. The fast acquisition time (3.6 μs to 75 μV) and low aperture jitter (40 ps) make it ideal for use with fast A/D converters.

The AD386 is complete with an internal hold capacitor, and it incorporates a compensation network which minimizes the track-to-hold charge offset and dielectric absorption. The AD386 also includes an internal differential amplifier for very high accuracy applications.

Typical applications for the AD386 include sampled data system, peak hold function, strobe measurement system and simultaneous sampling converter systems. When used with autozero and autocalibration techniques, this T/H combined with a high linearity A/D will offer true 16-bit performance (0.00076% linearity) over the industrial temperature range, and 14-bit performance (0.003% linearity) over the military temperature range.

TERMINOLOGY

Aperture Delay: the time required by the internal switch(es) to disconnect the hold capacitor from the input, which produces an effective delay in the sample timing.

Aperture Jitter: the uncertainty in Aperture Delay caused by internal noise and the variation of switching thresholds with signal level. The error caused by aperture jitter depends on the rate of change of the input and as such determines the maximum input frequency which can be sampled without error.

Pedestal: a step change in the output voltage which occurs when switching from track mode to hold mode.

Hold Mode Settling Time: the time required for the pedestal to reach its final value to within a specified fraction of full scale.

Droop: the change in the held output voltage resulting from leakage currents.

Feedthrough: the fraction of input signal variation which appears at the output in hold mode as a result of capacitive coupling.

Dielectric Absorption: the tendency of charges within a capacitor to redistribute themselves over time, resulting in "creep" in the voltage of an open circuit capacitor after a large rapid change.

Acquisition Time: the time required after entering track mode for the voltage on the hold capacitor to settle to within a specified fraction of full scale. This is usually specified for a full-scale step change in output voltage.

Settling Time: the time required in track mode for the output to reach its final value within a specified fraction of full scale following a step change in the input voltage.

Nonlinearity: the degree to which a plot of output versus input deviates from the straight line defined by the end points. It is usually specified as a percentage of full scale.

THEORY OF OPERATION

The architecture of the AD386 differs from that usually encountered in inverting Track-and-Hold (T/H) circuits. The hold capacitor in a conventional T/H (Figure 14) is always connected from the amplifier's output to its inverting input. In track mode switch A is open and switch B is closed. Since the summing junction is a virtual ground, the voltage across the capacitor follows the input. The switches change state in hold mode which disconnects the capacitor from the input and holds the output voltage constant. The clamping action of switch A reduces the variations across switch B, improving feedthrough performance.

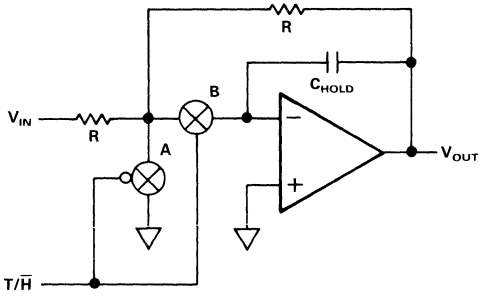

Figure 14. Conventional Inverting Integrator T/H

This circuit forces several tradeoffs. The hold capacitor's charging current is limited by the input resistor. Either the resistor or the capacitor, or both, must be made small to obtain fast acquisition times. A small resistor creates greater demands on the circuit which drives the T/H, while a small capacitor leads to increased pedestal and droop. In addition, the parallel combination of the feedback resistor and the hold capacitor acts as a low pass filter and constrains both bandwidth and acquisition time.

The AD386 uses a four-switch flyback architecture which removes the hold capacitor from the feedback loop during track mode (Figure 15). Switches A and C are open in track mode while switches B and D are closed. This maximizes bandwidth and provides minimum acquisition time because the charging current delivered to the hold capacitor is limited only by the amplifier's output capability. The hold capacitor can be made larger, subject to amplifier stability, since it no longer appears in parallel with the feedback resistor. This helps to reduce droop and pedestal. Switches A and C close in hold mode while switches B and D open, which connects the hold capacitor to the amplifier's inverting input.

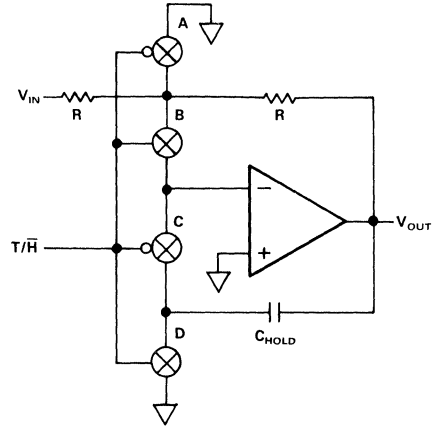

Figure 15. Four-Switch Inverting Flyback T/H

Additional switches and capacitors, not shown in the figure, provide first order cancellation of amplifier and switch leakage currents, switching charge injection, and switch feedthrough. Finally, a small amount of positive feedback is used to reduce dielectric absorption effects.

TRACK-AND-HOLD ERROR CONTRIBUTIONS IN SAMPLED-DATA SYSTEM

Any track-and-hold amplifier imposes performance limits on the system in which it is used. Some of these limits can be derived from the theory of sampled-data systems, some are intrinsic to the T/H, and some depend on details of the system design. Many subtle effects come into play as system resolution increases to 14 or 16 bits, and these can contribute significant errors. Understanding T/H error sources is critical to maintaining signal integrity in a high resolution data acquisition system.

FREQUENCY LIMITATIONS

Three factors set fundamental limits on system performance when digitizing high frequency signals. These are: T/H amplifier bandwidth, aperture uncertainty, and the maximum update rate of the T/H and A/D combination. The track mode bandwidth of the T/H must be significantly greater than the bandwidth of the signals being digitized to prevent the introduction of amplitude and phase errors. The 2 MHz small signal bandwidth of the AD386 attenuates a 35 kHz signal by 0.001 dB and shifts its phase by 1.0 degrees.

There are two different aperture related error terms. The first is aperture delay time, the delay between the HOLD command and the complete opening of internal switches in the T/H. This time amounts to a negative phase delay applied to the input signal because the T/H output can actually continue to track the input for a brief time after the HOLD command. Aperture delay time can be "tuned out" by advancing the assertion of HOLD.

Aperture jitter, the random variations in aperture delay time, causes errors which are directly related to the rate of change of the input signal and which cannot be eliminated by circuit adjustments.

A simple calculation provides the frequency at which aperture jitter produces an error of 1/2 LSB when the input is a full-scale sinusoid. The general result for an N-bit A/D converter is

$$F_{max} = \frac{V_{FS}}{V_{PP}} \times \frac{1}{2^{N+1} \times \pi \times Aperture\ Jitter}$$

where V_{FS} is the A/D converter's input range and V_{PP} is the peak-to-peak value of the input sinusoid. The worst case (minimum) value of F_{max} occurs when V_{PP} is equal to V_{FS}. If the T/H has an aperture jitter of 100 ps and is used with a 16-bit linear A/D, the maximum input frequency is 24.3 kHz.

The same T/H, when used with a 14-bit linear A/D, permits the processing of signals up to 97.1 kHz before aperture jitter-errors become observable. Figure 16 shows these errors as a function of frequency, assuming a full scale input sinusoid, for several values of aperture jitter.

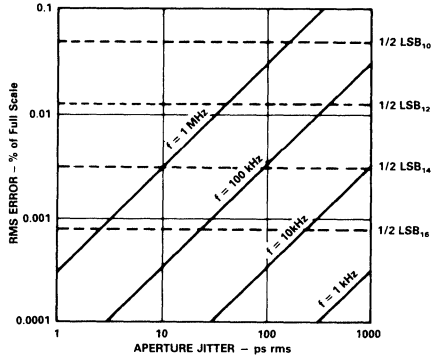

Figure 16. T/H Error vs. Aperture Jitter and Input Frequency

Aperture jitter is often expressed as an rms number. "Peak-to-peak" aperture jitter is usually defined as 6 times this rms value. This comes from probability theory, where 99.7% of the measurements of a random variable will be within 3 standard deviations of the variable's average value. Aperture jitter arises from broadband electrical noise, which is very nearly an ideal random process with a standard deviation equal to its rms value, so multiplication by 6 gives a good approximation to the noise's peak-to-peak value.

A second limit on the input frequency is imposed by the finite time required for signal acquisition and conversion. It is possible to reconstruct any uniformly sampled signal without loss of information provided the sampling rate is at least twice the bandwidth of the input signal; this is the Nyquist criterion, a fundamental result in sampling theory. This limits input frequency to

$$F_{max} = \frac{1}{2 \times (t_{ACQ} + t_{CONV} + t_{AP})}$$

where t_{ACQ} is the T/H acquisition time, T_{CONV} is the time required for the A/D conversion, and T_{AP} is the aperture delay of the T/H. The last term is usually very small and can be ignored. A system composed of a 3.6 μs T/H and a 10 μs A/D can be used successfully to digitize signals with frequency components up to 36.76 kHz. This limit is independent of input signal amplitude. Throughput rates and input frequency ranges for the AD386 in combination with various A/D converters are shown in Table I.

A/D	Conversion Time	Minimum Throughput
ADADC71	50 μs max	18.7 kHz
AD1376/78	17 μs max	48.8 kHz
AD1377	10 μs max	73.5 kHz

Table I. Throughput for AD386 with Various A/D Converters

NONLINEARITIES

Two phenomena directly affect the fidelity of a T/H's transfer function and can degrade system linearity. One of these error sources is track mode nonlinearity. It arises primarily from gain nonlinearity in the T/H's internal amplifier(s). Mismatches in the temperature coefficients of internal resistors may also contribute, but usually do so only for very low frequency signals. The AD386's track mode nonlinearity is about 1/6 16-bit LSB (Figure 17), as is the nonlinearity of the AD386's differential amplifier.

System linearity will also be reduced if the pedestal varies nonlinearly with signal level. Pedestal nonlinearity in the AD386 is below 8 microvolts per volt of input signal, or about 1/2 16-bit LSB.

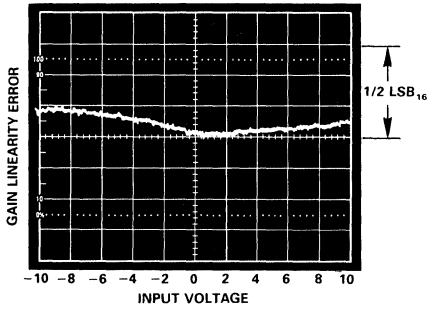

Figure 17. AD386 Track Mode Nonlinearity

FEEDTHROUGH, DROOP, AND DIELECTRIC ABSORPTION

Errors resulting from signal feedthrough and droop must be less than 1/2 LSB in order for the system's linearity to be maintained. The AD386 uses a symmetrical, compensated architecture to minimize both these effects. Feedthrough varies slightly with input frequency from −100 dB below 1 kHz to −86 dB above 100 kHz (Figure 10). This provides 16-bit accuracy for full-scale inputs up to at least 5 kHz and 14-bit performance to beyond 100 kHz.

The circuit's symmetry causes the droop rate to depend on differences in leakage currents between identical junctions under nearly identical bias conditions. The resulting droop is less than 1/2 16-bit LSB (10 V scale) at temperatures up to 85°C and 1/2 14-bit LSB (10 V scale) over the full military temperature range for hold times up to 100 μs.

Capacitors exhibit a memory phenomenon, dielectric absorption (DA), in fast charge, long hold applications. This arises from nonideal behavior of the dielectric material which allows charge storage in the bulk of the dielectric. This bulk charge cannot be removed rapidly because of the long time constant associated with the dielectric's high resistance. A capacitor with dielectric absorption can be modeled as an ideal capacitor in parallel with a series R-C circuit as shown in Figure 18. When such a capacitor is used as the hold capacitor in a T/H the held voltage will tend to creep back towards the voltage held for the previous conversion cycle. The degree and time constant of this behavior depends on the capacitor's dielectric material, as well as on the charge and hold time of the circuit.

Dielectric absorption will cause a variable "offset" if a T/H is used to sample multiple channels with widely varying signals. This causes an apparently nonlinear pedestal because the difference between the currently measured voltage and the previously measured voltage determines the magnitude of the DA error. The AD386 uses a high quality hold capacitor with low intrinsic DA. Residual DA errors are further reduced by laser trimming a compensation network during the manufacturing process. The trimming is performed under typical system timing conditions of 5 μs track, 45 μs hold. The post-trim dielectric absorption error is less than 1/2 16-bit LSB for full-scale changes between samples and hold times between 10 μs and 100 μs.

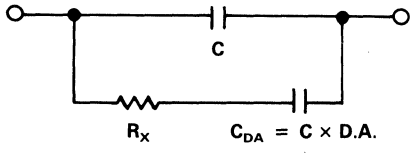

Figure 18. Capacitor Model with Dielectric Absorption

NOISE

Noise generated in a T/H adds to the held signal and causes variations in the output code of an A/D. This noise has two components, one which arises during track mode and another contributed during hold mode. The rms sum of these terms determines the noise performance of the T/H in the system.

Track noise is the noise which gets sampled when entering hold mode. An inverting T/H architecture such as that used in the AD386 has a noise gain of 2. This noise is low pass filtered in the R-C network comprised of the hold capacitor and the switch on resistance (see Figure 19a). The rms value of the track noise is

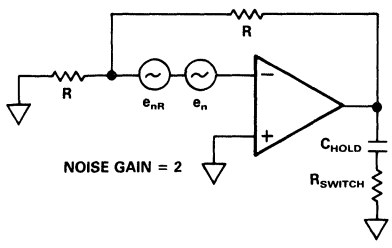
$$\langle e_{nT} \rangle = (op\ amp\ noise) \times (noise\ gain) \times (ENBW)^{1/2}$$

Op amp noise is the rms sum of the amplifier's broadband voltage noise and the thermal noise contributions of the input and feedback resistors, about 17 nV/$\sqrt{\text{Hz}}$. Other noise sources, including amplifier current noise and switch thermal noise, are negligible. ENBW, the equivalent noise bandwidth, is

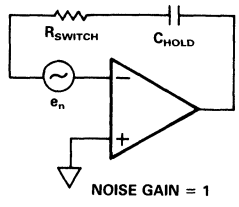
$$ENBW = \frac{\pi}{2} \times \frac{BW1 \times BW2}{BW1 + BW2}$$

where BW1 is the small signal bandwidth of the T/H in track mode (2 MHz for the AD386) and BW2 is the corner frequency of the R_{SWITCH}–C_{HOLD} combination (2.7 MHz). The resulting track noise in the AD386 is at most 46 μV rms.

Noise gain is reduced to 1 in hold mode, and input and feedback resistor thermal noise makes no contribution (Figure 19b). The equivalent noise bandwidth now depends on the T/H's small signal bandwidth and the characteristics of the A/D converter used in the system. This is because the signal at the input



a. Track Mode



b. Hold Mode

Figure 19. Dominant AD386 Noise Sources

of the comparator in a successive approximation A/D converter is filtered by the converter's input resistance and the summing junction capacitance. ENBW is calculated as before, but now BW1 is the T/H's small signal bandwidth in hold mode (4 MHz for the AD386), and BW2 is the bandwidth of the A/D's input R-C. BW2 is about 700 kHz in the AD ADC71 and AD1376 and roughly 1.7 MHz in the AD1377 and AD1378 (assuming a 10 V span). The respective values of ENBW are 940 kHz and 1.9 MHz. The hold noise contribution of the AD386 is about 16 μV rms when used with the AD ADC71 or AD1376 and 22 μV rms when used with the AD1377 or AD1378; this noise is 30% less for a 20 V span and 40% greater for a 5 V span because changes in the A/D's input resistance cause changes in BW2.

The total noise is the rms sum of these two results:

$$\langle e_n \rangle = [\langle e_{nT}^2 \rangle + \langle e_{nH}^2 \rangle]^{1/2}$$

This yields 49 μV rms and 51 μV rms for the two cases. Track noise dominates in both instances.

When the AD386's differential amplifier is used, its noise contribution will be band limited and sampled by the T/H. The equivalent bandwidth for this noise is also 1.8 MHz and the contribution to the track noise is 46 μV rms. The total track noise is the rms sum of 46 μV and 46 μV, or 65 μV rms, and the overall noise for the complete AD386 used with any of the above A/D converters is at most 70 μV rms.

The rms value represents one standard deviation if the noise has a Gaussian distribution, which is usually the case for wideband electrical noise. If a constant noise-free voltage is sampled a large number of times, the held result will be within one standard deviation of the ideal value 32% of the time, within two standard deviations 95% of the time, and within three standard deviations 99.7% of the time. The entries in Table II were calculated using three standard deviations as the definition of the peak-to-peak noise.

Span	No. Bits	rms Noise LSBs	p-p Noise LSBs
10 V	14	0.11	0.66
20 V	14	0.06	0.36
10 V	16	0.45	2.7
20 V	16	0.23	1.4

Table II. AD386 Noise Contribution as a Function of A/D Span and Resolution

POWER SUPPLY REJECTION

Variations on the power supply lines, both dc and ac, can lead to unwanted changes in the voltage acquired by a T/H. Power supply variations in track mode cause the output voltage, and hence the voltage across the hold capacitor, to vary. PSRR decreases with increasing frequency, making well regulated, low noise linear power supplies and proper bypassing essential in a high resolution data acquisition system.

Equally important, but usually forgotten or omitted, is hold PSRR. This is frequently much worse than track PSRR because parasitic capacitances which are not significant in track mode couple into the extremely high impedance nodes which exist in a T/H during hold mode. This specification is essential to the system designer, as hold mode PSRR often determines the performance required from the system's power supplies. The power supply rejection of the AD386 is specified and characterized in both track and hold modes.

Pedestal arises from the transfer of charge from the internal switching circuitry to the hold capacitor during the transition from track mode to hold mode. Pedestal in some T/H circuits is extremely sensitive to changes in the high and low levels of the external control signal. The AD386 uses an internal +5 V supply and logic buffers to prevent this behavior.

GROUNDING

All voltage measurements in a data acquisition system are eventually referenced to ground. Variations in the "ground" potential through the system resulting from resistive drops of power supply and signal return currents as well as from interference from external sources may add to the signal being digitized and produce false results. The grounding scheme in a high resolution system cannot be left to chance and must be planned as carefully as any other aspect of the system's design. Proper grounding and the reduction of externally induced ground noise are discussed at length in the following Applications section.

Applications

GROUNDING. DECOUPLING, AND LAYOUT CONSIDERATIONS

Many data acquisition systems have two or more ground pins which are not connected together within the device(s). These "grounds" may be referred to as Logic Power Return, Digital Return, Analog Ground, Analog Power Return, Signal Ground, etc., and they must be connected together somewhere within the system to establish a measurement reference point. Good grounding practice dictates that these grounds be tied at a single point, sometimes called a star or "Mecca" ground. In high resolution systems the star point is often located at the A/D, with a single, short, low impedance trace leading from there to the analog supply "common" terminal. The ideal is to use a solid analog ground plane beneath the T/H and A/D as the star point.

Because circuit traces have resistance and inductance, currents in the various ground runs can create voltage differences of hundreds of millivolts between "ground" in different parts of the system. Power supply and signal ground traces should be separate to prevent summing power supply return currents with analog signal currents, which would lead to measurement errors. It is also important to avoid closed circuit loops in system ground connections. A loop can act as a very effective antenna, coupling voltages created by stray magnetic fields into the measurement system.

Each of the AD386's power supply terminals should be capacitively bypassed to the ground plane as closely as possible to the device. This is best done using 0.01 μF to 0.1 μF ceramic capacitors. High frequency supply noise rejection may be further improved by placing small (4.7 Ω to 10 Ω) carbon composition resistors in series with the supply leads. These resistors, in combination with the ceramic capacitors, act as local low pass filters and prevent crosstalk between system components. The bypassing scheme should also include solid Tantalum capacitors of 1 μF to 10 μF from each supply to ground in the critical areas of the board. Proper grounding and bypassing techniques are shown in Figure 20.

All AD386 ground pins (Pins 2, 5, 7, 9, 18, 19, and 24) should be connected to the analog ground plane.

WARNING: Improper bypassing can result in poor settling performance or high frequency oscillations.

The metal cover of the AD386 is internally grounded to provide additional shielding. Do not make any external connection to the cover.

DIFFERENTIAL AMPLIFIER

Many high resolution applications require the ability to sense ground at the signal source. This is especially true in systems with physical or thermal constraints that make it necessary to locate the T/H and A/D at some distance from the transducer. Under these conditions stray electromagnetic fields may cause "ground" at the signal source to be at a different potential from "ground" at the A/D despite the designer's best efforts. This will give rise to measurement errors because the potential difference will appear to be added to the true signal. The AD386's differential amplifier may be used to eliminate this type of ground noise as shown in Figure 21.

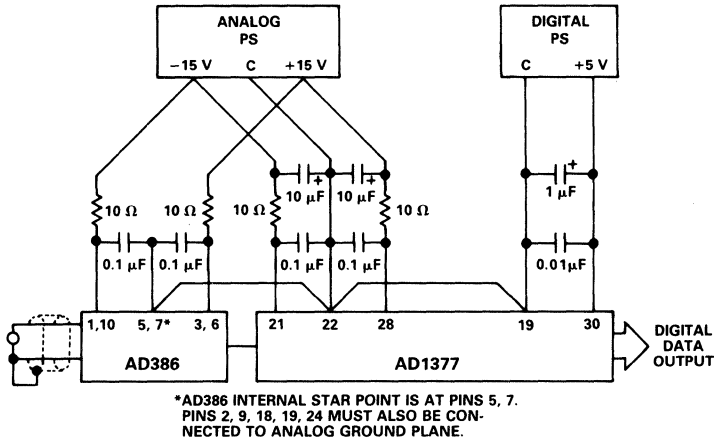


Figure 20. Proper Grounding and Supply Bypassing Techniques for a High Resolution Data Acquisition System

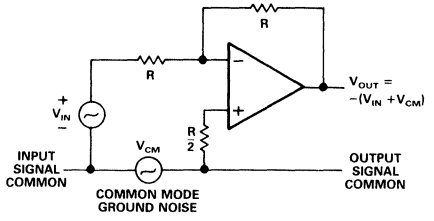
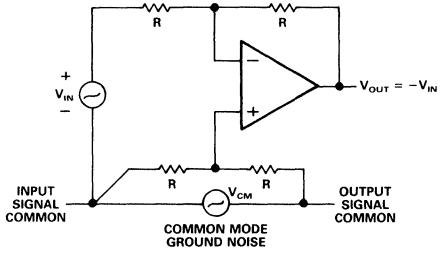


a. Without Differential Amplifier



b. With Differential Amplifier

Figure 21. Effects of Common Mode Noise

In extremely noisy environments it may be necessary to connect the differential amplifier to the signal source with shielded twisted pair cable. The shield should be connected to ground at the transducer and should be left floating at the AD386. This shielding technique is shown in Figure 22. The cable presents a capacitive load, and the signal source must be capable of driving this load without ringing or oscillations. The differential amplifier's noninverting input should be connected to Pin 24 if ground sensing is not required.

Another use of the differential amplifier is to restore signal polarity. Like most high resolution T/H amplifiers, the T/H in the AD386 operates in the inverting mode. The differential amplifier may be used to provide a second inversion so that the T/H output has the same polarity as the sensor output.

The differential amplifier also provides a low dynamic source impedance to the T/H section. This absorbs transients produced when the T/H switches from hold mode to track mode, providing optimal settling performance.

The T/H and differential amplifier have independent power supply connections. This permits a reduction in system power dissipation when the differential amplifier function is not needed.

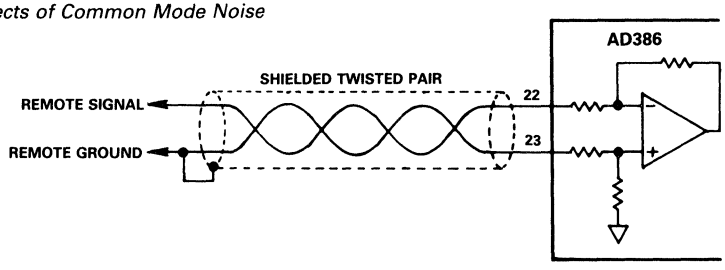


Figure 22. Remote Ground Sensing in a Noisy Environment

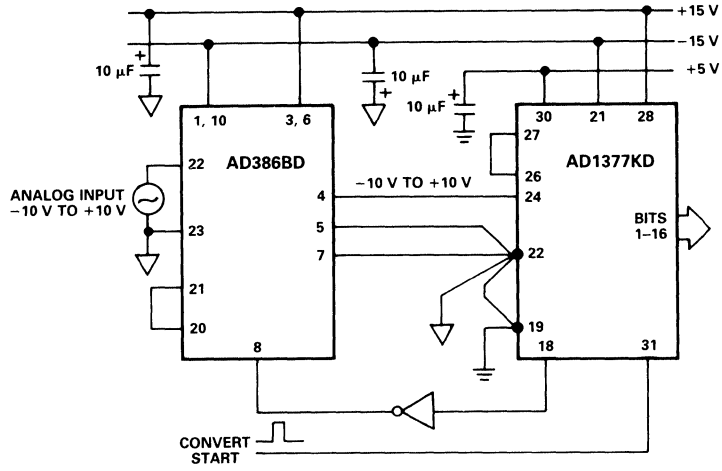

Figure 23. Basic Data Acquisition System (Some Supply Bypassing Omitted for Clarity)

6

GAIN AND OFFSET ADJUSTMENT

The usual practice in the design of data acquisition systems is to incorporate a single system level trim for offsets and a second for gain errors, rather than to trim each element in the signal processing chain. Traditionally these trims involve potentiometers or fixed resistors. The trims should be designed so that nulling static errors does not introduce new errors such as noise, increased thermal drift, or nonlinearity.

The offset, drift, and gain errors of the AD386 are laser trimmed during manufacture and no external adjustment capabilities are provided. This prevents the introduction of noise through offset adjust terminals and preserves the excellent gain linearity and drift performance. Most A/Ds provide for nulling gain and offset errors with a range sufficient to include the contributions of the AD386. Of course, it is also possible to include calibration routines in the system's software to eliminate mechanical adjustments.

HIGH RESOLUTION DATA ACQUISITION SYSTEM

The essential details of a high resolution data acquisition system using the AD386 are shown in Figure 23. Conversion is initiated by the falling edge of the CONVERT START pulse. This edge drives the A/D's STATUS line high. The inverter then drives the AD386 into hold mode. STATUS remains high throughout the conversion and returns low once the conversion is completed. This allows the AD386 to reenter track mode. The throughputs given in Table I were calculated based upon this circuit configuration.

One drawback of this connection becomes apparent if the system's grounding is marginal. The falling edge of CONVERT-START resets the successive approximation register within the A/D, causing transient currents in both the analog and digital return paths. These transients vary depending on the input signal and the prior conversion result. The same edge also drives the T/H into hold mode. The exact timing relationship of these two events depends upon differences in propagation delays. The T/H's held value may be affected if the A/D reset transient begins before the T/H has fully entered hold mode. The end result is system nonlinearity.

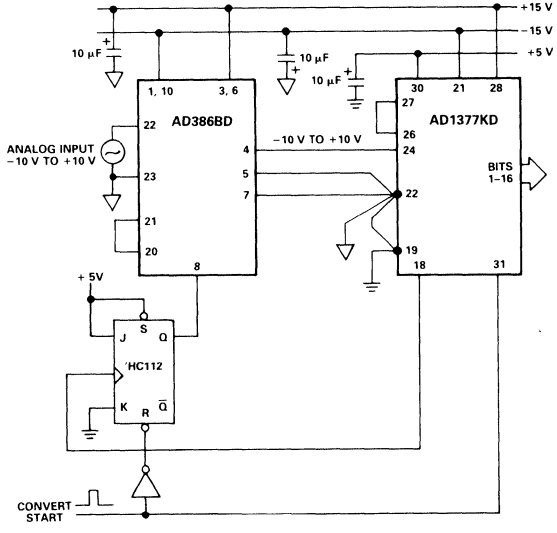

Figure 24. Improved Data Acquisition System (Some Supply Bypassing Omitted for Clarity)

This problem can be avoided with the addition of a flip flop as shown in Figure 24. The rising edge of CONVERT START places the T/H into hold mode before the A/D reset transients begin. The falling edge of STATUS places the AD386 back into track mode. System throughput will be reduced if a long CONVERT START pulse is used. Throughput can be calculated from

$$Throughput = \frac{1}{T_{ACQ} + T_{CONV} + T_{CS}}$$

where T_{ACQ} is the T/H acquisition time, T_{CONV} is the time required for the A/D conversion, and T_{CS} is the duration of CONVERT START. No significant T/H droop error will be introduced provided the width of CONVERT START is small compared with the A/D's conversion time.

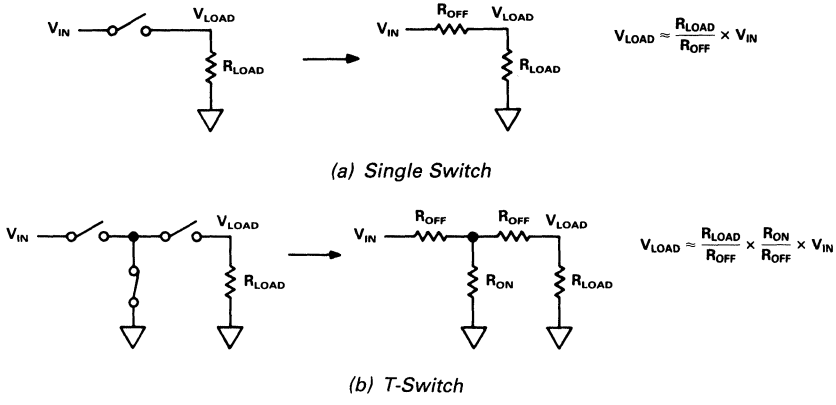

Figure 25. Single and "T" Analog Switches (Shown in OFF Position)

MULTICHANNEL SYSTEMS

The design of multiplexed data acquisition systems which maintain 14- or 16-bit signal fidelity is an extremely demanding task. One of the first difficulties encountered is the lack of adequate analog switches. The specified feedthrough performance of most switches and multiplexers is seldom better than −80 dB. This is an order of magnitude too high for a 16-bit system with its 8 parts-per-million sensitivity. A "T" switch configuration can be used to reduce feedthrough as shown in Figure 25. The improvement in "off" isolation relative to a single switch is substantial.

A few monolithic video T-switch ICs are now available and provide the necessary isolation in the dc-50 kHz frequency range. Unfortunately, these devices have voltage limitations which restrict their utility. It will usually be necessary to design a multiplexer using analog multiplexer and switch ICs. Figure 26 shows a simple 4-channel single-ended T-switch multiplexer and includes a high performance buffer (see below).

The on-resistance of analog switches and multiplexers is a nonlinear function of signal voltage. This will produce severe nonlinearity in a system in which a multiplexer supplies signals

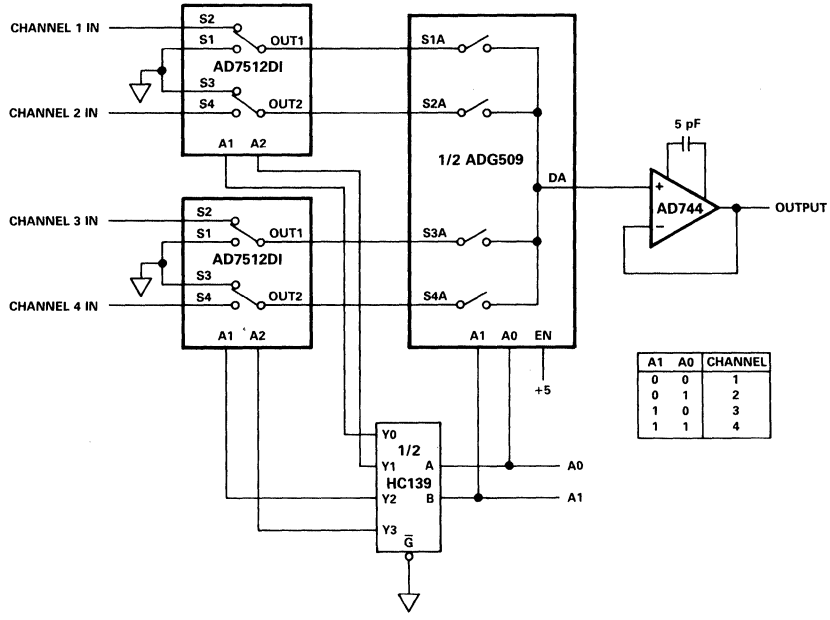

Figure 26. Four-Channel T-Switch Multiplexer(Power Supply Connections Not Shown)

directly to an AD386. A high-impedance buffer between the multiplexer and the T/H's input can solve this problem but may introduce several others.

An op amp in the noninverting gain-of-1 configuration is the obvious candidate for a buffer. The amplifier must settle quickly to maximize system throughput and must be extremely linear to maintain system performance. The linearity of this configuration depends upon the linearity of both the amplifier's open loop gain and common-mode rejection (linear errors in these parameters result only in system gain error, but nonlinear gain and CMRR produce system nonlinearity). Neither of these parameters is specified by most amplifier manufacturers.

A buffer may also increase system noise. Applications which require ground- sensing will require two buffers, resulting in 40% more noise than a one-buffer system.

Finally, a buffer will add its own offset to the signal being measured. Software calibration of the error and its drift is possible using a permanently grounded multiplexer channel.

The AD744 is a nearly ideal buffer for multiplexed systems. This amplifier provides offsets as low as 250 μV and an offset drift of 3 μV/°C while maintaining 16-bit linearity over the −40°C to +85°C temperature range. Typical settling times at room temperature are 2.3 μs (14 bits) and 3.5 μs (16 bits) for the AD744 combined with the AD386's differential amplifier. The increase in noise at the differential amplifier's output will be about 6 μV rms in a one-buffer system and roughly 12 μV rms in a two buffer system (recall that a 16-bit LSB in a 20 volt system is 305 μV). The AD744 is not unity-gain stable, and compensation is required. A 5 pF compensating capacitor is sufficient to ensure stability. The settling times listed above were measured using a 9 pF compensation capacitor which provides greater stability with moderate capacitive loads.

The NE5534 can also be used as a buffer to deliver 16-bit linearity. This amplifier also requires slight compensation to achieve unity-gain stability; 10 pF is sufficient. Settling is somewhat slower than the AD744, about 5 μs to 14 bits and 6 μs to 16 bits, including the AD386's differential amplifier when measured at room temperature. The 5534 has lower voltage noise and will cause only a 1 or 2 μV rms increase in the total noise at the differential amplifier's output. The NE5534 lacks the precision offset and drift performance of the AD744.

Multiplexed throughput can be improved with the proper choice of system timing. If the new input channel is selected while the AD386 is in Hold mode, then multiplexer, buffer, and differential amplifier settling can occur during the A/D conversion. In this case throughput is determined only by the sum of the T/H acquisition and A/D conversion times. The effects of T/H feedthrough must be considered when using this type of overlap in system timing.

There is another solution to many of the problems of multiplexed systems when the speed of channel switching is not critical: relays. Relays should be selected for good shielding, low thermal EMF, and low on-resistance. The only significant drawback of this approach, other than switching speed and size, is power dissipation. In all other respects relays offer a near-perfect solution to the problems of high resolution system design discussed above.

DYNAMIC PERFORMANCE

Dynamic characteristics such as signal-to-noise ratio (SNR) and total harmonic distortion (THD) are important in many signal processing applications. SNR and THD are affected by both the T/H and A/D. The errors contributed by the T/H are generally dependent upon the input signal frequency, while those contributed by the A/D converter usually are not. The dynamic performance of a T/H-A/D pair is characterized using Fast Fourier Transform (FFT) techniques.

Figures 27–31 show the results of several 1024-point FFTs which demonstrate the exceptional distortion and noise performance of the AD386 when combined with the AD1377. These FFTs were obtained using a circuit similar to that of Figure 24. The input signal was processed by both the differential amplifier and T/H sections of the AD386 and was sampled at an 83.333 kHz rate. The AD1377's clock was adjusted to yield an 8.0 μs conversion time, which provided 4.0 μs for the AD386 to acquire each new sample. The vertical scale for these figures is based on a full-scale input referenced as 0 dB. The system was configured for a 10 volt span.

Figures 27 and 28 illustrate the system's low frequency noise and distortion performance. The input frequency is 1.546 kHz. When the input is −0.3 dB, nearly full scale, the largest harmonic component is −102.8 dB (Figure 27). Total harmonic distortion, the rms sum of the second through fifth harmonics, is −99.9 dB. The signal to noise ratio is 89.9 dB. The ultimate noise floor can be determined using a lower level input. Reducing the input level about 20 dB, as in Figure 28, decreases the

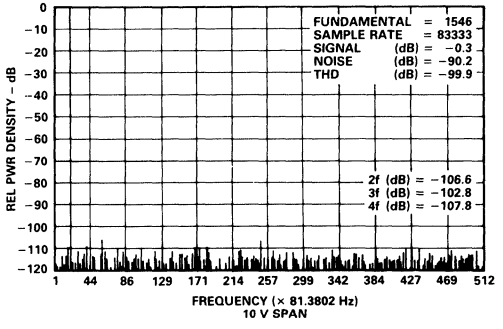

Figure 27.

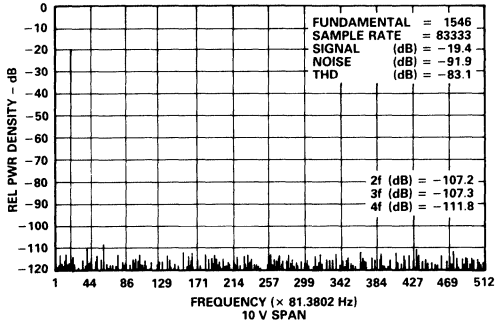

Figure 28.

noise floor by 1.8 dB to −91.9 dB. This corresponds to a total AD386 noise contribution of about 45 μV rms. The FFT noise floor would improve about 2 dB with the system configured for a 20 volt span because the effect of noise contributed by the AD386 is reduced as a result of the increased LSB size.

System performance just beyond the high end of the audio band is shown in Figure 29. Here the input is a −0.3 dB sinusoid at 21.24 kHz. The only significant harmonic component, the second harmonic, is −91.9 dB with respect to the fundamental, and THD is −91.1 dB. The noise floor is 0.5 dB greater than in Figure 27. The additional noise is contributed by higher-order harmonics; the second through fifth harmonics have been excluded from the noise floor calculations, but higher harmonics are considered to be "noise". These harmonics arise from the AD386's aperture jitter. The additional noise is consistent with an rms jitter of 40 ps.

In Figures 30 and 31, −0.3 dB and −20.1 dB inputs at 40.61 kHz show system performance near the Nyquist frequency. Even at this high frequency a full-scale input produces THD of only −84.6 dB, dominated by the second harmonic at −85.1 dB (Figure 31). In Figure 31 the harmonics have been eliminated by reducing the input level by a factor of 10.

ANALOG DEVICES

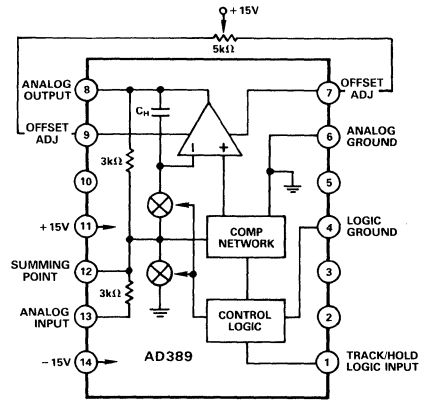
High Resolution Track-and-Hold Amplifier

AD389

FEATURES

Companion to High Resolution A/D Converters
Fast Acquisition Time: 2.5μs to ±0.003%
Low Droop Rate: 0.1μV/μs
Aperture Jitter: 400ps
Internal Hold Capacitor
Unity Gain Inverter
Low Power Dissipation: 300mW

AD389 FUNCTIONAL BLOCK DIAGRAM



6

PRODUCT DESCRIPTION

The AD389 is a high accuracy, adjustment free track-and-hold amplifier designed for high resolution data acquisition applications. The fast acquisition time (2.5μs to ±0.003%) and low aperture jitter (400ps) make it suitable for use with fast A/D converters to digitize signals up to 40kHz.

The AD389 is complete with an internal hold capacitor and it incorporates a compensation network which minimizes the sample to hold charge offset.

Typical applications for the AD389 include sampled data systems, peak hold functions, strobed measurement systems and simultaneous sampling converter systems. When used with autozero and autocalibration techniques, this T/H combined with a high linearity A/D will offer 14-bit performance over the converter's full no-missing-code temperature range.

The device is available in two versions: the "K" specified for operation over the 0 to +70°C commercial temperature range and the "B" specified over the full industrial temperature range, −25°C to +85°C. High reliability processing is available; contact factory for information.

PRODUCT HIGHLIGHTS

1. The AD389 is the ideal companion track-and-hold amplifier to 14-bit accurate A/D converters.
2. The AD389 provides separate analog and digital grounds, thus improving the device's immunity to ground and switching transients.
3. The droop rate is only 0.1μV/μs so that it may be used in slower high resolution systems without the loss of accuracy.
4. The fast acquisition time and low aperture make it suitable for high speed data acquisition systems and digital audio recording.
5. The AD389 T/H amplifier is ideal for applications requiring wide dynamic range.
6. Clever circuit design eliminates any measurable thermal tail (see Figures 11a and 11b).

ORDERING GUIDE

Model	Temperature Range	Package Option*
AD389KD	0 to +70°C	DH-14A
AD389BD	−25°C to +85°C	DH-14A

*See Section 14 for package outline information.

PIN CONFIGURATION

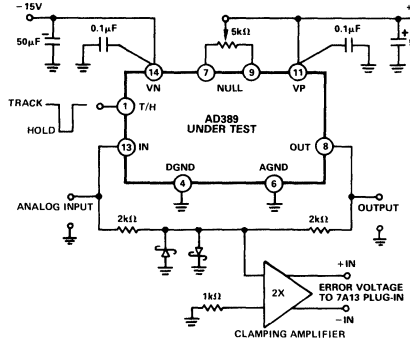

Figure 8. Pedestal and Acquisition Time Test Circuit

TERMINOLOGY

Aperture Time is the time required after the "hold" command until the switch is fully open and it produces a delay in the effective sampling timing.

Aperture Jitter is the uncertainty in Aperture Time. If the Aperture Time is "tuned out" by advancing the track-to-hold command with respect to the input signal, the Aperture Jitter now determines the maximum sampling frequency.

Acquisition Time is the time required by the device to reach its final value within a given error band after the track command has been given. This includes switch delay time, slewing time and settling time for a given output voltage change.

Droop is the change in the output voltage from the "held" value as a result of device leakage.

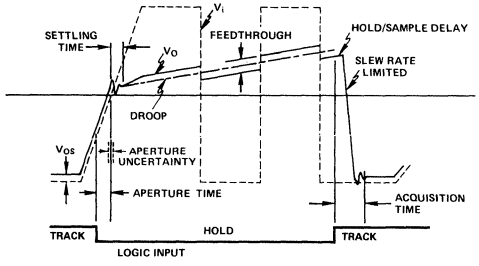

Figure 9. Pictorial Showing Various T/H Characteristics

Feedthrough is that component of the output which follows the input signal *after* the switch is open. As a percentage of the input, feedthrough is determined as the ratio of the feedthrough capacitance to the hold capacitance (C_F/C_H).

Pedestal during hold is a track-to-hold offset. This is an offset that occurs from such phenomena as charge dumps when switches are opened, and coupling of the logic signal transients.

Thermal Tail is the slow drift of the output stage as it settles to the final value with a thermally induced offset due to self-heating; see Figures 11a and 11b.

Transients are the spikes or glitches that occur on the output at the start and end of hold time.

GROUNDING

Many data-acquisition components have two or more ground pins which are not connected together within the device. These "grounds" are usually referred to as the Logic Power Return, Analog Common (Analog Power Return), and Analog Signal Ground. These grounds must be tied together at one point, preferably as close to the A-to-D converter as possible. Ideally, a single solid ground would be desirable. However, since current flows through the ground wires and etch stripes of the circuit cards, and since these paths have resistance and inductance, hundreds of millivolts can be generated between the system ground point and the ground pins of the AD389. Separate ground returns should be provided to minimize the current flow in the path from sensitive points to the system ground point. In this way supply currents and logic-gate return currents are not summed into the same return path as analog signals where they would cause measurement errors.

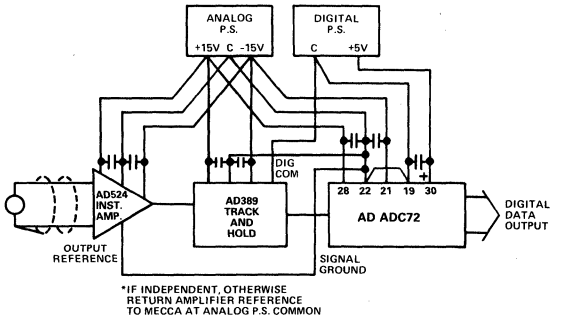

Figure 10. Basic Grounding and Decoupling Practice

DECOUPLING

The AD389 can only settle accurately and fast if the power supplies do not change during transients. Therefore, it is necessary to put 0.1 microfarad (0.1μF) decoupling capacitors right between the supply and analog ground pins and to have 50μF tantalum caps close by.

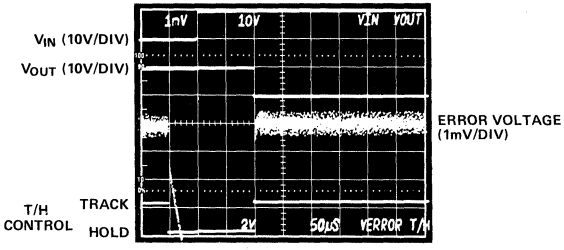

Figure 11a. Acquisition Time after 100μs in the Hold Mode. The AD389 Shows no "Thermal Tail".

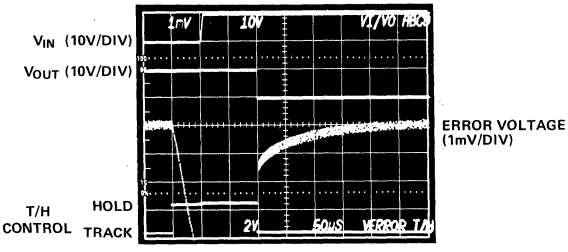

Figure 11b. Typical Thermal Tail and Acquisition Time of Other 12-Bit T/Hs Make them Unsuitable for High Resolution Applications

SAMPLED DATA SYSTEMS

The fast acquisition time of the AD389 when used with a high speed A/D converter allows accurate digitization of high frequency signals and high throughput rates in multichannel data acquisition systems. Figures 12 and 13 show the use of an AD389 with the ADC72 and AD376.

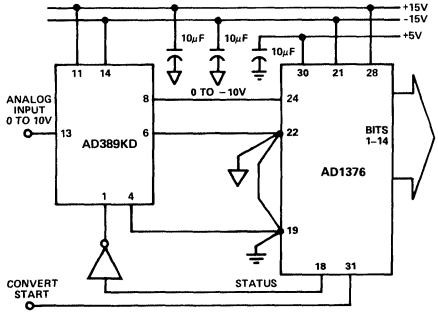

Figure 12. 20kHz–14-Bit, A/D Conversion System

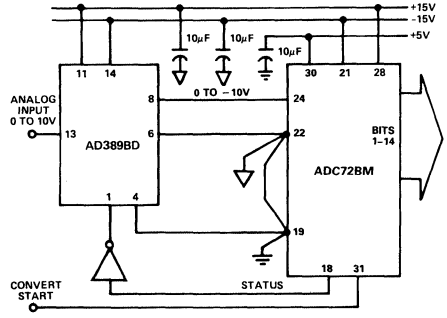

Figure 13. 8.3kHz–14-Bit, A/D Conversion System for −25°C to +85°C Operation

In sampled data systems there are two limiting factors in digitizing high frequency signals. The first limitation is the bandwidth and aperture uncertainty of the sample-and-hold amplifier. The second limitation is the maximum update rate for the T/H and A/D converter combination. For high throughput rate data acquisition systems all factors must be understood.

The aperture jitter is a result of noise within the switching network which modulates the phase of the hold command and is manifested in the variations in the value of the analog input that has been held. The aperture error which results from this jitter is directly related to the dV/dt of the analog input which is easily calculated as shown below. The error calculation takes into account the desired accuracy corresponding to the resolution of the A/D converter.

$$F_{max} = \frac{(\text{Full Scale Voltage})\ (2^{-N})}{(\text{Full Scale Voltage})\ (2\pi)\ (\text{Aperture Jitter})}$$

For an application with a 14-bit A/D converter with a 10V full scale:

$$F_{max} = \frac{(10)\ 2^{-14}}{(10)\ (2\pi)\ (4 \times 10^{-10}\ \text{sec})} = 24\text{kHz}$$

For an application with a 12-bit A/D converter with a 10V full scale:

$$F_{max} = \frac{(10)\ 2^{-12}}{(10)\ (2\pi)\ (4 \times 10^{-10}\ \text{sec})} = 97\text{kHz}$$

Note that some additional aperture delay and jitter are added if the AD389 is not driven directly from the convert start line, but from the status line, which from some converters is delayed.

The maximum throughput rate is the sum of the sample-and-hold acquisition time, settling time and the A/D conversion time.

The maximum input frequency is constrained by the Nyquist sampling theorem to be half of the maximum throughput rate. Input frequencies higher than half the maximum throughput rate result in "under sampling" or aliasing errors of the input signal. In the following table the maximum input frequency is reported as half of the throughput rate, with an ideal brickwall low pass filter has been placed in the signal path prior to the AD389 and A/D converter to eliminate aliasing.

AD389 in Combination With an	Throughput Rate	Input Frequency Range
ADC71 (13 bit)	22.2kHz	dc to 11.1kHz
ADC72 (14 bit)	16.7kHz	dc to 8.3kHz
AD1376 (14 bit)	40.0kHz	dc to 20kHz

Table I. T/H & ADC Combinations and Maximum Throughput Rate

T/H REQUIREMENTS FOR HIGH RESOLUTION APPLICATIONS

The characteristics required for high resolution track-and-hold amplifiers are low feedthrough, low pedestal shifts with changes of input signal or temperature, high linearity, low temperature coefficients, and minimal droop rate.

For sampling a 20kHz signal to 14 bit and 16 bits for example, the following specs are required:

Spec	14 Bit	16 Bit	AD389KD	Units
Aperture Jitter (max)	2.4	0.6	0.4	ns
Slew Rate (max w/20V pk-pk signal)	1.26	1.26	30	V/μs
Feedthrough (1LSB max)	−84.3	−96.3	−86	dB
Droop Rate (1LSB max in 15μs)	40.7	10.2	0.1	μV/μs
Droop Rate (1LSB max in 50μs)	12.2	3.0	0.1	μV/μs
Acquisition Time (to ± 1LSB max) for 20kHz Signal w/15μs ADC	10	10	3-5	μs
Pedestal Shift (max) with Input Signal	−84.3	−96.3	−86	dB
Gain Temperature Coefficient (max) for ± 10°C Ambient Operation	6.1	1.5	2.0	ppm/°C
Thermal Tail (max) within 50μs after Hold	1.2	0.3	0.1	mV
Linearity Error (max)	±0.0061	0.0015	0.003	%FSR

Table II. T/H Amplifier Requirements vs. AD389 Specs

Aperture Jitter will affect exactly when the switch closes, even though the T/H control line is driven by a very precise clock. All high speed sampled data systems are very dependent on low aperture jitter for digitizing high frequency signals for spectrum analysis and accurate signal reconstruction.

The T/H amplifier slew rate determines the maximum frequency tracking rate and part of the settling time when sampling pulses and square waves. The feedthrough from input to output while in the hold mode should be less than 1LSB. The amplitude of 1LSB of the companion A/D converter for a given input range will vary from 610μV for a 14-bit A/D using a 0 to 10V input range to 4.88mV for a 12-bit A/D using a ±10V input range. The hold mode droop rate should produce less than 1LSB of droop in the output during the conversion time of the A/D converter. For 610μV/LSB, as noted in the example above, for a 50μs 14-bit A/D converter, the maximum droop rate will be 610μV/50μs or 12μV/μs during the 50μs conversion period.

The linearity error should be less than 1LSB over the transfer function, as set by the resolution of the A/D converter. The T/H acquisition time, T/H settling time along, with the conversion time of the A/D converter determines the highest sampling rate. This in turn will determine the highest input signal frequency that can be sampled at twice a cycle per the Nyquist criteria. The pedestal shift due to input signal changes should either be linear, to be seen as a gain error, or negligible as with the feedthrough spec. The temperature coefficients for drift should be low enough such that full accuracy is maintained over some minimum temperature range. The droop rate and pedestal will shift more over temperature above +70°C (+158°F). For commercial and industrial users, these shifts will only appear above the highest temperatures their equipment will ever expect to experience. Most precision instrumentation is installed only in human inhabitable work spaces or in controlled enclosures if the area has a hostile environment.

Minimal thermal tail effects are another requirement of high resolution applications. The self-heating errors induced by the changing current levels in the output stages of T/H amps may cause more than 1LSB of error due to thermal tail effects. The performance of a typical AD389 in contrast to a typical 12-bit T/H circuit is shown in Figures 11a. and 11b. The test circuit is shown in Figure 8.

OFFSET ADJUST TRIM

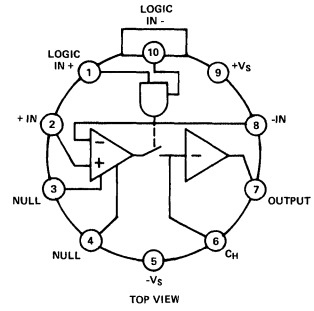
In most data acquisition systems only one offset adjustment is made. In many cases it is the offset adjust of the ADC that is used to cancel all other accumulated system offsets. The offset or pedestal of the AD389 can be nulled by means of 5kΩ potentiometer between pins 7, 9, and 11. If the offset of the AD389 is not adjusted, then connect pins 7 and 9 to pin 14, the negative supply. Otherwise the high impedance of the null pin together with parasitic capacitances can cause tail effects.

Low-Cost Sample-and-Hold Amplifier

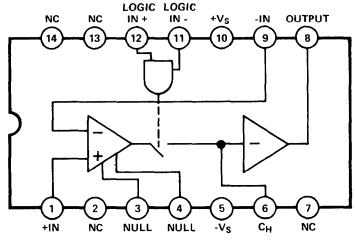
AD582

FEATURES
Suitable for 12-Bit Applications
High Sample/Hold Current Ratio: 10^7
Low Acquisition Time: 6μs to 0.1%
Low Charge Transfer: <2pC
High input Impedance in Sample-and-Hold Modes
Connect in Any Op Amp Configuration
Differential Logic Inputs

AD582 PIN CONFIGURATIONS



10-Pin TO-100



14-Pin DIP TO-116

PRODUCT DESCRIPTION

The AD582 is a low-cost integrated circuit sample-and-hold amplifier consisting of a high performance operational amplifier, a low leakage analog switch and a JFET integrating amplifier – all fabricated on a single monolithic chip. An external holding capacitor, connected to the device, completes the sample-and-hold function.

With the analog switch closed, the AD582 functions like a standard op amp; any feedback network may be connected around the device to control gain and frequency response. With the switch open, the capacitor holds the output at its last level, regardless of input voltage.

Typical applications for the AD582 include sampled data systems, D/A deglitchers, analog de-multiplexers, auto null systems, strobed measurement systems and A/D speed enhancement.

The device is available in two versions: the "K" specified for operation over the 0 to +70°C commercial temperature range and the "S" specified over the extended temperature range, -55°C to +125°C. All versions may be obtained in either the hermetic sealed, TO-100 can or the TO-116 DIP.

PRODUCT HIGHLIGHTS

1. The specially designed input stage presents a high impedance to the signal source in both sample and hold modes (up to ±12V). Even with signal levels up to $\pm V_S$, no undesirable signal inversion, peaking or loss of hold voltage occurs.
2. The AD582 may be connected in any standard op amp configuration to control gain or frequency response and provide signal inversion, etc.
3. The AD582 offers a high, sample-to-hold current ratio: 10^7. The ratio of the available charging current to the holding leakage current is often used as a figure of merit for a sample and hold circuit.
4. The AD582 has a typical charge transfer less than 2pC. A low charge transfer produces less offset error and permits the use of smaller hold capacitors for faster signal acquisition.
5. The AD582 provides separate analog and digital grounds, thus improving the device's immunity to ground and switching transients.

SPECIFICATIONS (typical @ +25°C, V_S = ±15V and C_H = 1000pF, A = +1 unless otherwise specified)

APPLYING THE AD582

Both the inverting and non-inverting inputs are brought out to allow op amp type versatility in connecting and using the AD582. Figure 1 shows the basic non-inverting unity gain connection requiring only an external hold capacitor and the usual power supply bypass capacitors. An offset null pot can be added for more critical applications.

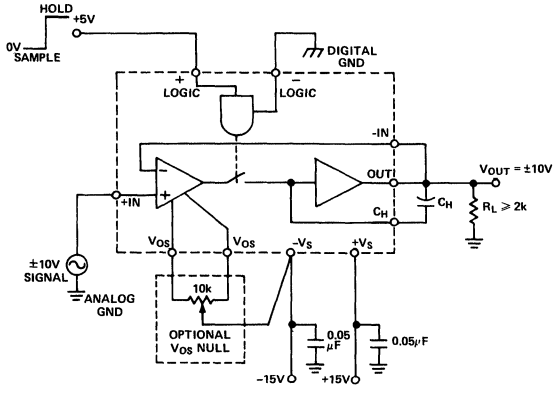

Figure 1. Sample and Hold with A = +1

Figure 2 shows a non-inverting configuration where voltage gain, A_V, is set by a pair of external resistors. Frequency shaping or non-linear networks can also be used for special applications.

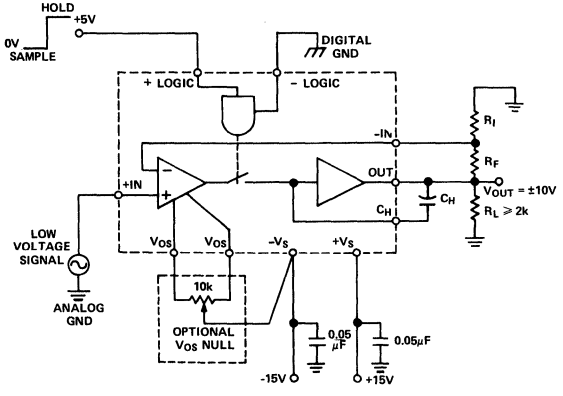

Figure 2. Sample and Hold with A = (1 + R_F/R_I)

The hold capacitor, C_H, should be a high quality polystyrene (for temperatures below +85°C) or Teflon type with low dielectric absorption. For high speed, limited accuracy applications, capacitors as small as 100pF may be used. Larger values are required for accuracies of 12 bits and above in order to minimize feedthrough, sample to hold offset and droop errors (see Figure 6). Care should be taken in the circuit layout to minimize coupling between the hold capacitor and the digital or signal inputs.

In the hold mode, the output voltage will follow any change in the $-V_S$ supply. Consequently, this supply should be well regulated and filtered.

Biasing the +Logic Input anywhere between -6V to +0.8V with respect to the -Logic will set the sample mode. The hold mode will result from any bias between +2.0V and ($+V_S$ - 3V). The sample and hold modes will be controlled differentially with the absolute voltage at either logic input ranging from $-V_S$ to within 3V of $+V_S$ (V_S - 3V). Figure 3 illustrates some examples of the flexibility of this feature.

DEFINITION OF TERMS

Figure 4 illustrates various dynamic characteristics of the AD582.

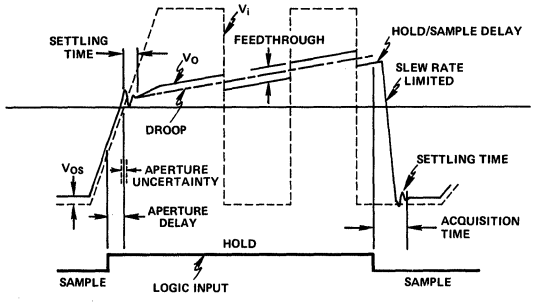

Figure 4. Pictorial Showing Various S/H Characteristics

Aperture Delay is the time required after the "hold" command until the switch is fully open and produces a delay in the effective sample timing. Figure 5 is a plot giving the maximum frequency at which the AD582 can sample an input with a given accuracy (lower curve).

Aperture Jitter is the uncertainty in Aperture Time. The Aperture Time can be eliminated by advancing the sample-to-hold command 200ns with respect to the input signal. The Aperture Jitter now determines the maximum sampling frequency (upper curve of Figure 5).

Acquisition Time is the time required by the device to reach its final value within a given error band after the sample command has been given. This includes switch delay time, slewing time and settling time for a given output voltage change.

Droop is the change in the output voltage from the "held" value as a result of device leakage. In the AD582, droop can be in either the positive or negative direction. Droop rate may be calculated from droop current using the following formula:

$$\frac{\Delta V}{\Delta T}\ (\text{Volts/sec}) = \frac{I(\text{pA})}{C_H(\text{pF})}$$

(See also Figure 6.)

Feedthrough is that component of the output which follows the input signal *after* the switch is open. As a percentage of the input, feedthrough is determined as the ratio of the feedthrough capacitance to the hold capacitance (C_F/C_H).

Sample-to-Hold Offset is an output shift or step caused by charge injection into the hold capacitor as the device is switched from sample to hold. The charge transfer generates a sample-to-hold offset where:

$$\text{S/H Offset (V)} = \frac{\text{Charge (pC)}}{C_H\ (\text{pF})}$$

This offset also has a dc component as shown in Figure 6.

ANALOG DEVICES

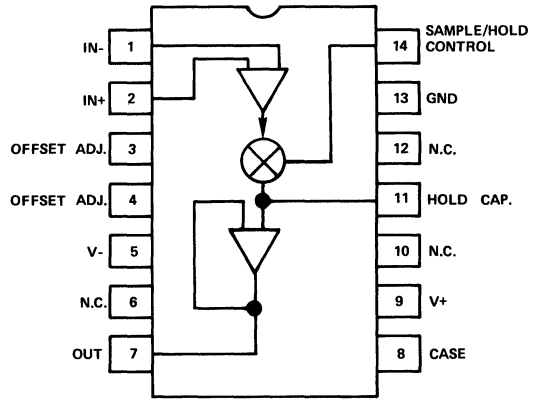
Sample-and-Hold Amplifier

AD583

FEATURES

High Sample-to-Hold Current Ratio: 10^6
High Slew Rate: 5V/μs
High Bandwidth: 2MHz
Low Aperture Time: 50ns
Low Charge Transfer: 10pC
DTL/TTL Compatible
May Be Used as Gated Op Amp

AD583 PIN CONFIGURATION



PRODUCTION DESCRIPTION

The AD583 is a monolithic sample-and hold circuit consisting of a high performance operational amplifier in series with a low leakage analog switch and unity gain amplifier. An external hold capacitor, connected to the switch output, completes the sample-and-hold or track-and-hold function.

With the analog switch closed, the AD583 functions like a standard op amp; any feedback network may be connected around the device to control gain and frequency response. With the switch open the capacitor holds the output at its previous level.

The AD583 may also be used as a versatile operational amplifier with a gated output for applications such as analog switches, peak holding circuits, etc.

PRODUCT HIGHLIGHTS

1. Sample-and-hold operation is obtained with the addition of one external capacitor.
2. Low charge transfer (10pC) and high sample-to-hold current ratio insure accurate tracking.
3. Any gain or frequency response is available using standard op amp feedback networks.
4. High slew rate and low aperture time permit sampling of rapidly changing signals.
5. Output, gated through a low leakage analog switch, also makes the AD583 useful for applications such as analog switches, peak holding circuits, etc.

AD585

FEATURES
3.0μs Acquisition Time to ±0.01% max
Low Droop Rate: 1.0mV/ms max
Sample/Hold Offset Step: 3mV max
Aperture Jitter: 0.5ns
Extended Temperature Range: −55°C to +125°C
Internal Hold Capacitor
Internal Application Resistors
±12V or ±15V Operation
Available in Surface Mount

APPLICATIONS
Data Acquisition Systems
Data Distribution Systems
Analog Delay & Storage
Peak Amplitude Measurements

PRODUCT DESCRIPTION

The AD585 is a complete monolithic sample-and-hold circuit consisting of a high performance operational amplifier in series with an ultralow leakage analog switch and a FET input integrating amplifier. An internal holding capacitor and matched applications resistors have been provided for high precision and applications flexibility.

The performance of the AD585 makes it ideal for high speed 10- and 12-bit data acquisition systems, where fast acquisition time, low sample-to-hold offset, and low droop are critical. The AD585 can acquire a signal to ±0.01% in 3μs maximum, and then hold that signal with a maximum sample-to-hold offset of 3mV and less than 1mV/ms droop, using the on-chip hold capacitor. If lower droop is required, it is possible to add a larger external hold capacitor.

The high-speed analog switch used in the AD585 exhibits aperture jitter of 0.5ns, enabling the device to sample full-scale (20V peak-to-peak) signals at frequencies up to 78kHz with 12-bit precision.

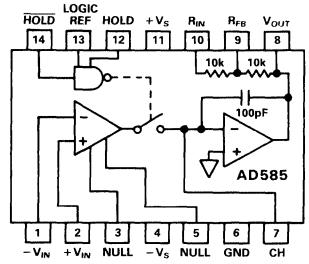
The AD585 can be used with any user-defined feedback network to provide any desired gain in the sample mode. On-chip precision thin-film resistors can be used to provide gains of +1, −1, or +2. Output impedance in the hold mode is sufficiently low to maintain an accurate output signal even when driving the dynamic load presented by a successive-approximation A/D converter. However, the output is protected against damage from accidental short circuits.

The control signal for the HOLD command can be either active high or active low. The differential HOLD signal is compatible with all logic families, if a suitable reference level is provided. An on-chip TTL reference level is provided for TTL compatibility.

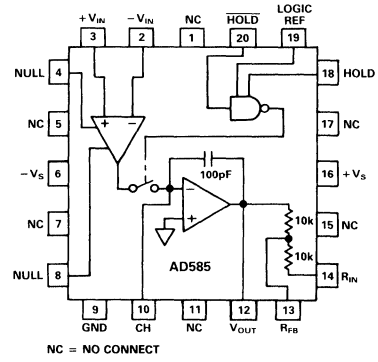
The AD585 is available in three performance grades. The JP grade is specified for the 0 to +70°C commercial temperature range and packaged in a 20-pin PLCC. The AQ grade is specified for the −25°C to +85°C industrial temperature range and is packaged in a 14-pin cerdip. The SQ and SE grades are specified for the −55°C to +125°C military temperature range and are packaged in a 14-pin cerdip and 20-pin LCC.

AD585 FUNCTIONAL BLOCK DIAGRAMS

DIP



LCC/PLCC PACKAGE



NC = NO CONNECT

PRODUCT HIGHLIGHTS

1. The fast acquisition time (3μs) and low aperture jitter (0.5ns) make it the first choice for very high speed data acquisition systems.
2. The droop rate is only 1.0mV/ms so that it may be used in slower high accuracy systems without the loss of accuracy.
3. The low charge transfer of the analog switch keeps sample-to-hold offset below 3mV with the on-chip 100pF hold capacitor, eliminating the trade-off between acquisition time and S/H offset required with other SHAs.
4. The AD585 has internal pretrimmed application resistors for applications versatility.
5. The AD585 is complete with an internal hold capacitor for ease of use. Capacitance can be added externally to reduce the droop rate when long hold times and high accuracy are required.
6. The AD585 is recommended for use with 10- and 12-bit successive-approximation A/D converters such as AD573, AD574A, AD674A, AD7572 and AD7672.

SAMPLED DATA SYSTEMS

In sampled data systems there are a number of limiting factors in digitizing high frequency signals accurately. Figure 9 shows pictorially the sample-and-hold errors that are the limiting factors. In the following discussions of error sources the errors will be divided into the following groups: 1. Sample-to-Hold Transition, 2. Hold Mode and 3. Hold-to-Sample Transition.

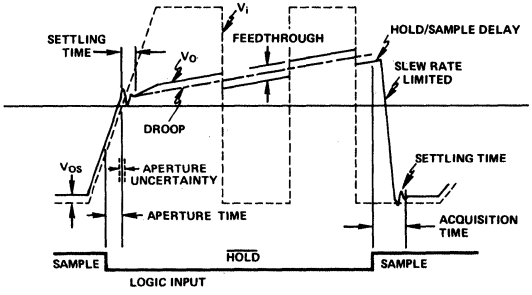

Figure 9. Pictorial Showing Various S/H Characterstics

SAMPLE-TO-HOLD TRANSITION

The aperture delay time is the time required for the sample-and-hold amplifier to switch from sample to hold. Since this is effectively a constant then it may be tuned out. If however, the aperture delay time is not accounted for then errors of the magnitude as shown in Figure 10 will result.

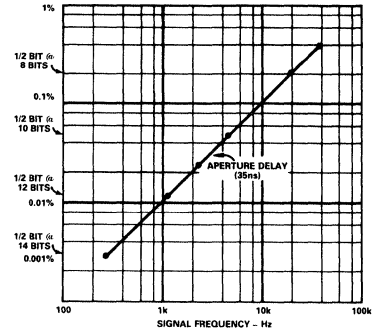

Figure 10. Aperture Delay Error vs. Frequency

To eliminate the aperture delay as an error source the sample-to-hold command may be advanced with respect to the input signal.

Once the aperture delay time has been eliminated as an error source then the aperture jitter which is the variation in aperture delay time from sample-to-sample remains. The aperture jitter is a true error source and must be considered. The aperture jitter is a result of noise within the switching network which modulates the phase of the hold command and is manifested in the variations in the value of the analog input that has been held. The aperture error which results from this jitter is directly related to the dV/dT of the analog input.

The error due to aperture jitter is easily calculated as shown below. The error calculation takes into account the desired accuracy corresponding to the resolution of the N-bit A/D converter.

$$F_{max} = \frac{2^{-(N+1)}}{\pi \text{ (Aperture Jitter)}}$$

For an application with a 10-bit A/D converter with a 10V full scale to a 1/2LSB error maximum.

$$F_{max} = \frac{2^{-(10+1)}}{\pi\ (0.5 \times 10^{-9})}$$

$$F_{max} = 310.8\text{kHz}.$$

For an application with a 12-bit A/D converter with a 10V full scale to a 1/2LSB error maximum:

$$F_{max} = \frac{2^{-(12+1)}}{\pi\ (0.5 \times 10^{-9})}$$

$$F_{max} = 77.7\text{kHz}.$$

Figure 11 shows the entire range of errors induced by aperture jitter with respect to the input signal frequency.

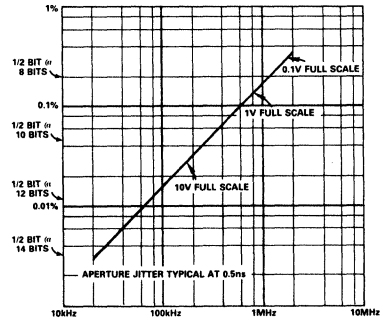

Figure 11. Aperture Jitter Error vs. Frequency

Sample-to-hold offset is caused by the transfer of charge to the holding capacitor via the gate capacitance of the switch when switching into hold. Since the gate capacitance couples the switch-control voltage applied to the gate on to the hold capacitor, the resulting sample-to-hold offset is a function of the logic level.

The logic inputs were designed for application flexibility and, therefore, a wide range of logic thresholds. This was achieved by using a differential input stage for HOLD and $\overline{\text{HOLD}}$. Figure 1 shows the change in the sample-to-hold offset voltage based upon an independently programmed reference voltage. Since the input stage is a differential configuration, the offset voltage is a function of the control voltage range around the programmed threshold voltage.

The sample-to-hold offset can be reduced by adding capacitance to the internal 100pF capacitor and by using $\overline{\text{HOLD}}$ instead of HOLD. This may be easily accomplished by adding an external capacitor between Pins 7 and 8. The sample-to-hold offset is then governed by the relationship:

$$\text{S/H Offset (V)} = \frac{\text{Charge (pC)}}{C_H \text{ Total (pF)}}$$

For the AD585 in particular it becomes:

$$\text{S/H Offset (V)} = \frac{0.3 \text{ pC}}{100\text{pF} + (C_{EXT})}$$

The addition of an external hold capacitor also affects the acquisition time of the AD585. The change in acquisition time with respect to the C_{EXT} is shown graphically in Figure 2.

HOLD MODE

In the hold mode there are two important specifications that must be considered; feedthrough and the droop rate. Feedthrough errors appear as an attenuated version of the input at the output while in the hold mode. Hold-Mode feedthrough varies with frequency, increasing at higher frequencies. Feedthrough is an important specification when a sample and hold follows an analog multiplexer that switches among many different channels.

Hold-mode droop rate is the change in output voltage per unit of time while in the hold mode. Hold mode droop originates as leakage from the hold capacitor, of which the major leakage current contributors are switch leakage current and bias current. The rate of voltage change on the capacitor dV/dT is the ratio of the total leakage current I_L to the hold capacitance C_H.

$$\text{Droop Rate} = \frac{dV_{OUT}}{dT}\ (\text{Volts/Sec}) = \frac{I_L(\text{pA})}{C_H(\text{pF})}$$

For the AD585 in particular;

$$\text{Droop Rate} = \frac{100\text{pA}}{100\text{pF} + (C_{EXT})}$$

Additionally the leakage current doubles for every 10°C increase in temperature above 25°C; therefore, the hold-mode droop rate characteristic will also double in the same fashion. The hold-mode droop rate can be traded-off with acquisition time to provide the best combination of droop error and acquisition time. The tradeoff is easily accomplished by varying the value of C_{EXT}.

Since a sample and hold is used typically in combination with an A/D converter, then the total droop in the output voltage has to be less than 1/2LSB during the period of a conversion. The maximum allowable signal change on the input of an A/D converter is:

$$\Delta V \text{ max} = \frac{\text{Full Scale Voltage}}{2^{(N+1)}}$$

Once the maximum ΔV is determined then the conversion time of the A/D converter (T_{CONV}) is required to calculate the maximum allowable dV/dT.

$$\frac{dV \text{ max}}{dt} = \frac{\Delta V \text{ max}}{T_{CONV}}$$

The maximum $\frac{dV \text{ max}}{dT}$ as shown by the previous equation is the limit not only at 25°C but at the maximum expected operating temperature range. Therefore, over the operating temperature range the following criteria must be met ($T_{OPERATION} - 25°C$) $= \Delta T$.

$$\frac{dV\ 25°C}{dT} \times 2^{\frac{(\Delta T°C)}{10°C}} \leq \frac{dV \text{ max}}{dT}$$

HOLD-TO-SAMPLE TRANSITION

The Nyquist theorem states that a band-limited signal which is sampled at a rate at least twice the maximum signal frequency can be reconstructed without loss of information. This means that a sampled data system must sample, convert and acquire the next point at a rate at least twice the signal frequency. Thus the maximum input frequency is equal to

$$f_{MAX} = \frac{1}{2(T_{ACQ} + T_{CONV} + T_{AP})}$$

Where T_{ACQ} is the acquisition time of the sample-to-hold amplifier, T_{AP} is the maximum aperture time (small enough to be ignored) and T_{CONV} is the conversion time of the A/D converter.

DATA ACQUISITION SYSTEMS

The fast acquisition time of the AD585 when used with a high speed A/D converter allows accurate digitization of high frequency signals and high throughput rates in multichannel data acquisition systems. The AD585 can be used with a number of different A/D converters to achieve high throughput rates. Figures 12 and 13 show the use of an AD585 with the AD578 and AD574A.

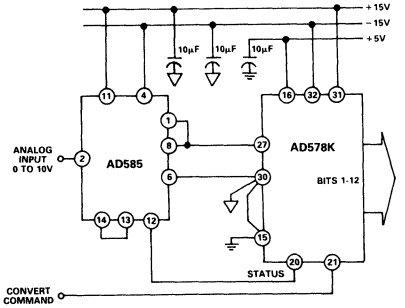

Figure 12. A/D Conversion System, 117.6kHz Throughput 58.8kHz max Signal Input

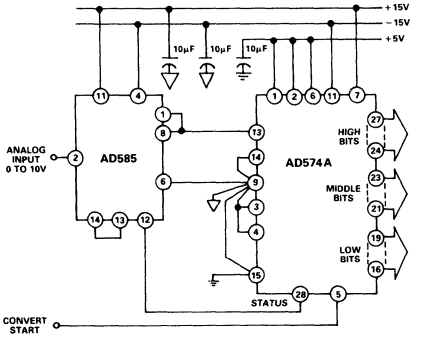

Figure 13. 12 Bit A/D Conversion System, 26.3kHz Throughput Rate, 13.1kHz max Signal Input

LOGIC INPUT

The sample-and-hold logic control was designed for versatile logic interfacing. The HOLD and $\overline{\text{HOLD}}$ inputs may be used with both low and high level CMOS, TTL and ECL logic systems. Logic threshold programmability was achieved by using a differential amplifier as the input stage for the digital inputs. A predictable logic threshold may be programmed by referencing either HOLD or $\overline{\text{HOLD}}$ to the appropriate threshold voltage. For example, if the internal 1.4V reference is applied to $\overline{\text{HOLD}}$ an input signal to HOLD between $+1.8$V and $+V_S$ will place the AD585 in the hold mode. The AD585 will go into the sample mode for this case when the input is between $-V_S$ and $+1.0$V. The range of references which may be applied is from $(-V_S + 4V)$ to $(+V_S - 3V)$.

OPTIONAL CAPACITOR SELECTION

If an additional capacitor is going to be used in conjunction with the internal 100pF capacitor it must have a low dielectric absorption. Dielectric absorption is just that; it is the charge absorbed into the dielectric that is not immediately added to or removed from the capacitor when rapidly charged or discharged. The capacitor with dielectric absorption is modeled in Figure 14.

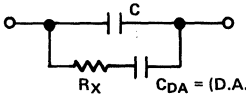

Figure 14. Capacitor Model with Dielectric Absorption

If the capacitor is charged slowly, C_{DA} will eventually charge to the same value as C. But unfortunately, good dielectrics have very high resistances, so while C_{DA} may be small, R_X is large and the time constant $R_X C_{DA}$ typically runs into the millisecond range. In fast-charge, fast-discharge situations the effect of dielectric absorption resembles "memory". In a data acquisition system where many channels with widely varying data are being sampled the effect is to have an ever changing offset which appears as a very nonlinear sample-to-hold offset since the difference between the voltage being measured and the voltage previously measured determines the fraction by which the dielectric absorption figure is multiplied. It is impossible to readily correct for this error source. The only solution is to use a capacitor with dielectric absorption less than the maximum tolerable error. Capacitor types such as polystyrene, polypropylene or Teflon are recommended.

GROUNDING

Many data-acquisition components have two or more ground pins which are not connected together within the device. These "grounds" are usually referred to as the Logic Power Return, Analog Common (Analog Power Return), and Analog Signal Ground. These grounds must be tied together at one point, usually at the system power-supply ground. Ideally, a single solid ground would be desirable. However, since current flows through the ground wires and etch stripes of the circuit cards, and since these paths have resistance and inductance, hundreds of millivolts can be generated between the system ground point and the ground pin of the AD585. Separate ground returns should be provided to minimize the current flow in the path from sensitive points to the system ground point. In this way supply currents and logic-gate return currents are not summed into the same return path as analog signals where they would cause measurement errors.

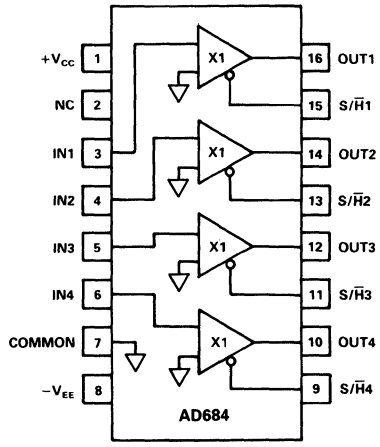
Four-Channel Sample-and-Hold Amplifier

AD684

FEATURES
Four Matched Sample-and-Hold Amplifiers
Independent Inputs, Outputs and Control Pins
500ns Hold Mode Settling
1μs Maximum Acquisition Time to 0.01%
Low Droop Rate: 0.01μV/μs
Internal Hold Capacitors
200ps Maximum Aperture Jitter
Low Power Dissipation: 360 mW
0.3" Skinny DIP Package

AD684 FUNCTIONAL BLOCK DIAGRAM



6

PRODUCT DESCRIPTION

The AD684 is a monolithic quad sample-and-hold amplifier (SHA). It features four complete sampling channels, each controlled by an independent hold command. Each SHA is complete with an internal hold capacitor. The high accuracy SHA channels are self-contained and require no external components or adjustments. The AD684 is manufactured on a BiMOS process which provides a merger of high performance bipolar circuitry and low power CMOS logic.

The AD684 is ideal for high performance, multichannel data acquisition systems. Each SHA channel can acquire a signal in less than 1μs and retain the held value with a droop rate of less than 0.01μV/μs. Excellent linearity and ac performance make the AD684 an ideal front end for high speed 12- and 14-bit ADCs.

The AD684 has a self-correcting architecture that minimizes hold mode errors and insures accuracy over temperature. Each channel of the AD684 is capable of sourcing 5mA and incorporates output short circuit protection.

The AD684 is specified for three temperature ranges. The J grade device is specified for operation from 0 to 70°C, the A grade from −40°C to +85°C and the S grade from −55°C to +125°C.

PRODUCT HIGHLIGHTS

1. Fast acquisition time (1μs) and low aperture jitter (200ps) make the AD684 the best choice for multiple channel data acquisition systems.
2. Monolithic construction insures excellent interchannel matching in terms of timing and accuracy, as well as high reliability.
3. Independent inputs, outputs and sample-and-hold controls allow user flexibility in system architecture.
4. Low droop (0.01μV/μs) and internally compensated hold mode error results in superior system accuracy.
5. The AD684's fast settling time and low output impedance make it ideal for driving high speed analog to digital converters such as the AD578, AD674, AD7572 and the AD7672.

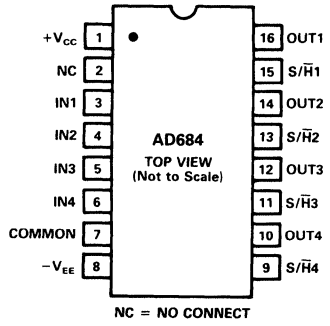
*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied.

PIN CONFIGURATION



CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

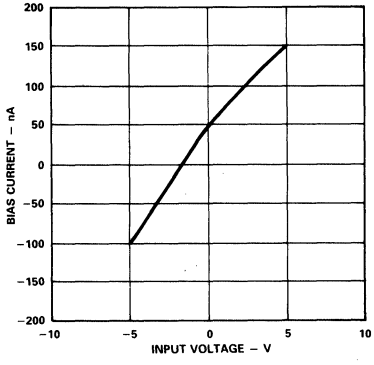
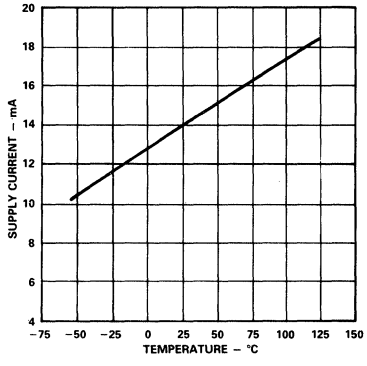
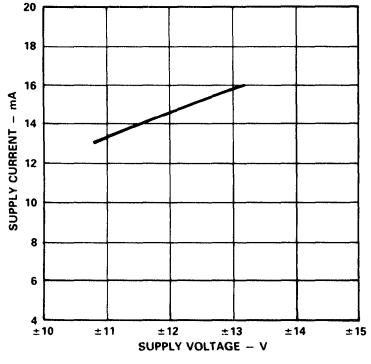
Effective Aperture Delay vs. Frequency



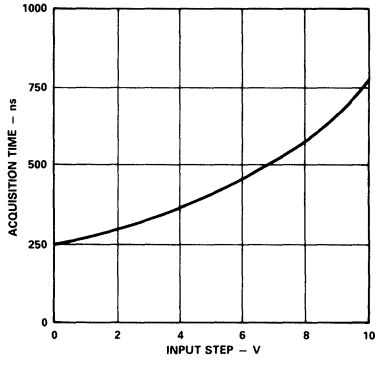
Bias Current vs. Input Voltage



Supply Current vs. Temperature



Supply Current vs. Supply Voltage



Acquisition Time (to 0.01%) vs. Input Step Size

DEFINITIONS OF SPECIFICATIONS

Acquisition Time — The length of time that the SHA must remain in the sample mode in order to acquire a full scale input step to a given level of accuracy.

