- RENAME now permits changing any or all of the qualifiers of a data set name during data set restore of non-VSAM data sets.
- RENAMEUNCONDITIONAL permits the restoration of data sets under a new name regardless of whether or not they previously existed on the target volume. Applies to non-VSAM data sets only.
- Additional filtering capability permits selection of data sets based on data set organization (DSORG), type of space allocation (cylinder, track, block or absolute track), and relative date (creation, expiration and last reference). The last reference relative date does not apply to VS1.

- A new NORUN parameter provides the ability to calculate the fragmentation index and list the data sets selected by the filter without actually executing a dump, restore or defragmentation.
- The FRAGMENTATIONINDEX parameter allows the setting of a threshold below which defragmentation will not be executed on the volume.
- A new WORKSIZE parameter permits the defragmentation of volumes with more data sets or extents than previously possible.
- Tracks can now be copied or restored to a volume in use.
- The TOLERATE(IOERROR) parameter now permits certain types of permanent input errors, allowing copy and dump to continue without termination.
- Cylinder-allocated data sets whose extents do not fall on a cylinder boundary will now be processed by DEFRAG.
- A user authorization exit now permits checking authorized use of Integrated Catalog Facility VSAM and non-VSAM password- or RACF-protected data sets.
- In conjunction with the Authorized Program Facility of the operating system, DFDSS permits the bypassing of RACF and password checking.

Previously announced functions for DFDSS are as follows:

Data Facility Data Set Services is a new utility with the following functions:

A DUMP statement allows dumping of data from DASD or MSS virtual volumes to tape, or to a data set on another DASD or MSS. A full volume, one or more data sets (from one or more volumes), or selected tracks may be dumped. Data sets, once they have been dumped may, optionally, be deleted. A data compress option is available to save space on the Dump Tape (or data set).

A RESTORE statement causes a previously created dump data set to be copied back onto a DASD device of the same type. Specific tracks or data sets may be restored even though the dump was taken for a full volume or multiple data sets. Data sets may, optionally, be renamed during the restore operation.

A DEFRAG control statement allows complete or partial consolidation of the fragmented free space on a volume. No additional devices, neither tape nor disk, are required for a DEFRAG.

A COPY statement copies a full volume or selected tracks between volumes of the same device type.

The COPYDUMP function copies the contents of a dump tape (or data set) onto one or more new tapes (or data sets) to provide multiple copies.

A PRINT statement supports printing of selected tracks, a selected data set or the VTOC.

Under OS/VS2 (MVS) dynamic allocation may be used to ease direct access storage device scheduling.

Data Set Filtering allows selection of data sets, based on specified criteria, during a dump, restore or DEFRAG operation. The criteria allowed are partially qualified data set names, creation date, expiration date, last referenced date and data set changed indicator (MVS only). The selection is by inclusion or exclusion for Dump and Restore, and by exclusion for DEFRAG.

Stand-alone restore provides full restore from a full volume dump tape or partial restore from a full volume, partial volume or data set dump tape. Stand-alone restore of dump tapes produced with compress option is not supported.

A User Installation exit will be provided to allow the customer to override DFDSS options selected by an individual user. This exit provides the customer with an opportunity to control and override user options before execution. For example, a user selection of optimization could be overridden by the customer via this exit.

Data Facility Data Set Services Release 1 control statements use Access Method Services syntax.

CUSTOMER RESPONSIBILITIES

Customers are responsible for ordering and installing Data Facility Data Set Services Release 2 and any prerequisite programs

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

Data Facility Data Set Services is designed to operate on any IBM processor using OS/VS1 Release 7, OS/VS2 Release 3.8, MVS/System Extensions, MVS/System Product, or MVS/XA and has the same constraints as these SCPs and BCPs.

PROGRAM PRODUCTS

Data Facility Data Set Services Release 2
Performance Improvement

Data Facility Data Set Services (cont'd)

Data Facility Data Set Services is a DASD Dump, Restore, and Defrag program that uses DASD, tape drives and unit record devices.

SOFTWARE REQUIREMENTS

Data Facility Data Set Services is designed to operate with OS/VS1 Release 7, OS/VS1 Basic Programming Extensions, or OS/VS2 Release 3.8 and all subsequent releases including System Extensions and System Product, and MVS/XA, unless otherwise stated.

Users of the IBM 3380 require the functions provided by OS/MVS Data Facility/Device Support (5740-AM7), MVS/370 Data Facility Product (5665-295) or MVS/XA Data Facility Product (5665-284). Users of the IBM 3375 must have the functions provided by either the programs listed above, or by OS/VS1 Data Facility/Device Support (5740-AM6).

The IBM 3380 and 3375 must be initialized by the Device Support Facilities utility of either the applicable operating system, the stand-alone program (5747-DS1), or equivalent.

Users wishing to use the Integrated Catalog Facility VSAM data set support in DFDSS Release 2 require the functions provided by MVS/370 Data Facility Product (5665-295).

COMPATIBILITY

Data Facility Data Set Services Release 2 is a complete replacement for all previous releases of DFDSS and is upward compatible for all prior functions.

DFDSS Releases 1, 1.1 and 1.2 cannot restore from dump tapes created by Release 2.

Data Facility Data Set Services Release 2 cannot restore by data set the Data Facility Extended Function cataloged VSAM data sets from dump tapes created by Releases 1, 1.1 or 1.2.

The PURGE keyword in a data set restore has been replaced by the REPLACE keyword. The PURGE keyword is still supported and has the same meaning as before.

CONVERSION

Data Facility/Data Set Services uses Access Method Services syntax for its control statements. Users of IEHDASDR and the DASDR licensed program (5740-UT1) will be required to alter control statements of existing job steps to run with Data Facility/Data Set Services.

SECURITY

Data Facility Data Set Services Release 2 complies with and conforms to the data security and auditability controls of the systems it supports. The target or source data may be either RACF- or password-protected, which would require a user to be RACF-authorized or to supply the password. User management is responsible for evaluating, selecting, applying and implementing such features, and for the appropriate administrative and application controls.

PERFORMANCE

Measurements of MVS test environments have shown that Data Facility/Data Set Services can provide significant reductions in processor and elapsed time for full volume dumps, when compared to DASDR (5740-UT1). These improvements are summarized below:

Data Facility Data Set Services
Performance Improvement

From Device	Processor Time	Elapsed Time
3330-11	18 %	21 %
3350	26 %	28 %

These estimates are based on measurements performed on a 3031 Processor running a single region of OS/VS2(MVS) with a pre-release version of Data Facility/Data Set Services installed. Test volumes of composite average data sets (as described at GUIDE 47, Fall 1978) were used on the specified DASD, dumping to a 3420 Magnetic Tape Unit mdl 6. Performance Option 1, which uses equivalent resources and logic to that of DASDR, was specified. Data Facility/Data Set Services defaults to dump only the used portion of SAM and PAM allocated space.

This performance data is derived from a select set of test cases and is given for information purposes only. There is no warranty or guarantee that the same performance characteristics will apply to other users or system configurations. Actual performance improvements are dependent on many factors, including volume contents and organization, user specifications of performance options and the devices involved.

Further measurements of MVS test environments have shown that DFDSS Release 2 can provide significant reductions in processor and elapsed time for both dumping and restoring VSAM data sets when compared to EXPORT/IMPORT. These improvements are summarized below:

	Processor Time	Elapsed Time
DUMP (option 1) versus EXPORT	600 %	200 %
DUMP (option 4) versus EXPORT	700 %	200 %
RESTORE versus IMPORT	600 %	800 %

Note: DFDSS DUMP/RESTORE is not a total functional replacement for EXPORT/IMPORT in all circumstances.

These estimates were based on measurements performed using the 3380 DASD and the 3420-6 Tape Units on a 3031 Processor running a single region of OS/VS2 MVS with a pre-release version of Data Facility Data Set Services Release 2 installed. Test data included VSAM data sets of various types, containing differing numbers of records and record sizes.

SYSTEM/370 ENERGY MANAGEMENT SYSTEM 5740-U11

PURPOSE

The S/370 Energy Management System provides the Electric Utility Industry with a modular set of supervisory and application programs to aid in the control of medium to large power networks.

DESCRIPTION

The S/370 Energy Management System is designed to provide host processor logic in a hierarchy of processors serving an electric utility company at the regional, system, or pool operating center level. The S/370 Energy Management System communicates with and through S/7(s) to IBM 3707 Remote Data Acquisition and Control Stations, the basic data gathering device. The processing load is performed by the online host S/370; data acquisition and power device control functions are performed by the S/7(s) on command from the host.

Major functions provided include:

Data Acquisition -- Retrieves data from the power network, converts this information to standard engineering units, provides limit checking and status monitoring.

Supervisory Control -- Central point of network control. Network status and alarm conditions detected by the data acquisition routines can be displayed for operator action. Control actions to activate power system devices are accepted and verified, then forwarded through the network to the proper destination. Original data base parameters describing the points being measured within the power network can be varied by a system operator, given the proper security authorization.

Load Frequency Control (LFC) -- Power network performance data, in conjunction with user-supplied parameters, is used to compute power requirements necessary to supply the system frequency and tie-line loadings. LFC can be suspended by the operator, or can operate in one of three selectable modes:

- Flat frequency - maintenance of scheduled frequency, tie-line obligation ignored.
- Flat tie-line maintenance of tie-line obligation, frequency deviations ignored.
- Tie-line bias control - deviations from both tie-line obligations and scheduled frequency received balanced consideration.

Economic Dispatch Control -- Computes each generating unit participation to economically deliver the load to distribution points. Generation unit capacity, fuel and operational costs, line losses, and interchange obligations are considered for either all units under control of the LFC program module or all units within the power system.

HIGHLIGHTS

Utilizes the IBM 5985 mdl H02 Color Display Control Unit (3456 character positions, 127 program changeable character set, seven colors, alphanumeric keyboard, up to 48 special function keys).

- Configuration options covering a range of power network sizes ranging from a minimum system consisting of a single S/370 and S/7, to a duplexed S/370 network supporting two levels of system control lower than that performing the major monitoring function.
- Offline system preparation functions, including data base and display compilers.
- Control hierarchy time synchronization.
- Logging of events, alarms, and historical data.
- Support for stripchart recording, and audible alarms.

CUSTOMER RESPONSIBILITIES

- Management and control of the Power System.
- Understanding the utility network and the desired control strategy.
- Selecting and preparing an appropriate equipment site.
- Selecting of S/7 and S/370 options and parameters to tailor the system to the user's environment.
- Providing data set contents for defining initial values, limits and other control parameters.
- Ordering and installing required system control programs, program products, and PRPQs.
- Initiating orders for required computer and terminal equipment needed in the system.
- Installing all required instrumentation and common carrier facilities to meet minimum equipment requirements.
- Designing and implementation of any specialized application programs and display formats required.
- Training of personnel.

- Insuring accuracy of initial data, network, and real-time sensor data input definitions.
- Insuring that the completed System contains all reasonable check points and controls to maintain the power system integrity and the desired level of service and availability.
- Reviewing S/370 Energy Management System security and restart facilities to select those appropriate for the protection of the power network.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The diversity of electric power networks capable of being served by the S/370 Energy Management System require that configuration assistance (available through the Energy Management Systems Center), be used in the decisions required to select hardware and programming options. Typical systems are shown as a guideline:

For compilation: A S/370 mdl 135 I (524,288 bytes), and appropriate system console, input, output, residence, and data sets as outlined in the Sales Manual under the heading "Operating System/Virtual Storage 1".

Typical System: A S/370 mdl 145 I (524,288 bytes), (including one byte multiplexer channel, two block multiplexer channels, and floating point). The configuration must include sufficient I/O devices to support the requirements for system output, system residence, and system data sets. Sufficient direct access storage must be provided to satisfy user information storage requirements. Direct access devices may be chosen from a 3333 Disk Storage and Control (Integrated), a 3330 Disk Storage Facility, or a 3340 Direct Access Storage Facility (or combinations).

The system requires a S/7 processor for power system local and remote data acquisition and control. This system must be attached to the host S/370 via the Channel Attachment feature (RPQ D08112).

Also required in the minimum configuration is an IBM 5985-H02 Color Display Control Unit (RPQ Y94176), an IBM 5941-H02 Display Console (RPQ 7H0014), Channel Adapter to attach to the S/370 (RPQ Y94177) and customer-supplied color TV monitors.

Distribution and support of S/370 Energy Management System require the availability of one 9-track tape drive.

SOFTWARE REQUIREMENTS

Special Real-Time Operating System (PRPQ 5799-AHE), Display Management System (PRPQ 5799-AFD), and S/7 Energy Management System (5707-U11) are all prerequisites to the installation of a S/370 Energy Management System.

The program product runs in an OS/VS1 Release 4 environment on S/370. OS/VS1 (5741-VS1) must therefore be already installed, or ordered together with the products already discussed in this section. Program product modules are written in S/370 Assembler language, Access method used are EXCP, BDAM, QSAM and BTAM.

S/370 Energy Management System is not supported under VM/370.

DEVELOPMENT MANAGEMENT SYSTEM/CICS/VS
RELEASE 4
DMS/CICS/VS-OS (5740-XC5)
DMS/CICS/VS-DOS (5746-XC4)

PURPOSE

Development Management System/CICS/VS (DMS/CICS/VS) is an advanced application generator designed to simplify the implementation of interactive data processing applications. The preprogrammed display management, file and data base management, and message handling facilities of DMS/CICS/VS make it possible to implement online applications with little or no traditional programming. DMS/CICS/VS does this by providing preprogrammed facilities that perform functions that are common to most online applications such as: Screen and function selection, screen display, multi-screen paging, and message routing between display stations. Preprogrammed data base and file functions for searching, browsing, inquiring, data entry, record adding and updating are provided as well as other functions that regularly appear in online programs.

PRODUCT OVERVIEW

DMS/CICS/VS applications are defined non-procedurally using the interactive Application Generation facilities. Application developers describe their data files and records, display screen images, and application processing logic using DMS/CICS/VS interactive development dialogs. DMS/CICS/VS 'programming' is done using a fill-in-the-blanks technique that encourages the application developer to concentrate on what the application should do, not how a program is supposed to do it. For example, at the same time the display screen data fields are defined, the data editing and validation requirements are specified. These editing and validation requirements are specified using a menu selection technique rather than procedural code such as COBOL. This approach reduces errors and the time normally required for coding. This fill-in-the-blanks approach is used throughout the application definition process, making it possible to achieve much higher levels of productivity than possible using traditional programming techniques. Furthermore, the preprogrammed facilities of DMS/CICS/VS create a design structure for online applications that can reduce the time spent on this key part of application development.

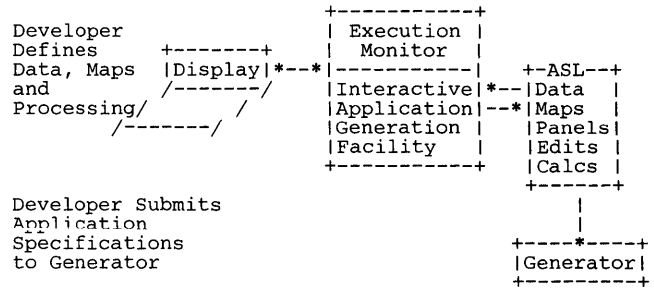

DMS/CICS/VS has a repository for application specifications. Because of this facility, components of previously developed applications may be easily reused in a new application. In addition, it is a simple process to develop a set of application 'models' that can be easily modified for new applications that have a similar structure. This technique is especially useful for new and inexperienced programmers. It allows them to create a new application effectively by simply copying and modifying prior work.

For those parts of applications where the supplied functions do not precisely fit the need, DMS/CICS/VS offers a simple calculation language. These calculation/edit statements may be used to specify arithmetic operations, multi-field data editing and movement of data between fields. They may also be used to alter the normal flow of the application. While the calculation language makes it possible to fully develop many online applications, DMS/CICS/VS also provides an interface to other traditional programming language programs via a calc/edit 'CALL' statement.

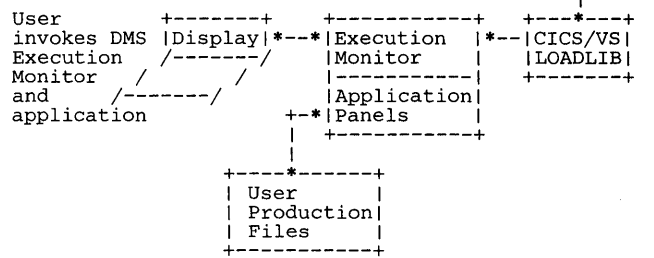

The DMS/CICS/VS product consists of two pieces, an execution-time monitor that contains the precompiled facilities, and an Interactive Application Generation Facility (IAG) that allows the application to be defined.

In the diagram that follows, it can be seen that as the DMS/CICS/VS application is defined, the specifications are placed in the Application Specification Library (ASL). When the specifications are complete, they are processed through a generator. This step prepares the application for execution in a production environment.

APPLICATION DEVELOPMENT ENVIRONMENT

PRODUCTION ENVIRONMENT

In addition to creating data definitions initially using IAG dialogs, DMS/CICS/VS also provides an IBM Data Dictionary extraction utility. This utility uses the dictionary Program Access Facility to read data base definitions out of the dictionary and place them into a format in which they can be directly loaded onto the ASL. When loaded to the ASL, they can be marked as read-only so that consistency between the ASL and Data Dictionary will be maintained.

HIGHLIGHTS

- The DMS/CICS/VS Application Generation feature allows the application designer to specify application requirements using either an Interactive Application Generator (IAG) or the forms base application generation capability.
 - The Panel Description Form defines the data which specifies the processing sequence of operator responses, the routing of messages, the location of static fields on a display panel and the location and type of the variable display fields. In addition, calculation/edit statements are used to perform simple arithmetic operations, permit data editing and permit altering of the DMS/CICS/VS processing flow without the necessity of coding user exits.
 - The File Description Form describes a file or group of files and the format of the records in the file.
 - The Data Transfer Form specifies the files and fields involved and the operations performed for batch functions such as file-to-file update or initial file load from existing user files.
 - The Interactive Application Generation Facility provides for data, panel and application definition and has the capability to provide clarification and explanations of functions that may not be understood by the user.
- Flexible panel definition provides:
 - Referencing as many as four data bases or files by each panel for data entry, inquiry or update.
 - Control of field mode. For example, selected fields of records being updated can be displayed in protected mode, preventing their modification by the operator.
 - Chained supervisor functions. DMS/CICS/VS operations may be combined to avoid the need for several operator responses to perform a set of functions with a single logical purpose.
 - Communication fields for interpanel communication with DMS/CICS/VS. Data can be passed between a series of related panels. This information can be prespecified in the panel description, entered by the operator or entered by a user-written program. Communication fields also provide a convenient interface to user data-editing routines.
 - Field level functions. Functions available at the data field level include dollar edit, code conversion and user exit programs.

DMS/CICS/VS R4 (cont'd)

Data field initialization. Data entry fields may be initialized by input from the panel description form, file data or communication field data.

- Extensive 3270 Information Display Station support:

Screen sizes supported are: 480, 960, 1,920, 2,560, 3,440. The IAG does not support the 480 screen size.

All 3270 field attributes are supported.

Minimum data transmission. Only fields which are modified are transmitted from the display to the central processing unit. Nulls are not transmitted.

Program function key support. Use of a program function key is interpreted as an operator response and can be controlled by the panel designer. Up to 24 program function keys can be supported.

Selector light-pen support. Detectable fields may be used for control function selection or multiple key selection.

Numeric lock feature support. Data entry fields may be defined as numeric, causing the keyboard to lock when an attempt is made to enter a nonnumeric character.

Audible alarm support. The alarm may be sounded when a specified panel is displayed.

- Operator identification card reader support. Up to 37 data characters may be entered using the magnetic card reader.
- Images or messages can be routed from one display station to another display station or to a 3284/3286 or 3287/3289 Printer. Transactions can be logged into a sequential data set for subsequent online or offline processing.
- Application security through use of CICS/VS and DMS/CICS/VS signon procedures can be used to control operator access to predetermined applications.
- Ability to hold records for update across multiple panels, both files and data bases are supported.
- Three data integrity options. A DMS-only option provides data integrity for files that are unique to the DMS/CICS/VS environment, preventing simultaneous update of the same data, while allowing read-only inquiries to take place. System Data Integrity is an option which provides data integrity at the CICS/VS subsystem level, offering protection for files shared by DMS and non-DMS applications. The third option uses a Save and Compare technique which provides system-wide data integrity without the necessity of maintaining CICS/VS or DL/I locks on the data being updated.
- User program exits before and after execution of DMS/CICS/VS file and data routing operations. This permits an extension of the calculation/edit capabilities for unique application dependent editing and cross-checking of data prior to its incorporation into data bases, files or display at the 3275/77 or 3276/78 Display Station. These exit points are also available to perform calculation/edit operations.
- Formatted Data Facility allows the user to perform editing, calculations and application logic in a user exit by symbolic rather than physical reference to data fields. This is allowed immediately before a panel is displayed or immediately after a response is entered. The facility can be used with COBOL, PL/I, RPG II or Assembler language to simplify the use of user exits.
- Search capabilities using generic arguments to produce a list of keys or records. The list may be routed to a 3275/77 or 3276/78 Display Station or a CICS/VS transient data destination.
- Extensive file support.

Support is provided for grouped DMS/CICS/VS files, key-sequenced VSAM files, indexed sequential files and sequential files. All files are supported in fixed length record format. The intersystem communication facility is also supported.

Group files allow single logical files to be specified as a group of multiple physical files, making access to the files more efficient and providing for a soft fail capability. If one physical file becomes inoperative, it can be taken offline and restored without affecting the operation of the remaining physical files in the group.

Batch facilities are provided for single key-sequenced VSAM files.

- DL/I Data Base Facility:

Supports the CICS implementation of IMS/VS (DB) and DL/I DOS/VS for:

- Inquiry - Single, multiple or repeated segments and repeated segments within repeated segments (\$RPT within \$RPT).
- Insertion - Single, multiple or repeated segments.
- Update - Single or multiple segments and repeated dependent segments.

- Deletion - Single or multiple segments, or by group.

Access to DL/I data bases from secondary indexes is permitted.

Subscreens of data (windows) can be defined to contain repetitive occurrences of DL/I segments. These panels can be paged until all occurrences of these segments have been displayed. The number of segments to be displayed or number of pages to be displayed can be dynamically selected by the operator.

The user can also selectively access all occurrences that match specified keys or qualification statements.

Both fixed and variable length records are supported.

CUSTOMER RESPONSIBILITIES

The user should become thoroughly familiar with both the operating system and the Customer Information Control System (CICS), before beginning to plan for and install the Development Management System/CICS/VS. In order to install DMS/CICS/VS and its facilities to implement online applications, the user must first:

1. Install all required communication equipment (display stations, control units, modems, transmission control units).
2. Generate a CICS/VS system in accordance with his system configuration and installation requirements.
3. Generate optional data base and data dictionary systems in accordance with his system configuration and installation requirements.
4. Select DMS/CICS/VS system generation options and link-edit the options program module.
5. Define record layouts for all files to be accessed by DMS/CICS/VS during either interactive or batch operation.
6. Define layouts and hierarchies for all data bases to be accessed by DMS/CICS/VS during either interactive or batch operation.
7. Describe the application.
8. Describe data transfer operations required for the application.
9. Generate file, index, panel and data transfer specifications using DMS/CICS/VS application generation programs.
10. Generate interface DBDs for data base accessing. Optionally, the DB/DC Dictionary can be used to generate these DMS/DBDs.
11. Add DMS/CICS/VS and user program names, user-defined panel names, data file descriptions, and data base descriptions to CICS/VS tables.
12. Provide for the backup of online files by:
 - Establishing a procedure for copying files at periodic intervals.
 - Using CICS/VS automatic file journaling facility for DMS/CICS/VS.

Once the system is operational, only the procedures in step 12 must be performed on a regular basis. For implementing new applications or additional modifications of existing applications, the appropriate combination of steps 5 through 11 must be performed. The IAG will assist in steps 5, 6, and 7.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The machine configuration for the Development Management System/CICS/VS varies according to the user's application needs. The requirement for operation under CICS/VS is any IBM S/370, IBM 303X Processor or IBM System 4300 with enough real storage to meet the combined operating requirements of CICS/VS, the host operating system, the appropriate access methods and other user required applications. CICS/VS machine options and storage requirements are discussed in the *CICS/VS General Information Manual*.

Sufficient I/O devices must be included to support the requirements for system input, system output, system residence and system data sets. Also included must be sufficient direct access storage devices to satisfy user information storage requirements. A magnetic tape unit (9-track) must be available for program distribution and maintenance.

At least one 3275/3277 or 3276/3278 Display Station (local or remote) must be included in all configurations.

The system supports the following terminals; only those features mentioned are supported.

- 3178
- 3271 mdls 1, 2, 11, 12
- 3272 mdls 1, 2
- 3274 mdls 1A, 1B, 1C, 1D, 51C, (SNA or BSC)
- 3275 mdls 1, 2, 11, 12
- 3276 mdls 1, 2, 3, 4, 11, 12, 13, 14
- 3277 mdls 1, 2
- 3278 mdls 1, 2, 3, 4
- 3279 mdls 2A, 2B, 3A, 3B (base color mode)

PROGRAM PRODUCTS
DMS/CICS/VS R4 (cont'd)

- 3284 mdls 1, 2
- 3286 mdls 1, 2
- 3287 mdls 1, 2. 1C, 2C (black and white only)
- 3288 mdl 2
- 3289 mdls 1, 2
- 3290 (3270 compatibility mode)
- 3790 DSC Mode (3790 Configuration Support #9165)
- 8775 mdls 11, 12 (in 3270 compatibility mode)
- 3270 options as follows:
 - EBCDIC Transmission Code (#9761)
 - ASCII Transmission Code (#9762)
 - Keyboard Numeric lock (#4690)
 - Selector Light-Pen (#6350)
 - Audible Alarm (#1090)
 - Operator Identification (#4600)

The appropriate telecommunication control units and line adapters must be included in the configuration. Use of a printer with the PL/I (SC) character set is recommended for printing application generation output.

SOFTWARE REQUIREMENTS

DMS/CICS/VS is written in S/370 Assembler language and operates under the control of the currently supported version(s) of CICS/VS, and subsequent releases unless otherwise stated in future revisions of this document. The programming system requirements for DMS/CICS/VS are the same as those for CICS/VS.

Product	DOS/VSE	VS1	MVS
	Component ID	Component ID	Component ID
VSAM	5746-SC-VSM	5741-SC-1DE	5752-SC-1DE
DAM		5741-SC-1D7	5752-SC-1D7
ISAM		5741-SC-1D8	5752-SC-1D8
DL/I	5746-XX-1		
IMS/DB		5740-XX-2	5740-XX-2
DB/DC Data Dictionary	5746-XX-C	5740-XX-F	5740-XX-F

CICS/OS/VS (5740-XX1) operates under the IBM Operating System (OS/VS1 or OS/VS2). See the *CICS/VS General Information Manual* for the required programming system components.

CICS/DOS/VS (5746-XX3) operates under the IBM Disk Operating System (DOS/VS and DOS/VSE). See the *CICS/VS General Information Manual* for the required programming system components.

STORAGE REQUIREMENTS

The following are estimates which may be used for planning purposes only to determine virtual storage requirements in the online processing environment. They do not include storage for the operating system, DL/I, other CICS/VS applications running concurrently with DMS/CICS/VS in the same partition or for the CICS/VS modules and tables required to support DMS/CICS/VS.

	10-Terminal System		Additional Bytes Per Unit
	DOS/VSE	OS/VS	
DMS/CICS/VS			1000/900
Trans. Work Areas	10,000	9,000	per terminal
DMS/CICS/VS			
Online Supervisor	9,000	8,500	
DMS/CICS/VS			
loadable modules	81,000	78,000	
Transmission line buffer	2,000	2,000	2,000/line
DMS/CICS/VS terminal working storage	81,000	78,000	
	117,000	112,500	

DMS/CICS/VS uses the task control, storage control, program control, terminal control, file control transient data, temporary storage and dump control facilities of CICS/VS. In addition, space must be available for CICS/VS tables and transaction control areas (TCAs). Each DMS/CICS/VS panel requires an entry in the processing program table (PPT). In addition, for each terminal there are normally two entries in the destination control table (DCT). The temporary storage auxiliary table size should be increased by about ten entries per terminal (more if extensive use of the online file search function of DMS/CICS/VS is anticipated).

DL/I requires the following dynamic storage during the time a given panel is accessing a DL/I data base:

- 500 bytes
- plus
- the sum of segment lengths in the Data Base Description (DBD)
- plus
- 178 bytes for each segment card on the panel description form (including the one generated for the root segment)

Additional storage must be allowed for record I/O buffers, access methods, and user code. Users must study their applications to determine the amount of additional storage required, based on the size of buffers and the number of terminals that may require I/O areas concurrently.

The transmission line buffer size depends on the type of 3270 devices attached to the line. Typically, about 1,500 bytes of working storage per terminal are required for DMS/CICS/VS. This amount is dependent on screen size and the complexity of the user's applications.

The performance of programs in a virtual storage environment is highly dependent on the system resources available, the programs that operate concurrently and system and application data set placement. For improved online performance, adequate real resources (main storage, processor computing capability, channels, direct access devices, etc.) must be available. For planning purposes, the following estimates of real storage requirements for DMS/CICS/VS may be used.

	Bytes
DMS/CICS/VS online supervisor	4,000
DMS/CICS/VS loadable modules	26,000
Transmission line buffers	2,000/line

DL/I and CICS/VS modules and tables, access methods and variable dynamic storage impose additional real storage requirements.

RPOs ACCEPTED: No

**MVS/SYSTEM EXTENSIONS
5740-XE1**

DESCRIPTION

MVS/System Extensions is an enhancement to MVS offering increased performance (through control program improvements) and installation management and control enhancements to MVS users. The Program Product is available for the IBM 3031, 3032 and 3033 Processors, and for the S/370 mdl 158 and 168 processors with the S/370 Extended Feature installed.

Release 1, Modification Level 1 (R1.1) of the MVS/System Extensions provides performance enhancements and some control improvements. Release 2, Modification Level 0 (R2.0) of the MVS/System Extensions replaces Release 1 and maintains its performance and control enhancements. In addition, Release 2 makes new installation management functions available in the SMF, SRM and operator-message handling areas.

Performance Improvements

MVS/System Extensions R1.0 test measurements have been completed on the S/370 158, 168, 3031, 3032 and 3033 processors.

The following results have been obtained comparing MVS Release 3.7 with MVS/System Extensions R1.0 to MVS Release 3.7 without MVS/System Extensions. Both systems include SUs 4, 5, 7 and the other SU prerequisites for MVS/System Extensions R1.0:

- Supervisor state execution time reductions ranging from 20 percent to 27 percent.
- Uniprocessor throughput improvements ranging from 14 percent to 18 percent.
- Multiprocessor throughput improvements ranging from 17 percent to 20 percent

Actual performance will vary depending upon customer environment and storage and I/O configuration. No assurance can be given that an individual user will achieve the test results.

- A throughput improvement of about 14%.
- Additional multiprocessing improvements providing greater throughput potential for AP and MP installations.

Actual performance will vary depending upon customer environment and installation use of product improvements.

Utilization of the S/370 Extended Facility/Feature/Additional Feature provides the following enhancements:

- Several high frequency control program paths are improved.
- Additional level of storage protection has been implemented to protect critical low storage from inadvertent alteration.
- Dynamic address translation hardware is made more efficient by reducing the duplicate entries in the Translation Lookaside Buffer and improving the programming signals that indicate certain Translation Lookaside Buffer entries must be purged.

CUSTOMER RESPONSIBILITIES

Individual accounts should examine the following sections and apply the information to their specific environments.

RELEASE 1.0 HIGHLIGHTS

Path Length Improvements: Reductions in processor execution (CPU) time are achieved through path length improvements for important system functions.

Based upon selected path length measurements, CPU time savings per occurrence by path for MVS/System Extensions R1.0 compared to VS2 3.7 and prerequisite SUs 4, 5 and 7 (Scheduler, Supervisor 1 and 2), are derived as below. Processor execution time savings will vary depending on specific account environments.

I/O Paths and Related Services

Improvements have been achieved through optimization of code in mainline paths and in dispatcher and interrupt handler paths. For I/O PURGE and HALT, a new UCB scanning technique and usage of branch entry services has shown a CPU time reduction.

Derived CPU Time Savings

EXCP	22%
EXCPVR	13%
SIO (EXCP)	12%
SIO (ASM)	14%
PURGE (CLOSE)	41%
PURGE (QUIESCE)	38%
I/O HALT	42%

Storage Management Improvements

A reduction of SRB usage during page fault processing, faster paths for fixing or freeing pages, first time page reference processing and Unreferenced Interval Count (UIC) updating and a decrease in the frequency of UIC updating are among improvements that have been added. When SRM detects the availability of a sufficient amount of real storage, TSO address spaces going into TERMINAL WAIT might not be physically swapped out, resulting in a CPU time savings in the swap path of up to 59%.

Derived CPU Time Savings

PAGE FAULT	32%
SWAP	11%
FAST PAGE FIX	73%
PURGE TLB processing (MP/AP only)	up to 95%
UIC updating path	31%

Supervisor Control Improvements

Reduction of LOCAL and DISPATCHER LOCK requirements, usage of the CPU TIMER for time recording and a READY TCB pointer technique are among the changes to the dispatcher. Improvements to interrupt handling have been made by optimizing I/O recursion handling and reducing paths in the program FLIH for page fault handling. Usage of the S/370 Extended Facility/Feature provides significant path length improvements in the system TRACE function. Code optimization has yielded a further reduction in processor execution time for these supervisor functions.

Derived CPU Time Savings

SRB dispatch	40%
TCB dispatch	20%
Overall average dispatch	31%
LOCAL LOCK OBTAIN/RELEASE	30%
CMS LOCK OBTAIN/RELEASE	71%
I/O Interrupt FLIH	62%
EXTERNAL Interrupt FLIH	5%
PROGRAM Interrupt FLIH (PAGE FAULT with I/O)	12%
PROGRAM Interrupt FLIH (PAGE FAULT with no I/O)	17%
SVC/SIO/I/O Interrupt/SRB dispatch	12%
Dispatch task exit prologue	21%

Supervisor Service Improvements

Improvements in SVC FLIH processing and a reduction in LOCAL lock requirements for EXIT prologue, yield a CPU time savings for SVC paths. MODESET and CALLDISP are changed to type 6 SVCs, and PURGEDQ uses FESTAE which does not obtain the LOCAL lock. Improvements in WAIT/ POST and VALIDITY CHECK result in a reduced path for these functions.

Derived CPU Time Savings

SVC Type 1/Exit	28%
SVC Type 2,3,4/Exit (no locks)	32%
SVC Type 6/Exit	3%
MODESET	29%
CALLDISP	27%
PURGEDQ	31%

Contention Improvements: Reduction in contention for system resources provides additional CPU time savings and improved system performance in UP, AP and MP environments.

- LOCAL LOCK usage is reduced in dispatcher, EXIT prologue, system issued PAGE FIX/PAGE FREE requests, MODESET/CALLDISP, PAGEFAULT and PURGEDQ paths.
- Channel Balancing Algorithms, selectable via SYS1. PARMLIB, and Logical Channel (LCH) Redrive Rotation allow for a reduction of channel contention.
- System responsiveness is increased through reduction of disabled supervisor time.
- Fewer dispatchable units in the page fault path allow for reduced contention for that function.

Additional contention improvements are achieved through shorter paths for system functions where serialization does occur. For example:

Derived CPU Time Savings

Suspension of SRB for LOCAL LOCK in LOCAL LOCK OPTION on SCHEDULE	53%
Request for SYNCHRONOUS OPTION on PAGE FIX with I/O	35%

For S/370 AP and MP environments contention is further reduced.

MVS/System Extensions (cont'd)

- The dispatcher eliminated dispatcher lock usage permitting parallel dispatching and decreasing contention for other dispatcher lock users (TIMER, POST, etc.).
- I/O PURGE usage of the UCB lock has been reduced.
- Holding time for the SALLOC lock is reduced through faster PAGE FIX/PAGE FREE and the improvements in the PURGE TLB processing function.
- Frequency of SIGP is decreased through the improved PURGE TLB processing function and reduction of IOS usage of SIGP, resulting in an additional reduction of disabled time.
- Improved work selection is achieved through MEMORY SWITCH modifications.
- Enabled dispatcher spin when unable to dispatch allows for improved system responsiveness.

Control Improvements: Control improvements allow for more effective allocation of resources.

SRM Control items provide the customer with improved control over the distribution of services/resources to do his work.

- The Multi-programming Level (MPL) target adjustment function (adjusting the number of swappable address spaces allowed in storage for a domain) can now use service rate as a means of distributing resources among domains of work. A service objective for a domain may be specified to control total service rate to a domain or average service rate to ready users within a domain.
- The APG function has been enhanced to optionally include multiple mean-time-to-wait groups, multiple fast rotate priorities, and a new function in SRM called time slice dispatching. These enhancements will permit better control over dispatching priorities from the IPS and allow an installation to regulate a multi-subsystem environment including nonswappable address spaces.
- A Priority Queuing option for controlling I/O requests against logical channels has been added to allow the user to improve the response time of specific users or critical applications.

An IOS Control item allows the user additional tuning capability:

- Three optional channel selection algorithms: Sequential, Last Channel Used and Rotate, are supported. A new SYS1.PARMLIB member allows the user to select the appropriate algorithm on a logical channel (LCH) basis.

Improved resource usage recording allows for better system control:

- Service values can now include SRB time at the installation's option. The different components of service values are now recorded separately by SMF.
- The dispatcher now uses the CPU timer for time recording to increase accuracy.

RELEASE 2.0 HIGHLIGHTS

SMF Enhancements: A major revision to SMF provides more data with increased installation control over the amount of data collected, and allows a non-disruptive migration to full utilization of the new function.

- **Selectivity of SMF data:** Installations may now choose exactly which record types they want to record, and which types they do not want to record. Thus, users can now avoid collecting records they do not need, and reduce SMF overhead and data file space usage. This also aids migration to MVS/System Extensions Release 2 -- new record types can be avoided until the installation is prepared to use them. Selectivity is available either at a system level, or at the TSO, started task or batch level.
- **New SMF data:** Several enhancements improve the quantity and quality of overall SMF data.
 - Data is now collected for started tasks (type 4, 5, 14, 15, 20, 30 and 40 records).
 - A new record (type 30) is made available to standardize a record format for all jobs. This record will contain data found in type 4, 5, 20, 34, 35 and 40 records, and can be used in place of them for a potential reduction in complexity and savings in SMF and post processing times. In addition, new data in the type 30 record includes:
 - DDNAME for device entries.
 - SRB and TCB Processor time for the initiator.
 - Job number assigned by the job entry subsystem.
 - Total address space EXCP count.
 - Mount counts for DASD, tape and Mass Storage Subsystem.
 - JOBLIB/STEPLIB EXCP counts in record types 4, 30, 34.

- Another new record (type 90) indicates the changes in SMF and system status. Records are written at IPL, switch SMF, halt EOD, set time and date, SETDMN and SET SMF/IPS/OPT command time. Also an IPL prompt record can be requested by the installation. IPL prompt allows the operator to enter reliability data at IPL which is written to the SMF file in a type 90 record.

- Type 23 records (new) record certain SMF status data. The number of records and buffers written and the maximum number of full SMF buffers are now recorded.

- Finally, type 32 records are introduced. When this release is used in conjunction with the TSO Command Package licensed program (5740-XT6), the type 32 records will contain the total count of each TSO command and subcommands of EDIT, ACCOUNT, OUTPUT and OPERATOR by command and subcommand type. TSO commands issued as subcommands are not counted except as noted above. In other cases where subcommands are issued, the detail portion of the type 32 records will not contain meaningful data for the TSO products and user applications and their respective subcommands. Complete details will be available in the publications at FCS.

- **Functional accounting:** By using the new type 32 records, in conjunction with the TSO Command Package licensed program (5740-XT6), installations can begin to implement the concept of "functional accounting", or charging users for resources in terms they understand. With the type 30 records for TSO and the type 32 records, installations can determine the average resource usage per type of TSO command, subject to the limitations on type 32 records, above, and then bill on the basis of a fixed charge per TSO command. (Note: The TSO Command Package licensed program (5740-XT6) is required to place TSO data in type 32 records).
- **The SMF writer has been redesigned** to reduce bottlenecks and loss of data, and to improve SMF services. Chief among the improvements has been to change the SMF data sets to preformatted VSAM data sets accessed in SRB mode. In addition, where possible, SMF is making use of branch entries to MVS services and offering a branch entry to SMF to eligible components. These changes contribute to a path length reduction in writing SMF buffers.

Other SMF writer enhancements include the capability to designate up to 36 SMF data sets and up to 99 SMF buffers as an installation option. (To save space, buffers above an installation designated minimum number are only allocated on demand). A dump utility program is provided to move data from the new SMF datasets into data sets that can be archived. This makes the SMF data sets available for re-use. The output of the dump program is compatible with the old SMF data set format and can be used by current accounting routines. This utility also has record and file concatenation and selection capabilities on a time, date, system ID and record type basis. Installation exits are called during the dump process to allow additional selection/processing capability.

Installations currently restrained from recording full SMF data because of performance considerations will find data recording ability improved with Release 2.

- **Compatible migration:** An installation's data reduction programs do not have to be modified to install this release (as long as they do not use the *active* SMF data file for input). Current data reduction programs can continue to be used as long as necessary, and the new SMF data can be phased in at any convenient time.
- **Minimize loss of SMF data due to system failure:** Before Release 2, SMF data for long running jobs is lost if the system fails before the job ends. There are cases where data is lost after presentation to SMF because the buffer containing the data does not fill up and, therefore, is not written out before some system failure. To minimize these losses with Release 2, installations can specify that interval data be collected in type 30 records. The interval times are installation specifiable on a job type (batch, TSO, etc.) basis. To minimize the loss of data in the SMF buffers in the event of a system failure, installations may also specify the maximum time that data may reside in an SMF buffer before being written.
- **SMF flexibility:** To ease usage of all the new SMF options, operator commands will be available to display and change the current options. SMF will allow installations to distinguish between job types (batch, TSO, etc.) in record selection, in interval time specification and in invocation of installation exits in order to more closely match data requirements with data collection. All SMF installation exits reside in their own load modules for ease of installation replacement.

SRM Enhancements: The SRM is significantly enhanced in Release 2. Control of system resources to meet installation defined goals is necessary for effective usage of the system. Release 2 SRM contains enhancements to centralize and improve system control, to improve the RMF reporting of certain transactions and to ease the use of certain SRM facilities.

MVS/System Extensions (cont'd)

- **Centralized control:** One of the main factors in determining how SRM allocates system resources to address spaces is the performance group of the address space. Thus, proper performance group number assignment becomes an important part of allocating the appropriate resources to each user. Before Release 2, control of performance group number assignment was distributed across several components. With Release 2, a single system service is available to allow the assignment of performance group numbers. This optional facility, managed by the SRM, uses a new SYS1.PARMLIB member called the installation control specification. Installations may now specify in the PARMLIB member which performance group numbers are permitted, or required, to be assigned to batch jobs, TSO users or users of IBM or user written subsystems, started tasks, mounts, etc., for both transaction control and reporting. (To support this function, installations can now specify up to 999 performance groups in the IPS).

If the installation control specification PARMLIB member is not provided, the current methods of assigning performance groups are used. In addition, units of work can be migrated to installation control specification control individually to ease the conversion process.

- **Improved resource control:** Release 2 contains several improvements in resource control:

– Storage isolation

The storage isolation function protects selected groups of users from having frames stolen during real storage shortages. Thus, these users are less affected by fluctuations in real storage availability. In particular, storage isolation can be used to protect the working set of a critical interactive (e.g., DB/DC) application when its transaction load fluctuates and there is a shortage of real storage. With sufficient frames for its working set, the application should have fewer periods of excessive paging, resulting in more consistent response times. Storage isolation can also be used to place an upper limit on the number of frames held by a user when there is a shortage of real storage. Frames in excess of this limit are favored for stealing. The storage isolation function applies both to private area and common frames.

– Storage load balancing and selectivity of load balancers

In addition to the Processor and I/O load balancing functions, a new storage load balancing function is designed to minimize periods of real storage contention. The function detects real storage imbalances, either shortages or excessive availability, and favors heavy users of real storage for swap-out or swap-in accordingly. The load balancing functions (storage, processor and I/O) can be requested individually or in any combination for selected groups of users.

– Extended priority I/O queuing

With Release 1, deferred I/O requests could be queued on a logical channel either in a FIFO manner, or by priority according to address space dispatching priority. With Release 2, installations will optionally be able to specify I/O priority different from dispatching priority for appropriate address spaces.

– TSO response time objective

Using a new response time parameter in the first period of a TSO performance group, installation management can specify the desired response time for trivial TSO transactions. By limiting response time when the system is under-utilized and reserving excess capacity for future applications, end users are less affected by fluctuations in the system's workload.

- **Improved reporting**

– Privileged user reporting.

Privileged address spaces have, in the past, not had their SRM service statistics made available to RMF for reporting. With Release 2, these statistics will be made available to RMF so that RMF may report a more complete picture of system activity.

– Subsystem transaction reporting.

In conjunction with the installation control specification assignment of performance group numbers to individual transactions, SRM now has the capability to keep service statistics for transactions managed by subsystems (modifications to the subsystems are necessary to provide transaction data to SRM).

RMF can report this subsystem transaction data via the online monitor, background reports or post-processing summaries. The reported data consists of transaction rate, response time and, in certain cases, service consumption. This reporting permits direct feedback on an installation's performance objectives and eliminates the need for multiple report processors. Note: For transaction reporting to be active, a subsystem must issue the

new SYSEVENT macro instructions to provide transaction data to SRM.

When MVS/System Extensions Release 2 is used in conjunction with the TSO Command Package licensed program (5740-XT6), data on TSO commands can be kept and reported. Furthermore, the installation can optionally have SRM treat each command within a CLIST as an individual transaction rather than treating the entire CLIST as a single long transaction.

- **Ease of use improvements:** Because proper installation usage of SRM is important for effective system control, Release 2 eases the usage of certain SRM facilities. The introduction of the installation control specification (above), for example, will make it possible for the installation to ensure jobs are assigned to the correct performance groups.

Other improvements include:

– Constants to PARMLIB

The characteristics of MVS can be altered by adjusting the value of SRM constants. In the past, alteration of some of these values has required modification of IBM code. To ease this burden, Release 2 is making approximately 30 key SRM constants specifiable in PARMLIB member IEAOPTXX. In addition, a SET command is available to dynamically change these values by changing from one IEAOPTXX member to another.

– Device allocation selection options

Before Release 2, four SRM algorithms were supported to control selection of tape devices from the eligible device list at allocation time. However, if the installation wanted an algorithm other than the default algorithm supplied, modification of IBM code was required. With Release 2, any one of the four algorithms can be chosen using a new keyword in the IEAOPTXX member of PARMLIB.

Action Message Retention Facility: Proper and timely handling of operator messages is important in any system. Certain messages that require the operator to take some action are called action messages, and are given particular message descriptor codes (1, 2, 3 and 11). Before Release 2, these messages could roll off the operator's screen with no easy way for the operator to reconstruct the set of unsatisfied action messages. The action message retention facility allows the operator to retrieve all unsatisfied action messages.

When the operator activates the facility, the system retains all action messages (descriptor codes 1, 2, 3 and 11) displayed on the operator console(s) until either the system detects that the required action is performed and deletes the message or the operator requests that the message be deleted. The operator retrieves outstanding action messages that have rolled off or have been erased from the screen by entering the DISPLAY R command.

Immediate action messages (descriptor codes 1 and 2) and critical eventual action messages (descriptor code 11) appear at a higher intensity on consoles that support dual intensity displays. Intensification of these messages helps the operator to distinguish them from other messages. Action messages can be deleted with the CONTROL command or with the delete operator message (DOM) macro instruction. If the action message retention facility is deactivated, those messages that have been retained will remain until the operator or the issuer requests their deletion.

When Release 2 is used in conjunction with the TSO Command Package licensed program (5740-XT6), retained action messages may be displayed from a TSO terminal in operator mode.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

MVS/System Extensions requires the S/370 Extended Facility of the IBM 3031, 3032 and 3033 Processors, or the S/370 Extended Feature on IBM S/370 mdls 158 and 168. MVS/System Extensions supports the following processors:

Model 158-1	UP/MP/AP
Model 158-3	UP/MP/AP
Model 168-1	
with RPQ S20579	UP/MP
Model 168-1	
with RPQ S20580	AP
Model 168-3	UP/MP/AP
3031 Processor	UP/AP
3032 Processor	UP
3033 Processor	UP/MP/AP

The minimum total storage required by MVS/System Extensions depends on many factors. These include an installation's configuration, the subsystems, program products, problem programs in use and others. However, the following are the approximate real and virtual storage changes for the MVS/System Extensions:

PROGRAM PRODUCTS

MVS/System Extensions (cont'd)

	Release 1	Release 2*
Nucleus (real)	30,000	6,200
PLPA (virtual)	10,000	66,300

* Release 2 figures are in addition to those provided for Release 1. Additional storage requirements are variable - see the *General Information Manual*, (GC28-0872-3) for full details.

The specified operating environment may change, and will be restated at FCS.

SOFTWARE REQUIREMENTS

MVS/System Extensions R1.0 operates on MVS Releases 3.7 and 3.8:

- On MVS Release 3.7, MVS/System Extensions R1.0 requires the following selectable units as prerequisites: 4, 5, 7, 16, 17, 27, 33, 51 and 55.
- On MVS Release 3.8, MVS/System Extensions R1.0 has no prerequisite selectable units.
- On MVS Release 3.7 or 3.8, when MVS Processor Support 2 (SU64) is installed on a system containing MVS/System Extensions R1.0, an MVS/System Extensions - Processor Support 2 feature must also be installed.

MVS/System Extensions R2.0 operates only on MVS Release 3.8:

- On MVS Release 3.8, MVS/System Extensions R2.0 requires the following prerequisite: Processor Support 2
- With MVS/System Extensions R2.0, the MVS/System Extensions - Processor Support 2 feature is not required.

Information concerning prerequisite PTF's required for installation of MVS/System Extensions is in the program directory shipped with the product.

INSTALLATION CONSIDERATIONS

MVS/System Extensions requires a Stage 1 assembly followed by the normal SMP apply. Alternatively, a full SYSGEN can be used for installation. See the program directory for additional installation information.

In order to support MVS with MVS/System Extensions installed as a guest operating system under VM/370, the VM/System Extensions program product (5748-XE1) is required.

To use the functions provided by RMF, the OS/VS2 MVS Resource Measurement Facility, Version 2, Release 2 is required.

COMPATIBILITY

Presently, there are no known incompatibilities between MVS and currently available PPs caused by MVS/System Extensions that will not be eliminated by FCS. However, modifications to some Program Products may be necessary for them to execute on MVS with the MVS/System Extensions installed. PTFs or new versions or releases for certain PPs will be provided. Details will be announced at availability.

User written programs using standard external interfaces will run with MVS/System Extensions. Programs that interrogate control program control blocks may require modifications. Licenses will receive documentation on MVS/System Extensions control blocks.

The Release 2 enhancements in the SMF area may require certain changes in an installation's accounting procedures - See the *General Information Manual* (GC28-0872-3) for complete details.

IBM devices supported by MVS today will continue to be supported by MVS with the MVS/System Extensions installed.

MF/1 and DSS will not be supported with the MVS/System Extensions.

Program Products supported by MVS Release 3.7 or 3.8 should continue to run with MVS/System Extensions installed (with the RMF exception noted). APARs will be accepted for any such IBM program product that does not run successfully after MVS/System Extensions is installed.

For program support purposes, MVS/System Extensions Release 1 and the MVS/System Extensions - Processor Support 2 feature will be considered current until December, 1980.

OS/VS2 MVS/System Extensions General Information Manual	GC28-0872

**OS/VS2 MVS TSO 3270 EXTENDED DISPLAY
SUPPORT SESSION MANAGER
Release 2 Modification Level 0 (5740-XE2)****PURPOSE**

The TSO Session Manager provides a full screen display facility. It complements the full screen functions of the TSO 3270 Display Support and Structured Programming Facility program product. The combination of these two products provides full screen 3270 display support for the entire TSO environment.

DESCRIPTION

The TSO Session Manager, available to the TSO user from logon to logoff, has facilities that enhance TSO in several key areas.

Journaling of TSO Sessions - gives the 3270 Display user the benefits of a hardcopy typewriter terminal by providing a complete journal of all input and output activity for the interactive session. All or part of this session journal can be made available during the TSO Session. This gives the user the capability to recall an earlier part of a session for the purpose of reviewing prior input/output, making up new input from portions of the journal for resubmitting, or executing in context. The journal is kept in MVS virtual storage for immediate viewing on the display screen. In addition, the user may keep a permanent record by copying all or part of the journal to a data set or directing it to a hardcopy printer.

A new TSO concept defines "streams" of input and output data that are kept in MVS virtual storage. These data streams provide the capability for the session journal and other data to be maintained as a virtual sheet of typewriter paper that can be viewed via Session Manager windows.

Customizing of 3270 Display Terminal - users can now dynamically tailor the display screen, data streams and program function (PF) keys to fit their needs. The Session Manager also provides users with default screen layout and program function key definitions at Logon time to manage session input and output. The default environment is defined via an IBM provided and/or installation provided default module(s) to give users additional selectivity.

The PF key defaults provide window scrolling, screen snapshots and command entry functions. User definition (or customization) of PF keys and windows may be done at any time during the session. PF keys can be used to perform repetitive functions such as changing screen displays or invoking TSO commands, TSO CLISTs or Session Manager commands. Users can alternate between use of default definitions and previously saved and customized definitions.

The user may also define multiple windows (up to 25) and specify which data streams are to be displayed in each window.

In Release 2, mdl 3276 and 3278 Display terminals are supported in three screen modes, giving users a 2560 and 3440 character (32, and 43 lines) display area as well as the 1920 character (24 lines) default mode. This will extend the size of windows that an installation may define and provide for retention and viewing of more data on the screen at any one time.

Up to 24 Program Function Keys as provided on models 3276/2378 Displays are supported. Each set of 12 PF Keys (basic and optional feature) are defined to provide the same (12) default definitions. Users may then redefine any of the PF Keys (up to 24) to provide a customized environment.

Full-Screen Support for all Line-oriented TSO Functions - user written applications and Execution Processors such as TSO Test, PL1 Checkout Compiler Program Product and COBOL Interactive Debug now get full-screen support without having to rewrite existing applications. Full-screen support includes: Full screen I/O, customization of PF keys and windows and use of the session journal.

Installation Management Exits - In Session Manager Release 2 installations can now write routines to monitor the user's terminal session and log all or selected activity. The installation can also select the data streams to be monitored. The user exits have the capability of recording the line of data and stream name along with a time stamp.

HIGHLIGHTS

Retention of desirable typewriter terminal features -- the session journal facility can be used to view or print all or part of a session's input/output during a session.

Up to 9 data streams -- streams retain session journal and other inputs/outputs for interactive use during session. Unique streams contain data such as TSO input, TSO output, Session Manager command interactions and messages.

User control of display -- although a default of four windows for input/output is provided, dynamic customization allows the definition of up to twenty-five windows. Users may use one or more windows to view any data stream.

Scrolling capabilities -- Users can scroll forward, backward, left and right over data displayed in any window.

Up to twenty four program function keys -- default definitions of PF keys and user customizations of PF Keys allows the user to perform many time saving functions; they can execute TSO commands, CLISTs and Session Manager commands.

Co-existence with other full screen applications -- Session Manager relinquishes control of the display screen when a full-screen I/O is invoked. It resumes control when the full-screen application ends.

Saving and restoring of PF key definitions -- users may define sets of PF keys. Those definitions can be saved in virtual storage and later restored.

Highlighting of user input -- user entered commands recorded in the TSOUI stream are highlighted on the display screen to differentiate from system output in that stream.

Highlighting of currently executing command -- users can watch the execution of commands in the TSOIN stream by watching the highlighting move down the stack of commands displayed on the screen.

Unlocked keyboard capability -- the keyboard can remain unlocked thereby allowing users to enter data even while a program may be executing.

Audible alarm support (if terminal feature is present) -- the alarm alerts users when new data is displayed, messages have been received or user input is required.

Message stacking -- messages sent to a user's terminal do not interrupt the session. They are stacked and then displayed at the user's convenience. The sounding of the audible alarm signals the receipt of messages as they are stacked.

Display support from logon to logoff -- full-screen support is given to all line-oriented commands and modes without need for program modifications.

Multitasking -- Session Manager commands can execute while TSO commands are executing.

Session Manager commands as an alternative to PF keys -- by using Session Manager commands, users at display terminals lacking PF keys can still manage the screen and perform PF key-like functions such as scrolling.

Three new TSO commands -- SMCOPY copies a stream to a data set, SMFIND is used to locate data in a stream and SMPUT allows a user to issue a Session Manager command directly from the main TSO command input window.

These functions extend the facilities of the 3270 display terminal to the line-oriented TSO environment. They allow the user greater control over the interactive session, with the objective of increased user productivity.

Since users have the option of using defaults or their own customized definitions, they may determine exactly what is to be displayed at the terminal and maintain control over the display terminal throughout the session. The complete history of the session is available to the user. This saves re-execution of time consuming commands by allowing the user to review previous output. New inputs formed from the journal also save keystrokes.

Relationship between Session Manager and the TSO 3270 Display Support and Structured Programming Facility Program Product (SPF).

SPF is a TSO command processor which was specially designed to take advantage of 3270 Display Terminal features (scrolling, program function keys, full screen read/write and split screen) for context editing, data set and library maintenance and utility functions. The TSO 3270 Session Manager does not attempt to duplicate the capabilities of the SPF command processor. Instead, it provides support of 3270 Display Terminal features for other TSO command processors which were originally designed for use on keyboard printer terminals and which work in a line-oriented mode. Application execution and testing/debugging activities using TSO Test, the PL1 Checkout Compiler program product and the COBOL and FORTRAN Interactive Debug program products are among the key user tasks for which Session Manager provides new display support.

Installations where the TSO workload consists primarily of editing, data set browsing and remote job submission may find that SPF adequately addresses their display support requirements. Installations where application execution makes up the majority of the TSO workload may find that the Session Manager adequately meets their needs. However, installations where the workload consists of a full range of TSO capabilities should consider both SPF and the Session Manager.

Task Control: Since the Session Manager operates in parallel with the TSO Terminal Monitor Program (TMP), The Session Manager com-

MVS TSO 3270 Session Manager (cont'd)

mands may be entered via keyboard or program function keys, even while other TSO commands are executing.

Interactive Debugging: The users of program development and debugging programs such as TSO Test, PL1 Checkout Compiler or COBOL Interactive Debug will be able to take advantage of the full screen functions; multiple windows and data streams, and assign PF keys to commonly used test functions (i.e., displaying a set of registers, a key data area or buffer).

The user no longer has to reexecute TSO commands just to have the output redisplayed since the session journal can be viewed at any time during the session to examine or evaluate output or reenter test input or commands. Printing the journal to hardcopy gives a permanent log of the test session. Additional data such as comments may be directed to the journal to highlight a particular part of the test session.

Display Technique: The Session Manager partitions the 3270 display screen to provide multiple input/output "windows" or "viewports" through which data streams can be viewed. The user may define as many as 25 unique windows.

Data is viewed by scrolling or moving a window over a data stream in a forward, backward, left or right direction. This operation may be performed in any of the windows on the screen.

Data Streams: A data stream is a collection of input and/or output commands, data, messages, etc. that are associated with a user TSO session under the Session Manager. The concept of data streams allows input and output to be saved in virtual storage and selectively displayed on one or more of the "windows" of the display screen. Each data stream is maintained in virtual storage. Input from the terminal and output destined for the terminal is placed in one of these data streams as defined by the Session Manager defaults and/or by the user. The data stream can be viewed through a window as it is being updated. The streams have a default size that may be modified by the installation. All data is placed in the stream starting from the top and progressively filling up the allotted space. When all allocated space is full, the data will wrap around to the top of the stream.

One or more streams may be displayed in one or more windows of the display screen. By use of scrolling (see "Display Techniques") these streams may be viewed by the user as if viewing a data set. Session Manager streams are:

TSOIN	Input for TSO commands and applications, etc., is placed in this stream. This data will be read by TSO as if it were input from the terminal keyboard.
TSOOUT	Output from TSO (ready, prompts, messages, application output) is placed in this stream. Additionally, the input from the TSOIN stream is placed here. This gives a complete record of the terminal session. This stream when journaled to an output data set looks identical to the terminal sheet produced by a TSO typewriter terminal.
SMIN	Session Manager input commands are placed in this stream.
SMOUT	Session Manager diagnostics and informational messages output are placed here.
HEADER	Column indicators, scroll values and locked or unlocked status of the main window are placed in this stream.
MESSAGE	Collection point for messages sent from outside the user memory.
EXTRA1, EXTRA2, EXTRA3	Output from SNAPSHOT commands of screen images is placed in the EXTRA1 stream. The other two streams are inactive until targeted for use by Session Manager commands.

Program Function Keys: The program function keys can be dynamically defined by the user. The user may "program" them to suit his needs and change them at any time during the session. They can be used to invoke frequently used CLISTs Session Manager commands, provide input to programs and allow many repetitive type functions.

Casual users or new users may choose to utilize the supplied defaults rather than define their own.

Program function keys as defined in the default environment may be changed at any time during a session.

PF Keys for Models 3276/3278 Displays

PF Key 1 - PF Key 12 are assigned defaults in exactly the same manner as with the 3275/3277 models with 78-key keyboards. The additional 12 PF Keys on these modules (PF Key 13 - PF Key 24) are also supplied the same default definitions as PF Key 1 - PF Key 12. The installation or user may then choose to redefine any of these PF Keys dynamically, or at Logon via specification of a unique default module.

Default PF keys include:

For SNAPSHOTs

- PF 4 Takes a snapshot of the screen image and places it in a data stream.
- PF 1 Prints the stream containing the snapshots of the screen.

For SCROLLING: Scrolling takes place in the main window which defaults to the TSOOUT stream but may be redefined by the user.

- PF 2 Sets a scrolling value for PFKs 7, 8, 10, 11 to specify amount of scroll.
- PFs 7,8,10,11 For scrolling backward, forward, left and right respectively.
- PF 9 Used to scroll backward to oldest data in a stream.
- PF 12 Used to move main window to newest data in a stream and unlock it, thereby allowing scrolling to take place.

Command Entry/Searching

- PF 3 Begins Session Manager command entry in the main window.
- PF 5 Used to scroll the main window backwards until a text string entered by the user is found.
- PF 6 Alternates the current window between viewing the TSOIN and TSOOUT streams.

Session Manager Commands: Commands are provided to allow the user to define, control and modify the display environment.

Defaults are provided for many command operands for ease of use. These commands may be entered from the keyboard, or by defining a program function key to cause command execution, or via TSO CLISTs.

Change Commands: Allow modification of the cursor, a PF key, a stream, windows, terminal attributes or functions of a stream.

Define/Delete: To define a window, its size, associated stream and other attributes; and to delete the window.

Screen Control Commands: Provide function equivalent to the program function key default definitions: (e.g., FIND (same as PF 5) to find a text string, SCROLL (same as PF 7-12).

FIND LINE Command identifies the line number of a specific line being viewed in a stream window.

Session Control Commands

- **Query Command:** informs the user of what the Session Manager environment is, including current definitions of windows, streams, PF key settings and session functions.
- **SAVE/RESTORE Command:** allows a user to save PF keys, screen or window display environments on a LIFO stack (Last In First Out) and restore the environment.
- **RESET Command:** reestablishes the defaults provided at Session Manager startup.
- **END:** Terminates the Session Manager display support or the TSO session.
- **PUT:** Allows the user to insert a character string in any stream. Insertion of a TSO input stream will cause the string to be executed as a TSO command.

TSO Commands

Three commands are supplied with the Session Manager.

- **SMCOPY:** Copies all or part of a data stream or a data set to another data stream or data set. The target data set may be SYSOUT, enabling any TSO stream, including the session journal, to be printed at a system printer.
- **SMFIND:** This command locates a character string in a Session Manager stream.
- **SMPUT:** A command that sends a specified text string to a specified stream. A string sent to the TSOIN stream will be interpreted as a TSO command.

Help Command: Help Data Set members are supplied to give information on Session Manager commands and its TSO commands.

Message Handling: When a message is received in the users TSOOUT stream the Audible Alarm, if present, will be sounded. A user can then display the message in a designated window by utilizing a PF key assigned to TSOOUT.

CUSTOMER RESPONSIBILITIES

Installation of this program product will require installation personnel to be knowledgeable in OS/VS2 MVS TSO.

PROGRAM PRODUCTS

MVS TSO 3270 Session Manager (cont'd)

User Guidelines: *TSO 3270 Extended Display Support-Session Manager Users Guide and Reference Manual GC28-0912-0* ... this publication introduces the user to the Session Manager by providing a "how to" primer in the context of using the IBM-supplied default display environment. In addition, command syntax and System Programmer reference information is provided.

TSO HELP Data Set - Session Manager provides additional members for the TSO SYS1.HELP data set to provide the user with descriptive information and syntax for Session Manager commands and new TSO commands.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

This licensed program is designed to operate on an IBM S/370 under OS/VS2 MVS with the Time Sharing Option. There are no additional hardware requirements.

• **Terminals**

The following terminals are supported by the Session Manager:

- 3275 or 3277 mdl 2, 3275 mdl 12
- 3276 mdls 2, 3, 4, 12, 13, 14
- 3278 mdls 2, 3, 4 (local or remote attachment - SNA or non-SNA)*

Session Manager also supports any 3270 data compatible terminal (1920 character matrix only). It will also support the 3276 and 3278 mdls 3, 4, 13 and 14 in 1920 character default mode as well as in extended screen capacity mode.

*3278 mdls 3, 4 are available on the 3274 controller and on the 3276 controller.

• **Keyboards supported are:**

- 75-Key EBCDIC Typewriter (#4621)
[Requires (#9881)]
- 87-Key EBCDIC Typewriter (#4627)
[Requires (#9882)]
- 66-Key EBCDIC Typewriter (#4630)
- 78-Key EBCDIC Typewriter (#4633)
- 78-Key Operator Console (#4632)
- 66-Key EBCDIC Typewriter/APL (#4637)*
- 78-Key EBCDIC Typewriter/APL (#4638)*
- 78-Key Text (#4639)*
- Character Set: EBCDIC (#9882)

* **Note:** Feature #1066 is a prerequisite for these three keyboards. These three keyboards will be supported via PTF subsequent to FCS of the Session Manager.

Features supported but not required are:

- Audible Alarm (#1090)
- Print Dual Case Character Set (RPW-8K0366).
- Data Analysis - APL Feature (#1066 on the 3277 mdl 2 Display Station and the 3271/ 3272 Control Unit)

SOFTWARE REQUIREMENTS

The Session Manager is designed to work with MVS Release 3.7 with TSO/TCAM Level 9 or Level 10, TSO/VTAM Level 1 or Level 2 and subsequent releases and modifications unless otherwise stated.

In order to take advantage of the increased screen capacity features of the 3276/3278 Display terminals (Models 3, 4, 13, 14) TSO with the ACF/VTAM or ACF/TCAM program product installed is required.

This licensed program is distributed in the Basic Assembler language.

Storage Estimates: Virtual storage requirement for TSO 3270 Extended Display Support-Session Manager are:

- PLPA 6,536 bytes
- Private Area 316,824 bytes

The approximate space requirements increase for the system libraries (based on IBM 3330 Disk Storage with a 13,030 byte track size) are:

Library		Tracks
SYS1.SMLIB	159,000 bytes	13
SYS1.MACLIB	20,700 bytes	2
SYS1.HELP	21,600 bytes	2
SYS1.LPALIB	5,800 bytes	1

PROGRAM PRODUCTS

**MATHEMATICAL PROGRAMMING SYSTEM
EXTENDED/370
(MPSX/370)
MIXED - INTEGER PROGRAMMING
(MIP/370)**

5740-XM3	MPSX/370	OS/VS and VM/370 with CMS
Feature	MIP/370	OS/VS and VM/370 with CMS
5746-XM2	MPSX/370	DOS/VS and DOS/VSE
Feature	MIP/370	DOS/VS and DOS/VSE

DESCRIPTION

MPSX/370 and its optional feature MIP/370 are new products based on their predecessors MPSX (5734-XM4) and its MIP feature. MPSX/370 and MIP/370 provide new and enhanced capabilities and improved performance when compared to MPSX and MIP. The scope of operational models that can be optimized by MPSX/370 and MIP/370 has been extended.

Mathematical programming applications are found in all industries. Some of the best-known applications are: material allocation, ingredient blending, creation of animal feedlots, production planning, investment analysis, capital budgeting, plant/warehouse location, machine loading, work force allocation, and production/distribution.

MPSX/370 solves linear and separable programming problems. It uses the revised simplex method (LU form of the inverse) with free or bounded variables and ranged constraints, and provides a full set of facilities for problem revision, crashing and reduction, selective printed and filed analysis of output and solutions, parameterizations, getoff/restart, and report writing. Dynamic storage allocation, matrix scaling, dynamic adjustment of tolerances, cycling and multiple pricing, together with the LU form of the inverse, provide increased performance. Two control languages can be used to direct the optimization; the MPS Control Language (MPSCL) is specific to MPSX/370 which contains its own compiler and executor, the Extended Control Language (ECL) is based on PL/I and permits using MPSX/370 within complex applications and coding more sophisticated algorithms. Direct communication between control program and MPSX/370 data and results is provided for this purpose.

The optional MIP/370 feature of MPSX/370 (described below) solves mixed integer linear programming problems, linear programming problems in which designated variables must take integral values. It uses a "branch and bound" method. Numerous control options are present and a specific method is used for "Special Ordered Sets".

The Matrix Generator and Report Writer (MGRW) (5734-XMC) is an existing program product whose Version 1 Modification Level 2 and subsequent releases are designed to operate under MPSX/370 OS/VS. It is a language which provides MPSX/370 users with facilities to build models, to analyze the results, and to produce reports in a meaningful format.

MPSX/370 and its MIP/370 feature are designed to operate under OS/VS, DOS/VS, DOS/VSE and VM/370 with CMS. Terminal communication to monitor MPSX/370 runs can be achieved through the use of OS/VS2 TSO and VM/370 with CMS.

MPSX capabilities not supported by MPSX/370 are: the Generalized Upper Bounding (GUB) feature, input and output in communication format (READCOM/MARVEL), and input in non-MPSX format (TRANSLATE).

HIGHLIGHTS

MPSX/370:

- Program logic provides for a maximum of 16,383 rows and virtually an unlimited number of columns.
- State-of-the-art techniques provide increased performance over and greater numerical stability than MPSX:
 - New high performance INVERT procedure.
 - LU form of the inverse formed in INVERT and maintained in optimization.
 - Devex method as option for the choice of the incoming vector.
 - Automatic adjustment of multiple pricing and cycling.
 - Dynamic adjustment of tolerances.
 - Automatic detection and correction of degeneracy.
 - Dynamic storage allocation and improved data organization.
- Two control languages are available:
 - MPSCL, specific to MPSX/370, contains its own compiler and executor and provides easy control of straightforward optimization. (MPSCL was the control language of MPSX and MPS/360).

- ECL, a new control language based on PL/I, is designed to provide an interface for MPSX/370 and user programs other program products, and data bases through the use of DL/I. ECL also affords the possibility of building recursive applications through use of its facilities to store matrix data (INQUIRE) and optimization results (SOLUTION, RANGE, TRANCOL, TRANROW) into ECL arrays and to use ECL structures, to revise the problem file, to modify the work-matrix, and to insert a starting solution taken from data stored into ECL structures (REVISE, MODIFY, INSERT, FORCE). Using ECL, new algorithms can be built by calling internal computational routines (e.g., FTRAN, CHUZR) and accessing internal MPSX/370 arrays. (Users should consider PL/I array size limitations.)
- The OS/VS, VM/370 and DOS/VS versions are fully compatible with each other.
- Optimization can be monitored from a terminal using OS/VS2 TSO and VM/370.
- A primer is provided to help the beginner use MPSX/370.
- Many MPSX capabilities have been enhanced in MPSX/370:
 - Improved problem file organization, with provision for automatic protection of filed items.
 - Additional free input data format.
 - Optional user control of storage allocation.
 - A new INSERT procedure, making specification of outgoing variables unnecessary. INSERT has new options that handle insertion of a solution into a revised problem, a reduced problem, or a multiblock problem solved by block.
 - FORCE, a new procedure to improve a starting basis or perform postoptimal analysis.
 - INQUIRE and MODIFY, new procedures that inquire and modify the matrix.
- MPSX/370 and MIP/370 facilities compatible with MPSX and MPSX/MIP include:
 - MPSX control language compatible
 - Input data compatible
 - Output files - Standard format
- MPSRG, a former IBM Type 2 program, an easy-to-use report generator language is part of MPSX/370.
- The MPSX features that have been deleted from MPSX/370 are: communication format I/O (READCOM/MARVEL), the Generalized Upper Bounding (GUB) feature, and input in non-MPSX format (TRANSLATE).

MIP/370

All improvements to MPSX/370 apply equally to MIP/370 (high performance, the new control language ECL, full compatibility of DOS/VS, OS/VS and VM/370 versions, monitoring through OS/VS2 TSO, and VM/370, primer). Highlights specific to MIP/370 are:

- The "branch and bound" method has been improved, increasing its performance over that of MIP "branch and bound". Among the improvements are:
 - LU form of the inverse in MIXFLOW.
 - New strategies and choice criteria.
 - A specific algorithm for Special Ordered Sets (Special Ordered Sets are rows expressing that the sum of a set of bivalent variables (0-1 variables) must be equal to 1; such rows are frequent in decision models).
 - Improved organization of data.
- Program logic provides for a maximum of 32767 integer variables and Special Ordered Sets. (However, a realistic limit is very much smaller and is dependent on problem type and structure).
- Comprehensive facilities are provided to control the search for integer solutions, limit the search according to user criteria, and study multi-block models using a stagewise strategy.
- Full control of the printed output has been provided.

USE

MPSX/370 is made of a set of procedures, each of them performing a specific function such as input data conversion, building of a starting solution, primal optimization, solution editing, etc. MIP/370 is an

PROGRAM PRODUCTS

MPSX/370 and MIP/370 (cont'd)

additional optional set of procedures. MPSX/370 and MIP/370 procedures may be called from a user control program, a sequence of operations used to solve a given mathematical programming problem. Processing of an MPSX/370 problem is performed in two job steps. The first job step invokes a compiler to compile the user control program. The second job step is the execution of the compiled user control program. The compiler and executor for the MPS control language (MPSC) are contained in MPSX/370. For the extended control language (ECL), the PL/I Optimizing or Checkout compiler must be used.

CUSTOMER RESPONSIBILITIES

The customer must have a knowledge of mathematical programming to construct a mathematical model of the process he wishes to study or optimize.

To use MPSX/370 to optimize or study the model, the customer must formulate the model information as input data to MPSX/370, write an MPSX or ECL control program to perform the desired optimization calculations, and execute the control program.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

MPSX/370 under DOS/VS or DOS/VSE:

The minimum machine configuration to install, execute, and support MPSX/370 and its optional MIP/370 feature under DOS/VS or DOS/VSE is:

- Minimum operating system real storage requirements.
- Universal instruction set.
- At least 132 print positions, when the system output is a printer.

On S/370, MPSX/370 DOS/VS operates under under DOS/VS or DOS/VSE. On 4300 processors, MPSX/370 DOS/VS operates under DOS/VSE. It has been designed to operate under DOS/VSE with the Program Product VSE/Advanced Functions.

MPSX/370 under OS/VS

The minimum machine configuration to install, execute, and support MPSX/370 and its optional MIP/370 feature under OS/VS is:

- Minimum operating system real storage requirements.
- Universal instruction set.
- At least 132 print positions, when the system output is a printer.

On S/370s or 303X processors, MPSX/370 (OS/VS and VM/370 with CMS) operates under OS/VS1 or OS/VS2. On 4300 processors, MPSX/370 (OS/VS and VM/370 with CMS) operates under OS/VS1 Release 7 and subsequent releases unless otherwise identified.

MPSX/370 under VM/370 with CMS

The minimum virtual machine configuration to install, execute, and support MPSX/370 and its optional MIP feature under VM/370 is:

- MPSX/370 alone: CMS virtual machine with 700K storage (MPSC) or 850K (ECL) and mini-disk space equivalent to 6 cylinders of a 3330 disk or 3000 512-byte blocks of an FBA device.
- MPSX/370 with MIP/370: CMS virtual machine with 800K storage (MPSC) or 950K (ECL) and mini-disk space equivalent to 8 cylinders of a 3330 disk or 4000 512-byte blocks of an FBA device.

If the system output is a printer, it must have at least 132 print positions.

On S/370s or 303X processors, MPSX (OS/VS and VM/370 with CMS) operates under the control of CMS which in turn operates under the control of VM/370.

On 4300 processors, MPSX/370 (OS/VS and VM/370 with CMS) operates under the control of CMS which in turn operates under the control of VM/370 Release 6 and subsequent releases unless otherwise identified. MPSX/370 has been designed to operate under VM/370 with either the Program Product VM/BSE Release 2 or the Program Product VM/System Extensions Release 2, and their subsequent releases unless otherwise identified.

Address Space Requirements (DOS/VS, OS/VS and VM/370)

Compilation

For an MPSC Program, execution of DPLCOMP requires 128K. For an ECL Program, executed by a PL/I compiler, an estimate of minimum virtual region size is given in:

- OS PL/I Optimizing Compiler, Programmer's Guide, SC33-0006
- OS PL/I Checkout Compiler, Programmer's Guide, SC33-0007-01
- PL/I Optimizing Compiler, Programmer's Guide, SC33-0008-02

Execution

The minimum address space required to execute a control program is:

$$O + P + D + E$$

where:

- O is the size of the MPSX/370 system and procedures.
 - O = 300K under DOS/VS or OS/VS
 - O = 360K under VM/370 without the MIP/370 feature.
 - O = 450K under VM/370 with the MIP/370 feature.
- P is the size of the ECL program, if any.
- E is non-zero only if n MPSX/370 internal files are located on FBA devices under DOS/VSE. The value of E is: n x 8K.
- D is the address space for problem data.

The address space D required for problem data depends mainly on the number of rows and integer variables of the problem, although the number of columns and non-zero elements have secondary impacts on storage requirements. Figure 1 gives D with respect to number of rows and number of integer variables:

Rows	LP Problem with No Integer Variables		LP Problem with i Integer Variables where i is the Number of Integer Variables plus the Number of SOS	
	Minimum	Designed Norm	Minimum	Designed Norm
200	35,000	70,000/ 97,000	45,000 + 87i	80,000 +100i/ 107,000 +200i
500	55,000	140,000/ 228,000	67,000 +87i	152,000 +100i/ 240,000 +200i
800	75,000	219,000/ 358,000	89,000 +87i	233,000 +100i/ 372,000 +200i
1,200	102,000	323,000/ 532,000	119,000 +87i	340,000 +100i/ 550,000 +200i
1,600	128,000	416,000/ 700,000	148,000 +87i	436,000 +100i/ 720,000 +200i
2,000	156,000	500,000/ 880,000	179,000 +87i	523,000 +100i/ 903,000 +200i
3,000	222,000	720,000/ 1,300,000	253,000 +87i	750,000 +100i/ 1,330,000 +200i
4,000	290,000	930,000/ 1,750,000	330,000 +87i	970,000 +100i/ 1,800,000 +200i
6,000	424,000	1,360,000/ 2,600,000	477,000 +87i	1,400,000 +100i/ 2,650,000 +200i
8,000	558,000	1,800,000/ 3,500,000	630,000 +87i	1,900,000 +100i/ 3,600,000 +200i
10,000	692,000	2,200,000/ 4,350,000	780,000 +87i	2,300,000 +100i/ 4,450,000 +200i
16,000	1,100,000	3,500,000/ 7,000,000	1,230,000 +87i	3,600,000 +100i/ 7,100,000 +200i

- Designed Norm gives an estimate of the range of address space for problem data recommended for the specified problem size. The first amount implies an acceptable proportion of I/O operations: the second amount implies no or very low proportion of I/O.
- Minimum gives an estimate of the minimum address space for problem data required for the specified problem. It entails a high I/O rate.
- Choice of a virtual region size to optimize a problem should be done according to these estimates plus real storage availability.

Files (DOS/VS and OS/VS):

MPSX/370 requires approximately two cylinders on a 3330 or an equivalent amount of space on other direct access storage devices for the system residence file. MIP/370 requires additional direct access space of approximately ten tracks on a 3330 or the equivalent on other devices.

During execution, MPSX/370 requires a minimum number of utility files for permanent and temporary data storage. However, if a set of optional files is available and is specified by the user, it can be used by the system for greater flexibility and more efficient problem solution. The amount of space they require depends on the size of the problem. A rough estimate of the space required can be obtained by using the formula 1,000,000 + 100e bytes where e is the number of non-zero elements of the problem.

PROGRAM PRODUCTS

MPSX/370 and MIP/370 (cont'd)

SOFTWARE REQUIREMENTS

MPSX/370 and MIP/370 are written in Assembler. Both operate on S/370 virtual storage configurations in virtual mode, under the current release of DOS/VS, DOS/VSE, OS/VS1 and OS/VS2, which themselves can operate under control of VM/370. MPSX/370 and MIP/370 use the SAM data management facilities of DOS/VS and the BSAM and BDAM data management facilities of OS/VS and VM/370. Terminal monitoring of MPSX/370 runs is possible under the control of OS/VS2 TSO and VM/370.

The following program products are prerequisites for using the extended control language:

Program Product	DOS/VS	OS/VS
PL/I Resident Library	5736-LM4	5734-LM4
PL/I Transient Library	5736-LM5	5734-LM5
PL/I Optimizing Compiler	5736-PLi	5734-PLi

Under OS/VS or VM/370 with CMS, the PL/I Checkout Compiler (5734-PL2) can replace both the PL/I Optimizing Compiler and the PL/I Transient Library, in particular when monitoring an ECL control program in interactive mode from a terminal. MPSX/370 is a prerequisite for using MIP/370.

DOCUMENTATION: (available from Mechanicsburg)

PROGRAM PRODUCTS

**PROJECT ANALYSIS AND CONTROL SYSTEM
PROJACS DOS/V5 (5746-XP1)
PROJACS OS/V5 (5740-XP1)****DESCRIPTION**

PROJACS is a set of programs designed to aid management fulfill its responsibilities in the planning and controlling of projects using the critical path method.

The effective management of a complex project involves the following aspects: Determining the tasks which are to be performed, planning and supervising their execution and controlling the use of resources such as men, machines, material and money.

PROJACS is a modular tool for helping management carry out these functions. It consists of a Main Processor and three optional features: The Resource Allocation Processor, the Cost Evaluation Processor and the Network Preparation Processor.

The functions of the Main Processor are: Generation and updating of networks, time analysis of a network by the critical path method, output of reports and the supervision of the other processors. The Resource Allocation Processor (optional feature) provides schedules based on resource availability. The Cost Evaluation Processor (optional feature) computes costs and summarizes them with respect to functional subdivision of the project. The Network Preparation Processor (optional feature) facilitates network generation and updating by means of standard module library management and a network drawing capability.

HIGHLIGHTS**Main Processor**

- Modularity.
- Flexibility of program control through use of control statements.
- Eight calendars and eight work weeks.
- Direct access Master File containing up to 500 networks.
- Each network may contain up to 100 subnets.
- Up to 5,000 activities per subnet and 15,000 per network.
- PERT/CPM and Precedence notations.
- Parallel interfacing of subnets within a network.
- Four types of precedence relationships with positive or negative lags.
- Multiple starts and ends.
- Five types of scheduled dates.
- Nine milestone levels.
- Four organization tables, each one being a five-level tree structure.
- Progress Reporting.
- Timenow date and backwards computation.
- Ability to freeze dates and floats for comparison with further computations.
- Flexible report generation: Activity selection, sorting options and report formatting.

Resource Allocation Processor

- Fixed-time or fixed-resource scheduling of multiple projects.
- Used-by-job and carried forward resources.
- Dated and cyclic changes for resource availabilities.
- Operation concept allowing variable resource requirements for an activity.
- Resource Generation.
- Replacement of an operation by an alternate one.
- Allocation of up to 50 resources.

Cost Evaluation Processor

- Computation of direct costs based on resource requirements and resource rates.
- Two types of resource rates: Normal and overtime.
- Resource rates varying with time.
- Overhead costs and budgets defined for organization table entries.
- Costs summarization by time periods and organization table entries.

Network Preparation Processor

- Concept of standard module which is a subnet used in several networks.

- Possibility of cataloging up to 100 standard modules in the Standard Module Library and retrieving them for inclusion into new networks.
- Ability to draw a network or some parts of it on the printer.

PROJACS is designed as a replacement product for PCS/360 customers since most of the highlights are improvements over PCS/360, and a conversion program is provided to facilitate the migration of PCS/360 customers to PROJACS. This program is distributed with the Main Processor and produces a deck of cards in PROJACS format for any network stored in the PCS/360 Permanent Storage File.

USE

The Main Processor can be used without any of its optional features. The other processors can be used independently of each other, but they always require the Main Processor. The Cost Evaluation Processor may use results from the Resource Allocation Processor.

CUSTOMER RESPONSIBILITIES

Current users of PCS/360 should convert their networks into PROJACS data format using the conversion program. All users must be familiar with the fundamentals of the critical path techniques and learn the particular features of this system. Tailoring of output reports to user requirements necessitates preparation of the most frequently used reports and, in certain cases, translation of headings before actual use of the program.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS****PROJACS DOS/V5:**

The minimum machine configuration to install, execute and support PROJACS DOS/V5 in addition to DOS/V5 requirements:

IBM S/370 (96K bytes) with the floating point feature.

One direct access storage device (2314/2319, 3330 or 3340).

One card reader.

The program requires an address space of 400K bytes.

The direct access storage space needed depends on the application size. For most applications, a direct access storage space of 10M bytes is sufficient.

PROJACS OS/V5:

The minimum machine configuration to install, execute and support PROJACS OS/V5 is:

- IBM S/370 mdl 135 (144K bytes) with the floating point feature.

- I/O units as required by OS/V5.

- One Direct Access Storage Device in addition to OS/V5 requirements.

The program requires an address space of 600 bytes.

The direct access storage space needed depends on the application size. For most applications, a direct access storage space of 10M bytes is sufficient.

SOFTWARE REQUIREMENTS

PROJACS is mainly written in PL/I with a few routines in Assembler. It operates on S/370 Virtual Storage configurations in virtual mode under DOS/V5, OS/V51 and OS/V52 and under DOS/V5, OS/V51 and OS/V52 executing under VM/370. It uses SAM and DAM data management facilities.

PROJACS DOS/V5:

The following program products are prerequisites for execution of the program:

DOS PL/I Transient Library (5736-LM5)

DOS/V5 Sort/Merge (5746-SM1)

Note: If 3330 or 3340 DASD support is not required, DOS Sort/Merge (5743-SM1) can be used or if only 2314/2319 direct access facilities are used, the DOS tape and disk Sort/Merge (360N-SM-483) can be used.

The DOS PL/I Resident Library (5736-LM4) is also required for installing and servicing the program.

The DOS PL/I Optimizing Library (5736-PL1) is required to compile the source modules.

PROGRAM PRODUCTS

PROJACS (cont'd)**PROJACS OS/VS:**

The following program products are prerequisites for execution of the program:

- OS PL/I Transient Library (5734-LM5).
- OS/VS Sort/Merge (5740-SM1) or OS Sort/Merge (5734-SM1).

Note: The OS/VS Sort/Merge provides additional features and improved performance over OS Sort/Merge and is required for 3330 mdl 11 or 3340 DASD support.

The OS PL/I Resident Library (5734-LM4) is also required to install and support the program.

The OS PL/I Optimizing Compiler (5734-PL1) is required to compile the source modules.

Program Product Specifications (GH19-1083) ... *General Information Manual* (GH19-1055).

HIERARCHICAL STORAGE MANAGER (HSM) RELEASE 3.2 (5740-XRB)

PURPOSE

Hierarchical Storage Manager provides value to customers by helping them to manage DASD space efficiently in Total Storage Management environments. Critical online DASD storage is optimized for new applications when HSM moves inactive data to secondary storage. Applications are isolated from secondary storage containing inactive migrated and backed-up data because application programs access primary online DASD only. People resources are made available for application development as HSM automatically performs space management and incremental backup functions. Critical DASD space becomes available for new users and the growth of their new applications.

SPECIAL SALES INFORMATION

In addition to the benefits provided by the space and availability management functions described above, consider the advantages offered by key HSM functions described here.

ISPF panels for HSM space maintenance is a data-set-oriented function which provides end-users with online capability to easily manage their own data without having to review periodic data center reports.

The DASD conversion function can reduce your customer's installation workload by 'moving' HSM-supported data from one DASD volume device type to the same or different volume device type, such as the 3380 and 3375. In addition, HSM will automatically reblock physical sequential data sets on the initial 'move' to the 3380 and 3375 if the SETSYS CONVERSION option is chosen.

The data compaction option can save HSM-owned space on secondary storage devices. IBM internal accounts that are using HSM have documented an average byte compaction ratio of approximately 2 during migration, which translates into an average space saving of 50%.

The average storage space saving that can be attained in a given environment for new applications is dependent on the total number, size, type and content of the data sets selected, the devices used, and the functions enabled for compaction. HSM will use additional CPU resources when data sets are compacted and decompact.

HSM supports the 3380, 3375, 3350 and 3330 Direct Access Storage, and MSS devices for all space and backup management functions, and the 3420 Tape Subsystem for the retirement and backup management functions. A combination of compacted real DASD as Migration Level 1 volumes, and virtual DASD as Migration Level 2 volumes, provides an attractive price/performance space management combination for large HSM configurations.

DESCRIPTION

Data set movement within the hierarchy is automatically initiated by HSM in batch and interactive environments based upon installation parameters and data set references. HSM provides a device-independent link between HSM-managed primary and secondary devices by managing them as a hierarchy to store subsequent user data such as HSM migration and backup data.

HSM automatic functions are supplemented by command functions which users can execute from their terminals. End-user commands can be executed from ISPF panels for HSM.

HSM executes as a continuously-running task with MVS/XA, MVS/370, or with MVS/XA and MVS/370 in multithost environments. HSM operates below the 16 megabyte line under MVS/XA. User-written HSM exit algorithms that will be used in MVS/XA environments must be link-edited to remain below the 16 megabyte line.

HSM space management provides three major daily space management functions:

- **Data Set Migration:** The migration function can be used to move inactive data sets from a primary volume with the migrate attribute to a DASD or virtual migration volume, or from migration level 1 volumes to migration level 2 volumes. A minimum migration age may be user-specified for each primary volume.
- **Data Set Deletion:** The deletion function with a specified inactive age criterion can be used to automatically scratch inactive data sets from primary volumes with the delete-by-age attribute. In addition, an HSM volume command can be issued to scratch inactive data sets from migration volumes, from non-HSM-managed volumes, and from any primary volume. The command function can also be used to supplement the automatic function performed on a primary volume.
- **Data Set Retirement:** The retirement function can automatically scratch inactive data sets on primary volumes with the delete-if-backed-up attribute if the backup function has created current backup copies. The backup and retirement functions jointly provide HSM with the capability to retire, automatically or by command, inactive data sets from primary volumes to tape, DASD, or mass storage volumes. In addition, an HSM volume command can be

issued to retire inactive data sets from migration volumes, from non-HSM-managed volumes, and from any primary volume. The command function can also be used to supplement the automatic space management function specified for a primary volume.

HSM space management process also provides:

- **Data Set Recall:** The recall function can automatically move the migrated data sets to a primary volume when they are referenced. Recall is a multitask function.
- **Related Functions:** The related functions include extent reduction for non-VSAM data sets, compression of partitioned data sets, small-data-set-packing on migration level 1 volumes, and scratching of list and utility data sets. HSM moves only used space for sequential and partitioned data sets.

HSM availability management provides options such as the days on which backup will run, the number of days between consecutive backups of a data set, the number of versions to be retained, and the time of day when backup will run. HSM availability management also provides:

- **Data Set Backup:** HSM provides multitask incremental backup for a maximum of 15 volume backup tasks, with a default of two. Each customer should determine the number of concurrent volume backup tasks that is practical in his environment. Changed data sets on primary volumes can be copied to tape, DASD, or mass storage backup volumes, automatically or by command. Changed and unchanged data sets on a volume can be backed up by command.
- **Data Set Recovery:** Recovery is the process of explicitly restoring a backup version of one or all the data sets that were on a primary volume to the same or a different primary volume by an explicit command. The data set recovery command is also used to return a retired data set back to a DASD volume. In addition, HSM can be used to supplement a volume restore utility. For example, a primary volume can be restored to the level of a weekly volume dump tape created by Data Facility Data Set Services (5740-UT3), and then restored to the current day level by using HSM.

By providing data-set-oriented Interactive System Productivity Facility (ISPF) panels, HSM gives end-users the capability to easily review the status of all or a subset of their cataloged data. On an exception basis, they may use the ISPF panels to delete their primary and HSM-migrated data sets (and optionally any HSM backup copies), condense, backup, migrate, recall, and recover their data, and alter the backup frequency and number of backup versions retained by HSM. HSM space maintenance for data sets provides:

- ISPF panels for the display of data set status and detail information.
- Space maintenance commands with defaults for ease of use in executing data set administrative tasks from the ISPF panels.
- Tutorial ISPF panels for user guidance in doing HSM space maintenance.
- Optional parameter entry ISPF panels for experienced end-users to enter any command keyword.

The data compaction option can save significant storage space in HSM environments. The compacted data can reside on DASD, tape (backup and retired data sets only), and mass storage volumes in HSM-owned space. HSM data compaction:

- Is transparent to user and application programs, and occurs during automatic, command, volume, and data set functions, and
- Is enabled by SETSYS command to compact data sets during migration, backup-to-DASD, backup-to-tape, all, or none (default).
- Uses a Huffman frequency-encoding algorithm to compact data only as data sets are moved or copied from a primary or from a non-HSM controlled volume.
- Has optional tables tailored to compact source, object, and general (default) data sets as specified.
- Has enhanced user exits for user-written algorithms to approve or disapprove compaction of eligible data sets during volume migration and backup.
- Automatically decompacts data sets during recall and recover operations, even with the option disabled for all functions.

Other HSM functions and capabilities include:

- **DASD Conversion:** An HSM-authorized administrator can 'move' HSM-supported data from one DASD volume device type to the same or different volume device type. This function is designed to make it easier to convert current HSM-supported DASD to the 3380 and 3375 DASD.

HSM R3.2 (cont'd)

- **Batch and TSO Support:** HSM space management and backup processes support both batch and TSO environments.
- **Multihost Support:** HSM can be active on more than one host in a multihost environment, and must be available on all hosts in a JES3 environment. HSM-managed volumes and control data sets must be on sharable units if more than one host requires access to the data.
- **Reblocking:** An optional conversion aid that automatically reblocks migrated data sets from non-3380 and non-3375 volumes when they are initially recalled to 3380 or 3375 volumes.
- **Tape Backup:** Backup of primary volumes to tape daily backup volumes. Tape or DASD spill backup volumes can be specified if the daily backup volumes are DASD.
- **Tape Backup Volume Control:** This function selects, assigns, and recycles the HSM tape backup volumes. Recycling is by command, or is automatic if all of the versions on a tape have been superseded.
- **User Exits:** HSM provides information to several optional user exits which permit user-written algorithms to approve, disapprove, selectively control reblocking, change certain HSM selections, and invoke functions related to HSM.
- **Control Data Sets:** HSM uses migration, backup, and offline control data sets to manage the data sets in the HSM-owned space on migration and backup volumes.
- **3850 Mass Storage System:** MSS provides low-cost-per-megabyte data storage frame models to store migrated, backed-up, and retired batch and TSO data sets managed by HSM for subsequent use.
- **Integrity:** A command is provided to initiate reconstruction of up-to-date HSM control data sets from backup versions and journal records.
- **Additional User Capabilities:** Commands are provided to determine HSM status, change parameter settings, specify JES3 presence, and determine the utilization status of the journal and control data sets.
- **Devices Supported:** 3380, 3375, 3350, 3330 mdls 1 and 11 and the 3850 Mass Storage System for primary, migration, and backup volumes, and the 3420 (9-track) for backup volumes.
- **Access Methods:** SAM, PAM, movable DAM, and VSAM data sets are supported by HSM.
- **Coexistence:** The HSM data compaction option in Release 3.1 must not be enabled in a multihost environment until it is installed on all hosts, otherwise a Release 3.0 host could attempt to recall a compacted data set and destroy it.
HSM Release 3.2 can coexist with HSM Release 3.1 in a multihost environment.
See the *OS/VS2 MVS Hierarchical Storage Manager System Programmer's Reference and Operations Guide* (SH35-0023) for other guidelines and restrictions that may apply to a multihost coexistence environment.
- **RACF Support:** HSM interfaces with RACF for data set protection.
- **JES3 Support:** HSM space management and backup processes support data sets in a JES3 environment where SETUP is used.

CUSTOMER RESPONSIBILITIES

The HSM installation consideration details documented in the *OS/VS2 MVS Hierarchical Storage Manager System Programmer's Reference and Operations Guide* (SH35-0023) include most of the following items:

- Order the HSM Independent Study Program.
- Request a review of the HSM Preventive Service Planning (PSP) information.
- Develop an HSM installation plan.
- Install the prerequisite SCP code, and functional prerequisites for HSM.
- Install HSM Release 3.0, 3.1 and 3.2 on one HSM host.
- Define the HSM migration, backup, and offline control data sets.
- Define the required and optional HSM parameters.
- Allocate the HSM log, the journal data set, the small-data-set packing data sets, and backup copies of the control data sets.
- Identify volumes to be specified as primary for space management and backup functions.
- Identify volumes to be used for migration and backup data.
- Create VATLIST entries if desired.

- Set up a procedure for starting HSM.
- Set up a procedure to maintain backup copies of HSM control data sets.
- Set up a procedure for dumping and printing log data sets.
- Set up TSO and TSO/E HELP members.
- Link-edit any user-written exit routines.
- Set up a SYS1.PARMLIB member for HSM parameters.
- Identify to HSM if JES3 is used.
- Ensure consistency of HSM/JES3 pool definition and recall option across processors.
- Execute single host test plan prior to multihost test and production.
- Install HSM Releases 3.0, 3.1 and 3.2 on all HSM hosts.
- Install HSM Data Compaction Option (3.1) on all hosts, and test prior to production.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

HSM is designed to operate on IBM processors which are supported by JES2 and JES3, under MVS/System Product Version 2 (MVS/XA), MVS/System Product (MVS/SP) Version 1, MVS/System Extensions (MVS/SE), and OS/VS2 (MVS) Release 3.8, as specified under "Software Requirements".

The supported storage devices include the IBM 3380, 3375, 3350, 3330 mdls 1 and 11, and the 3850 for primary, migration and backup volumes, and the IBM 3420 Tape (9-track) for backup volumes.

SOFTWARE REQUIREMENTS

HSM operates with JES2 and JES3 under MVS/XA and MVS/370 as specified below:

The functional prerequisites for HSM with MVS/XA are as follows:

- **JES2:** JES2 component of MVS/SP-JES2 2.1.0 (5740-XC6) or subsequent release.
- **JES3:** JES3 component of MVS/SP-JES3 2.1.0 (5665-291) or subsequent release.
- **RACF:** RACF Release 4 (5740-XXH) or subsequent release.
- **ISPF panels for HSM space maintenance:** HSM Release 3.1 (5740-XRB) and ISPF Release 1.1 (5668-960) or subsequent release. The BROWSE command requires ISPF/PDF MVS Release 1.1 (5668-268) or subsequent release.

The functional prerequisites for HSM with MVS/370 (MVS/SP, MVS/SE and MVS 3.8) are as follows:

- **JES2:** JES2 component of MVS/SP-JES2 1.1.0 (5740-XY5), or JES2 Release 4.1, an integral part of OS/VS2, 5752-VS2, (optionally with 3800 Enhancements); or NJE for JES2, 5740-XRB, (optionally with NJE for JES2 3800 Enhancements).
- **JES3:** JES3 component of MVS/SP-JES3 1.1.0 (5740-XYN), or JES3 Release 3 selectable unit with OS/VS2, 5752-VS2 (optionally with JES3 3800 Enhancements, and JES3 Networking PRPQ, 5799-AZT).
- **3800 or 3375 Devices:** MVS/370 DFP Release 1 (5665-295) or subsequent release, or DFDS (5740-AM7).
- **RACF:** RACF Release 4 (5740-XXH) or subsequent release.
- **HSM space management of VSAM data sets:** MVS/370 DFP Release 1 (5665-295) or subsequent release, or DFEF (5740-XYQ).
- **ISPF panels for HSM space maintenance:** HSM Release 3.1 (5740-XRB) and ISPF Release 1.1 (5668-960) or subsequent release. The BROWSE command requires ISPF/PDF MVS Release 1.1 (5668-268) or subsequent release.

Storage Requirements: The private HSM virtual address space recommended to use all Release 3.2 functions is 3 megabytes.

Customer Education: A self-study course, Hierarchical Storage Manager Implementation for MVS (32905), consisting of two video cassettes and associated texts, is available from Science Research Associates (SRA). The self-study course does not include the HSM Release 3.2.

INSTALLATION INFORMATION

Customers planning to install HSM should request their IBM programming support or support center representative to review the HSM Preventive Service Planning (PSP) information.

PROGRAM PRODUCTS

HSM R3.2 (cont'd)

The HSM basic materials tape shipped from the IBM program library contains the service updated Releases 3.0 (base) and 3.1 (incremental addition), and the new Release 3.2 (incremental addition).

Release 3.0 contains the base HSM functions. Release 3.1 contains the data compaction option, usability improvements, and changes required for HSM operation with MVS/XA. Release 3.1 enhancements contain the DASD conversion, performance improvements, minimum age by volume, and 'SYSx.' space management, initially shipped on PUT tape 83-01 (APAR OZ64320), which will be integrated into the Release 3.1 incremental addition on a subsequent HSM service update. Release 3.2 contains the ISPF panels for HSM space maintenance.

HSM Release 3.1 (5740-XRB) and ISPF Release 1.1 (5668-960) are installation prerequisites for HSM Release 3.2. The BROWSE command requires ISPF/PDF MVS Release 1.1 (5665-268).

Release 3.2 must be installed on a Release 3.0/3.1 (any Release 3.1 level) base by SMP4 or SMP/E as described in the HSM Program Directory. HSM Releases 3.0 and 3.1 may be installed by SMP4, SMP/E or SYSGEN.

HSM supports SAM, PAM, movable DAM, and VSAM-type data sets.

DATA SECURITY, AUDITABILITY and CONTROL

HSM complies with and conforms to the data security and auditability controls of MVS/XA or MVS/370 environments. If RACF is available, HSM will invoke that licensed program to provide and maintain RACF user data set protection. Customer management is responsible for the selection, application and adequacy of those controls.

OS/VS2 MVS Hierarchical Storage Manager General Information (GH35-0007).

MVS SYSTEM INTEGRITY APPLIES: Yes

RPQs ACCEPTED: No.

PROGRAM PRODUCTS

**STORAGE AND INFORMATION RETRIEVAL SYSTEM/
VIRTUAL STORAGE (STAIRS/VS)
OS/VS (5740-XR1)**

PURPOSE

The conventional method for indexing documents in a specialized information system or a library has been fatiguing and cumbersome work for specialists. Today, documents, articles from periodical magazines, patent texts, and their abstracts, can be converted into machine-readable form for entry into a computer system.

Once entered, the material can be used during subsequent searches, using the language of the technical area involved, to retrieve the desired documents.

The full texts, or their associated bibliographic identifiers (such as title, author, publisher, and source), make up a dynamically growing file of data which can be searched by specialists in law, engineering, medicine, sales, marketing, management, and other fields, to retrieve material of interest pertaining to their own spheres.

DESCRIPTION

The Storage And Information Retrieval System/Virtual Storage (STAIRS/VS) Release 4 is an enhancement of the current release (Release 3.0) of STAIRS/VS and will replace it.

In addition to the service corrections that have been incorporated into STAIRS/VS Release 4.0, the new release will have the following functional enhancements:

- **PRINT/MAIL Improvements**
 - The Print/MAIL commands will support additional (optional) parameters, such as:
 - End-user information (address or others) listed at print time
 - Comment line
 - Display of all PRINT/MAIL requests of the terminal session
 - Cancellation and reactivation of PRINT/MAIL requests during the terminal session
 - Confirmation of a print request is forced, if a certain (data base-defined) number of documents is exceeded.
- **SAVE/EXEC Improvements**
 - Displaying the names of saved profiles
 - Displaying the queries of a saved profile
 - SDI (Selective Dissemination of Information) function for saved profiles
- **SIGN-ON/OFF and Other Improvements**
 - News function
 - Status display after use of the command CHANGE, at sign-off, and on request, containing user and data base name, time of day, session time, and accounting information
 - The command EDIT allows the user to edit a saved query profile without execution

STAIRS/VS is a terminal-oriented multi-user dialog system for the storage and retrieval of information, which also allows for batch processing. It offers the user a variety of resources for data base creation and maintenance and, especially, for data base searching and display and/or printing of documents and/or formatted data.

STAIRS/VS operates under the IBM operating systems OS/VS1 Release 7.0 and OS/VS2 MVS Release 3.8 and MVS/SP Version 1 Release 3.0 (collectively referred to as OS/VS) or subsequent releases unless otherwise identified.

For data communication, STAIRS/VS uses the facilities of the IBM S/370 Customer Information Control System/Virtual Storage (CICS/VS) Version 1, Program Number 5740-XX1, Release 5 or the IBM Information Management System/Virtual Storage (IMS/VS) Version 1, Program Number 5740-XX2, Release 1.6 (OS/VS1) or Release 2 (OS/VS2 MVS) or subsequent releases of both systems unless otherwise identified.

Device-dependent message-formatting routines are provided by STAIRS/VS for the IBM 3270 Information Display System (display units with screens of 24, 32 or 43 lines that are 80 characters wide, and associated printers), for the IBM 2740 and 2741 Communication Terminals, and for 'batch' simulated terminals (combination of an input and an output data set). While all of the above terminals are supported by STAIRS/VS under CICS/VS, the IBM 2741 and the IBM 2740 without the Station Control feature are not supported by STAIRS/VS under IMS/VS; this is because they are supported by IMS/VS as response terminals only.

HIGHLIGHTS

Documents can be searched and retrieved with a highly flexible form of dialog in which previous queries can be extended or referred to. Query

formulation varies from everyday language to mathematical formulation in terms of:

- Boolean and context logic for the document text and/or
- Comparison operators for the contents of formatted fields.

Query formulations can be saved for current or later use, a feature which serves as a 'current awareness profile' capability. There are two modes of saving queries: Either in a reserved area accessible only to the user who had saved the queries, or in a common pool accessible to any user of the installation. The saved queries can be displayed and modified online.

It is possible to add a user-written exit module (in Assembler or PL/I language) for user-specific processing of:

- SEARCH query prior to processing by STAIRS/VS, and/or
- The document list resulting from a retrieval step.

The contents of the formatted fields of the documents can be modified online. The modified fields are immediately available for the SELECT function. The documents that are presented as answers by the system can be ranked according to their probable relevance or they can be sorted according to the contents of a formatted field. Search and display can be restricted to a subset of paragraphs of the documents.

Documents viewed on display terminals can be paged forward and backward.

In an IBM 3270 display terminal, the keywords of a query, where appearing in the text, can be displayed with double intensity - if CICS/VS is used. The paging command P* can be used to skip to the next page of the displayed document on which a word is highlighted.

There are two options for document highlighting. With global highlighting, all words from the query occurring in the displayed text are highlighted. With query highlighting, only those words in the displayed text are highlighted that match the logic of the query. With this option also synonyms of query-words are highlighted - if they match the query logic.

It is also possible to have those paragraphs displayed or printed automatically which contain query hits - even if they have not been specified for display.

Retrieved documents, or pages of them (when using a display terminal), can be copied immediately on a print-terminal (e.g., the IBM 3284 Printer). They can also be transmitted for later printing on a high-speed printer. Words from the queries can be underscored in the printed output. This function corresponds to highlighting of query words at IBM 3270 display terminals. Only global highlighting, however, is provided; all words from the queries are underscored regardless of the logic of the queries.

The number of data bases that can be handled online is limited only by the capacity of an OS/VS installation for DD-statements per job-step.

Up to sixteen different data bases of identical structure can be concatenated and searched by one query, as if they were a single data base. This holds for each subset of the sixteen data bases, thus providing the capability of retrospective search as well as current information selection.

Up to four data bases of identical structure can be merged to a single data base. This provides a possibility of reorganization for a (logical) data base consisting of concatenated (physical) data bases.

A retrieval dialog which has been interrupted by system or machine malfunction can be continued, after the system has been restarted, at any other terminal by means of the STAIRS/VS warm-start function. The data base restart/recovery facilities of IMS/VS are not effective for STAIRS/VS.

Facilities to help maintain the privacy and security of data bases are incorporated in the system. Security of data can be enhanced at data base, document, paragraph, and field levels by means of registered user names, passwords, and privacy codes.

When CICS is used, data bases may be created online and concatenated to existing ones so that the extended data bases can, subsequently, be used for retrieval with STAIRS/VS. The input for this online data base creation can be produced in the appropriate format by means of the IBM Advanced Text Management System (ATMS-III/OS/VS, Program Number 5740-XYL), which operates only under control of CICS/OS/VS.

Alternatively, the ATMS output for STAIRS/VS may be used as input for the Batch Data Base Creation program of STAIRS/VS. This program is of course also applicable to STAIRS/VS under control of IMS/VS. Input for batch data base creation in the same format can also be generated by the Document Composition Facility, Release 2 (5748-XX9) and the Distributed Office Support System/370 (5740-XY9).

PROGRAM PRODUCTS

STAIRS/VS (cont'd)**CUSTOMER RESPONSIBILITIES**

This section briefly discusses the activities to make STAIRS/VS operational; it gives a rough guideline for assessing the total installation effort. It is assumed that a system running under OS/VS with either CICS/VS or IMS/VS with the Data Communication Feature has already been installed.

The major implementation steps are:

- STAIRS/VS must be installed according to the installation description and the distribution tape.
- The required tables for CICS/VS or the control blocks for IMS/VS must be regenerated including the entries required for STAIRS/VS.
- The supplied sample data base can be accessed using the sample users to verify the installation.
- User registration records for the anticipated users of the system must be generated.
- Documents to be incorporated into the STAIRS/VS data base(s) must be edited according to the input specifications of the Data Base Creation programs. The data base(s) must be loaded and appropriate DSCBs generated. The users must be registered for the data base(s). The data base(s) must be included in the File Control Table, and DD cards for the data base data sets must be included in the Job Control of the online STAIRS/VS job and the Print utility.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

For compilation and/or execution of STAIRS/VS, an IBM S/370, an IBM 3031, 3032, or 4300 Processor with a main storage capacity large enough to run IMS/VS or CICS/VS is required.

The additional storage required for STAIRS/VS may vary widely, depending on the number of active terminals and the used system:

- For STAIRS/VS under CICS/OS/VS
120K bytes for the first terminal and 8K bytes for each additional active terminal in the CICS/VS region. If online data base creation is used, 125K bytes are required additionally: 60K bytes for the Online Data Base Creation program and 65K bytes for the Sort/Merge program.
- For STAIRS/VS under IMS/VS
A batch message processing region with 200K bytes for the first terminal and 8K bytes for each additional active terminal.
- The batch Data Base Creation and Maintenance programs of STAIRS/VS require an address space of 128K bytes.

For the data bases and other STAIRS/VS data sets, the same devices are used as supported by OS/VS and CICS/VS.

One IBM nine-track magnetic tape device is required for the installation.

At least one 1920-character or larger IBM 3270 display station, attached to the appropriate control unit, or an IBM 2740 or IBM 2741 Communicating Terminal must be available. The Communicating Magnetic Card Selectric Typewriter mdl 6610 and the IBM Displaywriter System can be used as IBM 2741 terminals via switched lines, if CICS/OS/VS and BTAM are used. The IBM 2740 without the Station Control feature and the IBM 2741 are supported only if CICS/OS/VS is used.

SOFTWARE REQUIREMENTS

Most modules of STAIRS/VS are written in the IBM Assembler language and use the macro language facility. Some batch utilities are written in PL/I. All modules are distributed in both source and load module form. Thus, for the execution of the PL/I modules, only the PL/I Transient Library, Program Number 5734-LM5, is required. If a STAIRS/VS module written in PL/I is to be compiled (for APAR corrections, program modifications, or user-written exits), the PL/I Optimizing Compiler, Program Number 5734-PL/I, and the PL/I Resident Library, Program Number 5734-LM4, are also necessary. For data base creation, the OS/VS Sort/Merge, Program Number 5740-SM1, is used. If online data base creation under CICS/OS/VS is used, ATMS-III/OS/VS, Program Number 5740-XYL, is needed.

STAIRS/VS is designed for an online OS/VS environment and requires the following programs:

- OS/VS1 Release 7.0 or OS/VS2 MVS Release 3.8 or MVS/SP Version 1, Release 3.0.
- CICS/OS/VS Version 1, Program Number 5740-XX1, Release 5 or IMS/VS Version 1, Program Number 5740-XX2, Release 1.6 (OS/VS1) or Release 2.0 (OS/VS2 MVS) with the Data Communication feature.

Subsequent releases of the above programs are also supported unless otherwise provided by IBM.

MVS SYSTEM INTEGRITY APPLIES: Yes

RPOs ACCEPTED: No

5740-XR8 - NJE for JES2 NETWORK JOB ENTRY FACILITY FOR JES2

PURPOSE

JES2 with the NJE facility is upward compatible from JES2 and provides additional functional enhancements. It supports the interconnection of NJE for JES2 configurations via binary synchronous communications (BSC) lines and channel-to-channel (CTC) adapters. The purpose is to exchange job input, job system output (SYSOUT) data, NJE for JES2 operator commands, and operator messages between NJE subsystems operating on OS/VS2 MVS Release 3.7. The job input and SYSOUT distinctions are controlled by installation provided defaults, JOB control statements, and/or operator commands.

SPECIAL SALES INFORMATION

NJE for JES2 is designed for customers with geographically separated processors. It also may be used with configurations in the same geographic location as an alternative to the JES2 multi-access spool facility. It builds upon and uses the facilities of JES2 RJE MULTI-LEAVING for transmission of job input, job SYSOUT, operator commands, and operator messages between OS/VS2 Release 3.7 systems using NJE over binary synchronous communications (BSC), Synchronous Data Link Control (SDLC) and channel-to-channel (CTC) adapter connections. It also expands the capability of the multi-access spool facility in that communications flow through the spool volumes shared by members of a multi-access spool node. NJE for JES2 has the following features:

A job entry network can consist of up to 99 nodes (where a node can be a single processor (UP, MP), a multiprocessor or a multi-access spool configuration) each interconnected via BSC communication lines, SDLC lines or CTC adapters.

Nodes may be interconnected in any manner, using any mix of BSC leased point-to-point lines, BSC dial-up lines, and channel-to-channel adapters. Network configurations may change dynamically during normal operations; such changes are automatically taken into account by the NJE network path managers.

The channel-to-channel special feature attached to block multiplexer channels of S/370 mdls 145, 148, 155II, 158, 165II and 168 is supported for network communications. See *System/370 Special Feature: Channel-to-channel Adapter*, (GC22-6983).

The 2701 Data Adapter Unit with the Text Transparency feature, 2703 Transmission Control, and 3704/3705 Communication Controllers (in the emulation mode) are supported for network communications in point-to-point transparent-text transmission mode over binary synchronous communication lines.

NJE for JES2 supports the following combinations of BSC, SDLC and CTC adapter and multi-access spool connections:

1. Up to seven systems may be connected via the multi-access spool to form a node.
2. Up to 99 nodes may be defined in the network.
3. More than one BSC and/or CTC adapter connection may be used in a multi-trunk connection between nodes.
4. Any and all members of a node may be connected to any member of other nodes via the BSC, SDLC, and CTC adapter connections. Such connections may create multiple-path arrangements.
5. NJE will keep track of as many as eight alternate paths and may use more than one path for concurrent communication between two nodes.

Except for the additional communication equipment required to handle NJE lines and the minimal additional address space NJE requires, NJE for JES2 makes no direct requirements for additional hardware. NJE activity causes buffers to be fixed in storage during normal NJE operations, thus requiring more main storage in heavily loaded systems. Additional SPOOL volumes may also be required to hold the jobs and SYSOUT data that will pass through the system.

DESCRIPTION

The Network Job Entry (NJE) facility provides for the transmission of selected jobs and in-stream data sets, system output (SYSOUT) data sets, operator commands and messages, and job accounting information from one computer system to another across a communication link.

A job entry network consists of one or more interconnected computer systems (called nodes), running under OS/VS2 MVS. These nodes have the capability of communicating with one another and passing the information indicated above from one node to the next. The number of nodes which can exist within a job entry network ranges from one to 99.

The nodes can be single processors (UP/AP), tightly coupled multiprocessor processors, or multi-access spool systems.

A job may enter the network via any JES2 local or remote input device and will be queued for transmission to another node if the node of entry is not the execution node. A job designated for execution at another node is either transmitted directly to that node or is transmitted through

intermediate nodes located along a path to the execution node. Transmission of jobs along BSC communications links is handled on a store-and-forward basis; that is, a job must be completely received by a node before any action will be taken to either execute the job or transmit the job to another node. Once a job has been completely received by a node, the transmitting node frees the resources that were allocated to the transmitted job. Transmission of jobs through ACF/VTAM links is logically direct to the execution node.

The execution node is determined in one of three ways: [1] when the job enters the job entry network, a default execution node is defined based upon the device upon which the job entered the system, [2] the default execution node may be overridden by the submitter of the job through a /*XEQ or /*ROUTE XEQ control statement submitted as part of the job, [3] the execution node may be explicitly defined by the use of NJE operator commands.

As a job is received on an intermediate node along BSC communications links, it is spooled and queued. If that node is not the execution node, the job will be queued for transmission to the next node in the path to the execution node. Transmission to the next node will not be initiated until the job has been completely received from the previous node. As a job leaves a node, its resources on that node are freed. Intermediate nodes supported by ACF/VTAM and ACF/NCP/VS will not require the host processor and spool resources.

When a job reaches its execution node, it is queued for conversion and execution. The input data sets which have been transmitted with the job are available to the job through the normal spooling access methods. Output data sets are generated and spooled in the normal fashion, and may be directed to one or more destinations. If the destination node(s) is different from the execution node the appropriate output data sets are queued for transmission to the destination node(s). If SYSOUT spinoff is specified (FREE=CLOSE or equivalent), the output is eligible for transmission as soon as the data set has been closed. Otherwise, the SYSOUT data sets of a job are saved until execution is complete. After execution is completed the output is eligible for transmission to the appropriate destination node(s). SYSOUT data sets designated to be held for TSO retrieval on a node other than the execution node are transmitted to their destination node to be held.

The destination node(s) for output is determined in one of four ways: [1] when the job enters the job entry network, a default output destination is defined based upon the device upon which the job entered the system, [2] the default output destination may be overridden by the submitter of the job through a /*ROUTE control card submitted as part of the job, [3] the output destination of a particular data set or group of data sets can be specified through DEST parameters on either JCL Data Definition (DD) statements or on /*OUTPUT control statements submitted as part of the job, [4] the output destination can be explicitly defined through use of NJE for JES2 operator commands.

The output for a job may pass through intermediate nodes on the way to a destination node(s). In the BSC case, however, transmission to the next node will not be initiated until the output has been completely received from the previous node. Upon receipt by the destination node it is queued for normal output processing. Resources are freed as all output is completely transmitted or outputted for a given job. Intermediate nodes supported by ACF/VTAM and ACF/NCP/VS will not require the host processor and spool resources.

Operator commands may be directed to any node in the network for processing. Command responses are passed back to the originating console. Five NJE for JES2 commands have been identified as global network commands. These commands allow the operator to display jobs, hold jobs, release jobs, cancel jobs, and route jobs that currently reside at another node in the job entry network. The authority of any operator to control jobs in the network has two elements. First is the authority assigned to the operator's console within its own node. Second is the authority assigned to the operator's node, as defined at the node in which the command is to be processed.

At each stage of processing, appropriate accounting information is collected and produced on the processing node for local accounting. In addition, network accounting number support is included. This new facility permits accounting numbers to be assigned across the network and provides initialization parameters, conversion tables and routines and user exits to convert local accounting numbers to network accounting numbers and vice versa. All accounting information is produced through standard System Management Facilities (SMF).

Release 2 of NJE provides all of the capabilities of Release 1, plus additional remote job entry support. Using VTAM, this support allows connection of remote workstations through 3791 Communication Controllers. Connection can be made either through local channel attachment or via SLDC communication lines. New data set header support allows data sets destined for remote devices attached to the 3791 to be spooled at the remote workstation. Multiple logical unit support permits the concurrent operation of multiple devices as remote workstations.

PROGRAM PRODUCTS

NJE for JES2 (cont'd)

NJE for JES2 Initialization: NJE for JES2 provides for the initialization of NJE control blocks and the definition of nodes in a job entry network. The actual connections between nodes may be defined by NJE initialization statements, but they are normally determined dynamically by the network path managers. Warm-start recovery of NJE processes active at the time of a failure is also provided.

RTAM: NJE for JES2 Remote Terminal Access Method supports connection protocols between directly connected job entry subsystems. This allows for the passing of network connection control records to the network path manager for action. Other enhancements include support of the channel-to-channel adapter in a manner equivalent to a high-speed communication line, support of additional logical stream types required by NJE, and support of dynamic assignment of transmission buffer sizes at connection time.

Network Path Manager: A network path manager, running in each processor in the job network, interfaces with RTAM and the multi-access spool facility to communicate with all adjacent network path managers. Decentralized network control is achieved by transmitting connection information records throughout the network, thereby maintaining a dynamic picture of the network in each node. The network path managers control the routing of data through the network by providing best-path and alternate-path information to other NJE components. The network path managers at each node participate equally in the configuration-monitoring process. No single node is designated as a network manager: Any subset of an NJE network can function entirely on its own.

Job Transmitter and Receiver: A job transmitter has been provided and the NJE for JES2 input service component has been designed to allow transmission of jobs from the input node, through the network, to the execution node. The job is routed along a path determined by the network path managers. When a job is completely received and queued for the next function, the transmitting system frees all resources for the next job.

System Output Transmitter and Receiver: A system output transmitter and receiver have been provided to transmit the system output data sets to the appropriate nodes (as determined either by default or by explicit programmer or operator action). The output is routed through paths determined by the network path managers. When a group of data sets has been completely received and queued (either for output or further transmission to another node), the transmitting node frees all resources used in the transmission of the data sets.

NJE for JES2 Console Services: The console services component has been designed to pass commands, responses and messages through the network via the paths determined by the network path managers. The remote console processor used for remote job entry (RJE) has been designed to recognize and forward messages and commands from one node in the network to another. The messages and commands are forwarded through the network via communications lines by the RTAM RJE console interface, and are forwarded across shared-spool devices by the multi-access spool facility. The remote console processor also provides services to the network path manager for the passing of network connection information across shared-spool connections.

Commands: Commands have been provided to allow the operator to both control the network and obtain information about it. New commands and new operands of existing JES2 commands allow the operator to send messages and commands through the network. The operator can control the NJE transmitting and receiving components in the same manner that RJE devices are controlled. Nodal command authority provides maximum flexibility in each installation's ability to control the effect of commands from other nodes on its operation.

CUSTOMER RESPONSIBILITIES

A customer installing the Network Job Entry Facility for JES2 should be a prior user of JES2 with appropriate personnel trained and experienced in OS/VS2 MVS. When installing NJE for JES2 every effort should be made to keep the initial configuration to a minimum number of nodes. After experience is obtained, additional nodes may be planned and added individually. Large network configurations require careful planning by experienced IBM and customer personnel to help ensure that maximum benefits are achieved through the proper use of the system.

SPECIFIED OPERATING ENVIRONMENT

SOFTWARE REQUIREMENTS

NJE for JES2 has been designed and released to run on OS/VS2 MVS Release 3.7 and on MVS 3.7 under VM/370. If problems are encountered when operating NJE for JES2 under VM/370, it may be required to recreate the problem in a standalone OS/VS2 MVS environment.

Operation of NJE for JES2 in a VM/370 environment is intended for use in a program development and testing environment and for other uses where performance is not critical. If your customer has specific throughput or terminal response requirements for NJE in a VM/370 environment, you should plan to benchmark under VM/370 to ensure that any proposed configuration will meet the customer's performance needs.

The language used to produce NJE for JES2 is the S/370 Assembler Language.

COMPATIBILITY

Release 1 of JES2 with the NJE Facility is upward compatible from Release 4.0 (Selectable Unit) and contains the same base function. It will support all programs, functions and devices that operate with JES2 Release 4.0.

The currency, availability and functions provided by JES2 Release 4.0 and Release 4.1 are unchanged by this program product. Current users of JES2 who do not have a job networking requirement should continue operating with the current release of JES2.

Prerequisites: The Network Job Entry Facility for JES2 requires the installation of Selectable Unit 10 as a prerequisite to the use of the 3800 Printing Subsystem. Use of SNA devices for RJE workstations will require either VTAM2, or the SCP for ACF/VTAM and ACF/VTAM, as well as the appropriate level of the NCP. Use of SDLC communications links in the NJE network will require installation of ACF/VTAM Version 1 with the Multisystem Networking Facility for ACF/VTAM or ACF/VTAM Version 2.

PLANNING INFORMATION

JES2 users should be aware that any modifications made have to be reapplied prior to the use of a new release of NJE for JES2.

Channel-to-channel Adapter: NJE supports the CTC adapter as a communication link when it is attached to a block multiplexer channel. The use of the CTC adapter by NJE for JES2 must be separate from any other use of the CTC adapter.

PROGRAM PRODUCTS

**VS TSIO
5740-XR9****PURPOSE**

VS TSIO provides the VS APL (Release 2) user, running under VSPC, with many of the data management facilities of the OS/VS operating systems.

VS TSIO facilitates the migration of APLSV (PRPQ 5799-AJF or PRPQ 5799-AQC) customers to VS APL, and may also provide valuable additional functions to other VS APL users.

The VS TSIO program product consists of an Auxiliary Processor and several associated workspaces. The Auxiliary Processor enables users to perform input and output operations on SAM, PAM and BDAM files. If authorized, users can create OS/VS sequential, direct or partitioned data sets, create SYSOUT data sets and submit batch jobs. The workspaces facilitate the use of the Auxiliary Processor, support a file system of APL objects and perform translations to and from various data representations in files.

HIGHLIGHTS

Services provided through VS TSIO include:

- Creation and deletion of data sets.
- Sequential reading and writing of data sets.
- Direct reading and writing of records in a data set by their index numbers.
- Output using sysout data sets.
- Renaming a data set.
- Facilities for applications to synchronize the use of files being shared by VS TSIO users.
- Facilities for data set protection.
- Capabilities allow a user to import or export OS SAM, PAM and BDAM files into or out of VSPC libraries dynamically.
- Indirect data set access. Allows selected users a controlled access to another user's protected data sets.
- Submission of batch jobs by authorized users to a job entry subsystem, under the control of an APL program.
- Creation and deletion by specially authorized users of entries in the operating system catalog, or the reading of the volume table of contents (VTOC) of a direct access device.
- Sending of messages by authorized users to the OS/VS console.

Note that VS TSIO does not support data sets created with the indexed sequential access method (ISAM), or the virtual storage access method (VSAM). (However note that VS APL can access VSAM files through another auxiliary processor provided with VS APL for use under VSPC or VM/CMS.)

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

The VS TSIO auxiliary processor operates in its own partition or region separate from VSPC. The workspaces distributed with VS TSIO operate in the same partition or region as VSPC, along with the VS APL language processor.

Since VS TSIO operates in a virtual environment, its performance is a function of the real storage available. A minimum of 128K bytes of virtual storage is required.

During installation, 12 cylinders of IBM 3330 space (or the equivalent) are required, of which 5 must be retained to run VS TSIO. In addition, the workspaces distributed with VS TSIO require 150,000 bytes in the VSPC object library. User DASD data sets created or accessed by VS TSIO are not included in the above.

SOFTWARE REQUIREMENTS

VS TSIO operates with VS APL Release 2 (5748-AP1) using VS Personal Computing (VSPC). VS TSIO operates either with OS/VS1 VSPC (5740-XR5), or with MVS VSPC (5740-XR6).

VS TSIO uses the basic sequential access method (BSAM), the basic direct access method (BDAM) and the basic partitioned access method (BPAM) to access data sets. Devices supported by VS TSIO are those supported by BSAM, BDAM and BPAM.

VS TSIO is written in Assembler language. The distributed workspace is written in APL.

PROGRAM PRODUCTS

**TELEPROCESSING NETWORK SIMULATOR
RELEASE 5.0
TPNS (5740-XT4)**

PURPOSE

Teleprocessing Network Simulator (TPNS) is a telecommunications testing package that enables a user to test and evaluate his application programs before actual terminal installation. The purpose of TPNS is to provide controlled generation of message traffic into a telecommunications subsystem or application through the use of processing rather than by large amounts of terminal hardware and terminal operator time. TPNS provides the ability to simulate a specified network of terminals and their associated messages, allowing the user to alter network conditions and message loads during a run. Thus, TPNS can be used to stress-test telecommunications application programs with volume messages to evaluate the reliability and approximate performance characteristics under expected operating conditions.

HIGHLIGHTS

- Supports Start/Stop, BSC and SDLC Terminals as indicated below.
- Runs under any current release of OS/VS2 (MVS), OS/VS2 (SVS) and OS/VS1 or subsequent releases of these SCPs unless otherwise specified.
- Utilizes flexible, easy-to-use script language.
- Allows for comprehensive operator intervention and modification during the test run, either manually or automatically through the inclusion of operator commands in the message decks.
- Variable message mix and traffic rate.
- Content of generated message may be varied based upon the content of a message received from the application program.
- Message logging and time stamping for offline analysis.
- Preprocessor for checking syntax prior to run.
- Online and offline reports.
- Multiple networks may be simulated simultaneously and independently to multiple subsystems on one or more processors.
- Logic tests on both input and output to allow dynamic changes in message mix during the test run.
- Random generation of test data.
- Multiple console support to allow remote console support of the simulator.
- Logic trace capabilities for logic test debugging.
- High-level message generation by having the TPNS NCP program automatically add necessary line control and terminal framing characters.
- Line trace capabilities for access method debugging.
- Drives application programs running under IBM data communication programs such as IMS, CICS, VSPC, TSO, TCAM, VTAM, BTAM, ACF/VTAM and ACF/TCAM.
- Simulates parallel sessions.
- Supports negotiable bind.
- Supports data encryption.
- Operates within the same S/370 as the application program under test (Simplex Mode) or with TPNS driving application programs in one or more processors (Duplex Mode).
- Exercises the interfaces between the terminal control unit, communication lines and the application program as used in the operational system.
- The ability to simulate S/S terminals up to 1200 bps.
- The ability to use application messages/data to generate TPNS messages. Data received in response to a previous message can be used in a succeeding message.
- Condensed interval reports.
- Enhanced logic testing - logic check can be performed at message generation time.
- Additional console commands to alter the message sequence dynamically.
- Improved network printout.
- Line/terminal device status on interval reports.
- Readable interpretation of the SNA command codes and headers on the log.
- Message rates routed to the console in addition to the printer.
- Ability to observe traffic of individual devices while executing via a monitor.
- All TPNS supported terminals can be simulated using the Advanced language.
- The capability to write messages to the console operator from the TPNS script.

For domain simulation only, TPNS can share an NCP6 or NCP7.1 3705 with ACF access methods in a multi-tail environment, i.e., neither dedicated 3705 nor special TPNS 3705 control program is necessary. When simulating terminals controlled by the system under test, such as

non-SNA terminals, TPNS will continue to require a dedicated 3705 executing a TPNS 3705 Control Program.

DESCRIPTION

The principle use of TPNS is to drive the online application program in the following manner:

- Simulate start-stop (S/S), Binary Synchronous (BSC), or Synchronous Data Link Control (SDLC) terminals and the networks to which they would be attached.
- Generate data from descriptions of application messages and transmit those real messages to a running teleprocessing application program.
- Vary the frequency of message transmission within desired limits.
- Time-stamp and log all messages sent from and received by the simulated terminals.
- The user may analyze the message contents for accuracy of data transmitted. The user may also analyze the sending and receiving times to approximate application performance in response times and message rates. TPNS supports a broad range of terminal types and provides flexible, generalized message generation facilities that can be used to simulate a wide variety of telecommunications operations. The following terminal and device types are simulated by TPNS:
 - Start/Stop communication terminals on leased communications facilities:
 - 1050 Data Communications System
 - 2740 Communication Terminal mdl 1 (with Station Control and Record Checking)
 - 2740 Communication Terminal mdl 2 (with Station Control, Record Checking and Buffered Receive).
 - 2741 Communication Terminal
 - AT&T 83B3 Selective Calling System
 - Western Union Plan 115A Outstation
 - Start/Stop Communication terminals on switched communications facilities
 - Western Union mdl 33/35 TWX (break not supported)
 - Binary Synchronous Communication Terminals:
 - 3270 Information Display System Mcls 1 and 2
 - 3262, 3268 mdl 2, 3271 mdls 1 and 2, 3274 Mdl 1C, 3276 Mcls 1, 2, 3 and 4, 3277, 3278, 3284, 3286, 3287, 3288, 3289 (EBCDIC only)
- In addition, the following IBM BSC disciplines are supported:
 - BSC1 (Point-to-Point leased BSC)
 - BSC2 (Point-to-Point dial BSC (terminal answer only)
 - BSC3 (Multipoint BSC)
- The types of BSC terminals which may be simulated using the above BSC 1, 2 and 3 line disciplines include the following:
 - 1130
 - 1800 Data Acquisition and Control System
 - System/3
 - System/34
 - System/36
 - System/7
 - System/360 mdl 20
 - System/360 mdl 25
 - System/360
 - S/370
 - 2770 Data Communication System
 - 2780 Data Transmission Terminal
 - 3780 Data Communications Terminal
- Note: TPNS provides no support for special features on these BSC 1, 2, and 3 devices. Multileaving (mdl 20 Workstation) is supported.
- Synchronous Data Link Control (SDLC) line discipline for Systems Network Architecture (SNA) terminals on leased half-duplex, leased full-duplex, or dial communication facilities:
 - 3600 Finance Communication System
 - 3650 Retail Store System (Supported as 3600-Compatible Device)
 - 3660 Supermarket System (Supported as 3600-Compatible Device)
 - 3614 Consumer Transaction Facility
 - 3624 Consumer Transaction Facility
 - 3767 Communication Terminal
 - 3770 Data Communication System
 - 3790 Communication System

PROGRAM PRODUCTS

TPNS Release 5 (cont'd)

8100 DPPX Information System
8100 DPPX or DPPX/SP Information System
8100 DPCX Information System

Note 1: In order to execute SNA Dial Communications, the application program must run under an OS/VS operating system which also supports SNA Dial.

Note 2: TPNS SNA simulation is not intended to simulate code residing in the logical control unit other than that code required to transmit and receive message traffic.

TPNS also provides support for devices attached to the 8100 systems via teleprocessing links or remote loop. The level of support for a remote loop is from the 3842 remote loop controller downward; i.e., TPNS simulates the entire remote loop with its attached devices.

Specific device support includes functions of the 3276 and 3278 displays and the 3262, 3268 mdl 2, 3287 and 3289 printers as currently implemented by TPNS. New support for the 8775 character display enhanced functions of highlighting and the APL character set is provided. TPNS also simulates a certain class of devices that use "device headers" rather than the standard SNA headers. These devices include the 3641, the 3642, the 3643, the 3646, and the 3289 mdl 3 with its attached devices. The 3645 and the 3647 devices are supported to the extent that they are compatible with TPNS simulation for logical unit type 1 and the 3641 respectively. The 3644 is supported by allowing the user to specify the device header in the scripting statements.

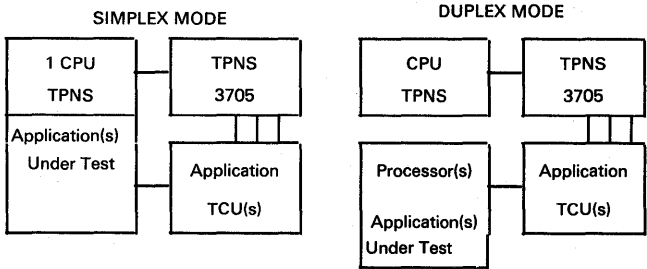

Powerful and comprehensive scripting facilities are provided, by the Advanced Scripting Language, to specify TPNS simulation options at execution time. The script describes the terminal, network configuration and message rates desired by the user. In addition, the script defines teleprocessing messages meaningful to the online application program under test. Individual segments of information in the messages may be generated by different methods including random, table lookup and constants. TPNS provides a comprehensive logic test capability to compare certain data or text received or sent by TPNS. Thus, scripts can vary message data from the simulated terminals based on the content of a prior response from the application program.

Preparation of scripts is simplified by providing common default values for the keyword parameters used in the scripting language.

A facility exists to allow message generation from a single script for multiple terminals. This facility is especially useful in a time sharing environment.

Multiple networks may be simulated concurrently to provide messages for driving multiple telecommunication applications or multiple processors.

TPNS can operate in either simplex or duplex mode. In simplex mode, TPNS and the subsystem (the driven telecommunication application) under test reside in a single processor and execute in separate regions under OS/VS. In duplex mode, two or more processors are required. TPNS resides in one and drives various telecommunication applications in the other(s). Neither simplex nor duplex operation requires that either processor be dedicated to the test run. Dedicated duplex processors would be used primarily for critical application performance approximations. In either mode, TPNS requires a dedicated 3705-I or 3705-II Communications Controller (See exception below), and the application under test requires another transmission control unit (TCU) of the appropriate type required by the application programs.

For domain simulation only, TPNS can share an NCP6 or NCP7.1 3705 with ACF access methods on a multi-tail environment, i.e., neither dedicated 3705 nor special TPNS 3705 control program is necessary. When simulating terminals controlled by the system under test, such as non-SNA terminals, TPNS will continue to require a dedicated 3705 executing a TPNS 3705 Control Program.

TPNS can drive various application programs running under IBM data communication products such as IMS, CICS, VSPC, VTAM, TSO, TCAM, BTAM, ACF/VTAM and ACF/TCAM.

A preprocessor program is provided to syntax check network and message configuration script statements. Two postprocessor programs are provided: one to list out the TPNS log tape in a formatted report,

and one to selectively calculate a response time analysis by network communication line. The response time calculated by the postprocessor is the time required for the application to respond to an input message. The user has, as his option, the ability to write his own response time analysis program using the various TPNS time stamps. TPNS also provides functions for graphing the results of the analysis program.

Properly used, TPNS may reduce testing time and required testing resources while improving the thoroughness of testing for telecommunication applications.

TPNS can provide repeatability for functional testing, a collection of comprehensive transaction messages for regression testing, and message rate statistics for approximating application performance, response times and evaluation of telecommunication network design.

CUSTOMER RESPONSIBILITIES

The customer is responsible for the following functions to install TPNS:

- Generating an appropriate OS/VS SCP including arranging OS/VS2 system authorizations to include necessary references to TPNS modules and placing the provided source, object and macro statements into appropriate OS/VS libraries.
- Generating a functional 3705 Control Program for TPNS. Preparing high-level macro statements to describe type(s) of network(s) whose simulation is desired, and compiling the TPNS 3705 Control Program from provided libraries.
- Ordering and installing the necessary communications equipment to support the application and TPNS environment.
- Providing communication line connections between the TPNS 3705 and the application TCU with appropriate line adapters.

For line speeds of up to 1200 bps, a workable method of connecting two 3704/3705s is to equip the TPNS 3705 with the low-speed local attachment Type 1C Line Set (#4713) and the application 3704/3705 with the low speed external modem Type 1A Line Set (#4711) for driver runs. Equip both 3704/3705s with Business Machine Clock (#4650) specifying the appropriate line speed. These 3704/3705s so equipped can be cable-connected for a distance not exceeding 200 feet.

Another method is to provide external modems on both 3704/3705s or TCUs and connect those modems by common carrier channels or by short cables between the line connectors on a plug board or patch panel. Equivalent physical paths may also be used.

If use of common carrier lines is planned, the customer is responsible for contacting the local common carrier and arranging for the necessary communication services.

- Arranging for appropriate engineering changes required by TPNS. The TPNS 3705 requires engineering change levels to include EC 311283 or REA 23-13007 if SDLC lines are to be used. This engineering change level must also be installed on the application 3705 if NCP Release 3.1 or later is used. If data set eliminators are being used for SDLC simulation, the application 3705 must have the previously mentioned EC or REA and the NCP must be level 3.1 or later.

The customer is responsible for the following functions to use TPNS in simulation tests:

- Determining and specifying significant network configuration, operational and timing alternatives to test.
- Developing the appropriate test data for meaningful transaction messages and application conditions.
- Executing the provided programs for transaction rate tables, or developing unique rate tables to characterize the application activity.
- Preparing TPNS scripts or message files to define the messages and operating parameters.
- Executing report programs to analyze message data transfers and performance approximations.
- Interpreting output results and modifying application programs and test parameters for subsequent runs.
- Developing specialized analysis programs to examine message data or time stamps for the TPNS log tape.

In connection with suggested customer use of TPNS, whether by formal proposal or not, the customer must be furnished, in writing, with the following statement as well as the other pertinent customer responsibilities as set forth above.

"The terminal network simulations provided by TPNS are believed to be sound, but IBM does not warrant or guarantee that users can or will achieve similar results on networks with actual terminals attached. Other IBM terminal devices announced as compatible with the IBM devices specifically simulated by TPNS may be supported in compatibility mode. The simulations will be equivalent only to the extent that the compatible devices function identically. It is the user's responsibility to determine and validate input data and

TPNS Release 5 (cont'd)

determine the extent to which these simulation results are relevant to the user's application and system environment."

SPECIFIED OPERATING ENVIRONMENT
HARDWARE REQUIREMENTS

The minimum machine configuration required to run TPNS is an IBM S/370 mdl 145 with conditional swapping feature. (TPNS will run in mdls 155II, 158, 165II, 168 and the 3031, 3032, 3033, 3081, 4341, 4361 and 4381 Processors.) The TPNS virtual region size (V=V or V=R) required for a minimum network of up to five lines and five terminals is 448K. The *TPNS Program Reference Manual* contains additional information necessary for calculating individual region requirements. The TPNS preprocessor will report the control block size required for a TPNS network for each run.

One tape drive is required if message logging is desired. In addition, multiple drives may be specified for alternating tape reels of log messages.

For TPNS simulation runs, DASD storage space is required for the following partitioned data sets:

- User network/message definition records
- TPNS load modules
- 3705 Control Program load modules
- External file message text (optional)
- Rate tables (optional)

For a TPNS 3705 Control Program system generation run, 800 tracks of IBM 3330 DASD storage (or equivalent space on IBM 2314, 3340 or 3350 DASD) is required for TPNS and TPNS 3705 Control Program macro libraries, object libraries and tables.

At least two transmission control units are required. (See exception above. One 3705 must be dedicated to TPNS during the simulation run. The other TCU may be either a 2701/2702/2703 or another 3704/3705 as required by the application under test. TPNS supports multiple 3705s when necessary.

The TPNS 3705 (3705-I or 3705-II) requires a Type 1, Type 2, Type 3 or Type 4 Channel Adapter, a Type 2 or Type 3 Communications Scanner and sufficient start-stop, BSC, or SDLC line adapters to simulate the line configuration required. Each line whose simulation is desired must have an existing communication line or cable connection between the 3705 allocated to TPNS and the TCU allocated to the application program under test.

Note: The System Support Programs for Advanced Communication Function NCP/VS program product (5735-XX1) are required if the user has multiple Type 4 channel adapters and the "NROS" feature (#9566) on the 3705s to be used with TPNS.

The TPNS 3705 requires a minimum of 80K storage. Additional 3705 storage is required for line support and control blocks for large networks. Formulas for TPNS 3705 storage requirements are defined in the *TPNS Program Reference Manual*.

SOFTWARE REQUIREMENTS

TPNS executes in the virtual mode (V=V) or real storage (V=R) under any current release of OS/VS2 (MVS), OS/VS2 (SVS), and VS/1 or subsequent releases of these SCPs unless otherwise specified.

A modified IBM 3705 Control Program is provided which performs part of the simulation and can only be used with TPNS. The user must perform the TPNS 3705 Control Program system generation to define the TPNS 3705 line configuration.

Source code for TPNS and TPNS 3705 Control Program will be available as optional material.

The 3705 Communications Controller and Network when used by TPNS will be serviced off line by Field Engineering.

**TSO COMMAND PACKAGE
5740-XT6****PURPOSE**

The TSO Command Package program product augments the function available to the OS/VS2 (MVS) TSO user, and facilitates the use of TSO commands in background mode.

The EDIT Recovery facility provides the capability of recovering data entered during an abnormally terminating EDIT session.

Miscellaneous TSO Command Package Functions provided include additional default values permitted to be supplied in the TSO user's *User Attribute Data Set* (UADS) entry, and subcommand and keyboard modifications.

TSO Command Package also increases the range of background processing by providing modifications facilitating the use of existing TSO commands in background mode.

HIGHLIGHTS

- Operation of TSO commands in background mode facilitated.
- TSO Edit recovery capability.
- ATTRID available as subcommand of EDIT.
- CKPOINT subcommand of EDIT.
- FREE available as subcommand of EDIT.
- D available as abbreviation of DOWN subcommand of EDIT.
- MSGCLASS, JOBCLASS and SYSOUT CLASS defaults can be specified in UADS entry.
- Length of DEST keyboard is eight characters, consistent with JCL
- Keywords on both commands and subcommands to reduce the need for prompting.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

TSO Command Package has no unique hardware requirements.

SOFTWARE REQUIREMENTS

The TSO Command Package program product requires OS/VS2 (MVS) Release 3.7 at the current service level. In addition, this program product also operates in a VM/370 environment under the control of OS/VS2 (MVS).

Storage Estimates: The approximate auxiliary storage requirement for the system libraries:

SYS1.CMDLIB	110,117 bytes
SYS1.HELP	334,080 bytes
SYS1.LINKLIB	66,439 bytes
SYS1.LPALIB	455,806 bytes
SYS1.MACLIB	650,800 bytes

DOCUMENTATION (available from Mechanicsburg)

PROGRAM PRODUCTS

**OPERATIONS PLANNING and CONTROL (OPC)
RELEASE 3.0 (5740-XT9)****PURPOSE**

OPC provides data processing management with a system for planning, controlling and automating the handling of batch production in the operations department. Both long range and short range planning may be automated for all pre-processor, processor and post-processor work stations, as required by each individual installation. The workflow through the data center is monitored in real time. The status at any work station, or of any application anywhere in the center, is immediately available to the production control personnel via color or monochrome terminals. Error prone and repetitive operator tasks, such as ensuring that jobs are run in the correct order, submitted at the right time, etc., are automated by OPC.

PRODUCT HIGHLIGHTS

Items OPC addresses are:

- **Operations Planning** - OPC can be used to automatically produce long range (typically monthly) and short range (typically daily or per shift) plans for the whole operations department. OPC takes into account dependencies on preparatory work, the processor jobs, and post processing. Long Range plans can be used to establish service level agreements with end user departments, as well as for capacity and peak load planning. The daily planning can be done at a detailed level. Uncompleted work will automatically be carried over from the previous daily plan. A detailed daily plan for each work station is available online.
- **Production Control** - OPC can provide up-to-the-minute status at any work station, and of any application anywhere in the production chain in the data center. Late applications are highlighted, as are critical operations. A list of all applications ending in error is available online. Run book information can be displayed online to each work station operator.
- **Automation** - OPC automates complex and/or repetitive operator tasks, by automatically controlling when a job is ready to be executed, dependent on, for example, the time of day or prerequisite preparation or jobs. When a job is ready to run, OPC is designed to automatically pick out the correct version of the JCL, submit the job (if not done beforehand), and release it.

RELEASE 3 HIGHLIGHTS

- **Use of current MVS/SP and MVS/SE2 Support.**
In MVS/SP and MVS/SE2, a number of existing user exits have been made separate load modules instead of being linked into SMF modules. This design change is taken care of in OPC's installation procedures. The new SMF record type 30 is supported, which means that the old type 4 and 5 records are not required by OPC in an MVS/SE2 installation.
- **Automatic reporting of events.**
OPC can now automatically handle events from general work stations, that is, a user program can automatically report to OPC when an operation has been started, completed successfully, or terminated in error. This function can be used in, for example, spooling, keypunching and remote job entry applications.
- **Enhanced diagnostic aids.**
A number of additions and modifications have been made, aiming at a quicker and more automated error diagnosis:
 - An extended, formatted OPC minidump.
 - Explicit PTF-level clearly identified in object modules.
 - Extended diagnosis when problems occur in Job Tracking.
 - An APAR packaging program which can be submitted from OPC online or as standalone.
 - The OPC Status record now displayed.
- **The System Modification Program Release 4 (SMF4) is used to install and maintain OPC.**
- **Access to application data by job name.**
OPC now allows a processor work station operator to check job status by job name.
- **Enhanced use of TSO terminal support.**
Certain exceptional data in OPC is now highlighted, or, for a 3279 Color Display Station, displayed in a different color. This applies to error messages, lines for which incorrect data was entered, 'late' operations on a ready list, and occurrences that are considered 'critical'.
- **Listing an application's external dependencies.**
OPC now allows you to get a listing in application order showing external predecessors and successors by application.

CUSTOMER RESPONSIBILITIES

In addition to fulfilling the specified operating environments shown below, it is the responsibility of the customer to install the program and to build and maintain the OPC data bases.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

This licensed program is designed to operate on the following IBM machines:

S/370 mdl 148, 155II, 158, 165II, 168, 303X, 308X, 4361-5 or 4381 Processors.

For online plans and monitoring, suitable terminals must be available; all of the following, or equivalent, are supported by OPC:

- IBM 3275 Display Station - mdl 2
- IBM 3276 Control Unit Display Station - mdls 2, 3, 4, 12, 13 or 14
- IBM 3277 Display Station - mdl 2
- IBM 3278 Display Station - mdls 2, 3 or 4
- IBM 3279 Color Display Station - mdls 2A, 2B, 3A or 3B

OPC Terminals run under Multiple Console Support (MCS) and/or TSO.

The appropriate Control Units are required for the terminals.

OPC does not require any V=R storage.

SOFTWARE REQUIREMENTS

This licensed program requires the functions provided by the following IBM programs:

- OS/VS1 Release 7.0 and subsequent releases, unless otherwise identified.
- OS/VS2 (MVS) Release 3.8 and subsequent releases, unless otherwise identified, with any of the following:
 - JES2.
 - JES3.
 - MVS/SE Release 2.
 - MVS/SP Release 1 and subsequent releases, unless otherwise identified.
- VSAM for data base access.
- IBM OS/VS Sort/Merge program product (5740-SM1) or its equivalent
- System Modification Program Release 4 (SMP4) for installation.
- TSO for full use of the OPC online dialog.

CONVERSION

Users of OPC Release 2.0 can continue to use their existing data bases without any conversion.

RPQs Accepted: No

TELECOMMUNICATION CONTROL SYSTEM ADVANCED FUNCTION (TCS-AF) 5740-XXD

PURPOSE

Telecommunications Control System - Advanced Function (TCS-AF), based on Telecommunications Access Method (TCAM), provides the user with the facilities to implement a high function single or multicomputer teleprocessing system. While TCS-AF capabilities can enhance a single CPU TCAM or TCAM/VTAM System, TCS-AF is primarily intended for users with multiple online VS systems, who need a multicomputer networking capability to communicate between terminals and applications in separate systems.

DESCRIPTION

TCS-AF enables user migration to the SNA environment by either of two paths, depending on the base level of TCAM with which it is used: (1) TCAM Levels 8 and 9 for SNA device support using TCAM-through-VTAM, or (2) the announced level of TCAM for SNA support using TCAM direct control of NCP/VS, without VTAM.

Many of the TCS-AF facilities described below utilize functions provided by TCAM. TCAM through VTAM, the 3704/3705 Network Control Program (NCP) and/or the operating system. Facilities that depend heavily on TCAM are referred to as *TCS-AF/TCAM*, while those that are due to TCS-AF itself are so described.

In single and multicomputer TCS-AF/TCAM systems, there is terminal sharing (among TCAM applications) in either session or transaction modes of operation. Generally, a terminal or application program can communicate with any other terminal or application programs in the network, subject, in general, only to non-mappable device-dependent characteristics, to user-imposed constraints, and to the restrictions indicated below. Terminals need not be dedicated to a particular application environment, and even various types of terminal devices can be shared among different application programs; there can also be application-to-application and terminal-to-terminal traffic. Communication line use is also shared among different application programs and terminals. The terminal operator is effectively isolated from the intricacies of the network architecture, and deals with other network resources (terminals and/or applications) as logical entities, without regard for their actual physical location or hardware identity.

TCS-AF itself features high function facilities for large network configurations that incorporate more than one central processor and/or elaborate application program subsystems. It is practical to share the intercomputer links between interactive and bulk-type traffic because of extensive TCS-AF/TCAM message-priority recognition and queuing facilities. TCS-AF/TCAM capabilities for management of multicomputer links also include automatic load-balancing across multiple links, alternate path and indirect routing, and checkpoint/restart.

TCS-AF incorporates reliability, availability, and serviceability features, including an operator control facility especially tailored for ease in controlling large systems.

Message traffic is stored on main-storage and/or disk queues, the latter permitting checkpoint/restart reconstruction back to time-of-failure. A retrieval program is included to permit retrieval of disk-queued messages by user-authorized terminals. System support programs are provided for on-line monitoring of application status throughout a complete multicomputer network, and for synchronizing intercomputer transmissions to help provide message integrity. Facilities are supplied for manipulating the message queues for destinations, and for accumulating real-time traffic statistics.

A wide variety of application program environments can be supported by TCS-AF/TCAM. Generally, application programs are run in another region or partition than the TCS-AF/TCAM control programs, and application program failures will not affect other programs or network operation. TCS-AF can provide telecommunication control for application subsystem environments (CICS/VS, for example), making these application environments accessible, not only throughout the shared terminal network of a single computer, but also to other shared terminals connected to other computers in a multiprocessor network. Message transmission between terminals and application programs may be handled either in a transaction mode (where each message is routed to its destination(s) based on data in the message) or in a session mode (where routing information is developed once and then maintained during an extended interchange of messages).

User application programs written in Assembler language, in COBOL or PL/I can interface directly with TCS-AF. (For application programs written either in COBOL or PL/I to interface to TCS-AF/TCAM the following compiler must be used: OS/VS COBOL Compiler and Library (5740-CB1); OS Full American National Standard COBOL V4 Compiler and Libraries (5734-CB2); OS PL/I Optimizing Compiler (5734-PL1). The TCS-AF/TCAM/application program interface appears to the application program as a sequential access method (SAM) interface, so that many applications may be tested using sequential input/output devices, before they are run in the actual online system. Application program checkpoints can be coordinated with the checkpoint facilities of the TCS-AF/TCAM control program.

TCS-AF FEATURES and CAPABILITIES

The lists which follow, although not exhaustive, summarize the principal features of a TCS-AF/TCAM system. Features of interest to both users of single computer networks and users of multiple interconnected networks are presented first, and then those features applicable only in a multicomputer network are described. The functions discussed include some that are performed entirely by TCS-AF, as well as others that are derived from facilities offered by TCAM (or TCAM through VTAM), 3704/3705 Network Control Program (NCP/VS) or the operating system. TCS-AF/TCAM is able to supply a range of services for control of complex networks because it communicates with other programming systems -- including the user's own application programs -- to utilize capabilities from these different sources to help satisfy each user's particular requirements.

Single and Multiple Processor Capabilities

Terminal sharing among diverse application programs or application program subsystems: each terminal device can access numerous programs, instead of having to be dedicated to a single application environment. In general, the only constraints in TCS-AF/TCAM terminal-sharing facilities are those that the user can specify -- to restrict access to critical or confidential data, according to the user's own security needs, or the restrictions stated below.

The TCS-AF/TCAM control program provides message *priority* and *queuing* facilities, as well as space (disk queues) for detaining low-priority transmission traffic while high-priority interactive application traffic is serviced. Communication lines, particularly intercomputer links, can therefore be shared among different types of application traffic, generally without significant response degradation of high priority (interactive) traffic.

As each message passes through the TCS-AF/TCAM message control program -- first, when it is sent from its origin to the message queue maintained for its destination, and later, when it is taken from the queue and sent to the destination station or application -- user-specified message handling code can be used to analyze, validate, and/or edit the message data, and to handle unusual and/or error conditions. These segments of code, called *message handlers*, are a powerful tool that permits access to the message at critical processing times. Each terminal or application environment is associated with a particular set of message handler (MH) code, designed to help satisfy the common telecommunication needs of similar terminals or applications.

Message handler code enables the user to manipulate messages both immediately after they arrive in the central processor, and, again, just before they are sent out to terminals or application programs. Message handlers, therefore, allow some application programs under TCS-AF/TCAM to maintain a high degree of *device independence*. Many device-dependent characteristics can be edited out before a message is passed to an application program, and messages can be formatted for necessary device peculiarities before they are passed to the line from TCS-AF/TCAM. For those users who want to use 3270-type devices with application programs that support a data stream from 2260-like devices, TCS-AF itself supplies an easy-to-use facility that provides this function, without, in most cases, requiring alteration of the application program code.

Message traffic can be routed in *session mode*, where a temporary bond is established between a terminal and an application program for a period of extended conversation. While this session bond is in effect, the control program will automatically recognize that any message entered by the terminal is intended for the application program. There are two session concepts in TCS-AF/TCAM environment; (1) an SNA session which is established between a Logical Unit (LU) and TCS-AF/TCAM, and (2) a logical TCS-AF/TCAM session which is established between a Logical Unit and a TCS-AF/TCAM application program.

Alternatively, traffic between terminals and application programs can, using the TCS-AF/TCAM message handlers, be routed in *transaction mode*, in which the destination of the message is implied by the message data itself. Transaction mode routing is intended for those environments where the message destination normally is different for each message.

TCS-AF/TCAM message handlers can also be used to support terminal-to-terminal *message switching* facilities. Messages can be analyzed and routed to the appropriate destination(s) on the basis of fields in the message header. A wide variety of message formats can be supported by using TCS-AF/TCAM facilities.

Application-to-application routing: Just as terminals can route traffic to other terminals (message switching), applications can route traffic to other TCS-AF/TCAM application programs. Thus, the output from an application can be routed directly, through the TCS-AF/TCAM control program, to another application program for further processing.

TCS-AF (cont'd)

Message identification and format *validity* may be *checked prior to transmission/transfer* to the ultimate destination(s). Invalid messages can be detected and handled by user-designed error procedures without involving the destination application program.

TCS-AF operator control incorporates command language facilities (beyond TCAMs) especially suited for *large system management*: network resources can be addressed as groups, rather than individually; many system status information items are displayed only on an exceptions-to-normal basis; routine operator commands can be automatically generated by TCS-AF itself, freeing the system operator's attention for more important tasks.

By the use of operator control facilities the system control operator can *manipulate* the destination message *queues*. Unsent messages on the line/terminal queues can be redirected to alternate destinations, copied to another destination queue, or not sent to their destination, based on the operator's action.

A versatile message *retrieval support program* allows a single operator command to initiate the retrieval of one or number of messages. The selection of messages to be retrieved can be specified as message source/destination, as a range of message input/output sequence numbers, or as message entry date/time period. Only user-authorized terminals can enter TCS-AF retrieval commands.

TCS-AF supplies a *model Message Control Program (MCP)* to assist the user in implementing his single or multiple CPU network.

TCS-AF Capabilities for Multicomputer Networking:

Diverse processor configurations are supported in a TCS-AF multicomputer network. Some (or all) of the processors in the network can control both terminals and applications; some can control terminals only, and some can control only application programs.

The TCS-AF multicomputer architecture can be *transparent* to the terminal operator, who need never even know which processor in the network is running the application program he is accessing or where any terminal he addresses is actually located.

Distributed application descriptions and status: Each active processor may know critical attributes (e.g., session or transaction mode, priority of input) for application programs with which its terminal set converses. Application program status information is dynamic (e.g., up, down for the day, or temporarily down); Dynamic data like this is continually exchanged among any processors involved, without operator involvement.

Indirect routing: Message traffic can be passed from one processor system to a destination in another processors system by way of one or more intermediate processors which serve as transmission links.

Alternate routing: In a multiple processor network, the normal path between any given pair of processors may become unavailable due to failure of an intercomputer link or of an intermediate processor; the user can specify alternate back-up paths to be used automatically when TCS-AF detects that a path is unusable. Using an alternate path does not disrupt ongoing application program sessions. *Response-time-sensitive* TCS-AF/TCAM priority and queuing logic may speed fast-response (interactive) traffic through bottlenecks that arise due to failures. The alternate routing logic used is present among the network processors which continually exchange *dynamically-updated* data -- a more reliable and rapidly-responding method than centralized control can provide. This flexible and reliable routing control is capable of detecting and handling dead-end, ping-pong, and looping error situations caused by critical line or CPU failures.

Load-balancing across multiple intercomputer links: If the user provides more than one line between two processors, TCS-AF can automatically, on a dynamic message-by-message basis, balance the inter-CPU traffic over as many links as are available.

Flexible centralization or decentralization: Although several functional areas (session management, transaction routing, operator control, alternate routing) have been described as decentralized, any of these can be centralized. This flexibility allows a TCS-AF/TCAM system to match geographic, technical, operational, or business organizational realities of the environment.

TCS-AF facilities allow a user to write a network *interface to non-TCS-AF systems*: Such an interface might range in complexity from a special message handler in the TCS-AF network coupled with some processing in the other system, to an application program that would relay messages in and out of TCS-AF. The user who wants to couple together two processors both containing TCS-AF/TCAM with the channel-to-channel adapter may interface the processors via a user-written application program residing in each processor to pass through the intercomputer traffic.

RESTRICTIONS and CONSIDERATIONS

Access to a TSO subsystem is restricted to terminals directly attached to the processor in which the TSO subsystem is located.

Considerations attendant to TCAM operation in the VTAM environment remain when TCS-AF/TCAM is used with VTAM. These considerations are described in *OS/VS TCAM Concepts and Facilities* (GC30-2042).

CUSTOMER RESPONSIBILITIES

To successfully install and use TCS-AF, the customer must first order and install all required communications equipment ... meet minimum machine configuration requirements ... generate OS/VS1 or OS/VS2 system with TCAM ... train all persons installing, operating, or maintaining TCS-AF in TCAM, TCS-AF, and OS/VS ... design the multicomputer networking functions ... design, code and test the MCP ... and develop conversion procedures and schedules. VTAM and/or NCP training and system generation is also required for those systems utilizing TCS-AF/TCAM with VTAM.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

TCS-AF in conjunction with TCAM operates under OS/VS1 on a S/370 Mdl 135, 145, 158, 155II, 165II, 168, 3158-3, or 3168-3.

TCS-AF in conjunction with TCAM operates under OS/VS2 on a S/370 Model 145, 158, 155II, 165II, 168, 158MP, 168MP, 3158-3, 3168-3 and the 3031, 3032, 3033 or 3081 Processors. The MP systems are supported only under OS/VS2 Release 3.

For a system using the TCS-AF Model MCP, the recommended real main storage available to the TCS-AF/TCAM region should be not less than 140K. This includes space only for a 2-line, 5-terminal configuration, and is storage beyond that required by the host operating system and by VTAM. An increase in the size of the network, additional TCS-AF, TCAM, or VTAM functions, or additional message handlers will require more real main storage.

The *TCS-AF Operations Guide* must be used to estimate the real main storage requirements of TCS-AF for each specific customer system.

The data communication link between processors is comprised of one or more BSC lines. These links are controlled by TCAM and/or TCAM through VTAM.

PRPQs will not be accepted at this time.

Terminal Support: TCS-AF can operate with any device that is supported by the base level of TCAM used in the TCS-AF/TCAM system. Terminal devices using Systems Network Architecture may be supported through VTAM using TCAM levels 8 and 9, or Start-stop and binary-synchronous line control devices are supported by all TCAM levels. Details of device support and attachment are contained in the *TCAM Concepts and Facilities* manual (GC30-2042) for TCAM-through-VTAM, and the *TCAM Concepts and Applications* manual (GC30-2049) for TCAM with direct NCP/VS support. (Figures summarizing terminal support capabilities and attachment dependencies are also available in the sales manual pages for TCAM system control programming.)

TCS-AF provides enhanced support for the 3270 Information Display System. (local and BSC remote), including:

- Status and sense information interpretation
- Improved 3284/86 printer scheduling
- Printer copy request (remote attachment only)
- Device independence for applications written to support 2260 terminals

SOFTWARE REQUIREMENTS

This program product is available to work with the following system control programming TCAM release levels:

TCAM 5F	OS/VS Releases 1.6 and 1.7
TCAM 8	OS/VS1 Release 4.0; OS/VS2 Releases 3.0, 3.6, 3.7
TCAM 9	OS/VS1 Releases 5.0 and 6.0; OS/VS2 Release 3.7

TCS-AF for TCAM/NCP/VS-Direct is available now.

When each TCAM release level is no longer considered to be current, programming support for TCS-AF on that release level will be discontinued; support for discontinued levels will be withdrawn and central programming services will no longer be provided.

COMPATIBILITY

TCAM MCPs must be recoded to take advantage of TCS-AF presence in the system.

TCS-AF (cont'd)**DATA SECURITY**

TCS-AF provides *authorization facilities* oriented towards permitting only user-authorized station devices to access certain user-specified application programs or subsystems or to utilize system facilities like TCS-AF operator control and retrieval. Further details on data security are contained in the TCS-AF Concepts and Facilities Manual (GH20-1735).

PERFORMANCE CONSIDERATIONS

As with other large virtual systems, the performance of TCS-AF in a virtual storage environment is highly dependent on the system resources available. Particular attention to ensuring the adequacy of real resources (main storage, processor computing capability, direct access devices and channels) is required to achieve satisfactory throughput and response time.

In addition to the system configuration, performance is influenced by many factors including:

- Paging characteristics of TCS-AF and other programs executing concurrently.

- The relative processor dispatching and I/O device scheduling priorities assigned to TCS-AF and other programs executing concurrently.

- User design and implementation of the message control program (MCP).

To verify specific performance, benchmarking the TCS-AF system may be appropriate.

The rate and efficiency with which data is transferred between processor nodes is extremely critical to achieving response time objectives. Internodal performance is dependent upon many factors including:

- The number of messages and data characters transferred between processor nodes.

- The number of data links available and the effective data rate which can be achieved by them.

- Conditioning of the data links and error conditions which may be encountered.

- The assignment of priority levels to maximize throughput and/or improve the response characteristics of critical data.

- The user's ability to utilize load-balancing across multiple links.

TCS-AF recognizes the response sensitivity of the internodal connection and permits accumulation of statistics related to data movement, which can be used in planning performance improvements.

DB/DC DATA DICTIONARY DOS/VS (5746-XXC), OS/VS (5740-XXF)

PURPOSE

The DB/DC Data Dictionary is a central collection of information about data resources that are needed for efficient data management. The DB/DC Data Dictionary improves the manageability of a data processing installation by storing, processing and reporting on definitions, descriptions and relationships of data. This document uses the name Dictionary when referring to either DB/DC Data Dictionary program product unless otherwise noted.

DESCRIPTION

The Dictionary deals with categories of subjects, the relationships between subjects, and the attributes which characterize subjects and relationships. Categories are families of items, such as data bases, programs or personnel. The data base category would, for example, contain individual data base descriptions as subjects. Relationships represent the interaction between subjects. For example, a relationship between a pair of subjects representing an application program and a data base might indicate that the program accesses that data base. Attributes describe properties of a subject or relationship such as size, frequency, or the date a relationship was established.

The name, DB/DC Data Dictionary, represents two products - one that operates in the OS/VS environment (program product 5740-XXF), and the other that operates in the DOS/VS environment (program product 5746-XXC). In the OS/VS environment the product operates with the following DB/DC systems: IMS/VS DB or IMS/VS DB/DC (5740-XX2), or CICS/OS/VS (5740-XX1) with IMS/VS DB. In the DOS/VS environment, the product operates with the following DB/DC systems: DL/I DOS/VS (5746-XX1) with or without CICS/DOS/VS (5746-XX3). If the Dictionary is to be used only in a batch environment, either the IMS/VS Data Base System or DL/I DOS/VS is required.

The Dictionary utilizes DL/I data bases to store definitions of data and data usage under these subject categories:

- data base - physical, logical, primary or secondary index DL/I data bases, or non-DL/I data sets
- segment - DL/I data base segments or non-DL/I records
- element - fields or group data items
- PCB - DL/I program communication blocks
- system definition - IMS/VS system definition information
- system - major application systems, such as a payroll system
- job - processing units corresponding to single jobs
- program - major programs or job steps
- modules - functional subsections of programs
- transaction - DL/I or non-DL/I transactions
- PSB - DL/I program specification blocks
- dduser - security information and passwords of all dictionary users
- category - installation-defined subject-category definition
- relationship type - installation-defined relationship types
- attribute type - installation-defined attributes of subject categories

A data definition is entered into the dictionary through either the dictionary command language or the interactive display form facility. The definitions may contain the following entry types:

- subject name - user name for this subject, plus dictionary qualifiers for the name
- aliases - other names by which this subject is known to the user
- attributes - anticipated entries of various characteristics for a given subject category
- description - text describing the subject, with user-specified format and content
- user data - for any user information that cannot be included as attribute data, with user-specified format and content
- relationships - cross references between this subject and other subjects in the same or other subject categories
- relationship data - information about the nature of the relationship between certain kinds of subjects

DESCRIPTION OF RELEASE 1.0

Centralized Source of Information and Control: The dictionary can be a central source of information about a company's data resources, including application data still in test stages.

Automated Capture of Existing Definitions: COBOL source either from sequential files or COBOL copy libraries can be read by the dictionary to obtain initial record definitions, as can the DBD (data base description) and PSB (program specification block) libraries. Additional information can be added by using dictionary commands, or copied from existing dictionary descriptions. For conversion from non-DL/I systems to DL/I data bases, the Data Base Design Aid (5748-XX4) assists in data base design and produces output in the form of dictionary commands which can be directly accepted by the dictionary.

Flexibility of Use: The command language lets the user add, change, relate or delete information in all subject categories, scan the information for selective retrieval, copy existing definitions and obtain varied

output in machine and human-readable form. Provisions are also made for storing non-DL/I data and user-unique data, thus enabling installations to integrate all their data definitions into one central dictionary.

Interactive Display for IMS/VS: Most dictionary commands can be executed online through the 3270 Display System. In addition, a task-oriented facility is provided that guides the user in entering specific definitions and displaying current dictionary contents. Each display form is designed for one specific DL/I definition. (For example, a different form is provided for defining a physical data base than for defining a primary index data base.) Each form has an associated explanation frame that provides information on how to use it. This method of entering definitions can help reduce errors by avoiding omissions, contradictions and misspellings. It can also be productive in that a single form may result in many dictionary commands being executed.

Extensive Reporting Capability: Users can obtain predefined reports on the complete contents of a subject category or full details of definitions and their relationships in printed or (online) display form. A SCAN facility provides for user-specified selective retrieval of information from the dictionary. Hierarchical data base structures can be printed out in indented formats. Common to both the OS/VS and DOS/VS dictionary versions are printed reports that are equivalent in content to most of the formatted display frames available with the online (IMS/VS) interactive displays. Additional custom reports, if desired, can be generated using GIS/VS. No GIS/VS data description tables (DDTs) for the Dictionary data bases will be provided in the licensed documentation.

Systematized Control of Data Base Modifications: If all data resources are described in the dictionary, it becomes a useful tool for controlling standards, versions and modifications. Its reports, naming conventions, search capability and cross-references help in studying the effect of proposed change. Until standardization is achieved, the dictionary assists in control of duplicate names by keeping track of multiple occurrences.

DBD and PSB Generation: Dictionary commands can process stored definitions to produce source statements for the generation of data base descriptions and program specification blocks suitable for host DL/I libraries.

Data Structure Generation: Another output of the dictionary is data declarations suitable for inclusion in COBOL, PL/I or Assembler Language programs.

DESCRIPTION OF RELEASE 2.0

Release 2.0 of the dictionary contains all the function of Release 1.0, except the REPORT_ALL function which was dropped, and in addition provides the following new functions:

Batch Forms Input: The input capability of the DB/DC Data Dictionary has been enhanced in Release 2.0 by a batch forms input facility, which permits element and segment definitions and text information to be prepared on pre-printed forms and entered into the dictionary via a batch job stream. Segment and element definitions may include not only the usual set of subject attributes, but also the identities of elements and subelements contained within the subject, thus providing a definition of subject structure. Text information which may be entered consists of descriptions and user data for any subject category, and commentary for segments and elements. The forms may be used to create new subjects and to add data to existing subjects. A report is produced showing the data that was entered and any diagnostic messages produced. The facility provides an alternative to the COBOL_IN command for capturing large amounts of segment and element information, and brings to the batch user the convenience of forms for bulk data entry.

COBOL Input Enhancements: The COBOL_IN command in Release 1.0 has been enhanced by making the dictionary updating phase of the command a user option. With updating suppressed, the COBOL_IN command produces a listing of the information that would be stored in the dictionary with updating selected, and optionally a punch data set containing the dictionary commands which would do this updating. In this way the user may verify the suitability of COBOL source statements before committing the information to the dictionary, and may use the punched commands, modified as necessary, to enter the correct definitions into the dictionary.

IMS/VS System Definition Support: The role of the dictionary as the centralized source of information and control has been enhanced through the addition of a facility for documenting the information contained in the IMS/VS DATABASE, APPLCTN and TRANSACT system definition macros. A subject category, the System Definition, has been added, along with new attributes for transactions and program specification blocks (PSBs), and relationship categories for relating system definitions to data bases, transactions, and PSBs. Existing commands and interactive display facilities have been extended to permit the entry and reporting of system definition information. A STAGE_1_OUT command permits system definition information to be produced in machine-readable records in the format of IMS/VS

Data Dictionary (cont'd)

DATABASE, APPLCTN and TRANSACT macros, so that these records can be incorporated directly into IMS/VIS Stage 1 system definition job streams. The command includes an IMS/VIS release parameter, to permit the user to specify the release of IMS/VIS for which the macros are being produced. The support extends the control function of the dictionary to the system definition activity of the IMS/VIS DB/DC user, and provides documentation aid for the IMS/VIS DB and DL/I user migrating to IMS/VIS DB/DC.

Extend Relationship Facility: An EXTEND_RELATIONSHIP command has been provided to relate each of the elements in a segment, or each of the first-level subelements in an element, to another subject. For example, a single EXTEND_RELATIONSHIP command may be used to relate each of the fields in segment XYZ to program ABC. Previously, such relationships had to be established through individual ADD_RELATIONSHIP commands. The new command provides a convenient way of making implied relationships explicit.

Recalculate Segment Facility: A RECALCULATE_SEGMENT command has been provided to restore consistency to a set of related segment and element definitions whose lengths and other attributes have been updated independently of one another. The command uses current element and subelement lengths and justification attributes to recalculate segment lengths and element starting positions, and optionally updates the dictionary with the new information. With updating suppressed, a punch data set of the equivalent updating commands may optionally be produced. A report showing the old and new attributes is produced. The command makes it unnecessary to use individual CHANGE_IN and CHANGE_RELATIONSHIP_DATA commands on the subjects and relationships in a structure in order to make the structure consistent.

Reports Enhancements: A report, the indirect subject reference report, has been provided to assist the user in locating references to elements, segments and data base subjects which have been stored as part of the dictionary data. The report is useful in maintaining dictionary consistency through its existing maintenance facilities.

The usability of the glossary report has been enhanced by permitting the user to specify the number of description lines to be shown for each subject, and to optionally suppress the printing of subject attributes. The user may also specify that the report be sorted on any combination of the four components of subject name (status code, subject code, user name and occurrence number). For example, if status code is selected as the major sort field, the report that results may be physically separated into sections each dealing with a different status code.

Output Enhancements: A PUNCH command is provided to create 80-character machine-readable records from user data segments previously entered through the dictionary updating facilities. User data segments are typically used for program source and job control language statements, and the PUNCH command makes it convenient to include these statements in the users' job streams.

The STRUCTURES_OUT command is enhanced to permit the optional inclusion of comment records holding the dictionary attributes of the subjects from which the structures are generated. This provides a ready reference to these dictionary subjects, e.g., in case the structures must be modified. Also added is an installation option which permits the user to set the level number increment in generated structures so that it conforms to installation programming practices. For COBOL structures, the PICTURE clause has been aligned for readability.

DESCRIPTION OF RELEASE 3.0

The following enhancements are provided in Release 3.0 of DB/DC Data Dictionary. The enhancements are available in both the OS/VIS and DOS/VIS products.

CICS/VIS Interactive Display Forms Facility: An interactive user interface for CICS/OS/VIS and CICS/DOS/VIS Dictionary installations is provided which is equivalent to the IMS/VIS Interactive Display Forms Facility including the Release 3.0 enhancements.

Security Facility: A Security Facility provided is available as an installation option. A 'signon' validation function allows the installation to determine the set of Dictionary users. A user profile security function can be used to partition the Dictionary according to status codes, subject categories and ability to update and/or view data.

- **Signon Security:** Users can be identified to the Dictionary, and IDs validated via passwords, to control access within the Dictionary. Users may use the signon validation provided by the Dictionary or in an online environment:
 - If the customer has IMS/VIS V1 R1.5 installed, then the IMS/VIS user identification security feature may be used to pass a validated user ID to the Dictionary.
 - MVS customers with both IMS/VIS V1 R1.5 and RACF Release 3 (5740-XXH) and subsequent releases installed may use the IMS/VIS supported RACF signon facility to pass a RACF validated user ID to the Dictionary.
 - If the customer has CICS/VIS installed, the operator identification may be passed by CICS/VIS to the Dictionary.

- **User Profile Security:** User profile security provides a means for restricting a user's access to the dictionary by status code and by subject category. The security check is applied during initial reference to a dictionary subject, for example, in batch prior to execution of each command and online prior to processing a request on the header display form or display forms where the REUSE action is allowed.

The status code portion of a subject name is used as the security key. A user's profile may allow read/write access, read-only access, or no access to subjects based on their status code.

Use of the Dictionary may also be restricted by subject category. Each user is able to access only that group of Dictionary categories identified in that user's profile.

Enhanced PL/I Support: PL/I data attributes may now be specified explicitly, replacing the PL/I text strings used previously. This enhanced support is comparable to that for COBOL data attributes. The command language, the Interactive Display Forms Facility, and the Batch Forms Input Facility have been extended to support the entry and maintenance of the new attributes.

A batch PLL_IN function accepts PL/I structure declarations stored in %INCLUDE libraries or as sequential files, and creates the appropriate subjects and relationships in the Dictionary. Updating can optionally be suppressed, in which case only a report of the definitions that would have been stored in the Dictionary is produced.

The STRUCTURES_OUT function generates PL/I data declarations directly from the new PL/I attributes, rather than from the current text strings. Output consists of a report and card images suitable for inclusion in a %INCLUDE library.

A conversion aid is supplied to assist in converting the PL/I information in an existing Release 2 Dictionary to the form required by the new PL/I support.

GIS/VIS Descriptor Support: The Dictionary has been enhanced to support attributes of the type used by query products such as GIS/VIS. The command language and the Interactive Display Forms Facility has been extended to support the entry and maintenance of the new attributes. A DDT_OUT function is provided that generates statements which may be inserted into the installation's OS/VIS or DOS/VIS GIS Data Description Table (DDT) generation job stream.

Extensibility Facility: This facility permits an installation to extend its dictionary to include up to 200 new subject categories representing, for example, personnel, organizational entities, hardware devices, etc., of particular importance in its own data processing operations.

Similarly, the installation is able to define new *types* of relationships. One or more different types of relationships may be defined between installation-defined subject categories, or between an installation-defined subject category and a Dictionary-supplied category.

The installation may associate a set of attributes and validation rules with each defined subject category and relationship-type. In addition, the installation is able to supply its own installation written routines for subject name and attribute value validation.

Subjects and relationships in installation-defined categories may be created and maintained through the Dictionary update language, batch forms, or through the Interactive Display Forms Facility using a set of generalized display formats. Through any of these facilities, subjects and attributes may be referred to by their installation-defined names and keywords, just as are Dictionary-supplied subjects and attributes.

Program Access Facility: The Program Access Facility provides a means for programs to access the information contained in the Dictionary and to request services of the dictionary program. The data structures seen through the Program Access Facility are essentially those seen by the user of the current command language and Interactive Display Forms Facility: namely, subjects and relationships. Users of the Program Access Facility do not need to be aware of the Dictionary data base structure.

The Program Access Facility permits customer-written routines to request functions such as:

- Retrieve attributes of individual subjects and relationships.
- Retrieve lists of subjects in a specified category or related to a specific subject.
- Retrieve description and user-data text.
- Provide output to printer, terminal and punch.

The Program Access Facility supports routines written in COBOL, PL/I, and Assembler. These routines are started via Dictionary command, and execute in the Dictionary region. They request dictionary services through the CALL facilities in these languages.

A number of aids for writing programs that use the Program Access Facility are included. In addition, a sample program in each of the supported programming languages is included with Release 3.0.

Data Dictionary (cont'd)

Usability/Productivity/Performance Improvements

STRUCTURES_OUT Enhancements: A user may specify a prefix or suffix (or both) which will be concatenated with each subject name in an output structure.

If only length, data type, and (optionally) number of decimal place attributes are provided for each field in a structure, then STRUCTURES_OUT can generate equivalent structures for COBOL, PL/I, and Assembler.

Dictionary Default Specification: A new macro is provided that allows an installation to establish its own defaults for certain Dictionary parameters.

Report and SCAN Enhancements

- The GLOSSARY report is modified to permit the reporting of individual subject categories or subsets.
- The SCAN report is similarly enhanced to permit limiting the scan to individual subject categories or subsets, plus a capability to specify starting positions for scanning. The installation will also be able to control the maximum number of subjects to be reported when operating in either online or batch environments.
- The formats of various reports have been modified to improve readability.

Batch and BMP Checkpoint: The Dictionary allows the installation to request that checkpoint calls be taken at periodic intervals when run in a BMP or Batch environment. A new command allows a user to request checkpoints at specific points in a batch input stream.

Online Usability Enhancements: With Release 3.0, the online user can:

- Switch conveniently between display forms and commands during the same interactive session.
- Reuse certain display-forms repeatedly (for example, to define many different elements), without having to return to the header form.
- Easily page through a list of data within a subject entry, using a default DOWN count.
- Take advantage of a processing default for the ENTER key. That is, pressing the ENTER key will, where applicable, be equivalent to selecting the process action.

Text Data Enhancements

- The maximum length of a line of description text has been increased from 40 to 72 characters.
- The maximum number of lines of description and of the five sets of user-data text that can be stored in the Dictionary for a given subject have been increased from 255 to 999.
- A new USERDATA form that displays seven 80-character lines of text will be available, in addition to the current USERDATA display-form, which displays 15 lines of user-data text, each line truncated at 72 characters. Either form may be selected as an installation option. The maximum length of a line of user-data text remains unchanged at 80 characters.

Element Type-Code Revised: Release 2.0 element type-codes have been revised to be consistent with assembler conventions for data types. The Release 3.0 conversion package transforms Release 2.0 element type-codes to the revised Release 3.0 format.

DESCRIPTION OF OS/VS RELEASE 4.0

DB/DC Data Dictionary OS/VS Release 4.0 (5740-XXF) contains support for the field level sensitivity function which is part of IMS/VS Version 1 Release 1.5 (5740-XX2) Data Base System and some additional usability/productivity enhancements. Release 4.0 of the Dictionary includes all of the functions of the OS/VS Release 3.0 product and adds new functions.

The field level sensitivity function of IMS/VS gives an installation the ability to limit the data which an application may view, not only at the segment level, but also at the field level within the segment. In IMS/VS DL/I, a PSB (view) for an application may now limit the application's sensitivity to only certain fields within a segment of a data base. Previously, a PSB (view) could only limit sensitivity to segments within a data base, not its fields. The Dictionary will now support this function.

Field Level Sensitivity Support

The IMS/VS Version 1 Release 1.5's field level sensitivity function is supported by a new Dictionary facility which provides the capability to define logical views of a given IMS/VS DL/I segment. Each logical view consists of an appropriate subset of the segment's fields which comprise that view. The following Dictionary functions will provide support for the new logical view:

- PSB_IN recognizes the existence of SENFLD information and creates logical views.

- PSB_OUT produces SENFLD statements when required.
- The COPY and DELETE_STRUCTURE commands provide for copy and deletion of a logical view as part of a hierarchical structure.
- Dictionary update commands and Interactive Display Forms provide for the definition and modification of logical views and their associated relationships.
- Information on logical views is retrievable through the Program Access facility.
- Several of the Dictionary reports are enhanced to include information on logical views.
- The SCAN command is enhanced to retrieve logical views of a particular segment or the segment to which a logical view is related.
- The Segment Definition Form of the Batch Forms facility is redesigned to support definition of logical views.
- Usability/Productivity Enhancements
 - A new option on the DELETE command provides the ability to delete aliases of a subject whenever the subject itself is deleted.
 - A new DVALUES parameter is added to DBD_OUT, PSB_OUT, and DDT_OUT. If DVALUES=YES is specified, a comment record will be included in the generated output to identify the Dictionary entry.
 - An enhancement to PSB_OUT will allow the same PCB to be produced in different relative locations in different PSBs.
 - PSB_IN is no longer restricted to a physical hierarchical segment order for sensitive segments.

DESCRIPTION OF DOS/VS RELEASE 4

DOS/VS DB/DC Data Dictionary Release 4 (5746-XXC) contains support for the field-level sensitivity function and other enhancements. The name 'Dictionary' as used in this description refers to DOS/VS DB/DC Data Dictionary Release 4 unless otherwise noted. Release 4 of the Dictionary includes all of the functions of the DOS/VS DB/DC Data Dictionary Release 3 product and adds new functions.

The field-level sensitivity function of DL/I DOS/VS gives an installation the ability to limit the data which an application may view, not only at the segment level, but also at the field level within the segment. In DL/I DOS/VS, a Program Specification Block (PSB) for an application may now limit the application's view to only certain fields within a segment of a data base. Previously a PSB (view) could only limit sensitivity to certain segments within a data base, not its fields. The Dictionary will now support this function.

FIELD-LEVEL SENSITIVITY SUPPORT: The DL/I DOS/VS's field-level sensitivity function introduced in Version 1 Release 5 is supported by a new Dictionary facility which provides the capability to define logical views of a given DL/I DOS/VS segment. Each logical view consists of an appropriate subset of the segment's fields which comprise that view. The following Dictionary functions provide support for the new logical view:

- PSB_IN recognizes the existence of SENFLD and VIRFLD information and creates logical views.
- PSB_OUT produces SENFLD and VIRFLD statements when required.
- The COPY and DELETE_STRUCTURE commands provide for copy and deletion of a logical view as part of a hierarchical structure.
- Dictionary update commands and interactive display forms provide for the definition and modification of logical views and their associated relationships.
- The STRUCTURES_OUT command produces data structures for logical views.
- Information on logical views is retrievable through the Program Access Facility.
- Several of the Dictionary reports are enhanced to include information on logical views.
- The SCAN command is enhanced to retrieve logical views of a particular segment or the segment to which a logical view is related.
- The Segment Definition Form of the Batch Forms Facility is redesigned to support definition of logical views and their associated relationships.

SUPPORT OF ADDITIONAL DL/I DOS/VS FUNCTIONS: DL/I DOS/VS Version 1 Releases 5 and 6 have included other enhancements which are now supported by the Dictionary. Dictionary adds support for the following DL/I DOS/VS enhancements:

PROGRAM PRODUCTS

Data Dictionary (cont'd)

- PSB_IN recognizes when the Automatic Definition Sequencing feature of DL/I DOS/V5 Version 1 Release 5 has been used and calculates field start positions.
- DBD_IN and DBD_OUT allow usage of the Automatic Segment Size Calculation features of DL/I DOS/V5 Version 1 Release 5.
- DBD_IN recognizes and DBD_OUT produces the POINTER=NOTWIN parameter introduced in DL/I DOS/V5 Version 1 Release 5.
- DBD_IN recognizes and DBD_OUT and STRUCTURES_OUT produces the new element type codes introduced in DL/I DOS/V5 Version 1 Release 5.
- DBD_IN recognizes and DBD_OUT produces the IMS/V5 compatibility parameter introduced in DL/I DOS/V5 Version 1 Release 6.

USABILITY/PRODUCTIVITY ENHANCEMENTS

- A new option on the DELETE command provides the ability to delete aliases of a subject whenever the subject itself is desired.
- A new DVALUES parameter is added to DBD_OUT, PSB_OUT, and DDT_OUT. If DVALUES=YES is specified, a comment record is included in the generated output to identify the Dictionary entry. These commands, as well as the STRUCTURES_OUT command, provide the ability to request that the name used in the DVALUES command be the primary name rather than the alias.
- An enhancement to PSB_OUT allows the same PCB to be produced in different relative locations in different PSBs.
- A time and date stamp is added to Dictionary log records.
- Printing the password is suppressed when logging the Dictionary SIGN_ON command.

CUSTOMER RESPONSIBILITIES

A customer installing the DB/DC Data Dictionary must collect and record the descriptions and relationships concerning the data entities to be stored in the dictionary.

AVAILABILITY

DB/DC Data Dictionary OS/V5 Release 4.0 (5740-XXF) is available now. The planned availability date for DOS/V5 DB/DC Data Dictionary Release 4 is January 29, 1982.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The machine configuration required for DB/DC Data Dictionary is determined by the requirements of the host operating system, DB/DC system and objectives of the installation. A customer installing the DB/DC Data Dictionary must have at least the minimum machine configuration for IMS/V5, CICS/V5 and/or DL/I DOS/V5.

The disk storage requirement is a function of the specific number of descriptors stored by the installation.

For OS/V5 and DOS/V5 Dictionary Release 3: The DB/DC Data Dictionary product gives the customer the option of creating several dictionary load modules that perform subsets of the function provided by the Dictionary. This allows the customer to create smaller load modules when the installation does not need the full range of Dictionary function available for Release 3.0. The virtual storage requirement of each program will not exceed 550K for overlay configurations, exclusive of operating system and DB/DC system requirements. A virtual storage size of 900K to 1300K will be required for various non-overlay configurations.

For Dictionary OS/V5 Release 4.0: The virtual storage requirement of each program, exclusive of operating and DB/DC system requirements, requires approximately 1380K of storage for online operation (approximately 440K if the overlay structure is utilized), or approximately 1040K of storage for batch operation (approximately 420K if the overlay structure is utilized).

The Dictionary will support display terminals with at least 24 lines of 80 characters which are supported by the underlying IMS/V5 or CICS/OS/V5 system. These terminals will be required to operate the online (teleprocessing) version of the Dictionary and are handled through normal IMS/V5 and CICS/OS/V5 system support.

For DOS/V5 DB/DC Data Dictionary Release 4: The machine requirements for Dictionary Release 4 are determined by the requirements of the host operating system, DB/DC system, and objectives of the installation. A customer installing the Dictionary must have at least the minimum machine requirements as defined by IBM for DL/I DOS/V5 (5746-XX1) and/or CICS/DOS/V5 (5746-XX3).

The Dictionary gives the customer the option of creating several load modules that perform subsets of the function provided by the Dictionary. This allows the customer to create smaller load modules when the installation does not need the full range of function available. The full-function virtual storage requirements of each program,

exclusive of operating and DB/DC system requirements, is approximately 600K of storage for online operation, or approximately 1000K of storage for batch operation (approximately 600K if the overlay structure is utilized).

The Dictionary will support display terminals with at least 24 lines of 80 characters which are supported by the underlying CICS/DOS/V5 system. These terminals will be required to operate the online (teleprocessing) version of the Dictionary, and are handled through normal CICS/DOS/V5 system support.

The CICS/DOS/V5 Basic Mapping Support (BMS) source code furnished with the Dictionary will provide input/output formatting for all terminals that are supported by CICS/DOS/V5 and meet the above screen size requirements.

SOFTWARE REQUIREMENTS

Release 4.0 of the DB/DC Data Dictionary OS/V5 product (5740-XXF) operates as an application program under IMS/V5 V1 R1.5 (5740-XX2), or CICS/OS/V5 V1 R4.0/R4.1 (5740-XX1) with IMS/V5 V1 R1.5 DB (5740-XX2), and subsequent releases unless otherwise specified.

Note: DB/DC Data Dictionary OS/V5 Release 3.0 will not be supported on CICS/OS/V5 V1 R5.0.

For OS/V5 Dictionary, a System Modification Program Release 4 (SMP4) job stream will be provided as a file on the distribution tape for installation of the DB/DC Data Dictionary OS/V5 Release 4.0 using SMP4. Program service will be provided periodically in SMP4 format for object code. DB/DC Data Dictionary OS/V5 Release 3.0 provided an SMP3 or SMP4 job stream.

Release 3.0 of the DB/DC Data Dictionary DOS/V5 product (5746-XXC) operates with:

- DL/I DOS/V5 V1 R4.0 (5746-XX1) and
- CICS/DOS/V5 V1 R4.0 (5746-XX3), if Interactive Display Forms are used,

Release 4 of the DOS/V5 DB/DC Data Dictionary product (5746-XXC) operates with DL/I DOS/V5 (5746-XX1) Version 1 Release 5, DL/I DOS/V5 Version 1 Release 5 HLP1 ICR, DL/I DOS/V5 Version 1 Release 6, and subsequent releases unless otherwise specified. The Dictionary's Interactive Display Forms Facility operates with CICS/DOS/V5 (5746-XX3) Version 1 Release 5 with HLP1 ICR (ICR2) or subsequent releases unless otherwise specified.

For operating system requirements, see DL/I DOS/V5 or CICS/DOS/V5 programming systems support in the appropriate DL/I DOS/V5 or CICS/DOS/V5 documentation. Dictionary requires VSE/Advanced Function Release 2 and subsequent releases unless otherwise specified.

If the SORT option of the REPORT command is specified, use the DOS/VSE Sort/Merge Program, 5746-SM1, (or a SORT program with an equivalent program interface).

For operating system requirements, see IMS/V5, or DL/I DOS/V5, or CICS/V5 programming system support in the appropriate IMS/V5, or DL/I DOS/V5, or CICS/V5 documentation.

For DOS/V5 DB/DC Dictionary: A Maintain System History Program (MSHP) job stream will be provided for installation of the DOS/V5 DB/DC Data Dictionary Release 4.

The Dictionary source language is Basic Assembler Language (BAL) with the following exceptions:

- Three modules written using the CICS/V5 High Level Programming Interface and BAL.
- PL/I macros and sample program for PL/I users of the Program Access Facility.
- COBOL macros and sample program for COBOL users of the Program Access Facility.

The Dictionary is distributed primarily in object code format. Source code is available as optional machine readable material.

Product Currency: The following table shows the currency period of DB/DC Data Dictionary through the date shown:

DB/DC DATA DICTIONARY	CURRENCY DATE	
	5740-XXF OS/V5	5746-XXC DOS/V5
R3.0	5/81	*

* Program Currency will be provided by IBM until discontinued upon 12 months written notice.

COMPATIBILITY/CONVERSION

Data Dictionary (cont'd)

Release 1.0 of the DB/DC Data Dictionary was an evolutionary development of two IBM Field Developed Programs, the IMS Dictionary System (5798-BBA) and the IMS Dictionary Enhancements (5798-CEE). It incorporates the functions of these FDPs, plus:

- DOS/VS operation
- Interactive display forms facility (IMS/VS only)
- Enhancement of Report function
- COBOL Input Command
- Improved and enhanced Structures Out
- Hierarchical Delete capability
- Copy command
- Relocate command for modifying hierarchical structures
- Ten additional levels of test status

Release 2.0 includes all of the function of Release 1. Release 1.0 command streams and display terminal procedures are usable in Release 2, with two exceptions: The REPORT_ALL command is no longer valid, since its function has been included in the enhanced glossary report; and the update option default for COBOL_IN has been changed.

The internal format of the dictionary has been modified in Release 2 to incorporate a new subject category, new relationship categories, and new attributes. This means that dictionary data bases created under Release 1.0 must be converted to the new format to run under Release 2. A conversion procedure, which makes use of standard IMS/VS DB system or DL/I DOS/VS utilities, is provided in the documentation.

Release 2.0 also includes conversion aids to assist the user in converting to Release 2.0 from the IMS Dictionary System (5798-BBA) and the IMS Dictionary Enhancements (5798-CEE) Field Developed Programs.

Release 3.0 includes all of the function of Release 2.0. The internal format of the DB/DC Data Dictionary data bases is modified in Release 3.0. This means that the data bases created under Release 2.0 must be converted to the new format to run under Release 3.0. A conversion package is provided with Release 3.0 to:

- transform Release 2.0 element type-codes to revised Release 3.0 formats.
- convert Release 2.0 description text to the longer length supported in Release 3.0.
- aid in converting Release 2.0 PL/I data to Release 3.0 PL/I data formats.

Note: No conversion aid or support is provided to assist installations moving from the FDP or Release 1.0 Dictionary products to Release 3.0.

Dictionary OS/VS Release 1 includes all of the functions of Release 3.0. The internal format of the DB/DC Data Dictionary data bases is modified in Release 4.0. The IMS/VS DL/I Utilities can be used to convert Dictionary OS/VS Release 3.0 data bases to Release 4.0 format.

DOS/VS DB/DC Data Dictionary Release 4 includes all the functions of the DOS/VS DB/DC Data Dictionary Release 3. The internal format of the Dictionary data bases is modified in Release 4. The DL/I DOS/VS utilities can be used to convert Dictionary Release 3 data bases to Release 4 format.

Note: No conversion aid or support is provided to assist installations moving from the FDP or Release 1.0 and 2.0 Dictionary products to Release 4.0.

AUDITABILITY

The dictionary is of interest to internal auditors, as well as others concerned with data integrity because of its data description and documentation capabilities, and its use as a vehicle for controlling and tracking data base changes. Dictionary use may be monitored through the standard logging facilities in IMS/VS, CICS/VS and DL/I DOS/VS, and through the optional logging of commands by the Dictionary.

DATA SECURITY

The Dictionary operates as an application program under DL/I and its use is controlled with the standard security features of IMS/VS or CICS/OS/VS for OS/VS Dictionary, and the standard security features of DL/I DOS/VS or CICS/DOS/VS for DOS/VS Dictionary. Attempts to access Dictionary data in an MVS environment outside of IMS/VS can also be controlled through the use of RACF.

Dictionary provides a Security Facility composed of two functions: Signon validation and a user profile security.

PERFORMANCE CONSIDERATIONS

The Release 3.0 interactive display enhancements may significantly reduce the number of transactions, region schedules, etc., required in support of the Dictionary online user.

For example, the Release 3.0 online enhancements permit the entry and editing of 10 different data element definitions with 33% fewer region schedules than Release 2.0.

There is no significant change in the performance of the DB/DC Data Dictionary OS/VS and DOS/VS Release 3.0 function in Release 4.0. CICS/OS/VS users should also refer to the note in the "Programming Requirements" section.

MVS INTEGRITY

IBM will accept APARs describing situations where the installation of the DB/DC Data Dictionary program product causes an exposure to the system integrity of OS/VS2 MVS.

RPQs ACCEPTED: No

TERMS and CONDITIONS: See PP Index

OS/VS DB/DC DATA DICTIONARY VERSION 1 RELEASE 5 5740-XXF

PURPOSE

The OS/VS DB/DC Data Dictionary is a central collection of information about data resources that are needed for efficient data management. The OS/VS DB/DC Data Dictionary improves the manageability of a data processing installation by storing, processing and reporting on definitions, descriptions and relationships of data. This document uses the name Dictionary when referring to either DB/DC Data Dictionary program product unless otherwise noted.

DESCRIPTION

The Dictionary deals with categories of subjects, the relationships between subjects, and the attributes which characterize subjects and relationships. Categories are families of items, such as data bases, programs or personnel. The data base category would, for example, contain individual data base descriptions as subjects. Relationships represent the interaction between subjects. For example, a relationship between a pair of subjects representing an application program and a data base might indicate that the program accesses that data base. Attributes describe properties of a subject or relationship such as size, frequency, or the date a relationship was established.

The name, DB/DC Data Dictionary, represents two products - one that operates in the OS/VS environment (program product 5740-XXF), and the other that operates in the DOS/VS environment (program product 5746-XXC). In the OS/VS environment the product operates with the following DB/DC systems: IMS/VS DB or IMS/VS DB/DC (5740-XX2), or CICS/OS/VS (5740-XX1) with IMS/VS DB. In the DOS/VS environment, the product operates with the following DB/DC systems: DL/I DOS/VS (5746-XX1) with or without CICS/DOS/VS (5746-XX3). If the Dictionary is to be used only in a batch environment, either the IMS/VS Data Base System or DL/I DOS/VS is required. See the pages for DOS/VS Data Dictionary.

The Dictionary utilizes DL/I data bases to store definitions of data and data usage under these subject categories:

- DATA BASE - physical, logical, primary or secondary index DL/I data bases, or non-DL/I data sets
- SEGMENT - DL/I data base segments or non-DL/I records
- ELEMENT - fields or group data items
- PCB - DL/I program communication blocks
- SYSTEM DEFINITION - IMS/VS system definition information
- SYSTEM - major application systems, such as a payroll system
- JOB - processing units corresponding to single jobs
- PROGRAM - major programs or job steps
- MODULES - functional subsections of programs
- TRANSACTION - IMS or non-IMS transactions
- PSB - DL/I program specification blocks
- DDUSER - access control information and passwords of all dictionary users
- CATEGORY - installation-defined subject-category definition
- RELATIONSHIP TYPE (RELTYPE) - installation-defined relationship types
- ATTRIBUTE TYPE - installation-defined attributes of subject categories or relationship types
- STRUCTURE TYPE (STRTYPE) - installation-defined structure types

A data definition is entered into the dictionary through either the dictionary command language or the Interactive Display Form Facility. The definitions may contain the following entry types:

- subject name - user name for this subject, plus dictionary qualifiers for the name
- aliases - other names by which this subject is known to the user
- attributes - anticipated entries of various characteristics for a given subject category
- description - text describing the subject, with user-specified format and content
- user data - for any user information that cannot be included as attribute data, with user-specified format and content
- relationships - cross-references between this subject and other subjects in the same or other subject categories
- relationship data - information about the nature of the relationship between certain kinds of subjects

HIGHLIGHTS

Release 1 contained:

Centralized Source of Information and Control
Automated Capture of Existing Definitions
Flexibility of Use
Interactive Display for IMS/VS
Extensive Reporting Capability
Systemized Control of Data Base Modifications
DBD and PSB Generation
Data Structure Generation

Release 2 contained:

Batch Forms Input
COBOL Input Enhancements
IMS/VS System Definition Support
Extend Relationship Facility
Recalculate Segment Facility
Reports Enhancements
Output Enhancements

Release 3 contained:

CICS/OS/VS Interactive Display Forms Facility
Security Facility (Access Control)
Signon Authorization
User Profiles
Enhanced PL/I Support
GIS/VS Descriptor Support
Extensibility Facility
Program Access Facility
Usability/Productivity/Performance Improvements
Structures_OUT Enhancements
Dictionary Default Specification
Report and Scan Enhancements
Batch and BMP Checkpoint
Online Usability Enhancements
Test Data Enhancements
Element Type-Code Revised

Release 4 contained:

Field Level Sensitivity Support
Usability/Productivity Enhancements

Centralized Source of Information and Control: The dictionary can be a central source of information about a company's data resources, including application data still in test stages.

Automated Capture of Existing Definitions: COBOL source either from sequential files or COBOL copy libraries can be read by the dictionary to obtain initial record definitions, as can the DBD (data base description) and PSB (program specification block) libraries. See "Enhanced PL/I Support" for a description of PL/I language support. Additional information can be added by using dictionary commands, or copied from existing dictionary descriptions.

Flexibility of Use: The command language lets the user add, change, relate or delete information in all subject categories, scan the information for selective retrieval, copy existing definitions and obtain varied output in machine and human-readable form. Provisions are also made for storing non-DL/I data and user-unique data, thus enabling installations to integrate all their data definitions into one central dictionary.

Interactive Display for IMS/VS: Most dictionary commands can be executed online through the 3270 Display System. In addition, a task-oriented facility is provided that guides the user in entering specific definitions and displaying current dictionary contents. Each display form is designed for one specific DL/I definition. (For example, a different form is provided for defining a physical data base than for defining a primary index data base.) Each form has an associated explanation frame that provides information on how to use it. This method of entering definitions can help reduce errors by avoiding omissions, contradictions and misspellings. It can also be productive in that a single form may result in many dictionary commands being executed.

Extensive Reporting Capability: Users can obtain predefined reports on the complete contents of a subject category or full details of definitions and their relationships in printed or (online) display form. A SCAN facility provides for user-specified selective retrieval of information from the dictionary. Hierarchical data base structures can be printed out in indented formats. Printed reports are equivalent in content to most of the formatted display frames available with the online (IMS/VS) interactive displays. Additional custom reports, if desired, can be generated using GIS/VS. No GIS/VS data description tables (DDTs) for the Dictionary data bases will be provided in the licensed documentation.

Systemized Control of Data Base Modifications: If all data resources are described in the dictionary, it becomes a useful tool for controlling standards, versions and modifications. Its reports, naming conventions, search capability and cross-references help in studying the effect of proposed change. Until standardization is achieved, the dictionary assists in control of duplicate names by keeping track of multiple occurrences.

DBD and PSB Generation: Dictionary commands can process stored definitions to produce source statements for the generation of data base descriptions and program specification blocks suitable for host DL/I libraries.

OS/VS Data Dictionary V1R5 (cont'd)

Data Structure Generation: Another output of the dictionary is data declarations suitable for inclusion in COBOL, PL/I or Assembler language programs.

Batch Forms Input: The input capability of the Dictionary has been enhanced in Release 2 by a batch forms input facility, which permits element and segment definitions and text information to be prepared on pre-printed forms and entered into the dictionary via a batch job stream. Segment and element definitions may include not only the usual set of subject attributes, but also the identities of elements and subelements contained within the subject, thus providing a definition of subject structure. Text information which may be entered consists of descriptions and user data for any subject category, and commentary for segments and elements. The forms may be used to create new subjects and to add data to existing subjects. A report is produced showing the data that was entered and any diagnostic messages produced. The facility provides an alternative to the COBOL_IN command for capturing large amounts of segment and element information, and brings to the batch user the convenience of forms for bulk data entry.

COBOL Input Enhancements: The COBOL_IN command in Release 1 has been enhanced by making the dictionary updating phase of the command a user option. With updating suppressed, the COBOL_IN command produces a listing of the information that would be stored in the dictionary with updating selected, and optionally a punch data set containing the dictionary commands which would do this updating. In this way the user may verify the suitability of COBOL source statements before committing the information to the dictionary, and may use the punched commands, modified as necessary, to enter the correct definitions into the dictionary.

IMS/VS System Definition Support: The role of the dictionary as the centralized source of information and control has been enhanced through the addition of a facility for documenting the information contained in the IMS/VS DATABASE, APPLCTN and TRANSACT system definition macros. A subject category, the System Definition, has been added, along with new attributes for transactions and program specification blocks (PSBs), and relationship categories for relating system definitions to data bases, transactions, and PSBs. Existing commands and interactive display facilities have been extended to permit the entry and reporting of system definition information. A STAGE_1_OUT command permits system definition information to be produced in machine-readable records in the format of IMS/VS DATABASE, APPLCTN and TRANSACT macros, so that these records can be incorporated directly into IMS/VS Stage 1 system definition job streams. The command includes an IMS/VS release parameter, to permit the user to specify the release of IMS/VS for which the macros are being produced. The support extends the control function of the dictionary to the system definition activity of the IMS/VS DB/DC user, and provides documentation aid for the IMS/VS DB and DL/I user migrating to IMS/VS DB/DC.

Extend Relationship Facility: An EXTEND_RELATIONSHIP command has been provided to relate each of the elements in a segment, or each of the first-level subelements in an element, to another subject. For example, a single EXTEND_RELATIONSHIP command may be used to relate each of the fields in segment XYZ to program ABC. Previously, such relationships had to be established through individual ADD_RELATIONSHIP commands. The new command provides a convenient way of making implied relationships explicit.

Recalculate Segment Facility: A RECALCULATE_SEGMENT command has been provided to restore consistency to a set of related segment and element definitions whose lengths and other attributes have been updated independently of one another. The command uses current element and subelement lengths and justification attributes to recalculate segment lengths and element starting positions, and optionally updates the dictionary with the new information. With updating suppressed, a punch data set of the equivalent updating commands may optionally be produced. A report showing the old and new attributes is produced. The command makes it unnecessary to use individual CHANGE_IN and CHANGE_RELATIONSHIP_DATA commands on the subjects and relationships in a structure in order to make the structure consistent.

Reports Enhancements: A report, the indirect subject reference report, has been provided to assist the user in locating references to elements, segments and data base subjects which have been stored as part of the dictionary data. The report is useful in maintaining dictionary consistency through its existing maintenance facilities.

The usability of the glossary report has been enhanced by permitting the user to specify the number of description lines to be shown for each subject, and to optionally suppress the printing of subject attributes. The user may also specify that the report be sorted on any combination of the four components of subject name (status code, subject code, user name and occurrence number). For example, if status code is selected as the major sort field, the report that results may be physically separated into sections each dealing with a different status code.

Output Enhancements: A PUNCH command is provided to create 80-character machine-readable records from user data segments previously entered through the dictionary updating facilities. User data

segments are typically used for program source and job control language statements, and the PUNCH command makes it convenient to include these statements in the users' job streams.

The STRUCTURES_OUT command is enhanced to permit the optional inclusion of comment records holding the dictionary attributes of the subjects from which the structures are generated. This provides a ready reference to these dictionary subjects, e.g., in case the structures must be modified. Also added is an installation option which permits the user to set the level number increment in generated structures so that it conforms to installation programming practices. For COBOL structures, the PICTURE clause has been aligned for readability.

CICS/VS Interactive Display Forms Facility: An interactive user interface for CICS/OS/VS Dictionary installations is provided which is equivalent to the IMS/VS Interactive Display Forms Facility including the Release 3 enhancements.

Access Control Facility: An Access Control Facility provided is available as an installation option. A 'signon' validation function allows the installation to determine the set of Dictionary users. A user profile security function can be used to partition the Dictionary according to status codes, subject categories and ability to update and/or view data.

- **Signon Authorization:** Users can be identified to the Dictionary, and IDs validated via passwords, to control access within the Dictionary. Users may use the signon validation provided by the Dictionary or in an online environment:

- If the customer has IMS/VS V1 R1.5 installed, then the IMS/VS user identification security feature may be used to pass a validated user ID to the Dictionary.

- MVS customers with both IMS/VS V1 R1.5 and RACF Release 3 (5740-XXH) and subsequent releases installed may use the IMS/VS-supported RACF signon facility to pass a RACF-validated user ID to the Dictionary.

- If the customer has CICS/OS/VS installed, the operator identification may be passed by CICS/OS/VS to the Dictionary.

- **User Profiles:** User profile security provides a means for restricting a user's access to the dictionary by status code and by subject category. The access check is applied during initial reference to a dictionary subject, for example, in batch prior to execution of each command and online prior to processing a request on the header display form, or display forms where the REUSE action is allowed.

The status code portion of a subject name is used as the security key. A user's profile may allow read/write access, read-only access, or no access to subjects based on their status code.

Use of the Dictionary may also be restricted by subject category. Each user is able to access only that group of Dictionary categories identified in that user's profile.

Enhanced PL/I Support: PL/I data attributes may now be specified explicitly, replacing the PL/I text strings used previously. This enhanced support is comparable to that for COBOL data attributes. The command language, the Interactive Display Forms Facility, and the Batch Forms Input Facility have been extended to support the entry and maintenance of the new attributes.

A batch PLI_IN function accepts PL/I structure declarations stored in %INCLUDE libraries or as sequential files, and creates the appropriate subjects and relationships in the Dictionary. Updating can optionally be suppressed, in which case only a report of the definitions that would have been stored in the Dictionary is produced.

The STRUCTURES_OUT function generates PL/I data declarations directly from the new PL/I attributes, rather than from the current text strings. Output consists of a report and card images suitable for inclusion in a %INCLUDE library.

A conversion aid is supplied to assist in converting the PL/I information in an existing Release 2 Dictionary to the form required by the new PL/I support.

GIS/VS Descriptor Support: The Dictionary has been enhanced to support attributes of the type used by query products such as GIS/VS. The command language and the Interactive Display Forms Facility have been extended to support the entry and maintenance of the new attributes. A DDT_OUT function is provided that generates statements which may be inserted into the installation's OS/VS or Data Description Table (DDT) generation job stream.

Extensibility Facility: This facility permits an installation to extend its dictionary to include up to 200 new subject categories representing, for example, personnel, organizational entities, hardware devices, etc., of particular importance in its own data processing operations.

Similarly, the installation is able to define new types of relationships. One or more different types of relationships may be defined between installation-defined subject categories, or between an installation-defined subject category and a Dictionary-supplied category.

The installation may associate a set of attributes and validation rules with each defined subject category and relationship-type. In addition,

OS/VS Data Dictionary V1R5 (cont'd)

the installation is able to supply its own installation-written routines for subject name and attribute value validation.

Subjects and relationships in installation-defined categories may be created and maintained through the Dictionary update language, batch forms, or through the Interactive Display Forms Facility using a set of generalized display formats. Through any of these facilities, subjects and attributes may be referred to by their installation-defined names and keywords, just as are Dictionary-supplied subjects and attributes.

Program Access Facility: The Program Access Facility provides a means for customer-written programs to access the information contained in the Dictionary and to request services of the dictionary program. The data structures seen through the Program Access Facility are essentially those seen by the user of the current command language and Interactive Display Forms Facility, namely, subjects and relationships. Users of the Program Access Facility do not need to be aware of the Dictionary data base structure.

The Program Access Facility permits customer-written routines to request functions such as:

- Retrieve attributes of individual subjects and relationships.
- Retrieve lists of subjects in a specified category or related to a specific subject.
- Retrieve description and user-data text.
- Provide output to printer, terminal and punch.

The Program Access Facility supports routines written in COBOL, PL/I, and Assembler. These routines are started via Dictionary command, and execute in the Dictionary region. They request dictionary services through the CALL facilities in these languages.

A number of aids for writing programs that use the Program Access Facility are included. In addition, a sample program in each of the supported programming languages is included with Release 3.0.

Usability/Productivity/Performance Improvements

STRUCTURES_OUT Enhancements: A user may specify a prefix or suffix (or both) which will be concatenated with each subject name in an output structure. If only length, data type, and (optionally) number of decimal place attributes are provided for each field in a structure, then STRUCTURES_OUT can generate equivalent structures for COBOL, PL/I, and Assembler.

Dictionary Default Specification: A new macro is provided that allows an installation to establish its own defaults for certain Dictionary parameters.

Report and SCAN Enhancements

- The GLOSSARY report is modified to permit the reporting of individual subject categories or subsets.
- The SCAN report is similarly enhanced to permit limiting the scan to individual subject categories or subsets, plus a capability to specify starting positions for scanning. The installation will also be able to control the maximum number of subjects to be reported when operating in either online or batch environments.
- The formats of various reports have been modified to improve readability.

Batch and BMP Checkpoint: The Dictionary allows the installation to request that checkpoint calls be taken at periodic intervals when run in a BMP or Batch environment. A new command allows a user to request checkpoints at specific points in a batch input stream.

Online Usability Enhancements: With Release 3.0, the online user can:

- Switch conveniently between display forms and commands during the same interactive session.
- Reuse certain display-forms repeatedly (for example, to define many different elements), without having to return to the header form.
- Easily page through a list of data within a subject entry, using a default DOWN count.
- Take advantage of a processing default for the ENTER key. That is, pressing the ENTER key will, where applicable, be equivalent to selecting the process action.

Text Data Enhancements

- The maximum length of a line of description text has been increased from 40 to 72 characters.
- The maximum number of lines of description and of the five sets of user-data text that can be stored in the Dictionary for a given subject have been increased from 255 to 999.
- A new USERDATA form that displays seven 80-character lines of text will be available, in addition to the current USERDATA display-form, which displays 15 lines of user-data text, each line truncated at 72 characters. Either form may be selected as an

installation option. The maximum length of a line of user-data text remains unchanged at 80 characters.

Element Type-Code Revised: Release 2 element type-codes have been revised to be consistent with assembler conventions for data types. The Release 3 conversion package transforms Release 2 element type-codes to the revised Release 3 format.

Field Level Sensitivity Support: OS/VS DB/DC Data Dictionary Release 4 contains support for the field level sensitivity function which is part of IMS/VS Version 1 Release 1.5 (5740-XX2) Data Base System and some additional usability/productivity enhancements. Release 4 of the Dictionary includes all of the functions of the Release 3 product and adds new functions.

The field level sensitivity function of IMS/VS gives an installation the ability to limit the data which an application may view, not only at the segment level, but also at the field level within the segment. In IMS/VS DL/I, a PSB (view) for an application may now limit the application's sensitivity to only certain fields within a segment of a data base. Previously, a PSB (view) could only limit sensitivity to segments within a data base, not its fields. The Dictionary will now support this function.

The IMS/VS Version 1 Release 1.5's field level sensitivity function is supported by a new Dictionary facility which provides the capability to define logical views of a given IMS/VS DL/I segment. Each logical view consists of an appropriate subset of the segment's fields which comprise that view. The following Dictionary functions will provide support for the new logical view:

- PSB_IN recognizes the existence of SENFLD information and creates logical views.
- PSB_OUT produces SENFLD statements when required.
- The COPY and DELETE_STRUCTURE commands provide for copy and deletion of a logical view as part of a hierarchical structure.
- Dictionary update commands and Interactive Display Forms provide for the definition and modification of logical views and their associated relationships.
- Information on logical views is retrievable through the Program Access facility.
- Several of the Dictionary reports are enhanced to include information on logical views.
- The SCAN command is enhanced to retrieve logical views of a particular segment or the segment to which a logical view is related.
- The Segment Definition Form of the Batch Forms facility is redesigned to support definition of logical views.

Usability/Productivity Enhancements

- A new option on the DELETE command provides the ability to delete aliases of a subject whenever the subject itself is deleted.
- A new DVALUES parameter is added to DBD_OUT, PSB_OUT, and DDT_OUT. If DVALUES=YES is specified, a comment record will be included in the generated output to identify the Dictionary entry.
- An enhancement to PSB_OUT will allow the same PCB to be produced in different relative locations in different PSBs.
- PSB_IN is no longer restricted to a physical hierarchical segment order for sensitive segments.

DESCRIPTION of RELEASE 5

Language Preprocessor: The Release 5 Language Preprocessor Facility provides the capability to retrieve language data structures and other source code directly from the Dictionary. The Preprocessor accepts as input a source program in COBOL, PL/I or Assembler language. It modifies the source program by recognizing COPY statements (in COBOL or Assembler language) or %INCLUDE statements (in PL/I) and replacing them with the data retrieved from the Dictionary.

The status code of the data structures retrieved from the Dictionary may vary within one source program without a change to the program itself.

The output of the Preprocessor (i.e., the modified source program) is suitable for input to the host language compiler or assembler.

Explicit Structures Facility: A new facility provides the installation with the capability to define 'structures' over its Dictionary data (for example, subjects and relationships). A Dictionary structure can include subjects and relationships in 'standard' categories, in installation-defined categories or both. Structure definitions are recorded as structure-type subjects in a new STRTYPE category. An IBM-supplied default structure-type is provided which simulates the built-in structure used in previous releases. New and existing Dictionary facilities provide the capability to process structures of Dictionary data.

OS/VS Data Dictionary V1R5 (cont'd)
Enhanced COPY and DELETE STRUCTURE Functions

- The COPY and DELETE_STRUCTURE commands are enhanced to process structures of Dictionary data (subjects and relationships) with reference to a particular structure-type definition. Thus, structures of subjects in 'standard' categories, in installation-defined categories or both can be copied and deleted.
- Additional enhancements to the COPY command include the capability to select the status of subjects to be copied, the capability to specify the action to be taken when the subject to be copied matches one already existing in the Dictionary, and the capability to preview the results of a copy without actually updating the Dictionary data bases.
- Additional enhancements to the DELETE_STRUCTURE command include the capability to select the status of subjects to be deleted and the capability to preview the results of the command without updating the Dictionary data bases.

Structure Reporting: The new STRUCTURE_REPORT command provides a report of a structure of Dictionary data. The structure to be processed can be identified with reference to a particular structure-type definition, or the path to be taken in reporting a structure can be explicitly specified within the command. This facility provides a 'where-used' report of subjects at any or all levels of a Dictionary structure.

Portability Facility: The Portability facility provides the capability to transfer Dictionary data from one Dictionary to another. Provision is made with the EXPORT command to extract selected Dictionary data and create output in a format (Dictionary commands and batch forms) which can be input to another Dictionary.

The exported output can then be previewed for its effect on the receiving Dictionary without updating its data bases, by using the PREVIEW command. When any potential conflicts have been resolved, the exported stream can be entered into the receiving Dictionary.

Dictionary Customization Enhancements

- A new facility is provided which will permit installations to modify the definitions of installed Extensibility subject categories and relationship-types. The modified definition replaces the existing installed definition. Within certain restrictions, changes and/or additions may be made to attribute definitions. Limited types of changes to subject name validation rules may also be made.

Data existing under the old definition is automatically converted to the new definition during the replacement processing. A processing report identifies data which may have been invalidated by the new definition.

- A subject name validation exit is provided for standard categories, in addition to the subject name validation exit already available for installation-defined categories.

Enhanced IMS/VS System Definition Support: The Dictionary support for the IMS/VS DATABASE and TRANSACT macros is enhanced to include all parameters present for IMS/VS Version 1 Releases 2 and 3.

Interactive Display Forms Facility Enhancements: Several enhancements have been made to the Interactive Display Forms Facility:

- New actions are provided on the ALIASES, DESCRIPTION, USER DATA and PL/I DATA forms to permit the user to transfer directly from one of these forms to another without having to return to the subject definition form.
- The display forms that are used to edit and display lists of relationships from one subject to other subjects are enhanced. New actions permit the user to 'mark' one of the relationships displayed on the form and directly transfer to the form displaying the definition of the related subject.
- The COMMAND form can now be accessed directly from any of the other display forms. It is no longer necessary to return to the Header form to access the COMMAND form.
- The RELATED ENTITIES form is replaced by the 'Selected' SUBJECT-RELATIONSHIPS form. This enhancement allows the display of related subjects in either standard or Extensibility categories with a common form.
- The 'Unselected' SUBJECT-RELATIONSHIP form is enhanced to display relationships to subjects in both standard and installation-defined categories.
- A 'mode' function is provided for most of the forms that are used to edit and display lists of relationships from one subject to other subjects. A default of 'old has been made consistent for these forms.
- A number of display forms are modified to provide the capability to display and edit the definition for a 'file' data base (DBTYPE=F). This capability provides equivalence to that previously available only via Dictionary commands.

Enhanced Operational Characteristics

- The new Output Routing Facility will provide users with more control over the destination of the output from Dictionary commands in both the batch and online environments:
 - Users can route output to an OS/VS sequential or partitioned data set.
 - IMS/VS users can specify the output destination as an IMS/VS logical terminal.
 - Facilities are also provided for imbedding Dictionary output within header and trailer data (such as JCL). One application of this function is that Dictionary output can include JCL and, under MVS/370 or MVS/XA, be directed to an MVS internal reader.
- Two new facilities provide enhanced command processing flexibility:
 - Provision is made for the repetitive execution of a single command for a group of Dictionary subjects. Individual category/subject name pairs are placed in a 'stack'. A stack may be located in a set of User Data within the Dictionary data bases, or in an OS/VS sequential or partitioned data set. One way to build a stack is with output from SCAN or STRUCTURE_REPORT commands. The SETSTACK command identifies the location of the stack; the RUNSTACK command causes a specified Dictionary command to be repetitively executed for each member of the stack.
 - Dictionary commands themselves can be executed from a list stored in a specified subject's set of User Data. The location of the command list is specified with the SETCLIST command. The RUNCLIST command causes all the commands in the list to be executed in turn.
- The output page size option provides the capability to specify the number of lines on a page of printed output. This value is used by Dictionary commands that generate printed output.
- Two new serviceability functions are introduced:
 - A TRACE function permits users to obtain a trace of Dictionary execution, and
 - A SNAP dump function permits users to invoke snap dumps during Dictionary execution.

Enhanced Dictionary Access Control: Several enhancements have been made to the Dictionary's Access Control Facility:

- The access profiles established for individual Dictionary users can now contain a list of one or more groups of commands that are authorized for that user. Separate lists can be established for the batch and online environments. If a command is issued by a user for which authorization is not established in the access profile, the command is rejected.
- The action of the COPY and DELETE_STRUCTURE commands is changed to prevent copying or deleting subjects to which the user is not authorized.
- A user can be authorized to establish a relationship between two subjects with different status codes when 'update' authorization exists for one of the status codes and 'view' authorization exists for the other status code, and authorization to both categories exists.

Miscellaneous Usability/Productivity Enhancements

- The subject name defaults (status code, subject code and occurrence number) can be established on a user-by-user basis within the access profile.
- The PUNCH command is enhanced to 'punch' lines of description text in addition to lines of User Data.
- The DELETE_DATA and DELETE_RELATIONSHIP_DATA commands are enhanced to allow deletion of all data of a particular attribute group. The DELETE_DATA command is enhanced to allow deletion of a range or all lines of Description or User Data text; this is helpful in managing text data which was updated outside the Dictionary environment.
- Changes to the CICS/OS/VS transaction environment achieve efficiencies in the use of storage when multiple screens of data have been presented.
- A capability has been added which allows multiple online Dictionary regions in the CICS/OS/VS environment.

CUSTOMER RESPONSIBILITIES

A customer installing the OS/VS DB/DC Data Dictionary should consider the following series of steps:

- Obtain management commitment.
- Implement Data Administration - Many new users already have a Data Administration function and thus, must only incorporate the Dictionary into the existing environment and procedures. For users without such function, it is important to establish one.

OS/VS Data Dictionary V1R5 (cont'd)

- Define Dictionary objectives - What are the services and benefits desired from the Dictionary?
- Develop a Dictionary implementation plan - Like all other projects, a plan for Dictionary implementation must be developed and approved. Since full implementation of the Dictionary objectives will usually require time, it is important that the plan be phased, implementing support on the basis of priority, effort and benefit.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The machine configuration required for IBM OS/VS DB/DC Data Dictionary is determined by the requirements of the host operating system, DB/DC system, and objectives of the installation. A customer installing the OS/VS DB/DC Data Dictionary Release 4 or Release 5 must have at least the minimum machine configuration as defined by IBM for IMS/VS or CICS/OS/VS. The disk storage requirement is a function of the specific number of descriptors stored by the installation.

The virtual storage requirement of the Dictionary Release 4 program, exclusive of operating and DB/DC system requirements, requires approximately 1,380K of storage for online operation (approximately 440K if the overlay structure is utilized), or approximately 1,040K of storage for batch operation (approximately 420K if the overlay structure is utilized).

The virtual storage requirement of the Dictionary Release 5 program, exclusive of operating and DB/DC system requirements, requires approximately 1,700K of storage for online operation (approximately 510K if the overlay structure is utilized), or approximately 1,400K of storage for batch operation (approximately 500K if the overlay structure is utilized).

The Dictionary will support any display terminals supported by IMS/VS or CICS/OS/VS with at least 24 lines of 80 characters. The Message Format Services (MFS) and Basic Mapping Support (BMS) code is furnished with the Dictionary and provides input/output formatting for the IBM 3270 displays.

SOFTWARE REQUIREMENTS

OS/VS DB/DC Data Dictionary Release 4 program product (5740-XXF) operates as an application program under:

- IMS/VS Version 1 Release 1.5 (5740-XX2).
- CICS/OS/VS Version 1 Release 4.0/R4.1 (5740-XX1) with IMS/VS Version 1 Release 1.5 Data Base System.
- and subsequent releases unless otherwise specified.

OS/VS DB/DC Data Dictionary Release 5 program product (5740-XXF) operates as an application program under:

- IMS/VS Version 1 Release 1.6, Release 2 and Release 3 (5740-XX2).
- CICS/OS/VS Version 1 Release 5 (5740-XX1) with IMS/VS Version 1 Release 1.6 or Release 2 Data Base System.
- CICS/OS/VS Version 1 Release 6 with IMS/VS Version 1 Release 2 or Release 3 Data Base System.
- and subsequent releases unless otherwise specified.

The following compilers/assemblers are supported by the Dictionary Release 5 Language Preprocessor facility:

- OS PL/I Optimizing Compiler and Libraries Release 4 (5734-PL1, 5734-LM4, 5734-LM5, 5734-PL3).
- OS/VS COBOL Release 2.3 (5740-CB1).
- VS Assembler H Release 5 (5734-AS1).
- Assembler H Version 2 Release 1 (5668-962).

A System Modification Program job stream will be provided as a file on the distribution tape for installation of the Dictionary Release 5 using SMP Release 4. Program service in SMP format will be provided periodically. Items shipped as object code in the basic material will be serviced in object code. Items shipped as source code will be serviced in source code. The MFS formats are serviced in source code only.

For operating system requirements, see IMS/VS or CICS/OS/VS programming system support in the appropriate IMS/VS or CICS/OS/VS documentation.

The Dictionary is distributed primarily in object code format. Source code is available as optional machine-readable material.

COMPATIBILITY/CONVERSION

Dictionary Release 4 includes all of the functions of Dictionary Release 3. The internal format of the Dictionary data bases is modified in Release 4. The IMS/VS V1 Utilities can be used to convert Dictionary Release 3 data bases to Dictionary Release 4 format. **Note:** No conversion aid or support is provided to assist installations moving from releases prior to Dictionary Release 3.

Dictionary Release 5 includes all of the functions of Dictionary Release 4. The internal format of the Dictionary data bases is modified in Release 5. The IMS/VS V1 Utilities can be used to convert Dictionary Release 4 data bases to Dictionary Release 5 format. **Note:** No conversion aid or support is provided to assist installations moving from releases prior to Dictionary Release 4.

AUDITABILITY

The dictionary is of interest to internal auditors, as well as others concerned with data integrity, because of its data description and documentation capabilities, and its use as a vehicle for controlling and tracking data base changes. Dictionary use may be monitored through the standard logging facilities in IMS/VS and CICS/OS/VS, and through the optional logging of commands by the Dictionary.

DATA SECURITY

The Dictionary operates as an application program under IMS/VS Version 1, and its use is controlled with the standard security features of IMS/VS or CICS/OS/VS for OS/VS Data Dictionary. The Dictionary provides an access control facility composed of signon validation and a user access profile function. A user's access to the Dictionary can be restricted by status code, subject category access, and command usage.

Attempts to access dictionary data in an MVS/370 and MVS/XA environment outside of IMS/VS can also be controlled through the use of RACF.

PERFORMANCE

In general, there is no significant change in the performance of Dictionary Release 4 function in Release 5. In certain circumstances, degradation may occur in the performance of the COPY and DELETE_STRUCTURE functions. Dictionary Release 5 publications will contain guidelines on how to minimize any potential degradation.

AVAILABILITY

OS/VS DB/DC Data Dictionary Release 4 is available now. OS/VS DB/DC Data Dictionary Release 5 will be shipped to Early Support Program customers in May 1983. OS/VS DB/DC Data Dictionary Release 5 general availability date is planned to be 1st Quarter 1984.

PROGRAM CURRENCY

Program services previously announced for OS/VS DB/DC Data Dictionary Release 4 will be available until 12 months notification by IBM.

MVS INTEGRITY

IBM will accept APARs describing situations where the installation of the DB/DC Data Dictionary program product causes an exposure to the system integrity of OS/VS2 MVS/370 or MVS/XA. This program is intended to run authorized.

RPQs ACCEPTED: No

TERMS and CONDITIONS: See PP Index

PROGRAM PRODUCTS

**RESOURCE ACCESS CONTROL FACILITY
RACF (5740-XXH)**

PURPOSE

RACF Release 4 provides the checking needed to assist an installation in controlling user access to applications, permanent DASD data sets, tape and DASD volumes, CICS/VS and IMS/VS transactions and transaction groups, TCAM, VTAM and BTAM terminals defined to TSO or IMS/VS and user-defined resources and resource groups. RACF will perform user identify verification when batch (JES2 or JES3), IMS and TSO users enter the system and check the authorization of users and user groups to DASD data sets and other protected resources based upon this verified identity. Access authorization information is maintained on one or more DASD data sets that can be shared between independent (MVS) operating systems for which RACF is licensed.

RACF extends the data security and auditability capabilities available in MVS, CICS/VS and IMS/VS. Users identify themselves at the time they enter the system through IMS SIGNON, TSO logon or the batch job initiator, and RACF verifies their identity. For IMS, RACF also checks the authorization of the user to the IMS program product. Once a user is accepted on the system, his ability to access data is controlled by information previously entered and maintained by a security administrator in the RACF data set. Access is either granted or denied automatically and operator intervention is not required. Messages describing detected unauthorized access attempts can be routed to a security console for immediate action. An audit trail of access information can be generated through SMF for later analysis. In addition, RACF can maintain detailed statistics about the objects in the RACF data set, such as access counts and date last referenced.

SPECIAL SALES INFORMATION

For an installation to safeguard its data, it must not only consider the functions provided through the system, but also provide the necessary physical protective measures and implement effective information management practices. Thus, while no guarantee can be made for complete security of any system, the installation goal of improved security at an appropriate cost can best be attained through consideration of

the full spectrum of available measures. Installation security is the customer's responsibility. The capabilities of RACF have been designed to help the customer attain his data security goals.

The customer should use RACF as a part of his overall, comprehensive security and auditability plan. He should be encouraged to consider all facets of security (e.g., physical aspects, systems, procedures, controls, backup, recovery, organization, vital records, data classification and data disposal) when developing his plan.

HIGHLIGHTS

- Positive identification of system users for batch, IMS and TSO by password [or for TSO (including TSO through VTAM) and IMS/VS by Operator Identification Card (OID)].
- Automatic authorization checking for users to the IMS program product, DASD data sets, CICS/VS and IMS/VS transactions and transaction groups, tape volumes, DASD volumes and terminals, according to installation rules.
- Provision for installation definition of resources and resource groups to be protected by RACF (with appropriate installation written resource manager calls).
- Five rules of allowable access to data sets.
- Grouping of related users and related resources for administrative convenience.
- Provide for different levels of user authority within a group.
- Automatic access authorization capability.
- Optional establishment of resource ownership.
- Enforcement of DASD data set naming conventions.
- User controlled audit trail generation through SMF.
- Exits provided for installation tailoring.
- Support for more than one RACF data set, so that profiles for protected resources can be spread across DASD devices.
- Support for simultaneous update of a backup RACF data set.
- Installation controlled statistics for management and systems maintenance personnel that aid in identifying low usage resources.
- TSO commands for creation and maintenance of the RACF data set entries.
- Utilities for manipulating the RACF data set.
- Installation definition and control of RACF invocation by programs not executing in an authorized state.
- Profile Modeling - RACF automatically creates new individual profiles through the use of this optional modeling function for ADSP users and groups.
- Generation Data Group (GDG) Data Set Support provides a means by which each member of a GDG uses a common model profile derived from the GDG base name.
- List Checking for Groups - permits users connected to a given group to access resources available to another group to which the user is defined, without requiring a reconnection.
- Password Processing Improvements - provides for greater control of password processing through the use of new installation exits and new built-in options for monitoring and approving user assigned passwords.

- Fail Soft Processing - deactivates RACF and continues IPL when RACF failure occurs at system initialization. In the event of RACF failure or deactivation by authorized operator intervention after IPL, the installation may continue operating without stopping all normal job processing through required operator intervention upon access of a RACF-protected resource.
- RACF Command Improvements - improvements to make RACF parameters consistent across RACF commands and improve RACF usability.
- Installation Exit Parameter List Extensions.
- Profile Installation Data Field - new installation data field INSTDATA, 255 bytes long, added to the RACF group and data set profile. Existing RACF commands supporting this data field were modified to handle a 255-character data field.
- New IMS and CICS class descriptor table entries. Sample table in SAMPLIB and ICHERCDE macro in MAACLIB.
- RACF/HSM support improvements.
- Documentation and Support of RACF ICHEINTY Macro.
- Generic Profile Support - Allows the consolidation of the security requirements of several similarly named and similarly used resources with a single generic profile definition.
- Global Access Checking - Provides the ability to bypass RACHECK profile processing for selected data sets with selected generalized access levels.
- RACF Logging Enhancements - Provides the capability to selectively audit resource accesses based on access level.
- Single-level Data Set Name Support - Provides the capability to RACF-protect data sets whose names consist of a single qualifier.
- Always Call Support - Provides support for resource managers that will call RACF for all access attempts of all data sets, whether or not they are RACF-indicated.
- Report Writer Facility Enhancements - Provides the ability to produce a report which selectively includes records created because of the GLOBALAUDIT option rather than just the AUDIT option.
- RACDEF Post-processing Installation Exit - New exit which may be used to improve installation control by altering the outcome of RACF processing or performing additional checking.

HIGHLIGHTS of RELEASE 6

In addition to the features of Release 5, Release 6 encompasses the following enhancements:

- ISPF panels are provided to simplify the use of the RACF commands. A comprehensive set of tutorials is also provided through the ISPF 'Help' facility.
- Authorities by Group allows an installation to extend its delegation of RACF authorities, on a non-global basis.
- Group ownership of profiles is provided as an alternative to user ownership.
- A grace period facility provides an option to allow access on a selected basis to a user who would normally be denied access to the resource(s). A warning message is given to the unauthorized user, and optionally, a record is written to SMF. This facility will assist the installation in implementing an orderly transition to a secure system.
- User passwords and OI CARD data may now be encrypted using the Data Encryption Standard (DES) algorithm. A corresponding decryption capability is not provided, in order to preserve the security of passwords. A user installation exit is provided which permits the installation to enter its own encryption key or to substitute a different encryption algorithm.
- Data Set Naming Convention Support allows an installation to specify their own naming convention via a table. This will eliminate the need for many installations to code RACF exits for the function.
- The automatic revoke feature is enhanced to allow the security administrator to intervene when a SPECIAL user is about to be revoked.
- Generic Resource Profile Enhancements:
 - Volume generic profiles can be defined for fully-qualified data set names which relate to data sets of the same name on different volumes, for example, SYS1.LINKLIB.
 - Generic profile names may now contain a percent sign and/or an asterisk to represent a portion of a node/qualifier.
 - Generic profiles stored in all user address spaces may be dynamically refreshed or updated through the use of a RACF command available to the security administrator.
- Failsoft Enhancements:
 - The Global Access Checking facility will be used, if available, during failsoft processing.
 - Control will be passed to the RACHECK and RACDEF pre-processing exits before the system operator is informed of the access or prompted for a decision.
 - All resource accesses that are allowed or denied by the operator or failsoft processing will be logged.

RACF (cont'd)

- The PERMIT command supports a RESET option; this allows an access list to be emptied of users and groups.
- The LISTDSD command is extended to include a volume parameter; this allows a profile for one or more data sets on a specific volume to be listed, without listing all other profiles of the same name on other volumes.
- A new FRACHECK post-processing installation exit is provided.
- The password exit is enhanced to provide the exit with the current and historical user passwords, in addition to the current parameters.
- The Started Procedures Table is now a discrete load module. Selected started procedures may be considered as privileged, meaning that all RACHECKs will be accepted unconditionally. In addition, the table may include a generic entry.
- Support for multi-tasking environments has been enhanced. This support allows the RACF ACEE control block to be associated with individual tasks within the same address space.
- RACF publications are restructured to correspond to different user responsibilities such as: RACF Planner, Security Administrator, Systems Programmer, Auditor, End-User.

AUDITABILITY ENHANCEMENTS

- A Data Security Monitor offers the installation a new auditing tool. This facility enables an installation to monitor the status of various control mechanisms against previously established norms. Reports summarize the MVS/RACF system security status.
- At an installation's option, real data set names are logged to SMF.
- The RACF Report Writer is enhanced to provide a new report which summarizes resource events by owner.
- The SMF records generated by the new grace period facility may be selected and reported by the Report Writer.
- A RACF auditor now has the capability to list any RACF profile.

PERFORMANCE ENHANCEMENT

- RACF Buffer Management is enhanced to retain RACF profiles in memory for re-use on a most recently referenced basis.

SECURITY MANAGEMENT RESPONSIBILITIES

The MVS user environment under RACF is not significantly different from conventional TSO and batch environments. The user creates, uses and deletes his data in the normal manner. The differences appear in sharing of data between users, formulating rules for this data sharing and, in the absence of password, prompting when accessing protected data sets.

In the IMS/VS environment, the security administrator can, through the use of RACF/TSO commands, define users who are authorized access to IMS/VS. He can also define IMS/VS transactions and transaction groups to RACF, and authorize users to these protected transactions.

When the user population is large and access to sensitive resources is possible through several applications, the administration of the rules to control access can become burdensome and difficult to enforce in a conventional system. Through the use of RACF, the installation can define, and automatically or manually, implement and maintain access rules in a centralized manner. This approach has the added benefit of removing redundancies and inaccuracies that arise from associating these control rules with each application.

The administrator of RACF may assume a wide variety of duties, depending on the installation requirements. These duties include:

- Defining users and groups of users and delegating administrative authority to define new users and resources.
- Maintenance of user definitions, including addition and deletion of users and groups for all or part of the user community.
- Structuring resource groups to facilitate the defining of user/resource access relationships.
- Conversion of existing resources to protected status.
- Using RACF/TSO commands to define the authority of users and groups to access resources that have been covered.
- Handling user problems and questions.

DIRECT SYSTEM SUPPORT for RACF

The RACF function consists of two parts; the RACF program product (described in the opening text and highlights) and the System Support for RACF. Based on RACF checking, selected software resource managers provide control over their protected resources. The direct system support for RACF consists of the following five macro instructions which may be used for installation coding of data security functions:

RACINIT	Identifies a user and verifies that the user who is entering the system is defined to RACF, has supplied a valid password and/or OID card and, where applicable, has the required terminal authorization.
RACHECK	Determines if a user's request to obtain use of a RACF-protected resource is authorized by RACF.
RACDEF	Defines, modifies and deletes DASD data set and tape volume profiles.

RACLIST	Constructs in-storage profiles for use by fast path RACHECK, and for use in implementing installation-defined resource groups.
FRACHECK	A RACHECK-like function, using in-storage profiles (built by RACLIST). It is designed for performance-oriented applications.

These macros are used by the system, RACF, IMS/VS, CICS/VS, the TSO Command Package program product and the TSO Extensions (TSO/E) program product. They are documented in the appropriate MVS publications.

Report Writer: By use of the Report Writer, a RACF installation can display RACF-generated SMF records and statistics generated from these records.

Specifically the Report Writer allows a user to:

1. Specify criteria to select a subset of the RACF SMF records (Types 20, 30, 80 and 81) to be processed.
2. Request that selected records be displayed, and in what order.
3. Request various reports summarizing system and resource access.
4. Provide an installation-written routine to handle additional record selection criteria, and to generate additional output.
5. Save the records selected in a data set for future access by the Report Writer.

An installation can use the Report Writer to:

- Convert RACF SMF records into readable form.
- Understand how RACF protected resources are being accessed in terms of activity and authorization level.
- Generate specialized reports for distribution to appropriate personnel.
- Examine security violation attempts which have been detected by RACF.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

For TSO operator identification card support, RACF Release 5 or Release 6 can be used with the following subset of the IBM devices supported by TSO:

- Operator identification card reader on the IBM 3270 Information Display System (SNA and non-SNA devices).
- ID Reader on the IBM 3771 Communication Terminal (mdls 1, 2, 3), 3773 Communication Terminal (mdls 1, 2, 3), 3774 Communication Terminal (mdls 1, 2), and 3775 Communication Terminal (mdl 1).
- Magnetic stripe reader on the IBM 3767 Communication Terminal (SNA devices only).
- Magnetic Slot Reader and Magnetic Hand Scanner on an IBM 3278 or a 3279 attached to an IBM 3274 with the 10/63 alphanumeric character set.

RACF Release 6 is designed to operate on the IBM processors supported by OS/VS2 MVS Release 3.8 or the MVS/System Product or the MVS/System Extension program product. There are no special hardware requirements in addition to those normally required by these products.

For IMS/VS operator identification card support, RACF has no unique dependencies.

An optional, dedicated security console is supported by RACF. RACF routes messages to this console for detected unauthorized access attempts. The console may be any of the terminals supported by MVS that have console capabilities.

Performance considerations may necessitate the addition of DASD systems (IBM 3330, 3340, 3350, 3375 or 3380), an additional DASD controller or an additional channel. See the Performance section for a further discussion of these considerations.

Also, the various RACF logging options selected by the installation and the number of protected resources for which logging is selected as well as the frequency of RACHECK of these resources will determine the volume of SMF data generated by RACF. The installation should review this additional volume of SMF data to determine the possible need for additional DASD capacity.

The approximate space required for the system libraries (based on the IBM 3330 disk storage and track size of 13,030 bytes) for RACF is:

Library	Tracks for Release 4	Tracks for Release 5
SYS1.LINKLIB	70	71
SYS1.LPALIB	13	14
SYS1.MACLIB	3	3
SYS1.HELP	13	13
SYS1.SAMPLER	1	1

RACF requires the allocation of one or more non-VSAM data sets on direct access storage for all RACF access control information. The

PROGRAM PRODUCTS

RACF (cont'd)

RACF data set should be on a permanently resident volume and, if it is to be shared between systems that have RACF installed, it must be on a shared direct access device. The direct access space needed for the RACF data set depends mainly on the number of users, groups, user-group connections, and resources defined to RACF. The size also depends on the name lengths of the entities defined to RACF and on how well the space within the RACF data set is utilized. On the average, a RACF data set requires approximately 320K bytes for each 1,000 entities defined to RACF.

Storage Estimates: The approximate virtual storage requirements for RACF Version 1, Release 6 are:

FLPA	6,800 bytes
PLPA	130,000 bytes
SCA	412 bytes
LSQA*	4,200 bytes
Private Area	8,200 bytes

CSA** Variable (Variable between 5,000 and 270,000 bytes depending upon installation control of resident indexes; the default is 15,400 bytes)

- * Minimum use is 4,200 bytes. This will increase with the number of Generic Profiles used by each user during a session or job.
- ** When RACF-protected VSAM catalogs are being used by jobs in the system, the amount of storage increases by approximately 100-200 bytes per catalog in use. The precise storage used depends on the number of users authorized to the catalog.

To use the RACF ISPF Panels, ISPF (5668-960) must be installed.

SOFTWARE REQUIREMENTS

The RACF Release 4 program product requires the MVS/System Product or MVS/System Extensions or MVS Release 3.8.

RACF is supported by TSO in a current TCAM or VTAM environment.

Additionally, the MVS TSO Command Package program product (or equivalent), must be available if the installation wishes to use SUBMIT command parameters to facilitate the submission of batch jobs that access RACF-protected resources.

If the installation wishes to use RACF for IMS/VS user identification and resource authorization, it must have installed IMS/VS Version 1, Release 1.5.

If the additional RACF facilities of CICS/VS are to be used, CICS/VS Version 1 Release 5 (or later release) must be installed.

If the installation uses Hierarchical Storage Manager (HSM) and plans to use the RACF Release 4 GDG Modeling and/or naming convention exit, HSM Release 3 (or later release) must be installed.

Current data management offerings, including Hierarchical Storage Manager (HSM) Releases 3.0 and 3.1, do not support the always call interface. If the Global Access Checking and the Generic Profile facilities are elected for use with the current data management and HSM offerings, the data sets protected or using these facilities will not be protected for the execution of the data management or HSM functions.

The OS/VS Sort/Merge program product (5740-SM1) or equivalent must be available if the Report Writer is to be used.

CONVERSION

RACF Release 4 is upward compatible from Release 3.

RACF Release 5 is upward compatible from RACF Release 3 or 4.

RACF Release 6 is upward compatible from RACF Release 4 or 5.

The RACF data set initialization utility must be executed to convert from Release 4 to Release 5. Following the execution of the utility, Release 4 and Release 5 can share the same RACF data set.

The RACF data set initialization utility must be executed to convert from Release 5 to Release 6. Following the execution of the utility, Release 5 and Release 6 can share the same RACF data set.

PERFORMANCE

Use of RACF adds both processor and I/O activity to the system. Additional activity is performed in the following areas:

- Each TSO logon, IMS SIGNON and job initiation.
- Each RACHECK of a protected resource (FRACHECK, not RACHECK, is used for IMS transaction authorization).

There is additional processing associated with the administrative use of RACF commands and the automatic protection and deletion of protected DASD data sets and tape volumes. Additional contention may be caused by the serialization of RACF processing and the I/O to the RACF data set.

The primary performance cost depends on the number of protected resources and how often these resources are accessed. Installation controllable RACF options that can affect this performance include:

- The logging selected for protected resources.
- The recording of statistical information about RACF-defined users, groups and resources.
- The number of resident RACF data set index blocks.

Performance can also be influenced by the placement of the RACF data set. The RACF data set should be placed on a less frequently used channel and volume to minimize contention with other high usage data sets. The use of multiple RACF data sets can reduce this contention.

The use of resident index blocks enhances the performance of RACF by reducing the number of I/O operations required to the RACF data set. The installation can control the number of index blocks in the RACF data set that are to be made resident in the CSA.

Sharing the RACF data set between processors may further affect performance. RACF data index blocks can be made resident when the RACF data set resides on a shared device.

If a backup RACF data set is to be updated simultaneously with the primary RACF data set, the performance cost will increase accordingly. This cost will depend upon the options selected in maintaining the backup copy.

The ASP/JES3 licensing exception does not apply to new programs, features or versions.

For Program Support purposes the prior release of RACF, (Release 3), will be considered current until six months after FCS of Release 4.

SYSTEM INTEGRITY

IBM will accept APARs describing any situation where the installation of RACF causes an exposure to the System Integrity of MVS.

RPOs ACCEPTED: No

PROGRAM PRODUCTS

**5740-XX1 - CICS/OS/VS
5746-XX3 - CICS/DOS/VS
CUSTOMER INFORMATION CONTROL SYSTEM**

PURPOSE

These programs, together with the previous versions of CICS (CICS/DOS-ENTRY (5736-XX6), CICS/DOS-STANDARD (5736-XX7) and CICS/OS STANDARD VERSION 2 (5734-XX7)), form an upward compatible family of data base/data communication (DB/DC) products providing a common application interface. They facilitate the implementation of terminal-oriented applications and together provide an upward migration path between versions and releases of CICS on the same operating system and between operating systems.

SPECIAL SALES INFORMATION

Data base/data communication systems are applicable to a wide range of uses. Some of the functional applications that are most frequently encountered are:

Inquiry - Selective prestructured retrieval of information from a data base (master file). Inquiry is characterized by a small amount of keyed input with output returned to the requesting terminal.

Browsing - Special case of inquiry where the terminal operator does not have a complete or explicit key to the desired data. Browsing is characterized by selectively displaying generic portions of the data base until the desired information is found.

Order Entry - Input of data base-oriented information interactively from terminals. Order Entry is characterized by extensive immediate validation (editing).

Data Entry - Essentially the replacement of keypunch operations by direct entry of keyed data from terminals into the computing system, thereby reducing the exposure to transcription errors. Data Entry is characterized by high volume and limited editing.

Data Collection - Entry of data usually from terminals, not key driven, that may or may not interact immediately with the data base. Data Collection is characterized by moderate editing and batch control.

Message Switching/Broadcasting - The routing of information entered from any valid terminal to one or more destinations (terminals) without data base interaction. Message Switching/Broadcasting characterized by, but not limited to, administrative (text-type) data.

Order Distribution - Input of data base-oriented information from one terminal on the system to trigger the distribution of (potentially) different information to one or more hardcopy terminals. Order Distribution is characterized by the application logic (program) which, for example, routes a shipping order to the most appropriate location where the inventory is available. This application is almost invariably an extension of Order Entry.

CICS/VS is a general purpose system applicable to a wide variety of applications and customers. It can be used on all S/370, 308X and 43XX processors under the appropriate system configurations and VS operating systems, and will be most productive in an installation where the workload is mixed, varying in size, complexity and type. In addition to the above general functional applications, CICS/VS now provides support for many particular advanced application areas.

The marketing representative should be cautioned that the development of an online system can be a large and complex undertaking. A complete understanding of the applications, programming system and data communications environment is essential and the key to a successful installation of CICS/VS is the development of a comprehensive and effective implementation plan by the branch office and the customer. A simple application should be implemented first, preferably in a test environment. The power of CICS/VS can be appreciated and effectively employed only as experience is gained in the use of its basic capabilities. Particular emphasis should be placed on system design to allow future growth by the addition of new applications and extension to allow future growth by the enhancements, with minimum disruption to already implemented online applications. In addition, application program design, data base organization and access techniques require thorough analysis.

Although CICS/VS itself provides a comprehensive file handling capability, which is satisfactory for many applications, the full capabilities of a data base/data communication system can only be obtained by use of DL/I with CICS/VS.

DESCRIPTION

CICS/VS is a general-purpose DB/DC interface between the operating system and application programs written in COBOL, RPG II, PL/I or Assembler. A high level programming interface is provided to allow the application programs to request CICS/VS facilities such as task and terminal management, to format data to terminals and to interface to system service programs. Many of the same facilities may also be invoked by using a macro-level interface. The user can generate a CICS/VS system configuration applicable to the needs of the installation and define the environment in which the system is to execute. User exits are provided for optional processing as required. Although CICS/VS itself provides comprehensive file handling that is satisfactory for many applications, fuller capabilities can be obtained by use of DL/I with CICS/VS.

CICS/VS provides an option for the user to run multiple connected CICS/VS regions within a system. Use of multiple CICS/VS regions can simplify testing of user application programs, improve integrity and system utilization.

CICS/VS includes intersystem communication facilities for communication between connected systems. CICS/VS-managed resources, for example files and data bases, may be distributed between connected CICS/VS systems and accessed by application programs without awareness of the location of these resources. Alternatively, a CICS/VS transaction may communicate directly with a CICS/VS or IMS/VS transaction on another system, so supporting distributed transaction processing. CICS/VS Intersystem Communication uses SNA multi-system networking facilities and transaction-to-transaction communication requires ACF/VTAM Version 1 Release 2 or its equivalent or ACF/VTAM Version 2.

In the area of security, CICS/VS provides facilities to help prevent unauthorized access of information. Through an optional sign-on facility, terminal operators who are authorized to access the online applications, first identify themselves to the system. By the use of security codes allocated by the user to each operator, CICS/VS determines which functions may be performed by the operator. The master terminal operator is warned of attempted unauthorized access and the event can be logged by CICS/VS. These security facilities can be extended through an interface to a separate security management program, in particular to OS/VS2 (MVS) Resource Access Control Facility (RACF). RACF can be used to control a user's access to CICS/OS/VS and its transactions, and access to a CICS/VS address space from another.

CICS/VS provides many of the facilities necessary for the standard data communication applications of inquiry, order entry, data entry, data collection, message switching, broadcasting, order distribution and data base browsing. The functions needed to support these applications are provided through the following CICS/VS logical components:

- System Management.
- System Service.
- System Monitoring.
- System Reliability.
- System Support.
- Application Services.
- Intersystem Services.

Each of these components contain one or more functions which provide services to the user-written application programs. Most services are requested directly by the application programs through use of the high level programming interface or via the CICS/VS macro instructions, but some are performed automatically by CICS/VS to support certain functions basic to a DB/DC environment.

The System Management component contains

Task Management - Provides the dynamic multi-tasking facilities necessary for effective, concurrent transaction processing. The functions performed by this component include priority scheduling, transaction synchronization and control of serially reusable resources.

Storage Management - Controls main storage allocated to CICS/VS, taking advantage of virtual storage architecture. The functions performed by this component include storage acquisition, disposition, initialization and request queuing.

Program Management - Provides a multiprogramming capability through dynamic program management while offering a real-time program fetch capability.

Time Management - Provides control of various time-dependent task control functions (system stall detection, runaway task control, task synchronization, etc.) and allows tasks to be initiated, based on specified intervals of time or time of day. The intersystem communication facilities and Multi-Region Operation of CICS/VS allow such a transaction to be initiated on a connected CICS/VS system or region.

CICS/VS (cont'd)

Terminal Management - Provides for communication between terminals and user-written application programs through the Terminal Control program. The Virtual Telecommunications Access Method/Network Control Program (VTAM/NCP), the Basic Telecommunications Access Method (BTAM) and the Telecommunications Access Method (TCAM, CICS/OS/VS only) are used for terminal management and line control services. The High Performance Option (HPO) of CICS/OS/VS on MVS can utilize the VTAM authorized (fast) path. Other access methods, such as the Graphics Access Method (GAM, CICS/OS/VS only), can be utilized by the Terminal Control Program. Terminal Management provides for the coexistence of the various access methods through the Terminal Control Program. Communication is normally initiated from the terminal for the processing of applications, however, automatic task initiation from the host is also supported.

The testing of application programs may be performed by the simulation of terminals through sequential devices such as card readers, line printers, disk, tape, etc.

File Management - Provides data set support using direct or keyed access through VSAM, ISAM and BDAM. For VSAM, ISAM and BDAM, this function supports updates, additions, random retrieval and sequential retrieval (browsing) of logical data from the data set. For VSAM only, this function supports alternate indexes, reusable data sets, relative record data sets, physical record deletion, LOCATE mode (read-only retrieval), mass record insertion, get previous record and skip sequential processing.

The High Performance Option (HPO) of CICS/OS/VS on MVS provides support for VSAM 'improved control interval processing' (ICIP). Changes and accesses to data sets and DL/I data bases, defined as recoverable, can be automatically logged for use during an Emergency Restart or by Dynamic Transaction Backout. CICS/OS/VS provides access to the Data Language/I (DL/I) facilities of IMS/VS (5740-XX2). CICS/DOS/VS application programs can access DL/I data bases by using the interface to DL/I DOS/VS (5746-XX1).

Intersystem communication and Multi-Region Operation facilities allow files or DL/I data bases on a connected CICS/VS system to be accessed. CICS/VS also allows sharing of a DL/I data base (either OS/VS or DOS/VS) between concurrently active batch regions and CICS/VS with optionally, program isolation scheduling.

Transient Data Management - Provides an optional queuing facility for the management of data in transit to and from user-defined destinations, either intrapartition or extrapartition. Intrapartition destinations are queues of data on direct access devices developed for input to one or more CICS/VS transactions and are accessible only by CICS/VS transactions within the CICS/VS address space. Extrapartition destinations are data sets that are external to the CICS/VS address space and reside on tapes or direct access devices. The intersystem communication facilities and multi-region operation of CICS/VS allow transient data queue destinations to be on connected CICS/VS systems or regions. Changes made to intrapartition queues, defined as recoverable, can be automatically logged for subsequent use following an abnormal termination by Emergency Restart or Dynamic Transaction Backout. Intrapartition queues can use either BDAM or VSAM.

Temporary Storage Management - Provides an optional general purpose "scratch pad" facility, allowing an application program to temporarily store data in program storage or on a direct access device. This facility is used for Basic Mapping Support terminal paging, message switching (broadcasting), data queuing, retention of control information, and so on. The intersystem communication facilities and multi-region operation of CICS/VS allow temporary storage to be defined as on a connected CICS/VS system or region. Changes made to auxiliary temporary storage data, defined as recoverable, can be automatically logged for subsequent use following an abnormal termination by Emergency Restart or Dynamic Transaction Backout (DTB).

Journal Management - Provides facilities to create, manage and retrieve special-purpose sequential data sets known as journals during real-time execution of CICS/VS. Journals can be created to contain user-requested output as well as data automatically logged by other CICS/VS management facilities. Automatically logged data is required as input by the Restart and Dynamic Transaction Backout functions of the System Reliability component of CICS/VS.

Sync-point Management - Works in conjunction with other CICS/VS components, such as Transient Data Management, Temporary Storage Management and File Management, to provide the facilities needed for an Emergency Restart or Dynamic Transaction Backout following abnormal termination. The intersystem communication facilities and multi-region operation of CICS/VS will, where possible, ensure the protection of resources and synchronization needed to enable recovery in a connected CICS/VS system environment. In an emergency restart, changes made to protected resources (e.g., Transient Data intrapartition queues, auxiliary temporary storage data, data sets and data bases)

can be backed out for those tasks which were in-flight at the time of failure of the CICS/VS system. With Dynamic Transaction Backout, changes to the protected resources can be backed out on an individual transaction basis, in the event of abnormal termination of that transaction, while the rest of the CICS/VS system operates normally. The protected resources can alternatively be backed out by calling for Rollback. This is the way users can cancel the changes made to the protected resource back to what they were at previous sync-point or task initiation. These backouts are based on system information about the tasks, recorded (logged) during online execution of CICS/VS; for Restart the information is recorded on the system log and for Dynamic Transaction Backout it is recorded on a dynamic log, which may reside in main storage with possible overflow to disk. Some transactions backed out by DTB may, optionally, be restarted automatically.

The System Service component contains

Signon/Signoff - Provides terminal operator identification (security). It optionally interfaces with an external security manager, including RACF on OS/VS2 (MVS).

Master Terminal Function - Provides dynamic user control of the system. A master terminal operator can change the status and values of parameters used by CICS/VS and thereby alter the operation of the system. The operator may enable/disable entries in several CICS/VS tables and terminate any task currently in the system. When a table entry is disabled, it is not accessible for normal processing. CICS/VS provides a display-oriented master terminal transaction, CEMT, for user control of CICS/VS.

Supervisory Terminal Function - Performs a subset of the services available to the master terminal. They are limited to terminals under a given supervisor's jurisdiction.

Operator Terminal Function - Terminal operators who are neither supervisory nor Master Terminal operators are only able to control the Service status and processing of their own terminal using the CSOT transaction. Operator terminal requests are checked for validity and processed by the Master Terminal program.

System Statistics - Provides the capability to either specifically request or automatically log system statistics. A facility exists to request statistics either for the complete system operation or for a subset involving terminal usage. The capability is available to optionally reset the counters after requested statistics have been output, thereby allowing extended continuous operation. An automatic statistics facility allows CICS/VS system statistics to be recorded on a sequential data set at regular intervals as defined by the user, and for detailed and/or summary reports to be printed offline via a utility program. Counters are not reset after output of automatic statistics.

Asynchronous Transaction Processing (ATP) - Provides the capability to read and queue (store) batched input from an appropriate device and to dequeue and write to an appropriate device the resulting output data. ATP is performed concurrently with other terminal activity. Although designed specifically for batch terminals this facility can also be used with certain interactive terminals (i.e., 2740, 2741). ATP is not available through VTAM.

Dynamic Open/Close - Allows the user to dynamically Open/Close data sets during the real-time execution of CICS/VS.

Time of Day Control - CICS/VS adjusts the expiration times it maintains in response to changes in the time of day maintained by the operating system, and then resets its date and time of day to the date and time of day maintained by the operating system.

Customer Engineering Support - A terminal test facility primarily designed to assist the customer engineer in installing new terminals during real-time execution of CICS/VS, transmits all printable characters or echoes a message upon request. Additionally, the VTAM Teleprocessing Online Test Executive Program (TOLTEP) may be utilized to test Start/Stop, BSC and SDLC lines. Testing of SDLC teleprocessing subsystems is not conducted by VTAM; such testing is a function of the subsystems themselves. For devices supported through BTAM-ES, CICS/DOS/VS includes facilities similar to those provided by the service aid Facility Error Recognition System (FERS).

Message Switching - Provides the user with a general-purpose message switching capability during real-time execution of CICS/VS. Messages may be routed to one or more terminals by specifying the transaction code CMSG along with optional parameters and message text.

The System Monitoring component contains

Trace Management - Provides a program debugging facility that reflects the execution of CICS/VS macro instructions and HPLI commands by CICS/VS management programs and service programs and by user-written application programs. The auxiliary trace facility provides the ability to record trace entries on sequential data sets and permits selective printing via a utility program.

CICS/VS (cont'd)

Dump Management - Provides a facility to assist in analysis of programs and transactions undergoing development or modification. Specified areas of main storage are dumped onto a sequential data set, either tape or disk, for subsequent offline formatting and printing using a CICS/VS utility program. This facility is independent of other similar purpose facilities available under the operating systems, access methods or special purpose packages.

Monitoring Facilities - Provides an integrated data gathering mechanism in CICS/VS, offering the user improved facilities for monitoring the performance of the CICS/VS system, and for providing accounting data on an individual user basis. The mechanism consolidates and extends data previously available in CICS/VS, offering a single interface on which analysis routines can be based. The user may dynamically choose the level of recording, dependent on his needs for accounting, performance or exception data. In this way, he has granularity in the level of information recording, yet a common mechanism for analysis programs to process and extract relevant information. Monitoring data can optionally be written to System Management Facility (SMF) files in CICS/OS/VS. Monitoring data on SMF is intended for use on MVS.

The System Reliability component contains

System Recovery Management - Provides for the interception of program interrupts and operating system ABENDs to allow, where possible, the transaction or CICS/VS, respectively, to continue processing. In the case of a program interrupt, control may be passed to a user error handling routine to attempt recovery; otherwise the individual transaction may be terminated. In the case of a system ABEND, an attempt may be made by CICS/VS or by the user to recover from the ABEND. It may be possible for the user-handling procedure to simply terminate the individual transaction rather than ABEND the whole of CICS/VS. In the event of a single transaction being abended, for whatever reason, CICS/VS can backout any changes made by that transaction to recoverable resources, as described under Dynamic Transaction Backout below. This includes recoverable resources being accessed from a connected CICS/VS system or region, using the intersystem communication facilities or multi-region operation of CICS/VS.

Dynamic Transaction Backout (DTB) - Performs online backing-out of the effects of a transaction, which abnormally terminates, while the rest of the CICS/VS system operates normally, thus providing immediate recovery of data base integrity following a transaction failure. DTB will backout to the last user-defined "sync" point, or the start of the task, the changes made to protected CICS/VS resources (e.g., Native Files, DL/I Data Bases, Intrapartition Transient Data, Auxiliary Temporary Storage, VTAM Terminal Messages). The ABEND may be initiated either by the application program or by CICS/VS; backout will follow automatically if DTB was specified in the appropriate CICS/VS tables at system (table) generation time. This includes those transactions accessing resources managed by a connected CICS/VS system or region, using the intersystem communication facilities or multi-region operation of CICS/VS.

Transaction Restart - This option allows certain transactions which have been abnormally terminated and backed out by Dynamic Transaction Backout to be restarted. It is particularly appropriate where program isolation is being used with the CICS/VS-DL/I interface, where deadlock resolution may result in a transaction being abnormally terminated. Transaction Restart enables certain such transactions to be restarted immediately, so that in many circumstances the terminal operator need not be aware of the abnormal termination and restart.

Emergency Restart - Allows the user to re-establish the status of features, such as Intrapartition Transient Data queues, auxiliary temporary storage data, selected data bases and selected data sets, to a predefined point in the event of an abnormal termination of the CICS/VS system. This function is performed by recovery modules which are invoked by System Initialization during an emergency restart. This recovery function reads data from the system log onto which management functions have logged control information during the previous online operation. Logged data from changes made to protected resources (e.g., protected data sets, data bases, auxiliary temporary storage queues, and Transient Data intrapartition destinations) are collected during emergency restart and those changes made by in-flight transactions are automatically backed-out (e.g., previous data restored). This includes transactions accessing such resources from a connected CICS/VS system using the intersystem communication facilities or multi-region operation of CICS/VS. Exits are available during emergency restart to allow user participation.

Abnormal Condition Program - Is used by program control to analyze the abnormal condition (except those associated with a terminal or node (SNA Logical Unit)) and to take appropriate action for those not handled directly by the operating system.

Program Error Program - Allows the user to provide his own corrective action in response to a programming error by coding his own error program. If provided, this program is linked to by the abnormal condition program. CICS/VS provides the option of disabling the transaction code associated with the program in error, thus preventing the recurrence of the error until it can be corrected.

Terminal/Node Abnormal Condition Program - Is used by terminal control to analyze abnormal conditions that are not handled directly by the operating system. It links to a user-written error program (see below) to attempt recovery from transmission errors and to allow tasks to continue processing. For BTAM, TCAM and GAM applications, a Terminal Abnormal Condition Program is used and for VTAM applications a Node Abnormal Condition Program is used.

Terminal/Node Error Program - Allows the user to provide his own corrective action in response to a terminal I/O error. It is linked to by the Terminal/Node Abnormal Condition Program (see above) when a terminal error occurs. For BTAM, TCAM and GAM applications, a Terminal Error Program is provided by the user and for VTAM applications the user provides a Node Error Program.

The System Support component contains

System Generation - Allows the user to define and structure CICS/VS to meet unique real-time, teleprocessing and, with DL/I, data base requirements. This is accomplished through the use of CICS/VS system generation macro instructions. For all CICS/VS users a preassembled version of the full function system, based on the sample system, is available.

Environment Definition - Allows the user to create system control tables and system service tables that define and control the environment in which CICS/VS is to operate.

System Initialization - Allows the user to initialize CICS/VS, using specific tables and modules, to meet his unique real-time, teleprocessing and, with DL/I, data base requirements. The user is also able to override any of the parameters specified in the System Initialization Table through the Master terminal console or system input device. This facility is both flexible and dynamic and is resident only long enough to bring CICS/VS into real-time execution.

System Termination - Allows the user to terminate operation of CICS/VS in an orderly manner by gathering information for restart, closing data sets and returning control to the operating system.

Program Preparation - A translator is provided for the High Level Programming (Command Level) Interface and a preprocessor is provided for CICS/VS macro instructions included in high level language (ANS COBOL, COBOL/VS or PL/I) application programs. For the High Level Programming Interface a single-step translator converts the EXECUTE statements into the appropriate source language for subsequent compilation and performs checking during the process. The EXEC interface supports commands written in PL/I, ANS COBOL, COBOL/VS, RPG II or Assembler language application programs. For CICS/VS macro instructions included in high level language application programs a three-step preprocessor is available.

Trace Utility - The Offline Trace Utility program formats and prints the output from Trace Management. Control cards may be used to select trace entries; e.g., those associated with specific terminals, tasks or time of day.

Dump Utility - Formats and prints output of the CICS/VS Dump Control program. Operating in batch mode with a dump data set that is not online to CICS/VS, this utility allows each storage area, program and table entry to be identified, formatted and printed separately with actual and relative addresses for faster diagnostic analysis.

Formatted Dump Program - Produces a dump of the CICS/VS partition or region with various CICS/VS control tables and areas identified. Each control block is printed separately, preceded by a heading, important fields within them are printed by name. It is invoked by abnormal termination of CICS/VS, by specifying DUMP at CICS/VS shutdown, or by Master Terminal Operator SNAP command.

System Log/Journal Utilities - Preformat magnetic tape or disk extents to be used as system log or journals. Allows the user to place an end-of-file mark on magnetic tapes used by journals after an abnormal system termination.

The Application Services component contains

Basic Mapping Support - Provides message routing, terminal paging, and device independence services. Message Routing allows application programs to send output messages to one or more terminals not in direct control of the transaction. Terminal Paging allows the user to prepare output without regard to the physical size of the output terminal; the output can then be retrieved by pages in any order. Device Independence allows the user to prepare output without regard to the required control

CICS/VS (cont'd)

characters; CICS/VS automatically inserts the required control characters and eliminates trailing blanks from each line.

Execution (Command Level) Diagnostic Facility - Permits the interception of application program EXEC commands before and after their execution. It therefore allows the application programmer to test an application program written using the EXEC commands in an online interactive manner at source level. It enables the user to step through the CICS/VS commands in the application, checking their validity, and making temporary modifications to argument values and responses as required. Information is displayed on a 3270 terminal, with 1920 character screen size or above, which may be the one being used to run the application under test.

Command Interpreter - The command interpreter is a display oriented program designed to assist in the writing, syntax checking and execution of an EXEC command. It enables an operator of a display (with screen size of at least 1920 characters and supporting the 3270 data stream) to enter a command for CICS/VS to check and optionally execute. Default options are indicated by CICS/VS, together with diagnosis of missing or incorrect parameters. Once a command has been developed to the satisfaction of the user, he may request its execution. This enables the user to check the operation of the command and inspection of the user's screen resulting from the operation. The facility can also be used to create or inspect test data (e.g., transient data) for use with the testing of application programs.

Built-in Functions - Provide additional functions for the application programmer through the use of CICS/VS macro instructions. **Table Search** provides the means of conveniently searching a table for a specific entry and having some value within that entry returned; if the desired entry is not in the table, the user can elect to have a fault value returned. **Phonetic Conversion** provides the means of converting a source name into a key, based upon the phonetic sound of the name, which can then be used to access a data base name file; this function allows the organizing and accessing of data set names based on names that might be misspelled, mispronounced or misunderstood. **Field Verify** enables the contents of a data field to be verified as entirely numeric, alphabetic or packed decimal data; a branch to the appropriate routine can then be taken accordingly. **Field Edit** provides the means of removing alphabetic or special characters from numeric fields and converting the result to EBCDIC or packed decimal format. **Bit Manipulation** allows the high-level language application program to test for a bit on/bit off condition and branch accordingly. **Input Formatting** provides the means of converting free-form input from the terminal operator into a predefined fixed format more easily manipulated; the free-form input may be positional or keyword-oriented. **Weighted Retrieval** allows the user to search a specified group of records on a VSAM data set on the basis of fixed and/or variable selection criteria. No built-in functions are available through the High Level Programming Interface.

The Intersystem Services component contains

Function Shipping Support - Manages the sending and receiving of CICS/VS requests relating to resources on remote CICS/VS systems. The requests may be shipped over an ISC link using SNA networking or between CICS/VS regions using multi-region operation. The support uses a mirror transaction in the remote CICS/VS system in order to execute the request on behalf of the originating application program and return appropriate information, including sync-point data.

Transaction Routing Support - Routes messages between CICS/VS regions using multi-region operation so that operators on terminals associated with one region may use transactions running on a connected region.

Transaction-to-Transaction Support - Provides a mechanism for a transaction on a CICS/VS system to converse with a transaction on a remote system over an ISC link using SNA networking facilities or between CICS/VS regions using multi-region operation. This enables the user to write an application as two complementary transactions, one executing in a system local to the originating terminal, and the other in a remote system.

CICS/VS VERSION 1

Currency: CICS/DOS/VS Version 1 Releases 4.1, 5.0 and 6.0 and CICS/OS/VS Releases 5.0, 6.0 and 6.1 are supported. Program services for these releases will be available until discontinued by IBM upon twelve months written notice.

Of the previous releases of CICS/DOS/VS Version 1, Releases 0.0, 0.1, 1.0, 1.1, 2.0, 3.0 and 4.0 are no longer supported.

Of the previous releases of CICS/OS/VS Version 1, Releases 0.0, 0.1, 1.0, 1.1, 2.0, 3.0, 4.0 and 4.1 are no longer supported.

Compatibility:

Application Programming: CICS/OS/VS V1R1.6 provides upward compatibility with V1R5 and V1R6.0 at both source and object level for

CICS application programs, subject to the exceptions summarized below. Any other exceptions which are identified will be documented. This means that CICS applications which execute correctly under CICS/OS/VS V1R5 and V1R6.0 will execute correctly under CICS/OS/VS V1R6.1 without requiring retranslation and re-assembly or re-compilation.

- Command level programs are upwards compatible at both source and object level provided they conform to the interface as defined in the *Application Programmer's Reference Manual (Command Level)* (SC33-0077).
- Macro level programs are upwards compatible at both source and object level providing they conform to the interfaces as defined in the *Applications Programmer's Reference Manual (Macro Level)* (SC33-0079).
- Exceptions: The following functions are not supported by CICS/OS/VS V1R6.0 or V1R6.1:
 - CICS Version 1 compatibility options.
 - The 2260 compatibility option (note: 2260 displays are supported as in CICS/OS/VS V1R5).
 - FASTER Language Facility.

System Programming: The following functions are not supported by CICS/OS/VS V1R6.1:

- Static user exits in transient data and temporary storage management modules.
- BDAM for intra-partition transient data file.

Users migrating from MVS/370 to MVS/XA must order and install the MVS/XA feature.

Intercommunication: CICS/OS/VS V1R6.1 supports Intersystem Communication links to CICS/VS V1R5.0 and CICS/VS V1R6.0. CICS/VS V1R5 supports Intersystem Communication links to CICS/VS V1R4.0 and 4.1. CICS/OS/VS V1R6.1 supports MRO links to CICS/OS/VS V1R5 and CICS/OS/VS V1R6.0.

HIGHLIGHTS OF CICS/OS/VS VERSION 1 RELEASE 6 MODIFICATION 1

Multi-Region Operation (MRO) Improvements: Changes have been made in CICS/OS/VS V1R6.1 to improve the performance of the multi-region operation (MRO) of CICS/VS.

- A new version of the mirror program is provided which will reduce the overhead for most function-shipped requests on an inter-region communication link.
- A new transformer routine is provided to reduce the path length required to transform CICS/VS requests and replies from a parameter list form into an address-free form and back again.
- MVS cross-memory services can be selected and used for transferring data. This will not require the issuing of an SVC nor the scheduling of a service request block (SRB).

Use of cross-memory services will improve the acceptability of MRO as a virtual storage relief alternative, since it eliminates most of the overhead in the original design. Customers who use MRO primarily for security reasons will have a trade-off to make because they will lose the total separation between systems normally provided by separate address spaces.

- Changes have been made to the function shipping code with the objective of optimizing it for MRO.

Installability Improvements:

- CICS/OS/VS V1R6.1 may be ordered with an MVS/370 option or an MVS/XA option. MVS/XA specific materials are excluded from the MVS/370 option and vice-versa. Both options are functionally equivalent and include a pre-generated CICS system which is appropriate for most users. This simplifies the CICS installation process by reducing the need for users to perform CICS module assemblies. Migration from MVS/370 to MVS/XA will require re-installation using the MVS/XA feature tape. IMS users will still need to do a partial CICS generation after installing IMS/VS.
- This modification to CICS/OS/VS V1R6.0 includes the VTAM variant of the high performance option (HPO) within the basic CICS/VS system. Its activation will be via system initialization (rather than system generation) options. This VTAM variant of HPO is enabled independently, either in the system initialization table or by parameter override.

The specification of the two CICS SVC numbers is also completed at initialization time.

- Transient data customization is modified by:
 - Elimination of static user exits.
 - Automatic generation of full function support for input from, and output to extra-partition data sets.
 - Automatic generation of full function support for intra-partition queues, automatic transaction initiation and full recovery.

PROGRAM PRODUCTS

CICS/VS (cont'd)

- Removal of support for BDAM intra-partition transient data. The intra-partition transient data file will need to be changed to VSAM.
- Temporary storage customization is modified by:
 - Elimination of static user exits.
 - Automatic generation of full function support.

Performance Enhancements: The following performance enhancements are provided:

Transient Data and Temporary Storage Performance Improvements: CICS/OS/VS V1R6.1 will provide significant improvements to the performance of VSAM intra-partition transient data, and to the performance of auxiliary temporary storage requests through:

- Support for multiple buffers.
- Support of concurrent I/O operations.
- Support for subtasking.

These performance improvements for VSAM intra-partition transient data and to temporary storage performance are achieved as follows:

Multiple Buffers: The provision of multiple buffers will allow CICS/VS to reduce the number of VSAM requests that have to be executed, and thus reduce a possible bottleneck, by retaining more control intervals in virtual storage. The provision of multiple buffers will reduce the amount of I/O required by:

- Reducing the number of READs since the required control interval may already be in main storage.
- Reducing the number of WRITES since the temporary storage record or queue may be deleted before shortage of buffers forces I/O.

VSAM requests will continue to be executed as dictated by the requirements of physical and logical recovery.

Concurrent I/O Operations: Concurrent I/O operations will be achieved through:

- Use of multiple buffers.
- Use of multiple VSAM strings.
- Replacement of queue global serialization by queue local serialization.

System Initialization table (SIT) options will allow the user to control the number of VSAM strings and the number of buffers used for I/O. The number of strings may not exceed the number of buffers.

Increasing the number of strings will increase the potential for concurrent I/O and hence affect channel activity. Increasing the number of buffers will tend to reduce the total amount of I/O.

The customer has statistics to evaluate the effects of increasing the number of buffers. Improved performance and reduced bottlenecks must be traded against the virtual storage required for the additional buffers.

Subtasking: VSAM intra-partition transient data requests or auxiliary temporary storage requests will be passed to an operating system subtask to increase the ability of a single CICS system to make better use of a tightly-coupled multiprocessor.

The MVS subtask that handles VSAM requests from file control has been extended to handle VSAM requests from transient data and auxiliary temporary storage. Each request will be placed on a work queue from which it will be dequeued by the subtask. The subtask will pass the request to VSAM and, following completion of the I/O, will notify the main task (CICS) that the relevant transaction may be redispached.

Journal Control Performance Improvements: CICS/OS/VS V1R6.1 has changed the environment in which journal output requests are made so that BSAM I/O requests made by journal control can be executed under a separate MVS subtask. This is intended to increase the ability of a single CICS system to make better use of a tightly-coupled multiprocessor.

With this support, a BSAM request for journal control will be placed on a work queue from which it will be dequeued by code running under an MVS subtask. The subtask will issue the request and synchronize with the main task (CICS) to allow the transactions requiring the work to continue when they are able.

This support is provided only for journal output requests from the journal control program.

The same MVS subtask that handles VSAM requests from file control (and now transient data and auxiliary temporary storage), has been extended to handle BSAM requests from journal control. Use of the subtask is optional and is controlled at initialization.

Virtual Storage Constraint Relief (VSCR): The following improvements in file control are provided in CICS/OS/VS V1R6.1:

- Support providing for the use of VSAM (DFP) buffers above 16MB (MVS/XA).

- Support providing for the use of VSAM (DFP) record management code above 16MB (MVS/XA). (This is also available with CICS/OS/VS V1R5 and V1R6.0.)
- Support for separate local shared resources (LSR) pools for CICS and IMS.
- Use of local shared resources (LSRs) by alternate index paths and base clusters with an upgrade set.

MVS/XA Data Facility Product (MVS/XA DFP) Release 1.1 is required for the support of the first three of these improvements.

VSAM buffers above 16MB: With this support, buffers for all VSAM files defined in the FCT together with the local shared resource pool will automatically be allocated above the 16MB line (subject to minor restrictions below).

There are no options associated with this improvement. The support is transparent to both macro- and command-level application programs. Programs do not have to be in 31-bit addressing mode in order to access files having buffers above 16MB.

This will provide substantial virtual storage constraint relief (VSCR) for MVS/XA customers with large VSAM buffer areas.

There are three types of files which will not have their buffers allocated above 16MB, namely, improved control interval processing files, indirect access files, and segmented record files.

VSAM Record Management Code above 16MB: The ability to place VSAM record management code above 16MB will provide further VSCR for MVS/XA users.

Separate LSR Pools for CICS and IMS: For MVS/XA users with CICS, this support will allow CICS to build a separate LSR pool above 16MB (SHRPOOL=1). The LSR pool for IMS will be built below 16MB (using the default SHRPOOL=0).

Use of LSR with Alternate Index Paths: This support will allow alternate index paths and base clusters with an upgrade set to use Local Shared Resources, thus removing a current restriction and providing further VSCR for many users.

Command Level Enhancements:

- The high-level (EXEC DL/I) command language for processing DL/I data bases, already announced for CICS/OS/VS users for COBOL and PL/I application programs running in a CICS online, shared data base (SDB), or IMS batch environment, is now announced for CICS/OS/VS for applications written in Assembler language.

- 31-Bit mode application support for command level DL/I transactions is also supported by CICS/OS/VS V1R6.1 for applications written in Assembler language.

This support, which requires the function provided by IMS/VS V1R3, is an aid to the migration of application programs to allow use of MVS/XA extended storage. This gives virtual storage constraint relief (VSCR) for applications using DL/I services without requiring any change to DL/I data bases. Command level DL/I applications can now be written to run in 31-bit addressing mode. The CICS Execution Diagnostic Facility for DL/I is available in this environment. No support is planned for call-interface programs (CICS services or DL/I services) to run in 31-bit addressing mode.

- In addition, a language improvement is provided whereby it is possible to specify a character string literal for the compared value in the WHERE clause, instead of a program data area. This capability is provided for Assembler language and PL/I application programs which use OS EXEC DL/I.

Application Program Enhancements: The command level (EXEC) programming interface was introduced in CICS/VS V1R3 and has been enhanced in subsequent releases. It is designed to simplify the CICS application programmer's task, isolate application code from CICS internal code dependencies, and through EDF and CECL, simplify the program test and debug tasks.

CICS users are encouraged to use the command level programming interface for all application program development. The macro level interface continues to be supported for program compatibility and maintenance purposes.

All enhancements to the application programming interface, and in particular, the CICS support for MVS/XA in CICS/OS/VS V1R6.0 and CICS/OS/VS V1R6.1, are provided at the command level interface and are supported by EDF.

CICS/VS Monitoring Enhancements:

- The sample program DFHXMOLS has been enhanced to provide assistance in verifying that CICS monitoring function has been installed correctly.

- Additional performance class data is captured:
 - Message lengths by transaction - will be collected such that input-lengths and output-lengths are separately identifiable.

PROGRAM PRODUCTS

CICS/VS (cont'd)

- Program storage by transaction, and program deletion value.
- Short-on-storage condition and/or maxtask indications are recorded for each task that experiences either.
- The usability of journaling operations for CICS monitoring facilities has been improved by retaining the journal position following a CICS restart, and by ensuring that a dictionary record is available on each volume or extent.
- Online access to the global performance records produced by the CICS/VS monitoring facility is provided. Access to the three types of task-related records was provided in V1R6.0; this facility is now being extended to the global performance record.

CICS/VS Library: This release of CICS/OS/VS is accompanied by updates to the CICS library provided with CICS/OS/VS V1R6.0.

Customers are advised to update their CICS SLSS (System Library Subscription Service) profiles to include the new manuals introduced with this release.

Customers will require the CICS/OS/VS V1R6.0 manuals as a base set.

All the information about the changes and enhancements in the new release is contained in the new books. These books are:

- *CICS/OS/VS V1R6.1 Release Guide* (GC33-0171)
- *CICS/OS/VS V1R6.1 Installation and Operations Guide* (SC33-0172)
- *CICS/OS/VS V1R6.1 Messages and Codes* (SC33-0173)
- *CICS/OS/VS V1R6.1 Data Areas* (LC33-0174).

The *Data Areas* book will also contain diagnosis reference and problem determination information.

Planned availability for the *Release Guide* is July 1983. Planned availability of the other manuals is August 1983.

IMS/VS DB Data-Sharing and Data Base Recovery Control (DBRC)

Support: The key points of the CICS/OS/VS V1R6.1 support for IMS/VS DB data-sharing and DBRC (Data Base Recovery Control), in conjunction with IMS V1R3 are:

- Data-sharing support will allow data bases to be shared among CICS/VS, IMS/VS DC, and batch IMS/VS DB subsystems under control of the same MVS system (or on VTAM-connected processors with the data bases on shared DASD). The sharing is performed with full integrity.

Block level or data base level sharing is provided with this support.

- DBRC support will allow the user to take advantage of the Data Base Recovery Control (DBRC) facility of IMS/VS. This facility simplifies the procedures which the user has to employ when performing recovery operations on data bases. DBRC support will be available to the CICS/VS user who uses IMS/VS V1R3, and has a CICS system disk log or standard labelled tape system log. In the case of the disk log user, an offline utility will be supplied by IMS which will allow the disk extents to be copied to standard labelled tape under DBRC control.
- Intra-host block level data sharing can provide better performance than multi-region operation (MRO) DL/I function shipping. The greater the proportion of DL/I function shipping calls to the total number of data base requests, the greater the potential for performance improvement.

This support offers improved performance for batch programs sharing data bases with CICS/VS, compared to the CICS/VS shared DB support available with CICS V1R5.0, V1R6.0 or V1R6.1. It allows the full use of IMS/VS DB batch function (including GSAM and extended checkpoint/restart) thus avoiding the restrictions imposed by 'shared DB'.

This support also improves the usability of multiple CICS subsystems with DL/I applications by providing equal access to physical and logical data bases, while still appearing as 'local' data bases to all sharing subsystems. This will make the use of MRO more attractive in order to gain MP transaction throughput improvements and virtual storage constraint relief by splitting applications into more than one address space.

In addition to these enhancements, CICS/VS data-sharing will enable the IMS DC user to access data bases used by CICS/VS (via COPICS, for example).

- CICS supports the IMS option of 'open for input'. Sharing of a data base, with integrity, is provided by allowing a data base to be defined as either 'read only' or as 'open for update' for a given CICS system. This state can be changed dynamically. A single updater can share the data base with multiple readers (including IMS/VS DB and IMS/DC) running in different address spaces on the same MVS system.

This is available without requiring either CICS shared data base support or IMS DBRC and data-sharing.

HIGHLIGHTS of CICS/VS VERSION 1 RELEASE 6

MVS/XA SUPPORT: CICS/OS/VS V1R6 and V1R5 may be used in the MVS/XA environment as well as the MVS/370 and VS1 environments. CICS applications which conform to the interfaces defined in the *CICS/VS Application Programmer's Reference Manuals* and which execute correctly under CICS/OS/VS should require no change to execute as 24-bit programs in an MVS/XA environment.

In addition, CICS/OS/VS V1R6 supports the 31-bit addressing and extended virtual storage facilities of MVS/XA in a number of ways:

- In the MVS/XA environment, CICS/OS/VS V1R6 will use the extended virtual storage area to store Temporary Storage records written to main storage. This applies for both 24-bit mode and 31-bit mode programs.
- Support is provided for command-level (EXEC CICS) application programs assembled with Assembler H V2, to use 31-bit addressing. This support enables such programs to be loaded in extended virtual storage rather than in the CICS dynamic storage area.
- CICS/OS/VS V1R6 supports command-level requests for remote as well as local resources from programs executing in 31-bit addressing mode. Macro level requests and DL/I calls from 31-bit programs are not supported.
- Full Execution Diagnostic Facility (EDF) support is provided for 31-bit programs. Extended virtual storage areas may be displayed and altered using EDF.
- CICS DUMP and TRACE provide equivalent support to both 31-bit and 24-bit programs.
- The EXEC CICS GETMAIN command is enhanced by the addition of a FLENGTH keyword. For programs executing in 31-bit mode, FLENGTH will allow the allocation of up to 1,024 megabytes (1 gigabyte) of virtual storage via the MVS/XA GETMAIN command. For 24-bit mode programs, irrespective of the operating system environment, FLENGTH will allow allocation of up to 65,520 bytes of virtual storage. FLENGTH is supported by both CICS/DOS/VS V1R6 and CICS/OS/VS V1R6.
- CICS/OS/VS V1R6 will support the execution of transactions which consist of a combination of 24-bit and 31-bit command level programs. This support may be used to extend existing applications and to support program-by-program conversion of existing 24-bit transactions to the 31-bit mode of operation.

IMPROVED IMS/VS SUPPORT: Support for the IMS/VS DB user has been enhanced in CICS/OS/VS V1R6 and can offer improved usability and data base integrity.

With IMS/VS V1 Release 2 or 3:

- DL/I data base integrity is improved in the event of CICS dynamic transaction backout failure or emergency restart failure. DL/I data bases which fail to be backed out will be automatically closed by CICS.
- The CICS CEMT RECOVERDB command has been improved to give better usability and increased data base integrity. The command will now force end-of-volume on the system log only once for a group of data bases, thus avoiding fragmentation of the log and the loss of log data that previously occurred through excessive switching between disk log extents.
- The CICS DL/I trace has been improved to include response codes on exit from the CICS-IMS interface.

With IMS/VS V1 Release 3:

- CICS/OS/VS Command Level Programming Interface Support:
 - The CICS/OS/VS COBOL or PL/I programmer is provided with a new set of EXEC DLI commands for processing of IMS/VS data bases in a CICS/OS/VS environment including online, CICS/VS shared data base, and IMS/VS DL/I batch applications. The EXEC DLI language is supported by the CICS Execution Diagnostic Facility (CEDF), is upwards compatible with the DL/I DOS/VS language, and is extended for IMS/VS functions.
- In the OS/VS2 MVS or MVS/XA environments, the number of concurrent DL/I transactions supported by CICS/OS/VS V1R6 is increased from 31 to 255.
- New initialization options available to CICS/OS/VS V1R6 enable the IMS/VS R3 user:
 1. To hold and access IMS modules in the LPA, for improved systems integrity.
 2. To pagefix ISAM/OSAM buffers for performance tuning.
- IMS/VS V1R3 users will not need to create a CICS PSB for configuring the IMS/VS nucleus at CICS initialization.
- CICS modules do not have to be link-edited with IMS/VS V1R3 modules. Therefore, the IMS/VS load library is not required during

PROGRAM PRODUCTS

CICS/VS (cont'd)

CICS V1R6 generation, and, in addition, application of IMS maintenance to a CICS-DL/I system is simplified.

- CICS/OS/VS-DL/I Primer Sample Programs - Code will be provided to support the CICS/OS/VS-DL/I Primer sample programs. This code will be integrated with the IMS/VS Primer code from previous releases of IMS/VS and will be distributed as a part of the IMS/VS V1R3 Data Base System.

INSTALLABILITY IMPROVEMENTS

- CICS/OS/VS V1R6 may be ordered with a VS1 option or an MVS option. VS1 specific materials are excluded from the MVS option and vice-versa. Both options include a pregenerated CICS system. Previously this was available only for VS1 systems. This simplifies the CICS installation process by reducing the need for users to perform CICS module assemblies.
- The CICS/OS/VS-supplied installation job stream has been simplified by dividing it into a number of smaller jobs for separate installation tasks.
- Installation and Operation Guides for CICS/OS/VS and CICS/DOS/VS are included in the new CICS library. These manuals guide users through the tasks of installing and operating the CICS system.
- For users performing their own system generation, this task has been simplified. For example, the number of BMS operands has been reduced from twenty-three to three, allowing users to generate, or, in CICS/DOS/VS, select one of three BMS systems (full, standard or minimum) as desired. The twenty-four options of the FILSERV keyword of File Control have been replaced by the three options VSAM, ISAM and DAM.
- To help simplify the tasks of installation and service application for CICS/DOS/VS, machine-readable material in this release is provided in two parts: Basic material and optional material.

The basic material includes fewer library files than V1R5, simplifying service application using MSHP. The files include a core-image library, a relocateable library, and source libraries. The core-image library contains a comprehensive set of pregenerated CICS modules, tables and sample programs such that, for many users, the need to perform their own system generation will be eliminated. The relocateable library includes modules required for link-editing with user applications. The source includes that required for user resource definition, and for those CICS modules for which system generation is supported in this release.

Optional material is provided as a separately orderable feature, and comprises source code for CICS modules (in the basic material) only in pregenerated form. Optional material is not supported for system generation. Local program support, corrective and preventive service are not provided for licensed optional source material.

APPLICATION PROGRAMMING ENHANCEMENTS: The command level (EXEC) programming interface was introduced in CICS/VS V1R3 and has been enhanced in subsequent releases. It is designed to simplify the CICS application programmer's task, isolate application code from CICS internal code dependencies, and through EDF and CECL, simplify the program test and debug tasks.

CICS users are recommended to use the command level programming interface for all application program development. The macro level interface continues to be supported for program compatibility and maintenance purposes.

All enhancements to the application programming interface in CICS/VS V1R6 are provided at the Command level interface and are supported by EDF. Enhancements for the application programmer include:

- A new CICS transaction, CEBR, enables a user to display the contents of individual temporary storage queues. This capability can be useful in program development and problem determination.
- In CICS/VS V1R6, BMS can process both aligned and unaligned BMS maps interchangeably.
- Support is provided for BMS input maps containing fields which are not ordered in ascending sequence by position. This can be useful during application development. Field layouts on a screen may be varied without the need to modify associated application code.
- Two new CICS commands, PUSH and POP, allow all current HANDLE CONDITION specifications to be suspended if these are not appropriate to a called subroutine or program, and to be restored when control is returned to the calling program.
- New keywords MAXLENGTH and NOTRUNCATE can be specified on RECEIVE or CONVERSE commands. MAXLENGTH specifies the minimum amount of data to be received at a given time. Unlike the LENGTH field, it is not overwritten during program execution. NOTRUNCATE specifies that when the data available exceeds the length requested by an application program, the remaining data will

not be discarded, but retained for retrieval with subsequent commands.

SECURITY ENHANCEMENTS

- Users of the MVS external security management program, Resource Access Control Facility (RACF, 5740-XXH), may take advantage of the following additional security enhancements:
 - APPLID validation - This may be used by RACF to restrict sign-on to a specific CICS system to specific operator groups.
 - TERMINAL validation - The terminal validation facilities of RACF may be used in the CICS environment to restrict use of particular terminals to specific operator groups.
 - Local DL/I PSB validation - RACF may be used to validate a DL/I PSB from applications executing in a local CICS system. This is in addition to the facility introduced in CICS/VS V1R5 to validate DL/I PSBs originating from batch programs using the CICS/VS shared DB interface or from a connected CICS/VS region.
- User exit security is improved to ensure that any program invoked from a user exit is authorized as a CICS program.
- In CICS/VS V1R6, the number of transaction security values available with the CICS sign-on program and sign-on table is increased from 24 to 64.
- A new resource level security value of PUBLIC is introduced. When assigned to a resource, it makes that resource available to any transaction requiring it, irrespective of the resource level check value associated with the transaction.
- User management is responsible for evaluating, selecting, applying and implementing security features, and for the appropriate administrative and application controls.

JOURNAL MANAGEMENT and RESTART ENHANCEMENTS

- CICS/OS/VS V1R6 introduces support of IBM standard label tapes for use as CICS or user journals. This provides a more secure and usable alternative to present tape journal control procedures which remain available.
- CICS standard label tape journals may be either linear or cyclic.
 - A cyclic tape journal comprises a finite number of tape volumes which are reused in sequence. Such a journal could serve for the CICS System Log.
 - A linear journal may comprise an indefinite number of tape volumes and re-use of any volume is under user control. Linear journals may be appropriate for accumulating long audit trails.
- For each standard label journal, CICS/OS/VS maintains a list in chronological order of the tapes used, and keeps a record of which volumes have been written to and closed. This information persists across all restarts including cold starts of the CICS system.
- For standard label tape journals, CICS communicates tape mounting requirements to the system operator using the tape volume identifiers.
- CICS statistics in the CICS/VS shutdown summary are enhanced to report the identification of the last tape in each journal.
- CICS/VS V1R6 includes new master terminal (CEMT) commands for disk and tape journals to control opening and closing of individual journals, and a CEMT command (SWITCH) to allow a user to choose when the end-of-volume occurs.
- A new CICS START option, AUTOMATIC, allows CICS to determine which type of restart (warm or emergency) to perform by reference to the state of the system as maintained on the restart data set. This offers improved reliability and reduced operator interaction in system shutdown/restart operations.

CICS RESOURCE DEFINITION ONLINE

- CICS/VS V1R6 introduces a new, interactive process for defining groups of CICS transactions, programs, mapsets, partition sets and profiles, and the capability to dynamically add or alter these resources (PPT and PCT entries) on a running CICS system.
 - These new facilities are provided in a CICS-supplied transaction called CEDA which includes: A set of commands for the management of groups of related resources; a set of commands for the management of lists of groups; a command to manage dynamic reconfiguration of a running CICS system; and a command to perform cross-checking within a group of resources or within a list of groups.
- Resources defined using CEDA are held on a VSAM file called the CSD (CICS System Definition). Related resource definitions are held on the CSD in named groups. A group may comprise, for example, all definitions of the resources, like programs, maps, and transactions constituting one application. The CSD also contains lists of groups defined using CEDA.

PROGRAM PRODUCTS

CICS/VS (cont'd)

- Groups from the CSD can be installed on a CICS system at initialization time. In addition, dynamic modification to a running CICS system may be made using the INSTALL GROUP command of the CEDA transaction. This command causes all definitions in the specified group to be added dynamically to the CICS system.
- Facilities are provided to allow coexistence with and staged migration from the present offline methods of CICS resource definition for those resource types supported by CEDA. Users may use some definitions from the CSD and some from PPTs and PCTs created by existing procedures.
- An offline utility is provided to initialize and create or extend a CSD. A MIGRATE command creates transaction, program, mapset, partition set and profile definitions on the CSD from PPTs and PCTs which have been assembled and link-edited to a load library using CICS/VS Version 1 Release 6 table macros. A COPY command allows definitions to be copied from the same or another CSD.
- All CEDA commands which modify a CSD or a running CICS system may be logged to provide an activity audit trail.

SYSTEM AVAILABILITY ENHANCEMENTS: The capability to add and modify CICS PPT and PCT entries online can contribute to improved system availability. Further support in CICS/VS V1R6 which can help improve system availability includes:

- CICS/VS V1R6 will support Session Outage Notification, an SNA facility supported in ACF/VTAM V1R3, ACF/VTAM V2R1 and ACF/TCAM V2 Releases 3 and 4. This support will enable automatic recovery from session failure to be attempted by CICS in some cases depending upon the nature of the session failure.
- Support is provided so that modules or programs with PPT entries may reside in the operating system link pack area (LPA) or shared virtual area (SVA) provided they have the read-only attribute. Many CICS-supplied modules are read-only and eligible for inclusion in the LPA. Such modules and programs are protected from being overwritten, thus improving availability and integrity characteristics in both MRO and single region environments.

PERFORMANCE and TUNING IMPROVEMENTS

- VSAM subtasking, introduced via a PTF to CICS/OS/VS V1R5, is included in CICS/OS/VS V1R6. It is an option applicable to MVS only. It enables VSAM file control requests from CICS to be handled by an operating system subtask. This allows parallel execution of the subtask with the main CICS task on MP, AP or dyadic processors with consequent improvement in system utilization.
- In this release, Basic Mapping Support (BMS) may be generated, or in the case of CICS/DOS/VS V1R6, selected as a minimum, standard or full function version. The minimum version has substantially shorter path length and storage requirements than the other two versions. The minimum version code is automatically invoked in the other two BMS options for certain commonly used command level SEND and RECEIVE MAP requests to and from 3270 displays and printers.
- CICS/VS V1R6 supports the SNA large message processing enhancements of ACF/VTAM V2R1. This allows messages comprising multiple request units (RUs) to be transmitted to SNA devices in a single SEND request from CICS to VTAM, thereby reducing operating system task switches. CICS will also be able to send data from discontinuous buffers, thus avoiding the data moves associated with building single buffers.
- CICS management of temporary storage is improved. A user now has more scope to adjust the control interval size of the VSAM temporary storage file to tune system performance. Temporary storage records may now exceed the size of the control interval.
- The address space for a CICS system running under MVS can now be made swappable. With this, it is possible to run multiple separate CICS systems in the same processor by allowing the operating system to swap out CICS address spaces which have been inactive for some predefined period of time. This facility may be particularly useful in a system with multiple low activity CICS address spaces to help optimize overall system utilization.

INTERCOMMUNICATION ENHANCEMENTS

- Multi-Region Operation (MRO) was introduced in CICS/VS V1R5 and offers transaction routing and function shipping. These facilities, where appropriate, enable users to organize their CICS workload into multiple connected CICS regions for improved testing, integrity and, in multiprocessing environments, overall system utilization. CICS/VS V1R6 extends MRO to include support for distributed transaction processing where an application may be written as complementary transactions, each executing in an MRO connected region.
- CICS/VS V1R6 introduces new support for CICS-to-CICS program-to-program communication in an SNA environment. This new support requires ACF/VTAM V2R1. It includes the existing

CICS-to-CICS application programming facilities and offers the following additional functions:

- Program-to-program error notification.
 - A new command enables a pair of user programs to inform each other of errors, to synchronize processing and to exchange data to recover from application-detected errors without transactionabend.
- Application program selection of synchronization level.
 - An application is able to select whether or not an SNA session is to participate in CICS synchpoint processing. As an example, an inquiry-only application may be designed to run without CICS synchpoint processing. A further option allows the user to perform resynchronization under application program control rather than via CICS synchpoint processing.
- Resynchronization improvement.
 - If a session failure occurs during the execution of a CICS synchpoint request, resynchronization of the session partners will be attempted to establish the state of protected resources at the point of session failure. This is done before any local resources are committed or backed out.
- User control of allocation of work across a set of parallel sessions.
 - This allows work to be allocated to specific routes between systems and also allows different types of transactions to be managed so that they do not interfere with each other. For example, a user can associate low data volume, fast response transactions with one set of sessions and high data volume, slow response transactions with another set of sessions.
- Synchpoint rollback.
 - This may include an ISC session. This means that a remote program may be notified when the partner program issues synchpoint rollback and both may continue processing instead of being abnormally terminated.

The new support is based on SNA extensions and involves new SNA session definitions. The SNA extensions are designed to provide common session protocols for document interchange and distributed data processing. This provides the base for CICS users to establish a single network definition for distributed office and distributed data applications. A new publication, *Systems Network Architecture: Transaction Programmer's Reference Manual LU Type 6.2* (GC30-3084) provides general guidance for programmers writing transaction programs based on the SNA extensions.

CICS users who are implementing CICS program-to-program applications for the first time should use the new support and SNA extensions.

Users with existing CICS program-to-program applications are recommended to implement the session definition changes. Existing applications should, in general, require no change to execute on sessions using the SNA extensions. Users who do not plan to implement the new support until later may continue to run existing CICS program-to-program applications without change on CICS/VS V1R6.

Applications based on CICS to IMS program-to-program communication are unaffected by the SNA extensions. The existing CICS to IMS support is the base for the development of user program-to-program communication between these subsystems.

- A new publication, the *Intercommunication Facilities Guide*, will be available with CICS/VS V1R6. It presents a comprehensive description of intersystem communication (both CICS/VS to CICS/VS and CICS/VS to IMS/VS) and multi-region operation for system programmers, application designers and developers and technical support personnel.

DEVICE SUPPORT ENHANCEMENTS

- The sharing of a 3270 display screen between BMS and GDDM Release 2 is simplified. CICS will allow the definition of BMS maps which have size and position but which contain no fields. New options on the CICS ASSIGN statement enable the size and position of a map to be passed as input to a GDDM call. This information may be used by GDDM to position graphic fields in areas of the display screen which contain no BMS fields.
- CICS/VS V1R6 supports the attachment of 3270 SNA terminal devices which can send/receive ASCII-7 or ASCII-8 data streams. CICS converts the ASCII data to and from EBCDIC for application programs. The ASCII-7 support is confined to the 3274 mdls 1C or 51C, 3276 mdl 12, 3278 and 3287 devices using basic 3270 data streams only. The ASCII-8 support applies to 3270 displays and printers with basic or extended 3270 or SCS data streams.
- Support of extended attributes (e.g., color and highlighting) was provided in CICS/VS V1R5 for devices which supported the 3270 extended data stream. CICS/VS V1R6 adds support of extended attributes for printers which support the extended SCS (SNA

PROGRAM PRODUCTS

CICS/VS (cont'd)

- Character String) data stream and for 3270 printers using the NLEOM mode of operation.
- A BMS statement, SEND CONTROL, allows an application program to build and transmit device controls, such as cursor position and alarm set, without associated display data.
- Program control is provided for the 10/63 Magnetic Stripe Reader (MSR) in command level programs via a new keyword, MSR, on the BMS SEND MAP, SEND TEXT, and SEND CONTROL commands. The new option applies to 10/63 Magnetic Stripe Readers attached to 8775 or 3643 terminals.
- Support for vertical forms control is extended to all 3270 printers through the addition of a FORMFEED keyword on BMS SEND commands.
- The use of the trigger field validation attribute of 8775 displays to initiate input to a CICS application program is supported. A new option of the HANDLE AID command allows the application program to pass control to a handling routine upon receiving input from a trigger field.
- In CICS/VS V1R5, basic terminal control support of 8775 display screen partitioning facilities was provided. Enhancements to this support are included in this release. Applications may be designed to exploit multiple partitions on appropriately featured displays via extensions to the CICS command level program interface. A new CICS mapset-like object, the partition-set, is introduced. A partition-set defines a screen layout in terms of one or more partitions. It has a name, it may be suffixed, and is stored as a CICS program like a BMS mapset. The command level enhancements allow an application program to load a predefined partition-set onto a display and to set the current output partition and expected input partition for outbound and inbound data respectively.
- A new option, Katakana, is provided in the CICS terminal control table (TCT) macro for 3270 devices with the Katakana feature. When specified, output from the CICS-supplied transactions such as CEMT will be displayed in upper case characters only. This is necessary because the codes normally used for lower case characters are used for Katakana characters in 3270 Katakana devices.
- Input from non-Katakana 3270 display terminals to CEMT and CECI may now optionally be in lower case characters for command keywords as well as for data.
- Support is provided for 8100 DPCX DXAM files in CICS command level programs. DXAM files may be accessed via the CICS batch data interchange programs using the ADD, REPLACE and ERASE commands.

PROBLEM DIAGNOSIS/SERVICEABILITY AIDS

- CICS transaction dumps and formatted dumps will include a short explanatory header (symptom string) for use by the user and the IBM service representative in problem diagnosis via SSF (Software Support Facility). The header will contain the abend code and associated component and module identifiers.
- User-supplied titles may be inserted at the top of operator-requested dumps.
- CICS transaction dumps will include the latest command level COMMAREA.
- The diagnostic information available with storage violation dumps is improved.
- A new option enables users to suppress on a transaction basis the generation of entries in the CICS trace table.
- The CICS trace utility program will support the printing of trace data for a particular occurrence of a transaction.
- The size of the trace entry has been enlarged to 32 bytes. Each entry now includes a time stamp and user trace entries may optionally include an 8-character resource name.
- New system messages indicating storage violation and short-storage conditions are provided for system operator guidance.

ADDITIONAL USER EXIT FACILITIES: In addition to the improved user exit security (see "Security Enhancements") other user exit facilities in CICS/VS V1R6 are:

- A user exit in the CICS terminal control program gives the user access to output messages before they are transmitted.
- The task-related user exit, which was provided in CICS/DOS/VS V1R5, is included in this release of CICS/OS/VS V1R6 and CICS/DOS/VS V1R6. It is so called because it can be invoked directly by a user-written Assembler language program within a task; it does not have to be driven by a CICS management program. This type of exit may be useful where a CICS system is to communicate with a non-CICS program which manages recoverable resources.

- A user exit in the CICS monitoring control program enables a user to access monitoring data as it is about to be written to a journal.

REVISED CICS/VS LIBRARY: This release of CICS/VS is accompanied by extensive changes and improvements to the CICS library designed to make information more task related as well as easier to find and understand.

The additions to the CICS library include:

- CICS/OS/VS V1R6 Release Guide
- CICS/DOS/VS V1R6 Release Guide

These are designed primarily for current users and describes the new releases including installation, operation and customization considerations.

- Installation and Operations Guide (OS/VS)
- Installation and Operations Guide (DOS/VS)
- Customization Guide
- Resource Definition Guide
- Recovery and Restart Guide
- Performance Guide
- Intercommunication Facilities Guide

HIGHLIGHTS of VERSION 1 RELEASE 5

Availability Dates: Version 1 Release 5 is available.

Multi-region Operation: CICS/VS Multi-region Operation (MRO) provides the ability to run multiple connected CICS/VS regions within a system (partitions in DOS/VSE and OS/VS1, address spaces in OS/VS2) while sharing terminals, transactions and other resources. Terminal users normally perceive a single CICS/VS image. Individual CICS/VS regions can be started and stopped without interrupting other regions.

Three major facilities are offered in MRO:

- Transaction routing between CICS/VS regions, so that operators at terminals of one CICS/VS region can run transactions in any connected CICS/VS region. This applies to application programs written to the High Level Programming (EXEC) Interface or to the macro interface.
- Function shipping, so that application programs written to the High Level Programming Interface (or the DL/I CALL interface) can also access resources of any connected CICS/VS region, without requiring knowledge of the placement of these resources. The resources are accessed through the File Control, Transient Data, Temporary Storage, Interval Control Transaction Initiation and DL/I functions of CICS/VS.
- Shared CICS/VS management modules, providing a mechanism for placing CICS/VS management modules in the system Link Pack Area (CICS/OS/VS) or Shared Virtual Area (CICS/DOS/VS). This allows the code to be shared between regions and thus offers reduced paging. It also offers increased integrity in both MRO and single region environments.

These facilities have numerous potential uses. The user may choose two CICS/VS regions or many, and each region may run many applications or one. For example, new CICS/VS application programs can be tested concurrently with production operation of CICS/VS, using a separate test region and so reducing possible impact on production without inhibiting access to existing resources and without requiring terminals to be dedicated to the test region. CICS/VS operation in a multiprocessor system can be improved by running CICS/VS in multiple OS/VS MVS address spaces. A CICS/VS system can be divided on a departmental basis, providing independent operation for one department while maintaining controlled access to resources of another department.

User specification of the CICS/VS region to be associated with terminals, transactions and other resources enables the overall CICS/VS system to be optimized across the CICS/VS regions. Terminals and other resources normally associated with a production application should be defined in the same region as the applications programs so that the overheads associated with inter-region communication are minimized. The ability to define the number of CICS/VS regions and the resources to be controlled by each region, enables the user to choose the appropriate level of performance, integrity and ease of operation.

A CICS/VS transaction, CRTE, is provided which enables a terminal operator with appropriate security access to invoke from one region a transaction in a connected CICS/VS region without the need for any transaction table modifications in the first CICS/VS region. This facility is useful for testing transactions on MRO connected systems, and is particularly useful for invoking the master terminal transaction in a specific connected CICS/VS region.