Small Signal Bandwidth — The frequency at which the held output amplitude is 3dB below the input amplitude, under an input condition of a 100mV p-p sine wave.

Full Power Bandwidth — The frequency at which the held output amplitude is 3dB below the input amplitude, under an input condition of a 10V p-p sine wave.

Effective Aperture Delay — The difference between the switch delay and the analog delay of the SHA channel. A negative number indicates that the analog portion of the overall delay is greater than the switch portion. This effective delay represents the point in time, relative to the hold command, that the input signal will be sampled.

Aperture Jitter — The variations in aperture delay for successive samples. Aperture jitter puts an upper limit on the maximum frequency that can be accurately sampled.

Hold Settling Time — The time required for the output to settle to within a specified level of accuracy of its final held value after the hold command has been given.

Droop Rate — The drift in output voltage while in the hold mode.

Feedthrough — The attenuated version of a changing input signal that appears at the output when the SHA is in the hold mode.

Hold Mode Offset — The difference between the input signal and the held output. This offset term applies only in the hold mode and includes the error caused by charge injection and all other internal offsets. It is specified for an input of 0V.

Tracking Mode Offset — The difference between the input and output signals when the SHA is in the track mode.

Nonlinearity — The deviation from a straight line on a plot of input vs. (held) output as referenced to a straight line drawn between endpoints, over an input range of −5V and +5V.

Gain Error — Deviation from a gain of +1 on the transfer function of input vs. held output.

Interchannel Isolation — The level of crosstalk between adjacent channels while in the sample (track) mode with a full scale 100kHz input signal.

Interchannel Aperture Offset — The variation in aperture time between the four channels for a simultaneous hold command.

Differential Offset — The difference in hold mode offset between the four SHA channels.

Power Supply Rejection Ratio — A measure of change in the held output voltage for a specified change in the positive or negative supply.

Sampled dc Uncertainty — The internal rms SHA noise that is sampled onto the hold capacitor.

Hold Mode Noise — The rms noise at the output of the SHA while in the hold mode, specified over a given bandwidth.

Total Output Noise — The total rms noise that is seen at the output of the SHA while in the hold mode. It is the rms summation of the sampled dc uncertainty and the hold mode noise.

Output Drive Current — The maximum current the SHA can source (or sink) while maintaining a change in hold mode offset of less than 2.5mV.

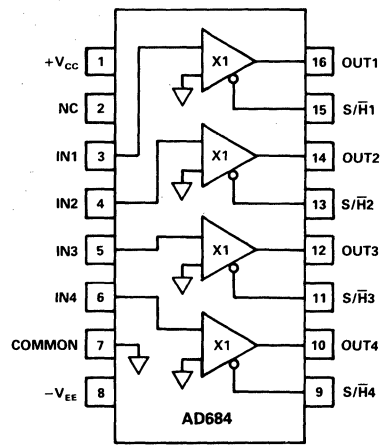
6

FUNCTIONAL DESCRIPTION

The AD684 is a complete quad sample-and hold amplifier that provides high speed sampling to 12-bit accuracy in less than 1μs.

The AD684 is completely self-contained, including on-chip hold capacitors, and requires no external components or adjustments to perform the sampling function. Each SHA channel can operate independently, having its own input, output and sample/hold command. Both inputs and outputs are treated as single ended signals, referred to common.

The AD684 utilizes a proprietary circuit design which includes a self-correcting architecture. This sample-and-hold circuit corrects for internal errors after the hold command has been given, by compensating for amplifier gain and offset errors, and charge injection errors. Due to the nature of the design, the SHA output in the sample mode is not intended to provide an accurate representation of the input. However, in hold mode, the internal circuitry is reconfigured to produce an accurately held version of the input signal. To the right is a block diagram of the AD684.



Functional Block Diagram

DYNAMIC PERFORMANCE

The AD684 is compatible with 12-bit A-to-D converters in terms of both accuracy and speed. The fast acquisition time, fast hold settling time and good output drive capability allow the AD684 to be used with high speed, high resolution A-to-D converters like the AD674 and AD7672. The AD684's fast acquisition time provides high throughput rates for multichannel data acquisition systems. Typically, the sample and hold can acquire a 10V step in less than 750ns. Figure 1 shows the settling accuracy as a function of acquisition time.

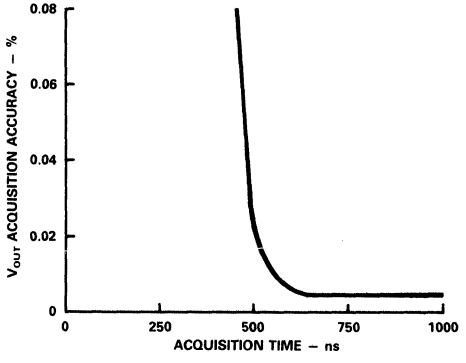


Figure 1. V_{OUT} Settling vs. Acquisition Time

The hold settling determines the required time, after the hold command is given, for the output to settle to its final specified accuracy. The typical settling behavior of the AD684 is shown in Figure 2. The settling time of the AD684 is sufficiently fast to allow the SHA, in most cases, to directly drive an A-to-D converter without the need for an added "start convert" delay.

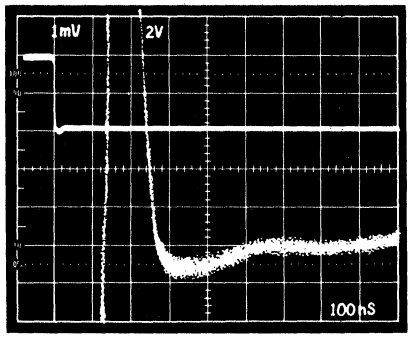

Figure 2. Typical AD684 Hold Mode

HOLD MODE OFFSET

The dc accuracy of the AD684 is determined primarily by the hold mode offset. The hold mode offset refers to the difference between the final held output voltage and the input signal at the time the hold command is given. The hold mode offset arises from a voltage error introduced onto the hold capacitor by charge injection of the internal switches. The nominal hold mode offset is specified for a 0V input condition. Over the input range of −5V to +5V, the AD684 is also characterized for an effective gain error and nonlinearity of the held value, as shown in Figure 3. As indicated by the AD684 specifications, the hold mode offset is very well matched between channels and stable over temperature.

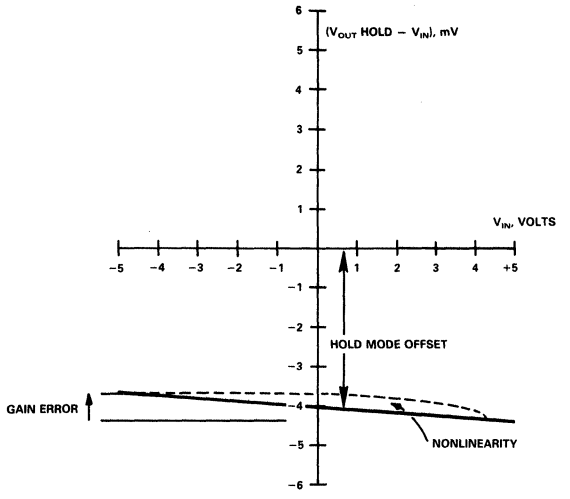

Figure 3. Hold Mode Offset, Gain Error and Nonlinearity

For applications where it is important to obtain zero offset, the hold mode offset may be nulled externally at the input to the A-to-D converter. Adjustment of the offset may be accomplished through the A-to-D itself or by an external amplifier with offset nulling capability (e.g., AD711). Only a single adjustment of the offset is necessary for the four SHA channels as a result of the excellent matching among them. The offset will change less than 0.5mV over the specified temperature range.

SUPPLY DECOUPLING AND GROUNDING CONSIDERATIONS

As with any high speed, high resolution data acquisition system, the power supplies should be well regulated and free from excessive high frequency noise (ripple). The supply connection to the AD684 should also be capable of delivering transient currents to the device. To achieve the specified accuracy and dynamic performance, decoupling capacitors must be placed directly at both the positive and negative supply pins to common. Ceramic type 0.1μF capacitors should be connected from V_{CC} and V_{EE} to common.

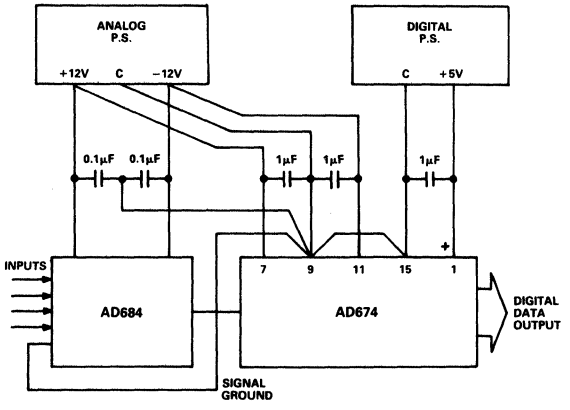

Figure 4. Basic Grounding and Decoupling Diagram

The AD684 does not provide separate analog and digital ground leads as is the case with most A-to-D converters. The common pin is the single ground terminal for the device. It is the reference point for the sampled input voltage and the held output voltage and also the digital ground return path. The common pin should be connected to the reference (analog) ground of the A-to-D converter with a separate ground lead. Since the analog and digital grounds in the 684 are connected internally, the common pin should also be connected to the digital ground, which is usually tied to analog common at the A-to-D converter. Figure 4 illustrates the recommended decoupling and grounding practice.

NOISE CHARACTERISTICS

Designers of data conversion circuits must also consider the effect of noise sources on the accuracy for the data acquisition system. A sample-and-hold amplifier that precedes the A-to-D converter introduces some noise and represents another source of uncertainty in the conversion process. The noise from the AD684 is specified as the total output noise, which includes both the sampled wideband noise of the SHA in addition to the band limited output noise. The total output noise is the rms sum of the sampled dc uncertainty and the hold mode noise. A plot of the total output noise vs. the equivalent input bandwidth of the converter being used is given in Figure 5.

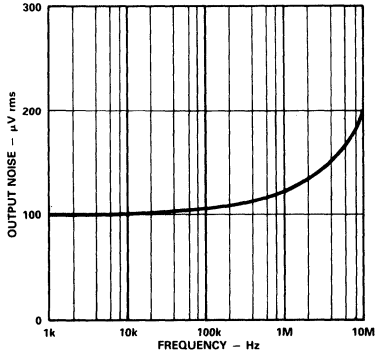

Figure 5. RMS Noise vs. Input Bandwidth of ADC

DRIVING THE ANALOG INPUTS

For best performance, it is important to drive the AD684 analog inputs from a low impedance signal source. This enhances the sampling accuracy by minimizing the analog and digital crosstalk. Signals which come from higher impedance sources (e.g., over 5k ohms) will have a relatively higher level of crosstalk. For applications where signals have high source impedance, an operational amplifier buffer in front of the AD684 is required. The AD713 (precision quad BiFET op amp) is recommended for these applications.

HIGH FREQUENCY SAMPLING

Aperture jitter and distortion are the primary factors which limit frequency domain performance of a sample-and-hold amplifier. Aperture jitter modulates the phase of the hold command and produces an effective noise on the sampled analog input. The magnitude of the jitter induced noise is directly related to the frequency of the input signal.

A graph showing the magnitude of the jitter induced error vs. frequency of the input signal is given in Figure 6.

The accuracy in sampling high frequency signals is also constrained by the distortion and noise created by the sample-and-hold. The level of distortion increases with frequency and reduces the "effective number of bits" of the conversion.

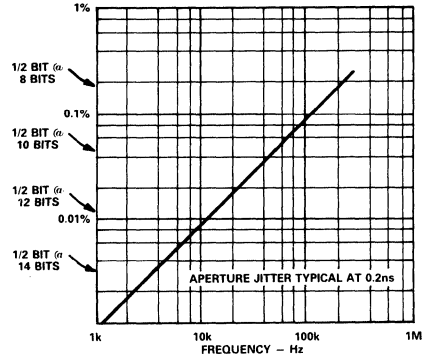

Figure 6. Error Magnitude vs. Frequency

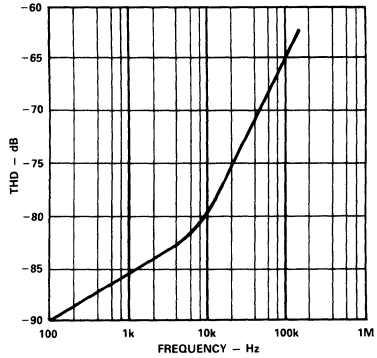

Figure 7. Total Harmonic Distortion vs. Frequency

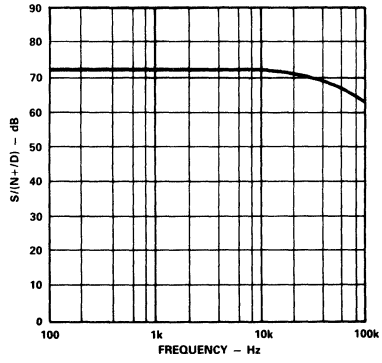

Figure 8. Signal/(Noise and Distortion) vs. Frequency

Measurements of Figures 7 and 8 were made using a 14-bit A-to-D converter with V_{IN} = 10V p-p and a sample frequency of 100KSPS.

DATA ACQUISITION APPLICATIONS

Figure 9 shows a typical data acquisition circuit using the AD684 and the high speed 12-bit A-to-D converter, the AD7672. Four input signals are simultaneously sampled by the AD684 as the $\overline{\text{HOLD}}$ command is given. One of the four held outputs is selected by the ADG201, quad CMOS switch, and buffered by the AD711. The AD588 provides the reference voltage with switches A–B and C–D selecting a −5V to +5V or 0 to +5V input range.

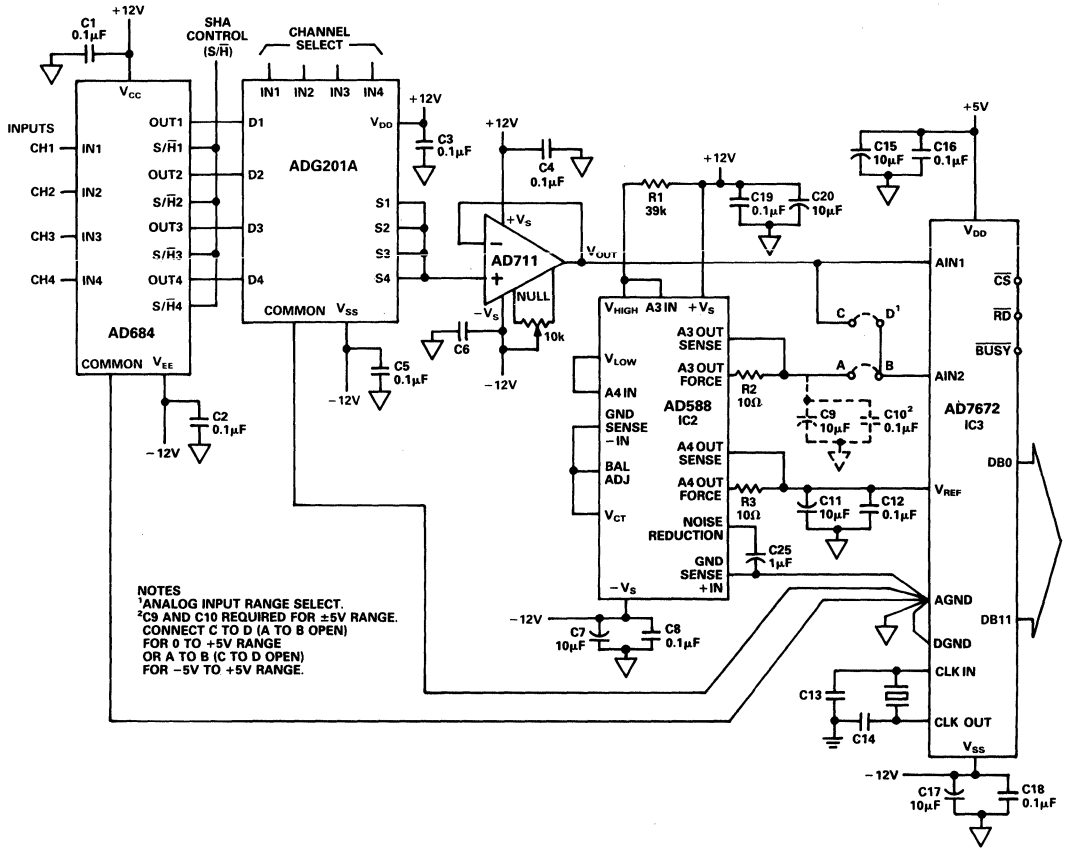

Figure 9. Data Acquisition System Using the AD684 and the AD7672

ANALOG DEVICES

Low Cost 16-Bit Accurate Sample-and-Hold Amplifier

AD1154

FEATURES

Low Nonlinearity: ±7.6 ppm max (1/2 LSB @ 16-Bit Accuracy)
Fast Acquisition Time to ±0.00076%: 3.5 μs
Low Droop Rate: 0.02 μV/μs
Aperture Jitter: 150 ps
±10 V Input Range
Hold Mode Feedthrough Rejection of −106 dB
14-Pin Metal DIP
Gain of +1 V/V
Low Cost

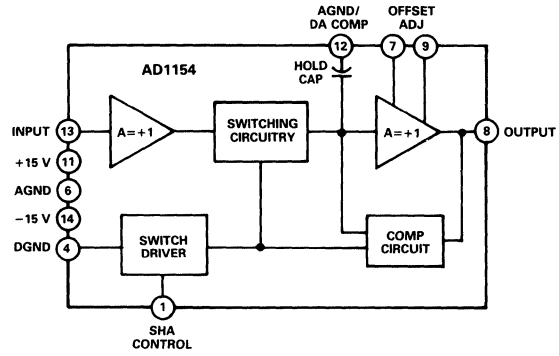
AD1154 FUNCTIONAL BLOCK DIAGRAM



6

GENERAL DESCRIPTION

The AD1154 is a high accuracy, low cost sample-and-hold amplifier (SHA) designed to be used in high resolution data acquisition systems. It is complete with internal hold capacitor and proprietary capacitor trimmed compensation circuitry. Its accuracy (0.00076% of full scale range) and dynamic performance allow it to be used with high speed 16-bit A/D converters. The AD1154's low price enables users to upgrade the front end performance of 14-bit systems without increasing system cost. Its gain accuracy and droop rate in "hold" mode also allow accurate conversion by slower 16-bit A/D converters having conversion times of up to 7.6 ms.

The AD1154 is a hybrid noninverting sample-and-hold amplifier (SHA) with a gain of +1 V/V. It can be utilized in most inverting SHA applications by inverting the digital data. The AD1154 is packaged in a compact 14-pin metal DIP.

Typical applications for the AD1154 include data acquisition systems, strobed measurement systems, peak hold circuits and simultaneous sample-and-hold functions. The AD1154 is available in two grades, both operating over the −25°C to +85°C temperature range. The "A" grade is specified for 15-bit accurate systems, while the "B" grade offers superior performance for true 16-bit applications.

PRODUCT HIGHLIGHTS

1. Fast acquisition and low jitter make it the right choice for high speed, high accuracy data acquisition.
2. Its low droop rate (0.02 μV/μs) allows it to be used in slower systems without noticeable performance degradation.
3. The AD1154 is ideal for systems requiring wide dynamic range.
4. Low price reduces overall system cost.
5. Unity gain buffer architecture allows ease of use.

TERMINOLOGY

Accuracy is the peak deviation of the output from a straight line through the endpoints of the transfer function. It is expressed as a percentage of the full scale output range. Note that this parameter is measured in hold mode because the actual voltage to be converted is the voltage present at the output of the device during the hold mode.

Acquisition Time is the time required by the device to reach its final value within a given error band after the sample/track command has been given assuming that the input amplifier has settled. This includes switch delay time, slewing time and settling time for a given output voltage change.

Aperture Time is the time required after the hold command for the switch to open fully. The sample is, in effect, delayed by this interval, and the hold command would have to be advanced by this amount for precise timing.

Aperture Jitter is the range of variation in the aperture time. If the aperture time is "tuned out" by advancing the hold command a suitable amount, this spec establishes the ultimate timing error, hence, the maximum sampling frequency to a given resolution.

Charge Transfer (or offset step or pedestal) is the charge transferred to the storage capacitor when switching to the hold mode.

Droop Rate is the rate of change in output voltage over time while in the hold mode. The droop rate will determine how long a signal can be accurately held before it changes more than 1 LSB.

Feedthrough is the fraction of the input signal variation or ac input waveform that appears at the output in hold. It is caused by stray capacitive coupling from the input to the storage capacitor, principally across the open switch.

Small Signal Bandwidth is the maximum analog signal frequency that can be tracked before the gain is reduced by 3 dB. This assumes the signal amplitude is small enough so as not to be slew rate limited.

Switching Transient Settling Time is the time required for the device to stabilize in the hold mode to within specified limits of its final value after the hold mode signal has been given.

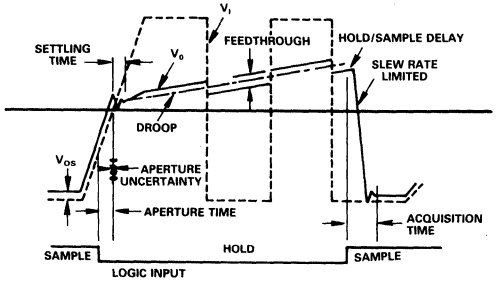

Figure 7. T/H Characteristics

INVERTING VS. NONINVERTING ARCHITECTURE

The AD1154 has a gain of +1 V/V. Many S/H amplifiers use an inverting architecture and hence have a gain of −1 V/V. The AD1154, because of its noninverting architecture, does not have an externally accessible summing point. This pin is found on most inverting S/Hs and is typically not used. In applications where the summing junction is not connected, the AD1154 can be used as a direct hardware replacement by tying Pin 12 to ground, but the output is of opposite polarity.

GROUNDING CONSIDERATIONS

The AD1154 is a true 16-bit performance sample/hold amplifier. In order to insure proper operation of the device, great care must be taken in managing the ground tracks. It is recommended that Pins 4, 6 and 12 of the AD1154 be tied together directly outside of the package. This point should then be tied to the analog ground of the A/D converter, as shown in Figure 8. This track should be as short and wide as possible to minimize voltage drops. Also note from the figure that any other analog grounds in the signal path should be joined to the A/D converter analog ground.

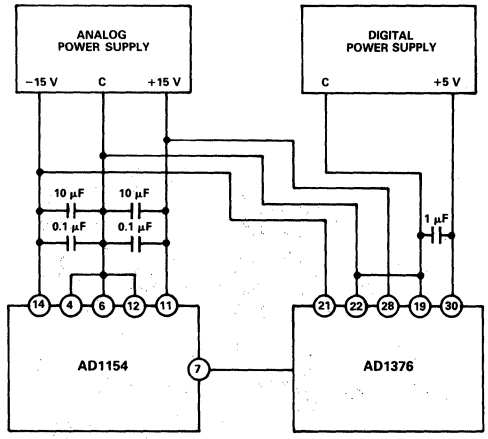

Figure 8. Basic Grounding and Power Supply Bypassing Practice

DIELECTRIC ABSORPTION COMPENSATION

The hold capacitor used in the AD1154 is a high quality ceramic chip capacitor. This capacitor's dielectric absorption characteristics are typically better than high quality film capacitors. In addition, the AD1154 provides a means for compensating for the dielectric absorption of the capacitor if better performance is required. If dielectric absorption compensation is not used, Pin 12 should be tied to ground. Please refer to the section titled "DISCUSSION OF DIELECTRIC ABSORPTION" for more detailed information.

POWER SUPPLY BYPASSING

The AD1154 utilizes high speed amplifiers in its design. These amplifiers require quiet power supplies that are free from spikes. For maximum performance it is recommended that both power supplies be bypassed with 0.1 µF ceramic capacitors in parallel with 10 µF tantalum capacitors located as close to the device as possible (see Figure 8).

DISCUSSION OF DIELECTRIC ABSORPTION

The hold capacitor of the AD1154 was chosen for its low dielectric absorption (D.A.) characteristics. D.A. is directly affected by the sample/hold mode switching durations and input levels. The AD1154 provides the user with a pin for external D.A. compensation circuitry. The AD1154's uncompensated D.A. performance is inherently superior, and in most applications the D.A. compensation pin should be connected to ground. Where additional compensation is desired to tailor the AD1154 to a specific user's application, only three resistors and a capacitor are required to optimize the AD1154's D.A. performance (see Figure 11).

If a capacitor is charged to a voltage, discharged for a moderate period of time, and then open circuited, the voltage on the capacitor will begin to creep back towards its initial value. This creep voltage is known as dielectric absorption. Dielectric absorption occurs because the dielectric material doesn't polarize instantly, the molecules need time to align themselves. As a result, not all of the energy stored in a capacitor can be quickly recovered upon discharge.

A first order model of the hold capacitor to include dielectric absorption effects is shown in Figure 9. In addition to the main capacitance, C_M, and the insulation resistance, R_I, there is an

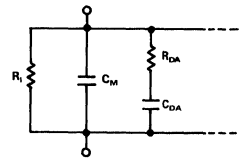

Figure 9. First Order Model of D. A. Effects

R_{DA} and a C_{DA}. When the capacitor is charged to some value, C_{DA} is also charged. When the capacitor is discharged, C_{DA} also discharges. But it must discharge through R_{DA}, and, if the capacitor is not discharged for a long enough period of time, C_{DA} will not completely discharge. As a result, when the capacitor is open circuited, C_{DA} will discharge into C_M causing the voltage across it to creep back towards its initial value. The actual model of the capacitor should contain additional R_{DA}s and C_{DA}s with increasing time constants in parallel with the one shown.

Figure 10 shows a circuit suitable for measuring the dielectric absorption of sample/hold amplifiers. The circuit operates as follows: R1 and C1 set the frequency of the SHA control; R2 and C2 set the amount of acquisition time allowed for the SHA. See the timing diagram of Figure 10.

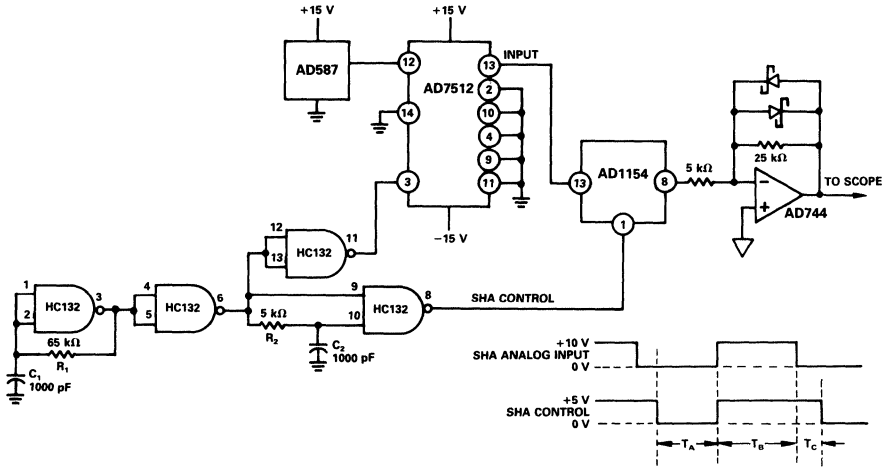

Figure 10. Dielectric Absorption Measurement Circuit

During T_B, the CONTROL line is high, the AD1154 is in the sample mode and the analog input charges the hold capacitor to +10 V. During T_C the analog input to the SHA is switched to ground, effectively shorting the hold capacitor for the remainder of the sample period. During T_A, the SHA is switched into hold mode and the hold capacitor is open circuited. The dielectric rebound can be observed on the oscilloscope during T_A. Refer to Figure 12.

Note that the dielectric absorption error is dependent on several factors: it is a function of how long the capacitor is charged (T_B), how long it is discharged (T_C) and how long it is observed while open circuited (T_A). These parameters can be modified by changing R1, R2, C1 and C2.

The AD1154 provides a pin to compensate for dielectric absorption. To use it, the circuit of Figure 11 must be employed.

To find the optimum values for R1, R2, R3 and C1 follow this procedure:

1. Adjust the D.A. measurement circuit (see Figure 10) to represent a typical sampling rate.
2. Observe the dielectric absorption error on the oscilloscope.
3. Pick (R1‖R2) • C1 to be equal to the approximate time constant (T_{const}) of the dielectric rebound on the oscilloscope (see photo in Figure 12).

4. R3 is used to adjust the magnitude of the compensation. To find an initial approximation for R3, the following relationship can be used:
   $R3 = [\text{Magnitude of D.A. error} \times (R1+R2)]/10 \times 1/(e^{-T_C/T_{CONST}} - e^{-T_A/T_{CONST}})$
5. R3 can then be fine trimmed for the flattest output during hold.

Using this method it is possible to reduce the effect of dielectric absorption by a factor of four or five. The typical values for resistors and capacitor given in Figure 11 are for a sample time of 20 μs, acquisition time of 5 μs and a hold time of 20 μs. When determining the values, R3 should be less than 10 Ω, and C1 should be as small as possible.

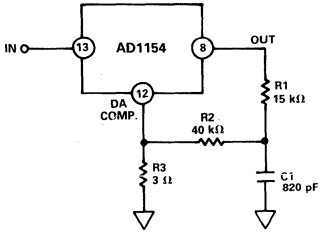

Figure 11. D/A Compensation Circuit with Typical Values

DYNAMIC SIGNALS

The primary purpose of using a sample/hold in front of an A/D converter is to hold the input constant while the A/D performs its conversion. Without a sample/hold, a 16-bit A/D converter would not be able to accurately digitize any signal whose slew rate exceeded 1 LSB divided by the conversion time. Or, for a 15 μs A/D with an input range of ±10 V this says:

$\text{Input Signal Slew Rate}_{MAX} = 1 \text{ LSB} \div \text{Conversion Time} = 20.3 \text{ V/S}$

Since the maximum slew rate of a sinusoid is defined as:

$\text{Slew Rate}_{MAX} = 2 \cdot \pi \cdot \text{Amplitude} \cdot \text{Frequency}$

This translates into a maximum input frequency of:

$F_{IN\ MAX} = \text{Slew Rate}_{MAX} \div (2 \cdot \pi \cdot \text{Amplitude}) = 0.32 \text{ Hz}$

By using a sample/hold, however, the maximum slew rate of the input signal is now limited by the aperture jitter of the sample/hold, which is usually orders of magnitude better than a conversion time. Specifically, for an AD1154 the analysis is:

$\text{Input Signal Slew Rate}_{MAX} = 1 \text{ LSB} \div \text{Aperture Jitter} = 2.035 \text{ V/μs}.$

Now the maximum input frequency becomes:

$F_{IN\ MAX} = \text{Slew Rate}_{MAX} \div (2 \cdot \pi \cdot \text{Amplitude}) = 32.4 \text{ kHz}.$

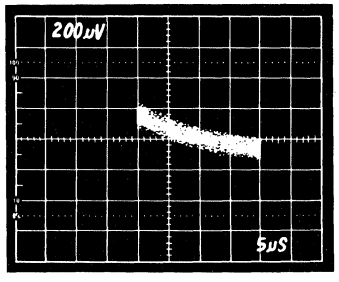

Figure 12. Dielectric Absorption

This represents a dramatic improvement over using the A/D converter by itself. The AD1154's 222 kHz throughput ($1/(T_{ACQ} + T_{SETT})$) and 150 ps aperture jitter allow it to digitize input signals of up to 32 kHz to 16-bit accuracy or up to a 128 kHz signal to 14-bits.

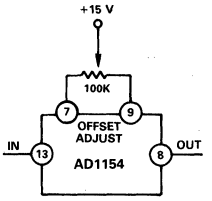

Figure 13. Offset Adjust Circuit

OPERATING INSTRUCTIONS

Offset Adjust

In most data acquisition systems only one offset adjustment is made. Usually the offset adjust of the A/D converter is used to null the combined system offsets. However, the offset or pedestal of the AD1154 can be nulled by connecting a trim potentiometer between Pins 7 and 9, and tying the wiper to +15 V (refer to Figure 13.) To null the pedestal, ground the input of the SHA and toggle the SHA CONTROL. Then adjust the pot until the output of the SHA in hold mode reads 0 V. Please note that each millivolt of offset adjust adjustment degrades linearity by 0.3 ppm.

APPLICATIONS

50kHz Sampling A/D System

Figure 14 shows a typical connection of the AD1154 to the AD1376 (16-bit 15.5 μs A/D converter). This combination will result in an A/D conversion system capable of sampling a 25 kHz signal at a 50 kHz throughput rate. (Where Throughput Rate = $T_{ACQ} + T_{SETTLE} + T_{CONV}$ = 3.5 μs + 1 μs + 15.5 μs = 20 μs.) This example has an input range of ±10 V, power consumption of < 1 W and 16-bit resolution. The accuracy of this system is limited to the AD1376's 14-bit performance.

Track-and-Hold

The AD1154's design is optimized for sample-and-hold applications and is internally compensated to guarantee 16-bit (0.00076%) hold mode gain nonlinearity. Even though the AD1154 is tailored specifically as a SHA, it may be used as a track-and-hold amplifier providing 15-bit (0.0015%) track mode gain nonlinearity.

GENERAL DESCRIPTION

The HTC-0300A is a hybrid microcircuit track-and-hold amplifier useful in a wide range of signal processing applications, including waveform measurements, analog signal delay, and signal sampling.

The unit has a typical aperture jitter of only 50 picoseconds rms; wide dynamic input range of ±10 volts; and laser-trimmed gain and offset which preclude a need for external adjustments. Its speed and precision are the result of innovative design techniques using a high-speed op amp and DMOSFET switches. These techniques also enhance device performance in feedthrough rejection, linearity, harmonic distortion, droop rate, and output voltage swing.

ORDERING INFORMATION

For a case temperature range of −25°C to +85°C, order the HTC-0300A; it is packaged in a 24-pin hermetically-sealed ceramic DIP.

A case temperature range of −55°C to +125°C is available with the HTC-0300AM, HTC-0300AM/883B, and the HTC-0300ATD/883B. The first two units are housed in 24-pin metal packages, and the latter unit is packaged in a hermetic 24-pin ceramic DIP.

All versions of the HTC-0300A are manufactured in a facility which has been certified to MIL-STD-1772.

Subgroup 11 – Switching tests at minimum rated temperatures.
Subgroup 12 – Periodically sample tested.

APPLICATIONS

Track-and-hold (T/H) amplifiers can be used in a wide variety of ways, but the most common application for these units is to place them ahead of an A/D converter. The combination of a T/H and converter is used when the bandwidth of the signal to be digitized is wider than the converter can handle by itself, i.e., the analog input is changing more than one LSB during the converter's conversion interval.

In applications of this type, the HTC-0300A "freezes" the incoming signal on command to present a nonchanging signal at the input stage of the converter.

The HTC-0300A T/H can reduce the aperture window to 100 picoseconds when used with the appropriate A/D. It can also be used for peak-holding functions, simultaneous sampling A/Ds (when combined with analog multiplexers), and other high-speed analog signal processing applications.

THEORY OF OPERATION

When operated in the "track" mode, the HTC-0300A functions as an operational amplifier with a gain of −1, following all changes in the analog input signal as they occur.

When a TTL-compatible digital logic "1" is applied to the Hold Command input of the T/H, the inverted analog output of the HTC-0300A is "held" at the value which was present at the time of the Hold Command, plus the aperture time. If the change from the "track" mode to the "hold" mode is accomplished via Pin 11, $\overline{\text{Hold}}$ Command input (Pin 12) must be connected to ground.

For applications which require an inverted Hold Command, this "freezing" of the inverted analog output can be accomplished with a digital "0" applied to the $\overline{\text{Hold}}$ Command (Pin 12) input. In this case, a digital "1" establishes the "track" mode of operation. For these, the Hold Command input (Pin 11) must be connected to +5V.

Refer to Figure 1, the HTC-0300A Track/Hold Waveforms.

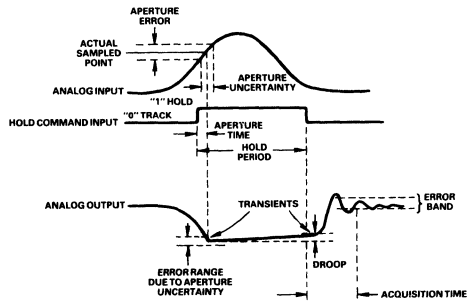

Figure 1. Track/Hold Waveforms – HTC-0300A

Two different intervals of time can affect the point on the analog input which is sampled when the T/H is switched from "track" to "hold". There is no major difference in operation whether this change in state is accomplished via the Hold Command or $\overline{\text{Hold}}$ Command; the functioning of the HTC-0300A is essentially the same, with only a slight difference in timing because of an additional logic package in the $\overline{\text{Hold}}$ Command signal path.

The delay interval, aperture time, is a constant and should not be regarded as an error source. The design of the HTC-0300A assures that aperture time is within its spec from unit to unit; and is also repeatable from one "hold" command to the next in any given unit. In this way, aperture time can be compensated with system timing to assure an optimum sampling point.

Aperture uncertainty, or "jitter", is the other interval affecting the held value. It is the result of noise signals which modulate the phase of the hold command and shows up as sample-to-sample variations in the value of the analog signal being "frozen."

As expected, the error resulting from jitter is directly related to the dV/dt of the analog input. If very-high-speed inputs are sampled, any given value of jitter will result in larger errors in the held value at the output as dV/dt increases. See Figure 2.

The high feedthrough rejection of the HTC-0300A in the hold mode is an important characteristic; it precludes errors being introduced during the conversion interval of the digitizer.

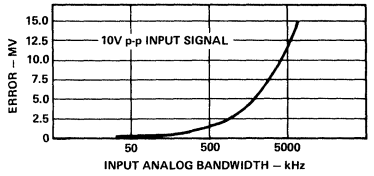

Figure 2. HTC-0300A Error Due to Aperture Uncertainty

As shown in Figure 1, droop is the amount the output changes during the hold period; this is the result of loading on the internal hold capacitor. Low droop rates are important in T/H amplifiers to insure they are appropriate for high-resolution digitizing. Excessive droop rates can negate the effectiveness of having converters of 10 or 12 bits or more. Lower-order bits may be in error because of changes in the held value during the conversion cycle, especially for successive-approximation converters.

The return to the "track" mode is accomplished by changing the digital logic level of the hold command; Figure 1 shows the hold command as it would appear at the (Pin 11) Hold Command input.

Acquisition Time is the interval required for the analog output to re-establish accurate tracking of the changing input and remain within a specified error band around its final value. The greater the change in the input value during the hold period, the longer this interval is. Nyquist sampling is the most stringent application.

Transients shown in Figure 1 are "spikes" which occur at the output of the T/H at the beginning and end of each "hold" period because of switching transients within the unit. When a T/H is used at the output of a D/A converter for "deglitching" discontinuities in the output of the converter, these transients occur at the update rate and can be filtered.

SAMPLE-AND-HOLD (S/H) MODE

Although it is generally used in the track-and-hold mode, the HTC-0300A can also be used as a sample-and-hold device. In the S/H mode, the output of the unit is usually in the "hold" mode, but is switched briefly to the "sample" (track) mode.

The width of the the sample pulse applied to the $\overline{\text{Hold}}$ Command input (or, if using inverted logic, the Hold Command input) is determined by (1) the acquisition time of the HTC-0300A, and (2) the desired accuracy of the sampled output. Output accuracy will also be a function of the amount of change which has occurred since the preceding sample.

This latter phenonmenon is illustrated in Figure 3. Note the analog input has changed drastically between the first and second hold commands. There is a considerably smaller change between the third and fourth pulses; as a consequence, movement in the held value of the output is correspondingly smaller.

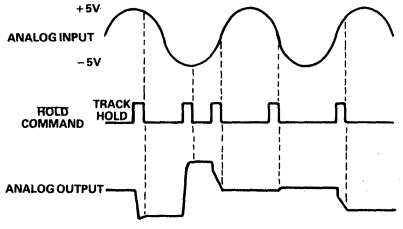

Figure 3. Sample/Hold Operation

Figure 4 illustrates settling accuracy versus acquisition time; closer accuracies require more time. The relationship approaches an asymptotic curve and is not a linear function.

The HTC-0300A is a "closed loop" T/H and is suitable for most applications requiring a track-and-hold for update rates up to 5–10MHz. (Note: 5MHz conversion rates are only a guide and are based on system acquisition time, not logic speed. Higher rates are possible with trade-offs in acquisition time.)

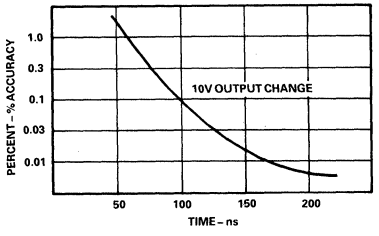

Figure 4. Settling Accuracy vs. Acquisition Time

For optimum performance, the HTC-0300A must have external bypass capacitors connected to the power supply pins close to the device. Electrolytic capacitors of 10 – 22μF and ceramic capacitors of 0.01 – 0.1μF on each supply will enhance performance of the unit.

Output loading has some restrictions. To avoid oscillations, limit capacitive loads to 250pF; the recommended resistive loading is 500Ω. Acquisition and settling times are relatively unaffected by capacitive loads up to 50pF and resistive loads down to 250Ω.

A massive ground plane, careful component layout, and physically separating digital and analog signals as much as possible are also among the multitude of items which can affect the operation of circuits that include the HTC-0300A T/H.

Cross coupling of analog and digital signals is often a major problem at high frequencies. Relatively low levels of ground plane noise can "mask" lower-order bits when the HTC-0300A is used in high-resolution digitizing. The user must exercise care in electrical and mechanical design to assure satisfactory performance.

GENERAL DESCRIPTION

The Analog Devices HTS-0010 Track-and-Hold is another example of Analog's continuing efforts to advance the state of the art in high-speed circuits.

The HTS-0010 adds breadth to a line of devices which offers designers the industry's widest range of track-and-hold and sample-and-hold units.

Its pinouts are similar to its predecessor HTS-0025 Track-and-Hold, but it provides enchanced performance in many of the characteristics established by that device. Two pins which are unused on the HTS-0025 are used on the HTS-0010, but with those exceptions, the two devices have identical pin assignments. This plug-in compatibility gives designers remarkable flexibility in selecting those parameters which are optimum for their applications.

The HTS-0010 Track-and-Hold (T/H) uses many of the proven design concepts which have made the HTS-0025 T/H the standard of comparison for high-speed circuits of this type. A dc-coupled Schottky diode bridge is driven by a high impedance buffer amplifier and followed by a low impedance output amplifier to achieve the best possible combination of speed and drive capabilities.

All models of the HTS-0010 are housed in a standard 24-pin metal DIP. The unit operating over a temperature range of 0 to +70°C is HTS-0010KD; the unit for a range of −55°C to +100°C is HTS-0010SD.

SPECIFICATIONS (typical @ +25°C and nominal power supplies unless otherwise noted)

NOTES

[1]Gain = $\frac{R_L \times 0.96}{R_L + 9}$

[2]Effective Aperture Delay Time is delay between Hold strobe and held value of analog output, referenced to analog input (see text).

[3]Pedestal temperature variation on HTS-0010SD is same as HTS-0010KD below +70°C, but increases between +70°C and +100°C.

[4]For acquisition time measurements, $R_L = 200\Omega$; $C_L = 3pF$.

[5]V_{CC}− may be tied to V_{EE} with adequate bypass capacitors (see text).

[6]Variations in V− (−15V) have greater effect on unit performance than variations in other supplies; PSRR shown is for V−.

[7]Maximum junction temperature is +150°C.

[8]Calculated using MIL-HNBK 217; Ground; Fixed; +70°C case temperature.

[9]See Section 14 for package outline information.

*Specifications same as HTS-0010KD.

Specifications subject to change without notice.

PIN DESIGNATIONS

POWER GROUND (PINS 7, 11 AND 21), ANALOG GROUND (PINS 18 AND 19), AND DIGITAL GROUND (PIN 6) MUST BE CONNECTED TOGETHER AND TO A LOW-IMPEDANCE GROUND FOR PROPER OPERATION. MAKE CONNECTIONS AS CLOSE TO DEVICE AS POSSIBLE. HYBRID CASE IS CONNECTED TO ANALOG GROUND INTERNALLY.

Applications

One of the main uses for track-and-hold (T/H) units is ahead of analog-to-digital (A/D) converters to allow digitizing signals with bandwidths higher than the A/D can handle by itself. The use of an appropriate T/H allows the converter to become a true "Nyquist converter", i.e., capable of digitizing analog signals whose maximum bandwidth is one-half the encoding rate.

The characteristics of the HTS-0010 T/H make it useful in multiple other applications beside this "standard" use of devices of this kind. It can be used in sample and hold circuits, peak holding applications, simultaneous sampling A/Ds (with appropriate analog multiplexing), and for many other data processing needs.

Refer to Figure 1, HTS-0010 Interconnection Diagram.

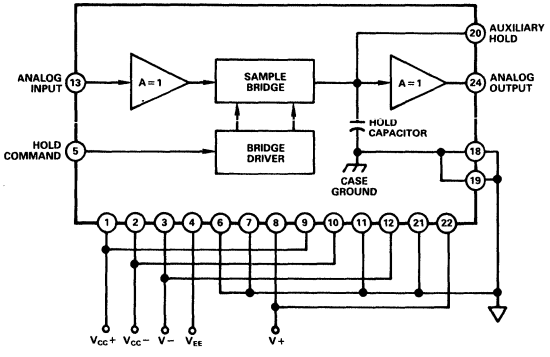

Figure 1. HTS-0010 Interconnection Diagram

Bypass capacitors are used internally on all power supply leads on the HTS-0010 track-and-hold. External bypassing of all power supplies with 0.01μF–0.1μF ceramics will help performance. In addition, electrolytic capacitors of 10-22 microfarads on each supply will also enhance the HTS-0010's operation

A massive ground plane, careful component layout, and physically separating analog and digital signals are among the other considerations which can have major effects in improving the high-speed characteristics of the HTS-0010 track-and-hold.

As shown in Figure 1, supply voltages must be applied to all pins for which they are designated. In addition, it is extremely important to connect all grounds together, and to a solid, low-impedance ground plane. These connections must be made as close to the hybrid as physically possible.

Five different voltages are shown for powering the HTS-0010. These are the voltages which are used in final test and calibration and are the recommended voltages for best performance, but minor variations from these recommendations are possible.

For best performance, the amplifier supplies, $V_{CC}-$ and $V_{CC}+$ should be equal and opposite, as shown. If desired, the ECL logic supply ($V_{EE} = -5.2V$) can be used also for $V_{CC}-$, to eliminate the need for a separate power supply voltage. If it is, bypass capacitors should be used at each supply pin to decrease the possibility of logic switching noise introducing extraneous signals.

TRACK-AND-HOLD MODE

When operated in the "track" mode, the HTS-0010 T/H functions as a buffer amplifier, following all changes in analog input as they occur. The user selects the point at which digitizing is to be done by applying an external ECL-compatible HOLD COMMAND to Pin 5.

Refer to Figure 2, Track/Hold Waveforms.

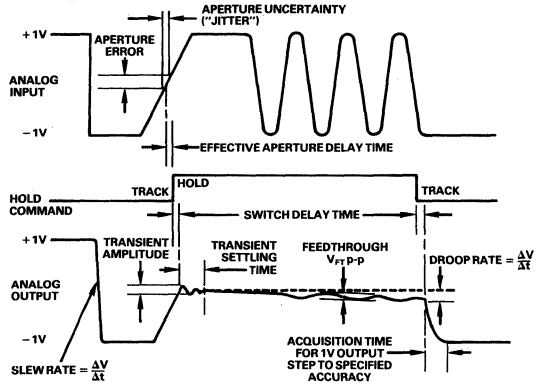

Figure 2. Track/Hold Waveforms

A varying, ideal analog input is shown at the top of Figure 2 for purposes of illustrating the response of the HTS-0010 to various types of inputs. This method of presentation helps show some of the critical, and often misleading, parameters of high-speed track-and-hold devices.

During the track mode, the unit operates as a high-speed buffer amplifier, with the output following input changes as they occur. In this mode, the response of the HTS-0010 is limited primarily by the slew rate characteristics of the device. As a result, the analog output is a faithful reproduction of the input as long as the highest frequency component of the input signal does not exceed the bandwidth of the unit.

The analog output shown on the bottom of Figure 2 tracks the input until a HOLD COMMAND is applied to Pin 5. When this pulse arrives, the sample bridge of the HTS-0010 disconnects the hold capacitor from the input. The short, but finite, interval required for this action is called aperture time.

Two other delay intervals combine with aperture time. One is delay in the hold command caused by propagation delay in the bridge driver; for purposes of discussion, this is a digital delay (t_d) because it is the time required for logic switching to occur. The other is propagation delay through the input buffer amplifier, which is an analog delay (t_a) because it affects the analog input signal being applied to the hold capacitor (see HTS-0010 Block Diagram).

Each of these three components is critical in the design of track-and-hold circuits, but the user needs to be concerned only with their combined overall effect. The combination is specified here as Effective Aperture Delay Time and is defined as the interval between the leading edge of the hold command and that instant when the input signal is equal to the held value.

Basically, effective aperture delay time is a measure of the difference between the analog and digital delay (t_d–t_a) and can assume a zero, positive, or negative value depending upon the comparative lengths of the two delays. In the HTS-0010, the analog delay (t_a) is greater than the switching delay (t_d), and causes the unit to hold an input voltage which occurred before the hold command because the hold capacitor sees a delayed version of the input signal.

The specification for Effective Aperture Delay Time is a more useful measurement for assessing T/H performance than is the measurement of only aperture time because it includes all three

of the components which have an effect on how quickly the device can make the change from the track mode to the hold mode.

The time intervals discussed above help explain what happens when the HTS-0010 makes the change from the track mode to the hold mode. In normal operation, however, they become academic discussions since most users of the T/H are more interested in when the held value has reached its steady state.

Aperture uncertainty or "jitter," is the result of noise signals of various kinds which modulate the phase of the hold command. This jitter shows up as a sample-to-sample variation in the value of the analog signal which is being "frozen."

Aperture uncertainty manifests itself as an aperture error, as shown in Figure 2. The amplitude of the error is related to the dV/dt of the analog input. For any given value of aperture uncertainty, aperture error will increase as the input dV/dt increases.

The design characteristics of the HTS-0010 insure that effective aperture delay time is within its specification from unit to unit; and is also repeatable from one "hold" command to the next within any unit. Therefore, it should not be regarded as an error source the way aperture uncertainty is. Effective aperture delay time can be compensated with system timing which correctly establishes the beginning of the hold period.

Referring again to Figure 2, a switching transient appears in the analog output as a result of this transition from "track" to "hold." The Specifications table includes the maximum amplitude and duration of this transient; and also includes information on the switch delay time which precedes it. The held output is settled to within 1mV 6-15ns after the leading edge of the hold signal.

Feedthrough rejection is a measure of the amount of leakage from input to output during the hold interval after the HTS-0010 has settled to its specified accuracy. High feedthrough rejection is important because it assures no errors will be introduced during the conversion interval of the converter used at the output of the T/H.

In the illustration, V_{FT} is the small amount of "ripple" voltage on the held value of analog output. The ratio of output feedthrough to input signal is measured in dB and is equal to:

$$20 \log \left[\frac{V_{FT\ p\text{-}p}}{V_{IN\ p\text{-}p}} \right]$$

As shown, droop is that amount of change in the analog output which occurs during the hold interval. Improving (lessening) the droop rate can be accomplished by adding capacitance in parallel with the internal hold capacitor, but at the expense of slowing down the T/H and its ability to handle high-speed signals.

Applications which require longer hold times than the standard HTS-0010 provides may require external capacitance in parallel with the internal hold capacitor. For these, the user can parallel extra capacitance by connecting it between pin 20 and ground. The droop rate will be improved, but the overall speed and bandwidth of the T/H will be reduced. This extra connection should be made close to the hybrid case or it may introduce small amounts of electrical noise.

Switch delay time shown in Figure 2 is the interval between the end of the hold command and the start of movement in the analog output as it begins to retrack the analog input. This delay occurs at both the beginning and the end of the hold interval and is primarily the result of propagation delay through the output buffer amplifier.

Acquisition time is the time required for the output of the T/H to reacquire and begin tracking accurately the analog input after the T/H has returned to the "track" mode. The acquisition time "clock" starts when the output begins moving and stops when the output has settled to its specified accuracy. As might be expected, longer acquisition times are required for larger signals and/or greater accuracy.

High slew rates are also important during acquisition time, but the desire for speed must be tempered with practical considerations. If the design of the unit achieves only speed without regard for overshoot, the acquisition time will be lengthened. Excessive "ringing" around the signal being acquired precludes applying successive hold commands at MHz update rates.

SAMPLE-AND-HOLD (S/H) MODE

Although generally used in the track-and-hold mode, the HTS-0010 can also be used as a sample-and-hold device for applications where this capability is needed.

The operation of the unit is essentially a "mirror" of the T/H operation, in that the output is usually in the "hold" mode but is switched to the "sample" (track) mode for brief intervals.

The width of the sample pulse which is used will be based on factors which are different for each application. Basically, the user establishes the width of this pulse by taking into account:

1. The acquisition time of the HTS-0010.
2. The desired accuracy of the sampled output.
3. The maximum amount of change which has occurred since the preceding sample.

This latter phenomenon is illustrated in Figure 3 Sample/Hold Operation.

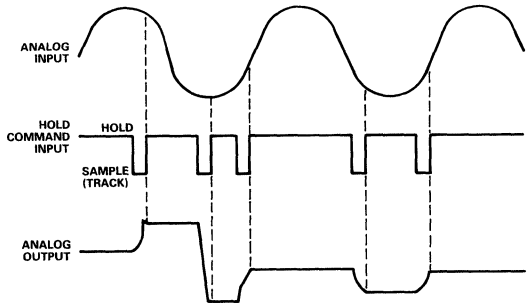

Figure 3. Sample/Hold Operation

When operating as a S/H, the signal applied to the HOLD COMMAND input (Pin 5) is usually a digital logic "1" which holds the HTS-0010 output at the input value present at the time of the sample/hold pulse.

Figure 3 shows asynchronous pulses applied to cause the output to reslew to new values. The trailing edge establishes the sample (track) mode; the leading edge returns the output to "hold".

In Figure 3, the analog input applied to the unit has changed drastically between the first and second sample (track) pulses. Smaller differences in the input values are present at the times of the second and third pulses. These differences in input show

up as differences in the amount of movement of the analog output.

The exceptional acquisition time of the HTS-0010 makes it extremely attractive for sample-hold applications because of its ability to acquire new output values quickly. This characteristic of the device allows the use of a narrow sample pulse and an inherently faster sample rate, limited only by the factors enumerated earlier.

Refer to Figure 4 Settling Accuracy vs. Acquisition Time.

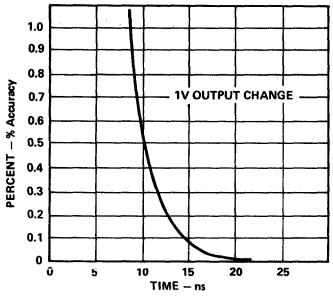

Figure 4. Settling Accuracy vs. Acquisition Time

This graph illustrates that closer accuracies require correspondingly longer amounts of time to acquire the signal. As shown, the accuracy/time relationship approaches an asymptotic curve, as opposed to being a linear function.

Another point to consider in Figure 4 is the output change which is illustrated is for a 1V change. If the output is required to change less than one volt (as it is between the second and third pulses in Figure 3, for example), the amount of time required to acquire the new value will be less than that which is shown.

When using the HTS-0010 or any other high-speed track-and-hold in the real world of data acquisition for fast-changing signals, the line between the device operating as a T/H or a S/H tends to "blur."

The designer using it as a T/H ahead of an A/D converter will generally vary the amount of "hold" time to obtain optimum operation for his particular application. When that performance is achieved, the HTS-0010 may, in the strictest sense of the word, be operating as a sample-and-hold. But it is useful to regard the two modes of operation separately when discussing the theory of operation of the unit.

DIFFERENCES: HTS-0010 VS. HTS-0025

As noted earlier, pin designations for the HTS-0010 T/H are similar to the predecessor HTS-0025 T/H. Two pins not used on the HTS-0025 are used for HTS-0010 functions, and attempts to use it as a "drop-in" replacement for the HTS-0025 need to take this into account.

Pins 20 and 21 on the HTS-0010 are used for auxiliary hold and power ground, respectively. These pins are not used on the HTS-0025 because that unit does not have a capability for accepting external capacitance in parallel with the hold capacitor; nor does it have as many ground connections. If circuits using the HTS-0025 are using those pin locations as tie points, it may preclude the possibility of substituting a model HTS-0010 unit in the circuit.

Current drive on the HTS-0010 is slightly less than it is on the HTS-0025 ($\pm$40mA vs. $\pm$50mA) but 3dB bandwidth is higher (60MHz vs. 30MHz).

The user of the HTS-0010 can reasonably expect higher speeds because of improvements in aperture uncertainty (5ps rms vs. 20ps rms); switching transient amplitude (15mV vs. 30mV); and acquisition time (10ns vs. 20ns for 1% settling). Noise levels in the track mode are also improved (40μV vs. 0.1mV maximum).

Voltage supplies for the internal amplifiers ($V_{CC}+$ and $V_{CC}-$) have a wider range on the HTS-0025 than they do on the HTS-0010 but $V_{CC}-$ can be connected to V_{EE} if desired, as explained elsewhere in the data sheet.

ORDERING INFORMATION

All versions of the HTS-0010 track/hold are housed in 24-pin metal dual in-line hybrid packages. For commercial applications operating over a temperature range of 0 to +70°C, specify model HTS-0010KD. For a temperature range of −55°C to +100°C, specify model HTS-0010SD. A temperature range of −55°C to +100°C and processing to MIL-STD-883, Method 5008, are available in the model HTS-0010SD/883.

Mating individual pin sockets are available from AMP. Knockout end type are part number 6-330808-0; open end type are 6-330808-3.

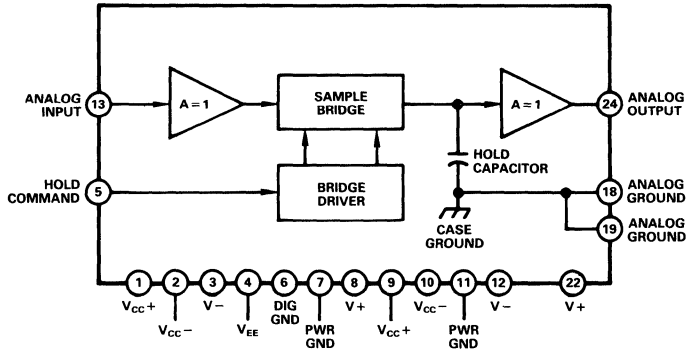
Ultrahigh Speed Hybrid Track-and-Hold Amplifier

HTS-0025

FEATURES
Aperture Jitter of 10ps
Acquisition Time 25ns
Output Current ±50mA
Slew Rate 250V/μs

APPLICATIONS
Data Acquisition Systems
Radar Systems
Instrumentation Systems
Medical Electronics
High Resolution Displays

HTS-0025 FUNCTIONAL BLOCK DIAGRAM



6

GENERAL DESCRIPTION

The Analog Devices HTS-0025 Track-and-Hold is another in Analog's range of track-and-hold (T/H) amplifiers useable in a variety of high-speed circuits. The HTS-0025 is part of a line of devices which offers designers the industry's widest range of track-and-hold and sample-and-hold units.

Design concepts used in the HTS-0025 T/H have made it the standard of comparison for high-speed circuits of this type. A dc-coupled Schottky diode bridge is driven by a high-impedance buffer amplifier and followed by a low impedance output amplifier. This achieves the best possible combination of speed and drive capabilities.

The pinouts of the HTS-0025 are similar to the HTS-0010 Track-and-Hold, so designers can select either the HTS-0025 or HTS-0010 for their particular applications. This kind of flexibility makes it possible to choose those parameters which are optimum for each application.

All models of the HTS-0025 are housed in a standard 24-pin metal DIP. The unit operating over a temperature range of 0 to +70°C is HTS-0025; the unit for a range of −55°C to +100°C is HTS-0025M.

POWER SEQUENCE FOR HTS-0025 T/H

1. V_{CC}+ and V_{CC}− must be applied simultaneously with, or ahead of, V+ and V− 15-volt supplies.
2. If V_{CC}+ and V_{CC}− are present, either V+ or V− can be applied first.
3. Output goes to V_{CC}+ if V+ is applied first in presence of V_{CC}+ and V_{CC}−.
4. Output goes to V_{CC}− if V− is applied first in presence of V_{CC}+ and V_{CC}−.
5. Recommended procedure is to use a single switch between source of ac power and all power supplies connected to HTS-0025 T/H. Operation of that switch then applies all dc supplies to T/H, which is a preferred way to power up unit.

NOTES

[1] One ECL 10k Gate, no resistor; requires 1kΩ to −5.2V
[2] Effective Aperture Delay Time is delay between Hold strobe and held value of analog output, referenced to analog input (see text).
[3] For acquisition time measurements, R_L = 200Ω; C_L = 13pF.
[4] V_{CC}+ may be tied to V+; V_{CC}− may be tied to V− or V_{EE} with adequate bypass capacitors (see text).
[5] Maximum power shown based on V_{CC}+ = V+; V_{CC}− = V−. Power is reduced to 2.0W maximum with V_{CC}+ = +5V and V_{CC}− = −5V.
[6] Variations in V− (−15V) have greater effect on unit performance than variations in other supplies; PSRR shown is for V−.
[7] Maximum junction temperature is +150°C.
[8] Calculated using MIL-HNBK 217.
[9] See Section 14 for package outline information.

*Specifications same as HTS-0025.
Specifications subject to change without notice.

POWER GROUND (PINS 7 AND 11), ANALOG GROUND (PINS 18 AND 19), AND DIGITAL GROUND (PIN 6) MUST BE CONNECTED TOGETHER AND TO A LOW-IMPEDANCE GROUND FOR PROPER OPERATION. MAKE CONNECTIONS AS CLOSE TO DEVICE AS POSSIBLE. HYBRID CASE IS CONNECTED TO ANALOG GROUND INTERNALLY.

6

Applications

One of the main uses for Track-and-Hold (T/H) units is ahead of analog-to-digital (A/D) converters to allow digitizing signals with bandwidths higher than the A/D can handle by itself. The use of an appropriate T/H allows the converter to become a true "Nyquist converter", i.e., capable of digitizing analog signals whose maximum bandwidth is one-half the encoding rate.

The characteristics of the HTS-0025 T/H make it useful in multiple other applications besides this "standard" use of devices of this kind. It can be used in sample and hold circuits, peak holding applications, simultaneous sampling A/Ds (with appropriate analog multiplexing), and for many other data processing needs.

Refer to Figure 1, HTS-0025 Interconnection Diagram.

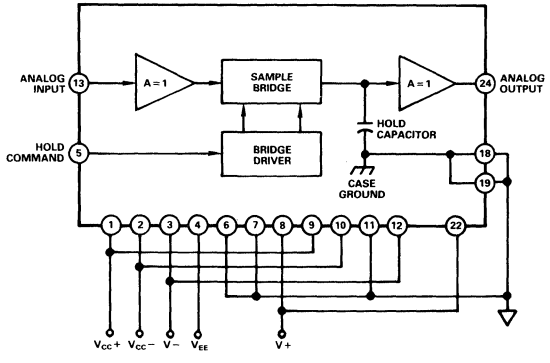

Figure 1. HTS-0025 Interconnection Diagram

Bypass capacitors are used internally on all power supply leads on the HTS-0025 Track-and-Hold. External bypassing of all power supplies with 0.01μF–0.1μF ceramics will help performance. In addition, electrolytic capacitors of 10-22 microfarads on each supply will also enhance the HTS-0025's operation.

A massive ground plane, careful component layout, and physically separating analog and digital signals are among the other considerations which can have major effects in improving the high-speed characteristics of the HTS-0025 Track-and-Hold.

As shown, supply voltages must be applied to all pins for which they are designated; it is extremely important to connect all grounds together, and to a solid, low-impedance ground plane as close to the hybrid as physically possible.

The five different voltages shown are the voltages used in final test and calibration, and are the recommended voltages for best performance; minor variations are possible.

For best performance, amplifier supplies, $V_{CC}-$ and $V_{CC}+$ should be equal and opposite. The ECL logic supply (V_{EE} = −5.2V) can be used also for $V_{CC}-$; if it is, bypass capacitors should be used at each supply pin to decrease the possibility of logic switching noise introducing extraneous signals.

TRACK-AND-HOLD MODE

When operated in the "track" mode, the HTS-0025 T/H functions as a buffer amplifier, following all changes in analog input as they occur. The user selects the point at which digitizing is to be done by applying an external ECL-compatible HOLD COMMAND to Pin 5.

Refer to Figure 2, Track/Hold Waveforms.

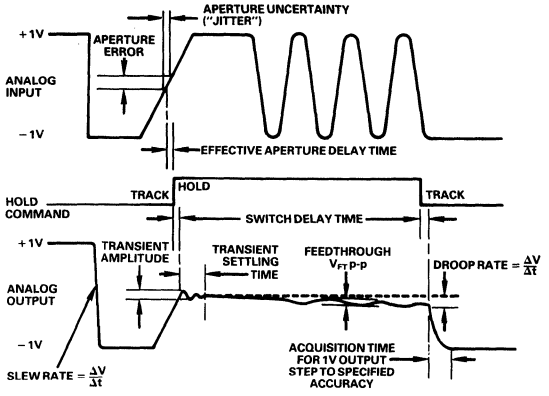

Figure 2. Track/Hold Waveforms

A varying, ideal analog input is shown at the top of Figure 2 for purposes of illustrating the response of the HTS-0025 to various types of inputs. This method of presentation shows many of the critical, and sometimes confusing, parameters of high-speed track-and-hold devices.

In the track mode, the response of the HTS-0025 is limited primarily by the slew rate characteristics of the device. As a result, the analog output is a faithful reproduction of the input as long as the highest frequency component of the input signal does not exceed the bandwidth of the unit.

The analog output shown on the bottom of Figure 2 tracks the input until a HOLD COMMAND is applied to Pin 5. When this pulse arrives, the sample bridge of the HTS-0025 disconnects the hold capacitor from the input. The short, but finite, interval required for this action is called aperture time (t_{sa}).

Other delay intervals combine with aperture time. One is delay in the hold command caused by propagation delay in the bridge driver; for purposes of discussion, this is a digital delay because it is the time required for logic switching to occur. Another is propagation delay through the input buffer amplifier, which is an analog delay because it affects the analog input signal being applied to the hold capacitor (see HTS-0025 Block Diagram).

Each of these three components is critical in the design of track-and-hold circuits, but user concern is limited only to their combined effect. The combination is specified here as Effective Aperture Delay Time and is defined as the interval between the leading edge of the hold command and that instant when the input signal is equal to the held value.

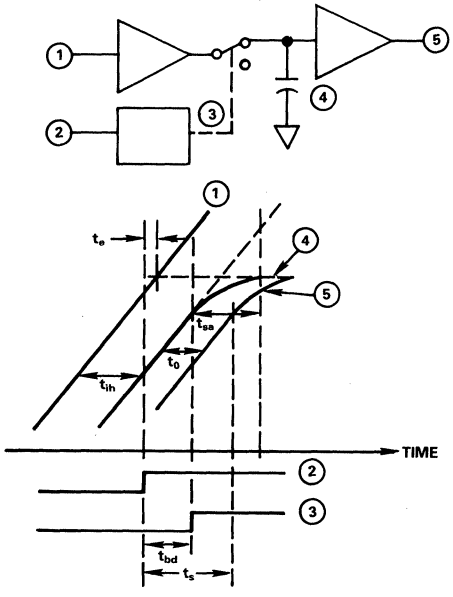
Additional details on the timing intervals in T/H circuits are shown in Figure 3.

The model T/H shown at the top of Figure 3 contains the basic elements of the HTS-0025, shown in their simplest form. The lower portion of the figure calls out multiple intervals of incremental time involved in switching from "track" to "hold" but no attempt is made to assign numerical values to them. Their definitions are intended solely to help understand the theory of T/H operation.

Effective aperture delay time (t_e) is digital delay plus averaging of the switch delay, minus analog delay. Depending on the comparative lengths of these combined delays, the value of t_e can be zero, positive, or negative.

The specification for Effective Aperture Delay Time is a more useful measurement for assessing T/H performance than aperture time because it includes all three of the components which have an effect on how quickly the device can make the change from the track mode to the hold mode.

In normal operation, these time intervals become academic discussions since users of the T/H are more interested in when the held value has reached its steady state.



(1) ANALOG INPUT
(2) ENCODE COMMAND INPUT
(3) SWITCH CONTROL
(4) HOLD CAPACITOR
(5) ANALOG OUTPUT

t_{ih} = ANALOG DELAY INPUT TO HOLD CAPACITOR = (DELAY FROM (1) TO (4))

t_{bd} = DIGITAL DELAY THROUGH BRIDGE DRIVER (DELAY (2) TO (3)).

t_{sa} = APERTURE TIME OF SWITCH

t_e = EFFECTIVE APERTURE DELAY TIME = $t_{bd} + \frac{t_{sa}}{2} - t_{ih}$ (DELAY (2) TO (1)).

t_s = SWITCH DELAY TIME = $t_{bd} + t_o$ (DELAY (2) TO (5)).

t_o = OUTPUT BUFFER DELAY (DELAY (4) TO (5))

Figure 3. T/H Timing Intervals

The waveforms in Figure 3 are idealized and based on an analog input which has a constant dV/dt. Other phenomena which are involved, such as transients, "jitter," etc. are illustrated in Figure 2.

Aperture uncertainty, or "jitter," is the result of noise signals of various kinds which modulate the phase of the hold command. This jitter shows up as a sample-to-sample variation in the value of the analog signal which is being "frozen".

Aperture uncertainty manifests itself as an aperture error, as shown in Figure 2. The amplitude of the error is related to the dV/dt of the analog input. For any given value of aperture uncertainty, aperture error will increase as the input dV/dt increases.

The design of the HTS-0025 insures that effective aperture delay time is within its specification from unit to unit; and is also repeatable from one "hold" command to the next within any unit. Therefore, it should not be regarded as an error source the way aperture uncertainty is. Effective aperture delay time can be compensated with system timing which correctly establishes the beginning of the hold period.

A switching transient appears in the analog output as a result of the transition from "track" to "hold." The Specifications table includes the maximum amplitude and duration of this transient; and also includes information on the switch delay time which precedes it. The held output is settled to within 5mV 20-25ns after the leading edge of the hold signal.

Feedthrough rejection is a measure of the amount of leakage from input to output during the hold interval after the HTS-0025 has settled to its specified accuracy. High feedthrough rejection is important because it assures no errors will be introduced during the conversion interval of the converter used at the output of the T/H.

In the illustration, V_{FT} is the small amount of "ripple" voltage on the held value of analog output. The ratio of output feedthrough to input signal is measured in dB and is equal to:

$$20 \log \left[\frac{V_{FT\ p\text{-}p}}{V_{IN\ p\text{-}p}} \right]$$

As shown, droop is that amount of change in the analog output which occurs during the hold interval.

Switch delay time shown in Figure 2 is the interval between the edges of the hold command and the start of movements in the analog output. This delay occurs at both the beginning and the end of the hold interval and is primarily the result of propagation delay through the output buffer amplifier.

Acquisition time is the time required for the output of the T/H to reacquire and begin accurate tracking of the analog input after the T/H has returned to the "track" mode. The acquisition time "clock" starts when the output begins moving and stops when the output has settled to its specified accuracy. As might be expected, longer acquisition times are required for larger signals and/or greater accuracy.

High slew rates are also important during acquisition time, but the desire for speed must be tempered with practical considerations. If the design of the unit achieves only speed without regard for overshoot, the acquisition time will be lengthened. Excessive "ringing" around the signal being acquired precludes applying successive hold commands at MHz update rates.

SAMPLE-AND-HOLD (S/H) MODE

Although generally used in the track-and-hold mode, the HTS-0025 can also be used as a sample-and-hold device for applications where this capability is needed.

The operation of the unit is essentially a "mirror" of the T/H operation, in that the output is usually in the "hold" mode but is switched to the "sample" (track) mode for brief intervals.

The width of the sample pulse which is used will be based on factors which are different for each application. Basically, the user establishes the width of this pulse by taking into account:

1. The acquisition time of the HTS-0025.
2. The desired accuracy of the sampled output.
3. The maximum amount of change which has occurred since the preceding sample.

This latter phenomenon is illustrated in Figure 4 Sample/Hold Operation.

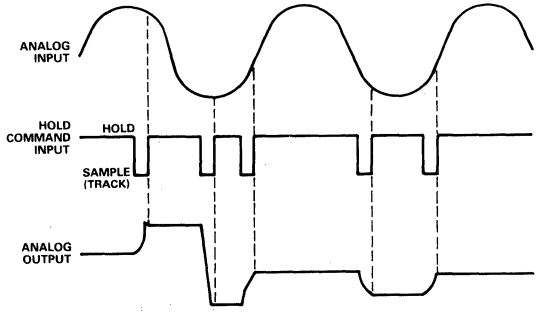


Figure 4. Sample/Hold Operation

When operating as a S/H, the signal applied to the HOLD COMMAND input (Pin 5) is usually a digital logic "1" which holds the HTS-0025 output at the input value present at the time of the sample/hold pulse.

Figure 4 shows asynchronous pulses applied to cause the output to reslew to new values. The trailing edge establishes the sample (track) mode; the leading edge returns the output to "hold".

In Figure 4, the analog input applied to the unit has changed drastically between the first and second sample (track) pulses. Smaller differences in the input values are present at the times of the second and third pulses. These differences in input show up as differences in the amount of movement of the analog output.

The acquisition time of the HTS-0025 makes it extremely attractive for sample-hold applications because of its ability to acquire new output values quickly. This characteristic of the device allows the use of a narrow sample pulse and an inherently faster sample rate, limited only by the factors enumerated earlier.

Refer to Figure 5 Settling Accuracy vs. Acquisition Time.

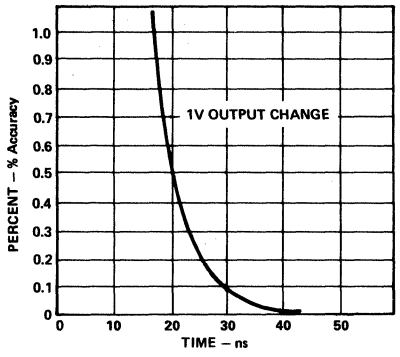

Figure 5. Settling Accuracy vs. Acquisition Time

This graph illustrates that closer accuracies require correspondingly longer amounts of time to acquire the signal. As shown, the accuracy/time relationship approaches an asymptotic curve, rather than being a linear function.

Another point to consider in Figure 5 is the illustrated output change is for a 1V change. If the output is required to change less than one volt (as it is between the second and third pulses in Figure 4, for example), the amount of time required to acquire the new value will be less than that shown.

When using the HTS-0025 or any other high-speed track-and-hold in the real world of data acquisition for fast-changing signals, the line between the device operating as a T/H or a S/H tends to "blur."

The designer using it as a T/H ahead of an A/D converter will generally vary the amount of "hold" time to obtain optimum operation for his particular application. When that performance is achieved, the HTS-0025 may, in the strictest sense of the word, be operating as a sample-and-hold. But it is useful to regard the two modes of operation separately when discussing the theory of operation of the unit.

ORDERING INFORMATION

All versions of the HTS-0025 track/hold are housed in 24-pin metal dual in-line hybrid packages. For commercial applications operating over a temperature range of 0 to +70°C, specify model HTS-0025. For a temperature range of −55°C to +100°C, specify model HTS-0025M. A temperature range of −55°C to +100°C and processing to MIL-STD-883, Method 5008, are available in the model HTS-0025MB.

Mating individual pin sockets are available from AMP. Knockout end type are part number 6-330808-0; open end type are 6-330808-3.

Orientation
CMOS Switches & Multiplexers

Analog Devices offers a complete line of monolithic CMOS analog multiplexers and switches, which utilize a high-breakdown CMOS process, in conjunction with a double-layer interconnect for high density. Both 8- and 16-channel multiplexers are available in one-line and two-line (4- and 8-channel differential) versions. The switches are dielectrically isolated duals and quads available in a variety of contact forms. Both direct and inverted logic options are available for the most popular types. The popular AD7510/11/12DI (quad SPST/dual SPDT), which utilize dielectric isolation, are latchup-proof and can withstand overrange to ±25V beyond the supplies.

CMOS switches have extremely low quiescent power dissipation, require little drive or supply current while switching and are low in cost. Their R_{ON} is low and is, to a first order, independent of applied voltage; in the off condition, leakage is quite small, both across the gate and to the drive and supply circuits. Most types respond to TTL/DTL as well as CMOS logic.

Definitions for terminal nomenclature used in the data sheets are given below, and a summary of device functions appears on the preceding page. General information on the nature of CMOS, its advantages, its applications and its protection, is to be found in the *Analog CMOS Switches and Multiplexers*, available from Analog Devices upon request.

MULTIPLEXER TERMINOLOGY

R_{ON}: Ohmic resistance between the output and an addressed input.

R_{ON} vs. Temperature: R_{ON} drift over the temperature range.

ΔR_{ON} between Switches: Difference between the R_{ON}s of any two switches.

R_{ON} vs. Temperature between Switches: Difference between the R_{ON} drifts of any two switches.

I_S: Current at any switch input, S1 through S_N. This is a leakage current when the switch is open.

I_{OUT}: Current at the output. This is a leakage current when all switches are open.

$I_{OUT} - I_S$: Difference between the current going into terminal "S" and the current going out of terminal "out" when terminal "S" is addressed.

V_{INL}: Digital threshold voltage for the low state.

V_{INH}: Digital threshold voltage for the high state.

C_S: Capacitance between any open terminal "S" and ground.

C_{OUT}: Capacitance between the output terminal and ground with all switches open.

C_{S-OUT}: Capacitance between any open terminal "S" and the output terminal.

C_{SS}: Capacitance between any two "S" terminals.

$t_{TRANSITION}$: Delay time when switching from one address state to another.

t_{OPEN}: "OFF" time of both switches when switching from one address state to another.

t_{ON}(En): Delay time between the 50% points of the enable input and the switch "ON" condition.

t_{OFF}(En): Delay time between the 50% points of the enable input and the switch "OFF" condition.

V_{DD}: Most positive voltage supply.

V_{SS}: Most negative voltage supply.

I_{DD}: Positive supply current.

I_{SS}: Negative supply current.

SWITCH TERMINOLOGY

R_{DS}: Ohmic resistance between terminals D and S.

$I_D(I_S)$: Current at terminals D or S. This is a leakage current when the switch is OFF.

I_{DS}: Current flowing through the closed switch.

$I_D - I_S$: Leakage current that flows from the closed switch into the body. (This leakage will show up as the difference between the current I_D going into the switch and the outgoing current I_S.)

$V_D(V_S)$: Analog voltage on terminal D (S).

$C_S(C_D)$: Capacitance between terminal S (D) and ground. (This capacitance is specified for the switch open and closed.)

C_{DS}: Capacitance between terminals D and S. (This will determine the switch isolation over frequency.)

$C_{DD}(C_{SS})$: Capacitance between terminals D (S) of any 2 switches. (This will determine the cross coupling between switches vs. frequency.)

t_{ON}: Delay time between the 50% points of the digital input and switch "ON" condition.

t_{OFF}: Delay time between the 50% points of the digital input and switch "OFF" condition.

V_{INL}: Threshold voltage for the low state.

V_{INH}: Threshold voltage for the high state.

$I_{INL}(I_{INH})$: Input current of the digital input.

C_{IN}: Input capacitance to ground of the digital input.

V_{DD}: Most positive voltage supply.

V_{SS}: Most negative voltage supply.

I_{DD}: Positive supply current.

I_{SS}: Negative supply current.

CMOS
4/8 Channel Analog Multiplexers
AD7501/AD7502/AD7503

FEATURES
DTL/TTL/CMOS Direct Interface
Power Dissipation: 30μW
R_{ON}: 170Ω
Standard 16-Pin DIPs and 20-Terminal Surface Mount Packages

GENERAL DESCRIPTION

The AD7501 and AD7503 are monolithic CMOS, 8-channel analog multiplexers which switches one of 8 inputs to a common output depending on the state of three binary address lines and an "enable" input. The AD7503 is identical to the AD7501 except its "enable" logic is inverted. All digital inputs are TTL/DTL and CMOS logic compatible.

The AD7502 is a monolithic CMOS dual 4-channel analog multiplexer. Depending on the state of 2 binary address inputs and an "enable", it switches two output buses to two of 8 inputs.

Storage Temperature . . . . . −65°C to +150°C
Lead Temperature (Soldering, 10sec) . . . . . +300°C

CAUTION

1. Do not apply voltages higher than V_{DD} and V_{SS} to any other terminal, especially when V_{SS} = V_{DD} = 0V all other pins should be at 0V.
2. The digital control linputs are diode protected; however, permanent damage may occur on unconnected units under high energy electrostatic fields. Keep unused units in conductive foam at all times.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only, and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

ANALOG DEVICES

DI CMOS Protected Analog Switches

AD7510DI/AD7511DI/AD7512DI

FEATURES
Latch-Proof
Overvoltage-Proof: ±25V
Low R_{ON}: 75Ω
Low Dissipation: 3mW
TTL/CMOS Direct Interface
Silicon-Nitride Passivated
Monolithic Dielectrically Isolated CMOS
Standard 14-/16-Pin DIPs and 20-Terminal Surface Mount Packages

GENERAL DESCRIPTION

The AD7510DI, AD7511DI and AD7512DI are a family of latch proof dielectrically isolated CMOS switches featuring overvoltage protection up to ±25V above the power supplies. These benefits are obtained without sacrificing the low "ON" resistance (75Ω) or low leakage current (500pA), the main features of an analog switch.

The AD7510DI and AD7511DI consist of four independent SPST analog switches packaged in either a 16-pin DIP or a 20-terminal surface mount package. They differ only in that the digital control logic is inverted. The AD7512DI has two independent SPDT switches packaged either in a 14-pin DIP or a 20-terminal surface mount package.

Very low power dissipation, overvoltage protection and TTL/CMOS direct interfacing are achieved by combining a unique circuit design and a dielectrically isolated CMOS process. Silicon nitride passivation ensures long term stability while monolithic construction provides reliability.

TIMING AND CONTROL SEQUENCE

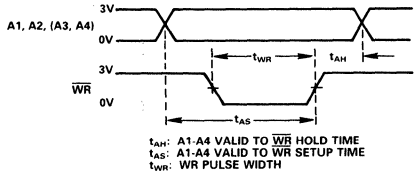

Figure 1. Timing and Control Sequence

TIMING AND CONTROL SEQUENCE

Figure 1 shows the timing sequence for latching the switch address inputs. The latches are level sensitive and, therefore, while $\overline{WR}$ is held low the latches are transparent and the switches respond to the address inputs. The digital inputs are latched on the rising edge of $\overline{WR}$.

NOTE: All digital input signals rise and fall times measured from 10% to 90% of 3V. $t_R = t_F$ = 20ns.

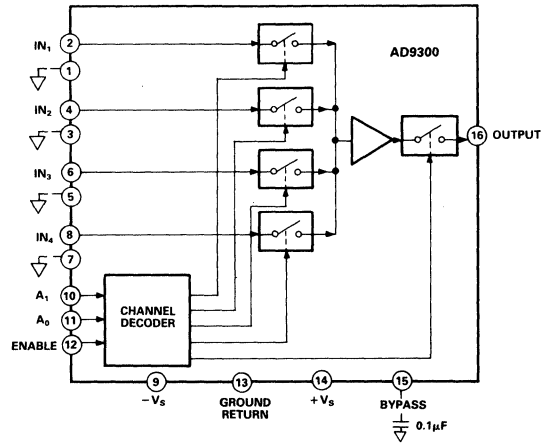
AD9300 FUNCTIONAL BLOCK DIAGRAM
(Based on Cerdip)



GENERAL DESCRIPTION

The AD9300 is a monolithic high-speed video signal multiplexer useable in a wide variety of applications.

Its four channels of video input signals can be randomly switched at megahertz rates to the single output. In addition, multiple devices can be configured in either parallel or cascade arrangements to form switch matrices. This flexibility in using the AD9300 is possible because the output of the device is in a high-impedance state when the chip is not enabled; when the chip is enabled, the unit acts as a buffer with a high input impedance and low output impedance.

An advanced bipolar process provides fast, wideband switching capabilities while maintaining crosstalk rejection of 75dB at 10MHz. Full power bandwidth is a minimum 30MHz. The device can be operated from ± 10V to ± 15V power supplies.

The AD9300KQ is packaged in a 16-pin ceramic DIP, and the AD9300KP is packaged in a 20-pin PLCC; both are designed to operate over the commercial temperature range of 0 to +70°C. For military temperatures of −55°C to +125°C, order part number AD9300TQ, which is also a 16-pin ceramic DIP. In addition, the AD9300 is available in a 20-pin LCC as the model AD9300TE, which operates over a temperature range of −55°C to +125°C.

ORDERING INFORMATION

[1]Permanent damage may occur if any one absolute maximum rating is exceeded. Functional operation is not implied, and device reliability may be impaired by exposure to higher-than-recommended voltages for extended periods of time.

[2]Military Subgroups apply to military-qualified devices only.

[3]Measured at extremes of temperature range.

[4]Measured as slope of V_{OUT} versus V_{IN} with $V_{IN} = \pm 1V$.

[5]Measured as worst deviation from end-point fit with $V_{IN} = \pm 1V$.

[6]Full Power Bandwith (FPBW) based on Slew Rate (SR). $FPBW = SR/2\pi V_{PEAK}$

[7]Measured between 20% and 80% transition points of ±1V output.

[8]T-Step = Sin^2X Step, when Step between 0V and +700mV points has 10%-to-90% risetime = 125ns.

[9]Measured with a pulse input having slew rate >250V/μs.

[10]Measured at output between 0.28Vdc and 1.0Vdc with V_{IN} = 284mV p-p at 3.58MHz and 4.43MHz.

[11]This specification is critically dependent on circuit layout. Value shown is measured with selected channel grounded and 10MHz 2V p-p signal applied to remaining three channels. If selected channel is grounded through 75Ω, value is approximately 6dB higher.

[12]This specification is critically dependent on circuit layout. Value shown is measured with selected channel grounded and 10MHz 2V p-p signal applied to one other channel. If selected channel is grounded through 75Ω, value is approximately 6dB higher. Minimum specification in ( ) applies to DIPs.

[13]Consult system timing diagram.

[14]Measured from address change to 90% point of −2V to +2V output LOW-to-HIGH transition.

[15]Measured from address change to 10% point of +2V to −2V output HIGH-to-LOW transition.

[16]Measured from 50% transition point of ENABLE input to 90% transition of 0V to −2V output.

[17]Measured from 50% transition point of ENABLE input to 10% transition of +2V to 0V output.

[18]Measured while switching between two grounded channels.

[19]Maximum power dissipation is a package-dependent parameter related to the following typical thermal impedances:

16-Pin Ceramic $\theta_{JA} = 87°C/W$; $\theta_{JC} = 25°C/W$

20-Pin LCC $\theta_{JA} = 74°C/W$; $\theta_{JC} = 10°C/W$

Specifications subject to change without notice.

EXPLANATION OF TEST LEVELS

Test Level I	–	100% production tested.
Test Level II	–	100% production tested at +25°C, and sample tested at specified temperatures.
Test Level III	–	Sample tested only.
Test Level IV	–	Parameter is guaranteed by design and characterization testing.
Test Level V	–	Parameter is a typical value only.
Test Level VI	–	All devices are 100% production tested at +25°C. 100% production tested at temperature extremes for military temperature devices; sample tested at temperature extremes for commercial/industrial devices.

EXPLANATION OF GROUP A MILITARY SUBGROUPS

Subgroup 1	–	Static tests at +25°C. (5% PDA calculated against Subgroup 1 for high-rel versions)
Subgroup 2	–	Static tests at maximum rated temperature.
Subgroup 3	–	Static tests at minimum rated temperature.
Subgroup 4	–	Dynamic tests at +25°C.
Subgroup 5	–	Dynamic tests at maximum rated temperature.
Subgroup 6	–	Dynamic tests at minimum rated temperature.
Subgroup 7	–	Functional tests at +25°C.
Subgroup 8	–	Functional tests at maximum and minimum rated temperatures.
Subgroup 9	–	Switching tests at +25°C.
Subgroup 10	–	Switching tests at maximum rated temperature.
Subgroup 11	–	Switching tests at minimum rated temperature.
Subgroup 12	–	Periodically sample tested.

MECHANICAL INFORMATION

Die Dimensions	84 × 104 × 18 (max) mils
Pad Dimensions	4 × 4 (min) mils
Metalization	Aluminum
Backing	None
Substrate Potential	$-V_S$
Passivation	Oxynitride
Die Attach	Gold Eutectic
Bond Wire	1.25 mil, Aluminum; Ultrasonic Bonding or 1 mil, Gold; Gold Ball Bonding

FUNCTIONAL DESCRIPTION

$IN_1 - IN_4$	Four analog input channels.
GROUND	Analog input shielding grounds, not internally connected. Connect each to external low-impedance ground as close to device as possible.
A_0	One of two TTL decode control lines required for channel selection. See Logic Truth Table.
A_1	One of two TTL decode control lines required for channel selection. See Logic Truth Table.
ENABLE	TTL-compatible chip enable. In enabled mode (logic HIGH), output signal tracks selected input channel; in disabled mode (logic LOW), output is high impedance and no signal appears at output.
$-V_S$	Negative supply voltage; nominally -10V dc to -15V dc.
$+V_S$	Positive supply voltage; nominally $+10$V dc to $+15$V dc.
OUTPUT	Analog output. Tracks selected input channel when enabled.
BYPASS	Bypass terminal for internal bias line; must be decoupled externally to ground through 0.1μF capacitor.
GROUND RETURN	Analog signal and power supply ground return.

AD9300 Timing

THEORY OF OPERATION

Refer to the functional block diagram of the AD9300.

As shown on the drawing, this diagram is based on the pinouts of the DIP packaging of the models AD9300KQ and AD9300TQ. The AD9300TE is packaged in a 20-pin leadless chip carrier (LCC), but the extra pins are used for ground connections; the theory of operation remains the same.

The AD9300 Video Multiplexer allows the user to connect any one of four analog input channels ($IN_1 - IN_4$) to the output of the device, and to switch between channels at megahertz rates.

The input channel which is connected to the output is determined by a 2-bit TTL digital code applied to A_0 and A_1. The selected input will not appear at the output unless a digital "1" is also applied to the ENABLE input pin; unless the output is enabled, it is a high impedance. Necessary combinations to accomplish channel selection are shown in the Logic Truth Table.

Bipolar construction used in the AD9300 insures that the input impedance of the device remains high, and will not vary with power supply voltages. This characteristic makes the AD9300, in effect, a switchable-input buffer. An on-board bias network makes the performance of the AD9300 independent of applied supply voltages, which can have any nominal value from ±10V dc to ±15V dc.

Although the primary application for the AD9300 is the routing of video signals, the harmonic and dynamic attributes of the device make it appropriate for other applications. The AD9300 has exceptional performance when switching video signals, but can also be used for switching other analog signals requiring greater dynamic range and/or precision than those in video.

As shown in Figure 1, Input and Output Equivalent Circuits, each analog input is connected to the base of a bipolar transistor. If Channel 1 is selected, a current switch is closed and routes current through the input transistor for Channel 1.

If Channel 2 is then selected by the digital inputs, the current switch for Channel 1 is opened and the current switch for Channel 2 is closed. This causes current to be routed away from the Channel 1 transistor and into the Channel 2 input transistor. Whenever a channel's input device is carrying current, the analog input applied to that channel is passed to the output stage.

The operation of the output stage is similar to that of the input stages. Whenever the output stage is enabled with a HIGH digital "1" signal at the ENABLE pin, the output transistor will carry current and pass the selected analog input.

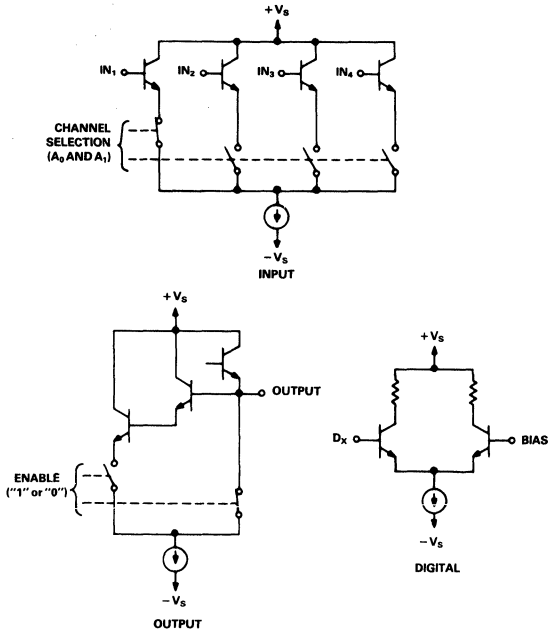

Figure 1. Input and Output Equivalent Circuits

When the output stage is disabled (by virtue of the ENABLE pin being driven LOW with a digital "0"), the output current switch is opened. This routes the current to other circuits within the AD9300 which keep the output transistor biased "off". These circuits require approximately 1μA of bias current from the load connected to the output of the multiplexer. In the absence of a terminating load and the resulting dc bias, the output of the AD9300 "floats" at −2.5V.

In summary, when the AD9300 is enabled by the ENABLE pin being driven HIGH with a digital "1", the selected analog input channel acts as a buffer for the input; and the output of the multiplexer is a low impedance. When the AD9300 is disabled with a digital "0" LOW signal, the selected channel acts as an open switch for the input; and the output of the unit becomes a high impedance. This characteristic allows the user to wire-or several AD9300 Analog Multiplexers together to form switch matrices.

AD9300 APPLICATIONS

To ensure optimum performance from circuits using the AD9300, it is important to follow a few basic rules which apply to all high-speed devices.

A large, low-impedance ground plane under the AD9300 is critical. Generally, GROUND and GROUND RETURN connections should be connected solidly to this plane. GROUND pin connections are signal isolation grounds which are not connected internally; they can be left unconnected, but there may be some degradation in crosstalk rejection. GROUND RETURN, on the other hand, serves as the internal ground reference for the AD9300 and should be connected to the ground plane *without exception.*

It is recommended that the AD9300 be soldered directly into circuit boards, rather than using socket assemblies. If sockets must be used, individual pin sockets are the preferred choice, rather than a socket assembly. A second requirement for proper high-speed design involves decoupling the power supply and internal bias supply lines from ground to improve noise immunity. Chip capacitors are recommended for connecting 0.1μF and 0.01μF capacitors between ground and the $\pm V_S$ supplies (Pins 9 and 14), and the BYPASS connection (Pin 15).

The output stage of the unit is capable of driving a 2kΩ‖10pF load. Larger capacative loads may limit full power bandwidth and increase t_{OFF} (the interval between the 50% point of the ENABLE high-to-low transition and the instant the output becomes a high impedance.)

For applications such as driving cables (See Figure 2), output buffers are recommended.

CROSSPOINT CIRCUIT APPLICATIONS

Four AD9300 multiplexers can be used to implement an 8 × 2 crosspoint, as shown in Figure 11. The circuit is modular in concept, with each pair of multiplexers (#1 and #2; #3 and #4) forming an 8 × 1 crosspoint. When the inputs to all four units are connected as shown, the result is an 8 × 2 crosspoint circuit.

D_2 or D_5	D_1 or D_4	D_0 or D_3	OUT_1 or OUT_2
0	0	0	S_1
0	0	1	S_2
0	1	0	S_3
0	1	1	S_4
1	0	0	S_5
1	0	1	S_6
1	1	0	S_7
1	1	1	S_8

8 × 2 Crosspoint Truth Table

The truth table describes the relationships among the digital inputs ($D_0 - D_5$) and the analog inputs ($S_1 - S_8$); and which signal input is selected at the outputs (OUT_1 and OUT_2). The number of crosspoint modules that can be connected in parallel is limited by the drive capabilities of the input signal sources. High input impedance (3MΩ) and low input capacitance (2pF) of the AD9300 help minimize this limitation.

Adding to the number of inputs applied to each crosspoint module is simply a matter of adding AD9300 multiplexers in parallel to the module. Eight devices connected in parallel result in a 32 × 1 crosspoint which can be used with input signals having 30MHz bandwidth and 1V peak-to-peak amplitude. Even more AD9300 units can be added if input signal amplitude and/or bandwidth are reduced; if they are not, distortion of the output signals can result.

When an AD9300 is enabled, its low output impedance causes the "off" isolation of disabled parallel devices to be greater than the crosstalk rejection of a single unit.

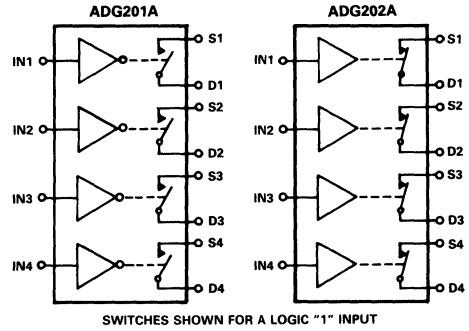
ADG202A Replaces DG202

ADG201A/ADG202A FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The ADG201A and ADG202A are monolithic CMOS devices comprising four independently selectable switches. They are designed on an enhanced LC²MOS process which gives an increased signal handling capability of ±15V. These switches also feature high switching speeds and low R_{ON}.

The ADG201A and ADG202A consist of four SPST switches. They differ only in that the digital control logic is inverted. All devices exhibit break before make switching action. Inherent in the design is low charge injection for minimum transients when switching the digital inputs.

PRODUCT HIGHLIGHTS

1. Extended Signal Range:
   These switches are fabricated on an enhanced LC²MOS process, resulting in high breakdown and an increased analog signal range of ±15V.
2. Single Supply Operation:
   For applications where the analog signal is unipolar (0V to 15V), the switches can be operated from a single +15V supply.
3. Low Leakage:
   Leakage currents in the range of 500pA make these switches suitable for high precision circuits. The added feature of Break before Make allows for multiple outputs to be tied together for multiplexer applications while keeping leakage errors to a minimum.

NOTE
[1]Overvoltage at IN, S or D will be clamped by diodes. Current should be limited to the Maximum Rating above.

*COMMENT: Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability. Only one Absolute Maximum Rating may be applied at any one time.

CAUTION
ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

NOTES
[1]To order MIL-STD-883, Class B processed parts, add /883B to T grade part numbers. Contact your local sales office for military data sheet. For U.S. Standard Military Drawing (SMD), see DESC drawing 5962-86716.
[2]See Section 14 for package outline information.
[3]Also available in SOIC package (ADG201HSKR).
[4]PLCC: Plastic Leaded Chip Carrier.
[5]LCCC: Leadless Ceramic Chip Carrier.

PRODUCT HIGHLIGHTS

1. 50ns max t_{ON} and t_{OFF}:
   The ADG201HS top grades (K, B, T) have guaranteed 50ns max turn-on and turn-off times over the full operating temperature range. The lower grades (J,A,S) have guaranteed 75ns switching times over the full operating temperature range.
2. Single Supply Specifications:
   The ADG201HS is fully specified for applications which require a single positive power supply in the +10.8V to +16.5V range.
3. Low Leakage:
   Leakage currents in the range of 100pA make these switches suitable for high precision circuits. The added feature of break-before-make allows for multiple outputs to be tied together for multiplexer applications while keeping leakage errors to a minimum.

Extended (S, T Version)	−55°C to +125°C
Storage Temperature Range	−65°C to +150°C
Lead Temperature (Soldering 10sec)	+300°C

NOTES

[1]If V_{SS} is open circuited with V_{DD} and GND applied, the V_{SS} pin will be pulled positive, exceeding the Absolute Maximum Ratings. If this possibility exists, a Schottky diode from V_{SS} to GND (cathode end to GND) ensures that the Absolute Maximum Ratings will be observed.

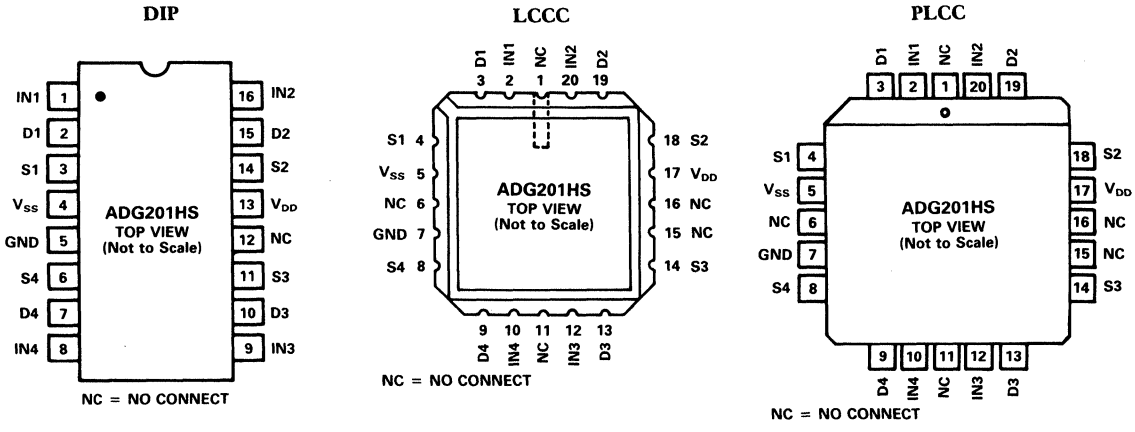
[2]Overvoltage at IN, S or D, will be clamped by diodes. Current should be limited to the maximum rating above.

*COMMENT: Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

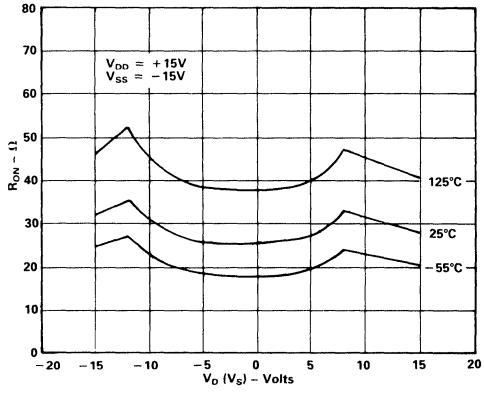
CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

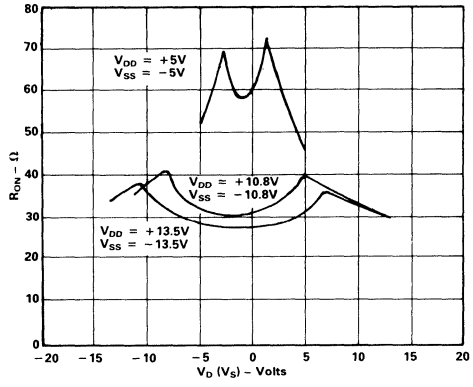
PIN CONFIGURATIONS



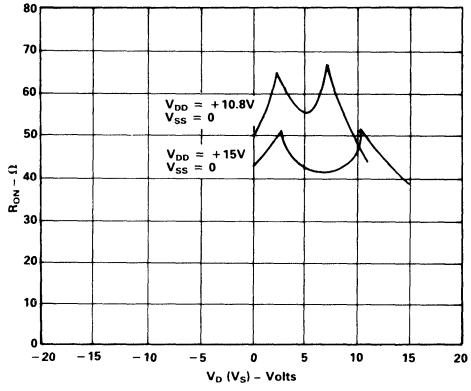
The switches are guaranteed functional with reduced single or dual supplies down to 4.5V.



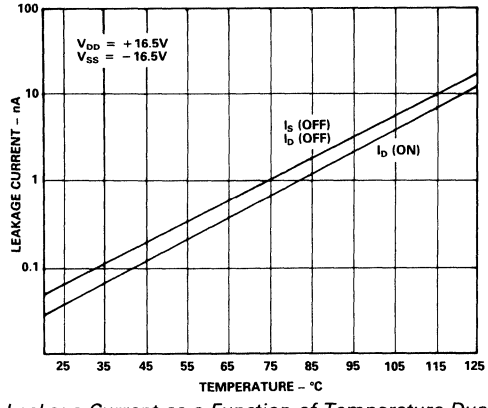
R_{ON} as a Function of V_D (V_S): Dual Supply Voltage



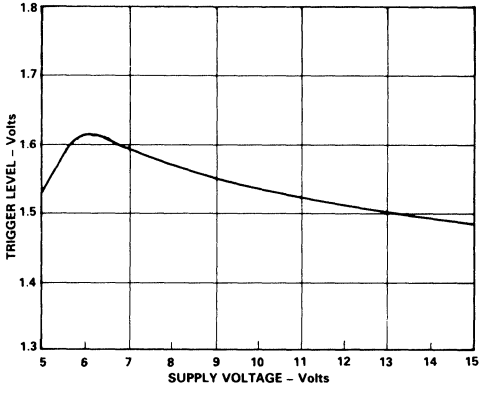
R_{ON} as a Function of V_D (V_S): Dual Supply Voltage, T_A = +25°C



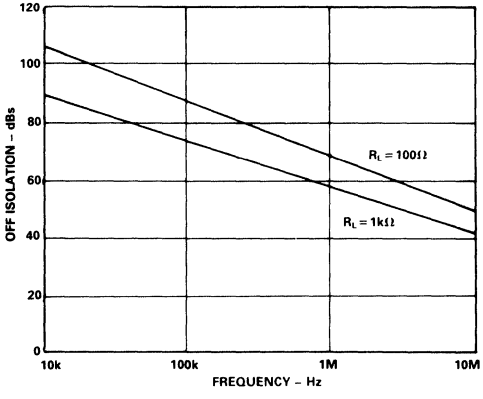
R_{ON} as a Function of V_D (V_S): Single Supply Voltage, T_A = +25°C



Leakage Current as a Function of Temperature Dual Supply Voltage. (Note: Leakage Currents Reduce as the Supply Voltages Reduce)

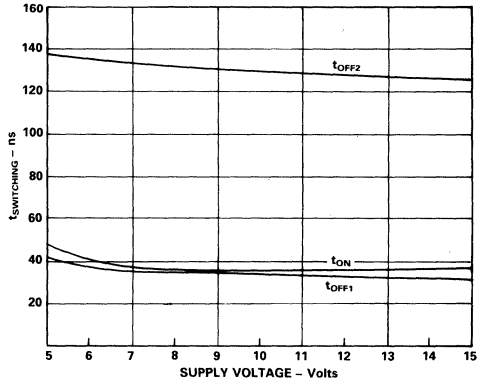


Trigger Levels vs. Power Supply Voltage, Dual or Single Supply, T_A = +25°C

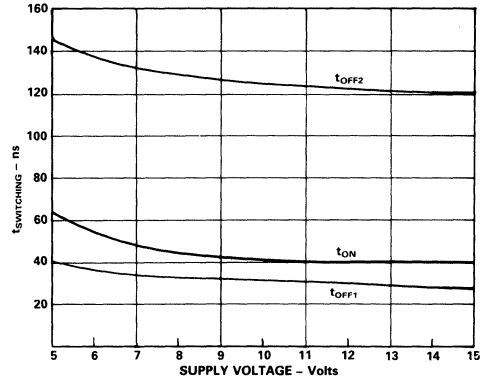


Off Isolation vs. Signal Frequency; Dual or Single 15V Supplies, T_A = +25°C

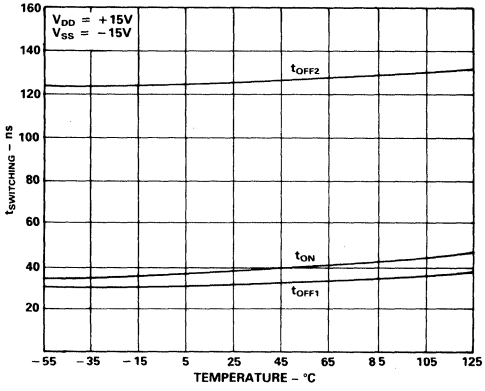
Typical Performance Characteristics (Continued)



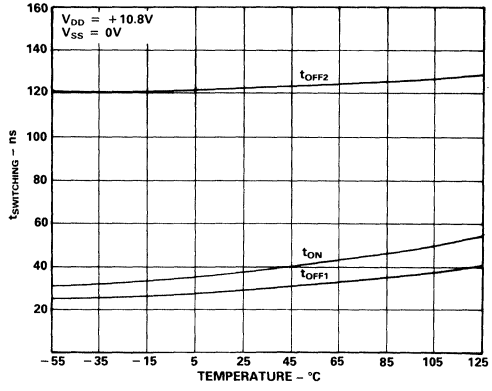
Switching Time vs. Supply Voltage (Dual Supply): T_A = +25°C. (Note: See Test Circuit 4. For V_{DD} <10V, V_S = V_{DD})



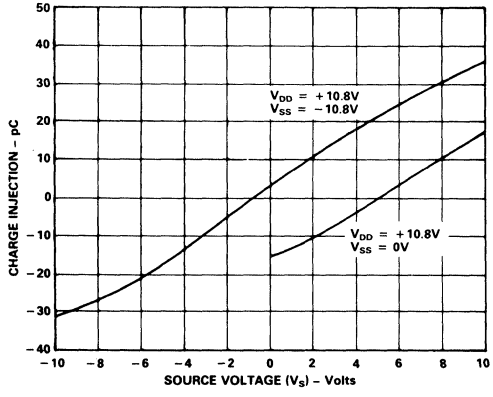
Switching Time vs. Supply Voltage (Single Supply): T_A = +25°C. (Note: See Test Circuit 4. For V_{DD} <10V, V_S = V_{DD})



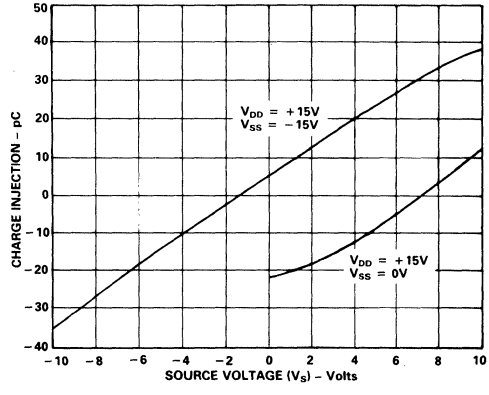
Switching Time vs. Temperature: Dual Supply Voltage



Switching Time vs. Temperature: Single Supply Voltage



Charge Injection vs. Source Voltage (V_S) for Dual and Single 10.8V Supplies: T_A = +25°C



Charge Injection vs. Source Voltage (V_S) for Dual and Single 15V Supplies: T_A = +25°C

Note: All digital input signal rise and fall times measured from 10% to 90% of 3V. $t_R = t_F = 5ns$. Decoupling capacitors (0.01μF min) from V_{DD} and V_{SS} to GND are recommended to achieve specified performance.

SINGLE SUPPLY DISK DRIVE APPLICATION

The excellent performance of the ADG201HS with single supply operation makes it suitable in applications such as disk drives where only positive power supply voltages are normally available. The accompanying circuit shows a typical application for the ADG201HS in the read/write head switching section of a disk drive. The circuit allows data (0s and 1s) to be written to and read from a disk. The principal advantage offered by the ADG201HS is that it retains very fast switching speed with single supply operation (see Single Supply Specifications). This allows disk drives to run at higher data rates.

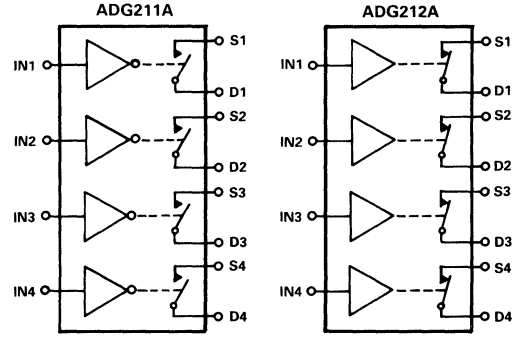
ANALOG DEVICES

LC²MOS Quad SPST Switches

ADG211A/ADG212A

FEATURES
- **44V Supply Maximum Rating**
- **±15V Analog Signal Range**
- **Low R_{ON} (115Ω max)**
- **Low Leakage (0.5nA typ)**
- **Single Supply Operation Possible**
- **Extended Plastic Temperature Range (−40°C to +85°C)**
- **TTL/CMOS Compatible**
- **Standard 16-Pin DIPs and 20-Terminal PLCC Packages**
- **Superior Second Source:**
  - **ADG211A Replaces DG211**
  - **ADG212A Replaces DG212**

ADG211A/ADG212A FUNCTIONAL BLOCK DIAGRAMS



SWITCHES SHOWN FOR A LOGIC "1" INPUT

GENERAL DESCRIPTION

The ADG211A and ADG212A are monolithic CMOS devices comprising four independently selectable switches. They are designed on an enhanced LC²MOS process which gives an increased signal handling capability of ±15V. These switches also feature high switching speeds and low R_{ON}.

The ADG211A and ADG212A consist of four SPST switches. They differ only in that the digital control logic is inverted. In multiplexer applications, all switches exhibit break-before-make switching action when driven simultaneously. Inherent in the design is low charge injection for minimum transients when switching the digital inputs.

[3]PLCC: Plastic Leaded Chip Carrier.

PRODUCT HIGHLIGHTS

1. Extended Signal Range:
   These switches are fabricated on an enhanced LC²MOS process, resulting in high breakdown and an increased analog signal range of ±15V.
2. Single Supply Operation:
   For applications where the analog signal is unipolar (0V to 15V), the switches can be operated from a single +15V supply.
3. Low Leakage:
   Leakage currents in the range of 500pA make these switches suitable for high precision circuits. The added feature of Break before Make allows for multiple outputs to be tied together for multiplexer applications while keeping leakage errors to a minimum.

[4]PLCC: Plastic Leaded Chip Carrier.
[5]LCCC: Leadless Ceramic Chip Carrier.

PRODUCT HIGHLIGHTS

1. Easily Interfaced:
   Digital inputs are latched with a $\overline{WR}$ signal for microprocessor interfacing. A 5V regulated supply is internally generated permitting wider tolerances on the supplies without affecting the TTL digital input switching levels.
2. Single Supply Operation:
   For applications where the analog signal is unipolar (0V to 15V), the switches can be operated from a single +15V supply.
3. Low Leakage:
   Leakage currents in the range of 500pA make these switches suitable for high precision circuits. The added feature of Break before Make allows for multiple outputs to be tied together for multiplexer applications while keeping leakage errors to a minimum.

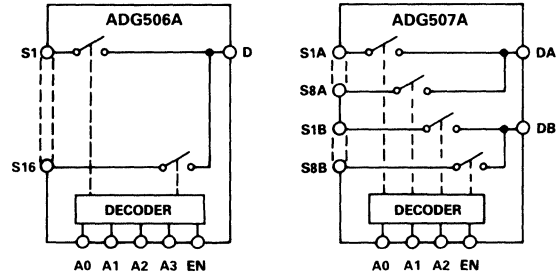
ADG506A/ADG507A FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The ADG506A and ADG507A are CMOS monolithic analog multiplexers with 16 channels and dual 8 channels respectively. The ADG506A switches one of 16 inputs to a common output depending on the state of four binary addresses and an enable input. The ADG507A switches one of 8 differential inputs to a common differential output depending on the state of three binary addresses and an enable input. Both devices have TTL and 5V CMOS logic compatible digital inputs.

The ADG506A and ADG507A are designed on an enhanced LC^2MOS process which gives an increased signal capability of V_{SS} to V_{DD} and enables operation over a wide range of supply voltages. The devices can comfortably operate anywhere in the 10.8V to 16.5V single or dual supply range. These multiplexers also feature high switching speeds and low R_{ON}.

PRODUCT HIGHLIGHTS

1. Single/Dual Supply Specifications with a Wide Tolerance:
   The devices are specified in the 10.8V to 16.5V range for both single and dual supplies.
2. Extended Signal Range:
   The enhanced LC^2MOS processing results in a high breakdown and an increased analog signal range of V_{SS} to V_{DD}.
3. Break-Before-Make Switching:
   Switches are guaranteed break-before-make so that input signals are protected against momentary shorting.
4. Low Leakage:
   Leakage currents in the range of 20pA make these multiplexers suitable for high precision circuits.

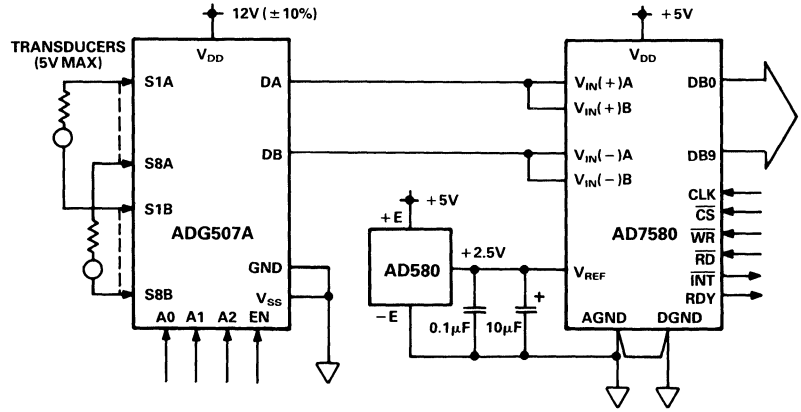
SINGLE SUPPLY AUTOMOTIVE APPLICATION

The excellent performance of the multiplexers under single supply conditions makes the ADG506A/ADG507A suitable in applications, such as automotive and disc drives, where only positive power supply voltages are normally available. The following application circuit shows the ADG507A connected as an 8-channel differential multiplexer in an automotive, data acquisition application circuit.

The AD7580 is a 10-bit successive approximation ADC which has an on-chip sample-hold amplifier and provides a conversion result in 20μs. The ADC has a differential analog inputs and is configured in the application circuit for a span of 2.5V over a common-mode range 0 to +5V. Wider common-mode ranges can be accomodated. See the AD7579/AD7580 data sheet for more details. The complete system operates from +12V (±10%) and +5V supplies. The analog input signals to the ADG507A contain information such as temperature, pressure, speed etc.



ADG507A in a Single Supply Automotive Data Acquisition Application.

TERMINOLOGY

R_{ON}	Ohmic resistance between terminals D and S
R_{ON} Match	Difference between the R_{ON} of any two channels
R_{ON} Drift	Change in R_{ON} versus temperature
I_S (OFF)	Source terminal leakage current when the switch is off
I_D (OFF)	Drain terminal leakage current when the switch is off
I_D (ON)	Leakage current that flows from the closed switch into the body
V_S (V_D)	Analog voltage on terminal S or D
C_S (OFF)	Channel input capacitance for "OFF" condition
C_D (OFF)	Channel output capacitance for "OFF" condition
C_{IN}	Digital input capacitance
t_{ON} (EN)	Delay time between the 50% and 90% points of the digital input and switch "ON" condition
t_{OFF} (EN)	Delay time between the 50% and 10% points of the digital input and switch "OFF" condition
$t_{TRANSITION}$	Delay time between the 50% and 90% points of the digital inputs and switch "ON" condition when switching from one address state to another
t_{OPEN}	"OFF" time measured between 50% points of both switches when switching from one address state to another
V_{INL}	Maximum input voltage for Logic "0"
V_{INH}	Minimum input voltage for Logic "1"
I_{INL} (I_{INH})	Input current of the digital input
V_{DD}	Most positive voltage supply
V_{SS}	Most negative voltage supply
I_{DD}	Positive supply current
I_{SS}	Negative supply current

Power Dissipation (Any Package)	
Up to +75°C	470mW
Derates above +75°C by	6mW/°C
Operating Temperature	
Commercial (K Version)	−40°C to +85°C
Industrial (B Version)	−40°C to +85°C
Extended (T Version)	−55°C to +125°C
Storage Temperature Range	−65°C to +150°C
Lead Temperature Range (Soldering, 10sec)	+300°C

NOTE
[1]Overvoltage at A, EN, S or D will be clamped by diodes. Current should be limited to the Maximum Rating above.

*COMMENT: Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

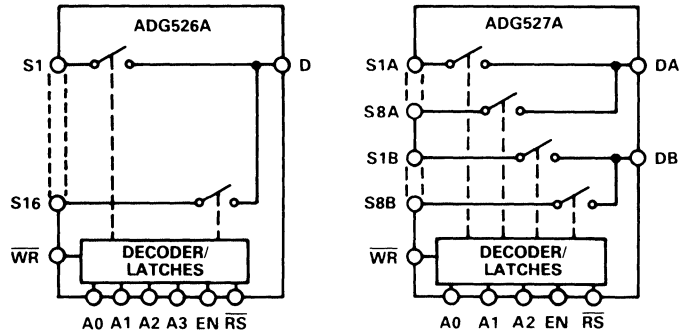
CMOS Latched 8/16 Channel Analog Multiplexers

ADG526A/ADG527A

FEATURES

- **44V Supply Maximum Rating**
- **V_{SS} to V_{DD} Analog Signal Range**
- **Single/Dual Supply Specifications**
- **Wide Supply Ranges (10.8V to 16.5V)**
- **Microprocessor Compatible (100ns $\overline{WR}$ Pulse)**
- **Extended Plastic Temperature Range (−40°C to +85°C)**
- **Low Leakage (20pA typ)**
- **Low Power Dissipation (28mW max)**
- **Superior Alternative to:**
  - **DG526**
  - **DG527**

ADG526A/ADG527A FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The ADG526A and ADG527A are CMOS monolithic analog multiplexers with 16 channels and dual 8 channels respectively. On-chip latches facilitate microprocessor interfacing. The ADG526A switches one of 16 inputs to a common output depending on the state of four binary addresses and an enable input. The ADG527A switches one of 8 differential inputs to a common differential output depending on the state of three binary addresses and an enable input. Both devices have TTL and 5V CMOS logic compatible digital inputs.

The ADG526A and ADG527A are designed on an enhanced LC²MOS process which gives an increased signal capability of V_{SS} to V_{DD} and enables operation over a wide range of supply voltages. The devices can comfortably operate anywhere in the 10.8V to 16.5V single or dual supply range. These multiplexers also feature high switching speeds and low R_{ON}.

PRODUCT HIGHLIGHTS

1. Single/Dual Supply Specifications with a Wide Tolerance:
   The devices are specified in the 10.8V to 16.5V range for both single and dual supplies.
2. Easily Interfaced:
   The ADG526A and ADG527A can be easily interfaced with microprocessors. The $\overline{WR}$ signal latches the state of the Address control lines and the Enable line. The $\overline{RS}$ signal clears both the address and enable data in the latches resulting in no output (all switches off). $\overline{RS}$ can be tied to the microprocessor reset pin.
3. Extended Signal Range:
   The enhanced LC²MOS processing results in a high breakdown and an increased analog signal range of V_{SS} to V_{DD}.
4. Break-Before-Make Switching:
   Switches are guaranteed break-before-make so that input signals are protected against momentary shorting.
5. Low Leakage:
   Leakage currents in the range of 20pA make these multiplexers suitable for high precision circuits.

Pulsed Current S or D
1ms Duration, 10% Duty Cycle 40mA
Digital Inputs[1]
Voltage at A, EN, $\overline{WR}$, $\overline{RS}$ . . . . . V_{SS} −4V to V_{DD} +4V or 20mA, Whichever Occurs First
Power Dissipation (Any Package)
Up to +75°C 470mW
Derates above +75°C by . . . . . 6mW/°C
Operating Temperature
Commerical (K Version) . . . . . −40°C to +85°C
Industrial (B Version) . . . . . −40°C to +85°C
Extended (T Version) . . . . . −55°C to +125°C
Storage Temperature Range . . . . . −65°C to +150°C
Lead Temperature (Soldering, 10sec) . . . . . +300°C

NOTE
[1]Overvoltage at A, EN, $\overline{WR}$, $\overline{RS}$, S or D will be clamped by diodes. Current should be limited to the maximum rating above.

*COMMENT: Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION
ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

TIMING DIAGRAMS

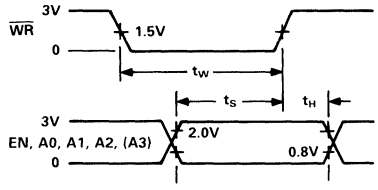

Figure 1

Figure 1 shows the timing sequence for latching the switch address and enable inputs. The latches are level sensitive; therefore, while $\overline{WR}$ is held low, the latches are transparent and the switches respond to the address and enable inputs. This input data is latched on the rising edge of $\overline{WR}$.

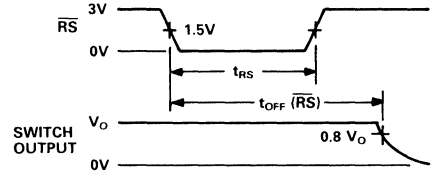

Figure 2

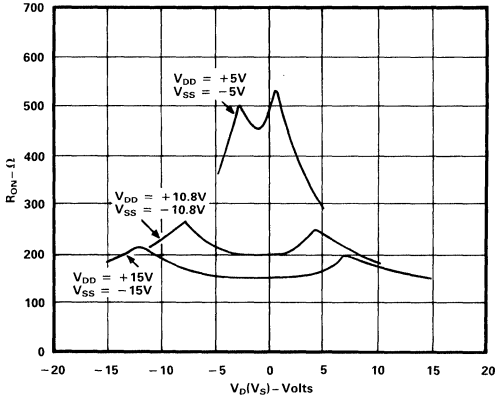
Figure 2 shows the Reset Pulse Width, t_{RS}, and Reset Turn-off Time, t_{OFF} ($\overline{RS}$).

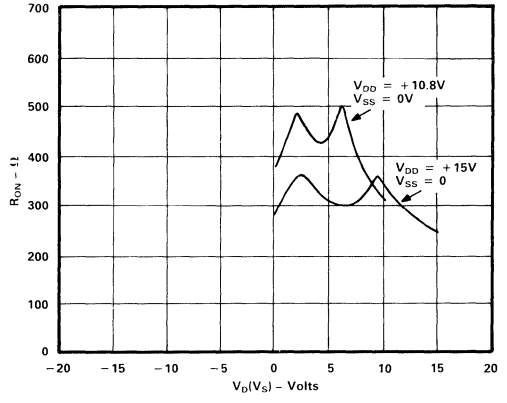
Note: All digital input signals rise and fall times measured from 10% to 90% of 3V. $t_R = t_F = 20ns$.

Typical Performance Characteristics

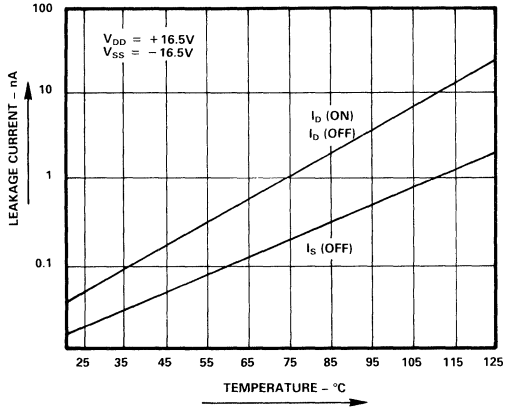
The multiplexers are guaranteed functional with reduced single or dual supplies down to 4.5V.



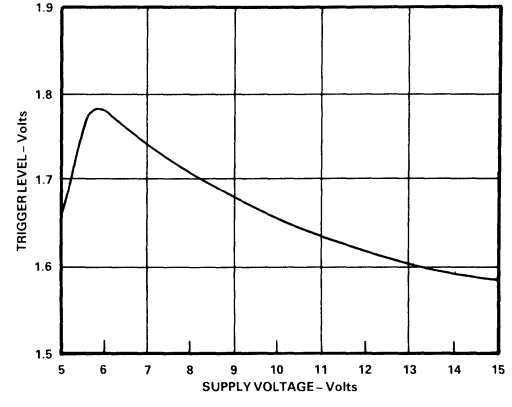
R_{ON} as a Function of $V_D(V_S)$: Dual Supply Voltage, T_A = +25°C



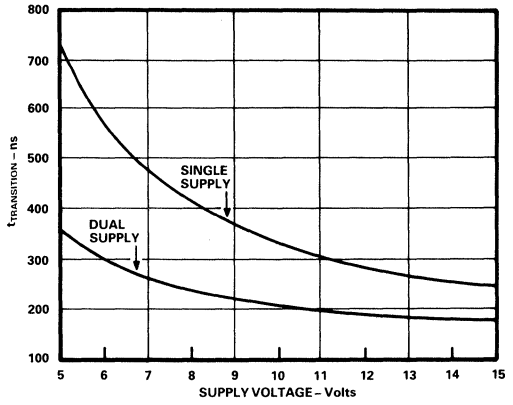
R_{ON} as a Function of $V_D(V_S)$: Single Supply Voltage, T_A = +25°C



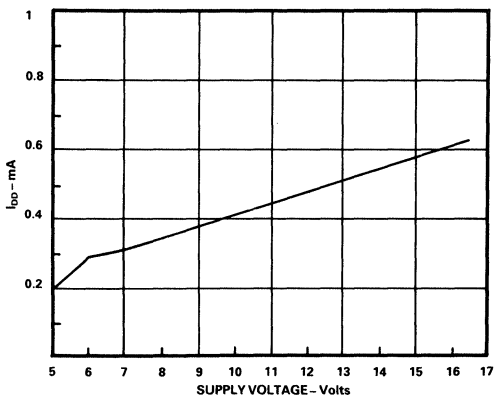
Leakage Current as a Function of Temperature (Note: Leakage Currents Reduce as the Supply Voltages Reduce)



Trigger Levels vs. Power Supply Voltage, Dual or Single Supply, T_A = +25°C



$t_{TRANSITION}$ vs Supply Voltage: Dual and Single Supplies, T_A = +25°C
(Note: For V_{DD} and $|V_{SS}| < 10V$; V1 = V_{DD}/V_{SS}, V2 = V_{SS}/V_{DD}. See Test Circuit 6)



I_{DD} vs. Supply Voltage: Dual or Single Supply, T_A = +25°C

TERMINOLOGY

R_{ON}	Ohmic resistance between terminals D and S
R_{ON} Match	Difference between the R_{ON} of any two channels
R_{ON} Drift	Change in R_{ON} versus temperature
I_S (OFF)	Source terminal leakage current when the switch is off
I_D (OFF)	Drain terminal leakage current when the switch is off
I_D (ON)	Leakage current that flows from the closed switch into the body
V_S (V_D)	Analog voltage on terminal S or D
C_S (OFF)	Channel input capacitance for "OFF" condition
C_D (OFF)	Channel output capacitance for "OFF" condition
C_{IN}	Digital input capacitance
t_{ON} (EN)	Delay time between the 50% and 90% points of the digital input and switch "ON" condition
t_{OFF} (EN)	Delay time between the 50% and 10% points of the digital input and switch "OFF" condition
$t_{TRANSITION}$	Delay time between the 50% and 90% points of the digital inputs and switch "ON" condition when switching from one address state to another
t_{OPEN}	"OFF" time measured between 50% points of both switches when switching from one address state to another
V_{INL}	Maximum input voltage for Logic "0"
V_{INH}	Minimum input voltage for Logic "1"
I_{INL} (I_{INH})	Input current of the digital input
V_{DD}	Most positive voltage supply
V_{SS}	Most negative voltage supply
I_{DD}	Positive supply current
I_{SS}	Negative supply current

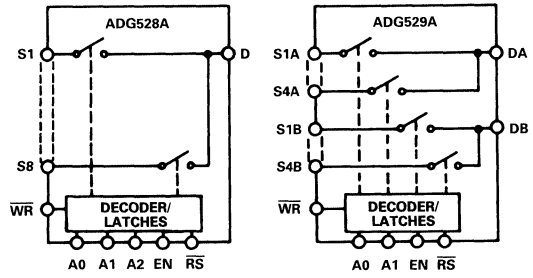
DG529

ADG528A/ADG529A FUNCTIONAL BLOCK DIAGRAMS



GENERAL DESCRIPTION

The ADG528A and ADG529A are CMOS monolithic analog multiplexers with 8 channels and dual 4 channels respectively. On-chip latches facilitate microprocessor interfacing. The ADG528A switches one of 8 inputs to a common output depending on the state of three binary addresses and an enable input. The ADG529A switches one of 4 differential inputs to a common differential output depending on the state of two binary addresses and an enable input. Both devices have TTL and 5V CMOS logic compatible digital inputs.

The ADG528A and ADG529A are designed on an enhanced LC^{2}MOS process which gives an increased signal capability of V_{SS} to V_{DD} and enables operation over a wide range of supply voltages. The devices can comfortably operate anywhere in the 10.8V to 16.5V single or dual supply range. These multiplexers also feature high switching speeds and low R_{ON}.

[4]LCCC: Leadless Ceramic Chip Carrier.

PRODUCT HIGHLIGHTS

1. Single/Dual Supply Specifications with a Wide Tolerance:
   The devices are specified in the 10.8V to 16.5V range for both single and dual supplies.
2. Easily Interfaced:
   The ADG528A and ADG529A can be easily interfaced with microprocessors. The $\overline{WR}$ signal latches the state of the address control lines and the enable line. The $\overline{RS}$ signal clears both the address and enable data in the latches resulting in no output (all switches off). $\overline{RS}$ can be tied to the microprocessor reset pin.
3. Extended Signal Range:
   The enhanced LC^{2}MOS processing results in a high breakdown and an increased analog signal range of V_{SS} to V_{DD}.
4. Break-Before-Make Switching:
   Switches are guaranteed break-before-make so that input signals are protected against momentary shorting.
5. Low Leakage:
   Leakage currents in the range of 20pA make these multiplexers suitable for high precision circuits.

7

Lead Temperature (Soldering, 10sec) . . . . . +300°C

NOTE
[1]Overvoltage at A, EN, $\overline{WR}$, $\overline{RS}$, S or D will be clamped by diodes. Current should be limited to the maximum rating above.

*COMMENT: Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

Orientation
Voltage References

A voltage reference is used to provide an accurately known voltage which can be utilized in a circuit or system. For example, measurement systems rely on precision references in order to establish a basis for absolute measurement accuracy. Any reference inaccuracy will undermine the accuracy of the overall system. Thus, ideal references are characterized by accurately set (and traceable to recognized fundamental standards) constant output voltage, independent of temperature, load changes, input voltage variation and time.

TYPES OF REFERENCES

Some of the available IC reference circuits use the bandgap principle: the V_{BE} of any silicon transistor has a negative tempco of about 2mV/°C, which can be extrapolated to approximately 1.2 volts at absolute zero (the *bandgap* voltage of silicon). Since identical transistors operating at constant current densities will have predictably different temperature coefficients of base-emitter voltage, it is possible to arrange circuit elements so as to null out the temperature coefficients associated with the two phenomena and produce a constant voltage (usually 1.2 volts). This temperature-invariant voltage can be amplified and buffered to produce a standard voltage value, such as 2.5V or 10.0V. The bandgap types cataloged here include the AD1403 and the AD580 (2.5V), the AD581 (10.0V) and the multi-output AD584 (2.5, 5.0, 7.5 and/or 10.0V).

Another popular form of reference circuit uses a selected low-drift Zener diode, followed by a buffer-amplifier-and-precision-gain stage to provide a standard output voltage.

A buried-Zener design provides lower noise and drift than bandgap references, with laser trimming of thin-film resistors for excellent accuracy and low drift versus temperature. This technique provides initial accuracy to ±1mV and temperature drifts as low as 1.5ppm in the AD588 (+10V, +5V, ±5V tracking, −5V and −10V outputs). Similar reference designs with single voltage outputs (AD586 and AD587, +5V and +10V respectively) have accuracies and temperature coefficients that are nearly as good as the AD588.

Several of the references allow the user to optionally connect a capacitor to a noise reduction pin on the IC and so further reduce the noise output of the reference. In the AD586, the wideband noise (to 1MHz) of 200μV peak-to-peak (p-p) is reduced to 160μV p-p by adding a 1μF capacitor to the noise reduction point.

Output current capability of the voltage reference must also be considered when selecting a reference. The amount of current that the reference must source, or sink, for the rest of the system affects which references are acceptable or may need additional buffering.

Kelvin connections provide output sense and force connections, so that the actual voltage at the load is sensed and any IR drops in the leads are compensated. The AD588 provides sense and force connections in its design.

DEFINITIONS OF SPECIFICATIONS

Line regulation. The change in output voltage due to a specified change in input voltage. It is usually expressed in percent per volt or microvolts per volt of input change.

Load regulation. The change in output voltage for a specified change in load current. It is generally expressed in microvolts per milliampere, or ohms of dc output resistance. This specification includes the effect of self-heating due to increased power dissipation at higher load currents.

Output voltage tolerance. The deviation from the nominal output voltage at 25°C and specified input voltage as measured by a device traceable to a recognized fundamental voltage standard.

Output voltage change with temperature. The change in output voltage from the value at 25°C ambient; it is independent of variations in the other operating conditions. Analog Devices specifies both an error band and an equivalent temperature coefficient (in ppm/°C) for most references. The error band (e.g., ±5mV, −55°C to +125°C) is defined graphically in terms of a box (voltage vertically, temperature horizontally) whose diagonals extend from 25°C to T_{max} and 25°C to T_{min}, with a slope equal to the stated temperature coefficient. Thus, the total absolute error for a particular reference over its specified temperature range is equal to the output voltage tolerance at 25°C plus the error band.

Turn-on settling time. The time, from a cold start, for the reference output to settle within a specified error band. This definition relates only to the electrical turn-on of the chip, and does not include thermal settling time which depends on the package, heat-sinking and load-current change.

Long-term stability. The change in output voltage versus time, specified in ppm/1000 hours.

Noise. The narrowband (0.1 to 10Hz) and wideband (to 1MHz) random noise on the reference output. It may be measured in μV p-p or in $nV/\sqrt{Hz}$.

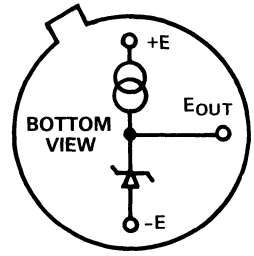
AD580*

FEATURES

Laser Trimmed to High Accuracy: 2.500V ±0.4%
3-Terminal Device: Voltage In/Voltage Out
Excellent Temperature Stability: 10ppm/°C (AD580M, U)
Excellent Long Term Stability: 250μV (25μV/Month)
Low Quiescent Current: 1.5mA max
Small, Hermetic IC Package: TO-52 Can

AD580 FUNCTIONAL BLOCK DIAGRAM

TO-52



PRODUCT DESCRIPTION

The AD580 is a three-terminal, low cost, temperature compensated, bandgap voltage reference which provides a fixed 2.5V output for inputs between 4.5V and 30V. A unique combination of advanced circuit design and laser-wafer-trimmed thin-film resistors provide the AD580 with an initial tolerance of ±0.4%, a temperature stability of better than 10ppm/°C and long-term stability of better than 250μV. In addition, the low quiescent current drain of 1.5mA max offers a clear advantage over classical zener techniques.

The AD580 is recommended as a stable reference for all 8-, 10- and 12-bit D-to-A converters that require an external reference. In addition, the wide input range of the AD580 allows operation with 5 volt logic supplies making the AD580 ideal for digital panel meter applications or whenever only a single logic power supply is available.

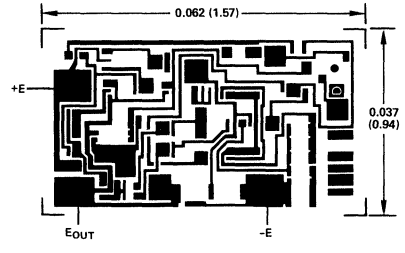
The AD580J, K, L and M are specified for operation over the 0 to +70°C temperature range; the AD580S, T and U are specified for operation over the extended temperature range of −55°C to +125°C.

PRODUCT HIGHLIGHTS

1. Laser-trimming of the thin-film resistors minimizes the AD580 output error. For example, the AD580L output tolerance is ±10mV.
2. The three-terminal voltage in/voltage out operation of the AD580 provides regulated output voltage without any external components.
3. The AD580 provides a stable 2.5V output voltage for input voltages between 4.5V and 30V. The capability to provide a stable output voltage using a 5-volt input makes the AD580 an ideal choice for systems that contain a single logic power supply.
4. Thin film resistor technology and tightly controlled bipolar processing provide the AD580 with temperature stabilities to 10ppm/°C and long term stability better than 250μV.
5. The low quiescent current drain of the AD580 makes it ideal for CMOS and other low power applications.

AD580 CHIP DIMENSIONS AND PAD LAYOUT

Dimensions shown in inches and (mm).



The AD580 is also available in chip form. Consult the factory for specifications and applications information.

NOTES

[1] See Section 14 for package outline information.

Specifications subject to change without notice.

Specifications shown in boldface are tested on all production units at final electrical test. Results from those tests are used to calculate outgoing quality levels. All min and max specifications are guaranteed, although only those shown in boldface are tested on all production units.

THEORY OF OPERATION

Most precision IC references use complex multichip hybrid designs based on expensive temperature-compensated zener diodes. Others are monolithic with on-chip zener diodes; these often require more than one power supply and, with the zener breakdown occuring near 6.3 volts, will not operate from a low voltage logic supply.

The AD580 family (AD580, AD581, AD584, AD589) uses the "bandgap" concept to produce a stable, low-temperature-coefficient voltage reference suitable for high accuracy data-acquisition components and systems. The device makes use of the underlying physical nature of a silicon transistor base-emitter voltage in the forward-biased operating region. All such transistors have approximately a -2mV/°C temperature coefficient, unsuitable for use directly as a low TC reference; however, extrapolation of the temperature characteristic of any one of these devices to absolute zero (with emitter current proportional to absolute temperature) reveals that it will go to a V_{BE} of 1.205 volts at 0K, as shown in Figure 1. Thus, if a voltage could be developed with an opposing temperature coefficient to sum with V_{BE} to total 1.205 volts, a zero-TC reference would result and operation from a single, low-voltage supply would be possible. The AD580 circuit provides such a compensating voltage, V_1 in Figure 2, by driving two transistors at different current densities and amplifying the resulting V_{BE} difference (ΔV_{BE} – which now has a positive TC); the sum (V_Z) is then buffered and amplified up to 2.5 volts to provide a usable reference-voltage output. Figure 3 is the schematic diagram of the AD580.

The AD580 operates as a three-terminal reference, which means that no additional components are required for biasing or current setting. The connection diagram, Figure 4 is quite simple.

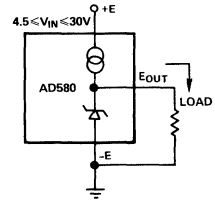

Figure 4. AD580 Connection Diagram

VOLTAGE VARIATION VS. TEMPERATURE

Some confusion exists in the area of defining and specifying reference voltage error over temperature. Historically, references are characterized using a maximum deviation per degree Centigrade; i.e., 10ppm/°C. However, because of the inconsistent nonlinearities in zener references (butterfly or "S" type characteristics), most manufacturers use a maximum limit error band approach to characterize their references. This technique measures the output voltage at 3 to 5 different temperatures and guarantees that the output voltage deviation will fall within the guaranteed error band at these discrete temperatures. This approach, of course, makes no mention or guarantee of performance at any other temperature within the operating temperature range of the device.

The consistent Voltage vs. Temperature performance of a typical AD580 is shown in Figure 5. Note that the characteristic is quasi-parabolic, not the possible "S" type characteristics of classical zener references. This parabolic characteristic permits a maximum output deviation specification over the device's full operating temperature range, rather than just at 3 to 5 discrete temperatures.

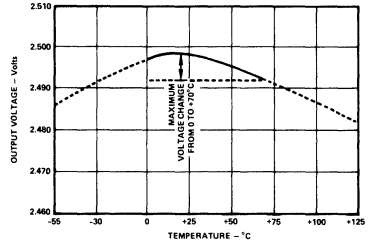

Figure 5. Typical AD580K Output Voltage vs. Temperature

The AD580M guarantees a maximum deviation of 1.75mV over the 0 to +70°C temperature range. This can be shown to be equivalent to 10ppm/°C average maximum; i.e. . .

$$\frac{1.75\text{mV max}}{70^\circ\text{C}} \times \frac{1}{2.5\text{V}} = 10\text{ppm}/^\circ\text{C max average}$$

The AD580 typically exhibits a variation of 1.5mV over the power supply range of 7 to 30 volts. Figure 6 is a plot of AD580 line rejection versus frequency.

NOISE PERFORMANCE

Figure 7 represents the peak-to-peak noise of the AD580 from 1Hz (3dB point) to a 3dB high end shown on the horizontal axis. Peak-to-peak noise from 1Hz to 1MHz is approximately 600μV.

THE AD580 AS A CURRENT LIMITER

The AD580 represents an excellent alternative to current limiter diodes which require factory-selection to achieve a desired current. This approach often results in temperature coefficients of 1%/°C. The AD580 approach is not limited to a specially selected factory set current limit; it can be programmed from 1 to 10mA with the insertion of a single external resistor. The approximate temperature coefficient of current limit for the AD580 used in this mode is 0.13%/°C for I_{LIM} = 1mA and 0.01%/°C for I_{LIM} = 13mA (see Figure 9). Figure 8 displays the high output impedance of the AD580 used as a current limiter for I_{LIM} = 1, 2, 3, 4, 5mA.

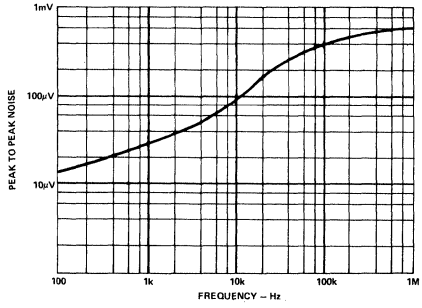

Figure 7. Peak-to-Peak Output Noise vs. Frequency

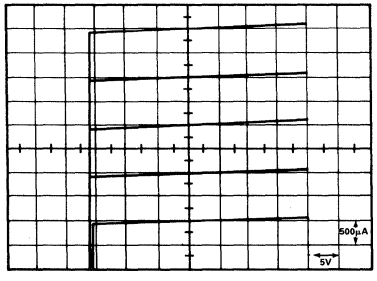

Figure 8. Input Current vs. Input Voltage (Integral Loads)

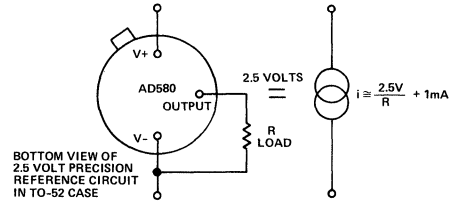

Figure 9. A Two-Component Precision Current Limiter

THE AD580 AS A LOW POWER, LOW VOLTAGE PRECISION REFERENCE FOR DATA CONVERTERS

The AD580 has a number of features that make it ideally suited for use with A/D and D/A data converters used in complex microprocessor-based systems. The calibrated 2.500 volt output minimizes user trim requirements and allows operation from a single low voltage supply. Low power consumption (1mA quiescent current) is commensurate with that of CMOS-type devices, while the low cost and small package complements the decreasing cost and size of the latest converters.

Figure 10 shows the AD580 used as a reference for the AD7542 12-bit CMOS DAC with complete microprocessor interface. The AD580 and the AD7542 are specified to operate from a single 5 volt supply; this eliminates the need to provide a +15 volt power supply for the sole purpose of operating a reference. The AD7542 includes three 4-bit data registers, a 12-bit DAC register, and address decoding logic; it may thus be interfaced directly to a 4-, 8- or 16-bit data bus. Only 8mA of quiescent current from the single +5 volt supply is required to operate the AD7542 which is packaged in a small 16-pin DIP. The AD544 output amplifier is also low power, requiring only 2.5mA quiescent current. Its laser-trimmed offset voltage preserves the ±1/2LSB linearity of the AD7542KN without user trims and it typically settles to ±1/2 LSB in less than 3μs. It will provide the 0 to -2.5 volt output swing from ±5 volt supplies.

TO-5
BOTTOM VIEW

PRODUCT DESCRIPTION

The AD581 is a three-terminal, temperature compensated, monolithic band-gap voltage reference which provides a precise 10.00 volt output from an unregulated input level from 12 to 30 volts. Laser Wafer Trimming (LWT) is used to trim both the initial error at +25°C as well as the temperature coefficient, which results in high precision performance previously available only in expensive hybrids or oven-regulated modules. The 5mV initial error tolerance and 5ppm/°C guaranteed temperature coefficient of the AD581L represent the best performance combination available in a monolithic voltage reference.

The band-gap circuit design used in the AD581 offers several advantages over classical Zener breakdown diode techniques. Most important, no external components are required to achieve full accuracy and stability of significance to low power systems. In addition, total supply current to the device, including the output buffer amplifier (which can supply up to 10mA) is typically 750μA. The long-term stability of the band-gap design is equivalent or superior to selected Zener reference diodes.

The AD581 is recommended for use as a reference for 8-, 10- or 12-bit D/A converters which require an external precision reference. The device is also ideal for all types of A/D converters up to 14 bit accuracy, either successive approximation or integrating designs, and in general can offer better performance than that provided by standard self-contained references.

The AD581J, K, and L are specified for operation from 0 to +70°C; the AD581S, T, and U are specified for the -55°C to +125°C range. All grades are packaged in a hermetically-sealed three-terminal TO-5 metal can.

***Covered by Patent Nos. 3,887,863; RE 30,586**

PRODUCT HIGHLIGHTS

1. Laser trimming of both initial accuracy and temperature coefficient results in very low errors over temperature without the use of external components. The AD581L has a maximum deviation from 10.000 volts of ±7.25mV from 0 to +70°C, while the AD581U guarantees ±15mV maximum total error without external trims from -55°C to +125°C.
2. Since the laser trimming is done on the wafer prior to separation into individual chips, the AD581 will be extremely valuable to hybrid designers for its ease of use, lack of required external trims, and inherent high performance.
3. The AD581 can also be operated in a two-terminal "Zener" mode to provide a precision negative 10 volt reference with just one external resistor to the unregulated supply. The performance in this mode is nearly equal to that of the standard three-terminal configuration.
4. Advanced circuit design using the band-gap concept allows the AD581 to give full performance with an unregulated input voltage down to 13 volts. With an external resistor, the device will operate with a supply as low as 11.4 volts.

APPLYING THE AD581

The AD581 is easy to use in virtually all precision reference applications. The three terminals are simply primary supply, ground, and output, with the case grounded. No external components are required even for high precision applications; the degree of desired absolute accuracy is achieved simply by selecting the required device grade. The AD581 requires less than 1mA quiescent current from an operating supply range of 12 to 30 volts.

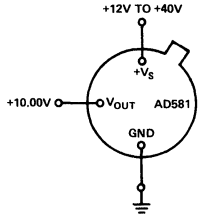

Figure 1. AD581 Pin Configuration (Top View)

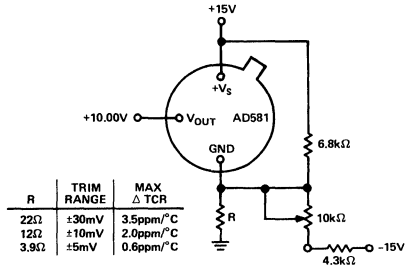
An external fine trim may be desired to set the output level to exactly 10.000 volts within less than a millivolt (calibrated to a main system reference). System calibration may also require a reference slightly different from 10.00 volts. In either case, the optional trim circuit shown in Figure 2 can offset the output by up to ±30 millivolts (with the 22Ω resistor), if needed, with minimal effect on other device characteristics.



R	TRIM RANGE	MAX Δ TCR
22Ω	±30mV	3.5ppm/°C
12Ω	±10mV	2.0ppm/°C
3.9Ω	±5mV	0.6ppm/°C

VOLTAGE VARIATION vs. TEMPERATURE

Some confusion exists in the area of defining and specifying reference voltage error over temperature. Historically, references have been characterized using a maximum deviation per degree Centigrade; i.e., 10ppm/°C. However, because of nonlinearities in temperature characteristics, which originated in standard Zener references (such as "S" type characteristics) most manufacturers have begun to use a maximum limit error band approach to specify devices. This technique involves measurement of the output at 3, 5 or more different temperatures to guarantee that the output voltage will fall within the given error band. The temperature characteristic of the AD581 consistently follows the S-curve shown in Figure 4. Five-point measurement of each device guarantees the error band over the -55°C to +125°C range; three-point measurement guarantees the error band from 0 to +70°C.

The error band which is guaranteed with the AD581 is the maximum deviation from the initial value at +25°C; this error band is of more use to a designer than one which simply guarantees the maximum total change over the entire range (i.e., in the latter definition, all of the changes could occur in the positive direction). Thus, with a given grade of the AD581, the designer can easily determine the maximum total error from initial tolerance plus temperature variation (e.g., for the AD581T, the initial tolerance is ±10mV, the temperature error band is ±15mV, thus the unit is guaranteed to be 10.000 volts ±25mV from -55°C to +125°C).

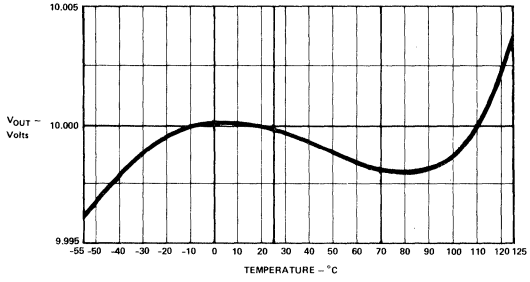

Figure 4. Typical Temperature Characteristic

OUTPUT CURRENT CHARACTERISTICS

The AD581 has the capability to either source or sink current and provide good load regulation in either direction, although it has better characteristics in the source mode (positive current into the load). The circuit is protected for shorts to either positive supply or ground. The output voltage vs. output current characteristics of the device are shown in Figure 5. Source current is displayed as negative current in the figure; sink current is positive. Note that the short circuit current (i.e., zero volts output) is about 28mA; when shorted to +15 volts, the sink current goes to about 20mA.

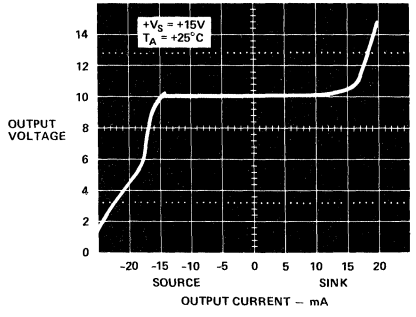

Figure 5. AD581 Output Voltage vs. Sink and Source Current

DYNAMIC PERFORMANCE

Many low power instrument manufacturers are becoming increasingly concerned with the turn-on characteristics of the components being used in their systems. Fast turn-on components often enable the end user to keep power off when not needed, and yet respond quickly when the power is turned on for operation. Figure 6 displays the turn-on characteristic of the AD581. This characteristic is generated from cold-start operation and represents the true turn-on waveform after an extended period with the supplies off. The figure shows both the coarse and fine transient characteristics of the device; the total settling time to within ±1 millivolt is about 180μs, and there is no long thermal tail appearing after the point.

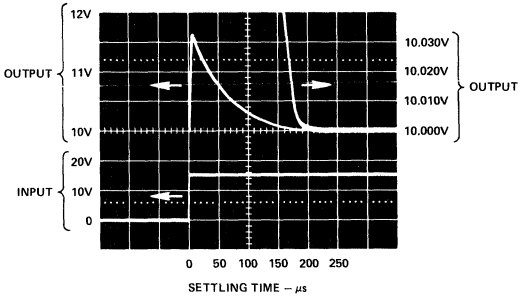

Figure 6. Output Settling Characteristic

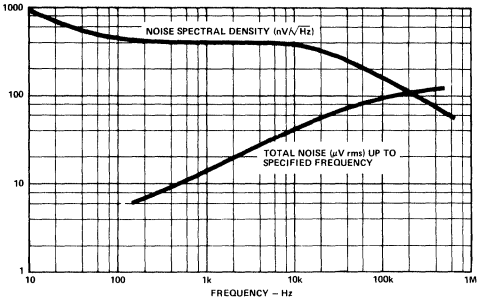

Figure 7. Spectral Noise Density and Total rms Noise vs. Frequency

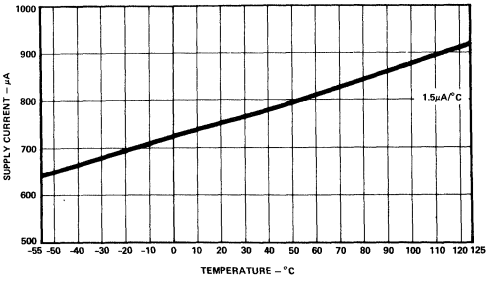

Figure 8. Quiescent Current vs. Temperature

PRECISION HIGH CURRENT SUPPLY

The AD581 can be easily connected with power pnp or power darlington pnp devices to provide much greater output current capability. The circuit shown in Figure 9 delivers a precision 10 volt output with up to 4 amperes supplied to the load. The 0.1μF capacitor is required only if the load has a significant capacitive component. If the load is purely resistive, improved high frequency supply rejection results from removing the capacitor.

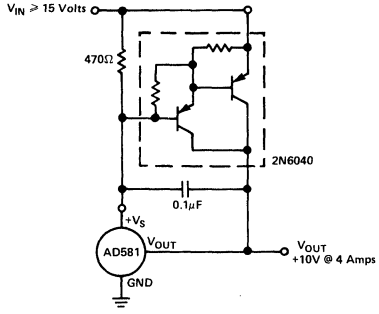

Figure 9. High Current Precision Supply

CONNECTION FOR REDUCED PRIMARY SUPPLY

While line regulation is specified down to 13 volts, the typical AD581 will work as specified down to 12 volts or below. The current sink capability allows even lower supply voltage capability such as operation from 12V ±5% as shown in Figure 10. The 560Ω resistor reduces the current supplied by the AD581 to a manageable level at full 5mA load. Note that the other bandgap references, without current sink capability, may be damaged by use in this circuit configuration.

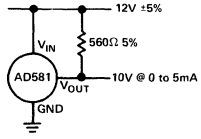

Figure 10. 12-Volt Supply Connection

THE AD581 AS A CURRENT LIMITER

The AD581 represents an alternative to current limiter diodes which require factory selection to achieve a desired current. This approach often results in temperature coefficients of 1%/°C. The AD581 approach is not limited to a defined set current limit; it can be programmed from 0.75 to 5mA with the insertion of a single external resistor. Of course, the minimum voltage required to drive the connection is 13 volts. The AD580, which is a 2.5 volt reference, can be used in this type of circuit with compliance voltage down to 4.5 volts.

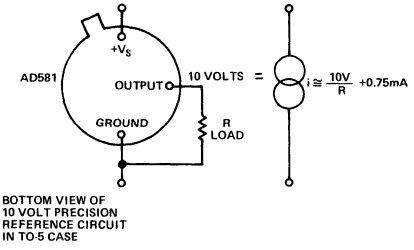

Figure 11. A Two-Component Precision Current Limiter

NEGATIVE 10-VOLT REFERENCE

The AD581 can also be used in a two-terminal "Zener" mode to provide a precision -10.00 volt reference. As shown in Figure 13, the V_{IN} and V_{OUT} terminals are connected together to the high supply (in this case, ground). The ground pin is connected through a resistor to the negative supply. The output is now taken from the ground pin instead of V_{OUT}. With 1mA flowing through the AD581 in this mode, a typical unit will show a 2mV increase in output level over that produced in the three-terminal mode. Note also that the effective output impedance in this connection increases from 0.2Ω typical to 2 ohms. It is essential to arrange the output load and the supply resistor, R_S, so that the net current through the AD581 is always between 1 and 5mA. The temperature characteristics and long-term stability of the device will be essentially the same as that of a unit used in the standard three-terminal mode. The operating temperature range is limited to -55°C to +85°C.

The AD581 can also be used in a two-terminal mode to develop a positive reference. V_{IN} and V_{OUT} are tied together and to the positive supply through an appropriate supply resistor. The performance characteristics will be similar to those of the negative two-terminal connection. The only advantage of this connection over the standard three-terminal connection is that a lower primary supply can be used, as low as 10.5 volts. This type of operation will require considerable attention to load and primary supply regulation to be sure the AD581 always remains within its regulating range of 1 to 5mA.

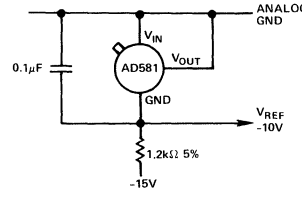

Figure 12. Two-Terminal −10 Volt Reference

10 VOLT REFERENCE WITH MULTIPLYING CMOS D/A OR A/D CONVERTERS

The AD581 is ideal for application with the entire AD7533 series of 10- and 12-bit multiplying CMOS D/A converters, especially for low power applications. It is equally suitable for the AD7574 8-bit A/D converter. In the standard hook-up, as shown in Figure 14, the +10 volt reference is inverted by the amplifier/DAC configuration to produce a 0 to -10 volt range. If an AD308 amplifier is used, total quiescent supply current will typically be 2mA. If a 0 to +10 volt full scale range is desired, the AD581 can be connected to the CMOS DAC in its -10 volt "Zener" mode, as shown in Figure 12 (the $-10V_{REF}$ output is connected directly to the $V_{REF\ IN}$ of the CMOS DAC). The AD581 will normally be used in the -10 volt mode with the AD7574 to give a 0 to +10 volt ADC range. This is shown in Figure 14. Bipolar output applications and other operating details can be found in the data sheets for the CMOS products.

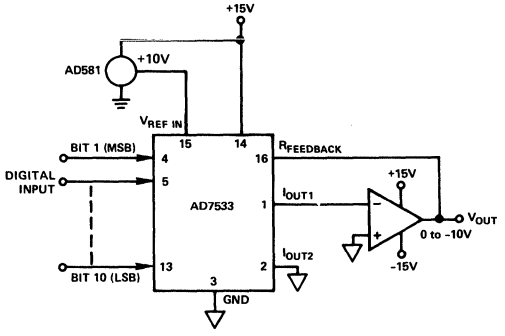

Figure 13. Low Power 10-Bit CMOS DAC Application

PRECISION 12-BIT D/A CONVERTER REFERENCE

The AD562, like most D/A converters, is designed to operate with a +10 volt reference element. In the AD562, this 10 volt reference voltage is converted into a reference current of approximately 0.5mA via the internal 19.95kΩ resistor (in series with the external 100Ω trimmer). The gain temperature coefficient of the AD562 is primarily governed by the temperature tracking of the 19.95kΩ resistor and the 5k/10k span resistors; this gain T.C. is guaranteed to 3ppm/°C. Thus, using the AD581L (at 5ppm/°C) as the 10 volt reference guarantees a maximum full scale temperature coefficient of 8ppm/°C over the commercial range. The 10 volt reference also supplies the normal 1mA bipolar offset current through the 9.95k bipolar offset resistor. The bipolar offset T.C. thus depends only on the T.C. matching of the bipolar offset resistor to the input reference resistor and is guaranteed to 3ppm/°C.

PRODUCT DESCRIPTION

The AD584 is an eight-terminal precision voltage reference offering pin-programmable selection of four popular output voltages: 10.000V, 7.500V, 5.000V and 2.500V. Other output voltages, above, below or between the four standard outputs, are available by the addition of external resistors. Input voltage may vary between 4.5 and 30 volts.

Laser Wafer Trimming (LWT) is used to adjust the pin-programmable output levels and temperature coefficients, resulting in the most flexible high precision voltage reference available in monolithic form.

In addition to the programmable output voltages, the AD584 offers a unique strobe terminal which permits the device to be turned on or off. When the AD584 is used as a power supply reference, the supply can be switched off with a single, low-power signal. In the "off" state the current drain by the AD584 is reduced to about 100μA. In the "on" state the total supply current is typically 750μA including the output buffer amplifier.

The AD584 is recommended for use as a reference for 8-, 10- or 12-bit D/A converters which require an external precision reference. The device is also ideal for all types of A/D converters of up to 14 bit accuracy, either successive approximation or integrating designs, and in general can offer better performance than that provided by standard self-contained references.

The AD584J, K, and L are specified for operation from 0 to +70°C and packaged in 8-pin plastic package; the AD584S and T are specified for the -55°C to-+125°C range. All grades are packaged in a hermetically sealed eight-terminal TO-99 metal can and 20-pin LCC for surface mount applications.

***Covered by U.S. Patent No. 3,887,863; RE 30,586**

PRODUCT HIGHLIGHTS

1. The flexibility of the AD584 eliminates the need to design-in and inventory several different voltage references. Furthermore one AD584 can serve as several references simultaneously when buffered properly.
2. Laser trimming of both initial accuracy and temperature coefficient results in very low errors over temperature without the use of external components. The AD584LH has a maximum deviation from 10.000 volts of ±7.25mV from 0 to +70°C.
3. The AD584 can be operated in a two-terminal "Zener" mode at 5 volts output and above. By connecting the input and the output, the AD584 can be used in this "Zener" configuration as a negative reference.
4. The output of the AD584 is configured to sink or source currents. This means that small reverse currents can be tolerated in circuits using the AD584 without damage to the reference and without disturbing the output voltage (10V, 7.5V and 5V outputs).

Applying the AD584

APPLYING THE AD584

With power applied to pins 8 and 4 and all other pins open the AD584 will produce a buffered nominal 10.0V output between pins 1 and 4 (see Figure 1). The stabilized output voltage may be reduced to 7.5V, 5.0V or 2.5V by connecting the programming pins as follows:

OUTPUT VOLTAGE	PIN PROGRAMMING
7.5V	Join the 2.5V and 5.0V pins (2) and (3).
5.0V	Connect the 5.0V pin (2) to the output pin (1).
2.5V	Connect the 2.5V pin (3) to the output pin (1).

The options shown above are available without the use of any additional components. Multiple outputs using only one AD584, are also possible by simply buffering each voltage programming pin with a unity-gain noninverting op amp.

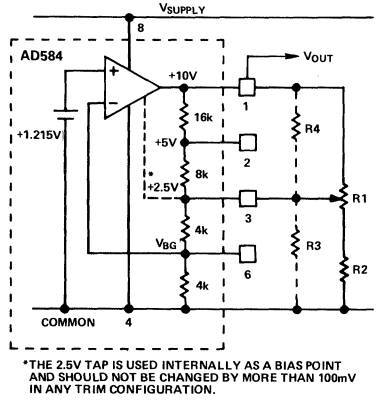

Figure 1. Variable Output Options

The AD584 can also be programmed over a wide range of output voltages, including voltages greater than 10V, by the addition of one or more external resistors. Figure 1 illustrates the general adjustment procedure, with approximate values given for the internal resistors of the AD584. The AD584 may be modeled as an op amp with a noninverting feedback connection, driven by a high stability 1.215 volt bandgap reference (see Figure 3 for schematic).

When the feedback ratio is adjusted with external resistors, the output amplifier can be made to multiply the reference voltage by almost any convenient amount, making popular outputs of 10.24V, 5.12V, 2.56V or 6.3V easy to obtain. The most general adjustment (which gives the greatest range and poorest resolution) uses R1 and R2 alone (see Figure 1). As R1 is adjusted to its upper limit the 2.5V pin 3 will be connected to the output, which will reduce to 2.5V. As R1 is adjusted to its lower limit, the output voltage will rise to a value limited by R2. For example, if R2 is about 6kΩ, the upper limit of the output range will be about 20V even for large values of R1. R2 should not be omitted; its value should be chosen to limit the output to a value which can be tolerated by the load circuits. If R2 is zero, adjusting R1 to its lower limit will result in a loss of control over the output voltage. If precision voltages are required to be set at levels other than the standard outputs, the 20% absolute tolerance in the internal resistor ladder must be accounted for.

Alternatively, the output voltage can be raised by loading the 2.5V tap with R3 alone. The output voltage can be lowered by connecting R4 alone. Either of these resistors can be a fixed resistor selected by test or an adjustable resistor. In all cases the resistors should have a low temperature coefficient to match the AD584 internal resistors, which have a negative T.C. less than 60ppm/°C. If both R3 and R4 are used, these resistors should have matched temperature coefficients.

When only small adjustments or trims are required, the circuit of Figure 2 offers better resolution over a limited trim range. The circuit can be programmed to 5.0V, 7.5V or 10V and adjusted by means of R1 over a range of about ±200mV. To trim the 2.5V output option, R2 (Figure 2) can be reconnected to the bandgap reference (pin 6). In this configuration, the adjustment should be limited to ±100mV in order to avoid affecting the performance of the AD584.