PROGRAM PRODUCTS

CICS/VS (cont'd)

Most existing application programs require no change in order to be invoked via transaction routing. Most HLP1 programs can also use data resources defined in a different region without requiring change in the application program. A case where transaction routing may not be transparent to the application program is where an application communicates with a user exit; full details of changes to existing programs required for multi-region operation will be documented at the time of availability.

Intersystem Communication Extensions: Intersystem communication support provides the capability for two or more CICS/VS or IMS/VS systems to communicate using SNA multi-system networking facilities. The existing support allows CICS/VS function requests to be shipped between CICS/VS systems. In CICS/VS V1R5 ISC is extended by providing use of SNA parallel sessions to offer throughput improvements and an ISC communications facility is provided for a direct transaction to transaction interface to CICS/VS and IMS/VS-MSC.

Direct transaction-to-transaction communication supports distributed transaction processing, where an application may be written as two complementary transactions, one executing in the system local to the originating terminal, the other in a remote system. User function can therefore be distributed between CICS/VS and/or IMS/VS-MSC systems in an SNA network, to complement the existing support where CICS/VS functions are distributed only between CICS/VS systems. An application program uses High Level Programming Interface commands in PL/I, COBOL or Assembler Language to initiate, maintain and terminate a conversation with an application program across a ISC link.

Often, direct communication between CICS/VS transactions can offer greater efficiency of data transfer than CICS/VS function shipping since several data records can be placed in each message instead of needing a message for each CICS/VS command. However, CICS/VS function shipping requires no special user programming for many applications. For transaction-to-transaction communication, CICS/VS provides sample programs to provide guidance on application programming techniques, to give access to some standard CICS/VS or IMS/VS transactions in remote systems and to provide a base on which user applications can be built.

CICS/VS transaction-to-transaction communication uses SNA protocols and is dependent on functions introduced in ACF/VTAM Version 1 Release 2. All CICS/VS Intersystem Communication functions depend on the facilities of ACF/VTAM Version 1, with its Multi-system Networking Facility for cross-domain links, or ACF/VTAM Version 2. Access methods offering compatible interfaces, ACF/TCAM V2 (R2 and subsequent) and ACF/VTAME, can also be used.

A queuing facility allows EXEC START requests to be queued on a local CICS/VS system if an ISC link is unavailable. This gives a batch capability in that many EXEC STARTS may be queued locally on temporary storage until an ISC session is acquired.

CICS/VS Version 1 Release 5 introduces further use of SNA facilities for all CICS/VS Intersystem Communication functions. The parallel session capability introduced in ACF/VTAM Version 1 Release 2 is used to offer the user a choice of the number of concurrent sessions allowed between systems. This can offer improvements across an ISC link. Use of negotiable session initialization parameters introduced in ACF/VTAM Version 1 Release 2 enables CICS/VS to adapt, where appropriate, to the capability of other subsystems in the SNA network.

Enhanced Master Terminal: Users of displays can use a new interactive interface for controlling the CICS/VS system. The Enhanced Master Terminal transaction, CEMT, offers a command syntax similar to that of the High Level Programming Interface, and allows abbreviations and defaulting of keywords. CICS/VS interprets the command and diagnoses errors and inconsistencies. This mechanism can therefore be used to construct commands interactively to inquire about, or change, the operation of CICS/VS. It is possible with a single command to inquire about or change the status of groups of resources (e.g., programs with names beginning ABC or terminals that are out of service). CEMT supports displays with screen size of at least 1920 characters and supporting the 3270 data stream. CEMT also supports use of the system console. The existing master terminal transaction, CSMT, continues to be available in Release 5 of CICS/VS Version 1.

The functions provided by the enhanced master terminal transaction can with some restrictions be invoked by a user program. This enables the system programmer to program certain operations which would otherwise have required action by the master terminal operator.

High-level Programming Interface Enhancements: CICS/VS Version 1 Release 5 further develops the High-level Programming (EXEC) Interface introduced in CICS/VS V1R3.0.

The Command Interpreter is a display-oriented program designed to assist in the writing, syntax checking and execution of an EXEC command. It enables an operator of a display (with screen size of at least 1920 characters and supporting the 3270 data stream) to enter a command for CICS/VS to check, and optionally execute. An application programmer can construct an EXEC command interactively, so using the Command Interpreter to complement the Execution Diagnostic Facility which enables an existing HLP1 program to be interactively

tested. The Command Interpreter takes the command, complete or partial, and checks its syntax. Default options are indicated by CICS/VS, together with diagnosis of missing or incorrect parameters. Once a command has been developed to the satisfaction of the user, he may request its execution. This enables the user to check the operation of the command and inspect diagnostic messages and the results of the operation, including inspection of the user's screen resulting from the operation. The facility can also be used to create or inspect test data (e.g., transient data) for use with the testing of application programs.

Further extensions to the high level programming interface include the ability to IGNORE specific error conditions completely and the ability to prevent the HANDLE condition from taking effect on specified EXEC commands.

CICS/DOS/VS supports a new High-level Programming (EXEC) Interface to DL/I DOS/VS for application programs written in COBOL or PL/I.

The CICS/DOS/VS Execution Diagnostic Facility is extended to support the EXEC DL/I DOS/VS interface in addition to the CICS/VS commands.

Security Enhancements: CICS/VS Version 1 R5 introduces an interface to external security management programs for verification of a user's access to CICS/VS and to check the user's authority to use transactions. This interface is available in CICS/DOS/VS and CICS/OS/VS and coexists with the internal CICS/VS facility. The new interface is designed to interface to the Resource Access Control Facility (RACF) (5740-XXH) on MVS so that RACF Release 3 facilities can be used to control user access to CICS/VS and its transactions. RACF can also be used to authorize access to a CICS/VS address space from another (e.g., when using the CICS/OS/VS Shared Data Base facility on MVS).

Extensions are also made to the authorization checking available to application programs using the High Level Programming Interface. In addition to the existing check of user access to a transaction, there is a new option to specify that authorization at a resource level should be checked for a transaction. This option is particularly relevant to generalized transactions which may access many different resources (e.g., files) according to user input. The option is used by CICS/VS provided transactions for Intersystem Communication, Execution Diagnostic Facility and Command Interpreter. For transactions specifying resource level authorization checking, the user specifies security keys for the resources to be protected in this way, for example in File Control Table entries.

Improvements to the CICS/VS signon procedure offer increased flexibility in signon, with passwords entered from a non-display field on a 3270 or from an over-struck field on terminals such as the 3767, use of an operator ID card in addition to keyed input and optional logging of all sign-on and sign-off actions. Non-display password and logging of sign-on/off were first made available in PTFs on CICS/VS V1R4.0.

Improved Monitoring Facilities: A data gathering mechanism in CICS/VS Version 1 Release 5 offers the user improved facilities for monitoring the performance of the CICS/VS system, and for providing accounting data on an individual user basis. The mechanism consolidates and extends data previously available in CICS/VS, offering a single interface on which analysis routines can be based. The user may dynamically choose the level of recording, dependent on his needs for accounting, performance or exception data. In this way he has granularity in the level of information recording, yet a common mechanism for analysis programs to process and extract relevant information. Monitoring data can optionally be written to System Management Facility (SMF) files in CICS/OS/VS. Monitoring data on SMF is intended for use on MVS in conjunction with MVS/System Extension Release 2.

New Device Support: CICS/VS supports the Network Terminal Option (NTO) program product (5735-XX7) so that additional terminals can be used with CICS/VS through ACF/VTAM or ACF/TCAM Version 2 with ACF/NCP/VS. Support through NTO offers an alternative to the existing support through BTAM and allows these terminals to use SNA networking facilities. CICS/VS support is specifically for Western Union Teletypewriter Exchange Service (TWX mdl 33/35) terminals and World Trade Teletypewriter Terminals (WTTY) and is designed so that existing TWX/WTTY application programs require minimal change for use with NTO. Physical attachment of terminals is as specified by NTO. The 3101 Display Terminal and the 3232 mdl 51 keyboard printer are supported as a TWX 33/35 substitute. The 6733 Communication Module is supported as a TWX 33/35 substitute.

CICS/VS supports the alphameric character set for magnetics on 3270 systems. Basic Mapping Support is extended so that application programs can use maps to support multiple 3270 screen sizes, including new sizes such as on the 3278 mdl 5, while remaining independent of screen size. Applications can also route messages to such displays, independent of screen size. BMS provides support of the extended attributes of color, extended highlighting and programmed symbols for 3270-type devices including the 3279 Color Display. BMS also supports additional functions of terminals attached to 8100 processors via the Data Stream Compatibility facility of 8100/DPCX or 8100/DPPX or DPPX/SP. Extended attributes for Extended Highlighting

PROGRAM PRODUCTS

CICS/VS (cont'd)

(underscore, blink and reverse video) and Field Validation (mandatory enter and mandatory fill) and programmed symbols can be specified on a field basis in output maps and modified dynamically by application programs.

Enhanced IMS/VS Support: The number of concurrent DL/I threads supported by CICS/OS/VS when used with IMS/VS Version 1 Release 1.6 or subsequent compatible releases is increased from 15 to 31.

Transaction dumps of CICS/OS/VS transactions which access IMS/VS DL/I will be extended to include DL/I control blocks.

The IMS/VS DB monitor is supported in the CICS/OS/VS environment through a new SIT option.

CICS/OS/VS Version 1 Release 5 introduces support of the OS/VS console as a CICS/VS terminal. This enables CICS/VS transactions to be invoked from the console and allows other CICS/VS operators to communicate with the console operator. In particular, the console can be used for CICS/VS Master Terminal functions to control CICS/VS terminals or to control several CICS/VS regions in conjunction with the Multi-region Operation. Normal operating system use of the console is not inhibited, and CICS/OS/VS supports multiple consoles where present. Console support is already available for CICS/DOS/VS.

Usability and Serviceability Aids: A new user exit mechanism, which in CICS/VS V1R5.0 coexists with existing exits, offers easier customization of CICS/VS. New user exit code can be incorporated without reassembly of CICS/VS management modules, aiding use of CICS/VS pregenerated modules. The new mechanism encompasses most of the existing customization points and is designed so that logical groups of exits can be controlled dynamically and independently. New user exit programs are written in Assembler Language, but have an improved interface with CICS/VS modules. Several exit programs can coexist at a single exit point, without requiring knowledge of each other and most existing exits can easily be converted to the new mechanism.

CICS/DOS/VS includes facilities designed to improve serviceability in a DOS/VSE environment. It includes functions similar to those provided to the CICS/DOS/VS user by the service aid Facility Error Recognition System (FERS). This provides problem determination data for communications problems associated with 3270 displays supported through BTAM-ES. The user can display statistics and details of communication problems related to BTAM-ES terminals and lines, individually or globally.

The DOS/VSE SYSDMP file can be used for CICS/DOS/VS problem data (e.g., partition dumps) so that this data can be accessed through VSE/Interactive Problem Control System (VSE/IPCS).

CICS/DOS/VS supports the Maintain System History Program in DOS/VSE (MSHP) for use in installing CICS/DOS/VS and its service updates. This enables a history file to be maintained with service level information on CICS/DOS/VS.

CICS/OS/VS supports the System Modification Program Release 4 (SMP4) for use in installing CICS/OS/VS and its service updates.

Auxiliary trace is enhanced by the provision of support for a second auxiliary trace file. This enables the installation to analyze one trace file while continuing to record on the other. Further, additional entries are now included in the CICS/VS trace table to record the interactions between CICS/VS and ACF/VTAM Version 1 or ACF/VTAM Version 2 or ACF/VTAME.

A new error message option for error messages written to 3270 displays by the message generation program (MGP) is provided. This allows such messages to be displayed on the last n lines of the screen (n lines is the length of the error message) instead of at the current cursor position. These messages may be displayed in this screen position with specified attributes such as color and extended highlighting.

New terminal status options are available which enable the user to prevent CICS/VS from automatically acquiring terminals.

SYSGEN parameters have been simplified by a reduction on the number of operands requiring consideration by the system programmer. This should reduce the number of times CICS/VS modules require to be regenerated.

In CICS/OS/VS the number of type 2 SVCs has been reduced to one. In addition, the SVC number can be provided in the SIT so that the user does not need to reassemble CICS/VS service modules if the SVC number is changed.

CUSTOMER RESPONSIBILITIES

To successfully install CICS/VS the customer must:

- Have installed at least the minimum required machine configuration.
- Have installed the correct level of operating system required by the CICS/VS product to be used.
- Ensure that appropriate training has been given to systems analysts, systems programmers, application programmers and

operators in CICS/VS and terminal-oriented applications and operations.

- Have a knowledge of data base concepts in order to design and create a data base or data files.
- Design and create formats and maps for terminals using the Basic Mapping Support.
- Have a knowledge of data communications applications in order to design and implement user application programs.
- Develop procedures to ensure adequate protection against accidental or deliberate loss or misuse of data.
- Develop appropriate backup procedures for vital applications.
- Plan for installation and operation of any remote terminals.
- Develop detailed schedules and procedures for conversion to an online environment.
- Ensure, for SNA terminals, that the appropriate personnel are proficient in VTAM or TCAM and 3704/3705 NCP/VS.
- Ensure, for intelligent subsystems, that the systems analysts and programmers are proficient in coding programs for the controllers and in understanding the interactions with the host.
- Be capable of generating the various CICS/VS control program modules and tables which satisfy the unique requirements of the installation.

BRANCH OFFICE RESPONSIBILITIES

Successful implementation of a CICS/VS system is a complex undertaking. The branch office must recognize and understand the tasks to be performed. Customer assistance may be required in areas such as education, systems design, application design, data base design, terminal network design and operations control.

To satisfy the potential requirements of the customer, the branch must have, or have ready access to, personnel who are skilled and knowledgeable in CICS/VS and the appropriate operating system together with BTAM, VTAM, TCAM, NCP/VS, VSAM, DL/I and industry-oriented subsystems as appropriate. While ultimate responsibility for the installation rests with the customer, IBM requires that the branch and marketing representative ensure that:

- The customer implementation plan is comprehensive and realistic.
- The programming system and hardware configuration selected for the CICS/VS environment will satisfy the requirements of the customer's application requirements.
- Appropriate education and training are offered to the customer management and technical personnel who will be involved in the implementation of the system.
- The customer is provided with appropriate qualified application planning assistance.
- Any requirements established under the Systems Assurance Program.
- The appropriate FE branch office is notified at the earliest possible opportunity to involve them in the planning and to ensure that they provide the required Class A service to the account.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

CICS/VS will operate on the IBM S/370, 308X or 4300 System given sufficient real storage to satisfy the combined requirements of CICS/VS, the host operating system, appropriate access methods, batch requirements and other customer-required applications. CICS/VS storage requirements are discussed under "Storage Considerations" below. The configuration must include sufficient I/O devices to support the requirements for system output, system residence and system data sets. Sufficient direct access storage must be available to satisfy the user information storage requirements and may consist of any direct access facility supported by the system configuration and the programming system. See also the documentation for the host operating system for details of any features and engineering change levels that are required.

Distribution and support of CICS/VS requires the availability of one 9-track tape drive.

CICS/VS does not save, restore or dump floating point registers and does not provide support for program checks resulting from floating point operations. For Assembler language programs this may result in unpredictable results when using floating point operations; the problem may be reduced by the Assembler programmer saving the floating point registers across CICS/VS EXEC commands or macro calls but unpredictable results may still occur in the event of a task switch during program check handling. This problem will not arise when application programs are written in ANS COBOL, COBOL VS, RPG II DOS/VS or PL/I.

PROGRAM PRODUCTS

CICS/VS (cont'd)

IBM DEVICE SUPPORT

CICS/VS support of terminals and programmable special features is shown at two levels. Table 1 below gives an overview, showing the terminal/system type and an indication of the access method supported. Table 2 gives further detail including relevant units and physical attachment where appropriate.

Two access method interfaces are shown in Table 1. Support of SNA networks was first introduced through VTAM. It is available through ACF/VTAM and, for devices also supported by these access methods, ACF/VTAME (CICS/DOS/VS) and the Record Interface introduced in ACF/TCAM Version 2 Release 2 (CICS/OS/VS). Table 1 shows this support under the column headed VTAM-type. The second interface is shown in the BTAM-type column. This support is available through BTAM (CICS/OS/VS) or BTAM-ES (CICS/DOS/VS).

The user should be aware that many terminals and control unit special features are transparent to programming and are therefore readily usable even though not specifically identified. In all cases, the appropriate line adapters or telecommunications control units must be used, as specified by the access method in use.

Another interface is available in CICS/OS/VS, supporting the use of TCAM with a Message Control Program. This, the TCAM GET/PUT interface, supports data stream rather than specific terminal types. CICS/OS/VS accepts any data stream from a TCAM or ACF/TCAM-supported terminal that can be edited in the message handler portion of the TCAM MCP to appear as an EBCDIC, basic SCS or IBM 3270 data stream. IBM 7770 support is not available through this interface. CICS/OS/VS BMS data stream support for IBM 3600, 3767, 3770 and 3790 logical units is also available through the TCAM direct interface to NCP/VS introduced in TCAM 10.

Table 2 gives detail of device support, including some units supported. In general, devices and features supported by systems and programmable controllers are transparent to CICS/VS but where CICS/VS provides specific device support the units are listed in Table 2. The column headed "attachment" provides further information on physical attachment. When using the VTAM interface, the attachment is a function of the access method, and the Network Control Program (where appropriate). Therefore the mode of connection of a terminal - local, SDLC, BSC, switched or nonswitched - is transparent to CICS/VS and CICS/VS support is dependent on the capabilities of the terminal, the Network Control Program and the access method. CICS/VS does not participate in the connection process and so switched/nonswitched is not shown in Table 2 for VTAM level support. When using the BTAM interface, the attachment is shown in detail. CICS/VS supports host initiated switch connections where appropriate autocall hardware is installed, but does not support manually established connections for call-out. CICS/OS/VS support of locally attached 2260s uses GAM and its support of 7770s is "BTAM-like".

Some devices are listed as being "supported as" a named device, meaning that the level of CICS/VS support is that offered to the named device. Other devices are listed as being "attached as" a named device, meaning that they are defined to CICS/VS as being the named device but they may operate with restrictions where they differ from the named device.

Where specific detail applies in Table 2, it is given in the notes. The following abbreviations are used:

- local = Channel- or adapter-attached
- SDLC = Synchronous data link control
- BSC = Binary synchronous communications
- s/s = Start/Stop transmission
- sw = Switched
- nonsw = Nonswitched

WTTY				

- Notes:**
- CICS/OS/VS provides support of the 2848 through GAM. CICS/DOS/VS provides support through BTAM.
 - For CICS/DOS/VS, using BTAM-ES, the Transmission Control Unit or ICA must be equipped as follows:
 - 2703-2741 Break feature (#8055) required
 - 3704/3705 - UNITXC = NO required in Emulator Generation or equivalent
 - ICA on mdl 135 - Unit Exception Suppression Feature (#9729-#9736) required
 - ICA on mdl 115 or 125 - Line Mode must be specified with Unit Exception Suppression
 - The Receive Interrupt (#4708) is supported under CICS/OS/VS only.
 - CICS/VS 2770 support includes optional 2772 feature #3650 (EBCDIC Transparency), #9936 (WACK response), #1490 (Buffer Expansion), #1910 (Conversational Mode), #1340 (Automatic Answering), #4610 (Identification), or #6310 (Security Identification) and #5010 (Multipoint).
 - 6-bit transcode is not supported. Support includes optional features #8030 (EBCDIC transparency) and #1340 (Automatic Answering) or #5020 (Multipoint).
 - 2980 support is for 2972 mdl 8 (RPQ 858160) or mdl 11 (RPQ 8582311) with 2980 mdl 1 (RPQ 835504), mdl 2 (RPQ 835505) or
- SDLC 3270s are supported only at the VTAM level, and the switched BSC 3275 (feature #3440) is supported only at the BTAM level. Printers attached to local or SDLC 3274s and SDLC 3276s are supported through the VTAM interface either as LU type 3 using 3270 printer data streams or as LU type 1 using SCS data streams (which is a subset of that used for SDLC 3767, 3770 and 3790 printers). The 3288 is supported as 3286 mdl 2. CICS/VS supports the 3270 Copy feature (#1550).
 - Devices and features supported by system/programmable controller are generally transparent to CICS/VS. In some cases CICS/VS provides specific device support, in which case the units are listed.
 - SDLC is supported at the VTAM level. 3600 BSC attachment (RPQ 8K0598) is supported at the BTAM level. The 3614 is supported both for loop attachment to the 3601 and SDLC attachment to the host via a 3704/3705 Communications Controller. The 3614 is supported by CICS/VS via BSC only when loop attached to the 3601/3602 Controllers. 3624 is supported as a 3614. The 3690 is supported as a 3602. BSC support is an integral function of 4700.
 - CICS/VS provides support for the Data Transfer Function of the SDLC Programmable mdls of the 3770 Data Communication System. The user is responsible for allocating data sets and managing the program library.
 - CICS/VS does not support the 3790/Data Entry Configuration using 3760s. The #9165 or #9169 configuration is required to support the CICS/VS enhancement first made available in Version 1 Release 3.0. Printers on 3790 systems are supported with a user provided function program or 3270 data stream compatibility with a 3270 printer data stream (LU3) or an SCS data stream supporting a subset of that for SDLC 3767 (LU1). The 3288 mdl 2 is supported as a 3286 mdl 2 when operating in 3270 mode.
 - S/370 and 4300 attachment by BSC requires a suitable telecommunications program (for example the VSE/3270 Bisync Pass Through Program) in the system connected to CICS/VS. Attachment by SDLC is supported by CICS/VS Intersystem Communication.
 - CICS/OS/VS provides support through GAM. CICS/DOS/VS provides support through BTAM.
 - Nonswitched as a multipoint device: System/7 Remote IPL is supported. Switched and as a Point-to-point Device: Remote IPL is not supported.
 - The System/32 with its SNA/SDLC workstation system utility program, and the System/34 and System/38, are supported as compatible versions of an appropriately featured 3770 Communication System operating as a batch logical unit. See Programming Announcement letters. The System/34, System/36 or System/38 user-written program is responsible for supporting the correct SNA sequences of the attached subsystem.
 - TWX and WTTY are supported by ACF/VTAM and ACF/TCAM via the Network Terminal Option program product (5735-XX7), with attachments as defined by NTO. At the BTAM level, TWX (Line Control Type) is attached on 8-level code at 110 bps on common carrier switched 150 bps networks. WTTY is attached at 50 bps on common carrier switched network where the terminals supported are those interfacing through IBM WT Corporation Telegraph Terminal Control with Telegraph Line Adapter. Transmission code used is International Telegraph Alphabet No. 2 (CCITT No. 2). Automatic host disconnect via WRITE break is not supported for OS. Autocall is not supported for DOS or OS.
 - 3740 support includes optional features #7850 (Terminal Identification) or #1685 (Multipoint), #5450 (Operator ID Card Reader), #1680 (Expanded Communications).
 - 3780 support includes features #3601 (EBCDIC Transparency), #9936 (WACK), #5010 (Multipoint) or #7651 (Switched), #1601 (Component Selection).
 - The 3643 is supported as a 3604.
 - 8775 support includes mandatory fill and mandatory enter field validation attributes.
 - Attachment is via the Loop Adapter #4830, #4831 and Data Link Adapter #4840 of the 4331 processor.
 - Under CICS/DOS/VS only.

CICS/VS (cont'd)

SOFTWARE REQUIREMENTS

SOFTWARE REQUIREMENTS FOR CICS/DOS/VS

CICS/DOS/VS V1R6 is designed to run with DOS/VSE with AF3.

CICS/DOS/VS V1R5 is also supported in this environment.

CICS/DOS/VS V1R6 will run on any subsequent release or modification of the above operating system unless otherwise stated. CICS/DOS/VS V1R6 does not support prior releases of the above operating system.

A current release of VSE/VSAM which supports the above operating system is required for CICS/DOS/VS V1R6 system generation and by certain CICS/VS options such as recovery/restart.

MSHP is required for use in installing CICS/DOS/VS V1R6 and its service updates.

CICS/DOS/VS V1R6 will run with the following TP access method programs at the current release level(s) supported by the above operating system releases. (Note: Some functions in CICS/DOS/VS V1R6 require ACF/VTAM V2).

BTAM/ES
ACF/VTAME
ACF/VTAM V1
ACF/VTAM V2

CICS/DOS/VS V1R6 will run with DL/I DOS/VS Release 1.6 or SQL/DS Release 1.

SOFTWARE REQUIREMENTS for CICS/OS/VS

CICS/OS/VS V1R6.1 is designed to run with the following operating system releases:

- MVS/SP V1R3 and above.
- MVS/SP V2R1.0 with MVS/XA Data Facility Product Release 1.0.
- MVS/SP V2R1.1 with MVS/XA Data Facility Product Release 1.1 (required for virtual storage constraint relief improvements).

CICS/OS/VS V1R6.1 will also run on subsequent releases or modifications of these operating systems unless otherwise stated. CICS/OS/VS V1R6.1 does not support prior releases of these operating systems.

CICS/OS/VS V1R5 and V1R6.0 are supported in these environments and also run with OS/VS1 Release 7.0 or OS/VS2 MVS Release 3.8 with SE2.

A current release of VSAM, or a program offering equivalent function, which supports the above operating system releases is required for CICS/OS/VS V1R6.1 system generation and by certain CICS/VS options such as recovery/restart.

SMP Release 4 (with PTF UR03129 if on an MVS/XA system) is required for use in installing CICS/OS/VS V1R6.1 and its service updates. System Modification Program Extended (SMP/E) (5668-949) can not be used with CICS/OS/VS.

CICS/OS/VS V1R6.1 will run with the following TP access method programs at the current release level(s) supported by the above operating system releases:

BTAM
BTAM/SP
TCAM10
ACF/TCAM V1
ACF/TCAM V2
ACF/VTAM V1
ACF/VTAM V2

CICS/OS/VS V1R6.1 will run with IMS/VS Version 1 Release 2 or 3.

Command Level DL/I requires the functions provided by IMS/VS Version 1 Release 3.

The DBRC (Data Base Recovery Control) facility, as available with IMS/VS Version 1 Release 3, may optionally be used to provide CICS system log management.

The data-sharing support requires the functions provided by IMS/VS Version 1 Release 3 and the DBRC facility.

For details of availability of IMS/VS Version 1 Release 3, refer to Programming Announcement dated November 5, 1982.

CICS/VS UNDER VM/370: CICS/OS/VS and CICS/DOS/VS may be run in a VM/370 virtual machine under control of DOS/VSE, OS/VS1 or OS/VS2 subject to the following considerations.

CICS/VS operating in a virtual machine has the same requirements as CICS/VS operating in a real machine. Other software components (e.g., Access Methods, Compilers and the release of OS/VS, DOS/VS or DOS/VSE under which CICS/VS runs) must be valid for that release of CICS/VS.

The minimum hardware requirements of CICS/VS operating in a VM/370 virtual machine are the same as those for CICS/VS running in

a real machine, and should be considered as additional to the minimum requirements for VM/370 itself, and any other virtual machines within the VM/370 environment.

Processor utilization and possibly terminal response times will be greater when CICS/VS is running under VM/370 than when it is running in a real machine. The effect on performance will be most noticeable when VM/370 is introduced into an installation where processor and main storage resources are already substantially committed to existing CICS/VS and other work.

If the impact on performance is significant, its effect may be partially or totally offset by the installation of additional main storage, a processor model upgrade or both.

The operation of CICS/VS running in a virtual machine may differ in certain respects from that obtainable when running in a real machine. Briefly the significant differences are:

1. BTAM support of the Autopoll feature will not work correctly under MVS if Wrplist polling is specified.
2. VM/370 does not support the 7770 Audio Response Unit.

Intersystem Communication Considerations: Intersystem communication functions are likely to increase the processor utilization and terminal response time. The effect on performance will be most noticeable when processors and main storage resources are already substantially committed to existing CICS/VS and other work.

If the impact on the performance is significant, then its effect may be partially or totally offset by the installation of additional main storage, a processor mdl upgrade or both.

STORAGE CONSIDERATIONS

The CICS/VS distributed and generated libraries require in the order of 80 million bytes of direct access storage, depending upon the system options generated and blocking factors chosen by the user (where applicable).

The system configuration required for the use of CICS/VS in a data base/data communication system will be largely determined by the scope of the environment to be supported and the nature of the user's application programs. CICS/VS is designed in a modular fashion with many system generation options so that the user can select the options that are meaningful to his operation with maximum economy of main storage.

Careful consideration must be given to avoiding overcommitment of the real storage resource in a small system to prevent significant response time degradation. CICS/VS functions that require a large amount of real storage may incur page faults beyond an acceptable level. In addition, certain terminal network configurations and/or data base organizations require larger access method storage. It is important that pageable real storage not be overcommitted by trying to include too many CICS/VS functions, too large or varied a terminal network, too many and/or complex data base structures, or too large a batch operation, if these are used frequently. Also placing the paging data set on the same DASD as high-usage data sets (data base and libraries) should be avoided.

No CICS/VS functions or configurations have been identified that would not perform in a small system provided it has sufficient real storage. However the use of many of the CICS/VS functions together in a normal error-free transaction can generate a requirement for significant amounts of real storage. The total storage requirement should be carefully examined to ensure that sufficient real storage is available in the system. Functions, features and characteristics which may require significant real storage include:

- CICS/VS options (e.g., intersystem communication, temporary storage or basic mapping support).
- All user application programs, especially those written in a high level language, although use of the PL/I Shared Library and reentrant programs may reduce the paging overhead and size of user programs.
- Large terminal networks and networks of more than one terminal type.
- Transfer of large volumes of data to and from a data base.
- Transaction rates that require several transactions to be processed simultaneously by the processor.
- Operating system access methods (ISAM, VSAM, VTAM, TCAM, DL/I, etc.) and their possible impact on the storage requirements of the operating system.

The effect on the real storage requirement of CICS/VS functions and application programs that are used only occasionally, e.g., abnormal or error situations, is of less significance.

If TCAM is used with CICS/OS/VS, the size of the user-written TCAM Message Control Program (MCP) should be taken into consideration when computing overall storage estimates.

PROGRAM PRODUCTS

CICS/VS (cont'd)

PERFORMANCE CONSIDERATIONS

The performance of CICS/OS/VS and CICS/DOS/VS is highly dependent on the system configuration, (Processor, I/O devices and terminal network), the users' application programs, the system loading and the CICS facilities being used.

It is the users' responsibility to prepare the system configuration and design his application programs to satisfy his performance requirements. Information in CICS/VS SRLs is provided to allow the user to estimate the major processor resources he requires (processor power, real and virtual storage, number of physical I/O operations) together with guidelines on writing his applications and configuring the system to achieve satisfactory performance characteristics. In order to verify specific performance requirements, benchmarking the CICS/VS system is highly recommended.

RPOs ACCEPTED: No

MVS SYSTEM INTEGRITY APPLIES: Yes

5740-XX2 - INFORMATION MANAGEMENT SYSTEM/VS

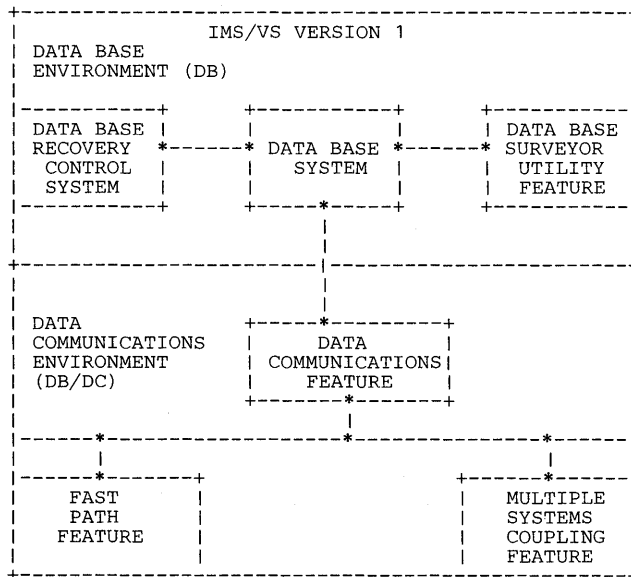

PURPOSE

Information Management System/Virtual Storage (IMS/VS) Version 1 is Data Base/Data Communication (DB/DC) program. IMS/VS supports user-written batch processing and teleprocessing applications. Batch and teleprocessing applications may execute concurrently or separately. IMS/VS provides: Data Base management services which support the implementation of multiple applications using a common data base ... Data Communications management services which support the implementation of multiple terminal-oriented applications using a common data base.

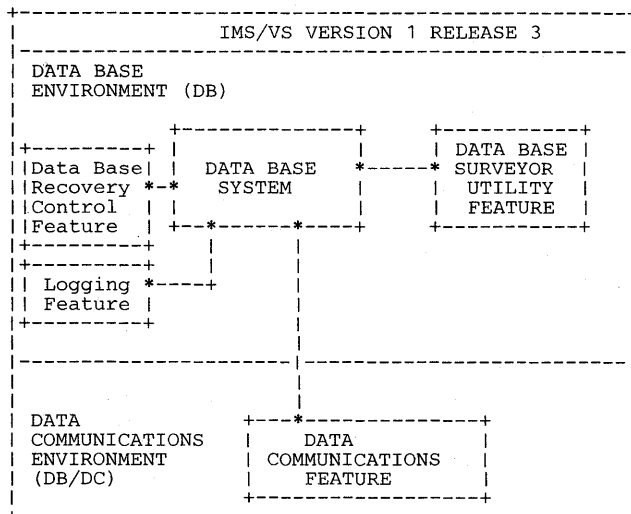

The data base management services are offered as basic material in an orderable component called the *Data Base (DB) System*. The data communications management services are offered as a feature in a separately-orderable component called the *Data Communication (DC) Feature*. The DB System is prerequisite to the DC Feature. When the basic DB System and the DC Feature are combined, the two form the *IMS/VS Data Base/Data Communication (DB/DC) System*. The IMS/VS System has been designed to facilitate transition from the DB to the DB/DC System.

Additional features, Fast Path (FP), Multiple Systems Coupling (MSC) with Intersystem Communication, Data Base Surveyor Utility, and Data Base Recovery Control Feature are described in the section "Features."

The following figure shows the relationship of the various IMS/VS Version 1 features to the Data Base System:

The following figure shows the relationship of the various IMS/VS Version 1 features to the Data System starting with IMS/VS Version 1 R3. New product packaging occurs in R3 where Fast Path and Multiple Systems Coupling are no longer separate features, but are a part of the IMS/VS Data Communication feature.

DESCRIPTION

Application programs call upon the data base and data communications management services through Data Language/I (DL/I). For the most part, application program use of DB/DC management services is independent of terminal and storage media programming considerations. IMS/VS provides installation management tools to control terminal and storage programming considerations independent of application programs. Installation management can approach the problem of enhancing productivity for the total community of applications and users without affecting the functional capabilities of the members of the community.

IMS/VS application programs can be insensitive to: The reorganization of stored data, the addition of new applications or data, changes in access methods organization or access strategy, and the introduction of new storage or terminal devices.

Data Base Management: The data base management services of IMS/VS assist the user in:

- Description of data base structures.
- Creation of data bases.
- Access to and maintenance of data bases.
- Reorganization of data bases.
- Recovery and reconstruction of data.
- Checkpoint/restart for DB environments.

Using IMS/VS utilities supplied, the customer describes the structure of the data base from two viewpoints; the stored data structure as seen by the system and the logical data structure as seen by the application. Only one description of the stored data exists. However, multiple descriptions of the logical data may exist. These data base descriptions are external to applications programs. They exist as stored data themselves and are referenced by the system when it is processing access requests for application programs.

Data base descriptions define symbolic names for data items (fields), segments and data bases. They map collections of fields into segments and segments into data bases. To access or maintain stored data, the application program generates a functional GET/PUT request for data base management services. As part of the functional request, the application program supplies symbolic names which identify the data (segment type) to be processed. The names used are those defined for the logical data structure, not the stored data structure. Through data base descriptions, the system maps the application-supplied logical data names to corresponding stored data names, determines an access strategy and performs the requested function against the stored data.

The data base descriptions contain information about organization, access strategy, the physical attributes of the data, the physical structure of the stored data segments and storage device characteristics.

Data bases may be stored in two general organizations: Hierarchical Sequential (HS) or Hierarchical Direct (HD). For HS-organized data the access method and basic processing strategy may be sequential or indexed sequential. For HD-organized data it may be direct or indexed direct. Within a single data base, the system description defines a hierarchical relationship among segments of the stored data structure. In addition, relationships can be established between segments in different hierarchical structures stored within the same data base. Finally, relationships can be established between segments in different hierarchical structures stored in different data bases. The ability to interrelate hierarchical data structures assists in nonredundant data storage and permits data to be accessed through multiple retrieval paths.

Reorganization and recovery of stored data bases are supported by a set of IMS/VS Utility programs.

Checkpoint/restart capabilities are available in the data base environment.

Data Communications Management: The data communications management services of IMS/VS provide:

- Application-independent terminal management.
- Input/output message traffic handling.
- Terminal and program message switching.
- Message format service for device independence.
- Transaction-initiated scheduling of application programs.
- Conversational/interactive application support.
- Diagnostic aids.
- System command and control language.
- Resource security.

IMS/VS (cont'd)

- Checkpoint/restart for DB/DC environment.
- Message class scheduling.
- Display terminal paging.
- Audio response.

Application programs generate requests for message input/output operations through Data Language/I. Messages are presented to the application programs in the same manner as data base requests. Data communications management services handle input and output traffic for the terminal network asynchronously to the processing performed by applications. In the characteristics response-oriented interchange between terminal and application, the application is aware of the origin of the message it processes and the destination of the output it produces in a symbolic manner. The application views the symbolic terminal as though it were a two-level hierarchical data structure. The first level represents a segment type "First Message Segment". The second represents a second segment type "Remaining Message Segments".

There is at least one symbolic name associated with each terminal managed by the system. Each transaction type known to the system also has a symbolic name. Messages entered by a terminal operator contain one of these two kinds of symbolic names. Based upon the characteristics of the name, an input message is sent to other terminals or to applications for processing. Applications may send messages to terminals or to other applications. The Multiple Systems Coupling Feature enhances this capability (see the "Features" section).

The Fast Path feature allows a variation to the application view and message handling. See the "Features" section for a further description.

IMS/VS order of message processing of a transaction (message) type is based on class and priority within class associated with its application program. The user specifies these parameters when he generates the IMS/VS DB/DC system.

Multiple application programs may be scheduled simultaneously against the same data base to a segment level.

When an application program updates a data base segment, other programs are prevented from accessing the updated segment until the updating program has completed its entire update procedure or reached a synchronization point. If the updating program terminates abnormally prior to completion of the update procedure, the updates it has made are backed out of the data base to the last point of synchronization.

With the Fast Path feature, data base recovery and data base update are accomplished a little differently. See the "Features" section for a further description.

Some applications have the requirement to interface with a terminal operator in a conversational or interactive exchange of related input-response messages. The system will maintain data for the application between the interchanges of a conversation. A single conversation involves only one terminal operator, but may take place with more than one application program.

A support facility is provided for IMS/VS users of SLU 1, 2, 4, P and LU6 and 2740, 2741, 3270 and 3600 terminals. This Message Format Service (MFS) allows application programs to deal with logical messages instead of device-dependent data, thus helping to make the application development function simpler. The same application program may deal with different device types with a single set of editing logic while device input and output varies to suit a specific device. The presentation of data on the device or operator input may be changed without application program changes. Full paging capability is provided for display devices. Input messages may be created from multiple screens of data.

Operation of the DB/DC system can be monitored and altered through a system command and control language. The commands provide dynamic display of the status of system resources such as communication lines, terminals, data bases, message queues and programs. In addition, they permit the status of system resources to be changed dynamically. IMS/VS diagnostic aids can be invoked through the command language.

Provision for system resource security is provided through a combination of password, terminal, data base and program protection features. Security facilities support is provided to log all IMS/VS detected attempts to violate IMS/VS communications security. Optionally, immediate notification to the master terminal of detected attempts to violate IMS/VS communication security is provided.

System resource integrity, reliability and recovery are provided through extensive checkpoint/restart capabilities.

Checkpoint/restart capabilities are available in both the batch and online environments.

HIGHLIGHTS

IMS/VS Version 1 is a general-purpose system that the user tailors to suit his environment. IMS/VS Version 1 Release functions are carried forward and are upward compatible with the exception of 3790 (limited inquiry). A summary description consists of the following highlights:

Application Support: Application programs can, for the most part, be designed to operate independently of data management access methods and organization.

Application-independent support is provided for a variety of storage and communication devices. The "System Requirements" section contains detailed device support information.

Storage protection is provided for each application program.

Transactions are scheduled according to class and priority.

Program isolation allows concurrent execution of two or more application programs which may update the same segment type in a data base. In addition, program isolation assists in data base integrity if a message processing program abnormally terminates.

Application Load Balancing (also known as Parallel Scheduling) permits the IMS/VS control region to schedule the same application program into more than one message region, or batch message region, simultaneously.

Transaction Load Balancing permits the IMS/VS control region to schedule the same transaction type into more than one message region simultaneously. This support, for message processing regions only, provides the user with the ability to process high volume transactions in parallel, and will allow processing of the same transaction on both processors of an MP/AP system simultaneously.

The Update Only Recovery Facility permits the user to define inquiry transactions (which do not change the data base) as unrecoverable. This may reduce line utilization because acknowledgment back to the terminal is not required.

Application Program Output Limits permits limits to be established for the size and number of application program output message segments. This facility enhances IMS/VS integrity by helping to minimize the impact of erroneous application program operation on the message queues.

Automated operator interface provides an IMS/VS interface that allows:

- An application program to issue, via DL/I calls, IMS/VS operator commands to receive the command responses.
- A user-written exit to monitor activity related to IMS/VS resources as reflected in IMS/VS messages to the master terminal operator, and in IMS/VS commands and command responses, and invoke action based on customer-specified criteria.
- A hard-copy or data set log of many operator commands, responses and synchronous output to the IMS/VS secondary master terminal.

The automated operator interface offers the following advantages:

- Reduces operator intervention.
- Increases information in hard copy audit trails.
- May reduce response time to errors reported to the Master Terminal Operator by IMS/VS.

The usage of the automated operator interface is optional and requires user-written programs and an optional user-written exit routine to perform processing desired by the installation.

Primer function is for new users of IMS/VS under OS/VS1 and OS/VS2 MVS to install IMS/VS more easily, design their initial data bases and applications, and begin operations with a subset of IMS/VS in a simple environment.

The Primer Function consists of:

- Manuals which supplement the existing IMS/VS library of publications: The *IMS/VS Primer*, *Primer Sample Listing*, *Master Terminal Operator Guides for BTAM and VTAM*, and a *Remote Terminal Operator Guide*.
- Sample application support including: Sample data bases, sample Data Base (batch) applications and sample Data Communication (online) applications.

System Services: Telecommunications and batch operations can execute concurrently or separately.

System definition allows a maximum upper limit of 5,000 each of physical terminals, logical terminals, programs, transactions and data bases. (A practical upper limit for execution is based on total system requirements for a particular IMS/VS installation.)

Security techniques are provided.

PROGRAM PRODUCTS

IMS/VS (cont'd)

Checkpoint/restart capabilities are provided for online message application programs.

Batch checkpoint/restart facility provides support to allow checkpoint and subsequent restart of batch and batch message application programs.

The immediate checkpoint eliminates the forced termination of MPPs at the time a simple checkpoint is taken. System activity is interrupted only during the time the system control blocks are actually being written to the log.

Extended Checkpoint/Restart permits batch programs to reestablish data base positioning and to reinitialize user-specified areas during an application program restart with user's DL/I calls. This helps provide improved programming and operating flexibility in restart processing.

The Optional Dual Log facility allows the user to maintain duplicate log tapes for increased reliability and provides a higher degree of system integrity than single logging.

Logical/Physical Logging permits each MPP and BMP to issue logging requests which are executed as a separate task in parallel with other tasks in an MP environment, thus facilitating better workload distribution.

The Track Recovery Option of the Data Base Data Set Recovery program allows re-creation at the track level rather than the data set level in the event of a permanent Read/Write error. The data base access method must be Enhanced VSAM.

The Utility Control Facility provides a method of performing most data base utility operations and maintenance in preparation for recovery and reorganization under the control of one job, and in one step. UCF's checkpoint/restart function enables the user to stop and then resume a utility operation as schedules permit.

The IMS/VS DB Monitor can provide a trace of internal activities of an IMS/VS DB System and a report program that prints summary and distribution reports of this collected data. The DB Monitor provides the capability for collecting data. The DB Monitor provides the capability for collecting performance data to investigate specific application designs, data base designs and resource allocations.

The IMS/VS DC Monitor can provide a trace of activity within the IMS/VS control region and dependent regions, and a report program that prints summary and distribution reports of this collected data. The DC Monitor provides the capability for collecting performance data to investigate specific application designs, data base designs and resource allocations.

System Definition Rewrite allows the user to define a larger IMS/VS system without a proportional increase in required input source statements. The user can define a larger and/or more complex IMS/VS system configuration without a proportional increase in Stage 1 processing time. System Definition Rewrite also contains additional documentation of macro instructions and copy members within the source statements that improves the serviceability of the System Definition function. The ability to define a larger IMS/VS system is achieved by allowing the user to define one or more transaction codes, data base names and logical terminal names on one occurrence of a macro statement. Also, the alphabetic sorting of application program names, transaction code names, data base names and logical terminal names that was previously done during Stage 1 will now be done within Stage 2 processing. This decreases Stage 1 processing time and allows these functions to occur during parallel Stage 2 assembly processing.

The Statistics Analysis Utility Program sort rewrite combines two functions, the first sort and the first edit pass, allowing record reduction earlier in the process and increasing usability.

The Formatted Dump allows IMS/VS to format and dump its control blocks and data areas as part of Abend processing. This will aid in problem determination, and allows a more rapid solution. The IMS/VS Formatted Dump is functional when IMS/VS operates on OS/VS1 and OS/VS2 (MVS).

Enhanced restart is designed to reduce the time required to restart an IMS/VS system through the reduction of or elimination of delays resulting from:

- Unnecessary tape reading.
- Records not needed for restart.
- Searching for starting checkpoint.
- Operator tape handling.
- Operator errors.
- Job initiation.

A direct-access data set called the "restart data set" is provided to record a minimal set of key information necessary for restart. If possible, restarting is done using this data set. Also system log termination can be performed during IMS/VS restart, rather than as a separate stand-alone utility job. The enhanced restart function includes the following:

- Restart from DASD data set (optional).
- Online log termination.
- Use of the dynamic log from shutdown of a previous IMS/VS system execution for data base backout at restart of a new IMS/VS execution.
- Elimination of the requirement for operator entry of the restart command.
- Availability of new DC Monitor reports in support of the DASD logging facility.

Enhanced Checkpoint/Restart increases the availability of the IMS/VS system by reducing the time required after either system failure or scheduled shutdown. The functions provided are:

- Online dumping of message queues by a simple checkpoint or at an IMS/VS shutdown.
- Restart without building the queues.

Online Image Copy Utility allows the user to copy data sets of a data base to tape or disk concurrent with online application usage. This utility makes it easier to schedule normal maintenance of data bases because the data bases being copied can still be used by online applications for inquiry or update. The Online Image Copy Utility runs in a BMP region.

The dynamic allocation/deallocation function for IMS/VS data bases removes the requirement that DL/I data bases and Fast Path Data Entry Data Base (DEDB) areas be initially allocated through Job Control Language (JCL). The data base will be allocated either at IMS/VS initialization or at the first attempt to use it. Also, the IMS/VS DC Monitor need not be allocated through JCL. DC Monitor log data sets are allocated at the time the DC Monitor is started and deallocated when the DC Monitor is stopped.

This function improves the overall availability of the IMS/VS Control Region, but is available only to the OS/VS2 MVS user.

The 3850 Mass Storage System (MSS) is supported for single track recovery by the IMS/VS Data Base Recovery Utility on VSAM data sets only. Track Recovery allows the user of large data bases to recover data from a permanent read error on the staging drive track without having to do a full data base recovery.

At the user's option, the following enhanced security and accountability capabilities are provided through the use of the Resource Access Control Facility (RACF) program product (5740-XXH) Release 3 and subsequent releases (for MVS only) or through a user-written security exit (for VS/1 and MVS):

- Verification of a user-identification at signon from a terminal.
- Validation of transaction level authorization for the specific user-identification logged on.
- Validation of program-to-program switches using modifiable PCBs.
- Validation of dependent region's authorization to access defined resources (PSBs, TRANs, LTERMs for BMP; TRAN for MPP; PSB for FP region).
- User-identification is logged with messages, terminal signon and signoff and data base changes for accountability. The IMS/VS Log Print utility may be used to print/copy log records associated with a user-identification for audit purposes.
- User-identification information is passed to the application program in the I/O PCB.

These security facilities provide control mechanisms within the scope of the IMS/VS product. To complement these facilities, RACF may be used for control of system resources outside the scope of IMS/VS.

If the user selects the Resource Access Control Facility (RACF) program product (5740-XXH) Release 3 and subsequent releases for the OS/VS2 MVS system, then its prerequisites must be applied to the user's OS/VS2 MVS Release 3.8 system.

These are security facilities that permit the control of access to one system's resources by another. Data protection facilities of communicating systems and subsystems should be considered when using the Intersystem Communication function.

A new parameter is available to the IMS procedure which allows the user to select the local storage option. This option permits the MVS user to load some IMS/VS modules and buffers that were in the Common Storage Area (CSA), into the private storage area of the IMS/VS control region.

The user can now have up to 31 dependent regions concurrently active in an online IMS/VS system.

IMS/VS Release 1.6 and subsequent releases are installable with SMP Release 4 and defines IMS/VS distribution and system libraries in an SMP format. SMP can support multiple IMS/VS nuclei in one

PROGRAM PRODUCTS
IMS/VS (cont'd)

RESLIB and multiple IMS/VS systems from a single set of distribution libraries.

Data Base Services: Data base support is supplied through Data Language/I.

Virtual Storage Access Method (VSAM) support is designed to take advantage of the virtual storage environment of S/370.

IMS/VS VSAM shared resource support can reduce main storage requirements (both fixed and variable) by sharing buffers and control blocks across VSAM data sets. Secondary indexing of IMS/VS data bases is automatically maintained by the system. VSAM must be used for the index data bases.

Variable Length Segments in IMS/VS data bases can be dynamically changed in length to best meet the needs of variable information. These data bases must be VSAM.

Log Tape Write Ahead support for ISAM/OSAM and VSAM based data sets is provided. Parallel DL/I permits calls to data bases to be processed in each Message Processing Region and/or Batch Message Processing Region with the exception of calls which require reading from an ISAM data set, which must be done in the IMS/VS control region. This eliminates the necessity of routing DL/I calls through the control region. In an MP environment it allows for DL/I execution to occur in both processors simultaneously.

Edit/Compression Routine Exits allow inclusion of user-written encode/decode routines to improve the utilization of direct access storage space for data base storage space. This is available for VSAM data sets only.

The General Sequential Access Method allows batch programs to access OS BSAM and VSAM ESDS data sets through DL/I in a BMP or Batch region. GSAM provides data set repositioning through Extended Checkpoint/Restart.

Low-Level Code and Continuity Checking is an application support program that can generate and update low-level codes in a HIDAM organized parts data base, and which can ensure the continuity of a manufacturing product structure. The application support program is a callable subroutine and becomes part of a user-written application program. The addition of these enhancements will assist in the migration to IMS/VS-DL/I from DBOMP, BOMP and CFMS program products.

The IMS/VS ISAM/OSAM buffer handler is a restructuring of the buffer handler to provide better look-aside buffering and to reduce buffer serialization interference. It applies to all operating systems.

The OSAM I/O Driver is a modification to the READ/WRITE access method routines of the OSAM access method. The EXCP interface to the IOS component of OS/VS2 (MVS) is replaced with an I/O Driver interface. This eliminates the requirement to map between EXCP and MVS/IOS control structures. In OS/VS1, the interface to IOS uses EXCPVR.

In addition, OSAM can optionally be used to write to the system log tape because the OSAM I/O Driver includes a write-to-tape interface that replaces the BSAM write-to-tape function. OSAM cannot be used to write to the log tapes in an IMS/VS DL/I Batch system that uses OS/VS Checkpoint/Restart.

The Partial Data Base Reorganization Utility allows a user to reorganize a specified range of HIDAM or HDAM data base records into a designated target area within the data base. The term "range" means a set of low-high key values in the primary index data set of a HIDAM data base or a set of low-high relative block numbers in the root addressable area of a HDAM data base.

This utility may increase the availability of the data bases by allowing a user to reorganize a portion of the data base. This allows shorter reorganization periods when data bases must be offline.

Field Level Sensitivity provides a mechanism to limit access to a subset of the fields in an IMS/VS DL/I data segment. Field Level Sensitivity is not supported for IMS/VS's GSAM data bases. It allows the application program independence from the sequence of the fields in a physical segment. Also changes to a field's position in a DL/I data base segment do not require changes in the user's application program. DL/I call syntax and functional call capabilities, including path calls, are unchanged.

When sensitive fields are retrieved by an application program, only those fields appear in the application program's I/O area in the order specified by the PSB. When those fields are from a variable length segment, special considerations apply. If an application program retrieves a segment without field sensitivity, then the I/O area contents are unchanged from previous IMS/VS releases.

The SENFLD statement is used for PSB generation. PSB generation should be rerun to take advantage of Field Level Sensitivity. Data Base Description (DBD) need not change if only currently named fields are being used.

Data Communication Services: Existing terminal support using BTAM can co-reside with VTAM support to facilitate conversion. The

terminals supported by IMS/VS are listed under "Data Communications" in the "System Requirements" section.

VTAM support allows utilization of VTAM network sharing capabilities and has the ability to access other program products and operating system programs through VTAM when terminals are not being used for IMS/VS operations.

Message Format Service (MFS) is provided for most terminal users and includes a paging feature for display devices (allows multiple screen output with forward and backward paging).

Message Format Service (MFS) Online Testing Facility support allows the creation of terminal and message formats utilizing MFS and testing these formats online while the IMS/VS system is being used in a production environment.

Conversational terminal operation is supported.

Conversational Processing provides scratchpad compression/expansion to reduce data movement and I/O requirements. A FIXED option reduces storage requirements for main storage scratchpads and reduces I/O for disk scratchpads.

Terminal operators can specify a range of resources to be operated on. Exception responses to command input allow entry of both the keyword and parameter in error.

Wait for input function enables the user to specify that a Message Processing Program or Batch Message Program can remain in its region until additional messages are available for processing. This permits transactions to bypass program initialization.

Response Mode operation for terminals optionally allows synchronization between the terminal operator and the application program. After input is received by IMS/VS, communication with the terminal is physically and/or logically stopped until the application program response is transmitted.

Response Alternate PCB permits definition of an alternate PCB which may be used by application programs to insert messages to logical terminals in EXCLUSIVE mode. This facility may also be used to satisfy the response requirements of physical terminals in conversation or in response mode by inserting a message to a component logical terminal instead of to the I/O logical terminal.

Message Delete Option optionally allows output message suppression on two levels: Sysinfo, which suppresses terminal status message DFS059, and NONIOPCB, which suppresses broadcasts, message switches, and alternate PCB messages. This terminal level option provides protection for printers that use a special form and/or depend on forms alignment.

User Message Table Option permits the user to define installation-specific messages which may be sent by user exit routines in the IMS/VS control region. This enhances the capabilities of the exit routines to perform data analysis and notify the terminal operator of errors without scheduling an application program.

Physical Terminal Input Edit Routine allows a user-written routine to edit device input that is not processed by Message Format Service before the IMS/VS basic edit processing occurs for all applicable terminal types. This facility allows additional editing and validation to occur prior to insertion of input into the message queue.

The MFS Language Utility increases usability and performance. Language facilities which provide for repetitive generation of MFLD/DFLD statements and powerful text substitution capability simplify source output preparation. Error detection, error correction, and status messages enhance usability. An optional facility allows concurrent execution of the utility and the IMS/VS control region, deferring update of the format library. A single job step may later update the online format library with the result of many compilations, thus reducing the activity which must take place when the control region is not active.

Multiple Physical Page Input Messages allows creation of an input message from multiple 3270 pages, providing additional application program device independence.

3270 SYSMSG Field allows users to define a field which may be used for IMS/VS error messages. This facility prevents destruction of the screen format and operator input when an error is detected by IMS/VS.

An IMS/VS DB/DC system requires an IMS/VS master terminal. The list of terminals that qualify is contained in the "Data Communications" portion of the "System Requirements" section.

Additional Operator Control allows operators to request the last logical page of a message. Operators may also request the next message and be notified if none is available.

Field and Segment Edit Exits allow user-supplied routines to perform common verification and editing functions after MFS editing, but prior to message queuing. Using this facility may simplify application programming requirements and improve performance by detecting errors before an application program is scheduled. If errors are

PROGRAM PRODUCTS

IMS/VS (cont'd)

detected, the message may be cancelled or returned to the input terminal (with or without modification).

Password Creation allows an IMS/VS password to be created from the 3270 operator identification card reader in addition to data from one or more fields.

MFS support includes attribute simulation for devices other than 3270 display, automatic page numbering, prompting at end of output, default literals for input message fields, removal of blank lines from output to printers and improved performance for long output messages.

Acknowledge-with-Reply allows recoverable input transactions to be sent to IMS/VS in System Network Architecture (SNA) exception response mode. A performance gain may be realized (depending on type of input) since an SNA response need not be sent except in the case of error. This can be optionally selected for the IMS/VS 3600 and SLU P support.

IMS/VS supports secondary logical units 1, 2, 4 and P and logical unit 6 (MSC Feature).

IMS/VS support for secondary logical unit P provides extended function for user-written programs in SNA programmable controllers. This support extends full IMS/VS functional capabilities to the user-written program within the remote controller and optionally includes the MFS Distributed Presentation Management (DPM) function.

The Message Format Service (MFS) provides a function, named Distributed Presentation Management (DPM), that supports Intersystem Communication and SLU P, for a user-written program in SLU P controllers or another system connected by Intersystem Communication. With DPM, message formatting is distributed between the remote program (which handles device-dependent formatting) and MFS (which handles device-independent formatting). This distribution of function allows a device-independent data stream to be transmitted between IMS/VS and the remote program, and the IMS/VS application program to use a single data structure, regardless of the data source or destination.

The VTAM Authorized Path, used to reduce the path length for certain VTAM macro statements, is available to VTAM terminals supported by IMS/VS on OS/VS2 MVS. (It has no effect on terminal support of non-VTAM devices.)

For BTAM BSC 3270 support, if a line or 3270 control unit error occurs, IMS/VS logs the error and attempts to automatically restart the appropriate component(s) before discontinuing use of the line or control unit. After attempting to restart the failing component(s) the specified number of times, if the error persists, IMS/VS discontinues using the failing component(s). If the restart attempt is successful, communication with the devices continues normally.

IMS/VS supports the 3270 subsystem through BTAM and VTAM as follows:

- IMS/VS support of the display screen sizes (960, 1920, 2460, 3440 and 3564 characters) is provided through IMS/VS Message Format Service (MFS).
- Formatted master terminal is only available in the 1920 size screen.

New models of the 3270 Information Display System have been announced previously. IMS/VS supports the additional functions of 3270 subsystems as follows:

- Support of 3278-5 display screen sizes through IMS/VS Message Format Service (MFS).
- Support of 3279 color display.
- Ability to specify features (integers F1-F10) for the 3270 device type as well as the currently accepted feature. The specifications are mutually exclusive with the feature specifications currently available for 3270.
- Ability to specify field attributes of color, extended highlighting and programmed symbols (PS).
- MFS editing can be bypassed with the use of reserved map names.
- Capability for 3270 screens to operate in unprotected mode.

Secondary Logical Unit 4 (SLU 4) support product functional capabilities include:

- Console.
- Card I/O.
- Printer.
- Word Processing Media 1, 2 and 3.

IMS/VS supports SLU 4 in an ACF/VTAM-based system environment. The user can have distributed processing and word processing concurrently.

- With SLU 4, users can enter and receive data from IMS/VS user application DL/I data bases.

- SLU 4 products with console, card or printers can be used with IMS/VS applications.
- IMS/VS applications can be expanded to include word processing units and define word processing medias 1, 2 and 3.

The basic edit process supports input data transparency for these new components.

The Multiple Systems Coupling feature was enhanced to include a VTAM connection in addition to the previous connection types (main storage-to-main storage, channel-to-channel, binary synchronous) for an IMS/VS-to-IMS/VS connection. Another function is available as part of the Multiple Systems Coupling feature. It is called Intersystem Communication and uses an IMS/VS subset of the SNA logical unit 6 (LU 6) protocols. Intersystem Communication allows communication between IMS/VS and other systems (such as CICS/VS or a user-written system), or IMS/VS to another IMS/VS system. With Intersystem Communication, users of other subsystems can use IMS/VS application programs, data bases (through user-written application programs) and terminals. Distributed Presentation Management (DPM) allows the distribution of the presentation management function of MFS to other subsystems.

IMS/VS application programs can be initiated from other systems without changing the IMS/VS application programs. For more information on Intersystem Communication, see the "Features" section. For details see the "Multiple System" part of the "System Requirements" section.

Support for MSC Directed Routing allows an application program to specify the multiple system name (MSNAME) and destination within that system for a message. The application program can receive the MSNAME of the system that originally scheduled it.

HIGHLIGHTS OF IMS/VS VERSION 1 RELEASE 2

DATA BASE SYSTEM

IMS/VS Data Sharing Facility: A Data Sharing Facility is being offered with the planned availability of IMS/VS Version 1 Release 2. The Data Sharing Facility is contained in the IMS/VS base product, the Data Base System. The Data Sharing Facility will allow accessibility and concurrent sharing of IMS/VS data bases by online and/or batch IMS/VS systems. When the concurrent sharing is done on one processor (UP/AP/MP) it is called intraprocessor sharing. When the concurrent sharing occurs between online and/or batch IMS/VS Systems in more than one processor, it is called interprocessor sharing.

An online IMS/VS system is application programs running in an MPP or BMP region of an IMS/VS system. A batch IMS/VS system is batch application programs running in one or more DL/I batch regions of an IMS/VS system. An installation may be all online or all batch IMS/VS systems, or a mix of both online and batch. Two levels of sharing capability are being offered, Data Base Level and Block Level. Data Base Level sharing is available under both OS/VS1 and OS/VS2 MVS operating systems. Block Level sharing is available only on the OS/VS2 MVS operating system. Block Level sharing is defined as locking at a physical block for ISAM/OSAM data bases and at a control interval for VSAM data bases. Data Base Level sharing is defined as locking at the IMS/VS DL/I data base level whether ISAM/OSAM or VSAM. For an interprocessor configuration, the maximum number of processors at the block level of sharing is two (2). At the data base level of sharing, the maximum number of processors which can participate is limited by the number of paths to the direct access device(s) upon which that data to be shared resides.

The IMS/VS Resource Lock Manager (IRLM): A component of IMS/VS Version 1 Release 2, governs and passes information on the usage and ownership of blocks of data within the same processor or across processors. IRLM is used for IMS/VS Data Sharing when doing Block Level sharing, which requires the OS/VS2 MVS operating system. Interprocessor sharing (across processors), requires ACF/VTAM (or ACF/TCAM Version 2 Release 2 or 3) with an IBM 3705 Communications Controller attached to each processor through a channel adapter. In addition to IBM 3705 Communications Controller support, ACF/VTAM Version 2 provides Channel-to-Channel (C-T-C) support on OS/VS2 (MVS).

An installation's performance requirements, when using the IRLM with an IBM 3705 Communications Controller, may require additional Communications Controller capacity. For higher performance environments, the use of ACF/VTAM Channel-to-Channel may be required.

IMS/VS DATA BASE RECOVERY CONTROL FEATURE (DBRC): The Data Base Recovery Control Feature (DBRC) of IMS/VS Version 1 Release 2 is required for the IMS/VS Data Sharing facility. DBRC has been enhanced to provide an authorization process for data sharing to determine whether the IMS/VS system is registered and whether the intended use of a data base is allowable.

Additional Information - IMS/VS Data Sharing Facility: Figure 1 is a block diagram showing how the parts of IMS/VS Data Sharing facility fit together. It shows an interprocessor configuration using ACF/VTAM

PROGRAM PRODUCTS

IMS/VS (cont'd)

and operating under OS/VS2 MVS at the block level of sharing which requires IRLM and DBRC.

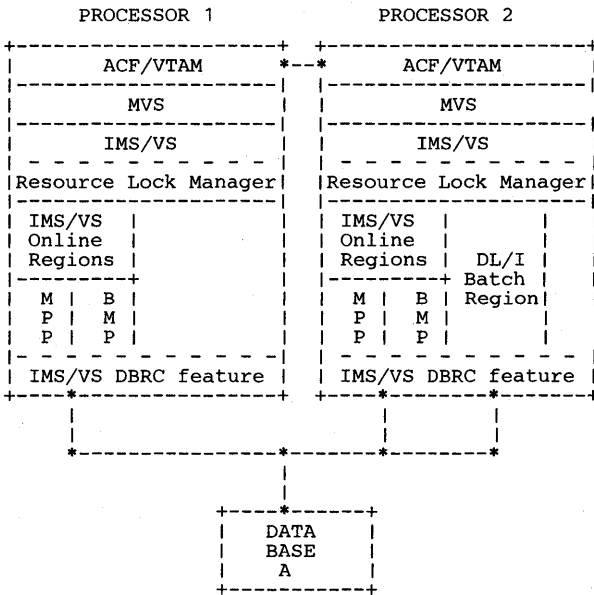

Figure 1. Example Configuration Interprocessor Sharing at Block Level

LEVELS OF SHARING: Two levels of sharing capability are being offered, Data Base Level and Block Level. Data Base Level sharing is available under both OS/VS1 and OS/VS2 MVS operating systems. Block Level sharing is available only on the OS/VS2 MVS operating system. Block Level sharing is defined as locking at a physical block for ISAM/OSAM data bases and at a control interval for VSAM data bases. Data Base Level sharing is defined as locking at the IMS/VS DL/I data base level whether ISAM/OSAM or VSAM.

There are various Read/Update environment rules that apply to both interprocessor and intraprocessor sharing as well as to the level of sharing, Data Base or Block. Figure 2 is a matrix of the Read/Update environments of IMS/VS Data Sharing.

IMS/VS-Data Sharing Read/Update Environments		
For: IMS/VS V1 Release 2	Interprocessor & Intraprocessor Sharing	Operating System VS1/MVS
Data Base Level Sharing	Single Update, All others READ only	VS1 or MVS
BLOCK LEVEL SHARING		
Block Level Sharing	Multiple UPDATES, Multiple READs	MVS only

Figure 2. IMS/VS Data Sharing Read/Update Environment Rules

Referring to Figure 2, interprocessor and intraprocessor sharing have the same Read/Update rules throughout the chart. Depending upon the level of sharing used, the rules are different. The "Read only" term used here includes programs that specify only that READ can run concurrently or includes programs that are willing to run with a single UPDATE.

See the description of DEDB Data Sharing under "Highlights of IMS/VS Version 1 R3".

DATA SHARING LIMITATIONS: The following are IMS/VS Data Sharing limitations:

- The maximum number of processors which can participate at the data base level of sharing is limited by the number of paths to the direct access device(s) upon which the data to be shared resides.
- The maximum number of processors at the block level of sharing is two (2) for an interprocessor configuration.
- Fast Path data bases and GSAM data sets are not supported by IMS/VS Data Sharing.

- Data protection and integrity are ensured at the block level of sharing data. There is an option at the block and data base level of sharing to read uncommitted update data.
- While existing CICS/OS/VS Version 1 Release 5 applications will run with IMS/VS Version 1 Release 2, CICS/OS/VS Version 1 Release 5 does not support the IMS/VS Version 1 Release 2 Data Sharing facility.

3375 Direct Access Storage Device Support: This 3375 Direct Access Storage Device support expands the existing IMS/VS OSAM device support to include Count-Key-Data (CKD) support of the 3375 Storage Facility. IMS/VS also supports 3375 through VSAM in all data formats.

3375 will be supported for use for data bases (HISAM, HIDAM, HDAM and HSAM), including Fast Path data bases, message queues, SPA, and for restart data sets using VSAM and OSAM. Users will be able to migrate data bases to 3375 without modification to application programs. 3375 and non-3375 stored data bases can coexist within an IMS/VS system.

IMS/VS V1 R2's 3375 Direct Access Storage Device support is planned for availability in 3Q81.

Support of Speed Matching Buffer for 3380: This support expands the IMS/VS OSAM device support to allow a high speed data transfer 3380 device to be connected to standard I/O channels through the Speed Matching Buffer feature (#6550) on the 3880 control unit.

IMS/VS V1 R2's support of Speed Matching Buffer for 3380 is planned to be available 4Q81.

DATA COMMUNICATION FEATURE

Printer Sharing: Printer Sharing provides the capability to share LU1, LU4 and 3270P devices with other VTAM based systems.

- IMS/VS will use the VTAM Q RELREQ options when requesting sessions for the above device types when they are defined as sharable units.
- For 3270P sharable devices (non-SNA), IMS/VS will request a VTAM session when the display operator requests COPY.
- A user exit will be provided for devices marked 'SHARE' and will be activated when a message is enqueued for that device and a session is not in effect. The exit may specify the following IMS/VS actions:
 - Proceed with the session request (default).
 - Do not request the session.
 - Schedule a user transaction.

Extended Printer Support (SNA and non-SNA): Extended Functions for SLU1 and 3270 family printers provides the capability for the following types of printers to use the following printer processing features while utilizing Message Format Service.

- Printers that use SLU1 SNA Character Data Streams (SCS1) and defined as SCS1.
 - For these SNA printers it will be possible to set vertical forms on a message by message basis, to set line density without losing a print line, and to use the extended presentation of data (color, highlighting, and programmed symbols) through Message Format Service (MFS).
- Printers Defined as 3270P.
 - For these non-SNA printers it will be possible to use the extended presentation of data (color, highlighting, and programmed symbols) through Message Format Service (MFS).

3604 Administrative Keyboard Display Model 7 Support: This support expands the IBM 3604 Administrative Keyboard Display mdl 7. Support extends the IMS/VS support of 3600 displays to include the 3604 mdl 7 with its larger screen size (24x80). Message Format service (MFS) can be utilized to format the 3604 mdl 7 screens. The MFS support is the same as that which was previously provided for 3600 displays.

Cross-Memory Services for Local Storage Option: Local Storage Option facility with Cross-Memory support extends the use of the Local Storage Option (LSO), available in IMS/VS V1 R1.6, by allowing LSO to run on MVS/System Program Release 2 utilizing the MVS Cross Memory services. This new LSO facility enables installations to optionally specify at IMS/VS system initialization time the selection of LSO with Cross Memory support.

The LSO, available in R1.6, necessitates the switching of execution from the dependent region TCB to a TCB in the control region. The new LSO with Cross Memory support available in IMS/VS V1 R2 eliminates the need to switch from a dependent region TCB to a control region TCB, while still providing parallel execution. It does this by using the Cross Memory Services in MVS/System Product Release 2. This capability allows the transfer of control from code in one memory to

IMS/VS (cont'd)

code in another, while retaining and utilizing the execution structure of the original memory.

Additional Highlights of IMS/VS V1 R2

Multiple OSAM Data Base Subpools: There can be multiple OSAM data base subpools of the same size. Each OSAM pool will carry a unique identifier that will allow specific data base data sets to be directed to a designated subpool at execution time and can be used to optimize buffer pool allocations to the unique reference characteristics of a data base. This permits further allocation of buffer pool resources to establish performance priority.

Log Tape Compatibility: With the introduction of Data Sharing, some log tape records have been modified to record the appropriate information necessary to provide the system restart and data base recovery. In order to maximize log tape compatibility between IMS/VS V1 R2 and prior releases, any new information will be added at the end of the existing log record data and before the sequence number.

Application Return Codes: Under processing options GOT and GON, a status code will be returned to an application program when the segment that the application program is trying to retrieve contains an invalid pointer. Previously, IMS/VS terminated the application program abnormally.

Increased Security Generation Limits: The IMS/VS security table size limitation of 32K bytes has been removed. The security table now has no specified size limit and is only bounded by practical resource limits. This aids the user that has extensive growth in the terminal networks and applications, resulting in more securable resources.

Improved Sort in System Definition: The internal SORT algorithm function of the IMS/VS System Definition Stage 2 has been improved to reduce the amount of time required to sort large numbers of system descriptors. The degree of improvement will vary depending on the number of resources defined to the System Definition.

Additional Trace Capabilities: There are three (3) new functions added to the IMS/VS trace capabilities.

- Lock activity of certain DL/I modules will be recorded in a trace table.
- Trace table activity can optionally be recorded on the log tape.
- Start and stop of all traces can be done from the IMS/VS master terminal or an IMS/VS procedure library member.

VSAM/OSAM Open for Input: VSAM/OSAM data sets will be opened for input if read processing intent is defined for the data base containing the data sets, otherwise the VSAM/OSAM data sets will be opened as usual for read and write.

Log Terminated Message: When the Log has been terminated, a confirmation message is sent to the master terminal operator and system console.

Single Message Dequeue: The /DEQUEUE command is enhanced to allow the next message to be sent from an LTERM to be deleted.

DATA BASE RECOVERY CONTROL FEATURE: The Data Base Recovery Control feature (DBRC) of IMS/VS Version 1 Release 2 has been enhanced to support the Data Sharing facility. The Data Sharing facility in IMS/VS Version 1 Release 2 requires DBRC for an IMS/VS system to share IMS/VS DL/I data bases with another IMS/VS system. DBRC is optional if the IMS/VS data sharing facility is not being used. The authorization process for data sharing determines if the IMS/VS system is registered and if the intended use of a data base is allowable.

A more complete description of the content of the facilities of DBRC in IMS/VS Version 1 Release 2 follows.

Data Sharing Support: DBRC supports the sharing of the IMS/VS DL/I data bases by multiple IMS/VS systems through the addition of exit routines for:

- Registering or deleting an IMS/VS system with DBRC.
- Authorizing the reading or updating of data bases.
- Setting or resetting data base status information when IMS/VS global commands are used.
- Closing data bases to remove their authorization.
- DSLOG log merge capabilities.

IMS/VS Utility Support: The automatic recording of recovery data in the RECON data set is achieved through exits to DBRC in the standard IMS/VS utilities. Additional IMS/VS utilities which now interface to DBRC are HISAM Reorganization Reload, HD Reorganization Reload, System Log Recovery, DEDB Log Tape Check and Copy, Data Base Backout and Prefix Update.

IMS/VS Control Program Interfaces: The IMS/VS control program provides exits which can give control to DBRC for recording information to be used in a recovery operation. These exits to DBRC provide the following functions:

- Processing of log tapes for use in the recovery process.

- Automatically allocating data bases from the online IMS/VS system.
- Signing an IMS/VS system on or off with DBRC.
- Authorizing or prohibiting use of an IMS/VS DL/I data base.
- Supporting a set of IMS/VS global commands.
- Opening a data base and ensuring that only one RECON data set pair contains the most current recovery generation information.
- Recording the detection on an I/O error on a data base.
- Recording the occurrence of a dynamic backout failure.
- Recording the occurrence of an ESTAE failure.
- Closing a data base to eliminate the IMS/VS system authorization of a data base.

DBRC Control Statements as IMS/VS Commands: A group of IMS/VS commands permits the master terminal operator or other authorized terminal users to invoke specific DBRC utilities through the IMS/VS commands. Therefore, an authorized terminal operator can read, display and change information in the RECON data set.

Enhancements to the DBRC Installation Process: An improved installation macro is provided that generates the JCL to install DBRC. This macro permits the user to add keywords in the JCL, to change or override the generated statements and to specify the data set names of the DBRC module libraries.

HIGHLIGHTS OF IMS/VS VERSION 1 RELEASE 3

NEW PROGRAMMING FACILITIES

DASD LOGGING: A new Logging feature is being introduced in IMS/VS with this release. It extends the use of DASD that has evolved over several releases to become a full DASD logging capability for log recording, dynamic backout, and restart activities. The IMS/VS online system log records will be written to DASD data sets. Multiple disk data sets will be used in a wraparound fashion. When filled, the online log must be archived. Archiving copies log data to a tape, disk or MSS data set. Archiving may be initiated automatically or manually at the user's option. Logging to DASD may also be used in IMS/VS batch systems. If desired, batch logging to tape may go directly to an archive data set.

The new IMS/VS Logging feature replaces the former online tape logging, dynamic logging, and restart disk logging. Tape logging for online IMS/VS systems will no longer be supported. Tape OSAM (TOSAM) is no longer supported.

IMS/VS V1 data communications now supports Log Write Ahead (LWA). For certain failures, under previous IMS/VS V1 releases, it was necessary to close the IMS/VS V1 system log using a main storage dump. With IMS/VS V1 R3, this is no longer necessary.

ENHANCED DATA BASE RECOVERY CONTROL (DBRC): The following enhancements are new in DBRC with IMS/VS Version 1 Release 3:

DASD Logging Support - A new Log Control function will be used to manage the online DASD log and it will be used to provide System Control facilities for the online DASD log, as well as for the archived log data sets.

Improved Fast Path DEDB Support - The DBRC function is also used to support sharing of DEDBs and DEDB's multiple Area data sets.

DBRC Generation Process Included in IMS/VS Process - The system generation process of IMS/VS includes the generation process of DBRC.

Virtual Storage Consideration - For IMS/VS online in MVS, DBRC will execute in a separate address space, eliminating increased storage requirements in the IMS/VS Control Region.

Command Improvements - New commands have been introduced to add information to the RECON data sets about the execution of the Image Copy and the Change Accumulation utilities.

Integrity Improvements - Options are provided on the INIT and CHANGE commands to force DBRC registration of all data bases, permitting users to increase operational integrity.

Optional Data Sharing Control - An option is provided to permit an installation to select the level of DBRC control desired. This allows for the use of DBRC for recovery and/or log control without introducing the added complexities of the data sharing environment.

RECON Recovery Online - RECON duality is now system maintained if the user assigns a spare RECON data set. In the event of RECON data set errors, the spare data set automatically replaces the failing data set.

RECON Reorganization Online - RECON Reorganization can be accomplished online via command.

Start Subsystems with one RECON - The user now has the option to allow IMS/VS subsystems to start with only a single RECON data set.

PROGRAM PRODUCTS

IMS/VS (cont'd)

Dynamic Allocation of RECON in MVS - Dynamic allocation of RECON data sets is optionally supported in the MVS environment.

Image Copy Recovery Period Support - In addition to the fixed cycle of Image Copy data sets identified by the user for each data base data set, a retention period may be specified to prevent the premature reuse of Image Copies.

Time Stamp Change Accumulation - Support is provided for executing the Change Accumulation Utility using a subset of log volumes.

Improved DSLOG Error Handling - On output error, the DSLOG Utility will continue to process logs to all output data sets that are not in error.

Migration and Coexistence - DBRC RECON data sets from previous releases of IMS/VS can be upgraded by command to IMS/VS V1 Release 3 format. DBRC fallback capability for IMS/VS Release 3 and/or coexistence with IMS/VS V1 Release 2 will be provided through the service process. IMS/VS V1 Release 1.6 DBRC fallback/coexistence is not supported.

ADDITIONAL DATA BASE RECOVERY CONTROL ENHANCEMENTS

- DBRC trace is extended to allow the use of a generalized trace facility (GTF) data set as an external trace table, in addition to the internal wrap-around trace table. This will assist diagnosis when the problem does not cause an ABEND. (This enhancement is also applicable to the CICS/OS/VS - DL/I environment.)
- Enhancements have been made to the online DBRC commands so they may be issued through an automated operator interface (AOI) application. The command output is sent as a single message (single or multi-segment).
- Command enhancements include additional flexibility for DELETE.LOG and LIST.DB commands. The NOTIFY.RECOV command has been extended to simplify RECON recovery. (This enhancement is also applicable to the CICS/OS/VS - DL/I environment.)
- A new SYSGEN parameter is provided to permit the installation to force DBRC use from any batch applications by overriding the execution-time parameter. (This enhancement is also applicable to the CICS/OS/VS - DL/I environment.)

ONLINE CHANGE: The capability is offered to introduce new system libraries online. The following resources may be added, changed, or deleted without bringing down IMS/VS: Data bases (excluding DEDBs and MSDBs), programs, transactions, MFS formats, ACBs, IMS/VS V1 security definitions, and Fast Path routing codes.

The ability to make online modifications makes the system more adaptable to changing needs, and allows longer periods of continued operation.

DATA SHARING ENHANCEMENT: The IMS/VS V1 Data Sharing Facility, introduced in IMS/VS V1 R2, has been enhanced to include Data Entry Data Bases (DEDBs).

- **DEDB Data Sharing** - Data sharing makes it possible for Fast Path application programs in separate IMS/VS systems, and in the same or separate IMS/VS processors, to access the same DEDB. Data sharing is not supported for MSDBs.

Fast path application programs and IMS/VS online application programs (mixed mode) in IMS/VS systems can share DEDBs; IMS/VS batch programs cannot access DEDBs.

IMS/VS systems may share DEDBs at the Area level or the Block level:

- When IMS/VS systems share a DEDB at the *Area level*, application programs in each IMS/VS system can read the data concurrently; or one IMS/VS system can update the data while the other IMS/VS systems have read-only access to it. Read-only access means that application programs are able to read the data, but they are not protected from reading data that is inconsistent. At the area level, IMS/VS systems share an area of the DEDB.
- When sharing at the *Block level*, several application programs in different IMS/VS systems on up to two processors may read or update the data concurrently. Readers are protected from reading inconsistent data. Block level data sharing is supported only for DEDBs that do not contain a sequential dependent segment type.

MVS/XA PORTABILITY SUPPORT: This release of IMS/VS integrates the support for MVS/XA SP V2 R1. In addition, it provides for upward system portability between MVS/SP V1 R3 and MVS/SP V2 R1. For example, a system generated on MVS/SP V1 R3 may be executed on an MVS/SP V2 R1 system. Thus, an IMS/VS Version 1 Release 3 system generated on MVS/SP V1 R3 can be installed on MVS/SP V1 R3 or MVS/SP V2 R1 and operate properly in either of these environments. A system generated on MVS/SP V2 R1 will operate only in that environment.

OSAM BUFFERS ABOVE 16M REAL STORAGE: OSAM buffers may reside in real storage above 16 megabytes if the user does an IMS/VS Version

1 Release 3 system generation on MVS/SP V2 R1 specifying the MVS/SP V2 R1 environment and has real storage in excess of 16M available.

VIRTUAL STORAGE CONSTRAINT RELIEF: With this release, IMS/VS will dramatically reduce the virtual storage requirements of the control region by movement of the IMS/VS Data Base function into a separate address space. Additional virtual storage constraint relief is achieved in an MVS/XA environment by Message Format Service (MFS) use of greater than 16-megabyte addressing. These capabilities add to the previously announced reduced virtual storage requirements of IMS/VS V1 R3, which were:

- DBRC in a separate address space in an IMS/VS DC environment.
- IRLM with cross-memory option has reduced CSA requirements.

The additional virtual storage made available in an IMS/VS system can be used (currently constrained by the lack of available virtual storage) for:

1. Increasing pool sizes.
2. Allowing growth in terminals and applications.
3. Flexibility in allocation of private area and common areas.
4. Reallocation of virtual storage to the above item may result in improved transaction rate.

IMS/VS V1 Data Base (DL/I) Separate Address Space: The Data Base (DL/I) separate address space in an IMS/VS V1 online (DB/DC) system running under MVS/XA or MVS/370, is an optional subordinate address space which contains most DL/I-related code, control blocks, and buffers for all the DL/I data bases on that system.

Local Storage Options allow the user to balance the storage allocated in the common area with the storage allocated to the private area. The Data Base separate address space option allows this storage to be allocated in a new address space, thereby providing virtual storage savings in both CSA and private memory.

The Data Base separate address space does not apply to Fast Path data bases, and is not applicable to the CICS/OS/VS - DL/I environment.

Note: For CICS/OS/VS - DL/I, virtual storage constraint relief continues to be provided in both the MVS/XA and MVS/370 environment by the CICS/OS/VS MRO facility and, additionally, by the CICS/OS/VS EXEC DLI command support and the CICS/OS/VS 31-bit mode application support in the MVS/XA environment.

MFS Utilization of MVS/XA Capabilities: In an MVS/XA environment, the MFS format pool, fetch request elements and directories will be moved to extended private storage.

The use of extended private storage addressing capabilities of MVS/XA can result in:

1. Better utilization of large real main storage.
2. More effective use of processor capability.

Reduced VSAM Pool Requirements: The minimum required number of buffers to be allocated to a VSAM buffer pool is reduced by three per CI size defined. In some cases, buffer pools larger than required were being created. The new algorithm will allow smaller buffer pools. The DL/I user selects the optimum number of buffers to meet the performance requirements of the system. The previous minimum was determined by application regions or CICS threads defined.

EXTENSIONS to DEDB STRUCTURE: DEDB's capabilities have been extended by:

- **Improved DEDB Structure for Flexibility** - The DEDB structure has been expanded. A DEDB can now contain up to 127 segment types, and up to 15 hierarchical levels, providing more flexibility in data base design and application programming. The 127 segment types can include one sequential dependent segment type, if desired.
- **Physical Child Last Pointer for Insert Performance** - Installations can now specify that they want new segments to be inserted at the end of a sequence of unkeyed segments. A physical child last pointer is used to make this insertion instead of traversing all the segments ahead of it.
- **DEDB Subset Pointers** - DEDB subset pointers allow direct access within a chain of DEDB direct dependent segments. Up to eight subset pointers may be defined per direct dependent segment type and used independently. This function may provide performance benefits for DEDBs with long twin chains of direct dependent segments.

Improved DEDB Availability

- **Block Deactivation** - In previous releases, all write errors stopped all access to the DEDB Area containing the write error. Other application programs and online users were unable to access any of the data in that Area until the write error was resolved.

PROGRAM PRODUCTS

IMS/VS (cont'd)

With this enhancement, if an I/O error occurs, any program trying to read the block of the data base in error will receive a status code indicating the error condition, the block will be deactivated, and the application program can then continue with other processing.

- **Multiple Area Data Set Support** - It is now possible to provide multiple copies of a DEDB Area. The advantage of this is in the protection it gives against data base I/O errors; if there is an error in one Area data set and an additional copy of that Area data set exists without an error, the system will access valid data from the alternate copy. Installations may define and create new copies of an Area online without stopping the Area. Only one copy at a time will be read from, but all copies will be updated concurrently.

FAST PATH APPLICATION PROGRAM ENHANCEMENTS

- **Multiple Segment Search Arguments** - Application program processing Data Entry Data Bases (DEDBs) may take advantage of the expanded DEDB structure by specifying up to fifteen Segment Search Arguments (SSAs) in data base calls. In previous releases, application programs were limited to one SSA when accessing a DEDB. Multiple SSAs provide more processing capabilities for application programs and may reduce the number of data base calls necessary to retrieve data from a DEDB.
- **Boolean Operators** - Fast Path application programs may specify multiple qualification statements in an SSA by using Boolean operators. With Boolean operators, the application program provides multiple search arguments to be used to determine if the segment can satisfy the data base call. Calls to DEDBs cannot use the independent AND, as it is only used for secondary indexing.
- **Command Codes** - Data base calls in application programs processing DEDBs may now make use of Command Codes in SSAs. Calls to DEDBs can use all the Command Codes except 'Q'. In addition, five new Command Codes are supported for use with the new Subset Pointer facility. Fast Path ignores Command Codes in calls processing sequential dependent segments.

SINGLE LOCK MANAGER: The Single Lock Manager allows MVS installations to utilize IMS/VS Resource Lock Manager (IRLM) or Program Isolation (PI) Lock Manager for locking services. When IRLM is specified, all locking services will be provided by IRLM. The IRLM is required for block level data sharing.

IRLM CROSS MEMORY SUPPORT: The IMS/VS Resource Lock Manager (IRLM) optionally supports the use of MVS Cross Memory. This provides for the movement of blocks and code from Common Storage Area (CSA) to the IRLM's private address space. If IRLM is used for program isolation, the CSA demands for program isolation may also be reduced.

255 USER-DEPENDENT REGIONS: If your operating system is OS/VS2 MVS or MVS/XA, the architectural limit has been increased from 31 to 255 for the number of concurrent, user-dependent regions and Fast Path output threads.

SYSTEM DEFINITION PERFORMANCE IMPROVEMENTS: An optional preprocessor has been introduced whose purpose is to perform name checking. The sorting which has been performed in Stage 2 will now be optionally performed in Stage 1 of system definition. The sort has been rewritten. The amount of performance improvement which will be realized is a function of the number of objects defined. The larger the number of objects, the larger will be the performance improvement. With a small number of objects, the improvement in performance may be up to 10%. With a large number of objects in system definition, the performance improvement may be up to 90% for control block system definition.

EXTENDED SYSTEM DEFINITION LIMITS: The limit of 5,000 occurrences for IMS/VS system definition macro statements has been removed for some macros, when Assembler H is used for the Stage 1 assembly. The DATABASE macro has a new limit of 32,700. For APPLCTN, TRANSACT, STATION, TYPE, TERMINAL, NAME, RTCODE, and SUBPOOL macros, there will be no limit other than the storage resources available to the system. If Assembler F is used, the maximum remains at 5,000.

IMS/VS VERSION 1 RELEASE 3 DL/I with CICS/OS/VS VERSION 1 RELEASE 6: IMS/VS Version 1 Release 3 only supports CICS/OS/VS Version 1 Release 6. IMS/VS Version 1 Release 3 is supported by CICS/OS/VS Version 1 Release 6. The following enhancements for the CICS/OS/VS-DL/I user will be available at general availability of IMS/VS Version 1 Release 3.

- **CICS/OS/VS DL/I Command Level Interface Support** - The CICS/OS/VS COBOL or PL/I programmer is provided with a new set of EXEC DLI commands for processing IMS/VS data bases in a CICS/OS/VS environment, including online, CICS/VS Shared Data Base, and IMS/VS DL/I Batch applications. The EXEC DLI language is supported by the CICS Execution Diagnostic Facility (CEDF), is upward compatible with the DL/I DOS/VS EXEC DLI language, and is extended for IMS/VS functions.

- In the OS/VS2 MVS or MVS/XA environments, the number of concurrent DL/I transactions supported by CICS/OS/VS V1 R6 is increased from 31 to 255.
- New initialization options available in CICS/OS/VS V1 R6 enable the IMS/VS V1 R3 user:
 1. To load and access IMS/VS modules in the Link Pack Area (LPA), for improved system integrity.
 2. To page fix ISAM/OSAM buffers for performance tuning.
- IMS/VS V1 R3 users will not need to create a CICS/OS/VS Program Specification Block (PSB) for configuring the IMS/VS nucleus at CICS/OS/VS initialization.
- CICS/OS/VS modules do not have to be link-edited with IMS/VS V1 R3 modules. Therefore, the IMS/VS load library is not required during CICS/OS/VS V1 R1.6 generation, and in addition, application of IMS/VS maintenance to a CICS/DL-I system is simplified.
- **CICS/OS/VS-DL/I Primer Sample Programs** - Code will be provided to support the CICS/OS/VS-DL/I Primer sample programs. This code will be integrated with the IMS/VS Primer code from previous releases of IMS/VS and will be distributed as a part of the IMS/VS V1 R3 Data Base System.

ENHANCED BMP RESTART: When restarting a Batch Message Processing program (BMP), it is no longer necessary to specify the exact checkpoint-id nor to change the JCL to point to the appropriate log. If the user chooses to use the enhanced BMP restart facilities, the BMP will restart from the last checkpoint-id without the need to mount log tapes, provided that the checkpoint data is on the online disk log.

IMPROVED MFS FORMAT POOL MANAGEMENT: The following improvements have been made to improve the performance and usability characteristics of the IMS/VS online DB/DC system:

- A new dynamic directory will be utilized. This will allow the user to specify the base directories content at initialization. Additional entries will be added dynamically by MFS as new formats are fetched during online execution. (MVS/XA only)
- Multiple concurrent I/O operations to the format library will be supported for retrieving format blocks. (MVS/XA only)
- MFS now supports up to 16 concatenated format libraries when executing in an MVS/XA environment.
- MFS buffer pool manager will utilize page load/page release to reduce page faults in the IMS/VS control region address space during MFS operations.
- A new hashing algorithm is provided to improve the performance of the MFS pool manager by reducing the search time to service a format fetch request.
- In addition to the above, existing limits on the following MFS objects are increased as indicated below:
 - The maximum MFS format pool will be increased to 99,999,000 bytes from the current limit of 999,000 bytes.
 - The maximum number of fetch request elements (FRE) is increased to 99,999 from the current limit of 65,536 (64K).

USABILITY ENHANCEMENTS

- The process of restarting a BMP has been simplified when its checkpoint records exist in the online log data set. It is no longer necessary to specify the checkpoint ID at restart time. This simplifies the overall process of restarting IMS/VS and BMPs which were executing at the time of an online IMS/VS or operating system failure. BMP application programs which fail may also be independently restarted so long as the checkpoint records still reside on the online log data set (OLDS).
- The Dequeue command is simplified by providing SINGLE, SNGL, and FIRST as synonyms for the PURGE1 parameter for purging the first message on the specified queue.
- Enhancements to the MFS language utility are added to ensure maximum available format library space for adding/changing descriptor members, and to eliminate unnecessary overhead in the maintenance of the PDS directory. Specifically, STOW-REPLACE will be used for changed format blocks, and an additional compress option is provided prior to the termination of phase 2 processing.
- The unconditional opening of all libraries by the MFS service utility is replaced by opening only the libraries required by the function requested. This will minimize an operator reply requirement when any of the libraries are data- or password-protected.

AVAILABILITY ENHANCEMENTS

- Selective dispatching enhancements have been made to reduce communication pool deadlocks during periods of unexpected high activity. Additional statistics are also provided on the log for later analysis and tuning.

PROGRAM PRODUCTS

IMS/VS (cont'd)

- As a part of the control region restructure with additional tasks, several potential wait conditions have been removed.
- Log latch contention has been reduced for simple checkpoint.

SERVICEABILITY ENHANCEMENTS

- The Lock Activity Trace Table has been merged with the DL/I Trace Table to ease debugging.
- Symbolic identifiers have been added to many control blocks to aid problem determination.
- Tracing facilities are extended to include additional resources to be traced, and optional logging.

GENERAL ENAHNCEMENTS

- SMP4 installation samples are included in the *IMS/VS V1 Primer Function Installation Guide* (SH20-9208).
- IMS/VS support is extended for IMS Message Re-queue (MR, 5796-ATP), Batch Terminal Simulator (BTS, 5668-948), and IMS Queue Loader (IQL, 5785-GAJ) so that installation of the aids is simpler and modifications to IMS/VS are no longer required.
- A warning message is available when the message queue data set reaches a user-specified threshold.
- CWAP can now be specified up to 9,999K.
- PSB size limits are increased to 512K. (Still 64K in CICS/OS/VS.)
- The number of Sensitive segments (SENSEG) is increased to 1,000.
- Symbolic parameters have been added to the DFSMPR procedure to simplify overriding positional parameters.

NEW PRODUCTS and DEVICES

NETWORK TERMINAL OPTION (NTO) DEVICE SUPPORT: The Network Terminal Option (NTO) program product (5735-XX7) is supported by IMS/VS for 33/35 Teletype and 274X start-stop devices. Terminals such as 3101, 3232 and S/23 that are compatible with the above terminals may be used. MFS SLU-1 console support is provided for these NTO attached terminals.

4700 FINANCE COMMUNICATION SYSTEM: The 4700 Finance Communication System is supported by IMS/VS. This support is functionally equivalent to the IMS/VS support of the 3600 Finance Communication System.

3290 INFORMATION PANEL SUPPORT: The 3290 Information Panel is supported as a 3270 and SLU-2. MFS supports full-screen addressability. The 3290 provides, in IMS/VS V1 R3, a screen size of 62 lines with 160 characters per line to allow more application flexibility. Full-screen addressing capability provides for more effective use of products such as the Report Management and Distribution System (RMDS, 5665-310).

DATABASE 2 ATTACHMENT SUPPORT: The Database 2 (DB2, 5740-XYR) offers relational data base capabilities for the MVS/XA and MVS/370 environments. DB2, through the Structured Query Language (SQL) supports data definition, retrieval, manipulation, and control operations. IMS/VS V1 R3 Data Communication feature (DC) attaches to DB2, providing relational data base capabilities in addition to those previously available through DL/I (full-function) and Fast Path. DB2 data may be accessed concurrently from IMS/VS V1 R3 Message Processing programs (MPP) and IMS/VS V1 R3 Batch Message Processing programs (BMP) and IMS/VS V1 R3 Fast Path programs.

Current application programs using DL/I data bases are not affected. New application programs may use the facilities of both DL/I and DB2 data bases.

In an environment with IMS/VS applications accessing DB2 data, IMS/VS V1 R3 DC coordinates recovery with DB2 so that potential inconsistencies can be resolved without loss of data.

Operator-issued commands are routed to DB2 to display and control the status of both the DB2 subsystem and its individual data bases.

For additional information about DB2, see pages for 5740-XYR.

Data Extract (DXT, 5668-973), announced with DB2, provides a method of selectively extracting data from existing IMS/VS data bases, VSAM and SAM files. This extracted data may then be loaded into DB2 tables. The primary benefits to the IMS/VS V1 R3 user are:

- Query Management Facility (QMF, 5668-972) access to operational data.
- IMS/VS V1 R3 access to data currently maintained in SAM/VSAM.

See pages for PP 568-972 and 5668-973.

FEATURES

New product packaging occurs in R3 where Fast Path and Multiple Systems Coupling are no longer separate features, but are a part of the IMS/VS Data Communications feature. The Data Base Recovery Control (DBRC) feature and the new Logging feature are packaged with the IMS/VS Data Base System, since they are required for its proper system definition, installation and operation.

Multiple Systems Coupling Feature Including Intersystem Communication: The Multiple Systems Coupling (MSC) feature is an IMS/VS feature. MSC extends the message routing facilities of IMS/VS to include transactions and logical terminals in other IMS/VS systems. The MSC feature allows these message routing facilities to occur between two or more IMS/VS DB/DC systems in one or more S/370(s) (UP or MP/AP).

Multiple Systems Coupling supports IMS/VS functions the way they are today, that is, transactions (messages), responses, program-to-program switches, and fixed-length conversational Scratch Areas, but on two or more IMS/VS DB/DC Systems. MSC allows the routing of messages through an intermediate IMS/VS system (and return) at the destination IMS/VS system for processing. In addition MSC Directed Routing allows an application program to specify the multiple system name (MSNAME) and destination within that system for a message. Routing is performed based on destination name (transaction code or logical terminal name).

IMS/VS Multiple Systems Coupling system-to-system communication is established by the following Multiple Systems Coupling connection types:

- Binary synchronous (BISYNC) communication line (BSC) which requires Basic Telecommunications Access Method (BTAM) and supports point-to-point contention mode (BSC1). BSC operates under OS/VS1 and OS/VS2 (MVS).
- Channel-to-channel adapter (CTC) (OS/VS2 (MVS) only). If the MSC feature of IMS/VS uses a CTC adapter, this adapter must be separate from any CTC adapter that is used by ASP, JES2-NJE or JES3.
- Main storage-to-main storage communication between two IMS/VS systems which reside in the same S/370. (Only one IMS/VS system will use VSAM global shared resources. The other IMS/VS system will not use parallel DL/I to process calls against a VSAM data base; VSAM calls will be processed in the IMS/VS control region.)
- VTAM using the LU 6 protocols which require the advanced communication function for Virtual Telecommunications Access Method (ACF/VTAM). LU 6 operates under OS/VS1 and OS/VS2 MVS.

In addition, the MSC feature permits communication between IMS/VS and another system (such as CICS/VS, a user-written system or another IMS/VS system) with the use of the Intersystem Communication function of MSC. With Intersystem Communication, users of other systems can use IMS/VS application programs, data bases (through user-written application programs), and terminals. Intersystem Communication uses an IMS/VS subset of the Logical Unit 6 (LU 6) protocols with the following functions:

- Parallel sessions.
- DPM through MFS support.
- Negotiable Session Initialization Parameters (BIND).
- Common system protocols.
- Architected system data stream formatting.

With Intersystem Communication, users in other systems can access IMS/VS data bases through IMS/VS application programs without changing the IMS/VS application programs. Intersystem Communication is available in both OS/VS1 and OS/VS2 (MVS).

Enhancements to Intersystem Communication (ISC)

- Simplification of SNA Protocols for Non-response Transactions and Unsolicited Output
 - For the Intersystem Communication user, the SNA protocols required to handle non-response transactions and unsolicited output have been simplified by reducing the number and types of SNA headers required to perform these functions.
- Error Recovery Enhancements
 - Discrimination in error handling is improved so that some errors detected on an Intersystem Communication session between IMS/VS and CICS/VS which previously caused the session to be terminated will generate an error message to the MTO and allow the session to continue.
- Improved Handling of Intersystem Communication Message Switches

PROGRAM PRODUCTS

IMS/VS (cont'd)

- If an Intersystem Communication Message Switch is sent to another system and is rejected by that system, the message switch will be deleted from the IMS/VS message queues and the error message will be routed back to the source terminal without terminating the Intersystem Communication session.

The Data Base system and the Data Communication feature of IMS/VS are prerequisites of the Multiple Systems Coupling feature.

Each IMS/VS System in an MSC configuration maintains its own recoverability. The device-dependent modules (DDM) of the physical connections were designed to ensure that messages are neither lost nor duplicated between two systems in the event of transmission or system failure. Commands allow changing the relationship between connections dynamically. Physical connections can be backed up by other connections. An unavailable S/370 can be backed up by another S/370. The corresponding IMS/VS System is executed in the backup S/370 and the involved connections are properly reassigned by the master terminal operator. Data and communication facilities involved must be sharable between systems. In addition, where the backup link is either BSC or channel-to-channel it must be exclusively allocated for that use.

Current IMS/VS functions are compatible between a non-MSC system and a Multiple Systems Coupling environment, thus providing upward growth and compatibility. The requirement is for fixed-length SPAs in MSC conversational transactions. No restriction applies to the support of IMS/VS Message Format Service-supported terminals, even if the processing is done in different IMS/VS Systems.

Message Format Service provides the same services and the same interface to application programs as in a non-MSC system environment. IMS/VS Message Format Service is not involved in any Multiple Systems Coupling system-to-system communication.

Conversational processing provides the same capabilities (using fixed-length SPAs) in a Multiple Systems Coupling environment as in a non-MSC IMS/VS System. Multiple Systems Coupling operation is normally transparent to both terminal users and application programs.

Program-to-program switches may be performed over system boundaries, and conversational steps may be processed in any system of the Multiple Systems Coupling configuration, independent of the location of the transaction initiating terminal.

IMS/VS system definition provides facilities to define the destinations (transactions and logical terminal names) which belong to another system of the MSC configuration. These remote designations determine the required Multiple Systems Coupling routing. Routing exit routines allow the user to customize the Multiple Systems Coupling routing and to avoid repetitive definitions for the same destination. Also, the types of connections and their relationships are defined during system definition.

There are three routing exit routines; Terminal Routing, Program Routing and Link Routing Exit. These routines are optional and user-provided.

The distribution of IMS/VS functions and resources may improve response times for transactions if the configuration is designed such that; (a) critical transactions are processed entirely in the system to which the terminal is attached, and (b) long-running transactions are routed to another system to avoid resource contention.

Two IMS/VS facilities are provided to recognize definition inconsistencies in an MSC configuration. The /MSVERIFY command may be used in the online environment to display inconsistencies between two systems. The IMS/VS MSC Verification Utility is an offline utility program which should be used to detect inconsistencies in the definition of two or more IMS/VS MSC systems.

Each IMS/VS system in a Multiple Systems Coupling configuration is operationally an independent unit. It exclusively owns its resources. That is, each system is controlled by its own master terminal.

The IMS/VS security facility applies to a Multiple Systems Coupling environment. Security maintenance is performed independently on a system basis. An IMS/VS Multiple Systems Coupling system may use transaction security to prevent transactions sent by unauthorized systems from being processed.

Statistics can be produced for a complete IMS/VS Multiple Systems Coupling configuration. The system log tapes will be merged (by a utility provided by MSC) from the separate systems into one data set. This data set will be in order by date and time and can then be processed by the standard IMS/VS statistics modules.

The following are additional IMS/VS DC Monitor reports that are available for Multiple Systems Coupling:

- MSC Traffic Report.
- MSC Queuing Summary Report.
- MSC Traffic Summary Report.

Fast Path Feature: See the description of improved Fast Path function under section "Highlights of IMS/VS Version 1 R3".

The Fast Path feature is a compatible extension of IMS/VS which is designed to enable the user to select either improved performance for simply structured transactions or full function for complex transactions, depending on the requirements of particular applications. Fast Path provides new facilities for those applications which need only selected IMS/VS function and a simple data structure, and may have large transaction volumes.

Major elements of the feature are expedited message handling, two new types of data bases and a new approach to data integrity and recovery through synchronization point processing. Highlights of each of these facilities follow.

Expedited Message Handling

- Utilizes DL/I calls and maintains the DL/I interface in support of expedited message processing.
- Dynamic selection and routing of input messages to either Fast Path processing or normal IMS/VS processing.
- Single-segment messages utilizing a buffer for each terminal accelerates the message flow through the system.
- Use of transaction response mode of operation.
- An output message is returned to the same terminal that originated the input. The response may be routed to a different component of the same physical terminal by use of the response alternate PCB. (Conversational processing and message switching are not available.)
- Fast Path, using an alternate terminal PCB, enables output from both message-driven and nonmessage-driven programs to be sent to:
 - A different logical terminal (LTERM) on the same IMS/VS system or another IMS/VS system using the MSC feature.
 - An IMS/VS application program on the same IMS/VS system or another IMS/VS system using the MSC feature.
- For the OS/VS2 (MVS) user, use of VTAM Authorized Path as supported by IMS/VS.
- A Load Balancing Group (LBG) scheduling approach combining IMS/VS facilities:
 - Multiple application copies.
 - Wait-for-input.
 - A Fast Path facility, employing simplified FIFO message queue management, speeds transaction processing. (The normal IMS/VS transaction message queuing and application scheduling facilities are bypassed.)
- Application independence is provided for a variety of storage devices and communication devices using VTAM or BTAM. (See the terminal chart under "Data Communications" for details.)
- Message Format Service.
- Use of protocol with 3600 and SLU P.

Main Storage Data Base

- A root only fixed length segment data base facility residing in main storage --- Main Storage Data Base (MSDB).
- Four types of MSDBs available to support application requirements.
- Use of DL/I calls, thus maintaining the DL/I interface for MSDBs.
- One DL/I call to permit access to data at the field level (Field) and the use of one call instead of two to update data.
- Two utilities to support maintenance and recovery.

Data Entry Data Base

- An additional data base facility residing on direct access storage --- Data Entry Data Base (DEDB).
This facility is designed to handle applications requiring the collection of a large volume of detailed data, with master record update capability available if desired.
- Data Entry Data Base organization containing a root segment type and a maximum of seven dependent types, one of which may be a sequential dependent segment, the others being called direct-dependent segments.
- DEDB provides data base partitioning which enables application processing to continue when all partitions of the data base are not online either planned or unplanned.
- A maximum of 240 DEDB areas (data sets) may be specified per data base.
- Use of VSAM Improved Control Interval Processing by DEDBs.
- Use of SRB interface to VSAM for MVS.
- Use of DL/I calls, thus maintaining the DL/I interface for DEDBs.
- One DL/I call to assist in effective utilization of DEDBs (Position).

IMS/VS (cont'd)

- Four utilities to provide support for formatting, extraction, deletion and reorganization.

Synchronization Point Processing

- Synchronization processing approach helps provide for MSDB and DEDB integrity and recovery.
- Facilitates parallel processing by executing the synchronization point in a dependent region.
- Updates MSDBs during synchronization point processing time.
- Schedules DEDB updates and terminal response messages to be performed after logging is completed.
- A common data base deadlock detection and common transaction synchronization point coordination between IMS/VS full function and Fast Path when Fast Path mixed mode is utilized.

The Fast Path feature available with IMS/VS R1.6 and subsequent releases allows Fast Path application programs to retrieve from as well as update all IMS/VS DL/I data bases.

All IMS/VS DB/DC (online) application programs (MPPs and BMPs) are able to retrieve from as well as update all IMS/VS Fast Path Data Entry (DEDB) and Main Storage Data Bases (MSDB):

Fast Path Feature Formatted Dumps: Fast Path control blocks are now included in the IMS/VS formatted dumps.

Fast Path Feature on OS/VS1: The Fast Path feature contained in this release of IMS/VS V1 operates under OS/VS2 MVS and OS/VS1 operating systems. For future planning purposes, the Fast Path Feature will be supported on the OS/VS2 MVS operating system only.

Selection Criteria: Fast Path can be selected for applications that meet these criteria:

- Transactions are initiated by a single-segment, response-type message.
- Input messages require only one response (this is necessary because transaction response mode is used).
- The input and output message lengths do not exceed that specified at system definition time for each terminal designated to handle Fast Path transactions.
- Transactions are designed to operate not only on root segments or no root segments with a maximum of seven dependent segments, one of which may be a sequential dependent segment, the others being called direct-dependent segments.
- DEDB now supports the dynamic allocate/deallocate on an area (data set) level.
- Fast Path allows the use of IMS/VS Message Format Service (MFS), but display formats are limited to one logical page.

Limitations: Fast Path is compatible with IMS/VS in many areas. It achieves some of its increased performance capability by limiting some function and adding others (e.g., the new DL/I calls). This section identifies areas which should be considered when planning for a Fast Path application, either a new one or one presently running on IMS/VS but being adapted or converted to Fast Path.

In the systems definition area, extensions to existing macros are provided to describe Fast Path. The basic process remains the same.

For processing input and output messages, the following should be noted:

- Normal IMS/VS conversational processing is not available, but a capability for simulating SPAs through MSDB exists.
- Fast Path transaction input from the IMS/VS master terminal is not supported.
- Fast Path uses a simplified message processing and queuing approach. Transaction codes and routing codes are used, but there is no use of priorities and message classes.

Fast Path data base facilities cannot be a part of an IMS/VS logical data base. The DL/I call formats and interface are maintained and two calls are not available for some data bases.

Fast Path and MSC can coexist on the same IMS/VS system, but Fast Path messages must be processed in the IMS/VS system in which they are entered.

The Data Base Surveyor Utility feature does not support Fast Path's Data Entry Data Bases (DEDB) and Main Storage Data Bases (MSDB), the partial Data Base Reorganization Utility or the Online Image Copy Utility. The Fast Path feature has its own online reorganization utility.

No OS/VS checkpoint is available for Checkpoint call, if the IMS/VS application (BMP) has access to Fast Path data bases.

No composite analysis is available for all activities of an application program using both IMS/VS and IMS/VS Fast Path data bases. To analyze the IMS/VS activities, the DC Monitor should be used. To

analyze the IMS/VS Fast Path activities, the Fast Path Log Tape Analysis Program should be used.

The Fast Path feature allows a variation to the application view and message handling. The Fast Path application views the symbolic terminal as though it were a one-level hierarchic data structure with a single message segment in and out. Each terminal has its own buffer associated with each terminal managed by the system. Each transaction type known to the system also has a symbolic name. Messages entered by a terminal operator contain only transaction names and associated data. Conversational processing and message switching are not supported by the Fast Path feature.

The Expedited Message Handling (EMH) facility of the Fast Path feature replaces the functions associated with the queue manager and the transaction scheduler and uses the following: Incore preallocated buffers, prescheduled application programs, and routing codes to direct transactions to application programs.

Data Base Surveyor Utility Feature: A data base report utility feature called "Surveyor" is available as a part of IMS/VS V1 R1.5. The function of this utility feature is to survey an IMS/VS data base (HDAM and HIDAM only) to aid the user in determining the need for reorganization and provide a report describing the physical organization and the free-space utilization. Surveyor allows for a full scan of an entire data base or a scan of a user-specified range of segments in a data base. Surveyor runs as either a batch job or BMP job. This utility complements and is intended to be used in conjunction with the Partial Data Base Reorganization Utility.

Data Base Recovery Control Feature: See the description of enhanced DBRC function under section "Highlights of IMS/VS Version 1 R3".

The IMS/VS Data Base Recovery Control feature is designed to assist IMS/VS installations with recovery of their data bases.

The feature consists of two utilities, processing that occurs when the feature is given control from the IMS/VS control program and the IMS/VS recovery utilities, and a number of data sets used to store the information needed for recovery. The full advantage of the feature is realized when you use an IBM 3850 Mass Storage System or other direct-access storage devices to store recovery-related data sets (thereby reducing the amount of tape handling that is associated with the recovery of data bases).

See the description of DASD Logging feature under section "Highlights of IMS/VS Version 1 R3".

CUSTOMER RESPONSIBILITIES

A customer installing IMS/VS must:

- Have installed at least the minimum machine configuration.
- Assure that appropriate OS/VS1 or OS/VS2 and S/370 training (including terminal and direct access storage education) be given to system analysts, application programmers, system programmers and system operators.
- Have OS/VS1 or OS/VS2 successfully installed (no customer should attempt to implement IMS/VS until the installation has achieved proficiency in the use of OS/VS1 or OS/VS2).
- If VTAM terminal support is to be used, ACF/VTAM is required.
- Have personnel educated in IMS/VS (a thorough knowledge and understanding of data base concepts and IMS/VS before installation are essential).
- Provide adequate protection against the accidental loss or misuse of his data (functions exist in IMS/VS to assist in providing data security).
- Plan for installation and operation of his remote terminals.
- Make sure personnel are trained in COBOL, PL/I or Assembler language.
- Specify transactions for each application defined.
- Describe the structure of each data base for IMS/VS and for the application.
- Specify and implement application programs.
- Define the physical and logical communications network.
- Provide, when the 7770 Audio Response Unit mdl 3 is used, the input, output and signon exit routines.
- Provide, when the 3270 Information Display System is used, message input and output descriptions using the message format language utility.
- Provide, when the S/3, S/7, S/32 (as a S/3) or S/34 (as a S/3) is used with IRSS, the necessary support programs in the remote processor and the support programs for bit handling, blocking, deblocking, synchronization and recovery functions.

PROGRAM PRODUCTS

IMS/VS (cont'd)

- Provide, when 3600 or SLU P systems are used, the necessary support program for the controller.
- Generate the IMS/VS control program by describing data bases, applications, transaction codes, message classes, terminals, queues, system libraries, buffering requirements, storage devices, capacity and programming system configuration to the IMS/VS system definition utility.
- Provide, when the 3740 Data Entry System is used, the signon exit routine.
- Apply necessary programming changes to OS/VS1 or OS/VS2 associated with the installation of IMS/VS.
- When considering backup, provide an alternate connection and necessary facilities to backup an unavailable Multiple Systems Coupling connection. Also, provide alternate or back up systems to increase the overall availability and recoverability of the Multiple Systems Coupling configuration. Each system in an IMS/VS Multiple Systems Coupling configuration uses the recovery capabilities of a non-MSM IMS/VS system. The Multiple Systems Coupling facility was designed to help ensure that messages are neither lost nor duplicated during their transmission from one system to another. Recovery is possible in the whole Multiple Systems Coupling configuration as long as no system is cold started or no log records were lost. Cold start or lost log records may impact the recoverability of the directly involved system and of any system which maintains communication with it. The impact of cold start or lost log records is the loss of messages which may be from or in transit to other IMS/VS systems.
- When installing the Data Base Recovery Control Feature:
 - Set up new recovery procedures for error situations and informational messages.
 - Establish frequency and type of recovery procedures to be used.
 - Define data base data sets, to be recovered by the feature, in the recovery-control data set.
 - Modify the JCL provided by the feature to match the installation requirements.
 - Establish procedures to recover the recovery-control data set.
 - Define security procedures for the recovery-control data set.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

Processors: IMS/VS Version 1 executes under the virtual storage operating systems (OS/VS1 and OS/VS2) in IBM S/370 mdls 138, 145, 148, 155II, 158, 165II, and 168 and the 303X, 308X and 4300 Processors. When operating with MVS/SP V1 R3 or subsequent releases, the following is recommended: With the IBM 3033 Processor, the Extension feature #6850 should be installed; with the IBM 3031 Processor, EC 209877 or later should be installed; and with the IBM 4341 Model Group 2, 4361-5 or 4381 Processor, the Extended Control Program Support (ECPS:MVS) facility should be installed. With MVS/Extended Architecture (MVS/XA), IMS/VS executes on the IBM 308X Processor Complex operating in extended architecture mode, with the MVS/System Product Version 2 (MVS/SP V2), and the Data Facility Product (DFP) installed.

It is suggested that the IBM S/370 mdl 138 be limited to the IMS/VS Data Base System only.

System Console: OS/VS1, OS/VS2 MVS and MVS/XA requirements apply.

Tape Units: At least one IBM 2400* or 3400 9-track tape unit is required for installation.

Direct Access: For system libraries and working storage space, any devices supported by the operating system are allowed.

For IMS/VS data base storage, within the capabilities and restrictions of BSAM, QSAM, ISAM and VSAM support, the following IBM devices are allowed:

2305 - mdls 1, 2*	Fixed-Head Storage
2314/2319**	Direct Access Storage Facility
3330 - mdls 1, 2, 11	Disk Storage
3333 - mdls 1, 11	Disk Storage and Control
3340	Direct Access Storage
3344	Direct Access Storage Facility
3350	Direct Access Storage
3375	Direct Access Storage
3380	Direct Access Storage
3850	Mass Storage Facility

* MVS/Extended Architecture does not support the 2305 mdl 1.

** MVS/Extended Architecture does not support these devices.

Fast Path: Fast Path function *operates only* in an OS/VS2 MVS or MVS/XA environment. All devices supported by the operating system are allowed for system libraries and working storage. MSDBs are stored as DASD data sets when Fast Path is shut down. The space required for MSDBs depends on their number and size. Direct access devices supported by IMS/VS and VSAM improved control interval processing (ICIP) are available for DEDBs.

Fast Path supports the following communication devices:

Terminal Type	Polled	Local Mode	SNA
2740-1 (Note 1)	BTAM		
2740-2	BTAM		
3270 (BSC/local)	BTAM	BTAM	
3270 (BSC/local)	VTAM	VTAM	
3600/Finance (Note 2)			VTAM
3767			VTAM
3770			VTAM
SLU 1 (Note 3)			VTAM
SLU 2			VTAM
SLU 4 (Note 3)			VTAM
SLU P			VTAM
LU 6			VTAM
NTO Devices			VTAM

Note 1: Station control only.

Note 2: 3614 support via 3601 only.

Note 3: Must have at least one input component.

Multiple Systems Coupling: Each IMS/VS system in a multiple systems configuration must consist of an entire IMS/VS DB/DC release with its own IMS/VS master terminal. The IMS/VS systems in the configuration must be compatible releases.

The following releases are compatible and may be connected:

- IMS/VS Version 1 Release 1.6.
- IMS/VS Version 1 Release 2.
- IMS/VS Version 1 Release 3.

When the physical link is a binary synchronous communications line, BTAM is required. Point-to-point contention mode (BSC1) is supported.

When the physical link is a main storage-to-main storage link, OS/VS1 and OS/VS2 MVS are supported.

When the physical link is a channel-to-channel adapter, the S/370 channel-to-channel adapter or a logical channel on the 3088 is required. An MSC channel-to-channel link is supported on OS/VS2 MVS and MVS/XA only.

When the MSC connection is via VTAM, if Intersystem Communications (ISC) is used, ACF/VTAM Version 1 Release 1 or later is required. The Synchronous Data Link Control (SDLC) line discipline is used. The parallel session capability is not available with ACF/TCAM.

Data Sharing Requirements

- For interprocessor sharing, either a 3705 controller or a channel-to-channel (CTC) link can be used. If a 3705 controller is used, ACF/VTAM Version 1 Release 3 Multisystem Networking Facility or a subsequent release with the appropriate ACF/NCP release is required. If a CTC link is used, ACF/VTAM Version 2 Release 1 is required.
- IMS/VS systems running under OS/VS1, OS/VS2 MVS or MVS/XA may share data at the data base level; for block level sharing, OS/VS2 MVS or MVS/XA is required.
- For block level sharing, the IMS/VS Resource Lock Manager (IRLM) is required. IRLM is a component of the IMS/VS Data Base System. IRLM must be defined as an OS/VS2 MVS subsystem and the appropriate ACF/VTAM definition provided.

PROGRAM PRODUCTS

IMS/VS (cont'd)

TERMINALS SUPPORTED by IMS/VS: The following table lists the terminals that IMS/VS supports.

Supported Product	Compatible Product	Contention	MODE Switched	Polled	Local	SNA	Notes
1050			BTAM	BTAM			
2260-1,-2				BTAM	GAM		
2265-1				BTAM			
2740-1	3767	BTAM	BTAM	BTAM			1
2740-2	(2740 mdls only)			BTAM			1,2
2741	CMCST	BTAM	BTAM				1,3
2770	3770 (BSC)			BTAM			
2780	5110	BTAM		BTAM			
2980				BTAM			4
3270			BTAM	B/V	B/V	VTAM	1,2
3600/Finance	4700					VTAM	1,2,5,8
3614						VTAM	4,5
3740	5280		BTAM				4,6
3767						VTAM	1,8
3770						VTAM	1,8
SLU 1 (i.e., 3230, 3232, 3262, 3268, 3767, 3770, 3770P, 3790 (type 2 batch & bulk print), 4700, 5210, 5280, System/32, System/34, System/36, System/38, 8100)						VTAM	1,2,9
SLU 2 (i.e., 3178, 3276, 3278, 3279, 3290, 3790 (3270 DSC feature), 3600 Admin PP, 4700, 5280, 5520, 8100, 8775, System/34, System/36, System/38, 6580)						VTAM	1,2
SLU 4 (i.e., 6670)						VTAM	1,2
SLU P (i.e., 3600, 3630, 3650, 3680, 3770PC, 3790, 4700, 5520, 8100, System/34, System/36, Series/1						VTAM	1,2,5,7
LU 6						VTAM	1,2
NTO (i.e., 33/35 TTY, 2740, 2741, 3101, 3232, 3767, S/23						VTAM	1,2
7770-3			ARAM				3,4
33/35 TTY	3101, 3102 S/23		BTAM				3
System/3				BTAM			7
System/7		BTAM		BTAM			7
System Console					WTO(R)		
Card Reader					BSAM		
Printer					BSAM		
Magnetic Tape					BSAM		
DASD Devices					BSAM		

KEY

- ARAM = IMS/VS audio response access method.
- BSAM = Basic sequential access method.
- BTAM = Basic telecommunications access method.
- B/V = BTAM or VTAM.
- GAM = Graphic access method. Graphic programming service is required to receive GAM.
- SNA = Systems network architecture. IMS/VS is independent of physical connection types used by VTAM for SNA.
- VTAM = Virtual telecommunications access method.
- WTO(R) = OS/VS write-to-operator/write-to-operator-with-reply (WTO/WTOR).

Notes:

1. The IMS/VS Message Format Service (MFS) is available for this device. MFS editing can be bypassed on a message-by-message basis.
2. IMS/VS Fast Path feature allows the use of the compatible terminals.
3. IBM does not provide error detection capability for this device. Therefore, only inquiry-only transactions are allowed, even though the non-inquiry capability exists.
4. User-written exit routines are required for the 3614, 3741 and 7770-3 terminals, and may be required in some environments for the 2890.
5. Although IMS/VS provides sample code for this terminal, additional user coding is required.
6. Connection between IMS/VS and this terminal requires a manual dial from the host.

7. IMS/VS provides no device resident code for this device. Additional user coding is required to attach it to IMS/VS.
8. These terminals can be defined by identification number and as SLUs. The support for the multiple definition is not necessarily the same.
9. Support of SLU 1 is with SCS data stream.

SOFTWARE REQUIREMENTS

IMS/VS Version 1 Release 3 operates under the following virtual storage operating system configurations:

- OS/VS1 Release 7.0
 - The Fast Path function is *NOT* supported for OS/VS1 operating system starting with this release of IMS/VS V1.
 - The IRLM is *NOT* supported for OS/VS1 operating system.
- OS/VS2
 - For S/370 environment (with their appropriate prerequisites):
 - MVS/System Product-JES2 (5740-XYS) or -JES3 (5740-XYN) Version 1 Release 3, referred to below as MVS/SP V1 R3;
 - With either MVS/370 Data Facility Product (5665-295), or OS/VS2 Data Facility Device Support (5740-AM7) and Data Facility Extended Function (5740-XYQ).
 - Data Facilities Extended Function Release 1 (5740-XYQ).
 - For MVS/Extended Architecture (MVS/XA) environment (with their appropriate prerequisites):
 - For MVS/System Product-JES 2 (5740-XC6) or -JES3 (5665-291) Version 2 Release 1, referred to below as MVS/SP V2 R1.

IMS/VS (cont'd)

- MVS/XA Data Facility Product Release 1 (5665-284), referred to below as MVS/XA DFP R1.
- For both operating systems:
 - IMS/VS V1 R3 requires OS Assembler H Version 2 (5668-962).

For proper execution of IMS/VS, system definition and system execution must be performed under the same operating system release. Unless required by the operating system, a new IMS/VS system definition using the same IMS/VS release does not make it necessary to recompile user application programs.

The selection of an OS/VS configuration has some effect on the potential performance, reliability and availability characteristics of IMS/VS. Certain options are required by IMS/VS in all of the applicable configurations.

IMS/VS is designed to be a portable system. That is, when generated using MVS/SP V1 R3, it can run on either a System/370 or a System/370 running in Extended Architecture mode.

IMS/VS Version 1 Release 3 can also be generated as a nonportable system. That is, when generated using MVS/SP V2 R1, it can run only on a System/370 running in Extended Architecture mode. MVS/XA comprises MVS/SP V2 R1 and MVS/XA DFP R1. If a nonportable system (one using MVS/XA) is generated, Assembler H Version 2 Release 1 is also required.

When the Data Communication feature is used, ACF/VTAM Version 1 Release 3 or later is required. Also, if BTAM is used on MVS/XA, then BTAM/SP (5665-279) is required.

An IMS/VS Data Base System operates only in pageable (V=V) storage. In a DB/DC system running under OS/VS1, OS/VS2 MVS, or MVS/XA, the control, message processing, and batch message regions operate in pageable storage.

When the IMS/VS control region or partition is run in a virtual environment, the user is given the ability to fix specific portions of the control program. This permits tuning of the IMS/VS system to a particular environment.

IMS/VS also operates in a VM/370 virtual machine under control of OS/VS1, OS/VS2 MVS or MVS/XA with the following restrictions:

- If binary synchronous terminals through BTAM are employed, communication line timeouts should be expected. Note that this timeout of terminals is not limited to VM/370, but when it does occur, it affects the recovery because polling is inconsistent when BTAM operates under VM/370.
- The IMS/VS Statistics Analysis Utility is not supported.
- If problems are encountered when operating IMS/VS under VM/370, it may be advantageous to re-create the problem in a standalone OS/VS environment.

IMS/VS operation in a VM/370 environment is intended primarily for use in program development and testing. IMS/VS can operate under VM/370 for production purposes. If you have specific throughput or terminal response time requirements, you should plan to benchmark under VM/370 to ensure that the proposed configuration will meet your needs. Consideration should be given to making the virtual machine running IMS/VS a favored virtual machine.

Programming Language: IMS/VS is written in Assembler and PL/S.

Access Methods: An IMS/VS Data Base System uses basic sequential access method (BSAM), queued sequential access method (QSAM), indexed sequential access method (ISAM) and/or virtual sequential access method (VSAM). IMS/VS uses VSAM shared resources support, which reduces main storage requirements by sharing buffers and control blocks across VSAM data sets. A DEDB uses VSAM ICIP only.

An IMS/VS DB/DC system uses, in addition, basic telecommunications access method (BTAM) and virtual telecommunications access method (ACF/VTAM). If local support for 2260 Display Stations is required, the graphic access method and graphic programming services are required. IMS/VS Version 1 Release 1.6 or later operates only with ACF/VTAM - not VTAM. If MSC or ISC will utilize parallel sessions or negotiable session initialization parameters (BIND), ACF/VTAM Release 2 or later is required.

Program Currency: IMS/VS Version 1 Releases 1.6 and 2 remain current. Their end-of-currency will be announced at least 12 months prior to effective date.

COMPATIBILITY

Between IMS/360 and IMS/VS: Application program source modules developed for previous versions of IMS (5736-CX3, 5734-XX6) are upward compatible to IMS/VS. IMS/VS provides substantial new functional enhancements over IMS/360 (5734-XX6).

Between IMS/VS Version 1 Releases: Application programs developed for IMS/VS Version 1 Releases are upward compatible. The user does not have to re-compile nor re-linkedit. Application programs which use MFS and use the input cursor field may require a change. See *Message Format Service User's Guide* (SH20-9053).

Between IMS/VS Version 1 Releases and IMS/VS Version 1 R1.4 and R1.5 Fast Path Feature: For Fast Path application programs running under IMS/VS, a system definition process must be done to develop the interfaces and definitions of the two new data bases, message processing, transactions, etc. The Fast Path feature offers new data base calls which, if used, require some application program modification. The use of these calls is not required for all programs. When migrating Fast Path application programs from IMS/VS V1 R1.4 to R1.5, different results are obtained in some areas, for example, status codes.

For Multiple Systems Coupling feature compatibility between IMS/VS V1 R1.3 and R1.4, between R1.4 and R1.5, between R1.5 and R1.6, and between R1.6 and R2: See the "Multiple Systems" subsection under the "System Requirements" section. Multiple Systems Coupling Feature (MSC) in IMS/VS V1 R1.5 and R1.6 is supported for communication with MSC in IMS/VS V1 R2.

For IMS/VS V1 R1.5: A /EXIT command issued during a conversation will delete the queued transaction if it exists as yet unprocessed in the system which originated the conversation. A code will be given to the user's conversation abnormal termination exit routine, and a message will be sent to the terminal operator, indicating the status of the transaction.

- Field Level Sensitivity is optional and does not require a change to the user's application program unless variable-length segments are used. DL/I call syntax is unchanged.

For IMS/VS V1 Release 3: Application programs developed for IMS/VS Version 1 are upward compatible to IMS/VS Version 1 Release 3. The Message Format Service (MFS) compatibility enhancement for downward compatibility of the IMS/VS Version 1 Release 3 MFS Format Library will be made available through the service process. The archive log data set of IMS/VS V1 R3 and the log data set of IMS/VS V1 R2 may be used with either IMS/VS V1 R2 or IMS/VS V1 R3 recovery utilities: Change Accumulation, Data Base Recovery, and Batch Backout. The IRLM available with IMS/VS V1 R3 must be used with IMS/VS V1 R2 when block level data sharing is used between R2 and R3. For Multiple Systems Coupling, IMS/VS V1 R1.6 and IMS/VS V1 R2 and IMS/VS V1 R3 are compatible and may be connected to each other. IMS/VS V1 R3 does not support OS/VS Checkpoint/Restart.

In addition to the Compatibility statements announced previously, the following are additional effects on the compatibility between IMS/VS V1 R2 and IMS/VS V1 R3: JCL changes may be required in the control region ... because of 3 multiple address spaces, a user's accounting routines may be affected ... a new ACBGEN will be required. Compatibility between IMS/VS Version 1 Release 2 and IMS/VS Version 1 Release 3 for Fast Path Data Entry Data Bases, for the IMS/VS Version 1 Release 2 level of Fast Path function, will be provided through the service process.

For Data Base Recovery Control Feature: The Data Base Recovery Control Feature supports Fast Path Data Entry Data Bases in IMS/VS V1 R1.5. No other Data Base Recovery control support is provided for Fast Path. Fast Path data bases and GSAM data sets are not supported by IMS/VS Data Sharing facility.

CONVERSION

The following are conversion considerations for R1.5:

- To utilize display formats currently designed for 3270 displays on new devices with larger screen capacity, users of IMS/VS V1 R1.1 or later may require changes to current MFS source definitions. Users of releases prior to IMS/VS V1 R1.1 will use currently defined MFS conversion procedures.
- Although any nonswitched 3270 may be used as the IMS/VS Master Terminal, the special MFS master terminal formatting option applies only to 24 x 80 screens (1920 characters).

PROGRAM PRODUCTS

IMS/VS (cont'd)

- Users of R1.5 will be required to generate allocation parameter lists for the data bases used in dynamic allocation.
- All data bases subject to dynamic allocation will be required to be cataloged.
- Before installing the Fast Path feature under IMS/VS V1 R1.5, see the "Limitations" subparagraph of the "Fast Path feature".
- S/3 and S/7 programs may have to be modified to handle a new system message error block.
- A user-written conversation abnormal termination exit routine may have to be modified to handle the new interface.
- PSB and ACB generations must be rerun after insertion of the new SENFLD statement(s). The field names must be the same as contained in the DBD generation information.
- A DL/I call with SSA cannot use a field (except key field) to which the application program is not sensitive.
- When using the Data Base Recovery Control Feature with IMS/VS V1 R1.4 or R1.5, all data base data sets under recovery control of the feature must be identified in the recovery-control data set. Data sets not under feature control can be recovered using currently defined IMS/VS procedures.

The following are considerations for R1.6:

- 3790 limited inquiry support is withdrawn. All other 3790 functions continue to be available (as SLU types 1, 2 and P).
- If VTAM is used, then IMS/VS V1 R1.6 requires ACF/VTAM, because IMS/VS V1 R1.6 does not support VTAM Level 2.
- IMS/VS V1 R1.6 will be installable using System Modification Program Release 4 (SMP4). Release 1.6 defines IMS/VS distribution and system libraries in a format for SMP installation. SMP installation removes the requirement by IMS/VS of providing unique input job streams for system installation. Users will no longer be required to execute separate installation procedures for SCPs or SUs and another for IMS/VS. Initialization of the ACDS and CDS for IMS/VS will occur during the IMS/VS SMP installation.

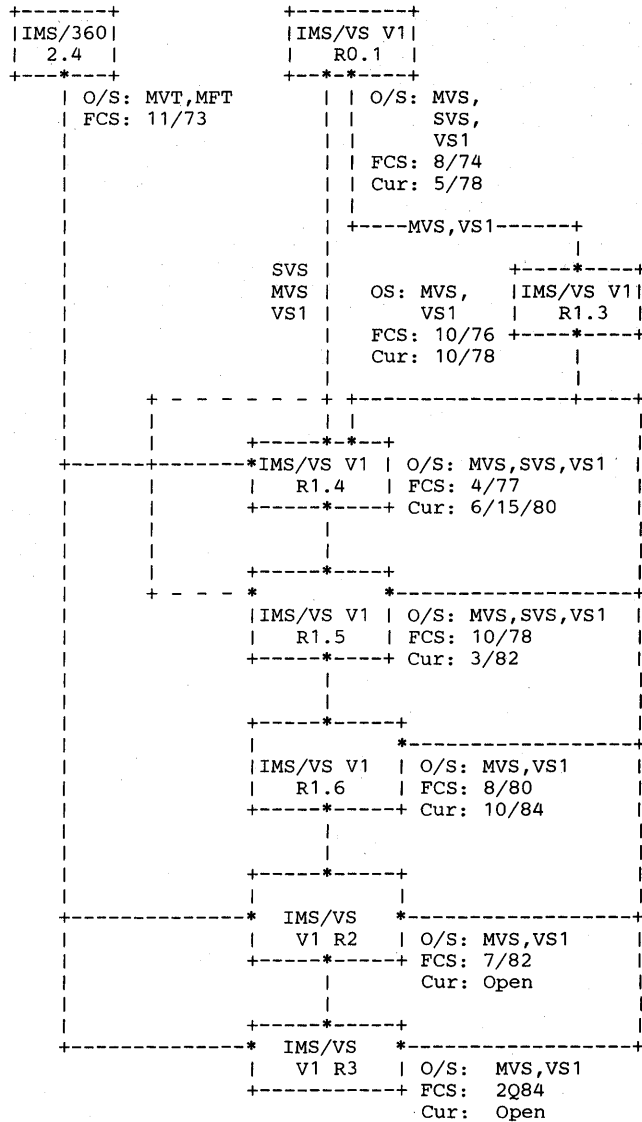

The following are considerations for R2:

- The ACB Library must be regenerated.
- IMS/VS Version 1 Release 2 will be installable using System Modification Program Release 4 (SMP4). Release 2 defines IMS/VS distribution and system libraries in a format for SMP installation. SMP installation removes the requirement by IMS/VS of providing unique input job streams for system installation.
- For IMS/VS Version 1 Release 2, the DBRC RECON data set from earlier releases must be converted to the new RECON data set format using the utility provided for that purpose. Access by IMS/VS V1 R2 DBRC and R1.6 DBRC features to the IMS/VS V1 R2 DBRC's RECON data set will be provided by a PTF.

See *IMS/VS Installation Guide* (SH20-9081) for installation information.

MIGRATION PATHS for IMS/VS USERS

The following chart shows the various migration paths possible for an IMS/VS user according to a particular operating system. Note the first customer ship dates and the currency dates to the right of each box. For details on currency see the above currency period table.

O/S Operating System
FCS First Customer Ship
Cur Currency

DATA SECURITY and AUDITABILITY

IMS/VS Version 1 is subject to all the controls of its environment such as those provided by the operating system, access methods and the subsystem to which it is communicating. It includes all security features and functions previously announced including the Resource Access Control Facility (RACF).

In addition, there are security facilities that permit the control of access to one system's resources by another. Data protection facilities of the communicating system and subsystem should be considered when using the intersystem communication function. Customer management is responsible for the selection, application and adequacy of those controls.

PERFORMANCE CONSIDERATIONS

The performance of IMS/VS in a virtual storage environment is highly dependent on the system resources available, the programs that operate concurrently and their relative priorities, and system and application data set placement. Performance also depends on the paging characteristics and storage reference patterns of IMS/VS and its application programs, the allocation of data sets to particular devices and the particular data being processed.

PROGRAM PRODUCTS

IMS/VS (cont'd)

In an MP/AP environment, performance of IMS/VS is also dependent upon the amount of concurrent processing considering the demand of processor time by the IMS/VS control region, message processing programs, batch message programs and other users of the system.

For specific online performance and response time requirements, particular attention must be given to ensuring that adequate real resources (main storage, processor computing capability, channels, direct access devices, etc.) are available. To verify specific performance, benchmarking the IMS/VS system may be appropriate.

Performance Considerations for the Fast Path Feature: An increased performance capability is available with the IMS/VS Fast Path feature. The main effect of these performance improvements can be greater transaction throughput rates than is achievable with the base IMS/VS system for a given processor utilization level. Fast Path performance gains are achievable in general by trading main storage space and function for performance, wherever such trades are consistent with the requirements of high-volume, limited-processing DB/DC applications. Because of these trade-offs, care must be taken that the functions in Fast Path are adequate for the given application and that sufficient real main storage is available to maintain acceptable paging rates.

Fast Path performance gains have been achieved by reducing the path length (number of processor instructions executed) in processing a transaction. These path length savings should improve overall performance whenever the processor is the limiting component in the installation. Path length reduction is achieved by:

- Expedited message handling
 - Single-segment messages only.
 - Terminal response mode only.
 - Simplified message queuing in main storage.
- Pre-scheduled application programs
 - Wait-for-input mode only.
- Expedited data base access
 - New main storage data base organization with single-call field updating.
 - New data entry data base organization for efficient insertion of variable-length segments.
- Use of advanced SCP support
 - VSAM Improved Control Interval Processing.
 - SRB dispatching (MVS).

Performance improvements can also result from the reduction or elimination of I/O and I/O contention:

- Main storage message queuing eliminates spill of message queues to DASD.
- Pre-loading of control blocks eliminates dynamic fetching.
- Main storage data bases eliminate I/O for some data base access.

Fast Path was designed to take advantage of the MVS, VTAM and SNA environments. In other environments, performance gains may still be achieved, but will not in general be as great. For example:

- Fast Path uses Acknowledge-with-Input for SNA programmable controllers such as the 3600 and SLU-P. For other terminal devices and line disciplines such as the 3270 BSC, path length savings relative to the IMS/VS base product will not be as great.
- Fast Path takes advantage of authorized program support in MVS, for example, SRB dispatching and suspend/resume. In other operating systems environments (VS1), the use of the equivalent standard application program facilities will in general cause longer path lengths.

Thus the potential exists for realizing performance enhancements for selected transactions and/or applications. However, certain precautions must be understood and met to achieve a desired performance level. Some of these were discussed in the previous section.

PLANNED AVAILABILITY

IMS/VS Version 1 Release 2 general availability was July 15, 1982. IMS/VS Version 1 Release 2 MVS/XA support general availability was 8/27/82. IMS/VS Version 1 Release 3 general availability is planned for 2nd Quarter, 1984. IMS/VS Version 1 Release 3 Early Support Program (ESP) is planned for 1st Quarter, 1983. The Fast Path function will be made available to the IMS/VS Version 1 Release 3 ESP during 3rd Quarter, 1983.

PROGRAM CURRENCY

The following table shows the end-of-currency period of IMS/VS Version 1:

IMS/VS VER - SION 1	END-OF-CURRENCY DATE
R1.5	3/82
R1.6	10/84
R2	*

* An IMS/VS V1 currency date has not been established. End-of-currency will be announced at least 12 months prior to effective date.

PREVENTIVE SERVICE

Preventive Service (PTFs) for IMS/VS Version 1 will be distributed to all licensed users. The PTFs contain solutions for problems resolved since the last preventive service tape and are installable with System Modification Program Release 4 (SMP4). Preventive PTFs are distributed with the object module and will include, as appropriate, source changes for the module in machine readable format.

MVS SYSTEM INTEGRITY

IBM will accept APARs describing situations where the installation of IMS/VS V1 R1.5 on OS/VS2 (MVS) R3.7 or R3.8 and IMS/VS V1 R1.6, R2 and R3 on OS/VS2 (MVS) R3.8 causes an exposure to the system integrity of OS/VS2 MVS and MVS/XA. This statement applies to the IMS/VS Data Base System as well as to the Data Communication, Multiple Systems Coupling, Fast Path, Logging, Data Base Recovery Control, and Data Base Surveyor Utility Features. This program is intended to run authorized.

RPCs ACCEPTED: No

PROGRAM PRODUCTS
**GENERALIZED INFORMATION SYSTEM/VIRTUAL
STORAGE
GIS/VS (5740-XX7)**
PURPOSE

GIS/VS is designed to enable the programmer or the non-data processing professional to maintain and extract information on a timely basis from an installation's data base. This is made possible by the use of a generalized high level language which is easy to learn yet powerful enough to handle complex multi-file data requests with extensive logic and computational requirements. In conjunction with IMS/VS (5740-XX2), GIS/VS can provide an integrated information system which uses the flexibility and power inherent in these two complementary DB/DC systems. Non-technical users of the data processing facility can formulate their own data requests and enter them directly into the computer either on a batch basis or via a remote IMS/VS terminal. As a result, the programmer work load and associated costs can be substantially reduced, and the total turnaround time normally required with the development, testing and execution of a reporting application or a one-time program can be drastically cut.

DESCRIPTION

GIS/VS in conjunction with the Operating System (including OS/VS1 and OS/VS2, SVS and MVS) provides a powerful technique for addressing specific customer needs for data processing, as well as many of the requirements of executive management information systems. Combined with IMS/VS, it provides a comprehensive information system. Access to either DL/I or non-DL/I files may be either batch or from an IMS/VS terminal. These files may then be temporarily or permanently modified and reported upon. In response to spontaneous and changing requirements, GIS/VS provides sets of generalized routines which enable data set creation, maintenance, and retrieval. With this program, existing or new files are described, including significant support for DL/I data bases, and then user-selected symbolic names serve to identify and locate both the appropriate file and the fields of data within it as needed by a GIS/VS procedure.

Using conventional programming practices, implementing a particular application ordinarily entails coding a multitude of routines. Once implemented, however, the system requirements usually prove unstable. Additional routines are needed to extend capabilities; revised coding is needed to produce reports not anticipated when the application was initially defined. Accordingly, a dynamic operational environment imposes a significant continuing demand on programmers to maintain existing programs.

In contrast, the GIS/VS user describes his new or existing files in a procedure that does not involve detailed programming. As a result of processing by a GIS/VS program component, these file descriptions enable the user to address the contents of his files by means of symbolic names. No longer must the user repeat, in every procedure, the size of each field, its unit, relative location and other data management parameters.

When the system user employs GIS/VS techniques to create, maintain and query his files, his procedures will be compiled by another GIS/VS program component after diagnostic testing to ensure their validity. The compiled, executable procedure code may then be applied to the file data or stored for later use and re-used when called from the GIS/VS library by the procedure's symbolic name.

As necessitated by the task being performed, GIS/VS procedures can link to non-GIS/VS routines referenced in the procedure specification. User routines written in other languages, such as PL/I, FORTRAN or COBOL, can access GIS/VS files.

A design provision enables a GIS/VS installation to invoke restrictions on the accessibility of sensitive data. Another provision enables selective recording of the occurrence of processing errors and the alternative actions to be taken.

In short, GIS/VS is a structured-file, information handling system designed for use in cross-industry applications. The system's design provides for a dynamic operational environment.

HIGHLIGHTS

GIS/VS has been designed to recognize that different customers will make different use of the many capabilities of GIS/VS and that many will start out using GIS/VS only for simple batch query into existing files. Accordingly, GIS/VS is priced as a basic query system with three optional features -- Advanced Query, Modify and Update/Create:

Basic Query System -- Permits the user to formulate simple queries on a batch basis against sequential or indexed sequential data sets. It can be used with OS/VS1 and OS/VS2. Up to sixteen different files may be addressed in a single query, but files may not be hierarchical. The ability to temporarily hold, resequence and list data in a report format is included. Also included are symbolic arithmetic functions. Significant capabilities include:

Formal Report Capability -- Provides language extensions to support the generation of report programs within a GIS/VS procedure. This feature enhances the Basic LIST capability by

permitting the specifications of a title page, page headers and trailers, summary lines conditioned on end of data and/or control field breaks and detailed lines, all with the flexibility to control the horizontal and vertical spacing of the printed output.

Control Statement Capability -- Provides language extensions to permit scanning of data fields, generation of procedure testable switches, and additional comparison operators for detecting increase or decrease of a field and absent or empty state of a field.

Utility Capability -- Provides language to save both external and compiled forms of GIS/VS language, performs corrections on saved language, executes a precompiled procedure or subprocedure and defines the necessary data set formats to support the execution.

Arithmetic Statement Capability -- Extends the language by providing four additional arithmetic verbs.

Processing Statement Capability -- Extends the language to provide totaling, counting, averaging and count of unique occurrences of data with both automatic and user controlled output.

Advanced Query Feature

Teleprocessing Support Capability -- Enables procedure (GIS/VS and non-GIS/VS) input from an IMS/VS terminal. Included are a syntax checker and capabilities for job status checking and output direction.

DL/I Query Support Capability -- Allows GIS/VS query against DL/I data bases. This feature, when combined with the Modify Feature (see below), allows DL/I files to be modified.

Modify Feature: Provides the MODIFY verb and the associated security logic to perform field level file maintenance activities. This feature is required for the DL/I File modify capability. Also included is the previously separate (in GIS/2) Edit/Encode capability. This extends the system processing by providing automatic data entry validation and conversion in file maintenance activities controlled from data description.

Update/Create Feature: Extends the language to provide segment addressing verbs, automatic I/O control and implied data format translation for addition and replacement of data in file creation or general file maintenance activities. Also included is the previously separate (in GIS/2) hierarchic file capability. This extends the file definition and processing support to provide for repeating groups of data. As many as fifteen levels of subordination may be specified, and at the most subordinate level, there may be multiple formats of data.

Note: Use of DL/I query or modify capabilities or IMS/VS terminal entry facility requires IMS/VS (5740-XX2).

DB/DC INTEGRATION

DL/I QUERY SUPPORT CAPABILITY: Contained within the Advanced Query Feature, provides the ability to extract information from an installation's DL/I data bases. This capability can be used with or without the GIS/VS Modify Feature. In addition, either the Data Base Package or the combined Data Base/Data Communications Package of IMS/VS (5740-XX2) must be installed. All DL/I data base organizations are supported except Fast Path data bases. The GIS/VS modify feature and the most current version of IMS/VS are prerequisites for DL/I file modification.

DL/I data bases need only be described to GIS/VS once; thereafter, reference to the contents of these data bases is by the symbolic names given in this description. The user need not restate such parameters of the data base as field lengths and units, location within segment, field output patterns, and data management parameters.

The GIS/VS Queries run either as Batch or as Batch Message Processing (BMP) IMS/VS (5740-XX2) application programs. Thus, online as well as offline data bases may be queried with the feature.

The user may query or modify multiple DL/I data bases at the same time, or may concurrently query or modify DL/I data bases and non-DL/I files.

He may also specify exactly the format of his output report, build a library of GIS/VS procedures, expand his arithmetic or logic capability, modify DL/I files, query up to sixteen data bases simultaneously and enter his interrogations from an IMS/VS terminal.

GIS/VS terminal operation under TSO control is also provided. Automatic background file processor job submission and status checking or TSO foreground compilation and execution are allowed as user options through system input parameter commands.

The LIST RECORD and HOLD/KEEP RECORD capabilities may not be employed on a DL/I data base, but the elemental forms of these statements may be used, including LI STing, HOLDing, or KEEPing complete segments. In conjunction with the MODIFY Feature, DL/I file

PROGRAM PRODUCTS

GIS/VS (cont'd)

fields or segments may be altered or deleted. Multiple files may be modified in one subprocedure.

The UPDATE/CREATE feature of GIS/VS may not be used to maintain DL/I data bases. The DL/I Query Support Feature can substantially reduce the time, effort and cost required to design, program and debug a batch inquiry into an installation's DL/I data base. This effectively increases the scope of tasks which may be performed. Thus, the implementation of complex, one-time information requirements becomes economically feasible.

TELEPROCESSING CAPABILITY

With the Teleprocessing Capability (also known as Terminal Entry Capability) the user may enter both GIS/VS and non-GIS/VS tasks from an IMS/VS terminal. Any GIS/VS procedure may be entered and will be checked to eliminate major syntax errors before GIS/VS passes the job on to a batch or BMP region for compilation and execution. Both the language processing and file processing output may be directed back to the originating terminal or to a remote location. Further, the status of the output may be checked and output quantity may be limited.

With the Teleprocessing Capability, the DB/DC user completes the information system loop.

HIGHLIGHTS OF GIS/VS R1.1

GIS/VS Version 1 Release 1 Modification 1 (GIS/VS R1.1), in addition to those capabilities currently provided in GIS/VS R1.0, is designed to provide the following functions:

- Automatic decimal alignment of numeric data, according to the user-defined decimal precision for numeric data fields and variables, during data manipulation and calculation in GIS/VS procedures. Automatic decimal alignment is not provided for user-written Edit, Encode and Decode routines.
- Limited phrase substitution for GIS/VS procedural language statements, which is designed to provide new language translation capabilities that permit users to tailor the GIS/VS procedural language to individual needs.
- Utilization of Virtual Storage, instead of DASD I/O, for five GIS/VS compilation work files.
- An improved installation procedure which is controlled by generation macros that are designed to eliminate excessive coding and punching of JCL.
- Enhancements to the LIST and MLIST statements that permit:
 - User controlled line spacing.
 - Suppression of header/line identification for single header output.
- Enhancements that are designed to improve usability by:
 - Eliminating a redundant parameter on the ENTER command of the GIS/VS R1.1 terminal interface.
 - Permitting the user to expand the size of the GISTASK data base in the GIS/VS R1.1 terminal interface.
 - Providing additional date and time formats for Formal Reports.
 - Providing three installation management exits with the Advanced Query Feature that allows insertion of user routines for accounting and control of GIS/VS tasks in an IMS/VS environment.
- Explicit support of the 3800 Printing Subsystem, via the Job Entry Subsystem of the host Operating System, including user controlled specification of output font. Note: This support is not available under the Operating System running under VM/370.
- Support, through message format services of IMS/VS, of the 3767 Communications Terminal and the 3770 Data Communications System and (in 3270 Data Stream Compatibility Mode) the 3790 Communication System. This support requires IMS/VS, Version 1, Release 1.3, or subsequent releases unless otherwise identified.

USE

As its initial input, the program accepts file descriptions reflecting an actual or proposed organization of data. These descriptions become permanent reference tables in storage until replaced as the operational requirements dictate. The system user then writes a series of procedure specifications and enters them with or without transaction data to create and maintain his data files. Similarly, a set of procedure statements is entered to select, manipulate and retrieve data residing in the files.

Fields of data are addressed by their user-assigned names. Entire files also have symbolic names by which they are addressed.

Task information such as data or specifications can be saved in secondary storage and recalled as part or all of a procedural input specification. With the use of the DL/I Query Support Capability, the user must build his DBDs and data bases. Next, he describes his data

bases to GIS/VS as they will be retrieved by DL/I, a process which need not be repeated unless the data base changes. Then he may query his data bases, either in batch mode or from an IMS/VS terminal, using all the query capabilities he has installed. The user need not concern himself with PSBs -- these are produced by the GIS/VS compiler as needed.

Customers planning to use the DL/I Query Support Capability or Teleprocessing Capability must first install IMS/VS (5740-XX2) -- either the Data Base Package or the combined Data Base/Data Communications Package.

CUSTOMER RESPONSIBILITIES

All persons installing, operating, or maintaining GIS/VS must have a working knowledge of the installation's Operating System.

With GIS/VS, as with other systems, considerable attention should be given to pre-installation systems design and analysis. The resulting choice of data organization and record design will affect processing speed, as well as each file's value in the overall information system.

As with other systems, the customer is responsible for providing adequate protection against accidental loss or misuse of his data. This includes an adequate review of the system's security provisions by the user.

Education: Education of customer personnel is necessary for successful installation. In addition, IMS/VS DC education is required for installations using the Teleprocessing Support Capability.

Customer system programmers responsible for describing existing files to GIS/VS or designing files to be created by GIS/VS require an in-depth knowledge of the file structures, OS/VS and/or DL/I Data Management organizations acceptable to GIS/VS, and the Data Description language employed by GIS/VS.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

Under OS/VS1 and OS/VS2, 384K bytes of virtual storage (V=V) are required for the Language Processing (compilation) phase of GIS/VS R1.1. It is recommended, however, that the minimum partition/region size be 512K bytes of virtual storage for a GIS/VS compilation. If limited phrase substitution is used, the compilation may require additional virtual storage, depending on the size of the phrase table selected.

An allotment of dynamic main storage in addition to that specified above is necessary for access methods. Additional dynamic main storage may permit multiprogramming with procedural execution(s) overlapped with one procedural compilation.

In addition to these amounts, an additional allotment of storage (70K message processing region) must be made for the IMS/VS Terminal Entry Message Processing region.

If limited phrase substitution is used during syntax checking, the message processing region may require additional virtual storage, depending on the size of the phrase table selected.

While the above dynamic main storage allocation does include space for all the necessary parameter tables to support multi-file operation, it does not necessarily guarantee successful compilation of a multi-file procedure. In addition to the parameter tables, sufficient memory must be available to hold, concurrently, the key Data Description Table (DDT) information for each file. A reserved area is included in the above for this purpose. The actual space requirement for multi-file compilation is, however, highly dependent on file complexity. The factors to be considered are the number of files involved (including the number of unique field and segment names), the actual number of fields and segments, and the quantity of edit, encode and decode specifications, field redefinitions and field security specifications. For this reason, it is not possible to set a fixed maximum (other than the system limit) on the number of files which can be used in one procedure. A program is provided with the Basic Retrieval System to calculate the memory requirements for key Data Description Table information during compilation for any specific combination of files described to GIS/VS.

Minimum essential I/O devices for GIS/VS system generation, program service and operation include a system input unit, one tape unit and a system output unit. For more efficient operation, two IBM 2314s, or one IBM 3330, or two IBM 3340s, or the equivalent, are recommended. These devices are in addition to the OS/VS secondary storage requirements and do not require dedication to GIS/VS. Total secondary storage requirements depend, of course, on the size and number of user files.

SOFTWARE REQUIREMENTS

GIS/VS programs are written in the OS/VS Assembler language and require no further coding by the system user. GIS/VS requires the following components and options of the Operating System.

GIS/VS (cont'd)

Operating System, Virtual Storage 1
or
Operating System, Virtual Storage 2
plus
Input/Output Support for BDAM

Utilities

Sort/Merge (360S-SM-023) or Program Product Sort/Merge-OS
(5734-SM1) or Program Product OS/VS Sort/Merge (5740-SM1)

Linkage Editor

Primary Data Management (BSAM, BPAM, QSAM)

Optional Data Management:

ISAM - User files may be defined as ISAM.

VSAM - User files may be defined as VSAM. VSAM user files are supported through the ISAM interface or through DL/I (IMS/VS).

DL/I - All DL/I (IMS/VS) file organizations are supported except Fast Path data bases.

GIS/VS operates under OS/VS1 or OS/VS2, or under OS/VS1 or OS/VS2 under VM/370. Optionally, GIS/VS can operate under TSO.

The Advanced Query Feature of GIS/VS requires IMS/VS (5740-XX2) and will operate under the most current version and release of IMS/VS, unless stated otherwise in a future revision of this document. The DL/I query support capability of the Advanced Query Feature requires the Data Base Feature of IMS/VS. The terminal interface capability of the Advanced Query Feature requires the Data Communications Feature of IMS/VS. The support for 3767, 3770 and 3790 provided with GIS/VS R1.1, requires IMS/VS, Version 1, Release 1.3, or subsequent releases unless otherwise identified.

Under OS/VS2, the interface for the 3800 Printing Subsystem is supported through the Job Entry Subsystem (JES2 or JES3).

**S/370 PLANNING, CONTROL AND DECISION
EVALUATION SYSTEM/INTERACTIVE (PLANCODE/I)
DOS/VS (5746-XX9) - OS/VS (5740-XX8)**

PURPOSE

PLANCODE/I is an interactive application program which provides facilities for the building and implementation of business planning models by means of a plan simulation language. The program is intended for the business professional. The user is guided by menu selections, and also has the possibility for 'expert' mode of operation. Functions are included to provide for the production of consolidated plans and to perform 'what if' type sensitivity analysis as well as statistical and financial calculations.

SPECIAL SALES INFORMATION

PLANCODE/I can be used in various business management areas such as:

- General Management
 - Strategic and Operating Plans
 - Budgets
- Financial Management
 - Cash Planning
 - Usage of Funds
 - Capital Investment Analysis
 - Loans and Capital Repayment Plan
- Marketing
 - Product Marketing Plan
 - Pricing Analysis
 - Sales Force Incentive Plan
 - Advertising Media Analysis
 - Distribution Channel Analysis
- Administrative Management
 - Personnel (hiring, salary, and assignment)
 - Education Plan
 - Space Evaluation, Building Plan
- Plan Management
 - Capacity Studies
 - Investment in New Equipment
 - Manufacturing Expenses
 - General Production Schedule

The program is intended to meet the needs of individuals who are not trained in the direct use of computers and want a facility that they can use easily in their planning cycle.

HIGHLIGHTS

PLANCODE/I provides:

- A double entry data table for calculation purposes. Its maximum dimensions are 1,500 rows and 60 columns.
- An English-like language that permits:
 - Referencing data elements with symbolic names supplied by the user,
 - Automatically repeating calculations on a row or on a set of rows,
 - Calling standard routines that perform calculations such as investment depreciation, production cost, learning curves, present value of capital expenditures, data extrapolation, etc.
- A report language that permits:
 - Specifying standard tabular report formats and charts.
 - Designing complex report layouts in free-format directly on a display terminal.
- A Planning Data Set which allows the user to store planning data.
- A model control feature which enables the user, conversationally, to request the running of a model and the display of the results in a required report. The user may request sensitivity analysis for a given model.
- Analysis facilities which allow analyzing data items in the Planning Data Set or entered directly from the terminal.

NEW WITH RELEASE 3

- Color Graphics Capabilities

An interface to the Interactive Chart Utility of GDDM/PGF is provided. This makes it possible to produce the common types of business graphs (line graphs, bar charts, etc.) interactively from PLANCODE/I data.

Charts produced by GDDM/ICU can be printed by the GDDM/ICU print function; see GDDM/ICU for supported printers.

- Monochrome charts can be constructed on 3290 Information Panel through the Interactive Chart Utility interface.

This capability is available for the VM/SP CMS, TSO and CICS/VS environments.

- Full-Screen Data File Editor

A full-screen editor for use with PLANCODE/I data files. The screen is divided into rows and columns of numeric fields, which can be directly updated in place. An entire data file is edited at one time, and scrolling is provided both in column and row directions.

3290 Information Panel with large-screen sizes can also be used with the full-screen data editor.

The full-screen editor uses GDDM as screen manager.

This capability is available for the VM/SP CMS, TSO and CICS/VS environments.

- Support for CICS SCS printers

This support makes it possible to direct PLANCODE/I output under CICS to printers that have SCS capability.

DESCRIPTION

PLANCODE/I is a terminal-oriented application program for building, testing and implementation of planning models.

Planning models can operate optionally on data supplied by the user from the terminal or on data stored in the Planning Data Set. Plan results can be stored in the Planning Data Set.

Comprehensive facilities are provided for the analysis of the effect of changes in input values on specified output values using 'what if' type sensitivity analysis.

Facilities are provided to enable the consolidation of results of planning models.

Planning model reports can be displayed in either tabular format or in a flexible free-format.

The PLANCODE/I Planning Data Set can be accessed from the terminal for the entering, display, or modification of data values.

Data analysis facilities are provided for the analysis of data values stored in the Planning Data Set or supplied directly from the terminal. These facilities include linear regression, exponential smoothing, multiple regression, and seasonal adjustment analysis. The results are displayed in either tabular or graphic form.

Syntax checking facilities are provided. The syntax is checked for each user input and any errors are diagnosed for correction by the user. Paging facilities are provided to enable users to control scanning of reports, data, etc.

PLANCODE/I is logically composed of six application areas or modes. These modes are:

- **Model mode**, for building and editing models
- **Report mode**, for designing and editing report layouts
- **Data mode**, for entering or displaying planning data
- **Execution mode**, for running models and displaying the results
- **Analysis mode**, for analyzing data using regressions, exponential smoothing, etc.
- **Procedure mode**, for generation of specific application usage of PLANCODE/I facilities for quicker and efficient operations.

CUSTOMER RESPONSIBILITIES

The customer must have installed the necessary IBM processor, appropriate terminals, and other required devices, and CICS/VS, IMS/VS, TSO or VM/SP CMS. To install PLANCODE/I, the customer will need operational personnel who are knowledgeable in CICS/VS or IMS/VS or TSO or VM/SP-CMS. The *PLANCODE/I Operations Guide* should be read and followed during the installation of the program product.

The user should be familiar with the fundamentals of financial and business planning techniques. The preparation of data, development of business planning models, definition of reports and interpretation of computed results are the responsibilities of the user.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

- PLANCODE/I OS/VS executes on IBM S/370, 30XX and 43XX Processors supported by MVS, MVS/XA or VM/SP CMS.
- PLANCODE/I DOS/VS executes on IBM 0, 30XX and 43XX Processors supported by VSE/Advanced Functions.

PLANCODE/I (cont'd)

- Direct Access Storage required by PLANCODE/I is 6 million bytes.
- PLANCODE/I OS/VVS and PLANCODE/I DOS/VVS executing under VM/SP CMS execute on IBM S/370, 30XX and 43XX Processors supported by VM/SP CMS.
- PLANCODE/I requires floating-point and decimal instruction sets.
- Virtual storage required by PLANCODE/I, in addition to the host environment is:
 - In TSO, PLANCODE/I requires a 2 megabyte Virtual Region (private space).
 - In IMS/VVS, 1,750K bytes for the first user and 250K bytes for each additional user of PLANCODE/I.
 - In CICS/VVS, 975K bytes for the first user of PLANCODE/I and 225K bytes for each additional user.
 - In VM/SP CMS, 2 megabytes of virtual storage for each user of PLANCODE/I.
- IBM terminals supported by PLANCODE/I under CICS/VVS:
 - 3270 Information Display System:
 - 12 PF keys are required.
 - Selector Light-Pen feature (optional) is supported for Option Selection on menu panels.
 - 3275 mdl 2
 - 3276 mdls 2, 3, and 4
 - 3277 mdl 2
 - 3278 mdls 2, 3 and 4
 - 3279 mdls 2A, 3A, 2B and 3B
 - 3268 Printer mdl 2
 - 3284 Printer mdl 2
 - 3286 Printer mdl 2
 - 3287 Printer mdl 2 and 2C
 - 3290 Information Panel
 - 3178-C20 Display Station
- IBM terminals supported by PLANCODE/I under TSO and VM/SP CMS:
 - 3270 Information Display System:
 - 12 PF keys are required.
 - Selector Light-Pen feature (optional) is supported for Option Selection on menu panels.
 - 3275 mdl 2
 - 3276 mdls 2, 3, and 4
 - 3277 mdl 2
 - 3278 mdls 2, 3 and 4
 - 3279 mdls 2A, 3A, 2B and 3B
 - 3290 Information Panel
 - 3178-C20 Display Station
- IBM terminals supported by PLANCODE/I under IMS/VVS:
 - 3270 Information Display System:
 - 12 PF keys are required.
 - Selector Light-Pen feature (optional) is supported for Option Selection on menu panels.
 - 3275 mdl 2
 - 3276 mdls 2, 3, and 4
 - 3277 mdl 2
 - 3278 mdls 2, 3 and 4
 - 3279 mdls 2A, 3A, 2B and 3B
 - 3268 Printer mdl 2
 - 3284 Printer mdl 2
 - 3286 Printer mdl 2
 - 3287 Printer mdl 2 and 2C
 - 3178-C20 Display Station

SOFTWARE REQUIREMENTS

PLANCODE/I OS/VVS (5740-XX8) operates under the control of CICS/VVS (5740-XX1) as a single transaction for each user, or under the control of IMS/VVS (5740-XX2) as a Wait for Input (WFI) transaction servicing all users, or under the control of TSO.

Under MVS/XA, PLANCODE/I OS/VVS operates in 24-bit addressing mode.

- Required releases: MVS/TSO 3.8, IMS/VVS 1.1.6 or 1.2, CICS/VVS 1.5 (CICS/VVS 1.6 for IBM 3290 support).
- The following components are required:
- Virtual Storage Access Method (VSAM)
 - PL/I Resident Library (5734-LM4)
 - PL/I Transient Library (5734-LM5)

- If access to DL/I is required under CICS/VVS, the IMS/VVS DB facility is required.

PLANCODE/I DOS/VVS (5746-XX9) operates under the control of CICS/VVS (5746-XX3) as a single transaction for each user.

- Required releases: DOS/VSE AF R2, CICS/VVS 1.5 (DOS/VSE AF R3 and CICS/VVS 1.6 for IBM 3290 support).
- The following VSE/Advanced Functions (5746-XE8) components are required:
 - VSE/VSAM (5746-AM2)
 - PL/I Resident Library (5736-LM4)
 - PL/I Transient Library (5736-LM5)

PLANCODE/I OS/VVS (5740-XX8) and PLANCODE/I DOS/VVS (5746-XX9) can also execute under VM/SP CMS.

- Required release: VM/SP R1.
- The following components are required:
 - Virtual Storage Access Method, VSAM
 - PL/I Resident Library (5734-LM4)
 - PL/I Transient Library (5734-LM5)

GDDM/PGF (5748-XXH) is required in utilizing the graphic and full-screen data file editor functions.

- Required release: GDDM R2 for full-screen data file editor and graphics, R3 for 3290 Information Panel support.

PLANCODE/I programs are written in the PL/I (as supported by OS and DOS PL/I Optimizing Compiler) language and in Basic Assembler language.

**SYSTEM/370 PLANNING, CONTROL AND DECISION
EVALUATION SYSTEM/STANDARD
PLANCODE/S
DOS/VS (5746-XXA) - OS/VS (5740-XX9)****PURPOSE**

PLANCODE/S is an application program which allows the building of Business Plans and Budgets, defined by the user, and the consolidation of these different Plans and Budgets at divisional or corporate levels. These plans and budgets permit the financial evaluation of the consequences of management decisions. In addition, PLANCODE/S enables the user to build a Budgetary Control application measuring actual results against planned objectives.

PLANCODE/S provides:

- A double entry data table for calculation purposes. Its maximum dimensions are 255 columns or 32,000 rows. The product of the number of columns and the number of rows must be less than 1,200,000.
- An English-like modeling language that permits:
 - referencing data elements with symbolic names supplied by the user, thus the planning process can be formulated in the planner's own language such as:
 - calling standard routines that perform calculations such as investment depreciation, production cost learning curves, present value of capital expenditures data extrapolation, etc.
- A report language that permits:
 - specifying standard report formats and charts.
 - designing user specified report layouts.
 - performing "housekeeping" calculations such as line-totals and ratios between two lines.
- A Planning Data Set which allows the user to store planning data in the form of multi-entry tables.
- A model execution feature for processing planning models, using data either coming from the Planning Data Set or directly from the user.
- A Budgetary Control facility that permits:
 - the definition of the hierarchy of the company responsibility center.
 - the merging of planned data with actual data.
 - the selection of reports to be produced and printed for each responsibility center.
 - the automatic consolidation of Budgetary Control reports.

HIGHLIGHTS

In a typical planning application, the planner generates several budgets or plans which differ by the planning calculations and/or the output formats. For example, the budgets of the production and sales departments differ in their planning calculations and output formats.

The budgets of two sales departments, however, may only have different output formats.

The user specifies calculations by building one or more programs, planning models made up of a PROGRAM command, followed by calculation statements using the PLANCODE/S planning language facilities. The user specifies the output format by using REPORT definition statements.

A planning application can be made up of as many programs as the user wishes. Any number of company responsibility centers can use the same program (if suitable) to build their plans. They can also use the same set of report definition statements, but they can define their respective report page headings at plan generation time. The user can build as many applications as needed.

Planning data can be stored in the form of multi-entry tables in the Planning Data Set. Up to four dimensions are allowed. The user is able, for example, to define data as being a set of plan items ordered by product type, department, and division name.

Then the user can read:

Either one plan item (for example, sales) for all products, departments and divisions, or,

Several items for all or a few selected products, all departments and for a specific division.

A double-entry data table, called a calculation matrix, is available for calculations done with up to 16 significant digits. The matrix lines correspond to the items of the plan; the columns usually correspond to the plan periods such as weeks, months, years, but they can also represent categories of the plan items such as lines for expense items and columns for expense distribution by products. Planning data can be entered into this calculation matrix directly from cards or by a command which extracts the data from the planning data set.

PLANCODE/S is designed in a modular approach. The user can initialize a section or mode by including a set of commands in the planning run input stream.

- *Model mode* for entering planning language statements and report generation specifications.
- *Data mode* for entering planning data, listing file contents, and file manipulations.
- *Execution mode* to run the planning models and print reports.

These modes are separate so that each can be used independently, but are integrated by means of the Planning Data Set.

CUSTOMER RESPONSIBILITIES

To install and run PLANCODE/S, the customer must define VSAM data sets (Planning Data Set System Files) and link-edit the PLANCODE/S object modules at installation time in order to obtain the executable module.

Customers can also define a message file in their own language if they do not want to use the English messages included in PLANCODE/S.

To run the Budgetary Control Programs, the user has the responsibility of defining the hierarchy of the company responsibility centers, and entering tables in which the rules for assigning actual data items to planned data items are defined.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS****PLANCODE/S DOS/VS (5746-XXA)**

PLANCODE/S DOS/VS runs on S/370 with floating point and decimal instruction sets, one disk storage drive, one printer and one card reader. The minimum real storage allocated to PLANCODE/S DOS/VS is 60K bytes in addition to the operating system requirements.

PLANCODE/S OS/VS (5740-XX9)

PLANCODE/S OS/VS runs on System/370 with floating point and decimal instruction sets, one disk storage drive, one printer and one card reader. The minimum real storage allocated to PLANCODE/S OS/VS is 60K bytes, in addition to the operating system requirements.

SOFTWARE REQUIREMENTS**PLANCODE/S DOS/VS (5746-XXA)**

PLANCODE/S DOS/VS operates in batch mode under the control of the Disk Operating System/Virtual Storage (DOS/VS) Release 34 and under the Disk Operating System/Virtual Storage DOS/VSE) and subsequent releases unless otherwise identified. It also operates in virtual machine mode under control of DOS/VS running under VM/370. It is written in PL/1. The Sequential and Virtual Storage Access Methods are used. The PL/1 Resident Library (5736-LM4) and PL/1 Transient Library (5736-LM5) of the PL/1 Optimizing Compiler (5736-PL1) are required.

PLANCODE/S OS/VS (5740-XX9)

PLANCODE/S OS/VS operates in batch mode under the control of the System/370 Operating System/Virtual Storage OS/VS1, Release 3.0 or OS/VS2, Release 1.7 or 2.0 and subsequent releases unless otherwise identified. It operates in virtual machine mode under control of OS/VS1 and OS/VS2 running under VM/370. It is written in PL/1. The Sequential and Virtual Storage Access Methods are used. The PL/1 Resident Library (5734-LM4) and PL/1 Transient Library (5734-LM5) are required.

PROGRAM PRODUCTS

CUSTOMER INFORMATION FACILITY/VS
5740-XYB (IMS/VS)
5740-XYC (CICS/OS/VS)
5746-XXS (CICS/DOS/VS)

PURPOSE

Customer Information Facility/VS Release 1 Modification Level 0 is a new set of application programs for the management and control of customer related data in a Financial Institution.

This system improves the efficiency of a Financial Institution by providing a central data base that contains all customer descriptive data, thus eliminating the requirement of repeating this data in multiple account files or data bases.

Cross-referencing between the Customer data base and Account data bases and within the Customer data base, provides the ability of determining a Customer's total relationship with the various service areas of the financial institution and with other customers.

The Customer Information Facility/VS operates as an application program under the IBM IMS/VS program product with the Data Communications feature or CICS/VS program product with either the IMS/VS program product data base or the Data Language/I DOS/VS (DL/I DOS/VS) program product. In both Systems, the Customer Information Facility/VS operates online through the IBM 3600 Finance Communication System and the IBM 3270 Information Display System.

Responsibility for security rests with the customer. All security features of IMS/VS and/or CICS/VS and/or DL/I DOS/VS are available to the user. The Customer must select and implement those features which are appropriate to his application and environment. Required additional security measures should be placed in the application programs.

The Customer Information Facility/VS operates in the following OS/VS1 and DOS/VS environments:

OS/VS1	DOS/VS
IMS/VS (5740-XX2)	CICS/DOS/VS
with DC Feature	(5746-XX3)
	and
or	DL/I DOS/VS
	(5746-XX1)
CICS OS/VS (5740-XX1)	
and	
IMS/VS (5740-XX2)	

HIGHLIGHTS

- **Central Source Of Information and Control:** The Customer Information Facility/VS is a central source of information about a Financial Institution's customers, including prospective customers. A financial institution officer can retrieve from this single source a display of a customer's total relationship with the financial institution.
- **Online Maintenance and Information Retrieval:** Online access is provided to the Customer Information Facility/VS data bases via IMS/VS or CICS/VS. These programs provide the ability to add, change, delete information in any of the data bases or scan the data bases for selective retrieval. Provisions are also made for storing user data in the form of comments.
- **Flexibility of Use:** The design philosophy of the Customer Information Facility/VS allows the user to integrate all or only selected applications into the Customer Information Facility/VS. Applications are integrated one at a time allowing a gradual migration to a fully integrated system. Modular system design facilitates user modification to the data bases or to the functional capabilities of the programs.
- **Extensive Reporting Capability:** Users can obtain predefined reports on the complete contents of the data base. Another function provides for user specified selective retrieval of information from the Customer Information Facility/VS data bases. Additional custom reports, if desired, can be generated using GIS/VS.
- **Aids to Capture Existing Customer Data:** Programs are provided to convert user supplied data from multiple application files and create the Customer data base and related Account data base(s) used by the Customer Information Facility/VS. For users of IBM Customer Information File FDPs, programs are provided to convert existing Customer and Account data bases to the format required by the Customer Information Facility/VS.
- **Support of the IBM 3600 Finance Communication System and the IBM 3270 Information Display System:** Access to the Customer Information Facility/VS data base from a numeric only terminal can be done if desired by means of the secondary index provided.
- **Use of Standard DB/DC Products:** The use of IBM data base/data communications products provides upward growth capabilities

among the versions of the Customer Information Facility/VS as well as compatibility with other applications developed under these DB/DC products.

- **Virtual Storage design:** The Customer Information Facility/VS is designed to take advantage of modern programming techniques and to improve the performance on virtual storage hardware.
- **Upward Compatibility:** The data base and screen format designs allow for upward migration as users of the system desire to move from the CIF/VS CICS/DOS/VS or the CIF/VS CICS OS/VS products to the CIF/VS IMS/VS product.
- **DASD Support:** The Customer Information Facility/VS can use all devices supported by IMS/VS or DL/I DOS/VS such as IBM 3330, 3340 and 3350.
- **EFTS Orientation:** The Customer Information Facility/VS provides significant enhancements over the current IBM FDPs and is designed to aid financial institutions in implementation of EFTS (Electronic Funds Transfer System).

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The Customer Information Facility/VS is designed to execute in IBM S/370 mdls 125 and above. The Customer Information Facility/VS requires a minimum virtual storage of 500K under DOS/VS and 600K under OS/VS1 and a minimum real storage of 150K under DOS/VS and 200K under OS/VS1 in addition to that required by the operating system and IMS/VS with the DC feature or CICS/VS and DL/I DOS/VS.

SOFTWARE REQUIREMENTS

Release 1 Modification Level 0 of the Customer Information Facility/VS source code will be produced and distributed using COBOL and Assembler language.

- **OS/VS1:** The Customer Information Facility/VS using IMS/VS (5740-XYB) Release 1 Modification Level) operates as a set of application programs under IMS/VS (5740-XX2) Version 1 Release 1.4 and subsequent releases unless otherwise identified and requires the Data Communications feature of IMS/VS.
- **DOS/VS:** The Customer Information Facility/VS using CICS OS/VS (5740-XYC) Release 1 Modification Level 0 operates as a set of application programs under CICS OS/VS (5740-XX1) Version 1 Release 3.0 and IMS/VS (5740-XX2) Version 1 Release 1.4 and subsequent releases unless otherwise identified.

- **DL/I DOS/VS:** The Customer Information Facility/VS using CICS/DOS/VS (5746-XXS) Release 1 Modification Level 0 operates as a set of application programs under CICS/DOS/VS (5746-XX3) Version 1 Release 3.0 and DL/I DOS/VS (5746-XX1) Version 1 Release 3.0 and subsequent releases unless otherwise identified.

For operating system requirements, see IMS/VS or CICS/VS and DL/I DOS/VS Programming System Support in the appropriate IMS/VS or CICS/VS and DL/I DOS/VS documentation.

Functional Compatibility: Release 1 of the Customer Information Facility/VS includes all the functions of the following FDPs:

- Customer Information File CICS (CIF) (OS) (5798-AMR)
- Customer Information File (CIF) using IMS DB/DC (5798-AWZ)
- Customer Information File (CIF) using DOS/CICS (5798-AHX)

CONVERSION

The Customer Information Facility/VS provides the customer with programs to assist in converting his data bases either from the current Customer Information File FDPs or from his present system.

Installing the Customer Information Facility/VS requires the customer to:

- Tailor the source programs to meet user requirements.
 - Provide a sort/merge routine and a COBOL Compiler/Library in the host system. The OS/VS Sort/Merge (5740-SM1), DOS/VS Sort/Merge (5746-SM1), OS/VS COBOL Compiler/Library (5740-CB1) and DOS/VS COBOL Compiler/Library (5746-CB1) meet these requirements.
 - Set up user tables with desired values.
- Customers initially installing the Customer Information Facility/VS will convert their existing system as follows:
- Organize and construct a sequential file containing the data to be used by the EDIT program.

PROGRAM PRODUCTS

CIF/VS (cont'd)

- Edit the file using the EDIT program until all data conforms to the new format.
- Load the information in the data bases with the programs supplied.

PERFORMANCE CONSIDERATIONS

The performance of the Customer Information Facility/VS Program Product is dependent on the system resources available, paging characteristics, concurrent processing and the particular data being processed.

General Information Manual	GH20-2018

AUTOMATED OPERATOR FACILITY RELEASE 1, MODIFICATION LEVEL 0 5740-XYD

PURPOSE

The Automated Operator Facility (AOF) is a transaction-driven data base/data communication program that runs as an application under IMS/VS Version 1, Release 1, Modification Level 5, with the Automated Operator Interface (AOI) function. AOF improves the operational use of IMS/VS in the data communication environment, and it can also improve the availability of service to IMS/VS application users by re-establishing the system more readily following shutdowns.

DESCRIPTION

AOF comprises the following:

- An application program that executes in a dependent BMP (Batch Message Processing) region.
- The AOI user exit program that executes in the IMS/VS control region.
- A DL/I data base.
- A partitioned data set.
- A data base maintenance program that executes as either a BMP program or a batch DL/I program.

The application program includes a main control program and a group of functional processors. The control program performs initialization and reporting functions, acquires input messages and directs them to the appropriate functional processors, and selects output messages. After initialization, it starts processing the message queue. Each transaction is edited to determine which functional processor is to be invoked to handle each transaction, and the program then branches to the processor that is to perform the particular function. The functional processors are: Application Grouping, Fast-Key, Network Status (Save, Update and Restore), and Sub-Network MTO (Master Terminal Operator.) The Application Grouping Functional Processor translates a transaction that addresses a user-defined application group into a set of IMS/VS commands which are then submitted to the AOI to perform the requested action on the entire group. An application group is a set of IMS/VS resources which are grouped according to user specifications (for example, data bases, transactions and terminals that will be devoted to an accounting application). The processor references information in the AOF data base which describes which network resources belong to the application group and then uses that information to generate IMS/VS commands dynamically.

The Fast-Key Functional Processor issues a pre-planned series of IMS/VS commands and certain AOF transactions that are stored as a member of a partitioned data set (PDS). These commands and transactions can be interspersed in the same member of the PDS.

The Network Status Save, Network Status Update and Network Status Restore functional processors, AOI user exit program and the AOF data base constitute a sub-system that assists the MTO in maintaining his IMS/VS environment. In general, these processors track the condition of resources and issue IMS/VS commands to the AOI at restart to restore the system to the same status that existed prior to shutdown.

The Sub-Network MTO Functional Processor allows a remote terminal operator to control a designated subset of an IMS/VS network. This control is similar to that which the MTO exercises over the entire network. The Sub-Network MTO can submit a transaction that includes a command that addresses particular resources under his control, or a transaction that results in the generation of commands that address that part of an application group under his control.

The AOF data base is a DL/I data base that supports the application group control, network status and sub-network MTO functions. Logical relationships are used to facilitate the search for the segments used to perform these functions.

The data base is maintained by the AOF Data Base Maintenance Program which defines, modifies, adds and deletes the stored information.

Data for the Fast-Key control function is stored in a partitioned data set (PDS). This PDS can be IMSVS.PROCLIB or any other PDS the user designates with a logical record length of 80 bytes. The PDS for Fast-Key data is used to provide a possible migration path from the IMS Master Terminal Operator Assist Facility FDP (Program Number 5798-CLK).

HIGHLIGHTS

AOF offers the following advantages:

- Permits the user to associate IMS/VS network resources into application groups and issue, with a minimum of keying, IMS/VS commands that address all of the resources within an entire group.
- Reduces the amount of keying required of the MTO by allowing a pre-planned series of IMS/VS commands to be issued when the MTO submits a single transaction to the system. This permits a

pre-defined operator command sequence to be automatically entered into IMS/VS at machine-readable speed.

- Records the status of modifiable attributes for certain network and application related resources and uses that data after restart to generate IMS/VS commands that restore the status to those resources that were modified prior to a shutdown (either planned or unplanned).
- Reduces the workload of an MTO by allowing a remote terminal operator to control a subset of IMS/VS network resources in a manner analogous to that in which the MTO controls an entire network.
- Can improve system availability to application users through faster re-establishment of the IMS/VS DC environment following any shutdown.

AOF can be used with the Multiple Systems Coupling (MSC) feature, but MSC resources are not supported by ACCF for automatic application grouping. AOF can be used with the Fast Path feature, but it cannot execute in an IFP (IMS/VS Fast Path) region. Fast Path data bases, transactions, areas, and routing codes can be operated upon, however, by AOF transactions.

CUSTOMER RESPONSIBILITIES

A customer who installs AOF must:

- Have successfully installed IMS/VS 1.1.5 with the Automated Operator Interface (AOI) function.
- Assure that appropriate AOF training be given system programmers and system operators.
- Modify, if desired, the AOI user exit source code to reference the user-defined transaction code for messages to the AOF, and assemble and link-edit the AOI user exit into IMSVS.PGMLIB.
- Execute the IMS/VS Security Maintenance Utility to accommodate the application program, data base, and terminals.
- Build a PDS for Fast-Key procedures or convert existing procedures for the IMS Master Terminal Operator Assist Facility (see the section "Conversion" for specific details).
- Become familiar with operating procedures for controlling a sub-network when remote terminal operators are designated as sub-network MTOs.
- Perform DBDGEN for the data base.
- Perform PSBGEN and ACBGEN for the application program and data base maintenance program.
- Prepare input for the AOF data base.
- Execute the AOF Data Base Maintenance Program to perform an initial load of the AOF data base.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

AOF does not need any hardware in addition to that which is required for the IMS/VS Data Base/Data Communication (DB/DC) System and does not require any terminals other than those which IMS/VS supports for master terminal operation. See the *IMS/VS General Information Manual* (GH20-1260) for a list of processing units and terminals supported by IMS/VS.

The minimum virtual storage requirements for AOS are listed below:

- Data Base Maintenance Program

When run as a DL/I program:	320K
When run as a BMP:	60K
- Application Program (BMP): 160K
- AOI User Exit Program (which runs in the control region): 1K

Both the AOF data base and PDS can reside on any direct access storage device supported by IMS/VS for DL/I data bases. The amount of space to be reserved for the data base is a function of the size of the network, the number of application programs, transactions, data bases and user-defined application groups. Space requirements for the PDS must be determined from the number and size of Fast-Key procedures developed for the PDS.

SOFTWARE REQUIREMENTS

AOF runs under IMS/VS Version 1, Release 1, Modification Level 5, and subsequent releases and modification levels unless otherwise stated. It requires the IMS/VS Data Base System combined with the Data Communication feature and the Automated Operator Interface (AOI) function which will be available with IMS/VS 1.1.5 as part of the

PROGRAM PRODUCTS

AOF (cont'd)

Data Communication feature. It can be used with both the Multiple System Coupling (MSC) and Fast Path features as described earlier in the "Highlights" section. At the time AOF becomes available, it will operate on the Operating System/Virtual Storage (OS/VS) releases that are supported by IMS/VS 1.1.5.

No supervisor calls (SVCs) are required in addition to those which are used by IMS/VS.

The AOF data base uses HIDAM (Hierarchical Indexed Direct Access Method).

AOF is coded in OS/VS Assembler language, and both object and source code will be distributed for this product.

CONVERSION

The Fast-Key component of AOF provides a capability which includes the functions of the IMS Master Terminal Operator Assist Facility FDP (5798-CLK), but the following considerations apply:

- If installed, the procedure for continuing commands across records must be revised since the AOF Fast-Key PDS requires that byte 72 be used or reserved for a continuation character.
- AOF does not allow command data or a period (.) at or beyond byte 72. It assumes that these positions are used for sequencing (and ignores them), but the MTO Assist Facility does not impose this restriction.
- If procedures have been created that allow the use of IMS/VS commands which are not supported by the Automated Operator Interface (AOI), such procedures cannot be converted to yield the same results under AOF.
- AOF reserves a range of procedure names (START001 through START999) for special purposes.

PERFORMANCE CONSIDERATIONS

The implementation of this product will have the following performance implications:

- The efficiency of the Master Terminal Operator should be improved since AOF automates many of the functions that are required to keep the system operational and to restore the system after a shutdown. In particular, the following MTO tasks can be performed much more readily with AOF: Restarting IMS/VS, varying offline IMS/VS resources, bringing back online IMS/VS resources that belong to a particular application area and restoring the resources of a network at restart to the status that existed prior to the last shutdown.
- The efficiency of the MTO should be further improved since AOF allows authorized remote terminal operators to exercise control over a sub-network in a manner similar to that which the MTO exercises over the entire IMS/VS network.
- Since the AOF application program executes as a quasi-system program in a dependent region, it will compete for IMS/VS resources along with other user application programs.
- The rate of throughput for user application transactions may be degraded because of the interception of commands and their responses by the AOI user exit program.
- Depending on the function requested, it is possible to construct command streams which could process for an extended period of time.

PROGRAM PRODUCTS

**OS/VS1 INFORMATION DISTRIBUTION
WORKSTATION SUPPORT
5740-XYE****DESCRIPTION**

OS/VS1 Information Distribution Workstation Support provides RJE support for the IBM 6670 Information Distributor (SDLC Version only). The IBM 6670 users can submit jobs and data to an OS/VS1 host for processing, and receive at the IBM 6670 job output, documents, letters and variable data generated at the OS/VS1 host. This output at the IBM 6670 can be processed or merged with constant data such as the body of a letter or report, and printed on cut sheet paper or recorded on magnetic cards.

HIGHLIGHTS

- Provides support for remote session initialization and data transmission to and from the IBM 6670 using the SNA protocol.
- Provides the RTAM support for SNA input data records other than default length.
- Provides the ability for JES SNA remote readers to utilize an expanded record length (up to 128 bytes).
- Provides the RTAM support for user specifiable SNA output destination selection.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

The Information Distribution Workstation Support program product operates on all IBM processors capable of supporting OS/VS1 RES with VTAM.

The OS/VS1 RTAM module size will increase by 4K bytes when using the Information Distribution Workstation Support program product.

SOFTWARE REQUIREMENTS

The Information Distribution Workstation Support program product operates with OS/VS1 Release 6.7 or any subsequent release unless otherwise stated, as well as the current or later releases of the following prerequisite programs:

ACF/VTAM Version 1	5735-RC2
ACF/VTAM Version 2	5662-280
SCP for ACF/VTAM	5741-VS1
ACF/NCP/VS	5735-XX1
SSP for ACF/NCP/VS	5735-XX3

In addition, OS/VS1 RES/RTAM (5741-SC1BB) must be installed.

PROGRAM PRODUCTS

SCREEN DEFINITION FACILITY
CUSTOMER INFORMATION CONTROL SYSTEM
RELEASE 3 MOD. LEVEL 0
OS/VS (5740-XYF) - DOS/VSE (5746-XXT)

PURPOSE

Screen Definition Facility/Customer Information Control System (SDF/CICS) is an online application development tool for the CICS/VS application programmer who wants to define or edit maps and map sets for the CICS/VS Basic Mapping Support (BMS). The online operation and the ease-of-use oriented functions of the program enhance productivity in map and map set development and maintenance.

DESCRIPTION

The online functions of Screen Definition Facility/CICS run as a CICS/VS application program in all system environments supported by CICS/VS Version 1 Release 5.0 (except OS/VS2 SVS) and CICS/VS Version 1 Release 4.1 on VSE/Advanced Functions Release 2.0. Release 3.0 of SDF/CICS supports all functions of Release 2.0. In addition, it offers usability enhancements, such as arrays of structures for maps and full screen field naming, new functions for user status control and object security, and a demo session facility.

NEW FUNCTIONS in RELEASE 3.0:

SDF/CICS Release 3.0 supports all functions as supported in Release 2.0 and includes the following new functions or enhancements:

- **Map Editor Usability Enhancements:**
 Arrays of structures for both input and output maps. With the full screen field naming function of the map editor, the names for fields can be defined by a full screen editor approach. New maps can be created starting from skeleton maps. A skeleton map is provided for the use of ELIAS-I developed application programs. Application structures created with the map editor can be reviewed and partially modified with the application structure review function.
 When editing a map, the user can select a format which shows column numbers for the map.
 The new support of multiple field marks will help to distinguish in field definition between different types of fields with different sets of field attributes.
- **SDF/CICS User Environment**
 A hierarchy of users: System user, master user and normal user. The system user defines user environments for new users of an installation and establishes their authorization to use SDF/CICS. He can also access password protected objects by overriding the password, and use the normal functions of SDF/CICS. The master user can control start-up and shut-down of an SDF/CICS installation, investigate the list of active users and also use the normal functions. A normal SDF/CICS user only has access to the normal functions, which can be further restricted in his individual user environment object as defined by the system user.
- **Multiple Map Specification Libraries**
 During a session, a user can have access to up to three libraries: The system library, one private library with read-only access and one private library with read/write access. These libraries are defined for each individual user by the user profile. This profile is defined by the SDF/CICS system user and can be modified by the individual user, if he is so authorized, by means of the profile editor.
- **Demo Session Support**
 The demo session facility can be used to define and display a sequence of screens, either full screen maps or pages. When defining the demo session, the user can define a sequence of screens for the demo session and which program function key is to select the successor screen.
 SDF/CICS Release 3.0 also includes predefined demo sessions which explain for the new SDF/CICS user how to use the map editor to define a new map and to convert an existing map for use on color display terminals.
- **Minor Usability Enhancements**
 The SDF/CICS user can now sign on a session with a fast command format transaction with parameters. Release 3.0 contains a specific News tutorial topic which explains all functions new to this release. This topic is accessible by the NEWS command.

FUNCTIONS AVAILABLE in RELEASE 2.0:

- Online definition and editing of maps and map sets.
- Support of device independence for maps and map sets.
- Library directory support.
- CICS/VS-BMS map generation.
- Page simulation.
- Session profiles of defaults.
- Online help and tutorial.

- Batch utilities.
- Conversion of CICS/VS-BMS defined maps and map sets.
- Conversion of Data Dictionary Segment Definitions to SDF/CICS maps.

Advantages

- **Online Development Productivity**
 Online application development offers higher programmer productivity than batch development. Bringing CICS/VS map definition online improves the overall productivity for CICS/VS application development. Providing arrays of structures both for input and output maps reduces the effort required to design and code application programs.
- **Early Test of Maps and Pages**
 By means of the test functions of the map and page editor, the end user can immediately review the application aspects of maps and pages. Data can be entered and all fields are displayed under control of their associated attributes, such as color, highlighting or programmed symbol set.
- **Online Demo Capability**
 With the online demo capability the end user can inspect the screens of a session as he defines them. Early demonstration for complete applications can also be generated with this function.
- **Ease-of-Use in Operation and Maintenance**
 The functions of SDF/CICS online operations are ease-of-use oriented. Sets of defaults that can be customized as session profiles for an installation or for specific users, assignment of functions to program function keys, library maintenance by means of directory lists, recovery from a range of system failures for objects in the library or in process during a session and a trace facility for online operation contribute to this goal.
- **Management of Map and Map Set Inventory in Installation**
 All maps and map sets defined in SDF/CICS are maintained in one library. The directory list of the library gives a complete overview of the inventory of maps and map sets in the installation as well as of their individual status.
- **Multiple-Device Support**
 By defining multiple-device maps and map sets, old applications can be adapted to support new devices without needing to modify or recompile the application program.
- **Online Education**
 The online tutorial with text and sample obviates the need for separate classroom education and reduces the need for the use of a hard copy reference manual.
- **Smooth Migration from BMS Macro-Defined Maps and Map Sets to SDF/CICS.**

CUSTOMER RESPONSIBILITIES

In order to install and use SDF/CICS successfully the customer must have installed the minimum machine configuration and the appropriate operating system required by CICS/VS and SDF/CICS and the devices as required for the SDF/CICS definition, testing and demo functions.

The distribution tape contains job and VSAM control statements which can be used by DOS/VSE, OS/VS1 and OS/VS2 (except SVS) customers to create a VSAM Master Catalog before installing SDF/CICS in the case that VSAM has not been used before.

The customer must update certain CICS/VS control tables in order to run SDF/CICS as a CICS/VS application. Card images of the macro statements to be inserted in the appropriate macro decks are contained on the distribution tape.

Finally the customer can tailor his SDF/CICS system to the needs of his installation by modifying and/or coding SDF/CICS system generation macros and/or modifying the distributed job stream.

SPECIFIED OPERATING ENVIRONMENT
HARDWARE REQUIREMENTS

SDF/CICS is designed to operate on the following IBM machines:

All IBM System/370, 303X and 3081 processing units and IBM 4300 processors capable of supporting CICS/VS Version 1, Release 5.0 with OS/VS and DOS/VSE, and CICS/VS Version 1 Release 4.1 with VSE/Advanced Functions Release 2.0.

The online part of SDF/CICS works as a CICS/VS transaction, thus requiring the same specified operating environment as announced for the respective CICS/VS version and releases.

The batch part of SDF/CICS occupies a single partition in DOS/VSE and OS/VS1, or a single address space in OS/VS2 (MVS). It does not generate additional requirements on the system configuration.

PROGRAM PRODUCTS

SDF/CICS (cont'd)

The minimum estimated virtual partition/region size for batch SDF/CICS is 256K bytes.

The configuration must provide sufficient direct access space to contain the VSAM files used both by online and batch SDF/CICS functions. For DOS/VSE, the VSE/VSAM licensed program must be installed. The VSAM functions used by SDF/CICS in OS/VS1 and OS/VS2 are basic and thus contained in the operating system.

The terminals supported by SDF/CICS as target devices are the same as those supported for the definition of maps by the Basic Mapping

The IBM SDF/CICS terminals, that is, those devices on which the SDF/CICS user enters or receives information, are:

3275 Control Unit	Mdl 2	BSC - remote
Display Station	Mdl 12	SDLC - remote
3276 Control Unit	Mdls 1,2,3,4	BSC - remote
Display Station	Mdls 11,12,13,14	SDLC - remote
3277 Display Station	Mdl 2	local and remote
3278 Display Station	Mdls 1,2,3,4,5	local and remote
3279 Display Station	Mdls 2A,2B,3A,3B	local and remote
8775 Display Station	Mdls 1,2	local and remote
	Mdls 11,12	SDLC - remote

For the restrictions on devices supported in a specific release of CICS/VS, the corresponding manuals for the release must be consulted. Some of the above listed devices may not be announced in your country. (IBM 3278 Display Station Mdl 52 is not announced in E/ME/A or DPD). This reference must not be construed to mean that IBM intends to announce these devices in your country.

Note that display devices with a width of 80 characters and a depth of 12 lines are no longer supported by SDF/CICS Release 3.0.

SOFTWARE REQUIREMENTS

SDF/CICS runs as a CICS/VS application program on all IBM S/370, 303X and 3081 processing units and IBM 4300 processors capable of supporting CICS/VS Version 1 Release 5.0 in the OS/VS1 and OS/VS2 (except SVS) environments and CICS/VS Version 4.1 and 5.0 in DOS/VSE, from VSE/Advanced Functions Release 2.0 on. CICS/VS is available as 5740-XX1 for OS/VS and 5746-XX3 for DOS/VSE.

If an SDF/CICS screen with extended attributes, such as extended color, extended highlighting or field validation, is to be used in the field initialization of the map editor or in the test functions, SDF/CICS must be used with CICS/VS Version 1 Release 5.0. For defining these attributes, all CICS/VS releases supported by SDF/CICS Release 2.0 can be used.

If the SDF/CICS user specifies a programmed symbol set attribute, it is his responsibility to ascertain that the specified symbol set is loaded to the device.

Whenever SDF/CICS is used with a display device in base color mode, the fields on SDF/CICS screens are displayed in base colors according to the attributes associated with the screens.

SDF/CICS supports application programming in S/370 Assembler language, PL/I, COBOL and RPG II. For each language required, the appropriate compiler and library must be installed if application programs are compiled or assembled on the system.

SDF/CICS uses the Virtual Storage Access Method (VSAM). For DOS/VSE, the VSE/VSAM licensed program must be installed. For OS/VS, the VSAM functions used by SDF/CICS are contained in the operating system.

SDF/CICS requires for its installation and operation the following support programs:

- Assembler
- System utilities:
 - DOS/VSE: MAINT, Linkage Editor
 - OS/VS: IEBUPDTE, Linkage Editor
- VSAM:
 - DOS/VSE: VSE/VSAM licensed program 5746-AM2
 - OS/VS: VSAM Access Method Services
- SMP (System Modification Program) Release 4 in OS/VS
- MSHP (Maintain System History Program) in DOS/VSE
- PTFHIST in DOS/VS Release 34

SDF/CICS provides job streams to transfer symbolic description maps to:

- VSE/Interactive Computing and Control Facility (VSE/ICCF, Program Number 5746-TS1).

The user can establish equivalent functions for the field-developed program:

- CICS/VS Source Program Maintenance (SPM II, Program Number 5798-CFT).

SDF/CICS can convert data dictionary segments, containing logically related data fields, from the following licensed programs into SDF/CICS maps:

- OS/VS: 5740-XXF, from Release 3.0 on.
- DOS/VS: 5746-XXC, from Release 3.0 on.

SDF/CICS provides a skeleton map for the use of the ELIAS-I program products:

- ELIAS-I: 5746-XXV
- ELIAS-I/VM: 5748-XXK

SDF/CICS defined maps can be exported to DPPX/Distributed Presentation Services of the IBM 8100 Information System.

- DPPX/DPS: 5760-XR1

The distributed Basic Material consists of pregenerated object modules, CICS/VS table entries and job streams to create the VSAM clusters necessary to run SDF/CICS.

Education: The online tutorial serves as computer-based education material. In particular, the online tutorial contains sample screens for the map editor, and two online demo sessions are included with the product to demonstrate a simple map definition session and a conversion of an old map to extended color field attributes.

COMPATIBILITY

The physical maps generated by SDF/CICS are fully compatible with equivalent maps generated by the map and map set definition macros of the CICS/VS Basic Mapping Support from the CICS/VS environments supported by SDF/CICS Release 3.0. The symbolic description maps generated by SDF/CICS are a compatible superset of maps that can be generated by the CICS/VS Basic Mapping Support, in particular, longer field names and arrays of structures can be defined and corresponding symbolic descriptions of maps can be generated.

CONVERSION

CICS/VS maps and map sets in their BMS macro source format can be converted by a batch utility of the program into SDF/CICS card formats which can then be loaded into the library.

MVS SYSTEM INTEGRITY APPLIES: Yes

RPOs ACCEPTED: No

PROGRAM PRODUCTS

**MASS STORAGE SYSTEMS EXTENSIONS (MSSE)
RELEASE 1 (5740-XYG)****DESCRIPTION**

The Mass Storage System Extensions licensed program introduces additional space management, data management, and problem determination capabilities for users of the 3850 Mass Storage System.

This licensed program can be used with OS/VS2 Release 3.8 (MVS) or OS/VS1 Release 6.7 (VS1).

HIGHLIGHTS**Space Management Facilities**

- System-initiated scratching of virtual volumes of expired data sets, uncatalogued data sets, or Generation Data Group (GDG) data sets.
- Listing of VSAM data space information (LISTDSET).
- Specifying 'date-last-used' as a selection criterion for listing or scratching data sets (LISTDSET/SCRDSET) (MVS Only).
- Specifying combinations of selection criteria in an LISTDSET/SCRDSET command.

Data Management Facilities

- Capability to copy mounted virtual volume (COPYV).
- Capability to copy only the allocated cylinders on a virtual volume (COPYV).
- Support for large sequential data sets.
- Staging data on a page-fault basis as an additional processing option.
- Staging VSAM data sets on a key or keyrange basis (MVS only).

Problem Determination Facility

- Centralized journaling of Mass Storage System messages.

CUSTOMER RESPONSIBILITIES

A customer installing the Mass Storage Extensions licensed program or the MVS/XA Facility must:

- Have installed at least the minimum machine configuration.
- Have the 3850 Mass Storage System installed.
- Assure that appropriate OS/VS1 or OS/VS2 (MVS) and S/370 training be given to systems programming, operations and space management personnel.
- Apply necessary programming changes to OS/VS1 and OS/VS2 (MVS) associated with the installation of the Mass Storage System Extensions licensed program.
- Specify, during the SYSGEN for OS/VS1, the option to include a WTO/WTOR user exit routine to support Centralized Journaling.
- Choose the necessary user options specified.
- Have installed the proper MSS microcode level.
- The Mass Storage Extensions licensed program must be installed prior to installing the MVS/XA Facility.
- Install MVS/SP Version 2, to place the 3081 in XA mode before using the MVS/XA Facility.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

The Mass Storage System Extensions licensed program can be utilized on all processing units to which the IBM 3850 Mass Storage System is attached. The Mass Storage System can be attached to IBM S/370 models 145, 148, 155II, 158, 165II and 168, and the IBM 3031, 3032, 3033, or 3081 Processors.

The MVS/XA Facility (Release 1.1 of MSSE) is required to attach the IBM 3850 Mass Storage System to IBM 3081 processors operating in XA mode with MVS/XA.

An installation can attach the 3850 Mass Storage System to from one to four systems which may be a combination of S/370 processors and XA Mode processors. The S/370 processors may operate with or without MSSE but cannot have the MVS/XA Facility installed. The attached XA processors must operate with the MSSE program product and the MVS/XA Facility.

The MVS/XA Facility is designed to operate with the IBM XA Mode processors exclusively.

The Mass Storage System Extensions licensed program, with or without the MVS/XA Facility, supports all the models of the IBM 3850 Mass Storage System. The appropriate level of MSS microcode must be installed to support the Mass Storage System Extensions licensed program.

SOFTWARE REQUIREMENTS

The Mass Storage System Extensions licensed program, with or without the MVS/XA Facility, operates with OS/VS1 Release 6.7 or OS/VS2 MVS Release 3.8 and subsequent releases unless otherwise specified.

The Mass Storage System Extensions licensed program with the MVS/XA Facility supports and requires the MVS/System Product Version 2, allowing the connection of the 3850 Mass Storage System to IBM processors executing in XA Mode only.

DOCUMENTATION
(available from Mechanicsburg)

General Information Manual (GH35-0034).

PROGRAM PRODUCTS

**MASS STORAGE SYSTEMS EXTENSIONS (MSSE)
MVS/XA FACILITY RELEASE 1.1
5740-XYG****PURPOSE**

The MSSE MVS/XA Facility of the 3850 Mass Storage System Extensions program product (5740-XYG) supports the IBM processors operating in the XA mode. This enables the user to upgrade from the IBM S/370 processors to the IBM processors operating in the XA mode.

The MSSE MVS/XA Facility supports all models of the IBM 3850 Mass Storage System. The MSSE program product must be installed prior to installing the MSSE MVS/XA Facility.

HIGHLIGHTS

- Supports the XA Mode of IBM processors.
- Ease of migration from IBM S/370 processors to XA mode processors.
- The 3850 Mass Storage System can be attached and shared by a combination of MVS/XA and S/370 processors.
- No reprogramming required.
- No data set conversion.
- User JCL remains the same.

CUSTOMER RESPONSIBILITIES

- Develop an MSSE MVS/XA installation plan.
- Must have the base MSSE program product installed.

SPECIFIED OPERATING ENVIRONMENT

An installation can attach the 3850 Mass Storage System to up to four systems which may be a combination of S/370 processors and XA mode processors. The S/370 processors may operate with or without MSSE, but cannot have the MSSE MVS/XA Facility installed. The attached XA processors must operate with the MSSE program product and the MSSE MVS/XA Facility.

HARDWARE REQUIREMENTS

The MSSE MVS/XA Facility is designed to operate with the IBM XA mode processors exclusively.

The Mass Storage Systems Extensions program product (5740-XYG) must be installed prior to installing the MSSE MVS/XA Facility.

This support applies to all models of the 3850 MSS in single and loosely-coupled (channel-to-channel attachment) UP and MP configurations.

SOFTWARE REQUIREMENTS

The MSSE MVS/XA Facility supports the MVS System Product Version 2, allowing the connection of the IBM 3850 Mass Storage System to IBM processors executing in XA mode.

Storage Requirements: Virtual storage requirements for the MSSE MVS/XA Facility remain unchanged from the MSSE program product.

DATA SECURITY and AUDITABILITY

The MSSE MVS/XA Facility complies with and conforms to the data security and auditability controls of an MVS environment. Customer management is responsible for the selection, application and adequacy of these controls.

**DISTRIBUTED OFFICE SUPPORT SYSTEM/370
RELEASE 1 - MOD. LEVEL 0 (5740-XY9)
DISTRIBUTED OFFICE SUPPORT SYSTEM/3730
RELEASE 1 - MOD. LEVEL 0 (5740-XYK)****DESCRIPTION**

The IBM Distributed Office Support System consists of licensed programs that provide document handling extensions to the IBM 3730 Distributed Office Communication System (abbreviated to IBM 3730 System in this document). It operates in an OS/VS environment under the IBM Information Management System/Virtual Storage (IMS/VS) or the IBM Customer Information Control System/Virtual Storage (CICS/VS) and offers both interactive and batch communication between IBM 3730 systems and an IBM host system such as the IBM S/370, the IBM 3031, 3032 or 3033 processors or the IBM 4300 processors. Significant capabilities of the Distributed Office Support System include:

- Host document filing with indexing.
- Filed document search and retrieval.
- Filed document access protection.
- Message switching between users of the same or different IBM 3730 systems.
- Submission of batch jobs to the host system from a 3732 terminal.

These functions are achieved by means of programs in the host and in each attached IBM 3730 System.

The user can file documents created at, and stored in, the IBM 3730 System in a document library maintained by the host system. While filing a document, the user can specify filing information that indexes the document and can be used for later retrieval of the document. This filing information consists of search arguments, such as the author, recipients and keywords describing the contents of the document. In addition, access codes can be added to help protect the document against unauthorized access.

To retrieve a filed document, users first identify it by a search request, either by the name of the document or by search arguments specified when the document was filed. Once a document has been identified, it can be restored in the IBM 3730 System, displayed on the screen of the IBM 3732, printed at the host or the IBM 3730 System or deleted.

In the Distributed Office Support System, end users are persons who use the IBM 3732 Text Display Station in a similar way to ordinary office equipment. They may be secretaries, typists, office clerks, editorial assistants, managers or others who need not have knowledge of data processing.

The message switching capability allows the user to send messages to other users in the system, for example, to inform them that a document has been filed and is available for retrieval.

The job submission capability allows the user to send predefined OS/VS jobs to the host system for batch execution. This capability may also be used to submit a document from the IBM 3730 System to the host along with the job. A user written program may place this document into a data set for subsequent host application processing. Additionally, with some user written conversion, the document may be imported into the Document Library Facility, program number 5748-XXE and then processed by the Document Composition Facility, program number 5648-XX9. This approach can be used to provide advanced composition functions such as multiple columns, footnote placement, automatic hyphenation and spelling verification of the document.

Filing and retrieval of documents can be performed interactively or in deferred mode. Deferred processing is particularly applicable for large documents because the operation is executed in parallel to other tasks performed at the terminal.

The Distributed Office Support System provides convenient techniques to ease the installation of the system and the maintenance of its data sets.

In a multiple-user document processing system, data security is of vital interest to its users. The Distributed Office Support System provides data security based on the interaction of the following:

- Access codes.
- Document ownership.
- Level of document privacy.

Access codes are assigned to end users centrally at the host and to documents during filing. An end user who needs to gain access to a filed document must be assigned one access code that matches one access code of the document to be retrieved. The profiles of eligible users can only be changed under central control.

The owner of a document is defined as the end user who issued the initial request to file this document in the host document library. The deletion of a document, for example, can only be initiated by the document owner.

The Distributed Office Support System distinguishes two types of documents: Private documents and public documents. Private documents are accessible to their owners alone and are, therefore, not assigned any access codes. Public documents, which are recognized by the presence of access codes, can be retrieved by all authorized end users.

In the Distributed Office Support System, passwords can be assigned to end users to control access to the central file.

These facilities for controlling access to protected resources are effective only within the context of the IBM Distributed Office Support System itself. The Resource Access Control Facility (RACF) program product, Program Number 5740-XXH, can be used to provide an integral foundation for security in IMS/VS under MVS, complementing the Distributed Office Support System's facilities by controlling access to system resources.

Access control within OS/VS1 outside the scope of the IBM Distributed Office Support System is not provided.

The following optional features are available with the Distributed Office Support System:

- **Host Print Facility:** By means of this feature, documents filed in the host library may be printed on a host-attached printer upon request from the IBM 3732 Test Display Station.
- **Direct Document Viewing Facility:** This feature allows end users to have documents in the host library displayed on their terminal screens without the need to copy the documents from the host document library to the associated IBM 3730 System permanent store. This speeds up the process of displaying documents.
- **STAIRS Input Formatter:** Using this feature, documents created at the IBM 3732 may be prepared for batch input to a STAIRS data base.

For the last feature, further processing may be required for a complete conversion.

HIGHLIGHTS

- Filing of IBM 3730 documents in host document library.
- Searching of documents in host document library, either by document name or by specification of search arguments.
- System-controlled indexing of external (hard-copy) documents.
- Retrieval of filed documents from host document library.
- Message switching between users.
- Submission of batch jobs to the host system from a 3732 terminal.
- Document access protection.
- Support of the IBM 3730 System Archive/Retrieval/Delete commands.
- Optional features for use with the IBM S/370 Storage and Information Retrieval System/Virtual Storage (STAIRS/VS), Program Number 5740-XR1.
- Optional features for printing of documents on host-attached printers and for direct viewing of documents from the host document library

CUSTOMER RESPONSIBILITIES

Customers generate the Distributed Office Support System by means of a set of specification statements. These statements provide options that may be selected to tailor the system to each company's individual needs.

SPECIFIED OPERATING ENVIRONMENT**DISTRIBUTED OFFICE SUPPORT SYSTEM/370 (5740-XY9):****HARDWARE REQUIREMENTS**

The minimum machine requirements to execute the Distributed Office Support S/370 are:

- One IBM S/370 mdl 138 or larger, or one IBM 3031 or larger, or one IBM 4331 or larger with a main and external storage capacity and peripheral equipment as required for, and supported by, IMS/VS or CICS/VS.

SOFTWARE REQUIREMENTS

The Distributed Office Support S/370 is written in the IBM S/370 Assembler language. It is designed to operate in the following environment on the host system and on the IBM 3704 or 3705 Communications Controller:

Dist. Office Support Sys. (cont'd)

Host System: OS/VS1 Release 6.0 (Release 7.0 for the IBM 4300 Processors) or OS/VS2 MVS Release 3.8, or subsequent releases of these unless otherwise specified, together with the Virtual Storage Access Method (VSAM) and one of the following licensed programs:

- IBM S/370 Information Management System/Virtual Storage (IMS/VS) Version 1, Program Number 5740-XX2, Release 1.5, including the Data Communication (DC) feature, together with its required associated programs, or a subsequent release unless otherwise specified. In IMS/VS, data management is performed by Data Language/1 (DL/I). Communication with the IBM 3730 System is via SLU type P. To identify the appropriate required and optional licensed programs for IMS/VS, refer to the IMS/VS Version 1 Release 1.5 announcement material.
- IBM S/370 Customer Information Control System/Virtual Storage (CICS/VS) Version 1, Program Number 5740-XX1, Release 4, together with its required associated programs, or a subsequent release unless otherwise specified. In CICS/VS, data management is performed by the Virtual Storage Access Method (VSAM). Communication with the IBM 3730 System uses the Full-Function Logical Unit. To identify the appropriate required and optional licensed programs for CICS/VS, refer to the CICS/VS Version 1 Release 4 announcement material.

In addition, the following programming support must be available:

- Either the Virtual Telecommunications Access Method (VTAM) Level 2, or the Advanced Communications Function for VTAM (ACF/VTAM), Program Number 5735-RC2, or the Advanced Communications Function for TCAM (ACF/TCAM) Version 2, Program Number 5735-RC3, Release 2, as required by IMS/VS or CICS/VS, respectively.
- An IBM OS/VS Sort/Merge program product.

IBM 3704 or IBM 3705

One of the following, as required by the network:

- 3704/3705 Network Control Program/Virtual Storage (NCP/VS), Program Number 5744-BA2, Release 5.0
- Advanced Communication Function for NCP/VS (ACF/NCP/VS), Program Number 5735-XX1

DISTRIBUTED OFFICE SUPPORT SYSTEM/3730 (5740-XYK):**HARDWARE REQUIREMENTS**

The minimum machine requirements to execute the Distributed Office Support S/3730 are:

- One IBM 3730 Distributed Office Communication System with Configuration Support (#9171) and Feature Codes (#9275) and (#9285) and with at least one IBM 3732 Text Display Station with keyboard and at least one print device, which can be either an IBM 3736 Printer or the IBM 3791 Line Print Feature. The host attachment is via either the IBM 3791 Local Channel Attachment Feature (#1515) to a byte or block multiplexer channel or the IBM 3791 SDLC Communications Feature (#6301, 6302, or 6303) to an IBM 3704 or 3705 Communications Controller.

SOFTWARE REQUIREMENTS

The Distributed Office Support S/3730 is written in IBM 3790 and IBM 3730 programming statements.

The following programming support must be available:

- Program Validation Services (PVS), as modified for the IBM 3730, and Subsystem Support Services (SSS).

DOCUMENTATION: (available from Mechanicsburg)

Licensed Program Design Objectives	GH12-5043
General Information Manual	GH12-5124

MVS SYSTEM INTEGRITY

IBM will accept APARs describing any situation where the installation of the Distributed Office Support System causes an exposure to the system integrity of MVS. However, this program is not intended to run in an authorized state at any time and should therefore represent no threat to the system integrity of MVS.

PROGRAM PRODUCTS

**ADVANCED TEXT MANAGEMENT SYSTEM - III
ATMS-III FORMATTER FEATURE
RELEASE 1
ATMS-III/OS/V5 (5740-XYL)
ATMS-III/DOS/V5 (5746-XXU)**

PURPOSE

The Advanced Text Management System-III (ATMS-III) is a conversational text processing system designed to enable a terminal user to enter, edit, store, format, proofread and display textual material in an efficient manner.

ATMS-III is based on, and is an extension to, previous versions of the ATMS and ATMS-II program products. ATMS-III runs under control of CICS/V5 (5740-XX1 for CICS/OS/V5 and 5746-XX3 for CICS/DOS/V5) Version 1 Release 4.0, and subsequent releases, unless otherwise identified. Because ATMS-III executes as a CICS/V5 application program, it is capable of being multi-tasked along with other CICS/V5 applications.

ATMS-III offers direct interfacing with the SCRIPT/V5 Formatter of the Document Composition Facility (5748-XX9) or a separate ATMS-III Formatter Feature, and asynchronous DASD peripheral processing which may be used for archiving in conjunction with the Document Library Facility (5748-XXE).

DESCRIPTION

APPLICATIONS OF ATMS-III

Following are some areas for which ATMS-III would prove applicable:

- Preparation of catalogs, manuals, directories, proposals, form letters, engineering changes, price lists and personnel record preparation for manufacturing, transportation or utilities.
- Editing of manuscripts and other copy, promotional literature, subscription handling and form letters for publishing.
- Maintenance of all forms of project documentation, research reports, specifications and documenting of field tests for scientists, engineers, laboratory directors and medical groups.
- Maintenance of wills, briefs, contracts and patent dockets, as well as preparation of specialized legal documents for lawyers and lawyer cooperatives.

ATMS-III also addresses the basic problem of maintaining current and accurate changes to a file of information. The change to a file of information in an ATMS-III data base is immediate, unlike batched updates, with immediate verification and retrieval of the updated information.

ATMS-III includes all the time-tested document-handling capabilities of ATMS and ATMS-II products. Some highlights of these capabilities are:

- Full function editing and variable display formats on the 3270. Providing flexible online entry and edit, the terminal operator can view the information in context, immediately seeing how corrections and modifications to a page will look.
- Support for the APL /Text and Data Analysis -Text Features of the IBM 3270 Information Display System with substitution of up to 217 characters during input for each of 28 assignable keys.
- User exit modules which gain control on unrecognizable commands, or during processes which recognize user processing indicators in text.
- Data Base backup and recovery. Full or partial saving/restoring of the ATMS-III data base is possible through this facility. The partial backup process will only record those documents that have changed since the last full or partial backup. The partial recovery will expand the data base only by the documents that do not already exist. The partial backup/recovery processes allow for time savings.
- Statistics collection of working storage activity and the ability to review, online, the collected statistics to evaluate the effectiveness of working storage blocking factors.
- Acceptance of non-ATMS sequential input to be placed directly in permanent storage as a document when the input contains a recognizable document header.
- Sorting of a document in working storage, by units, to organize the units in EBCDIC collating sequence, ascending or descending. (Due to the online nature of invoking the Sort/Merge program, this function is only available in ATMS-III/OS/V5.)
- Executing a sequential list of previously stored commands and any required command replies stored with the commands, as well as to suspend execution at any point for operator intervention. Up to nine character strings, specified in the command, may be substituted for symbols within the list.
- Generalized Markup Language. This facility allows for the entry of user-defined "tags" in a document. During document processing

for formatted output, or even for online processing, these "tags" are resolved, with user-supplied specifications substituted for them. The flexibility provided by this facility allows for such things as:

- Using different formatters (e.g., SCRIPT/V5 or the ATMS-III Formatter Feature), without changing the markup of the document.
- Changing the format of a document by supplying different sets of specifications, without changing the markup of the document.
- Changing the definition of the structure of a document to different postprocessors without changing the document itself.
- Inclusion of repetitively-used information without having to key the information each time it is required.
- Processing of separate documents as a single entity.
- Addressing letters or documents to a distribution list without repetitive typing.
- LEARN Lessons. These online, self-teaching lessons provide a means for learning the basic commands and functions of ATMS-III. Lessons are available for users of both keyboard-printer terminals and 3270 display stations.

The ease of correction provided by ATMS-III allows increased terminal operator entry speed through a minimum amount of interruption needed to immediately correct input errors. An effective text unit numbering technique allows for simplified document editing, alleviating the need for continual review for unit number verification. As units are entered, they are assigned a page and unit number which is retained until renumbering is specifically requested. This number retention allows for efficient production of high-volume publications, such as manuals, reports, parts catalogs and other technical journals.

Document Formatting Capabilities provided by the ATMS-III Formatter Feature include the functions of ATMS and ATMS-II products. These include such items as the ability to:

- Vary paragraph styles through the use of controls that allow implicit or explicit paragraphing specification, changing of print tab positions and returning to a previous mode, anywhere within the document.
- Dynamically change the text alignment, left, right or centered, for both formatted or unformatted mode text, allowing for such styles as ragged right, ragged left or ragged right and left.
- Dynamically control page numbering by setting a new value, adding a value to the current page number or resetting the page number to one, as well as specifying the page number style - Arabic or uppercase/lowercase Roman or uppercase/lowercase alphabetic.
- Control, even in conjunction with page numbering, a set of ten counters that may be output in alphabetic or numeric, in either Arabic or Roman styles. The counters may be set, incremented or reset, and output in a selected style with the values of 0 to 65535 or A to Z, AA to ZZ, etc.
- Validate text format controls during entry, edit, unit callout and replace phrase operations.
- Produce a proof printout of a document created for Condensed Text Format, using formatting rules similar to that used for peripheral output.
- Automatically hyphenate formatted output using ATMS-III hyphenation algorithms, as well as being able to specify required hyphenation points.
- Cause formatted or unformatted mode text to be split on a line allowing for automatic leader character insertion.

To provide for the printing of internally generated reports and operator-requested document listings, a basic list/report processor is included in ATMS-III for those users not wishing to include the ATMS-III Formatter Feature.

SCRIPT/V5 INTERFACE

The SCRIPT/V5 Interface provided by ATMS-III allows the user the option of using the ATMS-III Formatter Feature or the SCRIPT/V5 Formatter. The SCRIPT/V5 formatter offers such additional functions as:

- Multiple column formatting.
- Specification of multiple levels of headings.
- Optional generation of a table of contents.
- Footnotes.
- Boxed Text.

PROGRAM PRODUCTS

ATMS-III (cont'd)

- Extended Generalized Markup Language processes.
- Multiple levels of revision markers.
- Conditional document processing.
- 3800 Printing Subsystem support with multi-font printing including mixed pitch fonts.

Documents are entered with all the necessary SCRIPT/VS formatting control information using the basic ATMS-III entry and edit techniques. Documents created for either ATMS-III formatting or SCRIPT/VS formatting co-reside in the ATMS-III data base. In conjunction with the interface provided by the base ATMS-III system, support will be available when using SCRIPT/VS for the following functions, similar to that when using the ATMS-III Formatter Feature:

- Online text format and print.
- Peripheral text format and print.
- Condensed Text Format proofing and peripheral output.
- Peripheral renumber, format and print.
- Online/peripheral Master Document handling through recognition of SCRIPT/VS imbeds.
- Online/peripheral Generalized Markup Language tag resolution.
- Partially formatted screen display during 3270 editing.

ATMS-III provides the capability to communicate with various components of the IBM Office System 6 for:

- Acceptance of documents from magnetic card or diskette for inclusion in the ATMS-III data base.
- Output to printers or magnetic card, through either the ATMS-III or SCRIPT/VS formatter.
- Input and output translation of special codes and OCL information.
- Receiving of all or selected documents placed on a temporary storage queue by a formatter.
- Standard ATMS-III printer destination control functions for the listing and canceling of output requests.

Output support for these devices is fully integrated into the ATMS-III printer destination capabilities. CICS/VS temporary storage (in lieu of transient data) is used for all printer destination support.

ATMS-III PERIPHERAL PROCESSING

ATMS-III Peripheral Processing continues support of the synchronous functions, command set and queue processing of previous ATMS and ATMS-II products, which include:

- Creation or acceptance of archived documents (tape).
- Data base backup and recovery processes (tape).
- Output of specially formatted documents (using the ATMS-III Formatter) to be used for such post processing activities as:
 - High-speed printing of documents.
 - STAIRS/VS data base creation using documents output in the Condensed Text Format. In the OS/VS environment, an online STAIRS/VS data base creation capability can directly accept this output without manual data handling.
- Retrieval of documents from ATMS or ATMS-II backup or archive tapes, as well as from ATS/360 rollout or archive tapes, providing automatic text format control conversion and unit renumbering during the input processes
- Retrieval of non-ATMS-III produced sequential input, directly to permanent storage as a document, when the input contains a recognizable document header (tape)

Asynchronous peripheral processing, designed expressly for DASD peripheral data sets, consists of an additional set of functions and related commands to support:

- Processing of peripheral tasks asynchronously, at a lower priority than other terminal tasks, to alleviate online degradation during certain peripheral operations.
- Definition of a new type of document-based queue which eliminates the previous limitations on the number of queues and the number of entries for a queue.
- These new style queues are asynchronously processable and can be made automatically initiatable when a user-specified threshold is met, without control terminal operator intervention.
- These queues can be re-created during recovery processes from a master queue document saved during backup.
- Operator monitoring commands for these queues which allow for the listing and deleting of queue request entries.
- Queues which can be defined for system managed archive-in as well as for archive-out. Archiving, related to these asynchronously processable queues, is accomplished in conjunction with the Document Library Facility (5748-XXE) which provides for the storage and accessing of archived documents. Using the service programs of the Document Library Facility, the user may then produce lists of archived documents, as well as having access to the documents of other processing. Each archive queue can be defined for a separate library, if so desired.
- Queues which can be defined for "batch job submission". Documents containing job control statements, and any desired data, can be passed to the operating system's internal reader for batch execution, using a new ATMS-III "Internal Reader

Interface" capability. This internal reader interface is used by the asynchronous peripheral processes to archive documents to the Document Library Facility.

USE

ATMS-III is a modular program. The user selects the options needed to meet the installation's requirements during a system generation process. Activity within ATMS-III is initiated from a terminal, with terminal and file activity controlled by ATMS-III through the facilities of the CICS/VS program product and the operating system. Features are incorporated which assist in the serviceability of components of the system to provide maximum system availability.

CUSTOMER RESPONSIBILITIES

An individual who is thoroughly trained in ATMS-III and has experience in CICS/VS is required to install ATMS-III.

Education of the various types of terminal operators is a customer responsibility and is extremely important for this system. To assist in this education, IBM courses, LEARN lessons and an exercise book are available. Though ATMS-III can run primarily unattended, a control terminal operator should be readily available to monitor the operation of the system.

The customer is responsible for ordering and installing the communications equipment required.

ATMS-III has been designed so that customer-written application programs may be readily added. Although ATMS-III provides a basic set of text processing functions, there may be special cases where additional program functions are required. These additions may be made using ATMS-III programming conventions by a system programmer experienced in Assembler language.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The minimum machine configuration required for execution of ATMS-III corresponds to that required for the applicable CICS/VS program product which includes an IBM S/370 or other IBM processor as supported by CICS/VS.

While not required to be fully dedicated to ATMS-III, the following are required to execute ATMS-III:

- One IBM 2314, 3310 (2314 emulation mode), 3330, 3340 or 3350 Direct Access Storage device.
 - One IBM 2741 Communication Terminal with required Feature #9812 (incorporating the courier printing element, part number 1167043) and associated control unit. (An RPK printing element, part number 1167668, is required for 2741 PTTC/BCD and PTTC/EBCD terminals.)
 - or-
 - One IBM 3270 Information Display System Component as described below.
 - or-
 - One IBM 3767 Communications Terminal as a 2741 (with correspondence keyboard arrangement - feature #9381).
 - or-
 - One IBM Communicating Mag Card SELECTRIC® Typewriter, mdl 6610 with the Communicating Feature with Courier 72 printing element, part number 1167043, and corresponding keyboard and associated control unit.
 - One Magnetic Tape Unit and associated control unit must be available for the installation and maintenance of ATMS-III, and for use with dynamic backup/recovery and the archive facility. For other peripheral operations, the tape unit must be identified to CICS/VS.
- The following can be used to expand the capabilities of ATMS-III:
- Multiple IBM 2314, 3310, 3330, 3340 or 3350 Direct Access Storage devices.
 - Multiple IBM 2741 Communications Terminals and associated control units.
 - Multiple IBM 3767 Communication Terminals as 2741s (with correspondence keyboard arrangement - feature #9381).
 - Multiple IBM Communicating Mag Card SELECTRIC® Typewriters and associated control units.
 - Multiple IBM 3270 Information Display System components of the following types:
 - 3279 mdl 2A or 3A (basecolor) Color Display Station with 75-key or 87-key EBCDIC typewriter keyboard (#4621 or #4627) attached to an appropriate control unit.

PROGRAM PRODUCTS

ATMS-III (cont'd)

- 3279 mdl 2B or 3B (extended color) Color Display station with 75-key or 87-key EBCDIC typewriter keyboard (#4621 or #4627) or 87-key EBCDIC typewriter/Text Keyboard (#4629), supported in base color only, attached to an appropriate control unit. (Attribute Select Keyboards may be used, but no ATMS-III support is provided for color or programmed symbols.)
- 3278 Display Station mdl 2, 3, 4 or 5 with APL/Text Feature (#1120) and Text Keyboard (4629) and appropriately configured control unit.
- 3278 Display Station mdl 2, 3, 4 or 5 with 75-key or 87-key EBCDIC typewriter keyboard (#4621 or #4627) attached to an appropriate control unit.
- 3277 Display Station mdl 2 with Data Analysis - APL Feature (#1066) and Data Analysis - Text Feature keyboard (#4639) and appropriate control unit with Data Analysis - APL Feature (#1066) installed.
- 3277 Display Station mdl 2 with 78-key EBCDIC typewriter keyboard (#4633) attached to an appropriate control unit.
- 3276 Control Unit Display Station mdls 2, 3, 4, 12, 13 or 14 with 75-key or 87-key EBCDIC typewriter keyboard (#4621 or #4627) with appropriate control unit features.
- 3275 mdl 2 or 12 standalone Display Station with 78-key EBCDIC typewriter keyboard (#4633).
- 3268 mdl 2 Printer; APL/TEXT is standard function; the printer must be attached to a 3274 or 3276 Control Unit.
- 3288 mdl 2 printer, with or without Vertical Forms Feature (#9860), and with or without the Text Print Feature (#7800) installed attached to an appropriate control unit.
- 3289 Line Printer mdl 1 or 2 attached to an appropriate control unit. If printing of the 120-character TN/T11 character set is desired, the Text Print Feature (#1130) must be installed.
- 3287 Printer mdl 1 or 2, acting as a 3284/3286 mdl 2 with 3271/3272 Attachment (#8330) and 1920-character Print Operation (#9522) with Data Analysis-APL Feature (#1066) installed if optional text feature character printing is desired.
- 3287 Printer mdl 1 or 2, with 3274/3276 Attachment (#8331) with APL/Text Feature (#1120) and prerequisite Extended Character Set Adapter Feature (#3610) installed if optional text feature character printing is desired. A 3287 mdl 1C or 2C may be used, but no ATMS-III support is provided for color or programmed symbols.
- 3284 or 3286 mdl 2 printers attached to an appropriate control unit with Data Analysis-APL Feature (#1066) installed if optional Text Feature character printing is desired.
- 3284 printer mdl 3 attached to the standalone 3275 Display Station.
- 3262 Printer mdl 3 or 13, attached to an appropriate control unit, with either the 96-character EBCDIC set or the 128-character set.

The 3275 and 3277 Display Stations should have RPO 8K0366 for the display of lowercase characters. For the 3277, the Data Analysis - APL Feature (#1066) and Data Analysis - Text Feature keyboard (#4639) include this capability.

The 3284 and 3286 printers should have RPO 8K0366 for printing of lowercase characters, unless the Data Analysis - APL Feature (#1066) is installed.

- Components of the IBM Office System 6 (as online printers or for document transfer):
 - Mag Card II Communicating Typewriter
 - 6240 Mag Card Communicating Typewriter
 - 6640 Document Printer
 - 6670 Information Distributor (binary synchronous) protocol only
 - OS6/430, OS6/440, OS6/442, OS6/450, OS6/452 Information Processors
- A Card Read/Punch Unit.
- Magnetic Tape Units with associated control units supported by CICS/VS.
- A high speed printer producing at least a 132-character line. Uppercase and lowercase print capability is recommended.
- 3800 Printing Subsystem, as a high speed printer or for mixed font printing when used with the SCRIPT/VS formatter.

Note: Not all Office System 6 devices or 3270 features are available in all countries.

ATMS-III SPACE REQUIREMENTS

The address space required for ATMS-III/OS/VS or ATMS-III/DOS/VS is divided into two types:

- Frequently referenced storage areas.
- Infrequently referenced storage areas.

Frequently Referenced storage areas contain such components as ATMS-III subroutines, leader programs, communications area and tables and control blocks, as well as the CICS/VS TCA and TWA assigned at signon. They are either resident in storage or tend to reside there because of the frequency with which they are accessed. Estimates for these storage areas can be determined using the sum of the following:

DOKRVTR Module:

ATMS - III Resident Subroutines	7000
Immediate Message Buffer	88
Document Index Section	8(P+1)
Byte Map	(Note 4)
Index Control Block (CAICB)	56+20C
Control Storage Bit Map	R/8
ATMS-III Common Area	390
Table for Permanent Storage (Note 1)	40P
Table for Working Storage (Note 1)	36Wn
Table for Control Storage (Note 1)	56
Logical Unit Pointer Table	8 (P+Wn+3)
Operator Table	70p+2
Printer Destination Definitions	20Pd
Printer Destination Table	16Pt
Synchronous Queue Name Table	8SQ
Asynchronous Queue Function Table	2300
ATMS-III DASD I/O Program (DOKDIO)	1700
ATMS-III Enqueue Facility (DOKENQ)	2560
ATMS-III Peripheral I/O Program (DOKPIX)	1100
Tag Resolution Processor (DOKMR03)	1100
Fetch Document Information Processor (DOKMR04)	700
Generalized Markup Language Index Reserve Area:	
Indexes (each)	Note 8)
- Minimum	54+6E
- Maximum	54+22E
Resident Subdocuments	(Note 2)
LEARN Lesson Indexes	(Note 3)
ATMS-III Control Blocks (CICS/VS TCA with TWA)	2452T
ATMS-III Working Storage Buffers	(Note 5)
ATMS-III Document Enqueue Table	(Note 6)
ATMS-III Asynchronous Queue Table (Note 7)	56+24AQ
ATMS-III Text Leader Program (DOKTLO, 2741)	3400
ATMS-III Display Leader Program (DOKTL1, 3270)	3100
ATMS-III Graphic Display I/O Processor (DOKGIO)	8000
ATMS-III Input Conversion Processor (DOKFP32)	4000
3270 Device Characteristics Tables	2000
3270 Translate and Test Tables	1536

Where:

- AQ = The number of asynchronous peripheral queues defined.
- C = The number of index names in the default SEARCH list.
- E = The number of entries in the index.
- Op = The number of operators SYSGENed into the system.
- P = The number of Direct Access Storage devices containing permanent storage.
- Pd = The number of 3270 or Office System 6 printer destinations specified using DOKPDD statements during SYSGEN.
- Pt = The number of default printer destination table entries specified using DOKPDT statements during SYSGEN.
- R = The number of 132-byte control storage records.
- SQ = The maximum number of synchronous peripheral queues.
- T = The number of active terminals or display units. (The result for the ATMS-III control blocks includes the 384-byte CICS/VS TCA for each user.)
- Wn = The number of Direct Access Storage devices containing working storage.

Note 1: ATMS-III has three classes of storage: Working storage (WS), permanent storage (PS) and control storage (CS).

PROGRAM PRODUCTS

ATMS-III (cont'd)

Note 2: The amount is dependent upon the installation. If no Type C indexes are to be built (subdocuments made resident), the value is zero. When a greater value is specified, it must be sufficiently large to contain all resident subdocuments associated with the indexes built.

Note 3: The space required for LEARN lesson indexes depends on the method used for building the indexes. Using the method shown in the *ATMS-III Operations Guide*, it ranges from 1300 to 15,000 bytes. Any other method can significantly increase this amount.

Note 4: Each WS logical device has a corresponding byte map segment, the size of which is equal to the number of working storage blocks on the logical device divided by the number of blocks per assignable group.

Note 5: The amount of working storage buffer area required at any given time varies with the number of active terminals, the mix of commands being executed, the working storage blocksize and the allowable number of buffers. A reasonable average value would be:

$T * W S B L K S Z * X / 10$ where:

T = the number of active terminals

WSBLKSZ = the user-chosen WS blocksize

X = the lesser of the user-allowed buffers, or 3

Note 6: Provides for the enqueuing of from 111 to 3638 documents. Maximum is 2,016 bytes, maximum is 65,502 bytes.

Note 7: Maximum is 65,502 bytes.

Note 8: Maximum is twice the value specified at system generation.

Infrequently referenced ATMS-III storage areas are dynamically obtained by CICS/VS for ATMS-III as needed, and are returned when no longer needed. The temporary TIOA assignments, ATMS-III work areas and currently executing ATMS-III programs occupy this dynamically obtained address space. Therefore, the requirements for these storage areas can vary depending on how many terminals are active on the system, and which ATMS-III application functions are being performed.

For estimating infrequently referenced storage requirements, the following values are provided:

ATMS-III application program sizes (4K - 16K)

ATMS-III Formatter Feature program size (34K)

ATMS-III application program work areas (2K - 6K)

TIOA assignments:

2741 (232T)

3270 (varies by model, SYSGEN options and operator use - output TIOA is slightly larger than screen size).

3270 printers require additional TIOA storage while active.

Inclusion of such items as the Formatter Feature, the Generalized Markup Language facility and LEARN lessons require storage beyond that for the basic ATMS-III program modules and control tables. Use of the SCRIPT/VS formatter requires additional storage during online or peripheral formatting operations. The maximum allowable amounts are a system generation option as described in the *ATMS-III Program Reference Manual*.

DISK STORAGE REQUIREMENTS

The following estimates do not include requirements for CICS/VS or the Document Library Facility. Library space, as described below, is increased by 10% when the ATMS-III Formatter Feature is included:

OS/VS Environment

- Macro library space required for ATMS-III/OS/VS macro definition is approximately 17 cylinders on a 2314, 9 cylinders on a 3330, 34 cylinders on a 3340 or 3 cylinders on a 3350. Approximately 25 directory blocks will be required.
- ATMS-III/OS/VS source library space required for program modules is approximately 100 cylinders on a 2314, 60 cylinders on a 3330, 165 cylinders on a 3340 or 23 cylinders on a 3350. Approximately 15 directory blocks will be required.
- ATMS-III/OS/VS load library space required is 10 cylinders on a 2314, 5 cylinders on a 3330, 19 cylinders on a 3340 or 3 cylinders on a 3350. Approximately 15 directory blocks will be required.

DOS/VS Environment

- ATMS-III/DOS/VS source library space is approximately 132 cylinders on a 2314, 84 cylinders on a 3330 or 3350, or 354 cylinders on a 3340. Approximately 10 directory tracks will be required.
- ATMS-III/DOS/VS phases are loaded into the core image library and require approximately 18 cylinders on a 2314, 8 cylinders on a 3330 or 3350, or 71 cylinders on a 3340. Approximately 10 directory tracks will be required.

OS/VS or DOS/VS Environment

- Control storage: One cylinder on a 2314, 3330, 3340 or 3350.
- Permanent storage: One cylinder of permanent storage will contain approximately 3,200 units (50-60 bytes) of text on a 3330, 1,900

units on a 2314, 1,100 units on a 3340 or 6,900 units on a 3350. Actual requirements will depend on unit lengths in use.

- Working storage: One cylinder of working storage using the default working storage block size, will contain approximately 2,300 units (50-60 bytes) of text on a 3330, 1,600 units on a 2314, 1000 units on a 3340 or 6,500 units on a 3350. Actual requirements will depend on unit lengths in use as well as the user-specified working storage blocking factor.
- CICS/VS Temporary Auxiliary Storage: Used for online SCRIPT/VS formatting and online printer destination capabilities. The total amount required is a function of the page limits set for online printing, the number of concurrent ATMS-III users of these capabilities and the number of documents queued for online printing.

SOFTWARE REQUIREMENTS

ATMS-III is written in S/370 Assembler language. It runs under control of CICS/VS (5740-XX1 for CICS/OS/VS and (5746-XX3) for CICS/DOS/VS) Version 1 Release 4.0, and subsequent releases, unless otherwise identified. Refer to the CICS/VS pages for operating system support.

Terminal communication is handled by ATMS-III using an appropriate telecommunications method through CICS/VS, except that BTAM is required for ATMS-III support of keyboard-printer terminals.

Data management is handled by ATMS-III using direct buffering through the BDAM (OS) or DAM (DOS) access methods. For certain tape operations, the EXCP access method is used. The CICS/VS file control tables and open/close facilities are also used for data set control.

In addition, the following may also be required:

- OS/VS Sort/Merge (5740-SM1) if working storage sorts are to be done.
- Appropriate VSAM access method for use of CICS/VS auxiliary temporary storage if 3270 or Office System 6 printer destination capabilities are to be used.
- Document Composition Facility (5748-XX9, R2.0) and its ATMS-III Environment Feature if SCRIPT/VS formatting is to be done. CICS/VS temporary storage is used for online formatting, with VSAM required if auxiliary temporary storage is used.
- Document Library Facility (5748-XXE, R 2.0), and supporting VSAM access method, if advantage is to be taken of the asynchronous archive processes. If used in a DOS/VS environment, these functions require DOS/VSE with VSE/Advanced Functions Release 2 (5746-XE8), VSE/VSAM (5746-AM2) and VSE/POWER (5746-XE3).
- JES2 or JES3 (selectable unit in MVS Releases 3.7 or 3.8) in OS/MVS, POWER/VS in DOS/VS or VSE/POWER in DOS/VSE if document archiving to a library of the Document Library Facility or the batch job submit function is to be utilized.
- A user SVC is supplied for installation in an OS/VS1 environment when archiving to the Document Library Facility or batch job submit functions are to be utilized.

COMPATIBILITY

ATMS-III, with the Formatter Feature, is functionally upward compatible from ATMS and ATMS-II, as well as from ATMS/360 with the exception of field-oriented-data format change during input and output. A capability for retrieving ATMS backup or archive documents and ATMS/360 rollout or archive documents is provided. An existing ATMS or ATMS/360 data base is readily converted to an ATMS-III data base using these facilities. ATMS-II users will not have to do a backup and recover operation.

The ASP/JES3 licensing exception does not apply to programs, features, and versions announced after July 6, 1976. A license is required for each processor on which this program executes. See DP Marketing Announcement 276-57.

DATA SECURITY

Data security, which is a user responsibility, can be enhanced using a variety of means. These take the form of both ATMS-III and CICS/VS controls. These are:

- Selective controls on the use of the CICS/VS master terminal operator functions.
- CICS/VS operator signon and password procedures.
- ATMS-III operator signon and password procedures. The signon area contains multiple overstruck characters on a keyboard-printer terminal and is made non-displayable on a 3270 display station.
- Selective assignment of ATMS-III control terminal operators and privileged operators.

PROGRAM PRODUCTS

ATMS-III (cont'd)

- Operator assigned access words for getting and/or deleting documents and document indexes.
- Operator use of the lock and unlock commands.
- User assignment of 3270 printers for selected document routing

**ADVANCED TEXT MANAGEMENT SYSTEM - III
ATMS-III FORMATTER FEATURE
RELEASE 2 MODIFICATION LEVEL 0
ATMS-III/OS/V5 (5740-XYL)
ATMS-III/DOS/V5 (5746-XXU)**

PURPOSE

The Advanced Text Management System-III (ATMS-III) is a conversational text processing system which enables a terminal user to enter, edit, store, format, proofread and display textual material in an efficient manner.

ATMS-III is based on, and is an extension to, previous versions of the ATMS and ATMS-II program products. ATMS-III runs under control of CICS/VS (5740-XX1 for CICS/OS/V5 and 5746-XX3 for CICS/DOS/V5) Version 1.5.0, and subsequent releases, unless otherwise identified. Because ATMS-III executes as a CICS/VS application program, it is capable of being multi-tasked along with other CICS/VS applications.

ATMS-III offers direct interfacing with the SCRIPT/V5 Formatter of the Document Composition Facility (5748-XX9, R2.0 or R3.0) or a separate ATMS-III Formatter feature, and asynchronous DASD peripheral processing which may be used for archiving in conjunction with the Document Library Facility (5748-XXE, R2.0 or R3.0).

DESCRIPTION

APPLICATIONS OF ATMS-III

Following are some areas for which ATMS-III would prove applicable:

- Preparation of catalogs, manuals, directories, proposals, form letters, engineering changes, price lists and personnel record preparation for manufacturing, transportation or utilities.
- Editing of manuscripts and other copy, promotional literature, subscription handling and form letters for publishing.
- Maintenance of all forms of project documentation, research reports, specifications and documenting of field tests for scientists, engineers, laboratory directors and medical groups.
- Maintenance of wills, briefs, contracts and patent dockets, as well as preparation of specialized legal documents for lawyers and lawyer cooperatives.

ATMS-III also addresses the basic problem of maintaining current and accurate changes to a file of information. Unlike batched updates, the changes to the ATMS-III data bases are immediate, allowing immediate verification and retrieval of the updated information.

ATMS-III includes all the time-tested document-handling capabilities of ATMS and ATMS-II products. Some highlights of ATMS III capabilities are:

- Full function editing and variable display formats on the 3270. Providing flexible online entry and edit, the terminal operator can view the information in context, immediately seeing how corrections and modifications to a page will look.
- Support for the APL /Text and Data Analysis -Text features of the 3270 Information Display System with substitution of up to 217 characters during input for each of 28 assignable keys.
- Executing a sequential list of previously stored commands. Included in the list can be replies to the commands and a comprehensive set of control statements which allows for conditional execution, as well as for the creation of full-screen menus for operator input. Variables and counters can be set, and system items can be referenced for substitution purposes within a command list. Nested command list capabilities greatly expand the usefulness of this facility.
- User exit modules which gain control for:
 - Processing unrecognized commands.
 - Various functions which recognize user processing indicators in text.
 - Validating batch submission jobs.
 - Validating project accounting information.
 - Loading variables during command list execution.
- Supports an ATMS III data base using either VSAM or BDAM (DAM in DOS).
- Support for up to 9,999 operator numbers when a VSAM data base is used, and up to 4,000 operator numbers when BDAM is used. Separate operator add and delete commands are supplied for use by authorized operator administrators.
- Data Base backup and recovery. Full or partial saving/restoring of the ATMS-III data base is possible through this facility. The partial backup process will only record those documents that have changed since the last full or partial backup. The partial recovery will expand the data base by only those documents that do not already exist. The partial backup/recovery processes provide significant time savings.

- Statistics collection of working storage activity and the ability to review, online, the collected statistics to evaluate the effectiveness of user-specified working storage blocking factors. Current working storage allocations can be monitored to determine excessive operator use.
- Acceptance of non-ATMS sequential input to be placed directly in permanent storage as a document when the input contains a recognizable document header.
- Sorting of a document in working storage, by units, to organize the units in EBCDIC collating sequence, ascending or descending. (Due to the online nature of invoking the Sort/Merge program, this function is only available in ATMS-III/OS/V5.)
- Generalized Markup Language. This facility allows for the entry of user-defined 'tags' in a document. During document processing for formatted output, or during online processing, these 'tags' are resolved, with user-supplied specifications substituted for them. The flexibility provided by this facility allows for such things as:
 - Using different formatters (e.g., SCRIPT/V5 or the ATMS-III Formatter feature), without changing the markup of the document.
 - Changing the format of a document by supplying different sets of specifications, without changing the markup of the document.
 - Changing the definition of the structure of a document to different postprocessors without changing the document itself.
 - Inclusion of repetitively-used information without having to key the information each time it is required.
 - Addressing letters or documents to a distribution list without repetitive typing.
- LEARN Lessons. These online, self-teaching lessons provide a means for learning the basic commands and functions of ATMS-III. Lessons are available for users of both keyboard-printer terminals and 3270 display stations. Users may create additional lessons to assist in the teaching of unique installation applications.

The ease of correction provided by ATMS-III allows increased terminal operator entry speed by reducing the amount of interruptions needed to immediately correct input errors. An effective text unit numbering technique allows for simplified document editing, alleviating the need for continual review for unit number verification. As units are entered, they are assigned a page and unit number which is retained until renumbering is specifically requested. This number retention allows for efficient production of high-volume publications, such as manuals, reports, parts catalogs and other technical journals.

Document Formatting Capabilities provided by the ATMS-III Formatter feature include the functions of ATMS and ATMS-II products. These include such items as the ability to:

- Vary paragraph styles through the use of controls that allow implicit or explicit paragraphing specification, changing of print block positions, and returning to a previous mode, anywhere within the document.
- Dynamically change the text alignment, left, right or centered, for both formatted or unformatted mode text, allowing for such styles as ragged right, ragged left or ragged right and left.
- Dynamically control page numbering by setting a new value, adding a value to the current page number or resetting the page number to one, as well as specifying the page number style - Arabic, uppercase/lowercase Roman, or uppercase/lowercase alphabetic.
- Control, even in conjunction with page numbering, a set of ten counters that may be output in alphabetic or numeric, in either Arabic or Roman styles. The counters may be set, incremented or reset, and output in a selected style with the values of 0 to 65,535 or A to Z, AA to ZZ, etc.
- Validate text format controls during entry, edit, unit callout and replace phrase operations.
- Produce a proof printout of a document created for Condensed Text Format, using formatting rules similar to those used for peripheral output.
- Automatically hyphenate formatted output using ATMS-III hyphenation algorithms, as well as being able to specify required hyphenation points.
- Cause formatted or unformatted mode text to be split on a line allowing for automatic leader character insertion.

To provide for the printing of internally generated reports and operator-requested document listings, a basic list/report processor

PROGRAM PRODUCTS

ATMS-III (cont'd)

is included in ATMS-III for those users not wishing to include the ATMS-III Formatter feature.

SCRIPT/VS INTERFACE

The SCRIPT/VS Interface provided by ATMS-III allows the user the option of using SCRIPT/VS Formatter of the Document Composition Facility. The SCRIPT/VS formatter offers such additional functions as:

- Multiple column formatting.
- Specification of multiple levels of headings.
- Optional generation of a table of contents.
- Footnotes.
- Boxed text.
- Extended Generalized Markup Language processes.
- Multiple levels of revision markers.
- Conditional document processing.
- 3800 Printing Subsystem support with multi-font printing, including mixed pitch fonts.
- 4250 Printer with proportional font printing (Release 3, MVS or DOS/VSE environment).

ATMS III provides font library support for the 4250 Printer, which includes font library access, online library listing, and online error diagnostics review of a SCRIPT/VS asynchronous peripheral formatting run.

Documents are entered with all the necessary SCRIPT/VS formatting control information using the basic ATMS-III entry and edit techniques. Documents created for either ATMS-III formatting or SCRIPT/VS formatting co-reside in the ATMS-III data base. With the interface provided by the base ATMS-III system, support is available for the following functions, similar to that when using the ATMS-III Formatter feature:

- Online text format and print.
- Peripheral text format and print.
- Condensed Text Format proofing and peripheral output.
- Peripheral renumber, format and print.
- Online/peripheral Master Document handling through recognition of SCRIPT/VS imbeds.
- Online/peripheral Generalized Markup Language tag resolution.
- Partially formatted screen display during 3270 editing.

ATMS III to OFFICE SYSTEM 6 (OS/6) COMMUNICATION

- Acceptance of documents from magnetic card or diskette for inclusion in the ATMS-III data base.
- Output to printers or magnetic card, through either the ATMS-III or SCRIPT/VS formatter.
- Input and output translation of special codes and OCL information.
- Receiving of all or selected documents placed on a temporary storage queue by a formatter.
- Standard ATMS-III printer destination control functions for the listing and canceling of output requests.

Output support for these devices is fully integrated into the ATMS-III printer destination capabilities. CICS/VS temporary storage (in lieu of transient data) is used for all printer destination support.

ATMS-III PERIPHERAL PROCESSING

ATMS-III Peripheral Processing continues support of the synchronous functions, command set and queue processing of previous ATMS and ATMS-II products, which include:

- Creation or acceptance of archived documents (tape).
- Data base backup and recovery processes (tape).
- Output of specially formatted documents (using the ATMS-III Formatter) to be used for such post processing activities as:
 - High-speed printing of documents.
 - STAIRS/VS data base creation using documents output in the Condensed Text Format. In the OS/VS environment, an online STAIRS/VS data base creation capability can directly accept this output without manual data handling.
- Retrieval of documents from ATMS or ATMS-II backup or archive tapes, as well as from ATS/360 rollout or archive tapes, providing automatic text format control conversion and unit renumbering during the input processes.
- Retrieval of non-ATMS-III produced sequential input, directly to permanent storage as a document, when the input contains a recognizable document header (tape).

Asynchronous peripheral processing, designed expressly for DASD peripheral data sets, consists of an additional set of functions and related commands to support:

- Processing of peripheral tasks asynchronously, at a lower priority than other terminal tasks, to alleviate online degradation during certain peripheral operations.
- Definition of document-based queues which eliminates the previous limitations on the number of queues and the number of entries for a queue.
- These queues are asynchronously processable and can be made automatically initiatable when a user-specified threshold is met, without control terminal operator intervention.

- These queues can be re-created during recovery processes from a master queue document saved during backup.
- Operator monitoring commands for these queues allow for the listing and deleting of queue request entries.
- Queues can be defined for system managed archive-in, as well as for archive-out. Archiving, related to these asynchronously processable queues, is accomplished in conjunction with the Document Library Facility (5748-XXE) which provides for the storage and accessing of archived documents. Using the service programs of the Document Library Facility, the user may then produce lists of archived documents, as well as having access to the documents for other processing. Each archive queue can be defined for a separate library, if so desired.
- Queues can be defined for 'batch job submission'. Documents containing job control statements, and any desired data, can be passed to the operating system's internal reader for batch execution, using a new ATMS-III 'Internal Reader Interface' capability. This internal reader interface is also used by the asynchronous peripheral processes to archive documents to the Document Library Facility.

USE

ATMS-III is a modular program. The user selects the options needed to meet the installation's requirements during a system generation process. Activity within ATMS-III is initiated from a terminal, with terminal and file activity controlled by ATMS-III through the facilities of the CICS/VS program product and the operating system. Features are incorporated which assist in the serviceability of components of the system to provide maximum system availability.

CUSTOMER RESPONSIBILITIES

An individual who is thoroughly trained in ATMS-III and has experience in CICS/VS is required to install ATMS-III.

Education of the various types of terminal operators is a customer responsibility and is extremely important for this system. To assist in this education, IBM courses, LEARN lessons and an exercise book are available. Additional lessons can be created by the user to assist in the training of unique installation applications. The command list execution capability can be used to build installation-dependent 'help' facilities to describe unique operating characteristics. Though ATMS-III can run primarily unattended, a control terminal operator should be readily available to monitor the operation of the system.

The customer is responsible for ordering and installing the communications equipment required.

ATMS-III has been designed so that customer-written application programs may be readily added. Although ATMS-III provides a basic set of text processing functions, there may be special cases where additional program functions are required. These additions may be made using ATMS-III programming conventions by a system programmer experienced in Assembler language. Many additional functions can be implemented using the supplied user exits, or by taking advantage of the extensive command list processing capabilities.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The minimum machine configuration required for execution of ATMS-III corresponds to that required for the applicable CICS/VS program product which includes an IBM S/370 or other IBM processor as supported by CICS/VS.

While not required to be fully dedicated to ATMS-III, the following are required to execute ATMS-III:

- At least one Direct Access Storage device to contain the ATMS III data base. If an FBA device is used, the VSAM access method is required. Either VSAM or BDAM may be used to support an IBM 2314, 3330, 3340 or 3350. Other Direct Access Storage devices can only be supported using VSAM.
- One IBM 2741 Communication Terminal with required feature #9812 (incorporating the courier printing element, part number 1167043) and associated control unit. (An RPQ printing element, part number 1167668, is required for 2741 PTTC/BCD and PTTC/EBCD terminals.)
 - or-
 - One IBM 3270 Information Display System component as described below.
 - or-
 - One IBM 3767 Communications Terminal as a 2741 (with correspondence keyboard arrangement - feature #9381).
 - or-
 - One IBM Communicating Mag Card Selectric® Typewriter, mdl 6610 with the Communicating feature with Courier 72 printing element, part number 1167043, and corresponding keyboard and associated control unit.

ATMS-III (cont'd)

- One IBM Magnetic Tape Unit and associated control unit must be available for the installation and maintenance of ATMS-III, and for use with dynamic backup/recovery and the archive facility. For other peripheral operations, the tape unit must be identified to CICS/VS.

The following can be used to expand the capabilities of ATMS-III:

- Multiple IBM Direct Access Storage devices.
- Multiple IBM 2741 Communication Terminals and associated control units.
- Multiple IBM 3767 Communications Terminals as 2741s (with correspondence keyboard arrangement - feature #9381).
- Multiple IBM Communicating Mag Card Selectric® Typewriters and associated control units.
- Multiple IBM 3270 Information Display System components of the following types:
 - 3279 mdl 2A or 3A (basecolor) Color Display Station with 75-key or 87-key EBCDIC typewriter keyboard (#4621 or #4627) attached to an appropriate control unit.
 - 3279 mdl 2B or 3B (extended color) Color Display Station with 75-key or 87-key EBCDIC typewriter keyboard (#4621 or #4627) or 87-key EBCDIC typewriter/Text Keyboard (#4629), supported in base color only, attached to an appropriate control unit. (Attribute Select Keyboards may be used, but no ATMS-III support is provided for color or programmed symbols.)
 - 3278 Display Station mdl 2, 3, 4 or 5 with APL/Text feature (#1120) and Text Keyboard (#4629) attached to an appropriately configured control unit.
 - 3278 Display Station mdl 2, 3, 4 or 5 with 75-key or 87-key EBCDIC typewriter keyboard (#4621 or #4627) attached to an appropriate control unit.
 - 3277 Display Station mdl 2 with Data Analysis - APL feature (#1066) and Data Analysis - Text feature keyboard (#4639) and appropriate control unit with Data Analysis - APL feature (#1066) installed.
 - 3277 Display Station mdl 2 with 78-key EBCDIC typewriter keyboard (#4633) attached to an appropriate control unit.
 - 3276 Control Unit Display Station mdl 2, 3, 4, 12, 13 or 14 with APL/Text feature (#1120) and Text Keyboard (#4629).
 - 3276 Control Unit Display Station mdls 2, 3, 4, 12, 13 or 14 with 75-key or 87-key EBCDIC typewriter keyboard (#4621 or #4627) with appropriate control unit features.
 - 3275 stand-alone Display Station mdl 2 or 12 with 78-key EBCDIC typewriter keyboard (#4633).
 - 3288 Printer mdl 2, with or without Vertical Forms feature (#9850), and with or without the Text Print feature (#7800) installed for printing of the 120-character TN/T11 character set attached to an appropriate control unit.
 - 3289 Line Printer mdl 1 or 2 attached to an appropriate control unit. If printing of the 120-character TN/T11 character set is desired, the Text Print feature (#1130) must be installed.
 - 3287 Printer mdl 1 or 2, acting as a 3284/3286 mdl 2 with 3271/3272 Attachment (#8330) and 1,920-character Print Operation (#9522) with Data Analysis-APL feature (#1066) installed if optional text feature character printing is desired.
 - 3287 Printer mdl 1 or 2, with 3274/3276 Attachment (#8331) with APL/Text feature (#1120) and prerequisite Extended Character Set Adapter feature (#3610) installed if optional text feature character printing is desired. A 3287 mdl 1C or 2C may be used, but no ATMS-III support is provided for color or programmed symbols.
 - 7436 Printer mdl 1 operating as a 3287 mdl 1 or 2.
 - 3284 or 3286 mdl 2 Printers attached to an appropriate control unit with Data Analysis-APL feature (#1066) installed if optional Text feature character printing is desired.
 - 3284 Printer mdl 3 attached to the stand-alone 3275 Display Station.
 - 3262 Printer mdl 3 or 13, attached to an appropriate control unit, with either the 96-character EBCDIC set or the 128-character set.
 - 3230 or 3268 mdl 2 Printers attached to the appropriate control unit. If operated in non-SCS mode, feature #9507 must not be installed, since ATMS III uses multiple print operations to produce a single output page.

Printers may be operated in SCS mode.

The 3275 and 3277 Display Stations should have RPO 8K0366 for the display of lowercase characters. For the 3277, the Data Analysis - APL feature (#1066) and Data Analysis - Text feature keyboard (#4639) include this capability.

The 3284 and 3286 printers should have RPO 8K0366 for printing of lowercase characters, unless the Data Analysis - APL feature (#1066) is installed.

- Components of the IBM Office System 6 (as online printers or for document transfer:
 - Mag Card II Communicating Typewriter
 - 6240 Mag Card Communicating Typewriter
 - 6640 Document Printer
 - 6670 Information Distributor (SNA or binary synchronous) mode
 - OS6/430, OS6/440, OS6/442, OS6/450, OS6/452 Information Processors
- A Card Read/Punch Unit.
- Magnetic Tape Units with associated control units supported by CICS/VS.
- A high-speed printer producing at least a 132-character line. Uppercase and lowercase print capability is recommended.
- 3800 Printing Subsystem, as a high-speed printer or for mixed font printing when used with the SCRIPT/VS formatter.
- 4250 Printer for proportional font printing when used with the SCRIPT/VS R3.0 formatter in the MVS or DOS/VSE environment, through an asynchronous peripheral queue.

ATMS-III SPACE REQUIREMENTS

The address space required for ATMS-III/OS/VS or ATMS-III/DOS/VS is divided into two types:

Frequently referenced storage areas.

Infrequently referenced storage areas.

Frequently referenced storage areas contain such components as ATMS-III subroutines, text leader programs, the communications area, and tables and control blocks, and the CICS/VS TCA and TWA assigned to a user at signon. They are either resident in storage or tend to reside there because of the frequency with which they are accessed.

The *ATMS III Program Reference Manual* contains a complete list of the components residing in this storage, and the individual sizes needed to estimate the total requirements.

Infrequently referenced ATMS-III storage areas are dynamically obtained by CICS/VS for ATMS-III as needed, and are returned when no longer needed. The temporary task work area assignments, ATMS-III work areas and currently executing ATMS-III programs occupy this dynamically obtained address space. Therefore, the requirements for these storage areas vary depending on how many terminals are active on the system, and which ATMS-III functions are being performed.

Inclusion of such items as the Formatter feature, the Generalized Markup Language facility and LEARN lessons require storage beyond that for the basic ATMS-III program modules and control tables. Use of the SCRIPT/VS formatter requires additional storage during online or peripheral formatting operations. The maximum allowable amounts are a system generation option.

Requirements for this type of storage are also discussed in the *ATMS III Program Reference Manual*.

DISK STORAGE REQUIREMENTS

The following estimates do not include requirements for CICS/VS or the Document Library Facility. Library space, as described below, is increased by 10% when the ATMS-III Formatter feature is included:

OS/VS Environment

- Macro library space required for ATMS-III/OS/VS macro definition is approximately 23 cylinders on a 2314, 12 cylinders on a 3330, 42 cylinders on a 3340, 5 cylinders on a 3350, 5 cylinders on a 3375, or 4 cylinders on a 3380. Approximately 15 directory blocks will be required.
- ATMS-III/OS/VS source library space required for program modules is approximately 112 cylinders on a 2314, 66 cylinders on a 3330, 183 cylinders on a 3340, 26 cylinders on a 3350, 26 cylinders on a 3375 or 20 cylinders on a 3380. Approximately 15 directory blocks will be required.
- ATMS-III/OS/VS load library space required is 11 cylinders on a 2314, 6 cylinders on a 3330, 21 cylinders on a 3340, 4 cylinders on a 3350, 4 cylinders on a 3375, or 3 cylinders on a 3380. Approximately 15 directory blocks will be required.

DOS/VS Environment

- ATMS-III/DOS/VS source library space is approximately 158 cylinders on a 2314, 104 cylinders on a 3330, 269 cylinders on a

PROGRAM PRODUCTS**ATMS-III (cont'd)**

3340, 58 cylinders on a 3350, or 58 cylinders on a 3375. Approximately 10 directory tracks will be required.

- ATMS-III/DOS/VS phases are loaded into the core image library and require approximately 9 cylinders on a 2314, 5 cylinders on a 3330, 10 cylinders on a 3340, 4 cylinders on a 3350, or 4 cylinders on a 3375. Approximately 10 directory tracks will be required.

OS/VS or DOS/VS Environment**Using BDAM:**

- Control storage: One cylinder on a 2314, 3330, 3340 or 3350.
- Permanent storage: One cylinder of permanent storage will contain approximately 3,200 units (50-60 bytes) of text on a 2314, 1,900 units on a 2314, 1,100 units on a 3340 or 7,200 units on a 3350. Actual requirements will depend on unit lengths in use.
- Working storage: One cylinder of working storage using the default working storage block size, will contain approximately 2,300 units (50-60 bytes) of text on a 3330, 1,600 units on a 2314, 1,000 units on a 3340 or 6,500 units on a 3350. Actual requirements will depend on unit lengths in use and the user-specified working storage blocking factor.

Using VSAM:

- Control Data Set: One cylinder of CDS can contain approximately 1,200 document index records on a 3330, 850 on a 2314, 450 on a 3340, 2,500 on a 3375, and 3,500 on a 3380. Approximately 4 document index records can be contained in one FBA block.

To contain the remaining control records and to support Generalized Markup Language processing, add to the above total amount 6 cylinders for a 2314, 4 cylinders for a 3330, 10 cylinders for a 3340, 2 cylinders for a 3350, 2 cylinders for a 3375, 2 cylinders for a 3380, or 1,000 FBA blocks.

- Permanent storage: One cylinder of permanent storage will contain approximately 3,200 units (50-60 bytes) of text on a 3330, 1,900 units on a 2314, 1,100 units on a 3340, 7,200 units on a 3350, 7,200 units on a 3375 or 8,960 units on a 3380. Three FBA blocks, the minimum allowed, will contain up to 18 units of text. Actual requirements will depend on unit lengths in use.
- Working storage: One cylinder of working storage, using the default working storage blocksize, will contain approximately 2,300 units (50-60 bytes) of text on a 3330, 1,600 units on a 2314, 1,000 units on a 3340, 4,500 units on a 3350, 4,500 units on a 3375 or 6,400 units on a 3380. One FBA block will contain up to 4 units of text. Actual requirements will depend on unit lengths in use.
- CICS/VS Temporary Storage: Used for online SCRIPT/VS formatting and online printer destination capabilities. The total amount required is a function of the page limits set for online printing, the number of concurrent ATMS-III users of these capabilities and the number of documents queued for online printing.

Note: New installations may generate storage with the sample values shown in the *ATMS III Program Reference Manual*. If, after a period of time, this space is insufficient for the installation's needs, the space may be expanded.

SOFTWARE REQUIREMENTS

ATMS-III is written in IBM S/370 Asembler language. It runs under control of CICS/VS (5740-XX1 for CICS/OS/VS and 5746-XX3 for CICS/DOS/VS) Version 1.5.0, and subsequent releases, unless otherwise identified. Refer to the CICS/VS pages for operating system support.

Terminal communications is handled by ATMS-III using an appropriate telecommunications method through CICS/VS, except that BTAM is required for ATMS-III support of keyboard-printer terminals.

Data management is handled by ATMS-III using either VSAM or direct buffering through the BDAM (OS) or DAM (DOS) access methods. For certain tape operations, the EXCP access method is used. CICS/VS file control tables and open/close facilities are also used for data set control.

In addition, the following may also be required:

- OS/VS Sort/Merge (5740-SM1) if working storage sorts are to be done.
- Appropriate VSAM access method, if it is to be used for the ATMS III data base, or for use of CICS/VS auxiliary temporary storage if 3270 or Office System 6 printer destination capabilities are to be used.
- Document Composition Facility (5748-XX9, R2.0 or R3.0) and its ATMS-III Environment feature if SCRIPT/VS formatting is to be done. If the 4250 Printer is to be used, R3.0 is required. CICS/VS temporary storage is used for online formatting, with VSAM required if auxiliary temporary storage is used.

- Document Library Facility (5748-XXE, R2.0 or R3.0) and supporting VSAM access method, if advantage is to be taken of the asynchronous archive processes. If used in a DOS/VS environment, these functions require DOS/VSE with VSE/Advanced Functions Release 2 (5746-XE8), VSE/VSAM (5746-AM2) and VSE/POWER (5746-XE3).

- JES2 or JES3 (selectable unit in MVS Releases 3.7 or 3.8) in OS/MVS, or VSE/POWER in DOS/VSE if document archiving to a library of the Document Library Facility or the batch job submit function is to be utilized.

- A user SVC is supplied for installation in an OS/VS1 environment when archiving to the Document Library Facility or batch job submit functions are to be utilized.

A minimum OS/VS or DOS/VSE Assembler and Linkage Editor are required for the installation and maintenance of ATMS III.

COMPATIBILITY

ATMS-III, with the Formatter feature, is functionally upward compatible from ATMS and ATMS-II, as well as from ATS/360 with the exception of field-oriented-data format change during input and output. A capability for retrieving ATMS backup or archive documents and ATS/360 rollout or archive documents is provided. An existing ATMS or ATS/360 data base is readily converted to an ATMS-III data base using these facilities.

The ASP/JES3 licensing exception does not apply to programs, features, and versions announced after July 6, 1976. A license is required for each processor on which this program executes.

DATA SECURITY

Data security, which is a user responsibility, can be enhanced using a variety of means. These take the form of both ATMS-III and CICS/VS controls. These are:

- Selective controls on the use of the CICS/VS master terminal operator functions.
- CICS/VS operator signon and password procedures.
- ATMS-III operator signon and password procedures. The signon area contains multiple overstruck characters on a keyboard-printer terminal and is made non-displayable on a 3270 display station.
- Selective assignment of the ATMS-III control terminal operators, privileged operators, and operator administrators.
- Operator-assigned access words for getting and/or deleting documents and document indexes.
- Operator use of the lock and unlock commands.
- User assignment of 3270 printers for selected document routing

PROGRAM PRODUCTS
**MVS/SYSTEM PRODUCT-JES3
MVS/SP-JES3 RELEASE 1 (5740-XYN)**
PURPOSE

MVS/System Product-JES3 (MVS/SP-JES3) Release 1 provides all the performance and functional benefits of MVS/System Extensions (5740-XE1) and significant new enhancements. MVS/SP-JES3 Release 1 is available for the 4341, 4361-5 or 4381 with ECPS:MVS installed, for the 3031, 3032, 3033 Processors and on the S/370 mdl 158 and 168 Processors with the S/370 Extended Feature installed.

DESCRIPTION

Note: MVS/System Product (MVS/SP) is a generic term referring to announced releases of MVS/System Product-JES2 (5740-XY2) and MVS/System Product JES3 (5740-XYN) or topics common to both.

The significant new facilities are:

- Support for the 3380 Direct Access Storage with the 3880 Storage Control mdls 2 and 3 with the Data Streaming feature (#4850) on the 3031, 3032 and 3033 Processors or attached to a 3MB channel on the 4341, 4361-5 or 4381, when installed with the *iVVS* Data Facility/Device Support (5740-AM7) program product.
- Support for the 3278 and 3279 Display Stations as operator MCS consoles.
- Support for the 4341, 4361-5, or 4381 Processor with ECPS:MVS installed.

HIGHLIGHTS

MVS/SP-JES3 Release 1 installed on MVS 3.8 offers new support for the following:

- The 3380 Direct Access Storage with the 3880 Storage Control mdls 2 and 3 using either:
 - The Data Streaming feature (#4850) on the 4341, 3031, 3032 and 3033 Processors, or
 - the 3MB channel on the 4341, 4361-5 or 4381.

Device support is provided by MVS/SP-JES3 Release 1 installed with the MVS Data Facility Device Support Release 1 program product (5740-AM7). This support also permits the 3380 device to be used for paging and for system residence. The 3380 Direct Access Storage provides reduced access times and an increased data transfer rate when compared to previous IBM DASD units. The 3380 Direct Access Storage with the 3880 Storage Control mdls 2 and 3 introduces dynamic path selection facility. Dynamic path selection facility allows the operating system to access a reserved device via any of the available paths.

- The 3279 Color Display Station, all mdls, and the 3278 Display Station, mdls 1, 2, 3 and 4 attached via a 3274 mdl 1D control unit are supported as MCS consoles through device independent display operator console support (DIDOC5). The greater capacity screens are supported on the 3278 mdls 3 and 4 and on the 3279 mdls 3A and 3B. In addition, the color defaults are supported on all mdls of the 3279. These color defaults are blue for all normal traffic, white for all action messages and green for operator commands. Full program function key support is available for the 3278 and 3279 Display Stations.

In addition, the following MVS/System Extensions (5740-XE1) Performance and Functional Benefits are included as part of the MVS/SP-JES3 Release 1.

Performance Improvements: MVS/System Extensions test measurements completed on the S/370 158, 168 and 3031, 3032 and 3033 Processors have shown the following results:

A 20 to 27% reduction in control program supervisor state execution time, providing throughput improvements ranging from 14 to 18% for BATCH, TSO/BATCH and IMS/BATCH test environments on uniprocessors and 17 to 20% improvements on multiprocessor configurations as compared to MVS Release 3.7 with SUs 4, 5 and 7 installed.

Actual performance will vary depending upon customer environment, storage and I/O configuration. No assurance can be given that an individual user will achieve the test results.

SMF Enhancements: A major revision to SMF provides more data with increased installation control over the amount of data collected and allows a non-disruptive migration to full utilization of the new function.

SRM Enhancements: Control of system resources to meet installation-defined goals is necessary for effective usage of the system. The SRM is enhanced to centralize and improve system control, to improve the RMF reporting of certain transactions, and to ease the use of certain SRM facilities.

Action Message Retention Facility: Proper and timely handling of operator messages is important. Messages requiring operator action are given particular message descriptor codes. Prior to

MVS/System Extensions Release 2, these messages could roll off the operator's screen with no easy way for the operator to reconstruct the set of unsatisfied action messages. The action message retention facility allows the operator to retrieve all unsatisfied action messages.

See the *General Information Manual* (GC28-1025) for more detailed information.

CUSTOMER RESPONSIBILITIES

MVS Release 3.8 and the MVS Processor Support 2 must be installed prior to installing MVS/SP-JES3 Release 1.

SPECIFIED OPERATING ENVIRONMENT
HARDWARE REQUIREMENTS

MVS/SP-JES3 Release 1 requires the appropriate S/370 Extended Feature on IBM S/370 mdls 158 (#7730 or #7731) and 168 (#7730) or ECPS:MVS on the IBM 4341, 4361-5 or 4381. MVS/SP-JES3 Release 1 supports the following processors:

IBM mdl 158-1	UP/MP/AP
IBM mdl 158-3	UP/MP/AP
IBM mdl 168-1 with RPO S20579	UP/MP
IBM mdl 168-1 with RPO S20580	AP
IBM mdl 168-3	UP/MP/AP
IBM 4341 Processor Mdl Group 1	UP
IBM 4341 Processor Mdl Group 2	UP
IBM 4361-5 Processor	UP
IBM 4381 Processor	UP
IBM 3031 Processor	UP/AP
IBM 3032 Processor	UP
IBM 3033 Processor	UP/MP/AP
IBM 3033 Processor Mdl Group N	UP
IBM 3033 Processor Mdl Group S	UP

The minimum total storage required by MVS/SP-JES3 Release 1 depends on many factors. These include an installation's configuration, the subsystems, program products and problem programs in use. However, the following information will assist in approximating additional bytes of virtual storage required for the MVS/System Extensions and for MVS/SP-JES3 Release 1. The actual bytes of real storage needed will be less because PLPA and CSA are only partially backed by real storage.

To estimate the additional virtual storage required for MVS/SP-JES3 Release 1, use Chart 1 in the following manner:

- If the installation is running MVS 3.8 with the OS/VS2 MVS Processor Support 2 installed, the additional storage is the combined total of columns 1, 2 and 3.
- If the installation has MVS/System Extensions Release 1 installed, the additional storage is the combined total of columns 2 and 3.
- If the installation has MVS/System Extensions Release 2 installed, the additional storage is the amount in column 3.

CHART 1

	MVS/System Extensions Release 1 (Column 1)	MVS/System Extensions Release 2 (Column 2)	MVS/SP-JES3 Release 1 (Column 3)
Nucleus	30,000	6,200	10,500
PLPA	10,000	66,300	- 101,500 (Note 4)
CSA	---	Variable (Note 1)	---
SQA	500	Variable (Note 2)	4,000
LSQA	---	Variable (Note 3)	---

Notes:

1. Assuming four SMF buffers - requires an additional 8,000 bytes.
2. The amount of additional storage required in SQA depends on several variables:
 - Assuming 50 address spaces with interval accounting, two recording data sets and three subsystems defined to SMF, requires an additional 8,000 bytes.
 - Subsystem transaction reporting requires a minimum of 4,096 bytes.
 - The installation control specification requires for each subsystem name, an additional 28 bytes ... for each userid, transaction name and transaction class, an additional 20 bytes.
3. Each initiator requires an additional 40 bytes.
4. This reflects a reduction in PLPA of 101,500 bytes. It is achieved by an optional installation step. This step moves infrequently referenced modules from LPALIB to LINKLIB.

For more information, see the *General Information Manual* (GC28-1025-2).

PROGRAM PRODUCTS

MVS/SP-JES3 R1 (cont'd)**SOFTWARE REQUIREMENTS**

MVS/SP-JES3 Release 1 requires MVS Release 3.8 with MVS Processor Support 2 installed. MVS/SP-JES3 Release 1 completely replaces MVS/System Extensions (5740-XE1).

In order to support the IBM 3380 or the IBM 3375 Direct Access Storage, the MVS Data Facility Device Support program product (5740-AM7) is required.

RMF users must install RMF Version 2 Release 3.

RMF users of the MVS/SP-JES3 Release 1 Enhancement must install the RMF Version 2 Release 3 Enhancement supporting the MVS/SP-JES3 Release 1 Enhancement.

The specified operating environment may change and will be restated at time of product availability.

INSTALLATION CONSIDERATIONS

MVS/SP-JES3 Release 1 requires a stage 1 SYSGEN assembly together with a normal SMP Release 4 application. Alternatively, a full SYSGEN can be used for installation. The program directory will contain additional installation information.

To use the functions provided by RMF, the OS/VS2 MVS Resource Measurement Facility Version 2 Release 3 is required.

MVS/SP-JES3 RELEASE 1 COMPATIBILITY

MVS/SP-JES3 Release 1 operates with the following JES3 products:

JES3 Release 3

Optionally with:

JES3 3800 Enhancements

JES3 Networking PRPQ 5799-AZT

User-written programs that use standard external interfaces should continue to execute on an MVS system with the MVS/SP-JES3 Release 1 installed. Programs that interrogate MVS system control blocks may require modifications. Licensees will receive documentation on changes in control blocks at the time of availability.

When migrating from an MVS Release 3.8 or an MVS/System Extensions Release 1 environment, changes in an installation's accounting procedures may be required because of enhancements to SMF. (See the *General Information Manual*, GC28-1025-0, for details.) IBM devices currently supported by MVS Release 3.8 will continue to be supported by MVS with MVS/SP-JES3 Release 1 installed.

Any Installation Performance Specification (IPS) that is compatible with MVS Release 3.8 or MVS/System Extensions can be used unchanged with MVS/SP-JES3 Release 1.

IBM program products currently supported on MVS Release 3.8 or MVS Release 3.8 with the MVS/System Extensions program product should continue to run with MVS/SP-JES3 Release 1 installed (although for RMF users, the appropriate RMF release must also be installed). APARs will be accepted for MVS/SP-JES3 Release 1 when any such IBM program product does not run successfully after MVS/SP-JES3 Release 1 is installed.

MVS/SYSTEM PRODUCT-JES3 RELEASE 1 ENHANCEMENT

The enhancement for MVS/System Product-JES3 Release 1 provides the following functions:

- Support of the 3081, 3083 or 3084 Processor Complex.
- Support of the 3375 Direct Access Storage with the 3880 Storage Control mdls 1 and 2 is provided on the 3031, 3032 and 3033 Processors using the Data Streaming Feature. The 3375 Direct Access Storage is also supported on 4341, 4361-5 and 4381 Processors.
- Support of the 3880 Speed Matching Buffer Feature (#6550) with the 3031, 3032 and 3033 Processors and S/370 Mdl's 158 and 168.

DOCUMENTATION
(available from Mechanicsburg)

OS/VS2 MVS/System Product-JES3 and OS/VS2 MVS/System Product-JES2 General Information Manual (GC28-1025-2).

RPQs ACCEPTED: No.

PROGRAM PRODUCTS

**MVS/SYSTEM PRODUCT-JES3
MVS/SP-JES3 RELEASE 2 (5740-XYN)**

PURPOSE

MVS/System Product-JES3 Release 2 (MVS/SP-JES3 R2) incorporates all of the functional benefits of MVS/System Product-JES3 Release 1 and, in addition, provides functional and device support enhancements to the MVS Base Control Program and JES3. These enhancements offer an installation opportunities to reduce the system virtual storage requirements of system components and major subsystems, provide new facilities in the areas of multi-system support and operations management, as well as providing general functional and device support enhancements.

DESCRIPTION

MVS/SP-JES3 R2 consists of enhancements to two MVS components: The MVS Base Control Program (BCP) and JES3. The BCP component incorporates all of the functions of the BCP of MVS/SP-JES3 R1 and requires MVS Release 3.8 with the MVS Processor Support 2 function as prerequisites.

The BCP component of MVS/SP-JES3 R2 will operate with the JES3 component of MVS/SP-JES3 R2 or with the JES3 products that operate with MVS/SP-JES3 R1. The JES3 products supported in the latter case are:

- JES3 R3
- JES3 Networking PRPQ (5799-AZT)

This flexibility will enable an installation to stage its migration to MVS/SP-JES3 R2. When installed, the JES3 component of MVS/SP-JES3 R2 replaces JES3 R3 and the JES3 Networking PRPQ.

Note: JES3 R3 and JES3 R3 with the JES3 Networking PRPQ are supported with and without the JES3 3800 Enhancements.

BASE CONTROL PROGRAM (BCP) COMPONENT HIGHLIGHTS

The BCP component of MVS/SP-JES3 R2 incorporates all of the functions of the BCP of MVS/SP-JES3 R1 and, in addition, provides the following facilities:

- Cross Memory Services
- Global Resource Serialization
- Operational Interface enhancements
- Directed VIO
- Subsystem Definition facility

CROSS MEMORY: Cross Memory is an architectural extension supported by MVS. This extension facilitates communication among address spaces in an MVS/System Product-JES3 Release 2 environment. By providing a means to transfer data or program control directly between the private areas of address spaces, many benefits result. Because the prime users of Cross Memory services are intended to be MVS system components and subsystems, these benefits can be realized by an installation without any additional user programming. The benefits include:

- **Reduced System Virtual Storage Requirements:** The Cross Memory services of MVS/System Product-JES3 Release 2 enable the system virtual storage (Nucleus, PLPA, SQA, CSA) requirements for specific environments to be reduced. Certain data formerly found in the system virtual storage area can now be stored in new auxiliary address spaces and accessed via Cross Memory services. Such reduction can enable more system or private area virtual storage usage by other subsystems, new applications or current applications growth.
- **Enhanced Isolation:** The multiple address space structure of current MVS provides a considerable amount of data and program isolation. There are instances, however, when two address spaces must communicate with each other. This is generally accomplished through the scheduling of a Service Request Block (SRB) and involves the use of common virtual storage area (CSA/SQA). MVS/SP-JES3 R2 now provides the means by which inter-address space communication can occur without using common virtual storage, thereby isolating the program/data concerned from accidental modification or destruction by system components or authorized programs. Thus, the protection afforded to programs and data by the private area of an address space is extended to include instances of inter-address space communication.
- **Improved System Structure:** Currently, control block information residing in the common virtual storage area (CSA/SQA) is directly addressed by system components and other programs. Cross Memory services enables such control block information to be assigned to the private area of a system or subsystem auxiliary address space and accessed without the overhead of the current Service Request Block (SRB) mechanism. The isolation afforded by the private area of an address space allows controlled access to such data. The information required by system components, subsystems and their users can now be provided via an interface which is independent of the control block structures in the auxiliary address space. Reducing control block dependencies both

enhances system reliability and facilitates migration to new function.

- **Enhanced Authority Mechanism:** Cross Memory services provide the capability for authorized subsystems to define groups of address spaces having different levels of authorization for inter-address space communication. This represents a significant enhancement over existing facilities (for example, SRBs) which provide a single level of authorization to all address spaces (Key 0). Once such groups have been defined, a program may use Cross Memory services for inter-address space communication, but will be prohibited from accessing address space groups for which it has not been authorized.

Cross Memory Usage: Examples of system components/subsystems utilizing Cross Memory services in the MVS/SP-JES3 environment.

- Global Resource Serialization
- Operations Interface
 - Display Units (DU) command
- JES3 (optionally)
- IMS/VS

GLOBAL RESOURCE SERIALIZATION

- Global Resource Serialization, which extends the current ENQ/DEQ facility, provides additional function and improved RAS.
- Global Resource Serialization extends the ENQ function of resource serialization across system boundaries. Multiple MVS systems, interconnected through Channel-to-channel Adapters (CTCs), will now be able to serialize resource usage across systems.
- Additionally, Global Resource Serialization will run in its own address space utilizing the new Cross Memory architecture. Unlike the current ENQ facility, the Global Resource Serialization control blocks will reside in their own address space, thereby reducing the amount of system virtual storage required and, at the same time, improving the system RAS characteristics. By running in its own address space and by preventing addressability to its control blocks, Global Resource Serialization is isolating itself from accidental modification or destruction by other system components or authorized applications.
- Global Resource Serialization also addresses the need to provide information about resources without requiring that an application look at internal ENQ control blocks. MVS/SP-JES3 R2 eliminates dependencies on the structure of ENQ control blocks by providing a new macro service that allows applications to obtain resource status. Access to these control blocks is available only through this new macro service.
- Current ENQ/DEQ/RESERVE services provide three resource serialization scopes: STEP, SYSTEM and SYSTEMS. In a Global Resource Serialization environment, ENQ/DEQ requests specifying STEP or SYSTEM will be treated as requests for local resources and not communicated to other systems in the defined complex. ENQ/DEQ requests specifying SYSTEMS are requests for global resources and are communicated to all systems within the defined complex.

Global Resource Serialization provides the capability to override the default serialization from local to global, and vice versa, in instances where the SYSTEM and SYSTEMS scopes are used. This override is achieved by the invocation of exits that scan installation-specified 'inclusion' and 'exclusion' resource name lists. Global Resource Serialization invokes the 'inclusion' exit for each ENQ/DEQ request specifying a scope of SYSTEM (local serialization) to determine whether the installation requires that resource to be included in global serialization. For each ENQ/DEQ/RESERVE request specifying a scope of SYSTEMS (global serialization), the 'exclusion' exit is invoked to determine whether the installation requires that resource to be excluded from global serialization.

An exit that scans a RESERVE conversion list is also provided to allow device RESERVE requests to be overridden and converted to SYSTEMS (global serialization) requests, thereby allowing other systems in the defined complex to concurrently access the device.

Default exits and resource name lists are provided by IBM. An installation may modify these lists to meet the specific requirements of its operating environment.

- Thus, in the context of multi-system data set integrity, the conversion capabilities provided by Global Resource Serialization can be used to complement the data set level of serialization provided by JES3 Main Device Scheduling (MDS) by allowing existing RESERVE requests to be mapped to system-wide (global) ENQ requests and thereby avoid the volume level of serialization inherent in the use of the current RESERVE/RELEASE function.
- In order for an installation to achieve resource serialization across systems, the MVS systems must be interconnected via Channel-

MVS/SP-JES3 R2 (cont'd)

to-channel Adapters (CTCs). Global Resource Serialization requires dedicated CTCs, and, in order for an installation to obtain maximum configurability with Global Resource Serialization, each MVS system should have a CTC connection with every other system with which it serializes resource usage. To meet the additional CTC requirements of large installations, further CTC capability is provided for the 3033 Processor. For details, see RPQ 8P0882.

OPERATIONAL INTERFACE ENHANCEMENTS

A new facility, in conjunction with two enhanced commands, provides significant improvements in the operability of MVS Systems, particularly in large system installations. These enhancements allow the installation to reduce non-essential message traffic on the operator's console and also provide the operator with new system status information which will allow better control of job traffic and the I/O configuration.

- **Message Processing Facility (MPF):** The Message Processing Facility provides a means of reducing the number of messages to be displayed on the operator's console. The installation can determine the messages which it considers to be important and, through the use of this facility, suppress many non-essential ones.

The messages an installation wishes to suppress are listed by identifiers in a member of SYS1.PARMLIB. The SYS1.PARMLIB member selection may be changed at any time via the SET command and the message identifiers in use can be displayed by use of the DISPLAY MPF command. Suppressed messages are included in the hardcopy log with an indicator denoting the message has been suppressed.

Note: Action messages, command responses, responses from the Monitor (MN) command and Write to Operator with Reply (WTOR) messages (message codes 1, 2, 3, 5 and 11) will not be suppressed, even if they had been so specified by the installation.

- **Display Active (DA) Enhancements:** The DISPLAY A command is changed to provide additional information. It allows for improved operator awareness and displays information relevant to other operator commands. Included in this display are address space status, type of user, ASID, PER indicator, step must complete count, performance group number, domain number, CPU affinity, elapsed time, and CPU time for each address space.

The organization of the display is changed to better utilize the screen of the operator's console. The DISPLAY A command can also be restricted to one particular user (job, TSO user, etc.) or group of users with similar names so that it is easier to obtain the required pertinent information for specific users.

- **Display Units (DU) Enhancements:** Determining which jobs are using a device is important to a system operator or programmer trying to resolve why a device cannot be varied offline. With the enhancement to DISPLAY U, the operator can display the job names and ASIDs of device users, in order to decide what action should be taken. Improved recovery is also added to the allocation end of memory resource manager for shareable DASD devices. The additional system status information required for this extension is collected in a separate address space and accessed via Cross Memory services.

DIRECTED VIO

Directed VIO enables an installation to more effectively utilize high speed paging volumes for paging of critical response-oriented applications by separating VIO pages from these volumes. In addition, this facility will allow installations to utilize VIO more extensively and experience its benefits in environments where the limitation on high speed paging space was previously a concern.

A new keyword (NONVIO) is being provided as a system parameter, or as a PAGEADD option, to allow installations to specify local page data sets which are not to receive VIO pages. If enough other local page data set space is available, VIO pages will be directed to those local page data sets that were not on the directed VIO data set list. Only in the case of constrained VIO paging space can VIO pages potentially spill to the NONVIO local page data sets.

OTHER ENHANCEMENTS

- A Subsystem Definition Facility is provided to give an installation the capability of defining subsystems at IPL via one or more members of SYS1.PARMLIB, thereby eliminating the need to modify the Subsystem Name Table (IEFJSSNT).
- Several other enhancements have been made to the Base Control Program of MVS/System Product-JES3 Release 2 to facilitate the use of subsystems. Details of these enhancements will be documented in the *General Information Manual*, GC28-1025-0.

JES3 COMPONENT

The JES3 component of MVS/SP-JES3 R2 provides a generally compatible replacement to the JES3 R3 product, together with the functions of the JES3 3800 Enhancement, and is designed to improve the operational environment for JES3 users through enhancements to existing functions and the provision of new facilities. These include enhancements to the reliability and recovery aspects of the spooling subsystems, early tape volume release for jobs creating multi-volume tape data sets, two additional user exits, support of the 3375 and the 3380 Direct Access Storage devices in the JES3 spool environment, and support of the 3278 and 3279 display units in the JES3 console environment. New facilities include the option for the installation to reduce JES3's usage of system virtual storage, the support of the Message Processing Facility see BCP component of R2) in the JES3 console environment, and the provision of job networking capabilities for the JES3 Global Processor to enable its communication with other networking nodes (MVS/SP-JES3 R2, MVS/SP-JES2 R2, VM/SP with RSCS Networking program product, etc.) via Channel-to-channel adapters (CTCs) or binary synchronous communication lines. The job networking function was previously available only through the JES3 Networking PRPQ (5799-AZT).

JES3 HIGHLIGHTS of MVS/SP-JES3 R2

- **Spool Partitioning and RAS Facilities:** JES3 RAS characteristics are improved by permitting an installation to partition the JES3 spool. This reduces the likelihood that a single volume failure will result in the loss of the entire spool. New inquiry and modify capabilities allow an operator to determine those jobs affected by a volume failure and take actions consistent with installation objectives.
- **3375 and 3380 Direct Access Storage Support:** The 3375 and 3380 Direct Access Storage devices are supported as JES3 spool devices.
- **Common Service Area (CSA) Reduction:** Optionally, JES3's use of Common Service Area can be substantially reduced through the use of Cross Memory facilities and a new JES3 auxiliary address space. This allows for expanded CSA or private area for the subsystems, new applications or current application growth.
- **Job Networking:** Provides for the transmission of selected jobs and in-stream data sets, operator commands and messages, system output data sets, and job accounting information from one computer system to another across a communications link (binary synchronous or Channel-to-channel). This incorporates the functions previously available through the JES3 Networking PRPQ (5799-AZT).
- **Early Volume Release:** The user can specify that the tape volume used by a job is to be made available to other jobs at end of volume.
- **Message Processing Facility (MPF):** Users can elect to suppress the display of particular non-action JES3 messages which will appear only on the log devices.
- **3278/3279 Display Unit Support:** Support of these terminals by JES3 allows the user to take advantage of larger screen size and the 24 Program Function Keys.

MVS/SP-JES3 RELEASE 2: JES3 COMPONENT DESCRIPTION

Job Entry Subsystem 3 - JES3: The JES3 component of MVS/SP-JES3 Release 2 is designed to improve the operational environment of the computer installation by aiding many of the operator functions. JES3 can improve installation workload scheduling, increase the workload capacity, and reduce turnaround time. JES3 provides a single system image for the execution of many jobs concurrently on the connected processors.

JES3 can support up to eight JES3 processors, any of which can be a tightly coupled multiprocessor, operating under the control of MVS/SP-JES3 Release 2. A JES3 configuration consists of a global processor that controls all job input and output, and the scheduling of time sharing users, batch jobs and, optionally, devices. One to seven additional JES3 processors, called *JES3 local processors*, can be connected to the JES3 global processor. Each processor is attached to the JES3 global processor by a channel-to-channel (CTC) adapter which is used to interchange control information. The JES3 global processor handles all SYSIN and SYSOUT to and from peripheral devices.

JES3 design and the shared spool concept help to improve the overall complex availability by permitting any JES3 local processor, if properly configured, to assume JES3 global functions. Should the JES3 global processor fail in a loosely coupled multiprocessing configuration, the operator can move the JES3 global function to any properly configured JES3 local processor. The degree of this availability depends on the presence of appropriate alternate CTC paths and switchable peripheral devices.

The JES3 global processor must operate under MVS/SP-JES3 R2. Remote job processing from binary synchronous communications (BSC) and systems network architecture (SNA) terminals is supported. JES3

PROGRAM PRODUCTS

MVS/SP-JES3 R2 (cont'd)

also provides multiprogrammed background utilities which the operator can invoke.

As the installation workload grows, capacity can be increased by increasing the size of processors, by using multiprocessor configurations, and/or by adding additional JES3 local processors, operating under the control of MVS/SP-JES3 R2. JES3 enables such expansion with minimal disruption to the operational environment. Jobs are distributed to available processors depending on job priority, device requirements, user specification, and processor dependencies. (A processor dependency is an attribute of a job that requires it to execute on a specific JES3 processor. For example, if a job uses a device that is attached to only one processor, then the job has a processor dependency and must execute on the processor that can access the device).

Some of the features of JES3 are:

- Single operator interface to the entire system.
- Complex-wide data set integrity.
- Job Networking (BSC).
- Automatic scheduling of interdependent jobs (dependent job control).
- Optional auxiliary address space to reduce CSA requirements.
- Generalized peripheral scheduling and improved output service that includes related INQUIRY/MODIFY processing.
- Performance features, for example:
 - Ordered seek I/O queuing
 - SIO drivers for RJP, CTCs, spool and printers
 - Unserialized path for allocation
 - VTAM authorized path
 - Main store resident control blocks
- Extensive RAS capability, for example:
 - Functional recovery routines
 - ESTAE recovery routines
 - Alternate Path Channel-to-channel (ACTC)
 - Dynamic system interchange
 - Spool I/O error recovery, partitioning and RAS support
 - HOTSTART of JES3 address space
 - WARMSTART of JES3 system
- Automatic scheduling of up to seven attached local processors (including multiprocessors).
- Centralized console service with message suppression.
- Logical device grouping with consoles defined for the group.
- Installation-specified, operator-controlled job selection algorithms for scheduling local processors.
- Numerous user exits.
- Deadline scheduling.
- Simulated console support for non-programmable remote terminals (2770, 2780, 3780).
- Multitasking of the Converter/Interpreter and locates.
- Checkpoint/Restart support for jobs.
- SMF support.
- Early JCL diagnosis through JES3's use of the VS2 Converter and Interpreter.
- Support of TSO Foreground Initiated Background functions.

Job Networking: This facility provides for the transmission of selected jobs, in-stream data sets, operator commands and messages, system output data sets and job accounting information from one computer complex to another across binary synchronous telecommunications facilities or channel-to-channel adapters. The use of standard interface protocols enables communication among similar and dissimilar operating systems such as MVS/SP-JES3 R2, MVS/SP-JES2 R2 and VM/SP and the RSCS Networking program product. Routing from the originating network node to the destination node is controlled by a routing table at each node in the path. Strings of duplicated characters are compressed into shorter representations, reducing data flow between nodes. Operator commands permit manual intervention to control the network. JES3 Networking utilizes the security functions normally in effect at each node.

REMOTE JOB PROCESSING (RJP)

Binary Synchronous Communication (BSC): JES3 Remote Job Processing (RJP) permits the input, processing and output of jobs to and from terminals remote from the installation. This function is achieved through the use of the 3704 or 3705 Communications Controller (emulator mode), the 2701 Data Adapter, or the 2703 Transmission Control Unit to interface with binary synchronous communication (BSC) terminals. BSC remote terminals are used as remote card readers, printers and card punches, with job output routed optionally to any remote terminal or local output device.

For detailed information related to JES3 BSC RJP, see *Introduction to JES3*, GC28-0607.

Synchronous Data Link Control (SDLC): JES3 SNA RJP provides JES3 remote job processing support for SNA terminals in a terminal-sharing environment where multiple applications may establish logical connections with the terminal on a per-session basis. To achieve this flexibility of terminal-sharing, JES3 uses the VTAM or ACF/VTAM Version 1 or ACF/VTAM Version 2 application program interface for the support of the SDLC terminals which are attached to a 3704/3705 in network control mode.

SDLC job entry stations supported by JES3 are the 8100 Information System under DPPX or DPPX/SP, the 8100/DPCX Information System, the 5280 Distributed Data System, the 3790 Communication System and the 3770 Data Communication System (except for the 3773 mds P1, P2 and P3, all SDLC models are supported). Multiple Logical Unit (MLU) 3776 mds 3, 4 and 3777 mds 3, 4 with up to six independent and concurrent sessions are supported and System/36 is supported by Multiple Logical Units. Also supported are the 3262 Line Printer mds 2, 12, the 3784 Line Printer, the 3203 Printer mdl 3, the 3521 Card Punch, the 3501 Card Reader, and the 2502 Card Reader when attached to a 3770. In addition, JES3 supports the 6670 Information Distributor (SNA version) through the MVS/Information Distribution Workstation Support (see program product 5740-AMA). The 3790 Communication System and 8100/DPCX Information System support a single RJE workstation which can handle up to five logical concurrent processing sessions with JES3.

Functional characteristics of the JES3 SNA RJP support for SDLC terminals are as follows:

- Half duplex session flow.
- Multidrop operation.
- 3770 diskette, 8100/DPPX or DPPX/SP disk operations, 8100/DPCX disk operations, and 3790 disk operations are transparent to JES3.
- Data stream provides compression of repeated characters outbound to the 8100 Information System under DPPX or DPPX/SP with DPPX/RJE or DPPX/SP RJE, the 3790 Communication System, the 8100/DPCX Information System, the System/34, the System/36, and to the 3770 Data Communication System.
- Data compaction is supported outbound to the 8100 Information System under DPPX with DPPX/RJE or DPPX/SP with DPPX/SP RJE, the 3790 Communication System, the 3776 mds 3 and 4, the 3777 mds 1, 3 and 4 of the 3770 Data Communication System, and the 8100/DPCX Information System.
- Single or multiple LUs (allowing multiple sessions) in a job entry station.
- Provides device setup for the 3790 and the 8100 Information System under DPPX with DPPX/RJE or DPPX/SP with DPPX/SP RJE, and 8100/DPCX by use of the Peripheral Data stream Information Record (PDIR).

JES3 JOB MANAGEMENT

Input Service: Input Service consists of two phases, each consisting of several non-resident modules:

- **Reader phase:** Jobs are read from an input device and placed on a spool in batches.
- **Control statement processing phase:** Jobs are read from the spool and processed.

Interpreter Service: Interpreter service converts JCL statements to scheduler control blocks (SCBs) for use by the scheduler component. It also determines resource requirements and creates control blocks for use by JES3 main device scheduler (MDS) function. Every job must pass through the interpreter service before it can be scheduled for execution. This service comprises primarily the converter/interpreter (C/I) dynamic support programs (DSPs).

The critical option in creating MDS control blocks is choosing the type of setup for JES3-managed devices. The setup options available with JES3 are:

1. **Job Setup:** The interpreter assigns each unique volume used throughout the job to a separate device, except where JCL explicitly indicates otherwise. This type of setup generally improves job turnaround at the expense of efficient device usage.
2. **High Watermark Setup:** The interpreter assigns a number of mountable devices (discounting permanently resident or reserved

MVS/SP-JES3 R2 (cont'd)

volumes) of each device type equal to the maximum number of volumes required in any single job step, unless the JCL explicitly indicates otherwise. This type of setup makes efficient use of devices, but may slow job turnaround due to dismounting and mounting of volumes.

3. **Explicit Setup:** The programmer specifies in a JES3 control statement which DD statements are (and which are not) to be setup.

The entire MDS function is optional, and additionally, the automatic setup options (job and high watermark) are separately selectable for DASD, tape and MSS virtual devices. These options are supplied as an installation default and can be overridden by JES3 control statements.

Data Resource Management: The main device scheduler (MDS) is a JES3 facility that controls the setup of resources (devices, volumes and data sets) associated with job execution on a processor. MDS services consist of volume fetching, allocation of data resources, volume mounting and verification, and deallocation of data resources. MDS services are part of the main scheduler element in normal job processing. Once a job is in execution, MDS services can also be invoked to process dynamic allocation requests.

Volume Fetching: MDS determines a job's requirements for mountable volumes and issues operator messages to a tape or DASD library, requesting that the required volumes be "fetched" to the computer area. As an installation option, after the issuing of these messages, MDS will either make the job immediately eligible for data resource allocation, or will wait for operator "go ahead" that the required volumes are available.

Data Resource Allocation: Data resource allocation facilities fall into three overlapping categories: (1) Selection of a job relative to other jobs competing for resources; (2) selection of an eligible processor on which to attempt allocation; (3) assignment of devices, volumes and data sets to the selected job.

Selecting a Job: In general, jobs are considered for data resource allocation in priority order. The first job that can acquire data resources on an eligible processor will be granted those resources.

Selecting a Processor: This choice of a "setup" processor does not restrict the eligibility of that job to run on only that processor. In allocating devices, preference is given to devices that are shared by other processors eligible to execute the job. If all devices allocated to the job are shared by another processor, that processor also remains eligible to run the job.

Allocating Data Sets, Volumes and Devices: JES3 provides data set integrity protection across processors in the JES3 complex in accordance with the JCL-specified data set disposition and dynamic allocation. This means that a job which holds exclusive access to a data set will prevent other jobs from allocating successfully.

MDS keeps track of the volume currently mounted on each device to minimize volume movement and attempts to satisfy further requests for the volume on the device where it is already mounted. MDS supports dynamic device reconfiguration (DDR) through the subsystem interface.

Volume Mounting and Verification: Once all required resources have been assigned to a job, MDS issues "mount" messages, requesting that the operator mount the first required volume on a specified device. MDS then verifies that each volume has been correctly mounted by reading its volume label.

Once all required volumes for a job have been mounted and verified, the job is passed to the generalized main scheduler (GMS) for execution processing selection.

JES3 3850 MSS Features include: Allocation to mounted volumes for non-specific requests for new, non-VSAM data sets.

Access to Mass Storage Volumes can be shared by all JES3 system processors physically connected to the same 3850.

Virtual units may be partitioned (fenced) for use by specific job class groups or dependent job networks.

Data reuse is encouraged (without access to 3850 controller tables).

JES3 algorithms attempt to equalize the amount of staging/destaging activity across Staging Drive Groups.

Multiple 3850s can be supported in a JES3 loosely coupled processor configuration, where each 3850 is attached to a separate host (as previously announced, one operating system can only be attached to one MSS).

Deallocation of Data Resources: During job execution, MDS or DYNAL is notified, as each step completes, to deallocate resources that are not required by subsequent steps of the job (early resource release). Data resources may also be returned in the midst of job step execution via the dynamic deallocation subsystem interface. Finally, any resources still held at job end are released at that time. In all cases, returned resources immediately become available for assignment to other jobs.

Job Scheduling: JES3 functions as a resource manager and job scheduler. The scheduling and selection of jobs for execution are major functions of the job entry subsystem. JES3 provides a unique set of these functions that are especially designed for the multiprocessing environment. These functions are generalized main scheduling, which determines which jobs should be scheduled to execute on a processor; deadline scheduling, increasing the priority of a job when it has been scheduled to make the best use of the available resources; and dependent job control which allows jobs to be executed in a specified order.

Selection of a job for a processor is based on the capacity of that processor to provide sufficient resources. JES3 supports pooled devices among processors to further control job/processor selection.

Generalized Main Scheduling: Jobs are selected for execution by the generalized main scheduling (GMS) facility of JES3. Initialization parameters define the characteristics of each processor, job-selection mode criteria, and jobs categorized by class.

GMS uses the priority parameters specified at initialization to help select jobs for execution. The hierarchy of priorities is:

1. Processor priority (dynamic)
2. Job Class priority.

The priority aging feature allows JES3 to increase the priority of a job after it has been passed over for selection by JES3 an installation-specified number of times, because of a low priority relative to that of other jobs in the system. At an installation-specified priority barrier, JES3 will attempt to prevent lower priority jobs from capturing idle resources if they are known to be needed by a job at or above the barrier priority.

Deadline Scheduling: Deadline scheduling provides job scheduling algorithms that increase the probability of a job being scheduled by a specific time. The job's selection priority may be dynamically incremented as the job approaches its deadline for entering execution.

The deadline scheduling feature allows the installation to specify a time of day by which the job should be scheduled. If the job is not scheduled by this time, JES3 will increase the priority of the job at user-defined intervals until it is scheduled.

Dependent Job Control: Dependent Job Control (DJC) allows jobs to be executed in a specific order. DJC is a function within the JES3 system that manages jobs that are dependent upon each other. Job dependencies may occur because of data dependencies; they may be defined so as to achieve better device utilization; or they may be defined so as to manage job streams.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

MVS/System Product-JES3 Release 2 requires the appropriate S/370 Extended Feature on IBM S/370 mdls 158 (#7730 or #7731) and 168 (#7730). MVS/System Product-JES3 Release 2 supports the following processors:

IBM mdl 158-1	UP/MP/AP
IBM mdl 158-3	UP/MP/AP
IBM mdl 168-1 with RPQ S20579	UP/MP
IBM mdl 168-1 with RPQ S20580	AP
IBM mdl 168-3	UP/MP/AP
IBM 4341 Processor Mdl Group 1	UP
IBM 4341 Processor Mdl Group 2	UP
IBM 4361 Processor Mdl Group 5	UP
IBM 4381 Processor	UP
IBM 3031 Processor	UP/AP
IBM 3032 Processor	UP
IBM 3033 Processor	UP/MP/AP
IBM 3033 Processor Mdl Group N	UP
IBM 3033 Processor Mdl Group S	UP
IBM 3081 Processor Complex	Dyadic
IBM 3083 Processor Complex	UP
IBM 3084 Processor Complex	Dyadic

Details concerning optional 3033 Extension feature for 3033 processors may be found in the Machines section.

SOFTWARE REQUIREMENTS

MVS/System Product-JES3 Release 2 requires MVS Release 3.8 with MVS Processor Support 2 installed.

In order to support the following functions and devices in MVS/SP-JES3 Release 2, Data Facility Device Support program product (5740-AM7) is required:

- JES3 Early Volume Release
- Checkpoint/Restart facilities
- 3375 Direct Access Storage
- 3380 Direct Access Storage

Details of the MVS Data Facility Device Support program product may be found in the announcement letter.

RMF users must install RMF Version 2 Release 4.

MVS/SP-JES3 R2 (cont'd)

MVS/System Product-JES3 Release 2 consists of enhancements to two MVS components: The MVS Base Control Program (BCP) and JES3. The BCP component of MVS/System Product-JES3 Release 2 replaces the BCP component of MVS/System Product-JES3 Release 1. The JES3 component of MVS/System Product-JES3 Release 2 replaces both JES3 R3 and the JES3 Networking PRPQ (5799-AZT). In addition, the 3800 Enhancements provided for JES3 R3 are incorporated into the JES3 component of MVS/SP-JES3 R2. Installation details for MVS/SP-JES3 R2 will be provided at availability.

MVS/SYSTEM PRODUCT-JES3 RELEASE 2 COMPATIBILITY

User-written programs that use standard external interfaces should continue to execute on MVS Release 3.8 with the MVS/System Product-JES3 Release 2 installed. Programs that interrogate MVS system control blocks may require modifications. Documentation on MVS/System Product-JES3 Release 2 control blocks will be available March, 1981.

When migrating from an MVS Release 3.8 or an MVS/System Extensions R1 environment, changes in an installation's accounting procedures may be required because of enhancements to SMF (see the *General Information Manual*, GC28-1025-0).

IBM devices currently supported by MVS Release 3.8 will continue to be supported by MVS with the MVS/System Product-JES3 Release 2 installed.

Any Installation Performance Specification (IPS) that is compatible with MVS Release 3.8, the MVS/System Extensions program product or MVS/System Product-JES3 Release 1 can be used unchanged with MVS/System Product-JES3 Release 2.

IBM program products currently supported on MVS Release 3.8, or MVS 3.8 with the MVS/System Extensions program product, or MVS 3.8 with MVS/System Product-JES3 Release 1 should continue to run with MVS/System Product-JES3 Release 2 installed (although for RMF users, the appropriate RMF release, RMF V2 R4, must also be installed). APARs will be accepted for MVS/System Product-JES3 Release 2 when any such IBM program product does not run successfully after MVS/System Product-JES3 Release 2 is installed.

RPQs ACCEPTED: No.

PROGRAM PRODUCTS

**MVS/SYSTEM PRODUCT-JES3
MVS/SP-JES3 RELEASE 3 (5740-XYN)**

PURPOSE

MVS/System Product-JES3 Release 3 provides all of the functions of MVS/System Product-JES3 Release 2 together with: The ability to achieve new levels of capacity and responsiveness on 3033 processors via performance improvements implemented in conjunction with the 3033 Extension Feature; support for the Extended Addressing Feature, permitting up to 32 megabytes of addressable storage on 3033, 3081, 3083 and 3084 processors, thereby providing potential for further capacity and responsiveness; significant improvements in System RAS; extensions to the reconfiguration and recovery aspects of Global Resource Serialization; and the potential further savings in the system virtual storage requirements. RMF support for MVS/System Product-JES3 Release 3 is provided by a feature for RMF Version 2 Release 4.

BASE CONTROL PROGRAM HIGHLIGHTS

Performance: The performance improvements are achieved through:

- Reduction in processor execution time for high frequency control program functions.

Usage of the 3033 Extension Feature by many MVS components in combination with code optimization has resulted in shorter path lengths and reduced processor execution time for several highly used system functions. In particular, several system functions have been restructured to perform more effectively on IBM's large processors (3033 UP and above).

- Reduction in I/O wait time.

Restructure of the MVS paging subsystem and use of new slot allocation algorithms results in reduced I/O wait time for paging and swapping.

- Reduction in I/O through use of extended real storage.

MVS/SP R3 will utilize extended real storage to eliminate demand paging and swapping I/O operations, thereby freeing processor capacity for additional productive work and reducing I/O wait time.