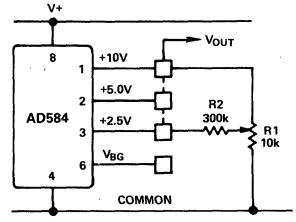

Figure 2. Output Trimming

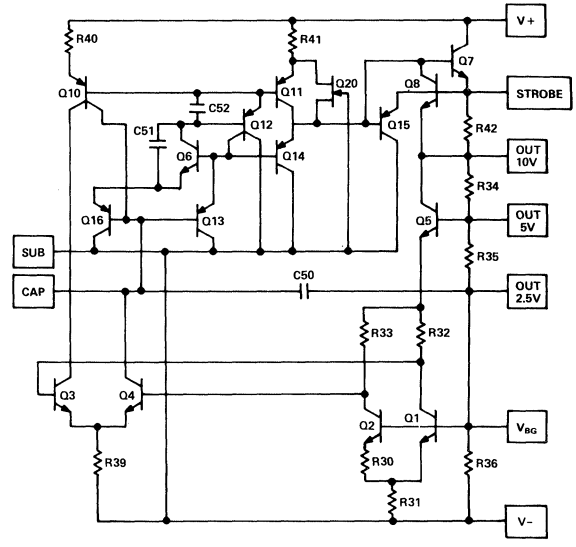

Figure 3. Schematic Diagram

PERFORMANCE OVER TEMPERATURE

Each AD584 is tested at five temperatures over the -55°C to +125°C range to ensure that each device falls within the Maximum Error Band (see Figure 4) specified for a particular grade (i.e., S and T grades); three-point measurement guarantees performance within the error band from 0 to +70°C (i.e., J, K, or L grades). The error band guaranteed for the AD584 is the maximum deviation from the initial value at +25°C. Thus, given the grade of the AD584, the designer can easily determine the maximum total error from initial tolerance plus temperature variation. For example, for the AD584T, the initial tolerance is ±10mV and the error band is ±15mV. Hence, the unit is guaranteed to be 10.000 volts ±25mV from -55°C to +125°C.

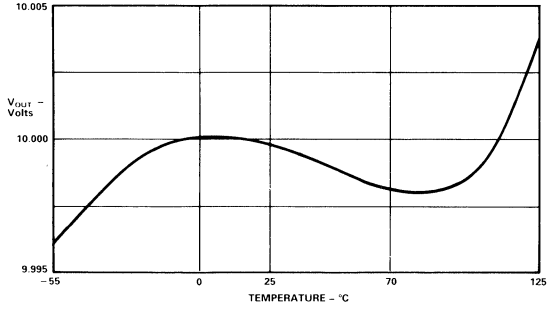

Figure 4. Typical Temperature Characteristic

OUTPUT CURRENT CHARACTERISTICS

The AD584 has the capability to either source or sink current and provide good load regulation in either direction, although it has better characteristics in the source mode (positive current into the load). The circuit is protected for shorts to either positive supply or ground. The output voltage vs. output current characteristics of the device is shown in Figure 5. Source current is displayed as negative current in the figure; sink current is positive. Note that the short circuit current (i.e., zero volts output) is about 28mA; when shorted to +15 volts, the sink current goes to about 20mA.

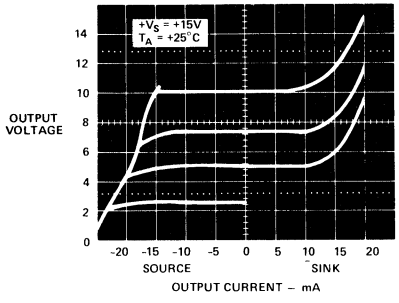

Figure 5. AD584 Output Voltage vs. Sink and Source Current

DYNAMIC PERFORMANCE

Many low power instrument manufacturers are becoming increasingly concerned with the turn-on characteristics of the components being used in their systems. Fast turn-on components often enable the end user to keep power off when not needed, and yet respond quickly when the power is turned on for operation. Figure 6 displays the turn-on characteristic of the AD584. Figure 6a is generated from cold-start operation and represents the true turn-on waveform after an extended period with the supplies off. The figure shows both the coarse and fine transient characteristics of the device; the total settling time to within ±1 millivolt is about 180μs, and there is no long thermal tail appearing after the point.

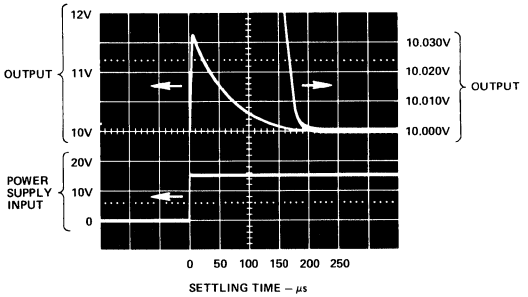

Figure 6. Output Settling Characteristic

NOISE FILTERING

The bandwidth of the output amplifier in the AD584 can be reduced to filter the output noise. A capacitor ranging between 0.01μF and 0.1μF connected between the Cap and V_{BG} terminals will further reduce the wideband and feedthrough noise in the output of the AD584, as shown in Figure 8. However, this will tend to increase the turn-on settling time of the device so ample warm-up time should be allowed.

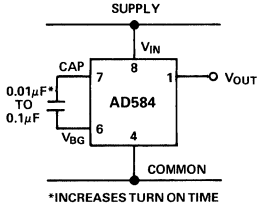

Figure 7. Additional Noise Filtering with an External Capacitor

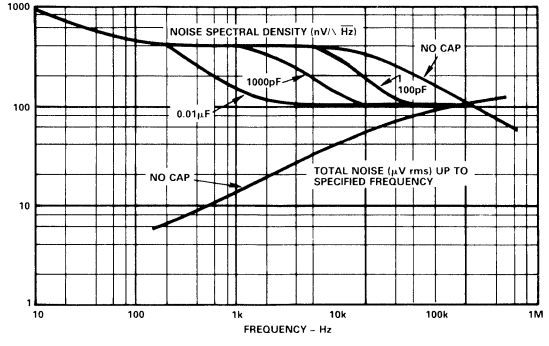

Figure 8. Spectral Noise Density and Total rms Noise vs. Frequency

Applications of the AD584

USING THE STROBE TERMINAL

The AD584 has a strobe input which can be used to zero the output. This unique feature permits a variety of new applications in signal and power conditioning circuits.

Figure 9 illustrates the strobe connection. A simple NPN switch can be used to translate a TTL logic signal into a strobe of the output. The AD584 operates normally when there is no current drawn from pin 5. Bringing this terminal low, to less than 200mV, will allow the output voltage to go to zero. In this mode the AD584 should not be required to source or sink current (unless a 0.7V residual output is permissible). If the AD584 is required to sink a transient current while strobed off, the strobe terminal input current should be limited by a 100Ω resistor as shown in Figure 9.

The strobe terminal will tolerate up to 5μA leakage and its driver should be capable of sinking 500μA continuous. A low leakage open collector gate can be used to drive the strobe terminal directly, provided the gate can withstand the AD584 output voltage plus one volt.

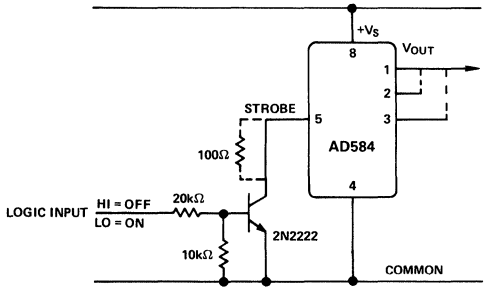

Figure 9. Use of the Strobe Terminal

PRECISION HIGH CURRENT SUPPLY

The AD584 can be easily connected to a power PNP or power Darlington PNP device to provide much greater output current capability. The circuit shown in Figure 10 delivers a precision 10 volt output with up to 4 amperes supplied to the load. The 0.1μF capacitor is required only if the load has a significant capacitive component. If the load is purely resistive, improved high frequency supply rejection results from removing the capacitor.

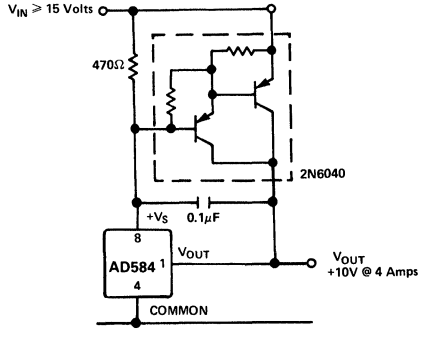

Figure 10. High Current Precision Supply

The AD584 can also use an NPN or Darlington NPN transistor to boost its output current. Simply connect the 10V output terminal of the AD584 to the base of the NPN booster and take the output from the booster emitter as shown in Figure 11. The 5.0V or 2.5V pin must connect to the actual output in this configuration. Variable or adjustable outputs (as shown in Figures 1 and 2) may be combined with +5.0V connection to obtain outputs above +5.0V.

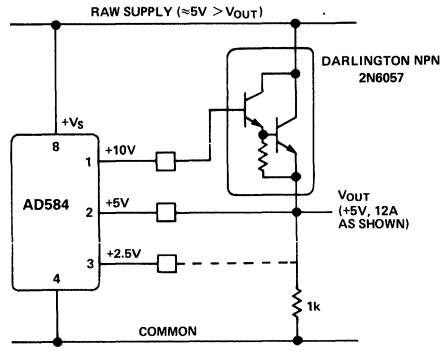

Figure 11. NPN Output Current Booster

THE AD584 AS A CURRENT LIMITER

The AD584 represents an alternative to current limiter diodes which require factory selection to achieve a desired current. Use of current limiting diodes often results in temperature coefficients of 1%/°C. Use of the AD584 in this mode is not limited to a set current limit; it can be programmed from 0.75 to 5mA with the insertion of a single external resistor (see Figure 12). Of course, the minimum voltage required to drive the connection is 5 volts.

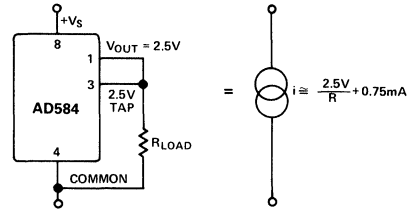

Figure 12. A Two-Component Precision Current Limiter

NEGATIVE REFERENCE VOLTAGES FROM AN AD584

The AD584 can also be used in a two-terminal "zener" mode to provide a precision -10, -7.5 or -5.0 volt reference. As shown in Figure 13, the V_{IN} and V_{OUT} terminals are connected together to the positive supply (in this case, ground). The AD584 common pin is connected through a resistor to the negative supply. The output is now taken from the common pin instead of V_{OUT}. With 1mA flowing through the AD584 in this mode, a typical unit will show a 2mV increase in output level over that produced in the three-terminal mode. Note also that the effective output impedance in this connection increases from 0.2Ω typical to 2Ω. It is essential to arrange the output load and the supply resistor, R_S, so that the net current through the AD584 is always between 1 and 5mA. The temperature characteristics and long-term stability of the

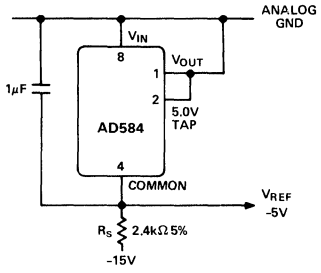

Figure 13. Two-Terminal -5 Volt Reference

device will be essentially the same as that of a unit used in the standard three-terminal mode. The operating temperature range is limited to -55°C to +85°C.

The AD584 can also be used in a two-terminal mode to develop a positive reference. V_{IN} and V_{OUT} are tied together and to the positive supply through an appropriate supply resistor. The performance characteristics will be similar to those of the negative two-terminal connection. The only advantage of this connection over the standard three-terminal connection is that a lower primary supply can be used, as low as 0.5 volts above the desired output voltage. This type of operation will require considerable attention to load and primary supply regulation to be sure the AD584 always remains within its regulating range of 1 to 5mA.

10 VOLT REFERENCE WITH MULTIPLYING CMOS D/A OR A/D CONVERTERS

The AD584 is ideal for application with the entire AD7520 series of 10- and 12-bit multiplying CMOS D/A converters, especially for low power applications. It is equally suitable for the AD7574 8-bit A/D converter. In the standard hook-up as shown in Figure 14, the standard output voltages are inverted by the amplifier/DAC configuration to produce converted voltage ranges. For example, a +10V reference produces a 0 to -10V range. If an AD308 amplifier is used, total quiescent supply current will typically be 2mA. The AD584 will normally be used in the -10 volt mode with the AD7574 to give a 0 to +10 volt ADC range. This is shown in Figure 16. Bipolar output applications and other operating details can be found in the data sheets for the CMOS products.

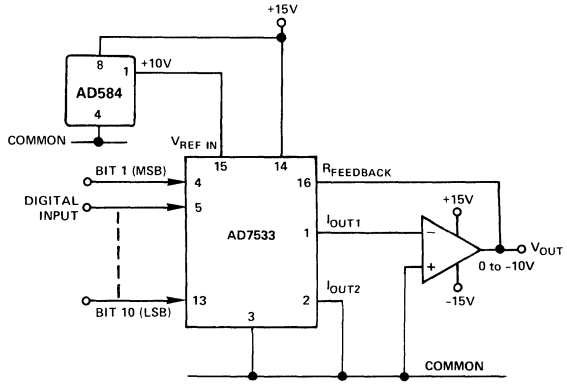

Figure 14. Low Power 10-Bit CMOS DAC Application

PRECISION D/A CONVERTER REFERENCE

The AD562, like many D/A converters, is designed to operate with a +10 volt reference element (Figure 15). In the AD562, this 10 volt reference voltage is converted into a reference current of approximately 0.5mA via the internal 19.95kΩ resistor (in series with the external 100Ω trimmer). The gain temperature coefficient of the AD562 is primarily governed by the temperature tracking of the 19.95kΩ resistor and the 5k/10k

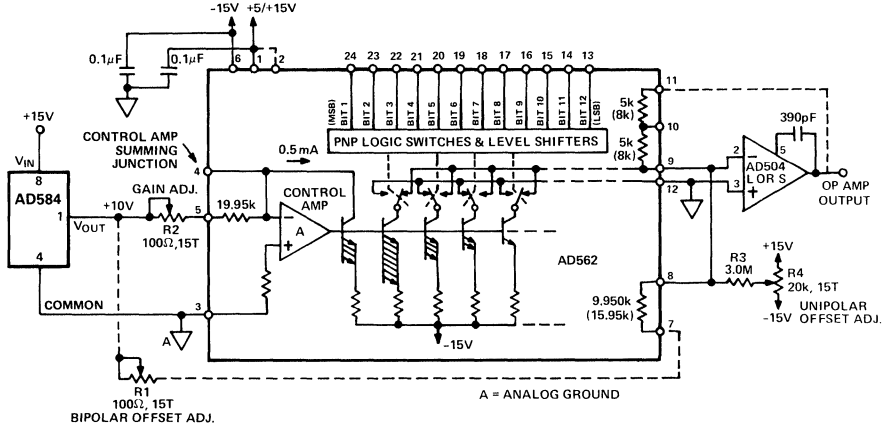

Figure 15. Precision 12-Bit D/A Converter

span resistors; this gain T.C. is guaranteed to 3ppm/°C. Thus, using the AD584L (at 5ppm/°C) as the 10 volt reference guarantees a maximum full scale temperature coefficient of 8ppm/°C over the commercial range. The 10 volt reference also supplies the normal 1mA bipolar offset current through the 9.95k bipolar offset resistor. The bipolar offset T.C. thus depends only on the T.C. matching of the bipolar offset resistor to the input reference resistor and is guaranteed to 3ppm/°C. Figure 17 demonstrates the flexibility of the AD584 applied to another popular D/A configuration.

PRODUCT DESCRIPTION

The AD586 represents a major advance in the state-of-the-art in monolithic voltage references. Using a proprietary ion-implanted buried Zener diode and laser wafer trimming of high stability thin-film resistors, the AD586 provides outstanding performance at low cost.

The AD586 offers much higher performance than most other 5V references. Because the AD586 uses an industry standard pinout, many systems can be upgraded instantly with the AD586. The buried Zener approach to reference design provides lower noise and drift than bandgap voltage references. The AD586 offers a noise reduction pin which can be used to further reduce the noise level generated by the buried Zener.

The AD586 is recommended for use as a reference for 8-, 10-, 12-, 14- or 16-bit D/A converters which require an external precision reference. The device is also ideal for successive approximation or integrating A/D converters with up to 14 bits of accuracy and, in general, can offer better performance than the standard on-chip references.

The AD586J, K and L are specified for operation from 0 to +70°C, and the AD586S and T are specified for −55°C to +125°C operation. All grades are packaged in an 8-pin cerdip package. The AD586J and the AD586K are also available in an 8-pin plastic surface mount small outline (SO) package.

PRODUCT HIGHLIGHTS

1. Laser trimming of both initial accuracy and temperature coefficients results in very low errors over temperature without the use of external components. The AD586L has a maximum deviation from 5.000V of ±3.625mV between 0 and +70°C, and the AD586T guarantees ±7.5mV maximum total error between −55°C and +125°C.
2. For applications requiring higher precision, an optional fine-trim connection is provided.
3. Any system using an industry standard pinout reference can be upgraded instantly with the AD586.
4. Output noise of the AD586 is very low, typically 4μV p-p. A noise reduction pin is provided for additional noise filtering using an external capacitor.

NOTES

[1]Maximum output voltage drift is guaranteed for all packages and grades. Cerdip packaged parts are also 100% production tested.

[2]The operating temperature ranged is defined as the temperatures extremes at which the device will still function. Parts may deviate from their specified performance outside their specified temperature range.

Specifications subject to change without notice.

Specifications in boldface are tested on all production units at final electrical test. Result from those tests are used to calculate outgoing quality levels. All min and max specifications are guaranteed, although only those shown in boldface are tested on all production units unless otherwise specified.

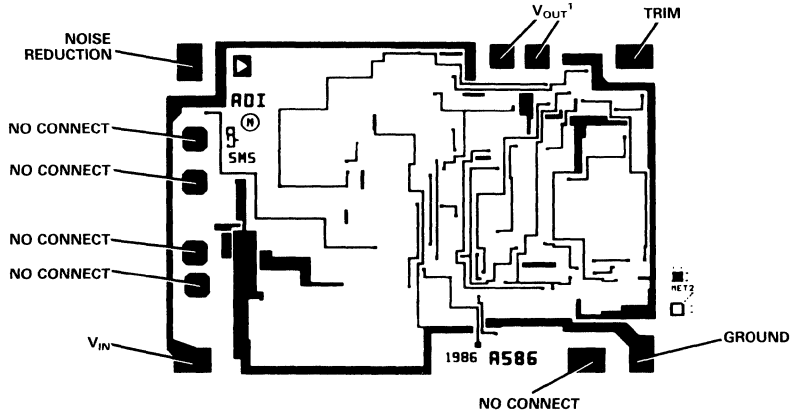
DIE LAYOUT



Die Size: 0.081 × 0.060 inches

NOTES

[1]Both V_{OUT} pads should be connected to the output.

Die Thickness: The standard thickness of Analog Devices Bipolar dice is 24 mils ± 2 mils.

Die Dimensions: The dimensions given have a tolerance of ± 2 mils.

Backing: The standard backside surface is silicon (not plated). Analog Devices does not recommend gold-backed dice for most applications.

Edges: A diamond saw is used to separate wafers into dice thus providing perpendicular edges half-way through the die. In contrast to scribed dice, this technique provides a more uniform die shape and size. The perpendicular edges facilitate handling (such as tweezer pick-up) while the uniform shape and size simplifies substrate design and die attach.

Top Surface: The standard top surface of the die is covered by a layer of glassivation. All areas are covered except bonding pads and scribe lines.

Surface Metalization: The metalization to Analog Devices bipolar dice is aluminum. Minimum thickness is 10,000Å.

Bonding Pads: All bonding pads have a minimum size of 4 mils by 4 mils. The passivation windows have 3.5 mils by 3.5 mils minimum.

THEORY OF OPERATION

The AD586 consists of a proprietary buried Zener diode reference, an amplifier to buffer the output and several high stability thin-film resistors as shown in the block diagram in Figure 1. This design results in a high precision monolithic 5V output reference with initial offset of 2.5mV or less. The temperature compensation circuitry provides the device with a temperature coefficient of under 5 ppm/°C.

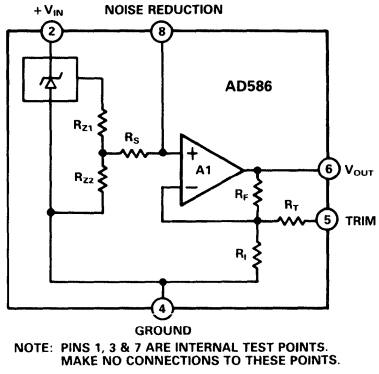

Figure 1. AD586 Functional Block Diagram

Using the bias compensation resistor between the Zener output and the noninverting input to the amplifier, a capacitor can be added at the NOISE REDUCTION pin (Pin 8) to form a low pass filter and reduce the noise contribution of the Zener to the circuit.

APPLYING THE AD586

The AD586 is simple to use in virtually all precision reference applications. When power is applied to Pin 2 and Pin 4 is grounded, Pin 6 provides a 5V output. No external components are required; the degree of desired absolute accuracy is achieved simply by selecting the required device grade. The AD586 requires less than 3mA quiescent current from an operating supply of +12V or +15V.

An external fine trim may be desired to set the output level to exactly 5.000V (calibrated to a main system reference). System calibration may also require a reference voltage that is slightly different from 5.000V, for example, 5.12V for binary applications. In either case, the optional trim circuit shown in Figure 2 can offset the output by as much as 300mV, if desired, with minimal effect on other device characteristics.

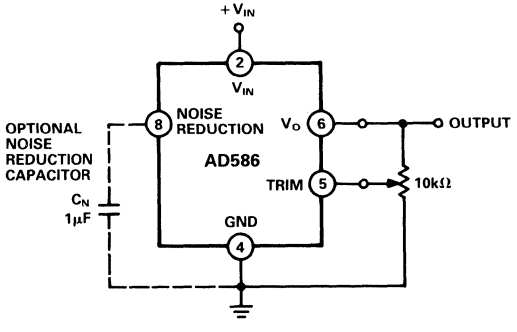

Figure 2. Optional Fine Trim Configuration

NOISE PERFORMANCE AND REDUCTION

The noise generated by the AD586 is typically less than 4μV p-p over the 0.1Hz to 10Hz band. Noise in a 1MHz bandwidth is approximately 200μV p-p. The dominant source of this noise is the buried Zener which contributes approximately $100nV/\sqrt{Hz}$. In comparison, the op amp's contribution is negligible. Figure 3 shows the 0.1Hz to 10Hz noise of a typical AD586. The noise measurement is made with a bandpass filter made of a 1-pole high-pass filter with a corner frequency at 0.1Hz and a 2-pole low-pass filter with a corner frequency at 12.6Hz to create a filter with a 9.922Hz bandwidth.

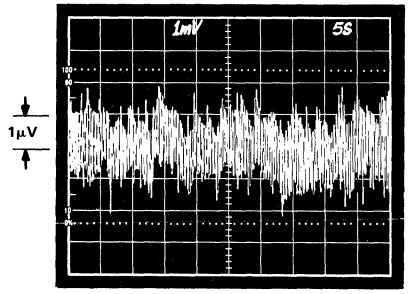

Figure 3. 0.1Hz to 10Hz Noise

If further noise reduction is desired, an external capacitor may be added between the NOISE REDUCTION pin and ground as shown in Figure 2. This capacitor, combined with the 4kΩ R_S and the Zener resistances form a low-pass filter on the output of the Zener cell. A 1μF capacitor will have a 3dB point at 12Hz, and it will reduce the high-frequency (to 1MHz) noise to about 160μV p-p. Figure 4 shows the 1MHz noise of a typical AD586 both with and without a 1μF capacitor.

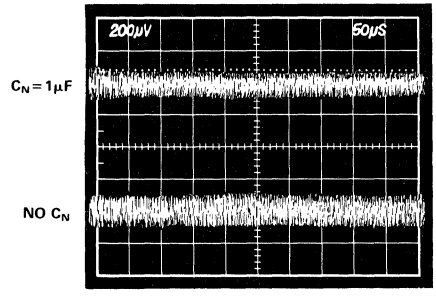

Figure 4. Effect of 1μF Noise Reduction Capacitor on Broadband Noise

TURN-ON TIME

Upon application of power (cold start), the time required for the output voltage to reach its final value within a specified error band is defined as the turn-on settling time. Two components normally associated with this are: the time for the active circuits to settle, and the time for the thermal gradients on the chip to stabilize. Figure 5 shows the turn-on characteristics of the AD586. It shows the settling to be about 60μsec to 0.01%. Note the absence of any thermal tails when the horizontal scale is expanded to 1ms/cm in Figure 5b.

Output turn-on time is modified when an external noise reduction capacitor is used. When present, this capacitor acts as an additional load to the internal Zener diode's current source, resulting in a somewhat longer turn-on time. In the case of a 1μF capacitor, the initial turn-on time is approximately 400ms to 0.01% (see Figure 5c).

DYNAMIC PERFORMANCE

The output buffer amplifier is designed to provide the AD586 with static and dynamic load regulation superior to less complete references.

Many A/D and D/A converters present transient current loads to the reference, and poor reference response can degrade the converter's performance.

Figure 6 displays the characteristics of the AD586 output amplifier driving a 0 to 10mA load.

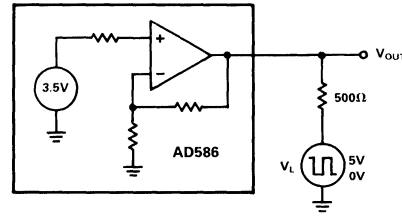

Figure 6a. Transient Load Test Circuit

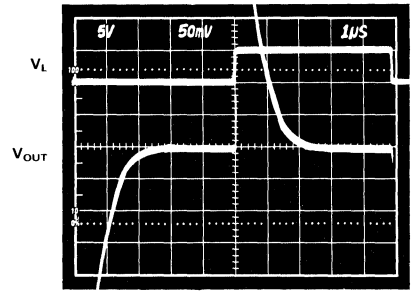

Figure 6b. Large-Scale Transient Response

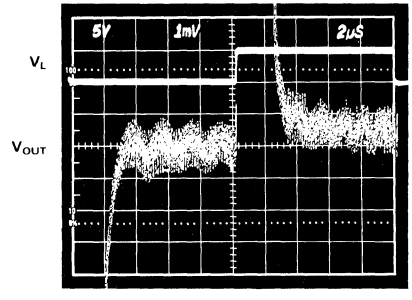

Figure 6c. Fine-Scale Settling for Transient Load

In some applications, a varying load may be both resistive and capacitive in nature, or the load may be connected to the AD586 by a long capacitive cable.

Figure 7 displays the output amplifier characteristics driving a 1000pF, 0 to 10mA load.

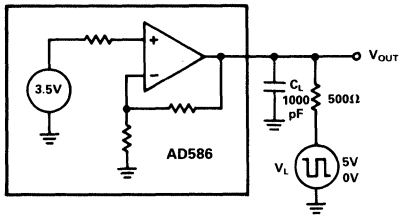

Figure 7a. Capacitive Load Transient Response Test Circuit

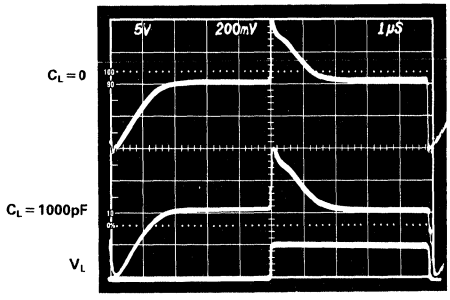

Figure 7b. Output Response with Capacitive Load

LOAD REGULATION

The AD586 has excellent load regulation characteristics. Figure 8 shows that varying the load several mA changes the output by a few μV. The AD586 has somewhat better load regulation performance sourcing current than sinking current.

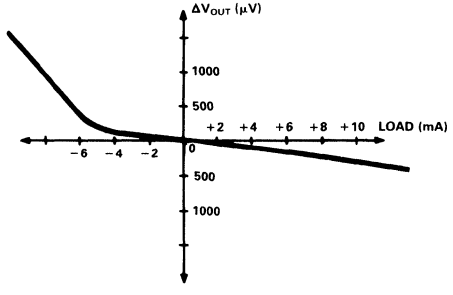

Figure 8. Typical Load Regulation Characteristics

TEMPERATURE PERFORMANCE

The AD586 is designed for precision reference applications where temperature performance is critical. Extensive temperature testing ensures that the device's high level of performance is maintained over the operating temperature range.

Some confusion exists in the area of defining and specifying reference voltage error over temperature. Historically, references have been characterized using a maximum deviation per degree Centrigrade; i.e., ppm/°C. However, because of nonlinearities in temperature characteristics which originated in standard Zener references (such as "S" type characteristics), most manufacturers have begun to use a maximum limit error band approach to specify devices. This technique involves the measurement of the output at three or more different temperatures to specify an output voltage error band.

Figure 9 shows the typical output voltage drift for the AD586L and illustrates the test methodology. The box in Figure 9 is bounded on the sides by the operating temperature extremes, and on the top and the bottom by the maximum and minimum output voltages measured over the operating temperature range. The slope of the diagonal drawn from the lower left to the upper right corner of the box determines the performance grade of the device.

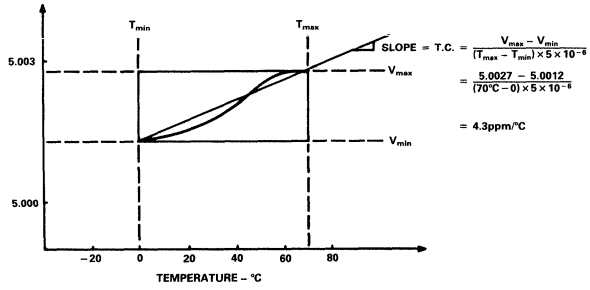

Figure 9. Typical AD586L Temperature Drift

Each AD586JQ, KQ and LQ grade unit is tested at 0, +25°C and +70°C. Each AD586SQ and TQ grade unit is tested at −55°C, +25°C and +125°C. This approach ensures that the variations of output voltage that occur as the temperature changes within the specified range will be contained within a box whose diagonal has a slope equal to the maximum specified drift. The position of the box on the vertical scale will change from device to device as initial error and the shape of the curve vary. The maximum height of the box for the appropriate temperature range and device grade is shown in Figure 10. Duplication of these results requires a combination of high accuracy and stable temperature control in a test system. Evaluation of the AD586 will produce a curve similar to that in Figure 9, but output readings may vary depending on the test methods and equipment utilized.

DEVICE GRADE	MAXIMUM OUTPUT CHANGE (mV)	
	0 TO +70°C	−55°C TO +125°C
AD586J	8.75	
AD586K	5.25	
AD586L	1.75	
AD586S		18.00
AD586T		9.00

Figure 10. Maximum Output Change in mV

NEGATIVE REFERENCE VOLTAGE FROM AN AD586

The AD586 can be used to provide a precision −5.000V output as shown in Figure 11. The V_{IN} pin is tied to at least a +6V supply, the output pin is grounded, and the AD586 ground pin is connected through a resistor, R_S, to a −15V supply. The −5V output is now taken from the ground pin (Pin 4) instead of V_{OUT}. It is essential to arrange the output load and the supply resistor R_S so that the net current through the AD586 is between 2.5mA and 10.0mA. The temperature characteristics and long-term stability of the device will be essentially the same as that of a unit used in the standard +5V output configuration.

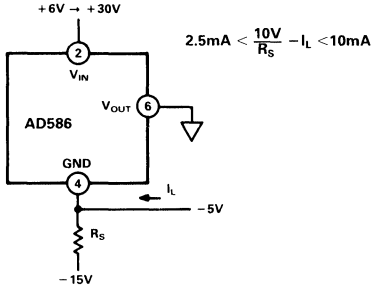

Figure 11. AD586 as a Negative 5V Reference

USING THE AD586 WITH CONVERTERS

The AD586 is an ideal reference for a wide variety of 8-, 12-, 14- and 16-bit A/D and D/A converters. Several representative examples follow.

5V REFERENCE WITH MULTIPLYING CMOS D/A OR A/D CONVERTERS

The AD586 is ideal for applications with 10- and 12-bit multiplying CMOS D/A converters. In the standard hookup, as shown in Figure 12, the AD586 is paired with the AD7545 12-bit multiplying DAC and the AD711 high-speed BiFET Op Amp. The amplifier DAC configuration produces a unipolar 0 to −5V output range. Bipolar output applications and other operating details can be found on the individual product data sheets.

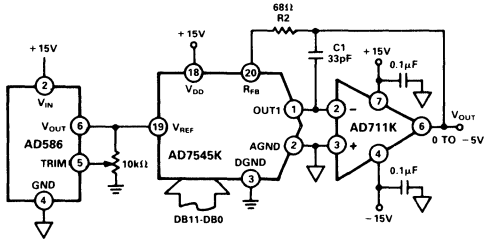

Figure 12. Low-Power 12-Bit CMOS DAC Application

The AD586 can also be used as a precision reference for multiple DACs. Figure 13 shows the AD586, the AD7628 dual DAC and the AD712 dual op amp hooked up for single supply operation to produce 0 to −5V outputs. Because both DACs are on the same die and share a common reference and output op amps, the DAC outputs will exhibit similar gain TCs.

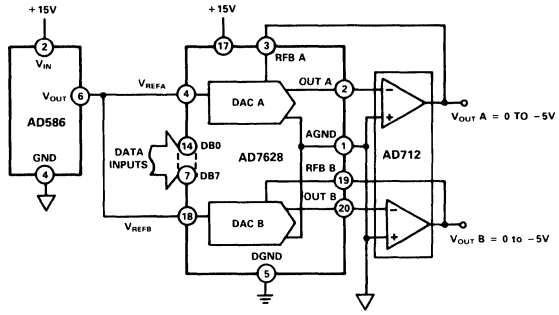

Figure 13. AD586 as a 5V Reference for a CMOS Dual DAC

STACKED PRECISION REFERENCES FOR MULTIPLE VOLTAGES

Often, a design requires several reference voltages. Three AD586s can be stacked, as shown in Figure 14, to produce +5.000V, +10.000V, and +15.000V outputs. This scheme can be extended to any number of AD586s as long as the maximum load current is not exceeded. This design provides the additional advantage of improved line regulation on the +5.0V output. Changes in V_{IN} of +18V to +50V produces an output change that is below the noise level of the references.

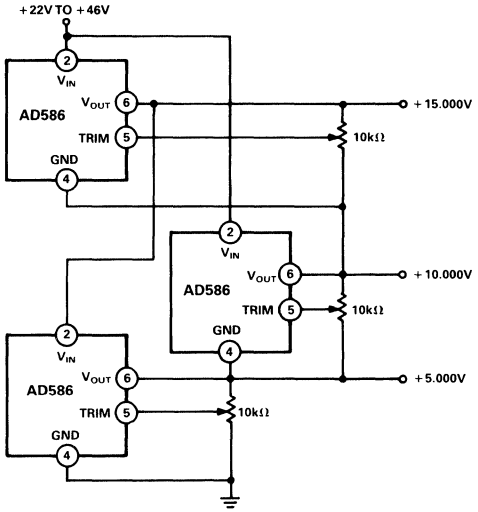

Figure 14. Multiple AD586s Stacked for Precision 5V, 10V and 15V Outputs

PRECISION CURRENT SOURCE

The design of the AD586 allows it to be easily configured as a current source. By choosing the control resistor R_C in Figure 15, you can vary the load current from the quiescent current (2mA typically) to approximately 10mA. The compliance voltage of this circuit varies from about +5V to +21V depending upon the value of V_{IN}.

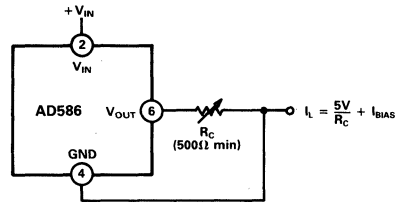

Figure 15. Precision Current Source

PRECISION HIGH CURRENT SUPPLY

For higher currents, the AD586 can easily be connected to a power PNP or power Darlington PNP device. The circuit in Figure 16 can deliver up to 4 amps to the load. The 0.1μF capacitor is required only if the load has a significant capacitive component. If the load is purely resistive, improved high-frequency supply rejection results can be obtained by removing the capacitor.

PRODUCT DESCRIPTION

The AD587 represents a major advance in the state-of-the-art in monolithic voltage references. Using a proprietary ion-implanted buried Zener diode and laser wafer trimming of high stability thin-film resistors, the AD587 provides outstanding performance at low cost.

The AD587 offers much higher performance than most other 10V references. Because the AD587 uses an industry standard pinout, many systems can be upgraded instantly with the AD587. The buried Zener approach to reference design provides lower noise and drift than band-gap voltage references. The AD587 offers a noise reduction pin which can be used to further reduce the noise level generated by the buried Zener.

The AD587 is recommended for use as a reference for 8-, 10-, 12-, 14- or 16-bit D/A converters which require an external precision reference. The device is also ideal for successive approximation or integrating A/D converters with up to 14 bits of accuracy and, in general, can offer better performance than the standard on-chip references.

The AD587J, K and L are specified for operation from 0 to +70°C, and the AD587S, T and U are specified for −55°C to +125°C operation. All grades are available in 8-pin cerdip. The J version is also available in an 8-pin Small Outline IC (SOIC) package for surface mount applications and the J and K grades also come in an 8-pin plastic package.

PRODUCT HIGHLIGHTS

1. Laser trimming of both initial accuracy and temperature coefficients results in very low errors over temperature without the use of external components. The AD587L has a maximum deviation from 10.000V of ±8.5mV between 0 and +70°C, and the AD587U guarantees ±14mV maximum total error between −55°C and +125°C.
2. For applications requiring higher precision, an optional fine-trim connection is provided.
3. Any system using an industry standard pinout 10 volt reference can be upgraded instantly with the AD587.
4. Output noise of the AD587 is very low, typically 4μV p-p. A noise reduction pin is provided for additional noise filtering using an external capacitor.

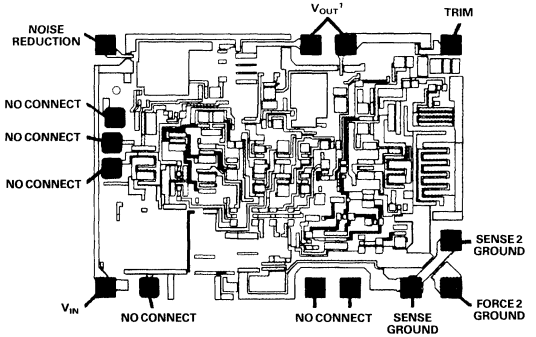
DIE LAYOUT



Die Size: 0.052 × 0.039 inches

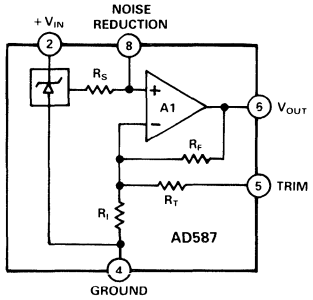
NOTES
[1]Both V_{OUT} pads should be connected to the output.
[2]Sense and force grounds must be tied together.

Die Thickness: The standard thickness of Analog Devices Bipolar dice is 24 mils ± 2 mils.
Die Dimensions: The dimensions given have a tolerance of ± 2 mils.
Backing: The standard backside surface is silicon (not plated). Analog Devices does not recommend gold-backed dice for most applications.
Edges: A diamond saw is used to separate wafers into dice thus providing perpendicular edges half-way through the die. In contrast to scribed dice, this technique provides a more uniform die shape and size. The perpendicular edges facilitate handling (such as tweezer pick-up) while the uniform shape and size simplifies substrate design and die attach.
Top Surface: The standard top surface of the die is covered by a layer of glassivation. All areas are covered except bonding pads and scribe lines.
Surface Metalization: The metalization to Analog Devices bipolar dice is aluminum. Minimum thickness is 10,000Å.
Bonding Pads: All bonding pads have a minimum size of 4 mils by 4 mils. The passivation windows have 3.5 mils by 3.5 mils minimum.

8

THEORY OF OPERATION

The AD587 consists of a proprietary buried Zener diode reference, an amplifier to buffer the output and several high stability thin-film resistors as shown in the block diagram in Figure 1. This design results in a high precision monolithic 10V output reference with initial offset of 5mV or less. The temperature compensation circuitry provides the device with a temperature coefficient of under 5ppm/°C.



NOTE: MAKE NO CONNECTIONS TO PINS 1, 7 AND 8.

Figure 1. AD587 Functional Block Diagram

A capacitor can be added at the NOISE REDUCTION pin (Pin 8) to form a low pass filter with R_S to reduce the noise contribution of the Zener to the circuit.

APPLYING THE AD587

The AD587 is simple to use in virtually all precision reference applications. When power is applied to Pin 2, and Pin 4 is grounded, Pin 6 provides a 10V output. No external components are required; the degree of desired absolute accuracy is achieved simply by selecting the required device grade. The AD587 requires less than 4mA quiescent current from an operating supply of +15V.

Fine trimming may be desired to set the output level to exactly 10.000V (calibrated to a main system reference). System calibration may also require a reference voltage that is slightly different from 10.000V, for example, 10.24V for binary applications. In either case, the optional trim circuit shown in Figure 2 can offset the output by as much as 300mV, if desired, with minimal effect on other device characteristics.

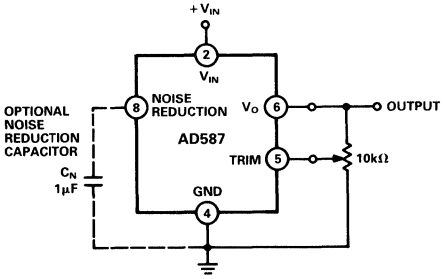


Figure 2. Optional Fine Trim Configuration

NOISE PERFORMANCE AND REDUCTION

The noise generated by the AD587 is typically less than 4μV p-p over the 0.1Hz to 10Hz band. Noise in a 1MHz bandwidth is approximately 200μV p-p. The dominant source of this noise is the buried Zener which contributes approximately 100nV/$\sqrt{\text{Hz}}$. In comparison, the op amp's contribution is negligible. Figure 3 shows the 0.1Hz to 10Hz noise of a typical AD587. The noise measurement is made with a bandpass filter made of a 1-pole high-pass filter with a corner frequency at 0.1Hz and a 2-pole low-pass filter with a corner frequency at 12.6Hz to create a filter with a 9.922Hz bandwidth.

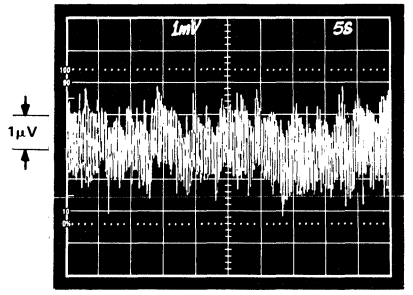

Figure 3. 0.1Hz to 10Hz Noise

If further noise reduction is desired, an external capacitor may be added between the NOISE REDUCTION pin and ground as shown in Figure 2. This capacitor, combined with the 4kΩ R_S and the Zener resistances, form a low-pass filter on the output of the Zener cell. A 1μF capacitor will have a 3dB point at 40Hz, and it will reduce the high-frequency (to 1MHz) noise to about 160μV p-p. Figure 4 shows the 1MHz noise of a typical AD587 both with and without a 1μF capacitor.

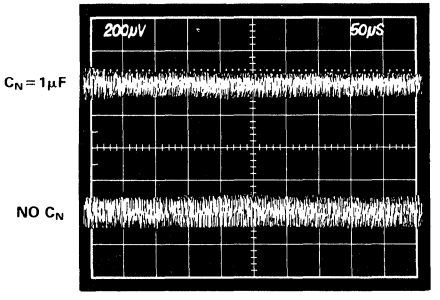

Figure 4. Effect of 1μF Noise Reduction Capacitor on Broadband Noise

TURN-ON TIME

Upon application of power (cold start), the time required for the output voltage to reach its final value within a specified error band is defined as the turn-on settling time. Two components normally associated with this are: the time for the active circuits to settle, and the time for the thermal gradients on the chip to stabilize. Figure 5 shows the turn-on characteristics of the AD587. It shows the settling to be about 60μs to 0.01%. Note the absence of any thermal tails when the horizontal scale is expanded to 1ms/cm in Figure 5b.

Output turn-on time is modified when an external noise reduction capacitor is used. When present, this capacitor acts as an additional load to the internal Zener diode's current source, resulting in a somewhat longer turn-on time. In the case of a 1μF capacitor, the initial turn-on time is approximately 400ms to 0.01% (see Figure 5c).

c. Turn-on with 1μF C_N

Figure 5. Turn-on Characteristics

DYNAMIC PERFORMANCE

The output buffer amplifier is designed to provide the AD587 with static and dynamic load regulation superior to less complete references.

Many A/D and D/A converters present transient current loads to the reference, and poor reference response can degrade the converter's performance.

Figure 6 displays the characteristics of the AD587 output amplifier driving a 0 to 10mA load.

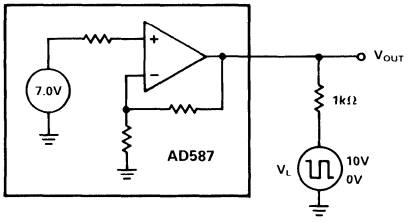

Figure 6a. Transient Load Test Circuit

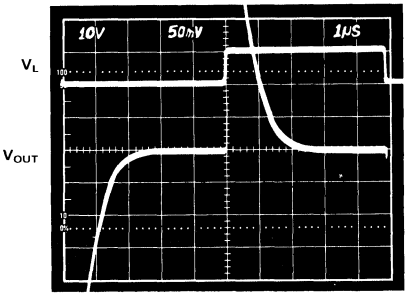

Figure 6b. Large-Scale Transient Response

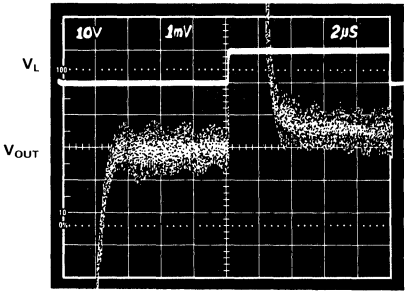

Figure 6c. Fine Scale Settling for Transient Load

8

In some applications, a varying load may be both resistive and capacitive in nature, or the load may be connected to the AD587 by a long capacitive cable.

Figure 7 displays the output amplifier characteristics driving a 1000pF, 0 to 10mA load.

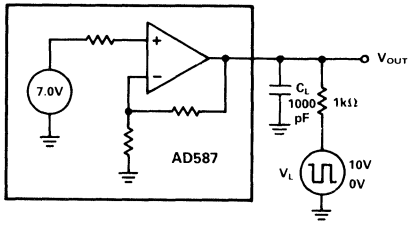

Figure 7a. Capacitive Load Transient Response Test Circuit

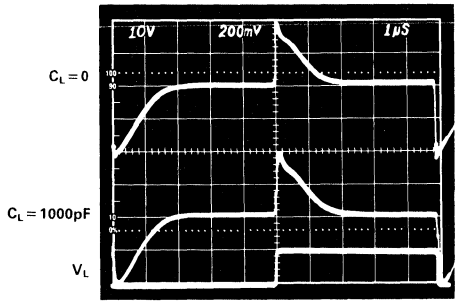

Figure 7b. Output Response with Capacitive Load

LOAD REGULATION

The AD587 has excellent load regulation characteristics. Figure 8 shows that varying the load several mA changes the output by only a few μV.

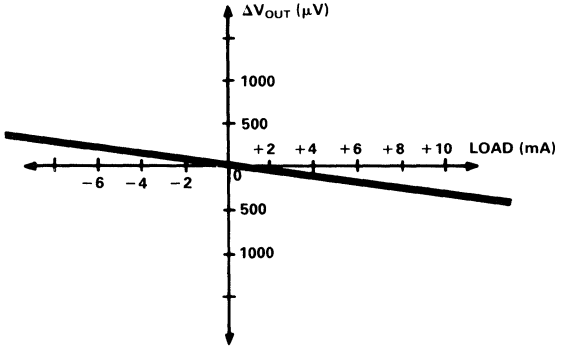

Figure 8. Typical Load Regulation Characteristics

TEMPERATURE PERFORMANCE

The AD587 is designed for precision reference applications where temperature performance is critical. Extensive temperature testing ensures that the device's high level of performance is maintained over the operating temperature range.

Some confusion exists in the area of defining and specifying reference voltage error over temperature. Historically, references have been characterized using a maximum deviation per degree Centrigrade; i.e., ppm/°C. However, because of nonlinearities in temperature characteristics which originated in standard Zener references (such as "S" type characteristics), most manufacturers have begun to use a maximum limit error band approach to specify devices. This technique involves the measurement of the output at 3 or more different temperatures to specify an output voltage error band.

Figure 9 shows the typical output voltage drift for the AD587L and illustrates the test methodology. The box in Figure 9 is bounded on the sides by the operating temperature extremes, and on the top and the bottom by the maximum and minimum output voltages measured over the operating temperature range. The slope of the diagonal drawn from the lower left to the upper right corner of the box determines the performance grade of the device.

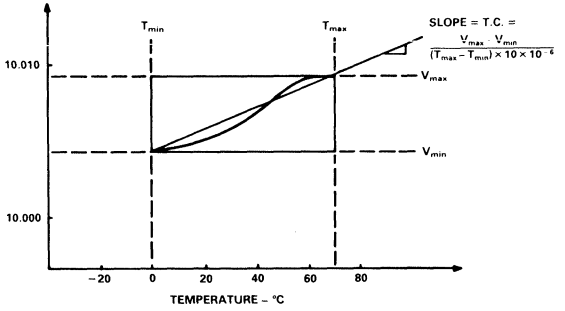

Figure 9. Typical AD587L Temperature Drift

Each AD587J, K, L grade unit is tested at 0, +25°C and +70°C. Each AD587S, T, and U grade unit is tested at −55°C, +25°C and +125°C. This approach ensures that the variations of output voltage that occur as the temperature changes within the specified range will be contained within a box whose diagonal has a slope equal to the maximum specified drift. The position of the box on the vertical scale will change from device to device as initial error and the shape of the curve vary. The maximum height of the box for the appropriate temperature range and device grade is shown in Figure 10. Duplication of these results requires a combination of high accuracy and stable temperature control in a test system. Evaluation of the AD587 will produce a curve similar to that in Figure 9, but output readings may vary depending on the test methods and equipment utilized.

DEVICE GRADE	MAXIMUM OUTPUT CHANGE (mV)	
	0 TO +70°C	−55°C TO +125°C
AD587J	24	
AD587K	12	
AD587L	8.5	
AD587S		46
AD587T		23
AD587U		14

Figure 10. Maximum Output Change in mV

NEGATIVE REFERENCE VOLTAGE FROM AN AD587

The AD587 can be used to provide a precision −10.000V output as shown in Figure 11. The V_{IN} pin is tied to at least a +3.5V supply, the output pin is grounded, and the AD587 ground pin is connected through a resistor, R_S, to a −15V supply. The −10V output is now taken from the ground pin (Pin 4) instead of V_{OUT}. It is essential to arrange the output load and the supply resistor R_S so that the net current through the AD587 is between 2.5mA and 10.0mA. The temperature characteristics and long-term stability of the device will be essentially the same as that of a unit used in the standard +10V output configuration.

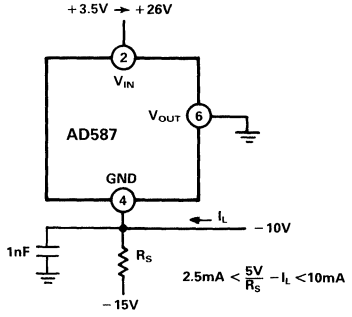

Figure 11. AD587 as a Negative 10V Reference

USING THE AD587 WITH CONVERTERS

The AD587 is an ideal reference for a wide variety of 8-, 12-, 14- and 16-bit A/D and D/A converters. Several representative examples follow.

10V REFERENCE WITH MULTIPLYING CMOS D/A OR A/D CONVERTERS

The AD587 is ideal for applications with 10- and 12-bit multiplying CMOS D/A converters. In the standard hookup, as shown in Figure 12, the AD587 is paired with the AD7545 12-bit multiplying DAC and the AD711 high-speed BiFET Op Amp. The amplifier DAC configuration produces a unipolar 0 to −10V output range. Bipolar output applications and other operating details can be found on the individual product data sheets.

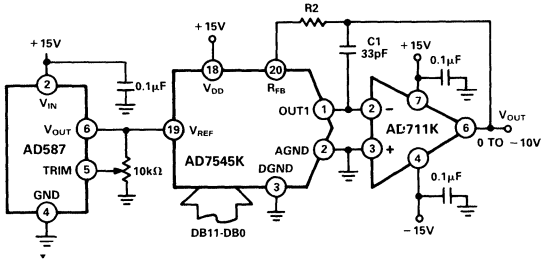

Figure 12. Low-Power 12-Bit CMOS DAC Application

The AD587 can also be used as a precision reference for multiple DACs. Figure 13 shows the AD587, the AD7628 dual DAC and the AD712 dual op amp hooked up for single supply operation to produce 0 to −10V outputs. Because both DACs are on the same die and share a common reference and output op amps; the DAC outputs will exhibit similar gain TCs.

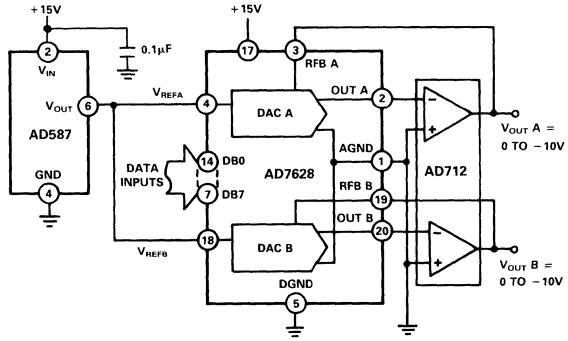

Figure 13. AD587 as a 10V Reference for a CMOS Dual DAC

PRECISION CURRENT SOURCE

The design of the AD587 allows it to be easily configured as a current source. By choosing the control resistor R_C in Figure 14, you can vary the load current from the quiescent current (2mA typically) to approximately 10mA.

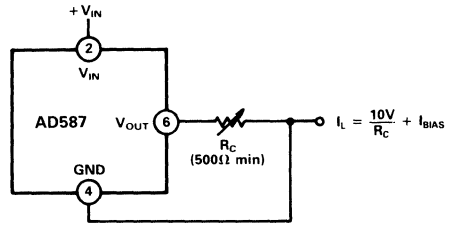

Figure 14. Precision Current Source

PRECISION HIGH CURRENT SUPPLY

For higher currents, the AD587 can easily be connected to a power PNP or power Darlington PNP device. The circuit in Figure 15 can deliver up to 4 amps to the load. The 0.1μF capacitor is required only if the load has a significant capacitive component. If the load is purely resistive, improved high-frequency supply rejection results can be obtained by removing the capacitor.

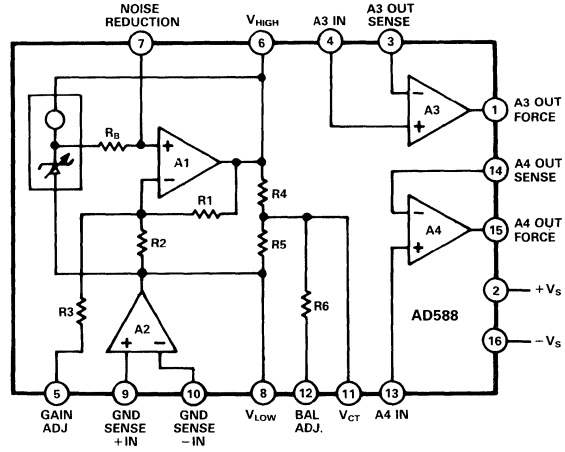
AD588 FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD588 represents a major advance in the state-of-the-art in monolithic voltage references. Low initial error and low temperature drift give the AD588 absolute accuracy performance previously not available in monolithic form. The AD588 uses a proprietary ion-implanted buried Zener diode, and laser-wafer-drift-trimming of high stability thin-film resistors to provide outstanding performance at low cost.

The AD588 includes the basic reference cell and three additional amplifiers which provide pin-programmable output ranges. The amplifiers are laser-trimmed for low offset and low drift to maintain the accuracy of the reference. The amplifiers are configured to allow Kelvin connections to the load and/or boosters for driving long lines or high-current loads, delivering the full accuracy of the AD588 where it is required in the application circuit.

The low initial error allows the AD588 to be used as a system reference in precision measurement applications requiring 12-bit absolute accuracy. In such systems, the AD588 can provide a known voltage for system calibration in software and the low drift allows compensation for the drift of other components in a system. Manual system calibration and the cost of periodic recalibration can therefore be eliminated. Furthermore, the mechanical instability of a trimming potentiometer and the potential for improper calibration can be eliminated by using the AD588 in conjunction autocalibration software.

The AD588 is available in six versions. AD588AD and BD grades are packaged in a 16-pin side-brazed ceramic DIP and are specified for the −25°C to +85°C industrial temperature range. The ceramic AD588SD and TD grades are specified for the full military/aerospace temperature range. For surface mount applications, the AD588AE, SE and TE grades will also be available in 20-pin LCC packages.

***Covered by Patent Number 4,644,253**

PRODUCT HIGHLIGHTS

1. The AD588 offers 12-bit absolute accuracy without any user adjustments. Optional fine-trim connections are provided for applications requiring higher precision. The fine-trimming does not alter the operating conditions of the Zener or the buffer amplifiers and thus does not increase the temperature drift.
2. Output noise of the AD588 is very low – typically 6μV p-p. A pin is provided for additional noise filtering using an external capacitor.
3. A precision ±5V tracking mode with Kelvin output connections is available with no external components. Tracking error is less than one millivolt and a fine-trim is available for applications requiring exact symmetry between the +5V and −5V outputs.
4. Pin strapping capability allows configuration of a wide variety of outputs: ±5V, +5V & +10V, −5V & −10V dual outputs or +5V, −5V, +10V, −10V single outputs.
5. Extensive temperature testing at −55°C, −25°C, 0, +25°C, +50°C, +70°C, +85°C and +125°C ensures that the specified temperature coefficient is truly representative of device performance.

NC = NO CONNECT

THEORY OF OPERATION

The AD588 consists of a buried Zener diode reference, amplifiers used to provide pin programmable output ranges, and associated thin-film resistors as shown in the block diagram of Figure 1. The temperature compensation circuitry provides the device with a temperature coefficient of 1.5ppm/°C or less.

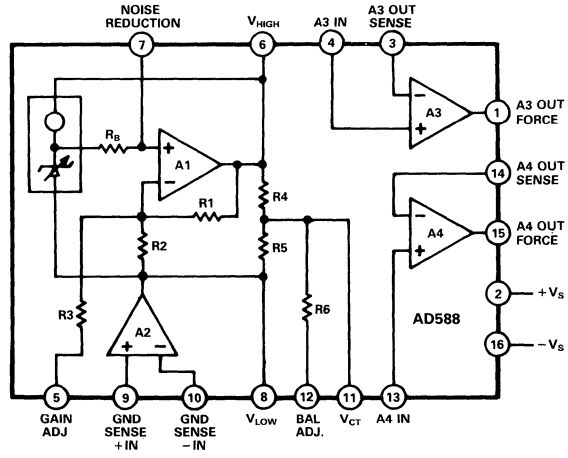

Figure 1. AD588 Functional Block Diagram

Amplifier A1 performs several functions. A1 primarily acts to amplify the Zener voltage from 6.5V to the required 10V output. In addition, A1 also provides for external adjustment of the 10V output through pin 5, the GAIN ADJUST. Using the bias compensation resistor between the Zener output and the non-inverting input to A1, a capacitor can be added at the NOISE REDUCTION pin (pin 7) to form a low pass filter and reduce the noise contribution of the Zener to the circuit. Two matched 10kΩ nominal thin film resistors (R4 & R5) divide the 10V output in half. Pin V_{CT} (pin 11) provides access to the center of the voltage span and pin 12 (BALANCE ADJUST) can be used for fine adjustment of this division.

Ground sensing for the circuit is provided by amplifier A2. The noninverting input (pin 9) senses the system ground which will be transferred to the point on the circuit where the inverting input (pin 10) is connected. This may be pin 6, 8 or 11. The output of A2 drives pin 8 to the appropriate voltage. Thus, if pin 10 is connected to pin 8, the V_{LOW} pin will be the same voltage as the system ground. Alternatively, if pin 10 is connected to the V_{CT} pin, it will be ground and pin 6 and pin 8 will be +5V and −5V respectively.

Amplifiers A3 and A4 are internally compensated and are used to buffer the voltages at pins 6, 8 and 11 as well as to provide a full Kelvin output. Thus, the AD588 has a full Kelvin capability by providing the means to sense a system ground and provide forced and sensed outputs referenced to that ground.

8

Applying the AD588

APPLYING THE AD588

The AD588 can be configured to provide +10V and −10V reference outputs as shown in Figures 2a and 2c respectively. It can also be used to provide +5V, −5V or a ±5V tracking reference as shown in Figure 2b. Table I details the appropriate pin connections for each output range. In each case, pin 9 is connected to system ground and power is applied to pins 2 and 16.

The architecture of the AD588 provides ground sense and uncommitted output buffer amplifiers which offer the user a great deal of functional flexibility. The AD588 is specified and tested in the configurations shown in Figure 2. The user may choose to take advantage of the many other configuration options available with the AD588. However, performance in these configurations is not guaranteed to meet the extremely stringent data sheet specifications.

As indicated in Table I, a +5V buffered output can be provided using amplifier A4 in the +10V configuration (Figure 2a). A −5V buffered output can be provided using amplifier A3 in the −10V configuration (Figure 2c). Specifications are not guaranteed for the +5V or −5V outputs in these configurations. Performance will be similar to that specified for the +10V or −10V outputs.

As indicated in Table I, unbuffered outputs are available at pins 6, 8 and 11. Loading of these unbuffered outputs will impair circuit performance.

Amplifiers A3 and A4 can be used interchangeably. However, the AD588 is tested (and the specifications are guaranteed) with the amplifiers connected as indicated in Figure 2 and Table I. When either A3 or A4 is unused, its output force and sense pins should be connected and the input tied to ground.

Two outputs of the same voltage may be obtained by connecting both A3 and A4 to the appropriate unbuffered output on pin 6, 8 or 11. Performance in these dual output configurations will typically meet data sheet specifications.

CALIBRATION

Generally, the AD588 will meet the requirements of a precision system without additional adjustment. Initial output voltage error of 1mV and output noise specs of 10μV p-p allow for accuracies of 12-16 bits. However, in applications where an even greater level of accuracy is required, additional calibration may be called for. Provision for trimming has been made through the use of the GAIN ADJUST and BALANCE ADJUST pins (pins 5 and 12 respectively).

The AD588 provides a precision 10V span with a center tap (V_{CT}) which is used with the buffer and ground sense amplifiers to achieve the voltage output configurations in Table I. GAIN ADJUST and BALANCE ADJUST can be used in any of these configurations to trim the magnitude of the span voltage and the position of the center tap within the span. The GAIN ADJUST should be performed first. Although the trims are not interactive within the device, the GAIN trim will move the BALANCE trim point as it changes the magnitude of the span.

Figure 2b. shows GAIN and BALANCE trims in a +5V and −5V tracking configuration. A 100kΩ 20-turn potentiometer is used for each trim. The potentiometer for GAIN trim is connected between pins 6 (V_{HIGH}) and 8 (V_{LOW}) with the wiper connected to pin 5 (GAIN ADJ). The potentiometer is adjusted to produce exactly 10V between pins 1 and 15, the amplifier outputs. The BALANCE potentiometer, also connected between pins 6 and 8 with the wiper to pin 12 (BAL ADJ), is then adjusted to center the span from +5V to −5V.

Trimming in other configurations works in exactly the same manner. When producing +10V and +5V, GAIN ADJ is used to trim +10V and BAL ADJ is used to trim +5V. In the −10V and −5V configuration, GAIN ADJ is again used to trim the magnitude of the span, −10V, while BAL ADJ is used to trim the center tap, −5V.

Range	Connect Pin 10 to Pin:	Unbuffered[1] Output on Pins −10V	−5V	0V	+5V	+10V	Buffered Output Connections	Buffered Output on Pins −10V	−5V	0V	+5V	+10V
+10V	8	–	–	8	11	6	11-13 & 14-15	–	–	–	15	–
							6-4 & 3-1	–	–	–	–	1
−5V or +5V	11	–	8	11	6	–	8-13 & 14-15	–	15	–	–	–
							6-4 & 3-1	–	–	–	1	–

[1]"Unbuffered" outputs should not be loaded.

Table I. AD588 Connections

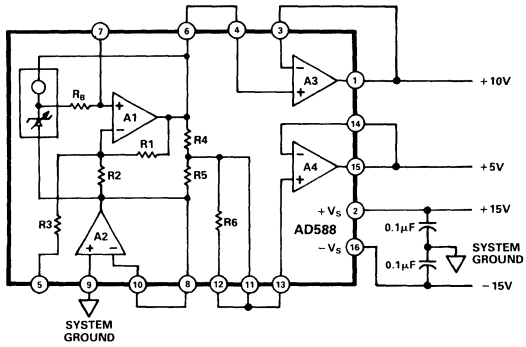

Figure 2a. +10V Output

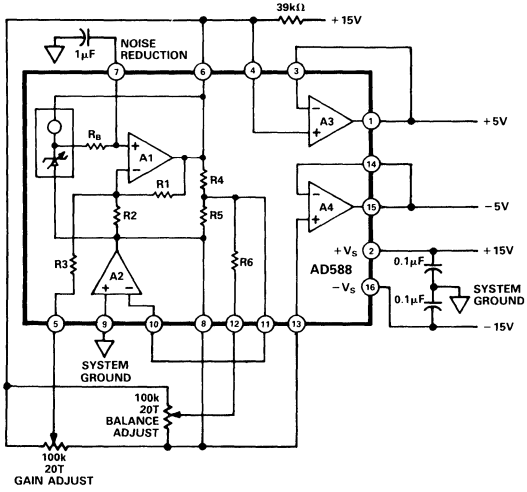

Figure 2b. +5V and −5V Outputs

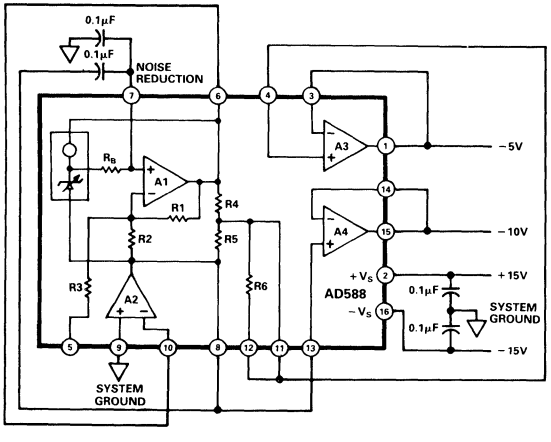

Figure 2c. −10V Output

In single output configurations, GAIN ADJ is used to trim outputs utilizing the full span (+10V or −10V) while BAL ADJ is used to trim outputs using half the span (+5V or −5V).

Input impedance on both the GAIN ADJUST and BALANCE ADJUST pins is approximately 150kΩ. The GAIN ADJUST trim network effectively attenuates the 10V across the trim potentiometer by a factor of about 1500 to provide a trim range of −3.5mV to +7.5mV with a resolution of approximately 550μV/turn (20 turn potentiometer). The BALANCE ADJUST trim network attenuates the trim voltage by a factor of about 1400, providing a trim range of ±4.5mV with resolution of 450μV/turn.

Trimming the AD588 introduces no additional errors over temperature so precision potentiometers are not required.

For single output voltage ranges, or in cases when BALANCE ADJUST is not required, pin 12 should be connected to pin 11. If GAIN ADJUST is not required, pin 5 should be left floating.

NOISE PERFORMANCE AND REDUCTION

The noise generated by the AD588 is typically less than 6μV p-p over the 0.1Hz to 10Hz band. Noise in a 1MHz bandwidth is approximately 600μV p-p. The dominant source of this noise is the buried Zener which contributes approximately 100nV/$\sqrt{\text{Hz}}$. In comparison, the op amp's contribution is negligible. Figure 3 shows the 0.1Hz to 10Hz noise of a typical AD588.

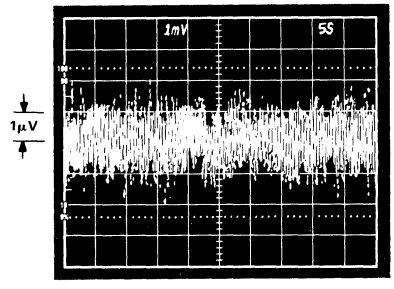

Figure 3. 0.1Hz to 10Hz Noise

If further noise reduction is desired, an optional capacitor may be added between the NOISE REDUCTION pin and ground as shown in Figure 2b. This will form a low pass filter with the 4kΩ R_B on the output of the Zener cell. A 1μF capacitor will have a 3dB point at 40Hz and will reduce the high frequency (to 1MHz) noise to about 200μV p-p. Figure 4 shows the 1MHz noise of a typical AD588 both with and without a 1μF capacitor.

Note that a second capacitor is needed in order to implement the NOISE REDUCTION feature when using the AD588 in the −10V mode (Figure 2c.). The NOISE REDUCTION capacitor is limited to 0.1μF maximum in this mode.

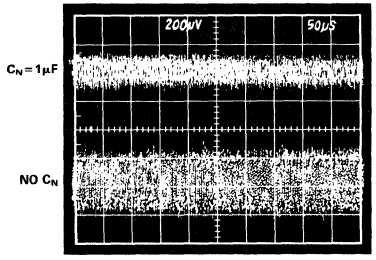

Figure 4. Effect of 1μF Noise Reduction Capacitor on Broadband Noise

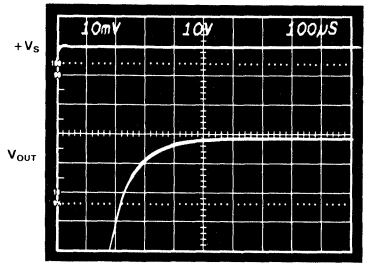
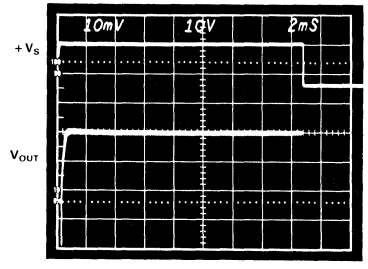
TURN-ON TIME

Upon application of power (cold start), the time required for the output voltage to reach its final value within a specified error band is the turn-on settling time. Two components normally associated with this are: time for active circuits to settle and time for thermal gradients on the chip to stabilize. Figure 5 shows the turn-on characteristics of the AD588. It shows the settling to be about 600μs. Note the absence of any thermal tails when the horizontal scale is expanded to 2ms/cm in Figure 5b.



a. Electrical Turn-On



b. Extended Time Scale

Figure 5. Turn-On Characteristics

Output turn-on time is modified when an external noise reduction capacitor is used. When present, this capacitor presents an additional load to the internal Zener diode's current source, resulting in a somewhat longer turn-on time. In the case of a 1μF capacitor, the initial turn-on time is approximately 60ms (see Figure 6).

Note: If the NOISE REDUCTION feature is used in the ±5V configuration, a 39kΩ resistor between pins 6 and 2 is required for proper startup.

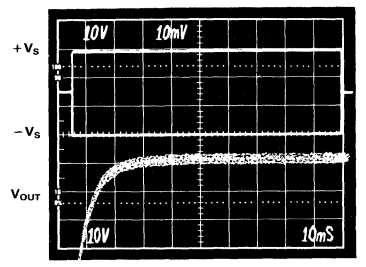


Figure 6. Turn-on with 1μF C_N

TEMPERATURE PERFORMANCE

The AD588 is designed for precision reference applications where temperature performance is critical. Extensive temperature testing ensures that the device's high level of performance is maintained over the operating temperature range.

Figure 7 shows typical output voltage drift for the AD588BD and illustrates the test methodology. The box in Figure 7 is bounded on the sides by the operating temperature extremes and on top and bottom by the maximum and minimum output voltages measured over the operating temperature range. The slope of the diagonal drawn from the lower left corner of the box determines the performance grade of the device.

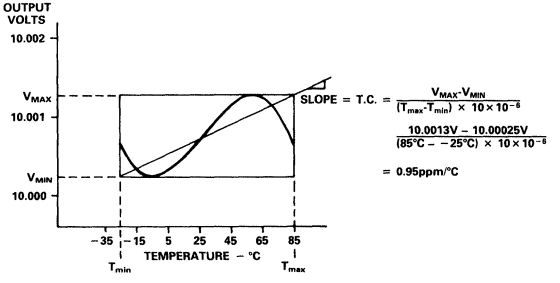

Figure 7. Typical AD588BD Temperature Drift

Each AD588A and B grade unit is tested at −25°C, 0°C, +25°C, +50°C, +70°C and +85°C. Each AD588S and T grade unit is tested at −55°C, −25°C, 0°C, +25°C, +50°C, +70°C and +125°C. This approach ensures that the variations of output voltage that occur as the temperature changes within the specified range will be contained within a box whose diagonal has a slope equal to the maximum specified drift. The position of the box on the vertical scale will change from device to device as initial error and the shape of the curve vary. Maximum height of the box for the appropriate temperature range is shown in Figure 8. Duplication of these results requires a combination of high accuracy and stable temperature control in a test system. Evaluation of the AD588 will produce a curve similar to that in Figure 7, but output readings may vary depending on the test methods and equipment utilized.

DEVICE GRADE	MAXIMUM OUTPUT CHANGE mV		
	0 TO +70°C	−25°C TO +85°C	−55°C TO +125°C
AD588AD	1.40 (typ)	3.30	
AD588BD	1.05	3.30	
AD588SD			10.80
AD588TD			7.20

Figure 8. Maximum Output Change – mV

KELVIN CONNECTIONS

Force and sense connections, also referred to as Kelvin connections, offer a convenient method of eliminating the effects of voltage drops in circuit wires. As seen in Figure 9a, the load current and wire resistance produce an error ($V_{ERROR} = R \times I_L$) at the load. The Kelvin connection of Figure 9b overcomes the problem by including the wire resistance within the forcing loop of the amplifier and sensing the load voltage. The amplifier corrects for any errors in the load voltage. In the circuit shown, the output of the amplifier would actually be at 10 volts + V_{ERROR} and the voltage at the load would be the desired 10 volts.

The AD588 has three amplifiers which can be used to implement Kelvin connections. Amplifier A2 is dedicated to the ground force-sense function while uncommitted amplifiers A3 and A4 are free for other force-sense chores.

In some single-output applications, one amplifier may be unused.

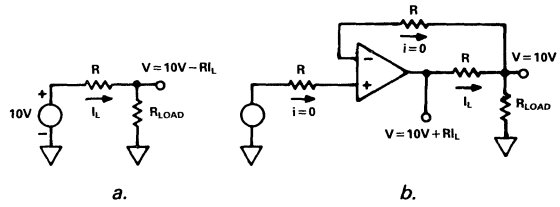

Figure 9. Advantage of Kelvin Connection

In such cases, the unused amplifier should be connected as a unity-gain follower (force + sense pin tied together) and the input should be connected to ground.

An unused amplifier section may be used for other circuit functions as well. The curves on this page show the typical performance of A3 and A4.

DYNAMIC PERFORMANCE

The output buffer amplifiers (A3 and A4) are designed to provide the AD588 with static and dynamic load regulation superior to less complete references.

Many A/D and D/A converters present transient current loads to the reference, and poor reference response can degrade the converter's performance.

Figure 10 displays the characteristics of the AD588 output amplifier driving a 0 to 10mA load.

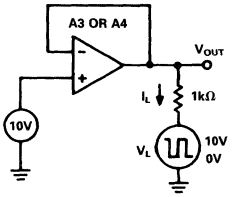

Figure 10a. Transient Load Test Circuit

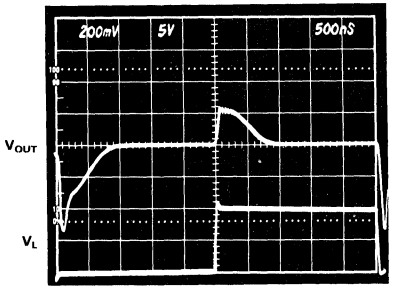

Figure 10b. Large-Scale Transient Response

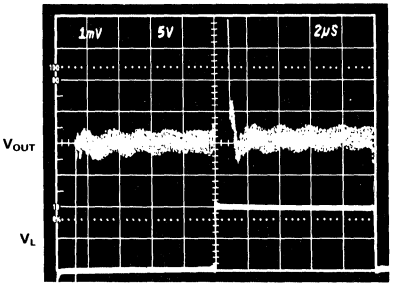

Figure 10c. Fine Scale Settling for Transient Load

Figure 11 displays the output amplifier characteristics driving a 5mA to 10mA load, a common situation found when the reference is shared among multiple converters or is used to provide a bipolar offset current.

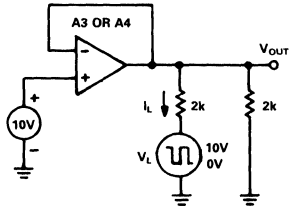

Figure 11a. Transient and Constant Load Test Circuit

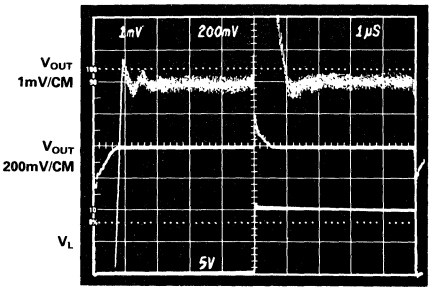

Figure 11b. Transient Response 5-10mA Load

In some applications, a varying load may be both resistive and capacitive in nature, or be connected to the AD588 by a long capacitive cable.

Figure 12 displays the output amplifier characteristics driving a 1,000pF, 0-to-10mA load.

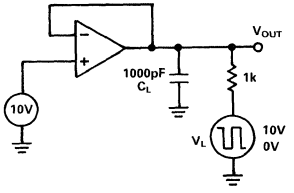

Figure 12a. Capacitive Load Transient Response Test Circuit

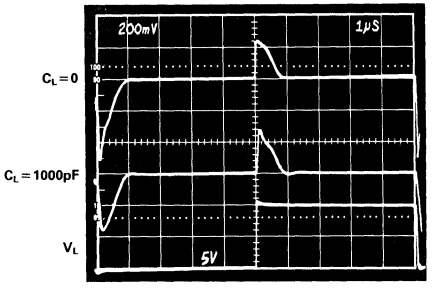

Figure 12b. Output Response with Capacitive Load

Figure 13 displays the crosstalk between output amplifiers. The top trace shows the output of A4, dc-coupled and offset by 10 volts, while the output of A3 is subjected to a 0-to-10mA load current step. The transient at A4 settles in about 1µs, and the load-induced offset is about 100µV.

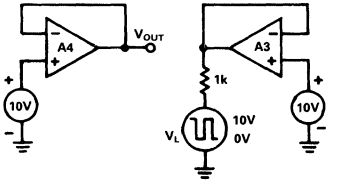

Figure 13a. Load Crosstalk Test Circuit

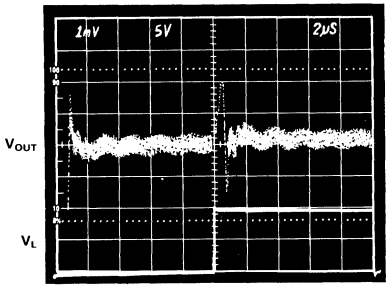

Figure 13b. Load Crosstalk

Attempts to drive a large capacitive load (in excess of 1,000pF) may result in ringing or oscillation, as shown in the step response photo (Figure 14a). This is due to the additional pole formed by the load capacitance and the output impedance of the amplifier, which consumes phase margin. The recommended method of driving capacitive loads of this magnitude is shown in Figure 14b. The 150Ω resistor isolates the capacitive load from the output stage, while the 1MΩ resistor provides a dc feedback path and preserves the output accuracy. The 150pF capacitor provides a high-frequency feedback loop. The performance of this circuit is shown in Figure 14c.

USING THE AD588 WITH CONVERTERS

The AD588 is an ideal reference for a wide variety of A/D and D/A converters. Several representative examples follow.

14-Bit Digital-to-Analog Converter – AD7535

High resolution CMOS D/A converters require a reference voltage of high precision to maintain rated accuracy. The combination of the AD588 and AD7535 takes advantage of the initial accuracy, drift and full Kelvin output capability of the AD588 as well as the resolution, monotonicity and accuracy of the AD7535 to produce a subsystem with outstanding characteristics.

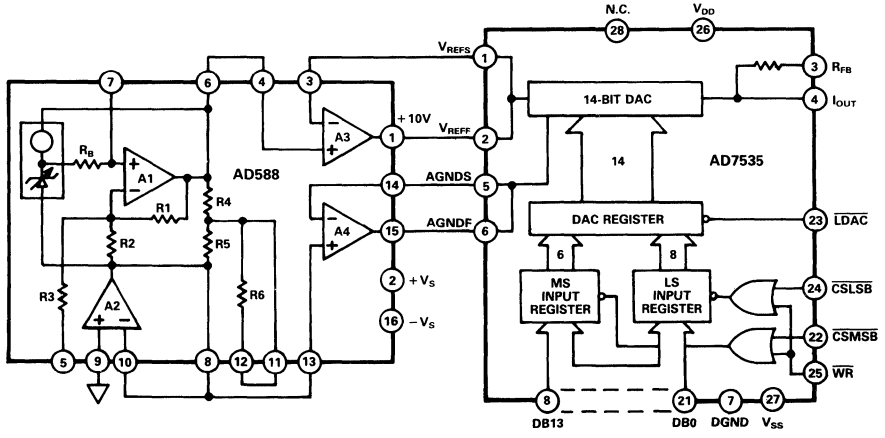

Figure 15. AD588/AD7535 Connections

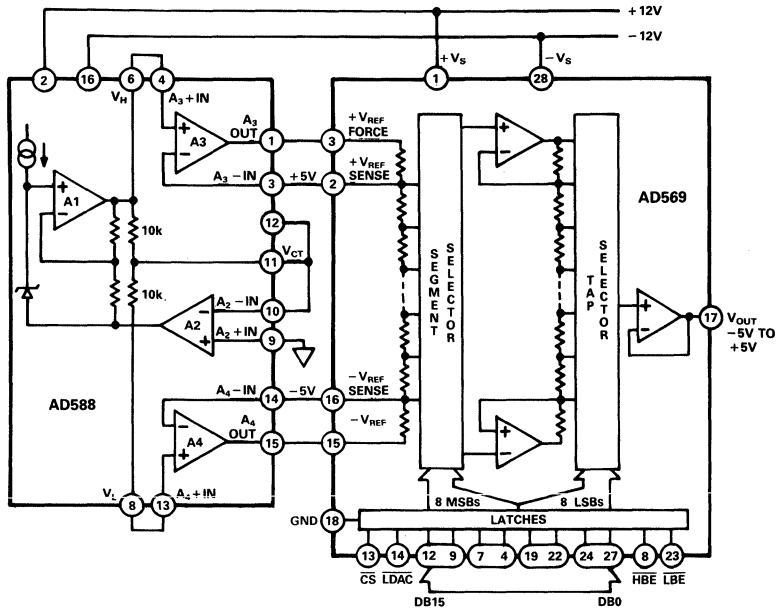

Figure 16. High-Accuracy ±5V Tracking Reference for AD569

16-Bit Digital-to-Analog Converter – AD569

Another application which fully utilizes the capabilities of the AD588 is supplying a reference for the AD569, as shown in Figure 16. Amplifier A2 senses system common and forces V_{CT} to assume this value, producing +5V and −5V at pins 6 and 8 respectively. Amplifiers A3 and A4 buffer these voltages out to the appropriate reference force-sense pins of the AD569. The full Kelvin scheme eliminates the effect of the circuit traces or wires and the wire bonds of the AD588 and AD569 themselves, which would otherwise degrade system performance.

SUBSTITUTING FOR INTERNAL REFERENCES

Many converters include built-in references. Unfortunately, such references are the major source of drift in these converters. By using a more stable external reference like the AD588, drift performance can be improved dramatically.