These improvements yield increased system throughput and responsiveness:

- Measurement and projection of test environments indicate that the MVS/System Product Release 3 will provide the following performance benefits to 3033 users with the 3033 Extension Feature installed in comparison to MVS/System Extensions Release 2:

- Throughput improvements generally of the order of 11% (UP) and 12% (AP/MP) for TSO/Batch environments.

- Throughput improvements of approximately 6% on UP and AP/MP for Batch intensive environments.

- Throughput improvements of approximately 7% on Batch, more on AP/MP for IMS/Batch environments. The IMS/VS projections utilized the then most current level of IMS/VS Version 1 Release 2 available in the fourth quarter of 1981.

- Throughput improvements generally of the order of 6% for intensive Batch and online IMS/Batch environments, with 3033 AP/MP environments experiencing additional throughput. The IMS/VS projections utilize the then most current level of IMS/VS Version 1 Release 2 available in the fourth quarter of 1981.

- Further throughput gains of up to 5% are expected for large multi-system establishments. Some of the performance improvements within MVS/SP R3 are sensitive to user I/O configuration and workload, the performance benefit increasing as size of I/O configuration and I/O rates increase, with the largest benefit accruing to processors configured for multi-system environments.
- New paging algorithms allow TSO environments to improve response time with increased capacity.

Extended Addressing: For customers who install the Extended Addressing Feature of the 3033 and additional storage, potential throughput improvements greater than those described above may be realized. MVS efficient use of additional real storage to eliminate paging I/O operations allows interactive environments such as TSO and IMS/VS to experience improved response time.

The actual performance benefit that an installation will experience will vary depending upon such considerations as customer environment and customer usage of the product improvements. The working sets of new system address spaces created in MVS/SP R2 and R3 may result in an increased real storage requirement and increased paging rates for some installations. No assurance can be given that an individual user will achieve the projected results.

New Levels of System RAS: The RAS enhancements provided by MVS/System Product Release 3 are a result of detailed studies of large MVS installations in 1978. They seek to avoid unscheduled IPLs caused by problems in the areas of I/O equipment, the MVS control program and operations.

Estimates indicate that over 20% of the unscheduled IPLs resulting from problems in these areas in the 1978 study have already been addressed by the general solutions in currently available products such as MVS Processor Support 2. MVS/System Product Release 3 now provides additional general solutions to detect and recover from such problems.

Projections for a 3033 environment indicate that MVS/System Product Release 3 addresses a further 19% of the unscheduled IPLs that resulted from problems in these areas in the 1978 study.

In addition, extensions have also been made to the recovery aspects of the Global Resource Serialization facility introduced in MVS/SP-JES3 R2.

Other Enhancements:

- The potential for additional savings in Common Service Area virtual storage.
- Utilization of Cross Memory Services by the Console Communications task provides the potential for further savings in Common Service Area virtual storage requirements.

JES3 Considerations: The JES3 component of MVS/SP-JES3 Release 3 provides a service update to the JES3 component of MVS/SP-JES3 Release 2.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

MVS/SP-JES3 Release 3 is designed to operate with the Extended Control Program Support Facility for MVS (ECPS:MVS) on IBM 4341, 4361-5 or 4381 Processors and the appropriate S/370 Extended Feature on S/370 mdls 158 (feature #7730 or #7731) and 168 (feature #7730). MVS/SP-JES3 JES3 Release 3 is designed to operate on the following IBM machines:

Model 158-1	UP/MP/AP
Model 158-3	UP/MP/AP
Model 168-1 with RPQ S20579	UP/MP
Model 168-1 with RPQ S20580	AP
Model 168-3	UP/MP/AP
4341 Processor Model Group 1	UP
4341 Processor Model Group 2	UP
4361 Processor Model Group 5	UP
4381 Processor	UP
3031 Processor	UP/AP
3032 Processor	UP
3033 Processor	UP/MP/AP
3033 Processor Model Group N	UP
3033 Processor Model Group S	UP
3081 Processor Complex	Dyadic
3083 Processor Complex	UP
3084 Processor Complex	Dyadic

SOFTWARE REQUIREMENTS

MVS/SP-JES3 Release 3 is designed to operate with MVS 3.8 with the MVS Processor Support 2 installed. The functions provided by either Data Facility Device Support Release 1 (5740-AM7) program product, or the MVS/370 Data Facility Product (5665-295) program product are required by the users of one or more of the following:

- The IBM 3375 Direct Access Storage
- The IBM 3380 Direct Access Storage
- Checkpoint/restart
- Extended Addressing feature and additional main storage beyond 16 megabytes

RMF users must install the RMF Version 2 Release 4 Enhancement that supports MVS/SP R3.

MVS/SP-JES3 Release 2 consists of enhancements to the MVS Base Control Program (BCP). The BCP component of MVS-SP-JES3 Release 3 replaces and enhances the BCP component of MVS/SP-JES3 Release 2. The JES3 component of MVS/SP-JES3 Release 3 is a service update to the JES3 component of MVS/SP-JES3 Release 2. Release 2 users who have the JES3 component of Release 2 installed will not be required to reinstall this component when migrating to Release 3.

DOCUMENTATION

(available from Mechanicsburg)

MVS/System Product General Information Manual (GC28-1025-2)

RPQs ACCEPTED: No

PROGRAM PRODUCTS

**MVS/SYSTEM PRODUCT-JES3
VERSION 1 RELEASE 3.1
MVS/SP-JES3 (5740-XYN)**

PURPOSE

MVS/SP-JES3 Version 1 Release 3.1 is a JES3-only update to MVS/SP-JES3 Version 1 Release 3. It consists of a complete replacement for the JES3 component in MVS/SP-JES3 Version 1 Release 3. The JES3 component of MVS/SP-JES3 Version 1 Release 3 provided a generally compatible replacement to the JES3 Release 3 (SU 26) product, together with the functions of the JES3 3800 Enhancement and the JES3 Networking PRPQ (5799-AZT).

JES3 HIGHLIGHTS OF MVS/SP-JES3 V1 R3.1

- Performance Improvements
 - Writer Output Multitasking

Enhancements to the JES3 output writer that permit a JES3 global to utilize IBM's tightly coupled processors more effectively are included in MVS/SP - JES3 Release 3.1. Writer output multitasking is a new feature that can be optionally invoked to offload a part of the JES3 writer processing from the primary JES3 task to a new task in the JES3 address space. The new task will support writer processing for the JES3 output writers - both local and remote.
- RAS Improvements
 - CTC Recovery Improvements

START command keywords and WTOR options allow the operator to redrive the primary CTC or switch to an alternate CTC on error situations.
 - JES3 Hotstart After MEMTERM

JES3 is changed to allow a hotstart without a re-IPL after the JES3 address space abnormally terminates (MEMTERM).
 - Initialization Recovery

JES3 initialization recovery provides increased flexibility in bringing up JES3, even though there may be certain errors in the initialization parameters, by substituting JES3 defaults for those parameters. Previously, JES3 terminated if such errors were detected in the initialization stream. This change allows an installation to correct the initialization stream errors using an active JES3. JES3 must be restarted to incorporate these corrections.
 - Out-of-Storage Errors

JES3 recovery processing is changed to free two 8K blocks of storage upon detection of an out-of-storage condition (80A, 878, or 804 ABEND) in the primary JES3 address space. This action increases the probability that recovery routines will complete without also encountering an out-of-storage condition. The operator will be notified of the out-of-storage condition when the next JES3 function is dispatched.
 - DD Statement Limits

The DD statement limits allow an installation to prevent an out-of-storage condition in the JES3 address space due to control block space required for DD statements. The installation will be able to specify limits for the number of DD statements in a job and/or the total number of DD statements allowed in JES3 converter/interpreter processing at one time. If a job exceeds the job DD statement limit, JES3 will cancel the job unless the installation overrides this decision in a new JES3 user exit routine.

If a JES3 converter/interpreter (C/I) subtask detects that the installation-defined limit for total number of DD statements in C/I processing is exceeded, the C/I subtask will WAIT until the limits are no longer exceeded. C/Is dedicated to TSO LOGONS do not participate in the DD limiting actions.

Operator commands are provided to allow dynamic installation control over both limits.
- DDR for Shared Tape

JES3's capacity to swap tape drives if a device fails or at the request of the operator is increased by allowing tape drives to be swapped with other tape drives regardless of the shared/nonshared status of the drives. Also, the eligible tape drives can be devices that are:

 - Being used by jobs that have not completed job set up processing.
 - Fenced for jobs of a different group than the job using the original tape drive.

- Operational Characteristics Enhancements

- Networking User Exit Standardization

The seven nonstandard user exits in JES3 networking are upgraded to make the networking user exits compatible with the rest of the JES3 user exits.

- SMF Exploitation

With SMF exploitation, the JES3 installation can selectively record the JES3-related SMF records and selectively invoke the JES3-related SMF user exit routines based on the work category of the associated job. The work categories include started tasks, TSO-related work, and batch work.

- MSS VUA Checkpoint

JES3 support for the 3850 Mass Storage System (MSS) is enhanced to include the offline/online status of MSS virtual units in new checkpoint records. This will allow the status of MSS virtual units to be preserved over a JES3 hotstart

- TSO Extensions (TSO/E) Support

JES3 supports the Interactive Data Transmission Facility (TRANSMIT and RECEIVE) commands included in the TSO/E Program Product (5665-285). JES3 interfaces with TSO to allow the transmission and receipt of data between specific users at different nodes in a network. JES3 will also issue a TSO SEND command to notify JES3 users of the receipt of data at their node. A new JES3 user exit is provided to allow the installation control over this TSO SEND function.

MVS/SP-JES3: JES3 COMPONENT DESCRIPTION

JOB ENTRY SUBSYSTEM 3 - JES3: The JES3 component of MVS/SP-JES3 is designed to improve the operational environment of the computer installation by aiding many of the operator functions. JES3 can improve installation workload scheduling, increase the workload capacity, and reduce turnaround time. JES3 provides a single system image for the execution of many jobs concurrently on the connected processors.

JES3 can support up to eight JES3 processors, any of which can be a tightly coupled multiprocessor, operating under the control of MVS/SP-JES3. A JES3 configuration consists of a global processor that controls all job input and output, and the scheduling of time sharing users, batch jobs and, optionally, devices. One to seven additional JES3 processors, called JES3 local processors, can be connected to the JES3 global processor. Each processor is attached to the JES3 global processor by a channel-to-channel (CTC) adapter which is used to communicate control information. The JES3 global processor handles all SYSIN and SYSOUT data to and from peripheral devices.

JES3 design and the shared spool concept help to improve the overall complex availability by permitting any JES3 local processor, if properly configured, to assume JES3 global functions. Should the JES3 global processor fail in a loosely coupled configuration, the operator can move the JES3 global function to any properly configured JES3 local processor. The degree of this availability depends on the presence of appropriate alternate CTC paths and switchable peripheral devices.

As the installation workload grows, capacity can be increased by increasing the size of processors, by using multiprocessor configurations, and/or by adding additional JES3 local processors, operating under the control of MVS/SP-JES3. JES3 enables such expansion with minimal disruption to the operational environment. Jobs are distributed to available processors depending on job priority, device requirements, user specification, and processor dependencies. (A processor dependency is an attribute of a job that requires it to execute on a specific JES3 processor. For example, if a job uses a device that is attached to only one processor, then the job has a processor dependency and must execute on the processor that can access the device).

Remote job processing from binary synchronous communications (BSC) and systems network architecture (SNA) terminals is supported. JES3 also provides multiprogrammed background utilities which the operator can invoke.

SOME OF THE FEATURES OF JES3 ARE:

- Single operator interface to the entire system.
- Complex-wide data set integrity.
- Job Networking (BSC).
- Automatic scheduling of interdependent jobs (dependent job control).
- Optional auxiliary address space to reduce CSA requirements.
- Generalized peripheral scheduling and improved output service that includes related INQUIRY/MODIFY processing.
- Performance features, for example:

PROGRAM PRODUCTS

MVS/System Product-JES3 V1 R3.1 (cont'd)

- Ordered seek I/O queuing.
- SIO drivers for RJP, CTCs, spool and printers.
- Unserialized path for allocation.
- VTAM authorized path.
- Main store resident control blocks.
- Optional invocation of JES3 writer processing as a separate JES3 task in the JES3 address space. This provides more utilization of IBM's tightly coupled processors.
- Extensive RAS capability, for example:
 - Functional recovery routines.
 - ESTAE recovery routines.
 - Alternate Path Channel-to-channel (ACTC).
 - Dynamic system interchange.
 - Spool I/O error recovery, partitioning and RAS support.
 - HOTSTART of JES3 address space.
 - HOTSTART without an IPL after JES3 abnormal termination (MEMTERM).
 - WARMSTART of JES3 system.
- Facilities to help prevent and recover from JES3 out-of-storage conditions.
- Automatic scheduling of up to seven attached local processors (including multiprocessors).
- Centralized console service with message suppression.
- Logical device grouping with consoles defined for the group.
- Installation-specified, operator-controlled job selection algorithms for scheduling local processors.
- Numerous user exits.
- Deadline scheduling.
- Simulated console support for non-programmable remote terminals (2770, 2780, 3780).
- Multitasking of the Converter/Interpreter and locates.
- Checkpoint/Restart support for jobs.
- SMF support.
- Early JCL diagnosis through JES3's use of the VS2 Converter and Interpreter.
- Support of TSO Foreground Initiated Background functions.

JOB NETWORKING: This facility provides for the transmission of selected jobs, in-stream data sets, operator commands and messages, system output data sets and job accounting information from one computer complex to another across binary synchronous telecommunications facilities or channel-to-channel adapters. The use of standard interface protocols enables communication among similar and dissimilar operating systems such as MVS/SP-JES3, MVS/SP-JES2 and VM/SP and the RSCS Networking program product. Routing from the originating network node to the destination node is controlled by a routing table at each node in the path. Strings of duplicated characters are compressed into shorter representations, reducing data flow between nodes. Operator commands permit manual intervention to control the network. JES3 Networking utilizes the security functions normally in effect at each node.

REMOTE JOB PROCESSING (RJP)

BINARY SYNCHRONOUS COMMUNICATION (BSC): JES3 Remote Job Processing (RJP) permits the input, processing and output of jobs to and from terminals remote from the installation. This function is achieved through the use of the 3704 or 3705 Communications Controller (emulator mode), the 2701 Data Adapter, or the 2703 Transmission Control Unit to interface with binary synchronous communication (BSC) terminals. BSC remote terminals are used as remote card readers, printers and card punches, with job output routed optionally to any remote terminal or local output device.

For more detailed information related to JES3 BSC RJP, see *JES3 Introduction* (GC23-0039).

SYNCHRONOUS DATA LINK CONTROL (SDLC): JES3 SNA RJP provides JES3 remote job processing support for SNA terminals in a terminal-sharing environment where multiple applications may establish logical connections with the terminal on a per-session basis. To achieve this flexibility of terminal-sharing, JES3 uses the VTAM application program interface for the support of the SDLC terminals which are attached to a 3704/3705 in network control mode.

SDLC job entry stations supported by JES3 are the 8100 Information System under DPPX or DPPX/SP, the 8100/DPCX Information System, the 5280 Distributed Data System, the 3790 Communication System and the 3770 Data Communication System (except for the 3773 mdls P1, P2 and P3, all SDLC models are supported). Multiple Logical Unit (MLU) 3776 mdls 3, 4 and 3777 mdls 3, 4 with up to six independent and concurrent sessions are supported and System/36 is supported by multiple logical units. Also supported are the 3262 Line Printer mdls 2, 12, the 3784 Line Printer, the 3203 Printer mdl 3, the 3521 Card

Punch, the 3501 Card Reader, and the 2502 Card Reader, when attached to a 3770. In addition, JES3 supports the 6670 Information Distributor (SNA version) through the MVS/Information Distribution Workstation Support (see program product 5740-AMA). The 3790 Communication System and 8100/DPCX Information System support a single RJE workstation which can handle up to five logical concurrent processing sessions with JES3.

Functional characteristics of the JES3 SNA RJP support for SDLC terminals are as follows:

- Half duplex session flow.
- Multidrop operation.
- 3770 diskette, 8100/DPPX or DPPX/SP disk operations, 8100/DPCX disk operations, and 3790 disk operations are transparent to JES3.
- Data stream provides compression of repeated characters outbound to the 8100 Information System under DPPX with DPPX/RJE or DPPX/SP with DPPX/SP RJE, the 3790 Communication System, the 8100/DPCX Information System, the System/34, the System/36, and to the 3770 Data Communication System.
- Data compaction is supported outbound to the 8100 Information System under DPPX with DPPX/RJE or DPPX/SP with DPPX/SP RJE, the 3790 Communication System, the 3776 mdls 3 and 4, the 3777 mdls 1, 3 and 4 of the 3770 Data Communication System, and the 8100/DPCX Information System.
- Single or multiple LUs (allowing multiple sessions) in a job entry station.
- Provides device setup for the 3790 and the 8100 Information System under DPPX with DPPX/RJE and 8100/DPCX by use of the Peripheral Data stream Information Record (PDIR).

JES3 JOB MANAGEMENT

INPUT SERVICE: Input Service consists of two phases, each consisting of several non-resident modules:

- **READER PHASE:** Jobs are read from an input device and placed on a spool in batches.
- **CONTROL STATEMENT PROCESSING PHASE:** Jobs are read from the spool and processed.

INTERPRETER SERVICE: Interpreter service converts JCL statements to scheduler control blocks (SCBs) for use by the scheduler component. It also determines resource requirements and creates control blocks for use by JES3 main device scheduler (MDS) function. Every job must pass through the interpreter service before it can be scheduled for execution. This service comprises primarily the converter/interpreter (CI) dynamic support programs (DSPs).

The critical option in creating MDS control blocks is choosing the type of setup for JES3-managed devices. The setup options available with JES3 are:

1. **JOB SETUP:** The interpreter assigns each unique volume used throughout the job to a separate device, except where JCL explicitly indicates otherwise. This type of setup generally improves job turnaround at the expense of efficient device usage.
2. **HIGH WATERMARK SETUP:** The interpreter assigns a number of mountable devices (discounting permanently resident or reserved volumes) of each device type equal to the maximum number of volumes required in any single job step, unless the JCL explicitly indicates otherwise. This type of setup makes efficient use of devices, but may slow job turnaround due to dismounting and mounting of volumes.
3. **EXPLICIT SETUP:** The programmer specifies in a JES3 control statement which DD statements are (and which are not) to be setup.

The entire MDS function is optional, and additionally, the automatic setup options (job and high watermark) are separately selectable for DASD, tape and MSS virtual devices. These options are supplied as an installation default and can be overridden by JES3 control statements.

DATA RESOURCE MANAGEMENT: The main device scheduler (MDS) is a JES3 facility that controls the setup of resources (devices, volumes and data sets) associated with job execution on a processor. MDS services consist of volume fetching, allocation of data resources, volume mounting and verification, and deallocation of data resources. MDS services are part of the main scheduler element in normal job processing. Once a job is in execution, MDS services can also be invoked to process dynamic allocation requests.

VOLUME FETCHING: MDS determines a job's requirements for mountable volumes and issues operator messages to a tape or DASD library, requesting that the required volumes be "fetched" to the computer area. As an installation option, after the issuing of these messages, MDS will either make the job immediately eligible for data

MVS/System Product-JES3 V1 R3.1 (cont'd)

resource allocation, or will wait for operator 'go ahead' that the required volumes are available.

DATA RESOURCE ALLOCATION: Data resource allocation facilities fall into three overlapping categories: (1) Selection of a job relative to other jobs competing for resources; (2) selection of an eligible processor on which to attempt allocation; (3) assignment of devices, volumes and data sets to the selected job.

SELECTING A JOB: In general, jobs are considered for data resource allocation in priority order. The first job that can acquire data resources on an eligible processor will be granted those resources.

SELECTING A PROCESSOR: This choice of a 'setup' processor does not restrict the eligibility of that job to run on only that processor. In allocating devices, preference is given to devices that are shared by other processors eligible to execute the job. If all devices allocated to the job are shared by another processor, that processor also remains eligible to run the job.

ALLOCATING DATA SETS, VOLUMES AND DEVICES: JES3 provides data set integrity protection across processors in the JES3 complex in accordance with the JCL-specified data set disposition and dynamic allocation. This means that a job which holds exclusive access to a data set will prevent other jobs from allocating successfully.

MDS keeps track of the volume currently mounted on each device to minimize volume movement and attempts to satisfy further requests for the volume on the device where it is already mounted. MDS supports dynamic device reconfiguration (DDR) through the subsystem interface for JES3 managed tape and disk drives.

VOLUME MOUNTING AND VERIFICATION: Once all required resources have been assigned to a job, MDS issues 'mount' messages, requesting that the operator mount the first required volume on a specified device. MDS then verifies that each volume has been correctly mounted by reading its volume label.

Once all required volumes for a job have been mounted and verified, the job is passed to the generalized main scheduler (GMS) for execution processing selection.

DEALLOCATION OF DATA RESOURCES: During job execution, MDS or DYNAL is notified, as each step completes, to deallocate resources that are not required by subsequent steps of the job (early resource release). Data resources may also be returned in the midst of job step execution via the dynamic deallocation subsystem interface. Tape volumes used by a job can be optionally made available to other jobs at the end of volume. Finally, any resources still held at job end are released at that time. In all cases, returned resources immediately become available for assignment to other jobs.

JOB SCHEDULING: JES3 functions as a resource manager and job scheduler. The scheduling and selection of jobs for execution are major functions of the job entry subsystem. JES3 provides a unique set of these functions that are especially designed for a loosely coupled environment. These functions are generalized main scheduling, which determines which jobs should be scheduled to execute on a processor; deadline scheduling, increasing the priority of a job when it has been scheduled to make the best use of the available resources; and dependent job control which allows jobs to be executed in a specified order.

Selection of a job for a processor is based on the capacity of that processor to provide sufficient resources. JES3 supports pooled devices among processors to further control job/processor selection.

GENERALIZED MAIN SCHEDULING: Jobs are selected for execution by the generalized main scheduling (GMS) facility of JES3. Initialization parameters define the characteristics of each processor, job-selection mode criteria, and jobs categorized by class.

GMS uses the priority parameters specified at initialization to help select jobs for execution. The hierarchy of priorities is:

1. Processor priority (dynamic).
2. Job Class priority.

The priority aging feature allows JES3 to increase the priority of a job after it has been passed over for selection by JES3 an installation-specified number of times, because of a low priority relative to that of other jobs in the system. At an installation-specified priority barrier, JES3 will attempt to prevent lower priority jobs from capturing idle resources if they are known to be needed by a job at or above the barrier priority.

DEADLINE SCHEDULING: Deadline scheduling provides job scheduling algorithms that increase the probability of a job being scheduled by a specific time. The job's selection priority may be dynamically incremented as the job approaches its deadline for entering execution.

The deadline scheduling feature allows the installation to specify a time of day by which the job should be scheduled. If the job is not scheduled by this time, JES3 will increase the priority of the job at user-defined intervals until it is scheduled.

DEPENDENT JOB CONTROL: Dependent Job Control (DJC) allows jobs to be executed in a specific order. DJC is a function within the JES3 system that manages jobs that are dependent upon each other. Job dependencies may occur because of data dependencies; they may be defined so as to achieve better device utilization; or they may be defined so as to manage job streams.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

The machine configurations specified for MVS/SP-JES3 Release 3 are unchanged for MVS/SP-JES3* Release 3.1.

SOFTWARE REQUIREMENTS

The JES3 component in MVS/SP-JES3* Release 3.1 is a complete replacement of the JES3 component in MVS/SP-JES3* Releases 2 and 3. If the JES3 component of MVS/SP-JES3* Release 3.1 is installed on any processor in a loosely coupled JES3 Complex, then it must be installed on all processors in the Complex.

The functions provided by either Data Facility Device Support Release 1 (5740-AM7) program product or the MVS/370 Data Facility Product (5666-265) program product are required by the users of one or more of the following:

- The IBM 3375 Direct Access Storage
- The IBM 3380 Direct Access Storage
- The IBM 3880 Storage Control mdl 11 or 13
- Checkpoint/restart
- JES3 early volume release facilities
- Extended Addressing feature and additional main storage beyond 16 megabytes

The JES3 component of MVS/SP-JES3* Release 3.1 requires MVS/SP Base Control Program (BCP) component.

* = Version 1.

COMPATIBILITY

The compatibility considerations for MVS/SP-JES3 Release 3.1 are unchanged from MVS/SP-JES3* Release 3.

RPQs ACCEPTED: No.

PROGRAM PRODUCTS

**DATA FACILITY EXTENDED FUNCTION
RELEASE 1 (5740-XYQ)**

PURPOSE

Data Facility Extended Function Release 1 consists of the following: A functional replacement for the VSAM and OS (CVOL) catalogs, to be called the Integrated Catalog Facility ... additional extensions to VSAM. The DFEF Integrated Catalog Facility may be used to replace all catalog functions and facilities.

HIGHLIGHTS

- New Catalog Structure
- Enhanced reliability and integrity
- Usability enhancements
- Performance improvements
- Backup and recovery facilities
- Elimination of VSAM catalog volume ownership
- Improved direct access storage utilization
- VSAM space management via DADSM
- VSAM SRB or cross-memory processing.
- Additional VSAM data sharing facilities.
- Implicit verify at OPEN.
- Improved VSAM TRACE processing.
- VSAM data set reference and change indicators.
- Supported by current versions of CICS/OS/VS and IMS/VS.

DESCRIPTION

NEW CATALOG STRUCTURE: The Integrated Catalog Facility defines two new catalog data sets: The Basic Catalog Structure and the VSAM Volume Data Set. These new data sets replace the current VSAM or CVOL catalog data sets.

The Basic Catalog Structure contains volume information for both VSAM and non-VSAM data sets. The Basic Catalog Structure may be located on any volume and multiple Basic Catalog Structure data sets may be defined on a single volume.

The VSAM Volume Data Set contains the data set characteristics for VSAM format data that resides on the same volume. There is one VSAM Volume Data Set on each volume that contains VSAM format data controlled by the Integrated Catalog Facility.

ENHANCED RELIABILITY AND INTEGRITY: The Integrated Catalog Facility offers major improvements to the reliability and integrity of the VSAM catalog.

The Integrated Catalog Facility is designed to reduce the potential of damaging the catalog and limits the scope of damage in the event of system failure during catalog processing.

The Integrated Catalog Facility also validity checks critical data during catalog processing.

USABILITY ENHANCEMENTS: By utilizing VSAM data sets, the Integrated Catalog Facility provides Access Method Services functions to:

- Reorganize catalogs
- Move catalogs to different device types
- Merge two catalogs into a single catalog
- Split a single catalog into two or more catalogs.

PERFORMANCE IMPROVEMENT: The Integrated Catalog Facility offers significant performance improvements over the current VSAM catalog and equal or better performance than OS (CVOL) Catalogs by:

1. Reductions in I/O requests.
 - Improved buffer handling for catalogs shared between systems will provide significant reductions in I/O requests. Comparisons with VSAM user catalogs provided savings for:
 - Locate -- 25 to 75 percent improvement
 - Define non-VSAM -- 50 to 70 percent improvement
 - Delete non-VSAM -- 60 to 70 percent improvement
 depending upon catalog request activity. Requests for VSAM entities will achieve even greater improvements.
 - Performance for OS (CVOL) Catalogs is highly dependent upon naming conventions, catalog size, and whether the catalog is regularly reorganized. Comparisons with an unorganized catalog provided savings for:
 - Locate -- 50 to 75 percent improvement
 - Define non-VSAM -- 20 to 50 percent improvement
 - Delete non-VSAM -- 25 to 50 percent improvement
 depending upon catalog request activity. A properly organized OS CVOL only occasionally out-performed DFEF:
 - Locate -- 0 to 50 percent improvement

- Define non-VSAM -- 12 percent loss to 30 percent improvement
 - Delete non-VSAM -- 0 to 40 percent improvement.
2. Improved concurrent catalog requests when searching and updating for all catalog entries.
 3. Concurrent processing is improved during VSAM OPEN/CLOSE processing.
 4. Catalogs not shared between loosely coupled systems can now be placed on shared direct access storage devices. The Integrated Catalog Facility will not issue a RESERVE under these conditions.
 5. The RECOVERABLE attribute for VSAM catalogs (catalog recovery area) does not exist with the Integrated Catalog Facility. This eliminates the overhead of duplexing all catalog updates.

In addition, VSAM KSDS performance options may be specified for the Basic Catalog Structure data set.

This performance data is derived from a select set of test cases and is given for information purposes only. There is no warranty or guarantee that the same performance characteristics will apply to other users or system configurations. Actual performance improvements are dependent on many factors, including control interval size, number of catalog entries, and the devices involved.

BACKUP AND RECOVERY FACILITIES: The catalog backup and recovery facilities provided allow the user to define simple and consistent recovery procedures for the catalog.

The Extended Function catalog supports catalog recovery without the RECOVERABLE attribute of VSAM catalogs. VSAM data set attributes, including the physical location on direct access storage, are maintained in the VSAM Volume Data Set which is on the same volume as the VSAM data set. This allows periodic EXPORTs of the Basic Catalog Structure, and a subsequent IMPORT in the event of failure of Basic Catalog Structure without concern for catalog and VSAM data set synchronization.

A new Access Method Services DIAGNOSE function is provided by DFEF. The DIAGNOSE function may be used to validate the content, format and consistency of the new Integrated Catalog Facility data sets. Additional enhancements to Access Method Services are included to support catalog backup and recovery.

The Integrated Catalog Facility allows the use of full volume backup and recovery for volumes containing either Basic Catalog Structure or VSAM data sets by maintaining VSAM data set attributes in the VSAM Volume Data Set on the data volume.

ELIMINATION OF VSAM CATALOG VOLUME OWNERSHIP: VSAM catalog volume ownership is eliminated. Data sets on any volume may be cataloged in any Basic Catalog Structure and multiple Basic Catalog Structure data sets may be defined on a single volume.

Users of the Resource Access Control Facility (RACF) are restricted from protecting identically-named VSAM data sets which are cataloged in separate Basic Catalog Structures residing on the same volume.

IMPROVED DIRECT ACCESS STORAGE UTILIZATION: All Integrated Catalog Facility records are VSAM logical records. This allows a considerable savings in the amount of direct access storage space required. For most non-VSAM data sets, only 20 percent of the space required by the current VSAM catalog will be used by Integrated Catalog Facility.

VSAM SPACE MANAGEMENT: All direct access storage space management for VSAM data sets in the Extended Function catalog environment will be performed by the system direct access device space management (DADSM) function. VSAM data spaces will not exist, and all VSAM data sets will appear as "UNIQUE-like" data sets. Functional equivalency to the current VSAM catalog will be maintained by removing the restrictions associated with current UNIQUE data sets.

VSAM SRB/Cross-Memory Mode Processing: In order to minimize the need for a VSAM application to switch execution modes, VSAM Record Management is extended to allow SRB and limited Cross-Memory Mode processing. This support includes:

- An additional User Processing Exit (UPAD) for request resumption (POST) when the user is operating in SRB/Cross-Memory mode.
- The elimination of SVC calls where possible, and new RPL codes to indicate to the VSAM application that the request must be issued in TCB mode.

Additional VSAM Data Sharing Facilities: The following VSAM Data Sharing facilities are supported to provide the VSAM application program more control of shared data:

- Exclusive Control Feedback. When an exclusive control conflict occurs, the address of the RPL which owns the resource and the RBA of the control interval will be returned to the user.

PROGRAM PRODUCTS

Data Facility Extended Function R1 (cont'd)

- A new Control Block Update facility is available to simplify programming for cross-system and cross-region VSAM data sharing under Share Option 3.
- The current restriction which prohibits Control Area (CA) splits under Cross-Region Share Option 4 will be eliminated. The restriction still applies to Cross-System Share Option 4 data sets.
- VSAM will support new facilities for shared resource processing which allow the user to invalidate VSAM data and index buffers (MRKBFR) or to cause VSAM to write a modified buffer to DASD storage (WRBFR).
- Extensions to the JRNAD exit are provided which allow the application program to maintain control over data and index control intervals.

of any other catalog. In an environment where an Integrated Catalog Facility is shared by multiple host systems, DFEF Release 1 program product must be installed on all systems that can access the shared catalog.

DOCUMENTATION
(available from Mechanicsburg)

General Information (GC26-3960) ... Licensed Program Specifications (GC26-3964).

MVS SYSTEM INTEGRITY APPLIES: Yes.

Improved ERASE Processing: Improved Control Interval (CI) ERASE processing allows previously used, empty CIs to be reused for any new records whose keys fall anywhere within the Control Area's range of keys.

Implicit VERIFY: When VSAM OPEN detects a condition requiring a VERIFY, it will automatically initiate VERIFY processing, unless otherwise specified by the user or when sharing VSAM data. The current warning message will still be issued. A message will indicate successful VERIFY processing.

VSAM Data Set Reference and Change Indicators: The last-accessed-date field and change data set indicators in the VTOC Format 1 data set control block (DSCB) are now maintained under control of a user exit for VSAM data sets which have been cataloged by DFEF.

CUSTOMER RESPONSIBILITIES

Primary among the customer responsibilities for using DFEF are: [1] have the prerequisite programs installed, [2] order and install DFEF.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

Data Facility Extended Function is designed to operate on the following IBM processors:

S/370 Model 158	UP/MP/AP
S/370 Model 158-3	UP/MP/AP
S/370 Model 168 with RPQ S20579	UP/MP
S/370 Model 168 with RPQ S20580	AP
S/370 Model 168-3	UP
4341 Processor Model Group 1	UP
4341 Processor Model Group 2	UP
4361-5 Processor	UP
4381 Processor	UP
3031 Processor	UP/AP
3032 Processor	UP
3033 Processor	UP/MP/AP
3033 Processor Model Group N	UP
3033 Processor Model Group S	UP
3081 Processor Complex	Dyadic

The approximate real and virtual storage changes for DFEF Release 1 are:

Nucleus (Real)	1K
PLPA (Virtual)	219K

The OS/VS2 MVS Data Facility Extended Function Program Directory contains information to enable the user to modify the contents of the PLPA following migration to Data Facility Extended Function for the purpose of removal of modules no longer required to support current VSAM catalogs.

SOFTWARE REQUIREMENTS

Data Facility Extended Function Release 1 requires the functions provided by the OS/VS2 MVS Data Facility Device Support Release 1 program product (5740-AM7) installed with MVS/System Product - JES2 Release 1 (5740-XY5) or MVS/System Product JES3 Release 1 (5740-XYN). Subsequent releases and modification levels of the prerequisite program product will also provide the necessary functions for Data Facility Extended Function, unless otherwise identified.

DFEF Release 1 users who intend to use the VSAM SRB/Cross-Memory Mode Processing will require the functions provided by either MVS/System Product - JES2 Release 2 program product or MVS/System Product JES3 Release 2 program product, when that release is available.

DATA FACILITY EXTENDED FUNCTION RELEASE 1 CONVERSION CONSIDERATIONS

The Integrated Catalog Facility may be used to replace and will coexist with all currently available catalog functions and facilities. Access Method Services CNVTCAT function will convert an existing VSAM user catalog or OS (CVOL) Catalog to an Integrated Catalog Facility. Individual catalogs may be converted without requiring the conversion

IBM DATABASE 2 (DB2) RELEASE 1
5740-XYR
PURPOSE

IBM Database 2 (DB2) is IBM's relational data base management system program product for the MVS/XA and MVS/370 environments. It may coexist with and complements Information Management System/Virtual Storage Version 1 Data Base System in these environments.

DB2 supports a relational data model. A DB2 data base can be thought of as a collection of tables. Data is defined in terms of tables and accessed through operations on tables. Data definition, retrieval, manipulation, and control operations are supported by the structured query language (SQL). SQL is a high-level, non-navigational data language available to users through an interactive terminal and through application programs written in COBOL, FORTRAN, PL/I, or Assembler language.

IBM Database 2 may be accessed concurrently by the IMS/VS Data Communication feature, by CICS/OS/VS, by TSO users, and by batch jobs. Figure 1 shows the configurations that are possible using IMS/VS Data Base System and/or DB2 as data base managers. Application programs running under control of the IMS/VS Data Communication feature or CICS/OS/VS may access DB2 data, IMS/VS Data Base data, or both.

DB2 operates as an MVS subsystem. DB2 is designed to utilize the XA architecture, including 31-bit virtual addressing and large real storage. DB2's architecture provides for very large data bases (up to 64 billion (64 x 10⁹) bytes per table). It is supported by a comprehensive set of data base utilities which operate online. Its security and authorization mechanism offers field content security and allows various levels of authority to be delegated to users as appropriate.

To assist IBM in introducing the significant new IBM Database 2 product, DB2 is currently being tested in a number of customer and IBM locations. Early experience with a limited number of users will assist IBM in evaluating the product in varied environments and in developing additional support material prior to general availability. An Early Support Program (ESP) is being planned for DB2. This ESP will be conducted by the NAD Dallas Systems Center; nominations will be through the NAD regions and NMD areas.

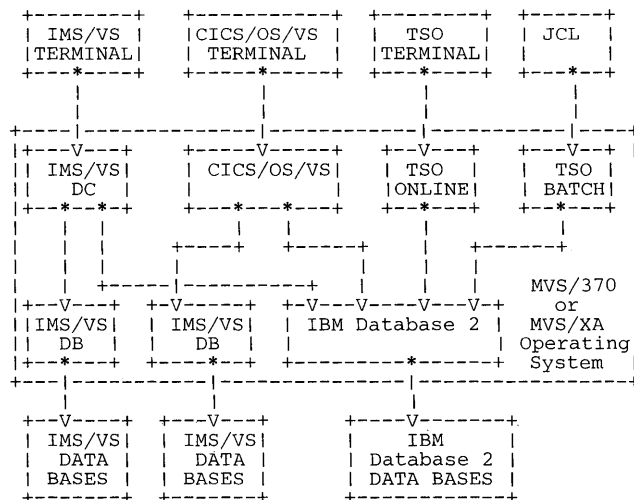

Figure 1. The IBM Database 2 environment.

HIGHLIGHTS

IBM Database 2 is an easy-to-install, easy-to-use program product supporting the relational data model with a high level language to access DB2 data. DB2 offers many functions in support of both traditional data base application areas and the information center. Specific highlights include:

- **Relational data model:** DB2 provides a basic tabular data structure. Data is viewed by the user as a series of rows and columns.
- **Structured Query Language (SQL):** SQL is an easy-to-use high-level language used for data manipulation, data definition, and control. It is not dependent on data paths, placement or order when accessing the relational data bases.
- **Continuous operations:** Data definitions may be dynamically changed without stopping DB2. Also, data base utilities can be run without stopping DB2.
- **Concurrent access to data:** DB2 may be accessed concurrently by the IMS/VS Data Communication feature, by CICS/OS/VS, by TSO users and by batch jobs. Additionally, application programs running under control of the IMS/VS Data Communication feature

or CICS/OS/VS may access DB2 data, IMS/VS Data Base data, or both.

- **Application programming:** Users may access and manipulate DB2 data using SQL through application programs written in COBOL, FORTRAN, PL/I and Assembler language.
- **DB2 Interactive (DB2I):** DB2I is an interactive facility based on Interactive System Productivity Facility (ISPF). Users may access and manipulate DB2 data interactively through DB2I. Additionally, other operations such as the DB2 data base utilities may be invoked through DB2I.
- **Base for Query Management Facility (QMF):** QMF operates with DB2 data in the MVS/XA and MVS/370 environments. See the QMF Announcement Letter for details on this product.
- **Large processor support:** DB2 operates in the MVS/XA and MVS/370 environments, thus providing support for the full range of processors supported by those operating systems.

DESCRIPTION

RELATIONAL DATA MODEL: DB2's relational data model is easy to learn and easy to use.

- **Simple Data Structure -** The basic data structures in DB2 are tables. A DB2 data base may contain many tables; the simple tabular data format protects the user from having to know and cope with more complicated representations of the data in storage. All relationships are represented by data in tables so users do not have to 'navigate' through data structures. The user may experience an increase in productivity, because there is no need to concentrate on how the data is to be accessed, but only on what data is to be accessed. DB2 determines how the data is to be accessed. This capability enables applications to be independent of the order and structure of the data base and contributes largely to the ease of learning and using DB2.
- **Structured Query Language (SQL) -** SQL is a high-level non-navigational language that helps application programmers to be more productive by allowing them to concentrate on the essential logic and data requirements of their applications. SQL statements reference data by name and/or value and not by data access paths, data placement, or order.

SQL, in a single statement, can access:

- One or more columns from a row of a table
- One or more columns from multiple rows of a single table
- One or more columns from multiple rows of multiple tables
- One or more columns calculated from other columns

Based on the data names and values specified in SQL statements, DB2 determines which operations are required to access or change the specified data.

SQL can be used for retrieval, insertion, deletion, updating, data definition, commitment of changes, and granting and revoking of DB2 authorization. SQL is consistent; it provides essentially the same features and syntax whether it is used interactively or invoked from a COBOL, FORTRAN, PL/I, or Assembler program. Most SQL statements can be tested interactively prior to including them in a program. Because of the scope, simplicity, and uniformity of this language, better communication among application analysts, programmers, data base administrators, and end users can be achieved.

- **High Productivity -** Both the data structures and the data language are simple. As a result:
 - The amount of data processing knowledge, training, and experience required to become productive with DB2 is minimal.
 - Data base administrators can design, define, and modify data bases quickly.
 - Application programmers can develop programs quickly, and hence can be highly productive.
 - Using SQL interactively, some users may create and maintain their own data bases without traditional application programming or data administration.
- Therefore, the application program backlog in many data base installations can be reduced.
- **Continuous Operation -** DB2 can operate for long periods without interruption. Many of the activities that may require other systems to stop running do not stop DB2's operation.
 - DB2 is a separate MVS subsystem and can be available even when IMS/VS, CICS/OS/VS or TSO is unavailable.
 - Data definitions may be added, deleted, or changed interactively without stopping DB2.

DB2 R1 (cont'd)

- DB2 utilities can perform their functions without stopping activity on other data bases. In some cases, concurrent activity on the same data base is permitted.

From time to time data base administrators or application programmers may want to make changes to information stored in data bases. Sometimes it will be necessary to add new tables or indexes to a data base or drop tables or indexes that are no longer being used. It is extremely important that transactions proceed as usual on unaffected parts of the system when such changes are being made.

These capabilities allow user data bases to evolve without disrupting ongoing processes and tables that have already been established.

ACCESS to DATA: IBM Database 2 data may be accessed concurrently by the IMS/VS Data Communication feature, by CICS/OS/VS, and by TSO users. TSO programs may be invoked interactively or by using JCL. Application programs running under the control of the IMS/VS Data Communication feature or CICS/OS/VS may access DB2 data, IMS/VS Data Base data, or both.

Users can operate on DB2 data interactively and/or through applications written in COBOL, FORTRAN (for TSO users only), PL/I, and Assembler language. In all cases, they access and manipulate the data using the SQL language.

DB2 Interactive (DB2I) is an ISPF-based interactive facility (ISPF means Interactive System Productivity Facility (see "Software Requirements"). Using DB2I, an authorized user can:

- Enter most SQL statements and view the results at the terminal
- Enter DB2 commands
- Perform other programming-related DB2 functions such as precompilation
- Run TSO-based applications
- Invoke the DB2 data base utilities

For example, using DB2I, application programmers can create and edit most SQL statements they plan to include in their programs, execute those statements, and receive and review the results at their terminals. They can also create, load, and delete test tables. They can use DB2I to check the contents of existing tables. DB2I is a powerful tool for application programmers, data base administrators, and system administrators.

The Query Management Facility (QMF) program product (5668-972) provides query and report writing capability for DB2 data bases. It allows non-DP professionals to create, save, modify, and execute queries and produce reports. QMF provides these functions in an easy-to-use way. Queries may be created using either SQL or query-by-example (QBE) syntax. Subject to DB2 authorization, QMF allows creation and maintenance of DB2 data bases, tables, indexes, etc..

DB2I and QMF are complementary. DB2I will be used primarily by DP professionals in the application development process. QMF will be used primarily by non-DP professionals as an easy-to-use alternative to writing application programs.

TECHNOLOGY EXTENDED: DB2 operates in the MVS/XA and MVS/370 environments. DB2 takes advantage of many new and existing hardware and software technologies. It operates with IMS/VS and CICS/OS/VS, so users familiar with these systems don't have to learn a new data communication (online) system. At the same time, DB2 provides a simple data base system for new users who may not be concerned with data communications. DB2 is designed to utilize the XA architecture, including 31-bit virtual addressing and large real storage.

- **Large Tables** - DB2's architecture allows tables to be very large, up to 64 billion (64 x 10⁹) bytes in size. Large tables can be divided into smaller parts that can be reorganized and recovered individually to improve their manageability.
- **Integrated Recovery** - DB2 has a comprehensive and integrated recovery mechanism. It has disk logging and automatic log archiving capabilities, automatic recovery on restart, and utilities to perform commonly needed recovery functions, such as image copy (see a list of the utilities and their functions under "Security, Recovery, Utilities and Installation". DB2 recovery is fully coordinated with the recovery of IMS/VS and CICS/OS/VS, with which it may operate. DB2 communicates with both IMS/VS and CICS/OS/VS so that potential inconsistencies can be resolved without loss of data.
- **Security** - DB2 has a very flexible and comprehensive authorization mechanism. For example, execution of a single SQL statement can grant someone the authority to retrieve data from a particular table, but might not allow that person to change any data in the table.

The flexibility and power of the authorization mechanism allows installations to choose to centralize control, decentralize control, or use these in combination. For example, the authority to control particular data bases can be delegated to individual users or to groups of users outside the central organization.

IMS/VS and CICS/OS/VS also have security capabilities. (See those program products' pages for details.) Also, through the security access facility (SAF) router of the operating system, Resource Access Control Facility (RACF, 5740-XXH) may be used to control access at the data set level.

ADDITIONAL DB2 DETAILS

Relational Data Model

- **Data Storage** - A relational data base is one that users perceive as a collection of tables. Tables in a relational data base are no different from any other tables. They are the same familiar and easy-to-use data structures seen and used every day in telephone books, airline schedules, newspapers, and many other places. They are made up of columns and rows. At the intersection of every column and row is a specific item of data. This specific item of data is called a 'value'.

In DB2, tables are not structurally related, so the user does not have to 'navigate' through structures to get to data. Instead, DB2 does the navigation. With DB2, all information is specified as data values. SQL provides statements to retrieve, update, insert, and delete data values.

- **Tables and Table Spaces** - Tables are logical data structures consisting of rows and columns. One or more tables are stored in a table space. In DB2, table spaces, not data bases, are the recoverable structure. A table space, and therefore the tables it contains, can be very large, up to approximately 64 billion (64 x 10⁹) bytes.

The relational operation that allows the user to retrieve data from two or more tables by matching them on a common column is called a 'join'. The join operation allows retrieval of data from two or more tables by joining on the basis of the common data they contain (for example, department numbers); then the needed information (for example, department numbers, department names, and managers' names) is selected from the combined tables.

- **Partitioned Table Spaces** - To make large table spaces manageable, DB2 supports partitioned table spaces. A table space can be divided into partitions on the basis of ranges of data values. Partitions also can be reorganized or recovered independently, reducing the time the table space is unavailable. Partitioning also allows active data to be stored on fast devices and inactive data on slower devices.

- **Views** - A DB2 view is an alternative representation of the data in one or more tables. Once a view has been defined, it can be used in most SQL statements just as a table would be. A view has two important advantages as a means of representing data in DB2: Views protect sensitive data and views further reduce complexity.

- **Storage Groups** - With DB2, users need not be concerned with defining MVS data sets. One or more storage groups can be defined indicating which DASD volumes are available for use. DB2 then invokes access method services of the Data Facility Product functions to define, extend, and delete data sets within the storage groups as required.

Alternatively, the user may choose to invoke access method services to predefine VSAM data sets to be used for DB2 tables. This approach allows placement of data and indexes on particular areas of DASD volumes.

The user may choose to use storage groups for some tables and to define his own data sets for others.

If neither storage groups nor user-defined data sets are specified, tables are built in a default storage group.

- **Data Bases** - A DB2 data base is a collection of table spaces (and, by extension, tables and indexes). The data base is an operational tool. Data bases may be started and stopped independently. A data base can be considered an entity for authorization purposes.

- **Indexes** - Indexes can be defined by the user to provide for faster access to data in a table. The index key is made up of one or more columns. Indexes can be defined interactively and created and deleted online. Users accessing DB2 data never explicitly name indexes in the data access statements. An index is used by DB2 if DB2 determines the index will provide fast access to the data. The following special types of indexes can be created:

- **Unique index** - This index forces uniqueness on the rows in a table. If a user wants to be sure that no duplicate employee numbers are entered into the employee table, a unique index, based on employee number, must be defined before the entries are attempted.

- **Clustering index** - A clustering index determines the physical order in which rows will be stored. A clustering index can be used to store data the way it will be most frequently accessed,

DB2 R1 (cont'd)

for example, by employee number or account number, or alphabetically by name.

- **DB2 Catalog** - The DB2 system catalog is a set of maintained tables that contain information about the data and objects that DB2 manages. Authorized users can retrieve the data in these tables in the same way as any other DB2 table -- with SQL statements. DB2 catalog tables contain information about, for example, tables, columns, indexes, storage, and authorization.
- **Structured Query Language (SQL)** - SQL is much more than a query language. It is also an easy-to-use data manipulation, data definition, and control language. Administrators, analysts, programmers, and interactive users all use SQL.
 - Application programmers may embed SQL statements in COBOL, FORTRAN, PL/I, and Assembler language programs to define a complete application. They can also test the 'data base' portions of these applications by trying out their SQL statements using the DB2 interactive facility (DB2I) before embedding them in their programs. SQL has similar capabilities and syntax whether entered interactively or embedded in an application program.
 - Data base administrators use SQL to define or change data base descriptors. They can also define and delete tables, indexes, and entire data bases.
 - System administrators use SQL to grant and revoke authorization of all other users to data. Properly authorized interactive users can use SQL to retrieve, create, and modify data from a terminal.
- **Automatic Access Path Selection** - DB2 uses information maintained within the DB2 system to 'navigate' to requested data. DB2 users don't have to know how data is represented in storage in order to retrieve and use it.

In many data base management systems the application programmer or data base administrator must decide whether to process data sequentially or to use one of possibly several indexes defined for that data. DB2 makes these decisions for the user. In fact, programmers never reference indexes in their programs. After the program is written, the programmer pre-compiles and binds his program. Bind is a procedure during which DB2 selects an access path to the data. DB2 will consider any indexes that exist when choosing the access path. Therefore, the program is insulated from additions and deletions of indexes.

DB2's ability to select access paths is important in minimizing program maintenance. For example, an administrator might decide to eliminate a seldom-used index. Programs which previously used the index would have their access paths automatically and dynamically reestablished by DB2 the next time they were executed. The logic of the application programs themselves is unaffected, and no program maintenance is required to cope with this change.

- **Set Level Operation** - The SQL language is based on mathematical set-level operations. Therefore, when DB2 processes data, it returns, updates, or deletes the entire set of data that meets the conditions specified by the user. This can reduce the application programming necessary to accomplish a given task.
- **Automated Declarations Generation** - Application programs must contain data declaration statements for data they read and process. To simplify the task of creating these statements, DB2 provides a declarations generator which uses information in the DB2 catalog to construct declaration statements for use in COBOL or PL/I programs.

Application programmers can invoke the declarations generator through DB2I, from TSO, or as a batch job. The generator produces a complete SQL description of the table and a complete PL/I or COBOL structure that corresponds to the DB2 table or view. Output from the declarations generator can be kept in libraries to provide a central, controllable repository for declarations.

The declarations generator saves application programmers the time they would otherwise spend coding data declarations. It also eliminates coding and keying errors that might result if the programmers entered their own declarations.

Access to Data: IBM Database 2 data may be accessed concurrently by IMS/VS Data Communications feature, by CICS/OS/VS, and by TSO users. TSO programs may be invoked interactively or by using JCL.

DB2I - An Interactive Tool - DB2 provides users an interactive online tool. Called DB2I for DB2 interactive, it uses Interactive System Productivity Facility (ISPF) to help users perform tasks interactively. To use DB2I, users sign on to TSO, enter ISPF, and select the menu for DB2I. That menu supports several activities. For example:

- SQL processor using file input (SPUFI) is an online function through which DB2 users can submit SQL statements. They can execute those statements and receive the results at the terminal. Using SPUFI, for example, application programmers can create their own

test tables and can test SQL statements prior to inclusion in programs; data base administrators can use SPUFI to define and administer data and to grant and revoke the authority to access data and programs; and system administrators can use it to grant and revoke privileges or to query the DB2 system catalog.

- **DECLARATIONS** - The DECLARATIONS panel is used to produce data declaration statements for tables and for COBOL or PL/I data structures.
- **BIND/REBIND/FREE** - This panel allows programmers to bind, rebind, and free their applications. These operations are integral to the application programming process.
- **PROGRAM PREPARATION** - Programmers can use this panel to prepare their programs for execution. They can pre-compile, compile, bind, link-edit, and run TSO applications.
- **RUN** - This panel is used to run TSO programs.
- **DB2 COMMAND** - Administrators can use this panel to enter DB2 commands. They can start, stop, and monitor data bases from this panel.
- **UTILITIES** - This panel can be used to invoke any of the data base utility programs provided with DB2.

Online Help - To help ensure ease-of-use, DB2 provides online help information. By pressing a program function key on the display terminal, DB2I users can retrieve panels of information that explain DB2 functions in detail. Over 500 panels are available.

TSO help text is also provided to aid the application programmer or data base administrator who is entering DB2 commands, precompiling, or using utilities directly from TSO.

The Application Programming Process - DB2 programmers write source programs containing embedded SQL statements. After programs are written, four steps must be performed before they can be run.

- **Precompilation** -- to check SQL syntax, produce a modified source program, and produce a DBRM (data base request module)
- **Compilation** -- to translate the modified source program (either a COBOL, FORTRAN, or PL/I compiler or an Assembler performs this step)
- **Bind** -- to process DBRM(s) to produce an application plan which is stored in the data base. At execution time, DB2 uses the application plan to control access to data.
- **Link-edit** -- to produce the final object module

The compiling and link-editing steps are the same using DB2 as they are in any other programming process. The precompile and bind, however, are unique and are discussed in the sections that follow.

The DB2 Precompiler - Before a DB2 COBOL, FORTRAN, PL/I, or Assembler program is compiled (or assembled), the DB2 precompiler processes it to extract the SQL statements for subsequent processing within DB2. In addition, the precompiler checks the syntax of the statements and copies them into a module called the DBRM (data base request module), which is input to the bind process.

Since the precompiler executes independently of DB2, programmers may precompile programs without access or reference to the rest of the DB2 system. Thus, programmers can have the syntax of data base calls checked before they bind or run their programs, avoiding unnecessary multiple runs and waste of processing time.

The BIND Process - Binding is the activity which converts the DBRM, a set of syntactically correct SQL statements, into a set of instructions to DB2. These instructions, called an 'application plan', tell DB2 where data is, how to get to it, and what to do with it. Binding does four things:

- It validates that the SQL statements are executable.
- It determines whether the person doing the bind is authorized to use the resources named in the SQL statements.
- It chooses the access path to the data.
- It builds a control structure to allow DB2 to access the data when the application program is executed.

The major advantage of the precompilation and bind process is that it can, at the user option, remove operations that can be done once from the program's normal processing. Then when a DB2 application runs, it simply processes data. Data base calls would not be translated or semantically checked. Access paths would not be built. All that processing would happen once, before the program runs. If a table or index used by an application plan is dropped, rebinding occurs automatically.

SECURITY, RECOVERY, UTILITIES, and INSTALLATION

Security and Authorization - DB2 provides two mechanisms that allow installations to protect data.

PROGRAM PRODUCTS

DB2 R1 (cont'd)

- **Authorization Statements** - Authorization statements in SQL are used to grant and revoke authority for all levels of data, command, and program access in DB2. Using these statements, administrators or data owners (users who have defined tables) can limit the data other users may see. They can even authorize the use of commands and data base utility programs. These authorization statements permit an installation to ensure that only properly authorized users perform data base operations.

- **Views** - Views play an important role in controlling access to sensitive data. A view that presents only certain rows or columns in a table can be defined. The user or application program accesses only the data defined in the view; other data in the table is not available.

The ability to define views combined with the ability to grant and revoke authorization to access those views and the tables on which they are based gives DB2 installations the control they need to keep valuable and sensitive data secure from both unauthorized and inadvertent activities.

Recovery - DB2 protects data from three types of failure: System, media, and application. Applications and transactions that use DB2 data operate across subsystem boundaries; DB2 supports fully synchronized recovery across these boundaries. The points at which changes to the data base are committed are synchronized so that recovery can be coordinated if a failure occurs at any point.

- On system failure, a restart of DB2 automatically restores data to a consistent state by backing out uncommitted changes and completing the processing of the committed changes.

Restart can be speeded and simplified since not all the data bases that were online at the time of failure need to be available when DB2 is restarted. Some data bases can be started later if the installation chooses.

- DB2 makes provisions for media recovery (e.g., failure of a disk device or failure of a read or write to disk) by providing disk logging and, optionally, dual logging. DB2 tracks log data sets and image copies so that recovery from media failures is simplified. Media recovery is accomplished through the use of image copy and recovery utilities. An incremental image copy capability speeds the image copy function by copying only blocks changed since the last image copy.

- If an application program fails, DB2 isolates the work associated with the failing program. It then backs out all uncommitted data changes dynamically, without interfering with other system activities.

Utilities - DB2 provides a number of fully integrated data base utility programs. They are executed online. The long-running ones are restartable. These utilities may be initiated by JCL, using supplied TSO CLISTS (command list, a set of TSO commands that perform a complete task when executed), or through the use of ISPF panels supplied with DB2. The major utilities provided with DB2 are:

- **Load** - from sequential media, SQL/DS unloaded data, or data extracted from other sources by the Data Extract (DXT).
- **Image Copy** - creates an image copy or incremental image copy
- **Recovery** - using image copy and log records
- **Reorganize** - unload and reload a full table space or a partition of a table space
- **Statistics** - updates the DB2 catalog with Bind and reorganization statistics

Installation - DB2 has been designed for easy installation in an MVS/XA and MVS/370 environment. No system generation process is required. Tailoring a DB2 system is accomplished by supplying parameters to supplied TSO CLISTS. Tailoring is simplified through use of supplied ISPF dialogs.

CUSTOMER RESPONSIBILITIES

A customer installing DB2 must:

- Have ordered and installed at least the minimum machine configuration.
- Have ordered and installed the prerequisite products.
- Assure that appropriate system and software training be given to system analysts, application programmers, system programmers, and system operators.
- Have personnel educated in DB2.
- Provide adequate protection against the accidental loss or misuse of his data (functions exist in DB2 to assist in providing security).
- Make sure personnel are trained in COBOL, FORTRAN, PL/I, or Assembler language.
- Have a knowledge and competency in VSAM.
- Specify and implement application programs.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

IBM Database 2 will operate on any IBM processor supported by MVS/SP V2 R1.1 or MVS/SP V1 R3. For the IBM 3033 Processor, it is recommended that hardware cross-memory extension feature (#6850) be used. The processors must have sufficient real storage to satisfy the combined requirements of IBM Database 2, MVS/XA or MVS/370, appropriate Data Facility Product, appropriate access methods, batch requirements, and other customer-required applications. The configuration must include sufficient I/O devices to support the requirements for system output, system residence, and system data sets. Sufficient direct access storage must be available to satisfy the user information storage requirements and may consist of any direct access facility supported by the system configuration and the programming system.

External Storage: DB2 is independent of both DASD and tape device type. Any DASD or tape device supported by Data Facility Product may be used. The following data sets are supported by the device types shown:

Active recovery log data sets	DASD
Archive recovery log data sets	DASD, tape, MSS
Image copy data sets	DASD, tape, MSS
Bootstrap data set	DASD
Data base data sets	DASD, MSS
DB2 catalog data sets	DASD
Work data sets (for utilities)	DASD, tape, MSS

Note: DB2 may be used with MSS (IBM 3850 Mass Storage Subsystem), with appropriate prerequisite program support but cannot be used with the MVS Hierarchical Storage Manager (HSM) (5740-XXB).

Data Communications Devices

DB2 uses the system console. An installation can control DB2 operations from:

- The system console
- Authorized IMS/VS terminals
- Authorized CICS/OS/VS terminals
- TSO terminals operated by authorized users

For the data communication devices supported by IMS/VS, CICS/OS/VS, and TSO, see the appropriate documentation.

SOFTWARE REQUIREMENTS

Operating System and Support Programs: IBM Database 2 requires the following licensed programs (or their equivalents):

For MVS/Extended Architecture (MVS/XA) environment (with the appropriate prerequisites for each product):

- MVS/System Product-JES2 (5740-XXC) or -JES3 (5665-291) Version 2 Release 1.1
- MVS/XA Data Facility Product Release 1.1 (5665-284)
- MVS TSO Extensions (TSO/E) Release 1 (5665-285)

For MVS/370 environment (with the appropriate prerequisites for each product):

- MVS/System Product-JES2 (5740-XXY) or -JES3 (5740-XXN) Version 1 Release 3
- MVS/370 Data Facility Product (5665-295) Release 1
- MVS TSO Command Package Release 1.1 (5740-XXT) or MVS TSO Extensions (TSO/E) Release 1 (5665-285)

For both MVS/370 and MVS/XA environments:

- OS/VS Sort/Merge Release 5 (5740-SM1)

For functional ease-of-use:

- Interactive System Productivity Facility (ISPF) (5668-960) and ISPF/Program Development Facility (ISPF/PDF)(5665-268)
- System Modification Program (SMP) Release 4

The other programs (or their equivalents) that may be used with IBM Database 2 are:

- Query Management Facility (QMF) Release 1 (5668-972)
- Data Extract (DXT) Release 1 (5668-973)
- Information Management System/Virtual Storage (IMS/VS) Version 1 Release 3 (5740-XX2)
- Customer Information Control System/OS/Virtual Storage (CICS/OS/VS) Version 1 Release 6 (5740-XX1)
- Resource Access Control Facility (RACF) Release 5 (5740-XXH)
- OS/VS COBOL Compiler and Library (5740-CB1)
- TSO Assembler Prompter (5734-CP2)
- TSO COBOL Prompter (5734-CP1)
- OS PL/I Optimizing Compiler and Libraries (5734-PL1, 5734-LM4, 5734-LM5, or composite 5734-PL3)
- VS FORTRAN Compiler and Library (5748-FO3)
- OS Assembler H (5734-AS1)
- Assembler H Version 2 (5668-962)

DB2 R1 (cont'd)**COMPATIBILITY/CONVERSION**

SQL/DS: The SQL language used by IBM's relational data base management system for DOS/VSE and VM systems, the SQL/DS program product (5748-XXJ), is broadly compatible with DB2's SQL. It is possible to move most data from SQL/DS to DB2 by unloading it from SQL/DS tables with the SQL/DS data base services utility and then loading it into DB2 tables with the DB2 load utility.

Information on conversion of SQL/DS programs and data to DB2 will be provided in the *IBM Database 2 Application Programming Guides* and the *IBM Database 2 Data Base Planning and Administration Guide*.

Virtual Storage Considerations: The DB2 storage requirements are dependent on various configuration and workload parameters including the number of users and their usage patterns, the number and size of data bases, and the number and complexity of applications. The following estimates of virtual storage requirements are provided for general guidance.

- For MVS/XA systems:

Common Storage Area (CSA) - Most of the DB2-required areas reside in the extended CSA. The residual CSA requirement is expected to be less than 100K bytes.

Private Address Space - Most modules, control blocks, and buffers reside in the extended private area. The minimum residual private address space requirement is approximately 2.5M bytes.

- For MVS/370 systems:

CSA - The minimum CSA is approximately 512K bytes. The typical CSA requirement is expected to be 512-532K bytes.

Private Address Space - For planning purposes the practical minimum virtual storage requirements for private address space should be considered to be 4.5-5.0M bytes. However, some users with minimum requirements may have DB2 systems requiring less than 4.5M bytes. Virtual storage requirements grow as the number of concurrent users and/or defined tables grows. Thus, the user should consider the maximum address space size that will be available to DB2 as part of his or her overall capacity planning procedures.

DATA SECURITY and AUDITABILITY

The IBM Database 2 function is subject to all the controls in its environment such as those provided by the operating system, access methods, and subsystems with which it is communicating. Customer management is responsible for the selection, application, and adequacy of those controls. For further description of the security available in DB2, see "Security, Recovery, Utilities and Installation".

IMS/VS and CICS/OS/VS also have security capabilities. (See those program products' descriptions for details.) Also, through the security access facility (SAF) router of the operating system, Resource Access Control Facility (RACF) (5740-XXH) may be used to control access at the data set level.

PERFORMANCE CONSIDERATIONS

The performance of IBM Database 2 in a virtual storage environment is highly dependent on the system resources available, the programs that operate concurrently and their relative priorities, and system and application data set placement. Performance also depends on the paging characteristics and storage reference patterns of DB2 and its application programs, the allocation of data sets to particular devices, table sizes, indexes created, and many other factors.

Performance of DB2 is also dependent upon the amount of concurrent demand for processor time by DB2 and other users of the system.

It is IBM's intent to provide improved DB2 utilization of 308X-class processors through the facilities of MVS/XA.

DOCUMENTATION

(available from Mechanicsburg)

The following 'task-oriented' documentation will be provided for IBM Database 2 users: *IBM Database 2 General Information ... IBM Database 2 Introduction to SQL ... IBM Database 2 Application Programming Guide for TSO Users ... IBM Database 2 Application Programming Guide for IMS/VS Version 1 Users ... IBM Database 2 Application Programming Guide for CICS/OS/VS Users ... IBM Database 2 Data Base Planning and Administration Guide ... IBM Database 2 System Planning and Administration Guide ... IBM Database 2 Operation and Recovery Guide ... IBM Database 2 Reference ... IBM Database 2 Reference Summary ... IBM Database 2 Sample Application Guide ... IBM Database 2 Installation ... IBM Database 2 Diagnosis Guide ... IBM Database 2 Diagnosis Reference ... IBM Database 2 Messages and Codes ... IBM Database 2 Program Directory ... IBM Database 2 Licensed Specifications.*

MVS SYSTEM INTEGRITY

IBM will accept APARs describing situations where the installation of IBM Database 2 introduces an exposure to the system integrity of MVS. This program is intended to run authorized. Refer to Programming Announcement dated October 21, 1981.

RPQs ACCEPTED: No

PROGRAM PRODUCTS

5740-XYS - MVS/SYSTEM PRODUCT-JES2 R1

PURPOSE

MVS/System Product-JES2 Release 1 provides all the performance and functional benefits of MVS/System Extensions (5740-XE1) and significant new enhancements. MVS/SP-JES2 Release 1 is available for the 4341, 4361-5 and 4381 with ECPS:MVS installed, for the 3031, 3032, 3033 Processors and on the S/370 mdl 158 and 168 Processors with the S/370 Extended Feature installed.

DESCRIPTION

Note: MVS/System Product (MVS/SP) is a generic term referring to announced releases of MVS/System Product-JES2 (5740-XYS) and MVS/System Product-JES3 (5740-XYN) or topics common to both.

The significant new Base Control Program facilities are:

- Support for the 3380 Direct Access Storage with the 3880 Storage Control mdls 2 and 3 with the Data Streaming feature (#4850) on the 3031, 3032 and 3033 Processors or attached to a 3MB channel on the 4341, 4361-5 and 4381, when installed with the MVS Data Facility/Device Support (5740-AM7) program product.
Data Streaming feature and on 4341 Processors.
- Support for the 3278, 3278 mdl 2A and 3279 Display Stations as operator MCS consoles.
- Support for the 4341, 4361-5 and 4381 Processors with ECPS:MVS.

HIGHLIGHTS

MVS/SP-JES2 Release 1 installed on MVS 3.8 offers new support for the following:

- The 3380 Direct Access Storage with the 3880 Storage Control mdls 2 and 3 using either:
 - the Data Streaming feature (#4850) on 3031, 3032 and 3033 Processors, or
 - the 3MB channel on the 4341, 4361-5 or 4381.

Device support is provided by MVS/SP-JES2 Release 1 installed with the MVS Data Facility/Device Support Release 1 program product (5740-AM7). This support also permits the 3380 device to be used for paging and for system residence. The 3380 Direct Access Storage provides reduced access times and an increased data transfer rate when compared to previous IBM DASD units. The 3380 Direct Access Storage with the 3880 Storage Control mdls 2 and 3 introduces dynamic path selection facility. Dynamic path selection facility allows the operating system to access a reserved device via any of the available paths.

- The 3279 Color Display Station, all mdls, and the 3278 Display Station, mdls 1, 2, 3 and 4 attached via a 3274 mdl 1D control unit are supported as MCS consoles through device independent display operator console support (DIDOCs). The greater capacity screens are supported on the 3278 mdls 3 and 4 and on the 3279 mdls 3A and 3B. In addition, the color defaults are supported on all mdls of the 3279. These color defaults are blue for all normal traffic, white for all action messages and green for operator commands. Full program function key support is available for the 3278 and 3279 Display Stations.

In addition, the following MVS/System Extensions (5740-XE1) Performance and Functional Benefits are included as part of the MVS/SP-JES2 Release 1.

Performance Improvements: MVS/System Extensions test measurements completed on the S/370 158, 168 and 3031, 3032 and 3033 Processors have shown the following results:

A 20 to 27% reduction in control program supervisor state execution time, providing throughput improvements ranging from 14 to 18% for BATCH, TSO/BATCH and IMS/BATCH test environments on uniprocessors and 17 to 20% improvements on multiprocessor configurations as compared to MVS Release 3.7 with SUs 4, 5 and 7 installed.

Actual performance will vary depending upon customer environment, storage and I/O configuration. No assurance can be given that an individual user will achieve the test results.

SMF Enhancements: A major revision to SMF provides more data with increased installation control over the amount of data collected and allows a non-disruptive migration to full utilization of the new function.

SRM Enhancements: Control of system resources to meet installation-defined goals is necessary for effective usage of the system. The SRM is enhanced to centralize and improve system control, to improve the RMF reporting of certain transactions, and to ease the use of certain SRM facilities.

Action Message Retention Facility: Proper and timely handling of operator messages is important. Messages requiring operator action are given particular message descriptor codes. Prior to MVS/System Extensions Release 2, these messages could roll off

the operator's screen with no easy way for the operator to reconstruct the set of unsatisfied action messages. The action message retention facility allows the operator to retrieve all unsatisfied action messages.

See the *General Information Manual* (GC28-1025-0) for more detailed information.

CUSTOMER RESPONSIBILITIES

MVS Release 3.8 and the MVS Processor Support 2 must be installed prior to installing MVS/SP-JES2 Release 1.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

MVS/SP-JES2 Release 1 requires the appropriate S/370 Extended Feature on IBM S/370 mdls 158 (#7730 or #7731) and 168 (#7730) or ECPS:MVS on the 4341, 4361-5 or 4381. MVS/SP-JES2 Release 1 supports the following processors:

IBM mdl 158-1	UP/MP/AP
IBM mdl 158-3	UP/MP/AP
IBM mdl 168-1 with RPO S20579	UP/MP
IBM mdl 168-1 with RPO S20580	AP
IBM mdl 168-3	UP/MP/AP
IBM 4341 Processor Mdl Group 1	UP
IBM 4341 Processor Mdl Group 2	UP
IBM 4361-5 Processor	UP
IBM 4381 Processor	UP
IBM 3031 Processor	UP/AP
IBM 3032 Processor	UP
IBM 3033 Processor	UP/MP/AP
IBM 3033 Processor Mdl Group N	UP
IBM 3033 Processor Mdl Group S	UP

The minimum total storage required by MVS/SP-JES2 Release 1 depends on many factors. These include an installation's configuration, the subsystems, program products and problem programs in use. However, the following information will assist in approximating additional bytes of virtual storage required for the MVS/System Extensions and for MVS/SP-JES2 Release 1. The actual bytes of real storage needed will be less because PLPA and CSA are only partially backed by real storage.

To estimate the additional virtual storage required for MVS/SP-JES2 Release 1, use Chart 1 in the following manner:

- If the installation is running MVS 3.8 with the OS/VS2 MVS Processor Support 2 installed, the additional storage is the combined total of columns 1, 2 and 3.
- If the installation has MVS/System Extensions Release 1 installed, the additional storage is the combined total of columns 2 and 3.
- If the installation has MVS/System Extensions Release 2 installed, the additional storage is the amount in column 3.

CHART 1

	MVS/System Extensions Release 1 (Column 1)	MVS/System Extensions Release 2 (Column 2)	MVS/SP-JES2 Release 1 (Column 3)
Nucleus	30,000	6,200	10,500
PLPA	10,000	66,300	- 101,500 (Note 4)
CSA	---	Variable (Note 1)	---
SQA	500	Variable (Note 2)	4,000
LSQA	---	Variable (Note 3)	---

Notes:

1. Assuming four SMF buffers - requires an additional 8,000 bytes.
2. The amount of additional storage required in SQA depends on several variables:
 - Assuming 50 address spaces with interval accounting, two recording data sets and three subsystems defined to SMF, requires an additional 8,000 bytes.
 - Subsystem transaction reporting requires a minimum of 4,096 bytes.
 - The installation control specification requires for each subsystem name, an additional 28 bytes ... for each user, transaction name and transaction class, an additional 20 bytes.
3. Each initiator requires an additional 40 bytes.
4. This reflects a reduction in PLPA of 101,500 bytes. It is achieved by an optional installation step. This step moves infrequently referenced modules from LPALIB to LINKLIB.

For more information, see the *General Information Manual* (GC28-1025-2).

SOFTWARE REQUIREMENTS

MVS/SP-JES2 Release 1 requires MVS Release 3.8 with MVS Processor Support 2 installed. MVS/SP-JES2 Release 1 completely

PROGRAM PRODUCTS

MVS/SP-JES2 R1 (cont'd)

replaces MVS/System Extensions (5740-XE1).

In order to support the IBM 3380 or the IBM 3375 Direct Access Storage, the MVS Data Facility/Device Support program product (5740-AM7) is required.

RMF users must install RMF Version 2 Release 3.

RMF users of the MVS/SP-JES2 Release 1 Enhancement must install the RMF Version 2 Release 3 Enhancement supporting the MVS/SP-JES2 Release 1 Enhancement.

The specified operating environment may change and will be restated at time of product availability.

INSTALLATION CONSIDERATIONS

MVS/SP-JES2 Release 1 requires a stage 1 SYSGEN assembly together with a normal SMP Release 4 application. Alternatively, a full SYSGEN can be used for installation. The program directory will contain additional installation information.

To use the functions provided by RMF, the OS/VS2 MVS Resource Measurement Facility Version 2 Release 3 is required.

MVS/SP-JES2 RELEASE 1 - JES COMPATIBILITY

MVS/SP-JES2 Release 1 operates with the following JES2 products:

Either JES2 Release 4.1
Optionally with:
JES2 3800 Enhancements.

or NJE for JES2 (5740-XR8)
Optionally with:
NJE for JES2 3800 Enhancements.

User-written programs that use standard external interfaces should continue to execute on an MVS system with the MVS/SP-JES2 Release 1 installed. Programs that interrogate MVS system control blocks may require modifications. Licensees will receive documentation on changes in control blocks at the time of availability.

When migrating from an MVS Release 3.8 or an MVS/System Extensions Release 1 environment, changes in an installation's accounting procedures may be required because of enhancements to SMF. (See the *General Information Manual*, GC28-1025-0, for details.) IBM devices currently supported by MVS Release 3.8 will continue to be supported by MVS with MVS/SP-JES2 Release 1 installed.

Any Installation Performance Specification (IPS) that is compatible with MVS Release 3.8 or MVS/System Extensions can be used unchanged with MVS/SP-JES2 Release 1.

IBM program products currently supported on MVS Release 3.8 or MVS Release 3.8 with the MVS/System Extensions program product should continue to run with MVS/SP-JES2 Release 1 installed (although for RMF users, the appropriate RMF release must also be installed). APARs will be accepted for MVS/SP-JES2 Release 1 when any such IBM program product does not run successfully after MVS/SP-JES2 Release 1 is installed.

MVS/SYSTEM PRODUCT-JES2 RELEASE 1 ENHANCEMENT

The enhancement for MVS/System Product-JES 2 Release 1 provides the following functions:

- Support of the 3081, 3083 or 3084 Processor Complex.
- Support of the 3375 Direct Access Storage with the 3880 Storage Control mdls 1 and 2 is provided on the 3031, 3032 and 3033 Processors using the Data Streaming Feature. The 3375 Direct Access Storage is also supported on the 4341, 4361-5 and 4381 Processors.
- Support of the 3880 Speed Matching Buffer Feature (#6550) with the 3031, 3032 and 3033 Processors and S/370 Mdl's 158 and 168.

RPQs ACCEPTED: No.

DOCUMENTATION
(available from Mechanicsburg)

OS/VS2 MVS/System Product-JES3 and OS/VS2 MVS/System Product-JES2 General Information Manual (GC28-1025-2).

PROGRAM PRODUCTS

5740-XYS - MVS/SYSTEM PRODUCT-JES2 R2

PURPOSE

MVS/System Product-JES2 Release 2 incorporates all of the functional benefits of MVS/System Product-JES2 Release 1 and, in addition, provides functional and device support enhancements to the MVS Base Control Program and JES2. These enhancements offer an installation opportunities to reduce the system virtual storage requirements of major subsystem and system components, provide new facilities in the areas of multi-system support and operations management, as well as providing general functional and device support enhancements.

DESCRIPTION of RELEASE 2

MVS/SP-JES2 R2 consists of enhancements to two MVS components: The MVS Base Control Program (BCP) and JES2. The BCP component incorporates all of the functions of the BCP of MVS/SP-JES2 R1 and requires MVS Release 3.8 with the MVS Processor Support 2 function as prerequisites.

The BCP component of MVS/SP-JES2 R2 will operate with the JES2 component of MVS/SP-JES2 R2 or with the JES2 products that operate with MVS/SP-JES2 R1. The JES2 products supported in the latter case are:

- JES2 R4.1
- NJE for JES2 R3 (program product 5740-XR8)

This flexibility will enable an installation to stage its migration to MVS/SP-JES2 R2. When installed, the JES2 component of MVS/SP-JES2 R2 replaces JES2 R4.1 and NJE for JES2 R3.

BASE CONTROL PROGRAM (BCP) COMPONENT HIGHLIGHTS

The BCP component of MVS/SP-JES2 R2 incorporates all of the functions of the BCP of MVS/SP-JES2 R1 and, in addition, provides the following facilities:

- Cross Memory Services
- Global Resource Serialization
- Operational Interface enhancements
- Directed VIO
- Subsystem Definition facility

CROSS MEMORY: Cross Memory is an architectural extension supported by MVS. This extension facilitates communication among address spaces in an MVS/System Product-JES2 Release 2 environment. By providing a means to transfer data or program control directly between the private areas of address spaces, many benefits result. Because the prime users of Cross Memory services are intended to be MVS system components and subsystems, these benefits can be realized by an installation without any additional user programming. The benefits include:

- **Reduced System Virtual Storage Requirements:** The Cross Memory services of MVS/System Product-JES2 Release 2 enable the system virtual storage (Nucleus, PLPA, SQA, CSA) requirements for specific environments to be reduced. Certain data formerly found in the system virtual storage area can now be stored in new auxiliary address spaces and accessed via Cross Memory services. Such reduction can enable more system or private area virtual storage usage by other subsystems, new applications or current applications growth.
- **Enhanced Isolation:** The multiple address space structure of current MVS provides a considerable amount of data and program isolation. There are instances, however, when two address spaces must communicate with each other. This is generally accomplished through the scheduling of a Service Request Block (SRB) and involves the use of common virtual storage area (CSA/SQA). MVS/SP-JES2 R2 now provides the means by which inter-address space communication can occur without using common virtual storage, thereby isolating the program/data concerned from accidental modification or destruction by system components or authorized programs. Thus, the protection afforded to programs and data by the private area of an address space is extended to include instances of inter-address space communication.
- **Improved System Structure:** Currently, control block information residing in the common virtual storage area (CSA/SQA) is directly addressed by system components and other programs. Cross Memory services enables such control block information to be assigned to the private area of a system or subsystem auxiliary address space and accessed without the overhead of the current Service Request Block (SRB) mechanism. The isolation afforded by the private area of an address space allows controlled access to such data. The information required by system components, subsystems and their users can now be provided via an interface which is independent of the control block structures in the auxiliary address space. Reducing control block dependencies both enhances system reliability and facilitates migration to new function.
- **Enhanced Authority Mechanism:** Cross Memory services provide the capability for authorized subsystems to define groups

of address spaces having different levels of authorization for inter-address space communication. This represents a significant enhancement over existing facilities (for example, SRBs) which provide a single level of authorization to all address spaces (Key 0). Once such groups have been defined, a program may use Cross Memory services for inter-address space communication, but will be prohibited from accessing address space groups for which it has not been authorized.

Cross Memory Usage: Examples of system components/subsystems utilizing Cross Memory services in the MVS/SP-JES2 R2 environment.

- Global Resource Serialization
- Operations Interface
- Display Units (DU) command
- IMS/VS

GLOBAL RESOURCE SERIALIZATION

- Global Resource Serialization, which extends the current ENQ/DEQ facility, provides additional function and improved RAS.
- Global Resource Serialization extends the ENQ function of resource serialization across system boundaries. Multiple MVS systems, interconnected through Channel-to-channel Adapters (CTCs), will now be able to serialize resource usage across systems.
- Additionally, Global Resource Serialization will run in its own address space utilizing the new Cross Memory architecture. Unlike the current ENQ facility, the Global Resource Serialization control blocks will reside in their own address space, thereby reducing the amount of system virtual storage required and, at the same time, improving the system RAS characteristics. By running in its own address space and by preventing addressability to its control blocks, Global Resource Serialization is isolating itself from accidental modification or destruction by other system components or authorized applications.
- Global Resource Serialization also addresses the need to provide information about resources without requiring that an application look at internal ENQ control blocks. MVS/SP-JES2 R2 eliminates dependencies on the structure of ENQ control blocks by providing a new macro service that allows applications to obtain resource status. Access to these control blocks is available only through this new macro service.
- Current ENQ/DEQ/RESERVE services provide three resource serialization scopes: STEP, SYSTEM and SYSTEMS. In a Global Resource Serialization environment, ENQ/DEQ requests specifying STEP or SYSTEM will be treated as requests for local resources and not communicated to other systems in the defined complex. ENQ/DEQ requests specifying SYSTEMS are requests for global resources and are communicated to all systems within the defined complex.

Global Resource Serialization provides the capability to override the default serialization from local to global, and vice versa, in instances where the SYSTEM and SYSTEMS scopes are used. This override is achieved by the invocation of exits that scan installation-specified 'inclusion' and 'exclusion' resource name lists. Global Resource Serialization invokes the 'inclusion' exit for each ENQ/DEQ request specifying a scope of SYSTEM (local serialization) to determine whether the installation requires that resource to be included in global serialization. For each ENQ/DEQ/RESERVE request specifying a scope of SYSTEMS (global serialization), the 'exclusion' exit is invoked to determine whether the installation requires that resource to be excluded from global serialization.

An exit that scans a RESERVE conversion list is also provided to allow device RESERVE requests to be overridden and converted to SYSTEMS (global serialization) requests, thereby allowing other systems in the defined complex to concurrently access the device.

Default exits and resource name lists are provided by IBM. An installation may modify these lists to meet the specific requirements of its operating environment.

- Thus, in the context of multi-system data set integrity, the conversion capabilities provided by Global Resource Serialization can be used to provide a data set level of serialization for MVS/JES2 installations.
- In order for an installation to achieve resource serialization across systems, the MVS systems must be interconnected via Channel-to-channel Adapters (CTCs). Global Resource Serialization requires dedicated CTCs, and, in order for an installation to obtain maximum configurability with Global Resource Serialization, each MVS system should have a CTC connection with every other system with which it serializes resource usage. To meet the additional CTC requirements of large installations, further CTC capability is provided for the 3033 Processor. For details, see RPO 8P0882.

OPERATIONAL INTERFACE ENHANCEMENTS: A new facility, in conjunction with two enhanced commands, provides significant improvements in the operability of MVS Systems, particularly in large

MVS/SP-JES2 R2 (cont'd)

system installations. These enhancements allow the installation to reduce non-essential message traffic on the operator's console and also provide the operator with new system status information which will allow better control of job traffic and the I/O configuration.

- **Message Processing Facility (MPF):** The Message Processing Facility provides a means of reducing the number of messages to be displayed on the operator's console. The installation can determine the messages which it considers to be important and, through the use of this facility, suppress many non-essential ones.

The messages an installation wishes to suppress are listed by identifiers in a member of SYS1.PARMLIB. The SYS1.PARMLIB member selection may be changed at any time via the SET command and the message identifiers in use can be displayed by use of the DISPLAY MPF command. Suppressed messages are included in the hardcopy log with an indicator denoting the message has been suppressed.

Note: Action messages, command responses, responses from the Monitor (MN) command and Write to Operator with Reply (WTOR) messages (message codes 1, 2, 3, 5 and 11) will not be suppressed, even if they had been so specified by the installation.

- **Display Active (DA) Enhancements:** The DISPLAY A command is changed to provide additional information. It allows for improved operator awareness and displays information relevant to other operator commands. Included in this display are address space status, type of user, ASID, PER indicator, step must complete count, performance group number, domain number, CPU affinity, elapsed time, and CPU time for each address space.

The organization of the display is changed to better utilize the screen of the operator's console. The DISPLAY A command can also be restricted to one particular user (job, TSO user, etc.) or group of users with similar names so that it is easier to obtain the required pertinent information for specific users.

- **Display Units (DU) Enhancements:** Determining which jobs are using a device is important to a system operator or programmer trying to resolve why a device cannot be varied offline. With the enhancement to DISPLAY U, the operator can display the job names and ASIDs of device users, in order to decide what action should be taken. Improved recovery is also added to the allocation end of memory resource manager for sharable DASD devices. The additional system status information required for this extension is collected in a separate address space and accessed via Cross Memory services.

DIRECTED VIO: Directed VIO enables an installation to more effectively utilize high speed paging volumes for paging of critical response-oriented applications by separating VIO pages from these volumes. In addition, this facility will allow installations to utilize VIO more extensively and experience its benefits in environments where the limitation on high speed paging space was previously a concern.

A new keyword (NONVIO) is being provided as a system parameter, or as a PAGEADD option, to allow installations to specify local page data sets which are not to receive VIO pages. If enough other local page data set space is available, VIO pages will be directed to those local page data sets that were not on the directed VIO data set list. Only in the case of constrained VIO paging space can VIO pages potentially spill to the NONVIO local page data sets.

OTHER ENHANCEMENTS

- A Subsystem Definition Facility is provided to give an installation the capability of defining subsystems at IPL via one or more members of SYS1.PARMLIB, thereby eliminating the need to modify the Subsystem Name Table (IEFJSSNT).
- Several other enhancements have been made to the Base Control Program of MVS/System Product-JES2 Release 2 to facilitate the use of subsystems. Details of these enhancements will be documented in the *General Information Manual*, GC28-1025-0.

JES2 COMPONENT

The JES2 component of MVS/System Product-JES2 Release 2 (MVS/SP-JES2 R2) provides a generally compatible replacement of both JES2 R4.1 and the NJE for JES2 program product (5740-XR8), together with the functions of the JES2 3800 Enhancements.

The JES2 component is designed to improve the operational environment for the JES2 user through the extension of existing functions and the provision of new facilities. Enhancements include improvements to the reliability and recovery aspects of the spooling subsystem, output processing, RJE and NJE, and extensions to RAS facilities. New facilities include the provision of user exit capabilities to assist the installation in tailoring JES2 to its operational environment, a spool offload program to help mitigate the effects of any future JES2 cold starts, and support of the 3375 and 3380 Direct Access storage devices as a JES2 spool and checkpoint device.

JES2 HIGHLIGHTS of MVS/SP-JES2 R2

Spool Device and RAS Support

- The new 3375 and 3380 Direct Access Storage devices are supported as spool and checkpoint devices.
- The means of defining a track group has been changed to more efficiently use the capacity of current devices and the 3380 and/or 3375 Direct Access Storage in a mixed spool environment.
- A new facility called Spool Partitioning provides a means of reducing the impact of the failure of a single storage device on the total spool space. The total number of volumes eligible for spool space allocation for each job can be limited. Through the use of this facility, the probability of a job's data becoming inaccessible due to a device failure can be reduced. Exit points are provided to enable the installation to control the allocation of spool space. The installation will also have the option of doing a warm start without all previously mounted volumes available.
- Bad Track Group Isolation attempts to prevent transient and/or limited failures of the media or device from affecting large numbers of jobs by propagation. Track groups in which an I/O error has occurred will be isolated in order to prevent them from being reassigned. Information about the error will be displayed on the operator's console.
- The JES2 User Exit facilities will enable installations to individually tailor the JES2 component of MVS/System Product-JES2 R2 to the requirements of their own operating environment.
- Specific IBM-defined exit points are provided at strategic points in JES2 code. The installation-supplied exit routines are 'logical extensions' of the JES2 environment. The exit code is assumed to be authorized.
- The installation is also provided with the general facility to specify its own exit points by coding the exit macros in the source code of JES2.
- Individual exit points can be controlled by initialization parameters and by system operator commands.

Improvements to the Operational Characteristics of Output Processing

- Released 'held' data sets (primarily those held by interactive system users) will be, when possible, gathered and printed with other non-held or released data sets, thereby minimizing the scattering of data sets across printers and reducing the amount of paper used for separator pages.
- Output devices, including both local and remote printers and punches, will now be allowed to select work based upon several route codes. An installation can, therefore, use a local printer to print work originally destined for a currently unavailable RJE station while still permitting that printer to continue selecting locally routed output.
- The line/card count displayed at the time an output group is selected for processing will be updated as the output is processed, thereby enabling a running count to be kept. Various operator commands will provide the updated count. In contrast, the current JES2 environment only provides an initial count.
- New operator commands and system messages give system operators the capability to specify output processing characteristics for groups of SYSOUT data sets, thus providing the installation with greater control of output groups.
- For printers with a forms flashing feature, a standard page format can now be defined as an installation default. JES2 will use the default when no forms flashing is specified via a job's JCL.
- JOB LOG, JCL Images, and System Messages data sets are now addressable using the JES2 JECL Output statement.
- Logical page size (LINECT) support of JES2 JECL JOBPARM statement is extended to the data set level via JES2 JECL output statement.

Improvements to RJE and NJE Facilities

- Support for RJE and NJE networks is expanded to 1,000 remotes and 1,000 nodes.
- Verification of successful signon is provided at remote workstations.
- The "JES2 JOB STATISTICS" will now be a part of the Job Log data set and will be transmitted to an RJE workstation or NJE node as part of the job, thus providing more complete job statistics.
- A transparent "STORE and FORWARD" facility is provided to allow jobs and data to be transmitted through a JES2 node.
- Data compression may now be specified on a line basis in addition to the currently supported workstation basis.

MVS/SP-JES2 R2 (cont'd)

Spool Offload Facility

- A new facility is provided to give the installation the capability to dump and later restore the data from the JES2 spool. This facility will function using either tape, DASD or MSS virtual volumes as the offload media.
- Release and spool device-independent data formats allow customers to use the spool offload facility as a future JES2 cold start circumvention mechanism when migrating from release to release or changing spool devices. At present, a cold start can cause loss of jobs and sysout data; this facility would permit a cold start to be performed without such losses or the need to drain the system.

RAS Improvements

- **Command Default Improvements:** Several commands have been changed to reduce their wide ranging effects if issued inadvertently by an operator. An 'ALL' subparameter will now have to be explicitly specified with commands having the potential to adversely impact the system operation.
- **Event Trace Extensions:** This facility has been enhanced to allow for the tracing of internal JES2 "processors" which do not have devices associated with them. This enhancement will assist in diagnosing problems in the areas of the command processor, conversion processor, line manager processor, etc.
- **Error Recovery Facility:** This new facility, similar in structure to the operating system's ESTAE/FRR recovery scheme, has been implemented to allow internal JES2 "processors" to deal with programming errors which previously caused JES2 termination. SYS1.LOGREC recording of all JES2 errors, regardless of whether recovery is successful, is also provided.

Other JES2 Enhancements

- **Resource Utilization Thresholds:** The installation will now be able to specify the threshold at which warning messages will be issued when the supply of key JES2 resources is about to become exhausted. The resources for which utilization thresholds will be monitored are: Console message buffers, local buffers, TP buffers, SMF buffers, JOEs, JOEs and track groups.
- **Operator Control of Pre-Execution Jobs:** The system operator is now able to change the class and priority of a job at any time through the use of the \$T command.
- **JES2 Message Identification:** The JES2 command responses now carry unique identifiers instead of the commonly used HASP000. This will expedite operator access to explanatory text in the system messages manual. In general, command response texts will remain unaltered. The HASP000 identifier will still be used but merely for the simple affirmative response 'OK'.
- **Extended \$Z Control:** The \$Z command is extended to enable operators at remote locations to control printers and punches at those locations.
- **Unlike Data Set Concatenation of SYS1.PARMLIB:** Installations will now be able to specify data sets of unlike attributes to be concatenated to the initialization parameter library, thereby providing greater flexibility for testing environments.
- **HASPRTAM Restructure:** To improve serviceability, the HASPRTAM module has been split into smaller modules by subfunctions.

MVS/SP-JES2 R2: JES2 COMPONENT DESCRIPTION

JES2 is a specialized component of MVS/SP-JES2 R2 which operates in the same Processor with MVS to perform the peripheral functions associated with batch job processing. JES2 is started as a job entry subsystem. Control of designated unit-record devices is taken, the specified intermediate storage direct access device(s) are initialized, and job processing begins. JES2 has four major processing stages which relate to its four major external functions. These are:

1. **INPUT STAGE** - This stage reads jobs simultaneously from a variable number of various types of online card readers and remote terminals. These jobs are then entered into a priority queue to await processing by the next stage.
2. **CONVERTER STAGE** - This stage passes the Job Control Language (JCL) to the MVS Converter which merges the specified procedures from the appropriate Procedure Library, performs a basic syntactical scan, and converts the JCL statements into an "internal text" format which JES2 SPOOLS for later use by the MVS Interpreter. The jobs are then queued by job class to await processing by the next stage.
3. **EXECUTION STAGE**- This stage removes jobs based upon priority and class from the queue established by the Converter Stage and passes those jobs to MVS for processing. Input cards are supplied as required to the executing program and print and punch records are received and written onto JES2 intermediate

storage. At the completion of a job, it is placed in a queue to await processing by the next stage.

4. **OUTPUT STAGE** - This stage transcribes the print and punch output generated by jobs in the previous stage to printers and punches. A variable number of various types of printers, punches and remote terminals can be operated simultaneously.

JES2 Standard Features: The standard features of JES2 include:

- **Job input service** provides for low-overhead reading of job streams and storing of data on SPOOLING volumes for later high-speed retrieval for up to 99 concurrently active local card readers in any combination of devices as follows: 2540 reader ... 2501 reader ... 2520 punch (with read feature) ... 3505 reader (80-column punched cards only) ... 3525 punch (with read feature).
- **Converter service** provides for the merging of the submitted JCL with user- or installation-selected procedure libraries and for an early scan of this combined JCL for syntactical errors.
- **Execution service** provides for selection of jobs and execution monitoring for up to 99 concurrently executing jobs as follows: Selection of jobs based upon job class and initiator priority class list of up to 36 classes for each initiator ... automatic delaying of jobs with duplicate OS jobnames ... automatic deblocking and blocking of user SYSIN/SYSOUT data ... counting of lines, cards, and execution duration with optional operator notification and/or cancellation ... interface for SMF counting of SYSIN data.
- **Multiple SPOOLING volume support** provides for balanced utilization of up to 36 volumes for any combination of any mdl of the following devices (one required): 2314 ... 3330 ... 2305 ... 3340 ... 3350 ... 3375 ... 3380.
- **Warm start capability** provides for checkpointing critical JES2 information sufficient for: Optionally restarting jobs which were executing ... restarting print and punch at the last checkpoint.
- **Job output print service** provides for low overhead printing of job streams, system message, and user data print output for up to 99 concurrently active local printers in any combination of devices as follows: 1403 Printer ... 3211 Printer ... 3800 Printing Subsystem ... 3203 mdl 4 and 5 ... 4245 Printer.
- **Special forms support** provides for the routing of print (on a job or data set basis) and punch data (on a data set basis) to special forms output queued for output as directed by the operator.
- **Internal Reader facility** provides the ability for any task within the system to submit jobs to JES2 for batch execution as though entered from a JES2 card reader.
- **Console Support** provides for direct entry for JES2 commands and JES2 abbreviated replies to WTORS through MVS operator consoles.
- **JES2 interfaces directly with the MVS SMF writer** to produce seven SMF records (types 6, 26, 43, 45, 47, 48 and 49). JES2 also provides two user SMF exits (IEFUSO and IEFUJP).
- **Job output punch service** provides for low overhead punching of job stream user punch output for up to 99 concurrently active local punches in any combination of devices as follows: 2520 punch ... 2540 punch ... 3525 punch.
- **Execution Batching** provides the facility for passing jobs directly to a processing program such as a "one-step" monitor, reducing the overhead of OS scheduling and allocation for short running jobs requiring limited system facilities.
- **Priority Aging** provides for automatically increasing the JES2 scheduling priority of jobs which have been in the system for extended periods of time.
- **Remote Job Entry** provides for high speed communications with binary synchronous and SDLC batch workstations which may be used for job stream input and output as well as operator control of the devices and jobs associated with the remote (see "JES2 RJE Features").

Use Exit Facilities

- The JES2 User Exit facilities enable installations to individually tailor the JES2 component of MVS/System Product-JES2 Release 2 to the requirements of their own operating environment.
- Specific IBM-defined exit points are provided at strategic points in JES2 code. The installation-supplied exit routines are "logical extensions" of the JES2 environment. The exit code is assumed to be authorized.
- The installation is also provided with the general facility to specify its own exit points by coding the exit macros in the source code of JES2.
- Individual exit points can be controlled by initialization parameters and by system operator commands.

MVS/SP-JES2 R2 (cont'd)

Spool Offload Facility

- A facility is provided to give the installation the capability to dump and later restore the data from the JES2 spool. This facility will function using either tape, DASD or MSS virtual volumes as the offload media.
- Release and spool device-independent data formats allow customers to use the spool offload facility as a future JES2 cold start circumvention mechanism when migrating from release to release or changing spool devices. At present, a cold start can cause loss of jobs and sysout data; this facility would permit a cold start to be performed without such losses or the need to drain the system.

Spool Partitioning Facility

- Spool Partitioning provides a means of reducing the impact of the failure of a single storage device on the total spool space. The total number of volumes eligible for spool space allocation for each job can be limited. Through the use of this facility, the probability of a job's data becoming inaccessible due to a device failure can be reduced. Exit points are provided to enable the installation to control the allocation of spool space: The installation will also have the option of doing a warm start without all previously mounted volumes available.

Error Recovery Facility

- This facility, similar in structure to the operating system's ESTAE/FRR recovery scheme, has been implemented to allow internal JES2 "processors" to deal with programming errors which previously caused JES2 termination. SYS1.LOGREC recording of all JES2 errors, regardless of whether recovery is successful, is also provided.

JES2 Multi-Access Spool Feature (MAS): JES2 in R3 MVS/SP-JES2 R2 allows from two to seven MVS Systems to share the JES2 input, job and output queues through the use of Shared DASD. This feature may be used to share the workload or a pool of JES2-controlled devices among processors. Jobs may be routed to any specific system or all systems in this multi-access spool complex. Furthermore, JES2-controlled unit record and remote devices need not, but may, be attached to each processor.

Each processor operates asynchronously within the multi-access spool complex, i.e., there is no master-slave relationship. Because of this operating design, any system in the complex can recover the workload accepted into the complex by any other system. Another system in the complex can have the RJE, TSO and unique unit record devices of the failing system physically switched to it and continue processing those jobs previously entered into the spool queue.

Another function supplied by the JES2 multi-access spool feature is the ability to isolate a processor for testing purposes. A processor may be designated as operating in independent mode, and in so doing, will only process jobs that are both routed to it and are themselves designated to be executed on that processor in independent mode.

JES2 RJE Features: Those features common to all JES2 RJE configurations are as follows:

- JES2 RJE supports up to 1,000 remote workstations communicating over nonswitched (point-to-point) or switched lines.
- JES2 RJE provides for concurrent operations over up to 1,000 lines assigned to unique communication line adapter addresses of the following types: SDA Type II on a 2701 for Binary Synchronous ... Synchronous Base on a 2703 for Binary Synchronous ... 3704 providing 270X emulation ... 3705 providing 270X emulation ... 3704/3705 SDLC.
- Output routing control provides for print and punch output to be directed to the devices attached to the remote, to the central system, or to other remotes as designated by JES2 initialization parameters, by control cards submitted with the job, or by operator command.
- Remote operator control provides a subset of the JES2 operator commands for display of information and control of jobs and devices associated with the remote.
- Operator message output provides for transmission of messages and responses to remote operators with online MULTI-LEAVING workstations with consoles immediately and optional saving of messages for all other remotes until the remote is online and has a printer available.
- Workstation programs, when required, are supplied as extensions of JES2 and are contained on the MVS distribution libraries in source form.
- Terminal support on the central system provides for communication with: 2772 (Binary Synchronous) ... 2780 (Binary Synchronous) ... 3780 (Binary Synchronous) ... 5110 Computer (as a 2772 BSC) ... S/360 mdls 20, 25, 30, 40, 50, 65, 65MP, 67 (in 65 mode), 75, 85, and 195 (MULTI-LEAVING) ... All virtual storage S/370 processors

(MULTI-LEAVING) ... 1131 (MULTI-LEAVING) ... System/3 (MULTI-LEAVING) ... System/32 or System/34 (MULTI-LEAVING as a System/3) and System/32 or System/34 (SDLC as a 3770) (MULTI-LEAVING) ... 8100/DPPX or 8100/DPPX/SP (multiple logical unit SDLC).

To achieve this flexibility of terminal-sharing, JES2 uses the VTAM application program interface for the support of the SDLC terminals which are attached to a 3704/3705 in network control mode.

SDLC terminals supported by JES2 in MVS are the non-programmable mdls of the 3771, 3773, 3774, 3775, 3776 and 3777 Communication Terminals, the S/32 (as a 3770), the S/34 (as a 3770), the 6670 Information Distributor (through the program product MVS/Information Distribution Workstation Support, 5740-AMA), the 3790 Communication System and the 8100/DPCX Information System. Support for the 3770 family of devices includes the the 3262 Line Printer mdls 2 and 12, the 3784 Line Printer, the 3521 Card Punch, the 3501 Card Reader and the 2502 Card Reader.

- The signon feature provides for remote identification and line security through remote and line passwords.
- Remote characteristics support utilizes the unique features on each remote as follows: Full text transparency (required for object decks) ... text compression ... print line width truncation ... outer size and blocking capabilities. **Note:** Multipoint or multidrop line features are prohibited.
- Remote job priority adjustment provides for favoring or limiting the JES2 scheduling priority of jobs submitted from each remote workstation.
- Line restart feature provides for warm starting of print output after remote workstation or line failures.

NJE Features: The Network Job Entry (NJE) facility provides for the transmission of selected jobs and in-stream data sets, system output (SYSOUT) data sets, operator commands and messages, and job accounting information from one computer system to another across a communication link.

A job entry network consists of one or more interconnected computer systems (called nodes), running under OS/VS2 MVS. These nodes have the capability of communicating with one another and passing the information indicated above from one node to the next. The number of nodes which can exist within a job entry network ranges from one to 1,000.

The nodes can be single processors (UP/AP), tightly coupled multiprocessing processors or multi-access spool systems.

A job may enter the network via any JES2 local or remote input device and will be queued for transmission to another node if the node of entry is not the execution node. A job designated for execution at another node is either transmitted directly to that node or is transmitted through intermediate nodes located along a path to the execution node. Transmission of jobs along BSC communications links is handled on a store-and-forward basis; that is, a job must be completely received by a node before any action will be taken to either execute the job or transmit the job to another node. Once a job has been completely received by a node, the transmitting node frees the resources that were allocated to the transmitted job. Transmission of jobs through ACF/VTAM links is logically direct to the execution node.

At each stage of processing, appropriate accounting information is collected and produced on the processing node for local accounting. In addition, network accounting number support is included. This permits accounting numbers to be assigned across the network and provides initialization parameters, conversion tables and routines and user exits to convert local accounting numbers to network accounting numbers and vice versa. All accounting information is produced through standard System Management Facilities (SMF).

Network Path Manager: A network path manager running in each processor in the job network interfaces with JES2 and the multi-access spool facility to communicate with all other network path managers. The network path managers control the routing of data through the network by providing best-path and alternate-path information to other NJE components. No single node is designated as a network manager; any subset of an NJE network can function entirely on its own.

CUSTOMER RESPONSIBILITIES

A customer using the Network Job Entry Facility for JES2 should be a prior user of JES2 with appropriate personnel trained and experienced in OS/VS2 MVS. When planning NJE, every effort should be made to keep the initial configuration to a minimum number of nodes. After experience is obtained, additional nodes may be planned and added individually. Large network configurations require careful planning by experienced IBM and customer personnel to help ensure that maximum benefits are achieved through the proper use of the system.

PROGRAM PRODUCTS

MVS/SP-JES2 R2 (cont'd)

Prerequisites: The Network Job Entry Facility for JES2 requires the installation of Selectable Unit 10 as a prerequisite to the use of the 3800 Printing Subsystem. Use of SNA devices for RJE workstations will require either VTAM2, or the SCP for ACF/VTAM and ACF/VTAM Version 1 or ACF/VTAM Version 2 as well as the appropriate level of MVS. Use of SDLC communicating links in the NJE network will require installation of ACF/VTAM Version 1 with Multisystem Networking Facility for ACF/VTAM or ACF/VTAM Version 2.

Channel-to-channel Adapter: NJE supports the CTC adapter as a communication link when it is attached to a block multiplexer channel. The use of the CTC adapter by NJE for JES2 must be separate from any other use of the CTC adapter.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

MVS/System Product-JES2 Release 2 requires the appropriate S/370 Extended Feature on IBM S/370 mdls 158 (#7730 or #7731) and 168 (#7730). MVS/System Product-JES2 Release 2 supports the following processors:

IBM mdl 158-1	IIP/MP/AP
IBM mdl 158-3	UP/MP/AP
IBM mdl 168-1 with RPO S20579	UP/MP
IBM mdl 168-1 with RPO S20580	AP
IBM mdl 168-3	UP/MP/AP
IBM 4341 Processor Mdl Group 1	UP
IBM 4341 Processor Mdl Group 2	UP
IBM 4361 Processor Mdl Group 5	UP
IBM 4381 Processor	UP
IBM 3031 Processor	UP/AP
IBM 3032 Processor	UP
IBM 3033 Processor	UP/MP/AP
IBM 3033 Processor Mdl Group N	UP
IBM 3033 Processor Mdl Group S	UP
IBM 3081 Processor Complex	Dyadic
IBM 3083 Processor Complex	UP
IBM 3084 Processor Complex	Dyadic

Details concerning optional 3033 Extension feature for 3033 processors may be found in the Machines section.

SOFTWARE REQUIREMENTS

MVS/System Product-JES2 Release 2 requires MVS Release 3.8 with MVS Processor Support 2 installed.

In order to support the following function and devices in MVS/SP-JES2 Release 2, the MVS Data Facility/Device Support program product (5740-AM7) is required:

- Checkpoint/Restart facilities
- 3375 Direct Access Storage
- 3380 Direct Access Storage

Details of the MVS Data Facility/Device Support program product may be found in the announcement letter.

RMF users must install RMF Version 2 Release 4.

MVS/System Product-JES2 Release 2 consists of enhancements to two MVS components: The MVS Base Control Program (BCP) and JES2. The BCP component of MVS/System Product-JES2 Release 2 replaces the BCP component of MVS/System Product-JES2 Release 1. The JES2 component of MVS/System Product-JES2 Release 2 replaces both JES2 Release 4.1 and the NJE for JES2 R3 program product (5740-XR8). In addition, the 3800 Enhancements provided for JES2 R4.1 and NJE for JES2 program product are incorporated into the JES2 component of MVS/SP-JES2 R2. Installation details for MVS/SP-JES2 R2 will be provided at availability.

MVS/SYSTEM PRODUCT-JES2 RELEASE 2 COMPATIBILITY

User-written programs that use standard external interfaces should continue to execute on MVS Release 3.8 with the MVS/System Product-JES2 Release 2 installed. Programs that interrogate MVS system control blocks may require modifications. Documentation on MVS/System Product-JES2 Release 2 control blocks will be available March, 1981.

When migrating from an MVS Release 3.8 or an MVS/System Extensions R1 environment, changes in an installation's accounting procedures may be required because of enhancements to SMF (see the *General Information Manual*, GC28-1025-0).

IBM devices currently supported by MVS Release 3.8 will continue to be supported by MVS with the MVS/System Product-JES2 Release 2 installed.

Any Installation Performance Specification (IPS) that is compatible with MVS Release 3.8, the MVS/System Extensions program product or MVS/System Product-JES2 Release 1 can be used unchanged with MVS/System Product-JES2 Release 2.

IBM program products currently supported on MVS Release 3.8, or MVS 3.8 with the MVS/System Extensions program product, or MVS 3.8 with MVS/System Product-JES2 Release 1 should continue to run

with MVS/System Product-JES2 Release 2 installed (although for RMF users, the appropriate RMF release, RMF V2 R4, must also be installed). APARs will be accepted for MVS/System Product-JES2 Release 2 when any such IBM program product does not run successfully after MVS/System Product-JES2 Release 2 is installed.

PROGRAM PRODUCTS

5740-XYS - MVS/SYSTEM PRODUCT-JES2 R3

PURPOSE

MVS/System Product-JES2 Release 3 provides all of the functions of MVS/System Product-JES2 Release 2 together with: The ability to achieve new levels of capacity and responsiveness on 3033 processors via performance improvements implemented in conjunction with the 3033 Extension feature; support for the Extended Addressing feature, permitting up to 32 megabytes of addressable storage on 3033, 3081, 3083 and 3084 processors, thereby providing potential for further capacity and responsiveness; significant improvements in System RAS; extensions to the reconfiguration and recovery aspects of Global Resource Serialization; and the potential further savings in the system virtual storage requirements. RMF support for MVS/System Product-JES2 Release 3 is provided by an enhancement for RMF Version 2 Release 4.

BASE CONTROL PROGRAM HIGHLIGHTS

Performance: The performance improvements are achieved through:

- Reduction in processor execution time for high frequency control program functions.
Usage of the 3033 Extension Feature by many MVS components in combination with code optimization have resulted in shorter path lengths and reduced processor execution time for several highly used system functions. In particular, several system functions have been restructured to perform more effectively on IBM's large processors (3033 UP and above).
- Reduction in I/O wait time.
Restructure of the MVS paging subsystem and use of new slot allocation algorithms results in reduced I/O wait time for paging and swapping.
- Reduction in I/O through use of extended real storage. MVS/SP R3 will utilize extended real storage to eliminate demand paging and swapping I/O operations, thereby freeing processor capacity for additional productive work and reducing I/O wait time.

These improvements yield increased system throughput and responsiveness:

- Measurement and projection of test environments indicate that the MVS/System Product Release 3, in conjunction with the associated enhancement of the Data Facility Device Support (DF DS) Release 1 program product, will provide the following performance benefits to 3033 users with the 3033 Extension Feature installed in comparison to MVS/System Extensions Release 2:
 - Throughput improvements generally of the order of 10% (UP) and 12% (AP/MP) for TSO/Batch environments.
 - Throughput improvements generally of the order of 6% for intensive Batch and online IMS/Batch environments, with 3033 AP/MP environments experiencing additional throughput. The IMS/VS projections utilized the then most current level of IMS/VS Version 1 Release 2 available in the fourth quarter of 1981.
 - Further throughput gains of up to 5% are expected for large multi-system establishments. Some of the performance improvements within MVS/SP R3 are sensitive to user I/O configuration and workload, the performance benefit increasing as the size of I/O configuration and I/O rates increase, with the largest benefit accruing to processors configured for multi-system environments.
- New paging algorithms allow TSO environments to improve response time with increased capacity.

Extended Addressing: For customers who install the Extended Addressing Feature and additional storage, potential throughput improvements greater than those described above may be realized. MVS's efficient use of additional real storage to eliminate paging I/O operations allows interactive environments such as TSO and IMS/VS to experience improved response time.

The actual performance benefit that an installation will experience will vary depending upon such considerations as customer environment and customer usage of the product improvements. The working sets of new system address spaces created in MVS/SP R2 and R3 may result in an increased real storage requirement and increased paging rates for some installations. No assurance can be given that an individual user will achieve the projected results.

New Levels of System RAS: The RAS enhancements provided by MVS/System Product Release 3 are a result of detailed studies of large MVS installations in 1978. They seek to avoid unscheduled IPLs caused by problems in the areas of I/O equipment, the MVS control program and operations.

Estimates indicate that over 20% of the unscheduled IPLs resulting from problems in these areas in the 1978 study have already been addressed by the general solutions in currently available products such as MVS Processor Support 2. MVS/System Product Release 3 now

provides additional general solutions to detect and recover from such problems.

Projections for a 3033 environment indicate that MVS/System Product Release 3 addresses a further 19% of the unscheduled IPLs that resulted from problems in these areas in the 1978 study.

In addition, extensions have also been made to the recovery aspects of the Global Resource Serialization facility introduced in MVS/SP R2.

Other Enhancements

- The potential for additional savings in Common Service Area virtual storage.
Utilization of Cross Memory Services by the Console Communications task provides the potential for further savings in Common Service Area virtual storage requirements.

JES2 Considerations: The JES2 component of MVS/SP-JES2 Release 3 provides a service update to the JES2 component of MVS/SP-JES2 Release 2.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

MVS/SP-JES2 Release 3 is designed to operate with the Extended Control Program Support Facility for MVS (ECP:SMVS) on 4341, 4361-5 and 4381 Processors and the appropriate S/370 Extended Feature on S/370 mds 158 (feature #7730 or #7731) and 168 (feature #7730). MVS/SP JES2 Release 3 is designed to operate on the following IBM processors:

Mdl 158-1	UP/MP/AP
Mdl 158-3	UP/MP/AP
Mdl 168-1 with RPO S20579	UP/MP
Mdl 168-1 with RPO S20580	AP
Mdl 168-3	UP/MP/AP
4341 Processor Model Group 1	UP
4341 Processor Model Group 2	UP
4361 Processor Model Group 5	UP
4381 Processor	UP
3031 Processor	UP/AP
3032 Processor	UP
3033 Processor	UP/MP/AP
3033 Processor Model Group S	UP
3033 Processor Model Group N	UP
3081 Processor Complex	Dyadic
3083 Processor Complex	UP
3084 Processor Complex	Dyadic

SOFTWARE REQUIREMENTS

MVS/SP-JES2 Release 3 is designed to operate with MVS 3.8 with the MVS Processor Support 2 installed. The functions provided by either Data Facility Device Support Release 1 (5740-AM7) program product or the MVS/370 Data Facility Product (5665-295) program product are required by the users of one or more of the following:

- IBM 3375 Direct Access Storage
- IBM 3380 Direct Access Storage
- Checkpoint/restart
- Extended Addressing feature and additional main storage beyond 16 megabytes

RMF users must install the RMF Version 2 Release 4 Enhancement that supports MVS/SP R3.

MVS/SP-JES2 Release 2 consists of enhancements to the MVS Base Control Program (BCP). The BCP component of MVS/SP-JES2 Release 3 replaces and enhances the BCP component of MVS/SP-JES2 Release 2. The JES2 component of MVS/SP-JES2 Release 3 is a service update to the JES2 component of MVS/SP-JES2 Release 2. Release 2 users who have the JES2 component of Release 2 installed will not be required to re-install this component when migrating to Release 3.

PROGRAM PRODUCTS

5740-XYS - MVS/SYSTEM PRODUCT-JES2 R3.2, 3.3**PURPOSE****RELEASE 3.2**

MVS/System Product-JES2 Release 3.2 provides support for the MVS/Operator Communication Control Facility (MVS/OCCF).

BCP HIGHLIGHTS

- Support for the MVS/Operator Communication Control Facility (MVS/OCCF) in a JES2 environment. MVS/OCCF is a Program Product that allows one or more remote MVS systems to be operated from a user-designated, controlling MVS system. MVS/SP Version 1 Release 3.2 provides the following function in support of MVS/OCCF.
 - MVS/OCCF can acquire or alter the use of a console. This support allows MVS/OCCF to obtain and release a console, change the routing codes of a console, or request that messages be broadcast to all subsystems.
- Multiple Console Support (MCS) console specifications can be initialized at IPL using the COMMAND member(s) of PARMLIB. After IPL, the master console operator or an operator at an MVS/OCCF console may direct commands to other consoles to correct system problems related to MCS consoles.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

The hardware configurations specified for MVS/SP Release 3 are unchanged with the installation of MVS/SP Release 3.2.

SOFTWARE REQUIREMENTS

MVS/SP-JES2 Release 3.2 will support the JES2 component in MVS/SP-JES2 Release 3 as well as SU23 and SU25.

The functions provided by either Data Facility Device Support Release 1 (5740-AM7) program product or the MVS/370 Data Facility Product (5665-295) program product are required by the users of one or more of the following:

- IBM 3375 Direct Access Storage
- IBM 3380 Direct Access Storage
- IBM 3880 Storage Control mdl 11 or 13
- Checkpoint/restart
- Extended Addressing feature and additional main storage beyond 16 megabytes

The functions of MVS/370 Data Facility Product (5665-295) are required by the users of the following:

- Tape labels and tape file structure support for ISO 1001-1979, ANSI X3.27-1978 and FIPS-1979

DOCUMENTATION

RELEASE 3.3

MVS/System Product - JES2 (MVS/SP-JES2) Release 3.3 provides ten new JES2 User Exits, improvements to the usability and operational characteristics of JES2 output processing and a new capability to dynamically add and delete spool data sets without warm starts.

JES2 HIGHLIGHTS**TEN NEW USER EXITS**

- Job Queue Work Select Exit
- Output Data Set/Copy Select Exit
- Notify Exit
- BSC RJE Sign on/Sign off
- SNA RJE Logon/Logoff
- Initialization Statement Exit
- SMF Record Exit
- Cancel/Status Exit
- End of Job Input
- Post Initialization Exit

User Control of Sysout Data Set Grouping

- New Output JCL statements which allow the user to specify which data sets are to be contained in an output work unit. The user can also specify the setup characteristics and the priority for the output group.
- Operational enhancements provide improved procedures for limiting the formation of demand setup groups, limiting which

output device will process demand setup groups, limiting the use of user specified priorities for output and reducing operator intervention. Overall these enhancements will assure that the efficient processing of user's output will not be disrupted by the increase in the amount of demand setup work.

Dynamic Add/Delete of Spool Data Sets

- Capability for the operator to dynamically add or delete spool data sets eliminating the need to resort to a warm start which impacts the normal processing of work.
- A number of operator commands will be enhanced to display the jobs on a volume or the volumes used by a job.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

The hardware configurations specified for MVS/SP Release 3 are unchanged with the installation of MVS/SP JES2 Release 3.3.

SOFTWARE REQUIREMENTS

MVS/SP-JES2 Release 3.3 requires the most current MVS/SP-JES2 Release 3 BCP component in March 1983 as a prerequisite. The JES2 component in MVS/SP-JES2 Release 3.3 contains all of the functional and device support enhancements as in the JES2 component of MVS/SP - Release 3 and is a complete replacement for the JES2 component in MVS/SP Release 3.

The functions provided by either Data Facility Device Support Release 1 (5740-AM7) program product or the MVS/370 Data Facility Product (5665-295) program product are required by the users of one or more of the following:

- IBM 3375 Direct Access Storage
- IBM 3380 Direct Access Storage
- IBM 3880 Storage Control mdl 11 or 13
- Checkpoint/restart
- Extended Addressing feature and additional main storage beyond 16 megabytes

The functions of MVS/370 Data Facility Product (5665-295) are required by the users of the following:

- Tape labels and tape file structure support for ISO 1001-1979, ANSI X3.27-1978 and FIPS-1979

Planning Information: MVS/SP-JES2 Release 3.3 requires a JES2 cold start.

RPQs ACCEPTED: No

DOCUMENTATION

An update to the *OS/VS2 MVS/System Product General Information Manual* (GC28-1025) is available.

**TREND ANALYSIS (CICS/OS/VS)
5740-XYT****PURPOSE**

Trend Analysis is a business graphics and data base system which provides a computer-based linkage between an organization's operating and planning information files and the data presentation needs of decision makers. Trend Analysis integrates the color graphics capabilities of the 3279 Color Display Station and the 3287 Color Printer with the data management capabilities of IMS/VIS-DB and the modeling and projection capabilities of PLANCODE, IBM's primary business planning product. Trend Analysis functions are invoked from a display station through easy-to-use menus which can be customized to meet special organizational requirements. Reports can be displayed or printed in a variety of tabular data or graphic report formats.

HIGHLIGHTS

- **Color Graphics:** Trend Analysis provides capabilities for creating color graphic displays and printouts of time series data. Color graphic displays can be produced in several different forms: Line graphs, surface and bar charts, histograms and pie charts. Combinations of up to 8 colors and 16 shading patterns can be used for the graphic charts.
- **PLANCODE-Trend Analysis Data Base Bridge:** Trend Analysis provides a bridge from PLANCODE to the Trend Analysis time series data base. Users can apply the data manipulation, projection and modeling capabilities of PLANCODE to the time series data which is subsequently used for data selection, formatting and presentation.
- **Terminal User Interaction:** Trend Analysis provides the display station user with the ability to view predefined reports or graphic charts, with preselected data elements, or to have the user interactively select, display and report on only items of of immediate interest.
- **Menu-oriented Selections:** Trend Analysis provides a series of menus from which the display station user may choose the options best suited to the information of interest. The easy-to-use menu selection approach permits users, with minimal training, to customize the information content and format of a desired report or graphic chart.
- **Data Organization:** Information stored for use by Trend Analysis is logically organized by selectable time periods (daily, weekly, monthly, quarterly, semi-annually and annually), organizations (such as companies, divisions, departments, subsidiaries), and by data elements (such as assets, expenses, sales, production, utilization).
- **Standard Report Types:** The Trend Analysis report writer formats data in one of three report types. These are the single period comparison (cross section) report, the historical comparison report and the historical analysis report. These three report types and their options are designed to correspond to the most common ways of examining time series information.
- **Calculator Facilities:** Trend Analysis permits the user to add, subtract, multiply and divide report data (for example, to create ratios). Some common statistical functions such as compound growth rate and standard deviation are also provided. The results of these calculations may be displayed and reported with other information from the data base.
- **Flexibility:** Trend Analysis is designed to provide generalized application customization capabilities. The supplied sample problem may be used as a basis for applications or the user can define specific screen layouts, processing sequences and data elements. Each Trend Analysis application may be tailored to meet specific organizational requirements.
- **User Exits:** To allow an organization to meet further processing requirements, user exits are provided for the addition of installation-written programming to supplement the data entry calculation and report writer facilities of Trend Analysis.
- **Data Maintainability:** Time series data may be maintained using either online or batch mode capabilities. Planning data in the Trend Analysis time series data base can be directly updated using the PLANCODE-Trend Analysis data base bridge or from an installation-written maintenance program using supplied time series data base interface modules.

CUSTOMER RESPONSIBILITIES

The customer must provide the proper operating environment by installing the required operating system, CICS/OS/VIS and IMS/VIS-DB program products, PL/1 and Sort/Merge program products, and the Graphical Data Display Manager with the Presentation Graphics Feature. If PLANCODE is to be used with the PLANCODE/Trend Analysis data base bridge, then either PLANCODE/I or PLANCODE/S must be installed.

Customer technical personnel must be trained and knowledgeable on the above products, as well as on any other products to be used in conjunction with Trend Analysis. Appropriate customer personnel must

be trained and knowledgeable in Trend Analysis functions and in the design and preparation of Trend Analysis applications.

The customer is responsible for developing procedures to ensure data security, for developing operating and backup procedures, and determining the overall tasks to be accomplished to install and operate Trend Analysis for his organization.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

Trend Analysis (CICS/OS/VIS) will run on an IBM S/370 or 4300 processor supported by CICS/OS/VIS and IMS/VIS-DB, equipped with floating point feature, and with sufficient storage to meet the combined requirements of the following software components:

- Host operating system.
- Terminal management subsystem.
- Data base management subsystem.
- Graphical Data Display Manager.
- Trend Analysis.
- PLANCODE/I or PLANCODE/S (if used with Trend Analysis).

Trend Analysis online uses 300K unoverlaid, and can be real or virtual depending on the customer's installation requirements.

Trend Analysis will provide graphic and alphameric support, as indicated, for the following display terminals and printers:

- Multiple IBM 3270 Information Display System components of the following types:
 - 3279 mdl 2B or 3B (extended color) Color Display Station with Program Symbols (#5781 and 5782) attached to an appropriate control unit (alphameric/color graphics).
 - 3279 mdl 2A or 3A (base color) Color Display Station attached to an appropriate control unit (alphameric only).
 - 3278 mdl 2, 3 or 4 Display Station with Program Symbols (#5781 and 5782) attached to an appropriately configured control unit (alphameric/monochrome graphics).
 - 3278 mdl 2, 3, 4 or 5 Display Station attached to an appropriate control unit (alphameric only).
Note: If a 3278 mdl 5 is to be used, alphameric output should be directed to a terminal printer having at least a 132-character print line.
 - 3277 mdl 2 Display Station attached to an appropriate control unit (alphameric only).
 - 3276 mdl 2, 3, 4, 12, 13 or 14 Control Unit Display Station with appropriate control unit features (alphameric only).
 - 3275 mdl 2 or 12 standalone Display Station (alphameric only).
Note: 32XX display stations are only supported with EBCDIC keyboard configuration.
 - 3289 mdl 1 or 2 Line Printer attached to an appropriate control unit (alphameric only).
 - 3288 mdl 2 Line Printer attached to an appropriate control unit (alphameric only).
 - 3287 mdl 1 or 2 Printer, acting as a 3284/3286 mdl 2, with 3271/3272 Attachment (#8330) and 1920-Character print operation (#9522) (alphameric only).
 - 3262 mdl 3 or 13 Line Printer attached to an appropriate control unit (alphameric only).
 - 3268 mdl 2 Printer attached to an appropriate control unit (alphameric only).
 - 3287 mdl 1 or 2 Printer, with 3274/3276 Attachment (#8331) (alphameric only).
 - 3284 or 3286 mdl 2 Printer attached to an appropriate control unit with Data Analysis-APL Feature (#1066) installed if optional text feature character printing is desired (alphameric only).
 - 3284 mdl 3 Printer attached to the standalone 3275 Display Station (alphameric only).
 - 3287 mdl 1 or 2 Printer, with Program Symbols (#5781 and 5782) attached to an appropriate control unit (alphameric/monochrome graphics).
 - 3287 mdl 1C or 2C Printer (extended color), with Program Symbols-4A (#5783) attached to an appropriate control unit (alphameric and extended color graphics).
- The 8775 Display Terminal Component of the 8100 Information System, running in 3270 compatibility mode.

Trend Analysis (cont'd)

- 8775 mdl 1, 2, 11 or 12 large-screen sizes (1,920, 2,560 or 3,440 characters) Display with Program Symbols (#5781 and #5782) attached to an appropriate control unit on an IBM 8100 Information System running DPPX/DSC or DPPX/SP/DSC or DPCX/ DSC (alphameric/monochrome graphics).

SOFTWARE REQUIREMENTS

The Trend Analysis (CICS/OS/VS) program product is written in the IBM PL/I language and operates in the OS/VS1 or MVS environment under control of the Customer Information Control System (CICS/OS/VS), Release 1.5, or subsequent releases, unless otherwise stated.

The following program products are required for a Trend Analysis installation:

- Customer Information Control System (CICS/OS/VS) (Program No. 5740-XX1)
- Information Management System (IMS/VS) Data Base System (Program No. 5740-XX2)
- PL/I OS Resident Library (Program No. 5734-LM4)
- PL/I OS Transient Library (Program No. 5734-LM5)
- OS/VS Sort/Merge (Program No. 5740-SM1) or equivalent
- Graphical Data Display Manager (GDDM) (Program No. 5748-XXH) with Presentation Graphics Feature (PGF)

If user-exit code is to be written, the PL/I OS Optimizing Compiler (Program No. 5734-PL1) will be needed.

If the PLANCODE/Trend Analysis data base bridge is to be used, either PLANCODE/I (5740-XX8) or PLANCODE/S (5740-XX9) will be required.

CONVERSION

Trend Analysis (CICS/OS/VS) is based on Trend Analysis/370. The range of graphic options has been increased through the use of the Graphical Data Display Manager (GDDM) program product. Color graphic output is now displayed on the IBM 3279 Color Display Station or printed on the IBM 3287 Color Printer, which is supported through CICS/OS/VS. Support for the S/7 and OEM color displays will not be provided in Trend Analysis (CICS/OS/VS); existing customer graphic option menus will have to be updated to reflect the enhanced graphic capabilities now available with Trend Analysis (CICS/OS/VS). Minor changes to the time series data base structure have been made, and a reload of existing customer Trend Analysis/370 time series data bases will be required; a set of conversion utilities will be provided with Trend Analysis (CICS/OS/VS) to assist in this task.

DATA SECURITY

Several levels of security are provided to the users of Trend Analysis:

- Terminal- and transaction-level security provisions of CICS/OS/VS.
- Password protection for each user application within Trend Analysis.
- Separate retrieval and update protection provisions for every time series data base record in Trend Analysis (for both online and batch mode).

The Graphical Data Display Manager (GDDM), with its Presentation Graphics Feature (PGF), does not provide any additional security features; however, it does not impede or detract from the usability of the security functions provided by Trend Analysis or by CICS/OS/VS, IMS/VS-DB and the host environment.

Tables generated by Trend Analysis are normally placed in main storage, which is obtained from the system when required. These tables are, therefore, protected from accidental or deliberate interference by other users to the extent provided its host environment.

PROGRAM PRODUCTS

**TELECOMMUNICATIONS CONTROL SYSTEM
ADVANCED COMMUNICATIONS FUNCTION
TCS-ACF (5740-XY3)**

PURPOSE

The Telecommunications Control System - Advanced Communications Function (TCS-ACF) program product provides enhanced installability and operability for users with single-system ACF/TCAM or TCAM/NCP/VS-Direct networks or systems utilizing the ACF/TCAM Multisystem Networking Facility. These functional capabilities are available to the user through TCS-ACF and a separately orderable TCS-ACF Networking Feature.

DESCRIPTION

- The TCS-ACF basic program enhances the user's functional capabilities within a single system in an ACF/TCAM network (with or without the ACF/TCAM Multisystem Networking Facility) or with TCAM/NCP/VS-Direct.
- The optional TCS-ACF Networking Feature, operating with the TCS-ACF basic program and the ACF/TCAM Multisystem Networking Facility, provides extended multisystem networking capabilities in ACF/TCAM systems.

Many of the TCS-ACF facilities described below utilize functions provided by ACF/TCAM or TCAM/NCP/VS-Direct, the ACF Network Control Program/VS and/or the operating system. Facilities that depend heavily on ACF/TCAM or TCAM/NCP/VS-Direct are referred to below as TCS-ACF/TCAM, while those that are due to TCS-ACF itself are so described.

In single and multicomputer TCS-ACF/TCAM systems, there is terminal sharing (among TCAM applications) in either session or transaction modes of operation. Generally, a terminal or application program can communicate with any other terminal or application program in the network, subject (in most cases) only to non-mappable device-dependent characteristics or to user-imposed constraints. Terminals need not be dedicated to a particular application environment; various types of terminal devices can be shared among different application programs. There can also be application-to-application and terminal-to-terminal traffic. Communication line use is also shared among different application programs and terminals. The terminal operator is effectively isolated from the intricacies of the network architecture, and deals with other network resources (terminals and/or applications) as logical entities, without regard for their actual physical location or hardware identity.

TCS-ACF itself with the TCS-ACF Networking Feature features high function facilities for large network configurations that incorporate more than one central processor and elaborate application program subsystems. The TCS-ACF user may selectively augment the SDLC intercomputer links provided through the ACF/TCAM Multisystem Networking Facility with BSC intercomputer links that also permit host-to-host networking routing. It may be practical to share intercomputer links between interactive and bulk-type traffic because of TCS-ACF message-priority recognition and queuing capabilities. TCS-ACF/TCAM capabilities for management of intercomputer links also include automatic load-balancing across multiple links, alternate path and indirect routing and checkpoint/restart.

Message traffic may be stored on main storage and/or disk queues, the latter permitting checkpoint/restart reconstruction back to time-of-failure. The TCS-ACF retrieval program is included to permit retrieval of disk-queued messages by user-authorized terminals. System support programs are provided for online monitoring of application status throughout a complete multicomputer network and for synchronizing intercomputer transmissions to help provide message integrity. Facilities are supplied for manipulating the message queues for destinations, and for accumulating real-time traffic statistics.

A wide variety of application program environments can be supported by TCS-ACF/TCAM. Generally, application programs are run in another region or partition so that the TCS-ACF/TCAM control program and application program failures will not affect other programs or network operation. ACF/TCAM can provide data communication control for application subsystem environments that can utilize the TCAM application program interface (CICS/VS, for example), making these application environments accessible, not only throughout the shared terminal network of a single computer, but also to other shared terminals connected to other computers in a multiprocessor network. User application programs written in Assembler language, COBOL or PL/I can interface directly with TCS-ACF/TCAM. (For application programs written in COBOL or PL/I to interface to TCS-ACF/TCAM, either the OS/VS COBOL Compiler and Library (5740-CB1) or the OS PL/I Optimizing Compiler (5734-PL1) must be used.) The TCS-ACF/TCAM application program interface appears to the application program as a sequential access method (SAM) interface, so that many applications may be tested using sequential input/output devices, before they are run in the actual online system.

Message transmission between terminals and application programs may be handled either in a transaction mode (where each message is routed to its destination(s) based on data in the message) or in TCS-ACF session mode (where routing information is developed once and then maintained during an extended interchange of messages).

Application program checkpoints can be coordinated with the checkpoint facilities of the TCS-ACF/TCAM control program.

TCS-ACF incorporates reliability, availability and serviceability features, including an operator control facility especially tailored for ease in controlling large systems, with provisions for adding specialized function user-written operator control commands.

FEATURES and CAPABILITIES: The following is a summary of the principal TCS-ACF functional capabilities beyond those provided through TCAM/NCP/VS-Direct or through ACF/TCAM.

TCS-ACF basic program for single S/370s and for individual S/370 hosts within an ACF/TCAM multisystem network:

- Selective automatic detection of programmed operator handling of network problems.
 - Automatic activation, monitoring and selective restart of the message control program and TCS-ACF system service tasks.
 - Matrix driven generator for building variable-content start-up and restart messages.
 - A versatile facility for retrieval of transmitted, disk-queued messages.
 - Retrieval may be requested via a TCS-ACF operator control command from authorized remote terminals.
 - Retrieval command allows choice of varied retrieval criteria.
 - Extended message-priority recognition and handling.
 - Operator control enhancements.
 - Commands for transferring, copying and purging unsent queued messages.
 - Facility for adding user-written commands.
 - Additional commands to facilitate large system management.
 - Enhanced MCP message handler capabilities.
 - Capability for execution of user-written code during inmessage/outmessage subgroup processing.
 - Additional MH macro facilities for message switching, editing, validation and routing.
 - Device-independent aids for use with IBM 3270 Information Display System.
 - 3284/5/8 Printer scheduling.
 - Data conversion for 2260 application programs.
 - Model MCP for installation and maintenance ease.
- TCS-ACF networking feature for S/370s operating with the ACF/TCAM multisystem networking facility and the TCS-ACF basic program:
- Prerequisite installation of the TCS-ACF basic program provides all capabilities described above.
 - Selective automatic interchange of local network and application status changes among active network S/370 hosts.
 - Alternate path facility over intercomputer links for host-to-host networking flow including:
 - Automatic detection of path failures.
 - Automatic programmed selection of alternative paths.
 - Automatic switch over to an alternate.
 - Automatic detection and handling of looping and echo error conditions.
 - Support of both transaction and session modes of operation.
 - Multicomputer networking message-switching capability.
 - Automatic checkpoint/restart synchronization of disk-queued host-to-host traffic for message-loss protection.
 - Selective automatic detection and programmed-operator handling of local network problems.
 - Load-balancing across multiple host-to-host links.
 - Message priority level recognition across intercomputer host-to-host paths.
 - A flexible statistics collection facility for accounting and system tuning.
 - Security and authorization facilities.
 - System-provided transmission/access-level control.

TCS-ACF (cont'd)

- Automatic generation of attempted-security-breach advisory messages.
- User-extendible and -modifiable.
- Operator control enhancements for multisystem networking.
- Capabilities aiding application program independence from device-characteristics considerations.
- Facilities to assist support of diverse network types and configurations, including:
 - Aids for developing user-written interfaces to non-TCS-ACF networks.
 - Capabilities applicable to loosely-coupled networks.
 - Capabilities applicable to inter-enterprise networks.
- Capabilities applicable to networks which are never totally deactivated (perpetual networks).
- A Model Message Control Program to facilitate installation and maintenance of users' systems.
 - Provided as operable, machine readable, Class A code.
 - A valid system base which users can modify for their own particular needs.

TCS-ACF NETWORKING OVERVIEW

In general, the capabilities of the TCS-ACF networking feature complement ACF/TCAM networking. The diagram (Figure A) below illustrates this concept.

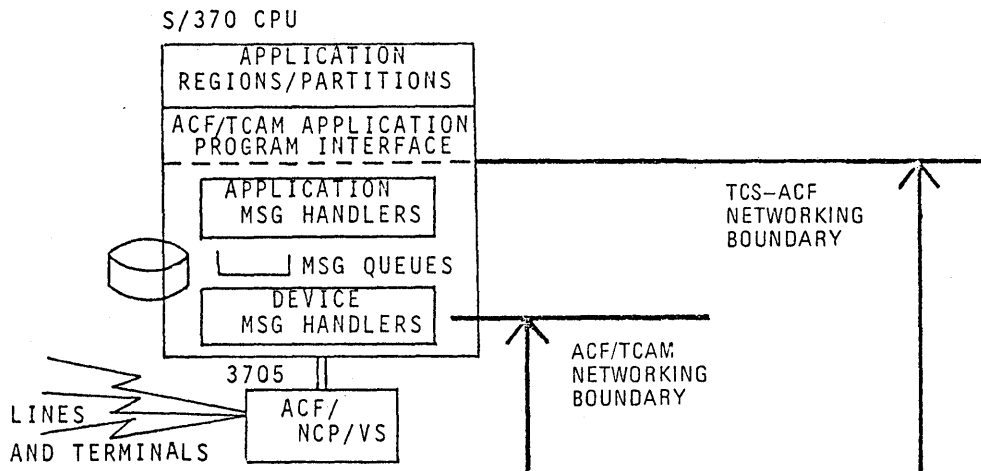

Figure A

This diagram shows one S/370 processor functioning as a host node of a multisystem network, and an attached 3705 Communications Controller with its ACF/NCP/VS controlling lines to other network nodes and terminals.

As shown in this diagram, ACF/TCAM networking involvement in an ACF/TCAM host extends as far as the device message handlers (user-specified code that deals with message transmission to and from the ACF/NCP/VS).

The diagram further depicts how the ACF-TCS networking structure extends into the host node to include additional message control program elements - the message queues and the application message

handlers (user-specified code that deals with message transfer to and from applications). Also within the TCS-ACF networking boundary are the TCS-ACF user-specified networking tables that TCS-ACF uses for message routing and network management.

The TCS-ACF ability to perform networking with extended host awareness of means of device and application message handler facilities and user-accessible to TCS-ACF networking tables, makes possible many of the TCS-ACF functional capabilities described in this document.

In the diagram (Figure B) below, a general overview of TCS-ACF networking structure is conceptually presented.

TCS-ACF (cont'd)

Figure B

A single TCS-ACF network as shown at key (1) in the diagram can encompass multiple ACF/TCAM networking systems, shown as hatched areas (2), and also can incorporate user interfaces to non-ACF/TCAM hosts (3). TCS-ACF's extension of the networking boundary further into the host processor (4), beyond the message queues and message handlers, coupled with the user-accessible TCS-ACF networking tables, permits enhanced capabilities, including:

- User involvement for specialized networking functions.
- Host-oriented functions, such as statistics gathering and access security authorization.
- Data staging on host queues for intercomputer traffic, for efficient line sharing and to smooth peak traffic loads.

In addition to those capabilities wholly provided through TCS-ACF, many TCS-ACF functions, key (5) in the diagram, make use of ACF/TCAM facilities implemented with the TCAM/ACF networking boundaries.

RELATION to ACF/TCAM and SNA

The SNA capabilities described in these pages are provided by ACF/TCAM, and do not represent TCS-ACF functional capabilities beyond those provided by the currently available TCS-ACF product (5740-XXD).

ACF/TCAM provides communication control capabilities, featuring queuing and message handlers, to enable message transmission and ancillary services in a Systems Network Architecture (SNA) environment. The optional ACF/TCAM Multisystem Networking Facility enables the linkage of ACF/TCAM systems (and, if desired, ACF/VTAM systems) into a multicomputer networking system, in which application programs and terminals may be accessed from applications or terminals attached to a different processor. ACF/TCAM supports many SNA, S/S and BSC terminal devices. When the ACF/TCAM Multisystem Networking Facility is utilized, the processors involved are linked via SDLC communication lines, under control of ACF/NCP/VS operating in IBM 3705 Communications Controllers. Intercomputer message traffic is managed in the context of SNA sessions. A SNA session between an application program and a terminal must be established by an initial *logon* transmission directed by way of the processor which maintains control of the terminal involved; subsequent transmissions (until the SNA session is terminated) may be routed by way of the intermediate ACF/NCP/VS and intercomputer links comprising the message path, without involving the terminal's host processor.

TCS-ACF augments the capabilities of ACF/TCAM as described in the "Features and Capabilities" section.

The additional facilities provided by the TCS-ACF basic program are intended to provide extended user flexibility, greater ease of system installation and operability aids especially appropriate for systems with large terminal networks. The TCS-ACF base product can alternatively

run with ACF/TCAM (with or without the Multisystem Networking Facility) or with TCAM/NCP/VS-Direct alone.

The TCS-ACF Networking Feature, running with the TCS-ACF base program and ACF/TCAM in conjunction with the ACF/TCAM Multisystem Networking Facility, provides networking that may selectively utilize host processor power for high-function capabilities. TCS-ACF Networking utilizes its own tables (built by user-coded TCS-ACF macro instructions) and can provide control beyond the boundary of SNA host processor awareness.

These characteristics of TCS-ACF's open architecture and extended control point capabilities, along with ACF/TCAM's structure of message handlers and queues, make TCS-ACF Networking particularly appropriate for:

- Controlled environments linking multiple SNA networking systems.
- Networking systems that interface with foreign (non-TCS-ACF) processors.
- Networking systems that include the TCS-ACF program product in some of the interconnected computers.
- Systems in which the user desires to incorporate his own code for specialized control involvement.
- Systems requiring the network elasticity that can be provided when data is staged (queued) across intermediate network host nodes.
- Incremental migration to full-function networking with the ACF/TCAM Multisystem Networking Facility.
- Large or complex systems requiring a high degree of programmed control for network management.

Using capabilities provided through the TCS-ACF Networking Feature, BSC intercomputer communication lines may link the system's processors through locally attached 370Xs to provide a host-to-host message flow; if any message path includes one or more processors acting as intermediate nodes, message traffic may be selectively relayed through each intermediate processor and queued at each processor, as well as at the originating and destination hosts. One or more BSC lines (in parallel), as required for the traffic load between any two host-node processors, may be used. If parallel lines are provided, TCS-ACF can optionally balance the traffic load, on a message-by-message basis, over the available lines. TCS-ACF provides an alternate BSC path capability for programmed error recovery, if an intercomputer link becomes unavailable. BSC intercomputer links are managed by TCS-ACF to provide intercomputer transmission according to message priority.

To take advantage of the SNA capabilities available through ACF/TCAM networking, the user may augment the TCS-ACF BSC intercomputer link capability described above with the SDLC intermodal links utilized by SNA session transmission. In this environment, BSC intercomputer links may be appropriate to permit an alternate path

TCS-ACF (cont'd)

capability, or to efficiently share the link between high-priority inquiry/response messages and low-priority traffic (bulk data transfer, for example), or to interface with non-TCS-ACF host processors. The user may design his system so that a portion of a particular routing path is via a TCS-ACF/TCAM-initiated SNA session over SDLC links (without intermediate host processor involvement) and a portion is handled using TCS-ACF networking control over either SDLC or BSC links.

RELATION to TCS-AF

Operation of TCS-ACF with the TCS-ACF Networking Feature in conjunction with ACF/TCAM provides TCS function equivalent to the currently available release levels of TCS-AF. For the user migrating from TCS-AF to TCS-ACF with the Networking Feature, functional TCS capabilities will remain the same, although additional function may be realized through operation with ACF/TCAM. TCS-AF (5740-XXD) is currently available to provide multisystem networking using TCAM Levels 5, 8 and 9. TCS-AF for TCAM/NCP/VS-Direct is available now. When each TCAM release level is no longer considered to be current, programming support for TCS-AF on that release level will be discontinued. Support for these levels will be withdrawn and central programming services will no longer be provided. TCS-AF will not support ACF/TCAM; TCS-ACF is available for that purpose. With the announcement of TCS-ACF, commitment by TCS-AF to support all subsequent TCAM releases and levels within 120 days of their availability is withdrawn.

Where related IBM programs (e.g., CICS/VS, TSO, SSS) operate with the current levels of TCS-AF, compatibility is retained for the levels of those programs that provide current support at the availability of TCS-ACF. Recompilation of the related programs is not required.

Compatibility is retained for existing user programs that utilize the current levels of TCS-AF. However, such programs may require changes to take advantage of the ACF multisystem networking capabilities offered through the ACF/TCAM Multisystem Networking Facility.

CUSTOMER RESPONSIBILITIES

To successfully install and use TCS-ACF, the customer must first order and install all required communications equipment ... generate an OS/VS1 or OS/VS2 system with ACF/TCAM or TCAM/NCP-Direct ... train all persons installing, operating or maintaining TCS-ACF in ACF/TCAM or TCAM/NCP-Direct, TCS-ACF and ACF/NCP/VS or NCP/VS ... code and test the MCP ... and develop conversion procedures and schedules.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

TCS-ACF requires the minimum IBM machine requirements of ACF/TCAM or TCAM/NCP-Direct and the appropriate operating system; OS/VS1 or OS/VS2 (SVS or MVS).

The *TCS-ACF Operations Guide* may be used to estimate the real main storage requirements of TCS-ACF for each specific customer system.

The data communication link connecting two processors in a TCS-ACF networking system utilizing ACF/TCAM with the ACF/TCAM Multisystem Networking Facility may be comprised of one SDLC link and/or one or more BSC lines.

Terminal Support: TCS-ACF provides terminal device support consistent with the level of TCAM or ACF/TCAM with which it is used. Consult the TCAM or ACF/TCAM pages for charts summarizing terminal support capabilities and device attachment dependencies.

SOFTWARE REQUIREMENTS

The TCS-ACF base program operates as a non-system task in conjunction with TCAM/NCP/VS-Direct or with ACF/TCAM, with or without the ACF/TCAM Multisystem Networking Facility, under OS/VS1 and OS/VS2 (SVS and MVS).

The TCS-ACF Networking Feature operates as a non-system task with the TCS-ACF base program and ACF/TCAM, in conjunction with the ACF/TCAM Multisystem Networking Facility, under OS/VS1 and OS/VS2 (SVS and MVS).

The chart below summarizes TCS-ACF and TCS-AF system programming dependencies:

	TCS-ACF Base Program	TCS-ACF Networking Feature*	TCS-ACF Program Product
TCAM Release Levels 5, 8 and 9		X	X
TCAM/NCP/VS-Direct ACF/TCAM	X	X	X
ACF/TCAM Multisystem Networking Facility (requires ACF/TCAM)		X	X

* Requires TCS-ACF base program, ACF/TCAM and ACF/TCAM Multisystem Networking Facility.

TCS-ACF will operate with the latest current level of NCP/VS available or with ACF/NCP/VS.

DATA SECURITY

TCS-ACF provides authorization facilities oriented towards permitting only user-authorized station devices to access certain user-specified application programs or subsystems or to utilize system facilities like TCS-ACF operator control and retrieval. Further details on data security are included in the *TCS-ACF Concepts and Facilities* manual.

DOCUMENTATION: (available from Mechanicsburg)

Telecommunications Control System - Advanced Communications Function Concepts and Facilities is available from from Mechanicsburg. For information about SNA functions available through ACF/TCAM, refer to *Introduction to Advanced Communications Function* (GC30-3033) and to *Advanced Communications Function for TCAM General Information Manual* (GC30-2050).

**RESOURCE MEASUREMENT FACILITY
RMF (5740-XY4)****PURPOSE**

Version 2 of the Resource Measurement Facility (RMF) is a significant functional extension of the system measurement capability provided in Version 1. RMF enables an installation to measure selected areas of system activity and obtain feedback that can be used to evaluate system performance.

RMF measures the utilization of individual processors, physical and logical channels, devices, real storage, external page storage, page and swap data sets, and address spaces. It also measures resource contention controlled by enqueueing, the interaction of real storage/processor/SRM, and the service being provided to different classes of users, as well as tracing the contents of fields from certain ASM/RSM/SRM control blocks.

RMF generates formatted printed reports, SMF records, and display reports describing the system activity measurements requested by an installation. The printed reports are routed to a SYSOUT data set that is made available for printing either immediately after the measurement interval or after RMF terminates. Hardcopy records of display reports can also be routed to a SYSOUT data set.

When SMF records are produced, their data can be formatted into the required reports at a later time by the post-processing facility. The post-processor can generate interval, duration, summary and plot reports.

HIGHLIGHTS

The following classes of system activity can be measured and reported in the form of SMF records and/or formatted printed reports:

- Processor activity
- Physical and logical channel activity
- Detailed I/O device activity and contention for:
 - Unit record devices
 - Graphics devices
 - Direct access storage devices
 - Communication equipment
 - Magnetic tape devices
 - Character reader devices
- Detailed system paging activity
- Detailed system workload activity
- Page/swap data set activity
- Enqueue activity
- ASM/RSM/SRM trace activity.

The following classes of system activity can be measured and reported on at a display station for immediate inspection or in the form of SMF records and/or formatted printed reports:

- Address space activity
- System paging activity
- Real Storage/processor/SRM activity

RMF Version Release 3 adds the following classes of activity:

- Enqueue activity
- Reserve activity
- Transaction activity.

RMF Version 2 Release 4 adds the following classes of activity:

- Domain activity
- Device activity
- Page Space activity
- Physical and Logical Channel activity.

User exits enable an installation to gather and report information on other areas of system activity through the facilities of RMF. Enhanced post-processing facilities permit data summarization and plotting. Dynamic modification of RMF control options is also possible.

RMF Version 2 Release 3 offers new Post Processor options which provide user selection and grouping of one or more system threshold values into sets. The Post Processor recognizes each set as an exception condition that, when exceeded, will generate information in the new Exception Report and optionally generate specified sets of interval reports. This new function can save performance analysis personnel time by decreasing the bulk of data that must be reviewed.

RMF Version 2 Release 4 provides a new Timed Updating Function. This enhancement allows a user to have a Monitor II command automatically repeated a given number of times with a given interval between each repetition. This has the effect of automatically updating the display as specified by the user. This release also provides the user with the capability to produce the desired Monitor II report by selecting the appropriate 3270 Programmable Function Key. The new Global Resource Serialization facility available with MVS/System Product-JES2 Release 2 or MVS/System Product-JES3 Release 2 will also be supported by RMF Version 2 Release 4.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

The approximate RMF auxiliary storage requirements for the system libraries are:

SYS1.LPALIB 22,000 bytes

Fixed storage requirements for RMF include temporarily fixed PLPA code space, temporarily fixed private area space and SOA global fixed space (SP245). The amount of storage used depends on the set of options that is requested for RMF processing.

There are no special hardware requirements in addition to the normal requirements of OS/VS2 MVS, with the following exceptions:

- Display reports can be run under TSO in a TSO display session or as a local 3270 display session started by an operator command. Display sessions require an IBM 3277 Display Station mdl 2, IBM 3278 Display Station mdl 2, or IBM 3276 Controller Display Station mdl 2. Monitor II display sessions now provide full screen support for the following terminals:

IBM 3276 mdls 2, 3 and 4 (Remote attachment only)

IBM 3278 mdls 2, 3 and 4 (attached to the IBM 3274 mdl 1D control unit)

IBM 3279 mdls 2A, 2B, 3A and 3B (attached to the IBM 3274 mdl 1D control unit)

- When the MVS/System Extensions program product or the MVS/System Product is installed, a 132-character printer is required to accommodate the extensions to the printed reports.

SOFTWARE REQUIREMENTS

RMF Version 2 can be used with OS/VS2 Release 3.7, which must have the following products installed:

- Supervisor Performance No. 1 (SU5).
- Supervisor Performance No. 2 (SU7).
- If MVS/System Extensions-Processor Support 2 feature is installed, the RMF (MVS/System Extensions Support) Processor Support 2 feature must also be installed.

RMF Version 2 can be used with OS/VS2 Release 3.8 (MVS) which must have the following products installed:

- If MVS Processor Support 2 is installed and the MVS System Extensions Program Product is not installed, the RMF Processor Support 2 feature must also be installed.
- If MVS/System Extensions Processor Support 2 feature is installed, the RMF (MVS/System Extensions Support) Processor Support 2 feature must also be installed.
- If MVS/System Extensions Release 2.0 is installed, the RMF (MVS/System Extensions Support) MVS/System Extensions Release 2 feature must also be installed.
- If MVS/System Extensions Release 2.0 is installed, RMF Version 2 Release 3 or the RMF (MVS/System Extensions support) MVS/System Extensions Release 2 feature, must also be installed.
- If MVS/System Product-JES2 Release 1 or MVS/System Product-JES3 Release 1 is installed, RMF Version 2 Release 3 must also be installed.
- If the Enhancement for MVS/System Product - JES2 Release 1 or MVS/System Product - JES3 Release 1 is installed, the Enhancement for RMF Version 2 Release 3 must also be installed.
- If MVS/System Product-JES2 Release 2 or MVS/System Product-JES3 Release 2 is installed, RMF Version 2 Release 4 must also be installed.
- If MVS/System Product - JES2 Release 3 or MVS/System Product - JES3 Release 3 is installed, the Enhancement for RMF Version 2 Release 4 must also be installed.

TERMS and CONDITIONS: See PP Index

PROGRAMMED CRYPTOGRAPHIC FACILITY 5740-XY5

PURPOSE

The Programmed Cryptographic Facility program product provides an installation with the ability to encipher and decipher data, and create and manage the keys associated with the data encryption. It employs a software implementation of the Federal Hardware Data Encryption Standard (DES) algorithm to encipher and decipher data using a 56-bit key. This facility may be used in conjunction with the ACF/VTAM Encrypt/Decrypt feature in a communications environment with the access method services REPRO function of either Access Method Services Cryptographic Option or MVS/XA Data Facility Product, or with installation encryption/decryption applications for data to be transmitted over communications lines, or stored on some physical device.

HIGHLIGHTS

Enciphers and decipheres data using a software implementation of the Federal Data Encryption Standard algorithm.

Provides a macro for invocation by the ACF/VTAM Encrypt/Decrypt feature, ACF/VTAM Version 2 or installation applications, for use in enciphering data for transmission over unprotected communications lines.

Provides a Key Generation utility to generate and store (in enciphered form) keys used in data encryption and decryption.

Provides a Key Management function to assist in maintaining the security of the cryptographic keys, and to perform manipulation of these keys with minimum user involvement.

Provides an assembler macro interface to the encryption/decryption algorithm enabling an installation to implement protection for data sets via the access method services REPRO function of either Access Method Services Cryptographic Option or MVS/XA Data Facility Product, or user applications.

Routes security messages to the security console and SMF for detected attempted security violation occurrences, and execution of the Key Generator utility.

DATA FILE ENCRYPTION/DECRYPTION CONSIDERATIONS

It is recommended that data encryption be used for entire data sets that need protection and are transcribed on transportable media or are to remain stored on some physical device. For online data protection, an authorization mechanism such as RACF should be considered. Access Method Services Cryptographic Option licensed program (5740-AM8) or MVS/370 Data Facility Product (5665-295) in the OS/VS2 MVS environment, or MVS/XA Data Facility Product Release 1 (5665-284) in the MVS/XA environment support the access method services REPRO function to give the user the ability to encipher and decipher data using the Programmed Cryptographic Facility. The user may also develop encryption/decryption routines using the services of the Programmed Cryptographic Facility licensed program.

CUSTOMER RESPONSIBILITIES

Primary among the customer responsibilities for using the Programmed Cryptographic Facility are:

Generating cryptographic keys (by means of the Key Generator Utility).

Providing adequate physical security for the Key Generator Utility output, and data sets used during key generation.