12-Bit Analog-to-Digital Conveter – AD574A

The AD574A is specified for gain drift from 10ppm/°C to 50ppm/°C, (depending on grade) using the on-chip reference. The reference contributes typically 75% of this drift. Therefore, the total drift using an AD588 to supply the reference can be improved by a factor of 3 to 4.

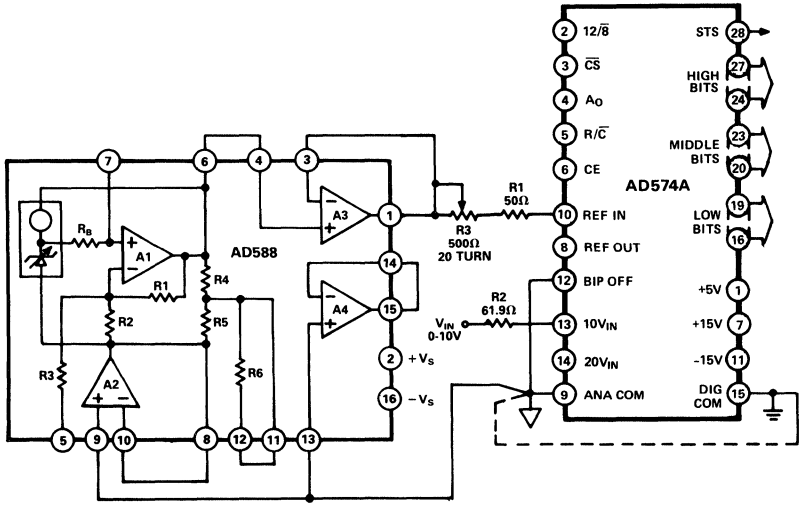

Figure 17. AD588/AD574A Connections

Using this combination may result in apparent increases in full-scale error due to the difference between the on-board reference by which the device is laser trimmed and the external reference with which the device is actually applied. The on-board reference is specified to be 10V ± 100mV while the external reference is specified to be 10V ± 1mV. This may result in up to 101mV of apparent full-scale error beyond the ± 25mV specified AD574 gain error. Resistors R2 and R3 allow this error to be nulled. Their contribution to full-scale drift is negligible.

The high output drive capability allows the AD588 to drive up to 6 converters in a multi-converter system. All converters will have gain errors that track to better than ± 5ppm/°C.

RTD EXCITATION

The Resistance Temperature Detector (RTD) is a circuit element whose resistance is characterized by a positive temperature coefficient. A measurement of resistance indicates the measured temperature. Unfortunately, the resistance of the wires leading to the RTD often adds error to this measurement. The 4-wire ohms measurement overcomes this problem. This method uses two wires to bring an excitation current to the RTD and two additional wires to tap off the resulting RTD voltage. If these additional two wires go to a high input impedance measurement circuit, the effect of their resistance is negligible. Therefore, they transmit the true RTD voltage.

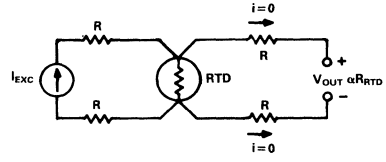

Figure 18. 4-Wire Ohms Measurement

A practical consideration when using the 4-wire ohms technique with an RTD is the self-heating effect that the excitation current has on the temperature of the RTD. The designer must choose the smallest practical excitation current that still gives the desired resolution. RTD manufactures usually specify the self-heating effect of each of their models or types of RTDs.

Figure 19 shows an AD588 providing the precision excitation current for a 100Ω RTD. The small excitation current of 1mA dissipates a mere 0.1mW of power in the RTD.

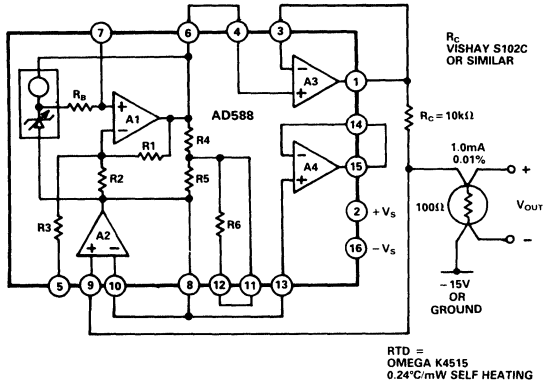

Figure 19. Precision Current Source for RTD

BOOSTED PRECISION CURRENT SOURCE

In the RTD current-source application the load current is limited to ± 10mA by the output drive capability of amplifier A3. In the event that more drive current is needed, a series pass transistor can be inserted inside the feedback loop to provide higher current. Accuracy and drift performance are unaffected by the pass transistor.

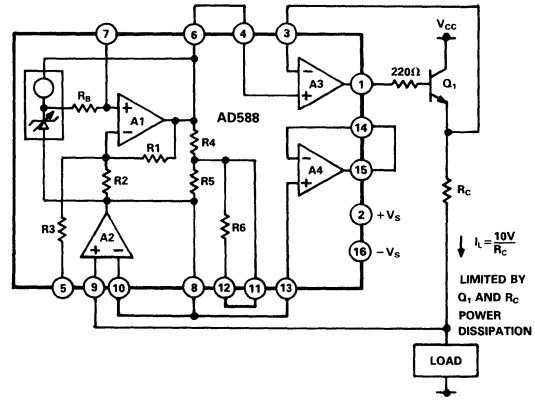

Figure 20. Boosted Precision Current Source

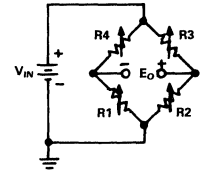
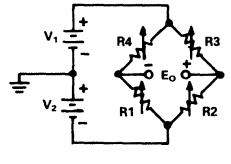
BRIDGE DRIVER CIRCUITS

The Wheatstone bridge is a common transducer. In its simplest form, a bridge consists of 4 two terminal elements connected to form a quadrilateral, a source of excitation connected along one of the diagonals and a detector comprising the other diagonal. Figure 21a shows a simple bridge driven from a unipolar excitation supply. E_O, a differential voltage, is proportional to the deviation of the element from the initial bridge values. Unfortunately, this bridge output voltage is riding on a common-mode voltage equal to approximately $V_{IN}/2$. Further processing of this signal may necessarily be limited to high common-mode rejection techniques such as instrumentation or isolation amplifiers.

Figure 21b shows the same bridge transducer, but this time it is driven from pair of bipolar supplies. This configuration ideally eliminates the common-mode voltage and relaxes the restrictions on any processing elements that follow.



a. Unipolar Drive



b. Bipolar Drive

Figure 21. Bridge Transducer Excitation

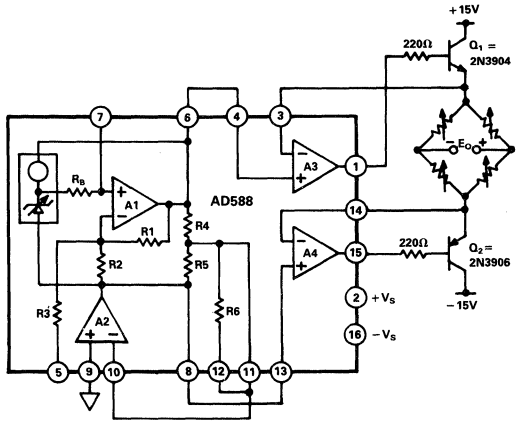


Figure 22. Bipolar Bridge Drive

As shown in Figure 22, the AD588 is an excellent choice for the control element in a bipolar bridge driver scheme. Transistors Q1 and Q2 serve as series pass elements to boost the current drive capability to the 28mA required by a typical 350Ω bridge. A differential gain stage may still be required if the bridge balance is not perfect. Such gain stages can be expensive.

Additional common-mode voltage reduction is realized by using the circuit illustrated in Figure 23. A1, the ground sense amplifier, servo's the supplies on the bridge to maintain a virtual ground at one center tap. The voltage which appears on the opposite center tap is now single-ended (referred to ground) and can be amplified by a less expensive circuit.

ANALOG DEVICES

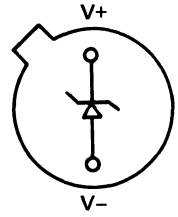
Two-Terminal IC 1.2V Reference

AD589

FEATURES

Superior Replacement for Other 1.2V References
Wide Operating Range: 50μA to 5mA
Low Power: 60μW Total P_D at 50μA
Low Temperature Coefficient:
10ppm/°C max, 0 to +70°C (AD589M)
25ppm/°C max, -55°C to +125°C (AD589U)
Two Terminal "Zener" Operation
Low Output Impedance: 0.6Ω
No Frequency Compensation Required
Low Cost

AD589 FUNCTIONAL BLOCK DIAGRAM



BOTTOM VIEW

PRODUCT DESCRIPTION

The AD589 is a two-terminal, low cost, temperature compensated bandgap voltage reference which provides a fixed 1.23V output voltage for input currents between 50μA and 5.0mA.

The high stability of the AD589 is primarily dependent upon the matching and thermal tracking of the on-chip components. Analog Devices' precision bipolar processing and thin-film technology combine to provide excellent performance at low cost.

Additionally, the active circuit produces an output impedance ten times lower than typical low-TC zener diodes. This feature allows operation with no external components required to maintain full accuracy under changing load conditions.

The AD589 is available in seven versions. The AD589J, K, L and M grades are specified for 0 to +70°C operation, while the S, T and U grades are rated for the full -55°C to +125°C temperature range.

PRODUCT HIGHLIGHTS

1. The AD589 is a two-terminal device which delivers a a constant reference voltage for a wide range of input current.
2. Output impedance of 0.6Ω and temperature coefficients as low as 10ppm/°C insure stable output voltage over a wide range of operating conditions.
3. The AD589 can be operated as a positive or negative reference. "Floating" operation is also possible.
4. The AD589 will operate with total current as low as 50μA (60μW total power dissipation), ideal for battery powered instrument applications.
5. The AD589 is an exact replacement for other 1.2V references, offering superior temperature performance and reduced sensitivity to capacitive loading.

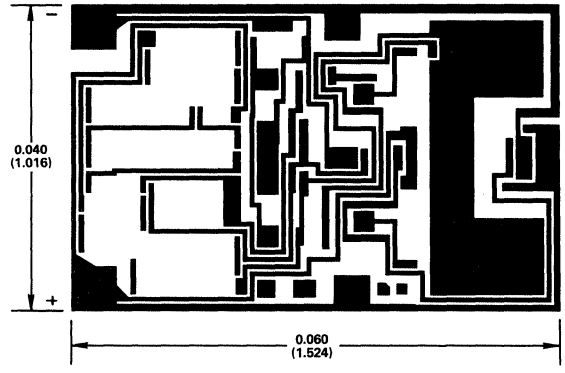
NOTES
[1]See following page for explanation of temperature coefficient measurement method.
[2]Optimum performance is obtained at currents below 500μA.
Stray shunt capacitances should be minimized. If strays cannot be avoided, a shunt capacitor of at least 1000pF is recommended.
[3]See Section 14 for package outline information.
Specifications shown in boldface are tested on all production units at final electrical test.
Specifications subject to change without notice.

ABSOLUTE MAXIMUM RATINGS

Current 10mA
Reverse Current 10mA
Power Dissipation[1] 125mW
Storage Temperature Range . . . . . –65°C to +175°C
Operating Junction Temperature Range . –55°C to +150°C
Lead Temperature (Soldering, 10sec) . . . . . +300°C

NOTE
[1]Absolute maximum power dissipation is limited by maximum current through the device. Maximum rating at elevated temperatures must be computed assuming $T_J \leq 150°C$, and $\theta_{JA} = 400 = C/W$.

AD589 CHIP DIMENSIONS AND PAD LAYOUT



THE AD589 IS AVAILABLE IN CHIP FORM WITH FULLY TESTED AND GUARANTEED SPECIFICATIONS. CONSULT FACTORY FOR AVAILABLE GRADES AND PRICING.

VOLTAGE VARIATION vs. TEMPERATURE

Some confusion exists in the area of defining and specifying reference voltage error over temperature. Historically, references have been characterized using a maximum deviation per degree Centigrade; i.e., 10ppm/°C. However, because of nonlinearities in temperature characteristics, which originated in standard zener references (such as "S" type characteristics) most manufacturers have begun to use a maximum limit error band approach to specify devices. This technique involves measurement of the output at 3, 5 or more different temperatures to guarantee that the output voltage will fall within the given error band. The temperature characteristic of the AD589 consistently follows the curve shown in Figure 1. Three-point measurement guarantees the error band over the specified temperature range. The temperature coefficients specified on page 2 represent the slopes of the diagonals of the error band from +25°C to T_{min} and +25°C to T_{max}.

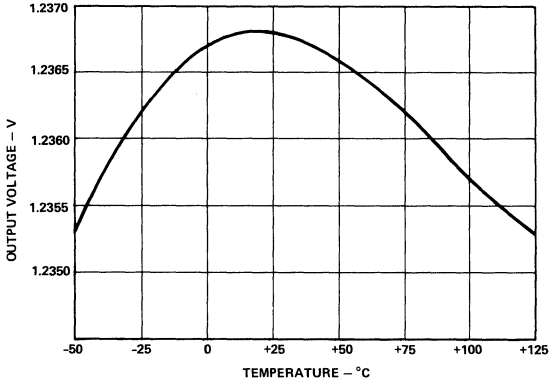


Figure 1. Typical AD589 Temperature Characteristics

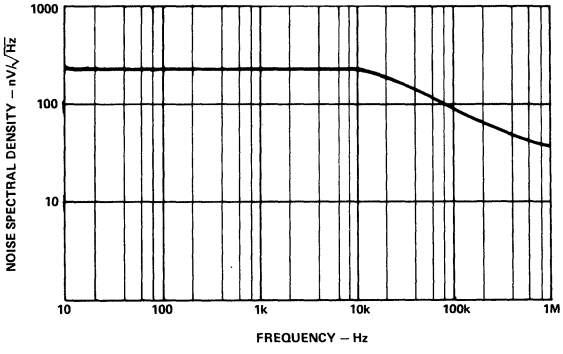

Figure 2. Noise Spectral Density

DYNAMIC PERFORMANCE

Many low power instrument manufacturers are becoming increasingly concerned with the turn-on characteristics of the components being used in their systems. Fast turn-on components often enable the end user to keep power off when not needed, and yet respond quickly when the power is turned on for operation. Figure 3 displays the turn-on characteristic of the AD589. This characteristic is generated from cold-start operation and represents the true turn-on waveform after an extended period with the supplies off. The figure shows both the coarse and fine transient characteristics of the device; the total settling time to within ±1 millivolt is about 25μs, and there is no long thermal tail appearing after that point.

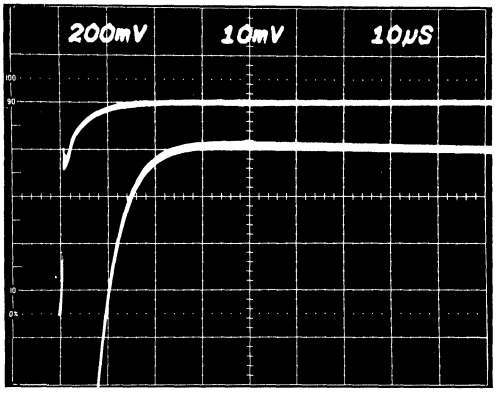

Figure 3. Output Settling Characteristics

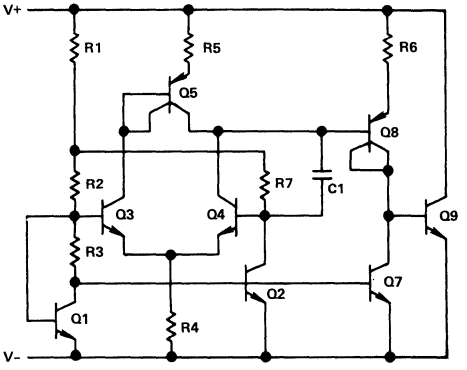

Figure 4. Schematic Diagram

APPLICATION INFORMATION

The AD589 functions as a two-terminal shunt-type regulator. It provides a constant 1.23V output for a wide range of input current from 50μA to 5mA. Figure 5 shows the simplest configuration for an output voltage of 1.2V or less. Note that no frequency compensation is required. If additional filtering is desired for ultra low noise applications, minimum recommended capacitance is 1000pF.

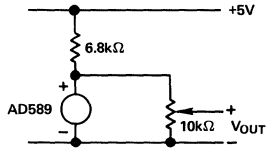

Figure 5. Basic Configuration for 1.2V or Less

The AD589 can also be used as a building block to generate other values of reference voltage. Figure 6 shows a circuit which produces a buffered 10V output. Total supply current for this circuit is approximately 2mA.

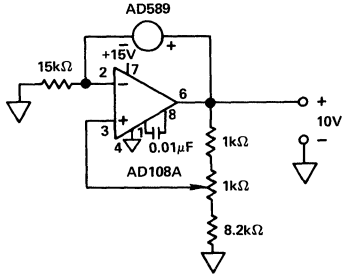

Figure 6. Single-Supply Buffered 10V Reference

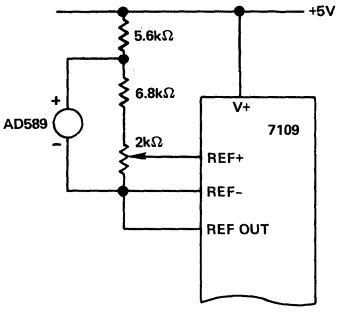
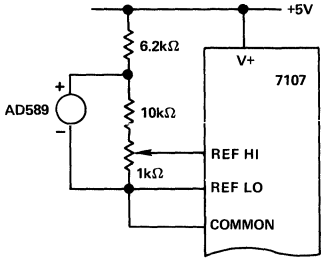
The low power operation of the AD589 makes it ideal for use in battery operated portable equipment. It is especially useful as a reference for CMOS analog-to-digital converters. Figure 7 shows the AD589 used in conjunction with two popular integrating type CMOS A/D converters.



a. With 7109 12-Bit Binary A/D



b. With 7107 Panel Meter A/D

Figure 7. AD589 Used as Reference for CMOS A/D Converters

The AD589 also is useful as a reference for CMOS multiplying DACs such as the AD7533. These DACs require a negative reference voltage in order to provide a positive output range. Figure 8 shows the AD589 used to supply an equivalent -1.0V reference to an AD7533.

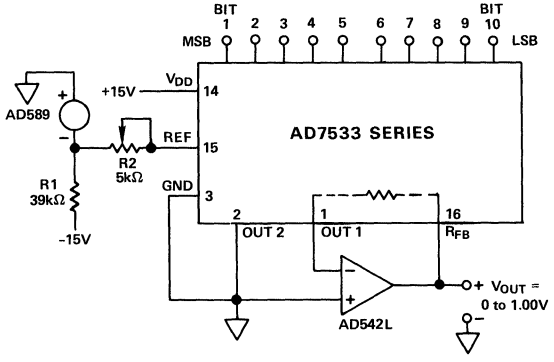


Figure 8. AD589 as Reference for 10-Bit CMOS DAC

ANALOG DEVICES

High Precision 8.192V Reference

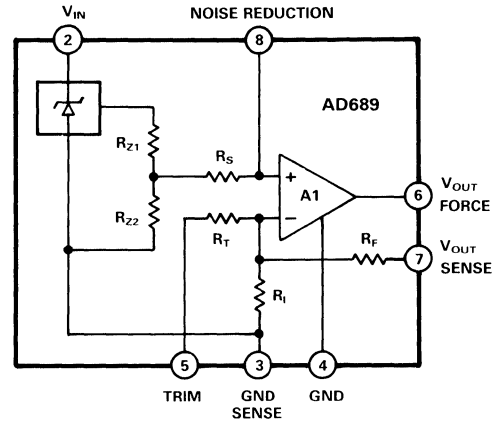
10ppm/°C max, −55 to +125°C (T Grade)
Noise Reduction Capability
Versatile Force and Sense Connections

AD689 FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD689 is the industry's first precision reference to deliver a voltage between traditional 5V and 10V references. The AD689 will accurately deliver 8.192V while operating on supply voltages of ±12V, with ±10% tolerances. All 10V references require greater than 10.8V (12V-10%) to operate properly, forcing the use of 5V references in most 12V systems. An 8.192V reference provides a major increase in signal range. The AD689 also features excellent static and dynamic line and load regulation characteristics.

The AD689 uses a proprietary ion-implanted buried Zener diode and laser wafer trimming of high stability thin-film resistors. Trimming is performed for initial accuracy and temperature coefficient, resulting in very low errors over temperature without the use of additional components.

The AD689 includes the reference cell and an amplifier which is laser trimmed for low drift. Force and sense connections can be made on both the amplifier output and ground to maintain the accuracy of the reference cell. This allows the AD689 to be used with boosters for driving long lines or high current loads while maintaining full accuracy at the load.

The AD689 is recommended for use in all data conversion applications where ±12V ±10% supplies preclude the use of both external and internal 10V references.

The AD689J, K and L are tested and specified for operation from 0 to +70°C, and the AD689S and T are tested and specified for −55°C to +125°C operation. All grades are packaged in an 8-pin cerdip.

PRODUCT HIGHLIGHTS

1. Laser trimming of both the initial accuracy and the temperature coefficient results in very low errors over temperature without the use of external components.
2. For applications requiring higher initial accuracy, an optional fine trim connection is provided. The trim range allows the output voltage to be accurately set down to 8.000V.
3. Output noise of the AD689 is very low, typically 2μV p-p. A noise reduction pin is provided for additional noise filtering with an external capacitor.
4. Force and sense connections allow remote sensing of load and ground variations to accurately supply 8.192V at the load.
5. The AD689 sources and sinks current with excellent regulation, allowing a variety of both positive and negative output voltage configurations.

NOTES

[1]Maximum output voltage drift is guaranteed for all packages and grades. Cerdip packaged parts are also 100% production tested.

[2]The operating temperature range is defined as the temperature extremes at which the device will still function. Parts may deviate from their specified performance outside their specified temperature range.

Specifications subject to change without notice.

Specifications in boldface are tested on all production units at final electrical test. Results from those tests are used to calculate outgoing quality levels. All min and max specifications are guaranteed. Those shown in boldface are tested on all production units.

ABSOLUTE MAXIMUM RATINGS*

V_{IN} to Ground . . . . . +36V
Power Dissipation (25°C) 500mW
GND to GNDS 200mV
Storage Temperature . . . . . −65°C to +150°C
Lead Temperature (Soldering, 10sec) . . . . . +300°C
Package Thermal Resistance
θ_{JC} . . . . . 22°C/W
θ_{JA} . . . . . 110°C/W
Output Protection: Output safe for indefinite short to ground or V_{IN}.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

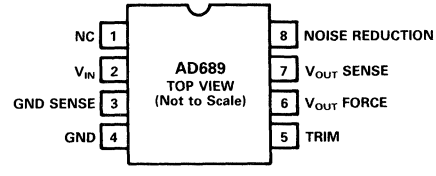
CONNECTION DIAGRAM



THEORY OF OPERATION

The AD689 consists of a buried Zener diode reference, amplifier and several high stabilty thin-film resistors as shown in the block diagram in Figure 1. This design results in a high precision, monolithic 8.192V output reference with initial errors of less than 4mV. The temperature compensation circuitry provides the device with a temperature coefficient of less than 5ppm/°C.

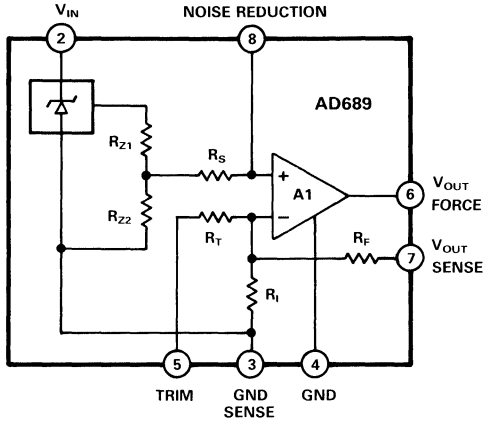


Figure 1. AD689 Functional Block Diagram

Amplifier A1 is configured to serve multiple functions. A1 primarily acts to amplify the Zener voltage from the buried Zener diode to the required 8.192V output. In addition, A1 is configured to allow force and sense connections from its output terminal to the feedback resistor (R_F) and from its ground reference to the buried Zener and input resistor (R_I) ground. A1 also provides adjustment of the 8.192V output through Pin 5, TRIM.

Separating A1 ground from the buried Zener diode ground provides many additional features. First it allows the AD689 to provide excellent load regulation when sourcing and sinking current. It reduces the total current that flows from the buried Zener diode ground to the sense node. This minimizes voltage drops due to parasitic impedances, hence allowing accurate sensing of voltage variations at the load ground. Finally, current variations due to temperature coefficients, which in turn cause voltage errors, are minimized by reducing the total current that would flow from a single ground point.

Using the bias compensation resistor (R_S) between the Zener output and the noninverting output of the amplifier, a capacitor can be added at the NOISE REDUCTION pin (Pin 8) to form a low pass filter and reduce the noise contribution of the Zener to the circuit.

APPLYING THE AD689

The 8.192V output of the AD689 allows convenient binarily scaled bit levels when used with data converters. With a 12-bit data converter the LSB would equal 8.192V/4096, or 2mV.

The AD689 is simple to use in virtually all precision reference applications. Pins 6 and 7 are connected together at the load; Pins 3 and 4 are grounded; and power is applied to Pin 2. No external components are required; the degree of desired absolute accuracy is achieved by simply selecting the required device grade. The AD689 requires less than 5mA quiescent current when operating from a supply of +10.8V to +36V.

An external fine trim may be added to null out initial voltage errors. The optional trim circuit shown in Figure 2 can adjust the 8.192V output from +8% (655mV) to −3% (−245mV) with minimal effect on other device characteristics.

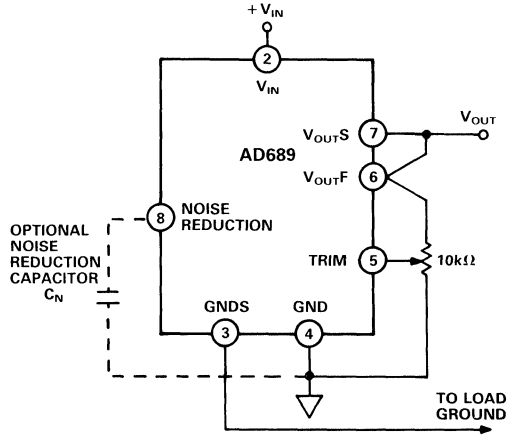

Figure 2. Optional Fine Trim Configuration

FORCE AND SENSE CONNECTIONS

Force and sense connections offer a convenient method of eliminating the effects of voltage drops in circuit wires. As seen in Figure 3a, the load current and wire resistance produce an error ($V_{ERROR} = R_W \times I_L$) at the load. The force and sense connection of Figure 3b overcomes the problem by including the wire resistance within the forcing loop of the amplifier and sensing the load voltage. The amplifier corrects for any errors in the load voltage. In the circuit shown, the output of the amplifier would actually be at 8.192V + V_{ERROR}, and the voltage at the load would be the desired 8.192V. If, for example, in Figure 3a the load resistor is sinking 8.192mA from the 8.192V reference and the load is 2 feet away using 28 gage wire (R = 0.066Ω/ft), the resulting V_{ERROR} would be $2 \times 0.066 \times 8.192\text{mA} = 1.08\text{mV}$. This represents greater than 0.5LSB of error in a 12-bit system.

Since amplifier A1 is not configured as a true buffer amplifier, the V_{OUT} SENSE pin (Pin 7) carries approximately 500μA of current. This level of current when used in the above example will result in 66μV of error, or 0.033LSB.

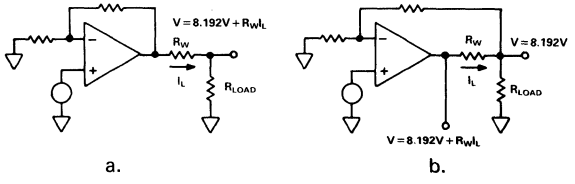

Figure 3. Advantage of Force and Sense Connections

GROUNDING CONSIDERATIONS

Analysis of the ground current magnitudes, ground current paths and ground impedances is crucial when high accuracy analog circuits are designed. The AD689 has two ground pins, GND (Pin 4) and GND SENSE (Pin 3). The GND pin is the ground reference for the internal operational amplifier. It will carry most of the quiescent current (I_Q = 5mA maximum) when the AD689 is sourcing current and up to an additional 8.192mA when the AD689 is sinking current. The GND SENSE pin is the reference for the buried Zener diode and gain setting resistors and carries approximately 1mA. Connecting GND SENSE to the load ground will allow the AD689 to accurately deliver 8.192V at the load, independent of variations of the "GND" voltage relative to the load ground.

The grounding method that is used depends on the accuracy requirements of the application. In general, GND SENSE should be connected to GND at the load ground, without connection to GND at the AD689.

Simple Ground Connection

Figure 4a shows a simple connection of the AD689 to a load resistor (R_L). GND and GND SENSE are connected at the load ground and the 8.192V is delivered across R_L.

High Accuracy Ground Connection and Analysis

Figure 4b shows the addition of Z_W, and Z_{G1} and Z_{GN}. They represent the sense wire, the AD689 ground wire and additional ground wire impedances. Also shown in Figure 4b is a power supply connected to the AD689 and to a block representing additional analog circuits. The total current that flows through Z_{G1} could be much greater than 1mA current from the GND SENSE pin, developing a potentially large voltage drop across Z_{G1}. If GND and GND SENSE are connected at the AD689, the AD689 would sense V_{ZG1} and deliver 8.192V + V_{ZG1} across R_L. To minimize the voltage error at the load, GND SENSE is connected instead at load ground. The voltage error now delivered at the load is reduced to V_{ZW}, where $V_{ZW} < V_{ZG1}$. For example, if Z_{G1} = Z_W and the total ground current flowing through Z_{G1} is 20mA, then V_{ZG1} = 20 (V_{ZW}) and the potential error at the load is reduced by a factor of 20.

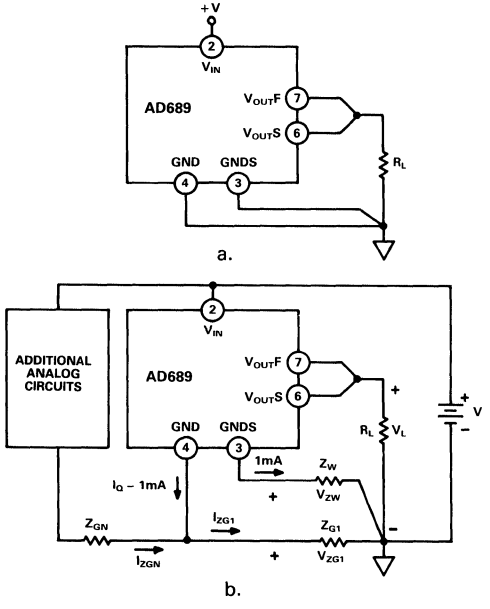

Figure 4. Grounding the AD689

NOISE PERFORMANCE AND REDUCTION

The noise generated by the AD689 is typically less than 2μV p-p over the 0.1Hz to 10Hz band. Noise in a 1MHz bandwidth is approximately 200μV p-p. The dominant source of this noise is the buried Zener which contributes approximately 100nV/$\sqrt{\text{Hz}}$. In comparison, the op amp's contribution is negligible. Figure 5 shows the 0.1Hz to 10Hz noise of a typical AD689. The noise measurement is made with a bandpass filter made of a 1-pole high-pass filter with a corner frequency at 0.1Hz and a 2-pole low-pass filter with a corner frequency at 12.6Hz to create a filter with a 9.922Hz bandwidth.

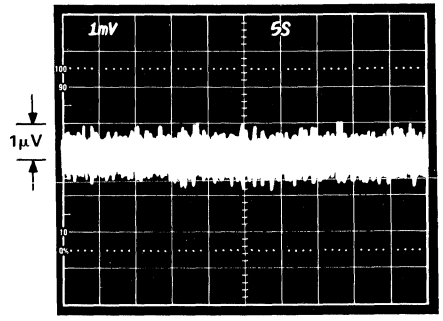

Figure 5. 0.1Hz to 10Hz Noise

If further noise reduction is desired, an external capacitor may be added between the NOISE REDUCTION pin and the GND pin as shown in Figure 2. This capacitor, combined with the 4kΩ R_S and the Zener resistances forms a low-pass filter on the output of the Zener cell. The addition of a 1μF capacitor forms a filter with a 3dB point at 12Hz, and it will reduce the high-frequency (to 1MHz) noise to about 200μV p-p. Figure 6 shows the 1MHz noise of a typical AD689 both with and without a 1μF capacitor.

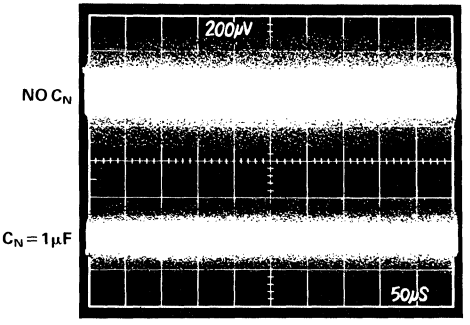

Figure 6. Effect of 1μF Noise Reduction Capacitor on Broadband Noise

TURN-ON TIME

Upon application of power (cold start), the time required for the output voltage to reach its final value within a specified error band is defined as the turn-on settling time. Two components normally associated with this are: the time for the active circuits to settle, and the time for the thermal gradients on the chip to

stabilize. Figure 7 shows the turn-on characteristics of the AD689. It shows the settling to be about 20μs to 0.01%. Note the absence of any thermal tails when the horizontal scale is expanded to 1ms/cm in Figure 7b.

Output turn-on time is modified when an external noise reduction capacitor is used. When present, this capacitor acts as an additional load to the internal Zener diode's current source resulting in a somewhat longer turn-on time. In the case of a 1μF capacitor, the initial turn-on time is approximately 100ms to 0.01%, as shown in Figure 7c.

DYNAMIC PERFORMANCE

The output amplifier is designed to provided the AD689 with static and dynamic load regulation superior to less complete references.

Many A/D and D/A converters present transient current loads to the reference, and poor reference response can degrade the converter's performance.

Figure 8 displays the characteristics of the AD689 output amplifier driving a 0 to +8.192mA load.

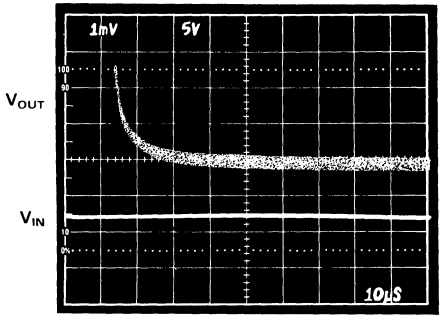

Figure 7a. Electrical Turn-On

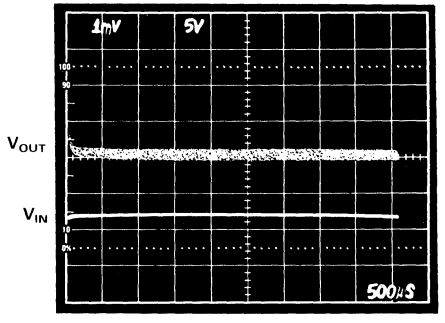

Figure 7b. Extended Time Scale

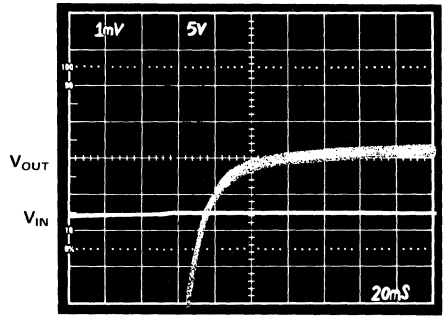

Figure 7c. Turn-On with 1μF C_N

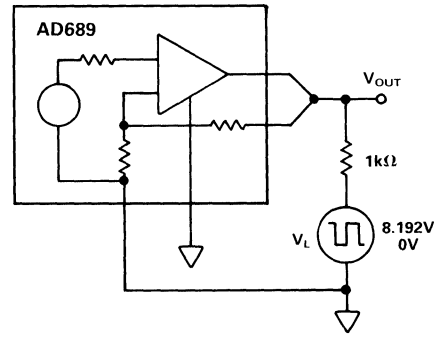

Figure 8a. Transient Load Test Circuit

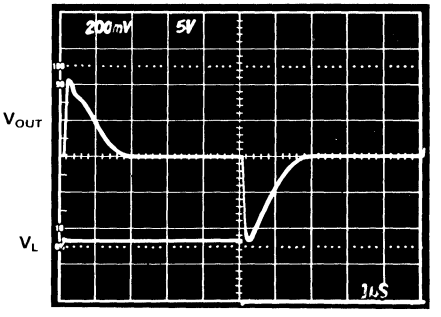

Figure 8b. Large-Scale Transient Response

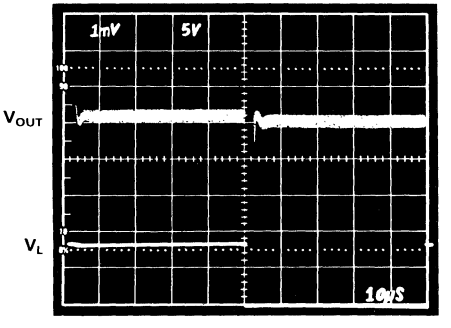

Figure 8c. Fine-Scale Settling for Transient Load

In some applications, a varying load may be both resistive and capacitive in nature, or the load may be connected to the AD689 by a long capacitive cable.

Figure 9 displays the output amplifier characteristics driving a 1000pF, 0 to +8.192mA load.

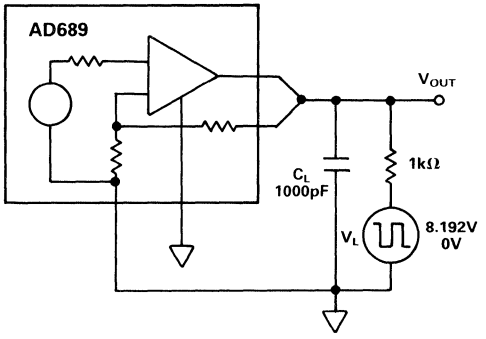

Figure 9a. Capacitive Load Transient Response Test Circuit

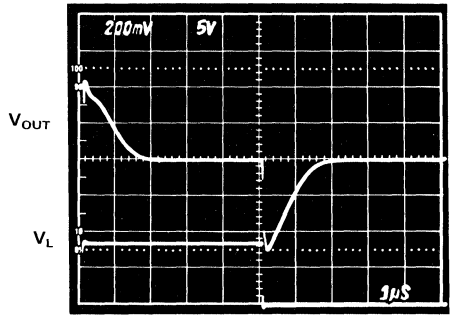

Figure 9b. Output Response with Capacitive Load

TRANSIENT SUPPRESSION IN NOISY ENVIRONMENTS

A precision reference must also exhibit excellent line regulation in noisy environments such as in switching power supply designs, and during electromechanical switching and inductive/capacitive load switching. These environments cause transients on the power supplies which must be internally rejected by the reference or bypassed with the use of external capacitors. Figure 10 shows PSRR versus frequency for the AD689. The voltage applied to V_{IN} is +12V dc plus a 2V p-p sine wave which is varied from 10Hz to 1MHz.

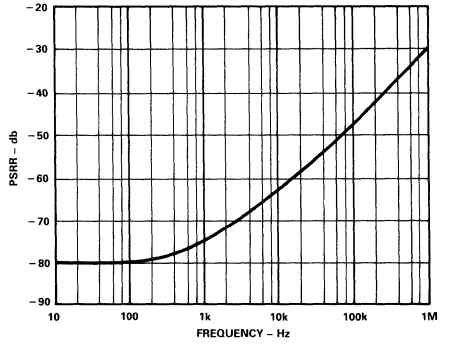

Figure 10. PSRR vs. Frequency

LOAD REGULATION

The AD689 has excellent load regulation characteristics. Figure 11 shows that varying the load a few mA changes the output by several μV. The AD689 exhibits linear load regulation both sourcing and sinking current. Separating the output amplifier ground from the buried Zener ground provides the excellent negative load regulation characteristic.

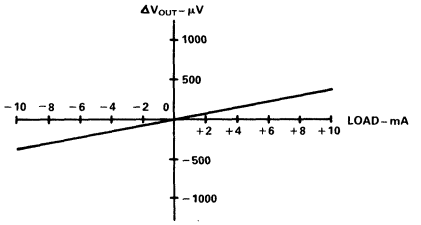

Figure 11. Typical Load Regulation Characteristics

TEMPERATURE PERFORMANCE

The AD689 is designed for precision reference applications where temperature performance is critical. Extensive temperature testing ensures that the device's high level of performance is maintained over the operating temperature range.

Some confusion exists in the area of defining and specifying reference voltage error over temperature. Historically, references have been characterized using maximum deviation per degree centigrade; i.e., ppm/°C. However, because of nonlinearities in temperature characteristics which originated in standard Zener references (such as "S" type characteristics), most manufacturers now use a maximum limit error band approach to specify devices. This technique involves the measuring of the output at three or more different temperatures to specify an output voltage error band.

Figure 12 shows the typical output voltage drift for the AD689L and illustrates the test methodology. The box in Figure 12 is bounded on the top and bottom by the maximum and minimum output voltages measured over the operating temperature range. The slope of the diagonal drawn from the lower left to the upper right corner of the box determines the performance grade of the device.

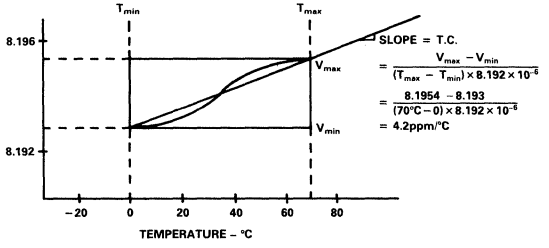

Figure 12. Typical AD689L Temperature Drift

Each AD689J, K, L grade unit is tested at 0, +25°C and +70°C. Each AD689S and T grade unit is tested at −55°C, +25°C and +125°C. This approach ensures that the variations in output voltage that occur as the temperature changes within the specified range will be contained within a box whose diagonal has a slope equal to the maximum specified drift. The position of the box on the vertical scale will change from device to device as initial error and the shape of the curve vary. The maximum height of the box for the appropriate temperature range and device grade is shown in Table I. Duplication of these results requires a combination of high accuracy and stable temperature control in

a test system. Evaluation of the AD689 will produce a curve similar to that in Figure 12, but output readings may vary depending on the test methods and equipment utilized.

Device Grade	Maximum Output Change – mV	
	0 to +70°C	−55°C to +125°C
AD689J	9.22	
AD689K	5.53	
AD689L	1.84	
AD689S		16.38
AD689T		8.19

Table I. Maximum Output Change in mV

USING THE AD689 FOR 12V, 12-BIT CONVERTERS

The AD689 is an ideal reference for use with data converters which require superior load regulation characteristics. The combination of excellent electrical specifications along with flexible force and sense connections allow the AD689 to be used in numerous applications. Several representative examples follow.

MONOLITHIC QUAD 12-BIT DAC – AD664

Four voltage output DACs in a monolithic package with flexible digital interface capabilites and 12-bit accuracies are just a few of the key features of the AD664. The AD689 can be utilized as the voltage reference input as shown in Figure 13 to provide convenient 2mV/LSB scaling. The AD689 is sensed at the AD664 to eliminate any voltage drops that might occur due to current flowing from the AD689 through wire resistances. In precision data conversion applications a voltage reference must maintain its output level during load variations. The AD689 maintains its 8.192V output with a maximum load regulation of 100μV/mA. The change of input resistance at the reference input of the AD664 is specified at 1.4kΩ. A load variation of 1.4kΩ at an input of 8.192V would result in a maximum of 0.3mV output change from the AD689; for the 12-bit AD664 this represents 0.15LSBs.

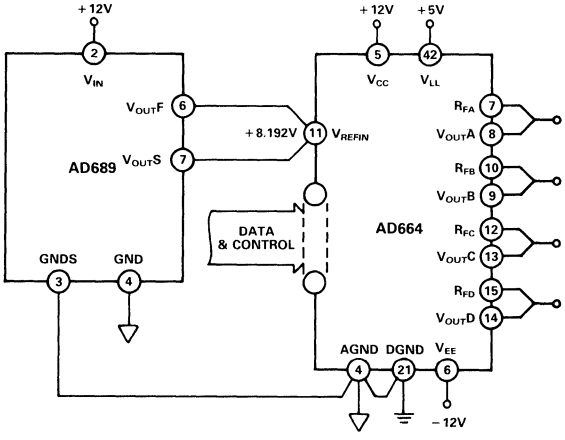

Figure 13. Quad 12-Bit DAC Application

±12V POWER SUPPLIES LIMIT REFERENCE SELECTION

In many systems with ±12V supplies, 5V references have to be substituted for 10V references due to headroom requirements from the supply input to the reference output. The AD689 is specified to operate with 12V ±10% supplies, increasing the voltage signal range by greater than 50% over systems using 5V references.

12-BIT DIGITAL-TO-ANALOG CONVERTER – AD767

The AD767 is specified to operate on supplies ranging from ±15V ±10% to ±12V ±5%. However, if ±12V ±10% supplies are used, then the supply voltage could drop to 10.8V. Because the internal 10V reference will not function properly at +10.8V, an external reference must be used. Figure 14 shows the AD689 connected through a trim resistor to REF IN (Pin 7) on the AD767. Additional trim range must be provided since the internal reference of the AD767 has a 1% tolerance (±100mV) and full-scale and bipolar offset are both trimmed with the internal reference. The connection of internal scaling resistors allows the AD767 to be configured in many voltage output ranges as shown in Table II. Tables III and IV show output voltage levels when the AD767 is configured in straight binary and offset binary modes.

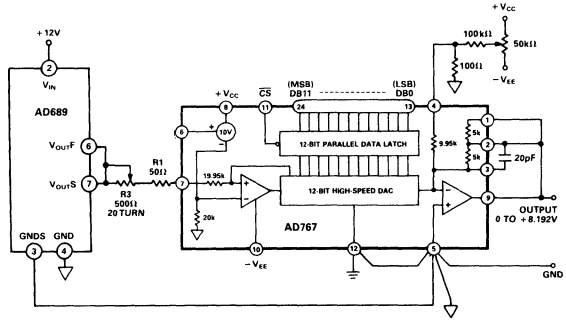

Figure 14. The AD689 as a Reference for the AD767

Output Range	Digital Input	LSB
±8.192V	Offset Binary	4mV
±4.096V	Offset Binary	2mV
±2.048V	Offset Binary	1mV
0 to +8.192V	Straight Binary	2mV
0 to +4.096V	Straight Binary	1mV

000	8.192V(2048/2048) = −8.192V

Note: 1LSB = $8.192V/2^{11}$ = 4mV

Table IV. Bipolar (Offset Binary) Codes

12-BIT ANALOG-TO-DIGITAL CONVERTER – AD574A

The AD574A is a complete 12-bit A/D converter with reference and clock. It is specified to operate on ±15V ±10% supplies or ±12V ±5% supplies. The internal +10V reference does not function properly with the use of ±12V ±10% supplies; the AD689 is then the ideal choice for an external reference. The AD689 also provides excellent temperature coefficent characteristics, reducing the gain T. C. by as much as 75% (depending on grade) over use of the internal reference. Figure 15 shows the AD689 connected in the optional trim configuration mode. The additional trim range is required since the internal reference of the AD574A has a ±20mV tolerance, and full scale and offsets are both trimmed with the internal reference. The force and sense outputs are connected as closely as possible to the AD574A, and the ground sense pin is connected at the ANALOG COMMON pin (Pin 9) of the AD574A. This ensures that the AD689 will accurately deliver the 8.192V at the reference input.

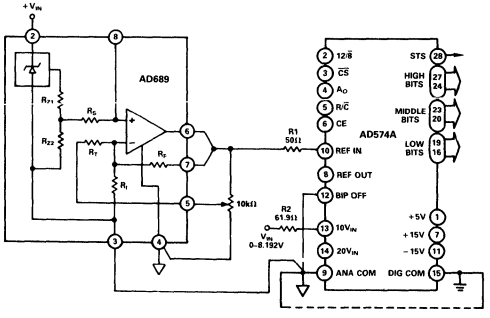

Figure 15. AD689/AD574A Connections

NEGATIVE REFERENCE VOLTAGE FROM AN AD689

The AD689 can be used to provide a precision −8.192V output as shown in Figure 16. The V_{IN} pin is tied to at least a +3V supply; the output pins are grounded; and the AD689 ground pins are connected through a resistor to a −12V supply. The equation provided in Figure 16 calculates the value of the resistor (R_S) such that when no load is connected the AD689 will sink the maximum current (8.192mA) plus the maximum quiescent current (5mA). When the load is connected, the AD689 will respond by reducing the current it sinks by the equivalent of the load current. The −8.192V output is produced at the ground pins (Pins 3 and 4) instead of the V_{OUT} pins. The temperature characteristics and long-term stability of the device will be essentially the same as that of a unit used in the standard +8.192V configuration.

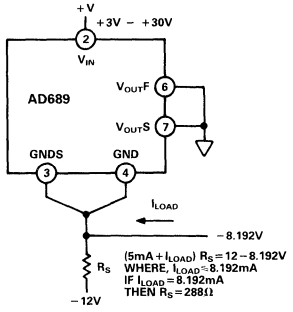

Figure 16. AD689 as a Negative 8.192V Reference

PRECISION CURRENT SOURCE

The design of the AD689 allows it to be easily configured as a precision current source. By choosing the control resistor R_C in Figure 17, you can vary the load current (I_L) from the quiescent current (2mA typically) to approximately 10mA. The compliance voltage (V_L) of this circuit varies depending upon the value of $+V_{IN}$ as shown in Figure 17.

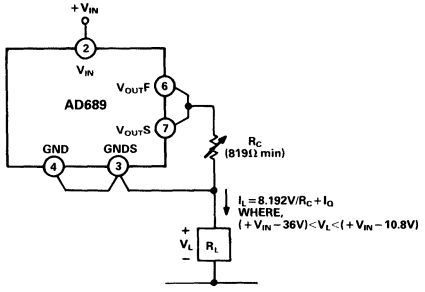

Figure 17. Precision Current Source

PRECISION HIGH CURRENT SUPPLY

For higher currents, the AD689 can easily be connected to a power NPN or power Darlington NPN device. The circuit in Figure 18 can deliver up to 4 amps to the load. Due to potential headroom limitations on the V_{OUT} FORCE (Pin 6) when the power supply drops to a minimum of 10.8V, a resistor (R) from the power supply to V_{OUT} FORCE (Pin 6) is added to provide the maximum base current required by the 2N6282. The AD689 will, therefore, only be required to sink current. This arrangement guarantees sufficient base drive for the Darlington if the power supply drops to 10.8V. The formula provided calculates the value of R based on the minimum power supply voltage expected, V_{BE} and I_B maximum.

$$R = \frac{V_{IN}\,(\min) - (8.192V + V_{BE} + I_B\,[\max] \times 20\Omega)}{I_B\,(\max)}$$

Where,

V_{IN} (min) ≥ 10.8V

I_B (max) ≤ 8.192mA

For example,

When, V_{IN} = 10.8V, I_C = 4A, I_B = 2mA (max),

V_{BE} = 1.2V

Then R = 684Ω

ANALOG DEVICES

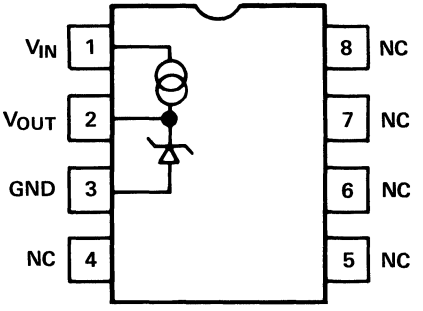
Low Cost, Precision 2.5V IC References

AD1403/AD1403A*

FEATURES

Improved, Lower Cost, Replacements for Standard 1403, 1403A
3-Terminal Device: Voltage In/Voltage Out
Laser Trimmed to High Accuracy: 2.500V ±10mV (AD1403A)
Excellent Temperature Stability: 25ppm/°C (AD1403A)
Low Quiescent Current: 1.5mA max
10mA Current Output Capability
Low Cost
Convenient Mini-DIP Package

AD1403/AD1403A FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD1403 and AD1403A are improved three-terminal, low cost, temperature compensated, bandgap voltage references that provide a fixed 2.5V output voltage for inputs between 4.5V and 40V. A unique combination of advanced circuit design and laser-wafer-trimmed thin-film resistors provides the AD1403/AD1403A with an initial tolerance of ±10mV and a temperature stability of better than 25ppm/°C. In addition, the low quiescent current drain of 1.5mA (max) offers a clear advantage over classical zener techniques.

The AD1403 or AD1403A is recommended as a stable reference for all 8-, 10- and 12-bit D-to-A converters that require an external reference. In addition, the wide input range of the AD1403/AD1403A allows operation with 5 volt logic supplies, making these devices ideal for digital panel meter applications and when only a single logic supply is available.

The AD1403 and AD1403A are specified for operation over the 0 to +70°C temperature range. The AD580 series of 2.5 volt precision IC references is recommended for applications where operation over the −55°C to +125°C range is required.

*Covered by Patent Numbers: 3,887,863; RE30,586.

PRODUCT HIGHLIGHTS

1. The AD1403A offers improved initial tolerance over the industry-standard 1403A: ±10mV versus ±25mV at a lower cost.
2. The three-terminal voltage in/voltage out operation of the AD1403/AD1403A provides a regulated output voltage without any external components.
3. The AD1403/AD1403A provides a stable 2.5V output voltage for input voltages between 4.5V and 40V making these devices ideal for systems that contain a single logic supply.
4. Thin film resistor technology and tightly controlled bipolar processing provide the AD1403A with temperature stabilities of 25ppm/°C.
5. The low 1.5mA maximum quiescent current drain of the AD1403 and AD1403A makes them ideal for CMOS and other low power applications.

Applying the AD1403/AD1403A

VOLTAGE VARIATION VS. TEMPERATURE AND LINE

Some confusion exists in the area of defining and specifying reference voltage error over temperature. Historically, references are characterized using a maximum deviation per degree Centigrade; i.e., 10ppm/°C. However, because of the inconsistent nonlinearities in zener references (butterfly or "S" type characteristics), most manufacturers use a maximum limit error band approach to characterize their references. This technique measures the output voltage at 3 to 5 different temperatures and guarantees that the output voltage deviation will fall within the guaranteed error band at these discrete temperatures. This approach, of course, makes no mention or guarantee of performance at any other temperature within the operating temperature range of the device.

The consistent Voltage vs. Temperature performance of a typical AD1403 is shown in Figure 6. Note that the characteristic is quasi-parabolic, not the possible "S" type characteristics of classical zener references. This parabolic characteristic permits a maximum output deviation specification over the device's full operating temperature range, rather than just at 3 to 5 discrete temperatures.

The AD1403 exhibits a worst-case shift of 7.5mV over the entire range of operating input voltage, 4.5 volts to 40 volts. Typically, the shift is less than 1mV as shown in Figure 3.

THE AD1403A AS A LOW POWER, LOW VOLTAGE PRECISION REFERENCE FOR DATA CONVERTERS

The AD1403A has a number of features that make it ideally suited for use with A/D and D/A data converters used in complex microprocessor-based systems. The calibrated 2.500 volt output minimizes user trim requirements and allows operation from a single low voltage supply. Low power consumption (1.5mA quiescent current) is commensurate with that of CMOS-type devices, while the low cost and small package complements the decreasing cost and size of the latest converters.

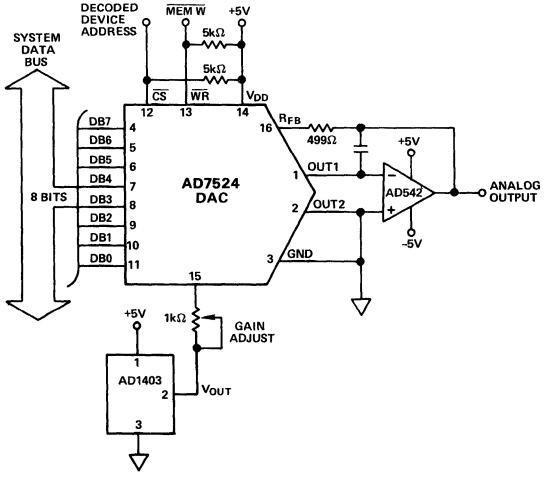

Figure 7. Low Power, Low Voltage Reference for the AD7524 Microprocessor-Compatible 8-Bit DAC

Figure 9 shows the AD1403A used as a reference for the AD7524 low-cost 8-bit CMOS DAC with complete microprocessor interface. The AD1403A and the AD7524 are specified to operate from a single 5 volt supply; this eliminates the need to provide a +15 volt power supply for the sole purpose of operating a reference. The AD7524 includes an 8-bit data register, and address decoding logic; it may thus be interfaced directly to an 8- or 16-bit data bus. Only 300μA of quiescent current from the single +5 volt supply is required to operate the AD7524 which is packaged in a small 16 pin DIP. The AD542 output amplifier is also low power, requiring only 1.5mA quiescent current. Its laser-trimmed offset voltage preserves the ±1/2LSB linearity of the AD7524KN without user trims and it typically settles to ±1/2LSB in less than 5 microseconds. It will provide the 0 volt to -2.5 volt output swing from ±5 volt supplies.

THE AD1403 AS A PRECISION PROGRAMMABLE CURRENT SOURCE

The AD1403 is an excellent building block for precision current sources. Its wide range of operating voltages, 4.5V to 40V, along with excellent line regulation over that range (7.5mV) result in high insensitivity to varying load impedances. The low quiescent current (I_I) of 1.5mA (max) and the maximum specified maximum load current of 10mA allows the user to program current to any value between 1.5mA and 10mA.

Figure 10a shows the AD1403 connected as a current source. Total current is equal to the quiescent current plus the load current. Most of the temperature coefficient comes from the quiescent current term I_I, which has a typical TC of 0.13%/°C (1300ppm/°C). The load voltage (and hence current) TC is much lower at ±40ppm/°C max (AD1403). Therefore, the overall temperature coefficient decreases rapidly as the load current is increased. Figure 10b shows the typical temperature coefficient for currents between 1.5mA and 10mA. Use of an AD1403A will not improve the TC appreciably.

ANALOG DEVICES

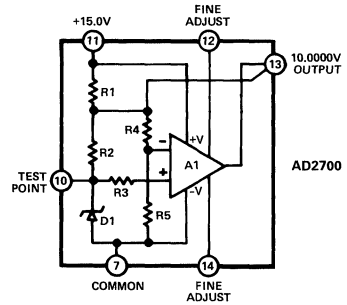
±10 Volt Precision Reference Series

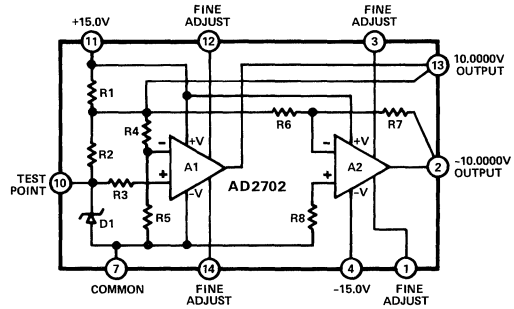
AD2700/AD2701/AD2702

FEATURES

Very High Accuracy: 10.000 Volts ±2.5mV (L and U)
Low Temperature Coefficient: 3ppm/°C
Performance Guaranteed -55°C to +125°C
10mA Output Current Capability
Low Noise
Short Circuit Protected
Available as /883B

AD2700 SERIES FUNCTIONAL BLOCK DIAGRAMS





PRODUCT DESCRIPTION

The AD2700 family of precision 10 volt references offer the user excellent accuracy and stability at a moderate price by combining the recognized advantages of thin film technology and active laser trimming. The low temperature drift (3ppm/°C) achieved with these technologies can be matched only by the use of ovens, chip heaters for temperature regulation, or with hand selected components and manual trimming. In addition, temperature-regulated devices are guaranteed only up to +85°C operation, whereas the U- and S-grade devices in the AD2700 family are guaranteed to +125°C.

The AD2700 is a +10 volt reference which is designed to interface with high accuracy bipolar D/A converters of 10 and 12 bit resolution. The 10mA output drive capability also makes the AD2700 ideal for use as a general positive system reference.

The AD2701 is a negative 10 volt reference especially designed to interface with CMOS D/A and A/D converters, as shown in the applications. For systems requiring a dual tracking reference, the AD2702 offers both positive and negative precision 10 volt outputs in a single package. Both are often used with 52XX Series 12-bit A/D converters which require -10V external references for high accuracy over wide temperature ranges.

All three devices are offered in "J" and "L" grades for operation from -25°C to +85°C and "S" and "U" grades for the -55°C to +125°C temperature range. Screening to MIL-STD-883 is available for "S" and "U" grades of the AD2700 family.

PRODUCT HIGHLIGHTS

1. Active laser trimming of both initial accuracy and temperature performance results in very high accuracy over the temperature range without external components. The AD2700/01/02 LD grades have a maximum output voltage error at 25°C of ±2.5mV with no external adjustments.
2. The performance of the AD2700 series is achieved by a well-characterized design and precise control over the manufacturing process.
3. The AD2700 series is well suited for a broad range of applications requiring an accurate, stable reference source such as high resolution data converters (12 or 14 bits), test and measurement systems and calibration standards.

[1] Specified with resistive load to common. Device not intended for use in driving a dynamic load.

[2] Output voltage error as a function of temperature is determined using the box method. Each unit is tested at T_{min}, T_{max} and +25°C. At each temperature V_{OUT} must fall within the rectangular area bounded by the minimum and maximum temperature and whose maximum V_{OUT} value is equal to V_{OUT} nominal plus or minus the maximum +25°C error plus the maximum drift error from +25°C. The box limits are noted below the drift values used to calculate the box.

[3] Analog Devices reserves the right to ship metal packages (outline DH-14B) in lieu of the standard ceramic packages for J and L grade parts.

Using AD2702 Reference with the Fast, High Accuracy AD5215 – 12-Bit ADC

USING AD2700 REFERENCE WITH THE AD7520 AND AN IC AMPLIFIER TO BUILD A DAC

The AD2700 series is ideal for use with the AD7520 series of CMOS D/A converters. A CMOS converter in a unipolar application as shown below performs an inversion of the voltage reference input. Thus, use of the +10 volt AD2700 reference will result in a 0 to -10 volt output range. Alternatively, using the -10 volt AD2701 will result in a 0 to +10 volt range. Two operational amplifiers are used to give a bipolar output range of -10 volt to +10 volt, as shown in the lower figure. Either the AD2700 or AD2701 can be used, depending on the transfer code characteristic desired. For more detailed applications information, refer to the AD7520 Data Sheet.

Table II. Code Table — Bipolar (Offset Binary) Operation

USING THE AD2700 VOLTAGE REFERENCE WITH D/A CONVERTER

An AD2700 Voltage Reference can be used with an inverting operational amplifier and an R-2R ladder network. If all bits but the MSB are off (i.e., grounded), the output voltage is $(-R/2R)E_{REF}$. If all bits but Bit 2 are off, it can be shown that the output voltage is $\frac{1}{2}(-R/2R)E_{REF} = \frac{1}{4}E_{REF}$: The lumped resistance of all the less-significant-bit circuitry (to the left of Bit 2) is 2R; the Thevenin equivalent looking back from the MSB towards Bit 2 is the generator, $E_{REF}/2$, and the series resistance 2R; since the grounded MSB series resistance, 2R, has virtually no influence — because the amplifier summing point is at virtual ground — the output voltage is therefore $-E_{REF}/4$. The same line of thinking can be employed to show that the nth bit produces an increment of output equal to 2^{-n} E_{REF}.

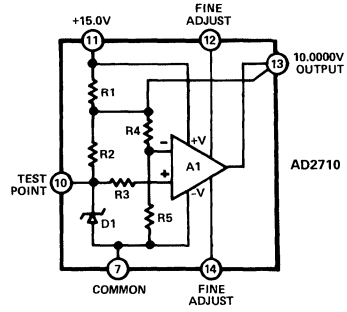
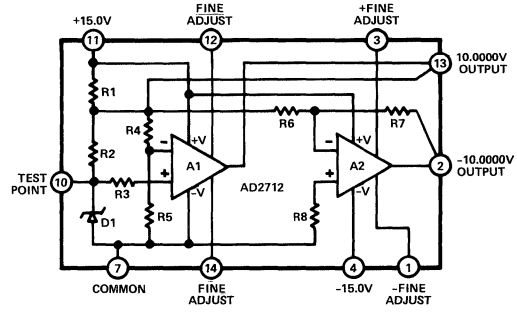
AD2710/AD2712 FUNCTIONAL BLOCK DIAGRAMS





PRODUCT DESCRIPTION

The AD2710 and AD2712 are temperature-compensated, hybrid voltage references which provide precise 10.000V output from an unregulated input level from 13.5 to 16.5 volts. Active laser trimming is used to trim both the initial error at +25°C as well as the temperature coefficient, which results in ultra high precision performance previously available only in oven-regulated modules. The 1.0mV maximum initial error and 1ppm/°C guaranteed maximum temperature coefficient of the AD2710L and AD2712L represent the best performance combination available without using ovens or heated substrates for temperature regulation.

The AD2710 series of precision 10.000 volt references offer the user unequalled accuracy and stability with performance guaranteed over the 0 to +70°C temperature range. The devices combine the recognized advantages of thin film technology and active laser trimming with a unique integrated ceramic package design to provide an excellent reference for use in applications requiring high accuracy and stability.

The AD2710 is recommended for use as a reference for 10-, 12- and 14-bit D/A converters which require an external reference. The device is also suitable for many types of high resolution A/D converters, either successive approximation or integrating designs. The 5mA output drive capability of the device also makes the AD2710 ideal for use as a master system reference.

For systems requiring a dual tracking reference, the AD2712 offers both positive and negative outputs in a single package. All units are packaged in an integrated ceramic 14-pin side-brazed package offering superior reliability over other package designs.

PRODUCT HIGHLIGHTS

1. Active laser trimming of both initial accuracy and temperature coefficient results in very high accuracy over the temperature range without the use of external components. AD2710 has a maximum deviation from 10.000 volts of ±1.00mV at 25°C with no external adjustments.
2. The AD2710 and AD2712 are well suited for a broad range of applications requiring an accurate, stable reference source such as data converters, test and measurement systems and calibration standards.
3. The performance of the AD2710 series is achieved by a well-characterized design and close control over the manufacturing process. This eliminates the need for temperature-controlled ovens to provide stability.
4. The advanced multilayer integrated ceramic package results in superior electrical performance as well as inherent high reliability.

NOTES

*Same as AD2710KN. **Same as AD2712KN performance.

[1] Specifications apply to both outputs of the AD2712.

[2] Refer to next page for definition of temperature-related error specifications.

[3] The AD2710LN and AD2712LN outputs are guaranteed for a maximum ±2ppm/°C temperature coefficient over the +15°C to +25°C temperature range. Refer to Figure 1.

[4] The +10V and −10V outputs of the AD2712 typically track within ±1ppm/°C over the specified temperature range.

[5] Negative power supply not required for AD2710.

[6] Use of the output trim will change the temperature coefficient approximately 0.3ppm/°C for each millivolt of adjustment.

[7] See Section 14 for package outline information.

Specifications subject to change without notice.

UNDERSTANDING THE SPECIFICATIONS

The AD2710 and AD2712 precision references are designed for applications requiring both the lowest possible initial error at room temperature and the lowest possible temperature drift. The specification for initial error is relatively straight-forward, and is the absolute error from exactly 10.000V. The specification for temperature drift, however, must be explained.

Various methods have been used to specify the temperature drift of voltage references, including the "butterfly", "box", and "modified-box" (or total error) methods. The AD2710 and AD2712 are specified with the "butterfly" method.

Using three or more temperatures provides the user with a tighter drift specification, eliminating possible mid-range excursions. The AD2710 and AD2712 have been designed and characterized as having a smooth drift curve with a virtually straight segment from +25°C to +70°C. The typical curve as shown is concave downward and gradually increases slope near 0°C.

As can be seen from Figure 1, the AD2710L and AD2712L +10V outputs will exhibit a maximum temperature coefficient of ±1ppm/°C (±2ppm/°C for "K" grade) from +25°C to +70°C. Over the short range between +15°C and +25°C, the AD2710L and AD2712L +10V outputs have a maximum drift of only ±2ppm/°C and a maximum drift of ±5ppm/°C from 0 to +15°C. The negative output of the AD2712L has a similar temperature coefficient characteristic with a maximum slope of ±2ppm/°C from +25°C to +70°C. This limit continues from +25°C to +15°C and then increases to a ±5ppm/°C maximum slope from +15°C and 0°C. Every unit is 100 percent tested and guaranteed to meet these specifications over the full 0 to +70°C temperature range.

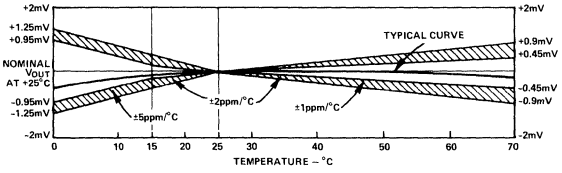

Figure 1. Maximum Change from +10V Output from +25°C Value vs. Temperature

All grades of the AD2710 and AD2712 are tested after a five minute warm-up period. This warm-up allows the entire circuit to attain thermal equilibrium. The warm-up drift is approximately 500 microvolts and is completely settled approximately three minutes after turn-on. Figure 2 shows the typical warm-up characteristics of the AD2710.

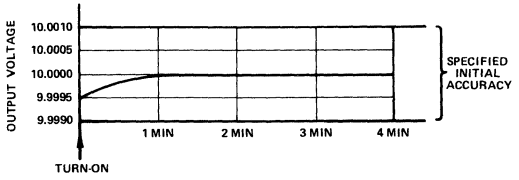

Figure 2. AD2710 Typical Warm-Up Drift

USING THE AD2710 AS A DAC REFERENCE

Digital-to-analog converters require a reference to establish the full scale output range. It is this reference which will ultimately determine the absolute accuracy of the converter. While many converters include internal reference sources, better overall performance can be obtained if a higher precision external reference is used.

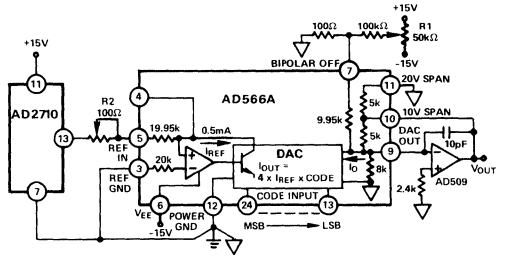

Figure 3. Low Drift 12-Bit D/A Converter

Figure 3 shows the AD2710 used with the AD566A high-speed 12-bit DAC. The AD566AKD is laser trimmed for ±1/4LSB maximum nonlinearity, and exhibits a gain temperature coefficient of 3ppm/°C. Use of the AD2710LN reference will result in a worst case total gain temperature coefficient of 4ppm/°C. After initial calibration of the DAC scale factor at room temperature, 12-bit absolute accuracy can be maintained over the +15°C to +70°C temperature range. The high output current capability of the AD2710 allows it to serve as a reference for up to 10 such converters in a system.

The resolution of the AD566A can be extended as shown in Figure 3 by summing the output of another DAC. In this example, an AD559 is used to provide 4 additional bits. Since the AD559 is driven from the same AD2710 reference as the AD566A which provides the higher-order bits, and uses a similar internal thin-film resistor ladder, it will exhibit first-order temperature tracking. While this circuit provides 16-bits of resolution, it is only as accurate as the AD566A used for the most significant bits. Use of an AD566AKD will typically achieve ±0.003% accuracy (±1/2LSB at 14 bits).

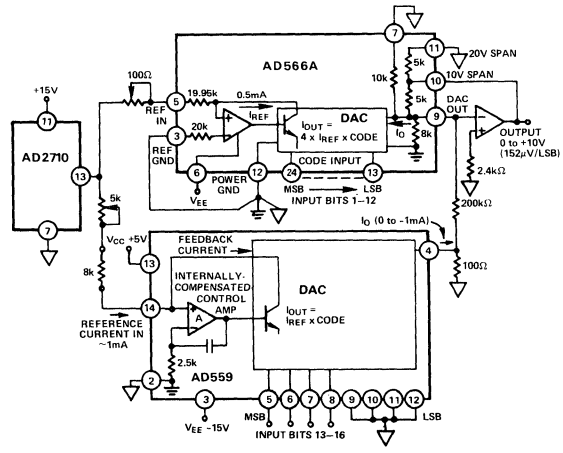

Figure 4. 16-Bit Binary DAC with AD2710 Reference

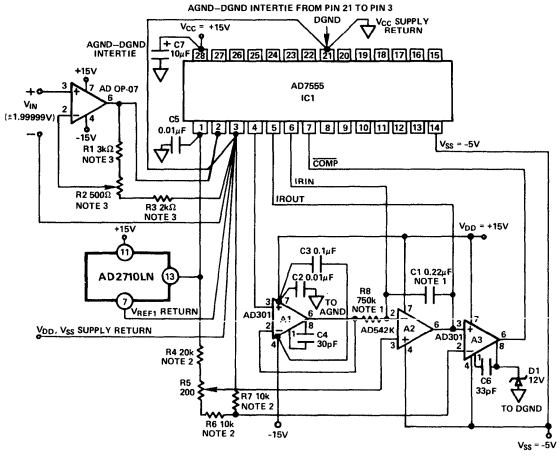
HIGH RESOLUTION ANALOG-TO-DIGITAL CONVERSION

The AD2710 is well-suited to both system and instrument-level analog-to-digital converter reference requirements. The excellent absolute accuracy and low temperature drift allow low-cost measurement systems to offer high levels of performance.

The AD7555 is a 4½/5½ digit ADC subsystem which uses the quad-slope conversion technique to achieve high accuracy at low cost. This patented conversion process performs automatic correction for offsets and other errors in the analog circuitry as a part of each conversion. Total scale factor drift 1.2ppm/°C is possible using the AD2710L reference and medium-precision external amplifiers. This represents a full scale drift of less than ±10 counts in ±200,000 from +15°C to +45°C. Less than 1 count of drift will occur in the 4 1/2 digit mode.

The AD7555 was designed for use with a 4.096V reference, which produces a ±2 volt input range. When the AD2710 is used, the input range is increased to ±4.88281V (24.4μV/count). The new scaling can be handled either by using a precision gain stage before the AD7555 analog input as shown or by using a microprocessor to digitally correct the scale. The actual input signal value can be computed by multiplying the count produced by the AD7555 by V_{REF1} (10 volts in this case), and dividing the result by 409600. Details of the digital circuitry of the AD7555 can be found on the AD7555 data sheet.

It should be noted that when the AD7555 is used with the AD2710 10 volt reference, it is necessary to use a V_{CC} greater than 10 volts. Thus the digital inputs and outputs of the ADC will be compatible with CMOS logic levels.



NOTES:
1. R8 C1 VALUES SHOWN ARE FOR 5 1/2 DIGIT MODE. FOR 4 1/2 DIGIT MODE R_8 = 360k, C_1 = 0.22μF. SUITABLE CAPACITORS AVAILABLE FROM COMPONENT RESEARCH CO. INC., 1655 26th STREET, SANTA MONICA, CA. 90404. (STOCK NUMBER FOR 0.22μF CAPACITOR IS D11B224KXW).
2. R4, R6, R7 1% TOLERANCE
3. R1, R3 SHOULD TRACK WITHIN 0.5ppm/°C. EITHER BULK METAL OR WIRE-WOUND RESISTORS (OR A THIN-FILM NETWORK) SHOULD BE USED. R2 SHOULD BE A LOW-TC TYPE POTENTIOMETER OR A SELECTED LOW DRIFT FIXED RESISTOR.

PRODUCT DESCRIPTION

The ADREF01 and ADREF02 are a 10V and 5V reference, respectively, that utilize a buried Zener diode for minimal noise and drift over temperature. The Zener diode provides a precise 10.0V (5.0V for REF02) output from an unregulated input voltage of 13.5V (10.8V for REF02) to 36V. Laser Wafer Trimming (LWT) is used to trim both the initial error at +25°C as well as the temperature coefficient.

The +10V output can be adjusted over a +3%, −1% range with minimal effect on device characteristics. The +5V output can also be adjusted over a +6%, −2% range with minimal effect on device characteristics. The ADREF01 and ADREF02 offer good drift characteristics, low power consumption, and good accuracy for applications requiring a low-cost reference.

These devices are recommended as references for 8-, 10- and 12-bit D/A converters that require an external reference. They are also ideal for all types of A/D converters with up to 12-bit accuracy.

The ADREF01E/ADREF02E and ADREF01H/ADREF02H are specified for operation from 0 to +70°C, and the ADREF01/ADREF02 and ADREF01A/ADREF02A are specified for operation between −55°C and +125°C. All grades are packaged in a hermetic 8-pin cerdip package.

PRODUCT HIGHLIGHTS

1. The ADREF01 is a second source equivalent to the industry standard REF01.
2. The ADREF01 provides a stable 10.000V output for input voltages between 13.5V and 36V.
3. Laser Wafer Trimming reduces ADREF01 initial offset error to 30mV (A and E grades).
4. The ADREF02 is a second source equivalent to the industry standard REF02.
5. The ADREF02 provides a stable 5.000V output for input voltages between 10.8V and 36V.
6. Laser Wafer Trimming reduces ADREF02 initial offset error to 15mV (A and E grades).
7. Temperature out pin enables the ADREF02 to be configured as a temperature transducer.
8. The buried Zener diode reference on both devices reduces noise to 4μV p-p and improves temperature stability to 8.5ppm/°C max (A and E grades).
9. Cerdip packaging provides hermeticity and machine insertability at a low price for the devices.

*See Section 14 for package outline information.

THEORY OF OPERATION

The ADREF01 and ADREF02 consist of a proprietary buried Zener diode reference, an output buffer amplifier, and several high stability thin-film resistors. This design provides an accurate 10V reference with initial offset of 30mV or less, or an accurate 5V reference with initial offset of 15mV or less, and a temperature coefficient of 8.5ppm/°C (A and E grades).

LOAD REGULATION

The ADREF01 and ADREF02 have excellent load regulation characteristics. Figure 1 shows that varying the load several mA changes the output by only a few μV. The ADREF02 has somewhat better load regulation performance sourcing current than sinking current.

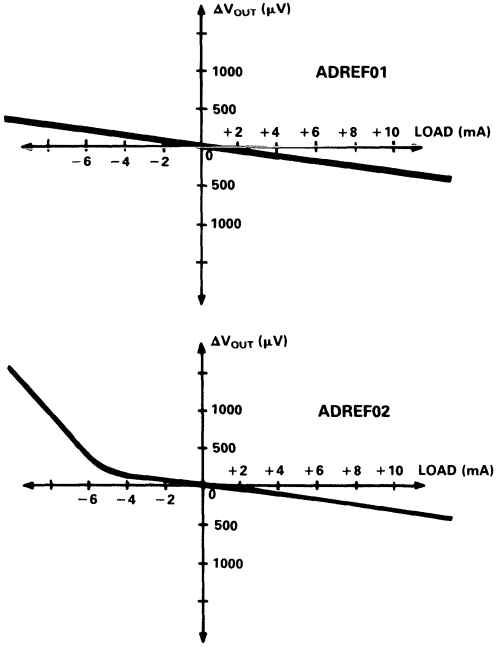

Figure 1. Typical Load Regulation Characteristics

TEMPERATURE PERFORMANCE

The ADREF01 and ADREF02 are designed for reference applications where good temperature performance is needed. Temperature testing ensures that the device's high level of performance is maintained over the operating temperature range.

Some confusion exists in the area of defining and specifying reference voltage error over temperature. Historically, references have been characterized using a maximum deviation per degree Centrigrade; i.e., ppm/°C. However, because of nonlinearities in temperature characteristics which originated in standard Zener references (such as "S" type characteristics), most manufacturers have begun to use a maximum limit error band approach to specify devices. This technique involves the measurement of the output at three or more different temperatures to specify an output voltage error band.

Figure 2 shows the typical output voltage drift for the ADREF01E and ADREF02E and illustrates the test methodology. The box in Figure 2 is bounded on the sides by the operating temperature extremes, and on the top and the bottom by the maximum and minimum output voltages measured over the operating temperature range. The slope of the diagonal drawn from the lower left to the upper right corner of the box determines the performance grade of the device.

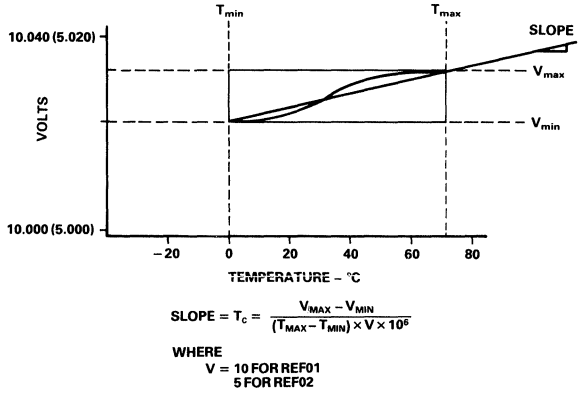

Figure 2. Typical ADREF01E/ADREF02E Temperature Drift

Each E and H grade unit is tested at 0, +25°C and +70°C. Each ADREF01/ADREF02 & A grade unit is tested at −55°C, +25°C and +125°C. This approach ensures that the variations of output voltage that occur as the temperature changes within the specified range will be contained within a box whose diagonal has a slope equal to the maximum specified drift. The position of the box on the vertical scale will change from device to device as initial error and the shape of the curve vary. The maximum height of the box for the appropriate temperature range and device grade is shown in Figure 3. Duplication of these results requires a combination of high accuracy and stable temperature control in a test system. Evaluation of the ADREF01 or ADREF02 will produce a curve similar to that in Figure 3, but output readings may vary depending on the test methods and equipment utilized.

DEVICE GRADE	MAXIMUM OUTPUT CHANGE (mV)	
	0 TO +70°C	−55°C TO +125°C
ADREF01H/02H	67.5/8.75	
ADREF01E/02E	36/2.98	
ADREF01/02		95/22.50
ADREF01A/02A		45.3/7.65

Figure 3. Maximum Output Change in mV

APPLYING THE ADREF01 AND ADREF02

The ADREF01 is simple to use in virtually all reference applications. When power is applied to Pin 2 and Pin 4 is grounded, Pin 6 provides a 10V output. No external components are required; the degree of desired absolute accuracy is achieved simply by selecting the required device grade. The ADREF01 requires less than 4mA quiescent current from an operating supply of +15V. The ADREF02 requires less than 3mA quiescent current from an operating supply of +12V or +15V.

An external fine trim may be desired to set the output level to exactly 10.000V or 5.000V when using ADREF02 (calibrated to a main system reference). System calibration may also require a reference voltage that is slightly different from 10.000V, for example, 10.24V for binary applications in the REF01 or 5.12V in the REF02. In either case, the optional trim circuit shown in Figure 4 can offset the output by as much as 300mV, if desired, with minimal effect on other device characteristics.

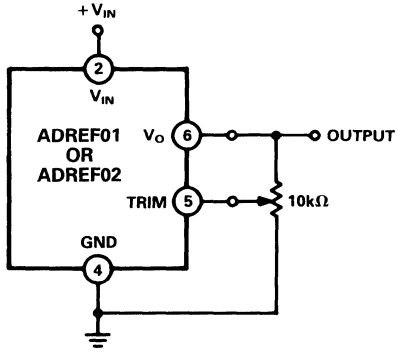

Figure 4. Optional Fine Trim Configuration

NEGATIVE REFERENCE VOLTAGE FROM AN ADREF01

The ADREF01 can be used to provide a −10.000V output as shown in Figure 5. The V_{IN} pin is tied to at least a +3.5V supply, the output pin is grounded, and the ADREF01 ground pin is connected through a resistor, R_S, to a −15V supply. The −10V output is now taken from the ground pin (Pin 4) instead of V_{OUT}. It is essential to arrange the output load and the supply resistor R_S so that the net current through the ADREF01 is between 2.5mA and 10mA. The temperature characteristics and long-term stability of the device will be essentially the same as that of a unit used in the standard +10V output configuration.