Providing protection of the Cryptographic Key Data set (e.g., by using RACF (Program No 5740-XXH) (MVS only), or password protection).

Maintaining secure duplicate copies of the keys used. A lost key will preclude deciphering and result in loss of ability to use data. This is a concern primarily when storing enciphered data on physical devices.

For an installation to safeguard its data, it must not only consider the functions provided through the Programmed Cryptographic Facility and other data processing techniques, but it must also provide the necessary physical protective measures and implement effective information management practices. For an overview of physical security and data security, refer to the following IBM publications:

The Considerations of Physical Security in a Computer Environment, G520-2700 ... *The Considerations of Data Security in a Computer Environment*, G520-2169 ... *Data Security and Data Processing, Volumes 1 and 2*, G320-1370 and GC20-1371 ... *42 Suggestions for Improving Security*, G520-2797 ... *Data Security Controls and Procedures - A Philosophy for DP Installations*, G320-5649 ... *Management Memorandum: Security Features of IBM S/370*, G320-5650 ... *OS/VS2 MVS Resource Access Control Facility (RACF)*, *General Information Manual*, GC28-0722.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The virtual and direct access storage requirements for the Programmed Cryptographic Facility, beyond normal OS/VS1, OS/VS2 MVS or MVS/XA requirements are:

Virtual Storage Requirements:

OS/VS2 MVS MVS/XA	OS/VS1	Approximate Storage Required
Common Service Area (CSA)	Pageable System Queue Area (PSQA)	550 bytes plus space for ACBs and other VSAM control blocks, data buffers and index buffers.
Pageable Link Pack Area (PLPA)	Pageable Supervisor Area	23,000 bytes.
Private Area	Partition	2,500 bytes.

Direct Access Storage Requirements:

Library	Approximate DASD Space
SYS1.NUCLEUS(OS/VS1)	
SYS1.LPALIB(OS/VS2 MVS)	24,000 bytes
SYS1.LINKLIB	15,000 bytes
JOBLIB or STEPLIB data set *	38,000 bytes
SYS1.MACLIB or a private macro library	108,000 bytes
Cryptographic Key Data Set	50 bytes/entry
Master Key Variant Data Set	240 bytes

* To control access to the key generator utility program, it is recommended that it be stored in a protected library that is accessed via a JOBLIB or STEPLIB DD statement.

No special hardware requirements exist for this program product, beyond either the IBM S/370 supported by OS/VS2 MVS or OS/VS1, or the IBM 3081 operating in Extended Architecture mode supported by MVS/XA.

The Programmed Cryptographic Facility will support an optional, dedicated security console (MCS, routing code = 9). The console may be any of the terminals supported by OS/VS1, OS/VS2 MVS or MVS/XA that have console capabilities.

COMMUNICATIONS ENCRYPTION/DECRYPTION CONSIDERATIONS

For implementation in a communications environment, this program is designed to operate with the ACF/VTAM Encrypt/Decrypt feature or ACF/TCAM Version 2 and with the 4701 Finance Communication Controller and the following terminals when they are equipped with Encrypt/Decrypt feature #3680:

3274 mdls 1C, 21C, 31C and 51C
3276 mdls 11, 12, 13 and 14
3776 mdls 3 and 4
3777 mdl 3

SOFTWARE REQUIREMENTS

The Programmed Cryptographic Facility can be used with:

OS/VS2 MVS Release 3.8 with, optionally, MVS/370 Data Facility Product (5665-295)

OS/VS1 Release 7

MVS/XA (5665-284) Data Facility Product in an MVS/XA environment

and subsequent releases and modification levels unless otherwise specified.

COMPATIBILITY

Existing 3600 host application programs may, with minor modifications, use the Programmed Cryptographic Facility program product macros.

DOCUMENTATION

Programmed Cryptographic Facility General Information Manual (GC28-0942).

RPQs ACCEPTED: No

PROGRAM PRODUCTS

CRYPTOGRAPHIC UNIT SUPPORT (5740-XY6)

PURPOSE

The Cryptographic Unit Support program product promotes security for sensitive data in communication and file applications through the use of cryptography. It provides an interface to the 3848 Cryptographic Unit, includes a process to generate cryptographic keys and a facility to manage those keys. The 3848 implements the Data Encryption Standard (DES) as published in Federal Information Processing Standard #46.

HIGHLIGHTS

Provides the capability to encipher and decipher data in hardware via an interface to the 3848 Cryptographic Unit.

Provides a key generation utility to generate and store (in enciphered form) keys used in data encryption and decryption.

Provides key management functions to enhance the security of the cryptographic keys and to perform manipulation of these keys with minimum user involvement.

Provides the capability to encrypt/decrypt data transmitted over communications lines by invocation of the appropriate macros by the:

ACF/VTAM Encrypt/Decrypt Feature or,
ACF/TCAM Version 2 or,
Installation Applications.

Supports file encryption through direct use of encryption macros in user-written applications or through either the Access Method Services Cryptographic Option licensed program (5740-AM8), MVS/370 Data Facility Product licensed program (5665-295), or the MVS/XA Data Facility Product licensed program (5665-284).

Routes security messages to the security console and writes records to the SMF data set for detection of attempted security violation occurrences and execution of the key generator utility as well as other significant events.

Provides error recovery and error recording for the 3848 cryptographic unit.

CUSTOMER RESPONSIBILITIES

Primary customer responsibilities for using the Cryptographic Unit Support are:

- Installing the host master key in the 3848 Cryptographic unit.
- Generating cryptographic keys (by means of the Key Generator Utility).
- Providing adequate physical security for the key generator utility output, and data sets used during key generation.
- Providing protection of the cryptographic key data set (for example, by using RACF (5740-XXH), MVS/XA or OS/VS2 MVS only), or password protection.

For an installation to safeguard its data, it must not only consider functions provided through the Cryptographic Unit Support program product and other data processing techniques, but it must also provide the necessary physical protective measure and implement effective information management practices. For general overview information on physical and data security, refer to the following IBM publications:

- *The Considerations of Physical Security in a Computer Environment* (G520-2700)
- *The Considerations of Data Security in a Computer Environment* (G520-2169)
- *Data Security and Data Processing, Volumes 1 and 2* (G320-1370 and G320-1371)
- *42 Suggestions for Improving Security* (G520-2797)
- *Data Security Controls and Procedures - A Philosophy for DP Installations* (G320-5649)
- *Management Memorandum: Security Features of IBM S/370* (G320-5650)
- *OS/VS2 MVS Resource Access Control Facility (RACF) General Information Manual* (GC28-0722).

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The Cryptographic Unit Support program product will run on the virtual storage IBM S/370 Mdl 145 through 168 and the IBM 3031, 3032, 3033 or 3081 Processors or 3081 Processor Complex operating in Extended Architecture mode to which an IBM 3848 is attached. The IBM Mdl 145-1 requires the no-charge special feature #1001, Advanced Program Support.

The program will support an optional dedicated console (MCS, routing code = 9). This console may be any of the terminals supported by MVS that has console capability.

STORAGE ESTIMATES GUIDELINES

The virtual and direct access storage requirements for the Cryptographic Unit Support Program Product, beyond normal MVS/XA or OS/VS2 MVS requirements, are:

VIRTUAL STORAGE REQUIREMENTS

	Approximate MVS Storage Required
Common Service Area (CSA)	554+A+(4076+(4096xB/5))
Pageable Link Pack Area (PLPA)	19,000 bytes
Private Area	2,000 bytes

A = storage for an ACB, for VSAM data buffers and index buffers, and for other VSAM control blocks. For information on the amount of space required for these control blocks, see *OS/VS Virtual Storage Access Method (VSAM) Programmer's Guide* or *OS/VS2 Access Method Services*.

B = number of Cryptographic Units defined at SYSGEN and B/5 not less than 1.

DIRECT ACCESS STORAGE REQUIREMENTS

Data Set or Library	Approximate DASD Space
SYS1.LPALIB	19,000 bytes
SYS1.LINKLIB	35,000 bytes
JOBLIB or STEPLIB data set*	48,000 bytes
SYS1.MACLIB of a private macro library	108,000 bytes
Cryptographic Key Data Set (CKDS)	58 bytes/entry
Master Key Variant Data Set (MKDS)	240 bytes

Note:

* To control access to the key generator utility program, it is recommended that it be stored in a protected library that is accessed via a JOBLIB or STEPLIB DD statement.

SOFTWARE REQUIREMENTS

The Cryptographic Unit Support Program Product was designed to be used with OS/VS2 (MVS) Release 3.8 (and subsequent releases until otherwise indicated). When used with OS/VS2 (MVS) the following selectable unit is required:

MVS Processor Support 2 (SU64)

When used with an OS/VS2 MVS system that includes the MVS/System Extensions program product (5740-XE1), the selectable unit listed above is required as well as the Processor Support 2 Feature of MVS/System Extensions. The Cryptographic Unit Support program product may be used with MVS/370 Data Facility Product (5665-295) and its prerequisites. It may also be used in an MVS/XA environment with MVS/XA Data Facility Product licensed program and either MVS/System Product-JES2 Version 2 (5740-XC6) or MVS/System Product-JES3 Version 2 (5665-291) licensed programs

COMMUNICATIONS ENCRYPTION/DECRYPTION CONSIDERATIONS

For implementation in a communications environment, this program is designed to operate with the ACF/VTAM Encrypt/Decrypt feature or ACF/TCAM Version 2 and with the 4701 Finance Communication Controller and the following terminals when they are equipped with Encrypt/Decrypt feature #3680:

- 3274 mdls 1C, 21C, 31C and 51C
- 3276 mdls 11, 12, 13 and 14
- 3776 mdls 3 and 4
- 3777 mdl 3

DATA FILE ENCRYPTION/DECRYPTION CONSIDERATIONS

It is recommended that data encryption be used for entire data sets that need protection and are transcribed on transportable media. For online data protection, an authorization mechanism such as RACF should be considered. The Access Method Services Cryptographic Option Release 1 licensed program (5740-AM8), MVS/370 Data Facility Product licensed program (5665-295), and the MVS/XA Data Facility Product licensed program (5665-284) support the Access Method Services REPRO function to give the user the ability to encipher and decipher data using the Cryptographic Unit Support program product. The user may also develop his own encryption/decryption routines using the macro services of the Cryptographic Unit Support program product.

COMPATIBILITY

The Cryptographic Unit Support program product was designed to allow operation of programs written to use the Programmed Crypto-

PROGRAM PRODUCTS

Cryptographic Unit Support (cont'd)

graphic Facility program product. The actual encryption/decryption will be performed in the 3848 Cryptographic Unit. Data files that were encrypted by the Programmed Cryptographic Facility can be decrypted by the Cryptographic Unit Support program product and the 3848. Compatibility and conversion guidelines regarding cryptographic keys are discussed in the *OS/VS2 MVS Cryptographic Unit Support General Information Manual* (GC28-1015).

PROGRAM PRODUCTS

**DATA BASE DESIGN AID (DBDA)
5740-XY8 (OS/VS)
5746-XXQ (DOS/VS)****PURPOSE**

The Data Base Design Aid (DBDA) is a collection of programs that assist the data base designer by performing a major portion of the data base logical design process.

Data base requirements which have been collected and recorded on DBDA Requirement Specification Forms are used to produce a logical design of the data base by mapping the data elements into segments and a hierarchical structure that shows the minimum set of relationships required by an integrated data base (one that services many application programs). The processing aids the data base designer by identifying inconsistencies or omissions in the input requirement, specifications, listing redundant data identified by the designer and producing a series of diagnostic and design reports. Using DBDA's suggested logical design to design a physical data base, the data base designer can expect to save from poor initial designs.

HIGHLIGHTS

Reduced Data Base Design Time: By automating analysis of the data requirements, DBDA can help reduce the design cycle time. This reduction can allow program development efforts to begin earlier in the implementation process.

Increased Data Base Design Quality: Because of its automated analysis of the data requirements, the use of DBDA helps create a more efficient and uniform initial design, as compared to manual methods.

Automated Analysis of Data Requirements: DBDA performs a comprehensive and thorough analysis of the data elements and their relationship to each other.

Standardized Data Requirements Gathering: DBDA provides a simple format for recording data base requirements. Requirements from various application areas within an organization can be recorded with an increased probability of completeness and consistency of content and meaning.

Emphasized Designer Control: DBDA analyzes design choices in structuring the data base and detects omissions, inconsistencies and redundancies in the data requirements. The results of this analysis are reported to the designer, who can then modify the data requirements and easily communicate the decisions to DBDA. The designer may also impose his own requirements and constraints on the design produced by DBDA. The analysis and restructuring can then continue or be repeated until the desired logical design is obtained.

Creation of Comprehensive Reports: DBDA produces design reports that define the structure of the data base and suggest a possible logical design. Diagnostic/edit reports are also produced that help the designer use DBDA in an iterative manner. They provide information on which to base design decisions and make corrections in the specifications of data requirements. In addition, both categories of reports are valuable as documentation of design decisions.

DBDA -- DB/DC Data Dictionary Interfaces: Two optional programs are supplied with DBDA to provide interfaces between DBDA and the DB/DC Data Dictionary. The DBDA Data Dictionary Command Generator enables both OS/VS and DOS/VS users to store the results of a DBDA design study into the DB/DC Data Dictionary: OS/VS DB/DC Data Dictionary (5740-XXF), and DOS/VS DB/DC Data Dictionary (5746-XXC). The DBDA Data Dictionary Information Extractor in OS/VS DBDA enables OS/VS users to extract from their dictionary a description of existing data structures. This facility can be employed by the user who wishes to support new application functions by expanding data structures, and makes it unnecessary to manually redescribe these structures for DBDA input.

CUSTOMER RESPONSIBILITIES

A customer installing DBDA must have at least the minimum machine configurations installed (described below under "System Requirements"). The customer's analysts must also collect and record data requirements.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

DBDA Version 2 requires an IBM S/370 (mdl 145 or larger for OS/VS users, mdl 115 or larger for DOS/VS users) with a direct access storage device supported by VSAM.

Minimum storage requirements above those of the host operating system are:

A virtual OS/VS region or partition of 512K bytes.

A virtual DOS/VS partition of 512K bytes when VSAM is resident in the SVA. If VSAM is not resident, the virtual partition required is 768K.

Input is via a card reader or by entry into an input data set from a terminal using TSO for OS/VS users, CMS for VM/370 users, SPM II or ETSS for DOS/VS users or any other terminal system that is capable

of generating a data set that can be read as SYSIN input. A printer is necessary for DBDA reports. One tape drive is required for DBDA installation on OS/VS; two tape drives are required for installation on DOS/VS. **SOFTWARE REQUIREMENTS**

DBDA Version 2 uses VSAM with multi-positioning and generic key searches. DBDA Version 2 executes in batch mode under all currently supported releases of OS/VS1, OS/VS2 and DOS/VS and subsequent releases unless otherwise specified.

The host system must include a sort/merge routine designed for VSAM files and the standard OS/DOS interface with E15 and E35 exits. OS/VS Sort/Merge (5740-SM1) and DOS/VS Sort/Merge (5746-SM1) meet these requirements.

DBDA does not require the execution of IMS/VS or DL/I DOS/VS. However, the optional DB/DC Data Dictionary Information Extractor in OS/VS DBDA requires any currently supported release of the DB/DC Data Dictionary OS/VS (5740-XXF) and IMS/VS Version 1 (5740-XX2) releases as required by the DB/DC Data Dictionary. Subsequent releases of IMS/VS and the DB/DC Data Dictionary will be supported unless otherwise specified.

DBDA is distributed in Assembler language.

COMPATIBILITY

Version 2 is upward compatible with Version 1.

CONVERSION

No conversion aids are required to migrate from Version 1 to Version 2.

DOCUMENTATION: (available from Mechanicsburg)

General Information Manual (GH20-1626).

**DOS SORT/MERGE
5743-SM1****PURPOSE**

The DOS Sort/Merge (5743-SM1) provides a number of functional improvements over the DOS Tape and Disk Sort/Merge 360N-SM-483, including support of the 3330/3333 Disk Storage Facility and the 3400-series Magnetic Tape Units. All the functions, facilities and options of the Type I program 360N-SM-483 as well as the earlier program product Tape and Disk Sort/Merge (5736-SM1) (now withdrawn) are included.

FEATURES

- Support for the 3330/3333 Disk Storage Facility and the 3410 and 3420 Magnetic Tape Units for input, output and work files.
- Reduction in minimum main storage requirements to 10K for all supported devices.
- Facility to specify any programmer logical unit number for input, output and work files.
- Work files on direct access devices can be specified as direct files as well as sequential disk files, making it easier to specify multi-extent disk work files.
- Disk input and/or output record lengths of the maximum track capacity are accepted.
- New and modified error messages.
- An option to get a storage dump at different levels of critical error messages.
- Message routing to console or printer.
- Work files on disk or 3400-series tape can optionally be erased.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

The minimum configuration supported by the Sort/Merge program is:

- Any IBM processor supported by DOS.
- A minimum partition of 10K for the Sort.
- One 2311, 2314 or 3330/3333 direct access device for system residence.
- Unit record equipment as required by the system.
- Three 2400-series or 3400-series tape units when tape work data sets are used.
- Sufficient direct access space when direct access input, output and/or work data sets are used.

5743-SM1 utilizes up to 512K of main storage. For work data sets, Sort/Merge (5743-SM1) utilizes up to eight extents on 2311, 2314, 2319 or 3330/3333 direct access devices or up to ten 2400/3400 series tape units.

SOFTWARE REQUIREMENTS

DOS Sort/Merge 5743-SM1 executes under Release 26 of the Disk Operating System and all subsequent releases. Sort/Merge support of the 3330 requires the 3330 device support provided in DOS Release 27.

COMPATIBILITY

A valid set of Sort control statements, and user-written exit routines prepared for the 360N-SM-483 program can be used without change for the 5743-SM1 program product. All data sets used and produced by 360N-SM-483 are supported by 5743-SM1.

5743-SM1 and 360N-SM-483 cannot exist in the same core-image library without renaming phases with identical names.

PERFORMANCE

When using the devices supported by 360N-SM-483, the DOS Sort/Merge 5743-SM1 has better or equal performance compared to the Type I Sort. The support of the 3330/3333 Disk Storage Facility utilizes the improved access time and larger track capacity of this device. For more information on the performance of 5743-SM1, see the "Timing Estimates" section of the *DOS Sort/Merge General Information Manual* (GC33-4020).

PROGRAM PRODUCTS

**INTERACTIVE PERSONNEL SYSTEM
Release 1 Modification Level 2
CICS/DOS/VS (5746-AM1)****PURPOSE**

The IBM Interactive Personnel System is designed to assist personnel functions in performing their required tasks efficiently and competently. Online-inquiry, online-update, as well as batch processing capabilities are offered. The data organization methods of the IBM Data Language/I Disk Operating System/Virtual Storage (DL/I DOS/VS) are used for data storage and retrieval. The online capability is made possible through the use of the data communication facilities of the IBM Customer Information Control System/Virtual Storage (CICS/DOS/VS).

DESCRIPTION

The Interactive Personnel System maintains three data bases:

- The personnel data base, which contains data related to employees.
- The positions data base, which holds data reflecting the organizational structure of a company, including reporting paths.
- The jobs data base, which contains data describing the jobs to be performed in a company and the skills required for these jobs.

These data bases are designed to meet a variety of administration and information requirements of the personnel functions of a company. If additional or different data is needed, the data bases can be customized. Facilities are available in the Interactive Personnel System to add, change or delete fields, segments or data bases. Also, new data base layouts can be defined.

A wide range of personnel administration and management is supported by the applications offered as part of the Interactive Personnel System. Some applications run in online mode and some in batch mode. The applications can be used without any modifications; however, they can be modified if necessary. Changes to the data bases or to the applications can be made easily using two system capabilities:

- Customizing of the data bases as mentioned above.
- Procedure definition language for the definition and modification of applications.

The procedure definition language is end-user-oriented and therefore easy to use. There are various procedure types, for example, a conversational inquiry or an online update, that define the skeleton of processing. A set of language keywords allows the specification of processing details such as input/output definitions, security specifications, editing options or user exit processing. This tool enables the user to define or modify applications with little effort. As part of the Interactive Personnel System, facilities for data security are offered in addition to the security facilities contained in the prerequisite data base/data communication systems. Security rules can be established for each user of the Interactive Personnel System. A hierarchy of security checks can be defined:

- Authorization to define or modify applications.
- Authorization to execute applications.
- Authorization to gain access to the application data bases.
- Authorization to use specific data within a record.
- Authorization to process the logging data base.

As part of the procedure definition language, editing features are included in the Interactive Personnel System to verify that the data entered into the data bases is correct. Editing can also be done on data that is to be displayed or printed. This includes, for example, code conversion.

Checking is done against user-defined tables that can be altered without program changes.

A set of government reporting and benefits tracking applications are offered as a separately-priced feature covering the following areas:

- Equal Employment Opportunity (EEO) Processing
- Occupational Safety and Health Act (OSHA) Processing
- Health Maintenance Organization (HMO) Tracking
- Benefits Tracking

These applications expand the personnel tracking capabilities of the Interactive Personnel System for private industry, providing the basis for the entry, update and processing of much of the information needed to comply with government reporting requirements.

The government reporting and benefits tracking applications use both online and batch mode processing. Sample data base segments are supplied for inclusion in the existing system data bases, and for the creation of an establishment data base to contain pertinent EEO data. Edit tables are also included for support of the establishment data bases.

These applications use the data base customization and procedure definition language capabilities of the Interactive Personnel System, and require no additional resources beyond the added data base segments, the establishment data base, and the table storage areas.

The system allows basic calculations. Complex calculations and complex data handling can be implemented in user exit routines that can be supplied as Assembler, PL/I or COBOL programs.

HIGHLIGHTS

- A set of three data bases for personnel, positions and job data.
- Personnel applications are offered to support many tasks in personnel administration and management. The applications are written using the procedure definition language.
- The system supports both online and batch processing.
- The Interactive Personnel System procedure definition language allows easy implementation of additional applications and modification of existing applications by the user.
- Customizing facilities are provided to adapt the system to the user's environment. Data bases, segments and fields can be added or changed.
- Data security and logging facilities are available.
- Data editing functions assist in data checking, data conversion and migration.
- Basic calculations are supported.
- User-exit modules within the applications can be written in PL/I, COBOL or Assembler language.
- Provisions are made for the translation of messages, commands and screen data into the customer's desired terminology.
- An optional feature is the logging of data base updated in a logging data base. The contents of the logging data base can be processed using Interactive Personnel System applications.

CUSTOMER RESPONSIBILITIES

The customer is responsible for the availability of the prerequisite machines and programming systems as listed in the "Specified Operating Environment".

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

This licensed program is designed to operate on the following IBM machines: IBM S/370 mdls 138 to 158, IBM 303X and IBM 43XX. The following environment is required for the execution of the program:

- Processor: One IBM processor supported by DOS/VS or DOS/VSE and CICS/DOS/VS.
- Virtual address space (figures do not include the partition-related parts of DOS/VS or DOS/VSE, VSAM, DL/I DOS/VS or CICS/DOS/VS):
 - 300K for programs running in a batch environment
 - 240K for programs running under CICS/DOS/VS plus 35K for each active task.

The figures can increase if complex applications are executed, or if program functions such as security, edit or user exits are extensively used.

- Direct access storage devices: One IBM direct access storage device as supported by DL/I DOS/VS. In addition, optionally, one or more IBM 3330, IBM 3340, IBM 3350, IBM 3310 or IBM 3370 direct access storage devices for sequential input and output files.
- Unit-record devices: One card read/punch device and one print device as supported by DOS/VS or DOS/VSE.
- Sequential access storage devices: One 9-track tape device for installation and support; and one or more 9-track tape device(s) for optional input and/or output.
- Telecommunication facilities: One IBM 3275 Display Station mdl 2 (with or without RPQ X81191: Arabic Left to Right) or mdl 12, or one IBM 3277 Display Station mdl 2 (with or without RPQ X81191).

The Interactive Personnel System can also be used with the IBM 3274/3276 subsystem in compatibility mode, with or without RPQ 7H0306 (Arabic Display Control).

The system is designed to support additional disk storage, tape units, processor storage and terminals.

SOFTWARE REQUIREMENTS

The system is designed to operate under the Disk Operating System/Virtual Storage (see Note 1).

PROGRAM PRODUCTS

**Interactive Personnel System
CICS/DOS/VS (cont'd)**

The system used the data base facilities of the IBM Data Language/I Disk Operating System/Virtual Storage (see Note 2) and the data communication facilities of the IBM Customer Information Control System/Virtual Storage (see Note 3).

Notes:

1. DOS/VS Release 34 or DOS/VSE Release 1, together with VSE Advanced Functions, Program Number 5746-XE8, Release 1 and VSE/VSAM, Program Number 5746-AM2, Release 1 or subsequent releases unless otherwise identified.
2. DL/I DOS/VS Version 1, Program Number 5746-XX1, Release 1.5 or subsequent releases unless otherwise identified.
3. CICS/VS Version 1, Program Number 5746-XX3, Release 4 or subsequent releases unless otherwise identified.

The IBM Interactive Personnel System is written in the IBM S/370 PL/I language and in the IBM S/370 Assembler language. Supplied user-exit routines are written in the IBM S/370 PL/I language, the IBM S/370 Assembler language or IBM S/370 COBOL.

Both source code and load modules are distributed. Normally, the user will run the load modules as distributed and, therefore, only require the PL/I Optimizing Compiler Transient Library, Program Number 5736-LM5, Release 5.0 or a subsequent release.

In addition, a DOS/VS Sort/Merge program product is required.

Modifications to the source code, including application of source fixes, require the use of either: PL/I Optimising Compiler and Libraries (5736-PL3) or, PL/I Optimising Compiler (5736-PL1) with PL/I Optimising Compiler Resident Library (5736-LM4).

VSE/VSAM RELEASE 1 5746-AM2

PURPOSE

VSE/VSAM is an access method designed to operate with direct access devices and to support both direct and sequential processing by means of either an index key (keyed accessing) or by means of relative byte address (addressed accessing). (Relative byte address refers to the displacement of a stored record, or control interval, from the beginning of the storage space allocated to the file to which it belongs.)

Three types of data sets are provided: key-sequenced data sets, which are ordered by a key field in the data record, entry-sequenced data sets, which are ordered by the sequence in which the records were loaded, and relative record data sets which are ordered by record number. Keyed accessing is used to access key-sequenced or relative record data sets, and addressed accessing is used to access both key-sequenced and entry-sequenced data sets. Key-sequenced and entry-sequenced data sets may be either fixed or variable length records, relative record data sets are fixed length records only.

VSE/VSAM is composed of two major elements: A data organization which minimizes data movement and which is suitable for data base applications; and routines for creating files in the VSAM organization, adding and deleting records and performing other data management functions. (See also "Access Method Services" under System Utility Programs.) Because the data organization and the access method routines are supported for both OS/VS and DOS/VS, VSE/VSAM provides full file portability.

HIGHLIGHTS

- Access to data via VSE/VSAM is controlled by macro instructions written under the conventions of the Assembler language. Access to files may be either direct or sequential, and may either be keyed (controlled by index key) or addressed (controlled by relative byte address).
- With VSE/VSAM, certain device-dependent calculations such as the optimum block size for a given device type will be carried out automatically. All data accessing is by relative byte within the storage space allocated to the file. These features minimize programmer effort when device types are to be changed.
- VSE/VSAM offers the DOS/VSE user the facility of a catalog (which will simplify JCL preparation), variable-length record support and password protection.
- Most existing COBOL, PL/I, RPG II, VS APL and Assembler language programs written for use with ISAM data sets may be used with VSAM data sets by means of the VSAM ISAM Interface Program. The ISAM Interface Program maps ISAM macro instructions into the corresponding VSAM requests. Refer to the "Program Product" pages for details regarding COBOL and PL/I support of VSE/VSAM.
- VSE/VSAM offers a multifunction service program to facilitate overall management of data. Such services as defining files initially, deleting VSAM files from the VSAM catalog, printing and copying data, listing the VSAM catalog and providing backup and portability features are controlled by this multifunction program. Converting files from the ISAM and SAM format to the VSAM format is another important function of this program.
- The VSE/VSAM user can expect to see performance improvements relative to DOS/VS ISAM. Performance gains with VSE/VSAM become increasingly significant as the number of insertions to the file rises. This is due to the elimination of the "chained record overflow" concept employed by ISAM. VSE/VSAM will effectively maintain its sequential, noninserted file performance as records are added to the file. While maintaining equivalent or better performance on direct retrieve and update, VSE/VSAM requires significantly less time to perform a record insert than does ISAM. These factors, coupled with the efficient index structure and with the VSE/VSAM performance options offer the potential of significant performance improvements relative to ISAM.

The functional enhancements inherent to VSE/VSAM (e.g., variable length records, device independence, etc.), and the relative performance improvements over ISAM may require additional pages of main storage.

Some VSE/VSAM performance improvements over DOS/VS ISAM are due to adaptations made to provide DOS/VS relocate support. These adaptations include dynamically allocating input/output areas and modules, having the index in main storage and reducing the usage of transient areas.

- A significant feature of VSE/VSAM is that of file and volume portability. Because the VSAM file organization and the access method routines are supported for both DOS/VS and OS/VS, VSE/VSAM provides full file portability.
- VSE/VSAM offers multiple levels of password protection to enhance file security.

Additional features are available to VSAM users. The primary objective of these features is to provide functions which will reduce the need to schedule redundant work, and improve compatibility with OS/VS by providing the following options:

Alternate Indexes: This feature permits application programs to access the records of a VSAM entry or key sequenced data set on the basis of keys other than the prime key. These alternate keys may be nonunique and must be contained in the base data record. Once an Alternate Index has been constructed by using Access Method Services, it may optionally be automatically updated whenever a data record is changed in the base data set to which it relates.

Relative Record Data Set: With this feature the data set is viewed as a numbered sequence of fixed length slots. Records may be inserted, updated, read or erased in these slots using VSAM keyed processing, with the slot (i.e., record) number as the key. No index is used since each record's physical location is calculated directly by VSAM from its record number and the characteristics of the data set.

Get Previous: This feature permits retrieval and update processing on the basis of descending key values, relative record numbers or relative byte addresses. Processing may begin either within or at the end of the data set.

Reusable Data Set: This capability allows a data set to be reused (i.e., reset to empty when opened and reloaded) many times without being deleted and redefined. A reusable data set may be any key sequenced, entry sequenced or relative record data set that does not have an alternate index associated with it and that does not reside on unique space. However, an alternate index may be a reusable data set.

Spanned Record: The Spanned Record feature allows a record to occupy multiple control intervals within a control area. If indexed, the keys must be in the first control interval.

Recovery: Extensions to the facilities within VSAM Catalog Management and Access Method Services permits limited access, via Access Method Services, to data that is not addressable by the catalog (due to the loss of, or damage to the catalog). Further, the user can restore addressability of the data and reconstruct the associated catalog entries.

User Catalogs: This facility is compatible with the one provided to OS/VS users. It can increase volume portability by allowing user catalogs to control VSAM data sets. A user catalog and its associated data can be moved from one system to another without reading or writing data sets.

Automatic Close at End of Job: This facility is similar to one provided to OS/VS users. It is designed to update the catalog entry and closes all open VSAM data sets within a partition. This helps to ensure that the data sets have been closed properly, whether the end of job was normal or abnormal.

HIGHLIGHTS of VSE/VSAM RELEASE 1

The new fixed block mode 3310 and 3370 DASDs are supported. Externally, the changes are reflected in the use of blocks rather than cylinders and tracks for space allocation.

The new 8809 Magnetic Tape Unit is supported in Access Method Services. (No special actions are taken to exploit the streaming capability of this device.)

The user has the opportunity to choose wither fast catalog access or optimum disk space utilization with a new define catalog parameter. Note that catalog which have been created using disk space optimization cannot be processed by OS/VSAM.

The user may acquire additional information about a catalog's data or index records through an additional operand on the SHOWCAT macro.

VSE/VSAM users can assign any area of direct-access storage devices to special classes of space for subsequent file allocation. This support is particularly useful for controlling high performance areas such as fixed-head areas on the IBM 3340, 3344 and 3350 DASDs.

The automatic correction of a duplicate record situation if a control interval split on a key-sequenced file (including alternate indexes and catalogs) is interrupted by a system failure.

A reduction in the time required to create and reload backup and portable copies of VSE/VSAM files and volumes. This is accomplished through enhanced I/O buffering and, optionally, control-interval-mode data retrieval. Note that portable copies created in CI-mode cannot be processed by OS/VSAM.

A larger set of physical-record sizes, for better use of track capacity, is now available for VSE/VSAM to choose from (only applies to CKD devices). Physical-record sizes now range from 0.5K bytes to 8K bytes in multiples of 0.5K bytes. Note that files residing on volumes which are to be portable to OS/VSAM must use physical record sizes of 0.5K, 1.0K, 2.0K or 4.0K bytes.

PROGRAM PRODUCTS

VSE/VSAM R1 (cont'd)

CUSTOMER RESPONSIBILITIES

It is the responsibility of the customer to specify the VSE/VSAM specific considerations when coding DOS/VSE supervisor generation macros. The user must provide sufficient real and virtual storage to execute VSE/VSAM. These requirements are detailed in the *VSE/VSAM Programmer's Reference* (SC24-5145).

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

VSE/VSAM will operate on any IBM system supported by DOS/VSE.

The IBM count-key-data direct access storage devices supported by VSE/VSAM are the 2314 Direct Access Storage Facility, the 2319 Disk Storage, the 3330 Disk Storage mdls 1 and 2, the 3330 Disk Storage mdl 11, the 3340 Disk Storage, the 3344 Direct Access Storage and the 3350 Direct Access Storage.

In addition, VSE/VSAM supports the fixed blocked mode IBM 3310 and 3370 Direct Access Storage Devices and the IBM 8809 Magnetic Tape Unit.

SOFTWARE REQUIREMENTS

VSE/VSAM Release 1 is designed to operate with VSE/Advanced Functions Release 1.

In addition VSE/VSAM Release 1 will run with CMS/DOS BSEP Release 2 in support of VM/IFS and DL/I DOS/VS. For the CMS/DOS user the VSE/Advanced Functions Release 1 is not required.

Service Requirements: Under certain error conditions VSE/VSAM customers will need additional tools (DITTO or equivalent products) to provide printouts from DASD areas for problem determination.

COMPATIBILITY

VSE/VSAM Release 1 provides current users of VSAM several new enhancements that may or may not affect portability to OS/VSAM and DOS/VSAM. Users of VSE/VSAM can achieve file and volume portability to other environments by using only those functions, types of files, and devices that are supported by all affected environments. Additionally, the VSE/VSAM user must in certain cases specify new parameters in order to produce compatible output for all environments. Additional information on items which affect portability can be found in the Sales Pages and the *General Information Manual*.

PERFORMANCE CONSIDERATIONS

VSE/VSAM provides various options to optimize performance and storage requirements. These options are specified through Access Method Services Commands. Some of the options that affect performance are the Control Interval size, I/O Buffer Space, Distributed Free Space, Preformatting Control Areas, various Index Options and Key Ranges.

VSE/VSAM keeps statistical information about a file in its catalog record which can help in deciding when to take action to improve performance.

The overall performance of VSE/VSAM will not change measurably except in those areas where special actions have been taken to improve the performance over that of the previous DOS/VS SCP versions of VSAM and Access Method Services. For details refer to the *General Information Manual of VSE/VSAM*.

**VSE/VSAM RELEASE 2 WITH
VSE/VSAM SPACE MANAGEMENT
FOR SAM FEATURE
5746-AM2**

VSE/VSAM is an access method designed to operate with direct access devices and to support both direct and sequential processing by means of either an index key (keyed accessing) or by means of relative byte address (addressed accessing). (Relative byte address refers to the displacement of a stored record, or control interval, from the beginning of the storage space allocated to the file to which it belongs.)

Three types of data sets are provided: Key-sequenced data sets, which are ordered by a key field in the data record, entry-sequenced data sets, which are ordered by the sequence in which the records were loaded, and relative record data sets which are ordered by record number. Keyed accessing is used to access key-sequenced or relative record data sets, and addressed accessing is used to access both key-sequenced and entry-sequenced data sets. Key-sequenced and entry-sequenced data sets may be either fixed or variable length records, relative record data sets are fixed length records only.

VSE/VSAM is composed of two major elements: A data organization which minimizes data movement and which is suitable for data base applications; and routines for creating files in the VSAM organization, adding and deleting records and performing other data management functions. (See also "Access Method Services" under System Utility Programs.) Because the VSAM data organization and the access method routines are supported for both OS/VS and DOS/VS, VSE/VSAM provides full file portability.

Highlights

- Access to data via VSE/VSAM is controlled by macro instructions written under the conventions of the Assembler language. Access to files may be either direct or sequential, and may either be keyed (controlled by index key) or addressed (controlled by relative byte address).
- With VSE/VSAM, certain device-dependent calculations such as the optimum block size for a given device type will be carried out automatically. All data accessing is by relative byte within the storage space allocated to the file. These features minimize programmer effort when changing device types.
- VSE/VSAM offers the DOS/VSE user the facility of a catalog (which will simplify JCL preparation), variable-length record support and password protection.
- Most existing COBOL, PL/I, RPG II, VS APL and Assembler language programs written for use with ISAM data sets may be used with VSAM data sets by means of the VSAM ISAM Interface Program. The ISAM Interface Program maps ISAM macro instructions into the corresponding VSAM requests. Refer to the "Program Product" pages for details regarding COBOL and PL/I support of VSE/VSAM.
- VSE/VSAM offers a multifunction service program to facilitate overall management of data. Such services as defining files initially, deleting VSAM files from the VSAM catalog, printing and copying data, listing the VSAM catalog and providing backup and portability features are controlled by this multifunction program. Converting files from the ISAM and SAM format to the VSAM format is another important function of this program.
- The VSE/VSAM user can expect to see performance improvements relative to DOS/VS ISAM. Performance gains with VSAM become increasingly significant as the number of insertions to the file rises. This is due to the elimination of the "chained record overflow" concept employed by ISAM. VSE/VSAM will effectively maintain its sequential, noninserted file performance as records are added to the file. While maintaining equivalent or better performance on direct retrieve and update, VSE/VSAM requires significantly less time to perform a record insert than does ISAM. These factors, coupled with the efficient index structure and with the VSE/VSAM performance options offer the potential of significant performance improvements relative to ISAM.

The functional enhancements inherent to VSE/VSAM (variable length records, device independence, etc.), and the relative performance improvements over ISAM may require additional pages of main storage.

Some VSE/VSAM performance improvements over DOS/VS ISAM are due to adaptations made to provide DOS/VS relocate support. These adaptations include dynamically allocating input/output areas and modules, having the index in main storage and reducing the usage of transient areas.

- A significant feature of VSE/VSAM is that of file and volume portability. Because the VSAM file organization and the access method routines are supported for both DOS/VS and OS/VS, VSE/VSAM provides full file portability.
- VSE/VSAM offers multiple levels of password protection.

Additional features are available to VSE/VSAM users. The primary objective of these features is to provide functions which will reduce the

need to schedule redundant work, and improve compatibility with OS/VS by providing the following options:

Alternate Indexes: This feature permits application programs to access the records of a VSAM entry or key sequenced data set on the basis of keys other than the prime key. These alternate keys may be nonunique and must be contained in the base data record. Once an Alternate Index has been constructed by using Access Method Services, it may optionally be automatically updated whenever a data record is changed in the base data set to which it relates.

Relative Record Data Set: With this feature the data set is viewed as a numbered sequence of fixed length slots. Records may be inserted, updated, read or erased in these slots using VSAM keyed processing, with the slot (i.e., record) number as the key. No index is used since each record's physical location is calculated directly by VSAM from its record number and the characteristics of the data set.

Get Previous: This feature permits retrieval and update processing on the basis of descending key values, relative record numbers or relative byte addresses. Processing may begin either within or at the end of the data set.

Reusable Data Set: This capability allows a data set to be reused (i.e., reset to empty when opened and reloaded) many times without being deleted and redefined. A reusable data set may be any key sequenced, entry sequenced or relative record data set that does not have an alternate index associated with it and that does not reside on unique space. However, an alternate index may be a reusable data set.

Spanned Record: The Spanned Record feature allows a record to occupy multiple control intervals within a control area. If indexed, the keys must be in the first control interval.

Recovery: Extensions to the facilities within VSAM Catalog Management and Access Method Services permits limited access, via Access Method Services, to data that is not addressable by the catalog (due to the loss of, or damage to the catalog). Further, the user can restore addressability of the data and reconstruct the associated catalog entries.

User Catalogs: This facility is compatible with the one provided to OS/VS users. It can increase volume portability by allowing user catalogs to control VSAM data sets. A user catalog and its associated data can be moved from one system to another without reading or writing data sets.

Automatic Close at End of Job: This facility is similar to one provided to OS/VS users. It is designed to update the catalog entry and closes all open VSAM data sets within a partition. This helps to ensure that the data sets have been closed properly, whether the end of job was normal or abnormal.

Highlights of VSE/VSAM Release 2

- Support is provided to allow VSE/VSAM catalogs and files to be maintained on DASD volumes which are shared between DOS/VSE systems with VSE/Advanced Functions Release 2 installed.
- Performance of requests to Catalog Management has been improved by altering the scanning algorithm and reducing the number of dictionary scans.
- SHAREOPTION 4 (full cross-partition sharing) has been improved by reducing overhead in the main-line paths.
- Automatic correction will be provided if duplicate record condition is caused by a system failure during a control area split.
- A new Access Method Services CANCEL command will be provided to give the user the ability to either cancel a job or the current job step.
- VSE/VSAM Space Management enhancements are provided to significantly improve DASD space management and usability. Support provided:
 - The ability to easily specify that the entire space or remaining space of a volume is to be owned by VSAM.
 - The ability to define a file in the VSAM catalog without allocating any space to it.
 - The elimination of the necessity to provide EXTENT JCL statements in most cases and the DLBL statement for some Access Method Services commands.
 - The ability to specify default parameters for Access Method Services DEFINE CLUSTER/AIX commands via default modelling.
 - The ability to specify a file-ID that generates partition or processor unique file-IDs for workfiles so that JCL may run in any partition or any processor.

VSE/VSAM R2 (cont'd)

HIGHLIGHTS of VSE/VSAM SPACE MANAGEMENT for SAM

Provided is the capability for the sequential access method (SAM) user to define and process a SAM file within VSAM data space giving automatic space management of the file. This support includes VSAM data spaces and all direct access devices that are supported by VSE/VSAM. It supports users of DTFSD (data and workfiles), DTFCP with DISK=YES, and DTFPH for DASD with MOUNTED = SINGLE. In addition, the user has the ability to access these files via VSAM access.

Through the use of VSE/VSAM Space Management, the SAM user can now place many details of space management responsibility on the system. By introducing space (ideally entire volumes) to VSE/VSAM, the user may leave the space management of that space (volume) to VSE/VSAM. If necessary the user may still subdivide the managed space through the use of VSE/VSAM space classes.

Note that SAM files in VSAM space are not supported by OS/VSAM.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

VSE/VSAM will operate on any IBM system supported by DOS/VSE.

The count-key-data direct access storage devices supported by VSE/VSAM are the IBM 2314 Direct Access Storage Facility, 2319 Disk Storage, 3330 Disk Storage mdls 1, 2, 3330 Disk Storage mdl 11, 3340 Disk Storage, 3344 Direct Access Storage, 3375 Direct Access Storage mdls A1, B1 and 3350 Direct Access Storage.

In addition, VSE/VSAM supports the fixed blocked mode IBM 3310 and 3370 Direct Access Storage Devices and the IBM 8809 Magnetic Tape Unit.

SOFTWARE REQUIREMENTS

The VSE/VSAM Release 2 is designed to operate with VSE/Advanced Functions Release 2.

For the VM/CMS user of VSE/VSAM Rel. 2, the VSE/Advanced Functions Rel.2 is required.

Service Requirements: Under certain error conditions VSE/VSAM customers will need additional tools (DITTO or equivalent products) to provide print-outs from DASD areas for problem determination.

COMPATIBILITY

VSE/VSAM Release 2 provides several new enhancements that may or may not affect portability to OS/VSAM and DOS/VSAM. Users of VSE/VSAM Release 2 can achieve file and volume portability to the other environments by using only those functions, types of files and devices that are supported by all affected environments. Additionally, the VSE/VSAM user must in certain cases, specify new VSE/VSAM parameters in order to produce compatible output for all environments. Additional information on items which affect portability can be found in the Sales pages and the *General Information Manual*.

PERFORMANCE CONSIDERATIONS

VSE/VSAM provides various options to optimize performance and storage requirements. These options are specified through Access Method Services Commands. Some of the options that affect performance are the Control Interval size, I/O Buffer Space, Distributed Free Space, Performing Control Areas, various Index Options and Key Ranges.

VSE/VSAM keeps statistical information about a file in its catalog record which can help in deciding when to take action to improve performance.

The overall performance of VSE/VSAM Release 2 will not change measurably except in those areas where special actions have been taken to improve the performance over that of VSE/VSAM Release 1. Additional information is provided in the *General Information Manual of VSE/VSAM Release 2*.

VSE/VSAM BACKUP/RESTORE FEATURE

The VSE/VSAM BACKUP/RESTORE Feature of VSE/VSAM Release 2 provides backup onto tape and restore from tape with high performance and low processor utilization. The VSE/VSAM BACKUP/RESTORE Feature is especially geared to the streaming mode of the 8809 tape drive.

Highlights

- Backup onto tape and restore from tape for the following VSAM objects:
 - Key-sequenced data sets (KSDS).
 - Entry-sequenced data sets (ESDS).
 - Relative-record data sets (RRDS).
 - Alternate Indexes (AIX).
 - SAM files in VSAM space in CI format (SAM ESDS).
- BACKUP will allow multiple VSAM objects to be backed up with a single command.

- For backup, the user can specify a generic name that identifies a group of related VSAM objects rather than the individual entry names for each of those objects.
- BACKUP provides the facility to backup all VSAM objects owned by a catalog with one single command.
- VSAM objects can be excluded from a generic backup.
- RESTORE allows multiple VSAM objects to be restored with a single command.
- For RESTORE, the user can specify a generic name that identifies a group of related VSAM objects, which he wants to be restored from a given backup file.
- VSAM objects can be excluded from a generic RESTORE.
- Interspersed, unwanted VSAM objects of a backup file can be skipped.
- VSAM objects can be restored to volumes different from the ones they have been backed up from as long as the device type remains the same.
- VSAM objects can be restored to different locations than they originally occupied on a volume.
- Volumes of the backup file can be selectively and randomly mounted during restoration in order to avoid unnecessary mounting of unused volumes.
- The size and the number of buffers for reading and writing determine the performance of the BACKUP/RESTORE function. The user can specify the size of the buffers in the BACKUP command and the number of buffers in both the BACKUP and the RESTORE command. In addition, he can request via Job Control whether or not the buffers should be fixed.
- The number of parameters to be specified on the BACKUP and RESTORE commands have been considerably reduced compared to the EXPORT/IMPORT commands. All but one of the remaining parameters (entry-name/*) are optional.

CUSTOMER RESPONSIBILITIES

It is the responsibility of the customer to provide sufficient real and virtual storage to execute VSE/VSAM and the VSE/VSAM BACKUP/RESTORE Feature. Storage requirements are detailed in the *VSE/VSAM Programmer's Reference* (SC24-5145).

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

VSE/VSAM BACKUP/RESTORE will run on any IBM hardware configuration supported by VSE/VSAM Release 2 with the exception of tape-less systems. In particular, the IBM 8809 tape drive will be supported in both start-stop mode and streaming mode.

SOFTWARE REQUIREMENTS

VSE/VSAM BACKUP/RESTORE is a feature of VSE/VSAM Release 2 and operates with VSE/Advanced Functions Release 2 and DOS/VSE.

COMPATIBILITY

The tape format produced by BACKUP and required by RESTORE is different from the format of the portable files produced by the Access Method Services EXPORT/EXPORTA commands of VSE/VSAM as well as OS/VSAM. As a consequence, portable files created by an EXPORT command cannot be processed by RESTORE nor can backup files created by BACKUP be processed by IMPORT. In other words, the RESTORE command is the only correct counterpart to the BACKUP command.

VSAM files created by VSE/VSAM can be backed up and restored without restrictions. VSAM files created by OS/VS or by DOS/VS VSAM releases prior to VSE/VSAM Release 1 cannot always be backed up and restored because of the new physical record size support available with VSE/VSAM Release 1.

PERFORMANCE

The VSE/VSAM BACKUP/RESTORE feature of VSE/VSAM Release 2 is designed to support the streaming mode of the 8809 tape drive. Streaming of the 8809 will occur within each data set extent (i.e., within each primary or secondary allocation) under the following conditions:

- 4331 processor
- 3310 DASD
- 8809 long gap, high speed
- Single batch
- 2 buffers (3 buffers for KSDS (NOIMBED))
- Buffer size 8K

The processor utilization for BACKUP/RESTORE in the case described above will not exceed 30%.

VSE/VSAM General Information	GC24-5143

TERMS AND CONDITIONS: See PP Index

PROGRAM PRODUCTS

**VSE/VSAM RELEASE 2 BACKUP/RESTORE FEATURE
5746-AM2**

PURPOSE

VSE/VSAM Backup/Restore Feature Release 2 offers enhancements to the support provided in the initial release. Files and their related catalog information, including empty objects, may be restored to a different device type. Additionally, the 3375 Direct Access Storage is supported for all operations.

HIGHLIGHTS

- Backup with DASD device-independent information.
- RESTORE to a device type different from that used for BACKUP.
- Modification at restoration.
- VSE/VSAM empty object support.
- Support for the 3375 Direct Access Storage.

CUSTOMER RESPONSIBILITIES

It is the responsibility of the customer to provide sufficient real and virtual storage to execute VSE/VSAM and the VSE/VSAM Backup/Restore feature. Storage requirements are detailed in *Using the VSE/VSAM Backup/Restore Feature*, SC24-5216.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

VSE/VSAM Backup/Restore will run on any hardware configuration specified by IBM as supported by VSE/VSAM Release 2 with the exception of tapeless systems.

SOFTWARE REQUIREMENTS

VSE/VSAM Backup/Restore is a feature of VSE/VSAM Release 2 and operates with DOS/VSE and VSE/Advanced Functions Release 2 or 3. Prerequisites for the 3375 support in VSE/VSAM Backup/Restore Feature Release 2 is the 3375 support in VSE/VSAM and VSE/Advanced Functions.

COMPATIBILITY

BACKUP produces the tape format required by RESTORE. This tape format is not compatible with the format produced by the Access Method Services EXPORT/EXPORTA commands of VSE/VSAM and OS/VSAM.

Files backed up under VSE/VSAM Backup/Restore Feature Release 1 can be restored by VSE/VSAM Backup/Restore Feature Release 2. Backup files created under Backup/Restore Release 2 can, as long as they do not contain empty objects, be restored by Backup/Restore Release 1. For details on compatibility with the previous release and compatibility with OS/VSAM, refer to *Using the VSE/VSAM Backup/Restore Feature*, SC24-5216.

PERFORMANCE CONSIDERATIONS

The enhancements to Backup/Restore will not adversely affect performance of current functions on a file basis.

A backup or restore may take longer if the catalog is used to manage a significant number of empty objects.

Restoration to a different device type will require additional processing, so that the program's ability to maintain streaming on the 8809 Tape Unit is affected. Using this function of Backup/Restore Release 2, a performance degradation can be expected compared to Backup/Restore Release 1. The actual degradation will depend on device geometry, control area size, and the number of CI splits and record deletions that have occurred in the file.

PROGRAM PRODUCTS

**VSE/VSAM RELEASE 3
5746-AM2****PURPOSE**

VSE/VSAM Release 3 provides significant enhancements designed to improve catalog reliability and integrity while providing additional serviceability and usability.

HIGHLIGHTS

- Restructuring of catalog define processing to define exposure if an interruption occurs

VSE/VSAM also reinitializes a broken free chain (list of available catalog records) and processes it. Formerly a broken free chain could cause a damaged catalog, requiring problem diagnosis and catalog repair.

- Enhanced VERIFY processing and support of Share Option 4

Enhancements have been made to VERIFY processing to reset all catalog fields that may have changed, including support for Share Option 4 files.

- Automatic invocation of VERIFY by OPEN

When a file is opened, OPEN determines whether the file was previously opened for output and not closed. If this is the case, OPEN calls VERIFY to check catalog records and update them when necessary. Formerly it was your responsibility to diagnose the error, issue the VERIFY command, and rerun the job. *Note:* Automatic verification does not occur for ESDSs being opened for CI access, for non CI-format SAM ESDSs, or for files that were interrupted during initial loading in SPEED mode.

- Catalog integrity checks added to VERIFY

You are now assured that correct catalog information exists for any file you open that was not closed on a previous open for output.

- DELETE enhancements allow removal of an incompletely defined file from the catalog

The new IGNOREERROR parameter for the DELETE command permits the deletion of incomplete catalog information, which could have resulted from a system catalog failure during DEFINE or DELETE processing. Previously, it was not permitted to define or delete a file if partial catalog information existed for it.

- A new Catalog Check Service Aid is available to validity check the catalog

This new service aid is invoked:

- By VSAM OPEN (after the automatic VERIFY described above) to validity check individual files.
- By DELETE IGNOREERROR processing which validity checks the entire catalog.

You can also invoke this service directly to verify the entire catalog structure.

By early identification of possible catalog errors, this service aid helps to prevent the propagation of such errors into other catalog records. Error messages identify a variety of catalog errors and assist in recovery.

If you invoke this service aid directly, the new PARM support lets you specify on the EXEC statement that the name and password of the catalog to be checked. Catalog job control statements and an operator response are not required.

- Multiple catalogs can own space on the same non-recoverable DASD volume

Multiple catalogs can now own space on the same DASD volume, as long as only one recoverable catalog owns space on that volume and only one catalog resides on that volume.

- VSE/VSAM components will invoke the system IDUMP facility when specific logical errors are encountered

VSE/VSAM will invoke the system IDUMP when specific internal logic errors are encountered and pass back information for diagnostic use.

- Access Method Services PARM command function is supported through the PARM parameter on the EXEC job control statement
- Ability to syntax check Access Method Services commands without executing the commands or modifying data

The SYNCHK keyword used in the PARM parameter of the EXEC job control statement permits you to verify the syntax of Access Method Services commands without actually executing them or modifying any data. Syntax checking permits faster identification of syntax errors and protects data from being modified by commands that execute improperly. You can check command syntax without having any VSE/VSAM catalogs or files mounted.

CUSTOMER RESPONSIBILITIES

The customer is responsible for specifying the VSE/Advanced Functions supervisor generation macros parameters that are appropriate for VSE/VSAM. The user must provide sufficient real and virtual storage to execute VSE/VSAM. These requirements are detailed in the *VSE/VSAM Programmer's Reference* (SC24-5145).

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

VSE/VSAM Release 3 is designed to operate on any IBM system supported by DOS/VSE and VSE/Advanced Functions Release 3.

The count-key-data direct access storage devices supported by VSE/VSAM are the IBM 2314 Direct Access Storage Facility, 2319 Disk Storage, 3330 Disk Storage mdls 1, 2 and 11, 3340 Disk Storage, 3344 Direct Access Storage, 3350 Direct Access Storage and the 3375 Direct Access Storage mdls A1 and B1.

In addition, VSE/VSAM supports the fixed blocked mode IBM 3310 and 3370 Direct Access Storage Devices.

The IBM 8809 tape drive is supported in addition to the IBM 2400 and 3400 series tape drives.

SOFTWARE REQUIREMENTS

VSE/VSAM Release 3 is designed to operate with DOS/VSE and VSE/Advanced Functions Release 3. For 3375 support, VSE/VSAM requires the VSE/Advanced Functions Release 3 functional PTF for 3375 or equivalent.

COMPATIBILITY

Files, catalogs, Access Method Services jobstreams and VSE/VSAM user programs created under prior releases of VSE/VSAM can be used under VSE/VSAM Release 3. Files, catalogs, Access Method Services jobstreams, and VSE/VSAM user programs created under VSE/VSAM Release 3 and not containing or utilizing new external functions can be processed on previous releases of VSE/VSAM. Access Method Services commands written for VSE should be compatible with OS/VSAM as long as no VSE-specific functions are used. Additional information on compatibility items is contained in the *VSE/VSAM General Information Manual* (GC24-5143).

The VSE/VSAM Space Management for SAM feature and the VSE/VSAM Backup/Restore Feature Release 2 are supported for use with VSE/VSAM Release 3.

PERFORMANCE CONSIDERATIONS

VSE/VSAM provides various options to optimize performance and storage requirements. These options are specified through Access Method Services commands. Some of the options that affect performance are the control interval size, I/O buffer space, distributed free space, preformatting control areas, various index options, and key ranges.

VSE/VSAM keeps statistical information about a file in its catalog record which can help in deciding when to take action to improve performance.

The overall performance of Release 3 compared to VSE/VSAM Release 2 will not change significantly except in areas where implicit validity checks are taken to ensure catalog integrity.

PROGRAM PRODUCTS

**VSE/IBM SYSTEM/3-3340 DATA IMPORT
RELEASE 1 (5746-AM3)**

PURPOSE

The VSE/IBM S/3 - 3340 Data Import to DOS/VSE is a utility program that assists the user in converting S/3 3348 files into DOS/VSE SAM or VSE/VSAM files. The VSE/IBM S/3 - 3340 Data Import Release 1 runs as a problem program under control of DOS/VSE with VSE/Advanced Functions and requires a minimum of 256K bytes of storage in a virtual partition. This program requires the 3340/3344 Direct Attachment feature #7851 on an IBM 4331 Processor. The VSE/IBM S/3 - 3340 Data Import Release 1 Program executes on any 4331 Processor supported by DOS/VSE with VSE/Advanced Functions.

HIGHLIGHTS

VSE/IBM S/3 - 3340 Data Import Release 1 is designed to convert S/3 files located on the main data area of a 3348 data module into DOS/VSE SAM or VSE/VSAM files.

Multi-Volume and Multi-Version (Generation Data Set) files can be converted. DOS/VSE naming conventions must be applied to Multi-Version files.

One or more files can be converted by one single run of this program.

The following figure illustrates the conversions supported by this program:

S/3 File Type	DOS/VSE File Type
Sequential Direct (Note 2)	SAM, VSE/VSAM ESDS or RRDS (Note 1)
Indexed Ordered or Unordered	VSE/VSAM KSDS (Note 1)
Indexed Unordered	VSE/VSAM ESDS (Note 3)

Note 1: Other VSE/VSAM file types possible, if advisable by record format and applications.

Note 2: Handled as sequential file.

Note 3: To get indexed capability, a secondary index must be built using the BLDINDEX function of VSE/VSAM.

Operating messages are provided for volume mounting. Program messages are supplied to provide a log about the conversions executed as well as error information.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

This program requires the IBM 3330/3340 Direct Attachment Feature #7851 on an IBM 4331 Processor. The storage requirement is 256K bytes in a virtual partition size of DOS/VSE.

Output device can be one of the following disks attached to a 4331 Processor:

- 3310, in native mode or emulating a 2314
- 3340

One printer and the operator console are required in addition.

SOFTWARE REQUIREMENTS

VSE/IBM S/3 - 3340 Data Import is designed to operate with VSE/Advanced Functions. VSE/VSAM is needed as well, since the output is performed via the VSE/VSAM REPRO function. The user of the VSE/IBM S/3 - 3340 Data Import utility is not concerned with loading and calling of VSE/VSAM. The REPRO function of VSE/VSAM is called automatically by the VSE/IBM System/3 - 3340 Data Import utility via the interface described in *VSE/VSAM: Using VSE/VSAM Commands and Macros (SC24-5144)*.

The input device must be known to DOS/VSE as a 3340 and assigned to SYS004.

COMPATIBILITY

Data sets produced by this program are fully compatible with DOS/VSE Sequential Access Method (SAM) and VSE/VSAM data sets. Input files must have been created by IBM S/3 Data Management.

| Licensed Program Specifications | GC33-6062 |

**VSE/FAST COPY DATA SET PROGRAM
RELEASE 1 (5746-AM4)****PURPOSE**

VSE/Fast Copy Data Set Program Release 1 is an enhanced version of the Fast Copy Disk Utility contained in DOS/VSE providing additional functions and improved performance.

VSE/Fast Copy Data Set Program Release 1 executes in the minimum virtual partition of VSE/Advanced Functions Release 2. The VSE/Fast Copy Data Set Program Release 1 is designed to operate with VSE/Advanced Functions Release 2 and executes on any configuration supported by this operating system.

HIGHLIGHTS

- Full Track Read for CKD Devices.

The Fast Copy Disk Utility has been upgraded to use the 'Read Multiple CKD' command for all devices/control units that accept this command. This may increase the performance of the utility significantly when backing up volumes.

- Copy/Restore Files with Relocation.

This function enables the user to copy or restore individual SAM files from disk to disk or restore from tape to disk to the same or different physical location.

- Partial Volume Dump/Copy.

This function enables the user to dump/copy groups of files.

Example: Copy all files of a volume with the exception of file A and file B.

The objective of this feature is a performance improvement of the volume function by avoiding the processing of unimportant files.

- NOREWIND-Option for Dump to Tape.

This function gives the ability to write 'Dump Files' consecutively on a tape. This is a prerequisite for an efficient dumping of several files onto a single tape.

- Multivolume File Copy/Dump/Restore.

With this function a single file (specified via DLBL/EXTENT) which spans several volumes (Multivolume File) may be dumped to one 'File Dump' or may be copied to one or several volumes of the same device type. Accordingly this 'File Dump' may be restored to one or several volumes.

- Selective Restore of Files from a Volume Dump.

The selective restore function allows the user to restore an individual file from a volume dump on tape (or disk).

The following example will clarify the capability of this function.

Assumption: - A complete 3350 disk pack containing 50 files has been dumped to tape.
 - During processing file 36 has been destroyed.

Action: - When restoring, this function will automatically search for file 36 on tape and restore only this file, thus maintaining the integrity of the other files.

This function is important for a nonremovable DASD-environment.

Access Methods Support

- Volume and partial volume support is access method independent.
- Single or multi volume files without relocation support SAM, DAM and ISAM.
- Single file with relocation supports SAM only.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

There are no additional hardware requirements other than those which exist for the host operating system. All DASD and tape devices supported by DOS/VSE are supported by the VSE/Fast Copy Data Set Program.

SOFTWARE REQUIREMENTS

The VSE/Fast Copy Data Set Program Release 1 executes in the minimum virtual partition of VSE/Advanced Functions Release 2. Executing the program in REAL-mode will improve the performance. The VSE/Fast Copy Data Set Program Release 1 is designed to operate with VSE/Advanced Functions Release 2.

COMPATIBILITY

The VSE/Fast Copy Data Set Program Release 1 can process dump files that were created by the corresponding DOS/VSE utility programs. The user can selectively restore from a volume dump file produced by the Fast Copy Disk Utility contained in DOS/VSE, and relocate SAM files contained in DOS/VSE dump datasets.

The program can process a tape that was produced by the Fast Copy Disk Volume utility from DOS/VS Release 34 or earlier. Such a tape can, however, only be used for the restore volume function.

The standalone support is identical with the DOS/VSE standalone Fast Copy Disk utility; in addition, the standalone Fast Copy Disk can restore a Partial Volume Dump.

PERFORMANCE CONSIDERATIONS

The new functions allow a reduction of the backup and restore times. The actual throughput improvement depends on how much from a volume was selected for the backup and how the block size varies. A throughput improvement of up to a factor of 2 can be expected if the blocksize or the number of blocks per track varies from track to track.

DOCUMENTATION

(available from Mechanicsburg)

General Information Manual (GC33-6081).

PROGRAM PRODUCTS

**VSE/FAST COPY DATA SET PROGRAM
RELEASE 2 Modification Level 0
5746-AM4****PURPOSE**

VSE/Fast Copy Version 1, Release 2, Modification Level 0 (V1.2.0) is an enhanced version of the VSE/Fast Copy Data Set Program Version 1.1 providing improved performance.

The enhancement is a new multi-buffering concept developed in order to provide streaming for the 8809 Tape Unit in most instances where alternate blocks are assigned or temporary read errors occur.

VSE/Fast Copy V1.2.0 is designed to operate with:

VSE/Advanced Functions Version 1, Release 3, Modification Level 5, and VSE/SP Version 1, Release 1, Modification Level 0

and executes on any configuration which they support. VSE/Fast Copy V1.2.0 requires a minimum virtual partition size of 148K bytes for FBA disks. The minimum virtual partition size required for CKD devices depends on the CKD device type.

HIGHLIGHTS

The new VSE Fast Copy V1.2.0 I/O Buffering Technique is designed to improve the performance of Fast Copy when dumping/restoring FBA disks to/from the 8809, compared to the current VSE Fast Copy Data Set Program Version 1 Release 1 when copying FBA disks with alternate block assignments or with temporary read errors.

VSE/Fast Copy V1.2.0 implements a multi-buffering concept for DUMP and RESTORE functions (no reorganization) to smooth the I/O-caused delays. A variable number of buffers (2 up to 24 - 16K bytes each) will be used depending on the free space available in the partition. A message informs the user of the actual number of buffers used for running the Fast Copy job.

VSE/Fast Copy V1.2.0 will also process tapes written with Release 1 in the double-buffering mode. Tapes for DUMP ALL/VOLUME and RESTORE ALL/VOLUME functions are compatible with the stand-alone version of Fast Copy included in VSE/Advanced Functions 1.3.5.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

VSE/Fast Copy Version 1, Release 2, Modification Level 0 will run on any IBM S/370, 303X and 4300 System supported by VSE/Advanced Functions Version 1, Release 3, Modification Level 5, and VSE/SP Version 1, Release 1, Modification Level 0. All DASD and tape devices supported in the DOS/VSE environments are supported by VSE/Fast Copy V1.2.0. There are no additional hardware requirements other than those specified for the above mentioned operating systems.

SOFTWARE REQUIREMENTS

VSE/Fast Copy V1.2.0 is designed to operate with either:

VSE/Advanced Functions Version 1, Release 3, Modification Level 5, or VSE/SP Version 1, Release 1, Modification Level 0.

When CKD disks are used, VSE/Fast Copy V1.2.0 operates in the minimum virtual partition of its operating system with two exceptions: The IBM 3350 requires 138K bytes and the IBM 3375 requires 184K bytes.

Working with FBA disks, the program requires for DUMP/RESTORE at least a virtual partition size of 148K bytes (including the minimum number of 2 buffers and GETVIS space). The multi-buffering mode is prompted by granting additional 16K bytes for each additional buffer up to a highest number of 24 buffers (reached at 500K bytes). The number of buffers used in the multi-buffering mode for FBA DUMP/RESTORE is controlled by selection of the partition size. Working with an intermediate data set on disk and executing the copy function will only require 2 buffers.

COMPATIBILITY

VSE/Fast Copy V1.2.0 can process tapes which have been created by Release 1 Fast Copy, with the stand-alone version of Fast Copy included in VSE/Advanced Functions Releases 1 to 3, and with the Fast Copy Disk Volume Utility from DOS/VS Release 34 or earlier.

These tapes are only processed in double-buffering mode. Tapes which have been created by Release 2 are also accepted by Release 1. Tapes written with VSE/Fast Copy V1.2.0 using the DUMP ALL or DUMP VOLUME function, can be restored with the VSE/Advanced Functions 1.3.5 Fast Copy Stand-Alone Utility in multi-buffering mode and vice versa.

PERFORMANCE CONSIDERATIONS

The VSE Fast Copy Data Set Program Version 1 Release 1 copying FBA disks (with alternate block assignments or with temporary read errors) to or from tape might show reduced performance compared to situations where it works with FBA disks without alternate block assignments or without temporary read errors. The performance degradation becomes apparent in particular if 8809 Tape Units are used. Because I/O time needed for the disk is then extended, the 8809

tape might lose its streaming capability if only two alternate buffers handle the data.

The new VSE Fast Copy V1.2.0 I/O Buffering Technique is designed to improve the performance of Fast Copy when dumping/restoring FBA disks to/from 8809. The performance improvements are quantified below.

- a. VSE Fast Copy V1.2.0 executing on a dedicated 4321 or faster CPU using at least four 16K byte I/O buffers will dump and restore (note 1) FBA disk packs to or from an 8809 at the 8809 streaming data rate (143K bytes-per-second with no media change).

This statement applies to a normal FBA disk drive. In case of high numbers of alternate block assignments or with temporary read errors, 8809 'backhitching' might still occur. Using as many 16K-byte I/O buffers as available might prevent 'backhitching' even in this case.

- b. These statements assume that the I/O buffers are not subject to paging.

Note 1: 'Restore' without 'Write Verification' (NOVERIFY).

DOCUMENTATION

(available from Mechanicsburg)

Licensed Program Specifications (GC33-6080) ... Program Summary (GC33-6158).

RPQs ACCEPTED: No

PROGRAM PRODUCTS

**VSE/3270 BISYNC PASS-THROUGH
5746-AM5****PURPOSE**

VSE/3270 Bisync Pass-Through allows a 4300, S/370 or 3031 Processor running under DOS/VSE to appear as a remotely-attached BSC 3271 control unit to an S/370, a 303X Processor or another 4300 Processor. 3270-type displays attached to the remote processor may alternately access local CICS/VS applications within it or new or currently existing applications on the remote host processor over a binary synchronous communications link.

HIGHLIGHTS

- Interactive host-connect capability to remote host applications or subsystems using ACF/VTAM, ACF/VTAME, ACF/TCAM, VTAM, TCAM, BTAM-ES or BTAM that support a remote BSC 3270-type display in today's environment.
- Terminal sharing between CICS/VS local and remote host applications. No modifications are required to application programs running on the host.
- Supports up to 32 IBM 3270-type displays and/or printers assigned to a simulated control unit of the Bisync Pass-Through Program. Terminals are controlled by CICS/VS and may be directly attached to the IBM 4331 Processor via the Display/Printer Adapter or locally or remotely attached to any supported processor via a local control unit or via BSC or SDIC lines.
- Customer paced migration. IBM 4300 Processors may be installed in a distributed environment with ACF/VTAME or ACF/VTAM Release 2 and host-connect to current host applications that may be under VTAM, TCAM, BTAM or ACF Products without MSNF. For full networking, host applications may then be migrated to ACF products with the Multisystems Networking Feature.

CUSTOMER RESPONSIBILITIES

The installation of Bisync Pass-Through will require initial planning by the customer to understand the environment in which Bisync Pass-Through will be installed plus the host access methods and subsystems that require host-connection. The next consideration is the number and type of terminals to use Bisync Pass-Through and whether hardwired addresses are required. At this time the customer may have to order local control units for the remote IBM 4300 Processor.

The customer is also responsible for installing an interface to the supplied user exit in order to audit user access to the Bisync Pass Through Program if required.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

The Bisync Pass-Through product will run on IBM 4300 Processors, S/370 or IBM 3031 supported by DOS/VSE and which have a minimum of 384K of memory. The Communications Adapter on the IBM 4331 Processor requires one BSC port using the Station Select feature.

IBM 4300 Processors, S/370 and IBM 3031 Processors with an IBM 3705 Communications Controller will also be supported. One port must be able to support a BSC link to the host in EP mode.

SOFTWARE REQUIREMENTS

VSE/3270 Bisync Pass-Through operates with:

Program Name

DOS/VSE
VSE/ADVANCED FUNCTION
CICS/DOS/VS 1.4

DEVICE SUPPORT

Directly Attached Terminals (via IBM 4331 Processor Display/Printer Adapter)

3278-2
3262-1, -11
3287-1, -2
3289-4

Locally Attached Control Units

3272-1, -2
3274-1A
3274-1B, 1D

Remotely Attached BSC Control Units

3271-1, -2
3274-1C
3275-2
3276-1, -2, -3, -4

Remotely Attached SDLC Control Units

(requires ACF/VTAME or ACF/VTAM Release 2)

3274-1C (Nonswitched connection only)
3276-11, -12, -13, -14

COMPATIBILITY

No modifications are required to DOS/VSE, CICS/DOS/VS or any access method either in the host processor or remote 4300 Processor.

CONVERSION

The capability will exist to "hardwire" Bisync Pass-Through for 3270 addresses of all connected displays and printers.

If 3277 displays and 32XX printers are being removed from an IBM remote 3271 control unit and attached locally to an IBM 4300 Processor, a local 3272 control unit is required. A single 3271, however, may be directly attached to the 4331 Processor Communications Adapter through the Local Attachment Interface.

When migrating to full networking, a BSC host link using the Bisync Pass Through program may co-exist with an SDLC link using ACF/VTAME or ACF/VTAM Release 2 with MSNF. In order to make this transition easier it is recommended that Bisync Pass-Through be installed initially using ACF/VTAME with the 4331 or 4361 Processor Communications Adapter on ACF/VTAM Release 2 on the 4300 Processors with an 3705 Communications Controller.

DATA SECURITY

Bisync Pass-Through provides a path to applications and data. Access to Bisync Pass-Through on the remote system can be controlled by the security features of CICS/VS. Access to host system services will be controlled by the host. This product is supported by DOS/VSE, CICS/DOS/VS and the security, auditability and control procedures that it provides. No logging or journalling of user access is provided by the Pass-Through Program, however an exit will be provided to the customer, and may be used as required as an additional layer of auditability of user access to the Pass-Through Program. User management is responsible for the selection, application, adequacy, and implementation of these features and for appropriate application and administrative controls.

VSE/3270 Bisync Pass-Through Licensed Program Design Objectives.*

PROGRAM PRODUCTS

**DOS/VS COBOL COMPILER AND LIBRARY (5746-CB1)
DOS/VS COBOL OBJECT LIBRARY (5746-LM4)**

PURPOSE

The DOS/VS COBOL Compiler and Library provide a number of improvements in function and performance over previous DOS IBM Full American National Standard COBOL Compilers. The Library is required for execution of compiled programs. The compiler and library operate under control of DOS/VSE, and support American National Standard COBOL, X3.23-1968. †

Release 3 supports American National Standard COBOL, X3.23-1974.

These program products are designed for use in a virtual storage environment under the DOS/VSE Operating System.

RELEASE 1 HIGHLIGHTS

- VSAM support - the new high performance access method
- FIPS FLAGGER - an installation management tool which helps enforce conformance to the Federal Information Processing Standard for COBOL as defined by FIPS Pub 21, March 15, 1972.
- MERGE FACILITY - allows the user to combine two or more identically sequenced files according to the ascending/descending order of imbedded key(s) in each record. Use of the Merge facility requires the DOS/VSE Sort/Merge Program Product (5746-SM1). *
- Support of 5425 Multi-Function Card Unit
- Support of 3886 Optical Character Reader **
- Support of 3340 Disk Storage
- Support of 5203 and 3203 Line Printers
- Support of 3540 Diskette Input/Output Unit
- Syntax-checking feature - a fast source program scan for syntax errors. No object code is generated when unconditional syntax checking is specified.
- Language supported by the previous versions of DOS Full ANSI COBOL is also supported in DOS/VS COBOL.

The following features are also available:

- Support of American National Standard Code for Information Interchange, X3.4-1968, which provides the user with the capability of accepting, creating and sorting American National Standard magnetic tapes * (the appropriate Sort/Merge program product is required when the Sort/Merge feature is used). †††
- Support of the American National Standard for Magnetic Tape Labels for Information Interchange, X3.27-1969. ††
- A formatted trace of the last user-specified number of procedures executed before an abnormal termination.
- The ability to print the number of the COBOL statement being executed when an abnormal termination occurs.
- Expansion of the condensed listing produced by the CLIST compiler option, and the Data Division map produced by the SYM compiler option, to include global tables, literal pools and register assignments.
- Optional alphabetically-ordered cross-reference listings, with significant performance improvement over the Version 2 (CB482) source-ordered cross-reference. The current cross-reference option which preserves source statement order is still supported, with similar performance improvement.
- A symbolic debug feature, which permits the programmer to debug in a high-level language, without resorting to the bits and control blocks of a DOS dump. Information given includes symbolically formatted dumps of named data areas taken dynamically at desired points in the Procedure Division, and a symbolically formatted dump at abnormal termination of execution. No new COBOL language is required to exercise this feature.
- An optional optimizer can be used to generate more concise object code, thereby decreasing object-time space requirements. (This optimizer cannot be used if any of the debugging options are in effect.)
- Support of the 3211 Printer with a 150-character line.
- Utilization of S/370 hardware.
- Double-buffering of ISAM data sets. *

RELEASE 2 HIGHLIGHTS

- LISTER - a facility for reformatted source listings with expanded, embedded cross-referencing information. Features of this new source listing include: Standard indentation for all DATA division level-numbers to show group structure, and for all IFs, etc., in the PROCEDURE division to facilitate tracing program logic. Alignment of PICTURE and VALUE clauses to highlight OCCURs and REDEFINES. Two-way, embedded cross-references to eliminate indirect

"lookups" (via a separate SXREF listing in a conventional COBOL compiler), "Reference-letters" to show type of reference, indicate overall usage of a program item, and reduce the need to look up each reference. Footnotes on PROCEDURE pages to show the definition of referenced data items, eliminating more "lookups". Two-column PROCEDURE division pages to compact the listing and further reduce FDs and PROCEDURE division SECTIONs reference to each other. Optional reformatted and renumbered source decks for manual use or for updating the BASIS library.

- VERB PROFILES - a facility which eases identification of verbs used in the source program, and of finding where the verbs are located. This facility is composed of two options: A verb summary feature and a verb cross-reference feature. Both the verb cross-reference and summary features use the format of the XREF and SXREF listings.
- EXECUTION STATISTICS - a facility which is both a debugging and an optimization aid. It consists of a summary of how often each COBOL source program verb is executed; all statistics are for an individual program execution and are printed at program termination. This is useful for knowing which sections of a program are heavily used and should be evaluated for efficient coding; it is of further use in monitoring whether all portions of a program have been executed during a debugging run.
- SORT-OPTION clause - gives the programmer greater control over the operation of the Sort/Merge program. In the Sort-file description entry, the SORT-OPTION clause specifies a working storage area which at object time will contain an OPTION control statement for the Sort/Merge program (5746-SM2).
- IBM FIXED BLOCK DISK DEVICES - The fixed block disk devices are supported at compile and execute time for all functions where DASD devices are supported by SAM and VSAM.
- Support of 3330-11 ††††
- Support of 3350 ††††

RELEASE 3 HIGHLIGHTS

- VSAM support through Standard COBOL I/O language for:
 - Alternate Indexes
 - Relative Record Data Sets
 in addition to previously supported Sequential and Indexed VSAM files.
- New enhanced file processing capabilities (through SAM and VSAM).
 - Relative and Alternate Keys, with passwords
 - FILE STATUS for Sequential files
- 1974 Standard COBOL language support, in addition to retaining previously supported 1968 Standard language.
- LANGLVL compiler option to allow language interpretation based on either the 1968 or 1974 Standard, for those language elements whose syntax is identical but whose semantics have been changed.

* Not available under CMS at object time.
 ** Not available under VM/SP at object time.
 † Formerly known as USA Standard COBOL, compatible with, and identical to, the international standard of the language: ISO 1989-1972 Programming Language COBOL.
 †† ANSI X3.27-1969 is technically identical to ISO 1001, Magnetic Tape Labeling and File Structure for Information Interchange, which is also supported.
 ††† ASCII is the US Version of the International Organization for Standardization (ISO) 646, 6- and 7-Bit Coded Character Set for Information Interchange. ISO 646 allocates several codes to National Use to provide room in derived National Standard for those alphabetic characters in excess of 26 which are used in some countries. Since the translation performed by DOS between EBCDIC and ASCII character accommodates the US choices for the nationally used positions, the translation is not entirely matched to National Code Standard in countries other than the US. Country Standards Authorities should be consulted about necessary translation adjustments which may be required before DOS support of National Code Standard is offered in those countries.
 †††† DOS/VS Release 34 or above is required.
 Not available for ISAM files.
 If the compiler is used under DOS/VSE with VSE/Advanced Function or subsequent releases of these products, then support is available for fixed block disk devices using SAM or VSE/VSAM.

DOS/VS COBOL Compiler/Library (cont'd)

- Support for Federal Information Processing Standard (FIPS) PUB 21-1 at the Low-Intermediate level.
- Enhancement to the Federal Information Processing Standard (FIPS) flagger to allow statement flagging based on either the 1975 FIPS PUB 21-1 (1974 ANS Standard) or the 1972 FIPS PUB 21 (1968 ANS Standard) specifications, according to the language option selected.
- New object program debugging capabilities (USE FOR DEBUGGING).
- Alternate collating sequence support.
- Expanded COPY library facilities.
- Extended data manipulation and arithmetic capabilities.
- Compilation return code passed from the compiler on exit.
- Support for 3375 disk devices is provided by the DOS/VSE operating system; the COBOL user may specify 3330, etc., in the COBOL ASSIGN statement and use 3375 at execution.
- Provision for accessing the DOS/VSE SORT/MERGE program (5746-SM2) directly from object code under both DOS/VSE and the VM/SP release of CMS/DOS.

INDUSTRY STANDARDS

The DOS/VS COBOL Release 3 Compiler and Library is designed according to the specifications of the following industry standards, as understood and interpreted by IBM as of May, 1980:

- American National Standard (ANS) COBOL, X3.23-1974. ANS COBOL is identical to ISO 1989-1978, approved in February 1978 by the International Organization for Standardization. The following ANS functional modules are included in DOS/VS COBOL:
 - 2 NUC 1,2 (Nucleus)
 - 2 TBL 1,2 (Table Handling)
 - 2 SEQ 1,2 (Sequential I-O except that the OPTIONAL phrase of the SELECT clause is treated as documentation, the REVERSED phrase of the OPEN verb does not cause file positioning, and the EXTEND phrase of the OPEN verb is not supported).
 - 2 REL 0,2 (Relative I-O)
 - 2 INX 0,2 (Indexed I-O) except that if records are READ using an alternate key, then updated using REWRITE, a subsequent READ or START using the alternate key may not reflect the update unless the file is closed and reopened prior to the READ or START.
 - 2 SRT 0,2 (Sort/Merge)
 - 2 SEG 0,2 (Segmentation)
 - 2 LIB 0,2 (Library) except for the multiple library facility.
 - 1 DEB 0,2 (Debug)
 - 1 IPC 0,2 (Inter-Program Communication)
 - 0 RPW 0,2 (Report Writer)
 - 0 COM 0,2 (Communication)
- The 1975 Federal Information Processing Standard (FIPS) PUB 21-1, Low-Intermediate level.
- American National Standard (ANS) COBOL X3.23-1968, which is identical to ISO 1989-1972. All processing modules are supported.
- The 1972 Federal Information Processing Standard (FIPS) PUB 21, High level.
- American National Standard Code for Information Interchange (ASCII) X3.4-1977, which is identical to ISO 646.
- American National Standard for Magnetic Tape Labels for Information Interchange, X3.27-1978, which is technically identical to ISO 1001.2.

CUSTOMER RESPONSIBILITIES

To install DOS/VS COBOL, the user:

- Chooses the default system parameters COBOL will use.
- Chooses the default compiler options for use during problem program compilation.
- Defines DOS/VS COBOL libraries to the DOS/VSE system.
- Sets up and executes MSHP (for DOS/VSE) for compiler and library.
- Uses the sample program provided to test for successful installation.

SPECIFIED OPERATING ENVIRONMENT

DOS/VS COBOL Release 2 is supported under DOS/VS (Release 29 and later) and under the CMS/DOS component of VM/370. It uses DOS VSAM as primary access method. Release 3 is supported under DOS/VSE Advanced Functions Release 3, and under the CMS/DOS component of VM/SP. It uses VSE/VSAM as primary access method. After September 30, 1982 (one year after the availability of Release 3), DOS/VS COBOL Release 2 will no longer be supported.

HARDWARE REQUIREMENTS

DOS/VS COBOL Release 3 is designed to operate on all IBM processors supported by DOS/VSE Advanced Functions Release 3.

Requirements: The DOS/VS COBOL Compiler Release 3.0 requires at least 128K bytes of virtual storage exclusive of the storage required by the operating system control program. It is possible that some programs will compile with less virtual storage than the 128K design point of the Compiler but performance will be degraded.

Additional virtual storage can be used to reduce compilation time by reducing the use of auxiliary storage normally used by the compiler.

The IBM machine must include the decimal instruction set. If floating point data is used, the machine must also include the floating point instruction set. The timer feature is required if the time taken for compilation or the time of compilation are to be recorded. Direct access storage space is required for Compiler residence; approximately 700 blocks of 1,024 bytes, regardless of the device type.

Four data sets, SYS001 through SYS004, are required for compilation. An additional data set, SYSLNK, is required for the CATAL or LINK options. SYS005 is required if the Symbolic Debugging feature is used. SYS006 is required if the FIPS flagger is used.

Execution: The storage requirements of the object program are a function of the COBOL language facilities used in the source program. The decimal instruction set is required, and if floating point data is to be used, the floating point instruction set is required. The timer feature is required if use is made of the TIME built-in function.

The object program can utilize the following IBM input/output devices if they are supported by the release of the DOS/VSE system used. Note that this list is complete for Advanced Functions Release 3. For later Advanced Functions releases, see the appropriate Advanced Functions documentation.

Using SAM Support

- Magnetic Tape Units: 2400, 3410, 3411, 3420, 8809
- Card Units: 1442, 2501, 2540, 2560, 3504, 3505, 3525, 5424, 5425
- Optical Mark Reader: 3881
- Optical Character Reader: 3886
- Diskette Unit: 3540
- Printers: 1403, 1443, 3203, 3211, 3262, 4245, 5203
- Direct Access Storage: Fixed block devices, 3375

Using SAM and DAM

- Direct Access Storage: 2311, 2314, 2319, 3330-1, 3333-11, 3340, 3344, 3350

Using ISAM Support

- Direct Access Storage: 2311, 2314, 3330-1, 3340, 3344, 3350 in compatibility mode

Using VSAM Support

- Direct Access Storage: 2314, 3330-1, 3330-11, 3340, 3344, 3350, fixed block devices, 3375

SOFTWARE REQUIREMENTS

The Compiler is designed to operate under DOS/VSE Advanced Functions Release 3, and subsequent releases unless otherwise stated in a revision of the specifications. DOS/VSE can operate as an independent system, or under control of VM/SP. DOS/VS COBOL Release 3 also operates under the CMS/DOS component of VM/SP. VSE/VSAM is the primary access method.

Requirements: SAM is used directly by the Compiler. The DOS/VSE system that supports a specific device is required for the Compiler to use that device. The timer system generation option is required if the time taken for compilation or the time of compilation are to be recorded.

Execution: For further processing, object modules produced by the DOS/VS COBOL Compiler require the DOS/VS COBOL Subroutine Library. If dynamically fetched subroutines are required during problem program execution, the Subroutine Library must be installed on the object machine. It may be necessary, therefore, to order 5746-LM4 separately. Otherwise, the object time subroutines can be link-edited on the source machine.

Object programs must be executed under DOS/VSE Advanced Functions Release 3 or the CMS/DOS component of VM/SP. All

PROGRAM PRODUCTS

DOS/VS COBOL Compiler/Library (cont'd)

object programs require SAM modules in the generated operating system.

If VSAM files are used, the Program Product VSE/VSAM Release 2, 5746-AM2, is required.

If the SORT or MERGE verbs are used, the Program Product DOS/VSE Sort/Merge Version 2, 5746-SM2, is required.

Object programs may also be executed as application programs in the CICS environment using CICS DOS/VS, 5746-XX3. Programs compiled with DOS/VS COBOL Release 3 will execute on any releases of CICS/VS on which programs compiled with Release 2.6 will execute.

Object programs may be executed under CMS/DOS, with the restrictions noted below.

Compilation and Execution under CMS/DOS: A minimum of 128K virtual storage is required in order to operate the Compiler under CMS/DOS, in addition to the storage needed by VM, CMS and CMS/DOS.

When executing a COBOL program under CMS/DOS, the same processor features are required as are necessary when executing under DOS/VSE. Under CMS/DOS, the DOS/VS COBOL Compiler Release 3.0 supports those I/O devices which are supported under DOS/VSE provided they are supported by VM/SP.

CMS Restrictions: Under CMS/DOS, the Compiler can accept and compile any COBOL source program that it can accept and compile under the control of DOS/VSE. The object code generated by the DOS/VS COBOL Compiler under CMS/DOS can be executed without restriction under the control of DOS/VSE. The object code generated under CMS/DOS can also be executed under CMS/DOS, with object time restrictions in the following areas:

- ISAM
- User label handling
- ASCII encoded tapes
- Spanned record processing
- Checkpoint/Restart
- Segmentation with LANGLVL(1)
- Positioning options of OPEN (EXTEND) and CLOSE
- Multi-volume data sets
- Use of SYSPARM for setting execution-time options AIXBLD and NODEBUG
- Use of VSAM alternate indexes (COBOL Alternate Record Key clause)

For more detailed information about the above restrictions under CMS/DOS, refer to *IBM CMS User's Guide for COBOL* (SC28-6469).

COMPATIBILITY

Programs coded for the IBM DOS Full American National Standard COBOL and DOS Subset American National Standard COBOL Compiler will compile on DOS/VS COBOL without modification.

Source programs written for the COBOL D Compiler must be converted before compiling them on the DOS/VS COBOL Compiler. The Language Conversion Program described in the publication *Conversion Aids: COBOL-to-American National Standard COBOL Language Conversion Program* (GC28-6400), facilitates such conversion.

Data set compatibility exists between DOS/VS COBOL and the other IBM DOS COBOL Compilers: Previous versions of the Full American National Standard COBOL Compiler, the Subset American National Standard COBOL Compiler, and the COBOL D Compiler. That is, data sets created by a program compiled on one of these compilers can be processed by a program compiled on DOS/VS COBOL.

The DOS/VS COBOL Library (5746-LM4) will operate with DOS Full American National Standard COBOL, Version 3 (5736-CB2), DOS Full American National Standard COBOL, Version 2 (360N-CB-482), and DOS Subset American National Standard COBOL (5736-CB1) compiled programs. Thus, a user having these programs need not recompile when going to the DOS/VS COBOL program product.

Object modules from the above mentioned compilers may be linked together in a program when operating under the DOS/VS Operating System.

BASIC MATERIAL

DOS/VS COBOL (5746-CB1) compiled and link-edited programs all require the presence of the DOS/VS COBOL Library at execution time. Note that a separate library may not be needed. The library packaged with the compiler can be used if the programs are executing on the same processor as the one on which they are compiled; otherwise, there must be a separate library (5746-LM4) for each processor on which the programs are executing.

The DOS/VS COBOL Library (5746-LM4) will operate with DOS Full American National Standard COBOL Version 3 (5736-CB2), DOS Full American National Standard COBOL Version 2 (360N-CB-482) and DOS Subset American National Standard COBOL (5736-CB1) compiled

programs. Thus, a user having these programs need not recompile when going to the DOS/VS COBOL program product.

However, if the following unique subset library routines are needed, either those modules must be brought over from a subset library, or the source programs must be recompiled:

ILBDFMBO to compare 2 operands - one or both of which is variable in length or is more than 256 bytes long.

ILBDFMCO to move when one or both operands is variable in length or is more than 256 bytes long.

ILBDIRMO to DISPLAY on SYSPUNCH.

ILBDNEFO to convert an abnormally signed item to a normally signed item.

ILBDRASO to DISPLAY multi-lines on SYSLST or CONSOLE, and to EXHIBIT, TRACE, DISPLAY.

ILBDROZO to DISPLAY on SYSLST or CONSOLE and to handle displays for READY TRACE.

ILBDSEGO to use the segmentation feature.

Object modules from the above mentioned compilers may be linked together in a program when operating under the DOS/VSE Operating System.

PROGRAM PRODUCTS

**VSE/3890 DOCUMENT PROCESSOR SUPPORT
5746-DC1**

PURPOSE

The 3890 VSE Support (5746-DC1) is used to read and stacker-select banking documents using the 3890 Document Processor. This support operates under VSE/Advanced Functions Release 2, SSX/VSE Release 3 and later releases. Device-dependent macros called stacker control instructions (SCIs) are provided with the support. These instructions are used to code an SCI program that controls stacker selection when loaded into the 3890.

This Support enables the user to:

- Define a 128-byte initialization record for the 3890 which includes:
 - Fields to be processed and their attributes.
 - Kill or rehandle pockets.
 - Count limit for which the merge function is used.
 - 3890 features to be active during a run.
- Load the 3890 control unit with initialization data and/or modify its contents.
- Start and stop document feeding during a run.
- Retrieve document data from the 3890.
- Image process documents: Reduces the number of rejects encountered during subsequent passes of the same document.
- Parallel Processing for multiple 3890s.

HIGHLIGHTS

The VSE/3890 Program Product supports:

- Stacker control program generation.
- Open and close processing.
- Reading documents.
- Image processing.
- Device control.
- Error handling.

CUSTOMER RESPONSIBILITIES

The VSE/3890 Support provides an interface between application code, VSE/Advanced Function Release 2 (which contains function necessary to operate this program product) and the IBM 3890.

The user must:

- Describe the 3890 data set(s) and any other data sets used for the run.
- Define the initialization record and assemble the SCI program.
- Open the data set(s).
- Load the 3890 Control Unit User Storage.
- Read a record from the 3890 and then process the record.
- Stop and start the 3890 as required.
- Close the data set(s) after all records of the data set have been processed.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The following IBM models and features are supported:

Models -	A1 through A6 B1 through B6
Features -	Item Number Endorse Microfilm

The IBM 3890 Document Processor is supported on the following Processors:

- IBM S/370 mdl 115 (with RPQ SU0057)
- IBM S/370 mdl 125 (with RPQ SU0057)
- IBM S/370 mdl 135
- IBM S/370 mdl 135-3
- IBM S/370 mdl 138
- IBM S/370 mdl 145
- IBM S/370 mdl 145-3
- IBM S/370 mdl 148
- IBM S/370 mdl 155-11

- IBM S/370 mdl 158
- IBM 3031 Processor
- IBM 4331 Processor
- IBM 4341 Processor

Attachment is via the byte-or-block-multiplexer channel.

A tape drive (1600/6250 bpi) is required to install this program product.

SOFTWARE REQUIREMENTS

This program product operates in conjunction with VSE/Advanced Functions Release 2, SSX/VSE Release 3 and subsequent releases.

The source code is distributed in assembler language as part of the basic material.

COMPATIBILITY

This program product will allow the 3890 VSE user to utilize the enhanced 4300 system as well as provide the following advantages over the current support which is the DOS/VS Application Installation Support FDP (#5798-BDC).

- Additional SCI Macros.
- Multiple Sorter Support Enhancements.
- Additional IREC Parameters.
- Additional SETDEV Function.

Users of the FDP can utilize these advantages by installing this program product. The changes and improvements that have been made will require the user to make minor modifications to his application program as well as the stacker select program. The extent of the changes required will depend on the user's specific implementation.

PROGRAM PRODUCTS

**ELECTRONIC PAYMENT SYSTEMS SUPPORT/
CHECK PROCESSING DOS/VS(DOSCHECK)
(5746-F12)**

DESCRIPTION

The Electronic Payment Systems Support/Check Processing DOS/VS (DOSCHECK) program product provides the DOS/VS user with a comprehensive check-processing system designed to exploit the advanced functional capabilities of the IBM 3890 Document Processor.

DOSCHECK is a performance-oriented system that operates in a wide range of IBM S/370 configurations (mdl 115 and above) in either dedicated or multiprogramming environments. Because DOSCHECK is designed explicitly for operation in a virtual storage environment and requires no prerequisite programming, the minimum-size processor required depends on user volumes rather than on program requirements.

DOSCHECK is designed to operate in two types of environments; in standalone bank installations and in remote check processing installations, such as commercial bank regional proof centers or Federal Reserve regional check processing centers. Both types of environments may operate as multibank facilities.

DOSCHECK operates as an independent system, controlling check sorting and associated listings without requiring any link to another computer. Captured check data is stored on disk for subsequent use as input to customer-written DDA and other applications. In a dedicated environment, these subsequent applications may be run in the same processor. In a remote environment, the check data may be written on tape or may be transmitted, using a customer-written program, to a central processor using the DOS/VS Remote Job Entry Workstation Program (5799-WHX).

The system may often be run without on-site systems programming personnel and often without a full-time console operator. The system may be run largely by the sorter operators, with a minimum of operating system interactions. In the case of remote installations, most program maintenance should be performed at the central site. A bank with several remote sites would want to keep the programs at each site identical to minimize maintenance, even though the remote sites may differ greatly in size.

HIGHLIGHTS

System Operation: The system is run largely by the reader/sorter operators using IBM 3277 Display Stations to control run setup. The operators use the terminal to specify the sort type and bank code prior to starting the sorter. While a sort is in progress, the terminal can also be used for jam or restart displays.

Initiation of a sorter run triggers automatic production of balancing reports and kill listings for the run. Printing of the listings can be overlapped with completion of the sorting run. An entry master list is produced as a byproduct of prime-pass runs. This list is a three-up detailed list of the input showing the deposit, batch, and block-balancing status of the run. The subsequent-pass master list, produced after all subsequent-pass runs, shows subsequent-pass items with the item numbers that were assigned on prime pass. Pass-to-pass differences and missing or free items are also highlighted. Each sorter run also causes automatic production of kill listings. The kill lists are seven-up and contain detail item amounts and incoming sequence numbers. Printing of all listings is on a deferred basis, taking place whenever a printer is available. The order of listings is determined by the order in which sorting is performed. Listing speed is not limited by sorter speed.

Document Preparation and Control: Data Preparation for DOSCHECK involves insertion of only those MICR inscribed control documents used to reconcile prime pass input dollar controls. Deposit slips and other credits may either precede or follow the items they control. Batches are the next highest level of control for proof-of-deposit work and the basic control level for inclearing work. MICR-inscribed batch tickets precede the batch items and contain the batch control total. Groups of batches from a common source form a block, which is preceded by a block slip. Block slips are the highest level of input dollar control. No further document preparation is necessary because the DOSCHECK cut-slip design avoids the need for divider slips, tracer slips or batch separators in the document input stream. Cut slips are automatically inserted from the 3890 merge feed whenever they are required to close out a kill or a rehandle pocket. This provides for rehandle control groups of more uniform size.

Data Sets: The all-items file contains images of all documents as they were read through the reader/sorters. This disk file is created by the MICR task using a chained sequential technique. Record allocation is in a sequential wrap-around fashion allowing retention of as many images as can be stored on the file. All detail lists are printed from this file. Subsequent-pass records are updated by the subsequent-pass master list program to include the incoming item sequence number. A tape copy of the all-items file is used for reconstruction of the file in case of disk hardware failure.

The cut-slip file is used both to index the all-items file and to store control totals. It is a direct-access file, based upon the unique serial numbers inscribed on the cut slips. The cut-slip file is updated to

indicate the time the bundle is rehandled as well as the time it is listed. Bundle-total information is included on the file for use in both pass-to-pass balancing and end-of-cycle accounting.

The endpoint master file contains information about the endpoints to which checks are sent. The records include indicative information for kill lists and information about options that pertain to the endpoint. The endpoint master file is not altered after it is loaded.

The print-queue file is used to store start requests for printing. The records are used by the writer subtasks to determine the order of listings to be produced.

CUSTOMER RESPONSIBILITIES

Users of the DOSCHECK program are responsible for performing tasks necessary to tailor it to the desired operational environment. Some of these tasks are:

- Tailor the parameters specified in the system-generation-options copybook to the actual configurations to be used.
- Generate the DOS/VS operating system as specified in the *DOS/VS System Generation Manual* and the *DOSCHECK Program Reference and Operations Manual*.
- Prepare specifications used as input to the sort-table generator.
- Write 3890 stacker control instruction SCI programming as desired to perform special editing for on-us documents.
- Prepare data cards to be used as input for the batch program supplied to build the endpoint master name-and-address file.
- Allocate and initialize the all-items and print-request-queue, and sort pattern files using the IBM utility CLRDK or equivalent.
- Allocate the cut-slip and writer work files.
- Interface the output files to the existing DDA posting and/or general ledger programs.
- Write programs to transmit DOSCHECK output data to a central location by using the DOS/VS Remote Job Entry Workstation Program (5794-WHX).
- Prepare or order uniquely numbered cut slip documents.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The minimum system configuration for this program is an IBM S/370 mdl 115 that can support a virtual partition of 200K and a real partition of 64K.

In addition to those devices used by DOS/VS, DOSCHECK requires the following:

Adequate DASD storage is required to contain the data files, work files and libraries used to install, maintain and operate the DOSCHECK system.

Two magnetic tape units are required for program installation and maintenance. A single tape unit is required for program execution.

A card reader is required for program installation and maintenance and, optionally, for program startup.

A 132 print position line printer is required for installation and execution of this program. The program supports from one to three dedicated printers, or, if operating under POWER/VS, it can share printers with jobs in other partitions.

The DOSCHECK program requires one local 3277 Display Station mdl 2 per 3890 Document Processor and can support up to six additional 3277 displays mdl 2 for reject reentry.

The DOSCHECK program requires a 3890 Document Processor (EC Level 143263 or later).

The DOSCHECK program uses the operator console for displaying messages and for entering print requests.

Note: Give consideration to the data rates of the devices used as they can have an impact on system throughput. In addition, if the computer is used for batch processing concurrently with check processing, examine the data rates of shared devices, such as channels and printers, to avoid system slowdowns. The "Factors Affecting Throughput" section of the *General Information Manual* should be consulted for additional considerations.

SOFTWARE REQUIREMENTS

DOSCHECK is written to operate under DOS/VS Release 33 and subsequent releases. The program is written in Assembler language and is distributed in source form. The following is a list of the programs used by DOSCHECK:

PROGRAM PRODUCTS

DOSCHECK (cont'd)

Disk Operating System/Virtual Storage (DOS/VS)

Sequential Access Method (SAM)

Direct Access Method (DAM)

Basic Teleprocessing Access Method (BTAM)

DOS/VS Assembler

DOS/VS Linkage Editor

DOS/VS System Utilities

DOSCHECK operates in a virtual storage partition of DOS/VS. The programs operate in a subtasking environment and make use of DOS/VS facilities across a wide range of configurations. Rather than employing a rigid planned overlay structure, the DOSCHECK package is link-edited as a single phase. Portions of the program are paged into real storage by DOS/VS as they are needed. The total amount of real storage allocated to the DOSCHECK partition can be used as a performance tuning factor. For certain portions of the system with critical performance requirements (such as sorter attachment), the programs perform explicit page fixing and Channel Command Word (CCW) translation to avoid performance degradation.

The MICR subtask controls up to four 3890s and their associated 3277s. Internal dispatcher logic is used to allow asynchronous operation of the sorters. The MICR task controls the initial writing of check data on the all-items file and on the cut-slip file. After a sufficient volume of checks has been sorted, the MICR task also puts a print request in the print queue file to start the appropriate listing (prime or subsequent-pass entry lists).

A separate subtask is attached for each printer. This writer subtask is reenterable and contains program code common to all listing programs. The common code includes special chained CCW routines used to optimize printer performance by printing an entire page at a time.

**5746-F52 - INTERACTIVE FINANCIAL SYSTEM 1 - DOS/VS
POSTINGS AND GENERAL LEDGER
IFS 1 RELEASE 1 Modification Level 4**

PURPOSE

The Interactive Financial System 1 is part of the Interactive Financial System (IFS). The Interactive Financial System is a set of application programs designed to perform accounting and related functions. The set consists of IFS 1, IFS 2, IFS 3 and IFS 4. IFS 1 allows posting either in interactive mode using 3277, 3278 or 3279 Display Stations or in batch mode. Any account and any voucher can be displayed and, if necessary, processed randomly at the terminal.

DESCRIPTION

This release introduces the following:

- The object code is provided in addition to the source code. Four options have been preselected in the object code:
 - The decimal character for monetary values is a period, and the character separating thousand values is a comma.
 - Printed text, text that appears on the screen, and messages are in English.
 - The data base management system is DL/I DOS/VS.
 - The daily work file is VSAM-organized.
- IFS programs can be customized to run with various I/O devices without the need to recompile programs.
- The format used to specify mailing addresses has been changed to allow extended addresses to be specified.
- Both IBM data base systems DL/I DOS/VS and DL/I-Entry DOS/VS are supported.
- Fixed Blocked Method (FBM) devices are now supported.

SPECIAL SALES INFORMATION

Primary Potential Industries:

- Manufacturing
- Process
- Distribution
- Health

Other Potential Industries:

- Transportation
- Insurance
- Media
- Finance

IFS may be run in parallel with other applications. In addition, IFS is well suited as a stand-alone application on a 4331.

HIGHLIGHTS

- IFS 1 provides the accounting data base organization and management functions for the four program products IFS 1 through IFS 4. Accounting data necessary for IFS 1-4 is stored in the following DL/I data bases:
 - The parameter data base contains general information on the installed IFS, for example, the accountant identifications, authorizations of accountants and terminals, table of clients, posting keys and payment conditions.
 - The accounts data base includes the impersonal and personal accounts per client and the related posting entries of the actual posting periods. Included are segments for historical and budget data and user-defined structuring of accounts for the balance sheet, profit and loss reports, or financial status reports (for use by IFS 2).
 - The match code data base is a secondary index data base for retrieval of accounts using match codes as search arguments.
 - The document data base is a secondary index data base allowing for retrieval of posting entries using voucher numbers as search arguments.
 - The combined data base includes key reference information useful for the secondary account coding function and for recording additional data about postings.
- A temporary non-DL/I file is used as intermediate storage for the posting material (Daily Work File).
- System restart facilities and data base recovery functions are available for IFS 1 through IFS 4.
- Accounting functions for up to 99 separately maintained clients (separately balanced subsidiaries or branches of a company) are possible.
- The main accounting functions that the user may request are:
 - Posting in interactive or batch mode.

– Display, creation and changing of account master data.

– Entering, verifying and posting in one operation, either directly at a display terminal, thereby saving the time consuming and costly manual transfer to intermediate recording media, or in machine-readable form. After entry in batch mode, this posting material is available for display and modification in interactive mode at a display terminal.

- Posting Interactively: Postings are entered and processed in groups (a sequence of related postings for which control totaling has to be performed). IFS 1 provides posting masks on the screen (corresponding to the conventional processing cycle) to handle these groups.
- Posting in Foreign Currencies: Postings in foreign currencies are done by entering the values in foreign-currency and/or in local-currency notation in specified foreign-currency accounts. These values are always stored in both local and foreign currency. If an amount is entered only in foreign-currency notation, a stored or entered currency exchange rate is used to calculate the corresponding local-currency amount.
- Posting of Unverified Invoice Receipts: Received purchase invoices can be recorded before verification to achieve, for example, tracking of unverified invoices, payment with optimum conditions, or early deduction of pretax. Unverified invoices are processed by common IFS posting facilities, using specific accounts (suspense accounts). These postings are displayed and reported separately.
- Standard Journal Entries/Forward Postings: Postings with explicit posting dates can be entered beforehand. Once entered, such postings are repeatedly posted at the specified dates (standard journal entries) or only once (forward postings).
- Match Code Function: The accountant can search for the account number of a debtor or creditor by means of match codes he defines himself.
- Posting Group and Account Display: Before a short-period summary is produced, the user can display on the screen a list of posting groups as entered, or all posting groups of an account for a certain period.
- Accounting Summaries: During short period summary (normally performed daily), IFS 1 provides various reports, such as a list of all postings entered (Journal) and a posting group list.

During a monthly summary, IFS 1 prepares a trial balance and a final account report.

In the annual summary, all the accounts of a client, as well as the supplementary postings of the preceding accounting year are printed.
- Data Integrity Precautions: These precautions help prevent unauthorized access to stored information. Before using the online facilities, each accountant must enter his name, authorization code and client number so that the system can determine what processing he is allowed to do for the given client, and which operation he is permitted to perform, for instance, display, maintain or post certain accounts or open new accounts.
- Creation of the general journal and the general ledger for each client.
- Provisions are made for the adaptation of messages, commands, and screen text according to national requirements.
- Testing and training can be carried out in parallel to normal operations by simply reserving one client for these purposes.

CUSTOMER RESPONSIBILITIES

The program products IFS 1-4 constitute an application package affecting several departments within a company.

The organizational prerequisites should be planned and considered early. The departments affected should be made familiar with the arrangements necessary in the financial accounting area.

Before IFS 1 can be installed and executed, the user must provide for:

- The definition of the company's account structure.
- The identification of all necessary accounting data by keys, codes or abbreviations.
- The definition of match codes to facilitate postings of debtors and creditors even if the account numbers are unknown (optional).
- The specification of control information about the different accounting procedures, for example, arrears procedure, sales tax procedure and discount posting procedure.
- The provision of account data in the required format.
- The initial loading of the collected account data into the data bases.

PROGRAM PRODUCTS

IFS 1 R1.4 (cont'd)

- The adaptation of messages, commands, screen text, report headings and currency amounts to national requirements, if required.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

This licensed program is designed to operate on the following IBM machines: IBM S/370 mdl 115 to 158, IBM 3031, IBM 4331 and IBM 4341. It uses, in online processing, 30K bytes of real storage in addition to the storage required for the operating system, CICS/DOS/VSE, DL/I-Entry DOS/VSE or DL/I DOS/VSE. For batch processing, approximately 130K bytes of real storage are required.

The minimum machine requirements for IFS 1 are:

- One IBM direct access storage device such as an IBM 2314, 3330, 3350, 3310 or 3370, or equivalent. To install IFS 1 and to execute the provided samples, approximately 90,000 adjacent FBM blocks, or the equivalent of 160 cylinders of an IBM 3330 disk pack are required.
- One IBM 2540 card reader, or any other device supported by the operating system to process SYSIN data.
- One IBM 4245 printer mdl 1, or an equivalent device supported by the operating system, with at least 132 print positions.
- One IBM tape unit, such as IBM 2400 or 3400 or equivalent.
- One IBM 3277 display station mdl 2 or equivalent with data entry keyboard.

SOFTWARE REQUIREMENTS

IFS 1 is written in PL/I and Assembler language and is supplied in the form of relocatable modules and source code. It operates under DOS/VSE Release 34, and under DOS/VSE, program number 5745-020 Release 1.0 or subsequent releases (with VSE/Advanced Functions, program number 5746-XE8 Release 1.0 or subsequent releases) and VSE/VSAM, program number 5746-AM2 Release 1.0 or subsequent releases, unless otherwise specified.

To recompile IFS 1, the DOS PL/I Optimizing Compiler, program number 5736-PL1 and the DOS/VSE Assembler are required.

To link-edit and execute IFS 1, the DOS PL/I Resident Library, program number 5736-LM4, the DOS PL/I Transient Library, program number 5736-LM5, and the DOS/VSE Sort/Merge Version 2, program number 5746-SM2, are required. IFS 1 uses the data management and access methods VSAM and SAM, with the exception of the Daily Work File which uses DAM or VSAM. The VSAM organization of this file supports FBM devices.

The online communication facility CICS/DOS/VSE Version 1, program number 5746-XX3, Release 4 or a subsequent release (unless otherwise indicated) is required.

For data base management, DL/I Entry DOS/VSE Version 2.0, program number 5746-XX7 or DL/I DOS/VSE Version 1, program number 5746-XX1, Release 4 or a subsequent release is required unless otherwise stated.

PERFORMANCE CONSIDERATIONS

The performance of the system may be influenced, in online and in batch mode, by VSAM specifications such as the buffer space, the control interval size and the record size. When the data base is distributed over more than one disk drive or when the index data base resides on a separate disk drive or when additional disk storage is allocated, this may result in an increase of performance.

Processing of open items in accounts that have a large number of open items may increase the online response time.

**5746-F53 - INTERACTIVE FINANCIAL SYSTEM 2
PROFIT & LOSS, BALANCE SHEET,
FINANCIAL STATUS REPORTS
IFS 2 RELEASE 1.3****PURPOSE**

The Interactive Financial System 2 is part of the Interactive Financial System (IFS). The Interactive Financial System is a set of application programs designed to perform accounting and related functions. The set consists of IFS 1, IFS 2, IFS 3 and IFS 4. IFS 1 Release 1 Modification Level 4 is a prerequisite to IFS 2. With IFS 2, the user can define the profit and loss statement, balance sheet and financial status report to his individual requirements.

DESCRIPTION

This release introduces the following:

- The object code is provided in addition to the source code. Four options have been preselected in the object code:
 - The decimal character for monetary values is a period, and the character separating thousand values is a comma.
 - Printed text and messages are in English.
 - The data base management system is DL/I DOS/VS.
 - The daily work file is VSAM-organized.
- IFS programs can be customized to run with various I/O devices without the need to recompile programs.
- The format used to specify mailing addresses has been changed to allow extended addresses to be specified.
- Both IBM data base systems DL/I DOS/VS and DL/I-Entry DOS/VS are supported.
- Fixed Blocked Method (FBM) devices are now supported.

SPECIAL SALES INFORMATION**Primary Potential Industries:**

- Manufacturing
- Process
- Distribution
- Health

Other Potential Industries:

- Transportation
- Insurance
- Media
- Finance

IFS may be run in parallel with other applications. In addition IFS is well suited as a stand-alone application on a 4331.

HIGHLIGHTS

IFS 2 is designed to:

- Prepare and print profit and loss statements.
- Prepare and print balance sheets for different posting periods, according to a format specified by the user.
- Prepare and print financial status reports in various formats.
- Print a summary of the status of user-selected accounts and account groups, differentiating between the various posting periods.
- Report the balance brought forward, the debit and credit turnover of the corresponding report period, the accumulated annual sales (debit and credit), and the current balance.
- Provisions are made for the adaptation of messages, report headings, and currency amounts according to national requirements.

CUSTOMER RESPONSIBILITIES

Before installing and executing IFS 2, the program product IFS 1, program number 5746-F52, which includes the IFS data base management must be installed.

In connection with the installation of IFS 1, the appropriate organizational prerequisites are to be resolved by the user.

The adaptation of messages, report headings and currency amounts to national requirements must be performed if applicable.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

This licensed program is designed to operate on the following IBM processors: IBM S/370 mdl 115 to 158, IBM 3031, IBM 4331 and IBM 4341. It uses approximately 130K bytes of real storage.

The minimum machine requirements for IFS 2 are:

- One IBM direct access storage device such as an IBM 2314, 3330, 3350, 3310 or 3370, or equivalent. To install IFS 2 and to execute

the provided samples, approximately 90,000 adjacent FBM blocks, or the equivalent of 160 cylinders of an IBM 3330 disk pack are required.

- One IBM 2540 card reader, or any other device supported by the operating system to process SYSIN data.
- One IBM 4245 printer mdl 1, or an equivalent device supported by the operating system, with at least 132 print positions.
- One IBM tape unit, such as IBM 2400 or 3400 or equivalent.

SOFTWARE REQUIREMENTS

IFS 2 is written in PL/I and is supplied in the form of relocatable modules and source code. It operates under DOS/VS Release 34 and under DOS/VSE, program number 5745-020 Release 1.0 or subsequent releases (with VSE/Advanced Functions, program number 5746-XE8 Release 1.0 or subsequent releases) and VSE/VSAM, program number 5746-AM2 Release 1.0 or subsequent releases, unless otherwise specified.

To recompile IFS 2, the DOS PL/I Optimizing Compiler is required.

To link-edit and execute IFS 2, the DOS PL/I Resident Library, program number 5736-LM4, the DOS PL/I Transient Library, program number 5736-LM5, and the DOS/VS Sort/Merge Version 2, program number 5746-SM2, are required. IFS 2 uses the data management and access methods VSAM and SAM with the exception of the Daily Work File which uses DAM or VSAM. The VSAM organization of this file supports fixed block architecture (FBM) devices.

For data base management, DL/I Entry DOS/VS Version 2.0, program number 5746-XX7, or DL/I DOS/VS Version 1, program number 5746-XX1, Release 4 or a subsequent release is required unless otherwise stated.

PERFORMANCE CONSIDERATIONS

The performance of the system may be influenced by VSAM specifications such as the buffer space, the control interval size, and the record size. When the data base is distributed over more than one disk drive or when the index data base resides on a separate disk drive or when additional disk storage is allocated, this may result in an increase of performance.

**5746-F54 - INTERACTIVE FINANCIAL SYSTEM 3
OPEN ITEM ACCOUNTING
IFS 3 RELEASE 1 Modification Level 3****DESCRIPTION**

The Interactive Financial System 3 is part of the Interactive Financial System (IFS). The Interactive Financial System is a set of application programs designed to perform accounting and related functions. The set consists of IFS 1, IFS 2, IFS 3 and IFS 4. IFS 1 Release 2 Modification Level 0 is a prerequisite to IFS 3. IFS 3 extends the account management functions provided by IFS 1 by the open item accounting procedure for debtor, creditor and impersonal accounts.

DESCRIPTION

This release introduces the following:

- The object code is provided in addition to the source code. Four options have been preselected in the object code:
 - The decimal character for monetary values is a period, and the character separating thousand values is a comma.
 - Printed text, text that appears on the screen, and messages are in English.
 - The data base management system is DL/I DOS/V5.
 - The daily work file is VSAM-organized.
- IFS programs can be customized to run with various I/O devices without the need to recompile programs.
- The format used to specify mailing addresses has been changed to allow extended addresses to be specified.
- Both IBM data base systems DL/I DOS/V5 and DL/I-Entry DOS/V5 are supported.
- Fixed Blocked Method (FBM) devices are now supported.

SPECIAL SALES INFORMATION**Primary Potential Industries:**

- Manufacturing
- Process
- Distribution
- Health

Other Potential Industries:

- Transportation
- Insurance
- Media
- Finance

IFS may be run in parallel with other applications. In addition, IFS is well suited as a stand-alone application on a 4331.

HIGHLIGHTS of IFS 3

- The user may select a display either of all open items, the overdue items, the matched items (that is, items with identical item match numbers), the settled items, or of all stored items of an account. This includes the request for account statements of open item accounts.
- Some information may be changed in an open-item account, such as:
 - Payment conditions
 - Item match numbers
 - Arrears letter level, arrears letter exclusion
 - Affirmation or negation of automatic matching
 - Textual Information
 - Verification department for purchase invoices

With the exception of the update of payment conditions and textual information, this information may be changed in one operation for the entire account.

- Payments may be matched to open items. Various calculation methods are available for posting payments and maintaining accounts.
- Open items are allocated to payments and the allocated items are marked as 'settled'. At the same time, the related postings (as a result of the allocation) are established. The sales tax is automatically corrected for the postings involving revenue reductions, and optionally, the cash discount posting is performed.
- Payments in foreign currency can be matched manually against open items in foreign currency. A possible currency exchange difference caused by different exchange rates, is automatically calculated and posted to specific accounts (Foreign-currency-exchange profit-and-loss accounts).
- At certain dates determined by the user, all the debtors' accounts, or a specified number of them, are scanned for overdue items to print arrears letters. The accounts excluded from arrears proce-

dures or debtor accounts not treated as open-item accounts are ignored.

- An account statement is printed for the due debits and can also be furnished for open items that are not yet due.
- The number of arrears letters written for each customer is recorded in the account data base as a basis for judgment on a customer's payment behavior.
- At the end of an arrears letter procedure, an address list of all debtors who have reached the highest arrears level is printed for the legal department.
- A list of matched open items can be written for all open-item accounts.
- A list of unverified invoices, sorted by verification department and client number, can be printed on request.
- Provisions are made for the adaptation of messages, commands, screen texts, report headings and currency amounts, according to national requirements.

CUSTOMER RESPONSIBILITIES

Before installing and executing IFS 3, the program product IFS 1, program number 5746-F52, which includes the IFS data management, must be installed.

In connection with the installation of IFS 1, the appropriate organizational prerequisites must be resolved by the user.

The adaptation of messages, commands, screen texts and report headings to comply with national requirements must be performed, if required.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

This licensed program is designed to operate on the following IBM processors: IBM S/370 mdl 115 to 158, IBM 3031, IBM 4331 and IBM 4341. It uses, in online processing, 30K bytes of real storage in addition to the storage required for the operating system, CICS/DOS/V5, DL/I Entry DOS/V5 or DL/I DOS/V5. For batch processing, approximately 130K bytes of real storage are required.

The minimum machine requirements for IFS 3 are:

- One IBM direct access storage device such as an IBM 2314, 3330, 3350, 3310 or 3370, or equivalent. To install IFS 3 and to execute the provided samples, approximately 90,000 adjacent FBM blocks, or the equivalent of 160 cylinders of an IBM 3330 disk pack are required.
- One IBM 2540 Card Reader, or any other device supported by the operating system to process SYSIN data.
- One IBM 4245 Printer mdl 1, or an equivalent device supported by the operating system, with at least 132 print positions.
- One IBM Tape Unit, such as IBM 2400 or 3400 or equivalent.
- One IBM 3277 Display Station mdl 2 or equivalent with data entry keyboard.

SOFTWARE REQUIREMENTS

IFS 3 is written in PL/I and Assembler language and is supplied in the form of relocatable modules and source code. It operates under DOS/V5 Release 34 and under DOS/VSE, program number 5745-020 Release 1.0 or subsequent releases (with VSE/Advanced Functions, program number 5746-XE8 Release 1.0 or subsequent releases) and VSE/VSAM, program number 5746-AM2 Release 1.0 or subsequent releases, unless otherwise specified.

To recompile IFS 3, the DOS PL/I Optimizing Compiler, program number 5736-PL1, and the DOS/V5 Assembler are required.

To link-edit and execute IFS 3, the DOS PL/I Resident Library, program number 5736-LM4, the DOS PL/I Transient Library, program number 5736-LM5 and the DOS/V5 Sort/Merge Version 2, program number 5746-SM2, are required. IFS 3 uses the data management and access methods VSAM and SAM with the exception of the Daily Work File which uses DAM or VSAM. The VSAM organization of this file supports FBM devices.

The online communication facility CICS/DOS/V5 Version 1, program number 5746-XX3, Release 4 or a subsequent release (unless otherwise indicated) is required.

For data base management, DL/I Entry DOS/V5, program number 5746-XX7, Version 2 or DL/I DOS/V5 Version 1, program number 5746-XX1, Release 4 or a subsequent release is required unless otherwise stated.

**5746-F55 - INTERACTIVE FINANCIAL SYSTEM 4
PAYMENT PROCESSING RELEASE 1.3****PURPOSE**

The Interactive Financial System 4 is part of the Interactive Financial System (IFS). The Interactive Financial System is a set of application programs designed to perform accounting and related functions. The set consists of IFS 1, IFS 2, IFS 3 and IFS 4. IFS 1 Release 2 Modification Level 0 and IFS 3 Release 2 Modification Level 0 are prerequisites to IFS 4. IFS 4 is designed to determine the maturity of open items by user-specified criteria, such as settlement periods and payment strategy, and to prepare and print a payment proposal list of the selected items.

DESCRIPTION

The user can change and release the payment proposal at the display terminal. When the user has released the payment proposal, IFS 4 can automatically post the related outpayments and print the payment orders.

This release introduces the following:

- The object code is provided in addition to the source code. Four options have been preselected in the object code:
 - The decimal character for monetary values is a period, and the character separating thousand values is a comma.
 - Printed text, text that appears on the screen, and messages are in English.
 - The data base management system is DL/I DOS/V.S.
 - The daily work file is VSAM-organized.
- IFS programs can be customized to run with various I/O devices without the need to recompile programs.
- The format used to specify mailing addresses has been changed to allow extended addresses to be specified.
- Both IBM data base systems DL/I DOS/V.S. and DL/I-Entry DOS/V.S. are now supported.
- Fixed Block Method (FBM) devices are now supported.

SPECIAL SALES INFORMATION

Primary Potential Industries:

- Manufacturing
- Process
- Distribution
- Health

Other Potential Industries:

- Transportation
- Insurance
- Media
- Finance

HIGHLIGHTS

- An automatic account payment procedure can be performed for user-defined accounting periods.
- A payment proposal list is prepared that shows the individual due invoices, the total amount of all due invoices per payment method, and the amounts for credit notes, prepayments, and cash discounts, separated according to the specified terms of payment.
- For due invoices in foreign currencies, the amounts are printed in both local and foreign currency and proposed for manual payment during payment processing. The foreign-currency amounts are summed up and printed as totals per currency.
- Unverified invoices are processed in the payment procedure in accordance with the payment option as specified for the creditor.
- The following alterations are possible using a display terminal before a payment proposal is released for payment processing:
 - A client's payment proposal can be withdrawn
 - Individual open items per creditor can be withdrawn
 - Other terms of payment can be specified
 - Manually-processed items can be inserted
 - Payment information, such as payment-due date or payment methods can be changed
 - Individual items can be removed for manual processing

Using the accepted payment proposal and the specified bank and method of payment, IFS 4 is designed to perform the postings automatically, that is, to creditors and cash accounts, and open items are matched and marked as settled.

- Payment orders, collective lists, and accompanying letters for the banks are printed in a format as required in Germany, but a payment file, containing payment order information, is prepared so that individual payment order forms can be created by user-written print programs.

- Provisions are made for the adaptation of messages, commands, screen texts, report headings, and currency amounts according to national requirements.

CUSTOMER RESPONSIBILITIES

Before installing and executing IFS 4, the program product IFS 1, program number 5746-F52, which includes the IFS data base management, must be installed. In addition, IFS 3, program number 5746-F54, must also be installed.

In connection with the installation of IFS 1 and IFS 3, the appropriate organizational prerequisites must be resolved by the user.

The adaptation of messages, commands, screen texts and report headings to comply with national requirements must be performed, if required.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

This licensed program is designed to operate on the following IBM processors: IBM S/370 mdl 115 to 165, IBM 3031, IBM 4331 and IBM 4341. It uses, in online processing, 30K bytes of real storage in addition to the storage required for the operating system, CICS/DOS/V.S., DL/I Entry DOS/V.S. or DL/I DOS/V.S. For batch processing, approximately 130K bytes of real storage are required.

The minimum machine requirements for IFS 4 are:

- One IBM direct access storage device such as an IBM 2314, 3330, 3310 or 3370, or equivalent. To install IFS 4 and to execute the provided samples, approximately 90,000 adjacent FBM blocks, or the equivalent of 160 cylinders of an IBM 3330 disk pack are required.
- One IBM 2540 card reader, or any other device supported by the operating system to process SYSIN data.
- One IBM 4245 printer mdl 1, or an equivalent device supported by the operating system, with at least 132 print positions.
- One IBM tape unit, such as IBM 2400 or 3400 or equivalent.
- One IBM 3277 display station mdl 2 or equivalent with data entry keyboard.

SOFTWARE REQUIREMENTS

IFS 4 is written in PL/I and Assembler language and is supplied in the form of relocatable modules and source code. It operates under DOS/V.S. Release 34 and under DOS/V.S.E., program number 5745-020 Release 1.0 or subsequent releases (with VSE/Advanced Functions, program number 5746-XE8 Release 1.0 or subsequent releases) and VSE/VSAM, program number 5746-AM2, Release 1.0 or subsequent releases, unless otherwise specified.

To recompile IFS 4, the DOS PL/I Optimizing Compiler, program number 5736-PL1 and the DOS/V.S. Assembler are required.

To link-edit and execute IFS 4, the DOS PL/I Resident Library, program number 5736-LM4, the DOS PL/I Transient Library, program number 5736-LM5, and the DOS/V.S. Sort/Merge Version 2, program number 5746-SM2, are required. IFS 4 uses the data management and access methods VSAM and SAM, with the exception of the Daily Work File which uses DAM or VSAM. The VSAM organization of this file supports FBM devices.

The online communication facility CICS/DOS/V.S. Version 1, program number 5746-XX3, Release 4 or a subsequent release (unless otherwise indicated) is required.

For data base management, DL/I Entry DOS/V.S., program number 5746-XX7, Version 2.0 or DL/I DOS/V.S. Version 1, program number 5746-XX1, Release 4 or a subsequent release is required unless otherwise stated.

PERFORMANCE CONSIDERATIONS

The performance of the system may be influenced by VSAM specifications such as the buffer space, the control interval size and the record size. When the data base is distributed over more than one disk drive or when the index data base resides on a separate disk drive or when additional real storage is allocated, this may result in an increase in performance.

PROGRAM PRODUCTS

COMMERCIAL BANK APPLICATION SYSTEM (CBAS)

CBAS Base Product ... 5746-F60
 Demand Deposit Accounting ... 5746-F61
 Savings Accounting ... 5746-F62
 Time Certificates of Deposit Accounting ... 5746-F63
 General Ledger Accounting ... 5746-F64
 Revolving Credit Accounting ... 5746-F65

PURPOSE

Commercial Bank Application System, a set of applications software for commercial banks, complements Customer Information Facility/VSE and uses the DOS/VSE environment to provide financial account processing. CBAS consists of the following program products: Commercial Bank Application System Base Product Support (CBAS Base) (The base programs provide common support for any one or more of the five application products in CBAS, 5746-F60 ... Commercial Bank Application System Demand Deposit Accounting (CBAS DDA), 5746-F61 ... Commercial Bank Application System Savings Accounting (CBAS SAV), 5746-F62 ... Commercial Bank Application System Time Certificates of Deposit (CBAS TCD), 5746-F63 ... Commercial Bank Application System General Ledger Accounting (CBAS GNL), 5746-F64 ... Commercial Bank Application System Revolving Credit Accounting (CBAS RVC), 5746-F65. The Commercial Bank Application System provides a commercial bank with batch application software to support key application areas. Using IBM's Data System products, CICS/DOS/VS, DL/I DOS/VS and CIF/VS, the product will support Demand Deposit Accounting, Savings Accounting, Time Certificates of Deposit Accounting, Revolving Credit Accounting and General Ledger Accounting.

HIGHLIGHTS

- Functionally integrated with CIF/VS to provide consistent customer and application data management.
- Standardized forms, codes and data.
- Comprehensive audit trail.
- Automatic transfers.
- Application generated inputs to the General Ledger application.
- Comprehensive reporting.

HIGHLIGHTS of CBAS BASE:

- CBAS Base is designed to contain the common code necessary to perform functions for any one or more CBAS application products.

HIGHLIGHTS of CBAS DDA: (Demand Deposit Accounting)

CBAS DDA is designed to provide:

- Collected balance analysis.
- Controlled overdraft limit.
- Multiple service charges.
- Multiple statement cycles.
- Optional Stop Payment reporting.
- Free form statement messages.
- Individual account analysis.
- Formatted direct deposit (Social Security Checks) processing.
- Interest bearing DDA (NOW accounts).

HIGHLIGHTS of CBAS SAV: (Savings Accounting)

CBAS SAV is designed to provide:

- Support of nine savings plans.
- Daily accrual accounting.
- Multiple interest payment methods.
- Free form statement messages.
- Multiple interest calculations.
- Multiple statement periods.

HIGHLIGHTS of CBAS TCD: (Time Certificates of Deposit Accounting)

CBAS TCD is designed to provide:

- Multiple payment methods.
- Multiple payment frequencies.
- Multiple maturities.
- Optional 1099 penalty reporting.

HIGHLIGHTS of CBAS RVC: (Revolving Credit Accounting)

CBAS RVC is designed to provide:

- Overdraft banking.
- Automatic loan checks.

- Cycled statements.
- Multiple interest rates.
- Overline reporting.

HIGHLIGHTS of CBAS GNL: (General Ledger Accounting)

CBAS GNL is designed to provide:

- Nine levels of reporting.
- Descriptive entries.
- Internal and external interfaces.
- Optional detailed statement reporting.
- Budget analysis.
- Seven year actual budget history.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

These licensed programs are designed to operate on:

Processors: IBM S/370, 3031, and 4300 Processors supported by DOS/VSE that meet the minimum processor storage requirements described below.

For batch or online processing, CBAS requires 100K bytes of real storage and 500K bytes of virtual storage, in addition to the storage required for the VSE operating system, CICS/DOS/VS and DL/I DOS/VS.

The minimum machine requirements for CBAS are:

- One IBM 4331 Mdl J01 Processor (1M).
- Two IBM 3370 mdl A01 or five IBM 3310 (3 mdl A02 and 2 mdl B01) direct access storage devices. To install CBAS and execute the provided samples, approximately 400,000 FBA blocks on the above devices or equivalent storage on IBM 3330, IBM 3340, or IBM 3350 direct access devices are required.
- One IBM 3262 printer or an equivalent device supported by the operating system, with at least 132 print positions.
- Three IBM 8809 tape drives or equivalent supported by the operating system.
- Two IBM 3277, 3278 or 3279 Display Stations mdl 2 or equivalent.

SOFTWARE REQUIREMENTS

CBAS is written in COBOL and Assembler language and is supplied in the form of core image phases and source statement books. It operates under the DOS/VSE operating system using an IPO/E environment, with VSE/Advanced Functions Release 2 (5746-XE8) or subsequent releases, and VSE/VSAM Release 2 (5746-AM2) with the VSE/VSAM Space Management for SAM and Backup/Restore features, or subsequent releases, unless otherwise specified.

To compile CBAS, the functions of the COBOL Compiler (5746-CB1) and DOS/VS Assembler are required.

To link-edit and execute CBAS, the COBOL Libraries (5746-LM4), the DOS/VS Sort/Merge Program Version 2 (5746-SM2) or equivalent, the online communication facility CICS/DOS/VS Version 1 Release 5 (5746-XX3), the data base management facility DL/I DOS/VS Version 1 Release 5 (5746-XX1) with the HLP1 Release 2 ICR, the Interactive Computing and Control Facility VSE/ICCF (5746-TS1), the Interactive Productivity Facility (5748-MS1), VSE/IPC Interactive Problem Control System (5746-SA1), VSE/POWER (5746-XE3), and the Customer Information Facility/VS (CIF/VS) Version 1 for DOS/VS (5746-XXS) with support for CBAS (to be available concurrently with CBAS availability), or subsequent releases, are required unless otherwise specified.

SECURITY, AUDIT and CONTROL

Extensive control and audit features are included in CBAS applications. Transaction journals and master file change lists are regularly produced. In addition, master file changes are controllable. Special programs are available to supply auditor and regulatory agency required data.

CBAS uses security features provided by the operating system (DOS/VSE), the data communications manager (CICS/DOS/VS), and the data base manager (DL/I DOS/VS). Security features of those products are also available to the user. Required additional security measures may be placed in the application programs. Since the appropriateness of controls may depend upon the environment, user management is responsible for their selection, implementation and adequacy.

Commercial Bank Application System General Information Manual

PROGRAM PRODUCTS

**HEALTH CARE SUPPORT ACCOUNTING SYSTEM
5746-H14**

PURPOSE

The Health Care Support/Accounting System consists of the Health Care Support/Accounting Base Program and the Health Care Support/Accounting Application Program. The Accounting System provides hospital accounting for the single or multiple hospital environment. The Accounting Application Program includes patient billing, accounts receivable, general ledger and inquiry.

DESCRIPTION

The Health Care Support/Accounting System is written in ANS COBOL and Assembler. Inquiry is provided through DOS CICS/STANDARD.

The Health Care Support/Accounting Base Program provides the basic facilities of the input edit tables, error reporting routines, utility subprograms, hospital profile and report format control adaptability features to the Health Care Support/Accounting Application Program and to a related medical system in the Health Care Support family, the Laboratory Information System (Program Product 5746-H12).

The design of the Health Care Support/Accounting System allows the individual user, in either a shared or non-shared environment, to tailor processing procedures and report formats to meet his particular requirements. Data security is maintained through input and data set identification. Each hospital is able to inquire into or modify only its own data.

The programs can be used, as released, for data entry and report output at the central computer location, or with the Health Care Support/Data Communications Program (Program Product 5746-H13) for remote batch data entry and output.

The Health Care Support/Accounting Application Program supports the application areas of patient billing, accounts receivable, general ledger and billing and provides inquiry under the Customer Information Control System (CICS). Accounting services are provided for both inpatients and outpatients, and include Medicare and other insurance proration and preparation of billing forms. In addition, in-patient census, cost allocation, revenue and statistics are provided.

This feature coupled with the Accounting Base Program is an enhancement of the Shared Hospital Accounting System (SHAS) Type II (360A-UH-11X). Following are the major enhancements to the SHAS program.

- Programs run under the Disk Operating System/Virtual Storage (DOS/VS).
- Device support has been extended to include System/370 devices.
- Programs have been converted to ANS COBOL from COBOL D.
- The inquiry programs now operate under CICS, thus allowing the foreground partition to process additional programs concurrently.
- To support outpatient functions, the following enhancements have been included: combining the inpatient and outpatient records into a single disk resident file, an alphabetic outpatient directory report and inquiry into outpatient accounts. Also provided is the facility to change an account from preadmit status to inpatient or outpatient, from inpatient to outpatient or from outpatient to inpatient
- In the General Ledger Application, the cost allocation program now accepts statistics and dollar amounts to calculate cost allocation ratios rather than requiring manual calculation of these ratios.

Features

The Accounting Base Program

- The use of the DOS/VS catalogued procedure library allows execution of job streams from catalogued job control statements.
- The Hospital Profile, a disk file containing each user's individual specifications of processing options.
- The Edit Specifications Table, for standardized editing of patient data.
- Error Reporting routines, to provide consolidated reporting of certain operational errors.
- The utility subprograms, used by application programs for common routines.
- Report Format Control, which allows the tailoring of many report formats to user specifications.

The Accounting Application Program

Patient Billing

- Creation of patient records for inpatients, outpatients and preadmitted patients.
- Charge posting with central pricing.

- Inpatient census reports prepared in four sequences: Alphabetic, nursing station (with or without patient's daily balance forward), doctor and religion.
- Automatic proration of charges between the patient and up to four insurance plans, including Medicare
- Inquiry under CICS into Inpatient and Outpatient Billing Indexes.
- Preparation of patient and insurance bills.
- Transfer to accounts receivable after final bill.
- Accumulation of revenue and usage data.
- Doctor statistics.

Accounts Receivable

- Preparation of statements.
- Recording of cash payments and adjustments.
- Accounts stored either on tape (off-line) or disk (on-line).
- Full status on-line inquiry under CICS if accounts are stored on disk.
- Aged trial balance.
- Selection of accounts by financial class.
- Listing of accounts requiring a final diagnosis.
- Listing of accounts with insurance receivables.
- Listing of accounts which have failed to meet installment payments.
- Bad debt reports.

General Ledger

- Ledger Posting.
- Trial Balance.
- Comparative Income and Expense Report.
- Balance Sheet.
- Operating Statement.
- Cost allocation methods suitable for Medicare -- stepdown and double apportionment with automatic calculation of cost allocation ratios.

USE

The Accounting System processes input data against patient and account master files. These files are established through procedures supported by the Accounting System programs. Patient admissions and dismissals, charges, payments and accounting transactions are processed for multiple or single hospitals. File update and report jobs are controlled by the central operator through DOS/VS catalogued procedures.

Balance and edit, maintenance and error reporting routines process data for all applications. Update routines in each application maintain and back up tape and disk master files. Report routines can select data for individual hospitals from billing and receivables tape and disk files.

CUSTOMER RESPONSIBILITIES

A thorough understanding of DOS/VS and of CICS by customers using inquiry ... knowledge of ANS COBOL and Assembler ... preparing master file data ... center operator training ... establishing proper transition and backup procedures ... selection of options through the Hospital Profile.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The minimum S/370 IBM machine configuration required to compile, execute, and maintain the Health Care Support/Accounting Base Program with the Health Care Support/Accounting Application Program or the Health Care Support/Laboratory Information System without teleprocessing terminals is: IBM 3125 Processing Unit mdl FE (98,304 bytes) with IBM 3333 Disk Storage and Control mdl 1 (2 drives), 1403 Printer/5425 Card Unit Power Prerequisite (4505), Integrated 1403 Attachment (#4662), 3411 Magnetic Tape Adapter (#4675), Integrated 3504 Card Reader Attachment (#4680), Integrated 3525 Card Punch Attachment (#4685) ... 1403 Printer mdl 2 ... IBM 3504 Card Reader mdl A1 ... IBM 3525 Card Punch mdl P1 ... One IBM 3411 Magnetic Tape Unit and Control Unit mdl 1 with an IBM S/370 mdl 125 Attachment (#7361) ... One IBM 3410 Magnetic Tape Unit mdl 1.

For a system with teleprocessing (inquiry only), the minimum S/370 configuration is: An IBM 3125 Processing Unit mdl G (131,072 bytes) with an Integrated Communications Adapter (#4640) with the necessary line groups and adapters for the terminals to be installed. The remainder of the configuration is the same as that for the non-teleprocessing system.

PROGRAM PRODUCTS

Health Care Support/Accounting (cont'd)

Supported processors are the IBM 3125, 3135, 3145, 3158 and 3031. For systems with inquiry, mdl G or larger is required.

Supported DASD devices are IBM 2314, 2319, 3333 and 3330. Supported printers are IBM 1403, 3211, and 4245. Supported card readers are IBM 2540, 3504, and 3505. Supported card punches are IBM 2540 and 3525. Supported tape drives are IBM 2400-series, 3410 and 3420.

Models and features are supported that are supported by the Disk Operating System/Virtual Storage (DOS/VS), ANS COBOL and CICS versions being used.

For further information, contact your medical industry marketing representative.

SOFTWARE REQUIREMENTS

The Health Care Support/Accounting System operates in virtual mode under the Disk Operating System/Virtual Storage (DOS/VS). Inquiry requires the Customer Information Control System/DOS-Standard (5736-XX7) and has all prerequisites of a CICS application program. Written in Assembler and ANS COBOL, the Accounting System also has the following requirements:

- System Control and Basic IOCS
- Direct Access Method
- Basic Telecommunications Access Method (Inquiry only)
- Assembler
- System Utilities
- Consecutive Tape IOCS
- Consecutive Disk IOCS
- Indexed Sequential File Management System
- Full ANS COBOL V3 Compiler and Library
- Tape and Disk Sort/Merge
- Virtual System Access Method

To support some devices, later versions of some of these programs may be required.

PROGRAM PRODUCTS

DOS FORTRAN IV LIBRARY OPTION 1 (5746-LM3)**PURPOSE**

The DOS FORTRAN IV Library Option 1 is an optional feature of the DOS FORTRAN IV Library that provides the ability to use new S/370 I/O devices with larger block sizes and to create and process magnetic tape files that conform to the American National Standard Code for Information Interchange. Library Option 1 is required for 3330, 3340, 3330 mdl 11, 3350, fixed block devices, 2560 and 5425 object time support. Library Option 1 is required for FORTRAN support of DOS/VSE with VSE Advanced Function Release 2. Support of other card readers, card punches and printers is commensurate with current DOS FORTRAN support for these device classes. Support of fixed block devices does not include object time support of direct access files.

DESCRIPTION

The features of the support include:

- 3330/3333 Disk Storage Facility
- 3340 Disk Storage Facility
- 3350 Disk Storage Facility
- 3330 Disk Storage Facility mdl 11
- Fixed Block Disk Device
- 3410 and 3420 Magnetic Tape Subsystems
- 3505 Card Reader and 3525 Card Punch
- 3211 and 4245 Printers
- 2560 Multifunction Card Machine
- 5425 Multifunction Card Unit

EBCDIC tape records can be expanded to a capacity of 32,767 bytes, disk records to track capacity size.

Data interchange with any computer system that supports the ASCII codes.

The ability to vary the blocksize of the records on tape from 18 to 2,048 bytes for ASCII as well as EBCDIC files. Tape capacity and tape processing time are improved by the ability to utilize larger blocksize.

Meets requirements for data interchange as defined by National and Federal Standards.

This is in addition to the existing support provided by DOS FORTRAN IV which includes:

- 3410 and 3420 Magnetic Tape Subsystems
- 3505 Card Reader and 3525 Card Punch
- 3211 and 4245 Printers

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

The minimum features required are those of the Disk Operating System and FORTRAN IV. These requirements are as follows:

- One I/O channel (either multiplexer or selector)
- One card reader (IBM 1442, 2501, 2520, 2540, 3505, 2560 or 5425)
- One printer (IBM 1403, 1404, and 1443, 3211 or 4245)
- One printer-keyboard (IBM 1052)
- One IBM 2311 Disk Storage Drive or IBM 2314 DASD or IBM 2319 Disk Storage or IBM 3330/3333 Disk Storage or IBM 3340 Disk Storage
- One 9-track IBM 2400/3400-series magnetic tape drive
- The standard instruction set
- The floating-point feature (#4427)
- FORTRAN compilation requires 40K bytes
- Object time execution of FORTRAN programs with ASCII support require at least 40K bytes in DOS releases prior to Version 5. The feature operates on S/360 if the ASCII support is required.

SOFTWARE REQUIREMENTS

In addition to the S/360 Disk Operating System with ASCII support, the following are required to operate DOS FORTRAN IV Library Option 1:

FORTRAN IV Compiler	360N-FO-479
FORTRAN Library	360N-LM-480

The DOS FORTRAN IV Compiler does not require a Library Option 1 to compile using the S/370 I/O devices.

The FORTRAN IV library with Option 1 will operate under the Disk Operating System, Release 27, and under all subsequent releases, versions, and modifications, unless otherwise stated in a future version of this document. The library will operate under DOS Releases 24 through 26 if the ASCII support option alone is desired.

Support of the 2560 Multi-function Card Machine is available with Release 28 and all subsequent releases, versions, and modifications unless otherwise stated in a future version of this document.

Support of the 3340 disk storage facility and the 5425 Multi-function Card Unit is available with Release 29 and all subsequent releases, versions, and modifications unless otherwise stated in a future version of this document.

Support of the 3350 and 3330 mdl 11 disk storage facilities is available with Release 34 and all subsequent releases, versions and modifications unless otherwise stated in a future version of this document.

Support of the fixed block disk storage devices is available with DOS/VSE with VSE/Advanced Functions Release 2 and all subsequent releases, versions and modifications unless otherwise stated in a future version of this document.

COMPATIBILITY

The DOS FORTRAN IV Library Option 1 in no way affects existing data sets. Data sets created by Library Option 1 are acceptable as input to any system that offers similar support. An ASCII file is specified by a CALL in the program to the OPSYS routine in the Library. Another compiler may require ASCII to be specified in a different way.

PROGRAM PRODUCTS

**LIFE INQUIRY/DATA ENTRY
5746-N11**

PURPOSE

Life Inquiry/Data Entry provides online terminal capability for inquiry into Consolidated Functions Ordinary (CFO) policy master records, policy value quotations, and direct entry of the file maintenance, accounting, and status transactions. Normally these transactions are input to the batch daily cycle programs, CFO II (5736-N13) and '62 CFO (Type II program 1401-IL-02X). Life Inquiry/Data Entry utilizes the 3270 Information Display System and operates under control of CICS/DOS/VS, CICS/OS/VS or IMS/VS.

Life Inquiry/Data Entry provides CFO II and '62 CFO users with a terminal entry facility for all CFO status, file maintenance and accounting transactions. Both CFO systems are sequential file, batch oriented processing systems. Inherent in these systems are 24-hour turnaround of policy information, and other delays associated with transaction preparation. Life Inquiry/Data Entry provides immediate policy and quotation information through 3270 screen displays. Terminal entry of the file maintenance, status, and accounting transactions provides online editing, transaction generation, and transaction warehousing for subsequent input to the CFO daily cycle.

A load/update utility program is provided to create and maintain the DASD (Direct Access Storage Device) policy master file. This program will also convert '62 CFO policy master records to the required CFO II format utilized by Life Inquiry/Data Entry. The DASD file which is created can be either a VSAM (Virtual Storage Access Method) file or a DL/I (Data Language/I) file.

DESCRIPTION

Life Inquiry/Data Entry, featuring the 3270 Information Display System, is designed to simplify CFO daily cycle transactions entry. The terminal operator simply enters a CFO transaction code and policy number. Life Inquiry/Data Entry responds with screen displays providing a 'conversation' with the terminal operator. The CFO transaction is then generated by the program and stored on a DASD file for subsequent input to the CFO daily cycle. A utility program is also provided which reformats the stored transactions into a form acceptable as input to the CFO daily cycle through program A00.

The inquiry function includes those status transactions in the batch system of CFO II and '62 CFO requesting policy image and quotation information.

The data entry logic provides transaction processing for all recognized CFO II and '62 CFO external transactions. In addition, two levels of editing are provided for all status transactions and the following high volume file maintenance transactions:

- Change name and address trailer
- Change billing fields
- Change par options
- Change suspend code
- Change state/area and branch/agency
- Add/delete change/notification trailer

In the event of a system failure, the restart facility provided with Life Inquiry/Data Entry will re-position the transaction output file, reconstruct the necessary operator and batch control tables, and allow the operator to identify the last transaction that was accepted.

HIGHLIGHTS

Improved policyholder and agent service - policy image and value quotation facilities in this terminal environment provide immediate answers to inquiries. This is in comparison to the turnaround in the CFO batch system.

Fewer rejected transactions in batch system - the editing facilities for the data entry transactions provide transaction correction at the terminal, thus reducing the number of rejections in the batch system and the overhead associated with correction.

Reduced turnaround of transaction entry - many transactions effectively require two daily cycles for entry, the first being an image display of the master record for the required information in the transaction. The need for this first cycle is eliminated because immediate image display and quote information is available via the 3270 Information Display system for entry of the transaction.

Reduced clerical effort in transcribing and keying transactions - since the program has access to the policy master file, much information required for keypunch creation of transactions is automatically generated by the program. The system also provides the user with the ability to have transactions entered at the point of origin - thereby eliminating the need for coding and, subsequently, keypunching the transactions.

Reduced paperwork - fewer hard-copy image and quotation requests are needed because of terminal displays. The overhead associated with internal routing of the batch system's printed output will be reduced due to lower volume.

Alpha Search Inquiry System (Program Number 5736-N14) interface - for CICS/VS, when the policy number is not readily available. Life

Inquiry/Data Entry processing may be initiated by policyholder name through an interface with the Alpha Search Inquiry System.

Utilization of the 3270 Information Display System - dual intensity screen, protected data fields, read modified data only, program tab, and 1920 character screen.

CUSTOMER RESPONSIBILITIES

To successfully install Life Inquiry/Data Entry, the user must:

Acquire a thorough knowledge and understanding of the Life Inquiry/Data Entry system, using the *Operations Guide* and *Program Reference Manual* written for the system.

Secure and generate the applicable CICS/DOS/VS, CICS/OS/VS, or IMS/VS system, and be knowledgeable in its operational and functional characteristics.

Be knowledgeable in the characteristics of the applicable operating system environment and in its data management facilities.

Insert values in the customer constants and customer tables supplied with the system.

Prepare parameters for tailoring the batch load/update program to the user's requirements.

Assemble and link the batch load/update program, the inquiry/data entry modules, and the transaction reformat program.

Create the DASD policy master file using the load/update program.

Review user modifications to the CFO daily cycle programs for their impact on the Life Inquiry/Data Entry system.

Develop appropriate procedures to input the data entry transaction file to the CFO daily cycle. This could include modifying program A00 to accept other than card input.

Train terminal operators in the operation of the 3270 Information Display Station.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The minimum machine requirement is a S/370 processor operating with DOS/VS or OS/VS or with these operating systems operating under VM/370. A virtual partition or region size of at least 64K bytes (excluding access methods) is required for the batch load/update program. The Life Inquiry/Data Entry online modules require a minimum virtual partition or region which has 24K bytes in addition to the CICS/VS requirement or 80K bytes in addition to the IMS/VS requirement. The additional storage is divided as follows:

Description	Bytes	
	CICS/VS	IMS/VS
I/O Areas and Work Areas	2K	2K
Transaction Work Area (CICS) or Scratch pad area (IMS)	2K	8K
Main Application Area	18K	68K
Reserved for Maintenance	1K	1K
Reserved for Customer Modifications	1K	1K
Total	24K	80K

DASD space is required for the policy master file, the program libraries, transaction storage, and the system control program requirements. An 80-column card reader, 132 character/line printer, and two tape units are required for the load/update program.

Also required is the 3270 Information Display System with appropriate control units (local or remote). The display stations must include a 1920 position display screen with an appropriate keyboard (either #4631, #4633, or #4635).

In addition, it is assumed that the minimum configuration for installing and executing CFO II (5736-N13) or '62 CFO (1401-IL-02X) is available.

CICS main storage estimates are explained in the section entitled "Storage Estimates and Considerations" of the *CICS General Information Manual* (GH20-1280). To determine IMS/VS storage estimate, complete the worksheet in the *IMS/VS System/Application Design Guide* (SH20-9025).

DL/I DOS/VS storage requirements are explained in the *DL/I General Information Manual* (GH20-1246).

SOFTWARE REQUIREMENTS

This program product runs under either a Disk Operating System (DOS/VS) or Operating System (OS/VS) environment on S/370 with virtual storage capabilities. The programs are written in S/370 Assembler language Communication with CICS/DOS/VS or CICS/OS/VS is via CICS macro instructions. Communication with IMS/VS is via standard calls to IMS.

PROGRAM PRODUCTS

Life Inquiry/Data Entry (cont'd)

The batch load/update program operates as a single task within a partition. The Life Inquiry/Data Entry modules operate as single tasks under control of CICS/DOS/VS, CICS/OS/VS, or IMS/VS.

For CICS/DOS: In addition to DOS/VS components and options specified for CICS, (see the section entitled "Programming Systems" in the *CICS General Information Manual* (GH20-1280)), the following components are required:

Virtual Storage Access Method (VSAM) or Data Language/I (DL/I) DOS/VS (5746-XX1).

DOS Sort/Merge (5746-SM1) or DOS/VS Sort/Merge (5743-SM1).

For CICS/OS/VS: In addition to the OS/VS components and the options specified for CICS (see the *CICS General Information Manual* GH20-1280), or those options specified for IMS (see the *IMS General Information Manual* GH20-1260); the following components are required:

Virtual Storage Access Method (VSAM) or IMS/VS Data Base System (5740-XX2).

OS Sort/Merge (5734-SM1) or OS/VS Sort/Merge (5740-SM1).

For IMS/VS: When operating under the control of IMS/VS Life Inquiry/Data Entry requires the full capabilities of IMS/VS DB/DC System (5740-XX2).

DOCUMENTATION: (available from Mechanicsburg)

General Information Manual (GH20-1499) ... *Sales Flyer* (G520-2846).

PROGRAM PRODUCTS

**BASIC TELECOMMUNICATIONS ACCESS METHOD
EXTENDED SUPPORT (BTAM-ES)
5746-RC5****PURPOSE**

The Basic Telecommunications Access Method Extended Support provides basic support for data communications on DOS/VSE systems.

HIGHLIGHTS

BTAM-ES is based on the Basic Telecommunications Access Method (BTAM) component of DOS/VS Release 34. It operates under the control of DOS/VSE and provides the same facilities as BTAM for performing the following operations:

- Initiating and answering calls to and from terminals on switched networks.
- Polling and addressing terminals on nonswitched multipoint lines.
- Changing the status of terminal lists.
- Transmitting and receiving messages.
- Posting completion status of messages.
- Managing buffer pools.
- Translating codes.
- Providing error recovery procedures.
- Providing online terminal test facilities.
- Keeping error statistics.

BTAM-ES supports the communications adapter of the 4331 Processor with Binary Synchronous and/or Start/Stop capability, in addition to the ICAs, 270X and 370X currently supported by BTAM.

BTAM-ES will operate on the DOS/VSE operating system in S/370 Compatibility mode or Extended Control Program Support for Virtual Storage Extended (ECPS:VSE) mode.

BTAM-ES will not operate with DOS/VS Release 34 or prior releases of DOS/VS.

DESCRIPTION**ADVANTAGES**

The BTAM-ES facilities may be used in all or any of the DOS/VSE system partitions in either real or virtual mode, or may be used to design a dedicated data communications system in a system with a single partition.

Like BTAM, BTAM-ES provides a multiple WAIT macro instruction for use by data communications line operations only. This macro instruction enables the data communications program to release control of the central processing unit until one or more of a series of events has occurred (such as the completion of a BTAM-ES READ or WRITE operation). Thus it provides for the efficient concurrent operation of lower priority programs.

BTAM-ES will provide support for a variety of BSC and start/stop devices as well as for various channel attached devices. The support covers both low and high speed devices. This gives BTAM-ES considerable flexibility and provides for a wide range of applications. (See BTAM-ES Terminal Support Chart 1 for a list of terminals supported).

The user may employ any of the IOCS macro instructions provided by the system in the design of his telecommunications application.

COMMUNICATION SERVICEABILITY FACILITIES

Communication Serviceability Facilities are provided on an optional basis by BTAM-ES. The user is strongly advised to include these facilities with BTAM-ES since they increase system availability by providing statistics and diagnostic aids for system repair and preventive maintenance.

The following facilities are provided:

- Error Recovery Procedures are provided on a line basis. The operation in error is retried. If the error persists a descriptive message is output to the system console. Certain nonrecoverable errors result in termination of the job and a storage dump. Diagnostic Write and Read commands (2701 only) are performed to isolate nonrecoverable errors to either the control unit or external source.
- Error Counts are maintained on a line basis and output to the system console if the error rate becomes excessive. The user program can request error statistics from the cumulative counters to be output to the system console.

- Online Terminal Test Procedures operate concurrent with user programs and do not impact user operations apart from the time taken to perform their functions. (When tests use the IBM 2760 the film should be reloaded before continuing the job.) Tests requested from a terminal can be returned to that terminal or to any other terminal on the same system. Normal operation is maintained for unaffected terminals within the system.

CUSTOMER RESPONSIBILITIES

To install and use BTAM-ES, the customer must:

- Design the data communications configuration.
- Order and install all required communications equipment.
- Install BTAM-ES and the corequisite BTAM System Control Programming (SCP) modules and macros (Program Number 5747-CG1).