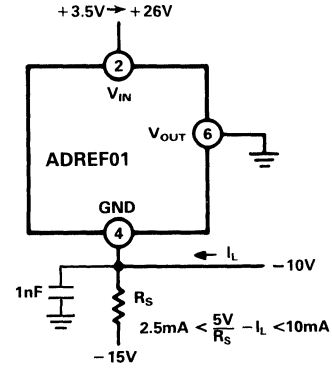

Figure 5. Negative 10V Reference

NEGATIVE REFERENCE VOLTAGE FROM AN ADREF02

The ADREF02 can be used to provide a −5.000V output as shown in Figure 6. The V_{IN} pin is tied to at least a +6V supply, the output pin is grounded, and the ADREF02 ground pin is connected through a 4kΩ resistor to a −15V supply. The −5V output is now taken from the ground pin (Pin 4) instead of V_{OUT}. It is essential to arrange the output load and the supply resistor R_S so that the net current through the ADREF02 is less than 5mA. The temperature characteristics and long-term stability of the device will be essentially the same as that of a unit used in the standard +5V output configuration.

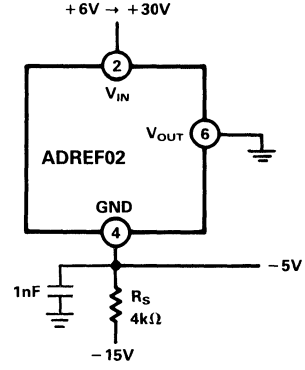

Figure 6. Negative 5V Reference

5V OR 10V REFERENCE WITH MULTIPLYING CMOS D/A OR A/D CONVERTERS

The ADREF02 is ideal for applications with 10- and 12-bit multiplying CMOS D/A converters. In the standard hook-up, as shown in Figure 7, the ADREF02 is paired with the AD7533 10-bit multiplying DAC and the AD711 high-speed BiFET op amp. The amplifier/DAC configuration produces a unipolar 0 to −5V output range. Bipolar output applications and other operating details can be found on the AD7533 data sheet. The ADREF01 can also be used in this configuration to produce a unipolar 0 to −10V output range.

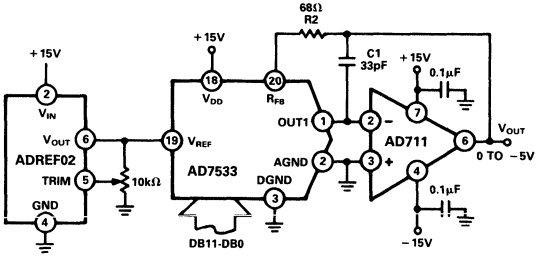

Figure 7. Low-Cost 10-Bit CMOS DAC Application

CURRENT SOURCE

The design of the ADREF01 allows it to be easily configured as a current source. The voltage drop from Pin 2 to Pin 4 in Figure 8 must remain between 13.5V and 36V. There will be a constant 10V drop across R_C. By choosing control resistor R_C you can vary the load current from the quiescent current (2mA typically) to approximately 10mA.

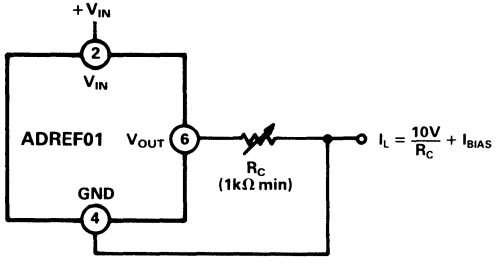

Figure 8. Current Source

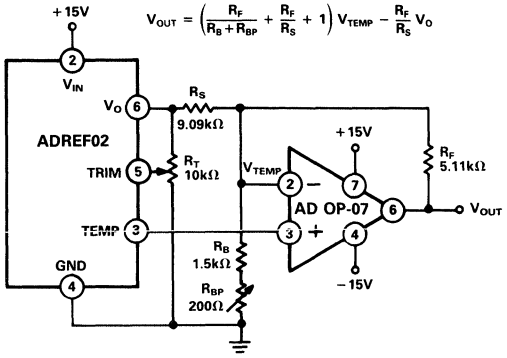
In the case of the ADREF02, the voltage drop across Pin 2 to Pin 4 from Figure 8 must remain between 8V and 36V. There will be a constant 5V drop across R_C (500Ω minimum)

$$I_L = \frac{5V}{R_C} + I_Q.$$

TEMPERATURE TRANSDUCER

The temperature out pin of the ADREF02 allows it to be used as a temperature transducer. The output of Pin 3 (TEMP) is a voltage that varies linearly with temperature. V_{TEMP} at 25°C is 630mV, and the temperature coefficient is 2.1mV/°C. In the configuration shown in Figure 9, V_{OUT} from Pin 6 of the ADREF02 provides a stable reference voltage for the AD OP-07 op amp. The temperature dependent voltage from the TEMP pin of the ADREF02 is amplified by the AD OP-07 to provide a wider full-scale range and more current sourcing capability.



TEMPERATURE	V_{OUT}
−55°C	−0.55V
0°C	0V
+125°C	+1.25V

Figure 9. Temperature Transducer

The resistor values in Figure 9 produce an output (V_{OUT}) that varies 10mV/°C from −0.55V to +1.25V over the military temperature range. The potentiometer R_T controls the offset of the transfer function, and the potentiometer R_{BP} controls its slope. The equation in Figure 9 can be used to set resistor values for other output ranges.

Boldface Type: Product recommended for new design.
*New product since the publication of the 1987/1988 Databooks.

Orientation
Data Acquisition Subsystems

Data acquisition subsystems provide many of the functional elements of a complete data acquisition system, in various combinations. By doing this, these subsystems allow complete performance to be provided and specified more easily than with systems built from individual components.

Among the functional blocks that data acquisition subsystems provide are:

- multiple channel input multiplexer
- programmable gain amplifier
- sample-hold amplifier
- microprocessor interface
- analog-to-digital converter
- converter reference

The data acquisition subsystems detailed on the following pages provide a wide span of performance capabilities. Resolutions of 12, 14, 15 and 16 bits, gain ranges of 64:1 up to 512:1 and throughputs from 18 to 50kHz are available. These specifications must be compared along with input range, package size, power consumption and linearity to decide which data acquisition subsystem, if any, is best for the application.

Complete 16-Channel, 12-Bit Data Acquisition Systems

AD363/AD364

FEATURES

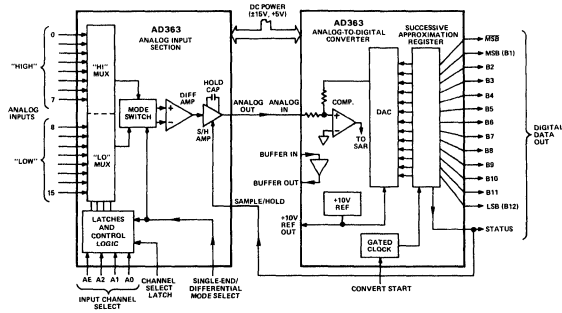
AD363

16-Channel Data Acquisition Input Stage with:
- **Digitally Controlled Channel Selection/Mode Control**
- **16 Single-Ended or 8 Differential Channels**
- **25kHz Throughput Rate**
- **Guaranteed No Missing Codes Over Temperature**

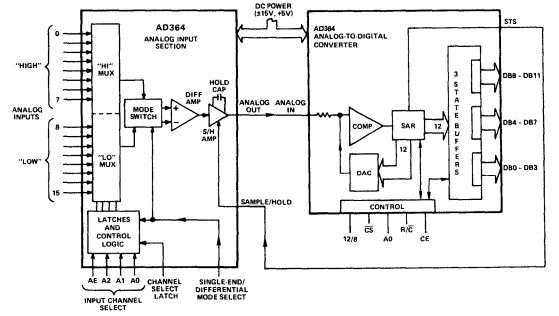
AD364

16-Channel Data Acquisition Input Stage with:
- **Digitally Controlled Channel Selection/Mode Control**
- **16 Single-Ended or 8 Differential Channels**
- **20kHz Throughput Rate**
- **Guaranteed No Missing Codes Over Temperature**
- **Three-State Buffered Digital Output**

AD363 FUNCTIONAL BLOCK DIAGRAM



AD364 FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTIONS

The AD363/AD364 are 16-channel data acquisition systems which condition and subsequently convert a voltage signal into a 12-bit digital word. The system consists of two devices, the analog input stage (AIS) and the analog-to-digital converter (ADC). The AIS includes a 16-channel multiplexer, a differential amplifier and a sample-and-hold amplifier. The ADC is a 12-bit successive approximation type converter with an on-board voltage reference and a three-state digital output. The AIS is manufactured using reliable hybrid circuit technology and is packaged in a 32-pin DIP. The ADC is a monolithic IC and is packaged in a 18-pin DIP.

The AD364 is a sixteen channel data acquisition system which conditions and subsequently converts a voltage signal into a 12-bit digital word. The system consists of two devices, the analog input stage (AIS) and the analog-to-digital converter (ADC). The AIS includes a 16-channel multiplexer, a differential amplifier and a sample-and-hold amplifier. The ADC is a 12-bit successive approximation type converter with an on-board voltage reference and a three-state digital output. The AIS is manufactured using reliable hybrid circuit technology and is packaged in a 32-pin DIP. The ADC is a single-chip IC and is packaged in a 28-pin DIP.

Both products are specified for operation over both commercial (0 to +70°C) and military (−55°C to +125°C) temperature ranges. The AD363 and AD364 are available with screening in accordance with the B Program of ADI Microelectronics. Please contact the factory or nearest sales office for details.

PACKAGE OPTIONS[5]		
Analog Input Section (DH-32E)	AD363RKD	AD363RSD
ADC Section (DH-32C)	AD363RKD	AD363RSD

NOTES:
[1] With 50Ω, 1% fixed resistor in place of Gain Adjust pot.
[2] Conversion time of ADC Section.
[3] One TTL Load is defined as I_{IL} = -1.6mA max @ V_{IL} = 0.4V, I_{IH} = 40μA max @ V_{IH} = 2.4V.
One LS TTL Load is defined as I_{IL} = -0.36mA max @ V_{IL} = 0.4V, I_{IH} = 20μA max @ V_{IH} = 2.7V.
[4] AD363K External Hold Capacitor is limited to +85°C; Analog Input Section and ADC Section may be stored at up to +150°C.
[5] See Section 14 for package outline information.
*Specifications same as AD363RK.
Specifications subject to change without notice.

AIS Functional Block Diagram

Concept

Figure 1 shows a general DAS application.

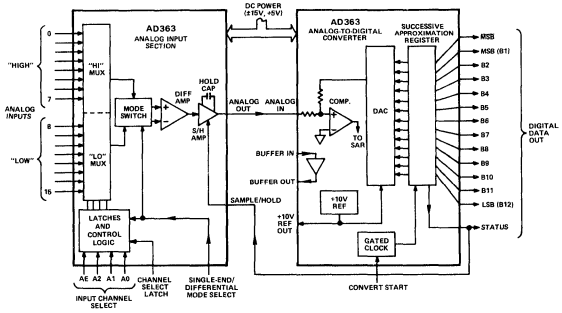

Figure 1. AD363

By dividing the data acquisition task into two sections, several important advantages are realized. Performance of each design is optimized for its specific function. Production yields are increased thus decreasing costs. Furthermore, the standard configuration packages plug into standard sockets and are easier to handle than larger packages with higher pin counts.

System Timing

Figure 2 is a timing diagram for the circuit shown in Figure 1 and operating at maximum conversion rate.

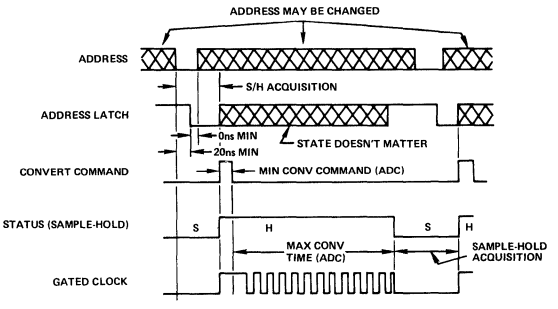

Figure 2. DAS Timing Diagram

The normal sequence of events is as follows:

1. The appropriate Channel Select Address is latched into the address register. Time is allowed for the multiplexers to settle.
2. A Convert Start command is issued to the ADC which, in response, indicates that it is "busy" by placing a Logic "1" on its Status line.
3. The ADC Status controls the sample-and-hold. When the ADC is "busy", the sample-and-hold is in the Hold mode.
4. The ADC goes into its conversion routine. Since the sample-and-hold is holding the proper analog value, the address may be updated during conversion. Thus multiplexer settling time can coincide with conversion and need not affect throughput rate.
5. The ADC indicates completion of its conversion by returning Status to Logic "0". The sample-and-hold returns to the Sample mode.
6. If the input signal has changed full-scale (different channels may have widely-varying data) the sample-and-hold will typically require 10 microseconds to "acquire" the next input to sufficient accuracy for 12-bit conversion.

After allowing a suitable interval for the sample-and-hold to stabilize at its new value, another Convert Start command may be issued to the ADC.

Single-Ended/Differential Mode Control

The AIS features an internal analog switch that configures the Analog Input Section in either a 16-channel single-ended or 8-channel differential mode. This switch is controlled by a non-TTL logic input applied to pin 1 of the Analog Input Section:

"0": Single-Ended (16 channels)
"1": Differential (8 channels) (+4.0V min)

When in the differential mode, a differential source may be applied between corresponding "High" and "Low" analog input channels.

It is possible to mix SE and DIFF inputs by using the mode control to command the appropriate mode. In this case, four microseconds must be allowed for the output of the Analog Input Section to settle to within ±0.01% of its final value, but if the mode is switched concurrent with changing the channel address, no significant additional delay is introduced. The effect of this delay may be eliminated by changing modes while a conversion is in progress (with the sample-and-hold in the "Hold" mode). When SE and DIFF signals are being processed concurrently, the DIFF signals must be applied between corresponding "High" and "Low" analog input channels. Another application of this feature is the capability of measuring 16 sources individually and/or measuring differences between pairs of those sources.

Input Channel Addressing

Table I is the truth table for input channel addressing in both the single-ended and differential modes. The 16 single-ended channels may be addressed by applying the corresponding digital number to the four Input Channel Select address bits, AE, A0, A1, A2 (pins 28–31). In the differential mode, the eight channels are addressed by applying the appropriate digital code to A0, A1 and A2; AE must be enabled with a Logic "1". Internal logic monitors the status of the SE/DIFF

9

Mode input and addresses the multiplexers singularly or in pairs as required.

ADDRESS				ON CHANNEL (Pin Number)		
					Differential	
AE	A2	A1	A0	Single Ended	"Hi"	"Lo"
0	0	0	0	0 (11)	None	
0	0	0	1	1 (10)	None	
0	0	1	0	2 (9)	None	
0	0	1	1	3 (8)	None	
0	1	0	0	4 (7)	None	
0	1	0	1	5 (6)	None	
0	1	1	0	6 (5)	None	
0	1	1	1	7 (4)	None	
1	0	0	0	8 (27)	0 (11)	0 (27)
1	0	0	1	9 (26)	1 (10)	1 (26)
1	0	1	0	10 (25)	2 (9)	2 (25)
1	0	1	1	11 (24)	3 (8)	3 (24)
1	1	0	0	12 (23)	4 (7)	5 (23)
1	1	0	1	13 (22)	5 (6)	5 (22)
1	1	1	0	14 (19)	6 (5)	6 (19)
1	1	1	1	15 (18)	7 (4)	7 (18)

Table I. Input Channel Addressing Truth Table

When the channel address is changed, six microseconds must be allowed for the Analog Input Section to settle to within ±0.01% of its final output (including settling times of all elements in the signal path). The effect of this delay may be eliminated by performing the address change while a conversion is in progress (with the sample-and-hold in the "hold" mode).

Input Channel Address Latch

The AIS is equipped with a latch for the Input Channel Select address bits. If the Latch Control pin (pin 32) is at Logic "1", input channel select address information is passed through to the multiplexers. A Logic "0" "freezes" the input channel address present at the inputs at the "1"-to-"0" transition (level-triggered).

This feature is useful when input channel address information is provided from an address, data or control bus that may be required to service many devices. The ability to latch an address is helpful whenever the user has no control of when address information may change.

Sample-and-Hold Mode Control

The Sample-and-Hold Mode Control input (pin 13) is normally connected to the Status output (pin 20) from an analog to digital converter. When a conversion is initiated by applying a Convert Start command to the ADC, Status goes to Logic "1", putting the sample-and-hold into the "Hold" mode. This "freezes" the information to be digitized for the period of conversion. When the conversion is complete, Status returns to Logic "0" and the sample-and-hold returns to the "Sample" mode. Eighteen microseconds must be allowed for the sample-and-hold to acquire ("catch up" to) the analog input to within ±0.01% of the final value before a new Convert Start command is issued.

The purpose of a sample-and-hold is to "stop" fast changing input signals long enough to be converted. In this application, it also allows the user to change channels and/or SE/ DIFF mode while a conversion is in progress thus eliminating the effects of multiplexer, analog switch and differential amplifier settling times. If maximum throughput rate is required for slowly changing signals, the Sample-and-Hold Mode Control may be wired to ground (Logic "0") rather than to ADC Status thus leaving the sample-and-hold in a continuous sample mode.

Analog Input Section Offset Adjust Circuit

Although the offset voltage of the AIS may be adjusted, that adjustment is normally performed at the ADC. In some special applications, however, it may be helpful to adjust the offset of the Analog Input Section. An example of such a case would be if the input signals were small (<10mV) relative to the AIS voltage offset and if a gain stage was to be inserted between the AIS and the ADC. To adjust the offset of the AIS, the circuit shown in Figure 4 is recommended.

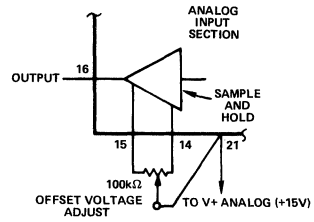

Figure 4. AIS Offset Voltage Adjustment

Under normal conditions, all calibration is performed at the ADC Section.

Other Considerations

Grounding: Analog and digital signal grounds should be kept separate where possible to prevent digital signals from flowing in the analog ground circuit and inducing spurious analog signal noise. Analog Ground (pin 17) and Digital Ground (pin 2) are not connected internally; these pins must be connected externally for the system to operate properly. Preferably, this connection is made at only one point, as close to the AIS as possible. The case is connected internally to Digital Ground to provide good electrostatic shielding. If the grounds are not tied common on the same card with the AIS they should be connected with back-to-back general purpose diodes as shown in Figure 5. This will protect the AIS from possible damage caused by voltages in excess of ±1 volt between the ground systems which could occur if the key grounding card should be removed from the overall system. The device will operate properly with as much as ±200mV between grounds, however this difference will be reflected directly as an input offset voltage.

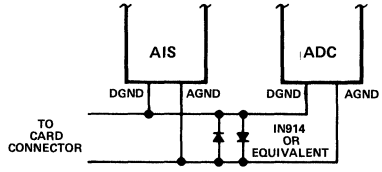

Figure 5. Ground-Fault Protection Diodes

Power Supply Bypassing: The ±15V and +5V power leads should be capacitively bypassed to Analog Ground and Digital Ground respectively for optimum device performance. 1μF tantalum types are recommended; these capacitors should be located close to the system. It is not necessary to shunt these capacitors with disc capacitors to provide additional high frequency power supply decoupling since each power lead is bypassed internally with a 0.039μF ceramic capacitor.

ANALOG DEVICES

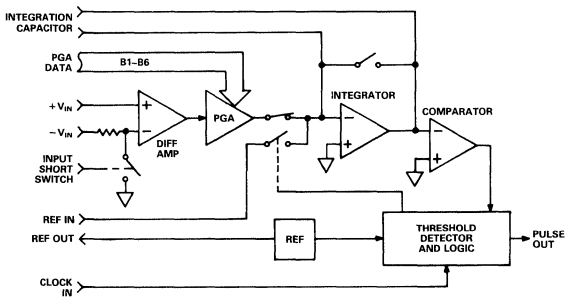
High Resolution Programmable Gain DAS

AD367

FEATURES
Differential Input – Programmable Gain Amplifier
6-Bit (1 of 64) Gain Control
Internal −10V Reference
15-Bit Integral Nonlinearity
±305μV Resolution
10ms Conversion Time
External Integration Capacitor
Programmable Conversion Time

APPLICATIONS
Medical Instruments
Blood Analyzers
Analytical Instrumentation
Data Acquisition Systems
Chromatography
Process Control

AD367 FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD367 is a wide dynamic range integrated circuit which contains all the analog functions needed to construct a high resolution, high accuracy integrating Data Acquisition System. It utilizes hybrid technology to incorporate a programmable gain amplifier, integration amplifier, −10V reference, comparator, and control logic in a 24-pin hermetic dual-in-line package.

The programmable gain amplifier provides 6-bits (1 of 64) gain control which are digitally selectable with CMOS voltage levels. The dual slope converter uses time to quantitize the analog input signal. The differential front-end allows true differential inputs with high common mode rejection, or single-ended inputs with ground sense capability. This conversion technique has inherent high frequency noise immunity and excellent normal mode noise rejection at frequencies that are integal multiples of $1/T_1$ (T_1 = the signal integration period). The conversion accuracy is independent of both the integration capacitance and clock frequency, since they affect both the signal integration phase and reference integration phase in the same ratio. A microprocessor and software routine or any digitizing timer that accepts TTL inputs can be used to count clock pulses to digitize the AD367 output. The integration capacitor is external, therefore conversion time may be adjusted by the user. The nominal value is 0.012μF for an integration time of 4ms and total conversion time of 10ms. By choice of integration capacitor and clock frequency the integration time is programmed from a minimum of 2ms to a maximum of 20ms. The maximum conversion rate is 200 samples per second.

PRODUCT HIGHLIGHTS

1. The AD367KM provides true 15-bit (±0.00305% FSR maximum linearity error) performance with 305μV resolution.
2. The differential input programmable gain amplifier front end has 6-bit (1 of 64) gain control. This provides gains of 0.282V/V to 24V/V, or input full-scale ranges of 0.417V to 10.0V for maximum flexibility.
3. The integration capacitor is external. Integration time is user-programmable, from 2ms to 20ms. The maximum conversion rate is 200 conversions per second.
4. The dual slope integration conversion technique provides superior high frequency noise immunity, and excellent normal mode noise rejection of frequencies which are multiples of the inverse of the integration period.
5. An internal precision −10.0V reference is provided, but an external reference may be used for multi-channel applications where use of a system reference is required.
6. The pulse-width output is easily converted to digital binary format by the addition of external IC counter-timers. The counter clock rate is independent of the integrator clock rate.

9

AD367 Functional Block Diagram

BASIC OPERATION

The AD367 is a high resolution dual slope integrating converter building block. Its output is a pulse width whose duration is proportional to the input voltage and the gain selected. The active-low output pulse is used to gate a separate counter which accumulates pulses from a high speed clock. This partition of the analog-to-digital conversion function into an analog processing section and digital counting greatly reduces the potential for crosstalk between the noisy digital function and the low-level signal processing performed by the analog front-end. This preserves the inherent rejection of high frequency normal mode noise that is a prime advantage of the dual slope conversion technique.

INPUT STAGE

The AD367 is internally partitioned into a differential-input amplifier, a single-ended user-programmable gain amplifier, and the actual dual-slope converter. The differential amplifier allows digitization of input signals with common mode voltages of up to ±10V. It has a nominal input impedance of 100kΩ and is configured for unity gain.

The programmable gain amplifier (PGA) is programmed via a 6-bit digital code. If "B_1", represents the logical value of the most significant gain-selected bit, "B_2" the next most significant bit, etc., then the gain of the PGA is:

$$G = \frac{(128B_1 + 64B_2 + 32B_3 + 16B_4 + 8B_5 + 4B_6 + 3) \times 24}{255}$$

The gain-select pins are internally pulled-up to the +15V supply. Gain programming can be accomplished using either an open collector TTL Driver such as the 7406 or with 4000-series CMOS (V_{DD} = 15V). For fixed gain applications the gain-select pins can be tied to analog ground or left open as required.

B_1	B_2	B_3	B_4	B_5	B_6	GAIN (V/V)

Table I. AD367 PGA Truth Table

INTEGRATOR STAGE

The AD367 integrator stage uses the dual slope conversion technique. A simplified dual slope converter is shown in Figure 1. While the input pulse is applied to clock in, the input signal is applied to the integrator. After a predetermined period the input pulse is removed, a reference signal of opposite polarity is applied to the integrator, and the output pulse is initiated. At the moment the integrator is switched to the reference (deintegration) phase the accumulated charge on the integrating capacitor is proportional to the average value of the input over the integration interval. The deintegration of the reference is an opposite going ramp with slope V_{REF}/RC. When the integrator output reaches zero, the comparator is tripped and the output pulse is terminated. This completes the conversion cycle. Since the charge gained in the integration phase is proportional to $V_{IN} \times T$ (see Figure 1) and the amount of charge lost is proportional to $V_{REF} \times t$ (and equal to the amount of charge gained) t is proportional to V_{IN}/V_{REF}. The converter output is thus a pulse whose width is proportional to the input voltage. A dual slope converter is therefore a Voltage-to-Time converter. If the output pulse is used to gate a binary counter, the output of the counter will be binary digital representation of the input voltage.

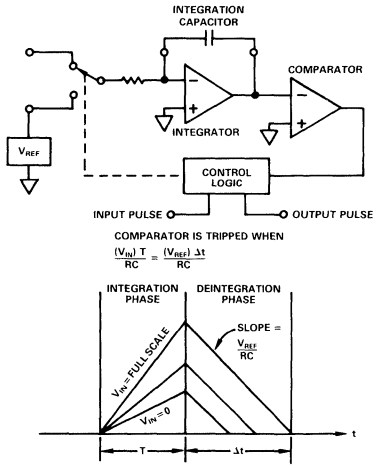

Figure 1. Simplified Basic Dual Slope Converter

ADVANTAGES OF DUAL-SLOPE INTEGRATION

Conversion accuracy is independent of the length of the clock period and the integrating capacitance. Theoretical accuracy depends only on the absolute value of the reference and the stability of the clock. Even changes in other components such as the comparator input offset voltage have no effect as long as they do not change during a conversion. Differential linearity is excellent since the technique is analog and inherently free from discontinuities.

AD367 DETAILED OPERATION

The input differential amplifier operates with input voltages within the common mode range of 0 to 10V. The input resistance is 100kΩ (80kΩ minimum) and there is a shorting switch on the noninverting input for user calibration in single-ended mode.

The input shorting switch shorts $+V_{IN}$ to ground through 20kΩ to limit the short circuit current of the driver. The AD367 inputs must be buffered. The AD OP-07 is well recommended for this purpose, due to its low noise. For source impedances of less than 5-10kΩ the AD OP-27 would be an even better choice. Note: The high 1/f noise of most FET and BiFET amplifiers make them unsuitable for this application.

The offset of the PGA section is not trimmable per se, however, the direct PGA output is available on Pin 4. Great care must be exercised to avoid introducing extraneous signals at this point. A more detailed procedure for offset trim and calibration of the AD367 is given below in the calibration section.

The dual slope converter section is configured for a nominal full-scale input voltage of 10V. In addition, the zero point of the converter is offset by 5% full scale. This guarantees that the converter linearity will not be degraded for inputs near zero. Maximum linearity is obtained when the gain is programmed so that the maximum full-scale input voltage produces an output pulse of maximum duration consistent with the desired conversion rate. Alternatively the gain can be set to provide a 10V signal to the integrator (or Pin 4, the output of the PGA) when a full-scale input is supplied.

The built-in offset is also used to protect against possible negative polarity inputs while taking very low level measurements (or "dark current" readings from optical sensors). The offset pulse is accomplished by using a portion of the internal reference as the threshold voltage to signal the end of conversion as shown in Figure 2. This voltage appears on Pin 7 and is factory set for

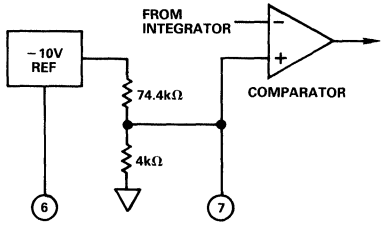

Figure 2.

−0.510V, which yields a nominal 200μs offset pulse with a 0.012μF integration capacitor. This offset pulse width may be adjusted by using a 100kΩ potentiometer as shown in Figure 3.

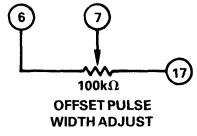

Figure 3.

The leading edge of an externally applied negative going clock pulse initiates a conversion. The AD367 will output a pulse whose width is proportional to the input signal. The output pulse is active low. Its leading (falling) edge is triggered by the rising edge of the external clock, and its trailing edge is dependent upon the input signal level. When using the internal reference or with an external −10V reference a clock pulse of 4ms provides an integrator full-scale range of 10V with a 0.012μF integration cap.

For other reference and integration capacitor values the signal integration period should be adjusted to prevent saturation of the integrator, i.e., the maximum integrator deflection should not exceed 10V.

The AD367 Transfer Function is:

$$\text{Pulse Width} = \frac{-V_{IN}}{V_{REF}} \times \frac{R_{INT2}}{R_{INT1}} T_1 + \frac{V_{OS}\, C\, R_{INT2}}{V_{REF}}$$

Where:

T_1 = The clock period
V_{OS} = Voltage Offset (−0.510V nominal)
C = Integration Capacitor
R_{INT1} = Signal Integration Resistor = 340kΩ
R_{INT2} = Reference Integration Resistor = 327kΩ
V_{REF} = −10V (if internal voltage reference is used)

Figure 4 shows the AD367 operation for a near full-scale input voltage. The input signal is integrated as the negative slope, and the reference voltage as the positive slope. The output pulse is low until the positive going edge (the reference integration phase) exceeds $-V_{OS}$ (+0.510V). The rising edge of the clock coincides with the knee of the integrator and the falling edge of the output.

Figure 5 shows a good view of the offset at work. A slight negative input voltage will not cause an absence of output pulse ($V_{IN} > -0.05V$).

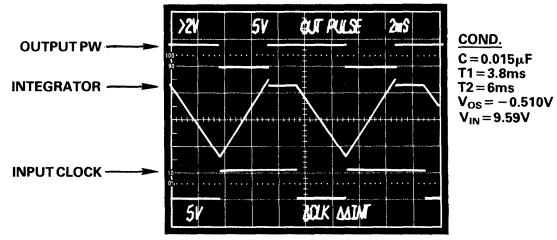

Figure 4.

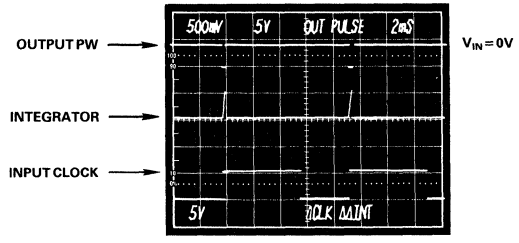

Figure 5.

To maximize the resolution and accuracy of the converter, the PGA gain should be set such that the maximum input signal voltage provides a 10V signal to the integrator (Pin 4). Then the clock pulse width and integration capacitor should be selected using the relation:

$$\frac{T_1}{C_{INT}} \cong R_{INT1} = 340k\Omega$$

This ensures that the maximum dynamic range of the integrator is used, and will result in the best linearity from the converter. Polystyrene or Teflon capacitors only are recommended. The AD367 Timing Diagram is shown in Figure 6.

PGA settling under worst-case conditions (Gain = 24, full-scale input voltage step) is typically 70μs, as shown in Figure 8. The PGA output must be allowed to settle before a conversion is initiated, or the first conversion result after an input voltage change ignored if the AD367 is operated in continuous conversion mode. Figure 9 shows the PGA settling after a change from minimum to maximum gain (0.282 to 24 V/V), which is also 70μs typically.

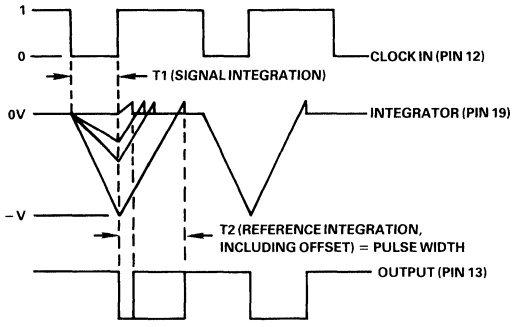

Figure 6. AD367 Timing Diagram

CALIBRATION

The AD367 should be endpoint calibrated for maximum system accuracy. Calibration is a straightforward procedure:

1. Choose a gain consistent with keeping the output of the programmable gain amplifier at or below 10V when a full-scale input voltage is applied.
2. Apply a zero input signal, V_Z. Use the shorting switch if the input is single-ended. The shorting switch will ensure a good ground potential at the input.
3. Measure the output offset pulse, PW_{OS}.
4. Apply a known full-scale voltage, V_{FS}, to the inputs.
5. Measure the output full-scale pulse, PW_{FS}.
6. Subsequent measurements will give, to within ±0.00305% FSR, the input voltage according to the following equation:

$$V_{IN} = (\text{Pulse Out} - PW_{OS}) \times \frac{(V_{FS} - V_Z)}{(PW_{FS} - PW_{OS})} + V_Z$$

INPUT, GROUNDING, AND DECOUPLING CONSIDERATIONS

For most applications, the AD367 will be used with single-ended inputs and the internal −10V reference. The connections for this mode of operation are shown in Figure 7, including input buffering, power supply decoupling, and input ground sense. As with many data acquisition components, the AD367 has separate analog and digital grounds. These pins (15 and 17) are not connected internally, but should be tied together at one point as close to the converter as possible. Ideally, a single solid ground plane under the converter is desirable. Current flows through the wires and etch stripes of circuit cards, and since these paths have resistance and inductance, hundreds of millivolts can be generated between the system analog ground and the ground pins of the AD367. Separate wide conductor stripe ground returns should be provided for high resolution converters to minimize IR losses from current flow in the converter to system ground run. Care must be taken to prevent digital logic return currents from being summed into the same return path as analog signals to prevent measurement errors.

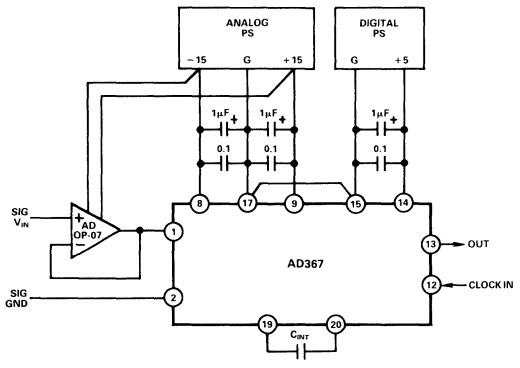

Figure 7. Input Connections for Single-Ended Operation

Each of the AD367's supply terminals should be capacitively decoupled as close to the AD367 as possible. A large value capacitor, such as 1μF, in parallel with a 0.1μF capacitor is usually sufficient. Analog supplies should be decoupled to the analog ground pin, and the logic supply to the digital ground pin.

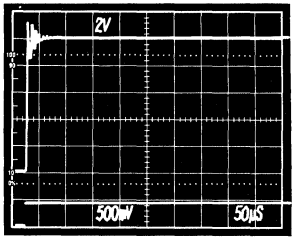

Figure 8. AD367 PGA Section Settling

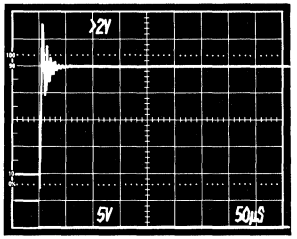

Figure 9. AD367 PGA Section Gain Settling

The metal case is at analog ground potential for shielding. Care should be exercised to prevent shorting to board circuitry beneath the part.

GENERAL INTERFACE CONSIDERATIONS

The control logic of the AD367 and the synchronous counter scheme shown in Figure 10 makes direct connection to most microprocessor buses possible. While it is impossible to describe the details of the interface connections for every microprocessor, a representative example is presented here.

Analog-to-digital converters, like any I/O device, may be interfaced to microprocessors by several methods. These include direct memory access (DMA), isolated or accumulator I/O, and memory-mapped I/O. DMA is the fastest, since conversions occur automatically and data updates into memory are transparent to the processor. DMA logic is very processor-dependent and requires specialized dedicated hardware.

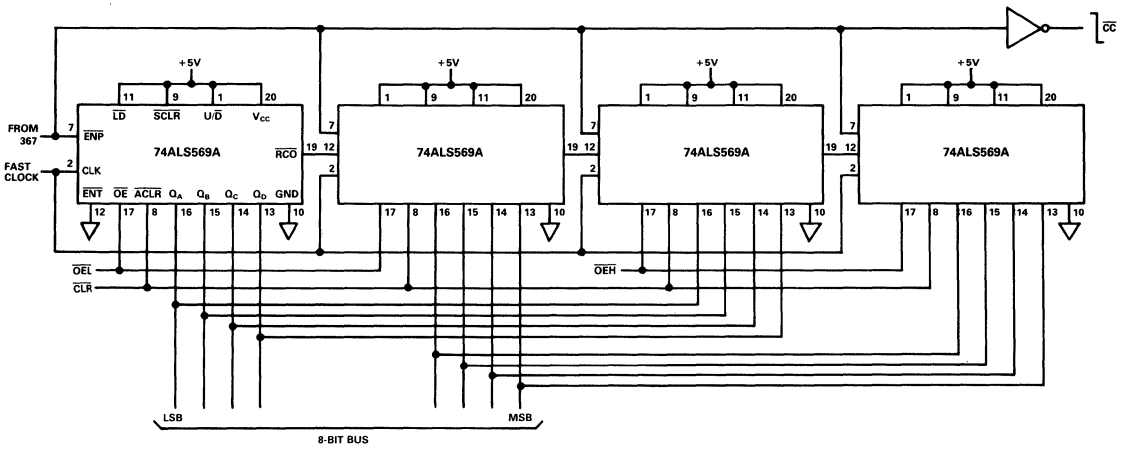

Figure 10. General Counter Scheme 8-Bit Bus

Memory-mapped and accumulator I/O are more often used and easier to implement. Accumulator I/O uses a distinct set of control signals which, combined with the address bus, define a totally separate I/O address space. The architecture is simple from a hardware standpoint, since address decoding requirements are not severe, and distinct I/O pulses are easily located for system debugging. However, processors using accumulator I/O can generally only send data to an output device from the accumulator. This can make for cumbersome software, since processor controlled transfers of I/O data to a memory location cannot be accomplished in a single instruction.

Memory-mapped I/O assigns the I/O device to one or more locations in the logical memory space of the microprocessor. This technique has the advantage that the full range of memory reference instructions may be used to operate on the data. The potential disadvantages include limiting the memory space available for program and data memory, somewhat more complex address decoding and more difficult isolation of device select pulses for system debugging. Nevertheless, many microprocessors offer only the memory-mapped I/O.

CONNECTING COUNTERS FOR DIGITAL OUTPUT

Figure 10 shows a simple circuit for converting the AD367 pulse width output to binary digital code using the 74LS569A synchronous counter. This scheme is compatible with μP systems using an 8-bit wide data bus structure, such as the 6809. It is easily upgraded to 16-bit structures by connecting OEH to OEL and connecting the 16 outputs directly to the bus instead of together.

Decode logic for the 6809μP is shown in Figure 11.

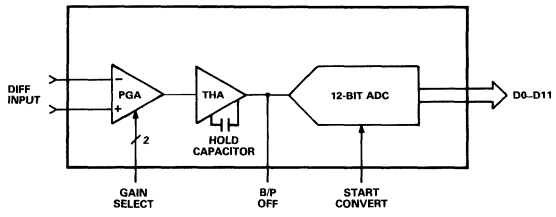
AD368/AD369 FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD368/AD369 are low cost, wide dynamic range data acquisition systems which condition and subsequently convert an analog signal into a 12-bit digital word. They include a programmable gain amplifier, a track-and-hold amplifier, and a 12-bit analog-to-digital converter – all in a 28-pin dual in-line package.

The digitally programmable-gain amplifier (PGA) of the AD368 enables the user to select binary-based gains of 1, 8, 64, and 512. These gain steps are especially useful in extending system dynamic range in DSP applications. The PGA of the AD369, with gains of 1, 10, 100, and 500, allows the user to choose full-scale input voltage ranges of 10V, 1V, 100mV, and 20mV, respectively. In addition, the precision differential input of the PGA provides the AD368/AD369 with excellent common-mode rejection.

The track-and-hold amplifier (T/H) features excellent linearity, low noise, and an internal hold capacitor.

The successive approximation analog-to-digital converter (ADC) features true 12-bit operation, with 0.012% max nonlinearity (B-grade). The user can select bipolar or unipolar operation to digitize both ac and dc input signals.

The AD368/AD369 provide a completely specified (industrial and military temperature ranges) and tested function in a space saving 28-pin hermetic package for system designers with cost, space, and time constraints.

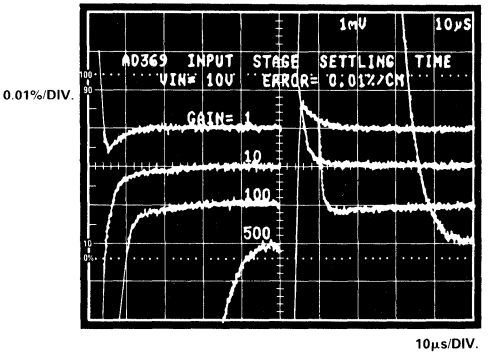
AD369 Input Stage Output Voltage



AD369 Input Stage Settling Time

ANALOG INPUT

An analog multiplexer and resistor network form the gain switching circuit of the PGA. As shown in Table I, the user selects a gain according to the state of binary address inputs G0 and G1.

Also shown in the table is the input range data. The full-scale range of the DAS is 10V, and an LSB value is 4.8μV/4.9μV in the gain 512/500 mode; therefore, the dynamic range of the AD368/AD369 is 126dB.

The PGA uses a monolithic instrumentation amplifier, which is based on the classic three-op-amp approach. The differential analog input is amplified, according to gain selection, by two input op amps. The third amplifier, a unity gain subtractor, removes any common-mode signal and yields a single-ended output.

DATA CONVERSION

The track-and-hold amplifier is a monolithic device with an internal hold capacitor. It has an acquisition time of ≤3μs.

Input signals are digitized using a successive-approximation A/D converter. The rising (L to H) edge of the Convert Start pulse resets the internal flip-flops of the SAR. The falling (H to L) edge of the pulse initiates the conversion. After an aperture delay of 230ns, the track and hold amplifier goes into the hold mode, and the Status output goes High, indicating a conversion is in progress. Conversion time from the falling edge of the CS pulse is 15μs, maximum. A low output on the Status line indicates that the conversion is complete. The data at the output is valid at least 15ns before the Status goes low (see timing diagram). This gives sufficient setup time so that data may be latched to an external register on the falling edge of the Status pulse. The T/H amplifier returns to the tracking mode when the Status line goes low. Data is valid at the output until the next falling edge of a C/S pulse. After a maximum of 3μs acquisition time, a new C/S pulse may be issued to begin a new conversion. Timing diagrams are shown in Figure 1.

Figure 1a shows timing when a conversion sequence has first begun. All functions are being performed in series. This is the timing for the first data conversion, assuming a new gain must be selected.

The timing in Figure 1b assumes conversions are progressing continuously. After a conversion has been initiated by the falling edge of the C/S pulse, a new analog signal may be inputted to the DAS or a new gain may be selected. The figure shows that if a new gain is selected, no more than 2μs later, the new voltage begins settling at the PGA output. In the G = 512/500 mode, the determining factor for conversion speed is the amplifier settling time and, if necessary, the gain switching time. If the PGA gain is not switched, the conversion time for G = 512/500 becomes 50μs, maximum, and a minimum throughput rate of 20kHz can be achieved.

CALIBRATING THE AD368/AD369 WITH TRIMPOTS

This is a calibration procedure which is implemented with potentiometers, resistors, and LEDs. The hardware can be incorporated on the board which utilizes the AD368/AD369 for convenient field calibration.

The ideal transfer function of the AD368/AD369 in Figure 2 shows that the output code steps up from all ones to all zeros as the analog input voltage increases from the minus full scale limit to the plus full scale limit. The purpose of the calibration is to put the first and last bit transitions where they belong; 1LSB above −FS and 1LSB below +FS respectively.

The transfer function shows that for each output code there is an associated quantization uncertainty of 1LSB. For a given code, there is an LSB wide range of possible analog input voltages. Only at the transition point between two adjacent codes is there a precise correlation between input voltage and digital output. This circumstance must be utilized in the calibration or the accuracy may be off by ±1/2LSB.

In reality, due to noise on the analog input, the transitions do not occur as sharply as illustrated in the figure. When changing codes, the output will toggle constantly while moving from one value to the next. The desired transition point is obtained when 50% of the time the output is above this point and 50% of the time the output is below it. This transition point may be observed on an oscilloscope. Another way to measure this 50% duty cycle is by using a light emitting diode (LED) as shown in Figure 3. The duty cycle is approximately 50% when the LED is about halfway between minimum and maximum brightness.

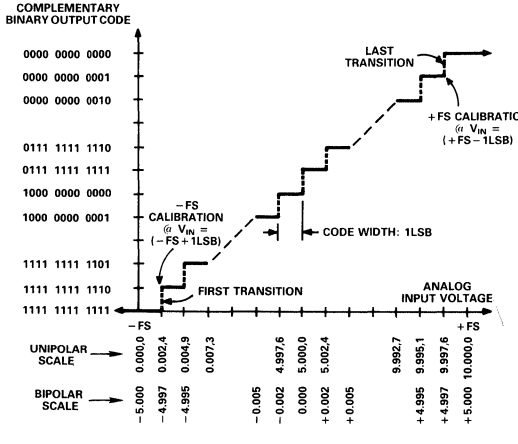

Figure 2. AD368/AD369 Transfer Function

UNIPOLAR MODE CALIBRATION

Figure 3 shows the AD368/AD369 in the unipolar mode of operation, with calibration hardware connected. The calibration begins with cancellation of the input stage offset by applying 0V to the input and manipulating R_{RTI} and R_{RTO} until the first transition occurs exactly at 0V, regardless of the amplifier gain. The next step in the calibration is to cancel the output stage offset by adjusting R_{RTO} to put the first transition at the proper input voltage of +1LSB. Finally, R_{SPAN} is adjusted and the last bit transition is put 1LSB below +FS.

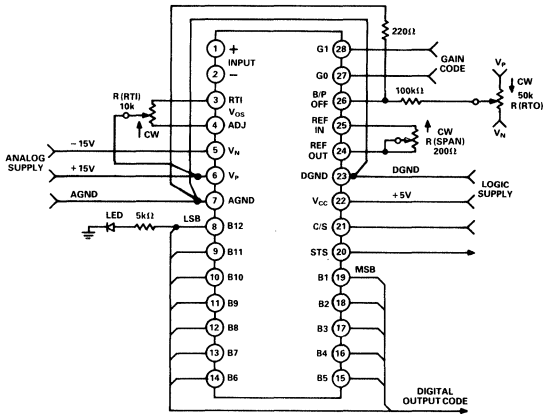

Figure 3. AD368/AD369 in the Unipolar Mode with RTI V_{OS}, RTO V_{OS} and Span Trimpots

Calibration steps for input stage offset voltage (V_{OS}) cancellation:

1. Connect the inputs to analog ground.
2. Set G=512/500 and turn R_{RTI} all the way clockwise (CW). This shifts the transfer function to the right, causing the output code to be all ones. The LED will light up.
3. Now turn R_{RTI} counterclockwise (CCW) until the LED dims to half brightness. The first transition is now positioned at the $V_{IN}=0$ line.
4. Switch to G=1 and turn R_{RTO} all the way CW. This will cause the output code to be all ones again.
5. Turn R_{RTO} CCW until the LED dims; the first transition is at 0V again.
6. Switch the gain to G=512/500, turn R_{RTI} CW just enough to assure an all ones code, then turn it CCW until the LED dims to half brightness.
7. Switch the gain back to one, turn R_{RTO} CW enough to assure an all ones code, then turn it CCW until the LED dims.
8. Repeat steps 5 and 6 until the LED brightness does not change when switching between G=1 and G=512/500. The input stage offset voltage is now zero.

Calibration steps for the output stage offset voltage (V_{OS}) cancellation:

1. Connect the inputs to a 2.44mV supply, as in Figure 4.
2. Set G=1, turn R_{RTO} all the way CW, assuring an all ones output and lighting the LED.
3. Turn R_{RTO} CCW until the LED dims to half brightness. The first transition is now 1LSB above 0V.

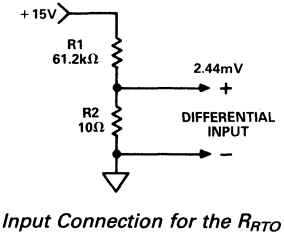

Figure 4. Input Connection for the R_{RTO} Calibration

Calibration steps for Gain Error (SPAN) cancellation:

1. Apply a precise 10V–2.44mV across the input of the AD368/AD369. A voltage divider as shown in Figure 5 can be employed; in conjunction with a precision voltmeter to verify an input of 9.997,56V.
2. Set G = 1, turn R_{SPAN} all the way CCW, assuring an output of all zeros.
3. Turn R_{SPAN} CW until the LED begins to light up (about half-brightness). At this point the last transition will be at +FS −1LSB.

The calibration in the unipolar mode is now complete.

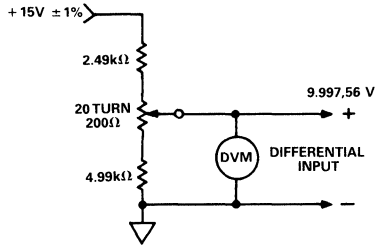

Figure 5. Input Connection for the R_{SPAN} Calibration

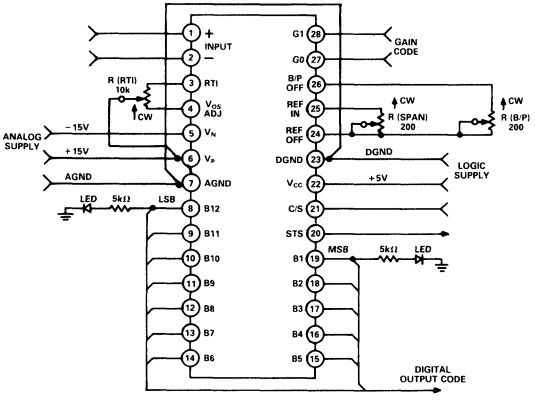

Figure 6. AD368/AD369 in the Bipolar Mode with Offset and Gain Trimpots

BIPOLAR MODE CALIBRATION

The AD368/AD369, with calibration hardware, are shown in Figure 6 for operation in the bipolar mode. The adjustments begin, as in the unipolar case, with the input stage V_{OS} cancellation. In this case however, the calibration is different because the 0V point is now at mid-scale; the MSB is used instead of the LSB. Next in the calibration is to adjust R_{RTO} and put the first LSB transition at an input voltage of −5V +1LSB. Last is the R_{SPAN} adjust to put the last bit transition 1LSB below +5V.

Input stage V_{OS} cancellation steps:

1. Connect the inputs to analog ground.
2. Select G = 512/500 and turn R_{RTI} until the MSB LED is at half-brightness.
3. Switch to G = 1 and adjust R_{RTO} until the LED is again at half-brightness.
4. Repeat steps 2. and 3. until the LED brightness does not change when gains are switched. This indicates that the input stage V_{OS} = 0V.

Output stage V_{OS} cancellation steps:

1. Set G = 1.
2. Connect the plus input to ground and the minus input to 4.997,56 volts using a voltage divider such as in Figure 7.
3. Turn R_{RTO} completely CW to assure an output code of all ones.
4. Now turn R_{RTO} CCW until the LSB LED dims to half-brightness. The first transition is now 1LSB above −FS.

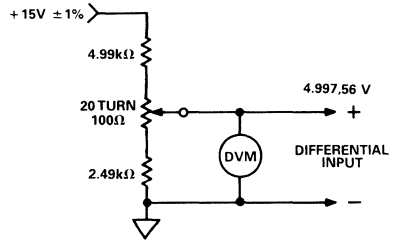

Figure 7. Voltage Divider to Derive RTO V_{OS} and Span Calibration Voltage

Gain Error cancellation steps:

1. Set G = 1.
2. Now connect the plus input to 4.997,56 Volts and the minus input to analog ground.
3. Turn R_{SPAN} completely CCW to assure an output code of all zeros.
4. Now turn R_{SPAN} CW until the LSB LED begins to light up. At this point the last bit transition will be at +FS −1LSB.

Calibration in the bipolar mode is now complete.

CALIBRATING THE AD368/AD369 WITHOUT TRIMPOTS

Figure 8 shows the AD368/AD369 in the unipolar mode with calibration hardware consisting of a Quad 8-Bit D/A Converter (AD7226) circuit instead of the previous trimpot configuration. The calibration procedure is basically the same as before except that instead of adjusting the potentiometers, three DACs are used to correct for offsets and gain error. Bipolar calibration may be accomplished by referring to Figure 6.

This calibration routine has some excellent benefits in addition to the elimination of potentiometers. Dipswitches may be used initially to set the 8-bit word values needed for each connection; however, after the word values are determined, this data may be stored into a memory (i.e., RAM) for auto-calibration in the field. The entire calibration may be accomplished under microprocessor control. Temperature offsets may be cancelled by using a temperature sensor in conjunction with a microprocessor.

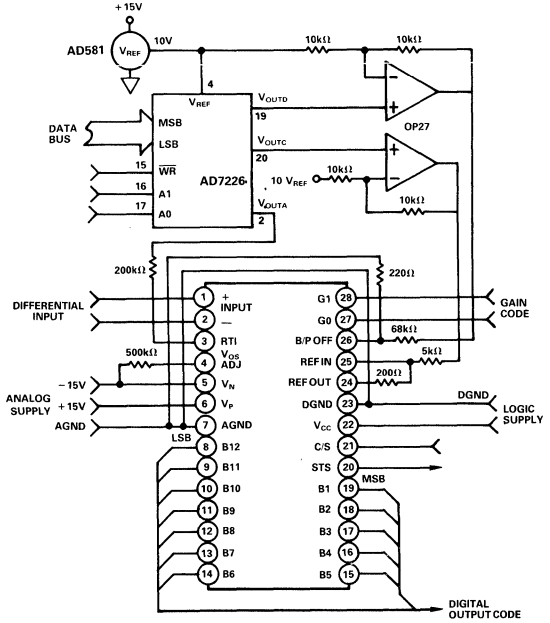

Figure 8. AD368/AD369 in the Unipolar Mode with D/A Circuit Replacing Trimpots

INPUT PROTECTION

There are two considerations when applying input protection for the PGA: 1) that maximum input current must be limited to less than 20mA and 2) that input voltages must not exceed the supplies. Outside the linear operating range, the input impedance of the AD368/AD369 becomes low and nonlinear due to the input transistors going into saturation. The graph in Figure 9 illustrates the input current vs. differential input voltage relationship without input protection.

Resistors of 1kΩ in series with each input would keep the currents within safe limits for input voltages in the range of $V_P = +15V$ to $V_N = -15V$. Figure 10 shows the external components necessary to protect the AD368/AD369 under all overload conditions at any gain. The diodes to the supplies are necessary if input voltages outside of the range of the supplies are encountered.

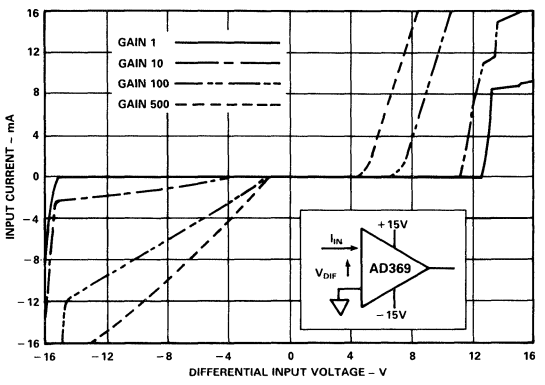

Figure 9. Input Current vs. Differential Input Voltage Without Input Protection

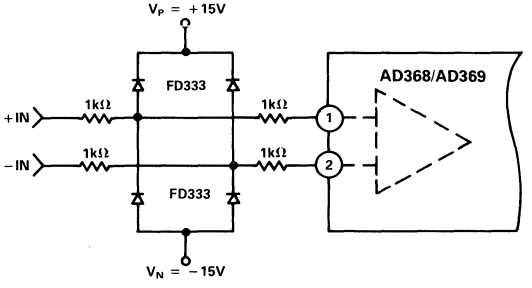

Figure 10. Input Protection Circuit for AD368/AD369

The equivalent noise resistance of the AD368/AD369 input stage is only 1kΩ. Input protection resistors, however, will quickly degrade this excellent noise performance. To reduce the noise encountered with added resistors, FETs may be used to limit the input current. FETs, such as the 2N4416, with low I_{DSS} and low on-resistance should be used. Figure 11 shows the protection circuit and Figure 12 shows the input current vs. the differential input voltage with the FET protection circuit. The 20kΩ resistor is put in series with the gate to limit the "reverse" I_{DSS} current and does not add to the noise.

The above input protection circuits also protect the AD368/AD369 in case there is a voltage applied to the input while the supplies are shut off.

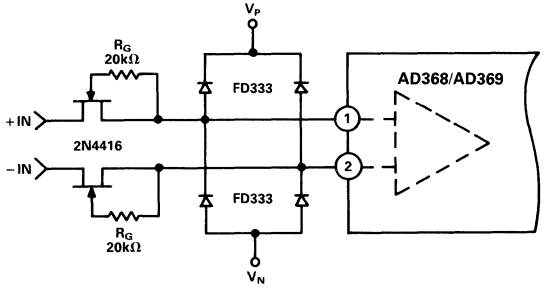

Figure 11. Low Noise Input Protection Circuit for AD368/AD369

If using multiplexers, proper device selection can provide AD368/AD369 input protection. Some MUXes limit the maximum current as well as the maximum output voltage to safe levels. Keep in mind that the on resistance of the MUX will add to the input stage noise.

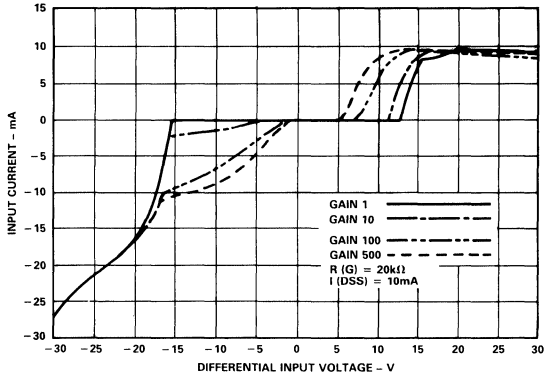

Figure 12. AD625 Input Protection with 2N4416 FETs and FD333 Clamping Diodes

GROUND RETURNS FOR INPUT BIAS CURRENTS

There must be a direct return path for the input bias currents of the PGA input transistors; otherwise, they will charge external capacitances, causing the output to drift uncontrollably or saturate. Therefore, when amplifying floating input sources such as transformers, or ac-coupled sources, there must be a dc path from each input to ground as shown in Figure 13.

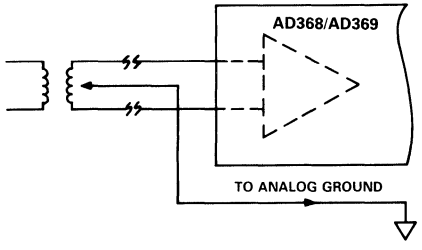

Figure 13a. Ground Returns for Bias Currents with Transformer Coupled Input

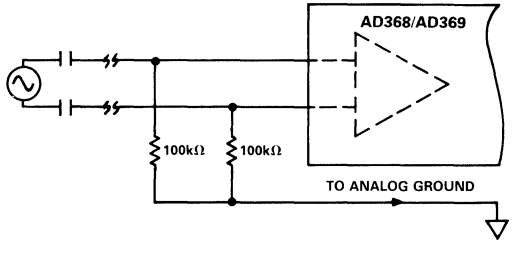

Figure 13b. Ground Returns for Bias Currents with ac Coupled Inputs

GROUND CONNECTIONS

The digital and analog ground pins of the AD368/AD369 should be tied together as close to the package as possible to avoid noise coupling from the digital ground to the analog circuit. When an application calls for separate grounding entirely, a 0.1μF capacitor should be connected between the AGND and DGND pins to filter out any noise.

POWER SUPPLY DECOUPLING

Each of the AD368/AD369 supply terminals should be capacitively decoupled as close to the IC as possible. A 1μF in parallel with a 0.1μF capacitor is usually sufficient. Analog supplies are decoupled to the analog ground pin and the Logic supply is decoupled to the digital ground pin.

TRACK-AND-HOLD ERRORS

The aperture delay time is the time required for the track-and-hold amplifier to switch from track to hold. Since this is effectively a constant, it may be tuned out by advancing the track-to-hold command with respect to the input signal.

Unlike the aperture delay time, aperture jitter is a true error source and must be considered. Aperture jitter is a result of noise within the switching network. It causes variations in the value of the analog input being held. The aperture error which results from this jitter is directly related to the dV/dT of the analog input and may limit the signal bandwidth. The aperture jitter of the T/H in the AD368/AD369, however, is small enough that the instrumentation amplifier will limit the signal frequency well below the frequency at which the jitter error would be of concern.

Droop rate is the change in output voltage per unit of time while in the hold mode. Hold mode droop originates as leakage from the hold capacitor, of which the major contributors are switch leakage current and bias current. This dV_{OUT}/dT is equal to the ratio of the total leakage current, I_l to the hold capacitance, C_H. The droop rate of the T/H in the AD368/AD369 is included in the differential nonlinearity specification.

COMMON-MODE REJECTION

Common-mode rejection is a measure of the change in output voltage when both inputs are changed by equal amounts. These specifications are usually given for a full-range input voltage change. Care should be taken to assure that both input lines are balanced with regard to parasitic capacitances and source resistances; otherwise, the excellent common-mode rejection of the AD368/AD369 will be degraded.

ERRORS DUE TO BANDWIDTH LIMITATIONS OF THE AD368/AD369

When using the AD368/AD369 to digitize sine-wave signals, it is important to know the frequency at which the system response roll-off will cause an error of 1/2LSB.

The ratio of output to input voltage for the instrumentation amplifier of the AD368/AD369 is:

$$| V_O/V_I | = G/ | (1+jf/f_a) | = G/[1+(f/f_a)^2]^{0.5}$$

where f_a equals the −3dB bandwidth and a single-pole roll-off is assumed.

It can be shown that the V_O/V_I ratio will have an error of 1/2LSB for a 12-bit A/D converter when:

$$f(1/2LSB) = f_a/\sqrt{2^{12}} = f_a/64.$$

The instrumentation amplifier will have reached the limit of 12-bit precision for signal frequencies of $f_a/64$. The frequency can be doubled at the expense of two bits of accuracy.

The frequency at which the amplitude of a 10V p-p sine wave is reduced by one half of an LSB is typically 10kHz, 3.5kHz, 1.7kHz, and 0.5kHz at gains of 1, 10, 100, and 500 respectively.

NOISE CONSIDERATIONS

Assuming normally distributed or white noise, the rms noise voltage E_n of a system is a function of its noise bandwidth BW_N. The correlation between −3dB bandwidth (BW) and BW_N is dependant upon the frequency response of the system under consideration.[1] For a 6dB/octave filter, the ratio is $\pi/2 = 1.57$. For a "brick wall" filter it is one. The noise correlation is simply: $E_N = e_N\sqrt{BW_N}$, where e_N is the noise density ($nV/\sqrt{Hz}$).

The noise of the input signal must also be added to the noise of the DAS. Again, in calculating the rms noise contribution of the signal, the BW_N of the source must be considered. If not filter limited before the AD368/AD369 input, the BW_N of the PGA, as stated above, must be used, which is about $\pi/2$ times its −3dB bandwidth.

Input protection resistors will also contribute to the total system noise. The rms noise voltage of a 1kΩ resistor over a noise bandwidth of 1Hz is 4nV. So, the noise voltage of a resistor, R(kΩ) and a noise bandwidth, BW_N(Hz) is: $E_N(R) = 4nV\sqrt{R \times BW_N}$.

The total system rms noise is given by the equation:

$$E_N(\text{system}) = \sqrt{E_N(AD369)^2 + [G \times E_N(R_{IN})]^2 + [G \times E_N(\text{sig})]^2}$$

Once the system rms noise value is known, the probability of the peak-to-peak value of the noise exceeding an LSB is given in Table II.

LSB/E_N	Probability of Noise Exceeding 1LSB
1.0	62.0%
2.0	32.0%
3.0	13.0%
4.0	4.6%
5.0	1.2%
5.15	1.0%
6.0	0.27%
6.6	0.10%

Table II.

[1]See "Low Noise Electronic Design," by C. D. Motchenbacher, F. C. Fitchen.

OTHER CONSIDERATIONS

One of the more overlooked problems in designing ultra-low-drift dc amplifiers is thermocouple induced offset. In a circuit comprised of two dissimilar conductors (i.e., copper, kovar), a voltage known as the "Seebeck" or thermocouple emf is generated when the two junctions are at different temperatures. Standard IC lead material (kovar) and copper form a thermocouple with a high thermoelectric potential (about 35μV/°C). This means that care must be taken to insure that all connections in the input circuit of the AD368/AD369 remain isothermal. In addition, the user should also avoid air currents over the circuitry since slowly fluctuating thermocouple voltages will appear as "flicker" noise.

The base emitter junction of an input transistor can rectify out-of-band signals (i.e., RF interference). These rectified voltages act as small dc offset errors. In the case of a resistive transducer, a small capacitor (e.g. 150pF) across the input working against the internal resistance of the transducer may suffice to provide an RC filter without affecting system bandwidth. Again, every effort should be made to match the capacitance at Pins 1 and 2, to preserve CMR.

ANALOG DEVICES

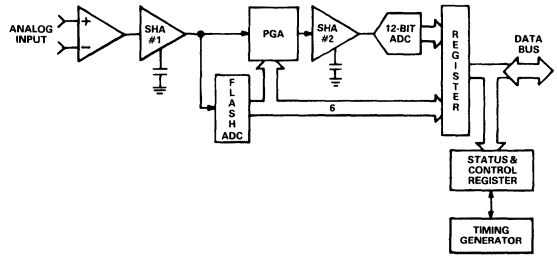
18-Bit Floating Point Data Acquisition System

AD1330

FEATURES
18-Bit Dynamic Range
12-Bit Significand
6-Bit Normalization
100 kHz Conversion Rate
Sample-and-Hold Included
Status Word

APPLICATIONS
Sonar Signal Processing
Vibration Analysis
PC Data Acquisition
Medical Instrumentation
General Purpose DSP

AD1330 FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD1330 is an 18-bit Floating Point Data Acquisition System. The device will digitize signals up to 50 kHz, at conversion rates up to 100 kHz. The output word format consists of an 18-bit word expressed as a 12-bit 2s complement significand and a 6-bit normalization term. The device offers 12-bits of resolution and 18-bits of dynamic range.

The AD1330 incorporates all of the necessary circuitry to acquire, hold and digitize the input signal, and output a digital representation. A complete AD1330 consists of two hybrids, one a 32-pin and the other a 48-pin. The 32-pin hybrid contains the "front end" or Analog Input Section (AIS), while the 48-pin package contains the "back-end" or Conversion & Control Section (CCS).

The analog input section consists of: differential amplifier, sample-and-hold and programmable gain amplifier. The differential amplifier and sample-and-hold have been optimized for low noise, low harmonic distortion and wide dynamic range. The differential amplifier provides optional ground sensing. Ground sensing is enabled by connecting the sense input to analog ground at the signal source. In addition, the user may select whether to bypass the differential amplifier since the input and output connections are made available at the package pins. Operation of the sample-and-hold is via the SHA1H-L and SHA1S-L signals which are internally generated by the control logic. The SHA is compensated for droop, distortion and feedthrough. The PGA incorporates an auto-zero loop to remove dc offsets. The auto-zero loop is enabled by connecting the auto-zero out to PGA in. All control signals to the PGA-AUTOZ-L, SHORT-L and GAIN-L through GAIN64-L are generated by the control logic.

The CCS contains a 7-bit flash ADC, a second SHA, 12-bit ADC, control logic and bus interface logic. The flash ADC generates the first conversion product (normalization constant) which in turn is used to set the gain of the PGA. The SHA is used to pipeline the analog input and to hold it for conversion by the successive approximation 12-bit ADC. The congrol logic generates all of the required timing and control signals to the AIS and CCS. The bus interface circuitry (BI) provides a high speed interface to a 16-bit data bus. The AD1330 generates an interrupt signal which may be used to initiate a read cycle. Reading of output data clears the interrupt; otherwise the interrupt is automatically cleared and output data is updated after 4.8 microseconds.

On each conversion cycle there are three output words available from the AD1330. The first two contain the ADC and normalization outputs; the third contains the status world. A complete result is obtained by multiplying (or scaling) the ADC result by the normalization constant.

The AD1330 has four operating modes: auto gain, fixed gain, forced gain and autocalibrate. In auto gain mode the PGA gain is set during each conversion cycle according to the result from the flash ADC. This process maximizes the amplitude of the signal presented to the 12-bit ADC thereby optimizing the resolution and accuracy of the conversion process. The fixed gain mode holds the last gain setting and inhibits any further updates to the PGA. The forced gain mode allows the user to set a specific gain via the data bus. In autocalibrate, the AD1330 corrects for any offset voltages in the second SHA and 12-bit ADC. Mode selection should be made immediately after reading the previous result. Changing modes before readback may overwrite the output data and is not recommended. Autocalibrate takes 10 microseconds, and one such cycle is initiated on powerup and at any time RST-L is asserted.

Complete 12-Bit Sampling A/D Converter for Digital Signal Processing

AD1332

FEATURES

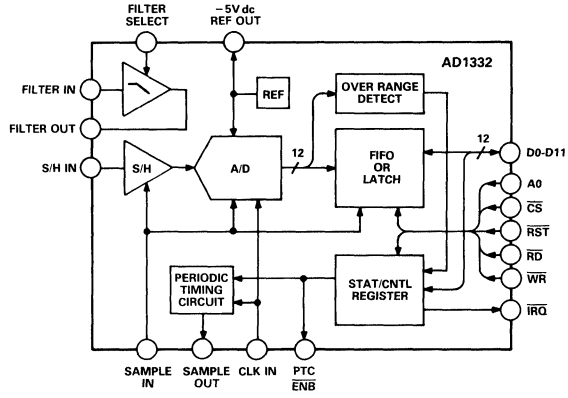
Complete A/D System for DSP Includes:
- **4th Order Antialiasing Filter**
- **12-Bit Sampling A/D Converter**
- **32-Word FIFO Memory**
- **Fully Asynchronous, High Speed Digital Interface**

Sample Rate up to 125kHz
Entire System is Dynamically Specified
15ns Data Access Time Allows "No Wait State" Interface to: ADSP-2100 (A), TMS320C25 DSP56000, NECμPD77230

APPLICATIONS

Sonar Signal Processing
Vibration Analysis
Ultrasound Imaging
PC Data Acquisition
High Speed Modems
Motion Control
Speech Processing

AD1332 FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD1332 is a complete, 12-bit A/D converter system optimized for use in high speed digital signal processing (DSP) applications. The device consists of a fourth order antialiasing filter, a 12-bit sampling A/D, a fully asynchronous high speed digital interface and a 32-word FIFO memory. The AD1332 is manufactured using highly reliable advanced hybrid circuit assembly techniques and is packaged in a 40-pin hermetic DIP.

The antialiasing filter is an active four-pole Butterworth. Cut-off frequencies (f_C) are user-selectable (capacitor programmable), and operation is specified for f_C up to 50kHz. The filter may be bypassed entirely if desired.

The 12-bit sampling A/D converter can convert ±5V full-scale signals at sample rates up to 125kHz. The rate is programmable by means of a single external clock. The entire converter system is specified and tested for signal-to-noise ratio and total harmonic distortion.

The digital interface provides a true asynchronous link between the A/D and a high speed microprocessor. Data transfer is controlled by generating an interrupt signal when data is available. Interrupts can be generated when the FIFO is full (32 words), half-full (16 words), or when a single word of data is ready (FIFO bypassed). In addition, the AD1332 can generate an interrupt signal when the A/D conversion results are overrange.

The AD1332 provides a completely specified and tested system that bridges the interface and specification gap between A/D converters and high speed DSP.

SPECIFICATIONS (T_A = +25°C, V_S = ±15V, V_{DD} = +5V, unless otherwise noted)

Parameter	AD1332BD Min	Typ	Max	Units
FILTER (C1–C4 = 500pF ±1%)				
Input Impedance	8	10		kΩ
Voltage Range	±10			V

NOTES
*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

ORDERING GUIDE

Model	Temperature Range	Package Option*
AD1332BD	−40°C to +85°C	DH-40A
AD1332TD/883B	−55°C to +125°C	DH-40A

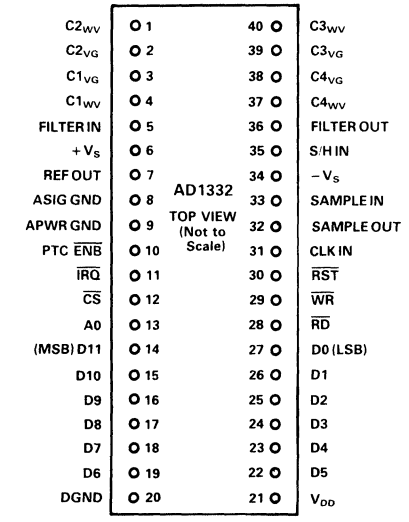
PIN CONFIGURATION



PIN DESCRIPTIONS

Pin	Mnemonic	Function
3, 4	C1vg, C1wv	Pins where 4 equal value capacitors are added to set filter corner.
2, 1	C2vg, C2wv	Frequency f_C according to:
39, 40	C3vg, C3wv	
38, 37	C4vg, C4wv	$f_C = 25\text{kHz} \div C$, C in nF
5	FILTER IN	Filter input.
36	FILTER OUT	Filter output.
35	S/H IN	Sample and hold analog input.
8	ASIG GND	Analog signal ground.
7	REF OUT	−5V reference output.
6, 34	$+V_S$, $-V_S$	Analog power supplies.
9	APWR GND	Analog power ground.
31	CLK IN	External clock input to the A/D converter and the Periodic Timing Circuit.
32	SAMPLE OUT	Periodic Timing Circuit output. Connection to SAMPLE IN sets sample rate at $f_{CLK} \div 20$.
33	SAMPLE IN	S/H and A/D converter control input.
10	PTC $\overline{\text{ENB}}$	Input and (open-drain) output used to enable periodic timing externally or through μP interface.
11	$\overline{\text{IRQ}}$	Open drain interrupt request. User programmable to become active on any of the following conditions: One A/D conversion result available; FIFO half full or full; A/D conversion results overrange.
12	$\overline{\text{CS}}$	Chip select input.
13	A0	Address bit zero. Selects data path from FIFO/latch (low) or from/to Status/Control register (high).
27-22	D0-D5	Bidirectional 3-state data lines. D11 is A/D converter MSB when D0–D11 are outputs.
19-14	D6-D11	D7 is Status/Control register MSB.
28	$\overline{\text{RD}}$	Read control input (D0–D11).
29	$\overline{\text{WR}}$	Write control input (D0–D7).
30	$\overline{\text{RST}}$	Reset. In reset state, FIFO is transparent & overrange detector is disabled.
20, 21	DGND, V_{DD}	Digital power supply.

Bit	Mnemonic	Function
7	FLAG	Logical OR of status Bits 4 & 6.
6	DATA	Set if $\overline{IRQ}$ becomes active because data is available. Reset when FIFO is read from if FIFO used. Reset when $\overline{IRQ}$ becomes inactive if latch is used.
5	ORUN	Set when FIFO has overrun. Reset by control Bit 6.
4	ORNG	Set if $\overline{IRQ}$ became active because of overrange condition. Reset by control Bit 4.
3-0	X	Not defined.

DISCUSSION

General

The AD1332 is a complete solution for sampling and quantifying signals in the audio bandwidth and provides a direct parallel interface to a high speed microprocessor for digital signal processing (DSP). A block diagram of the AD1332 is shown on page 1.

DSP is the mathematical manipulation of dynamic signals which have been represented in numerical form. To successfully process a signal, the signal must be sampled and quantified such that accuracy is preserved and aliasing is avoided. The AD1332 provides this capability by enabling the user to coordinate its antialiasing filter cutoff frequency with the converter sample rate, completely independent from the DSP processor speed.

Sampled Data Systems

The process of sampling a continuous-time signal x(t) at a sample rate f_S causes a periodic replication in the frequency domain of the continuous time Fourier transform (CTFT) x(f) of the original signal about integer multiples of f_S. If the sample rate is selected too low for the bandwidth of x(t), the replicated transforms will overlap with adjacent transforms as illustrated in Figure 14b. This overlap is known as frequency aliasing and will cause distortion if the samples are used in an attempt to reconstruct the original time signal.

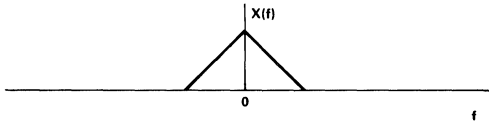

Figure 14a. Original Continuous-Time Fourier Transform (CTFT) or x(t)

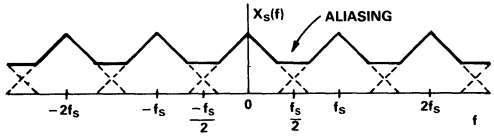

Figure 14b. Sampling Produces Aliased Replications of x(f)

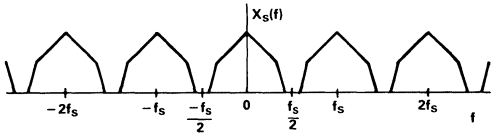

Figure 14c. Replications of x(f) when x(t) is Band Limited

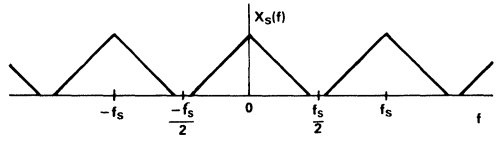

Figure 14d. Replications of x(f) when x(t) is Over Sampled

Aliasing can be avoided by limiting the bandwidth of x(t) to a maximum frequency F_O with an antialiasing filter and sampling at $f_S > 2F_O$, which is known as the Nyquist criteria. In practice, for a fixed sample rate, the amount of aliasing that occurs can be reduced by attenuating interferences outside of the frequency bandwidth of interest as illustrated in Figure 14c. Similarly, for a fixed amount of attenuation outside of the frequency bandwidth of interest, the amount of aliasing that occurs can be reduced by increasing the sampling rate as illustrated in Figure 14d.

The amount of aliasing that is acceptable in a given application should be less than the minimum detectable signal, which is set by the A/D converter signal-to-noise ratio. The amount of aliasing that will occur is a function of the

(1) frequency bandwidth of interest
(2) strength of interferences outside of (1)
(3) filter order and
(4) sample rate.

The user must select (3) and (4) given a converter with a particular SNR to correctly sample a signal in (1) given (2).

Quantization Effects

For an ideal A/D converter, the noise floor is determined by the quantization level used in the digitization process. The signal-to-noise ratio (SNR) for an A/D converter is the ratio of the rms magnitude of the fundamental frequency to the rms sum of all nonharmonically related signals up to half the sampling frequency. SNR is therefore a figure of merit associated with a converter that defines the minimum detectable signal. The theoretical limit on SNR due to quantization noise is

$$\text{SNR max (dB)} = 6.02N + 1.76$$

where N is the number of bits in the converter. For a 12-bit converter such as the AD1332, the maximum SNR is 74dB.

ANTIALIASING FILTER

Features Description

The antialiasing filter in the AD1332 is an active 4th order Butterworth approximation of a low pass filter. A key feature of the Butterworth approximation is a maximally flat magnitude response. For Butterworth filters, attenuation at the cutoff frequency f_C is 3dB and "rolloff" after f_C is 20dB per decade, per pole. Actual AD1332 filter frequency responses for 25kHz and 50kHz cutoff frequencies are shown in Figures 15a and 15b.

It can be shown that an LC ladder filter designed for maximum power transfer from the source exhibits extremely low sensitivity to component variations. This property of the LC filter is exploited

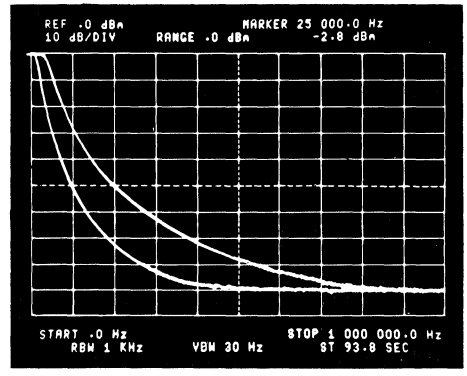

Figure 15a. Filter Response, f_C = 25kHz & 50kHz (C1–C4 = 1000pF & C1–C4 = 500pF)

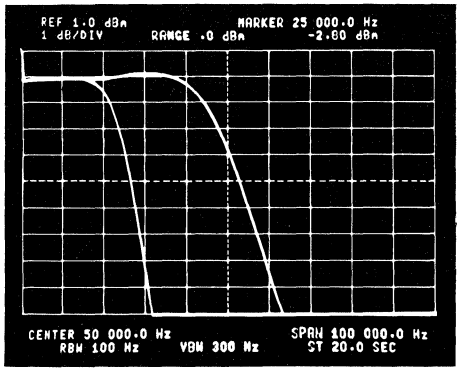

Figure 15b. Filter Passband Response, f_C = 25kHz & 50kHz (C1–C4 = 1000pF @ C1–C4 = 500pF)

in the design of the AD1332 antialiasing filter, which is an RC-active simulation of an LC "prototype." The active components consist of low noise, high-speed operational amplifiers which enable the AD1332 filter to maintain extremely low distortion and consistent response characteristics for cutoff frequencies up to 50kHz. The passive components are precisely trimmed thin-film resistors and external capacitors supplied by the user.

Since the circuit configuration is extremely insensitive to component variations, tight (1%–2%) tolerance capacitors are not required unless the cutoff frequency must be precisely controlled. For example, Figure 16 compares the passband response when capacitors C1–C4 are 1000pF 1% tolerance versus the response when one of the capacitors (C3) is 10% high (1100pF). Note that no additional passband "peaking" is observable, although the cutoff frequency has changed approximately 5% from Figure 15's 25kHz to 23.75kHz.

In contrast to switched capacitor filters, the AD1332 filter does not require a clock, prefiltering nor post-filtering since it is not a sampled data system.

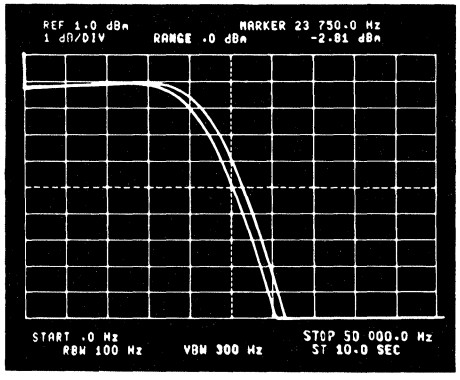

Figure 16. Filter Passband Response, f_C = 25kHz (C1–C4 = 1000pF & C1, C2, C4 = 1000pF, C3 = 1100pF)

Operational Description

Four equal value capacitors are used to select the cutoff frequency f_C according to the equation:

$$f_C = 25\text{kHz} \div C$$

where C is the capacitor value in nF. Good quality, low dissipation factor capacitors such as monolithic ceramic, metallized polycarbonate or polystyrene should be used. If polystyrene capacitors are used, the lead connected to the outer foil should be connected to the AD1332 Cwv (working voltage) pins. If the filter is not used; C1vg (Pin 3), C2vg (Pin 2), C3vg (Pin 39) and C4vg (Pin 38) should all be tied to ASIG GND (pin 8).

SAMPLING A/D CONVERTER

Features Description

The AD1332 provides a complete analog to digital converter function that allows the user to select a sample rate up to 125kHz while maintaining true 12-bit accuracy. As shown on page 1, the AD1332 includes an on-board sample and hold amplifier and low drift voltage reference. The analog input voltage range is from −5V to +5V and the digital output coding is Offset Binary (see Table I). Twos complement coding can be obtained by inverting the MSB (D11).