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

BTAM-ES runs in a virtual storage environment on the IBM processors supported by the Disk Operating System Virtual Storage Extension (DOS/VSE) in S/370 Compatibility mode or in Extended Control Program Support for Virtual Storage Extended (ECPS:VSE) mode.

Communications Facilities: See BTAM-ES Terminal Support Chart 2.

Communications Controller Support: See BTAM-ES Terminal Support Chart 1.

SOFTWARE REQUIREMENTS

BTAM-ES is designed to run on DOS/VSE with the VSE/Advanced Functions program product.

Use of BTAM-ES requires the concurrent installation of corequisite BTAM SCP modules and macros (Program Number 5747-CG1) which should only be installed by BTAM-ES users.

COMPATIBILITY

The BTAM-ES functions are source compatible with the functions of the BTAM component of DOS/VS Release 34.

As indicated under Migration Considerations, reassembly and link edit of the BTMOD macro is required.

DATA SECURITY, AUDITABILITY AND CONTROL

User management is responsible for the implementation of appropriate administrative and application controls to prevent unauthorized access to the system.

PLANNING AND MIGRATION CONSIDERATIONS

Planning Considerations: In a multiple partition environment, the teleprocessing program will normally operate in a high priority partition that will include the BTAM-ES modules and macros combined with the user's message processing routines.

Data Communications Considerations: All data communications devices with the exception of the 2701 SDA-II, the Integrated Communications Adapters of S/370 mdl 135/138, the Communications Adapter of the 4331 Processor, the 2840-2260 (local), the 3270 (local) and the 3704-3705-1/3705-II must be attached to the multiplexer channel, and no burst mode device may co-exist on the channel with data communications devices. Support for the 2701 SDA-II attached to a selector channel is limited to nonswitched (leased or private line connection) networks.

Refer to the appropriate processor or device documentation for specific attachment capabilities.

All start/stop terminals on a multipoint nonswitched line must be of the same type. Different types of terminals may be mixed within the same problem program.

Various BSC terminals and remote processors are supported by BTAM-ES.

Different types of BSC terminals may be mixed on the same multipoint line in a nonswitched network or on the same computer phone number in a switched network. The BSC terminal mix capability is shown in the BTAM-ES Terminal Support Chart 2.

Migration Considerations: For BTAM application programs running on DOS/VS Release 34, the BTMOD macro must be reassembled on DOS/VSE to produce the BTAM-ES logic module which must then be link edited with the BTAM application program. Reassembly of the whole BTAM application program is required to obtain the latest maintenance level of the BTAM macros.

In order to take advantage of new capabilities provided by the DOS/VSE system, changes may be required to user application programs now running on DOS/VS Release 34.

PROGRAM PRODUCTS

BTAM-ES (cont'd)

PERFORMANCE and STORAGE CONSIDERATIONS

Response time in a BTAM-ES system is dependent on a variety of processors and data communications load factors, such as:

- Line speeds.
- Number, type and organization of terminals.
- Number and type of macro instructions used.
- Amount of processing performed by the application programs.

For application programs using BTAM-ES, storage requirements depend on the BTAM-ES modules and macros themselves and also on the extent of the following user-specified areas and functions: I/O buffer areas ... terminal lists ... message processing routines ... number of macro instructions issued ... number of lines supported ... number of terminals per line ... line procedure specifications.

The design objective for BTAM-ES is to have no more than a minor increase in storage requirements over BTAM on DOS/V5 Release 34.

BTAM-ES TERMINALS SUPPORTED

BTAM-ES supports the following terminals, programmable features, transmission control units and communications controllers. Programmable features which change the control or transmission characteristics and which are not shown are not supported. Attempts to use BTAM-ES with unsupported features can cause unpredictable results.

The user should be aware that many terminal and control unit special features are transparent to programming, and therefore readily usable even though not specifically identified. Note that the appropriate line adapters and hardware attachment features must be included in the system configuration.

Terminals that are functionally equivalent to those specifically supported by BTAM-ES may also function satisfactorily with BTAM-ES; the customer is responsible for establishing equivalency. IBM assumes no responsibility for the impact that any changes to the IBM-supplied programs or products may have on such terminals.

REMOTE ATTACHMENT

Terminals and Terminal Features

SS LINES:

IBM TERMINALS

- 1030 Data Collection System on nonswitched lines:
 - 1031 Input Station (Mdl's A1, A2, A3, A4, A5, A6, A7) :
 - Supported: Attachment of 1031, 1033, 1034, 1035
 - 1031 Input Station (mdls B1, B2, B3, B4, B5, B6, B7) :
 - Supported: Attachment of 1035
 - 1033 Printer
 - 1034 Card Punch
 - 1035 Badge Reader
- 1050 Data Communication System on switched or nonswitched lines:
 - 1051 Control Unit (mdls 1,2) :
 - Supported: Attachment of 1052, 1053, 1054, 1055, 1056, 1057, 1058, 1092, 1093
 - #1313 - Automatic EOB
 - #4795 - Line Correction
 - #4796 - Line Correction Release
 - #5465 - Open Line Detection
 - #6100 - Receive Interrupt
 - #9698 - Text Time-Out Suppression
 - #9700 - Transmit Interrupt
 - 1052 Printer-Keyboard (mdls 1,2) :
 - Supported: #1313 - Automatic EOB
 - #9567, #9597 - PTTC/BCD Code
 - #9571, #9591 - PTTC/EBCD Code
 - 1053 Printer (mdl 1) :
 - Supported: #9567, #9597 - PTTC/BCD Code
 - #9571, #9591 - PTTC/EBCD Code
 - 1054 Paper Tape Reader (mdl 1)
 - 1055 Paper Tape Punch (mdl 1)
 - 1056 Card Reader (mdls 1,3)
 - 1057 Card Punch (mdl 1)
 - 1058 Printing Card Punch (mdls 1,2)
 - 1092 Programmed Keyboard (mdls 1,2)
 - 1093 Programmed Keyboard (mdls 1,2)

2848 Display Control (mdls 1,2,3) on nonswitched lines:

- Supported: Attachment of 2260, 1053
- #3901 - Extended Cursor Control
- #4787 - Line Addressing
- #5340 - NonDestructive Cursor
- #5341 - NonDestructive Cursor Adapter
- 2260 Display Station (mdls 1,2) :
 - Supported: #3606 - Extended Cursor Control, Alphameric Keyboard
 - #4766 - Alphameric Keyboard
 - Not Supported: Tab feature of #3606
- 1053 Printer (mdl 4) :
 - Supported: #9567, #9597 - PTTC/BCD Code
 - #9571, #9591 - PTTC/EBCD Code

- 2845 Display Control (mdl 1) on nonswitched lines:
 - Supported: Attachment of 2265, 1053
 - #3301 - Destructive Cursor
 - #4801 - Line Addressing
 - Not Supported: #7801 - Tab
- 2265 Display Station (mdl 1) :
 - Supported: #4766 - Alphameric Keyboard
- 1053 Printer (mdl 4) :
 - Supported: #9567, #9597 - PTTC/BCD Code
 - #9571, #9591 - PTTC/EBCD Code

- 2740 Communication Terminal (mdl 1) on switched or nonswitched lines:
 - Supported: #3255 - Dial Up (switched only)
 - #6114 - Record Checking
 - #7479 - Station Control (nonswitched only)
 - #8028 - Transmit Control (switched only)
 - #8301 - 2760 Attachment
 - #9567, #9597 - PTTC/BCD Code
 - #9571, #9591 - PTTC/EBCD Code
 - Correspondence Code

- 2740 Communication Terminal (mdl 2) on nonswitched lines:
 - Supported: #1495, #1496 - Buffer Expansion
 - #1499 - Buffer Receive
 - #6114 - Record Checking
 - #9571, #9591 - PTTC/EBCD Code

- 2760 Optical Image Unit (mdl 1) on switched or nonswitched lines
- 3232 Keyboard Printer (Mdl 51) on switched lines supported as a CPT-TWX 33-35

- 3767 Communication Terminal (mdls 1,2) (supported as a 2740-1) on switched or nonswitched lines:
 - Required: #7111 - 2740-1 Start/Stop
 - Supported: #9560 - Station Control

- 3767 Communication Terminal (mdls 1,2,3) (supported as a 2740-2) on nonswitched lines:
 - Required: #7112 - 2740-2 Start/Stop

- 6733 Typewriter Communication Module on switched lines supported as CPT/TWX 33/35

IBM PROCESSORS AS TERMINALS

(For details of programming support provided within the Processor when acting as a terminal, see appropriate sales pages)

- System/7 (supported as a 2740-1 with checking) on switched or nonswitched lines:
 - Required: #1610 - Asynchronous Communication Control

NON-IBM TERMINALS

- AT&T 83B3 Line Control Type on nonswitched lines
- CPT/TWX (mdl 33/35) Line Control Type on switched lines
- World Trade Telegraph on nonswitched lines
- WU 115A Line Control Type on nonswitched lines

BSC LINES:

IBM TERMINALS

- 2790 Data Communication System on switched or nonswitched lines:
 - 2715 Transmission Control Unit (mdl 2) :
 - Required: 2740
 - Supported: Attachment of 2798, 1035, 1053
 - #3801 - Expanded Capability
 - #4850 - Local 2740 Adapter
 - #9401 - Point-to-point Nonswitched
 - #9402 - Point-to-point Switched
 - #9403 - Multipoint Nonswitched
 - 2740 Communication Terminal (mdl 1)
 - 2798 Guidance Display Unit (mdl 1)
 - 1035 Badge Reader (mdl 1)
 - 1053 Printer (mdl 1)

PROGRAM PRODUCTS

BTAM-ES (cont'd)

2770 Data Communication System on switched or nonswitched lines:
2772 Multipurpose Control Unit:

Supported: Attachment of 0050,0545,1017,1018,1053,
1255,2203,2213,2265,2502,5496
#1340 - Automatic Answering
#1490 - Buffer Expansion (256 bytes)
#1491 - Buffer Expansion Additional (512
bytes)
#1910 - Conversational Mode
#3250 - Display Format Control
#3650 - EBCDIC Transparency
#3860 - 144 Character Print Line
#4610 - Identification
#4690 - Keyboard Correction
#5010 - Multipoint Data Link Control
#5890 - Horizontal Format Control
#6555 - Space Compression/Expansion
#7705 - Synchronous Clock
#7950 - Transmit-Receive - Monitor-Print
#9140 - Extended Re-Entry
#9402 - Line Termination - 2-wire
#9761 - Transmission Code EBCDIC
#9762 - Transmission Code ASCII
#9936 - Immediate WACK

0050 Magnetic Data Inscrber
0545 Output Punch (mdls 3,4)
1017 Paper Tape Reader (mdls 1,2)
1018 Paper Tape Punch (mdl 1)
1053 Printer (mdl 1)
1255 Magnetic Character Reader
2203 Printer (mdls A1,A2) :
Supported: #5558 - Print Positions, 24 Additional
2213 Printer (mdls 1,2)
2265 Display Station (mdl 2)
2502 Card Reader (mdls A1,A2)
5496 Data Recorder

2780 Data Transmission Terminal on switched or nonswitched lines:

Supported: #1340 - Automatic Answering
#1350 - Automatic Turnaround
#3401 - Dual Communication Interface
#5010 - Multiple Record Transmission
#5020 - Multipoint Line Control
#5820 - 120 Character Print Line
#5821 - 144 Character Print Line
#6400 - Selective Character Set
#7850 - Terminal Identification
#8030 - EBCDIC Transparency
#9150 - Extended Retry Transmission
#9761 - ASCII Transmission Code
#9762 - EBCDIC Transmission Code

2980 General Banking System on nonswitched lines:

2972 Station Control Unit (mdl 8 - RPQ 858160, mdl 11 - RPQ
858231) :
Supported: Attachment of 2980,2971
RPQ 835503 - Buffer Expansion
RPQ 858165,858182 - 96-Character Buffer
2980 Teller Station (mdl 1 - RPQ 835504, mdl 4 - RPQ 858147)
2980 Administrative Station (mdl 2 - RPQ 835505)
2971 Remote Control Unit (mdl 3 - RPQ 858144)

3270 Information Display System on nonswitched lines:

3271 Control Unit (mdls 1,2) :
Supported: Attachment of 3277,3284,3286, 3287,3288
#1550 - Copy
#9761 - EBCDIC Code
3274 Control Unit (mdl 1C, 21C, 31C, 51C [supported as a 3271]):
Supported: Attachment of 3262, 3268 mdl 2, 3277,
3278, 3284, 3286, 3287, 3288, 3289
Buffer sizes of 960,1920,2560,3440 are also
supported.
3276 Control Unit Display Station (mdls 1,2,3,4) [supported as a
3271] :
Supported: Attachment of 3268 mdl 2, 3278, 3287
#6350 - Selector Light Pen
#9082 - EBCDIC Character Set.
Buffer sizes of 960,1920,2560,3440 are also
supported

3277 Display Station (mdls 1,2) :
Supported: #6350 - Selector Light-Pen
#9082 - EBCDIC Character Set.

3278 Display Station (mdls 1,2,3,4) [supported as 3277] :
Supported: #6350 - Selector Light Pen
#9082 - EBCDIC Character Set.
Screen sizes of 960,1920,2560,3340 are also
supported

3262 Printer (mdls 3, 13) [supported as a 3286-2]
3268 Printer (mdl 2) [supported as a 3284 or 3286]
3284 Printer (mdls 1,2) :
Supported: #9089 - EBCDIC Character Set.
3286 Printer (mdls 1,2) :

Supported: #9089 - EBCDIC Character Set.
3287 Printer (mdls 1,2) [supported as a 3284 or 3286]
Supported: #9082 - EBCDIC Character Set.
3288 Printer (mdl 2) [supported as a 3286-2] :
Supported: #9089 - EBCDIC Character Set.
3289 Printer (mdls 1,2) [supported as a 3286-2]

3270 Information Display System on switched lines or nonswitched
lines:

3275 Display Station (mdls 1,2) :
Supported: Attachment of 3284
#6350 - Selector Light-Pen
#9089 - EBCDIC Character Set.
#9761 - EBCDIC Code
3284 Printer (mdl 3) :
Supported: #9089 - EBCDIC Character Set.

3624 Consumer Transaction Facility (mdl 1, 2, 11, 12) (supported as a
2772)

Supported: Attached to a 3704/3705 via nonswitched
lines only

3650 Programmable Store System (Supported as a S/3) on switched or
nonswitched lines:

3651 Store Controller (mdls 25, 75) :
Supported: Attachment of 3275, 3653, 3657 3659, 3675,
3683, 3685, 3784

3275 Display Station (mdl 3)
Supported: Attachment of 3284

3284 Printer (mdl 3)
3653 Point of Sale Terminal
3657 Ticket Unit
3659 Remote Communications Unit (mdl 1)
3663 Supermarket Terminal (mdl 1P and 3P)
3683 Point of Sale Terminal (mdl 1)
3685 Display Control Unit (mdls 1, 2)
Supported: Attachment of 3686-1

3784 Printer (mdl 1)

3660 Supermarket Scanning System (supported as a S/3) on switched
lines:

3651 Store Controller (mdls A60, B60) :
Supported: Attachment of 3663,3669
3663 Supermarket Terminal (mdls 1,2) :
Supported: Attachment of 3666, 3667
3666 Checkout Scanner (mdl 1)
3667 Checkout Scanner
3669 Store Communications Unit (mdl 1)

3660 Supermarket Key-Entry System (supported as a S/3) on switched
lines:

3661 Store Controller:
Supported: Attachment of 3663
3663 Supermarket Terminal (mdls 1,2,3)

3680 Programmable Store System (supported as a S/3) on switched or
nonswitched lines:

3684 Point of Sale Control Unit mdls 1 or 2

3735 Programmable Buffered Terminal (mdl 1) on switched or
nonswitched lines:

Supported: Attachment of 5496,3286
#5010 - Multipoint Data Link Control
#9761 - EBCDIC Code
#9762 - ASCII Code

3286 Printer (mdl 3)
5496 Data Recorder (mdl 1)

3741 Data Station (mdl 2) on switched or nonswitched lines:

Supported: Attachment of 0129,3713,3715,3717
#1680 - Expanded Communications
#1685 - Expanded Communications/
Multipoint Data Link Control
#5450 - Operator Identification Card Reader
#7850 - Terminal Identification

0129 Card Data Recorder (mdl 2)
3713 Printer (mdl 1)
3715 Printer (mdls 1,2)
3717 Printer (mdl 1)

3741 Programmable Workstation (mdl 4) on switched or nonswitched
lines:

Supported: Attachment of 0129,3713,3715
#1680 - Expanded Communications
#1685 - Expanded Communications/
Multipoint Data Link Control
#5450 - Operator Identification Card Reader
#7850 - Terminal Identification

0129 Card Data Recorder (mdl 2)
3713 Printer (mdl 1)
3715 Printer (mdls 1,2)

3747 Data Converter (mdl 1) on switched or nonswitched lines:
Supported: #1660 - Communications Adapter

PROGRAM PRODUCTS

BTAM-ES (cont'd)

3770 Data Communication System (supported as a 2770) on switched or nonswitched lines:

3771 Communication Terminal (mdls 1,2,3) :
Required: #1460 - SDLC/BSC, Switch Control, or #1461 - BSC Point-to-point, or #1462 - BSC Multipoint
Supported: #1201 - ASCII Code

3773 Communication Terminal (mdls 1,2,3,P1,P2,P3):
Required: #1460 - SDLC/BSC, Switch Control, or #1461 - BSC Point-to-point, or #1462 - BSC Multipoint
Supported: #1201 - ASCII Code

3774 Communication Terminal (mdls 1,2,P1,P2) :
Required: #1460 - SDLC/BSC, Switch Control, or #1461 - BSC Point-to-point, or #1462 - BSC Multipoint
Supported: #1201 - ASCII Code

3775 Communication Terminal (mdls 1,P1) :
Required: #1460 - SDLC/BSC, Switch Control, or #1461 - BSC Point-to-point, or #1462 - BSC Multipoint
Supported: #1201 - ASCII Code

3776 Communication Terminal (mdls 1,2) [supported as a 2772/3780]:
Required: #1460 - SDLC/BSC, Switch Control, or #1461 - BSC Point-to-point, or #1462 - BSC Multipoint
Supported: #1201 - ASCII Code

3777 Communication Terminal (mdl 1) [supported as a 2772/3780]:
Required: #1460 - SDLC/BSC, Switch Control, or #1461 - BSC Point-to-point, or #1462 - BSC Multipoint
Supported: #1201 - ASCII Code

3780 Data Communications Terminal (mdl 1) [supported as a 2772 without component select] on switched or nonswitched lines:

Supported: #3601 - EBCDIC Transparency
#5010 - Multipoint Data Link Control
#5701 - Print Positions, Additional
#9761 - EBCDIC Code
#9762 - ASCII Code

4700 Finance Communication System on BSC nonswitched lines:
4701 Controller

5110 Computer (supported as a 2772) on switched or nonswitched lines:

Required: #2074 BSCA
Supported: Attachment of a 5103, 5106, 5114
The 5110 emulates the following 2772 features:
Auto Answer
Buffer expansion additional
144 Character print line
Identification
Multipoint Data Link Control
Horizontal Format Control
Space Compression/expansion
Synchronous Clock
Transmission Code EBCDIC

5230 Data Collection System (supported as a 3741-2,-4) on switched or nonswitched point-to-point lines:

5231 Controller (mdl 2):
Required: #2704 - BSCA

5260 Retail System (supported as a 3741) on switched or nonswitched point-to-point lines
5265 Communicating Model

5275 Direct Numerical Control Station (mdl 1) [supported as a 3275 with EBCDIC Code and EBCDIC Character Set] on switched or nonswitched lines

6670 Information Distributor (supported as a 2770) on switched, nonswitched or local attach lines:

Supported: The 6670 emulates the following 2770 features: (All items listed are standard on the 6670)
Automatic Answering
Buffer Expansion (256 bytes)
Buffer Expansion (512 bytes)
EBCDIC Transparency
Identification (Terminal only)
Space Expansion
Synchronous Clock
Extended Retry (Transmission)
Transmission Code EBCDIC
Transmission Code ASCII

(For details of programming support provided within the Processor when acting as a terminal, see appropriate programming sales manual pages)

1130 Computing System on switched or nonswitched lines:

1131 Central Processing Unit:
Required: #7690 - Synchronous Communications Adapter

1800 Data Acquisition and Control System on switched or nonswitched lines:

1826 Data Adapter Unit:
Required: #7550 - Communication Adapter

5280 Distributed Data System (supported as a 3271-2) on nonswitched lines:

5285 or 5288 Processor
Required: #3270 - 3270 Emulation Communications Adapter

5280 Distributed Data System (supported as a 3741) on switched or nonswitched lines:

5285 or 5288 Processor
Required: #2500 Communications Adapter

Series/1 (supported as a S/3) on switched or nonswitched lines:

4953 or 4955 Processor:
Required: #2074, #2075, or #2094 Binary Synchronous Communications Adapter

System/3 on switched or nonswitched lines:

5406 or 5410 or 5415 Processing Unit:
Required: #2074 - Binary Synchronous Communications Adapter

System/7 (supported as a S/3) on switched or nonswitched lines:

5010 Processor Module:
Required: #2074 - Binary Synchronous Communications Adapter

System/32 (supported as a S/3) on switched or nonswitched lines:

5320 System Unit:
Required: #2074 - Binary Synchronous Communications Adapter

System/34 (supported as a System/3) on switched or nonswitched lines:

5340 System Unit:
Required: #2500, #3500 or #4500 Communications Adapter feature

System/36 (supported as a System/3) on switched or nonswitched lines:

5360 System Unit:
Required: #2500 or #4500 Communications Adapter feature

System/38 (supported as a 3271 mdl 2) on a nonswitched line:

5381 System Unit
Required: #1501 or 1502 Communications Attachment #2001 or 2003 Communications Control

System/360 mdl 20 on switched or nonswitched lines:

2020 Processing Unit:
Required: #2074 - Binary Synchronous Communications Adapter

System/360 mdls 25,30,40,50,65,65MP,67(65mode), 75,85,91, 195 on switched or nonswitched lines:

Processing Unit:
Required: #4580 - Integrated Communications Attachment, or 2701 Data Adapter Unit, or 2703 Transmission Control, or 3704 Communications Controller in emulation mode, or 3705-I Communications Controller in emulation mode, or 3705-II Communications Controller in emulation mode

All virtual storage S/370 Processors or 4300 Processors on switched or nonswitched lines:

Processing Unit:
Required: #4640 - Integrated Communications Adapter, on S/370 mdls 115, 125, 135, 135-3, 138 or #1601 - Communications Adapter on 4331 Processor, or 2701 Data Adapter Unit, or 2703 Transmission Control, or 3704 Communications Controller in emulation mode, or 3705-I Communications Controller in emulation mode, or

PROGRAM PRODUCTS

BTAM-ES (cont'd)

3705-II Communications Controller in emulation mode

LOCAL ATTACHMENT

TRANSMISSION CONTROL UNITS AND COMMUNICATIONS CONTROLLERS

Integrated Communications Adapter of S/370 mdl 115:
Required: #4640 - Integrated Communications Adapter
Supported: #1291-#1296 - Autocall

Integrated Communications Adapter of S/370 mdl 125:
Required: #4640 - Integrated Communications Adapter
Supported: #1291-#1296 - Autocall

Integrated Communications Adapter of S/370 mdl 135, 135-3, 138:
Required: #4640 - Integrated Communications Adapter
Supported: EBCDIC Code is a standard feature
#9763-#9780 - Transparency
#9681-#9688 - ASCII Code
#9689-#9696 - 6-bit Transcode

Communications Adapter of 4331 Processor:
Required: #1601 Communications Adapter
Supported: #9681-#9688 - S/S Transmission Mode
#9671-#9678 - BSC Transmission Mode
Not Supported: #9691-#9698 - SDLC Transmission Mode

2701 Data Adapter Unit on local channel:
Supported: #1302, #1303, #1314 - Autocall
#3455 - Dual Code
#3463-#3465 - Dual Communication Interface
#8029 - Transparency
#9060 - EBCDIC Code
#9061 - ASCII Code
#9062 - 6-bit Transcode

2702 Transmission Control Unit on local channel:
Supported: #1290 - Autocall
#1319 - Autopoll
#8055 - 2741 Break

2703 Transmission Control Unit on local channel:
Supported: #1340, #1341 - Autocall
#7715 - EBCDIC Code
#7716 - ASCII Code
#7717 - 6-bit Transcode
#8055 - 2741 Break
#9100 - Transparency for ASCII

2715 Transmission Control Unit (mdl 1) on local channel:
Supported: See "2790" under *Local Terminals*

3704/3705-I/3705-II Communications Controller on local channel:
Supported: EBCDIC Code, ASCII Code, Autopoll and EBCDIC Transparency do not have special feature codes in the 3704/3705 EP/VS PEP

2795 Data Entry Unit (mdl 1)
2796 Data Entry Unit (mdl 1)
2797 Data Entry Unit (mdl 1)
2798 Guidance Display Unit (mdl 1)
1053 Printer (mdl 1)

3270 Information Display System on local channel:
3272 Control Unit (mdls 1,2) :
Supported: Attachment of 3277, 3284, 3286, 3287, 3288

3277 Display Station (mdls 1,2) :
Supported: #6350 - Selector Light-Pen
#9082 - EBCDIC Character Set.

3284 Printer (mdls 1,2) :
Supported: #9082 - EBCDIC Character Set.

3286 Printer (mdls 1,2) :
Supported: #9082 - EBCDIC Character Set.

3287 Printer (mdls 1,2) [supported as a 3284 or 3286 attached to 3272-1 or -2] :
Supported: #9082 - EBCDIC Character Set.

3288 Printer (mdl 2) (supported as a 3286-2) :
Supported: #9089 - EBCDIC Character Set.

3270 Information Display System on local channel: [Supported as a 3272]
3274 Control Unit (mdl 1B, 1D, 21B, 21D, 31D)
Supported: Attachment of 3262, 3268 mdl 2, 3277, 3278, 3284, 3286, 3287, 3288, 3289
Buffer sizes of 960, 1920, 2560, 3440 are also supported

3277 Display Station (mdls 1,2)
Supported: #6350 - Selector Light Pen
#9082 - EBCDIC Character Set.

3278 Display Station (mdls 1,2,3,4) [Supported as 3277]
Supported: #6350 - Selector Light Pen
#9082 - EBCDIC Character Set.
Screen sizes of 960, 2560, 3440 are also supported

3262 Printer (mdls 3, 13) [supported as a 3268-2]
3268 Printer (mdl 2) supported as a 3284 or 3286
3284 Printer (mdls 1, 2)
Supported: #9089 - EBCDIC Character Set.

3286 Printer (mdls 1, 2)
Supported: #9089 - EBCDIC Character Set.

3287 Printer (mdls 1,2) [Supported as a 3284 or 3286]
Supported: #9082 - EBCDIC Character Set.

3288 Printer (mdl 2) [Supported as a 3286-2]
Supported: #9089 - EBCDIC Character Set.

3289 Printer (mdls 1,2) [Supported as a 3286-2]

3270 Information Display System attached to the 4331 Processor Display/Printer Adapter and Display/Printer Adapter Expansion (Supported as a 3277-2):
3278 Display Station (mdl 2) [Supported as a 3277-2]
Supported: #9082 - EBCDIC Character Set.

3268 Printer (mdl 2) supported as a 3284 or 3286
3287 Printer (mdls 1,2) [Supported as a 3284 or 3286]
Supported: #9082 - EBCDIC Character Set.

2770 Audio Response Unit (mdl 3) on local channel

LOCAL TERMINALS

2848 Display Control (mdls 1,2,3) on local channel:
Supported: Attachment of 2260, 1053
#3901 - Extended Cursor Control
#4787 - Line Addressing
#5340 - NonDestructive Cursor
#5341 - NonDestructive Cursor Adapter

2260 Display Station (mdls 1,2) :
Supported: #3606 - Extended Cursor Control, Alpha-numeric Keyboard
Not Supported: Tab feature of #3606

1053 Printer (mdl 4):
Supported: #9567, #9597 - PTTC/BCD Code
#9571, #9591 - PTTC/BCD Code

2790 Data Communication System on local channel:
2715 Transmission Control Unit (mdl 1) :
Supported: Attachment of 2740, 2791, 2793
#3801 - Expanded Capability
#4850 - Local 2740 Adapter
Not Supported: #8110 - Two Processor Switch

2740 Communication Terminal (mdl 1)
2791 Area Station (mdls 1,2) :
Supported: Attachment of 1035, 2795, 2796, 2797, 2798, 1053

1035 Badge Reader (mdl 1)
2795 Data Entry Unit (mdl 1)
2796 Data Entry Unit (mdl 1)
2797 Data Entry Unit (mdl 1)
2798 Guidance Display Unit (mdl 1)
1053 Printer (mdl 1)
2793 Area Station (mdl 1) :
Supported: Attachment of 2795, 2796, 2797, 2798, 1053

M = Group of terminals which can operate on same BSC MP line and same line speed.

S = Group of terminals which can share the same phone number(s).

Notes:

- (a) If shown, the terminal type in parenthesis designates the programming support provided. E.g., "System/7 (2740-1)" means "the System/7 is supported as a 2740-1".
- (b) S/360 mdl's 25, 30, 40, 50, 65, 65MP, 67 (65 mode), 75, 85, 91, 195 with either BOS, BPS, DOS or OS. Any virtual storage S/370 Processor with either BOS, BPS, DOS, OS, DOS/VSE, DOS/VSE, OS/VS1 or OS/VS2.
- (c) 4331, 4341, 4361, 4381 Processors with either DOS/VSE or OS/VS1.
- (d) Terminal operates on local channel using nonswitched programming support.
- (e) Supported at 134.5 bps only.
- (f) IPL of S/7 is not supported in this network configuration.
- (g) 4331/4361 Processor Display/Printer Adapter.
- (h) 8130, 8140 Processors with DPPX/BASE or DPPX/SP and DPPX/DSC program products.

Legend:

- SS = Start/Stop
- BSC = Binary Synchronous Communications
- Local = Local Channel Attachment
- X = supported
- = not supported

PROGRAM PRODUCTS

**5746-RC7 - ACF/VTAME
ADVANCED COMMUNICATIONS FUNCTION
for VTAM ENTRY****PURPOSE**

Advanced Communications Function for VTAME Entry is a program product for users of the Disk Operating System/Virtual Storage Extended (DOS/VSE). ACF/VTAME provides support for the Communications Adapter (CA) of the 4331 Processor and also provides support for various channel attached devices. Key ACF/VTAM and ACF/NCP/VS functions are supported in ACF/VTAME including support for multisystem networking. The functions provided by ACF/VTAME are compatible with the analogous functions provided by ACF/VTAM Version 1 Release 2.

HIGHLIGHTS

- Support for the 4331 Communications Adapter instead of the 3705 Communications Contoller.
- Support for a variety of devices:
 - SNA-SDLC devices.
 - BSC 3270 devices.
 - SNA and nonSNA channel attached devices.
- Upwards compatible with ACF/VTAM Version 1 Release 2.
- Allows concurrent use of multiple ACF/VTAME application programs.
- Controls the sharing of network resources among ACF/VTAME application programs.
- Provides for application program to application program and application program to terminal sessions.
- Provides a multisystem networking capability as part of ACF/VTAME.
- Support of CICS/DOS/VS, VSE/POWER, DSX and other related IBM programs.
- Support of the Network Operation Support Program (NOSP) program product.
- Support of the Network Communication Control Facility (NCCF) program product.

ADVANTAGES

- ACF/VTAME is an access method with which users can build a variety of data communications systems. Its support for the Communications Adapter of the 4331 Processor provides for an entry version SNA system. It also provides support for a variety of related IBM programs as well as for user-written application programs.
- ACF/VTAME on DOS/VSE provides a Record Application Program Interface (Record API) compatible with the ACF/VTAM Version 1 Release 2 or ACF/VTAM Version 2 Record API on DOS/VSE, OS/VS1 and OS/VS2 (MVS).
- Allows the user to control sessions and data flow between application programs and terminals. A single request for a session or for data can be directed simultaneously to more than one terminal.
- Provides for the direct transmission of messages between application programs and terminals. It makes the lines and the Communications Adapter transparent to the application program.
- Allows for the sharing of network resources among the various applications. This provides for a more efficient use of lines, terminals and the Communications Adapter since these resources are not dedicated to a single application program.
- ACF/VTAME can be used in a single system environment as well as in a multiple systems environment using its multisystem networking functions.
- In a multiple systems environment, ACF/VTAME may be connected through an SDLC cross-domain link to other processors that have installed one of the following IBM program products:
 - ACF/VTAME
 - ACF/VTAM Version 1 with the Multisystem Networking Facility feature
 - ACF/VTAM Version 2
 - ACF/TCAM with the Multisystem Networking Facility feature

This allows application programs and terminals that are controlled by ACF/VTAME to communicate with application programs in another domain of the multiple system network. It also allows terminals controlled by another domain to communicate with ACF/VTAME application programs.

- ACF/VTAME provides network operation control facilities that allow the user to monitor and reconfigure the network to meet fluctuating requirements. The program operator facility allows an authorized user-written application program to enter ACF/VTAME network operator commands and to receive ACF/VTAME network operator messages.
- The Network Operation Support Program (NOSP) or the Network Communication Control Facility (NCCF) program product may also be used with ACF/VTAME to enable a properly authorized network operator to monitor and control the data communications network. Either NOSP or NCCF can be run as a subtask of ACF/VTAME in a single partition.
- ACF/VTAME's RAS functions and modular design assist in providing a reliable data communications network, assist in problem determination and ease maintenance. ACF/VTAME takes advantage of the facilities provided by the DOS/VSE Maintain System History Program (MSHP) to ease installation and maintenance. Online terminal tests are available for selected terminals through the Teleprocessing Online Test Executive Program (TOLTEP). These tests can be run concurrently with user programs.

CUSTOMER RESPONSIBILITIES

To install and use ACF/VTAME, the customer must:

- Design the single or multiple system network.
- Order and install all required communications equipment.
- Install ACF/VTAME and the corequisite ACF/VTAME System Control Programming (SCP) modules.
- Define the single or multiple system network to ACF/VTAME (and to ACF/VTAM and/or ACF/TCAM, if applicable) in each host.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

ACF/VTAME runs in a virtual storage environment on the IBM 4331 Processor in S/370 Compatibility mode or in Extended Control Program Support for Virtual Storage Extended (ECPS:VSE) mode.

ACF/VTAME supports the Communications Adapter for SDLC and BSC lines. BSC support is for nonswitched EBCDIC 3270 only. Start/stop lines are not supported by ACF/VTAME.

ACF/VTAME also supports various SNA and nonSNA channel attached devices.

COMMUNICATIONS FACILITIES

A wide range of line type and modem type variations are supported by the CA. The variations recognized by ACF/VTAME are nonswitched line, switched call in, switched call out and switched network back up. For a complete list of supported attachments, consult the 4331 CA documentation. The following is an extract from the CA list:

EIA RS232C/CCITT V.24, V.28
EIA RS366/CCITT V/25
DDS
CCITT V.35

ACF/VTAME and the CA support 4-wire data communications facilities in Half Duplex data mode.

Full SNA-SDLC and BSC line protocols (for BSC 3270 only) are supported, including multipoint line control. Switched support for SNA devices is also provided.

COMMUNICATIONS CONTROLLER SUPPORT:

In a multisystem network, ACF/VTAME can communicate with a suitably featured ACF/NCP/VS in a 3705 (controlled by another domain) over an SDLC line but will not provide control point functions for NCP. That is, ACF/VTAME does not support a channel attached or remote 3705 and cannot take over or own resources in a line attached NCP.

 4331 Display/Printer Adapter (3272-2) [Note 5]
 4331 Loop Adapter (3274-1A) [Note 6]

* All of the above terminals have both single and multisystem support. The terminal type in parentheses designates the programming support provided by ACF/VTAME. E.g., "8130 (3791)" means "the 8130 is supported as a 3791". In a multisystem network, terminals supported by ACF/VTAM and ACF/TCAM, including those supported by ACF/VTAM through the Network Terminal Option program product, can communicate with ACF/VTAME application programs.

- Note 1: Nonswitched connection only.
- Note 2: Switched connection only.
- Note 3: Buffer sizes of 960, 1920, 2560 and 3440 characters are supported.
- Note 4: With SDLC/BSC Switch in SDLC mode.
- Note 5: 4331 Display/Printer Adapter and Display/Printer Adapter Expansion, supported as a 3272-2.
- Note 6: 4331 Loop Adapter Feature supported as a 3274-1A.
- Note 7: Buffer size of 1,920 is supported.

SOFTWARE REQUIREMENTS

ACF/VTAME is designed to run on DOS/VSE with the VSE/Advanced Functions program product.

Use of ACF/VTAME requires the concurrent installation of corequisite VTAM system control programming (SCP) modules (Program Number 5747-CG2). These SCP modules should only be installed by ACF/VTAME users.

ACF/VTAME will operate in a VM environment using a DOS/VSE guest operating system with the VSE/Advanced Functions program product in a 4300 Processor in S/370 Compatibility mode. Operation of ACF/VTAME under VM/370 may add additional processor overhead. If a user has specific throughput or terminal response requirements for a VM system, a benchmark under VM/370 should be planned to ensure that any proposed configuration will meet the user's performance needs.

RELATED IBM PROGRAMS

The following related IBM programs and program products are supported by ACF/VTAME:

DB/DC	CICS/DOS/VSE
Job Entry	VSE/POWER
Interactive	IIS, VSE/ICCF (*)
Device Support	SSS, BTP, DSX
Communications Network Mgmt.	NOSP, NCCF

(*): VSE/ICCF is supported by ACF/VTAME through CICS/DOS/VSE.

Note: Refer to the appropriate pages and Announcement Letters for information on programming support for specific devices supported and other related IBM program capabilities.

COMPATIBILITY

The ACF/VTAME Record API is compatible with the ACF/VTAM Version 1 Release 2 or ACF/VTAM Version 2 record API.

The ACF/VTAM Release 1 record API is compatible with the ACF/VTAME API and with the ACF/VTAM Release 2 API except for the "SIMLOGON CONALL" function that has been changed to operate compatibly with the "OPNDST CONALL" function. However, user programs written at the ACF/VTAM Release 1 level may require changes to take advantage of the new capabilities offered by ACF/VTAME and ACF/VTAM Release 2.

The following is a summary of the functions unique to ACF/VTAME and of some of the key ACF/VTAM Release 1 and Release 2 functions included or excluded in ACF/VTAME.

ACF/VTAME Unique Functions:

- Support of the SDLC Communications Adapter
- Support of the BSC Communications Adapter (for nonswitched BSC 3270)

ACF/VTAM Version 1 Release 1 Functions Included in ACF/VTAME:

- SNA-SDLC terminal support (in Half Duplex data mode).
- Channel attached device support (3270, 3790).
- Record API.
- Record mode support for BSC 3270 terminals.
- Application program to application program communications.
- Program operator interface (POI).
- Cross domain sessions.
- Switched network backup.
- Host transit node.
- Inbound message traffic pacing.
- Display command enhancements.
- Dynamic allocation of buffers.
- Internal VTAM trace.

ACF/VTAM Version 1 Release 2 Functions Included in ACF/VTAME:

- Networking capabilities for channel attached 3270 terminals and for channel attached 3790.
- Application program to application program parallel sessions.
- Negotiable session initialization parameters.
- Terminal connectivity test.
- Enhanced network operator control for session termination.
- Support of the Network Communication Control Facility (NCCF) program product.

ACF/VTAM Version 1 Release 1 Functions Excluded from ACF/VTAME:

Control of the IBM 3705 Communications Controller with ACF/NCP/VSE.
 Functions supported in conjunction with the 3705 with ACF/NCP/VSE:

- Support of the IBM 3271-11,-12 and 3275-11,-12.
- Configuration restart.
- Host backup.
- Tuning statistics.
- Line tracing.
- Backup links between 3705s.
- Backup link testing.

Basic mode API (for support of various start/stop and BSC devices:)

- Support of Full Duplex SDLC lines.

ACF/VTAM Version 1 Release 2 Functions Excluded from ACF/VTAME:

Additional functions in support of the 3705 with ACF/NCP/VSE.

- Support of the Network Terminal Option program product.
- Support of improved display and dump facilities for ACF/NCP/VSE.
- Dynamic reconfiguration of nonswitched SNA-SDLC devices under ACF/NCP/VSE.
- Enhanced SDLC data link test with ACF/NCP/VSE.
- Intensive mode recording of SDLC data link errors.

ACF/VTAME (cont'd)

MIGRATION AND PLANNING CONSIDERATIONS

ACF/VTAME vs ACF/VTAM CONSIDERATIONS: To decide between installing ACF/VTAME with a Communications Adapter or installing ACF/VTAM with a 3705 and ACF/NCP/VS, the user should consider the following factors:

- The number of lines required in the network.
- The need for the additional ACF/VTAM or 3705 - ACF/NCP/VS functions in the user's data communications network, such as:
 - Support for Full Duplex SDLC lines.
 - Host Backup capabilities.
 - More extensive network problem determination functions.
 - Support of some start/stop terminals with the Network Terminal Option program product.
 - Support of 3271-11,-12 and 3275-11,-12.
- System performance requirements that may be affected by:
 - The additional processor cycles required to operate the Communications Adapter.
 - The somewhat greater working set size of ACF/VTAME.
 - The somewhat greater path lengths of ACF/VTAME.

COMMUNICATIONS NETWORK CONSIDERATIONS

For SNA-SDLC, ACF/VTAME supports switched and nonswitched lines attached to the Communications Adapter. Nonswitched networks are supported as point-to-point or multipoint as appropriate for the device. Switched networks are supported as point-to-point, manual dial or automatic dial, and automatic answer. Each station has a unique transmission identifier within the network, as defined by the installation.

BSC support is for nonswitched EBCDIC BSC 3270 devices.

MULTISYSTEM CONSIDERATIONS

Use of ACF/VTAME in a multiple system environment requires the Communications Adapter with an SDLC link to another domain. Also required is the definition of the resources in other domains with which ACF/VTAME will communicate. This is accomplished via CDRM (Cross Domain Resource Manager), CDRSC (Cross Domain Resources), and Path Table definition statements.

ACF/VTAME will communicate with ACF/VTAM and ACF/TCAM through an SDLC-line-attached 3705 with ACF/NCP/VS. ACF/VTAM and ACF/TCAM require the Multisystem Networking Facility feature for this communication.

In a multisystem network, the terminals supported by ACF/VTAME can communicate with ACF/VTAM, ACF/TCAM and other ACF/VTAME application programs in other domains. Similarly, the terminals supported by ACF/VTAM and ACF/TCAM in other domains, including those supported by ACF/VTAM through the Network Terminal Option program product, can communicate with ACF/VTAME application programs.

In a mixed ACF/VTAME - ACF/TCAM multisystem environment, the ability of ACF/VTAME to determine the device characteristics of terminals controlled by ACF/TCAM is limited to those indicators defined and maintained by ACF/TCAM. In particular, the ability to determine the physical device address used in the 3270 copy function is not supported.

OTHER CONSIDERATIONS

When used only for data communications between a channel attached device and an application program in the same processor, or between two application programs in the same processor, ACF/VTAME does not require the Communications Adapter.

CONVERTING FROM BTAM TO ACF/VTAME

Conversion to ACF/VTAME from BTAM or other access methods involves most of the same considerations and advantages of a move to ACF/VTAM, except that ACF/VTAME users will not have ACF/NCP/VS considerations.

Except for nonswitched BSC 3270, ACF/VTAME does not support BSC or start/stop devices. However, applications that support BSC or start/stop devices with the BTAM Extended Support (BTAM-ES) program product may coexist in the same host with ACF/VTAME. The Communications Adapter of the 4331 Processor, if equipped with the appropriate hardware features, supports concurrent use of any two of the three line disciplines: SDLC, BSC, start/stop. This eases the migration of existing BTAM systems to ACF/VTAME through the concurrent use of ACF/VTAME and BTAM-ES. It should be noted, however, that ACF/VTAME and BTAM-ES cannot share lines. The terminals controlled by BTAM-ES application programs do not participate in the ACF/VTAME single or multiple domain network. If a line is controlled by a BTAM-ES application program, the BTAM-ES application program must be terminated before the given line may be activated through ACF/VTAME.

MIGRATING ACF/VTAME to ACF/VTAM

On DOS/VSE, ACF/VTAME application programs will run without change or recompilation on ACF/VTAM Version 1 Release 2 or 3 or ACF/VTAM Version 2.

Recompilation of ACF/VTAME application programs is required for them to run with ACF/VTAM Version 1 Release 2 or 3 or ACF/VTAM Version 2 on OS/VS1 or OS/VS2 MVS. Moreover, changes may be required to the portions of the application programs that are dependent on operating system functions and facilities.

The main considerations in a migration from ACF/VTAME to ACF/VTAM Version 1 Release 2 or ACF/VTAM Version 2 will be:

- Conversion of Communications Adapter (CA) major node definitions to an NCP generation for ACF/NCP/VS.
- Transfer of the communication lines from the CA to the 3705.

Note that ACF/VTAME and ACF/VTAM cannot be run concurrently on the same processor, except using VM/370. However, the communications adapter support in ACF/VTAM Version 2 Release 1 for VSE facilitates the migration from ACF/VTAME to ACF/VTAM Version 2.

DATA SECURITY, AUDITABILITY AND CONTROL

ACF/VTAME enables the installation to establish and maintain the integrity of the data communications network. The installation can control sessions between application programs and terminals. The installation can also control the access and use of data within the system.

Like ACF/VTAM, ACF/VTAME provides a confidential text capability. The data on sessions defined by the user to contain confidential text is not included in buffer traces. Moreover, buffers containing confidential text are cleared before being returned to the buffer pool.

User management is responsible for the selection, application, adequacy and implementation of these features and for appropriate application and administrative controls.

PERFORMANCE AND STORAGE CONSIDERATIONS

Machine and estimated storage requirements will be provided in the *Advanced Communication Function for VTAM Entry (ACF/VTAME) Installation (SC27-0439)*.

The design objectives for ACF/VTAME are to have total storage requirements and path lengths somewhat greater for ACF/VTAME than for an equivalent ACF/VTAM Release 2. This is due to the significant number of NCP-like functions performed by ACF/VTAME, which in an ACF/VTAM system, are performed by the network control program (ACF/NCP/VS) in the 3705 Communications Controller.

Specific user storage requirements will be dependent on the specific configuration and upon the following user-specified areas and functions:

- I/O buffer areas.
- Number and organization of terminals.
- Number and type of macro instructions used.

Note also that the Communications Adapter on the 4331 shares the processor for its processing and will thus have some effect on the total system performance as compared to an equivalent system using a 3705.

Response time in a single system environment is dependent on a variety of processor and data communication load factors, such as:

- Line speeds.
- Number, type and organization of terminals.
- Number and type of ACF/VTAME commands and exits used by the application programs.
- Amount of processing performed by the application programs.

Response time in a multisystem environment will depend on the factors above and on various network load factors, including the number of nodes traversed.

PROGRAM PRODUCTS

**DOS/VSE REMOTE JOB ENTRY
WORKSTATION PROGRAM PRODUCT
5746-RC9**

PURPOSE

The DOS/VSE Remote Job Entry Workstation Program enables a S/370, 3031 Processor Complex or the 4300 Processor to function simultaneously as:

A Multi-leaving Remote Job Entry Workstation for submitting jobs to a central system for execution under OS/VS.

A local processor for execution of DOS/VSE batch jobs in other DOS/VSE partitions.

DESCRIPTION

The DOS/VSE RJE Workstation Program executes in one partition of DOS/VSE; other partitions can be used to run other DOS/VSE jobs.

The Workstation Program includes a teleprocessing communication supervisor, input/output device support and operator command routines to allow the remote computer (workstation) to transmit jobs to a central computer. Jobs are entered on a workstation operating under DOS/VSE. They are submitted to a central computer for OS/VS processing under one of the following systems:

- VM/370 Release 5 with RSCS, VNET PRPO or
- VM/370 Release 6 with RSCS Networking PP.
- OS/VS1 Release 6 with RES.
- OS/VS2 Release 1.7 with ASP Version 3.1 or
- HASP II Version 4.0.
- OS/VS2 Release 3.7 with JES2 or JES3 or
- NJE for JES2 PP.

Data sets, as well as jobs, can be transmitted between the workstation and the central computer. Two utility programs are distributed with the DOS/VSE RJE Workstation Program. These utilities are link-edited into the OS/VS Link Library. JCL statements are transmitted from the workstation to the central computer to cause execution of the utilities under OS/VS to provide the data set transmission function.

The Workstation Program executes in virtual mode under DOS/VS on a S/370 mdl 115, 125, 135, 138, 145, 148, 155II or 158, or 3031 Processor Complex or 4300 Processor. The system must be equipped with binary synchronous communication facilities. The DOS/VSE Workstation Program and the Remote Terminal Access Method (RTAM), used by each of the OS/VS systems to service workstations, provide Multi-leaving support to allow fully synchronized two-directional transmission of data between the central computer and one or more devices on the workstation.

Each workstation requires a DOS/VSE RJE Workstation Program generated to conform to the hardware at the workstation location, the software at the central installation and the optional functions desired. Thus, for example, the program can be tailored to provide support for file transmission, spooling, telecommunication line tracing and specific devices and features on the workstation.

The DOS/VSE RJE Workstation Program includes routines to:

Enable binary synchronous transmission to and from the central computer, perform communication line error processing and error logging and trace communication line reads and writes onto tape.

Support up to seven input functions, with job streams permitted from a card reader, tape, disk or diskette.

Support up to seven print and seven output functions, that print, punch, create files or spool print and punch output onto tape or disk, or write it on a diskette. Device support is provided for the card interpret function of the 3525 Card Read Punch and for the forms control buffer (FCB on 3203, 3211 and 5203 printers) and universal character set buffer (UCSB on 1403, 3203, 3211 and 5203 printers).

Support up to seven output writers running concurrently that punch, create files or spool punch output onto tape or disk, or write it on a diskette.

Analyze commands entered at the workstation, process local commands and transmit central system commands. The central system commands enable the workstation user to monitor and control the execution of jobs submitted from the workstation to the central computer.

Print messages transmitted from the central computer or other workstations, and send messages entered at the workstation.

Operation of the DOS/VSE RJE Workstation Program is initiated by a LOGON/SIGNON statement entered at the workstation and transmitted to the central computer. A password and workstation identification, specified during generation of the program, can be required to help security of data and prevent unauthorized access to the central computer. The workstation session need not encompass the total time for processing jobs submitted to the central computer. The program can be terminated after transmitting the jobs, then restarted later to obtain the output.

Since the workstation is used for local batch processing as well as for transmitting jobs to the central computer, the DOS/VSE RJE Workstation Program competes with other DOS/VSE jobs for resources. The dynamic assignment of symbolic devices to physical I/O units by the program helps to optimize usage of all I/O resources. However, the operator must start input units to submit jobs, and start output units when notified by the central computer that output is ready for transmission. The DOS/VSE Workstation Program can unassign the units at end of file, if this option is specified.

Monitoring and control of job processing by the workstation operator is provided. The operator can control the transmission of output to other workstations or to output units on the central computer. A central display command enables the operator to check the status of transmitted jobs. With the local command MAP, the operator can verify that workstation functions are started and that central requests to transmit output are serviced. Although automatic recovery action for communication line errors is provided, the operator can review severe errors that may affect turnaround time, by using the LOG command. In addition, the TRACE command can be used to record complete line traffic.

HIGHLIGHTS

Non-dedicated workstation: The DOS/VSE RJE Workstation Program occupies one partition of DOS/VSE; other partitions can be used for batch processing of DOS/VSE jobs.

Job transmission: Jobs are transmitted over a binary synchronous communication lines for execution under OS/VS on the central computer.

Data set transmission: Sequentially-organized data sets can be transmitted between the central computer and the workstation.

Full Multi-leaving support: The DOS/VSE RJE Workstation Program and the Remote Terminal Access Method (RTAM) provide telecommunications support to transmit data concurrently between the central computer and multiple I/O devices at the workstation.

Output spooling: Output data can be spooled onto tape or disk devices and later printed or punched via a spool utility provided with the program.

FCB and UCSB load facility: The operator is notified when loading of the forms control buffer (FCB) or universal character set buffer (UCSB) is required, and can load the buffer with operator commands.

Dynamic assignment of I/O units: Input/output units are automatically assigned to functions as required and unassigned at end of file, without operator intervention.

Operator communication: The operator has full communication with the system via local commands to the workstation, system commands to the central computer and message transmission to and from the central computer and other workstations.

DEVICE SUPPORT

Input/Output units on the workstation computer that are supported by the DOS/VSE RJE Workstation Program include:

- Card Readers
- 2501, 3504, 3505
- Card Read Punches
- 2520, 2540, 2560, 1442, 3525
- Printers
- 1403 (and 1403 with UCS), 1443, 3203, 3211, 3262, 4245, 5203 (and 5203 with UCS)
- Magnetic Tape
- 2400, 8809, 3410, 3420
- Direct Access Storage Devices
- 2314/2319, 3330, 3340, 3344, 3350, 3310, 3360
- Diskette
- 3540

USE

The DOS/VSE RJE Workstation Program offers advantages to the user in increased processing capability at the workstation, more efficient production at the central computer and convenient support of DOS/VSE to OS/VS transition.

The DOS/VSE user with limited local processing capability gains access, through the DOS/VSE RJE Workstation Program, to a central computer and to OS/VS. Thus, jobs submitted at the workstation can use all the processing power and programming functions of the central computer. Data sets maintained on the central computer are also available to the workstations.

Companies with a centralized OS/VS system can benefit from use of the DOS/VSE RJE Workstation Program. It enables online input and immediate processing of information from remote offices, plus direct distribution of reports to those locations, thus eliminating the delays

PROGRAM PRODUCTS

DOS/VSE RJE Workstation Program (cont'd)

and inefficiencies inherent in the conventional shipping of jobs and reports.

The DOS/VSE user converting to OS/VS can use the DOS/VSE RJE Workstation Program as a transition aid. By establishing a temporary interface to an OS/VS system, the user can test programs under OS/VS and convert production runs from DOS/VSE to OS/VS operation, without interrupting scheduled work under DOS/VSE.

CUSTOMER RESPONSIBILITIES

Order and install communications equipment based on processing needs.

Generate DOS/VSE Supervisor for remote processor with options required by DOS/VSE RJE Workstation Program.

Tailor DOS/VSE RJE Workstation Program to include desired features.

Establish password and priorities for workstation.

Install DOS/VSE RJE Workstation Program and test with application programs.

Train system operators in use of OS/VS commands in addition to DOS/VSE and DOS/VSE RJE Workstation Program commands and operation

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

The minimum machine requirements for the DOS/VSE RJE Workstation program are the same as those needed for operation of any IBM S/370, 3031 Processor Complex or 4300 Processor supported by the IBM Disk Operating System/Virtual Storage Extended (DOS/VSE). The I/O device configuration is dependent on the functions to be utilized.

In addition, the system must be equipped with a communication line and one of the following binary synchronous communication facilities:

- Integrated Communications Adapter (ICA).
- Communications Adapter (CA).
- 2701 Data Adapter Unit.
- 2703 Transmission Control Unit.
- 3704 Communications Controller in Emulation Mode.
- 3705 Communications Controller in Emulation Mode.

The Workstation Program can transmit to the central computer via a point-to-point (leased or switched) communication line that may be either two-wire half duplex or four-wire half duplex.

The typical size of a Workstation Program is approximately 40K bytes of virtual storage. Real storage partition allocation is not required.

The amount of processor storage required for execution of the DOS/VSE RJE Workstation Program depends on the following factors:

- Number of service processors running concurrently.
- Number and size of communication line buffers.
- Speed of communication lines.
- Operator communication facilities used.
- I/O functions generated (spool/file transmission).
- Type of I/O units used.
- Optional functions generated and used (TRACE/UCSB/FCB, etc.).

SOFTWARE REQUIREMENTS

The DOS/VSE RJE Workstation Program is written in Assembler language and runs in virtual mode on a S/370, 3031 Processor Complex or 4300 Processor under control of the Disk Operating System/Virtual Storage Extended (DOS/VSE) and the VSE/Advanced Functions Program (5746-XE8). It executes in a single partition of DOS/VSE using standard multitasking. There is no known technical dependency on the VSE/Advanced Functions program product by the DOS/VSE Workstation Program. However, the specified operating environment for DOS/VSE includes the VSE/Advanced Functions program product.

There are certain limitations.

If the DOS/VSE System has a 3800 printer that is to be used for local printing of output from the DOS/VSE RJE Workstation Program, the DOS/VSE RJE workstation program provides support for the basic print/space functions of the 3800 printer. Other 3800 printer functions, including burst and flash must be provided by using the DOS/VSE RJE workstation program in conjunction with the VSE/POWER program product (5746-XE3). These additional functions can then be specified by using the DOS/VSE RJE workstation 1st command.

The DOS/VSE Supervisor requires specific options to support the DOS/VSE RJE Workstation Program. The supervisor generation macros NAPCOMR and SYSCOM are required for generation of the workstation program. If POWERVS = Yes is specified, IPW\$DDE and IPW\$DPD are also required. A DOS/VSE Supervisor Generation may be necessary, to include the Supervisor options required.

DOCUMENTATION
(available from Mechanicsburg)

General Information Manual ... Licensed Program Specifications.

PROGRAM PRODUCTS

**VSE INTERACTIVE PROBLEM CONTROL SYSTEM
VSE/IPCS RELEASE 3 (5746-SA1)****PURPOSE**

VSE/IPCS assists in problem determination by providing a uniform mechanism for reporting and diagnosing software failures.

The VSE System contains facilities that collect problem data resulting from errors detected within the Supervisor, subsystems or user programs. The problem data is recorded on a DASD file.

VSE/IPCS provides problem dump data management, creation of a problem description report with a symptom string, problem dump data display, special formatting of the VSE System and VSE/POWER control blocks and assistance with APAR reporting.

VSE/IPCS can be executed in either a VSE System partition or a VSE/ICCF partition.

To operate, VSE/IPCS commands are entered from either the system input device, the system console or a VSE/ICCF controlled terminal.

HIGHLIGHTS**• Problem Data Collection**

The System Dump and Standalone Dump programs provided with the VSE System perform the problem data collection. The option is provided to collect storage dumps and supplementary information on SYSDMP, a newly defined Symbolic Unit.

• Problem-Data Management

The migrate utility program of VSE/IPCS can offload SYSDMP contents to magnetic tape. This feature allows not only for economizing on direct access storage space, but also for processing on another VSE System installation.

• Problem Description Report

VSE/IPCS searches the available problem data and prepares a structured summary of the problem. Operator comments may be added via commands. The resulting Problem Description Report can be viewed or printed. Problem symptoms contained in the report can be compared to symptoms of other problems to determine if the current problem is a duplicate of a previous problem.

• Display and Analysis

Support is provided for storage dumps in either S/370 mode or ECPS:VSE mode. Via commands, all or selected parts of the dump can be formatted and displayed on the system console or can be printed.

• APAR Submission

The APAR function creates a report with known information filled in by the system. This report is used as source information required for filling in the standard APAR form. The APAR form, together with the console log and a printed dump, or optionally a magnetic tape containing the offloaded dump, can then be submitted to IBM. Only problems arising from IBM System Control Programs (SCP), Program Products and their respective documentation are covered by the APAR process.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

VSE/IPCS operates in either S/370 mode or Extended Control Program Support (ECPS:VSE) mode on any IBM S/370, 303X or 4300 Processor that meets the minimum requirements for the VSE System.

VSE/IPCS provides support for SYSDMP on the following DASD devices: 2314, 2319, 3330-1, 3330-11, 3350, 3340 (both 35 and 70MB), 3344, 3310 and 3370.

The interface to VSE/IPCS is via the system console or card reader and printer or a VSE/ICCF terminal.

IPCS requires 400 blocks of Core Image Library space and a 200K virtual partition. The migrate utility requires 140 blocks of Core Image Library space and a 116K virtual partition.

DASD space is required for the IPCS dump buffer, a work file used during IPCS processing. The size of this file is dependent on the maximum size of a dump on the SYSDMP files and other factors as described in the *VSE/IPCS General Information Manual* (GC34-2017).

A VSE supported tape drive is required for the migrate utility (a component of VSE/IPCS) and the IPCS PUTDUMP function.

SOFTWARE REQUIREMENTS

VSE/IPCS may operate under VSE/ICCF but is not dependent upon it.

VSE/IPCS Release 3 operates with VSE and its subsequent releases and modification levels unless otherwise stated, using Release 3 of the VSE/Advanced Functions program product. Because of differences in dump formats, VSE/IPCS Release 3:

- Does not operate with or process dumps from SYSDMP files produced by Releases 1 or 2 of VSE/Advanced Functions.
- Does not process tapes produced by VSE/IPCS Releases 1 or 2.

DEPENDENCIES

VSE/IPCS Release 3 is designed to operate with the VSE System using Release 3 of the VSE/Advanced Functions program product. SYSDMP, the VSE System Logical Unit, and MSHP, the Maintain System History Program must be included in this environment. VSE/IPCS can operate under VSE/ICCF, but is not dependent upon it.

SECURITY

Security of information at the user installation must be externally controlled. The installation must continue to take specific action to prevent unauthorized access to dumps containing sensitive data.

PERFORMANCE CONSIDERATIONS

The problem data collection mechanism is invoked by the system or by the operator when an error is detected by the VSE System. Storage is recorded on SYSDMP, always assigned to a direct access storage device. The performance impact on any other continuing programs is the same as when a dump is recorded on SYSLST, and SYSLST is assigned to a direct access storage device. The partition in which VSE/IPCS is to be executed can be assigned any priority desired to conform to the customer's performance requirements. During VSE/IPCS operation the response time for the various VSE/IPCS commands will vary with the complexity of the command, the size of the dump, the speed of the processor and the current system load.

RPQs ACCEPTED: No

PROGRAM PRODUCTS

**DOS/VS SORT/MERGE
5746-SM1****PURPOSE**

The DOS/VS Sort/Merge provides additional features and improved performance in virtual mode over the DOS Sort/Merge (5743-SM1). All sort and merge applications that run on 5743-SM1 will run on the DOS/VS Sort/Merge without changes to the control statements or to the interface with user programs with the following exceptions:

- 2311 workfiles are not supported.
- The design point is 16K virtual storage (10K for 5743-SM1).

DOS/VS Sort/Merge operates only in a S/370 virtual systems environment on DOS/VS Release 29 and subsequent releases.

HIGHLIGHTS

- Support of the 3340 Disk Storage Facility for input, output and work data sets.
- Support of Key-Sequenced and Entry-Sequenced VSAM data sets for input to and output from the sort and merge.
- Ability to incorporate a user-written routine to read input for merging. This feature was previously available only for sorting applications.
- Ability to specify a subset of the input file to be selected for the sort or merge by using new types of control statements. The selection of a record may be based upon one or more relations between two fields in the record, or between a field in the record and a constant in the control statement. Floating point data may not be used as a basis for selection.
- Ability to specify that the sorted or merged output records should contain selected parts of the input records by using a new type of control statement.
- Ability to request that a summary sort should be performed and which fields should be summarized by using a new type of control statement. When two records have equal control fields, the contents of the summary fields are added, the sum is placed in one of the records and the other record is deleted. Floating point data may not be summarized.
- Ability to specify a collating sequence other than EBCDIC and/or ASCII by using a new type of control statement.

Other Features: DOS/VS Sort/Merge includes all functions, facilities and options of the 5743-SM1 program product among which are:

- Support of the 3330/3333 Disk Storage and the 3410, 3411 and 3420 tape devices for input, output and work data sets.
- Ability to be invoked by DOS COBOL, PL/I or the Auto Report Feature of RPG II programs.
- Ability to operate in both foreground and/or background partitions.
- Ability to sort or merge on control fields with mixed data formats.
- Ability to use any programmer logical unit numbers for input, output and work data sets.
- Ability to route messages to either the console device or the printer device.
- Ability to produce unblocked variable length records in the output file.
- Ability to accept records of full-track length in sort applications.

The Rotational Position Sensing feature of the 3330/3333 and 3340 Disk Storage Facility will be supported by DOS/VS Sort/Merge for input, output and work data sets. This support will be concurrent with the DOS/VS support of RPS.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

The minimum IBM configuration supported by the DOS/VS Sort/Merge program is:

- Any IBM processor supported by DOS/VS.
- A minimum virtual or real partition of 16K for the Sort/Merge.
- One disk storage device for system residence.
- Unit record equipment as required by the system.
- Three tape units when tape work data sets are used.
- Additional tape units if tape input/output is desired.
- Sufficient direct access space when direct access input, output and/or work data sets are used.

DOS/VS Sort/Merge will utilize storage given by the smallest of the following values: STORAGE, SIZE or Partition Size. If for virtual mode neither STORAGE nor SIZE is specified, Sort/Merge will calculate its

requirements (though it will then try to limit the storage requirement to 64K). For work data sets Sort/Merge will utilize up to 8 extents on 2314, 2319, 3330, 3333 or 3340 direct access devices or up to ten 2401, 2415, 2420, 3410, 3411 or 3420 tape units.

SOFTWARE REQUIREMENTS

DOS/VS Sort/Merge executes under the IBM DOS/VS Operating System. Sort/Merge support of the 3340 Disk Storage requires the DOS/VS release which provides 3340 support. Sort/Merge support of the RPS feature requires the DOS/VS release which provides RPS support.

COMPATIBILITY

A valid set of Sort/Merge control statements, Job control statements and user written exit routines prepared for the 5743-SM1 program product or Type I 360N-SM-483 program can be used without change for the DOS/VS Sort/Merge program product with the following exceptions:

- 2311 workfiles are not supported.
- The design point is 16K virtual storage (10K for 5743-SM1).

SAM data sets used and produced by DOS/VS Sort/Merge are completely compatible with the data sets used and produced by 5743-SM1 (and 360N-SM-483 for non-ASCII data sets).

360N-SM-483 or 5743-SM1 cannot reside together with the DOS/VS Sort/Merge program product in the same (Private) Core Image Library without renaming those phases that have identical names.

PERFORMANCE

The DOS/VS Sort 5746-SM1 is designed to improve performance in virtual mode compared to 5743-SM1. It is particularly important to use this new sort if the user plans to run his DOS/VS system with significant overcommitment of real storage. In real mode the performance of the two sorts is approximately the same. In either mode, this assumes the same storage allocation, devices, etc. The support of the 3340 Disk Storage in 5746-SM1 utilizes the improved access and data transfer time of the 3340.

PROGRAM PRODUCTS

**DOS/VS-VM/SP SORT/MERGE
VERSION 2 RELEASE 5 (5746-SM2)****PURPOSE**

DOS/VS-VM/SP Sort/Merge Version 2, Release 5, Modification 0 provides additional functions that improve the productivity of DOS/VS-VM/SP Sort/Merge Version 2 users running under the control of DOS/VS Releases 33 and 34, DOS/VSE with VSE/Advanced Functions, and CMS with VM/SP.

DESCRIPTION**NEW with RELEASE 5.0**

DOS/VS-VM/SP Sort/Merge Version 2, Release 5.0 provides new functions which are designed to improve the productivity of the DOS/VS-VM/SP Sort/Merge Version 2 user. These include:

- **Enhanced Control Field Handling**
 - The maximum number of control fields that can be specified are increased from 12 to 64.
 - The maximum total length of the control fields is increased from 256 bytes to 3,072 bytes.
- **New COPY function**
 - A new function - COPY - is added to permit an input file to be copied to an output file within the invocation of DOS/VS-VM/SP Sort/Merge Version 2. Functions available in merging files such as user exits, INCLUDE/OMIT, OUTREC and ANA-LYZE are available to be used with the COPY function.
- **Enhanced ADDROUT function (ADDROUT=D)**
 - A new ADDROUT=D keyword on the OPTION control statement will permit each sorted output record of DOS/VS-VM/SP Sort/Merge Version 2, Release 5.0 to contain the direct access address of the input record followed by the corresponding control field. This function was previously available in DOS/VS Sort/Merge (5746-SM1) and is now incorporated into DOS/VS-VM/SP Sort/Merge Version 2, Release 5.0 (5746-SM2).
- **Enhanced OUTREC function**
 - The currently available OUTREC function in DOS/VS Sort/Merge Version 2 Release 4.0 is being enhanced to permit the reformatting of input records to DOS/VS-VM/SP Sort/Merge Version 2, Release 5.0 to include padding with blanks and/or binary zeros before, between, and/or after the input fields.
- **A new function - INREC**
 - INREC will allow the input records to DOS/VS-VM/SP Sort/Merge Version 2 to be formatted before they are sorted. With this function, it is now possible to reformat input records before sorting without having to develop and maintain E15 exit programs. Thus, INREC may be used to reduce the size of input records to achieve more efficient sorting. This function has the same functional capabilities of OUTREC with the following additions:
 - INREC will not operate with COPY
 - The input records will be reformatted before sorting by INREC. Output records will be in the format specified by INREC, unless OUTREC is specified.
 - When INREC is specified, DOS/VS-VM/SP Sort/Merge Version 2, Release 5.0 reformats the input records after user exit E15 and/or INCLUDE/OMIT processing is completed.
 - In general, INREC should be used to reduce the length of input records as much as possible to achieve the most efficient sort. OUTREC should be used to reformat the records for output.
- **New Installation Options and Control Options**
 - A new keyword - ALTSEQ - provides the capability to specify a default alternate collating sequence in the installation macro to be used by DOS/VS-VM/SP Sort/Merge Version 2, Release 5.0 when comparing AQ format control fields defined in the SORT, MERGE, OMIT, and INCLUDE control statements.
 - Another new installation keyword - CHALT - is provided to be used in the installation macro to specify that the alternate collating sequence will apply to control fields specified with format CH as well as AQ in the SORT, MERGE, OMIT, and INCLUDE control statements.
 - The ALTSEQ control statement will completely override the default alternate collating sequence.
 - Two new keywords - CHALT and NOCHALT - have been added to the OPTION control statement. These new keywords permit the sort user to override the corresponding installation options at DOS/VS-VM/SP Sort/Merge Version 2 execution time. CHALT specifies that the alternate collating sequence applies to control fields specified in CH format as well as AQ formats. NOCHALT

specifies that the alternate collating sequence applies only to control fields specified in AQ format.

DOS/VS-VM/SP Sort/Merge, Version 2 Release 5.0, includes other important features available in its previous releases:

Capabilities with VM/SP-CMS

- Operating under the CMS/DOS environment of VM/SP, DOS/VS-VM/SP Sort/Merge Version 2, Release 5.0 can:
 - Sort or merge records from up to nine input files and, if necessary, use direct access devices as intermediate work areas.
 - Use CMS files as intermediate work files when needed.
- Sort/Merge accepts CMS, DOS, SAM, and VSAM files for input to sort or merge. There can be up to nine input files. Output can be to CMS or VSAM files.
 - CMS files are supported in two formats. They can be in regular CMS format or in simulated VSE format. CMS files are normally assumed to be in regular CMS format and are processed as such. CMS files are processed as simulated VSE files only when filemode 4 has been specified for the file on the DLBL command or as input to the DOSSORT EXEC.
 - Variable length simulated VSE files contain record descriptor words (RDW), while regular CMS variable length files do not. Sort adds an RDW to regular CMS variable length files prior to sorting or merging. The length of the RDW must be included when specifying sort or merge control fields.
 - Sort output to simulated VSE variable length files includes the record descriptor word.
 - Simulated VSE file support in Sort/Merge allows users to design and develop applications under CMS for use in DOS/VS or VSE/Advanced Function environments without changing Sort/Merge's control statements.

Intermediate work files (CMS format) can be on minidisks that are formatted with 1K, 2K, or 4K-byte block sizes. 800-byte block size CMS minidisks are not supported for sort work file use.

Program Invocation with CMS with VM/SP

- Sort/Merge can be executed using the DOSSORT EXEC, by the FETCH command, or by calling it from another program operating under CMS/DOS with VM/SP.
- The DOSSORT EXEC is provided as an easy means of getting started using Sort/Merge with CMS. It provides the following functions:
 - Prepares the environment and performs housekeeping needed to run Sort/Merge.
 - Sets default values.
 - Assigns units.
 - Issues DLBL commands for files used.
 - Can, when needed, prompt the user for file ID information (file name, file type, file mode).
 - Prompts for the names of DOS-LIBs containing user exits.
- DOS/VS-VM/SP Sort/Merge Version 2 can be initiated from programs written in:
 - Basic Assembler language (sort and merge)
 - DOS/VS COBOL (sort and merge)
 - DOS/PL/I (sort only)
 - DOS/VS RPG II with the Auto-Report Feature (sort only)

Capabilities with DOS/VS, DOS/VSE with VSE/Advanced Functions, and VM/SP-CMS

- Acceptance of VSAM-managed SAM files (CI-format) as input and output files. They may be accessed either as SAM or VSAM files. Managed files may be used as work files. It is possible to mix managed and non-managed files.
 - Note: Not applicable to operation under CMS with VM/SP.
- Use of Simplified Symbolic Unit Handling and DOS/VSE Simplified Job Control for VSAM and VSAM-managed SAM files.
 - Note: Not applicable to operation under CMS with VM/SP.
- DOS/VSE: The program will be able to detect whether it executes in S/370 compatibility mode or ECPS:VSE mode. When it runs in ECPS:VSE mode, the relocating channel function of the E-series hardware will be used by the program.
- Fixed Block Architecture (FBA): Devices operating in Fixed Block Mode can be used as input, output, work or checkpoint data sets.

PROGRAM PRODUCTS

DOS/VS Sort/Merge V2 R5.0 (cont'd)

- Variable length spanned records: The program will allow SAM input and output files to contain spanned records.
Note: Not allowed when operating under CMS with VM/SP.
- Installation/Generation Options: The program options EQUALS, ERASE, DIAG, DUMP, VERIFY, PRINT=, ROUTE=, STORAGE=, SORTIN=, SORTOUT= and SORTWK= may receive installation unique default values.
- SORT or MERGE control fields can overlap each other.
- OUTREC fields can be located beyond byte 4092 of a record.
- When the program is invoked, the control statement images are optionally printed.
- When the program is invoked, messages may be routed to a printer other than SYSLST.
- A new statement, ANALYZE, makes it possible to get information on how Version 2 will optimize, and what capacity a sort job will have, without actually sorting or merging.
- More and better information messages and improved diagnostic handling.
- Automatic sequence checking in sort applications.
- Command chaining: The program will, if sufficient storage is available, use command chaining when it reads SAM input or writes SAM output for CKD (Count-Key-Data) and tape devices in sort applications. In most cases where command chaining is used, significant performance improvements can be experienced. The smaller the input/output block sizes of a sort application are, the greater the possibilities for performance improvements are. This function is not available for VSAM-managed SAM files. For those files and FBA files a large control interval (CI) may give similar results.
Note: Not applicable to operation under CMS with VM/SP.
- Can sort records from up to nine input files, using direct access devices as work areas, and can merge up to nine presorted files.
- Has an improved disk sorting technique that reduces workfile space requirements and provides performance improvements for presequenced files, compared to earlier IBM DOS Sort/Merge offerings.
- Under certain conditions, sorting can be performed in main storage, regardless of whether workfiles have been allocated.
- Reentrant code is used in most of the program modules. These can therefore be stored in the SVA (Shared Virtual Area) to obtain enhanced performance.
Note: Not applicable to operation under CMS with VM/SP.
- Subtasking of the program is allowed, that is, more than one sort program can be used concurrently in a partition.
Note: Not applicable to operation under CMS with VM/SP.
- Work files can be allocated on a combination of any two of the permitted device families.
- Input and output files can be any VSAM data set, or SAM data sets on tape or disk devices.
- Split cylinder input and output CKD SAM files are allowed.
Note: Not applicable to operation under CMS with VM/SP.
- A mixture of device types (tape and disk) is allowed for the input files to any sort or merge job.
- Control statement syntax is simplified, compared to earlier IBM DOS Sort/Merge offerings.
- The Sort/Merge can be dynamically invoked by programs written in COBOL, PL/I, the Auto Report Feature of RPG II or Assembler language.
- Input records can be fixed or variable length, blocked or unblocked.
Note: For CMS support, see above.
- The input order of records with equal control fields can be preserved.
- Input records can be included or omitted from the output.
- Records with equal control fields can be summarized.
- Output records can be reformatted.
- Deviation from the standard EBCDIC collating sequence can be specified (alternative collating sequence).
- ASCII collating sequence can be specified.
- The checkpoint/restart facility of the DOS/VS system can be used.
Note: Not applicable to operation under CMS with VM/SP.
- Final sort output can be given in the form of CKD direct access addresses of the input records for SAM data sets, and relative byte addresses for VSAM entry sequenced data sets (ESDS). For

VSAM relative record data sets (RRDS), the output can be given as a relative record number.

- The program may be extended at certain points called program exits.
- A formatted dump of the Sort/Merge communication areas, and trace information, is obtained if the program ends abnormally and the DUMP option has been specified.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The program is designed to execute on any IBM configuration supported by DOS/VS Releases 33 and 34, DOS/VSE or VM/System Product.

Work File Devices

DOS/VS and DOS/VSE: 3370 (FBA), 3310 (FBA), 3350, 3340/3344, 3330 mdls 1, 2 and 11, and 3333 mdls 1 and 11, 3375, and 2314/2319 devices.

VM/SP: Work files can be allocated on those devices supported by VM/System Product for use with CMS files. The work files can be on minidisks that are formatted with 1K, 2K or 4K-byte block sizes. 800-byte block size minidisks are not supported for work files.

Input/Output Files

DOS/VS and DOS/VSE: Input/output files can reside on 3370 (FBA), 3310 (FBA), 3350, 3340/3344, 3330 mdls 1, 2 and 11, and 3333 mdls 1 and 11, 3375, 2314/2319, 2311, 3420, 3410, 2400, and 8809 in start/stop mode.

CMS: Input/Output files can reside on any of the above direct access devices supported by VM/System Product for use with CMS.

Note: The use of the above devices with Version 2 requires the release level of the control program and the hardware system in which support is provided.

SOFTWARE REQUIREMENTS

DOS/VS-VM/SP Sort/Merge, Version 2, is designed to run under DOS/VS Releases 33 and 34 and DOS/VSE with VSE/Advanced Functions, or under the CMS/DOS environment of VM/System Product.

When running under DOS/VS or DOS/VSE, the program requires that the relocating loader feature (standard in DOS/VSE, optional in DOS/VS Releases 33 and 34) be generated into the DOS/VS control program. The program also requires a minimum of 32K bytes of virtual storage when it is executed. VSAM and VSAM-managed SAM file processing with DOS/VSE requires VSE/VSAM, VSE/VSAM Space Management for SAM feature and VSE/Advanced Functions licensed programs to be present in the system.

When running under VM/SP, the program has no requirements for additional supporting products, unless VSAM files are used. In this case, VSE/VSAM Release 2 must be present in the system.

Installation: Sort/Merge is installed on VSE/Advanced Functions systems using MSHF. Installation on DOS/VS Release 33/34 systems is accomplished by running a restore job using the System Restore Facility. Installation on VM/SP is accomplished by loading the program from tape with VMFPLC2 (a standard VM/SP utility). Additionally, the CMSBAM and CMSDOS discontinuous saved segments must be defined and generated in the VM/SP system.

COMPATIBILITY

Release 5.0 is compatible with prior releases.

Some functions are restricted and cannot be performed if the input files are on devices in fixed block mode:

- ADDROUT cannot be used.
- BYPASS applies only to wrong length variable length "logical" records.

For VSAM-managed SAM files accessed through SAM:

- ADDROUT cannot be used.
- BYPASS applies only to CI in error instead of block in error.

Certain sort and system functions are handled differently by Sort/Merge and CMS from the way they are handled in the DOS/VS Release 33/34 and VSE/AF environments.

- ADDROUT is supported by VSAM files only.
- Nonstandard labels are not allowed.
- Tape files are not allowed.
- Split cylinder files cannot be used with CMS.
- DOS SAM records cannot be specified for output.
- Checkpoint option is ignored.

DOS/VS Sort/Merge V2 R5.0 (cont'd)

- DUMP option is ignored.
- BYPASS option is ignored.
- No page fixing is done and the VIRT option is ignored.
- Subtasking of Sort/Merge is not supported for use with CMS.
- VSAM-managed SAM files are not supported by VM/SP and CMS.
- INPFIL/OUTFIL BLKSIZE parameter is accepted for simulated VSE files only. It is ignored for regular CMS files.
- Sort or merge control statements for Sort/Merge applications invoked by the DOSSORT EXEC or the FETCH command must be contained in a CMS file.

Version 2, 5746-SM2, is functionally compatible with DOS/VS Sort/Merge, 5746-SM1, with the following exceptions:

- Tape workfiles cannot be used.
- Phase 2 program exits are ignored (E21, E25, E27).
- VSAM exit list must be used to handle additional I/O error processing at program exits E18, E38 and E39.
- Program exits E18, E38 and E39 are ignored for non-VSAM files.
- The workfile(s) cannot be pooled with other files. However, pooling of input and output files is now simplified, compared to earlier IBM DOS Sort/Merge offerings.
- Output data with a separate key (KEYLEN) cannot be requested.
- Minimum virtual storage has been increased to 32K bytes, from 16K bytes.
- No label processing can be performed by the user for the workfile(s).
- The sort options ALTWK, CALCAREA, TP, PRESEQ, and SIZE are ignored.
- The ALTSEQ function cannot be used with ASCII data.

Note: Programs, or user routines, relying on the internals of previous Sort/Merge programs will not execute properly. Furthermore, virtual storage requirements for a given application may have to be increased, especially if the program is not executed in the SVA.

CONVERSION

The *Programmer's Guide* for 5746-SM2 contains conversion information for users of old IBM DOS-DOS/VS Sort/Merge programs, the S/3 Disk Sort, and the S/360 model 20 Disk Sort/Merge program.

PERFORMANCE

Version 2 will in many cases give better performance in terms of reduced processor time and elapsed time than earlier IBM DOS Sort/Merge offerings. Performance improvements should be considerable for files that can be sorted in main storage, and for very large files if they have some degree of non-randomness. Furthermore, Version 2 does not require information about presequencing or filesize for its optimization.

When command chaining is used, the number of SIO operations are reduced, leading to shorter elapsed time and longer processor utilization in most cases.

Installations with a high sort or merge workload will reduce system overhead by storing the reentrant part of the program in the SVA.

The work space requirements are reduced by up to 40%.

Performance usually improves when main storage given to sort is increased, but the ratio between real and virtual storage space will also affect performance.

The sort for fixed length records has improved storage utilization and reduced requirements on the number of buffers.

The sort will, where applicable, attempt to fix buffer pages and translate channel programs to reduce system overhead.

The sort will optimize use of the workfiles and try to avoid disk arm contention.

Note: The above performance statements are not applicable to operation under CMS with VM/SP. Performance in the DOS/VS and DOS/VSE with VSE Advanced Functions environments is unchanged by DOS/VS-VM/SP Sort/Merge Version 2 Release 5.0.

PROGRAM PRODUCTS

**5746-SU1 - 1401/1440/1460 EMULATOR
IBM SYSTEMS 1401/1440/1460
EMULATOR PROGRAM RELEASE 1
5746-SU1**

PURPOSE

The IBM Systems 1401/1440/1460 Emulator Program -- hereafter referred to as the 1400 Emulator -- allows the execution of 1400 programs on 4331 Processors equipped with the 1400 Compatibility Feature and on 4341 and 4381 Processors with the 1400 Simulator generated as part of the 1400 Emulator. The simulation of disk I/O on fixed-block-mode devices is provided. The 1400 Emulator runs as a problem program under control of DOS Release 26, DOS/VS Release 34 and DOS/VSE with VSE/Advanced Functions. As a problem program it is possible to integrate the 1400 Emulator into a DOS, DOS/VS or DOS/VSE system and to take advantage of the capabilities of such a system. Several 1400 Emulators, up to the number of partitions available, can run concurrently.

HIGHLIGHTS

Emulation is provided for 1401, 1440 and 1460 systems with core storage sizes of from 1,400 to 16,000 positions of core storage. All basic features of these systems are emulated, together with the following optional features: Expanded Print Edit ... Inverted Print Edit ... High-Low-Equal Compare ... Multiply/Divide ... Processing Overlap ... Sense Switches ... Advanced Programming/Indexing ... Bit Test ... Print Storage ... Additional Print Control ... Space Suppression ... Column Binary ... Binary Transfer ... 51-column Card ... Punch-Feed Read ... Card Image (on 1442) ... Selective Stacker ... Scan Disk.

Features and operations not emulated are: Selective Tape Listing (on 1403) ... Compressed Tapes ... Mixed Density Tapes ... Read Compare Feature (on 1404).

The following input and output devices are emulated (full details of input and output device correspondence are to be found in the manual *1401/1440/1460 DOS/VS Emulator on S/370*): 1402 Card Read Punch ... 1442 Card Read Punch ... 1442 Card Reader ... 1444 Card Punch ... 1407 Console Inquiry Station ... 1447 Console ... 1403 Printer ... 1404 Printer (continuous forms only) ... 1443 Printer ... 729 Magnetic Tape Units ... 7330 Magnetic Tape Units ... 7335 Magnetic Tape Units ... 1301 Disk Storage ... 1311 Disk Storage ... 1405 Disk Storage.

Input and output devices not emulated are: 1445 Printer ... 7340 Hypertape Drive ... 1011 Paper Tape Reader ... 1012 Paper Tape Punch ... Optical Readers ... Magnetic Character Readers ... Teleprocessing Devices ... Audio Response Units.

Two tape formatting programs are provided with the emulator program: (1) to assist the user in converting his tape files before emulation so that they can be used more efficiently by the emulator program, and (2) to convert tape files produced during emulation back to the 1401/1440/1460 format so that they can then be used on the original system.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

The 1400 Emulator operates on any IBM 4331, 4341, or 4381 Processor. The IBM 1401/1440/1460 Compatibility Feature (for the 4331 Processor) is required unless the simulator option (for the 4341 and 4381 Processor) of the 1400 Emulator is used (see "Software Requirements", below).

The processor storage requirement under DOS Release 26 ranges from 24K to 44K bytes, depending on the configuration of the 1400 series machine to be emulated.

If the 1400 emulator is executed virtual under DOS/VS or DOS/VSE, the storage requirement is within the range of the minimum partition size.

If seven-track tape files are to be processed, the data conversion feature is required.

SOFTWARE REQUIREMENTS

The 1400 emulator is designed to execute under the control of DOS Release 26, under DOS/VS Release 34 or under DOS/VSE with VSE/Advanced Functions.

The following supervisor options are required:

EU	=	YES	For all DOS/VS or DOS/VSE Releases (if 7 track tapes are used)
OC	=	YES	For all DOS, DOS/VS or DOS/VSE Releases (standard with DOS/VSE)
PFIX	=	YES	For all DOS/VS or DOS/VSE Releases (standard with DOS/VSE)

The following emulator option is required if the 1401/1440/1460 Compatibility Feature is not available.

SIMUL	=	YES	(Results in reduced throughput).
-------	---	-----	----------------------------------

COMPATIBILITY

1400 application programs will run under the emulator without the need of modification, provided the programs are written in accordance with 1400 programming conventions and the chosen hardware configuration is compatible.

PERFORMANCE CONSIDERATIONS

In an I/O oriented environment where the CPU utilization is less than 50%, the 1400 Emulator Program Product, in conjunction with the 4331, will perform equal to CS 30 (S/360 mdl 30 under DOS) environments.

As CPU utilization increases, the relative performance of the 1400 Program Product on the 4331 will decrease.

PROGRAM PRODUCTS

**VSE/INTERACTIVE COMPUTING AND
CONTROL FACILITY - RELEASE 1
5746-TS1****PURPOSE**

The VSE/Interactive Computing and Control Facility (VSE/ICCF) program product is an interactive system designed to run on DOS/VSE with VSE/Advanced Functions. It is an extension of the ETSS FDPs (ETSS I, ETSS II and TCS/VS). The VSE/Interactive Computing and Control Facility extends the benefits of interactive computing to the DOS/VSE users of the 4300 Processors and S/370 across all industries.

The VSE/Interactive Computing and Control Facility is a tool for productivity increase, ease-of-use improvements and data security assistance (access control). The VSE/ICCF changes DOS/VSE from a batch to an interactive operating system, by adding interactive capabilities to the DOS/VSE batch operating system.

GENERAL DESCRIPTION

The VSE/Interactive Computing and Control Facility Program Product Release 1 (VSE/ICCF Release 1) is an adaption of the widely used DOS/VS Entry Timesharing System (FDP 5798-CLR) to DOS/VSE. VSE/ICCF Release 1 uses either CICS/DOS/VS (for local and remote, SS, BSC, SDLC) or its integrated Terminal Transaction Facility TTF (local 327X) for terminal control, thus allowing users to establish a single, unified terminal environment supporting both timesharing and transaction oriented applications.

Both 4300 Processors and S/370 are supported in VSE/ICCF Release 1. The fixed blocked mode DASD devices are supported as VSE/ICCF library, as SYSRES and for user files accessed by programs from the VSE/ICCF interactive partitions. Terminal access methods are local BTAM-ES for the integrated terminal transaction facility (TTF) or BTAM-ES and/or ACF/VTAM Version 1 Release 2 or Release 3 or ACF/VTAM Version 2 or ACF/VTAME if CICS/DOS/VS is used for terminal handling. The specified operating environment is DOS/VSE with VSE/Advanced Functions.

The VSE/Interactive Computing and Control Facility is an interactive system designed to extend the power of the computer to multiple terminal users concurrently. The functional capabilities brought to the terminal users can provide significant productivity benefits in many different user environments. The timeshared computer concept, while having nearly unlimited applications, has proven to be of particular benefit in the areas of individual problem solving, programming development and maintenance and education.

VSE/ICCF is a tool providing online program development and online library maintenance capability, a set of interactive usability aids, a powerful context and full screen editor, a text manipulation facility, a job entry function, a timesharing/job execution monitor, a facility for development and execution of interactive problem programs and data security assistance (access control).

For problem solving, VSE/ICCF provides the framework for even complex problem solving utilizing the user's various high level language application programs. The professional programmer may use the VSE/Interactive Computing and Control Facility not only for program development, but for library maintenance and creation of complex job streams.

High level language as well as Assembler programs may be compiled, tested and executed directly from the terminal. The user can write, edit, compile and execute programs without leaving the terminal. Execution of compilers and programs can be done either in interactive or batch partitions. Submit-to-batch is provided via VSE/POWER. In both modes, results can be received back at the terminal or directed to the system printer and punch. Interactive support of VS APL in a DOS/VSE environment is provided through CICS/VS and is not available in VSE/ICCF.

Interactive usability aids (Prompts) assist the user to create various DOS/VSE jobs without having to deal with DOS/VSE job control or job entry control language, thus lowering the skill requirements for the DOS/VSE user.

VSE/ICCF provides functions to assist the user in meeting his data security needs. Logging, auditing and reporting are executed by the complementary VSE/Access Control - Logging and Reporting program product (5746-XE7).

HIGHLIGHTS

- An interactive facility for DOS/VSE on 4300 Processors and S/370.
- An online library system to store programs, jobs and data.
- An online source program and data entry, update and maintenance facility -- an aid to help improve productivity.
- An online library maintenance tool with copy, purge, insert, rename and resequence functions, data compression capability, library change control and auditing assist functions -- another productivity and security tool.

- A powerful editing function -- context and full screen editor, improves the efficiency of correcting and updating programs, jobs and data in the VSE/ICCF libraries.
- A direct job execution facility -- providing compile-load-and-go capabilities in all DOS/VSE programming languages, interactively if desired, with results received back at the terminal or at the central system printer and punch.
- A facility to run most existing DOS/VSE batch programs (single task) of all DOS/VSE languages as interactive programs by substituting card input/printer-punch output through terminals.
- An environment to execute new interactive programs.
- A submit-to-batch via VSE/POWER -- allowing the user to initiate jobs from the terminal for later batch processing with printed results available at the terminal or at the main system printer, or both. Because of this capability, VSE/ICCF should be considered a "must" in cardless systems.
- Interactive usability aids -- prompter facilities to ease creation of DOS/VSE, VSE/POWER and VSE/ICCF jobs, ease installation and operation and to lower the skill requirements. These interactive usability aids are supported on display terminals with a screen of at least 1920 characters.
- System data security aid (access control) -- allowing each installation to select the security provisions most appropriate to local needs.
- A procedure processor with logic capabilities -- allowing the installation and the users to build their own commands and procedures.
- Dynamic disk space allocation -- freeing the installation from having to pre-allocate and pre-define files.
- Support of fixed blocked mode devices.
- Support of BTAM-ES and ACF/VTAM Version 1 Release 2 or Release 3 or ACF/VTAM Version 2 or ACF/VTAME TP access methods.
- 3270 Terminal System oriented -- Display terminal full screen support, program access keys and program function keys for command substitution, forward/backward paging, right/left line shift, etc.
- The ability to share terminal devices with CICS/VS, thus eliminating the need for separate terminal networks and duplicated terminal control functions.
- Storage protection for interactive partitions is standard.
- Improved interfaces to VSE/POWER -- This function called \$DQ (Display Queues) displays at VSE/ICCF terminals the status of jobs in VSE/POWER queues based on various selection criteria. Header and format of the displays are similar to those of VSE/POWER. A help function is available.
- Display current status of DOS/VSE partitions -- This function called \$DA (Display Active) displays the current status of DOS/VSE partitions by interrogating DOS/VSE control blocks and Job Accounting tables. In order to obtain the full benefit of the "Display Active" function, the Job Accounting parameter in the "FOPT" supervisor generation macro has to be specified.
- DL/I MPS support for one interactive partition -- This function allows concurrent access to DL/I files from jobs running in one interactive partition of VSE/ICCF and DOS/VSE partitions under control of DL/I/MPS.

DEVICE SUPPORT

Direct Access Support: The VSE/Interactive Computing and Control Facility supports the following direct access storage device types: 2314, 2319, 3330 (mdl 1, 2, 11), 3333, 3340, 3344, 3350, 3310, 3375 and 3370. RPS is a function supported in VSE/ICCF and may be specified if the block multiplex capability is present and RPS = YES is supported in the DOS/VSE supervisor.

Tape Support: VSE/ICCF supports all tape drives supported by DOS/VSE and VSE/Advanced Functions.

TERMINAL SUPPORT

Terminals supported through VSE/Interactive Computing and Control Facility with integrated Terminal Transaction Facility (TTF): VSE/ICCF with integrated TTF supports the following control units and terminals locally attached to a multiplexer, block multiplexer or selector channel or to the MSSS of 4300 Processors.

Control unit 3272 mdl 2 with 3277 mdl 2, 3284 mdl 2, 3286 mdl 2, 3287 mdl 1 and 2, 3288 mdl 2 terminals.

PROGRAM PRODUCTS
VSE/ICCF R1 (cont'd)

Control unit 3274 mdl 1B with 3268 mdl 2, 3277 mdl 2, 3278 mdl 2, 3284 mdl 2, 3286 mdl 2, 3287 mdl 1 and 2, 3288 mdl 2, 3289 mdl 1 and 2 terminals.

3278 Display terminals attached to the MSSS of 4300 Processors.

Terminals supported through VSE/Interactive Computing and Control Facility with CICS/DOS/VS: The 3272 and 3274 control units (mdls 1A, 1B) may be locally attached to a multiplexer, block multiplexer or selector channel. The 3271, 3274 (mdl 1C), 3275 control units may be remotely attached via nonswitched communication lines. In addition, the 3275 control units may be attached to dial-up switched lines. The 2740 (and 3767 in 2740 mode) may be remotely attached via non-switched communication lines. The 2741 terminal is supported on switched or nonswitched lines only as point-to-point devices.

Remote terminals/control units (3271, 3275 or 2740) of the same type may be multi-dropped from the same communication line. However, if multi-dropping 2740 (or 3767 in 2740 mode) terminals, it is recommended to use the buffered (2740 mdl 2) terminal. When including remote 3270s in the configuration, a line speed of 4800 BPS or higher is desirable, especially if multi-dropping 3271s or 3275s.

- 2740 Communication Terminal mdl 2 with record checking (required). If the buffered receive feature is installed, only the largest buffer size (440) will be supported by VSE/ICCF. If this feature is not installed, the minimum buffer size is adequate. The buffered receive feature will improve overall performance if multi-dropping IBM 2740/3767 terminals on a single line.
- 2741 Communication Terminal is supported.
- 3767 Communication Terminal, when equipped with the appropriate features to make it appear as one of the supported 2740 or 2741 configurations.
- 3277 Display Station (mdl 2 only) through the 3272 or 3271 mdl 2 Control Unit with, optionally, one or more 3284/3286/3287/3288 mdl 2 Printers. 3278 (mdls 2, 3, 4) through the 3276 (mdls 2, 3, 4, 12, 13, 14) or the 3274 control unit optionally with one or more 3268 mdl 2, 3284, 3286, 3287, 3288, 3289 Printers attached, or attached to the 4300 Processors MSSS in 3277 mode.
- The recommended keyboards for the 3276/3277 are the EBCDIC typewriter keyboard with the 12 program function keys or the operator console keyboard with the 12 program function keys. Although the program function keys are not required, their inclusion is recommended.
- 3275 Display Station (mdl 2 or mdl 12) with control with, optionally, one 3284 Printer mdl 3.
- The system console is supported as a terminal under CICS/VS, but not in TTF.

Other I/O Devices as Terminals

- Sequential devices such as card readers, line printers, tapes, and disks are supported as VSE/ICCF terminals under CICS/DOS/VS, but not in TTF. Under CICS/DOS/VS, the main system printer may be specified as a hardcopy terminal destination.

PROGRAMS SUPPORTED

Note: This is not a complete list of programs which are supported

Control Program

DOS/VSE
 VSE/Advanced Functions
 VSE/POWER
 VSE/VSAM

Language/SORT

DOS/VS RPG II
 DOS/VS COBOL
 DOS/VS PL/I Optimizer
 DOS FORTRAN IV
 VS/BASIC
 Assembler (contained in DOS/VSE)
 SORT/MERGE Version 2
 INTERACTIVE DEBUG FDP 5798 - CKF

Telecommunications

BTAM-ES (CICS and TTF)
 ACF/VTAM Version 1 Release 2 or Release 3 or
 ACF/VTAM Version 2 (CICS)
 ACF/VTAME (CICS)

Data Base/Data Communications

DL/I/DOS/VS
 CICS/DOS/VS
 VSE/Data Interfile Transfer, Testing and Operations Utility
 (VSE/DITTO)

APPLICATION AREAS

Usability and Installability of DOS/VSE: Interactive usability aids (Prompters) are provided to assist the end-users as well as system programmers, application programmers and operators in doing their jobs more efficiently. The interactive usability aids reduce the need for the DOS/VSE user to refer to the SRLs.

The prompters are interactive and easy to use facilities which allow a relatively inexperienced user to utilize the resources of DOS/VSE via display terminals.

Depending on the kind of job he wants to do, the user of the prompters needs to have only a basic knowledge of DOS/VSE. He does not have to know details of the various components of DOS/VSE, e.g., the format and sequence of required control statements, nor does he have to deal with the characteristics of a certain device he wants to use, e.g., number of blocks per diskpack.

The prompters are application programs running in a VSE/ICCF interactive partition. They act as an interface between the user and DOS/VSE and/or VSE/ICCF. The user enters his input from the terminal. The prompter then generates a DOS/VSE or VSE/ICCF job stream which may be saved as a member in the VSE/ICCF library and/or submitted to a DOS/VSE partition via VSE/POWER or executed in a VSE/ICCF interactive partition.

These interactive usability aids (Prompters) are available to create jobstreams in DOS/VSE JCL, VSE/POWER JECL and VSE/ICCF JES for VSE/VSAM AMS, System and Librarian Utilities, and user jobs.

INTERACTIVE PROGRAM DEVELOPMENT

Application Programming: Application programmers are supported in interactive program development and test, program maintenance, library maintenance as well as in creation of even complex jobstreams. Programming languages supported are all DOS/VSE compilers, e.g. ASSEMBLER, BASIC, COBOL, FORTRAN, PL/1, RPG II. Programs can be compiled and tested directly from the terminal with results received back at the terminal. A submit to DOS/VSE batch is also provided via VSE/POWER with results either displayed back at the terminal and/or directed to the system printer or punch. Invoking and defining DOS/VSE system utilities is also fully supported.

VSE/ICCF supports the "Interactive Debug Facility" FDP (5798-CKF), which provides extensive but easy to use tools for online program testing and debugging, thus enhancing programmer productivity even further. (Refer to SB21-1898 for detail).

DOS/VS RPG II Release 3 uses VSE/ICCF to utilize the interactive source entry facility.

The application programmer should experience higher productivity through some of the interactive usability aids, such as the prompters for JCL, VSE/VSAM and various utilities.

A terminal user can enter source programs, data, procedures and macros, DOS/VSE JCL or JECL statements and store this information as a member of the VSE/ICCF library. These library members may later be updated via a context or a full screen editor. Logical tabbing support is provided to facilitate entry of fixed format data. A library member can be displayed, paged, updated, deleted or edited at any time. Library changes can be traced with the utility function D TSAUDIT.

System Programming: The system programmer can use VSE/ICCF for library and system maintenance and to install/test new application packages. He will use the interactive usability aids for easier system organization.

Personal Computing and Problem Solving: VSE/ICCF provides the framework for even complex problem solving supporting VS BASIC, FORTRAN and PL/1.

The advantage of using VSE/ICCF for Personal Computing consists of the user having access to data files available in the system and thus allowing extensive data analysis (DA) for the End-Users. Supported are SAM, DAM, ISAM, VSAM and DL/I files.

Online Prompt: The interactive usability aids (Prompters) will assist users working with DOS/VSE services and programs.

Interactive Applications: Application programs developed for DOS/VSE batch (single task) processing can run in VSE/ICCF interactive partitions. This means, a program designed for batch processing can run interactively under VSE/ICCF. Programs developed to run in interactive partitions can also run in batch partitions. Programs can reside in the DOS/VSE system libraries as well as in the VSE/ICCF library.

The end-user's advantage in using VSE/ICCF is to access a DP-system at any time he wants to do "personal computing", and not being dependent on job scheduling in the DP-Shop. The end user can start jobs from the terminal for immediate execution in a VSE/ICCF interactive partition. Thus by using VSE/ICCF, long turn-around time can be avoided.

VSE/ICCF R1 (cont'd)

Interactive System Operation: The system operator has the capability to run the system interactively by preparing and invoking jobstreams via the terminal. He can display the status of a submitted job at his VSE/ICCF terminal and has access to VSE/POWER job queues to modify them. This facility is also available to a remote operator. The library of VSE/ICCF is a single and flexible easy-to-use procedure library. JCL, programs and data, and all other information necessary to operate a system can be stored. Nesting and mixing is possible. Variables can be included at job submission and/or execution time. Operating a DOS/VSE system from a VSE/ICCF terminal makes it possible to offer a cardless system with full DOS/VSE functions. VSE/POWER is required in conjunction with cardless interactive system operation.

The system operator and application programmer can be less skilled and/or experienced when using the DOS/VSE interactive usability aids.

Access Control: This function provides a facility to assist the user in protecting data from unauthorized usage, provided that programs properly use standard interfaces.

Certain facilities of DOS/VSE, for example the file protect facility, should be used as suggested by systems publications to enhance the value of the access control facility.

For an installation to safeguard its data, it must not only consider the functions provided through the system, but also provide the necessary physical protective measures and implement effective information management practices. The capabilities of VSE/ICCF have been designed to help customers attain their data security, however, protection may not be fully effective against programmers with detailed knowledge of the internal design of DOS/VSE. Thus, while no guarantee can be made for complete security of any system, the installation goal of improved security at an acceptable cost can best be attained through consideration of the full spectrum of available measures. Installation security is the customers responsibility.

The following functions are provided through VSE/ICCF:

User Identification and Verification: Identifies and verifies the user by user-id and password for authorization to use the system and to access protected resources. Users are defined in the VSE/ICCF profile and in the Security Resource Table.

Data Access Control: Allows the authorized user to access protected files and denies access to other users depending upon the security classes and read/write authorization levels assigned. Authorization classes are given to the user in the profile record and compared to the security classes and authorization levels assigned to the protected files in the Security Resource Table.

Program Access Control: The system also restricts access to protected private libraries as described above when an ASSGN SYSCLB/SYSRLB/SYSSLB or // EXEC is encountered. Another level of protection is offered to the user, since phases within core image libraries can also be protected based on the security classes assigned to the user and those assigned to protected resources.

Automatic and Dynamic Protection of Files and Programs: New files and programs can be protected automatically and dynamically through defining them within group names until the newly created name is placed in the tables for protected resources. The existing GROUP entries are always scanned after the library, file or phase name.

Logging and Reporting: VSE/ICCF creates a set of data for each access control related event. This data can be recorded into an access log file on disk and be printed by the VSE/Access Control - Logging and Reporting program product 5746-XE7 for auditing purposes.

CUSTOMER RESPONSIBILITIES

Installation and maintenance of VSE/ICCF is performed using DOS/VSE MSHP (Maintain System History Program). The user can choose between pregenerated systems and systems completely tailored to the users configurations and requirements. In the case of a pregenerated system, only the definition of tables (terminals, users, programs) is required. Tailoring of a system will require the compilation of VSE/ICCF. Details of this System Generation Process are described in *Installation Reference* (SC33-6067). (Note: CICS/DOS/VS is not in MSHP format.)

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

VSE/ICCF executes on any IBM S/370 and 4300 Processor which is supported by DOS/VSE and VSE/Advanced Functions. It is recommended that the system have at least 192K bytes of real processor storage, if the Terminal Transaction Facility (TTF) (part of VSE/ICCF) is used or, 256K bytes of real processor storage, if CICS/DOS/VS is used for terminal control. For performance reasons, at least two spindles of DASD are recommended to be attached to the system. Tape drives are not required for operation of VSE/ICCF. One terminal, preferably an IBM 327X display with keyboard, is required.

SOFTWARE REQUIREMENTS

VSE/ICCF Release 1 is designed to operate on DOS/VSE with VSE/Advanced Functions. Either Terminal Transaction Facility (TTF), available as part of VSE/ICCF, or CICS/DOS/VS provide terminal support. TTF uses BTAM-ES, CICS/DOS/VS uses either BTAM-ES or ACF/VTAM Release 2 or ACF/VTAME as the TP access method.

COMPATIBILITY

The following describes the compatibility between ETSS FDPs and VSE/ICCF:

VSE/ICCF provides language and command upward compatibility from the ETSS I and ETSS II FDPs. Libraries created under ETSS II are usable under VSE/ICCF. For conversion to fixed block mode or from ETSS I, a backup/restore is necessary. The command language for all functions remains basically unchanged.

For easy installation some of the supervisor and ETSS II generation options have been removed or defaulted in VSE/ICCF. For 4300 Processors, a few new parameters were added.

The dual partition function of ETSS II will not be supported in VSE/ICCF Release 1. However, VSE/ICCF with TTF can run in a second partition totally isolated from CICS/DOS/VS.

Submit to DOS/VSE batch is supported via VSE/POWER only. External messages have been formalized with the DOS/VSE system message assignment for subsystems.

FDPs and IUPs running under ETSS II 5798-CLR should continue to run under the VSE/ICCF program product.

The following FDPs will not be supported by VSE/ICCF:

- MTCS/VS 5798 - CFK Minimum Terminal Control System
- TCS/VS 5798 - CRX Now part of VSE/ICCF called Terminal Transaction Facility (TTF) providing minimum terminal support.

The following FDP has been tested for continued support on VSE/ICCF:

- ETSS & DOS/VSE Interactive Debug FDP 5798-CKF.

CONVERSION

General Considerations: Users of VSE/ICCF have to install the specified operational environment of DOS/VSE and VSE/Advanced Functions.

DOS/VS Entry Time Sharing System (ETSS II) to VSE/Interactive Computing and Control Facility: VSE/ICCF is externally compatible with the ETSS II FDP version. A terminal user will see only minor differences when the program product is installed. Installing VSE/ICCF is different from, but easier than installing ETSS II, because many installation parameters have been dropped or defaulted and MSHP is used for installation. Pregenerated systems are available. The differences are described in the *VSE/ICCF Installation Reference Manual* (SC33-6067).

An ETSS library created under the ETSS FDPs can be used under VSE/ICCF if the library still resides on a 2314, 2319, 3330 (mdl 1, 2, 11), 3333, 3340, 3344 or a 3350 direct access storage device. To move an ETSS library onto a 3310 or 3370 fixed block mode device, a VSE/ICCF backup/restore utility execution has to be performed.

The interfaces for the currently supported program products under ETSS II will continue to be supported under the VSE/ICCF Release 1 program product. The Minimum Terminal Control System (MTCS) will not be supported by the program product. The main functions of TCS/VS 5798-CRX are now integrated into VSE/ICCF (called Terminal Transaction Facility TTF), thus automatically available with VSE/ICCF.

Source Program Maintenance On Line (SPM) TO VSE/Interactive Computing and Control Facility

THE LIBRARY FILE: Formats, structure and blocking factors of the SPM Library file are different: Therefore VSE/ICCF cannot access a SPM library file without modification.

The first approach is to read a SPM Backup tape and modify it in order to get a tape which will be a valid input for the DTSUTIL program. The DTSUTIL utility program is a VSE/ICCF program which loads new members into the VSE/ICCF library file.

The second approach is to use VSE/ICCF procedures in order to select conversationally the existing SPM programs to be transferred as VSE/ICCF members.

COMMAND LANGUAGE: The VSE/ICCF command language is different from SPM because of extended functions of VSE/ICCF.

PERFORMANCE CONSIDERATIONS

The results of performance measurements taken on a 4331 Processor with 512K bytes of main storage (of which 326K were available to the user) show for the following different loads the amount of resources consumed by the VSE/ICCF with CICS/DOS/VS for terminal control:

PROGRAM PRODUCTS

VSE/ICCF R1 (cont'd)

Terminals and Lines	Message Rate/Min.	Response Times (Sec)		CPU Utilization %
		90% Avg.	Average	
10/1	30	.44	.74	20
20/2	60	.54	1.25	50
30/2	90	.71	1.74	65

Line mode was BSC, speed 4800 bps, attached to the ICA of the IBM 4331 Processor. All response times are system response times measured by TPNS; all terminals are remote terminals simulated by TPNS.

For the low-end user with five local attached terminals, similar measurements have shown the following performance when using TTF instead of CICS/VS.

Terminals	Message Rate/Min.	Response Times (Sec)		CPU Utilization %
		90% Avg.	Average	
5	15	.35	.75	12

Terminal activities: Data entered into the terminals consisted of:

- 40% text entered in /INPUT mode.
- 40% text entered in /EDIT mode together with simple EDIT commands.
- 20% library commands including copy, compress, decompress, delete, resequence and save of library members. Library member size was about 450 statements each. The performance data shown above was for a selected set of workloads and is for information purposes only. There is no warranty or guaranty that the same performance characteristics will apply to the users configuration.

HIGHLIGHTS of RELEASE 2

VSE/Interactive Computing and Control Facility Release 2 provides all functions of Release 1 and the following enhancements:

1. Use of the extended VSE/POWER interfaces:
 - a) The VSE/POWER queues can be displayed at the user terminal in the same way as is currently done at the operator console.
 - b) VSE/POWER jobs may be password protected. The VSE/POWER job numbers are used in addition to the job names to achieve uniqueness of names.
 - c) Access to VSE/POWER list and punch queues via GETL and GETP procedures.
 - d) Selective display of VSE/POWER print files by locating character strings.
2. VSE/VSAM share option 4 is supported for programs running in interactive partitions.
3. Support of concatenated relocateable libraries with LINKGO.

SPECIFIED OPERATING ENVIRONMENT

VSE/ICCF Release 2 executes on any IBM S/370, 3031 and 4300 Processors supported by VSE/Advanced Functions Release 2, which is a prerequisite product. For details, refer to the description of VSE/ICCF Release 1.

PERFORMANCE CONSIDERATIONS

For VSE/ICCF Release 2, no or only minor changes in the overall performance can be expected compared to Release 1. Improved performance will be obtained especially for the display of VSE/POWER list output due to the use of the buffered GETSPOOL function.

HIGHLIGHTS of RELEASE 3

Release 3 of VSE/ICCF provides the following new functions:

1. Support of the cross-partition communication facility (VSE-XPC) in interactive partitions.
2. Support of CICS/VS Multi-region operation.
3. Support of 3278 mdl 5 (wide screen) under CICS/VS Release 1.5.
4. Improved support of print output from Interactive Partitions.

5. Notification facility.
6. Extension of full screen support.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The minimum hardware requirements for VSE/ICCF Release 3 are the same as those for VSE/Advanced Functions Release 3 which is a prerequisite product.

For more information on the specific device types supported by DOS/VSE, see the *Introduction to the VSE System* (GC33-6108).

SOFTWARE REQUIREMENTS

VSE/ICCF Release 3 is designed to operate with VSE/Advanced Functions Release 3 which is a prerequisite product.

PERFORMANCE CONSIDERATIONS

For VSE/ICCF Release 3, no or only minor changes in the overall performance can be expected compared to Release 2. The performance may be improved through the reduction of the path length in the access routine for the ICCF library.

RELEASE 3 MODIFICATION LEVEL 5

VSE/Interactive Computing and Control Facility 1.3.5 (VSE/ICCF 1.3.5) improves serviceability of VSE/Interactive Computing and Control Facility Release 3, introduces better information about network activities together with VSE/POWER Version 2, and reduces restart time by eliminating unnecessary recovery runs.

Additional focus was given to quality enhancements, installability, and tailoring.

HIGHLIGHTS of RELEASE 3 MODIFICATION LEVEL 5

- **Multilevel Program Functions Keys**
The extension of the PF-key setting will be used to define and work with four different sets of PF-keys: One individual set for each, COMMAND mode, LIST/SPOOL-mode, EDIT-mode and EXECUTION/READ-mode. Each set can be up to 24 PF-keys and thus fully utilize the extended PF-key keyboards. This facility is used to substitute PF-keys for commands, etc., for ease-of-use and productivity purposes.
- **@Exit Macro Order in the ICCF Macro Language**
The new macro order will be used to exit a macro without reaching the physical end of a macro. This provides controlled flexibility in macro processing, comparable to procedures.
- **Removal of @ Prefix for Macro Invocations**
Macros may now be invoked in command mode by specifying the macro name without the @-prefix. Thus a terminal user can invoke macros like he can invoke procedures. This functional extension improves ease-of-use, and simplifies the human machine interface in VSE.
- **VSE/ICCF Notify Support**
A communication link will be established between VSE/ICCF and VSE/POWER (via NOTIFY) so that, for example, batch job ending messages can be routed to the terminal user who submitted the job. This function notifies the terminal user about the job events automatically rather than have him query the system to get the information, thus providing a better level of information. This function complements the NOTIFY support in VSE/POWER.
- **/INCLUDE Job Entry Statement Resolved by DTSUTIL**
The new parameter INCL will be introduced for the DTSUTIL-commands PRINT, PUNCH and PRTPCH to allow printing or punching of included members. This function provides ease-of-use in ICCF library handling. It relieves the user of analyzing library members to create extra PUNCH or PRINT commands for each /INCLUDE statement within members. The /INCLUDE statement will be automatically resolved by DTSUTIL.
- **Skip Recovery (via DTSANALS) if Library is Correct**
DTSANALS will have the capability through the optional parameter OPT on the commands ANALYZE, RECOVER, and REORG, to decide whether these commands should really be executed or not, depending on the current status of the ICCF library. This reduces and improves restart/recovery time because unnecessary recovery runs can be eliminated.
- **Generation Independence of ICCF**
The user no longer needs to reassemble many ICCF modules if he wants to tailor ICCF to his needs. All he has to do now is to assemble one table (DTSIGEN) and catalog it to the core image library. Also, if he wants to modify the ICCF security tables, he only needs to assemble and relink these tables, but he no longer needs to reassemble the ICCF control program. This is an ease-of-use item for the ICCF system administrator.

VSE/ICCF R1 (cont'd)**SPECIFIED OPERATING ENVIRONMENT****HARDWARE REQUIREMENTS**

VSE/Interactive Computing and Control Facility 1.3.5 has the same machine requirements and supports the same hardware as VSE/ICCF Release 3.

VSE/ICCF 1.3.5 supports the IBM 3290 Information Panel as a 3278 mdl 2-5 compatible display.

SOFTWARE REQUIREMENTS

- VSE/ICCF 1.3.5 requires CICS/VS 1.6.0 if CICS is the terminal control program.
- For the NOTIFY support, VSE/POWER 2.1.0 with PTF UD25257 is required.
- Either BTAM-ES 1.1.0 (CICS/VS or TTF) or ACF/VTAM 2.1.0 (CICS/VS only) is required.
- VSE/AF 1.3.5 (5746-XE8) is required.

COMPATIBILITY

VSE/ICCF 1.3.5 is fully compatible with VSE/ICCF Release 3 with the following exceptions:

- SEGMENT option has been removed from SUBMIT function.
- POWRPCH and NXTNTS tailoring options are ignored now.
- Other tailoring options used for shipped ICCF 1.3.5 system. (Reference: *Installation and Operations Reference*, SC33-6067).
- Interactive Debug (FDP 5798-CKF) no longer supported.

PROGRAM PRODUCTS

**VSE/DATA INTERFILE TRANSFER, TESTING
AND OPERATIONS UTILITY, RELEASE 3
5746-UT3**

PURPOSE

VSE/Data Interfile Transfer, Testing and Operations Utility licensed program (hereinafter referred to as VSE/DITTO) is a general-purpose utility program for card, magnetic tape and disk input/output devices. It provides the facility to list, copy, alter and create files or portions of files. The wide range of user-oriented functions is intended to aid programmer testing, reduce the need for separate specialized utility programs and provide greater operational productivity. VSE/DITTO offers the user an efficient and easy-to-use tool for testing and file-handling in both a batch and interactive environment.

HIGHLIGHTS of NEW FUNCTIONS in RELEASE 3

VSE/DITTO Release 3.0 provides the following new functions and improvements to existing functions:

3540-compatible diskette devices are supported with functions that are similar to those provided for disk support. These functions are:

- List diskette data on either a physical address or file basis.
- Scan, display and alter the volume identifier and alter or initialize the index track on a physical address basis.
- Copy diskette data to or from cards, tapes, disks or diskettes on a file basis.

A tapemap function (TMP) to list the contents of a tape reel.

The information listed includes the contents of the first record or records of a file, record length, number of records, and length of tape used in meters and feet.

A copy function for labeled tape files (TFT).

Single and multi-volume tape files can be copied or reblocked, or both.

Buffer functions to create simple test data on tape, SAM, ISAM, VSAM, and diskette files directly from data in an in-core buffer according to user specifications.

A display VTOC function (DVT) to list VTOC data, which can be sorted by name, date or extents. The listing can include information about free extents.

A process VTOC function (PVT) to rename or delete VTOC entries.

The tape and disk scanning functions (TRS and DRS) have been extended to operate in batch mode.

The disk to console (DCN) and disk dump (DD) functions have been extended to display and list the contents of home address, record 0, and record count fields.

The disk record load function (DRL) has been extended to allow CKD EOF records to be changed.

VSAM files can be created directly from card input (CVS function), and card files can be created directly from VSAM card-image files (VC and VI functions).

The SET function has been extended to also run in batch mode and to allow the user to specify:

- ASCII to EBCDIC translation (tape to printer functions).
- Exclusion of the header information from a listing produced by a tape or disk function, and left-justification of the listed data.
- Begin and end columns of data records to be printed.

Significant ease-of-use improvements, for example:

- Prompting messages accept the reply "U" to interrupt the function currently in use.
- A message is issued when a tape mark is reached during FSR (Forward Space Record) or BSR (Backspace Record) operations.
- A check is made for the presence of a tape ring in an input or output tape file.
- Volume identifier alteration functions do not change the volume identifier to blanks if EOB/ENTER is entered. TP (Tape to Printer), TPV (Tape to Printer, Variable Length Records), and TPD (Tape to Printer, Deblocked) can specify more than one file.
- The disk alteration functions (DRL, DID, EOF, and PVT) have been moved to a separate phase. This allows greater flexibility in reserving such functions in secured phases that require authorization levels.
- DEFAULT.MODEL.SAM.ESDS information is used, if available, when no job control EXTENT information is provided for VSAM-managed SAM files that are defined dynamically.

HIGHLIGHTS of NEW FUNCTIONS in RELEASE 2

- Environments with VSE/VSAM Release 2.0 installed can take advantage of VSAM's Space Managed SAM feature for the dynamic allocation of SAM files.
- Multivolume/labeled tape support is available for file-based functions to facilitate the copying and restoring of large files to tape.
- VSAM relative-record data sets (RRDS) are supported.
- More than one VSAM user catalog can be used in interactive mode.
- The user can specify his own DLBL filenames rather than the standard filenames previously required for executing a file-based function.
- New functions to print output data spooled to disk are available.
- The user can specify his own end-of-data delimiter for card input operations in interactive mode.
- Enhancements to the tape-to-console (TCN) and disk-to-console (DCN) functions provide for the repositioning to other records without reinvoking the function.
- New card I/O support allows execution on cardless systems and from procedure libraries.

CUSTOMER RESPONSIBILITIES

In order to install and use VSE/DITTO Release 3 successfully, the customer must have DOS/VSE and VSE/Advanced Functions installed (for details see "Software Requirements"). If VSAM functions are to be used, the VSE/VSAM program product (Program Number 5746-AM2) must be installed.

For installations which have implemented the security assist function of the VSE/Interactive Computing and Control Facility program product (Program Number 5746-TS1), VSE/DITTO allows the user to reserve selected function groups for authorized use.

The distribution medium contains a private core image library, a private relocatable library and a component history file. The distribution medium may be tape or disk. If it is tape, RESTORE format is used.

VSE/DITTO is installed by invoking the INSTALL COMPONENT function of the VSE/Maintain System History Program (MSHP).

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

VSE/DITTO is designed to operate on all IBM processors supported by VSE, that is, IBM S/370 mdls 115 to 158, 3031 and 4300 processors.

VSE/DITTO can be used with the following devices:

CARD	IBM 1442, 2501, 2520, 2540, 2560, 2596, 3504, 3505, 3525, 5424 and 5425.
TAPE	IBM 2401, 2420, 3410, 3411, 3420 and 8809.
DISK	IBM 2311, 2314, 3310, 3330-1, 3330-11, 3340, 3350, and 3370.
DISKETTE	All 3540-compatible devices.
CONSOLE	Any SYSLOG-eligible device (screens in keyboard/printer mode only).
PRINTER	All printers supported by VSE.

Specific Requirements

- IBM 3525 Card Punch features: VSE/DITTO supports either the two-line (feature #8839) or the multi-line (feature #5273) print feature for punched output. For interpreting pre-punched cards, in addition to one of the above print features, the punch card read feature (feature #1533) is required.
- IBM 2560 Multi-Function Card Machine features: Punched output can be interpreted if the 2560 is equipped with the card print feature (feature #1575, 1576 or 1577).

A minimum partition size of 128K bytes (including 48K bytes default GETVIS area) is sufficient for most executions of the program. Devices, such as 3350 DASDs or magnetic tapes which potentially contain large record sizes may, however, require additional buffer space and, consequently, larger partition sizes. Some file-based functions may require a larger GETVIS area.

SOFTWARE REQUIREMENTS

VSE/DITTO Release 3 is designed to operate under VSE/Advanced Functions Release 2.0 or Release 3.0 (Program Number 5746-XE8).

If VSAM functions are to be used, VSE/VSAM (Program Number 5746-AM2) must be installed. For the dynamic allocation of SAM files, the VSE/VSAM Space Management for SAM feature is required.

VSE/DITTO operates in any partition. All input/output areas are dynamically allocated, based on processing needs.

Do not reproduce without written permission

**VSE/OPERATOR COMMUNICATIONS CONTROL
FACILITY RELEASE 1 (5746-XC5)**

PURPOSE

The VSE/Operator Communication Control Facility (VSE/OCCF) is designed to reduce operator interaction for the operation of a DOS/VSE controlled IBM computing system and to allow operation of the system from a remote console. The program provides functions and services that allow the user to reduce the activities normally executed by an operator at the system console by predefined certain activities.

The functions and services of VSE/OCCF are of particular interest in a distributed data processing (DDP) environment where a network operator controls one or more DOS/VSE satellite systems. In this environment, operator attendance and DP skill at the satellite systems can be reduced to a minimum.

VSE/OCCF is also applicable in environments with several single systems. For example, a number of single systems can be controlled via terminals that are centralized at one location remote from the systems.

HIGHLIGHTS

The Routing Functions of VSE/OCCF permit control of one or several DOS/VSE satellites through one NCCF operator station. This NCCF operator station may be locally or remotely attached to the satellite system or to a remote host. Messages can be routed from the DOS/VSE satellites to the NCCF operator station; commands and replies can be routed back to the DOS/VSE satellites. There may be more than one NCCF operator station attached to the host, each controlling a separate set of DOS/VSE satellites.

Message Reduction is possible through suppression of information type messages and/or pregeneration of message replies. This reduces the time normally required at an operator's station and allows the operator to concentrate on those situations that really need attention; for example, responding to decision type messages. This means that personnel fulfilling general duties at satellite processor locations in a DDP environment can handle the occasionally required responses to messages and exceptional (error) conditions.

Translations and/or Modifications of Text for Operator Messages can be pre-defined and supplied to VSE/OCCF in table form to cause messages normally issued by the system in English to be displayed in other languages. This can eliminate potential language problems at the operator console by adjusting the messages to the skill available at the console (trained operator, end-user).

CUSTOMER RESPONSIBILITIES

Define the actions on messages together with the branch office support. Install message action and/or message translation table. These tables have to be generated by the customer.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

VSE/OCCF runs on any IBM processor that is supported by DOS/VSE and VSE/Advanced Functions current at availability of VSE/OCCF.

The operator console must be an IBM 3277 mdl 2 or 3278 mdl 2A CRT display device, or 3277 compatible system consoles of 3138, 3148, 3158 or 3031.

VSE/OCCF requires for its execution a partition of its own. The partition size depends on the specified functions. The DOS/VSE minimum partition size of 128K normally suffices for the single system environment without NCCF operator station support.

SOFTWARE REQUIREMENTS

VSE/OCCF is designed to operate with DOS/VSE and VSE/Advanced Functions on the release level available from PID at the time of program availability in either environment; the single system environment with or without remotely located control stations or the DDP environment with remote control.

For operation in the single system environment, where a locally attached console is used for controlling the system, no functions beyond those of DOS/VSE and VSE/Advanced Functions are required.

Operations in the single system environment, where a remotely located terminal is used for controlling the system, requires programming support depending on the processor as shown below:

Programming Support	Processor	
	4331	4341 or /370
DOS/VSE and VSE Advanced Functions	X	X
NCCF	X	X
VSE/OCCF	X	X
ACF/VTAME or ACF/VTAM	X	
ACF/VTAM		X

The programming requirements shown for the IBM 4341 apply to all processors supported by DOS/VSE and VSE Advanced Functions, except for the IBM 4331.

For specific terminal and communications support refer to the individual program products.

For operation in a DDP environment, ACF/VTAM Version 2 or the Multi-System Networking Facility feature of ACF/VTAM Version 1 is required in addition, provided that ACF/VTAM is the TP access method used. The host may be either an MVS VS1, or VSE host as shown below.

In particular, the programming support required in the host is as shown in the following two tables:

• MVS or VS1
• ACF/VTAM Ver. 1 (1) or ACF/VTAM Ver. 2
or
• ACF/TCAM (1)
• NCCF
(1) with the Multi-System Networking Facility feature

or

Programming Support	Processor	
	4331	4341 or /370
DOS/VSE and VSE/Advanced Functions	X	X
NCCF	X	X
ACF/VTAME or ACF/VTAM Ver. 1 or ACF/VTAM Ver. 2	X	
ACF/VTAM Ver. 1 (1) or ACF/VTAM Ver. 2		X
(1) with the Multi-System Networking Facility feature		

The programming requirements shown for the IBM 4341 apply to all processors supported by DOS/VSE and VSE/Advanced Functions, except for the IBM 4331.

For specific terminal and communication support refer to the individual program products.

COMPATIBILITY

Messages to the operator from user programs are only accepted if they follow the rules described in the VSE/OCCF documentation. The following restrictions apply:

- Messages with the same message-id (first up to eighth characters) but different text cannot be distinguished by VSE/OCCF. This means that different actions cannot be specified for messages with the same identifier.
- Messages longer than 247 characters cannot be processed by VSE/OCCF. These messages are truncated and an additional warning message is routed to the same destination as specified for the truncated message.
- The maximum reply/command length from an NCCF operator station is 80 characters. The 80 characters include all routing information which has to be typed in addition to the data. The number of characters required as routing information is environment dependent. If a program expects a command/reply longer than the maximum that can be typed, VSE/OCCF passes the data actually typed plus a residual count to the requestor.
- Channel programs have to follow the rules described in the VSE/OCCF documentation.

Do not reproduce without written permission

PROGRAM PRODUCTS

VSE/OCCF (cont'd)

SECURITY and INTEGRITY

The access control facilities of the program products VSE/ICCF together with VSE/Access Control Logging and Reporting allow a customer to restrict the access to VSE/OCCF or to user generated VSE/OCCF control tables to certain users. The security facilities of NCCF can be applied to restrict the remote DOS/VSE control to certain users.

DOCUMENTATION: (available from Mechanicsburg)

VSE/Operator Communication Control Facility (OCCF) General Information (GC33-6113).

VSE/Operator Communication Control Facility Installation Guide and Reference will be provided at the time the product is available.

PROGRAM PRODUCTS

**ADVANCED FUNCTIONS - DOS/VS
5746-XE2**

PURPOSE

Advanced Functions - DOS/VS provides additional facilities and improved performance over DOS/VS.

HIGHLIGHTS

Additional Partitions: Advanced Functions - DOS/VS provides support for up to seven partitions on DOS/VS Release 34. The level of multiprogramming is limited to six partitions when system residence is on 3340/3344 DASD.

Additional partitions provide users with the opportunity for continued growth within DOS/VS, improved batch capability for DB/DC environments and transition to products having multiple partition requirements (i.e., VTAM, VSPC).

Dynamic Partition Balancing: Advanced functions - DOS/VS dynamically changes the execution priority within a set of selected partitions. The priorities are assigned based on the Processor activity of these partitions within a specific time interval.

The partitions selected for partition balancing are specified during system generation, and can later be added or removed from the selected group by using an expanded PRTY command.

The dynamic partition balancing facility can minimize the task of scheduling jobs to balance processor resources and may improve throughput performance (see "Performance" section).

Asynchronous Operator Communications: With the new asynchronous operator communications facility, Advanced Functions - DOS/VS assigns reply numbers to all messages that require operator response. The system console remains free to display messages from other tasks and partitions, since the operator is not forced to reply to messages in the same sequence as they were displayed.

When the operator is ready to act upon a message, use of the reply-ID associates the response with the proper outstanding message. Responses to one message per active task may be deferred without causing DOS/VS to inhibit additional messages from appearing on the system console.

The capability of having multiple replies outstanding can permit more flexible operator action, reduce console bottleneck situations and allow more effective multiprogramming.

Console Support ... the asynchronous operator communications facility is supported for all DOS/VS operator console devices. The S/370 mdl 158 "Display" mode operator console can be specified as a 3277 only in conjunction with the Asynchronous Operator Communications feature and with the following restrictions:

- No light pen support.
- No support for the optional 3213 printer.

Fast Linkage Editor: The DOS/VS linkage editor sequentially reads single blocks from the relocatable library directory and uses a single buffer while searching for the appropriate entry. With Advanced Functions - DOS/VS installed, the linkage editor reads multiple directory records per EXCP and uses double buffering.

Since the directory lookup may be a significant portion of the total time required to include relocatable modules, the improved search can reduce linkedit times (see "Performance" section).

Private Library Device Independence: Advanced Functions - DOS/VS permits private libraries to reside on a DOS/VS supported DASD type different than that used for system residence.

Since private relocatable and source statement libraries are no longer restricted to the same DASD type as SYSRES, users have greater flexibility in configuring their system and converting to new DASD devices.

VM Linkage Enhancements Functions: Non-Paging Mode ... The linkage enhancements facility eliminates DOS/VS paging and CCW translation since these functions are performed by VM/370.

Pseudo Page-Fault Handling ... With the linkage enhancements support, a DOS/VS virtual machine spends less time in VM/370 page wait.

BTAM Dynamic CCW Modification ... The VM/370 overhead in servicing BTAM is reduced by eliminating use of the program control interrupt (PCI) linkage to test the autopoll CCW sequence.

CP Close ... The linkage enhancements facility enables POWER/VS to automatically close printer and punch files that have been spooled by POWER/VS at the end of each POWER/VS job.

Job Accounting ... The linkage enhancements support enables VM/370 to update the interval timer at the proper times, thereby improving the accuracy and repeatability of DOS/VS accounting in a VM/370 environment.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

Advanced Functions - DOS/VS requires DOS/VS Release 34 and a minimum processor storage size of 96K bytes as a prerequisite for installation. All other prerequisites for the installation and operation of Advanced Functions - DOS/VS are the same as for DOS/VS Release 34.

Clock Comparator and Processor Timer ... The Advanced Functions - DOS/VS product requires the optional Clock Comparator and Processor Timer feature of the S/370 mdls 135 and 145. All other DOS/VS supported systems include the Clock Comparator and Processor Timer as a standard feature.

SOFTWARE REQUIREMENTS

VM Environment ... A DOS/VS supervisor generated with linkage enhancements support can only be utilized in a VM/370 operating environment. A supervisor generated without the linkage enhancements facility can operate directly on a S/370 or in a virtual machine under VM/370.

When utilizing the linkage enhancements support of Advanced Functions - DOS/VS, the system requirements are:

- VM/370 Release 3 at a PLC 8 or later level.
- A real machine with a processor storage size of at least the minimum for VM/370.
- A virtual machine size of at least the total of the VSIZE and RSIZE specifications for the DOS/VS supervisor being used and less than 16 megabytes.

COMPATIBILITY

User programs that execute on DOS/VS Release 33 will generally be object-code compatible with Advanced Functions - DOS/VS installed on DOS/VS Release 34. An exception may be programs that do not use standard DOS/VS external user interfaces.

PERFORMANCE

Non-VM environment ... The Advanced Functions - DOS/VS performance improvements described below are relative to a DOS/VS Release 34 system without Advanced Functions - DOS/VS installed.

Dynamic Partition Balancing: For environments that contain non-paging combinations of strongly processor-oriented partitions and I/O-oriented partitions, dynamic partition balancing may improve overall throughput by up to 25%.

The maximum performance gains of partition balancing are typically achieved in systems that have untuned job scheduling and are monopolized by a high processor-utilization partition. Laboratory measurements have shown that small degradations may result from partition balancing if the workload environment is already optimally tuned, or if paging rates have activated the load leveler.

Fast Linkage Editor: The degree of performance improvement realized with the Advanced Functions - DOS/VS linkage editor facility is dependent upon the number of relocatable members to be included and the location of the members in the relocatable library.

The larger the library size and the further away from the beginning of the library that the member resides, the greater the linkedit performance improvement.

Laboratory measurements have shown that performance gains of up to 50% may be realized with the Advanced Functions - DOS/VS Linkage editor.

Multiprogramming Improvements: The system throughput gains that can be obtained by utilizing more partitions or by implementing asynchronous operator communications are dependent upon the specific processor and I/O configuration, the workload and the operator.

VM Environment: Measurements have shown that a DOS/VS system generated with linkage enhancements provides the following performance gains compared to the same system without linkage enhancements support:

System Type	Storage Size	Workload	Reduction In Processor Busy Time
138	1024K	Batch	13%
138	1024K	Batch + CICS	19%
138	1024K	Batch + CMS	13%
148	2048K	Batch	25%

All performance measurements were made with a systems measurement instrument (SMI) and included use of the Extended Control Program Support for VM/370.

Note that the S/370 mdl 138 measurements utilized a selector channel configuration, whereas the S/370 mdl 148 measurement was conducted on a block multiplexer channel configuration.

PROGRAM PRODUCTS

**VSE/POWER RELEASE 1 WITH
VSE/POWER REMOTE JOB ENTRY FEATURE
5746-XE3**

PURPOSE

The licensed program VSE/POWER Release 1 -- hereafter referred to as VSE/POWER -- is a program product developed on the POWER/VS component of DOS/VS Release 34. It is a spooling system that provides the user with automatic staging of unit-record input and output and priority scheduling for all programs executed under its control. VSE/POWER resides in one partition and is able to control all remaining partitions of the DOS/VSE environment placed under its control, provided these have a lower system dispatching priority than that of the VSE/POWER partition.

DESCRIPTION

VSE/POWER dynamically uses the address space and acquires real processor storage on an as-needed basis. Page frames released by VSE/POWER tasks are freed and returned to the page pool. Programs executing under VSE/POWER control may be executed in virtual or real mode.

VSE/POWER is generated by assembly of macros that allow the user to specify the options appropriate to his own system environment, and creates the VSE/POWER generation table. The resultant object deck contains the code necessary to invoke VSE/POWER.

The system maintains input and output queues on direct access storage for the card readers, diskette I/O units (input only), card punches and printers associated with the partitions under its control. These queues are filled or emptied by the appropriate physical devices. When a program under VSE/POWER control makes an input or output request to one of these devices, VSE/POWER presents it with the next record from the appropriate input queue or collects the record and places it in the appropriate output queue. These operations take place at main storage or direct access storage speeds: Hence, programs execute quicker and take better advantage of the system environment.

VSE/POWER is transparent to the programs executed under its control: these do not require modification to take advantage of the system's capabilities.

Since the queues are under optional operator control, the system operator can modify the order in which programs are executed by manipulating the queues with VSE/POWER operator commands. The effective substitution of direct access storage devices for unit-record devices reduces the number of the latter needed to operate the system efficiently in a multiprogramming environment.

The use of partition-independent input classes simplifies the operational characteristics of this licensed program. The dynamic partition scheduling provides automatic balancing of the input between the various partitions controlled by VSE/POWER.

VSE/POWER Release 1 will be available as a basic system that provides spooling in batch mode; this basic system may be upgraded by inclusion of the separately orderable optional VSE/POWER Remote Job Entry Feature that allows spooling via remote BSC or SNA terminals or SNA workstations. In the following, this feature will be referred to as the Remote Job Entry Feature.

HIGHLIGHTS

- Fully compatible with POWER/VS of DOS/VS Release 34.
- Support of DOS/VSE (5745-020) and related functions provided by the following products:
 - VSE/Advanced Functions (5746-XE8).
 - DOS/VS ACF/VTAM Release 2 (5745-010), (for RJE, SNA).
 - ACF/VTAME, Program Number 5746-RC7.
 - DOS/VS Network Control Program Version 5.0, Program Number 5747-AJ2.
 - DOS/VS Emulation Program, Program Number 5747-AG1. (For RJE, BSC, if IBM 370x Control Units are used.)
 - Virtual machine environment.
- Support for IBM 4300 Processors.
- Support of VSE/POWER files on Count/Key/Data (CKD) and Fixed Block Mode (FBM) devices. Also a mix of different DASD types is possible.
- SYSIN tape reader function. Blocked or unblocked standard-label or unlabeled tapes may be provided as SYSIN files on IBM 2400 or 3400 or 8809 Magnetic tape units.
- Save and restore capability. This backup facility enables the user to save VSE/POWER queues on tape and to restore saved queues from tape intermediate storage. It also allows the offline transfer of queues from and to different VSE/POWER installations.
- Nesting of "Source Library Include" (SLI) statements up to a usable level.

- For the Remote Job Entry Feature, a BSC multileaving facility allows the online transmission of VSE/POWER jobs between different VSE/POWER installations.
- Support of the 8809 Magnetic Tape Unit.
- Integration of the 3800 Printing Subsystem support.
- Expanded PALTER command which allows the input classes for a running partition to be changed without PSTOPping the partition.
- PHOLD command which allows the operator to HOLD the total VSE/POWER queue. Jobs in disposition D will be changed to disposition H, and those in disposition K will be changed to disposition L.
- Page count based on passing channel 1. This means that for jobs not using page eject it is now possible to perform restart of print output at a specified page number.
- SNA support of exchange media inbound.
- Support of the expanded communication feature for the 3741.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

In addition to the machine requirements for DOS/VSE, for VSE/Advanced Functions, for DOS/VSE ACF/VTAM (Program Number 5746-RC3, and co-requisite SCP component 5747-CF1) or ACF/VTAME Release 1 (Program Numbers 5746-RC7 and 5747-CG2) (optionally if the Remote Job Entry Feature is being used), and for user programs, VSE/POWER has the following machine requirements:

	Batch VSE/POWER (K Bytes)	RJE Feature Additional (K bytes)	
		RJE, BSC	RJE, SNA
Real Storage	14 - 128	4	--
Virtual Storage	172	40	34

The following is a list of the maximum numbers of resources supported by VSE/POWER (including the RJE feature):

- Up to 8 logical printers, 8 logical punches and 1 logical reader per partition.
- Up to 25 BSC terminals in concurrent operation.
- Up to 200 BSC terminals and SNA workstations in Synchronous Data Link Control (SDLC) mode. This figure may include up to 25 BSC terminals.
- For each SNA workstation, one console, one logical reader, one logical punch, up to three logical printers and up to six simultaneous sessions.

By providing more real, virtual and/or external storage as well as additional unit-record resources, the user may increase throughput and system performance.

SOFTWARE REQUIREMENTS

VSE/POWER Release 1 is designed to operate with VSE/Advanced Functions Release 1. If the Remote Job Entry Feature is being used, BSC operation has no dependencies. While operating in RJE-SNA mode, ACF/VTAM Version 1 Release 2 for DOS/VSE (Program Numbers 5746-RC3 and 5747-CF1) or ACF/VTAME Release 1 (5746-RC7 and 5747-CG2) and DOS/VS Network Control Program (5747-AJ2) must be installed.

COMPATIBILITY

Jobs executing under POWER/VS of DOS/VS Release 34 will also run under VSE/POWER without any modifications.

PERFORMANCE CONSIDERATIONS

Although the execution time of individual jobs may slightly increase due to a certain increase of processor requirements, the user can expect a higher overall system throughput even if there is only one unit-record device of each type (reader, punch, printer) available for all DOS/VSE partitions served by VSE/POWER compared to a system without spooling capability. By providing additional resources in terms of real and virtual storage, DASD space and unit-record devices, the system throughput may be further improved.

DOCUMENTATION: (available from Mechanicsburg)

Licensed Program Design Objectives	GH12-5031
General Information Manual	GH12-5128

PROGRAM PRODUCTS

**VSE/POWER RELEASE 2 WITH
VSE/POWER SHARED SPOOLING FEATURE
5746-XE3**

PURPOSE

The licensed program VSE/POWER Release 2 is an enhancement of VSE/POWER Release 1. It is a spooling system that provides the user with automatic staging of unit-record input and output and priority scheduling for all programs executed under its control. VSE/POWER resides in one partition and is able to control all remaining partitions of the DOS/VSE environment placed under its control, provided these have a lower system dispatching priority than that of the VSE/POWER partition.

DESCRIPTION

VSE/POWER makes dynamic use of the address space and acquires real processor storage on an as-needed basis. Page frames released by VSE/POWER tasks are freed and returned to the page pool. Programs executed under VSE/POWER control may be executed not only in virtual mode but also in real mode.

VSE/POWER is generated by assembly of macros that allow the user to specify the options appropriate to his own system environment, and creates the VSE/POWER generation table. The resultant object deck contains the code necessary to invoke VSE/POWER.

The system maintains input and output queues on direct access storage for the card readers, diskette I/O units (input only), card punches and printers associated with the partitions under its control. These queues are filled or emptied by the appropriate physical devices. When a program under VSE/POWER control makes an input or output request to one of these devices, VSE/POWER presents it with the next record from the appropriate input queue or collects the record and places it in the appropriate output queue. These operations take place at main storage or direct access storage speeds: Hence, programs execute quicker and take better advantage of the system environment.

VSE/POWER is transparent to the programs executed under its control: These do not require modification to take advantage of the system's capabilities.

Since the queues are under optional operator control, the system operator can modify the order in which programs are executed by manipulating the queues with VSE/POWER operator commands. The effective substitution of direct access storage devices for unit-record devices reduces the number of the latter needed to operate the system efficiently in a multiprogramming environment.

The use of partition-independent input classes simplifies the operational characteristics of this licensed program.

VSE/POWER will be available as a basic system that provides spooling in batch mode; this basic system may be upgraded by inclusion of the following separately orderable optional features:

- VSE/POWER Remote Job Entry Feature. This feature allows spooling via remote BSC or SNA terminals or SNA workstations.
- VSE/POWER Shared Spooling Feature. This feature allows different VSE/POWER systems operating on different machines to gain access to a common set of VSE/POWER queues and optionally a common account file.

HIGHLIGHTS

- 3262 Line Printer Support.
- Fully compatible with VSE/POWER Release 1 (except Cross Partition Communication Interface).
- Support of environments with up to 12 partitions.
- Improved Cross Partition Communication Interface (Q-display, security).
- Optionally, sharing of common VSE/POWER files between two or more VSE/POWER installations on different machines (Shared Spooling Feature).

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

In addition to the machine requirements for DOS/VSE, for VSE/Advanced Functions, for DOS/VSE ACF/VTAM (Program Number 5746-RC3, and co-requisite SCP component 5747-CF1) or ACF/VTAME Release 1 (Program Numbers 5746-RC7 and 5747-CG2) (optionally if the Remote Job Entry Feature is being used), and for user programs, VSE/POWER has the following machine requirements:

	Batch VSE/POWER (K Bytes)	RJE Feature Additional (K bytes)	
		RJE, BSC	RJE, SNA
Real Storage	14 - 128	4	--
Virtual Storage	176	40	34

If the Shared Spooling Feature is being used, 1K additional bytes of real storage, and 4K bytes of additional virtual storage have to be added to the above figures.

The following is a list of the maximum numbers of resources supported by VSE/POWER.

- Up to 8 logical printers, 8 logical punches and 1 logical reader per partition.
- Up to 25 BSC terminals in concurrent operation. (Remote Job Entry Feature installed.)
- Up to 200 BSC terminals and SNA workstations in Synchronous Data Link Control (SDLC) mode. This figure may include up to 25 BSC terminals. (Remote Job Entry Feature installed.)
- For each SNA workstation, one console, one logical reader, one logical punch, up to three logical printers and up to six simultaneous sessions. (Remote Job Entry Feature installed.)

By providing more real, virtual and/or external storage as well as additional unit-record resources, the user may increase throughput and system performance.

SOFTWARE REQUIREMENTS

VSE/POWER Release 2 is designed to operate with VSE/Advanced Functions Release 2. If the Remote Job Entry Feature is being used, BSC operation has no dependencies. While operating in RJE-SNA mode, ACF/VTAM Version 1 Release 2 for DOS/VSE (Program Numbers 5746-RC3 and 5747-CF1), or ACF/VTAM VSE Version 2 (Program Number 5666-280) or ACF/VTAME Release 1 (5746-RC7 and 5747-CG2), and DOS/VS Network Control Program (5747-AJ2) must be installed. If the Shared Spooling Feature is being used, DOS/VSE Advanced Functions Release 2 is required.

COMPATIBILITY

Jobs executing under POWER/VS of DOS/VS Release 34 and VSE/POWER Release 1 will also run under VSE/POWER Release 2 without any modifications. However, if the Shared Spooling Feature is being used and VSE/POWER job accounting is performed, the account records produced by VSE/POWER Release 2 are not compatible with those produced by Release 1. Therefore, a DSECT generation macro is provided for the alignment of symbolic addresses from the VSE/POWER Release 1 to the Release 2 record format. Programs using Cross Partition Communication Interface (GETSPOOL, PUT-SPOOL, etc) have to reassemble.

PERFORMANCE CONSIDERATIONS

Although the execution time of individual jobs may slightly increase due to a certain increase of processor requirements, the user can expect a higher overall system throughput even if there is only one unit-record device of each type (reader, punch, printer) available for all DOS/VSE partitions served by VSE/POWER compared to a system without spooling capability.

VSE/POWER Release 2 will be equal in performance as compared to Release 1. The contention between two systems may impact the performance when using shared spool files.

Licensed Program Design Objectives	GH12-5031
General Information Manual	GH12-5131

PROGRAM PRODUCTS

5746-XE6 - JOB ENTRY PROGRAM
5748-XE6 - FILE TRANSFER PROGRAM

PURPOSE

The Job Entry Program provides the basic interconnection mechanism between a DOS/VSE subhost, either a S/370, a 3031 Processor or 4300 Processors, to a job entry subsystem host, either under OS/VS or DOS/VSE, using ACF/VTAM Version 1 with the Multisystem Networking Facility (MSNF) feature or ACF/VTAM Version 2 or ACF/VTAME. It offers job submission from a subhost to a job entry subsystem at the host and routing of job output back to the originating subhost or to an alternate destination.

DESCRIPTION

JEP exclusively executes at the subhost together with VSE/POWER. It does not limit the number of subhosts that can be connected to the host concurrently. However, limits are imposed by the host capabilities. JEP communicates with the following entry subsystems at the host:

- OS/VS2 MVS JES2
- OS/VS2 MVS JES3
- OS/VS2 MVS NJE/JES2
- OS/VS1 RES/JES
- DOS/VSE with VSE/Advanced Functions and VSE/POWER with Remote Job Entry (RJE) feature.

Details on these systems are contained in the section "Specified Operating Environment".

JEP can also communicate with two or more host systems concurrently. The maximum number of host systems depends on SNA limits.

JEP employs VSE/POWER capabilities. It runs without requiring the VSE/POWER Remote Job Entry (RJE) feature as a prerequisite. However, the RJE feature and JEP can coexist. With the RJE feature installed, JEP offers the capability for SNA workstations and BSC terminals connected to VSE/POWER in the DOS/VSE subhost to submit jobs through the subhost to the host.

The File Transfer Program, referred to as FTP, expands the capabilities of JEP. It executes under DOS/VSE, OS/VS1 or OS/VS2. With JEP at the subhost the FTP installed at the host offers capabilities required to centralize program maintenance activities to the host, thus saving the user the cost for keeping programmer teams at each subhost location. With JEP and the FTP, jobs can be submitted from the host to the subhost, and the job output can be transmitted back to the originating host or to an alternate host system. Additionally, with the FTP installed at the host and the subhost, JEP and FTP offer transmission of sequential files between the DOS/VSE subhost and the host in both directions. The file transfers can be initiated in either direction either at the subhost or at the host.

HIGHLIGHTS

- Collection of data and periodic transmission of the data in the form of jobs or files to a divisional center or a corporate headquarters for integrated processing.
- Transmission of the output data to remote locations in the form of job output or files for final processing and/or printing.
- Transmission of data files between the host and the subhosts for processing at the host or at the subhost.
- Submission of jobs and routing of job output from the subhost to the host and from the host to the subhost in order to:
 - Allow for centralization of program maintenance at the host.
 - Utilize resources at a remote system which are not available at the submitting system.
 - Offload the submitting system, in particular in a DOS/VSE-to-DOS/VSE environment.
 - Submit OS/VS jobs at a DOS/VSE installation.
 - Submit DOS/VSE jobs at an OS/VS installation.
- Sharing of the communications link among various applications. JEP allows line sharing between transaction and batch applications in a DOS/VSE-to-DOS/VSE as well as a DOS/VSE-to-OS/VS environment.
- Coexistence: Together with VSE/POWER and the VSE/POWER RJE feature, JEP provides coexistence between SNA and BSC components. It allows job submission from SNA workstations, such as an IBM 3790 or BSC terminals such as an IBM 3740 through the DOS/VSE subhost to the host system, having the DOS/VSE subhost act as an intermediate subhost.
- Ease-of-Use: JEP and FTP offers ease-of-use in the areas of:
 - Installation and generation, where the VSE/POWER procedure is adopted for JEP. FTP does not require regeneration
 - Automatic initialization and LOGON to the host system as system generation option

- Operator communication with JEP using commands compatible with VSE/POWER commands

- Security and Integrity: When establishing a connection between JEP and a host system, security and integrity is assured by means of:
 - JEP generation parameters: Host connections can be established according to the generated configuration only.
 - Authorization passwords: Optional system internal and operator passwords are required at LOGON time.
 - User management is responsible for the selection, implementation and adequacy for such controls.

CUSTOMER RESPONSIBILITIES

VSE/POWER must be generated to include JEP.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The Job Entry Program (JEP) executes in the VSE/POWER partition of any IBM S/370, 3031 Processor or 4300 Processor (subhost) and requires a minimum of 64K bytes of virtual storage in this partition. For the communication between a S/370, a 3031 Processor or a 4300 Processor and the host system, a 3705 Communication Controller is required. A 4331 Processor also communicates with the host via the Communications Adapter with SDLC Transmission Mode.

The File Transfer Program (FTP) executes in the host and, optionally, in the subhost and requires up to 72K bytes of virtual storage in addition to the programming requirements listed below.

The host can be either an IBM S/370, 3031, 3032, 3033 or 4300 Processor with a 3705 Communications Controller or an IBM 4331/4361 Processor with the Communications Adapter with SDLC Transmission Mode.

The subhost can be either an IBM S/370, 4300 or 3031 Processor with a 3705 Communication Controller or an IBM 4331/4361 Processor with the Communications Adapter with SDLC Transmission Mode.

SOFTWARE REQUIREMENTS

The programming requirements for JEP and ETP are described separately for the subhost and the host. The programming systems mentioned in this section execute also in the environment of the Virtual Machine Facility/370 (VM/370). Where release numbers are given, the following statements apply also to subsequent releases or modification levels of the named programming systems unless otherwise stated.

Subhost

If the subhost is a S/370, a 3031 Processor or a 4300 Processor:

- DOS/VSE, Program Number 5745-020.
- VSE/Advanced Functions, Program Number 5746-XE8, Release 2.0.
- VSE/POWER, Program Number 5746-XE3, Release 2.0.
- ACF/VTAM Version 2, Program Number 5666-280.
- Advanced Communication Function for VTAM Version 1 (ACF/VTAM) with Multisystem Networking Facility (MSNF) feature, Program Number 5746-RC3, Release 2.0.

In this case, the Advanced Communication Function for Network Control Program/Virtual Storage (ACF/NCP/VS), Program Number 5735-XX3, Release 1.0 or 2.0 is required in the IBM 3705 Communications Controller.

If the subhost is an IBM 4331 Processor with the Communications Adapter for SDLC Transmission Mode:

- DOS/VSE, Program Number 5745-020.
- VSE/Advanced Functions, Program Number 5746-XE8, Release 2.0.
- VSE/POWER, Program Number 5746-XE3, Release 2.0.
- Advanced Communications Function for VTAM Entry (ACF/VTAME), Program Number 5746-RC7.

Host

Depending on the operating system used, the host can be:

- For DOS/VSE: S/370, 3031 or 4300 Processor.
- For OS/VS1: S/370, 3031, 3032, 3033 or 4300 Processor.
- For OS/VS2: S/370, 3031, 3032 or 3033 Processor.

PROGRAM PRODUCTS

JEP + File Transfer Program (cont'd)

If the host is a S/370, 3031, 3032, 3033 or 4300 Processor, the Advanced Communication Function for Network Control Program/Virtual Storage (ACF/NCP/VS), Program Number 5735-XX3, Release 1.0 or 2.0 is required in the IBM 3705 Communication Controller.

If the host executes under DOS/VSE, the same programming requirements as mentioned above under 'Subhost' apply, except that the Remote Job Entry (RJE) feature of VSE/POWER is required on the host. Additionally, VSE/POWER Release 1.0 (with the RJE feature) is also supported in conjunction with VSE/Advanced Functions Release 1.0.

For OS/VS, one of the following job entry subsystems is required:

- OS/VS1 Remote Entry Services/Job Entry Subsystem (OS/VS1 RES/JES), Program Number 5741-VS1, Release 6.0 or 6.7, with ACF Version 2, Program Number 5662-280, Advanced Communication Function for VTAM Version 1 (ACF/VTAM), Program Number 5735-RC2, Release 1.0 or 2.0 (OS/VS1 Release 6.7 only), including the Multisystem Networking Facility (MSNF) feature.
- OS/VS2, Program Number 5752-VS2, Release 3.7 with Job Entry Subsystem 2 (JES2) Release 4.1 (SU 25) or Job Entry Subsystem 3 (JES3) Release 3.0 (SU 23) or Network Job Entry/Job Entry Subsystem 2 (NJE/JES2), Program Number 5740-XR8, Release 3.0, together with one of the following:
 - ACF/VTAM Version 2, Program Number 5665-280.
 - Advanced Communications Function for VTAM Version 1 (ACF/VTAM), Program Number 5735-RC2, Release 1.0, or 2.0 (OS/VS 2 Release 3.8 only), including the MSNF feature.
 - Advanced Communications Function for TCAM (ACF/TCAM) Version 2, Program Number 5735-RC3, Release 2.0, including the MSNF feature (OS/VS Release 3.8 only).