Output Code	Center of Code Voltage (V)
000 . . . 000	−5.000000
011 . . . 111	−0.002441
100 . . . 000	0.000000
111 . . . 111	+4.997559

Table I. A/D Conversion Relationship

Operational Description

Analog signal information is converted to a 12-bit digital word by means of sampling the waveform and digitizing the sample using the successive approximation conversion technique. Two timing modes are available for sampling and converting the analog input.

Periodic Timing Mode

The periodic timing mode samples the input signal at equally spaced time intervals at a rate that is proportional to the input clock frequency. The connections required for the periodic timing mode for sample rates between 25kHz and 125kHz are shown in Figure 17. In this mode, the clock input is divided down internally to generate the SAMPLE OUT signal which is connected to the SAMPLE IN pin. The periodic timing circuit allots 7 clock periods to sample and hold acquisition and 13 clock periods to A/D conversion. The sample rate is therefore:

$$f_S = f_{CLK} \div 20$$

which is 125kHz for a 2.5MHz clock. The timing diagram for this mode is shown in Figure 18.

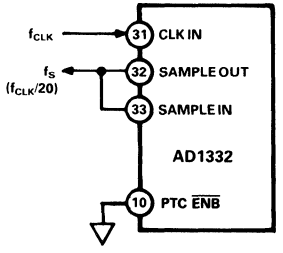

Figure 17. Periodic Timing Mode Connections

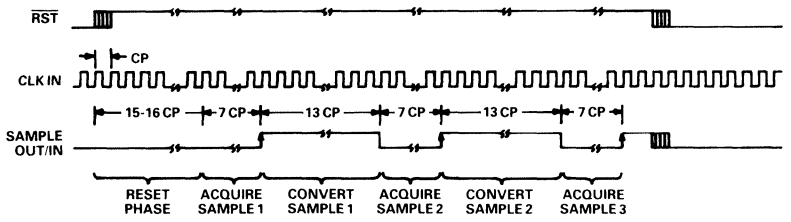

Figure 18a. Timing Diagram for Periodic Timing Mode (PTC $\overline{ENB}$ = 0)

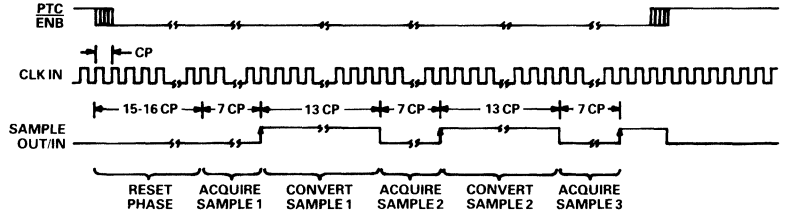

Figure 18b. Timing Diagram for Periodic Timing Mode ($\overline{RST}$ = 1)

PTC $\overline{ENB}$ functions as an "on/off" switch for the periodic timing circuit and is both an input and an open drain output. The periodic timing circuit can therefore be activated either through the microprocessor interface (via Control Register Bit 7) or externally by an open drain driver (such as the 74HC03). The circuit can also be permanently enabled by grounding PTC $\overline{ENB}$.

As shown in Figure 19, slowing the clock down below 1MHz will result in degraded performance at high temperatures when the sampled input "droops" during the A/D conversion. Figure 20 shows the modifications required to the circuit shown in Figure 17 to maintain 12-bit linearity over temperature. This circuit simply divides the SAMPLE OUT signal by an appropriate power of two to sample at the correct rate while maintaining a 500kHz to 2.5MHz A/D converter clock.

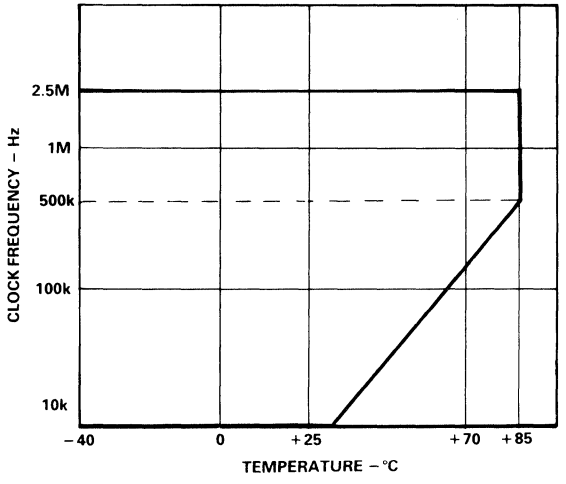

Figure 19. Range of Clock Frequencies vs. Temperature for 12-Bit Linearity

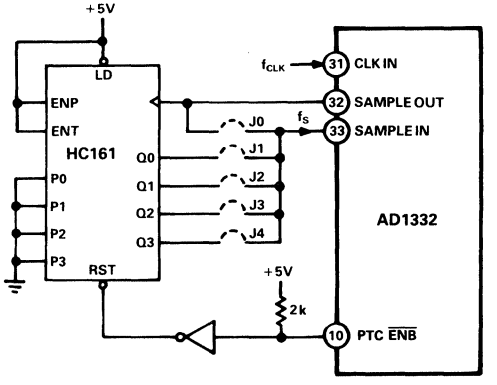

Jumper	f_{CLK}/f_S	f_S Range w/ 500kHz ≤ f_{CLK} ≤ 2.5MHz	
J0	20	25.00kHz –	125.00kHz
J1	40	12.50	62.500
J2	80	6.25	31.250
J3	160	3.125	15.625
J4	320	1.5625	7.8125

Figure 20. Periodic Timing Mode Connections when 500kHz≤f_{CLK}≤2.5MHz

It is important to note that since the clock is used to define the amount of time between samples that it should be crystal controlled since instability in the clock circuit will appear as additional timing uncertainty ("jitter") in the sample and hold, which will result in degraded SNR.

Externally Triggered Mode

If the periodic timing circuit is not used, conversions can be triggered externally by connecting the AD1332 as shown in Figure 21. The timing diagram for this mode is shown in Figure 22. The duty cycle for the CONVERT START command must allow a minimum of 2.8μs for sample and hold acquisition. Note that if the CONVERT START command is not synchronized to the clock input, up to 15 clock periods will be required to complete the conversion cycle so the maximum sampling rate in this mode will be 110kHz when a 2.5MHz clock is used.

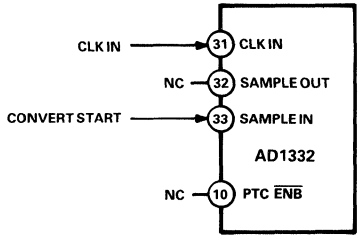

Figure 21. Externally Triggered Mode Connections

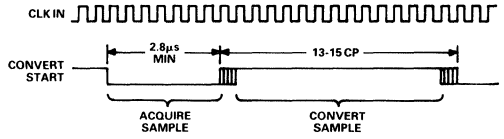

Figure 22. Timing Diagram for Externally Triggered Mode

Since the clock does not define the amount of time between samples, it need not be crystal controlled.

HIGH-SPEED DIGITAL INTERFACE

Features Description

The AD1332 completes the solution for A/D conversion in DSP applications by providing the systems designer a direct, high speed parallel digital interface. The prime feature of this interface architecture is that it operates completely asynchronously from the A/D converter and therefore allows the AD1332 to appear as "memory" to a microprocessor.

The combination of fully asynchronous operation with respect to the A/D conversion process and fast data access time allows the AD1332 user to upgrade to faster versions, or even different vendors, of DSP hardware without having to add synchronization or wait state logic. In addition, by virtue of hybrid circuit technology, the user is not required to add external circuitry to prevent digital feedthrough into the analog section.

The AD1332 data transfer is accomplished by employing an interrupt driven architecture. Interrupts can be programmed by the microprocessor to be generated when the FIFO is full (32 conversion results), half-full (16 conversion results) or after every conversion (FIFO is bypassed). The AD1332 digital interface also includes an overrange detect circuit, which can generate an interrupt if the sampled analog input signal exceeds positive or negative full scale, to alert the system that a conversion result has been generated that will result in a nonlinearity in the subsequent signal processing.

Operational Description

The AD1332 can interface directly to a microprocessor via standard data (D0-D11), address (A0) and control lines ($\overline{RD}$, $\overline{WR}$, $\overline{CS}$, $\overline{IRQ}$ and $\overline{RST}$).

Data Transfer

The data lines D0-D11 are bidirectional I/O that are TTL compatible and have 4mA drive capability. The data lines are used to transfer control information into, and A/D conversion results with status information out of, the AD1332. Address line A0 is an input that is used to select as the data path either A/D conversion results (A0 = 0) or the Control/Status Registers (A0 = 1) and would typically be the least significant address bit in the system if the AD1332 is "mapped" to adjacent memory locations. Chip-Select ($\overline{CS}$) is used to define a unique location in memory for the AD1332 and should be formed by decoding the upper address bits. Read ($\overline{RD}$) and Write ($\overline{WR}$) define the type of data transfer.

Figures 26 – 31 illustrate how the AD1332 interfaces to a number of popular single-chip digital signal processors.

Interrupts

Interrupt Request ($\overline{IRQ}$) is an open drain output that can be used to interrupt the processor on any of the conditions programmed in the control register. The processor should be programmed to interrupt on the falling edge of its Interrupt Request input.

FIFO Half-Full Interrupt

The timing for interrupts that are generated when the FIFO is half full is shown in Figures 23a and 23b. In both figures, $\overline{IRQ}$ becomes active when the 16th A/D conversion result is shifted into the FIFO. In Figure 23a, the processor responds immediately and a read cycle takes place before the next conversion cycle begins. Here, the completion of the read cycle shifts the first conversion result (which was just read by the processor) out of the FIFO, replaces it with the second conversion result and causes $\overline{IRQ}$ to become inactive since there are now 15 conversion results in the FIFO.

In Figure 23b, the processor does not respond before the next conversion cycle begins and $\overline{IRQ}$ becomes inactive. The FIFO continues to accept conversion results and the processor can read from the FIFO at any time so long as the FIFO has not overrun.

This mode allows the AD1332 to have a low interrupting priority since the processor has 340 A/D converter clock periods (17 conversions × 20 clock periods per conversion) in the periodic timing mode before the FIFO overruns. Therefore, the processor will have up to 136μs to respond at the maximum sample rate of 125kHz (since f_{CLK} = 2.5MHz).

FIFO Full Interrupt

The timing for interrupts that are generated when the FIFO is full is shown in Figures 24a and 24b. In both figures, $\overline{IRQ}$ becomes active when the 32nd A/D conversion result is shifted into the FIFO. In Figure 24a, the processor responds immediately and a read cycle takes place before the next conversion cycle begins. Here, the completion of the read cycle shifts the first conversion result (which was just read by the processor) out of the FIFO, replaces it with the second conversion result and causes $\overline{IRQ}$ to become inactive because there are now 31 conversion results in the FIFO.

In Figure 24b, the processor does not respond before the next conversion cycle begins and $\overline{IRQ}$ becomes inactive. The processor must read from the FIFO before the completion of the current conversion cycle or the FIFO will overrun.

This mode maximizes the memory capability of the AD1332 but requires a fairly high interrupting priority in the processor since the processor has only 20 A/D converter clock periods (1 conversion

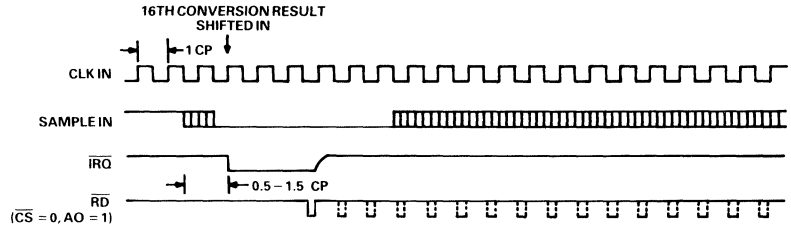

Figure 23a. Timing Diagram for Half-Full Interrupt (Read before 17th Conversion Started)

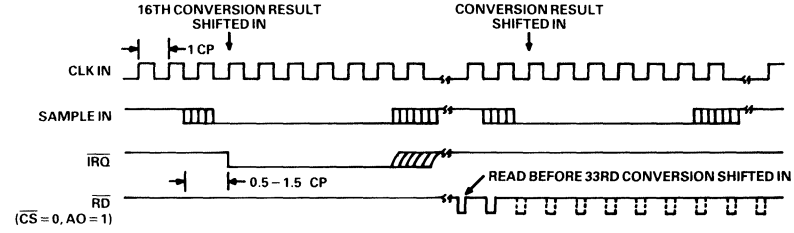

Figure 23b. Timing Diagram for Half-Full Interrupt (Read after 17th Conversion Started)

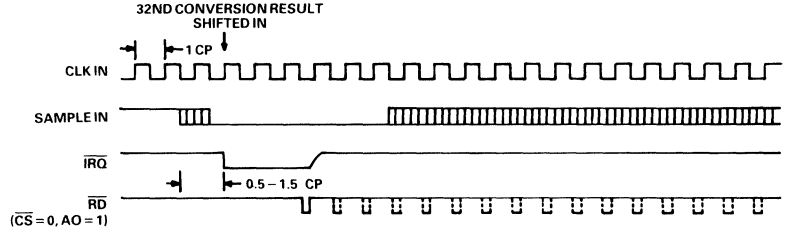

Figure 24a. Timing Diagram for Full Interrupt (Read before 33rd Conversion Started)

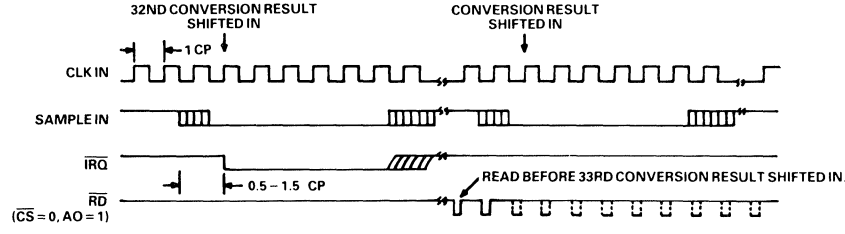

Figure 24b. Timing Diagram for Full Interrupt (Read after 33rd Conversion Started)

× 20 clock periods per conversion) in the periodic timing mode before the FIFO overruns. Therefore, the processor will have only 8μs to respond at the maximum sample rate of 125kHz (since f_{CLK} = 2.5MHz).

Conversion Results Overrange Interrupt

If the FIFO is used, the AD1332 can be programmed to generate interrupts when overranged conversion results are shifted into the FIFO. If $\overline{IRQ}$ became active as a result of an overrange condition, the only way it can become inactive is to clear Bit 4 of the control register. Typically, the user should clear the entire control register which will, in effect, remove the interrupt, reset the FIFO and reset the periodic timing circuit.

Should the overrange interrupt capability be used, Status Register Bits 4 and 6 can be used to identify whether the interrupt occurred as a result of an overrange condition or FIFO half full (or full).

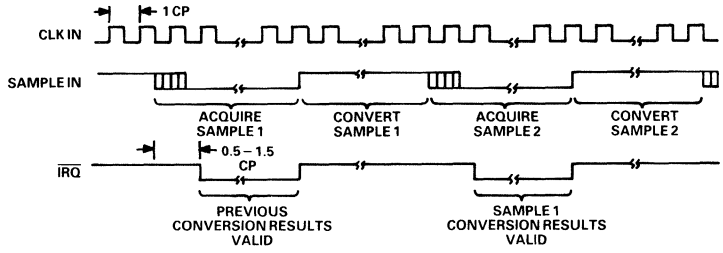

Figure 25. Timing Diagram for Single Conversion Interrupt

Single Conversion Interrupt (FIFO Bypassed)
The timing for interrupts that are generated when the FIFO is bypassed is shown in Figure 25. Here, $\overline{IRQ}$ becomes active at the completion of a single A/D conversion cycle, which may be up to two A/D converter clock periods after the sample and hold starts acquiring the next sample. $\overline{IRQ}$ remains active, independent of the read cycle, until the next conversion cycle begins. Data is valid so long as $\overline{IRQ}$ remains active.

This mode makes data available immediately after the conversion process has been completed, and is therefore very similar to the operation of a conventional A/D converter if $\overline{IRQ}$ is taken to mean conversion STATUS. This mode is most useful when a single conversion result is necessary to adjust a system parameter, such as the gain of a PGA that may be in front of an AD1332.

Since $\overline{IRQ}$ will only be valid for six A/D converter clock periods in periodic timing mode (2.4μs with a 2.5MHz clock), a high interrupting priority should be assigned by the processor. Should the single conversion result be necessary to adjust a system parameter as described above, it may be more efficient to "poll" the Status Register to determine when the conversion result is available.

Operation Other than with a Microprocessor
The AD1332 can be used in other microprocessor environments by grounding Pins 12, 13 and 28 ($\overline{CS}$, A0 and $\overline{RD}$), connecting Pin 29 ($\overline{WR}$) to V_{DD} and pulsing $\overline{RST}$ low. This will permanently enable the AD1332 3-state outputs and clear the control register, causing the FIFO to be bypassed.

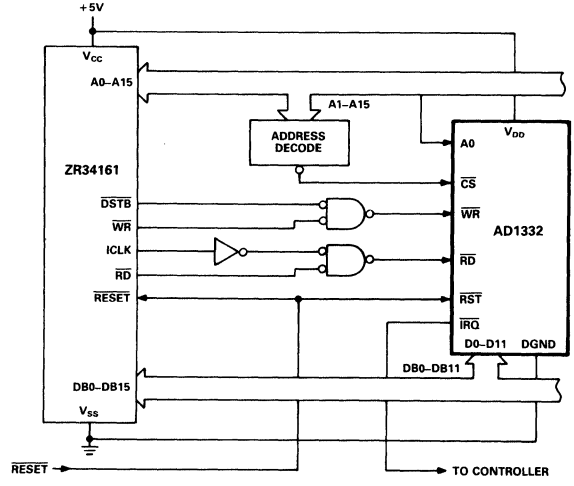

Figure 31. ZR34161 to AD1332 Interface

Multiple AD1332s

The architecture of the AD1332 allows multiple devices to be used in a microprocessor based system. Figure 32 illustrates how four AD1332s can be configured to simultaneously sample their analog inputs and reside in eight sequential locations in a microprocessor's memory address space. Since the AD1332s are sampling at the same rate, one AD1332 functions as the "master" and drives its own SAMPLE IN pin as well as those of the remaining devices ("slaves"). The Control Register of each device should be programmed to interrupt on the same condition so that the same number of conversion results are available from all devices.

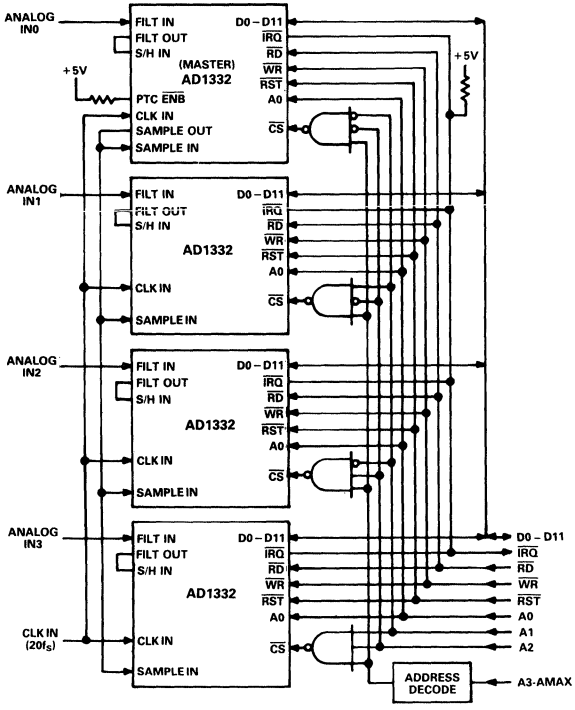

Figure 32. 4-Channel Simultaneous Sampling System

Sequential Sampling

Figure 33 illustrates how an AD1332 can be configured to sequentially sample sixteen channels of analog inputs. The circuit works as follows. The HC161 outputs Q0-Q3 form the address bits for the AD7506 muliplexer. Through the microprocessor interface, the periodic timing circuit is enabled and the HC161 is taken out of reset by setting Control Register Bit 7. Since the HC161 was reset, Channel 0 is initially selected. Following an AD1332 reset cycle (15-16 clock periods), 7 clock periods are used to acquire the Channel 0 input. Once acquired, the rising edge of SAMPLE OUT puts the AD1332 sample and hold into hold mode, starts the A/D conversion and advances the HC161 one count. Therefore, while Channel 0 is being converted, the multiplexer switches to Channel 1 and settles during the 13 clock periods required for A/D conversion.

The above continues until Channel 15 has been sampled, at which point the HC161 returns to an all zero count and commences another pass through the 16 channels. The process can be terminated by clearing Control Register Bit 7.

Since each channel is sampled on every 16th rising edge of the SAMPLE OUT signal, the effective sampling rate is:

$$f_S = (f_{CLK} \div 20) \div (\text{Number of Channels})$$

$$= f_{CLK} \div 320$$

Any number of channels can be sequentially sampled with slight modifications to the circuit shown in Figure 33.

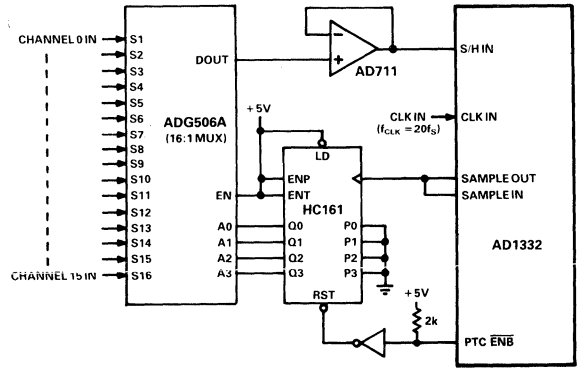

Figure 33. 16-Channel Sequential Sampling System

SUCCESSFULLY APPLYING THE AD1332

Grounding

In order to obtain the specified performance of the AD1332, proper grounding and power supply decoupling techniques must be observed. First, it is imperative that a ground plane be used. A ground plane provides a low resistance, low inductance path for currents to flow back to their source. Without a ground plane, currents will return to the source in such a way as to minimize the energy of the system and therefore parasitic inductances will exist in such undesirable locations as power supply lines and signal grounds.

Second, all three ground connections on the AD1332 must be tied together to the ground plane. The AD1332 APWR GND (Pin 9) carries the imbalance current from the analog power supplies ($\pm V_S$). APWR GND is also connected to the package seal ring/lid and therefore can cause coupling between the analog and digital sections if it is not tied directly to the ground plane.

ASIG GND (Pin 8) is the signal ground internal to the AD1332 and is "common" for the filter, −5V reference, sample and hold, and A/D converter. The current that flows through this pin from the A/D converter is a dynamic current that changes on every clock cycle. Inductance in this trace will therefore cause a reduction in performance in the entire analog section.

DGND (Pin 20) is a separate ground connection for the digital interface chip. It carries a dynamic current every time a digital output changes state, and inductance in the trace that connects to this pin will reduce the noise margin between the A/D converter and the digital interface chip.

Power Supply Decoupling

The power supply decoupling capacitors supply the instantaneous current to the AD1332 and also provide some high frequency filtering. The filtering aspect of the capacitors should not be counted on however, and the user should make every effort to

supply quiet, well regulated power supplies to the AD1332. Switching mode power supplies are not recommended for the analog power supplies $\pm V_S$.

Decoupling capacitors should be placed as close to the device as possible to minimize inductances in power supply traces. A 2.2μF (or greater) solid tantalum capacitor in parallel with a 0.1μF ceramic capacitor should be used for decoupling each $+V_S$ and $-V_S$. A 1.0μF (or greater) solid tantalum capacitor should be used for decoupling V_{DD}.

Transmission Line Effects

The digital interface has 10K ECL speed and with 15pF loading exhibits a typical edge rate of 1.4ns. High speed CMOS systems that incorporate the AD1332 must use careful PCB layout and impedance matching techniques to reduce crosstalk and voltage reflections.

Crosstalk

The fast edge rates with large voltage swings of CMOS systems can result in capacitive and inductive coupling (crosstalk) between adjacent PCB signal traces and may compromise signal integrity and reduce noise margins. The effect can be most severe on data lines that are near "clocked" control lines, such as Read, Write and Chip Select lines, when they actually change their logic state as a result of crosstalk.

To reduce crosstalk, the PCB layout should minimize long parallel traces. If this can not be avoided, clock lines should be shielded from data and address lines by running ground traces along side them.

Voltage Reflections

The gross impedance mismatch between high impedance CMOS inputs and low impedance CMOS outputs invites unwanted voltage reflections and "ringing" that can also compromise signal integrity and reduce noise margins. This level of mismatch causes a nearly equal and opposite negative pulse to be reflected back from the load to the source when the round trip delay of the line exceeds the rise or fall time of the driving signal. For a typical line delay of 0.055ns/cm with a 1.4ns edge rate, this translates to only 13cm (5 inches) for the AD1332. Provided the signal lines are over a ground plane, this may never be a problem since the added capacitance will reduce the edge rate.

The effect will be most severe on "clock" lines in synchronous systems such as Read, Write and Chip Select lines. For example, should the AD1332 Read control input ($\overline{RD}$) be double clocked as a result of a reflection while in a read cycle, in most cases the digital interface chip will be fast enough to respond. If the FIFO is being read from, a second shift out will occur and A/D conversion results will be lost.

Since CMOS output stages are not capable of delivering enough current to the load when a transmission line (PCB trace) is terminated in its characteristic impedance, a series damping is recommended when reflections must be reduced or eliminated. Here, a small resistor (typically 10Ω to 75Ω) is inserted in series with the transmission line as close to the source as possible. The goal is to match the series resistance plus driver output impedance to the transmission line impedance. This will keep the wave that is reflected back from the load to source from reflecting back to the load.

The primary disadvantage of series termination is that due to the voltage divider formed by the source resistance and line impedance, the voltage at the input to the line is midway between logic levels during the two way propagation delay time. This means that although any number of device inputs may be attached at the load end, other device inputs cannot be distributed along the transmission line.

ANALOG DEVICES Four-Channel 12-Bit Sampling A/D Converter for Digital Signal Processing

AD1334

FEATURES

Four-Channel A/D Converter for DSP Includes:
- **Simultaneous or Independent Sampling Capability**
- **12-Bit Accurate A/D Converter**
- **2-Bit Channel ID Tags Each Conversion Result**
- **32-Word FIFO Memory**
- **Fully Asynchronous, High Speed Digital Interface**

Single-Channel Sample Rate Up to 67kHz
Four-Channel Simultaneous Sample Rate Up to 28kHz
Entire System Dynamically Characterized
Minimal Effective Aperture Delay Mismatch from Channel-to-Channel & Device-to-Device
15ns Data Access Time Allows "No Wait State" Interface to: ADSP-2100 (A), TMS320C25 DSP56000, NECμPD77230
Low Power, 250mW/Channel

APPLICATIONS

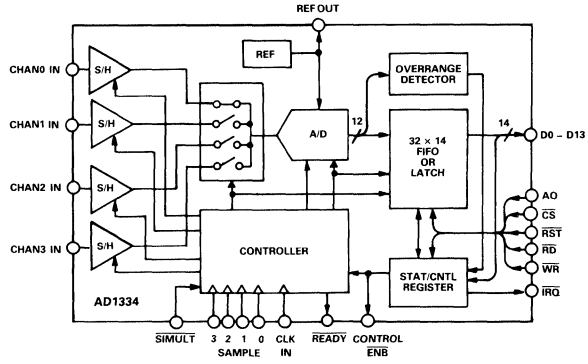
Sonar Signal Processing
Robotics/Machine Control
Disk-Drive Head Positioning
Vibration Analysis

PRODUCT DESCRIPTION

The AD1334 is a four-channel, 12-bit, sampling A/D converter system optimized for use in multichannel digital signal processing (DSP) applications. The device consists of four independent sample-and-hold amplifiers, a multiplexer, an A/D converter, a controller, a 32-word FIFO memory and a fully asynchronous high speed digital interface. The product is packaged in a 40-pin hermetic DIP.

The channel controller enables the AD1334 to appear as four independent channels of analog input by generating all of the timing necessary to ensure that the sampled channel is digitized to 12-bit accuracy. Upon receipt of a sample command, the controller will immediately place the sample-and-hold amplifier into hold mode and then prioritize and schedule the held value for A/D conversion. At the appropriate time, the sampled input is gated through the multiplexer and, after settling, is digitized by the A/D converter. The sample-and-hold amplifier is then returned to sample mode so that it can acquire the next sample.

AD1334 FUNCTIONAL BLOCK DIAGRAM



For effective use in simultaneous sampling applications, the sample-and-hold amplifiers are designed to provide a minimum amount of aperture delay time mismatch from channel-to-channel and device-to-device.

The 12-bit A/D converter can convert ± 5V full scale signals at sample rates up to 67kHz for single-channel operation. In the simultaneous mode, the AD1334 has a four-channel sample rate up to 28kHz. The entire converter system is specified and tested for signal-to-noise ratio, total harmonic distortion and channel-to-channel isolation.

The digital interface provides a true asynchronous link between the A/D and a high speed microprocessor. Data transfer is controlled by generating an interrupt signal when data is available. Interrupts can be generated when the FIFO is full (32 words), half-full (16 words), or when a single word of data is ready (FIFO bypassed). The AD1334 can also generate an interrupt when the A/D conversion results are overrange.

The AD1334 provides a completely specified and tested system that bridges the interface and specification gap between A/D converters and high speed DSP.

SPECIFICATIONS (T_A = +25°C, V_S = ±15V, V_{DD} = +5V and f_{CLK} = 2.5MHz unless noted)

Parameter	AD1334BD Min	Typ	Max	Units

NOTES

[1]Specifications are per channel in 4 Channel Simultaneous Mode (SAMPLE 0-3 connected together and $\overline{SIMULT}$ & CONTROL $\overline{ENB}$ = LOW), at f_S = 28kHz, and with SAMPLE 0-3 having an 80% duty cycle unless noted.

[2]Group delay is the negative of the 1st derivative of phase with respect to frequency and is a measure of the analog time delay through the S/H.

[3]Aperture delay is the time delay from the SAMPLE input to S/H switch opening and is a measure of the digital time delay through the S/H.

[4]Effective aperture delay is the difference between analog and digital time delays described in (2) and (3).

[5]THD of harmonics 2-7 of the fundamental.
SNR of fundamental less harmonics 2-7.

[6]Guaranteed over operating temperature and power supply voltage range tested at +25°C only.

[7]Isolation of any one channel from remaining three channels which have near maximum amplitude ac signals at their inputs.

[8]$\overline{RD}$, $\overline{CS}$, AO = LOW; $\overline{WR}$, $\overline{RST}$ = HIGH.

Specifications subject to change without notice.

Specifications in **boldface** are tested on all production units. All other specifications are guaranteed but not tested.

SWITCHING CHARACTERISTICS (over operating temperature and power supply voltage range, with C_{OUT} = 30pF or 100pF except where noted)

Parameter	Description	Conditions	Min	Max	Units
READ CYCLE

NOTES
*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

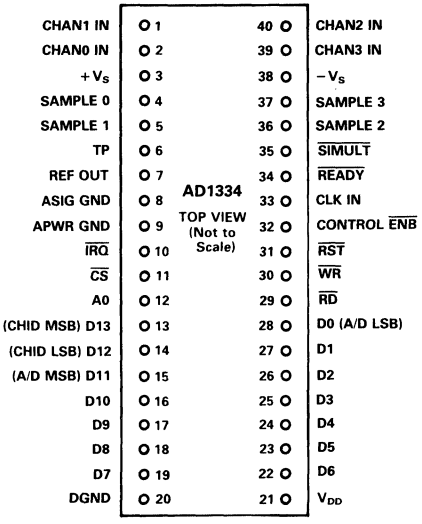
PIN CONFIGURATION



PIN DESCRIPTIONS

Pin	Mnemonic	Function
2	CHAN 0 IN	Channel 0 analog input.
1	CHAN 1 IN	Channel 1 analog input.
40	CHAN 2 IN	Channel 2 analog input.
39	CHAN 3 IN	Channel 3 analog input.
6	TP	Test Point (no connect).
32	CONTROL $\overline{ENB}$	Input and (open drain) output used to enable controller externally or through µP interface.
34	$\overline{READY}$	Output that, in simultaneous mode, indicates all channels have been successfully converted and device is ready to sample.
35	$\overline{SIMULT}$	Input that when LOW sets controller to simultaneous mode which keeps S/Hs in hold mode until all channels have been converted.
8	ASIG GND	Analog signal ground.
7	REF OUT	−5V reference output.
3, 38	$+V_S$, $-V_S$	Analog power supplies.
9	APWR GND	Analog power ground.
33	CLK IN	External clock input to the A/D converter and channel controller.
4	SAMPLE 0	Channel 0 S/H control input.
5	SAMPLE 1	Channel 1 S/H control input.
36	SAMPLE 2	Channel 2 S/H control input.
37	SAMPLE 3	Channel 3 S/H control input.
10	$\overline{IRQ}$	Open drain interrupt request. User programmable to become active on any of the following conditions: One A/D Conversion Result Available; FIFO Half Full or Full; A/D Conversion Results Over range.
11	$\overline{CS}$	Chip select input.
12	A0	Address bit zero. Selects data path from FIFO/latch (low) or from/to Status/Control register (high).
28–22	D0–D6	Bidirectional 3-state data lines. D11 is A/D converter MSB when D0–D13 are outputs. D7 is Status/
19–13	D7–D13	Control register MSB. D12 and D13 carry channel ID number.
29	$\overline{RD}$	Read control input (D0–D13).
30	$\overline{WR}$	Write control input (D0–D7).
31	$\overline{RST}$	Reset. In reset state, FIFO is transparent & overrange detector is disabled.
20, 21	DGND, V_{DD}	Digital power supply.

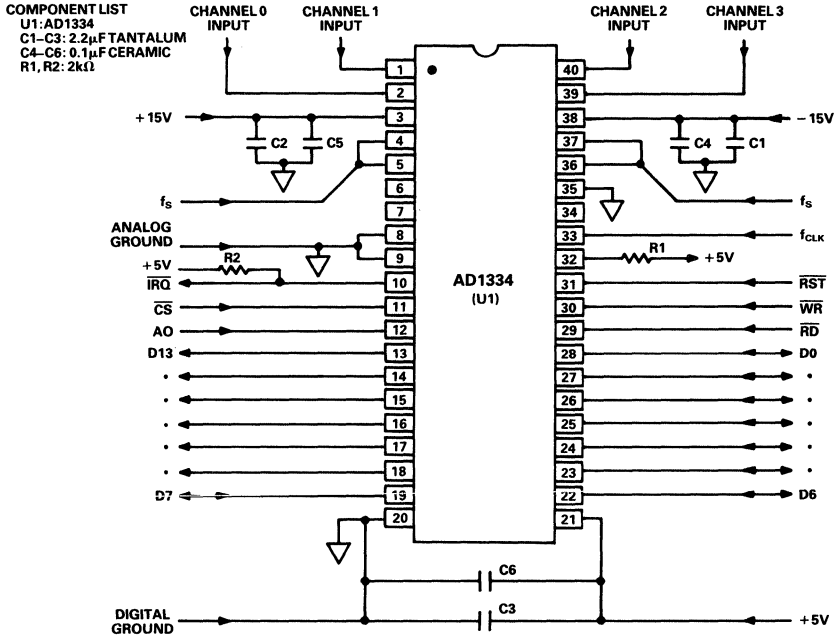


Figure 13. Typical Interface Circuit (Simultaneous Mode)

CONTROL AND STATUS REGISTER DESCRIPTIONS

Control

Bit→	7	6	5	4	3	2	1	0
	CTLEN	$\overline{L}$/F	$\overline{HF}$/F	ORNG	X	X	X	X

Bit	Mnemonic	Function
7	CTLEN	A "0" in this bit position will disable the controller. A "1" in this bit position will enable the controller.
6	$\overline{L}$/F	A "0" in this bit position will reset the FIFO and enable the transparent latch. $\overline{IRQ}$ will become active on the completion of an A/D conversion cycle. $\overline{IRQ}$ will become inactive on the start of the next A/D conversion cycle. A "1" in this bit position will enable the FIFO and activate $\overline{IRQ}$ when the FIFO is half full or full (depending on CBIT 5). $\overline{IRQ}$ will become inactive on the start of the next A/D conversion cycle or when the FIFO is read from.
5	$\overline{HF}$/F	A "0" in this bit position will cause $\overline{IRQ}$ to become active when the 16th word is shifted into the FIFO (if the FIFO is enabled). A "1" in this bit position will cause $\overline{IRQ}$ to become active when the 32nd word is shifted into the FIFO (if the FIFO is enabled).
4	ORNG	A "0" in this bit position will disable the overrange interrupt capability. A "1" in this bit position will activate $\overline{IRQ}$ if overranged (all "0"s or all "1"s) data is shifted into the FIFO. $\overline{IRQ}$ will become inactive when this bit is reset to "0."
3–0	X	Not defined.

Status

Bit→	7	6	5	4	3	2	1	0
	FLAG	DATA	ORUN	ORNG	X	X	X	X

Bit	Mnemonic	Function
7	FLAG	Logical OR of status Bits 4 & 6.
6	DATA	Set if $\overline{IRQ}$ becomes active because data is available. Reset when FIFO is read from if FIFO used. Reset when $\overline{IRQ}$ becomes inactive if latch is used.
5	ORUN	Set when FIFO has overrun. Reset by control Bit 6.
4	ORNG	Set if $\overline{IRQ}$ becomes active because of overrange condition. Reset by control Bit 4.
3–0	X	Not defined.

SAMPLE-AND-HOLD AMPLIFIERS

The four sample and hold amplifiers internal to the AD1334 combine precision high speed amplifiers and switches together with laser trimmed thin-film resistors to offer a performance and power efficient front end for multichannel applications. Each sample-and-hold amplifier is designed to minimize the effects of dc and ac error sources in simultaneous as well as independent sampling applications.

Operational Description

The sample and hold amplifier architecture is based on an integrator which results in a relatively low input impedance (2.5kΩ) and an acquisition time of 7.5μs (maximum). DC error sources are specified and controlled through the use of precision amplifiers, low leakage switches and package-level laser trimming of thin-film resistors.

Group delay is specified and controlled through the use of trimmed thin-film resistors, tight-tolerance hold capacitors and high speed amplifiers. Aperture delay is specified and controlled through the use of high speed CMOS logic and DMOS switches. The effective aperture delay, which is the delay seen by the user, is therefore controlled from channel to channel and from device to device. The effective aperture delay is negative because the held value corresponds to a value of input voltage that occurred before the amplifier was put into hold mode.

In applications where endpoint (+FS and −FS) accuracy is critical, the source impedance should be minimized because each ohm will typically change the gain of the sample and hold amplifier by 0.04%. This should not be a problem in most cases because the low impedance output of either a programmable gain amplifier or antialiasing filter will be connected to each of the AD1334's analog inputs.

CHANNEL CONTROLLER

The AD1334 Channel Controller enables the AD1334 to appear as four independent channels of analog input by generating all of the timing necessary to ensure that the sampled channel is digitized to 12-bit accuracy. Upon receipt of a sample command, the controller will immediately place the sample-and-hold amplifier into hold mode and then prioritize and schedule the held value for A/D conversion. At the appropriate time, the sampled input is gated through the multiplexer and, after settling, is digitized by the A/D converter. The sample-and-hold amplifier is then returned to sample mode so that it can acquire the next sample.

Operational Description

Timing is initiated on the rising edge of SAMPLE 0–3 control inputs. To minimize the effects of digital feedthrough from the control inputs, it is recommended that the falling edge occur before sample-and-hold acquisition (sample-and-holds have a maximum 7.5μs acquisition time) and after the A/D conversion is complete.

CONTROL $\overline{\text{ENB}}$ functions as an "on/off" switch for the controller and is both an input and an open drain output. The controller can therefore be activated either through the microprocessor interface (via control register Bit 7) or externally by an open drain driver (such as the 74HC03). The controller can also be permanently enabled by grounding CONTROL $\overline{\text{ENB}}$. The timing for enabling and disabling the controller as described above is shown in Figure 14.

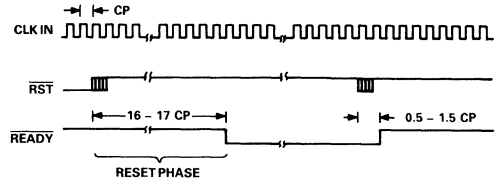

Figure 14a. Timing Diagram for Resetting Controller (CONTROL $\overline{ENB} = 0$)

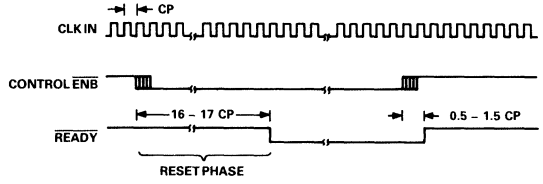

Figure 14b. Timing Diagram for Enabling Controller ($\overline{RST} = 1$)

The channel controller also adds 2 bits (D12 and D13) of data to each A/D conversion result for channel identification. Table I summarizes this relationship.

D13	D12	A/D Conversion Results From
0	0	Channel 0
0	1	1
1	0	2
1	1	3

Table I.

Two timing modes are available for sampling and converting each or all of the analog inputs. (Note – The timing diagrams shown refer to Channels "A,B,C,D" rather than "0,1,2,3." This was done because each channel is completely independent of the other three channels and, in fact, Channel A can be any of Channels 0, 1, 2 or 3, Channel B can be any of Channels 0, 1, 2 or 3, etc.)

Simultaneous Mode

Simultaneous mode is selected by connecting the $\overline{\text{SIMULT}}$ pin to logic low. This mode should be used when any 2, 3 or all 4 channels are to be sampled simultaneously (i.e., at the same instant in time). This mode keeps the sample-and-hold amplifiers on the sampled channels in hold mode until the sampled inputs have been digitized and will normally result in better channel-to-channel isolation relative to independent mode. The timing diagram for this mode is shown in Figure 15. Note that $\overline{\text{IRQ}}$ becomes active on the completion of every A/D conversion since the FIFO is not being used.

Prioritizing logic internal to the channel controller can be used to ensure that the channels are converted in a predetermined sequence. Synchronizing the sample control signal (rising edge of SAMPLE 0–3) to either the rising or falling edge of the clock will result in Channel 0 being converted before Channel 1, Channel 1 before Channel 2, and Channel 2 before Channel 3. An obvious advantage to this is that the user can choose to ignore data Bits 12 and 13 (D12 and D13) which carry the channel identification.

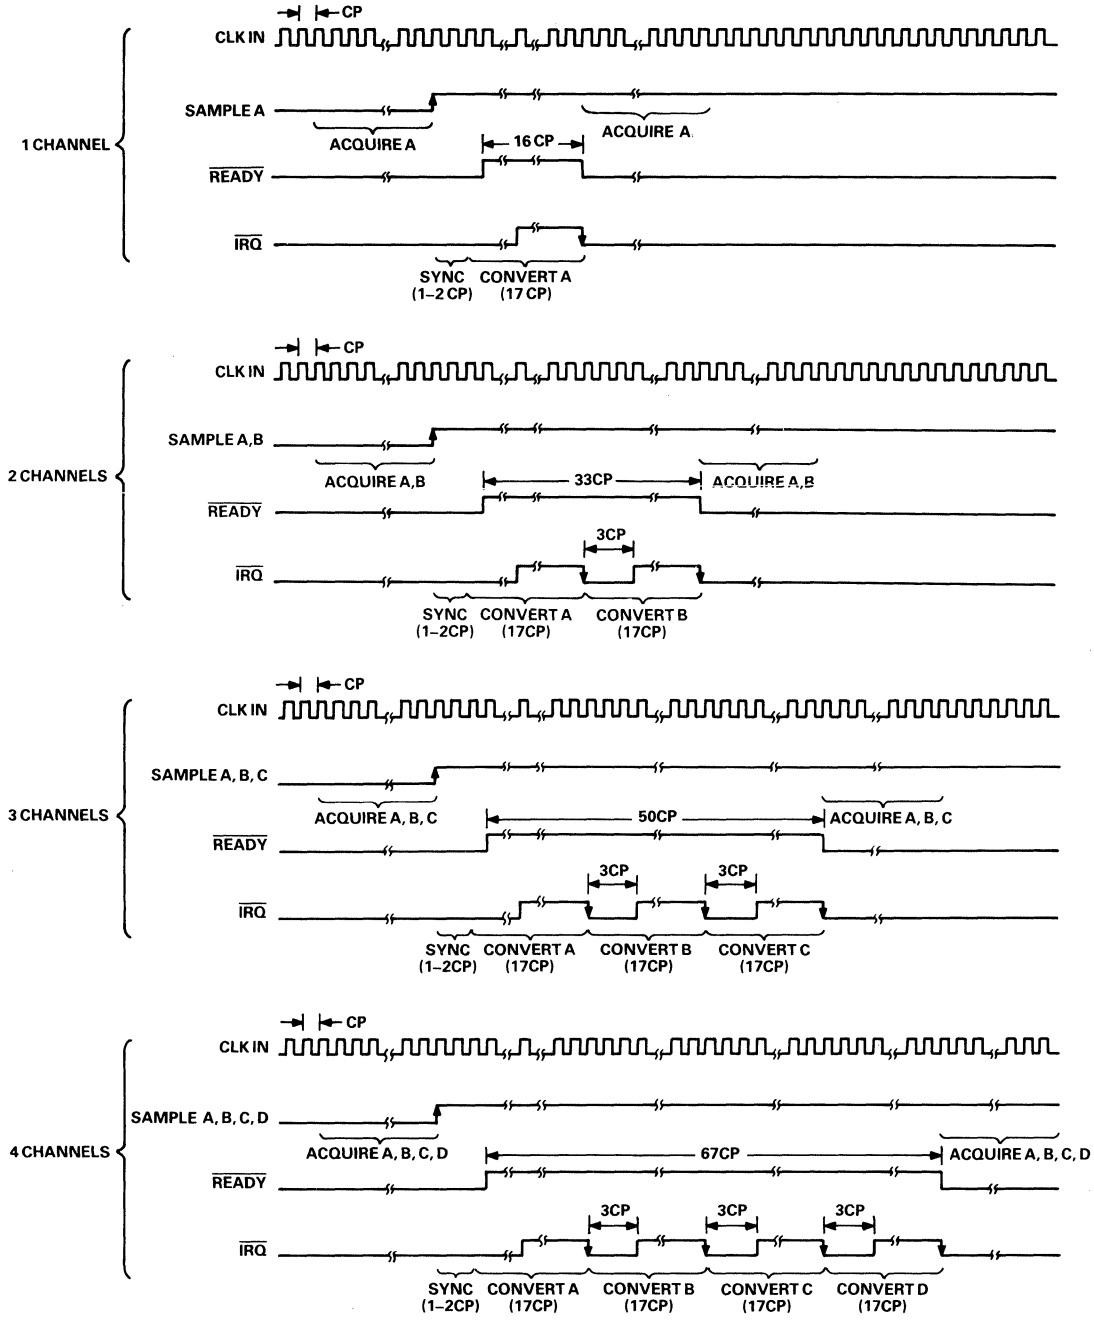

Figure 15. Timing for Simultaneous Sampling ($\overline{SIMULT}$ = Low, FIFO Not Used)

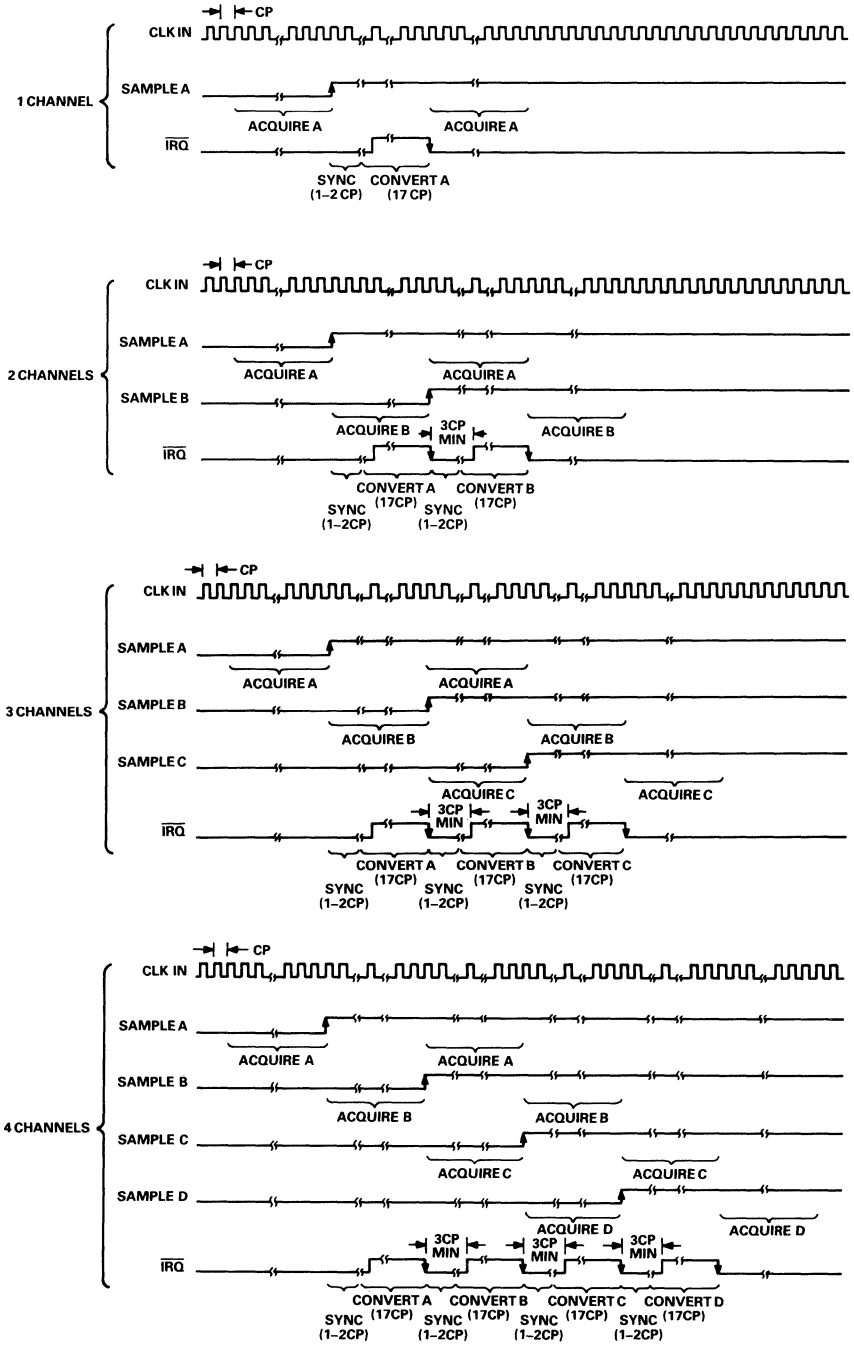

Figure 16. Timing for Independent Sampling ($\overline{SIMULT}$ = High, FIFO Not Used) w/Worst Case Skew of SAMPLE Control Inputs

If the FIFO is used, the falling edge of the $\overline{\text{READY}}$ signal, can be used as an interrupt signal to notify a processor that the 1, 2, 3 or 4 channels have been successfully converted and have been shifted into the FIFO. All conversion results can be read from the FIFO with the exception of the last one, which must fall through to the output (fall-through time is typically 400ns). $\overline{\text{READY}}$ can also be used as a signal to the device generating the sample command that the previous group of samples have been converted and that the next group of samples are being acquired.

Independent Mode

Independent mode is selected by connecting the $\overline{\text{SIMULT}}$ pin to logic high. This mode should be used when any number of channels are sampled independently. In contrast to simultaneous mode, this mode returns the sample-and-hold amplifier on the sampled channel to sample mode when the channel input has been digitized. This mode allows the AD1334 to emulate up to four independent sampling A/D converters, each of which can accommodate different sample rates and hence different signal bandwidths. The timing diagram for this mode is shown in Figure 16. Note that $\overline{\text{IRQ}}$ becomes active on the completion of every A/D conversion since the FIFO is not being used.

The $\overline{\text{READY}}$ signal has no implicit definition in this mode, other than the falling edge indicating that the controller has no conversions pending.

A/D CONVERTER

The analog input voltage range goes from −5V to +5V and the digital output coding is Offset Binary (see Table II). Twos complement coding can be obtained by inverting the MSB (D11).

Center of Code Voltage (V)	Output Code
−5.000000	000 . . . 000
−0.002441	011 . . . 111
0.000000	100 . . . 000
+4.997559	111 . . . 111

Table II. A/D Conversion Relationship

Operational Description

Analog signal information is converted to a 12-bit digital word by sampling the waveform and digitizing it using the successive-approximation conversion technique. Since the clock does not define the amount of time between samples, it need not be crystal controlled. Best performance will be obtained by operating the clock at the maximum 2.5MHz clock frequency.

HIGH SPEED DIGITAL INTERFACE

The AD1334 completes the solution for A/D conversion in DSP applications by providing the system's designer a direct, high speed parallel digital interface. The prime feature of this interface architecture is that it operates completely asynchronously from the A/D converter and therefore allows the AD1334 to appear as "memory" to a microprocessor.

The combination of fully asynchronous operation with respect to the A/D conversion process and fast data access time allows the AD1334 user to upgrade to faster versions, or even different vendors, of DSP hardware without having to add synchronization or wait state logic. In addition, by virtue of hybrid circuit technology, the user is not required to add external circuitry to prevent digital feedthrough into the analog section.

The AD1334 data transfer is accomplished by employing an interrupt driven architecture. Interrupts can be programmed by the microprocessor to be generated when the FIFO is full (32 conversion results), half-full (16 conversion results) or after every conversion (FIFO is bypassed). The AD1334 digital interface also includes an overrange detect circuit, which can generate an interrupt if the sampled analog input signal exceeds positive or negative full scale, to alert the system that a conversion result has been generated that will result in a nonlinearity in the subsequent signal processing.

Operational Description

The AD1334 can interface directly to a microprocessor via standard data (D0 – D13), address (A0) and control lines read ($\overline{\text{RD}}$, $\overline{\text{WR}}$, $\overline{\text{CS}}$, $\overline{\text{IRQ}}$ and $\overline{\text{RST}}$).

Data Transfer

The data lines D0 – D13 are bidirectional I/O that are TTL compatible and have 4mA drive capability. The data lines are used to transfer control information into, and A/D conversion results with status information and channel identification out of the AD1334. Address line A0 is an input that is used to select as the data path either A/D conversion results with channel ID (A0 = 0) or the Control/Status Registers (A0 = 1) and would typically be the least significant address bit in the system if the AD1334 is "mapped" to adjacent memory locations. Chip Select ($\overline{\text{CS}}$) is used to define a unique location in memory for the AD1334 and should be formed by decoding the upper address bits. Read ($\overline{\text{RD}}$) and Write ($\overline{\text{WR}}$) define the type of data transfer.

Figures 17–22 illustrate how the AD1334 interfaces to a number of popular single chip digital signal processors.

Interrupts

Interrupt Request ($\overline{\text{IRQ}}$) is an open drain output that can be used to interrupt the processor on any of the conditions programmed in the control register. $\overline{\text{READY}}$ can be used in simultaneous applications as an alternative processor interrupt signal as described above. In either case, the processor should be programmed to interrupt on the falling edge of its Interrupt Request input.

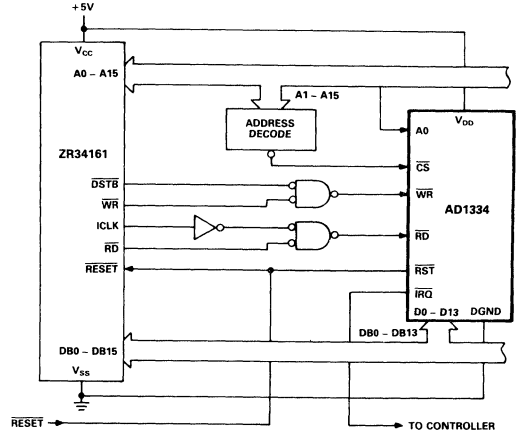

Figure 22. ZR34161 to AD1334 Interface

FIFO Half-Full Interrupt

The timing for interrupts that are generated when the FIFO is half-full is shown in Figures 23a and 23b. In both figures, $\overline{IRQ}$ becomes active when the 16th A/D conversion result is shifted into the FIFO. In Figure 23a, the processor responds immediately and a read cycle takes place before the next conversion cycle begins. Here, the completion of the read cycle shifts the 1st conversion result (which was just read by the processor) out of the FIFO, replaces it with the second conversion result and causes $\overline{IRQ}$ to become inactive since there are now 15 conversion results in the FIFO.

In Figure 23b, the processor does not respond before the next conversion cycle begins and $\overline{IRQ}$ becomes inactive. The FIFO continues to accept conversion results and the processor can read from the FIFO at any time so long as the FIFO has not overrun.

This mode allows the AD1334 to have a low interrupting priority since the processor has up to 17 additional A/D conversions before the FIFO overruns. Therefore, the processor will have up to 260μs to respond at the maximum sample rate of 65kHz.

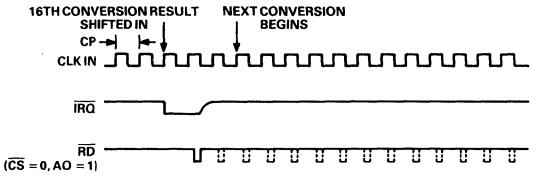

Figure 23a. Timing Diagram for Half-Full Interrupt (Read Before 17th Conversion Started)

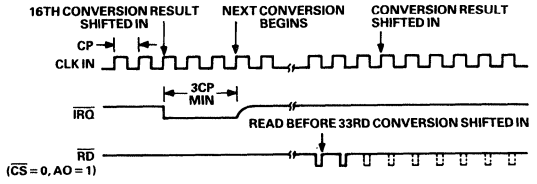

Figure 23b. Timing Diagram for Half-Full Interrupt (Read After 17th Conversion Started)

FIFO Full Interrupt

The timing for interrupts that are generated when the FIFO is full is shown in Figures 24a and 24b. In both figures, $\overline{IRQ}$ becomes active when the 32nd A/D conversion result is shifted into the FIFO. In Figure 24a, the processor responds immediately and a read cycle takes place before the next conversion cycle begins. Here, the completion of the read cycle shifts the first conversion result (which was just read by the processor) out of the FIFO, replaces it with the second conversion result and causes $\overline{IRQ}$ to become inactive because there are now 31 conversion results in the FIFO.

In Figure 24b, the processor does not respond before the next conversion cycle begins and $\overline{IRQ}$ becomes inactive. The processor must read from the FIFO before the completion of the current conversion cycle or the FIFO will overrun. This mode maximizes the memory capability of the AD1334 but requires a fairly high interrupting priority in the processor since the processor has only one A/D conversion before the FIFO overruns. Therefore, the processor will have only 15μs to respond at the maximum sample rate of 65kHz.

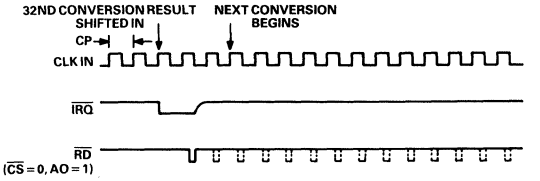

Figure 24a. Timing Diagram for Full Interrupt (Read Before 33rd Conversion Started)

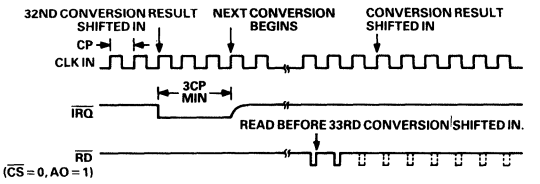

Figure 24b.Timing Diagram for Full Interrupt (Read After 33rd Conversion Started)

Conversion Results Overrange Interrupt

If the FIFO is used, the AD1334 can be programmed to generate interrupts when overranged conversion results are shifted into the FIFO. If $\overline{IRQ}$ became active as a result of an overrange condition, the only way it can become inactive is to clear Bit 4 of the control register. Typically, the user should clear the entire control register which will, in effect, remove the interrupt, reset the FIFO and disable the controller.

Should the overrange interrupt capability be used, Status Register Bits 4 and 6 can be used to identify whether the interrupt occurred as a result of an overrange condition or FIFO half-full (or full).

Single Conversion Interrupt (FIFO Bypassed)

The timing for interrupts that are generated when the FIFO is bypassed is shown in Figures 15 and 16. Here, $\overline{IRQ}$ becomes active at the completion of each A/D conversion cycle. $\overline{IRQ}$ remains active, independent of the read cycle, until the next conversion cycle begins, which is a minimum of three clock periods (1.2μs with 2.5MHz clock). Data is valid so long as $\overline{IRQ}$ remains active.

This mode makes data available immediately after the conversion process has been completed and is therefore very similar to the operation of a conventional A/D converter if $\overline{IRQ}$ is taken to mean conversion STATUS. This mode is most useful when a single conversion result is necessary to adjust a system parameter, such as the gain of a PGA that may be in front of an AD1334.

Since $\overline{IRQ}$ will only be valid for only three A/D clock periods (1.2μs with a 2.5MHz clock), a high interrupting priority should be assigned by the processor. Should the single conversion result be necessary to adjust a system parameter as described above, it may be more efficient to "poll" the Status Register to determine when the conversion result is available.

Operation Other Than with a Microprocessor

The AD1334 can be used in other than microprocessor environments by grounding pins 11, 12 and 29 ($\overline{CS}$, A0 and $\overline{RD}$), connecting Pin 30 ($\overline{WR}$) to V_{DD} and pulsing $\overline{RST}$ low. This will permanently enable the AD1334 three-state outputs and clear the control register, causing the FIFO to be bypassed.

Multiple AD1334s

The architecture of the AD1334 allows multiple devices to be used in a microprocessor based system. Figure 25 illustrates how four AD1334s can be configured to simultaneously sample their analog inputs and reside in eight sequential locations in a microprocessor's memory address space. The control register of each device should be programmed to interrupt on the same condition so that the same number of conversion results are available from all devices.

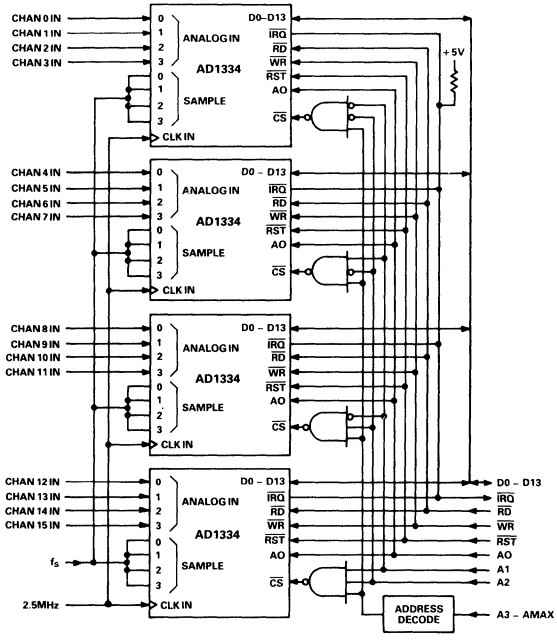

Figure 25. Sixteen-Channel Simultaneous Sampling System

Floating Point Converter

Figure 26 illustrates how to boost the dynamic range of the AD1334 by including it in a floating point A/D converter architecture. The AD526 is a single-ended programmable gain amplifier with gains of 1,2,4,8 and 16. Here, four AD526s are "hardwired" into gains of 1,2,4 and 8 to extend the dynamic range of the AD1334 to 15 bits. Fully differential inputs with gains up to 500 can be obtained by substituting the AD365 for the AD526.

The AD1334 is operated in simultaneous mode, with one AD526 per channel. Upon receipt of a sample command, the four channels are sampled and converted. Table III summarizes the input voltage range for each channel.

Channel	Input Voltage Range
0	−5V to +5V
1	−2.5V to +2.5V
2	−1.25V to +1.25V
3	−625mV to +625mV

Table III.

For each group of four samples, a processor can be used to discard the three A/D conversion results that were not converted on the optimum range. The system shown can provide results at sample rates up to 28kHz.

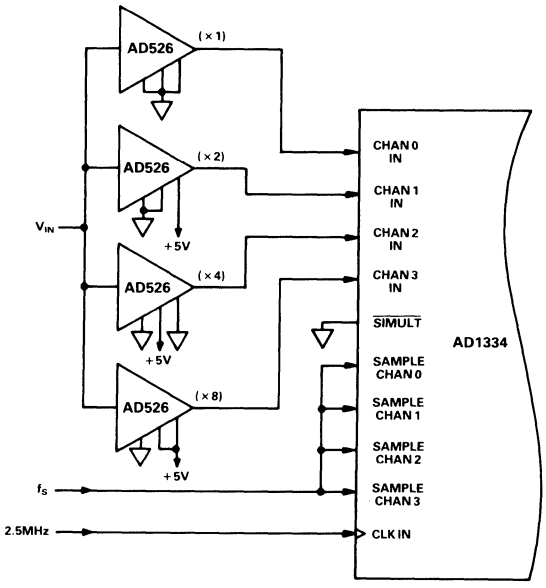

Figure 26. Fifteen-Bit Floating Point A/D Converter

SUCCESSFULLY APPLYING THE AD1334

Grounding

In order to obtain the specified performance of the AD1334, proper grounding and power supply decoupling techniques must be observed. First, it is imperative that a ground plane be used. A ground plane provides a low resistance, low inductance path for currents to flow back to their source. Without a ground plane, currents will return to the source in such a way as to minimize the energy of the system and therefore parasitic inductances will exist in such undesirable locations as power supply lines and signal grounds.

Second, all three ground connections on the AD1334 must be tied together to the ground plane. The AD1334 APWR GND (Pin 9) carries the imbalance current from the analog power supplies ($\pm V_S$). APWR GND is also connected to the package seal ring/lid and therefore can cause coupling between the analog and digital sections if it is not tied directly to the ground plane.

ASIG GND (Pin 8) is the signal ground internal to the AD1334 and is "common" for the −5V reference, sample-and-hold amplifiers, multiplexer and A/D converter. The current that flows through this pin from the A/D converter is a dynamic current that changes on every clock cycle. Inductance in this trace will therefore cause a reduction in performance in the entire analog section.

DGND (Pin 20) is a separate ground connection for the digital interface chip. It carries a dynamic current every time a digital output changes state, and inductance in the trace that connects to this pin will reduce the noise margin between the A/D converter and the digital interface chip.

Power Supply Decoupling

The power supply decoupling capacitors supply the instantaneous current to the AD1334 and also provide some high frequency filtering. The filtering aspect of the capacitors should not be counted on however, and the user should make every effort to supply quiet, well regulated power supplies to the AD1334. Switching mode power supplies are not recommended for the analog power supplies $\pm V_S$.

Decoupling capacitors should be placed as close to the device as possible to minimize inductances in power supply traces. A 2.2μF (or greater) solid tantalum capacitor in parallel with a 0.1μF ceramic capacitor should be used for decoupling each $+V_S$ and $-V_S$. A 1.0μF (or greater) solid tantalum capacitor should be used for decoupling V_{DD}.

Transmission Line Effects

The digital interface has 10K ECL speed and with 15pF loading exhibits a typical edge rate of 1.4ns. High speed CMOS systems that incorporate the AD1334 must use careful PCB layout and impedance matching techniques to reduce crosstalk and voltage reflections.

Crosstalk

The fast edge rates with large voltage swings of CMOS systems can result in capacitive and inductive coupling (crosstalk) between adjacent PCB signal traces and may compromise signal integrity and reduce noise margins. The effect can be most severe on data lines that are near "clocked" control lines, such as Read, Write and Chip Select lines, when they actually change their logic state as a result of crosstalk.

To reduce crosstalk, the PCB layout should minimize long parallel traces. If this can not be avoided, clock lines should be shielded from data and address lines by running ground traces along side them.

Voltage Reflections

The gross impedance mismatch between high impedance CMOS inputs and low impedance CMOS outputs invites unwanted voltage reflections and "ringing" that can also compromise signal integrity and reduce noise margins. This level of mismatch causes a nearly equal and opposite negative pulse to be reflected back from the load to the source when the round trip delay of the line exceeds the rise or fall time of the driving signal. For a typical line delay of 0.055ns/cm with a 1.4ns edge rate, this translates to only 13cm (5 inches) for the AD1334. Provided the signal lines are over a ground plane, this may never be a problem since the added capacitance will reduce the edge rate.

The effect will be most severe on "clock" lines in synchronous systems such as Read, Write and Chip Select lines. For example, should the AD1334 Read control input ($\overline{RD}$) be double clocked as a result of a reflection while in a read cycle, in most cases the digital interface chip will be fast enough to respond. If the FIFO is being read from, a second shift out will occur and A/D conversion results will be lost.

Since CMOS output stages are not capable of delivering enough current to the load when a transmission line (PCB trace) is terminated in its characteristic impedance, series damping is recommended when reflections must be reduced or eliminated. Here, a small resistor (typically 10Ω to 75Ω) is inserted in series with the transmission line as close to the source as possible. The goal is to match the series resistance plus driver output impedance to the transmission line impedance. This will keep the wave that is reflected back from the load to source from reflecting back to the load.

The primary disadvantage of series termination is that due to the voltage divider formed by the source resistance and line impedance, the voltage at the input to the line is midway between logic levels during the two-way propagation delay time. This means that although any number of device inputs may be attached at the load end, other device inputs cannot be distributed along the transmission line.

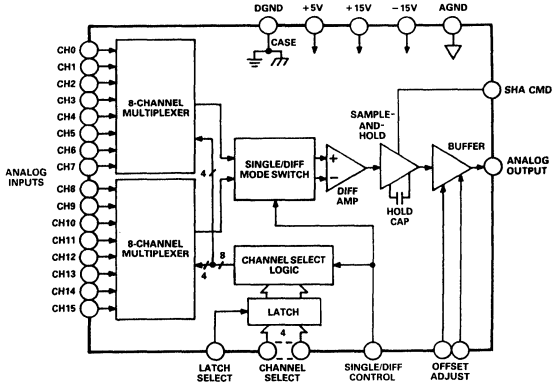
16-Channel, 12-Bit Data Acquisition System

AD1362

FEATURES

- **Pin and Functional Replacement for AD362:**
  - **Lower Power Dissipation**
  - **Lower Noise**
  - **Internal Hold Capacitor**
- **16 Single-Ended or 8 Differential Channels with Switchable Mode Control**
- **True 12-Bit Precision: Nonlinearity ≤0.005%**
- **High Speed: 10μs Acquisition Time to 0.01%**
- **Complete and Calibrated: No Additional Parts Required**
- **Versatile: Simple Interface to Popular Analog-to-Digital Converters**
- **High Differential Input Impedance ($10^{10}\Omega$) and Common Mode Rejection (80dB)**
- **Fully Protected Multiplexer Inputs**

AD1362 FUNCTIONAL BLOCK DIAGRAM



PRODUCT DESCRIPTION

The AD1362 is a complete, precision16-channel data acquisition system. The device contains two 8-channel multiplexers, a differential amplifier, a sample-and-hold with high-speed output amplifier, a channel address latch and control logic. The multiplexers may be connected to the differential amplifier in either an 8-channel differential or 16-channel single-ended configuration. A unique feature of the AD1362 is an internal user-controllable analog switch that connects the multiplexers in either a single-ended or differential mode. This allows a single device to perform in either mode without hard-wire programming and permits a mixture of single-ended and differential sources to be interfaced by dynamically switching the input mode control.

The sample-and-hold mode control is designed to connect directly to the "Status" output of an analog-to-digital converter so that a convert command to the ADC will automatically put the sample-and-hold into the "Hold" mode. An internal precision hold capacitor is included with each AD1362. The AD1362 output amplifier is capable of driving the unbuffered analog input of most high speed, 12-bit successive-approximation ADCs. The interface is thereby reduced to two simple connections with no additional components required.

The AD1362KD is specified for operation over a 0 to +70°C temperature range while the AD1362SD operates to specification from −55°C to +125°C. Processing to MIL-STD-883, Class B is available for the AD1362SD. Both grades are packaged in a hermetic 32-pin ceramic dual-in-line package.

PRODUCT HIGHLIGHTS

1. The AD1362, when used with a precision analog to digital converter, forms a complete, accurate, high-speed data acquisition system.
2. The 16-input channels may be configured in single-ended, differential or a mixture of both modes. Mode switching is provided by a user controllable internal analog switch.
3. Multiplexers, differential amplifier, sample-and-hold and high-speed output buffer provide complete analog interfacing capabilities.
4. Internal channel address latches are provided to facilitate interfacing the AD1362 to data, address or control buses.
5. The AD1362 is specified over the entire military temperature range, −55°C to +125°C. Processing to MIL-STD-883, Class B is available.

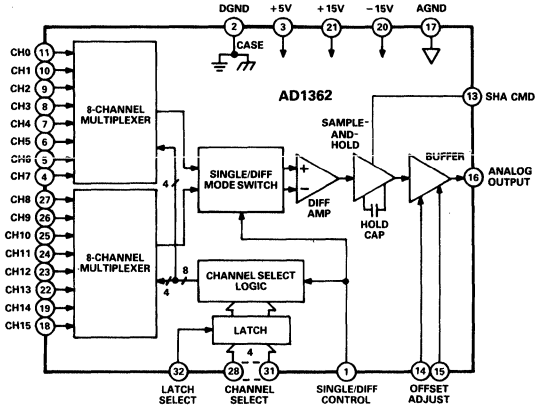
FUNCTIONAL DESCRIPTION

The AD1362 consists of two 8-channel multiplexers, a differential amplifier, a sample-and-hold with high speed output buffer, channel address latches and control logic as shown in the block diagram. The multiplexers can be connected to the differential amplifier in either an 8-channel differential or 16-channel single-ended configuration. A unique feature of the AD1362 is an internal analog switch controlled by a digital input that performs switching between single-ended and differential modes. This feature allows a single AD1362 to perform in either mode without external hard-wire interconnections. Of more significance is the ability to serve a mixture of both single-ended and differential sources with a single AD1362 by dynamically switching the input mode control.



AD1362 Block Diagram

Multiplexer channel address inputs are interfaced through a level-triggered ("transparent") input register. With a Logic "1" at the Latch Select input, the address signals feed through the register to directly select the appropriate input channel. This address information can be held in the register by placing a Logic "0" on the Latch Select input. Internal logic monitors the status of the Single-Ended/Differential Mode input and addresses the multiplexers accordingly.

A differential amplifier buffers the multiplexer outputs while providing high input impedance in both differential and single-ended modes.

The sample-and-hold is a high speed device that can also function as a gated operational amplifier. Its uncommitted differential inputs allow it to serve a second role as the output subtractor in the differential amplifier. A Logic "1" on the Sample-and-Hold Command input will cause the sample-and-hold to "freeze" the analog signal while the ADC performs the conversion. Normally the Sample-and-Hold Command is connected to the ADC Status output which is at Logic "1" during conversion and Logic "0" between conversions. For slowly changing inputs, throughput speed may be increased by grounding the Sample-and-Hold Command input instead of connecting it to the ADC status.

The output buffer is a high speed amplifier whose output impedance remains low and constant at high frequencies. Therefore, the AD1362 may drive a fast, unbuffered, precision ADC without loss of accuracy.

THEORY OF OPERATION

Concept

The AD1362 is intended to be used in conjunction with a high speed, precision analog-to-digital converter to form a complete data acquisition system (DAS). Figure 1 shows a general AD1362 with ADC DAS application.

By dividing the data acquisition task into two sections, several important advantages are realized. Performance of each design is optimized for its specific function. Production yields are increased thus decreasing costs. Furthermore, the standard configuration packages plug into standard sockets and are easier to handle than larger packages with higher pin counts.

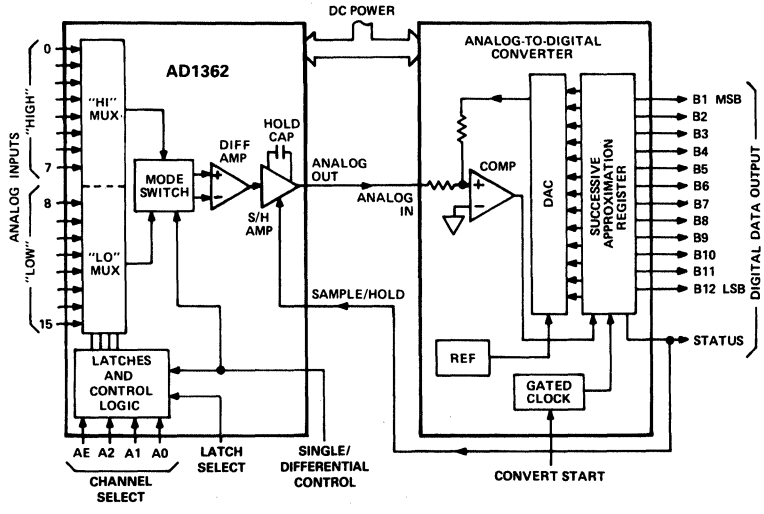


Figure 1. AD1362 with ADC as a Complete Data Acquisition System

System Timing

Figure 2 is a timing diagram for the AD1362 connected as shown in Figure 1 and operating at maximum conversion rate. The ADC is assumed to be a conventional 12-bit type such as the AD573 or AD ADC80.

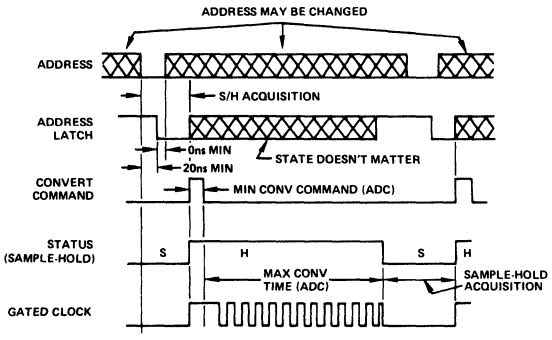

Figure 2. DAS Timing Diagram

The normal sequence of events is as follows:

1. The appropriate Channel Select Address is latched into the address register. Time is allowed for the multiplexers to settle.
2. A Convert Start command is issued to the ADC which, in response, indicates that it is "busy" by placing a Logic "1" on its Status Line.
3. The ADC Status controls the sample-and-hold. When the ADC is "busy," the sample-and-hold is in the Hold mode.
4. The ADC goes into its conversion routine. Since the sample-and-hold is holding the proper analog value, the address may be updated during conversion. Thus multiplexer settling time can coincide with conversion and need not affect throughput rate.
5. The ADC indicates completion of its conversion by returning Status to Logic "0." The sample-and-hold returns to the Sample mode.
6. If the input signal has changed full scale (different channels may have widely-varying data), the sample-and-hold will typically require 10 microseconds to "acquire" the next input to sufficient accuracy for 12-bit conversion.

After allowing a suitable interval for the sample-and-hold to stabilize at its new value, another Convert Start command may be issued to the ADC.

NOTE

Valid Output Data

Not all ADCs have all data bits available when Status indicates that the conversion is complete. Some successive approximation ADCs must have a Status delay built in or the final data bit will lag Status. This will result in two problems:

1. The sample-and-hold will return to Sample, disturbing the analog input to the ADC as it is attempting to convert the least significant bit. This may result in an error.
2. If the falling edge of Status is being used to load the data into a register, the least significant bit will not be valid when loaded.

An external delay or use of an ADC with a valid Status output is necessary to prevent this problem.

Single-Ended/Differential Mode Control

The AD1362 features an internal analog switch that configures the Analog Input Section in either a 16-channel single-ended or 8-channel differential mode. This switch is controlled by a TTL logic input applied to Pin 1:

"0": Single-Ended (16 channels)
"1": Differential (8 channels)

When in the differential mode, a differential source may be applied between corresponding "High" and "Low" analog input channels.

It is possible to mix SE and DIFF inputs by using the mode control to command the appropriate mode. In this case, four microseconds must be allowed for the output to settle to within ±0.01% of its final value, but if the mode is switched concurrent with changing the channel address, no significant additional delay is introduced. The effect of this delay may be eliminated by changing modes while a conversion is in progress (with the sample-and-hold in the "Hold" mode). When SE and DIFF signals are being processed concurrently, the DIFF signals must be applied between corresponding "High" and "Low" analog input channels. Another application of this feature is the capability of measuring 16 sources individually and/or measuring differences between pairs of those sources.

Input Channel Addressing

Table I is the truth table for input channel addressing in both the single-ended and differential modes. The 16 single-ended channels may be addressed by applying the corresponding digital number to the four Channel Select address bits, AE, A0, A1, A2 (Pins 28–31). In the differential mode, the eight channels are addressed by applying the appropriate digital code to A0, A1, and A2; AE must be enabled with a Logic "1." Internal logic monitors the status of the SE/DIFF Mode input and addresses the multiplexers singularly or in pairs as required.

ADDRESS				ON CHANNEL		
					Differential	
AE	A2	A1	A0	Single Ended	"Hi"	"Lo"
0	0	0	0	0	None	
0	0	0	1	1	None	
0	0	1	0	2	None	
0	0	1	1	3	None	
0	1	0	0	4	None	
0	1	0	1	5	None	
0	1	1	0	6	None	
0	1	1	1	7	None	
1	0	0	0	8	0	0
1	0	0	1	9	1	1
1	0	1	0	10	2	2
1	0	1	1	11	3	3
1	1	0	0	12	4	5
1	1	0	1	13	5	5
1	1	1	0	14	6	6
1	1	1	1	15	7	7

Table I. Input Channel Addressing Truth Table

When the channel address is changed, six microseconds must be allowed for the AD1362 to settle to within ±0.01% of its final output (including settling times of all elements in the signal path). The effect of this delay may be eliminated by performing the address change while a conversion is in progress (with the sample-and-hold in the "Hold" mode).

Input Channel Address Latch

The AD1362 is equipped with a latch for the input Channel Select address bits. If the Latch Select pin is at Logic "1," input channel select address information is passed through to the multiplexers. A Logic "0" "freezes" the input channel address present at the inputs at the "1"-to-"0" transition (level-triggered).

This feature is useful when input channel address information is provided from an address, data or control bus that may be required to service many devices. The ability to latch an address is helpful whenever the user has no control of when address information may change.

Sample-and-Hold Mode Control

The Sample-and-Hold Mode Control input is normally connected to the Status output from an analog to digital converter. When a conversion is initiated by applying a Convert Start command to the ADC, Status goes to Logic "1" putting the sample-and-hold into the "Hold" mode. This "freezes" the information to be digitized for the period of conversion. When the conversion is complete, Status returns to Logic "0" and the sample-and-hold returns to the "Sample" mode. Eighteen microseconds must be allowed for the sample-and-hold to acquire ("catch up" to) the analog input to within ±0.01% of the final value before a new Convert Start command is issued.

The purpose of a sample-and-hold is to "stop" fast changing input signals long enough to be converted. In this applicataion, it also allows the user to change channels and/or SE/DIFF mode while a conversion is in progress thus eliminating the effects of multiplexer, analog switch and differential amplifier settling times. If maximum throughput rate is required for slowly changing signals, the Sample-and-Hold Mode Control may be wired to ground (Logic "0") rather than to ADC Status thus leaving the sample-and-hold in a continuous Sample mode.

Analog Input Section Offset Adjust Circuit

Although the offset voltage of the AD1362 may be adjusted, that adjustment is normally performed at the ADC. In some special applications, however, it may be helpful to adjust the offset of the Data Acquisition System. An example of such a case would be if the input signals were small (<10mV) relative to AD1362 offset and gain errors. To adjust the offset of the AD1362, the circuit shown in Figure 3 is recommended.

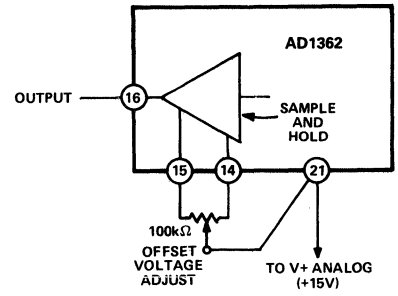

Figure 3. AD1362 Offset Voltage Adjustment

Under normal conditions, all calibration is performed at the ADC Section.

Other Considerations

Grounding: Analog and digital signal grounds should be kept separate where possible to prevent digital signals from flowing in the analog ground circuit and inducing spurious analog signal noise. Analog Ground and Digital Ground are not connected internally; these pins must be connected externally for the system to operate properly. Preferably, this connection is made at only one point, as close to the AD1362 as possible. The case is connected internally to Digital Ground to provide good electrostatic shielding. If the grounds are not tied common on the same card with the AD1362, the digital and analog grounds should be connected locally with back-to-back general-purpose diodes as shown in Figure 4. This will protect the AD1362 from possible damage caused by voltages in excess of ±1 volt between the ground systems which could occur if the key grounding card should be removed from the overall system. The device will operate properly with as much as ±200mV between grounds; however, this difference will be reflected directly as an input offset voltage.

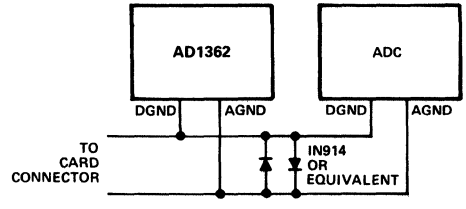

Figure 4. Ground-Fault Protection Diodes

Power Supply Bypassing: The ±15V and +5V power leads should be capacitively bypassed to Analog Ground and Digital Ground respectively for optimum device performance. One microfarad tantalum types are recommended; these capacitors should be located close to the system. It is not necessary to shunt these capacitors with disk capacitors to provide additional high frequency power supply decoupling since each power lead is bypassed internally with a 0.039μF ceramic capacitor.

Interfacing to Popular Analog to Digital Converters

The AD1362 has been designed to interface directly to most analog to digital converters; often no additional components are required and only two interconnections must be made. The direct interface requirements for the ADC are as follows:

1. The ADC Status output must be positive-true Logic ("1" during conversion).
2. Transition from "0" to "1" must occur at least 200ns before the most significant bit decision is made (successive approximation ADC) or before input integration starts (integrating type ADC).
3. Status must not return to "0" before the LSB decision is made.
4. If Status is being used to latch output data, it must not return to Logic "0" until all output data bits are valid and available.

Complete system throughput performance is determined by combining the worst-case specifications of the AD1362 and the ADC. If guaranteed system performance is required, the AD363 and AD364 are recommended. The AD363 includes an AD1362 and an AD572 12-bit, 25-microsecond precision ADC. The AD364 consists of an AD1362 and an AD574 12-bit, microprocessor compatible, low cost ADC. Each is specified as a complete, two-package system.

Figure 5a shows the AD1362 driving an AD ADC80. The AD ADC80 is a 12-bit, 25-microsecond, low cost ADC that meets all of the requirements listed above. Throughput rate is typically 30kHz with no missing codes over the operating temperature range.

Figure 5b shows a 10-bit application based on the AD1362 and the AD573, a complete low cost 10-bit, 25-microsecond ADC. In this case, one of the above requirements is not met:

1. $\overline{DR}$ ($\overline{DATA\ READY}$), as Status, is positive-true, but . . .
2. $\overline{DR}$ does not indicate that a conversion is in progress until 1.5μs after conversion starts.

The gating provided by U1 allows the applied convert command (CC) to initiate input hold at the AD1362. CC must last for more than 1.5μs so that $\overline{DR}$ may then assume control of Hold.

14-Bit & 15-Bit Sampling Analog-to-Digital Converters

DAS1152/DAS1153

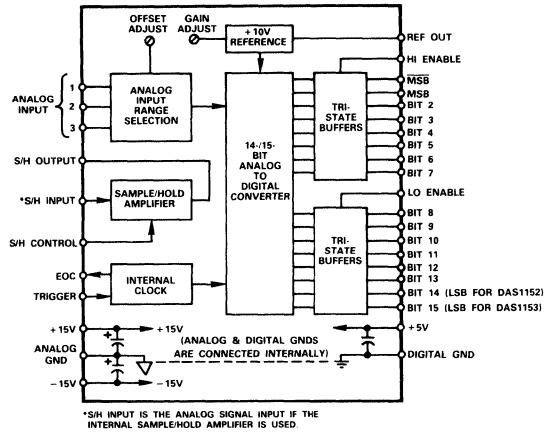
FEATURES

- **Complete with High Accuracy Sample/Hold and A/D Converter**
- **Differential Nonlinearity: ±0.002% FSR max (DAS1153)**
- **Nonlinearity: DAS1152: ±0.005% FSR max**
  DAS1153: ±0.003% FSR max
- **Low Differential Nonlinearity T.C.: ±2ppm/°C max**
- **High Throughput Rate: 25kHz min (DAS1152)**
- **High Feedthrough Rejection: −96dB**
- **Byte-Selectable Tri-State Buffered Outputs**
- **Internal Gain & Offset Potentiometers**
- **Improved Second Source to A/D/A/M 824 and A/D/A/M 825 Modules**

APPLICATIONS

- **Process Control Data Acquisition**
- **Automated Test Equipment**
- **Seismic Data Acquisition**
- **Nuclear Instrumentation**
- **Medical Instrumentation**
- **Robotics**

DAS1152/DAS1153 FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The DAS1152/DAS1153 are 14-/15-bit sampling analog-to-digital converters having a maximum throughput rate of 25kHz/20kHz. They provide high accuracy, high stability, and functional completeness all in a 2″ × 4″ × 0.44″ metal case.

Guaranteed high accuracy system performance such as nonlinearity of ±0.005% FSR (DAS1152)/±0.003% FSR (DAS1153) and differential nonlinearity of ±0.003% FSR (DAS1152)/±0.002% FSR (DAS1153) are provided. Guaranteed stability such as differential nonlinearity T.C. of ±2ppm/°C (DAS1153) maximum, zero T.C. of ±80μV/°C maximum, gain T. C. of ±8ppm/°C maximum and power supply sensitivity of ±0.001% FSR/% V_S are also provided by the DAS1152/DAS1153.

The DAS1152/DAS1153 make extensive use of both integrated circuit and thin film components to obtain their excellent performance, small size, and low cost. The devices contain a precision sample/hold amplifier, high accuracy 14-/15-bit analog-to-digital converter, tri-state output buffers, internal gain and offset trim potentiometers, and power supply bypass capacitors (as shown in Figure 1).

Four analog input voltage ranges are selectable via user pin programming: 0 to +5V, 0 to +10V, ±5V, and ±10V. Unipolar coding is provided in true binary format with bipolar coding displayed in offset binary and two's complement. Tri-state buffers provide easy interface to bus structured applications.

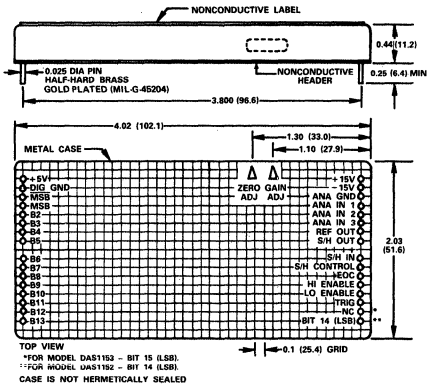
NOTES
*Specifications same as DAS1152
[1]Measured in hold mode, input 20V pk-pk @ 10kHz.
[2]Worst-case summation of S/H and A/D nonlinearity errors.
[3]FSR means Full Scale Range.
[4]When connecting the Convert Command and the S/H control terminals together, the pulse width must be long enough for the S/H amplifier to acquire the input signal to the required accuracy 4μs (max, DAS1152)/5μs (max, DAS1153). If the A/D converter is only used, the Convert Command pulse width should be 100ns min (see Figure 2).
[5]If only the ADC portion is used, the operating power supply voltage can be maintained at ±12V to ±17V. But if the S/H section is required, the operating voltage must be maintained at ±15V (±3%) or the S/H input voltage must be limited to −7V to +10V for a ±12V supply voltage.
[6]Recommended Power Supply: Analog Devices Model 923.

Specifications subject to change without notice.

OUTLINE DIMENSIONS

Dimensions shown in inches and (mm).



OPERATION

The DAS1152/DAS1153 are functionally complete data acquisition subsystems being fully characterized as such. All the necessary data acquisition and microprocessor interface elements are provided internal to these devices. Accuracy and performance criteria are tested and specified for the entire system. Thus, design time and associated high accuracy problems are minimized because layout and component optimization have already been performed.

For operation, the only connections necessary to the DAS1152/DAS1153 are the ±15V and +5V power supplies, analog input signal, trigger pulse, and the HI-ENABLE/LO-ENABLE tri-state controls. Analog input and digital output programming are user selectable via external jumper connections.

ANALOG INPUT SECTION

The analog input can be applied to just the A/D converter or to the internal sample/hold amplifier ahead of the A/D converter. When using just the A/D converter, apply the analog input per the voltage range pin programming shown in Table I. When using the sample/hold amplifier in conjunction with A/D converter, apply the analog input to the S/H INPUT terminal and connect the S/H OUTPUT terminal to the appropriate A/D converter analog input.

Analog Voltage Input Range	Connect V_{IN} or S/H Out To	Connect Analog Common To	Connect Ref Out To
0 to +5V	ANA IN 1, ANA IN 2, ANA IN 3	Ground	NC*
0 to +10V	ANA IN 2 ANA IN 3	Ground ANA IN 1	NC*
±5V	ANA IN 1	Ground, ANA IN 3	ANA IN 2
±10V	ANA IN 3	Ground, ANA IN 1	ANA IN 2

*No Connection

Table I. Analog Input Pin Programming

Errors due to source loading are eliminated since the sample/hold amplifier is a high-impedance unity-gain amplifier. High feedthrough rejection is provided for either single-channel or multichannel applications. Feedthrough rejection can be optimized, in multichannel applications, by changing channels at the rising or falling edge of the S/H control pulse.

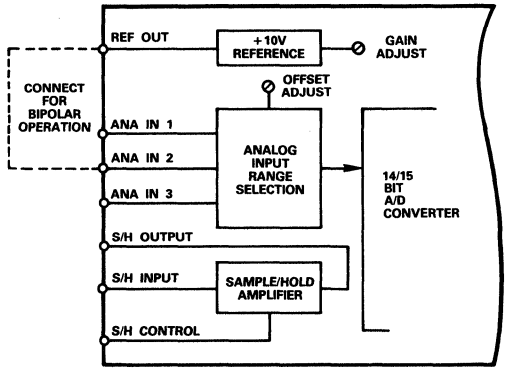


Figure 2. Analog Input Block Diagram

TIMING DIAGRAM

The timing diagram for the DAS1152/DAS1153 is illustrated in Figure 3. This figure also includes the sample/hold amplifier acquisition time.

If the sample/hold amplifier is required, the TRIGGER input and S/H CONTROL terminal can be tied together providing only one conversion control signal. When the trigger pulse goes high, it places the sample/hold amplifier in the sample mode allowing it to acquire the present input signal. The trigger pulse must remain high for a minimum of 4μs (DAS1152)/5μs (DAS1153) to insure accuracy is attained. If the sample/hold amplifier is not used, the trigger pulse needs to be only 100ns (min) in length to satisfy the A/D converter trigger requirements. At the falling edge of the trigger pulse, the sample/hold amplifier is placed in the hold mode, the A/D conversion begins, and all internal logic is reset. Once the conversion process is initiated, it cannot be retriggered until after the end of conversion.

With this negative edge of the trigger pulse the MSB is set low with the remaining digital outputs set to logic high state, and the status line is set high and remains high through the full conversion cycle. During conversion each bit, starting with the MSB, is sequentially switched low at the rising edge of the internal clock. The DAC output is then compared to the analog input and the bit decision is made. Each comparison lasts one clock cycle with the complete 14-/15-bit conversion taking 35μs/44μs maximum for the DAS1152/DAS1153 respectively. At this time, the STATUS line goes low signifying that the conversion is complete. For microprocessor bus applications, the digital output can now be applied to the data bus by enabling the tri-state buffers. For maximum data throughput, the digital output data should be read while the sample/hold amplifier is acquiring the new analog input signal.

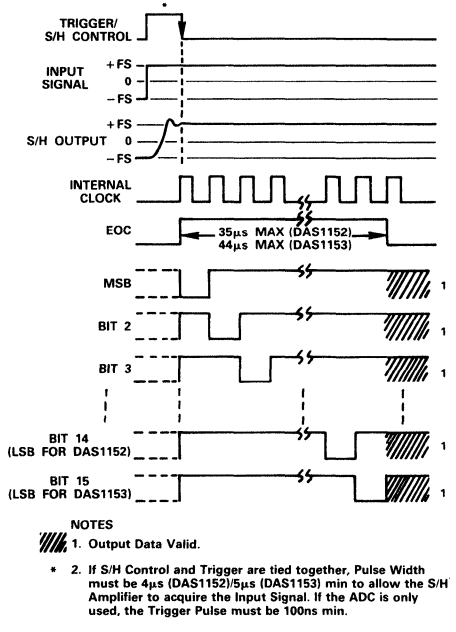

Figure 3. DAS1152/DAS1153 Timing Diagram

GAIN AND OFFSET ADJUSTMENT

The DAS1152/DAS1153 contain internal gain and offset adjustment potentiometers. Each potentiometer has ample adjustment range so that gain and offset errors can be trimmed to zero.

Since offset calibration is not affected by changes in gain calibration, it should be performed prior to gain calibration. Proper gain and offset calibration requires great care and the use of extremely sensitive and accurate reference instruments. The voltage standard used as a signal source must be very stable and be capable of being set to within ± 1/10LSB of the desired value at any point within its range.

OFFSET CALIBRATION

For a 0 to +10V unipolar range set the input voltage precisely to +305μV for the DAS1152 and +153μV for the DAS1153. For a 0 to +5V unipolar range set the input to +153μV for the DAS1152 and +76μV for the DAS1153. Then adjust the zero potentiometer until the converter is just on the verge of switching from 000.....000 to 000.....001.

For the ±5V bipolar range set the input voltage precisely to +305μV for the DAS1152 and +153μV for the DAS1153. For a ±10V bipolar range set the input voltage precisely to +610μV for the DAS1152 and +305μV for the DAS1153. Adjust the zero potentiometer until the offset binary coded units are just on the verge of switching from 000.....000 to 000.....001 and the two's complement coded units are just on the verge of switching from 100.....000 to 100.....001.

GAIN CALIBRATION

Set the input voltage precisely to +9.99909V (DAS1152)/ +9.99954V (DAS1153) for the 0 to +10V units, +4.99954V (DAS1152)/+4.99977V (DAS1153) for 0 to +5V units, +9.99817V (DAS1152)/+9.99909V (DAS1153) for ±10V units, or +4.99909V (DAS1152)/+4.99954V (DAS1153) for ±5V units. Note that these values are 1 1/2LSBs less than nominal full scale. Adjust the gain potentiometer until binary and offset binary coded units are just on the verge of switching from 11.....10 to 11.....11 and two's complement coded units are just on the verge of switching from 011.....10 to 011.....11.

DAS1152/DAS1153 INPUT/OUTPUT RELATIONSHIPS

The DAS1152/DAS1153 produces a true binary coded output when configured as a unipolar device. Configured as a bipolar device, it can produce either offset binary or two's complement output codes. The most significant bit (MSB) is used to obtain the binary and offset binary codes while ($\overline{\text{MSB}}$) is used to obtain two's complement coding. Table II shows the DAS1152/DAS1153 unipolar analog input/digital output relationships. Tables III and IV show the DAS1152/DAS1153 bipolar analog input/digital output relationships.

Table IV. DAS1153 Bipolar Input/Output Relationships

TRI-STATE DIGITAL OUTPUT

The ADC digital outputs are provided in parallel format to the output tri-state buffers. The output information can be applied to a data bus in either a one-byte or a two-byte format by using the HIGH BYTE ENABLE and LOW BYTE ENABLE terminals. If the tri-state feature is not required, normal digital outputs can be obtained by connecting the enable pins to ground.

POWER SUPPLY AND GROUNDING CONNECTIONS

Although the analog power ground and the digital ground are connected in the DAS1152/DAS1153, care must still be taken to provide proper grounding due to the high accuracy nature of these devices. Though only general guidelines can be given, grounding should be arranged in such a manner as to avoid ground loops and to minimize the coupling of voltage drops (on the high current carrying logic supply ground) to the sensitive analog circuit sections. Analog and digital grounds should remain separated on the PC board and terminated at the respective DAS1152/DAS1153 terminals.

No power supply decoupling is required since, the DAS1152/ DAS1153, contain high quality tantalum capacitors on each of the power supply inputs to ground.

Low Power 14-Bit, 15-Bit & 16-Bit Sampling Analog-to-Digital Converters

DAS1157/DAS1158/DAS1159

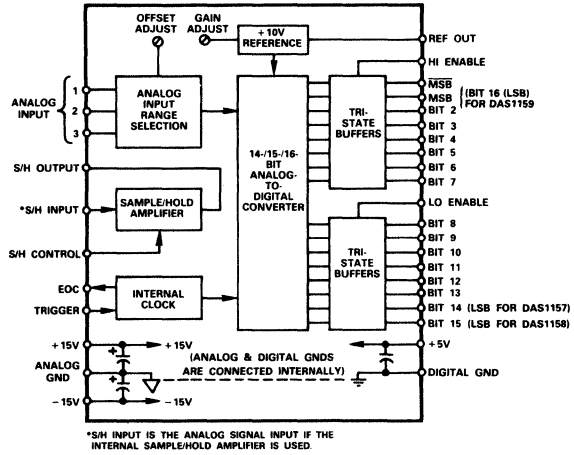
FEATURES

- **Complete with High Accuracy Sample/Hold and A/D Converter**
- **Low Power Consumption: 650mW max, $V_S = \pm 15V$**
- **Rated Performance: −25°C to +85°C**
- **Low Nonlinearity (DAS1158 and DAS1159)**
  - **Differential: ±0.0015% FSR max**
  - **Integral: ±0.003% FSR max**
  - **Differential T.C.: ±1ppm/°C max**
- **High Throughput Rate: 18kHz min**
- **Byte-Selectable Tri-State Buffered Outputs**
- **Internal Gain & Offset Potentiometers**
- **Improved Second Source to A/D/A/M-834 and A/D/A/M-835 Modules**

APPLICATIONS

- **Seismic Data Acquisition**
- **Portable Field Instrumentation**
- **Automated Test Equipment**
- **Process Control Data Acquisition**
- **Medical Instrumentation**

DAS1157/DAS1158/DAS1159
FUNCTIONAL BLOCK DIAGRAM



*S/H INPUT IS THE ANALOG SIGNAL INPUT IF THE INTERNAL SAMPLE/HOLD AMPLIFIER IS USED.

GENERAL DESCRIPTION

The DAS1157/DAS1158/DAS1159 are 14-/15-/16-bit sampling analog-to-digital converters. They are ideally suited for use in portable and remote data acquisition equipment where low power consumption (650mW maximum) and wide temperature range (−25°C to +85°C rated performance) are required.

DAS1157/DAS1158/DAS1159 provide guaranteed high accuracy and high stability system performance essential to medical, analytical and process control equipment: differential nonlinearity of ±0.0015% max and integral nonlinearity of ±0.003% max (DAS1158 and DAS1159); no missing codes guaranteed; gain T.C. of ±8ppm/°C max, zero T.C. of ±80μV/°C max and differential nonlinearity T.C. of ±1ppm/°C max.

The wide dynamic range will enhance the performance of critical measurements in gas and liquid chromatography, blood analyzers, distributed data acquisition in factory automation and power generating equipment, and in automatic test equipment.

The DAS1157/DAS1158/DAS1159 make use of Analog Devices' proprietary CMOS technology to achieve low power operation, while utilizing the latest integrated circuit and thin-film components to achieve the highest level of performance and reliability.

As shown in Figure 1, each device contains a precision sample/hold amplifier, high accuracy 14-/15-/16-bit analog-to-digital converter, precision reference, CMOS tri-state output buffers (for direct 8-bit or 16-bit bus interface), user accessible gain and offset adjust potentiometers, and power supply bypass capacitors, all in a compact low profile 2″ × 4″ × 0.375″ metal case package. No additional components are required for operation.

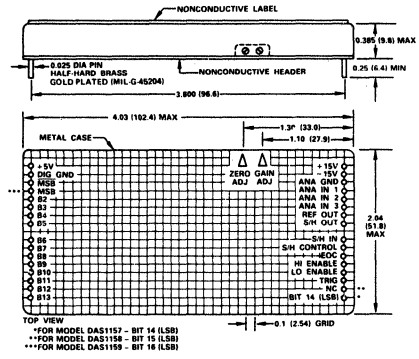
[2]Worst-case summation of S/H and A/D nonlinearity errors.
[3]FSR means Full Scale Range.
[4]Differential Nonlinearity in the 0 to +5V input range is specified as ±0.003% typical for the DAS1157, DAS1158 and DAS1159.
[5]When connecting the Trigger and the S/H control terminals together, the pulse width must be long enough for the S/H amplifier to acquire the input signal to the required accuracy (5µs min). If the A/D converter only is used, the Trigger pulse width should be 1µs min (see Figure 3).
[6]Low Byte Enable pin connections are Bits 8 through 15; High Byte Enable pin connections are $\overline{MSB}$, MSB or Bit 16 and Bits 2 through 7.
[7]DAS1159 unipolar coding is provided in a modified binary format (MSB complement) while bipolar coding is two's complement only. The MSB must be inverted for binary and offset binary codes.
[8]When the S/H section is required, $-V_S$ must be at least 5 volts more negative than the most negative analog input voltage (example: V_S = ±12V dc, therefore, maximum analog input is +10 and −7V).
[9]Recommended Power Supply: Analog Devices Model 923.

Specifications subject to change without notice.

OUTLINE DIMENSIONS

Dimensions shown in inches and (mm).



ASSEMBLY INSTRUCTIONS

CAUTION: This module is not an embedded assembly and is not hermetically sealed. Do not subject to a solvent or water-wash process that would allow direct contact with free liquids or vapors. Entrapment of contaminants may occur, causing performance degradation and permanent damage. Install after any clean/wash process and then only spot clean by hand.

OPERATION

For operation, the only connections necessary to the DAS1157/DAS1158/DAS1159 are the ±15V and +5V power supplies, analog input signal, trigger pulse, and the HI-ENABLE/LO-ENABLE tri-state controls. Analog input and digital output programming are user selectable via external jumper connections.

Input voltage ranges are selectable via user pin programming: 0 to +5V, 0 to +10V, ±5V and ±10V. Unipolar coding is provided in true binary format with bipolar coding displayed in offset binary and two's complement (DAS1157 and DAS1158). DAS1159 unipolar coding is provided in a modified binary format (MSB complement) while bipolar coding is two's complement only.

ANALOG INPUT SECTION

The analog input can be applied to just the A/D converter or to the internal sample/hold amplifier ahead of the A/D converter. When using just the A/D converter, apply the analog input per the voltage range pin programming shown in Table I. When using the sample/hold amplifier in conjunction with A/D converter, apply the analog input to the S/H INPUT terminal and connect the S/H OUTPUT terminal to the appropriate A/D converter analog input.

Analog Voltage Input Range	Connect V_{IN} or S/H Out To	Connect Analog Common To	Connect Ref Out To
0 to +5V	ANA IN 1, ANA IN 2, ANA IN 3	Ground	NC*
0 to +10V	ANA IN 2 ANA IN 3	Ground ANA IN 1	NC*
±5V	ANA IN 1	Ground, ANA IN 3	ANA IN 2
±10V	ANA IN 3	Ground, ANA IN 1	ANA IN 2

*No Connection

Table I. Analog Input Pin Programming

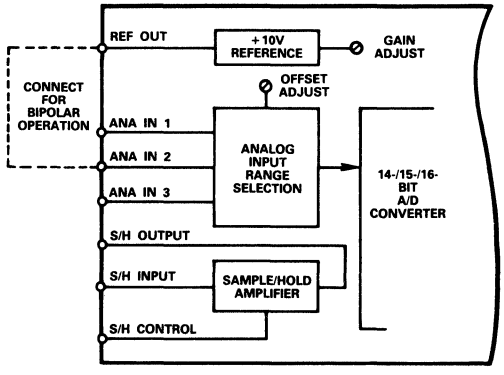


Figure 2. Analog Input Block Diagram

Errors due to source loading are eliminated since the sample/hold amplifier is a high-impedance unity-gain amplifier. High feedthrough rejection is provided for either single-channel or multichannel applications. Feedthrough rejection can be optimized, in multichannel applications, by changing channels at the rising or falling edge of the S/H control pulse.

TIMING DIAGRAM

The timing diagram for the DAS1157/DAS1158/DAS1159 is illustrated in Figure 3. This figure also includes the sample/hold amplifier acquisition time.

If the sample/hold amplifier is required, the TRIGGER input and S/H CONTROL terminal can be tied together providing only one conversion control signal. When the trigger pulse goes high, it places the sample/hold amplifier in the sample mode allowing it to acquire the present input signal. The trigger pulse must remain high for a minimum of 5μs to insure accuracy. If the sample/hold amplifier is not used, the trigger pulse needs to be 1μs (minimum) in length to satisfy the A/D converter trigger requirements. At the falling edge of the trigger pulse, the sample/hold amplifier is placed in the hold mode, all internal logic is reset and the A/D conversion begins. The conversion process can be retriggered at any time, including during conversion.

With this negative edge of the trigger pulse, the MSB is set high with the remaining digital outputs set to logic low state, and the end of conversion is set high and remains high through the full conversion cycle. During conversion each bit, starting with the MSB, is sequentially switched high at the rising edge of the internal clock. The DAC output is then compared to the analog input and the bit decision is made. Each comparison lasts one clock cycle with the complete 14-/15-/16-bit conversion taking 50μs maximum. At this time, the end of conversion line goes low signifying that the conversion is complete. For microprocessor bus applications, the digital output can now be applied to the data bus by enabling the tri-state buffers. For maximum data throughput, the digital output data should be read while the sample/hold amplifier is acquiring the new analog input signal.

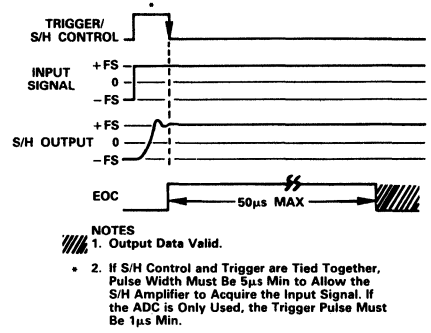

Figure 3. DAS1157/DAS1158/DAS1159 Timing Diagram

9

GAIN AND OFFSET ADJUSTMENT

The DAS1157/DAS1158/DAS1159 contain internal gain and offset adjustment potentiometers. Each potentiometer has ample adjustment range so that gain and offset errors can be trimmed to zero.

Offset calibration is not affected by changes in gain calibration, and should be performed prior to gain calibration. Proper gain and offset calibration requires great care and the use of extremely sensitive and accurate reference instruments. The voltage standard used as a signal source must be very stable and be capable of being set to within ±1/10LSB of the desired value at any point within its range.

OFFSET CALIBRATION

For a 0 to +10V unipolar range, set the input voltage precisely to +305μV for the DAS1157, +153μV for the DAS1158 and +76μV for the DAS1159. For a 0 to +5V unipolar range, set the input to +153μV for the DAS1157, +76μV for the DAS1158 and +38μV for the DAS1159. Then adjust the zero potentiometer until the converter is just on the verge of switching from 000.....000 to 000.....001 (DAS1157/DAS1158) or from 100.....000 to 100.....001 (DAS1159).

For the ±5V bipolar range, set the input voltage precisely to +305μV for the DAS1157, +153μV for the DAS1158 and +76μV for the DAS1159. For a ±10V bipolar range, set the input voltage precisely to +610μV for the DAS1157, +305μV for the DAS1158 and +153μV for the DAS1159. Adjust the zero potentiometer until the offset binary coded units are just on the verge of switching from 000.....000 to 000.....001 and the two's complement coded units are just on the verge of switching from 100.....000 to 100.....001.

GAIN CALIBRATION

Set the input voltage precisely to +9.99909V (DAS1157)/ +9.99954V (DAS1158)/+9.99977V (DAS1159) for the 0 to +10V units, +4.99954V (DAS1157)/+4.99977V (DAS1158)/ +4.99989V (DAS1159) for 0 to +5V units, +9.99817V (DAS1157)/+9.99909V (DAS1158)/+9.99954V (DAS1159) for ±10V units, or +4.99909V (DAS1157)/+4.99954V (DAS1158)/ +4.99977V (DAS1159) for ±5V units. Note that these values are 1 1/2LSBs less than nominal full scale. Adjust the gain potentiometer until binary and offset binary coded units are just on the verge of switching from 11.....10 to 11.....11 or modified binary and two's complement coded units are just on the verge of switching from 011.....10 to 011.....11.

DAS1157/DAS1158/DAS1159 INPUT/OUTPUT RELATIONSHIPS

The DAS1157/DAS1158 produces a true binary coded output when configured as a unipolar device. Configured as a bipolar device, it can produce either offset binary or two's complement output codes. The most significant bit (MSB) is used to obtain the binary and offset binary codes while ($\overline{\text{MSB}}$) is used to obtain two's complement coding. The DAS1159 produces a modified binary coded output when configured as a unipolar device. Configured as a bipolar device it can only produce two's complement output codes. The DAS1159 uses $\overline{\text{MSB}}$ to obtain the modified binary and two's complement output codes; the DAS1159 does not have an MSB output. Table II shows the DAS1157/ DAS1158/DAS1159 unipolar analog input/digital output relationships. Table III shows the DAS1157/DAS1158/DAS1159 bipolar analog input/digital output relationships.

Table III. Bipolar Input-Output Relationships

TRI-STATE DIGITAL OUTPUT

The ADC digital outputs are provided in parallel format to the output tri-state buffers. The output information can be applied to a data bus in either a one-byte or a two-byte format by using the HIGH BYTE ENABLE and LOW BYTE ENABLE terminals. If the tri-state feature is not required, normal digital outputs can be obtained by connecting the enable pins to ground.

POWER SUPPLY AND GROUNDING CONNECTIONS

No power supply decoupling is required since the DAS1157/ DAS1158/DAS1159 contain high quality tantalum capacitors on each of the power supply inputs to ground.

The analog and digital grounds are internally connected in the DAS1157/DAS1158/DAS1159. But in many applications, an external connection between the digital ground pin and analog ground pin is advisable for optimum performance.

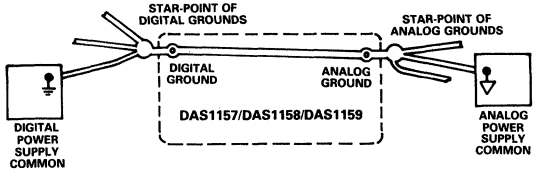

Figure 4. Typical Ground Layout for DAS1157/DAS1158/ DAS1159

Microcomputer I/O Boards

The RTI® Series consists of analog and digital input/output boards that are compatible with all of the popular microcomputer bus standards including:

- IBM PC/XT/AT*
- IBM PS/2*, Micro Channel* Architecture
- STD Bus
- VMEbus
- MULTIBUS*

All boards are 100% bus compatible and are optimized for peak performance on each bus. Different analog/digital conversion speeds, resolution and choice of analog output and channel expansion capability are available allowing customization of the bus based solutions. They are cost effective and provide a convenient means to interface a computer to the real world.

SIGNAL CONDITIONERS

For data acquisition applications requiring signal conditioning and transducer interface with high-voltage isolation, the 3B and 5B Series of signal conditioners or one of the analog signal conditioning panels can be connected directly to the RTI Series boards.

Both the 3B and 5B Series are unmatched in terms of isolation, reliability and ease of use. The 3B Series interfaces to the widest range of signals and is user configurable. The 5B Series consists of functionally complete, high performance, low cost signal conditioners. A family of multiplexed analog signal conditioning panels offers an alternative for systems with high point counts where single channel modularity is not required.

Via a variety of optional backplanes and convenient ribbon cabling to the RTI Series I/O Boards, signal conditioners bring real-world signals into the computer, including millivoltage, voltage, current, thermocouple, RTD, strain gage, LVDT and frequency. For further information on signal conditioners, see Linear Products Databook.

SOFTWARE

Many RTI Series boards are supported by MS-DOS* I/O driver software that provides easy to use, high level calls and commands for user written software programs for languages like Microsoft* BASIC (Interpreted and Compiled), QuickBASIC, C, Pascal, TURBO Pascal*, FORTRAN and MACRO Assembler.

Popular menu-driven data acquisition application software supports many of the RTI Series boards, including ASYST*, LABTECH* NOTEBOOK, LABTECH CONTROL, UnkelScope*, SNAPSHOT STORAGE SCOPE*, Control EG* and THE FIX*. These software packages make it easy to configure a complete solution using Analog Devices I/O and your choice of computer.

Application Specific Integrated Circuits

Analog Devices offers a full spectrum of capabilities in application specific integrated circuits (ASICs). These chip-level systems can implement designs with 12-bit accuracy and 16-bit resolution that formerly required board-level solutions.

Analog Devices can incorporate most of the functions of its standard monolithic parts in full-custom and semicustom ICs. Full-custom parts optimize performance and space requirements, while cell-based semicustom parts reduce development time and engineering expense. Development costs can be cut further by tailoring a predefined system-on-a-chip known as a Linear System Macro to your application.

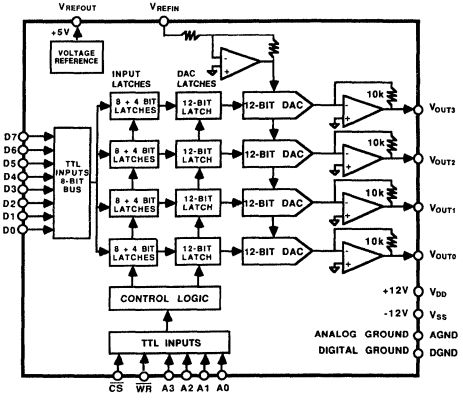
Analog's experienced design engineers work with powerful computer-aided design tools to design and lay out your circuit. Design centers are currently in Massachusetts, California and England.

Multiple locations for fabrication, assembly and testing ensure a ready supply of production parts. Products can be processed in full MIL-38510 certified facilities.

DESIGN EXAMPLES

Analog Devices has created a variety of customer-specific and function-specific ASIC parts. Described here are two Linear System Macros, a custom chipset and a semicustom chip.

AD75004 QUAD DAC



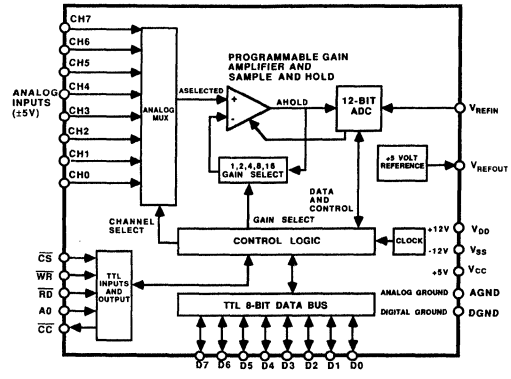
AD75004 Quad DAC

This circuit contains four separate 12-bit D/A converters with amplifiers for voltage output and an on-board reference. Double-buffering latches interface with an 8-bit parallel bus and permit updating of all four channels individually or simultaneously.

AD75003 Data Acquisition System

This DAS converts analog signals on 8 input channels to 12-bit values and interfaces via an 8-bit parallel bus. The chip integrates an 8-channel multiplexer, programmable-gain amplifier, sample-and-hold and 12-bit A/D converter with internal voltage reference.

AD75003 DATA ACQUISITION SYSTEM



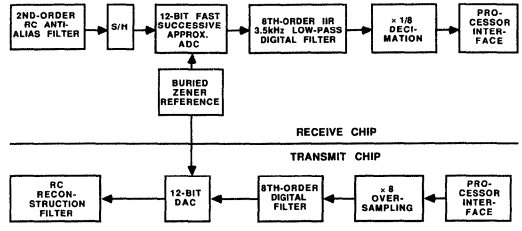
Derivative Circuits

The circuits outlined above can be modified to suit a specific customer's application. One such device is a semicustom, serial-interface DAS. The AD75003 design was altered to have programmable gains of 1 to 20 instead of 1 to 16, and a serial UART instead of an 8-bit parallel interface. In addition to the AD75003 functions, this part contains a precision instrumentation amplifier, a programmable line-frequency notch filter, a 7-bit trim DAC and a temperature sensor.

Modem Chipset

Library cells can be combined to form macro building blocks for high speed modems. This two-chip design concept filters and converts data to interface a digital signal processor with the analog circuitry of a 9600-baud modem. On one chip, the received signal passes through an antialiasing filter, sample-and-hold, 12-bit A/D converter, 8th-order digital filter and decimation. On the other chip, transmit data is 8× oversampled, then goes to an 8th-order filter, a 12-bit DAC and an active reconstruction filter.

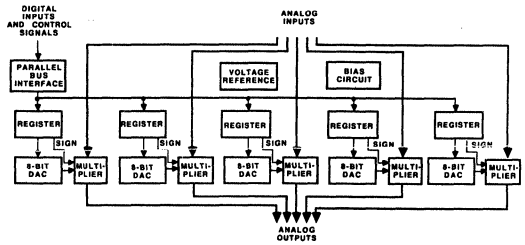
HIGH SPEED MODEM CHIPSET



11

Transversal Filter Element
This circuit implements five taps of a finite-impulse response filter. Each tap comprises an 8-bit DAC and a multiplier, which handle signals up to 40 MHz. A parallel interface sets the tap weights.

TRANSVERSAL FILTER ELEMENT



HIGH PERFORMANCE PROCESSES

Analog Devices' semicustom and custom circuits are fabricated using the same high performance processes as our standard ICs. These technologies include two mixed bipolar-CMOS processes, a high voltage CMOS process and high speed and low power bipolar processes. These processes can include thin-film resistors which may be laser trimmed for precise matching and stable performance over a wide temperature range.

The BiMOS II and Linear Compatible CMOS (LC^2MOS) processes combine bipolar and CMOS devices on one chip. Functional density is an order of magnitude greater than previous mixed-signal processes; over 20,000 devices can be placed on a single chip. Bipolar transistors provide low noise, low offset input stages and high power output stages. The CMOS devices offer high input impedance, and make dense logic and good switches for data converters, multiplexers and switched-capacitor filters. LC^2MOS also provides a JFET for very low input noise.

The bipolar-CMOS processes operate on supply voltages ranging from single +5 volts to split ±15 V, with signal levels ranging from single-ended +3 V to ±10 V. These processes are ideally suited for applications in data acquisition, instrumentation, industrial automation and telecommunications.

The High Voltage Switch (HVS) process provides quality analog switches that can operate with supply voltages up to ±22 volts. It can combine switches and multiplexers with CMOS logic.

The Flash bipolar process makes high speed linear signal processing, data conversion and ECL logic functions on one chip. Signal levels are ±4 volts with ±5 V supplies or up to +10 V with a +12 V supply. Applications include disk-drive read/write circuitry and high speed telecommunications equipment.

The Complementary Bipolar (CB) process features high speed PNP and NPN devices for precision, low power linear applications. It also offers low noise buried Zener references and dual-gate JFETs. CB runs on +5 V to ±15 V supplies.

The table below summarizes the processes available for designing ASICs. Other processes in development will offer even higher speed, denser logic and higher integration of analog and digital functions.

ANALOG DEVICES HIGH-PERFORMANCE PROCESSES FOR ASICs

Process	Power	Signal	Features
BiMOS II	±12 V	±8 V	Wide Variety of Precision Linear and Digital Functions
LC^2MOS	+5 V to ±15 V	+3 V to ±10 V	Wide Variety of Precision Linear and Digital Functions
HVS	+5 V to ±22 V	+2 V to ±18 V	High Voltage Switches, Muxes and Logic Functions
Flash	±5 V or +12 V	±4 V or +10 V	High Speed Linear and Digital Functions
CB	+5 V to ±15 V	+2 V to ±10 V	High Speed, Low Power Linear Functions

CELL LIBRARIES

Cell libraries for the bipolar CMOS processes are described below. These libraries are growing with the development of new processes, macrocells and cells. Many new catalog parts will also be available as cells. Your local sales office can give you current information on the cell libraries and available Linear System Macros.

Operational amplifiers are available in bipolar, JFET and CMOS configurations. Representative bipolar op amp cells have performance characteristics similar to an AD OP-27 and a slew-enhanced AD741. The LC^{2}MOS process offers JFET op amps, including an AD544 equivalent.

Instrumentation amplifiers with performance comparable to the AD521 and AD524 are available. Comparators suitable for 12-bit-accurate applications are available. Linear comparators have response times down to 100 nanoseconds and strobed comparators have setup/access times down to 50 nanoseconds.

Digital-to-analog converters range in resolution from 8 to 14 bits, and include cells similar to the AD667 and AD1856. Analog-to-digital converters vary from 8 to 12 bits in resolution, and include cells equivalent to the AD7572 and AD674. One half-flash ADC cell converts to 8-bit accuracy in 500 nanoseconds, and one successive approximation cell converts to 12 bits in 5 microseconds.

Support cells include sample-and-hold amplifiers with performance comparable to the AD585, low-voltage bandgap references comparable to the AD584 and low noise buried Zener references.

RC active filters and programmable switched-capacitor filters are available with specifications in these ranges:

Topology: all classical filter types
Frequency Range: 200Hz to 20kHz (switched-cap) or 100Hz to1MHz (RC)
Number of Sections: up to 10th-order (switched-cap) or 4th-order (RC)
Signal/Noise and THD: >72dB, compatible with 12-bit data acquisition.

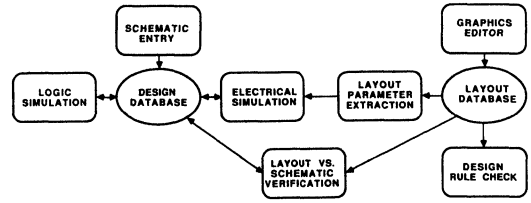
Logic cells include gates, counters, registers, PLA, RAM and ROM. Interface cells include 8-bit and 16-bit parallel I/O ports and UARTs.

DESIGN AND LAYOUT

Analog Devices engineers will design your integrated circuit, drawing on their years of experience and using powerful computer-aided design (CAD) tools. These comprehensive CAD tools help design, simulate and lay out the circuit and aid in generating test programs.

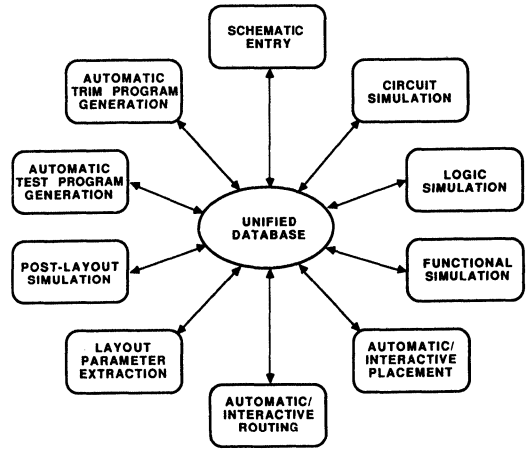
The following figure shows the standard design cycle which begins with schematic entry. After logic and initial electrical simulation, the designer uses the graphics editor to lay out the circuit. Parasitics and other data are extracted from the layout and circuit operation is simulated again. Finally, the system checks that the layout follows process design rules and matches the schematic.

IC DESIGN WITH
COMMERCIAL CAD SYSTEM



In addition to using these commercial CAD tools, Analog Devices has developed a proprietary compiler for mixed-signal IC design, called JANUS. By integrating all design functions into one environment with a common database, JANUS reduces design time by an order of magnitude.

IC DESIGN WITH JANUS
PROPRIETARY CAD SYSTEM



11

To speed schematic entry, the designer selects devices, cells and macrocells from comprehensive menus. Device generators allow the designer to specify devices for maximum performance and minimum size. Analog, logic and functional simulators verify the performance of individual cells and the overall chip design. Placement and routing algorithms complete circuit layouts automatically, yet allow interaction with the designer to handle special cases. When placing devices and cells, JANUS considers thermal and electrical matching as well as die area. An expert system optimizes routing to minimize interconnect length and number of vias. Post-layout simulation comprehends the parasitics of the final routing and is more accurate than the initial simulation.

Future goals for JANUS include automatically generating programs for production trim and test of analog/digital ICs.

TEST AND TRIM

Analog Devices has over 20 years of experience in testing complex circuits and manufactures commercial test systems for precision linear ICs. In each fabrication facility, a computer network integrates Analog Devices, Teradyne and LTX test equipment. The design, wafer probe and test areas share data on the network for statistical analysis and device modelling.

All Analog Devices ASICs are tested at the wafer level, and most are laser-wafer trimmed to achieve high accuracy. Untrimmed thin-film resistors match within 1% to 0.1%, depending on area. Trimmed resistors can match to better than 0.01%. Wafers may be laser drift trimmed with a hot-chuck probe to minimize the effects of temperature on accuracy.

After packaging, all parts are tested to assure that they meet guaranteed specifications. Environmental handlers can verify parts at multiple temperatures. Burn-in is performed as specified by the customer.

PACKAGING

Analog Devices ICs are available in most modern package types, including high pin-count and surface mount varieties. ASICs may be assembled in any of Analog Devices' standard packages, listed below. This list is constantly expanded and other packages may be used if they are suitable for high performance applications.

Available Packages

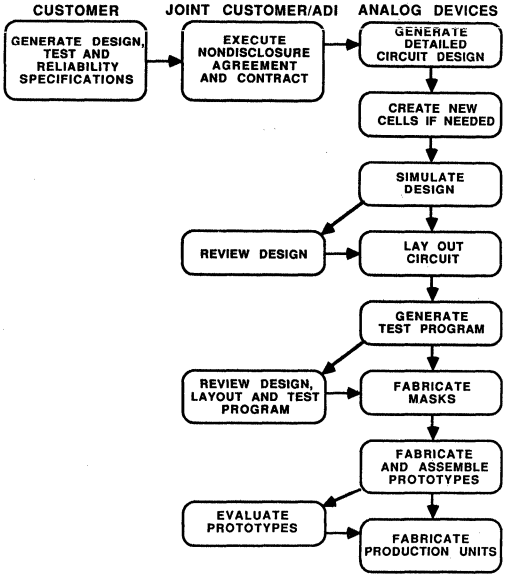
Pin-grid array (PGA): 68 to 144 pins
Leaded ceramic chip carrier (LDCC): 44 pins
Leadless ceramic chip carrier (LCC): 20 to 68 I/Os
Plastic quad flat pack (PQFP): 100 pins
Plastic leaded chip carrier (PLCC): 20 to 52 pins
Plastic dual in-line package (DIP): 14 to 64 pins
Side-brazed DIP: 14 to 64 pins
Frit-seal DIP (Cerdip): 14 to 28 pins
Small outline (SO): 14 and 16 pins

PROGRAM RESPONSIBILITIES AND INTERFACES

The following chart shows the major phases in developing an ASIC and responsibilities during each phase. The overall development time depends on the complexity of the circuit and on how custom the design is.

Your Analog Devices Sales Engineer is your first interface for ASIC development. Your local sales office can provide further information on Analog Devices' custom/semicustom capabilities.

PROGRAM RESPONSIBILITIES AND INTERFACES



Power Supplies
Modular AC/DC Power Supplies

GENERAL DESCRIPTION
Analog Devices offers a broad line of modular ac/dc power supplies that provide both OEMs and designers a reliable, easy to use, low-cost solution to their power requirements. Models are available in PC mountable and chassis mountable designs with 5 volt to 15 volt (single, dual, triple) outputs and current ratings from 25 mA to 5 amps. Since these modular supplies are fully encapsulated, no trimming or external component selection is necessary; simply mount the unit, connect power and output leads, and you're on the air! Most Analog Devices' power supplies are available from stock in both large and small quantities with substantial discounts being applied to large quantity orders.

AC/DC POWER SUPPLY FEATURES
- Current Limit Short Circuit Protection
- PC Mounted and Chassis Mounted Versions
- Single (+5 V), Dual (±12 V, ±15 V), and Triple (±15 V/+5 V, ±15 V/+1 V to +15 V) Output Supplies
- Current Outputs:
  25 mA to 1000 mA for Dual and Triple Output Supplies
  250 mA to 5000 mA for Single Output Supplies
- Wide Input Voltage Range
- Low Output Ripple and Noise
- Excellent Line & Load Regulation Characteristics
- High Temperature Stability
- Free-Air Convection Cooling; No External Heat Sink Required

GENERAL SPECIFICATIONS

Power Requirements	
Input Voltage Range:	105 V ac to 125 V ac
Frequency:	50 Hz to 250 Hz
Electrical Specifications	
Temperature Coefficient:	0.02%/°C
Output Voltage Accuracy:	±2%, max See Specifications Table
Breakdown Voltage:	500 V rms, min
Isolation Resistance:	50 MΩ
Short Circuit Protection:	All ac/dc power supplies employ current limiting. They can withstand substantial overload including direct short. Prolonged operation should be avoided since excessive temperature rises will occur.
Environmental Requirements	
Operating Temperature Range:	−25°C to +71°C
Storage Temperature Range:	−25°C to +85°C

SPECIFICATIONS – Typical @ +25°C and 115 V ac 60 Hz unless otherwise noted*

*Consult Analog Devices Power Supplies Catalog for additional information.
**Resistor programmable.
Specifications subject to change without notice.

Modular DC/DC Converters

GENERAL DESCRIPTION

Analog Devices' line of compact dc/dc converters offers system designers a means of supplying a reliable, easy to use, low cost solution to a variety of floating (analog and digital) power applications. These devices provide high accuracy, short circuit protected, regulated outputs with very low output noise and ripple characteristics.

Fourteen models are offered in five power levels of 1 watt, 1.8 watts, 4.5 watts, 6 watts and 12 watts. Input voltage versions include 5 volt, 12 volt, 24 volt and 28 volt with output ranges as follows: +5 volt, ±12 volts and ±15 volts at ±60 mA to 1000 mA output current capability.

Most models are high efficiency (typicaly over 60% at full load) and feature complete 6-sided continuous shielding for EMI/RFI protection. A π-type input filter is contained, in some models, which virtually eliminates the effects of reflected input ripple current. Most Analog Devices' dc/dc converters are available from stock in both large and small quantities with substantial discounts being applied to large quantity orders.

DC/DC POWER SUPPLY FEATURES

- Inaudible (>20 kHz) Converter Switching Frequency
- Continuous, Six-Sided EMI/RFI Shielding Except on 1 Watt and 1.8 Watt Models
- Output Short Circuit Protection (Either Output to Common)
- Automatic Restart After Short Condition Removed
- Automatic Starting with Reverse Current Injected into Outputs
- Low Output Ripple and Noise
- High Temperature Stability
- Free Air Convection Cooling
  No external heat sink or specification derating is required over the operating temperature range.

GENERAL SPECIFICATIONS FOR 1 W AND 1.8 W MODELS

Line Regulation – Full Range: ±0.3% (±1% max, 949)
Load Regulation – No Load to Full Load: ±0.4% (±0.5% max, 949)
Output Noise and Ripple: 20 mV p-p (with 15 μF tantalum capacitor across each output) 2 mV rms max, 949)
Breakdown Voltage: 300 V dc min (500 V dc min, 949)
Input Filter Type: π
Operating Temperature Range: −25°C to +71°C
Storage Temperature Range: −40°C to +125°C (+100°C, 949)
Fusing: If input fusing is desired, we recommend the use of a slow blow type fuse that is rated at 150%–200% of the dc/dc converter's full load input current.

GENERAL SPECIFICATIONS FOR 4.5 W, 6 W AND 12 W MODELS

Line Regulation – Full Range: ±0.07% max (±0.02% max, 951, 960 Series) (±0.1% max, 943)
Load Regulation – No Load to Full Load: ±0.07% max (±0.02% max, 951, 960 Series) (±0.1% max, 943)
Output Noise and Ripple: 1 mV rms max
Breakdown Voltage: 500 V dc min
Input Filter Type: π
Operating Temperature Range: −25°C to +71°C
Storage Temperature Range: −40°C to +125°C
Fusing: If input fusing is desired, we recommend the use of a slow blow type fuse that is rated at 150%–200% of the dc/dc converter's full load input current.

SPECIFICATIONS – Typical @ +25°C at nominal input voltage unless otherwise noted*

Model	Output Voltage Volts	Output Current mA	Input Voltage Volts	Input[1] Voltage Range Volts	Input Current Full Load	Output Voltage Error max	Temperature Coefficient /°C max	Efficiency Full Load min	Dimensions Inches

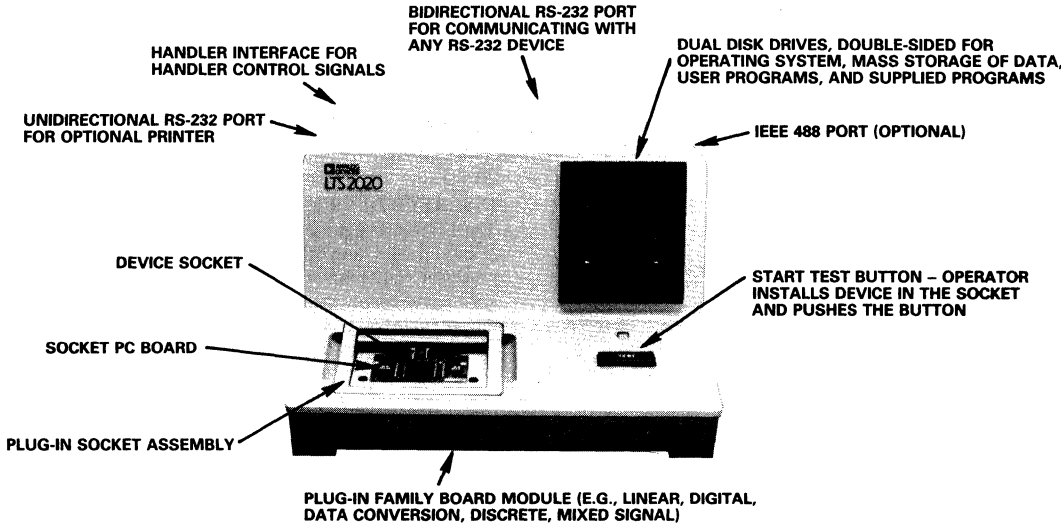
953	±15	±150	12	11/13	0.6 A	±0.5%	±0.01%	62%	2.0×2.0×0.38
945	±15	±150	28	23/31	250 mA	±0.5%	±0.01%	61%	2.0×2.0×0.38
951	±15	±410	5	4.65/5.5	3.7 A	±0.5%	±0.01%	62%	3.5×2.5×0.88

NOTES
[1]Models 940 and 941 will deliver up to 120 mA output current (and Model 943 will deliver up to 600 mA) over an input voltage range of 4.65 V dc and 5.5 V dc.
*Consult Analog Devices Power Suppies Catalog for additional information.
**Single-ended or unbalanced operation is permissible such that total output current load does not exceed a total of 120 mA.
Specifications subject to change without notice.

LTS-2020 Component Test Systems



THE LTS CONCEPT

The LTS-2020 is a versatile component test system which tests a multitude of components to the manufacturer's specifications (linear, digital, data conversion, and discrete devices). The system offers such features as RS-232 ports for networking, IEEE for compatibility with handlers and probers, dual disk drives for mass storage of data, automatic self-calibration, and a full statistical analysis software package.

The LTS-2020 provides several data output formats – datalog, yield analysis, and statistical analysis. The console provides the primary measurement and control functions to test a specific class of devices. The socket assembly is the mechanical and electronic interface for the family board and the DUT board. The DUT board plugs directly into the socket assembly and contains the circuitry and socket, specific to the actual device under test.

Analog Devices' component test systems are the first benchtop testers that are programmable in BASIC and fill-in-the-blanks CREATE. CREATE is menu-driven software which prompts the user for data sheet limits and conditions, then builds a completed test program for the specified device. Turnkey program libraries are available for each of the device families.

Far more than just comprehensive production testers, these test systems can handle complex engineering analysis and incoming inspection. They are the first systems that can provide all the capabilities of today's large centralized test systems at a price that is approximately one-third the cost. The LTS-2020 not only provides the flexibility of distributed or decentralized testing, it allows for cost effective multiple system purchases. They increase overall test reliability since the threat of a single big failure is eliminated in a distributed testing environment.

LTS-2020 Test Capabilities

MIXED SIGNAL TEST CAPABILITY

The LTS-2800 Mixed Signal Family Board and LTS-0680 Test Head perform a wide variety of ac and dc parametric tests on devices such as complex hybrids, octal DACs, ASICs, converters, and pulse width modulators. The family board supplies the dc pin drivers, the dc force and measure system, a V_{CC} buffer, an rms-to-dc conversion circuit, voltage and current sources, and a 24 × 5 switching matrix. With its 24 programmable pin drivers, the system can provide high and low digital voltages, a three-state (high impedance) output mode, and accurate voltages and currents (V/I source).

The family board incorporates a series of 12-bit calibrated sources, used for programming V_{IL} and V_{IH} voltage levels at the digital inputs of the device under test. A threshold source for programming voltage levels on a comparator is used to detect digital output voltage levels accurately. For forcing and measuring currents, a V/I source provides and measures 10 μA to 400 mA and voltages to ±20 V.

A switching matrix provides system flexibility by allowing any one of several capabilities to be switched to any of the pin drivers. These include the measure system, V/I source, V_{IH} and V_{IL} sources, the rms-to-dc circuit, and BNC input and output connectors for interconnection with external instruments using the IEEE-488 bus.

The LTS-0680 Mixed Signal Test Head contains a precise and versatile time measure unit which provides accurate ac measurement of propagation delays, slew rates, pulse widths, and rise and fall times. It also incorporates a 16-bit user data bus, 16-bit relay driver bus, four 12-bit programmable sources, and a user's expansion board. A square wave source to the DUT provides up to ±10 volt signals, from 1.22 kHz to 2.5 MHz.

LTS-2020 Test Capabilities (Continued)

LINEAR DEVICE TEST CAPABILITY

The LTS-2101 Operational Amplifier Family Board tests today's very demanding high precision op amps, comparators, and regulators. This board houses the test loop used in testing op amps and comparators and the pulse load circuitry used in developing the high currents needed for voltage regulator testing.

For testing devices under 100 μV, the LTS-2101 offers a tight offset spec of ±(0.25% + 5 μV). Use of low thermal Emf relays and a test loop gain of 10,045 ensures superior low level V_{OS} measurement performance for optimum repeatability of low level signals.

Testing of low current devices is achieved with the LTS-0614 Socket Assembly which is designed to test bias and offset currents with an accuracy of ±(5% + 25 fA) for any FET amplifier, including quad devices. Program libraries containing prewritten test programs for many standard op amps, comparators and regulators are available on disk.

ANALOG-TO-DIGITAL TEST CAPABILITY

The LTS-2200 ADC Family Board provides the test circuitry required for testing monolithic, hybrid, or modular ADCs. An on-board 16-bit microprocessor with 8K bytes of memory acts as a slave for the system console and executes preprogrammed test routines such as linearity, all codes existence, transition noise measurements, and conversion time measurements at high speed. Absolute accuracy can be measured within 200 μV. Linearity, differential nonlinearity, offset, gain, and PSSR are tested to ±0.05 DUT LSB +200 μV. Turnkey test packages are available for many of the standard ADCs currently in use.

DIGITAL-TO-ANALOG TEST CAPABILITY

The LTS-2302 DAC Family Board utilizes advanced state-of-the-art test techniques to provide comprehensive test capabilities for a wide variety of D/A converters. It will test both voltage and current output DACs, DACs with and without buffer registers, and serial or parallel input DACs to 16-bit accuracy.

High repeatability on low level signals is achieved because of the grounding scheme on the LTS-2302. The incorporation of high level components in the V/I circuits ensures true accuracy. In addition, the methodology for measuring low bit currents allows appropriate testing of this parameter on CMOS DACs.

Output leakage current on the LTS-2302 is measured with the bit drivers to the DAC set to logic 0. Current is measured using the I to V converter. A 1 MΩ resistor within the I to V circuitry ensures sensitivity, thereby measuring current down to ±1 μA full scale.

DIGITAL DEVICE TEST CAPABILITY

The LTS-2510 Digital Device Family Board provides 24-pin driver/detectors and a precision, four quadrant V/I source for testing SSI/MSI TTL and CMOS digital devices. This board contains four programmable device supplies and switching circuitry necessary for performing accurate parametric measurements on all device pins.

Together with the LTS-0655 remote ac test fixture, dynamic parametric testing of 24-pin SSI/MSI TTL digital devices can be achieved. Accuracies are achieved down to ±4% + 1.5 ns at a resolution of 500 ps. Dynamic parameters tested are propagation delay, setup, and hold times.

DISCRETE DEVICE TEST CAPABILITY

The LTS-2600 Transistor Family Board tests bipolar transistors, JFETs, diodes, and optocouplers. An on-board 16-bit microprocessor with 4K bytes of memory acts as a slave for the LTS system and coordinates the timing and pulse width control of the stimulus and measurement signals. In addition, the microprocessor monitors the interlock circuitry to insure safe handling of high power test signals.

MOSFET software packages support the testing of N and P channel enhancement mode and N channel depletion mode devices. Tests which may be performed on MOSFET devices include Idss, Igss, Igssf, Igssr, Id (off), Id (on), B Vdss, B Vgss, B Vgssf, B Vgssr, Vds (on), Vgs (th), Vgsoff, Vsd, Rds (on), and Gsf.

The Smartpower Test Fixture will support fast, accurate testing of devices such as Darlington Arrays, Differential Line Drivers/Receivers, and Transceivers/Repeaters. It contains a matrix board which facilitates the muxing of High Voltage/High Current V/Is, a nonometer, diffamp, 16-bit measure system, and mecca ground reference to any one of eight matrix points at the DUT site and eight dc pin drivers programmable to any one of four modes – V/I, V_{IH}, V_{IL} or Tristate. This configuration allows true digital dc parametric testing of the front end of smartpower devices while providing the high voltage and high current capability to test the discrete output stage.

ANALOG SWITCH TEST CAPABILITY

The LTS-2700 Analog Switch Family Board adds switch and multiplexer testing capability to the LTS-2020. This test capability, with CREATE software, allows datalogged device testing at the incoming inspection and semiconductor manufacturing levels and includes software power for use in component evaluation applications.

The LTS-2700 tests on and off drain to source leakage currents with an accuracy of 250 pA while forcing differential voltages up to 50 V (± 25 V from GND). Other tests performed are drain to source on resistance, greatest change in drain-source on resistance between channels, digital input current and supply current.

Twenty high integrity analog lines are provided – four to be used as drain connections and sixteen for source connections. Also provided are eight programmable digital drivers, four digital control bits, six variable power supplies, and one fixed +5 V supply. These combinations of sources provide testing of devices such as 4-channel switches, 16 to 1 multiplexers, and other combinations of switches and multiplexers.

2. The minimum limit for dimension b_1 may be 0.023" (0.58mm) for all four corner leads only.
3. Dimension Q shall be measured from the seating plane to the base plane.
4. This dimension allows for off-center lid, meniscus and glass overrun.
5. Applies to all four corners.
6. All leads – increase maximum limit by 0.003" (0.08mm) measured at the center of the flat, when hot solder dip lead finish is applied.
7. Eighteen spaces.

NOTES

1. (All leads) ϕb applies between L_1 and L_2. ϕb_1 applies between L_2 and 0.500″ (12.70mm) from the reference plane. Diameter is uncontrolled in L_1 and beyond 0.500″ (12.70mm) from the reference plane.
2. Measured from the maximum diameter of the product.
3. Leads having a maximum diameter 0.019″ (0.48mm) measued in gauging plane 0.054″ (1.37mm) + 0.001″ (0.03mm) – 0.000″ (0.00mm) below the base plane of the product are within 0.007″ (0.18mm) of their true position relative to the maximum width tab.
4. All leads – increase maximum limit 0.003″ (0.08mm) when hot solder dip finish is applied.

NOTES
1. (Three Leads) ϕb_2 applies between L_1 and L_2. ϕb applies between L_2 and 0.5″ (12.70mm) from seating plane. Diameter is uncontrolled in L_1 and beyond 0.5″ (12.70mm) from seating plane.
2. Leads having maximum diameter 0.019″ (0.48mm) measured in gauging plane 0.054″ (1.4mm) + 0.001″ (0.03mm) – 0.000″ (0.00mm) below the seating plane of the device are within 0.007″ (0.18mm) of their true positions relative to a maximum-width tab.
3. Measured from maximum diameter of the actual device.
4. All leads – increase maximum limit by 0.003″ (0.08mm) when hot solder dip finish is applied.

Ordering Guide

INTRODUCTION

This Ordering Guide should make it easy to order Analog Devices products, whether you're buying one IC op amp, a multi-option subsystem, or 1000 each of 15 different items. It will help you:

1. Find the correct part number for the options you want.
2. Get a price quotation and place an order with us.
3. Know our warranty for components and subsystems.

For answers to further questions, call the nearest sales office (listed at the back of the book) or our main office in Norwood, Mass. U.S.A. (617-329-4700).

MODEL NUMBERING

Many of the data sheets in the Databook for products having a number of standard options contain an Ordering Guide. Use it to specify the correct part number for the exact combination of options you want. I.C. and hybrid part numbers are created using one of these two systems:

Figure 1 shows the form of model number used for our proprietary standard monolithic ICs and many of our hybrids. It consists of an "AD" (Analog Devices) prefix, a 3-to-5-digit model number*, an alphabetic performance/temperature-range designator and a package designator. One or two additional letters may immediately follow the digits ("A" for second-generation redesigned ICs, "DI" for dielectrically isolated CMOS switches, e.g., AD536AJH, AD7512DIKD).

Figure 2 shows the somewhat different numbering scheme used by our Computer Labs Division for some hybrid circuits. The number starts with a three-character alphabetic prefix, followed by a hyphen, a three- or four-digit number, and alphabetic designators (as applicable) to indicate additional functional designations or options and packaging options.

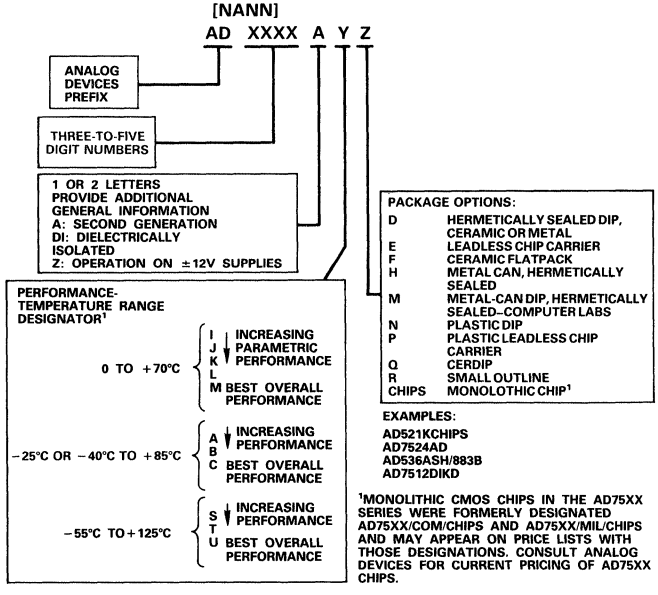

Figure 1. Model-Number Designations for Standard Analog Devices Monolithic and Hybrid IC Products. S, T and U Grades have the Added Suffix, /883B for Devices that Qualify to the Latest Revision of MIL-STD-883, Level B.

***For some models, the combination [digit][letter][two or three digits] is used instead of ADXXXX, e.g., 2S80.**

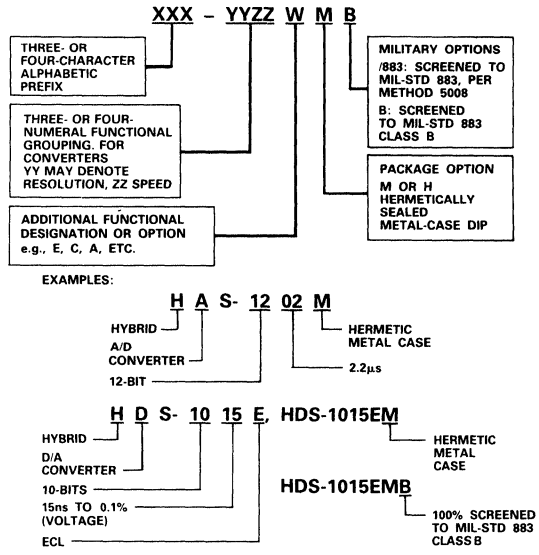

Figure 2. Computer Labs Video Hybrid Product Designations

SECOND SOURCE

In addition to our many proprietary products, we also manufacture devices that are fit-, form-, and function-compatible (and often superior in performance and reliability) to popular products that originated elsewhere. For such products, we usually add the prefix "AD" to the familiar model number (example: ADDAC85C-CBI-V).

ORDERING FROM ANALOG DEVICES

When placing an order, please provide specific information regarding model type, number, option designations, quantity, ship-to and bill-to address. Prices quoted are list; they do not include applicable taxes, customs, or shipping charges. All shipments are F.O.B. factory. Please specify if air shipment is required.

Place your orders with our local sales office or representative, or directly with our customer service group located in the Norwood facility. Orders and requests for quotations may be telephoned, sent via TWX or TELEX, or mailed. Orders will be acknowledged when received; billing and delivery information is included.

Payments for new accounts, where open-account credit has not yet been established, will be C.O.D. or prepaid. On all orders under fifty dollars ($50.00), a five-dollar ($5.00) processing charge is required.

When prepaid, orders should include $2.50 additional for packaging and postage (and a 5% sales tax on the price of the goods if you are ordering for delivery to a destination in Massachusetts).

WARRANTY AND REPAIR CHARGE POLICIES

All Analog Devices, Inc., products are warranted against defects in workmanship and materials under normal use and service for one year from the date of their shipment by Analog Devices, Inc., except that components obtained from others are warranted only to the extent of the original manufacturers' warranties, if any, except for component test systems, which have a 180-day warranty, and µMAC and MACSYM systems, which have a 90-day warranty. This warranty does not extend to any products which have been subjected to misuse, neglect, accident, or improper installation or application, or which have been repaired or altered by others. Analog Devices' sole liability and the Purchaser's sole remedy under this warranty is limited to repairing or replacing defective products. (The repair or replacement of defective products does not extend the warranty period. This warranty does not apply to components which are normally consumed in operation or which have a normal life inherently shorter than one year.) Analog Devices, Inc., shall not be liable for consequential damages under any circumstances.

THE FOREGOING WARRANTY AND REMEDY ARE IN LIEU OF ALL OTHER REMEDIES AND ALL OTHER WARRANTIES, WRITTEN OR ORAL, STATUTORY, EXPRESS, OR IMPLIED, INCLUDING ANY WARRANTY OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE.

Product Families Not Included in the Databook (But Still Available)

The information published in this Databook is intended to assist the user in choosing components for the design of *new* equipment, using the most cost-effective products available from Analog Devices. The popular product types listed below may have been designed into your circuits in the past, but they are no longer likely to be the most economic choice for your new designs. Nevertheless, we recognize that it is often a wise choice to refrain from redesigning proven equipment, and we are continuing to make these products available for use in existing designs or in designs for which they are uniquely suitable. Data sheets on these products are available upon request.

Substitution Guide for Product Families No Longer Available

The products listed in the left-hand column are no longer available from Analog Devices. In many cases, comparable functions and performance may be obtained with newer models, but – as a rule – they are not directly interchangeable. The closest recommended Analog Devices equivalent, physically and electrically, is listed in the right-hand column. If no equivalent is listed, or for further information, contact your local sales office.

Technical Publications

TECHNICAL PUBLICATIONS

Analog Devices provides a wide array of FREE technical publications. These include Data Sheets for all products, Catalogs, Application Notes and Guides and four serial publications. *Analog Productlog*, a digest of new-production information; *DSPatch™*, a newsletter about digital signal-processing (applications); *Analog Briefings*, current information about products for military/avionics and the status of reliability at ADI; and *Analog Dialogue*, our technical magazine, with in-depth discussions of products, technologies and applications.

In addition to the free publications, five technical reference books are available at reasonable cost. Subsystem products are supported with hardware, software, and user documentation, at prices related to content.

Brief descriptions of typical publications appear below. For copies of any items, to subscribe to any of our free serials or to request any other publications, please get in touch with Analog Devices or the nearest sales office.

CATALOGS

Data Acquisition Products Databooks. Contain selection guides, data sheets and other useful information about all Analog Devices ICs, hybrids, modules and subsystem components recommended for new designs. The 1989/90 series consists of:

DATA CONVERSION PRODUCTS DATABOOK—1989/90. Data Sheets and Selection Guides on D/A, A/D, V/F, and F/V Converters, Sample-Track/Hold Amplifiers, Voltage References, Multiplexers & Switches, Synchro-Resolver Converters, Data Acquisition Subsystems, Application-Specific ICs. (Available FREE.)

DSP PRODUCTS DATABOOK—1989. Data Sheets, Selection Guides and Application Notes on DSP Microprocessor, Microcoded Support Components, Floating-Point Components and Fixed-Point Components. (Available FREE.)

LINEAR PRODUCTS DATABOOK—1989/90. Data Sheets and Selection Guides on Op Amps, Instrumentation Amplifiers, Isolators, RMS-to-DC Converters, Multipliers/Dividers, Log/Antilog Amplifiers, RMS-to-DC Converters, Comparators, Temperature-Measuring Components and Transducers, Special Function Components, Digital Panel Instruments, Signal-Conditioning Components and Subsystems. (Available FREE.)

MILITARY PRODUCTS DATABOOK. Information and data on products processed in accordance with MIL-STD-883 Class B.

PERSONAL-COMPUTER BASED MEASUREMENT & CONTROL SOLUTIONS—Hardware and Software. Data acquisition for various buses, including PC/XT/AT* and PS/2* Micro Channel*, Modular Signal Conditioners, Signal-Conditioning Panels, Application Software, and Driver Software. Includes Do-It-Yourself Ordering Guides and Hot Line (1-800-4-ANALOG).

POWER SUPPLIES–Linear Supplies•DC-DC Converters. 12-page short-form catalog listing ac/dc power supplies, modular dc/dc converters, power-supply test procedures, transients, thermal derating, mechanical outlines of packages and sockets.

APPLICATION NOTES AND GUIDES

All are available upon request.

Application Notes.

A/D Converters:
- "Exploring the AD667 12-Bit Analog Output Port."
- "Interacing the AD7572 to High-Speed DSP Processors."
- "The AD7574 Analog-to-Microprocessor Interface."

Amplifiers:
- "An IC Amplifier User's Guide to Decoupling, Grounding, and Making Things Go Right for a Change."
- "Applications of High-Performance BiFET Op Amps."
- "A User's Guide to IC Instrumentation Amplifiers."
- "How to Select Operational Amplifiers."
- "How to Test Basic Operational Amplifier Parameters."
- "Low-Cost Two-Chip Voltage-Controlled Amplifier and Video Switch."
- "Using the AD9610 Transimpedance Amplifier."

D/A Converters:
- "AD7528 Dual 8-Bit CMOS DAC Application Note."
- "Analog Panning Circuits Provide Almost Constant Output Power."
- "Bipolar Operation with the AD7572."
- "Circuit Applications of the AD7226 Quad CMOS DAC."
- "CMOS D/A Converter Circuits for +5-Volt Supplies."
- "CMOS DACs and Operational Amplifiers Combine to Build Programmable-Gain Amplifiers."
- "Eighth Order Programmable Low-Pass Analog Filter Using Dual 12-Bit DACs."
- "Gain, Error, and Tempco of CMOS Multiplying DACs."
- "Generate 4 Channels of Analog Output Using AD7542 12-Bit D/A Converters and Control the Lot with Only Two Wires."
- "How to Obtain the Best Performance from the AD7572."
- "Interfacing the AD7549 Dual 12-Bit DAC to the MCS-48 and MCS-51 Microcomputer Families."
- "Simple DAC-Based Circuit Implements Constant Linear Velocity (CLV) Motor Speed Control."
- "Simple Interface Between D/A Converter and Microcomputer Leads to Programmable Sine-Wave Oscillator."
- "The AD7224 DAC Provides Programmable Voltages Over Varying Ranges."
- "Three-Phase Sine Wave Generation Using the AD7226 Quad DAC."

Digital Signal-Processing (Note: Four additional DSP Application Notes will be found in the *1989 DSP Products Databook*):
- "Considerations for Selecting a DSP Processor." (ADSP-2100A vs. TMS320C25)
- "Implement a Cache Memory in Your Word-Slice® System."
- "Implement a Writeable Control Store in Your Word-Slice® System."
- "Loading an ADSP-2101 Program via the Serial Port."
- "Sharing the Output Bus of the ADSP-1401 Microprogram Sequencer."

"Variable-Width Bit Reversing with the ADSP-1410 Address Generator."

Resolver-to-Digital Conversion:

"Circuit Applications of the 2S81 and 2S80 Resolver-to-Digital Converters."

"Dynamic Characteristics of Tracking Converters."

"Dynamic Resolution-Switching on the 1S74 Resolver-to-Digital Converter."

"Why the Velocity Output of the 1S74 and 1S64 Series R/D Converters Is Continuous and Step-Free Down to Zero Speed."

Sample-Holds:

"Applying IC Sample-Hold Amplifiers."

"Generate 4 Channels of Analog Output Using AD7542 12-Bit D/A Converters and Control It All with Only Two Wires."

Switches:

"ADG201A/202A and ADG221/222 Performance with Reduced Power Supplies."

"Overvoltage Protection for the ADG5XXA Multiplexer Series."

Temperature Measurement:

"A Cost-Effective Approach to Thermocouple Interfacing in Industrial Systems."

"Use of the AD590 Temperature Transducer in a Remote Sensing Application."

V/F Converters:

"Analog-to-Digital Conversion Using Voltage-to-Frequency Converters (AD651)."

"Operation and Applications of the AD654 IC V-to-F Converter."

Video Applications:

"Changing Your VGA Design from a 171/176 to an ADV471."

"Improved PCB Layouts for Video RAM-DACs Can Use Either PLCC or DIP Package Types."

"The AD9502 Video Signal Digitizer and Its Application."

"Video Formats & Required Load Terminations."

Application Guides.

Analog CMOS Switches and Multiplexers. A 16-page short-form guide to high-speed CMOS switches, CMOS switches with dielectric isolation and CMOS multiplexers. Also included are reliability data and information on single-supply operation.

Applications Guide for Isolation Amplifiers and Signal Conditioners. A 20-page guide to specifications and applications of galvanically isolated amplifiers and signal conditioners for industrial, instrumentation and medical applications.

CMOS DAC Application Guide 3rd Edition by Phil Burton (1989—64 pages). Introduction to CMOS DACs, Inside CMOS DACs, Basic Application Circuits in Current-Steering Mode, Single-Supply Operation Using Voltage-Switching Mode, The Logic Interface, Applications.

ESD Prevention Manual – Protecting ICs from electrostatic discharges. Thirty pages of information that will assist the reader in implementing an appropriate and effective program to assure protection against electrostatic discharge (ESD) failures.

High-Speed Data Conversion – A 24-page short-form guide to video and other high-speed A/D and D/A converters and accessories, in forms ranging from monolithic ICs to card-level products.

RMS-to-DC Conversion Application Guide 2nd Edition by C. Kitchin and L. Counts (1986—61 pages). RMS-DC Conversion: Theory, Basic Design Considerations; RMS Application Circuits; Testing Critical Parameters; Input Buffer Amplifier Requirements; Programs for Computing Errors, Ripple and Settling Time.

Surface Mount IC—A 28 page guide to ICs in SO and PLCC packages. Products include op amps, rms-to-dc converters, DACs, ADCs, VFCs, sample-holds and CMOS switches.

DSP MANUALS

Available at no charge for single copies; write on letterhead.

ADSP-2100 Family Support Publications—for the ADSP-2100 and ADSP-2101 single-chip signal processors.

ADSP-2100 USER'S MANUAL. Introduction, Computational Units, Data Moves, Program Control, System Interface, Instruction Set Overview, Appendixes. 162 pages.

ADSP-2100 CROSS-SOFTWARE MANUAL. Overview, System Builder, Assembler, Linker, Simulator, PROM Splitter, C Compiler, Instruction Set Overview, Appendixes. 240 pages plus Programmer's Reference Card.

ADSP-2100 EMULATOR MANUAL. Overview, Installation, Configuration, Operation, Development Examples, Trace Buffer, Appendixes. 144 pages.

ADSP-2100 EVALUATION BOARD MANUAL. Overview; Installation; Configuration; Operation; Analog Interface; Prototyping Connector; Demonstration Programs; Appendixes: Specification, Replacing Hardware, Terminal Emulation, Memory Expansion, Demo Disk, Schematics/Data Sheets. 156 pages.

ADSP-2101 USER'S MANUAL—Architecture. Introduction, Computational Units, Data Moves, Program Control, Timer, Serial Ports, System Interface, Memory Interface, Instruction Set Overview, Appendixes. 184 pages.

ADSP-2100 FAMILY APPLICATIONS HANDBOOK, Volume 1. Introduction, Fixed-Point Arithmetic, Floating-Point Arithmetic, Fixed-Coefficient Digital Filters, FFTs, Adaptive Filters, Image Processing, Linear Predictive Speech Coding, High-Speed Modem Algorithms, Bibliography. 178 pages.

ADSP-2100 FAMILY APPLICATIONS HANDBOOK, Volume 2. Overview, Graphics, Multirate Filters, PCM, ADPCM, Dual-Tone Multi-Frequency (DTMF). 248 pages.

ADSP-2100 FAMILY APPLICATIONS HANDBOOK, Volume 3. Introduction, Fast Fourier Transforms, Memory Interface, Multiprocessing, Host Interface, Sonar Beamforming. 168 pages.

Word-Slice User's Manual (ADSP-1401/ ADSP-1402 Program Sequencers and ADSP-1410 Address Generator). Introduction; Program Sequencers: Internal Architecture, Jumps, Interrupt Processing, System Interface, Instruction Set; ADSP-1410: Internal Architecture, Addressing Operations, Precision Modes, System Interface, Instruction Set. 218 pages.

Technical Publications

TECHNICAL REFERENCE BOOKS—Can be purchased from Analog Devices, Inc.; send check for indicated amount to One Technology Way, P.O. Box 796, Norwood, MA 02062. If more than one book is ordered, deduct a discount of $1 from the price of each book. VISA accepted; phone (617) 461-3392.

ANALOG-DIGITAL CONVERSION HANDBOOK: Third Edition, by the Engineering Staff of Analog Devices, edited by Daniel H. Sheingold. Englewood Cliffs, NJ: Prentice-Hall (1986). A comprehensive guide to A/D and D/A converters and their applications. This third edition of our classic is in hard-cover and has more than 700 pages, an Index, a Bibliography, and much new material, including: video-speed, synchro-resolver, V/F, high-resolution, and logarithmic converters, ICs for DSP, and a "Guide for the Troubled." Seven of its 22 chapters are totally new. $32.95

NEW–DIGITAL SIGNAL PROCESSING IN VLSI, by Richard J. Higgins. Englewood Cliffs NJ: Prentice-Hall (1990). An introductory 614-page guide for the engineer and scientist who needs to understand and use DSP algorithms and special-purpose DSP hardware ICs—and the software tools developed to carry them out efficiently. Real-World Signal Processing; Sampled Signals and Systems; The DFT and the FFT Algorithm; Digital Filters; The Bridge to VLSI; Real DSP Hardware; Software Development for the DSP System; DSP Applications; plus Bibliography and Index. $38.00

NONLINEAR CIRCUITS HANDBOOK: Designing with Analog Function Modules and ICs, by the Engineering Staff of Analog Devices, edited by Daniel H. Sheingold. Norwood MA: Analog Devices, Inc. (1974). A 540-page guide to multiplying and dividing, squaring and rooting, rms-to-dc conversion, and multifunction devices. Principles, circuitry, performance, specifications, testing, and application of these devices–Contains 325 illustrations. $5.95

SYNCHRO & RESOLVER CONVERSION, edited by Geoff Boyes. Norwood, MA; Analog Devices, Inc. (1980). Principles and practice of interfacing synchros, resolvers, and Inductosyns* to digital and analog circuitry. $11.50

TRANSDUCER INTERFACING HANDBOOK: A Guide to Analog Signal Conditioning, edited by Daniel H. Sheingold. Norwood MA: Analog Devices, Inc. (1980). A book for the electronic engineer who must interface transducers for temperature, pressure, force, level, or flow to electronics, these 260 pages tell how transducers work—as circuit elements—and how to connect them to electronic circuits for effective processing of their signals. $14.50