PROGRAM PRODUCTS

**VSE/ACCESS CONTROL - LOGGING and REPORTING
RELEASE 1 (5746-XE7)****PURPOSE**

The VSE/Access Control - Logging and Reporting Release 1 Program Product is part of the data security assist functions offered for all users of DOS/VSE and designed to assist in auditing a DOS/VSE data processing installation.

The system access control functions consist of the following:

Provided by DOS/VSE and VSE/Interactive Computing and Control Facility (VSE/ICCF) 5746-TS1:

- Utility and macro functions to define and maintain profiles for protected resources.
- User identification and verification for DOS/VSE batch jobs and VSE/ICCF jobs.
- Checking a user's authority to access protected data sets, libraries and programs.
- Creation of information about access related events to protected resources.

Provided by VSE/Access Control - Logging and Reporting 5746-XE7:

- Logging and recording of access related event information created by VSE/ICCF.
- Generation of reports for auditing.

HIGHLIGHTS

- Logging of information about access related events to protected resources (such as data sets, libraries, programs) to a sequential disk data set, called the log data set. Logging is optional.
- Logging is performed asynchronously by a DOS/VSE subtask attached to the VSE/Interactive Computing and Control Facility.
- Reporting provides a printout of selected data from the log data set for auditing purposes.
- Selection criteria are provided to the reporting module during program execution by means of control statements.
- Several reports corresponding to various selection criteria may be obtained in one program run.
- Access event data may be archived on a tape and restored from tape for deferred reporting.
- The log data set consists of two parts used alternatively: While one part is used for logging, the other part may be used for reporting.

CUSTOMER RESPONSIBILITIES

The customer is responsible for:

- Generating the access control option in DOS/VSE.
- Installing the program products VSE/Interactive Computing and Control Facility 5746-TS1 and VSE/Access Control - Logging and Reporting 5746-XE7.
- Setting up the access control environment (User identifications, authorizations, events to be logged).
- Specifying the reporting criteria.
- Starting the reporting program if the log data set is full.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

VSE/Access Control - Logging and Reporting requires the Compare and Swap instructions which is standard on the IBM 4300 Processors and on the IBM S/370 mdls 115, 125, 135-3, 138, 145-3, 148, 155-II and 158.

The Compare and Swap instruction is optionally available via the Conditional Swapping Feature (#1051) on the S/370 mdls 135 and 145 and via the Advanced Control Program Feature (#1001) on the S/370 mdl 145.

SOFTWARE REQUIREMENTS

VSE/Access Control - Logging and Reporting is designed to operate on DOS/VSE with VSE/Advanced Functions. VSE/Interactive Computing and Control Facility (VSE/ICCF) (5746-TS1) is required to generate the input data for VSE/Access Control - Logging and Reporting. If the data to be reported should be sorted, Sort/Merge Version 2 is required.

PERFORMANCE REQUIREMENTS

The performance of the logging program depends on the following factors:

- Number of entries generated for the internal log queue.
- Number of logging requests and size of the log data set.

- Priority of the main task to which the logging program is attached as a DOS/VSE subtask (VSE/Interactive Computing and Control Facility).

During measurements on S/370 mdl 145 with 3330 disk devices a CPU-time increase of less than 2.5% was observed for commercial oriented batch applications.

The performance of the reporting program depends mainly on the following factors:

- The time required to read the log data set. This time is related to the size of the log file and the number of records being selected for a requested report.
- The time to sort the different reports if this option was selected.
- The time required to print the reports.

The performance data shown above was for a selected set of workloads and is for information purposes only. There is no warranty or guaranty that the same performance characteristics will apply to the users and system configurations.

DOCUMENTATION: (available from Mechanicsburg)

Licensed Program Design Objectives (GH12-5045) ... *General Information Manual* (GH12-5130).

PROGRAM PRODUCTS

5746-XE8 - VSE/ADVANCED FUNCTIONS R1

PURPOSE

VSE/Advanced Functions provides all functions of Advanced Functions DOS/VS and significant new facilities: 7 Partitions for all SYSRES DASD types ... support of 3310 and 3370 in S/370 Compatibility Mode under VMLE ... implicit link ... area for job-to-job communication ... multiple label areas on SYSRES ... retain message with outstanding reply ... elimination of LBLTYP statement ... automated system initialization ... dump improvements ... fast B- and C-transient fetch ... fast OPEN of hard-copy file ... high-level SDL search ... multiple extent page data set ... JCL option for fast CCW translate ... VMLE enhancements.

HIGHLIGHTS

Additional Hardware Support

7 Partitions for all SYSRES DASD types: DOS/VSE now supports 7 partitions for all SYSRES DASD types, including 3340 DASD.

3310 and 3370 support in S/370 mode under VMLE: Provides 3310 and 3370 native mode support in S/370 mode. This allows a system running under VM/370 to access a 3310 device. This is accomplished by specifying the parameter VM=YES at Supervisor generation time.

Usability Improvements

Implicit Link: This ease-of-use function reduces the number of Job Control statements that are required for an application programmer for program compilation and testing. By specifying a "GO" parameter on the EXEC Job Control statement for the compiler step, the user may specify that the linkage editor and the compiled program are to be invoked automatically. Only the source program data and any additional data for the go step are required after the compiler step. If a serious error is encountered in either the compiler or link-edit step, the input stream is flushed to end of job (/ &).

Area for job to job communication: To enable the user to do job to job communication, a new area in the system GETVIS space is provided. Through the use of a JOBCOM macro the user is able to store up to 256 bytes of information. This information is not destroyed between jobs and can be retrieved in another program through the use of the corresponding parameters in the JOBCOM macro.

Multiple label areas on the SYSRES Volume: Currently, the label area has a fixed size and is defined as part of the SYSRES file. This new support allows the user to define label areas of varying size. During system start-up time, the user may select from the following options:

- Use the standard SYSRES label area.
- Define a label area via the DLA command.

This function facilitates SYSRES sharing across processors, and with multiple DOS/VSE guest systems in a VM environment.

Retain Message with Outstanding Reply: When asynchronous operator communication is utilized, sometimes the message disappears from the screen before the operator can reply. Now the message is retained on the screen until it is replied to, or until the operator deletes the message.

Elimination of LBLTYP Statement: The LBLTYP statement is no longer required as a linkage editor control statement to reserve space for labels. The LBLTYP statement was used to define the amount of storage to be reserved in the user's partition for processing of tape and nonsequential disk file labels for nonVSAM files. The elimination is possible through an ease-of-use feature which provides for dynamic storage allocation at OPEN time for the amount of storage required. This allows the user to eliminate the LBLTYP statement. If present, it is ignored.

Automated System Initialization: Automated System Initialization (ASI) reduces the operator's work normally required for system IPL and starting of subsystems in various partitions. All necessary information is cataloged in procedures which are executed automatically and bring up the system; VSE/POWER, VSE/ICCF, ACF/VTAM, etc. without operator intervention. The user may interrupt the IPL process, specify another procedure set or choose to do the interactive IPL as before. User supplied procedures can be included in ASI.

Dump Improvements: A high speed system dump can be taken each time a partition abends. The dump is written onto a new Symbolic Unit called SYSDMP. The dump data set may consist of two parts which are used alternatively in order to allow receiving and printing of dump data concurrently. Moreover a phase load list is set up and maintained which contains the phase names, begin addresses and end addresses of all phases most recently loaded into the partition. This provides the capability - after a program check - to determine the phase name of the phase in error.

Performance Improvements

Fast B- and C-transient fetch: This feature allows for fetching of highly used B- or C-transients from the SVA rather than from the core image library. The appropriate transients are loaded into the SVA at IPL time or by JCL. When a transient is to be used, instead of fetching it from the core image library, it is simply moved from the SVA into the

transient area. This increases the performance when heavy processing is being done in the core image library and reduces the B-transient area contention problem.

Fast OPEN of hard-copy file: At IPL, the amount of time required to search for the end of the hard-copy console log is reduced. This speeds up the IPL process significantly, especially if the file is large.

High-level SDL search: The SDL (System Directory List) is the directory of the SVA. In addition it may contain entries for load modules which have to be fetched from the CIL disk but for which the disk directory accesses should be avoided. The SDL is implemented as an incore list which is searched using the binary search technique. As the list resides in virtual storage, this technique might result in several page faults if the list is long (60 entries fit on one 2K page). The high-level SDL search uses a second level directory residing in fixed Supervisor storage which restricts the binary SDL search to just one page; only page boundary crossing entries need two pages. This feature increases the performance by reducing the number of page faults.

Multiple Extent Page Data Set: Allows the user to split his Page Data Set across several extents and/or volumes. This can increase the performance by allowing the user to place a high activity portion of his Page Data Set under the fixed head portion of the DASD device. Even without fixed heads, the user can use this facility to balance his I/O activity across different devices. The maximum number of extents is 15 (3 on one volume). The volumes must be either all of the type fixed block mode or all of the type CKD. The 2311 DASD is not supported.

JCL Option for Fast CCW Translate: Specification of "NOFASTTR" in the OPTION control statement causes the fast CCW translation to be switched off for the corresponding job. This option is meaningful for jobs for which it is unlikely that the same I/O areas and I/O control blocks will be reused. The option is temporary and valid for one job.

VMLE Enhancements: VMLE provides the following enhancements:

- CP commands SET PAGEX and SETRUN ON are issued automatically at IPL of DOS/VSE.
- BUFSIZE default is set to 5 for VMLE initialization.
- Speed of IPL of DOS/VSE on VM/370 is improved due to obtaining clear pages from VM.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

VSE/Advanced Functions is designed to execute on the same IBM machines as DOS/VSE, that is IBM S/370 115-158, 3031 Single Processor, and 4300 Processors. The minimum memory size supported is 160K bytes.

SOFTWARE REQUIREMENTS

VSE/Advanced Functions is designed to operate with DOS/VSE.

VM environment ... A DOS/VSE supervisor generated with Linkage Enhancements support can only be utilized in a VM/370 operating environment on an IBM S/370 or on an IBM 4300 Processor in S/370 mode. A supervisor generated without the Linkage Enhancements facility can operate directly on an IBM S/370, on an IBM 4300 Processor System in S/370 mode or in a virtual machine under VM/370. When utilizing the linkage enhancements support of VSE/Advanced Functions, the system requirements are:

- VM/370 release 4 or later release.
- A real machine with a processor storage size of at least the minimum for VM/370.
- A virtual machine size of at least the VSIZE specifications for the DOS/VSE supervisor being used + 200K, and less than 16 megabytes.

COMPATIBILITY

VSE/Advanced Functions is designed to run on DOS/VSE. The compatibility statement for DOS/VSE applies here as well.

PERFORMANCE CONSIDERATIONS

The performance improvements described below are stated for specific functions of the VSE/Advanced Functions Release 1.

1. For selected environments the following throughput improvements were observed on the S/370 mdl 145 with 3277 Display Station and 3330 DASD with 4 batch partitions and VSE/POWER:

Fast B-transient Fetch with approximately 2 B-transient calls per second, up to 15%. The measurement was done with applications such as COBOL Compile and Link and Payroll with ISAM-access method.

Fast C-transient Fetch (Display operator console usability improvement) with 25 screen lines/minute, up to 12%.

MULTIPLE Extent Page Data Set with an average Page I/O-rate of 10 pages/second, up to 8%, when the most used part of the Page Data Set resided on the fixed head portions of 3350

VSE/Advanced Functions R1 (cont'd)

DASDs. In the comparison measurement without this function only a small portion of the page data set resided on a single fixed head section of a 3350 DASD.

2. Other potential performance improvements items:

- JCL Option for Fast CCW Translate.
This function will selectively switch off the fast CCW-translate option for jobs which are unlikely to re-use the same I/O-areas and I/O control blocks. By this function processor overhead can be reduced (for example in DB/DC applications).
- 7 partitions for 3340 DASD.
- High level SDL Search.
- Fast open of hardcopy file at IPL-time.

For a measured workload which is considered to be representative, an overall system throughput improvement of 7% has been observed on the S/370 mdl 145 if VSE/Advanced Functions Release 1 is compared to Advanced Functions - DOS/VS.

DOS/VSE in ECPS:VSE mode improves the path length of the SVC 0 (CCB-macro) for DASD requests with normal CCW-translate up to 15% compared to DOS/VSE in S/370 mode. If the access method (VSAM) provides a list of pages to be fixed (IORB-macro), the effective path length of the SVC 0 is reduced by up to 25%. The SVC 0 path length is one part of the total path length of an application. Therefore the above stated improvement will show up as a smaller percentage on the complete application path length.

Because of the complexity of configurations and varied application of systems, customer by customer, there can be no guarantee that an individual user will achieve these same results. It is the customers responsibility to determine how these product improvements will affect his own operations.

5746-XE8 - VSE/ADVANCED FUNCTIONS R2

PURPOSE

VSE/Advanced Functions Release 2 provides all functions of VSE/Advanced Functions Release 1 and significant new facilities: 3262 Line Printer Support ... listlog utility ... additional DLBL information ... SYSLNK in VSAM managed space ... extended Volume command ... support of Volume mount requests ... DASD sharing across processors ... library sharing across processors ... assembler language macros to use DASD sharing services ... 208 tasks/12 partitions ... extended label area support ... system tailoring at IPL ... library sharing across partitions ... library concatenation ... online system generation ... DASD device independence for SAM/DAM Files ... B-transient area contention removal ... VSE-VM/370 linkage enhancements in an ECPS:VSE mode supervisor ... list VTOC improvements ... removal of certain hardwaits ... extended problem determination functions ... MSHP support of local APAR fixes ... reduced SYSGEN options.

RELEASE 2 HIGHLIGHTS

3262 Line Printer Support: The new 3262 Line Printer is supported as a System Printer of the PRT1 class. Since the error signaling differs from the currently supported Line Printers, user written error recovery procedures need to be adjusted.

Listlog Utility: This utility points out all job related SYSLOG messages on SYSLIST at End-of-Job time whenever a job is cancelled. It can also be invoked explicitly by specifying '//EXEC LISTLOG.'

Additional DLBL Information: New parameters that are required for the VSE/VSAM Space Management for SAM Feature are introduced in the DLBL statement.

SYSLNK in VSE/VSAM Managed Space: The SYSLNK processing by Job Control is extended to handle data in CI format not only on fixed block mode devices but also on CKD DASDs only in managed space. This is required for VSE/VSAM Space Management for SAM Feature. The workfiles for the linkage editor are now dynamically allocated and de-allocated in VSE/VSAM space.

Extended VOLUME Command: The displayed message for the VOLUME command for one specific device is extended by a parameter which prevents automatic assignments to this device. This function is needed for VSE/VSAM Space Management for SAM Feature. A new FREE command is added which enables the operator to reset a reserved status.

Support of VOLUME Mount Requests: Currently, OPEN expects the correct volume to be mounted on a drive determined by the SYSnumber and the corresponding ASSGN statement. If the drive is not ready, the "INTERVENTION REQUIRED" message will be issued when trying to access the VTOC.

If a pack is mounted with the wrong VOLID, OPEN will issue the message "WRONG PACK, MOUNT nnnnnn" and the operator can either honor the request by changing the pack, or he has to cancel the job. In any case, OPEN is waiting for a reply (NEWPAC, CANCEL or EOB).

Space management, however, will find out before issuing the OPEN, whether the requested VOLID is available and on what disk drive. If it is already available, the dynamic device assign service is used to obtain a LUB, and OPEN can continue.

If the needed VOLID is not online, then space management will find out via a new system service, if there is a disk drive available, which is currently not in use by the system. If such a "free" drive is found, the open service will prompt the operator to mount the requested disk pack there. If the system does not find a "free" or unused drive, the operator has to decide how to honor the pack mount request.

OPEN will then wait for the operator reply. Then it determines where the requested VOLID is mounted, assigns a logical unit to this disk drive (via the dynamic device assign) and continues.

A new system service and new VOLUME command options will assist the operator in this pack mounting activity.

DASD Sharing across Processors: This supervisor service extends the symbolic gating facility of LOCK/UNLOCK for inter-processor usage. The user gets one interface for internal and external gating with an additional parameter to specify the scope. If the external DASD sharing feature is not generated, then all requests are handled as internal ones. Thus the user need not be concerned about the current sharing situation.

208 User Tasks: Provides a total of 208 user subtasks that can be active concurrently in the system. Within one partition a maximum of 32 concurrent active tasks are allowed.

Twelve Partitions: VSE/Advanced Functions Release 2 supports up to twelve partitions.

Extended label area support: Extensions are provided in three areas:

- A user-defined label area may now be placed on any DASD device except 2311, and need not reside on the SYSRES disk.

- The permanent labels for FG partitions may now be loaded from the BG partition. This eliminates the need to start the respective FG partition for FG label loading.
- Labels may now be added or deleted by means of the new "Label ADD" and "Label DELETE" functions.

System Tailoring at IPL: Device specification at supervisor generation time is no longer required. The system determines at IPL time how many and which devices are attached and for which DASDs file protection is required.

Improved Librarian Functions: The following three functions are designed for ease-of-use and ease-of-installation.

- Multiple Procedure Libraries.
VSE/Advanced Functions Release 2 supports multiple procedure libraries.

- Shared Libraries across Partitions.

A library may be assigned to and accessed by more than one partition at the same time. Functions are provided which prevent multiple updates at the same time. All types of libraries may be shared. All libraries may reside on disk devices different from SYSRES. The support includes current disk devices and 3310 and 3370. Device types may be mixed.

- Concatenated Libraries.

This function provides concatenation of up to 30 libraries, 15 temporary and 15 permanent, within one job step. The various libraries may reside on fixed block mode or CKD devices which may be used intermixed. For compatibility reasons, the current system of private libraries is maintained so that existing jobstreams need not be changed, should the user elect not to use concatenated libraries. The library concatenation can be temporary or permanent.

Online System Generation: The capability is provided, to install and tailor a new VSE/Advanced Functions system under control of a running DOS/VSE system. The user can do this system generation in any DOS/VSE partition.

DASD Device independence for SAM/DAM files: This new support will be DASD device independent in the sense that the user's DTF will be dynamically initialized to reflect the type of DASD the data set resides on, no matter what device type the DTF was assembled with. In addition the user's program will always be changed to utilize a SAM or DAM logic module, residing in the SVA, so the user will always have the proper support required to access the actual DASD device.

B-Transient Area Contention Removal: Currently, DOS/VS has one B-transient area in the Supervisor and schedules this resource on a first-come, first-served basis. As the number of batch partitions increases, this resource can at times inhibit the performance of a system.

The most frequently used, or long running system services (OPEN, End-of-Job, Attention routines) are now repackaged into SVA-resident code, which will reduce the contention for the B-transient area significantly. Other important transients which communicate with the operator or initiate long lasting tape operations free up the transient area when communicating with the operator, or during the tape operation.

VSE-VM/370 Linkage Enhancements in ECPS:VSE Mode: When specifying VM=YES and MODE=E at the VSE Supervisor generation the DAT-bit will be set off, thereby improving performance for a VSE supervisor when running under VM/370.

List VTOC Improvements: The entries in the VTOC will now be listed in alphabetic sequence, and information about unused disk space is provided.

Removal of Certain Hardwaits: If SYSRES, the Page Data Set, SYSCLB or concatenated libraries reside on a device which is not ready, the System enters wait state. If the operator makes the device ready and presses the restart key, the System will now continue operation.

Extended Problem Determination Functions: On top of those problem determination functions offered with VSE/Advanced Functions Release 1, Release 2 provides additional support to get all job related messages in the SYSDMP file at the end of the related virtual storage dump.

MSHP Support for Local APAR Fixes: A new MSHP command, CORRECT, has been implemented to apply local APAR fixes with a recording of the event into the System History File.

Reduced SYSGEN Options: The supervisor generation macros CONFIG, PLOCS and VSTAB have been deleted. The underlying functions have either been made standard, deleted, moved to another macro or the specification is being made at IPL time. Several parameters in the three remaining macros SUPVR, FOPT and IOTAB have been deleted, as the corresponding functions are now standard (i.e., ICCF and RMS support), or the function has been deleted (the support for mixed parity tape processing on the 14XX emulator).

PROGRAM PRODUCTS

VSE Advanced Function R2 (cont'd)

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

VSE/Advanced Functions Release 2 is designed to execute on the same machines as DOS/VSE, that is IBM S/370 115-158, 3031, and 4300. The minimum memory size supported is 160K bytes.

All prerequisites for installation and operation of VSE/Advanced Functions are the same as for DOS/VSE.

The minimum hardware requirement for VSE/Advanced Functions Release 2 are:

- (1) A VSE-supported central processor i.e., IBM S/370 115-158, 3031 Single Processor, and 4300 Processors. VSE/Advanced Functions Release 2 requires the clock comparator and the CPU-timer (standard on all S/370 models except 135 and 145, and also standard on 4300 processors) and the floating point feature (not standard on S/370 115, 125, 135, 145 and 155).
- (2) Either of the following:
 - A card reader.
 - A diskette unit.
- (3) A VSE supported system printer.
- (4) One of the following:
 - Two disk drives, one of which must accommodate a removable disk pack.
 - Two fixed media disk drives and one magnetic tape drive.
 - One disk drive and two magnetic tape drives.

The IBM 2311 DASD is not supported as a system residence device.

For more information on the specific device types supported by DOS/VSE, see the *Introduction to DOS/VSE* (GC33-5370), Appendix A.

SOFTWARE REQUIREMENTS

VSE/Advanced Functions Release 2 is designed to operate with the related DOS/VSE SCP (Program Number 5745-030).

VM Environment: A supervisor generated without the linkage enhancements facility can also operate in a virtual machine under VM/370. When utilizing the linkage enhancements support of VSE/Advanced Functions, the system requirements are:

- VM/370 Release 6 or a later release.
- A real machine with a processor storage size of at least the minimum for VM/370.
- A virtual machine size of at least the VSIZE specifications for the DOS/VSE supervisor being used +200K, and less than 16 megabytes.

COMPATIBILITY

All application programs that execute on DOS/VSE with VSE/Advanced Functions Release 1 installed are object code compatible with VSE/Advanced Functions Release 2. For those customers converting from DOS/VS Release 34 the compatibility statement of DOS/VSE applies.

MIGRATION/COEXISTENCE

Data sets and external interfaces are fully compatible with previous releases except for the following:

- SAM and DAM OPEN will always link the users DTF to an IBM supplied logic module which resides in the SVA.

This precludes the use of existing logic modules for DASD files generated through the use of the CPMOD, DAMOD, DIMOD or SDMOD macros. It also precludes the use of user-written modules for DAM and SAM files
- Each DASD volume mounted on the system should have a unique VOLID in order for the system to enqueue just on the resource intended to be locked.
- The PRTY parameter that could previously be given at SYSGEN-time to change the default partition priorities has been deleted. Instead the PRTY command can be used to change those priorities at ASI (Automated System Initialization) time, just after IPL.
- Levels as listed are required for the following Program Products to run with VSE/Advanced Functions Release 2:
 - VSE/POWER Release 2
 - VSE/ICCF Release 2
 - VSE/VSAM Release 2
 - VSE/IPCS Release 2
 - VSE/DITTO with PTF UD 17431 (Put tape U5008)
 - DL/I DOS/VS Version 1 Release 5 with PTF 503

- CICS/DOS/VS Version 1 Release 4 Modification 1 with fixes for APAR number 86045
- DOS PL/I Resident Library Release 5 Modification 1
- DOS PL/I Transient Library Release 5 Modification 1
- DOS FORTRAN IV Library Option 1 Release 3
- VS APL Release 3 with PTF PP84931
- DOS/VS Sort/Merge Version 2 Release 3
- VSE/Access Control-Logging and Reporting with PTF UP14937, APAR PP86475

- Fetch protection of sensitive supervisor areas has been implemented so that programs in "problem" state (as opposed to supervisor state) cannot access these areas any more.

The following areas have been excluded:

- Low core including tables known to be used by programs in problem state.
- The tables/areas dynamically added at IPL time.
- User TCBs, if VTAM is supported.
- The pageable part of the supervisor if previously paged out (370-mode only).
- The new macro, EXTRACT, has been introduced to enable access to I/O control blocks. To use the new macro, and at the same time, retain the old code for execution on DOS/VS or DOS/VSE Advanced Functions Release 1 the macro SUBSID should be used.
- The COPYSERV program does not support the library improvements in VSE/Advanced Functions Release 2 i.e., does not support LIBDEF statements, Library Sharing or private procedure libraries. It is therefore recommended to use the COPYx-NEW function instead.
- The user may not issue imperative macros from an error exit for DTFSD or DTFDI (DASD) to the same DTF that caused the error exit to be invoked and ERREXT = omitted error exit interface will no longer be supported since ERREXT = YES is always assumed by the DTFSD logic modules.
- The Fastcopy functions are only available with the separate Program Product 5746-AM4

PERFORMANCE CONSIDERATIONS

A throughput increase as a result of extended multiprogramming support depends highly on the user's system usage. Main performance bottlenecks have been removed. Transient functions were moved from the transient area to the SVA.

VSE-VM/370 Linkage Enhancements in an ECPS:VSE mode supervisor will reduce VM control program overhead by eliminating VM Shadow Table creations and maintenance.

DOCUMENTATION
(available from Mechanicsburg)

VSE/Advanced Functions Release 2
General Information Manual (GC33-6093)

PROGRAM PRODUCTS

5746-XE8 - VSE/ADVANCED FUNCTIONS R3

PURPOSE

VSE/Advanced Functions Release 3 provides all functions of VSE/Advanced Functions Release 2 and significant new facilities.

RELEASE 3 HIGHLIGHTS

New Hardware Support:

Support of 4331 Model Group 2: The 4331 Model Group 2 processor will be fully supported.

Support of the 3033 Processor Complex: The 3033 Processor Model Groups S and N and the Model U (Single Processor) will be supported

Performance Improvement

Fast CCW translation for I/O requests with IORB: This service is an extension of the CCW translate support for I/O requests with IORB. This support is analogous to the previous CCW translation for I/O requests with CCB in ECPS:VSE mode. This is applicable to I/O requests that repeatedly use the same areas for I/O.

Usability Improvement

Simplifications of supervisor generation: System generation is simplified by reducing the number of supervisor generation parameters.

Support of ACF/VTAM and ACF/VTAME is now standard.

Availability Improvement

Job Information Block (JIB) table removal: Previous JIB Limitations have been removed by deletion of the JIB table. If assignments of logical units to actual I/O devices need be saved, the required information is written into an extendable table.

Reduction of the number of cancel conditions: A new way of handling I/O errors helps avoid cancel situations.

Improved handling of missing device interrupts: Soft waits caused by missing device interrupts are detected and corrective action is initiated. A soft wait state no longer goes undetected for an extended period of time.

Serviceability Improvement

Extension of the Maintain System History Program: MSHP is extended to improve the installation of IBM supplied fixes. A new function indicates whether a library member needs to be reassembled and relinked for installation of a fix.

Additional subsystem support for

Cross partition communication: This new facility allows one subsystem to communicate, across partition boundaries, with another subsystem or with an application program. The facility does not allow the communicating subsystem or application program to access areas in the other partition. The facility can be used for the exchange of both program control information and data.

The VSE/Operator Communication Control Facility: Whenever VSE/OCCF is active, the supervisor passes all I/O requests to or from the operator console to VSE/OCCF.

The VSE/Interactive Problem Control System: The stand-alone dump program retrieves, from the hard-copy file, the most recent 200 console messages and adds these messages to the dump output.

VM/VCNA under VM/SP: The Virtual Machine/VTAM Communications Network Application (VM/VCNA) program product allows VM/CMS systems to be full participants in a SNA network. VM/VCNA, in its own partition, executes in conjunction with the ACF/VTAME or ACF/VTAM partition on VSE/Advanced Functions Release 3 to provide SNA/BSC/local virtual machine console support for VM/SP.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The minimum hardware requirements for VSE/Advanced Functions Release 3 are:

- (1) An IBM processor supported by DOS/VSE, i.e., S/370 mdl 115-158, 3031 Single Processor, and 4300 Processors, with a processor storage of at least 160KB. DOS/VSE/Advanced Functions Release 3 also supports the 3033 single processors. Recommended minimum processor storage is 256KB. See also under "Compatibility" below. VSE/Advanced Functions Release 3 requires the clock comparator and the CPU-timer feature (standard on all S/370 models except 135 and 145, and also standard on 4300 processors) and the floating point feature (not standard on S/370 mdls 115-155).
- (2) A VSE-supported console.
- (3) Either of the following:
 - A VSE supported card reader.
 - A VSE supported diskette I/O unit.
- (4) A VSE supported system printer.

(5) A VSE supported magnetic tape drive.

(6) Either of the following:

- One VSE supported disk drive with a volume capacity of 120 megabytes or more of disk storage.
- Two or more VSE supported disk drives with removable disk packs if the volume capacity is less than 120 megabytes of disk storage. The total capacity of the volumes on the available disk drives must be at least 120 megabytes of disk storage.

The IBM 2311 DASD is not supported as a system residence device.

If data on DASD is to be shared using the available share control facility, this data must reside on a DASD other than 23XX or 3310.

SOFTWARE REQUIREMENTS

VSE/Advanced Functions Release 3 is designed to operate with the related DOS/VSE SCP, Program Number 5745-030 Release 3, and also when VSE/Advanced Functions is operating on a virtual machine under control of VM/370, VM/Basic System Extensions or VM/System Extensions program products or under VM/System Product, on IBM processors for which VSE guest support has been announced.

COMPATIBILITY

Minimum supervisor sizes are:

- For Mode=370, 112KB thereof 24KB pageable.
- For Mode=E, 106KB thereof 26KB pageable.

Users of S/370 processors with a processing storage less than 256KB should note that the Device Support Facilities (DSF) stand alone program, requires 256KB of real storage to execute successfully. These users should retain their previous standalone utilities provided with DOS/VS releases and with DOS/VSE SCP 5745-020.

For Users of DOS/VS or DOS: For application programs that have been executed successfully under DOS/VS or DOS, the compatibility restrictions are the same as those given in *Introduction to the VSE System*, GC33-6108.

Any restrictions given below for users of previous releases of VSE/Advanced Functions apply also to users of DOS/VS or DOS.

For Users of Previous Releases of VSE/Advanced Functions: An application program that has been executed successfully in the specified operating environment of VSE/Advanced Functions Release 2 will be executed successfully also in the specified operating environment of Release 3 if this application program interfaces with the operating system through IBM provided macros or through high-level language statements of supported compilers.

An application program that has been executed successfully under the DOS/VSE SCP with VSE/Advanced Functions Release 1 will be executed successfully also in the specified operating environment of Release 3 if this application program:

- Interfaces with the operating system through IBM provided macros or through high-level language statements of supported compilers.
- Does not alter its DASD SAM or DAM DTF blocks.

Also, a definition of processing priority for partitions via the PRTY parameter at the time of system generation is no longer valid. This processing priority may be defined during partition start-up within an automated system initialization procedure.

FORTRAN programs must be relinked with DOS/FORTRAN Library Option 1 Release 3 installed.

MIGRATION/COEXISTENCE

Levels as listed below are required for the following Program Products to run with VSE/Advanced Functions Release 3:

- VSE/POWER Release 2.
- VSE/POWER Version 2.
- VSE/VSAM Release 2.
- VSE/IPCS Release 3.
- VSE/DITTO Release 2.
- DL/I DOS/VS Version 1 Release 5.
- CICS DOS/VS Version 1 Release 5.
- DOS/VS COBOL Release 2 Modification 5 with APAR fix PP88903.
- DOS PL/I Resident Library Release 5 Modification 1.
- DOS PL/I Transient Library Release 5 Modification 1.
- DOS FORTRAN IV Library Option 1 Release 3.
- VS APL Release 3 with APAR fix PP84921.
- ACF/VTAM Version 1 Release 2 or Release 3
- ACF/VTAM Version 2

DATA SECURITY

Data Security and Auditability functions available in previous releases of DOS/VS and DOS/VSE are still available with VSE/Advanced Functions Release 3. However, the two program products, the

PROGRAM PRODUCTS

VSE/Advanced Functions R3 (cont'd)

VSE/Interactive Computing and Control Facility and the VSE/Access Control-Logging and Reporting Program have significant control and audit trail functions that augment DOS/VSE.

PERFORMANCE CONSIDERATIONS

Fast CCW translation for I/O requests with IORB: If CCW translation recognizes an IORB for a DASD I/O request with a fixlist already valid in the same form, then the pathlength for translation and retranslation is reduced. If the complete SVC 0 and interrupt processing is considered, this will result in an overall path length reduction of up to 20%.

5746-XE8 - VSE/ADVANCED FUNCTIONS V1.3.5

PURPOSE

VSE/Advanced Functions 1.3.5 (VSE/AF 1.3.5) provides support for the 3430 Tape Unit, the 3262-5, and 4245 Line Printers and incorporates functional enhancements (hardware support) previously announced and shipped as Small Programming Enhancements (SPEs) after VSE/AF 1.3.0 availability. Ease-of-use, availability and reliability of VSE/Advanced Functions are improved.

DESCRIPTION

HARDWARE SUPPORT

3430: A tape I/O device supported as a 3410-compatible tape unit. The support allows taking advantage of the 6,250 bpi read/write density of the 3430.

3262 Mdl 5, and 4245: New channel-attached printers that are supported as line printers of type PRT1.

FBA Disk Support also in S/370 Mode: The FBA disk support previously available only in ECPS:VSE mode is now also available in S/370 mode.

More Virtual Storage in S/370 Mode: In S/370 mode, up to 16MB of virtual address space can now be specified, regardless of the real memory size, like in ECPS:VSE mode. However, the 16MB of virtual address space is reduced by the supervisor size and the sum of the real partition sizes specified.

SIOF (START I/O FAST) Support: The SIOF instruction is used by the VSE/AF supervisor.

Along with the support of the SIOF instruction, the extended I/O architecture for improved I/O busy handling (SIO Queued) will be supported. The supervisor will process 'delayed I/O interrupts'. This support will be used by processors which can exploit this SIOF instruction. It can improve performance in environments with heavy I/O activities. The use of SIOF allows VM a better guest dispatching in case of I/O operations.

The support for the following machines and I/O devices has been announced and shipped as SPEs after the availability of VSE/AF Release 1.3.0 and is now incorporated in VSE/AF 1.3.5:

- 3033 and 4321 Processing Units
- 3279 mdl 2C Color Console
- 3375 CKD Disk Storage Device
- 3200 Printing Subsystem
- 4341 Mdl Groups 9 - 12

3033: A processing unit; it is supported by VSE/Advanced Functions in S/370 mode only for operation in single processor mode.

4321: A processing unit of the 4300 series; it operates in ECPS:VSE and S/370 mode.

3375 A CKD disk storage device.

3279 Mdl 2C: A color display operator console for attachment to a 4300 Processor. VSE/Advanced Functions includes support for color display on this console device.

4341 Mdl Groups 9 - 12: Mdl groups 9 - 12 of the 4341 Processor are supported in ECPS:VSE and S/370 mode.

AVAILABILITY/RELIABILITY IMPROVEMENT

End-of-task and error-exit handling: The task-to-supervisor linkage control allows a task to do its own error handling. The ABEND exit routine has been extended to be invoked for any type of termination (normal and abnormal) and, for a main task, before propagating the termination to its subtasks. This allows the task which is abended to keep control and to do controlled termination actions like invocation of VSAM automatic close, completion of pending I/O requests, free all locks etc. Using this function will more often leave a functioning system after an ABEND, and thus make recovery/restart much easier or avoid recovery at all.

USABILITY IMPROVEMENTS

Defining system files by volume identifier: During system start-up, system files such as the page data set or the VSAM master catalog may be defined by volume identifier instead of device address. This extension allows specification of volume serial number instead of device address in the IPL commands DEF, DLA, DLF and DPD.

Activating access control during system start-up: With the access control support being an IPL option, there is no longer a need for different supervisors, one with and one without this support.

Upper/lower case option: An option is available for controlling the output to SYSLSST of the utilities PRINTLOG and LISTLOG. This output may be all upper case or as presented by the program that writes to this device.

Turn off fast CCW translation for all partitions: The option can be useful if, for example, programs not gaining performance by fast CCW translation are scheduled to run from one system start-up to the next.

ISPF Support: This support allows using ISPF as dialog and panel manager in a VSE system with dialog and panel compatibility of other systems running ISPF. ISPF executes in an ICCF interactive partition.

Reduction of Supervisor generation parameters: The SEC (Security) supervisor generation parameter has been eliminated. This should make the system generation task easier and further improves ease-of-use.

REMOVED SUPPORT: The following system utilities are removed from VSE/AF 1.3.5:

- ALTBK (Assign Alternate Block)
- INTDK (Initialize Disk FBA)
- SURFANAL (Surface Analysis for FBA)

The services of these utilities are available through Device Support Facilities, a corequisite SCP support for VSE/Advanced Functions.

- OLTEP (OnLine Test Executive Program)
- EREP (Environmental Recording, Editing & Printing)

These functions are now available as separate SCP-class 2 programs.

EREP 2.2.0 is available for VSE/AF and VSE/SP 1.1.0. EREP 2.2.0 support for the VSE system environments is available concurrent with VSE/AF 1.3.5 and VSE/SP 1.1.0.

EREP 2.2.0 provides a new function called System Exception Report. This will strengthen and extend the analytic/diagnostic capabilities of EREP in VSE environments, enabling a more rapid identification of significant component failures within a system and each of its major subsystems.

The EREP, OLTEP and Device Support Facilities SCPs are automatically shipped with VSE/AF 1.3.5 for an IBM CPU registration.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

VSE/Advanced Functions 1.3.5 has the same machine requirements as VSE/Advanced Functions Release 3. (See Announcement Letter P80-207.

Note: VSE/AF 1.3.5 is the last release which supports the IBM processors S/370 mdls 115 and 125.

SOFTWARE REQUIREMENTS

Programming Corequisites:

- VSE/OLTEP 1.1.0 SCP (5656-092)
- EREP 2.2.0 SCP (5656-093)
- Device Support Facility 1.6.0 SCP (5747-DS2)

These System Control Programs are automatically delivered together with VSE/Advanced Functions 1.3.5 for a user with an IBM CPU registration.

COMPATIBILITY

VSE/AF 1.3.5 is fully compatible with VSE/AF 1.3.0.

Device support functions ALTERNATE BLOCK ASSIGN, SURFACE ANALYSIS FBA and CLEAR DISK FBA have been removed from VSE/AF 1.3.5. These functions are available through the Device Support Facility (DSF) program, which has to be ordered separately.

The Environmental Recording, Editing & Printing (EREP) functions have been dropped from VSE/AF 1.3.5. These functions are available through EREP Version 2, Release 2, Modification Level 0 program, which has to be ordered separately.

The OnLine Test Execution Program functions have also been removed. These functions are available through the OnLine Test Execution program, which has to be ordered separately.

VSE/ICCF 1.3.5 is required if VSE/ICCF is to be used in a VSE environment based on VSE/AF 1.3.5.

PROGRAM PRODUCTS

**STORAGE and INFORMATION RETRIEVAL SYSTEM/
DISK OPERATING SYSTEM with VIRTUAL STORAGE
STAIRS/DOS/VS (5746-XR4)**

PURPOSE

The conventional method used for indexing documents in a specialized information system or library is tiring and cumbersome work for specialists. Now, documents, articles from periodicals and magazines, patent texts, as well as their abstracts, can be converted into machine-readable form for entry into a computer system. Once entered, the material can be used during subsequent searches, using the language of the technical area involved, to retrieve the desired information. The full texts, or associated bibliographic identifiers (such as title, author, publisher and source), make up a dynamically growing file of data which can be searched by specialists in law, engineering, medicine, sales, marketing, management and others seeking material of interest pertaining to their own spheres.

DESCRIPTION

The Storage and Information Retrieval System/Disk Operating System with Virtual Storage (STAIRS/DOS/VS) is a conversion of the OS Program Product STAIRS/VS (5740-XR1, Release 2.1), operating in the DOS/VS environment. Except for online data base creation, STAIRS/DOS/VS provides all the functions and capabilities of STAIRS/VS Release 2.1.

STAIRS/DOS/VS is a terminal-oriented, multiple-user, dialog system for the storage and retrieval of information, which also allows for batch processing. It offers the user a variety of resources for data base creation and maintenance and, especially, for data base searching, displaying and/or printing of documents containing either, or both, unformatted text and formatted data.

The data is retrieved as the result of an online dialog between the user and the system in which the user formulates queries by means of Boolean or extended Boolean logic, or by the use of relational operators for the contents of formatted fields. Both types of queries can be combined.

The documents presented as answers by the system can then be ranked, in descending order of probable relevance, by one of five ranking algorithms based on information value, or sorted according to the contents of a formatted field.

Device-dependent message-formatting routines are provided by STAIRS/DOS/VS for the 3270 Information Display System (3275 mdl 2 and 3277 mdl 2 Display Units, 3284 and 3286 Printers), and for the 2740 and 2741 Communication Terminals.

HIGHLIGHTS

STAIRS/DOS/VS provides a highly flexible form of dialog which allows previous queries to be extended or referred to. Query formulation varies from everyday language to mathematical formulation in terms of extended Boolean logic. Query formulations can be saved for current or later use, a feature which serves as a current awareness profile capability. There are two modes of saving queries: In a reserved area accessible only to the user who had saved the queries, or in a common pool accessible to any user of the installation.

Documents presented on 3270 display terminals can be paged forward and backward and the keywords of a query, appearing in the text, can be displayed with double intensity. Search and display can be restricted to a subset of paragraphs of the documents. Retrieved documents, or pages (when using a display terminal), can be immediately copied to a terminal printer (for example, the 3284), or they can be transmitted for later printing on a high-speed printer.

It is possible to add user-written exit routines (in Assembler language only) for additional processing of:

- A SEARCH query prior to processing by STAIRS/DOS/VS, and/or
- The document list resulting from a retrieval step.

The contents of the formatted fields of the documents can be modified online. The modified fields are immediately available for the SELECT function. The number of data bases that can be handled online is limited only by the installation's resources and logical device assignments in the STAIRS/DOS/VS partition.

Up to sixteen different data bases of identical structure can be concatenated and searched as if they were a single data base, as well as for each subset of the sixteen data bases, thus providing the capability of retrospective search and current information selection.

Up to four data bases of identical structure can be merged to a single data base. This provides a possibility of reorganization for a (logical) data base consisting of concatenated (physical) data bases.

A previously interrupted retrieval dialog can be continued after the system has been restarted, at any other terminal, by means of the STAIRS/DOS/VS warm-start function.

CUSTOMER RESPONSIBILITIES

An individual who is thoroughly trained in STAIRS/DOS/VS and has considerable experience in CICS/DOS/VS is required to install STAIRS/DOS/VS.

The customer is responsible for ordering and installing all the communications equipment required.

STAIRS/DOS/VS has been designed so that customer-written application programs may be readily added. Special programs may be written by a system programmer in Assembler language according to STAIRS/DOS/VS programming rules.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The minimum machine configuration required to execute STAIRS/DOS/VS corresponds to the minimum machine configuration required for CICS/DOS/VS. For the minimum machine configuration for CICS/DOS/VS refer to the *Customer Information Control System (CICS/VS), General Information Manual*, (GH20-1280).

For compilation and/or execution of STAIRS/DOS/VS, the following minimum configuration is required:

- Processor: IBM S/370 mdl 135, 145, 155-II or 158 with minimum main storage capacity of 240K bytes.
- For the data bases and other STAIRS/DOS/VS files: IBM 3330, 3340 or 2314 Disk Storage facility.
- One console printer keyboard.
- One card reader and one printer.
- One IBM 3270, 2740 or 2741 terminal.
- For installation and support: One nine-track tape drive and associated control unit.
Note: STAIRS/DOS/VS supports mdl 11 of the IBM 3330. For physical device support, Programming RQP EF4346 (5799-WHZ) must be installed on DOS/VS.
- The Communicating Magnetic Card Selectric® Typewriter mdl 6610 is supported as a 2741 terminal via switched lines by STAIRS/DOS/VS.
- The IBM 2740 (without the station control feature) and the IBM 2741 are supported by STAIRS/DOS/VS.

For batch data base creation and maintenance, partition address space requirements range from 40K to 220K bytes depending on the functions being done. The *STAIRS/DOS/VS Operations Guide* includes the requirements for individual batch program execution.

The online address space requirements for STAIRS/DOS/VS may vary widely, according to the number of active terminals. A minimum installation might require address space of about 200K bytes for the combined CICS-STAIRS partition.

STAIRS/DOS/VS capabilities can be expanded by the addition of:

- Multiple 3330 Disk Storage facilities.
- Multiple 3340 Disk Storage facilities.
- Multiple 2314 Direct Access Storage Facilities.
- Multiple 2741 Communications Terminals and associated control units.
- Multiple Communicating Magnetic Card Selectric® Typewriters and associated control units.
- Multiple 3270 Information Display System components.
- A Card Read/Punch unit.
- Magnetic tape units with associated control units supported by CICS/DOS/VS.
- A high-speed printer producing at least a 132-character print line. If uppercase and lowercase high-speed printing is desired, a 3211 Printer with T11-5 Print train, a 1403 Printer mdl 2, 3, or N1, equipped with the Universal Character Set feature and the TN print train or a 4245 Printer with TN21 print band must be installed.

SOFTWARE REQUIREMENTS

STAIRS/DOS/VS operates on S/370 configurations in virtual mode under CICS/DOS/VS Version 1.1.1 and 1.2 (5746-XX3) in a DOS/VS Release 32 environment. STAIRS/DOS/VS will also operate with subsequent releases of these products unless otherwise stated in a future announcement.

PROGRAM PRODUCTS

STAIRS/DOS/VS (cont'd)

Most STAIRS/DOS/VS program modules are written in S/370 Assembler language, some batch utilities are written in PL/I. All modules are distributed in both source and load module form. Thus, for the execution of the PL/I modules, only the PL/I Transient Library program product (5736-LM5) is required. If a STAIRS/DOS/VS module written in PL/I is to be compiled (for APAR corrections or program modifications), the PL/I Optimizing Compiler program product (5736-PL1) and the PL/I Resident Library program product (5736-LM4) are also required. (For both execution and maintenance of STAIRS/DOS/VS, the PL/I Optimizing Compiler and Libraries (5736-PL3) may be used). For data base creation, STAIRS/DOS/VS uses the DOS/VS Sort/Merge program product (5746-SM1).

All data management facilities and input/output operations for STAIRS/DOS/VS are handled by CICS/DOS/VS or the SAM, DAM and ISAM DOS/VS access methods.

The minimum DOS/VS Assembler and Linkage Editor are required for installation and maintenance of the STAIRS/DOS/VS system. The DOS tape deblocking utility program is required to process the STAIRS/DOS/VS tape as received from PID for installation.

For further information relative to the CICS/DOS/VS programming system, see the CICS/VS pages and documentation.

DATA SECURITY

Facilities to help maintain the privacy and security of data bases are incorporated into the system. Security of data can be enhanced at data base, document, paragraph and field levels by means of registered user names, passwords and privacy codes.

DOS/VS level	Protection through TERMINAL IDENTIFICATION
CICS/DOS/VS level	Protection through USER NAME and PASSWORD
Data Base level	Protection through DATA BASE NAME and DATA BASE PASSWORD
Document level	Protection through DOCUMENT PRIVACY CODE
Paragraph Class level	Protection through PARAGRAPH PRIVACY VALUE
Field level	Protection through FORMATTED FIELD PRIVACY VALUE

PROGRAM PRODUCTS

CICS/DOS/VS EXTM (5746-XXB)

[NO LONGER AVAILABLE, effective May, 1983.]

PURPOSE

The basic function of the Extended Telecommunications Modules (EXTM) feature of CICS/DOS/VS is to establish and support data flow between a CICS/DOS/VS application and a corresponding user application for IBM advanced communication subsystems and preSNA terminals. Services required to support the necessary data flow (System Services Control Point, Session Control, etc.) are an integral part of EXTM. EXTM uses the functional capability of the 3704/3705 Network Control Program/VS (NCP/VS) for controlling terminal operations. Support utilities for the IBM advanced communication subsystems and utility services such as load and dump for 3704/3705 are included. A preprocessor is provided to aid the user during system generation. Normal CICS/DOS/VS functions are supported when using this program. EXTM has been designed to share and take advantage of the functions of CICS/DOS/VS in order to optimize attachment of SNA terminals to a CICS/DOS/VS system and can co-exist in the same partition with BTAM.

DESCRIPTION

EXTM provides support for the IBM advanced communication subsystems with CICS/DOS/VS on smaller mdls of S/370 processors (160K) as well as larger systems interested in an SNA interface tailored to the CICS/DOS/VS environment. The functions performed by EXTM are provided by the following facilities:

Application Program Interface: This module is an interface between the EXTM I/O Module and DFHZCP (which provides CICS/DOS/VS support for SNA terminals) and allows DFHZCP to operate as it does with VTAM. This interface supports the subset of VTAM macros used by CICS/DOS/VS and performs equivalent functions for CICS/DOS/VS. CICS/DOS/VS will continue to use the same control blocks with EXTM as with VTAM.

I/O Module: The I/O Module controls the transfer of data between the host computer and the 3704/3705. This includes blocking/ deblocking of I/O, constructing of channel programs, maintaining physical control of the 3704/3705 NCP/VS and initiating 3704/3705 control functions (activation/deactivation of lines, etc.). The I/O Module also provides an interface to the 3704/3705 load and dump services.

Linkage Module: The Linkage Module acts as an interface between the I/O Module and the CICS/DOS/VS user applications, for preSNA terminals, performing such functions as message synchronization and handling of read/write requests.

Master Terminal Functions: The EXTM Master Terminal Programs provide dynamic user control of the system for EXTM supported terminals. The EXTM master terminal operator can change the status and values of parameters used by CICS/DOS/VS and EXTM and thereby alter the operation of the system.

System Services Control Point: The function of the System Services Control Point (SSCP) is to establish and maintain sessions between the host computer and all nodes in the network. The SSCP will perform network initialization and dynamic node activation/deactivation requested through the EXTM master terminal commands.

Support Service Utilities: Utilities are provided for loading and dumping the 3704/3705. The utilities run under CICS/DOS/VS. These services can be invoked automatically and through EXTM master terminal commands.

Access to Subsystem Support Services batch created files is provided by EXTM for online transmission of subsystem data to the SNA terminal system controllers. This access can be invoked by the EXTM Master Terminal Facility. EXTM master terminal commands may be used to transmit subsystem data to the 3600, 3650 and 3790. Dumping of the 3600 is initiated by the 3600 user application program. EXTM recognizes the request and invokes a DUMP program, routing the 3600 system dump to a user-specified data set.

RAS Functions: Message integrity is achieved through the sequence number facilities inherent in SNA transmission services.

System/Network integrity is provided by serviceability aids which include:

- Path Information Unit (PIU) Trace
- Channel End Appendage Trace
- Miscellaneous Data Record (3704/3705) Statistics Recording
- 3704/3705 Formatted Dump Facility
- CICS/DOS/VS System Trace (a CICS/DOS/VS facility)
- 3704/3705 Line Trace
- Application Program Interface (API) Trace
- Concurrent Online Telecommunication Test

Concurrent Online Telecommunication Test: The EXTM Concurrent Online Telecommunications Test Program is the interface between the online test (OLT) programs and the Extended Telecommunications Modules (EXTM). It controls the selection and execution of the OLTs used for testing the teleprocessing terminals supported by EXTM. COLTT programs can be used to perform preventive maintenance, perform

problem determination, diagnose I/O errors and verify device repairs and engineering changes.

COLTT can be initiated from any alphanumeric terminal with input and output capability that is supported by CICS/VS and has sufficient output message size capacity.

Preprocessor: The Extended Telecommunications Modules Preprocessor is an installation aid whose output provides input for the generation of an NCP/VS, EXTM, and CICS/DOS/VS system generation including required CICS/DOS/VS tables. Users may select various levels of output from the preprocessor and save time in generating the job stream to install their systems. The preprocessor will generate a sample system based on device types specified, and will have additional cross-checking of parameters between CICS/DOS/VS, EXTM, and NCP/VS generations.

CUSTOMER RESPONSIBILITIES

The specific installation requirements must be determined by customers based on their need and available resources. Customer responsibilities for installing CICS/DOS/VS are detailed in the *CICS/VS General Information Manual* GH20-1280. For CICS/DOS/VS with the Extended Telecommunications Modules Feature the customer should:

- Order and install communications equipment based on processing needs.
- Train system analysts, programmers and operators in the use of DOS/VS, CICS/DOS/VS with Extended Telecommunications Modules, 3704/3705, NCP/VS, and subsystem design and programming language.
- Install the NCP/VS in the 3704/3705.
- Develop, write and test the subsystem application programs and/or customized images as required.
- Have installed the prerequisite versions of DOS/VS and CICS/DOS/VS.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The minimum configuration supported is:

- 3115 mdl GE (160K). IBM S/370 processor mdls and the IBM 3031 Processor supported by DOS/VS are supported by EXTM.
- IBM I/O devices to support a Virtual Storage Operating System (DOS/VS and CICS/DOS/VS).
- IBM 3704/3705 II Communications Controller with required channel prerequisites or, if appropriate, an IBM 3790 with LCA and required channel prerequisites.
- A minimum of one EXTM supported terminal.

Note 1: Only the standard IBM S/370 instruction set is used by EXTM. The CICS/VS instruction set requirement for preSNA support with EXTM is the same as with BTAM. The CICS/VS instruction set requirement for SNA support with EXTM is the same as with VTAM.

Note 3: See *EXTM General Information Manual* (GH20-1702) for EXTM configuration guidelines. The EXTM storage configuration aid, called STOREXTM, is available on HONE.

Note 4: The sizes of the CICS/DOS/VS partition and the DOS/VS supervisor are dependent upon the functions and parameters chosen. Appropriate SRLs should be used to configure these products.

Communication Device Support

Communications Controller Support: EXTM supports the IBM 3704 and 3705 Communications Controllers in either NCP/VS mode or NCP/VS with PEP. The emulation of PEP may be utilized by CICS/DOS/VS - BTAM or another partition. EXTM does not support the dynamic switching of lines between the emulation partition and NCP/VS when operating with PEP. Multiple IBM 3704s and 3705s may be attached to an EXTM system. Remote IBM 3704/3705 facilities, available under NCP/VS control, are supported by EXTM. The IBM terminals supported by the remote controller are the same IBM terminals supported by EXTM on a local controller.

- 3704 Communications Controller, mdls A3 and A4
- 3705-I Communications Controller, mdls A2 - D8
- 3705-II Communications Controller, mdls E2 - H8

Communication Systems and Terminals Supported

Start/Stop Transmission Terminals

- 2740 Communication Terminal mdl 1 with, optionally, Record Checking (#6114) Station Control (#7479)
- 2740 Communication Terminal mdl 2 with, optionally, Record Checking (#6114)

PROGRAM PRODUCTS

EXTM (cont'd)

Buffer Receive (#1499)
 2741 Communication Terminal with, optionally,
 Receive Interrupt (#4708)
 3767 Communication Terminal with Start/Stop Feature (#7111, #7112 or #7113) (supported as compatible version of appropriately featured 2740/2741)

Binary Synchronous Communications Terminals

2770 Data Communication System
 2772 Multipurpose Control Unit, with optionally,
 EBCDIC Transparency (#3650)
 WACK Response (#9936)
 Buffer Expansion (#1490)
 Conversational Mode (#1910)
 Multipoint Data Link Control (#5010)
 0545 Output Punch
 1053 Printer or
 2213 Printer
 2265 Display Station
 2502 Card Reader
 3270 Information Display System
 3271 Control Unit mdl 1 or 2, with EBCDIC Transmission Code (#9761) or ASCII Transmission Code (#9762), and
 3277 Display Station mdl 1 or 2, and, optionally
 3284 Printer mdl 1 or 2
 3286 Printer mdl 1 or 2
 3288 Printer mdl 2
 Copy (#1550 for 3271 Control Unit)
 3275 Display Station mdl 1 or 2 with EBCDIC Transmission Code (#9761) or ASCII Transmission Code (#9762), and optionally
 3284 Printer mdl 3
 3780 Data Communication Terminal with EBCDIC Transparency (#3601), WACK Response (#9936)
 Multipoint Data Link Control (#5010)
 3781 Card Punch with Component Selection (#1601) on 3780
 3770 Data Communication System with BCS feature (#1460 or #1461) (supported as compatible version of appropriately featured 2770)

Synchronous Data Link Control Terminals

3600 Finance Communication System
 3601 Finance Communication System Controller mdls 1, 2A, 2B, 3A and 3B with SDLC Communication Feature (#4501, #4502, #6301 or #6302)
 3602 Finance Communication System Controller mdls 1A and 1B with SDLC Communication Feature (#4501, #4502, #6301 or #6302)
 3604 Keyboard Display mdls 1, 2, 3, 4, 5 and 6
 3606 Financial Services Terminal mdls 1 and 2
 3608 Printing Financial Services Terminal mdls 1 and 2
 3610 Document Printer mdls 1, 2, 3 and 4
 3611 Passbook Printer (supported as a 3612) mdls 1 and 2
 3612 Passbook and Document Printer mdls 1, 2 and 3
 3614 Consumer Transaction Facility mdls 1, 2, 11 and 12
 3618 Administrative Line Printer mdl 1
 3624 Consumer Transaction Facility mdls 1, 2, 11 and 12
 3630 Plant Communication System
 3631 Communication System Controller mdls 1A and 1B with SDLC Communication feature (#4502, #6301 and #6302)
 3632 Plant Communication System Controller mdls 1A and 1B with SDLC Communication feature (#4502, #6301 and #6302) (3600 Compatible)
 3650 Retail Store System
 3651 Store Controller mdls A50 and B50
 3653 Point of Sale Terminal mdl 1
 3275 Display Station mdl 3
 3284 Printer mdl 3
 3790 Communication System
 3791 Controller mdls 1A, 1B, 2A and 2B with

SDLC Communication feature (#6301, #6302 or #6303) and Configuration Support #9165 and
 3792 Auxiliary Control Unit
 3793 Keyboard Printer mdl 1
 3277 Display Station
 3284 Printer mdls 1 and 2
 3286 Printer mdls 1 and 2
 3288 Printer mdl 2
 3767 Communication Terminal mdls 1, 2 and 3 with Vertical Forms Control feature (#8731) (optional)
 3770 Data Communication System with SDLC Communication feature (#1460 or #1470)
 3771 Data Communication Terminal mdls 1, 2 and 3
 3773 Data Communication Terminal mdls 1, 2 and 3 Programmable mdls P1, P2 and P3
 3774 Data Communication Terminal mdls 1 and 2 Programmable mdls P1 and P2
 3775 Data Communication Terminal mdl 1 Programmable mdl P1
 3776 Data Communication Terminal mdls 1 and 2
 3777 Data Communication Terminal
 3270 Information Display System
 3271 Control Unit mdls 11 or 12 with Copy (#1550)
 3277 Display Station mdls 1 or 2, and, optionally
 3284 Printer mdls 1 or 2
 3286 Printer mdls 1 or 2
 3288 Printer mdls 2
 3775 Display Station mdl 11 or 12 with
 3284 Printer mdl 3

Terminals Connected Via Local Attachment

3790 Communication System
 3791 Controller mdls 1A, 1B, 2A and 2B with Local Channel Attachment (#1515) and Configuration Support #9165 and
 3792 Auxiliary Control Unit
 3277 Display Station
 3793 Keyboard Printer
 3284 Printer mdls 1 and 2
 3286 Printer mdls 1 and 2
 3288 Printer mdl 2

The following table illustrates EXTM support of IBM SDLC devices on nonswitched or dial communicating facilities:

SDLC Device	Non-switched	Dial-in	Dial-out
3270	X		
3600	X	X	X
3614	X		
3624	X		
3630	X	X	X
3650	X		X
3767	X	X	X
3770	X	X	X
3790	X	X	X

Equivalent Terminals: Terminals that are functionally equivalent to those specifically supported by EXTM may also function satisfactorily with EXTM; the customer is responsible for establishing equivalency.

SOFTWARE REQUIREMENTS

The Extended Telecommunications Modules Feature is coded using S/370 Assembler Language.

EXTM operates in the following environment:

	EXTM V2 Rel. 0	EXTM V3 Rel. 0	EXTM V3 Rel. 1
DOS/VS Release	31 or 32	32 or 33	33 or *
NCP/VS Version	4.1 or 5.0	4.1 or 5.0	5.0 or **
CICS/DOS/VS Version	1.1.1 or 1.2	1.2 or 1.3	1.3 or *

* Currently available version at the time of EXTM V3.1 availability.

** ACF/NCP/VS support will be available at the availability of ACF/NCP/VS.

The support utilities for the subsystem controllers use CICS/DOS/VS VSAM which requires the Relocating Loader.

CICS/DOS/VS support of BTAM terminals remains unchanged. BTAM can coexist with EXTM in the CICS/DOS/VS partition. When supporting terminals via BTAM, they must interface to CICS/DOS/VS-BTAM via a separate control unit or via an IBM 3704/3705 in emulation mode or by using the Partitioned Emulator Program (PEP). VTAM can coexist with Extended Telecommunications Modules in the system but

EXTM (cont'd)

not in the same CICS/DOS/VS partition. Each system, VTAM and EXTM, must have its own 3704/3705.

EXTM/VTAM Selection Criteria: In selecting whether EXTM or VTAM should be used in a DOS/VS environment with CICS/DOS/VS, careful consideration should be given to the availability of the necessary minimum system configuration and to the functions required in the system.

PERFORMANCE CONSIDERATIONS

The performance of EXTM in a virtual storage environment is highly dependent on the system resources available, on any programs that operate concurrently and their relative priorities, on system and application data file placement, on system timing, etc. Performance also depends on the paging characteristics and storage reference patterns of CICS/DOS/VS and its application programs, on the allocation of data files to particular devices, and on the particular data being processed.

For specific online performance and response time requirements, careful attention should be given to ensure that adequate real resources (main storage, processor computing capability, channels, disk file arms, etc.) are available. To verify specific performance, benchmarking EXTM with CICS/DOS/VS and DOS/VS may be appropriate.

PROGRAM PRODUCTS

**COMMUNICATION ORIENTED MESSAGE SYSTEM
CORMES Release 1 Modification Level 0 (5746-XXM)****PURPOSE**

The Communication Oriented Message System (CORMES) is designed to build the central "paperless" message exchange system in an organization connecting terminal users and application programs of different functions. It provides communication links:

- For the exchange of information between terminal users (action messages).
- For the interaction between online application programs and terminal users (action messages).
- For triggering the execution of application programs based on the occurrence of prespecified events (trigger messages).

DESCRIPTION

CORMES operates under the IBM Disk Operating System/Virtual Storage (DOS/VS) Release 33 or subsequent releases unless otherwise identified.

For data base management, the system uses the data base facilities of the IBM S/370 Data Language/I Disk Operating System/Virtual Storage (DL/I DOS/VS) Version 1, program number 5746-XX1, Release 1, or subsequent releases unless otherwise identified.

For data communication, CORMES uses the facilities of the IBM S/370 Customer Information Control System/Virtual Storage (CICS/DOS/VS) Version 1, program number 5746-XX3, Release 2, or subsequent releases unless otherwise identified.

HIGHLIGHTS**Terminal user services:**

- Easy to use terminal functions to create, display, modify, and distribute action messages.
- Routing of action messages from one user to another.
- Linkage to online application programs to process a user-selected action message.

Application program services:

- User macros to simplify the creation of action and trigger messages in user-written programs and their transfer to the central message files.
- Triggering of application program execution according to prespecified events: A point in time, a time interval or a queue length.
- CORMES as a frame for the implementation of interactive application programs.

System services:

- Monitoring of the individual message queue of each terminal user by due date and priority of the received messages.

CUSTOMER RESPONSIBILITIES

This section briefly discusses the activities the user has to perform to make CORMES operational. It gives a rough guide for assessing the total installation effort. The assumption is that a system running under DOS/VS with DL/I DOS/VS and CICS/DOS/VS has already been installed.

The installation procedure allows an easy installation of the CORMES system including the sample by use of object code facility. The distributed source code will be used for the final adaptation to the existing system environment.

The major implementation steps are:

- Installation of the CORMES system according to the distribution tape and installation description.
- Execution of the supplied sample to verify the installation. This sample can also be used as a tool for training terminal users.
- Optionally, assembly of all CORMES online programs to include customer requirements.
- Modification and reassembly of existing programs for CORMES communication (according to the rules defined by CORMES) by use of macros and examples provided.
- Exchange of the sample files and tables by files and tables that describe the customer system.

The required changes within existing customer programs have been reduced to a minimum. In addition, macros are provided to simplify the program interactions. Support is provided for Assembler, PL/I and COBOL programs.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

For compilation and/or execution of CORMES, an IBM S/370 with the minimum main storage capacity for CICS/DOS/VS operation is required.

For CORMES, additional storage is required. For the first terminal 16,500 bytes and for each additional terminal 3,000 bytes; for the first application program 11,800 bytes and for each additional program 1,200 bytes.

For the data bases, and files the same devices are used as for the basic software of DOS/VS, CICS/DOS/VS and DL/I DOS/VS.

At least an IBM 3277 Display Station mdl 2 with a 66-key keyboard must be available. The Selector Light-pen (#6530) and program function keys are supported optionally. The IBM 3274 and 3276 are supported in compatibility mode.

The online address space requirements for CORMES may vary widely, according to the number of active terminals. A minimum installation might require address space of about 384K bytes for the combined CICS/VS and DL/I DOS/VS user task partition.

SOFTWARE REQUIREMENTS

CORMES is written in Assembler language and uses the macro language facility.

CORMES is designed for an online DOS/VS environment and requires the following programs:

- DOS/VS Release 33 and subsequent releases). *
- CICS/DOS/VS Version 1, program number 5746-XX3, Release 2 and subsequent releases). *
- DL/I DOS/VS Version 1, Program Number 5746-XX1, Release 1 and subsequent releases). *

* Unless otherwise identified in a future revision of this document.

Note: CORMES executes, and is supported by IBM, on S/370 virtual storage configurations running under DOS/VS in virtual mode, and DOS/VS under VM/370 in virtual machine mode.

PROGRAM PRODUCTS

**ENTRY LEVEL INTERACTIVE APPLICATION SYSTEM-ONE
VERSION 1 - RELEASE 1 (ELIAS-I)
5746-XXV**

PURPOSE

ELIAS-I is an interactive program which uses the facilities of the Interactive Productivity Facility (Program Number 5748-MS1). When correctly installed in its Specified Operating Environment (SOE) ELIAS-I is designed to provide a system which will facilitate the design, development and implementation of DB and or DB/DC programs with CICS/DOS/VS and/or DL/I DOS/VS using COBOL or PL/I and, optionally, DMS/CICS/VS-DOS.

DESCRIPTION

ELIAS-I presents, via its optional documentation and with supporting education, a design methodology for DB/DC applications which has been specially tailored to the user who is not experienced in DB/DC implementation and who has limited in-house skill. Hints and tips are provided to help facilitate the use of Improved Programming Techniques in the smaller system environment.

ELIAS-I interactive procedures are designed to provide assistance with DB/DC program implementation by providing a dialogue capability for the programmer. ELIAS-I bricks are also included in the product. These bricks are designed to be included in DB/DC application programs and to provide assistance in utilizing standard CICS/DOS/VS and DL/I facilities.

Procedures and bricks are provided for the following main functional areas:

- Assistance with DL/I data base definition. Procedures to generate DL/I nucleus, DBDs, PSBs, SSAs and the associated VSAM files, together with the associated COBOL or PL/I maps, and error recovery code.
- Assistance with DL/I data base maintenance. A procedure for loading, reorganization and backup/recovery of DL/I data bases.
- Assistance with CICS/DOS/VS screen map generation using Basic Mapping Support. Interactive definition of application screens to ELIAS-I design standards, together with maps in COBOL or PL/I and error recovery code.
- Assistance with program creation in COBOL or PL/I. Provision of skeleton programs with DL/I and CICS/DOS/VS maps, data areas and linkages, and error recovery code. "Fetch a brick" capability for CICS/DOS/VS and DL/I calls. Simple use of full screen editor to enter user source statements and test the resulting program.
- Assistance with writing COBOL or PL/I user exits for DMS/CICS/VS-DOS (Program Number 5746-XC4). For those customers who have DMS installed, a user exit capability similar to the above described program creation routines is available.

ELIAS-I, when installed in conjunction with the DOS/VSE System IPO-E, is designed to provide a comprehensive system for the design, development, programming, debugging, testing and operation of a DB/DC system using, in the main, interactive tools to accomplish the above tasks. Sample programs - working models of various DB/DC functions - are designed to illustrate, "how to do it", for the user new to DB/DC implementation. ELIAS-I also provides assistance for the experienced programmer whose productivity can be improved via the interactive program generation procedures.

ELIAS-I can be used in the following ways:

- Use with any DOS/VSE System IPO/E base to generate source code in COBOL or PL/I for:
 - Batch data base programs.
 - Online programs using CICS/DOS/VS or DMS/CICS/VS-DOS.
 - DB/DC programs using DL/I, CICS/DOS/VS and/or DMS/CICS/VS-DOS.

These source code programs can be tested and run on other DOS/VSE systems which contain the appropriate compilers and DC or DB components.

- Use with the DC version of any DOS/VSE System IPO/E base, together with COBOL or PL/I, to generate, test and put into production batch or DC programs which use CICS/DOS/VS and, optionally, DMS/CICS/VS-DOS.
- Use with the DB/DC version of any DOS/VSE System IPO/E base to generate, test and put into production batch, DB, DC or DB/DC programs which use CICS and/or DL/I, either COBOL or PL/I and, optionally, DMS/CICS/VS-DOS.

ELIAS-I has been designed to provide the maximum productivity benefits in the last case above; that is, when used in a full DB/DC environment together with CICS and DL/I, either COBOL or PL/I and, optionally, DMS/CICS/VS-DOS.

HIGHLIGHTS

- Interactive interface for definition of DL/I DOS/VS Data Bases.

- Interactive interface for definition of CICS/DOS/VS screens (using Basic Mapping Support or DMS/CICS/VS-DOS).
- Interactive program build facility for batch or online programs in COBOL or PL/I.
- Interactive facilities to enhance DMS/CICS/VS-DOS user exit programming.
- Comprehensive Data Base recovery and reorganization routines.
- Task oriented documentation.
- Sample programs to illustrate how DB/DC programs should be built.
- Designed to provide ease of use to DB/DC programming.
- Explain and Help facilities.
- Standard program design and error recovery routines designed to provide easier and reduced maintenance.

CUSTOMER RESPONSIBILITIES

See above. The customer should ensure that the functions of ELIAS-I match their application requirements and that they have sufficient terminals to realize the benefits of an online programming environment.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

ELIAS-I (5746-XXV) is designed to operate on the IBM S/370, 4300 and 303X processors supported by the DOS/VSE operating system.

- A typical DOS/VSE environment to support ELIAS-I might be:
 - IBM 4331 Processor - 1.0 megabyte storage; DASD - 5 Spindles 3310*; Console - 1 3278-2A; Printer - 1 3205-5*; 1 Card or Diskette Reader; Tape Drive - 1 8809*; Terminal - 1 3278-2 or 3277-2.
 - IBM S/370 - 1.0 megabytes storage; DASD - 5 Spindles 3340*; 1 Line Printer; 1 Tape Drive; Terminals - 1 3277-2 or 3278-2; 1 Card or Diskette Reader.

* = or equivalent devices supported by the Operating System.

SOFTWARE REQUIREMENTS

ELIAS-I is designed to operate with the specified releases of the following programs. The Interactive Productivity Facility (5748-MS1) is a prerequisite for using ELIAS-I.

		Release
DOS/VSE	5475-030	-
VSE/Advanced Functions	5746-XE8	2
VSE/ICCF	5746-TS1	2
VSE/POWER	5746-XE3	2
VSE/VSAM	5746-AM2	2
Interactive Productivity Facility	5748-MS1	2
CICS/DOS/VS	5746-XX3	1.4.1
DL/I DOS/VS	5746-XX1	1.5
DMS/CICS/VS-DOS	5746-XC4	2
COBOL/VS	5746-CB1	2.5
PL/I OPT. LIBS	5736-PL3	5.1
PL/I OPT.	5736-PL1	5.1
PL/I RES. LIB	5736-LM4	5.1
PL/I TRANS. LIB	5736-LM5	5.1
SORT/VS	5746-SM2	3
DB/DC Data Dictionary		
DOS/VS	5746-XXC	3
* ELIAS-I is transparent to the teleprocessing access method. Release 1 of the DOS/VSE System IPO/E supports only BTAM-ES.		

COMPATIBILITY

Programs written using ELIAS-I in conjunction with CICS/DOS/VS, DL/I DOS/VS, DMS/CICS/VS-DOS, COBOL or PL/I are designed to be able to run on any DOS/VSE System IPO/E which has installed the appropriate selection of the above mentioned component programs.

Ordering Instructions: ELIAS-I can be ordered separately from the System IPO/E. The customer will receive all necessary instructions for installing ELIAS-I on top of an installed system which contains the Interactive Productivity Facility and the other prerequisite programs described under "Programming Requirements".

A separate license is required under the terms and conditions of the Agreement for IBM Licensed Program.

PROGRAM PRODUCTS

**ENTRY LEVEL INTERACTIVE APPLICATION SYSTEM-ONE
RELEASE 2
ELIAS-I (5746-XXV)**

PURPOSE

ELIAS-I is an interactive program which runs under the control of the Interactive Productivity Facility, Program Number 5748-MS1. When correctly installed in its Specified Operating Environment (SOE), ELIAS-I is designed to provide a system which will facilitate the design, development and implementation of VSAM, DB, DC and/or DB/DC programs with CICS/DOS/VS, DL/I DOS/VS, and/or VSE/VSAM using COBOL or PL/I and, optionally, DMS/CICS/VS DOS.

ELIAS-I presents, via its optional documentation and with supporting education, a design methodology, especially oriented towards DB/DC applications, tailored to the user who is not experienced in DB/DC implementation and who has limited in-house skill. Hints and tips are provided to help facilitate the use of improved programming techniques in the smaller system environment.

ELIAS-I interactive procedures are designed to provide assistance with VSAM, DB, DC, and/or DB/DC program implementation by providing a dialog capability for the programmer. ELIAS-I bricks are also included in the product. These bricks are designed to be included in VSAM, DB, DC, and/or DB/DC application programs and to provide assistance in utilizing standard CICS/DOS/VS, DL/I DOS/VS and VSE/VSAM facilities.

DESCRIPTION

Procedures and bricks are provided for the following main functional areas:

- Assistance with DL/I data base definition. Procedures to generate DL/I nucleus, DBDs, PSBs, SSAs and the associated VSAM files, together with the associated COBOL or PL/I structures. A procedure to transport ELIAS-I defined DL/I control blocks and COBOL or PL/I structures into the DB/DC Data Dictionary DOS, Program Number 5746-XYC, is provided.
- Assistance with PSE import. A procedure to make available to ELIAS-I program generation procedure PSBs which have been defined without making use of ELIAS-I facilities.
- Assistance with DL/I data base maintenance. A procedure for loading, reorganization and backup/recovery of DL/I data bases.
- Assistance with CICS/DOS/VS screen map generation using Basic Mapping Support. Interactive definition of application screens to ELIAS-I design standards. These maps can be defined for use either with COBOL or PL/I application programs.
- Assistance with batch and online program creation and maintenance in COBOL or PL/I. Provision of skeleton programs with data areas, screen maps, linkage and error recovery code for DL/I (CALL or High Level Programming Interface), VSE/VSAM and CICS/DOS/VS.
- "Fetch a brick" capability for service requests related to DL/I (CALL or HLP interfaces), VSE/VSAM and CICS/DOS/VS either in batch or online programs written in COBOL or PL/I. Simple use of full screen editor to enter user source statements and test the resulting program.
- Assistance for writing COBOL or PL/I user exits for DMS/CICS/VS DOS, Program Number 5746-XC4. For those customers who have DMS installed, ELIAS-I provides support for writing user exits in either COBOL or PL/I, offering productivity improvements made available to the developers of traditional COBOL or PL/I programs.
- Assistance with "compile and link" jobstream creation. A procedure to generate a fully tailored jobstream in order to submit to batch for compiling and linking batch and/or online programs, as well as CICS/DOS/VS screen maps.

ELIAS-I, especially when installed in conjunction with the VSE System IPO-E DB/DC, Program Number 5750-AAA, is designed to provide a comprehensive system for the design, development, programming, debugging, testing and operation of a DB/DC system using, in the main, interactive tools to accomplish the above tasks. Sample programs - working models of various DB/DC functions - are designed to illustrate "how to do it" for the user new to DB/DC implementation. ELIAS-I also provides assistance for the experienced programmer whose productivity can be improved via the interactive program generation procedures.

HIGHLIGHTS

ELIAS-I provides:

- Interactive interface for definition of DL/I DOS/VS Data Bases.
- Interactive interface for definition of CICS/DOS/VS screens (using Basic Mapping Support or DMS/CICS/VS DOS).
- Interactive program build facility for batch or online programs in COBOL or PL/I.

- Interactive facilities to enhance DMS/CICS/VS DOS user exit programming.
- Data Base recovery and reorganization routines.
- Task-oriented documentation.
- Sample programs to illustrate how DB/DC programs may be structured.
- Ease of use for DB/DC programming.
- Dialogs and help functions available in the following languages: French, German, Italian, Katakana, Portuguese and Spanish in addition to English.
- Standard program design and error recovery routines designed to provide easier and reduced maintenance.

CUSTOMER RESPONSIBILITIES

See above. The customer should ensure that the functions of ELIAS-I match their application requirements and that they have sufficient terminals and machine power to realize the benefits of an online programming environment.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

ELIAS-I is designed to operate on any IBM S/370, 303X and 4300 processors supported by the VSE/Advanced Functions.

Elias-I runs under control of Interactive Productivity Facility, in a VSE/ICCF pseudo-partition with at least 768K bytes of virtual storage allocated.

The following space is required in the VSE libraries:

	CIL	BL	SSL
Installation/Serviceing	1051 (31)	4030 (61)	31620 (2022)
Execution	1051 (31)		

A typical minimum VSE DB/DC where ELIAS-I can be installed to support application programming development might be:

- IBM 4331 Processor - 1 megabyte of storage ... 3 spindles 3370 DASD ... 1 Console 3278-2A ... 1 Printer 3211, 4245 or 3203-5* ... 1 Card or Diskette Reader ... 1 Tape Drive ... 1 Terminal 3277-2 or 3278-2.
- IBM S/370: 1 megabyte of storage ... 8 Spindles of 3340 DASD* ... 1 Line Printer ... 1 Card or Diskette Reader ... 1 Tape Drive ... 1 Terminal 3277-2 or 3278-2.

* = or equivalent devices supported by the Operating System.

SOFTWARE REQUIREMENTS

This licensed program requires the functions provided by the Interactive Productivity Facility Release 3, Program Number 5748-MS1, running in conjunction with the following programs:

		Release
DOS/VSE	5475-030	-
VSE/Advanced Functions	5746-XE8	2.0
VSE/ICCF	5746-TS1	2.0
VSE/POWER	5746-XE3	2.0

The set of macros and application programs generated by ELIAS-I may interface with the following programs:

		Release
CICS/VS	5746-XX3	1.5
DL/I DOS/VS	5746-XX1	1.5 ICR 2
DOS/VS		
VSE/VSAM	5746-AM2	2.0
DMS/CICS/VS DOS	5746-XC4	2.0
DOS/VS COBOL	5746-CB1	2.5
PL/I Optimizing Compiler and Libraries	5736-PL3	5.1
DB/DC Data Dictionary	5746-XXC	3.0

and any teleprocessing access method supported by VSE/AF Release 2.0, Program Number 5746-XE8.

MIGRATION from ELIAS-I RELEASE 1: ELIAS-I Release 1 is upward compatible with ELIAS-I Release 2:

- Tables created by ELIAS-I Release 1 can be used directly by ELIAS-I Release 2 dialogs.
- Program skeletons generated using ELIAS-I Release 1 facilities can be accessed by ELIAS-I Release 2 editors.

ELIAS-I R2 (cont'd)

- ELIAS-I Release 2 bricks providing functions already existing in ELIAS-I Release 1 can be included in any ELIAS-I, Release 1 generated programs, without regeneration of the framework.

Restriction:

- ELIAS-I Release 2 editors can only use ELIAS-I, Release 2 bricks.

DOCUMENTATION

PROGRAM PRODUCTS

**DATA LANGUAGE/I-ENTRY DOS/V5
DL/I-Entry DOS/V5 (5746-XX7)**

PURPOSE

DL/I-Entry DOS/V5 is a data base management system developed to improve the user's ability to implement data base processing applications. It provides data organization methods conducive to the creation, interrelation and support of large common data bases. DL/I-Entry DOS/V5 executes as an application program in a virtual storage environment under DOS/V5.

DESCRIPTION

DL/I-Entry DOS/V5 executes in either batch or online mode. The online capability is made possible through use of the Customer Information Control System/DOS/V5 (CICS/DOS/V5), Program Product 5746-XX3, with which DL/I-Entry DOS/V5 interfaces as a normal message processing program. An evolution from batch to teleprocessing applications is thus possible.

Application programs call upon the data base management services through DL/I-Entry DOS/V5. DL/I-Entry DOS/V5 provides the application programs with a level of interface to the data base management services which is independent of data storage considerations. Through installation management tools provided by DL/I-Entry DOS/V5, data storage may be manipulated independent of application programs. Installation management can approach the problem of optimizing productivity for the total community of applications and users without affecting the functional capabilities of any of the members of that community. Existing DL/I-Entry DOS/V5 application programs can be insensitive to reorganization of stored data, addition of new applications or data, changes in access methods, organization, or access strategy, and the introduction of new storage devices.

The data base management services of DL/I-Entry DOS/V5 assist the user in:

- Description of data base structures.
- Creation of data bases.
- Access to retrieve or update data.

Using utilities supplied with the system, the user describes the structure of the data base from two viewpoints: The stored data structure as seen by the system, and the logical data structure as seen by the application. Only one description of the stored data exists. However, multiple descriptions of logical data may exist. These data base descriptions are external to application programs. They exist as stored data and are referenced by the system when it is processing access requests for the application programs.

Data base descriptions define the hierarchical relationships of segments making up a data base, the attributes of these segments, the access strategy and the storage device. To access or update stored data, the application program generates a functional GET/PUT level request for data base management services. As part of the functional request, the application program supplies symbolic names which identify the data to be processed.

Data bases are stored in the hierarchical sequential organization, and the access strategy may be sequential, indexed sequential or direct. Relationships can be established between segments in different hierarchical structures stored within the same or different data bases.

HIGHLIGHTS

- Application programs may process data bases independent of physical organization or storage device used.
- Users may write application programs in COBOL, PL/I or RPG II. Assembler Language may be used for customer programming.
- Data management services are provided by the DOS/V5 virtual storage access method (VSAM) for hierarchical indexed sequential and for hierarchical direct data bases.
- Data bases may be defined which permit relationships to be established between segments in different hierarchical structures stored within the same or different data bases.
- Secondary indexing provides indexed access to root segments within a data base.
- Backup and reload utility programs assist in reorganizing data bases, and provide statistics for tuning the data bases.
- DL/I-Entry DOS/V5 is an application source program compatible subset of DL/I DOS/V5, Program Product 5746-XX1, and is also upward compatible from VANDL-1, (PRPQ 5799-AEY).
- A utility is provided to convert VANDL-1 data bases to DL/I-Entry data bases. DL/I-Entry HSAM data bases can be processed by DL/I DOS/V5.
- Application programs using the Customer Information Control System/DOS/V5 (CICS/DOS/V5) may issue calls to process DL/I-Entry DOS/V5 data bases.
- Application programs can use the low-level code/continuity check feature to generate, check and update low-level codes. These are

useful in identifying the components or materials which make up a finished product. The feature is intended mainly for manufacturing applications, but not limited to them. Application programs which use the feature are upward source program compatible with DL/I DOS/V5 Version 1.1 (5746-XX1) and subsequent releases.

- A trace feature which dumps DL/I-Entry control blocks and information about DL/I-Entry calls during application program execution. The feature is an option intended primarily for use by IBM programming service representatives, and degrades application program performance.
- Batch and online interfaces are provided to support application programs written in RPG II Release 2.0 using data base access requests. These application programs are upward compatible to DL/I DOS/V5. The existing batch interface has been retained for RPG II users with application programs already written in default or explicit mode.
- A new online scheduling call has been added to assure that upward compatibility to DL/I DOS/V5 is retained for online applications.

The following chart illustrates the major features available for DL/I-Entry DOS/V5 and DL/I DOS/V5.

Feature	DL/I-Entry DOS/V5 V2.1.1	DL/I DOS/V5 V1.4
Batch processing	X	X
Online processing	X	X
Data base recovery facility		X
DBD generation utility	X	X
PSB generation utility	X	X
Preformatted control blocks		X
Low-level code/continuity check feature	X	X
Data Base Support		
Hierarchical sequential access method (HSAM)	X	X
Hierarchical indexed sequential access method (HISAM)	X	X
Hierarchical direct access method (HDAM)	X	X
Hierarchical indexed direct access method (HIDAM)		X
Application Program Data Management Support		
VSAM	X	X
SAM	X	X
Application Program Language Support		
PL/I	X	X
COBOL	X	X
RPG II	X	X
Assembler	X	X
Data Base Structures and Processing		
Physical data bases	X	X
Logical data bases	HISAM or HDAM only	HISAM or HDAM only
Hierarchical levels	15	15
Different segment types	63	255
Maximum segment size (bytes)	512	4K
Maximum key length (bytes)	250	255
Fields per segment	*1	255
Multiple segment search arguments	X	X
Secondary indexing	HISAM or HIDAM only	HIDAM or HDAM only
Shared source segment for multiple secondary indexes		
PCBs per PSB	20	20

*Note: Only one field is identifiable to DL/I-Entry; however, the data portion of the segment may be subdivided into user data fields.

Use: The DL/I-Entry DOS/V5 system is distributed as a set of preassembled modules and a set of macros.

The separately assembled modules are in object form and contain the executable code necessary to operate DL/I-Entry DOS/V5. The user must link-edit these modules into the core image library.

Additionally, the user must catalog the supplied macros into the source statement library. These macros permit the user to describe the characteristics of the application programs, data bases, transactions, and, optionally, the environment used in conjunction with the Customer Information Control System/DOS/V5 (CICS/DOS/V5). These options reflecting the user's requirements are assembled and then link-edited into the core image library.

PROGRAM PRODUCTS

DL/I-Entry DOS/VS (cont'd)**CUSTOMER RESPONSIBILITIES**

A customer installing DL/I-Entry DOS/VS must:

- Meet the system requirements (paragraph below).
- See to it that appropriate DOS/VS and S/370 training (direct access storage education) be given to system analysts, application programmers, system programmers and system operators.
- Have DOS/VS successfully installed (no customer should attempt to implement DL/I-Entry DOS/VS until the installation has achieved proficiency in the use of DOS/VS).
- Have personnel schooled in DL/I-Entry DOS/VS (a thorough knowledge and understanding of data base concepts and DL/I-Entry DOS/VS before installation are essential).
- Provide adequate protection against accidental loss or misuse of data.
- Have DOS/VS personnel trained in COBOL, PL/I, RPG II or Assembler Language.
- Specify and implement application programs.
- Perform DOS/VS support or service associated with the installation of DL/I-Entry DOS/VS.

In addition to the above, additional time considerations should be given if the user wishes to process in an online environment in conjunction with CICS/DOS/VS. Refer to the CICS/DOS/VS pages for details.

A customer who has already installed DL/I-Entry DOS/VS Version 1.0, 1.1 or 2.0 must recompile and link edit the DFHSIT macro with SIMODS = (A1, B1, C1, D1, E1, F1, G1, H1, DE, I1, J1) before executing under DL/I DOS/VS Version 2.1.1 to include the modified DL/I - Entry Phase (DE).

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

The minimum machine requirements for DL/I-Entry DOS/VS are the same as those needed for conventional operation of DOS/VS. The minimum machine configuration is an IBM S/370 mdl 115 or larger. For DL/I-Entry batch processing, add approximately 12K bytes of real storage (36K bytes of virtual storage) to VSAM or SAM storage requirements - for DL/I-Entry DOS/VS online processing add approximately 14K bytes of real storage (40K bytes of virtual storage) to VSAM and CICS/DOS/VS storage requirements. DL/I-Entry uses the CICS/DOS/VS I/O handling capability and buffer areas from CICS Dynamic Storage -- consult the CICS/DOS/VS pages and *General Information Manual* (GH20-1280) for latest information. For I/O, one IBM 2560 Card Reader/Punch (or equivalent) or one IBM 3540 Diskette I/O Unit; one IBM 3203 Printer (or equivalent); and (required for online processing only) any terminal device supported by CICS/DOS/VS.

Data base storage files may be on IBM 2314/2319 Direct Access Storage Facilities, IBM 3330/3333/3350 Disk Storage or IBM 3340/3344 Direct Access Storage.

SOFTWARE REQUIREMENTS

DL/I-Entry DOS/VS will run on S/370 under DOS/VS Release 34 and subsequent releases. DL/I-Entry will also run with DOS/VS under VM/370. DL/I-Entry DOS/VS is written in Assembler Language, and uses the Virtual Storage Access Method (VSAM) and Sequential Access Method (SAM) data management facilities.

The following components of the DOS/VS SCP (5745-010) are required:

- Control and service programs.
 - Initial program loader.
 - Supervisor.
 - Job control.
 - Linkage editor.
 - Relocating loader.
 - Libraries.
- Assembler.
- Data management.
 - Sequential Access Method.
 - Virtual Storage Access Method.

In addition to the above DOS/VS components, the user may require the following program products:

- DOS/VS COBOL Compiler and Library, 5746-CB1.
- Full ANS COBOL V3 Compiler, 5736-CB2, and Full ANS COBOL Library, 5736-LM2.
- PL/I Optimizing Compiler, 5736-PL1.
- PL/I Resident Library, 5736-LM4.
- PL/I Transient Library, 5736-LME.

- DOS RPG II Compiler, 5736-RG1.
- DOS/VS RPG II Compiler 5746-RG1

For online processing, the Customer Information Control System/DOS/VS (CICS/DOS/VS Version 1.4 or a subsequent version), Program Product 5746-XX3, is required.

DOCUMENTATION
(available from Mechanicsburg)

General Information Manual Version 2.1.1	GH12-5115
Program Product Specifications	GH12-5205

5747-CC1 - DOS/VSE 3800 PRINTING SUBSYSTEM IR**PURPOSE**

Support for the 3800 Printing Subsystem consists of Support Code within DOS/VSE and this Independent Release (IR). Together, they provide the DOS/VSE user with the same 3800 Printing Subsystem support as previously announced for DOS/VS Release 34.

HIGHLIGHTS

The IR provides the following components, which are unique to the 3800 Printing Subsystem:

- SETPRT
- IEBIMAGE
- IBM-supplied PRINTER CONTROL PHASES

The remaining 3800 support code is contained in DOS/VSE.

CUSTOMER RESPONSIBILITIES

It will be the customer's responsibility to install the IR. Installation instructions are contained in the Program Directory.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

The 3800 Printing Subsystem can be attached to the IBM 4331, 4341, 4361, 4381 Processors and IBM S/370 mdl 135*, 138*, 145, 148, 155II, 158 and the IBM 3031 Processor.

*Via RPQ #S00338 which approves 3800 attachment to 3135 and 3138.

SOFTWARE REQUIREMENTS

Prerequisite: The prerequisite to the installation of the DOS/VSE IBM 3800 Printing Subsystem IR is DOS/VSE or any subsequent release of DOS/VSE unless otherwise indicated.

COMPATIBILITY

This IR is compatible with DOS/VSE.

PROGRAM PRODUCTS

**VS APL
RELEASE 4.0 (5748-AP1)**

PURPOSE

VS APL is a program product that interprets statements written in APL. The APL language has a simple and uniform notation, tailored to interactive use at a terminal. The language was originated to define programs concisely using well-known symbols.

SPECIAL SALES INFORMATION

VS APL is designed for new and current users of APL. Users of other APL products may find that VS APL offers an alternative to their current product.

VS APL provides conversion aids to assist the user in converting APL functions and data defined under selected IBM APL products so that they can be used under VS APL. The conversion aids consist of batch programs and a workspace that provides for format and content conversion of APL/360 and APLSV workspaces.

The existence of a S/370 APL Assist feature in the system will not be functionally apparent to the terminal user. A performance improvement in interpreting APL statements may be obtained by utilizing the S/370 APL Assist feature.

DESCRIPTION

VS APL runs under the following systems:

- Customer Information Control System (CICS/VS),
- Time Sharing Option (TSO),
- Virtual Storage Personal Computing (VSPC), and
- VM/370 Conversational Monitor System (CMS).

VS APL provides a shared variable facility that allows APL users to communicate with non-APL programs called auxiliary processors, that operate outside the APL environment. Several auxiliary processors are distributed with VS APL. This auxiliary processor concept provides a method of extending the capability of the APL environment. Installation-supplied auxiliary processors can provide the customer with other specific capabilities. APL users under CICS/VS and VSPC can also communicate with other APL users via the shared variable facility.

VS APL consists of the following:

- VS APL Interpreter - interprets and executes APL statements.
- Executors - provide environment-dependent services for the interpreter, such as access to libraries and terminal input and output. One each is provided for CICS/VS, TSO, VM/370 CMS and VSPC.
- Auxiliary processors - provide functions outside of the APL workspace environment.
 - Under CICS/VS ten auxiliary processors are provided. Three auxiliary processors provide selected data management services for APL files, VSAM files, ISAM files and DL/I data bases. Other auxiliary processors allow a user to request a subset of CICS/VS services, display certain areas of main storage, read and write data in CICS/VS transient data destinations, and specify an APL command or statement that will be executed when evaluated terminal input is next requested. Two auxiliary processors provide the application control of the 3270 display facilities; one adds graphic data display capabilities, including color, programmed symbols and extended highlighting, by using the Graphical Data Display Manager (GDDM), program product 5748-XXH. Another auxiliary processor communicates with the VS APL session manager so that APL applications can issue commands to control the session and the screen.
 - Under TSO, nine auxiliary processors are provided. Auxiliary processors provide selected data management services for VSAM files, OS files supported by QSAM and unkeyed, relative record, fixed length files supported by BDAM. They also provide the capability for an APL application to specify an APL command or an APL statement that will be executed when terminal input is next requested, to issue TSO commands and to display alphameric and graphic data including color, programmed symbols, and extended highlighting, by using GDDM. Another auxiliary processor communicates with the VS APL session manager so that APL applications can issue commands to control the session and the screen. An auxiliary processor allows APL data to be written to auxiliary storage.
 - Under VM/370 CMS, eight auxiliary processors provide selected data management services for CMS files, VSAM files and OS files supported by QSAM. They also provide the capability for the APL application to specify the data to be accepted as terminal input when terminal input is next requested, to pass commands to CMS for execution, and to display alphameric and graphic data including color, programmed symbols and extended highlighting, by using GDDM. Another auxiliary processor communicates with the VS APL

session manager so that APL applications can issue commands to control the session and the screen. An auxiliary processor allows APL data to be written to auxiliary storage.

- Under VSPC, eight auxiliary processors provide selected data management services for VSPC library files and VSAM files maintained by the operating system, and two auxiliary processors provide for application control of the 3270 display facilities. One of the 3270 display control auxiliary processors adds graphic data display capabilities including color, programmed symbols and extended highlighting, by using GDDM; the operation of this auxiliary processor requires VSPC Version 2. They also provide the capability for the APL application to specify the data to be accepted as terminal input when terminal input is next requested, to pass commands to VSPC for execution and display certain areas of main storage.

- Shared Storage Manager - manages the communication between the interpreter and auxiliary processors. (For VS APL under VSPC, this is a component of VSPC.)
- Conversion Aids - facilitate migration of installations that wish to convert libraries and functions developed under certain other IBM APL products.
- Workspaces - contain various functions useful to installations. One workspace provides extensive graphics functions.

The VS TSIO auxiliary processor is available as program product (5740-XR9) for use with VSPC. VS TSIO accepts commands through shared variables and makes available to the APL application many of the data management facilities of the OS/VS operating system.

HIGHLIGHTS

- Offers interactive use of computers to enhance productivity in application development.
- Can be installed under CICS/VS, TSO, VM/370 CMS and VSPC.
- Utilizes the S/370 APL Assist feature when available.
- Supports the 3270 and 3767 APL features.
- Supports the 3232 APL functions.
- Supports ASCII terminals with APL special characters under VSPC, VM/CMS with VM System Product (Release 2), and under TSO with VTAM/NTO.
- Includes dynamic program control of error handling.
- Provides 3270 full screen management facilities.
- Provides access to VSAM files.
- Provides access to DL/I data bases (CICS/VS only).
- Allows for variable sized workspaces as required by the specific application.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

VS APL Release 4 is designed to operate on the following IBM processors:

- The System/370
- The 43XX processors
- The 30XX processors

The processor must have sufficient storage to meet the combined storage requirements of the host operating system, access methods, DB/DC or interactive subsystem, VS APL (including the installed auxiliary processors), and GDDM when used. The floating point feature is required for both GDDM and VS APL.

Terminal support for VS APL is provided by the host subsystem. The IBM 3767, IBM 3270 and IBM 8775, where supported, require the appropriate APL feature for terminal users who need to enter or display the APL special characters. Under VM/CMS, VS APL uses the virtual console of the CMS virtual machine as the terminal device.

Support for the 3232-11: Support for the 3232-11 attached to the 8100 Information System Processor is provided by DPPX/DSC.

For CICS/VS, only terminal services from VTAM, ACF/VTAM, or BTAM are supported. The supported terminals are IBM 3270 and 8775 displays (operating with at least an 80-character width) and printers attached to IBM 3270 control units or to IBM 3790 (displays as Logical Unit type 2 and printers as Logical Unit type 3). NOTE: The IBM 3790 does not support the APL or TEXT features. BTAM supports only non-SNA terminals.

For TSO, start/stop terminal support is through ACF/VTAM Version 1 or ACF/VTAM Version 2 and NTO.

VS APL Rel 4.0 (cont'd)

SOFTWARE REQUIREMENTS

VS APL is distributed in Assembler language (except the APL workspaces which are written in APL). The IBM proprietary language PL/S is used to produce the assembler source for some of the modules. VS APL operates under the following systems (minimum release is indicated):

- CICS/DOS/VS (5746-XX3) Version 1 Release 5 (VS APL under CICS/DOS/VS requires VSAM and VTAM, ACF/VTAM or BTAM. VS APL is not supported under either CICS/DOS/VS subset option or CICS/DOS/VS Entry Level System).
- CICS/OS/VS (VS1 and MVS) (5740-XX1) Version 1 Release 5 (VS APL under CICS/OS/VS requires VSAM and VTAM, ACF/VTAM Version 1 or ACF/VTAM Version 2 or BTAM).
- VM/System Product (5664-167) or VM/System Extensions Release 2 (5748-XE1) or VM/Basic System Extensions Release 2 (5748-XX8).
- VSPC-OS/VS1 Release 2 (5740-XR5) (note that the GDDM auxiliary processor and direct access to VSAM entry sequenced data sets is not supported in this environment).
- VSPC-OS/VS2 Release 2 (5740-XR6) (note that the GDDM auxiliary processor and direct access to VSAM entry sequenced data sets is not supported in this environment).
- VSPC Version 2 Release 1 (5665-283) (note that the GDDM Interactive Chart Utility, the Release 3 functions and some of the Release 2 functions are not available in this environment).
- TSO-MVS Release 3.8.

Note: Later versions, releases and modifications are supported, unless explicitly stated otherwise. Certain configurations may require a release later than the minimum release.

The Graphical Data Display Manager (GDDM) (5748-XXH) is required in order to use:

- The VS APL Session Manager under CMS or TSO
- The VS APL Session Manager Command auxiliary processor (AP 120) under CMS or TSO
- The GDDM auxiliary processor (AP 126)
- The GRAPHPAK workspace

Under VM/370 CMS, use of the auxiliary processor which interfaces to GDDM requires the VM/System Product (5664-167). GDDM is not supported by VM/System Extensions or by VM/Basic System Extensions.

Under VM/370 CMS, use of ASCII coded terminals requires the VM/System Product Release 2 (5664-167).

Use of GDDM Release 3 with TSO requires ACF/VTAM Version 1 Release 2 or Release 3 or ACF/VTAM Version 2 or ACF/VTAM Version 2 Release 4 or later releases. Use of the GDDM Interactive Chart Utility and the functions added with GDDM Releases 2 and 3 requires GDDM Release 3. Under VSPC, use of the GDDM auxiliary processor requires GDDM Release 2.

Use of NTO in the TSO environment requires ACF/VTAM Version 1 Release 2 or Release 3 or ACF/VTAM Version 2.

Use of the DL/I auxiliary processor (AP 125) under CICS/DOS/VS requires DL/I DOS/VS (5746-XX1).

SYSTEM CONFIGURATION: In a virtual storage environment, the amount of real storage required depends on the level of performance desired. For VS APL, the real storage requirements depend on a number of factors that include:

- S/370 processor model and operating system.
- Tuning parameters.
- Characteristics of device used for paging and library storage.
- Level and type of foreground and background activity.
- Size of VS APL workspaces.
- Shared Variable storage requirements.
- Number and level of activity of auxiliary processors.

If installed, the APL Assist feature for the S/370 mdls 135 and 145 requires additional control storage.

Terminals that are functionally equivalent to those specifically supported may also function satisfactorily. The customer is responsible for establishing equivalency. IBM assumes no responsibility for the impact that any changes to the IBM-supplied programs or products may have on such terminals. **Note:** The auxiliary processors provided with the CICS/VS environment do not support the Intersystem Communication facility of CICS/VS Version 1 Release 4.

STORAGE REQUIREMENTS: The main storage requirements to install VS APL depend on the method of installation, and the method of installation depends on the operating system.

Under OS/VS operating systems, the System Modification Program (SMP) Release 4 is used to install VS APL. See the *OS/VS System Modification Program (SMP) System Programmer's Guide (GC28-0673)* for more information on SMP. The auxiliary storage estimates for SMP data sets are in the following section. Auxiliary storage is required during installation and maintenance.

Under the DOS/VSE operating system, the Maintain System History Program (MSHP) is used. See the *VSE/Advanced Functions Maintain System History Program User's Guide (SC33-6101)* for more information.

Under VM/370 (CMS), the Program Level Change (PLC) procedure is used to install VS APL.

When installation is completed, permanent files containing the VS APL load modules, tables, and the VS APL library (or libraries) remain in auxiliary storage. The requirements for these files are discussed in the following section.

The amount of space required on storage devices for the load modules, tables, and the VS APL library (or libraries) depends on the devices and access methods used and the size and number of workspaces and files in the library. The following table provides an estimate of the number of bytes required by VS APL. The size given for the VS APL library includes only those workspaces provided with VS APL.

	CICS/VS	TSO	VSPC	CMS
Load modules and tables	700K	1,000K	220K	1000K
VS APL library	1000K	1000K	1000K	1000K
SMP data sets	1200K	1000K	1000K	NA

The storage estimates presented in this section are those to run VS APL with the VS APL Session Manager active, (except VSPC), one user having a workspace size of 96K bytes, and all the auxiliary processors provided with VS APL available, but not being used. Use of the auxiliary processors increases these estimates depending on which auxiliary processors are used and how they are used. For example, using the APL Data File auxiliary processor in CMS requires additional virtual storage for each record processed; the amount of additional virtual storage depends on the size of the APL object.

Not included in these estimates is storage required by operating systems, subsystems, other programs used in the course of processing VS APL requests, or other programs used by VS APL (such as the Graphical Data Display Manager).

CICS: Under CICS/VS, the virtual storage required to install and run VS APL consists of the VS APL specific requirements. VS APL requires 256K bytes of virtual storage for installation, and 350K bytes of virtual storage to operate. Each user who signs on requires approximately an additional 50K bytes of virtual storage (assuming no auxiliary processors are used) plus the workspace size (a multiple of 32K bytes). VS APL for CICS/VS under DOS also requires 2K bytes of fixed real storage. Virtual storage requirements for the auxiliary processors depend on the number of users of an auxiliary processor, and the buffer sizes used for passing data and control information. The shared storage manager, when active, requires a minimum of 20K bytes of virtual storage. These VS APL storage requirements are in addition to the virtual storage required by CICS/VS and GDDM, if used.

VSPC: Under VSPC, the virtual storage required to install and run VS APL consists of the VS APL specific requirements, the GDDM requirements, and the VSPC requirements. VS APL requires 256K bytes of virtual storage for installation and 212K bytes of virtual storage to operate. This VS APL requirement is in addition to the VSPC interactive environment requirements. In OS/VS2, 212K bytes per VSPC dependent address space is required for operation. If VS APL is placed in the system link pack area, only 212K bytes are required for operation.

CMS and TSO: Under CMS and TSO, VS APL can be installed so that the VS APL load modules can be shared between users of the same subsystem. The virtual storage requirements can be reduced if this is done. The virtual storage estimates that follow assume VS APL has been installed without shared VS APL load modules.

VS APL under CMS - 1,000K bytes
VS APL under TSO - 1,000K bytes

The additional virtual storage required by each additional user who signs on to VS APL is summarized in the following table:

TSO and CMS	
Load Modules shared	Shared module size is 400K. Virtual storage for one user minus the number of bytes of the shared load modules, plus/minus the difference in workspace size from 96K bytes.
Load Modules not shared	Virtual storage as for one user, plus/minus differences in workspace size from 96K bytes.

PROGRAM PRODUCTS

**3650 PROGRAMMABLE STORE SYSTEM
POS APPLICATION/RETAIL ENVIRONMENT PROGRAM
VERSION 1, RELEASE 2.1
5748-D14**

PURPOSE

The IBM 3650 Programmable Store System POS Application/Retail Environment program product provides basic controller and POS terminal application programs necessary to perform sales and nonsales functions for the retail environment.

The IBM Programmable Store System POS Application/Retail Environment programs are written in IBM Subsystem Program Preparation Support II (SPPS-II) giving the user flexibility to make program alterations. All options provided are selected by specifying choices and altering data values. If the IBM provided functions do not completely satisfy the user's particular needs, the programming capabilities of SPPS-II may be used to further customize the program.

This program will execute on the IBM 3651 controller mdls A25, B25, A75, B75, C75, D75 and the IBM 3653 Point-of-Sale Terminal mdl 1P and/or the IBM 3683 Point-of-Sale Terminal attached to the 3651 Controller. This program product is licensed at the IBM 3650 Store Controller and is assembled on a host system which can run under DOS/VSE, OS/VS1, or OS/VS2. The assembled program is then transmitted to the IBM 3650 Programmable Store System where all program execution takes place. A prerequisite is the IBM subsystem Program Preparation Support II (SPPS II) program product (5735-D16).

HIGHLIGHTS

- Retail sales functions for entries from the point-of-sale Terminal keyboard and/or wands.
- Multiple item pricing in any merchandise or modify-ticket entry.
- Accumulation of totals for a sales transaction and a sales period including:
 - Gross Plus
 - Gross minus
 - Net cash
 - Net non-cash
 - Transaction count (the Totals Retention Feature is required).
- Printed output at the point-of-sale terminal on the receipt tape, journal tape and/or document insert station.
- Facilities for controlling the sign on to selected functions by authorized personnel.
- Use of data files including:
 - Item Record
 - Check Verification
 - Operator/Terminal Accounting Totals
 - Department Totals
 - Item Movement (flash item totals)
 - Operator Authorization
 - Credit
- Use of a transaction log file for recording selected events.
- Nonsales facilities for recording in the accounting totals the monetary exchanges external to sales, transaction corrections, and procedures for assisting the operator in reconciling the tender in the tills.
- An in-store common data maintenance facility that provides access to the data files in the store controller to add, change, or delete records such as item records, credit, authorization records, and other user defined keyed files.
- In-store facility for changing selected program options, values, and descriptors without host processor intervention.
- In-store facility for accessing and/or clearing the item movement data.
- Set time and date facility.
- Support for off-line operation of the POS terminal.
- Support for selective initial program loads, which allows each terminal to be personalized to perform specialized retail store functions.
- Support for system control functions such as terminal status inquiries, system quiesce, and three types of totals readout and/or reset.
- Additional optional functions are described in such a manner that the user can incorporate these functions into a retail store system using SPPS-II programming.

CUSTOMER RESPONSIBILITIES

- Install the IBM 3650 Programmable Store System Host Support to:
 - Define and maintain the subsystem library (SLIB) and the data sets necessary to support the programmable store system.
 - Create the operational environment that will control the functions of the store controller and the terminals.
 - Provide communications between the host and the store controller to load the application programs and to recover application program dumps.
- Install the IBM Subsystem Program Preparation Support II (SPPS-II) program product.
- Place the IBM 3650 Programmable Store System POS Application/Retail Environment program release into a predefined data base.
- Select IBM extended functions.
- Customize source code as desired by providing user-written code.
- Assemble and link edit the IBM 3650 Programmable Store System POS Application/Retail Environment Program.
- Perform application definition.
 - Use the Programmable Store System Host Support to:
 - Create Application Definition Records.
 - Create Application Load Lists(s) (terminal).
 - Create Load initial tables to associate a load to a terminal address.
 - Assemble macro statements.
- Generate user files as required. For example:
 - Item Record
 - Check Verification
 - Operator Authorization
- Load the Store Controller.
 - Via IBM 3650 Programmable Store System Host Support:
 - Application Definition Record
 - IBM 3650 Programmable Store System POS Application/Retail Environment programs
 - Via user-provided transmission program:
 - Initialize user files

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The IBM 3650 Programmable Store System POS Application/Retail Environment program product is designed to operate with the following store system configuration as a minimum:

Controller: IBM 3651 mdl A25, A75, B25, B75, C75, D75 with 60K storage.

Terminal: One IBM 3653-1P Point-of-Sale Terminal with 36K storage and/or one IBM 3683-1 Point-of-Sale Terminal with 40K storage.

Host Communication: One IBM 3872 or equivalent modem

Additional storage capacity may be required in the store controller and/or terminal depending on the extended functions and options selected, the configuration, and the combinations of nonsales functions. Typical user terminal orders will reflect 44K storage for 3653 POSTs and 48K for 3683 POSTs dependent on application requirements. Storage requirements must be evaluated at the Systems Assurance Review.

SOFTWARE REQUIREMENTS

Host Requirements: This program product is licensed at the IBM 3651 Store controller and is assembled on a host system which can run under DOS/VSE, OS/VS1 or OS/VS2. The assembled program is then transmitted to the IBM 3650 Programmable Store System where all program execution takes place. The IBM Programmable Store System Host Support, BTAM for binary synchronous and VTAM or ACF/VTAM for SDLC are also required.

Programming Language: The IBM 3650 Programmable Store System POS Application/Retail Environment Program is written in the IBM Subsystem Program Preparation Support, II (SPPS-II) language a prerequisite program product (5735-D16).

Controller Environment: The IBM 3650 Programmable Store System POS Application/Retail Environment Program will support the IBM 3651 and 3653 and/or 3683 engineering change levels supported by

PROGRAM PRODUCTS

**3650 PROGRAMMABLE STORE SYSTEM POINT OF SALE
APPLICATION/REPORT CUSTOMIZER PROGRAM
VERSION 1 RELEASE 2
5748-D15**

PURPOSE

The IBM 3650 Programmable Store System POS Application/Report Customizer Program Product provides the user with the capability to prepare customized reports from data accumulated at the IBM Store Controller. Reports may be customized by:

- Specifying the means of selecting what data is to be reported:
 - by controlling which data records are to be read.
 - by the logical testing of data from specified fields within records.
 - by the use of controlled, reiterative processing.
 - by requesting input data from the terminal operator.
- Specifying the format of print images:
 - by indicating constant data.
 - by indicating data field print locations.
 - by controlling line spacing.
- Specifying output locations:
 - by controlling at which stations the output should be printed on the IBM 3663P or 3683 Supermarket Terminal.
 - or by specifying to which file the output should be spooled for later use.

This program will execute on the 3651 Controller (mdl A25, B25, A75, B75, and on the 3663 Terminal (mdl 1P, 3P), and/or 3683 Terminal (mdl 1, 1A, 2, 2A, 3, 3A).

HIGHLIGHTS

The program product may be used to produce reports such as:

- Cash Reports.
- Department Analysis Reports.
- Operator Performance Reports.
- Miscellaneous Transaction Recap Reports.

Two user-created Store Controller files are required. Report printing is operator initiated at the terminal.

CUSTOMER RESPONSIBILITIES

Assuming an operational 3650 PSS supermarket application system:

- Place the IBM 3650 Programmable Store System POS Application/ Report Customizer Program release into a predefined data base.
- Assemble and link edit the IBM 3650 Programmable Store System POS Application/Report Customizer Program.
- Construct a Report Specification File.
 - Name and describe each report.
- Construct a Print Format File.
 - Describe each report's output.
- Load the Store Controller.
 - Via IBM 3650 Programmable Store Systems Host Support
 - IBM 3650 Programmable Store System POS Application/Report Customizer Program
 - Via user-provided transmission program
 - Report Specification File
 - Print Format File
 - Initiate reports at terminal
 - Use IBM-provided operator guidance

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The IBM 3650 Programmable Store System POS Application/Report Customizer Program Product in a supermarket store environment is designed to operate with the following store system configuration as a minimum:

- Controller:** IBM 3651 mdl A25, B25, A75, B75, C75, D75; with 60K storage.
- Terminal:** One IBM 3683 mdl 1 Point of Sale Terminal with 32K bytes of storage and journal printer or 3683 mdl 1A, 2, 2A, 3, or 3A Point of Sale Terminal with 56K bytes of storage and journal

printer; or one IBM 3663-1P Supermarket Terminal or IBM 3663-3P Supermarket Terminal with an attached IBM 3663-2 Supermarket Terminal attached to the mdl 3P with 36K bytes of storage.

Host Communication: For IBM Controllers: 3651 mdl A25, B25, A75, B75, C75, D75. One IBM 3872 or equivalent modem over a switched or leased line. One 3669 Store Communications unit with the 3669 attachment feature over a switched line.

Backup: For IBM controllers: 3651 mdl A75, B75, C75, D75 with a 3669 attachment feature. One IBM 3669 Store Communications Unit (per store).

Additional storage capacity may be required in the Store Controller and/or terminal, depending upon the application programs and/or terminal configuration.

The IBM 3650 Programmable Store System PSS Application/Report Customizer Programmer's Guide, available with the IBM 3650 Programmable Store System POS Application/Report Customizer Program, may be used to estimate the real main storage requirements of the IBM 3650 Programmable Store System POS Application/Report Customizer Program for each customer system.

SOFTWARE REQUIREMENTS

Host Requirement: This program product is designed to be assembled on a System/370 or 4300 host processor with storage sufficient to accommodate DOS/VSE, OS/VS1 or OS/VS2 (MVS). Also used is the IBM 3650 Programmable Store System Host Support System Control Program which utilizes VSAM and, for transmission of this program product to and from the IBM 3650 Programmable Store System, BTAM for binary synchronous and VTAM or ACF VTAM for SDLC. All execution of this program product code takes place on the IBM 3650 Programmable Store System.

Programming Language: The IBM 3650 Programmable Store System POS Application/Report Customizer Program is written in the IBM subsystem Program Preparation Support II (SPPS-II) Program Product language, a co-requisite Program Product.

Controller Environment: The IBM 3650 Programmable Store System POS Application/Report Customizer Program will support the IBM 3651, 3663P and 3683 PSS engineering change levels supported by the latest current level of the IBM 3650 Programmable Store System Host Support and SPPS-II programs.

PROGRAM PRODUCTS

**3650 PROGRAMMABLE STORE SYSTEM
POINT OF SALE APPLICATION/
SUPERMARKET ENVIRONMENT PROGRAM
VERSION 1 RELEASE 2
5748-D21**

PURPOSE

The 3650 Programmable Store System POS Application/Supermarket Environment program product provides the basic controller and supermarket terminal application programs necessary to perform the checkout and accounting functions for the supermarket store environment similar to those provided in the 3660 Supermarket Scanning and Key Entry Systems.

The 3650 Programmable Store System POS application/Supermarket Environment program product is written in the Subsystem Program Preparation Support II (SPSS II) program product language, allowing the user to select options and make additions and deletions to functions. Options are selected by specifying choices. Extended Functions require program alterations as described by IBM as part of the documentation that accompanies this application program product, or require user programming in order to be implemented. If the IBM provided options and Extended Functions do not completely satisfy the user's particular needs, the programming capabilities of SPSS II may be used to further customize the program.

This program will execute on the 3651 Controller (mdl B25, A75, B75, C75, D75) and on the 3663 Terminal (mdl 1P, 3P), and/or the 3683 Terminal (mdl 1, 1A, 2, 2A, 3, 3A).

HIGHLIGHTS

A partial list of the functions provided by this program product are described below. Individual capabilities are implemented as combinations of the base program and Extended Function(s), unless specifically identified as base program only or Extended Function only.

- Customer checkout sales functions for scanned and/or keyed input at the supermarket terminals.
- Facility for controlling the sign-on to selected functions by authorized personnel only.
- Use of data files for item record lookup, check verification, check list, operator/terminal and store accounting totals, miscellaneous transactions, operator performance data, department totals, department totals by operator, item movement, and operator authorization.
- Use of a Transaction Log File for recording selected events for further processing.
- An accounting package that provides facilities for recording in the accounting totals the monetary exchanges external to sales, for closing accounting periods, and for assisting the operators in reconciling the tender in the tills for the accounting period.
- An in-store common data maintenance facility that provides access to the data files in the store controller to add, change, or delete records such as: item records, check verification records, operator authorization records, and other user defined files.
- In-store facility for changing selected program options, values, and descriptors without host processor intervention.
- In-store facility for accessing and/or clearing item movement data.
- Station monitoring for training and security uses. (Extended Function only)
- Shelf label preparation. (Base program only)
- Set date and time facility.
- Training mode for operator training.
- Facilities to help ensure the availability of the customer functions:
 - transfer from one terminal to another
 - Transfer checkout scanning and key entry functions, including backup reconciliation and item record lookup, via telephone communication, to the companion controller at another store. (Base program only)
 - Utilize terminal standalone mode (Extended Function only)
- Support for selective initial program loads, which allows each terminal to be personalized to perform specialized supermarket functions. (Base program only)
- Support for system control functions, such as terminal status inquiries and system quiescence. (Base program only)
- Additional Extended Functions described in the program documentation can be selected by the user to incorporate these functions into his supermarket system.

CUSTOMER RESPONSIBILITIES

- Install the IBM 3650 Programmable Store System Host Support to:
 - Define and maintain the subsystem library (SLIB) and the data sets necessary to support the supermarket store subsystem.
 - Create the "operational environment" that will control the functions of the store controller and the terminals.
 - Provide communications between the host and the store controller to recover application program dumps.
- Install the IBM Subsystem Program Preparation Support II (SPSS II) Program Product.
- Place the IBM 3650 Programmable Store System POS Application/ Supermarket Environment Program release into a predefined data base.
- Modify and customize the base application, as desired.
 - Insert and delete source code via IBM Extended Functions and/or user-written modules.
- Assemble and link edit the IBM 3650 Programmable Store System POS Application/Supermarket Environment Program.
- Perform application definition.
 - Use the Programmable Store System Host Support to:
 - Create an Application Definition record.
 - Create Application load list (terminals).
 - Create load ID table to associate a load to a terminal address.
 - Assemble macro statements.
- Generate user files as required (examples):
 - Item Record
 - Check Verification
 - Operator Authorization
- Load the Store Controller
 - Via IBM 3650 Programmable Store Systems Host Support
 - Application Definition Record
 - IBM 3650 Programmable Store System POS Application/Supermarket Environment Program
 - Via user-provided transmission program
 - Initialize user files

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The IBM 3650 Programmable Store System POS Application/Supermarket Environment Program Product is designed to operate with the following store system configuration as a minimum:

- Controller:** IBM 3651 mdl A75, B25, B75, C75, D75; with 60K storage.
- Terminal:** One IBM 3663-1P Supermarket Terminal with 42K bytes of storage or one IBM 3663-3P Supermarket Terminal with 42K bytes of storage with an IBM 3663-2 Supermarket Terminal attached to the mdl 3P. If scanning is to be performed, one IBM 3667 checkout scanner is also required, (applies only to the mdl 1P), or one IBM 3683 mdl 1, 2 or 3 Terminal with 56K bytes of storage and journal printer, or one IBM 3683 mdl 1A, 2A, or 3A Terminal with 56K bytes of storage and journal printer and one IBM 3687 checkout scanner if scanning is desired.
- Host Communications:** For IBM Controllers: 3651 mdl B25, A75, B75, C75, D75. One IBM 3872 or equivalent modem over a switched or leased line. One 3669 store communications unit with the 3669 attachment feature over a switched line.
- Backup:** For IBM Controllers: 3651 mdl A75, B75, C75, D75 with a 3669 attachment feature. One IBM 3669 Store Communications Unit (per store).

Additional storage capacity may be required in the store controller and/or terminal, depending on the extended functions and options

PROGRAM PRODUCTS

Supermarket Environment Program (cont'd)

selected, the configuration, and the existence of user application programs.

The *IBM 3650 Programmable Store System POS Application/Supermarket Environment Programmer's Guide*, may be used to estimate the real main storage requirements of the IBM 3650 Programmable Store System POS Application/Supermarket Environment Program for each specific customer system.

SOFTWARE REQUIREMENTS

Host Requirement: This program product is designed to be assembled on a System/370 or 4300 host processor using DOS/VSE, OS/VS1, or OS/VS2 (MVS) Operating Systems. Also used will be the IBM 3650 Programmable Store System Host Support System Control Program which utilizes VSAM and, for transmission of this program product to and from the IBM 3650 Programmable Store System, BTAM for binary synchronous and VTAM or ACF VTAM for SDLC. All execution of this program product code will take place on the IBM 3650 Programmable Store System.

Programming Language: The IBM 3650 Programmable Store System POS Application/ Supermarket Environment Program is written in the IBM Subsystem Program Preparation Support II (SPPS-II) Program Product Language, a corequisite Program Product.

Controller Environment: The IBM 3650 Programmable Store System POS Application/ Supermarket Environment Program will support the IBM 3651, 3683 and 3663P PSS engineering change levels supported by the latest engineering change levels supported by the latest current level of the IBM of the 3650 Programmable Store System Host Support and SPPS-II programs.

PROGRAM PRODUCTS

**3650 PROGRAMMABLE STORE SYSTEM
POINT OF SALE APPLICATION/
STORE DATA MANAGEMENT
VERSION 1 RELEASE 3
5748-D22**

PURPOSE

The IBM 3650 Programmable Store System Point of Sale Application/Store Data Management Program is a store controller Program Product which aids in the building and maintenance of user files in the store controllers.

The IBM 3650 Programmable Store System POS Application/Store Data Management Program complements the present host command processor capabilities. The ability is provided to have a delayed file maintenance procedure, as opposed to an immediate file change upon transmission from a host processor to a store controller. Also included is the capability to execute a data transmission function that synchronizes the files in a primary and a companion store controller.

This Program will execute on the 3651 Controller, (mdls A25, B25, A75, B75, C75, D75) and on the 3663 Terminal (mdls 1P, 3P) and/or 3653 Terminal (mdl 1P) and/or 3683 Terminal (mdl 1, 1A, 2, 2A, 3, 3A) attached to the 3651 Controller. The Program is designed to be assembled on a S/370 or 4300 host processor operating under DOS/VSE, OS/VS1 or OS/VS2 (MVS). A prerequisite is the IBM Subsystem Program Preparation Support II Program Product, 5735-D16, the language in which this program is written.

HIGHLIGHTS

- Provides extensions to Host Command Process Capabilities:
 - Read records in a sequential file.
 - Read a group of records based on a search argument.
 - Modify fields within records.
 - Generate report data from records and reset reported fields or records.
 - Report item movement by item code.
- Provides Delayed File Maintenance:
 - Via system time of day and hour.
 - Via system time recurrence daily at a specified hour or weekly at a specified day and hour.
 - Operator controlled maintenance.
- Provides Data Synchronization with a Companion Store Controller:
 - Creation of synchronous file from file maintenance procedure.
 - Capture of in-store item record changes.
 - Transmission to and from companion store files.

CUSTOMER RESPONSIBILITIES

Assuming an operational 3650 PSS supermarket application system:

- Place the IBM 3650 Programmable Store System POS Application/Store Data Management Program release into a predefined host data base.
- Assemble and link edit the IBM 3650 Programmable Store System POS Application/Store Data Management Program.
- Load the Store Controller.
 - Via IBM 3650 Programmable Store System Host Support IBM 3650 Programmable Store System POS Application/Store Data Management Program.
- Via user-provided transmission program:
 - Create Process Request Block(s),
 - Create source files (with necessary change file data) the format is dictated by the type of file process,
 - Create report data request files,
 - Modify the Data Set Name Table to include the above three file types,
 - Send the source files to the store controller and add the Process Request Block for the applicable source files.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The IBM 3650 Programmable Store System POS Application/Store Data Management Program Product is designed to operate with the following store system configuration as a minimum supermarket environment:

- Controller** IBM 3651 mdl A25, B25, A75, B75, C75, D75; with 60K storage.
- Terminal** One IBM 3683 mdl 1 Point of Sale Terminal with 32K bytes of storage or IBM 3683 mdl 1A, 2, 2A, 3, or 3A Point of Sale Terminal with 56K bytes of storage or one IBM 3663-3P Supermarket Terminal with an attached IBM 3663-2 Supermarket Terminal attached to the mdl 3P; with 36K bytes of storage.
- Host Communications** For IBM Controllers: 3651 mdl A25, B25, A75, B75, C75, D75. One IBM 3872 or equivalent modem over a switched or leased line. One 3669 Store Communications unit with the 3669 attachment feature over a switched line.
- Backup** For IBM Controllers: 3651 mdl A75, B75, C75, D75 with 3669 attachment feature. One IBM 3669 Store Communications Unit (per store).

The following store system configuration is the minimum for a retail environment:

- Controller** IBM 3651 mdl A25, A75, B25, B75, C75, D75; with 60K storage.
- Terminal** One IBM 3683 mdl 1 Point of Sale Terminal with 32K bytes of storage, or IBM 3653 mdl 1P Point of Sale Terminal with 36k bytes of storage.
- Host Communication** One IBM 3872 or equivalent modem.

Additional Storage capacity may be required in the store controller and/or terminal, depending on the options, configuration and combination of other functions and applications selected.

SOFTWARE REQUIREMENTS

Host Requirement: This program product is designed to be assembled on a S/370 or 4300 host processor with storage sufficient to accommodate DOS/VSE, OS/VS1 or OS/VS2 (MVS) operating systems. Also used is the IBM 3650 Programmable Store System Host Support System Control Program which utilizes VSAM and, for transmission of this program product to and from the IBM 3650 Programmable Store System, BTAM for binary synchronous and VTAM or ACF/VTAM for SDLC. All execution of this program product code takes place in the IBM 3650 Programmable Store System.

Programming Language: The IBM 3650 Programmable Store System POS Application/Store Data Management Program is written in the IBM Subsystem Program Preparation Support II (SPPS-II) program product language, a prerequisite program product.

Controller Environment: The IBM 3650 Programmable Store System POS Application/Store Data Management Program will support the IBM 3651, 3683, 3653 and 3663 PSS engineering change levels supported by the latest current level of the IBM 3650 Programmable Store System Host Support and SPPS-II programs.

This program product utilizes interfaces which are provided by the IBM 3650 Programmable Store System POS Application/ Supermarket Environment Program Product, the IBM 3650 Programmable Store System POS Application/Retail Environment Program Product or by a customer-written application.

PROGRAM PRODUCTS

**VSPC FORTRAN
5748-FO2****DESCRIPTION**

The VSPC FORTRAN processor is a one-pass, reenterable compiler that includes its own library of mathematical, input/output, and service routines. It runs under VSPC (Virtual Storage Personal Computing) under OS/VS1, OS/VS2 (MVS) and DOS/VS. VSPC FORTRAN is a terminal oriented compiler, with performance and ease-of-use as important considerations.

HIGHLIGHTS

- **Terminal entry:** Each user who signs on (logon process) to VSPC is presented his personal workspace in which he can build, manipulate and execute programs. Source programs are entered line-by-line, and errors can be corrected using the versatile commands of the VSPC editing facility. Resulting source programs can be compiled from the workspace in which they were created through the VSPC STORE or RUN commands. If the RUN command is chosen, the program will start execution after compilation.
- **Flexibility:** Simplicity of use makes VSPC FORTRAN suitable for the FORTRAN problem solver. Concerns with system functions are reduced, thereby allowing the user to keep his full attention on the applications and source programs needed to do his job.
- The LINK Processor provides the user with the capability to combine previously compiled object routines from the VSPC FORTRAN library.

In addition, OS object modules may be IMPORTED using the VSPC Service Program after being processed by the utility provided as part of the VSPC FORTRAN LINK processor.

IMPORTED modules are subject to restrictions as described in *VSPC FORTRAN General Information Manual* (GH20-9061).

- The language level of VSPC FORTRAN is that described in *IBM System/360 and System/370 FORTRAN IV Language*, GC28-6515, except that the Debug Facility, the DUMP and PDUMP service subroutines, and extended precision data types are not supported.
- Data exchange with other facilities under VSPC is supported with certain restrictions.

Additional Capabilities Include:

- List-directed input/output, which allows the issuance of READ and WRITE statements without a FORMAT statement.
- Free-form source input, which removes column restrictions and concern with tab settings and margin stops when entering FORTRAN source programs from a terminal. Standard fixed-form source is also accepted by the VSPC FORTRAN compiler; thus many existing FORTRAN programs can be compiled and executed under VSPC without change.
- A system subroutine, OPSYS, provides a means for associating a named VSPC file with a FORTRAN data set reference number and to specify or change the file processing mode. This same subroutine permits one VSPC FORTRAN program to invoke the execution of a second, completely separate, program and allows the second program to retrieve a parameter being passed to it. In addition, the "OPYS" subroutine allows the FORTRAN program to suspend execution for a specified time interval, to execute any command from a large subset of the VSPC command language, and to invoke the GDDM, PGF, and/or VSPC Full Screen Manager to perform screen-oriented applications on terminals of the 3270 Information Display System.

CUSTOMER RESPONSIBILITIES

Each customer installing, operating or supporting VSPC FORTRAN must have a working knowledge of VSPC and OS/VS1, OS/VS2 (MVS) or DOS/VS. No customer should attempt to install VSPC FORTRAN until the installation has achieved proficiency in the use of the operating system.

The customer is responsible for providing adequate protection against accidental loss or misuse of his data. This includes an adequate review of the system's security provisions by the user.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

VSPC FORTRAN operates in the environment provided by VSPC, and has no hardware dependencies in addition to those of VSPC. VSPC FORTRAN has no fixed storage requirement; the real storage required is a function of the performance required.

The virtual storage required to run VSPC FORTRAN consists of the IBM VSPC FORTRAN specific requirements and the VSPC requirements. IBM VSPC FORTRAN requires 132K bytes in addition to the VSPC interactive environment requirements. In OS/VS2 (MVS), 132K bytes per VSPC dependent address space is required. If VSPC FORTRAN is placed in the system link pack area, only 132K bytes are required. See

VS Personal Computing (VSPC) for OS/VS and DOS/VS: General Information (GH20-9070) for a discussion of the configurations of systems that include VSPC.

SOFTWARE REQUIREMENTS

VSPC FORTRAN, which is written in Assembler Language, operates under Virtual Storage Personal Computing (VSPC) in the OS/VS1, OS/VS2 (MVS) and DOS/VS environments. The LINK processor of VSPC FORTRAN is not supported in the DOS/VS environment of VSPC.

PROGRAM PRODUCTS

**VS FORTRAN RELEASE 3.0
COMPILER and LIBRARY (5748-FO3)
LIBRARY only (5748-LM3)**

PURPOSE

VS FORTRAN includes and extends most of the features of the current IBM OS/DOS FORTRAN products (i.e., H Extended, G1, F and their Libraries), it supports the new Standards language for FORTRAN (ANSI X3.9-1978 and ISO 1539-1980) and it provides IBM enhancements designed to improve the usability of this new FORTRAN offering. It is a single product usable in multiple operating systems. It compiles on and its object code runs on the then current release of each supported operating system at the time of availability of VS FORTRAN. Ease of migration is provided by source and object level compatibility with current IBM OS/DOS FORTRAN compilers (i.e., OS FORTRAN G1, OS FORTRAN H Extended and DOS FORTRAN F).

HIGHLIGHTS

- Support of the Standards language for FORTRAN (ANSI X3.9-1978 and ISO 1539-1980).
- Support for the American Standard FORTRAN, X3.9-1966.
- Support of the ANSI/ISA-S61.1-1976 Bit String Manipulation Functions.
- Support for the 31-bit addressing capabilities of MVS/XA.
- Major IBM extensions of current IBM OS/DOS FORTRAN compilers (i.e., OS FORTRAN G1, OS FORTRAN H Extended, the OS FORTRAN Mod II Library, DOS FORTRAN F and the DOS FORTRAN Option 1 Library).
- Support for VSAM ESDS and RRDS data sets and access to SAM Files in VSAM space via Basic Access Method.
- VM/370, DOS/VSE, SSX/VSE, MVS (with or without TSO), MVS/XA (with or without TSO/E), and VS1 support in a single product.
- Batch DEBUG.
- Symbolic batch dump.
- Cross compilation (VM/370, DOS/VSE, MVS and VS1).
- Free form source.
- Source code flagging for conformance to the Full or to the Subset new Standards language for FORTRAN (ANSI X3.9-1978 and ISO 1539-1980).
- Support of top-down programming by providing nested INCLUDE of source code.
- Source and object code compatibility with current IBM OS/DOS FORTRAN compilers: OS FORTRAN G1 (5734-FO2), OS FORTRAN H Extended (5734-FO3) and DOS FORTRAN F (360N-FO-479).
- Compiler and some Library routines are reentrant.
- Optimization levels 1, 2 and 3.
- Interactive Debug support is provided for VS FORTRAN with FORTRAN Interactive Debug (5734-FO5) Release 2.2.

INDUSTRY STANDARDS

VS FORTRAN is designed according to the specifications of the following industry standards as understood and interpreted by IBM as of April 1983:

- American Standard FORTRAN, X3.9-1966.
- International Organization for Standardization ISO R, 1539-1972 Programming Languages-FORTRAN.
- American National Standard Programming Language FORTRAN, ANSI X3.9-1978.
- International Organization for Standardization ISO, 1539-1980 Programming Languages - FORTRAN.
- ANSI/ISA-S61.1 1976 Bit String Manipulation Functions.

SPECIAL CUSTOMER INFORMATION

Support for the 1966 standard language will be provided until at least two years after initial shipment and may be discontinued by IBM upon twelve months' written notice. After discontinuance, only the new Standards language for FORTRAN (ANSI X3.9-1978 and ISO 1539-1980) and IBM extensions will be supported, and subsequent releases of the compiler may not offer the 1966 option.

CUSTOMER RESPONSIBILITIES

To install VS FORTRAN, the user:

- Chooses the default system parameters VS FORTRAN will use.
- Chooses the default compiler parameters for use during each problem program compilation.

- Defines VS FORTRAN libraries to the Operating System being used.
- Sets up and executes SMP4 (for MVS or VS1) or MSHP [for DOS/VSE or SSX/VSE (which uses installation prompters)] or VM/CMS EXECs provided (for VM/370) for compiler and library.
- Uses the sample program provided to test for successful installation.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The VS FORTRAN Compiler, Library and generated object modules are designed to operate on all models of the IBM S/370, IBM 30XX Processors and IBM 43XX Processors where supported by the operating systems listed in the "Software Requirements" section.

Under MVS and OS/VS1, IBM devices supported by access methods (BSAM, BDAM and VSAM) can be used by object modules produced by the VS FORTRAN Compiler when used in conjunction with the VS FORTRAN Library.

Under DOS/VSE with Advanced Functions, the VS FORTRAN device-independent interface supports IBM devices that are transparent through the VSAM interface, the SAM interfaces for non-DASD devices and the SAM/DAM device-independent interface provided by the Basic Access Method. For device and access method support in SSX/VSE, refer to SSX/VSE publications.

Not all features of every device are supported.

As a result of continuing enhancements, the VS FORTRAN Release 3.0 Compiler requires 980K of virtual storage (below the 16MB line) to handle a typical 100-statement FORTRAN source program; because the compiler is reentrant, a single copy can be used by multiple users. This 980K is for the compiler and its work areas only and does not include space for operating system overhead or other programs. Since VS FORTRAN does no page fixing, the minimum real storage for initiating a job is the only real storage requirement. No auxiliary storage is required as there are no work files used.

SOFTWARE REQUIREMENTS

The VS FORTRAN Compiler, Library and generated object modules run the current versions of VM/370 Release 6 (with or without VM/SP), VS1 Release 7, DOS/VSE with Advanced Function Release 3, SSX/VSE Release 2, MVS Release 3.8 (with or without TSO), MVS/SP Version 1 (with or without TSO), and MVS/XA (with or without TSO/E).

SMP4 (for MVS and VS1) or MSHP (for DOS/VSE) are required for installation. NOTE: VM/370 EXECs for installation are provided as part of VS FORTRAN for VM/370 users.

If VSAM sequential or relative record files are processed, one of the following programs is required:

1. Under VM/CMS - program number 5746-AM2
2. Under OS/MVS - program number 5752-VS2
3. Under OS/VS1 - program number 5652-VS1
4. Under DOS/VSE with Advanced Functions - program number 5746-AM2

If the VSE/VSAM feature for managed SAM space is used, then VSE/VSAM feature #6073 (for 1600 bpi) or #6074 (for 6250 bpi) is required.

COMPATIBILITY

Valid source statements written for current IBM OS/DOS FORTRAN compilers (i.e., G1, H Extended and F) are compiled correctly by VS FORTRAN using the 1966 level option. However, programs which use extended precision constants may not compile on DOS/VSE when using hardware without extended precision arithmetic.

Users may choose to compile existing source programs on either the 1966 language level or on the new language level. Language constructs that are supported only with the 1966 level do not compile using the new level option. Also, the new language provides different semantic meaning for some 1966 language constructs. The *Application Programming Language Reference* is supplied to define the incompatibilities between old language and new.

VS FORTRAN's 1966 language level was designed to adhere to the 1966 Standard. OS FORTRAN G1 and H Extended and DOS FORTRAN F are more forgiving of Standards violations. As a result, some invalid programs that run on OS G1, OS H Extended or F may not run on VS FORTRAN.

Current IBM OS/DOS FORTRAN customers may obtain the functions of the existing IBM OS/DOS FORTRAN compilers (i.e., OS FORTRAN G1, OS FORTRAN H Extended, the OS FORTRAN Mod II Library, DOS

PROGRAM PRODUCTS

VS FORTRAN R3 (cont'd)

FORTRAN F and the DOS FORTRAN Option 1 Library), except the following, by using the 1966 level option:

- The TSO "FORTRAN" command, which invokes the TSO FORTRAN Prompter in order to use FORTRAN G1, is not usable with VS FORTRAN. However, VS FORTRAN does run under TSO.
- The functions for bit handling, which are accepted (but not supported) by the FORTRAN H and FORTRAN H Extended compilers when the 'XL' compiler option is selected, are not allowed by VS FORTRAN.
- The automatic precision increase option, supported by FORTRAN H Extended, is not supported by the VS FORTRAN Compiler.

Upward compatibility of object modules generated from valid source programs is provided (i.e., such existing object modules can be link-edited together for execution with object modules produced by VS FORTRAN, and such object modules or new object modules can be executed with the new VS FORTRAN Library). In some cases, additional linkage editor control statements may be required (see *Application Programming Guide*). Processor options of current OS and DOS FORTRAN compilers have been consolidated wherever possible. Where two different option key words are used in OS and DOS for the same option, one common key word is used by the VS FORTRAN compiler. The following options are not supported by VS FORTRAN:

- BCD/EBCDIC - EBCDIC is assumed
- ANSF/NOANSF
- AUTODBL
- ALC/NOALC
- FORMAT/NOFORMAT
- XL

Differences exist between IBM FORTRAN H Extended bit functions and the ISA bit functions in VS FORTRAN. The FORTRAN H Extended bit functions work on logical and integer expressions of various lengths. The ISA functions work only on 4-byte integer expressions. The numbering mechanism for the bits for H Extended is such that bit 0 is the leftmost bit. For the ISA functions, bit 0 is the rightmost bit.

The subject of compatibility between releases of VS FORTRAN covers three aspects: Source programs are compiled into object modules, which when link-edited with the VS FORTRAN Library become VS FORTRAN load modules.

Valid source programs which compiled correctly on prior releases of VS FORTRAN will also do so on Release 3.0.

Existing object modules generated by previous releases of VS FORTRAN are compatible with object modules generated by Release 3.0 but must be link-edited together with the Release 3.0 library. Programs which have been compiled on previous releases of VS FORTRAN and which will be communicating with Release 3.0-compiled programs through CHARACTER arguments must be recompiled on Release 3.0 because of the change in parameter list format when CHARACTER arguments are being passed. Because of this change in passing arguments when CHARACTER data is involved, the SC compiler option will no longer be needed and will not be available.

Existing load modules which take advantage of the reentrant I/O library load module at a Release 2.0 level are compatible with the Release 3.0 reentrant I/O library load module. Those load modules using reentrant I/O modules at a level prior to Release 2.0 must be relinked with the Release 3.0 library.

CONVERSION

No conversion aids or other support are being provided to assist installations moving from current IBM OS/DOS FORTRAN products (i.e., OS FORTRAN G1, OS FORTRAN H Extended and DOS FORTRAN F) to VS FORTRAN due to the following:

- 1966 language option and new Standards language option.
- Source and object module compatibility.

ELECTRONIC PAYMENT SYSTEMS SUPPORT/ CHECK REPORTS 5748-F13

PURPOSE

Check Reports Release 1, Modification level 0 is a new tool for timely management decision making in a bank's check processing operation. The program generates a wide range of statistics, and computes a number of ratios, at a user-controlled frequency.

It is the intent of Check Reports to aid check processing management in its ongoing effort to improve personnel productivity, funds availability and machine utilization. A significant degree of automation in check processing has already been accomplished by two other IBM program products, and Check Reports carries this automation a step further. Either of the two program products serves as the base for Check Reports, depending on the user's operating system. These base program products are:

5734-F11 CPCS/3890: Check Processing Control System with the 3890 Feature, for OS/VS users;

5746-F12 DOSCHECK: Check Processing - DOS/VS, for DOS/VS users.

DESCRIPTION

Utilizing the advanced functional capabilities of the IBM 3890 Document Processor, the base product controls the flow of checks and related documents through each day's full operating cycle. The cycle starts with the initial pass ("prime pass") through the 3890 which captures, sequence-numbers, microfilms and sorts the documents. The cycle ends with the creation of complete files, containing a record for each item processed. These files are known as the ICRE (Input Create) and MCRE (Master Create) files.

Check Reports, operating in batch mode, reads the ICRE and MCRE files at the completion of each day's processing, creates a data base and generates a set of reports.

Check Reports expands its data base with each day's processing until data for a user specified number of days has been recorded. Thereafter, the user can purge the data no longer required. This method of data management enables the user to request, in addition to his regular daily reports, special reports as needed, for any dates or periods (weeks or months) within the past year.

User exit interfaces in Check Reports facilitate the addition of user-supplied function, such as assignment of availability (float), and application split-out. A sample user-exit program is provided for the latter.

HIGHLIGHTS

Check Reports include the following:

Prime Pass Reject Analysis: Rejects are related to total incoming volume, by data and source. Separate statistics are kept for on-us items. Rejects are summarized in seven error categories. Relative frequency of reject types is highlighted by percentages.

Prime Pass Reject Reason Detail: Based on user provided identification, reject counts and percentages can be generated in up to 50 reject reason categories. Examples: Missing amount field, P/C field invalid, account number unreadable. This report is the suggested tool for separating *physical* and *logical* rejects.

Incoming Work and Funds Availability Analysis: Item counts and dollar totals are tallied by date and time within source. Separate totals are provided for High Dollar Items, Credited Dollars and Reject Dollars. Float is summed, based on user input, in seven availability categories.

Endpoint and Funds Availability Analysis: Separate reports summarize item, bundle, dollar and availability totals by *cash letter*, and by *ABA number*. The latter gives the user the facility to scrutinize statistics for up to 12 ABA numbers or ABA groups associated with each endpoint. High Dollar and Low Dollar totals are individually summed.

3890 Document Processor Performance: Separate reports provide statistics on physical units, and their operators. The following is computed for each 3890: Hours in use, total documents, documents per hour, number of jams and jam time.

OLRR Operator and Inscrber Operator Productivity: Separate reports offer production statistics on the work of *OLRR* and *Inscrber* operators, with individual statistics for each operator.

Check Reports supplements the reporting function with two additional features:

History Creation: Each day's summary data remains accessible until purged by the user.

Application Split-Out: A user exit interface gives the application programs of the user the opportunity to create specialized subsets of the data, for the concurrent or subsequent processing of such applications as *DDA*, *Savings*, *General Ledger* and *Christmas Club*.

Check Reports includes a sample program to facilitate this process; the program creates a sample *Daily Balance Recap*.

Check Reports is responsive to unique user requirements, in that it provides several key options to the user:

Source Specification and Grouping: Sources may be *internal*, such as given branches, or teller stations, or inscribers or reader/sorters. They may be *external*, such as selected accounts, or commercial customers, or correspondents or other banks. They may be *grouped*, as well. For example, a *work unit* might be created which includes only a certain set of branch offices or correspondents, because statistics on these sources, viewed as a set, or group, are especially meaningful to the user.

ABA Selection for Endpoint Analysis: Check Reports will generate individual statistics for each specified ABA, immediately following the associated endpoint. ABAs may be grouped to permit a breakout by Federal Reserve district. Groups and individual ABAs may be mixed.

Frequency Control: User supplied control cards determine the frequency of each report. In addition to daily reports, the user can specify any given span of days for any given report, within the past year.

High Dollar, Low Dollar Control: To call *high* dollar items to special attention in both incoming work and endpoint analysis, and to further enhance endpoint analysis with *low* dollar statistics, the user can set his own thresholds for these controls, which can be instrumental in rescheduling work for optimal funds availability.

Summary or Detail Option: The user can elect either or both options with most reports. Summary reports combine data over the period specified. Detail reports furnish data at the lowest level of detail, which varies from report to report. A line item on a detail report may be, for example, an individual cash letter, an individual ABA number and associated statistics for a single day or reject analysis data for one source for one day.

CUSTOMER RESPONSIBILITIES

To obtain full value from Check Reports, it is recommended that the user perform all of the following tasks, including those designated optional:

Write routines which provide the number of days availability (float) for each item, to the *Incoming Work Analysis* and *Endpoint Analysis* report programs. These routines are optional, but in their absence no float information will appear on these reports.

Modify the 3890 stacker select routine, to include the assignment of a specific reason code to each rejected document. This task is optional, but if the user wishes to expand general error *categories* (such as account number error) into specific *error types* (such as account number missing, invalid or unreadable), the task is necessary.

Check Reports:

- Source names and identification codes for Reject Analysis and Incoming Work Analysis
- Titles for Reject Reason Codes
- Endpoint names and codes for Endpoint Analysis
- ABA Numbers and/or Groups for Endpoint Analysis
- High and Low Dollar Thresholds

Encode inscriber operator and machine identification into batch control documents.

Create and maintain the control deck for daily, and/or other periodic initiation of Check Reports. This is the vehicle for specifying all desired reports at the required frequency.

SPECIFIED OPERATING ENVIRONMENT

A customer currently using CPCS/3890 or DOSCHECK, will already have met the system requirements for Check Reports.

HARDWARE REQUIREMENTS

Minimum Configuration: Check Reports will operate on an IBM S/370 115 mdl G or larger, in a DOSCHECK environment, and on an IBM S/370 135 mdl HF or larger in a CPCS environment. In addition to the resource requirements of the operating system used, the following input/output device requirements apply:

Adequate DASD storage to contain the data files, work files and libraries used to install, maintain and operate Check Reports.

Two magnetic tape units for program installation and maintenance. A single tape unit is required for program execution.

A card reader for program installation and maintenance, and for program startup.

A 132-print-position line printer for installation and execution of Check Reports. The program supports one dedicated printer, or, if

PROGRAM PRODUCTS

**Electronic Payment Systems Support/
Check Reports (cont'd)**

operating under OS/VS or POWER/VS, the printer can be shared with jobs in other partitions.

The appropriate system configuration for each user is highly dependent on user volumes, processing techniques, and performance requirements. This configuration information is intended only as a guide. The IBM marketing representative can assist in detailed configuration planning.

SOFTWARE REQUIREMENTS

Check Reports is designed to work with either of these two program products:

5734-F11 CPCS/3890: Check Processing Control System with the 3890 Feature.

5746-F12 DOSCHECK: Check Processing - DOS/VS.

Check Reports, at any given time, will be compatible with the same operating system releases as CPCS/3890 and DOSCHECK. See the CPCS/3890 and DOSCHECK pages.

A customer currently using CPCS/3890 or DOSCHECK will have already met most of the Programming Systems requirements for Check Reports. Only these additional requirements remain to be met:

Virtual Storage Access Method (VSAM)
Access Method Services
OS/VS COBOL and OS/VS COBOL Library, for CPCS/3890
DOS/VS COBOL and DOS/VS COBOL Library, for DOS CHECK

Languages used in Check Reports are COBOL and Assembler. The program is distributed in source form. SCP, data management and support programs, and access methods used are as follows:

In a CPCS/3890 environment:

OS/VS Assembler
OS/VS Linkage Editor
OS/VS COBOL
OS/VS COBOL Library
Virtual Storage Access Method (VSAM)
Access Method Services
Sequential Access Method (SAM)

In a DOSCHECK environment:

DOS/VS Assembler
DOS/VS Linkage Editor
DOS/VS COBOL
DOS/VS COBOL Library
Virtual Storage Access Method (VSAM)
Access Method Services
Sequential Access Method (SAM)

COMPATIBILITY

See "Software Requirements" for a discussion of CPCS/3890 and DOSCHECK compatibility.

CONVERSION

In preparation for conversion, the customer should perform all tasks as described under "Customer Responsibilities".

PERFORMANCE CONSIDERATIONS

The performance of Check Reports is dependent upon many factors, all of which are basically under the user's control.

The performance of VS operating systems in virtual mode is dependent upon such factors as the system resources available, the programs running concurrently and their priorities, the system and application data set placement, the system timing and the DASD devices.

Individual program performance is dependent on the user controlled retention period for the daily summary data saved by Check Reports, and the frequency of user-specified reports which require the access of a large portion of the retained data.

VSAM performance will vary with the processing options selected and the type of processing that occurs. All of these considerations should be given careful attention by the systems programmer at the user installation.

DATA SECURITY

Data security is the responsibility of the user. Users may want to restrict access to the check reports data base. VSAM provides password protection of files against unauthorized use of data. The passwords are specified when the file or catalog is defined.

MVS users may use VSAM password protection, or the Resource Access Control Facility (RACF).

CHECK PROCESSING EXECUTIVE/3694 CHX/3694 (5748-F53)

PURPOSE

Check Processing Executive/3694 (CHX/3694) provides the application and device control functions for the 3694 Document Processor transport and operator interfaces.

HIGHLIGHTS

PROOF OF DEPOSIT/INSCRIBING FUNCTION: Provides for the proving (zero-balancing) and adjustment of deposits and Magnetic Ink Character Recognition (MICR) inscribing of items. Items are distributed to stackers under sort pattern control and optionally listed on distribution list printers. An audit trail for each item processed on the 3694 is printed on the 3694 Master List Printer. Data from the MICR code line and keyed data are captured on the 3694 diskette for later transmission to a Check Processing Executive/Virtual Storage (CHX/VS) program running on a host processor. (See Run Transmission Function.)

DEFERRED DISTRIBUTION LIST FUNCTION: Items previously captured on diskette can be listed on command using this function. The program reads items from the diskette and prints them on the assigned distribution list printer.

MACHINE CLOSEOUT: Provides information about the status of the machine (diskette) on the master list printer. Run summary information includes all machine counters (these show debit, credit and item transmission totals). A hard copy audit trail shows that the machine totals are in balance.

RUN TRANSMISSION: Provides for the transmission of the captured item data periodically during the day. Transmission frequency will be determined by the volume of items captured and by scheduling of transmission times at the CHX/VS location.

FINE SORT: Is used to sequence items into ascending sequence by key where the key is determined from the MICR codeline directly or by table lookup using the codeline data. Two sorting techniques are supported under fine sort: Digit-by-digit sorting (where one item pass is required per digit), and number conversion (where the key is examined as a whole, converted to a different base and a table is used to eliminate the effect of unused or unallocated numbers).

MICROFILMING: Optionally, full-function path and sorter-path items can be recorded on microfilm in duplex format. Frame marks ('Blips') are exposed on film, and the 12-digit item sequence number is also exposed on film.

'PAID' STAMPING: Any sorter-path run can be designated for face-cancelling items as 'PAID'.

RUN DEFINITION: Provides for end-user creation and maintenance of information pertaining to a machine run. Such information may include:

- Machine features to be active, such as
 - Sorter path/full-function path.
 - Item numbering.
 - Inscribing.
 - Microfilming.
 - 'PAID' Stamping.
- Application features
 - Pocket closeout thresholds.
 - Machine closeout counters.
 - Endpoint number assignment.
 - Identification of the user-written document validation exit routine to be used for on-us item editing.

PRE-ENCODED CAPTURE FUNCTION: Uses the 3694 sorter path, or full function path with inline corrections, to capture and process items that have been inscribed with MICR data. Inclearings can be processed using this function. Inclearings usually consist of fully inscribed debits that have been processed at other banks but which are drawn on-us.

CORRECTIONS PROCESSING: Complements the sorter path pre-encoded capture function by allowing rejected items to be entered into the system so that reconciliation can be performed. Non-readable rejects are rekeyed and re-edited. Captured data is inspected to determine which batches are out of balance. Exception master lists may be printed for each batch whose control amount still does not zero-balance to the captured item total. The operator can then locate errors and enter corrections for each error item.

CYCLE SORT/EXCEPTION SPLIT: Provides for document distribution under the control of a table supplied by the host. This function facilitates cycle sorting/bulk filing and enables the bank to separate stop-pay suspects and other exceptions identified by the host applications for manual review.

STATEMENT PREPARATION SORT: Provides for the fine sorting of items whose statement cycle has been selected. This function is used in

conjunction with Cycle Sort/Exception Split to facilitate bulk filing of items. Using a table of accounts for which statements have been prepared at the host system, the items corresponding to these statements are arranged in statement sequence.

In addition, when CHX/3694 is operating in a workstation which has a direct communication link to a host processor (as opposed to being attached to another 3694 or 3602 cluster coordinator), the following functions may be performed:

- 3262/3287 Printing - CHX/3694 supports either one 3287 printer or one 3262 mdl 3 or 13 line printer on a 3694 or 3602 communicating directly with an IBM System. Print line images sent from the host processor via OS/VS2 JES2 or JES3 or DOS/VSE VSE/POWER can be printed under operator control. This support is applicable to remote printing of various demand deposit accounting (and other host application) reports.
- Cycle Sort/Fine Sort Preparation - Cycle Sort/Fine Sort Preparation provides for the receipt of table data from the host for use in statement preparation fine sort.

When CHX/3694 operates as a cluster coordinator (3694 or 3602), it provides the following cluster control functions:

- Concentrated Data Transmission - manages the interface between the 3602 and up to eighteen attached 3694s, or between a 3694 and up to four additional attached 3694s. Using this function, data from clustered 3694 workstations can be transmitted through the cluster coordinator to the CHX/VS program in the host processor.
- Department (Cluster) Closeout - is analogous, at a cluster level, to Machine (Diskette) Closeout on a workstation level. Department closeout summarizes various data at the cluster level, including item counts, total debit/credit position and selected operational statistics. Individual machine closeouts must have been completed before the department closeout function can be performed.
- 3262/3287 Printing - CHX/3694 supports either one 3287 printer or one 3262 mdl 3 or 13 line printer on a 3694 or 3602 communicating directly with an IBM System. Print line images sent from the host processor via OS/VS2 JES2 or JES3, or DOS/VSE VSE/POWER can be printed under operator control. This support is applicable to remote printing of various demand deposit accounting (and other host application) reports.
- Cycle Sort/Fine Sort Table Distribution - Allows the cluster coordinator to route the table information to 3694s in the cluster. On demand, the table data is sent to the 3694 performing the sort function.

CUSTOMER RESPONSIBILITIES

To incorporate user-written document validation exit routines into CHX/3694, the user must have access to a system capable of assembling a program using the IBM 3694 Application MACRO Expansions program product; and 2) running the CHX/VS program product that processes the assembly output and transmits the result to CHX/3694.

Assembly of the CHX/3694 source programs (not required for creation of an operational diskette), requires a knowledge of the 3600 Finance Control Language (FCL) in addition to the preceding requirements.

For operation of CHX/3694, customers should follow procedures for program product initialization as specified in the *Program Reference Manual*. Users must supply appropriate parameters to tailor items such as the sort pattern to individual customer requirements. To operate CHX/3694, proof department personnel should be thoroughly familiar with the *3694 Operator's Handbook*.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

CHX/3694 is designed to run in conjunction with Check Processing Executive/Virtual Storage (CHX/VS) (5748-F54).

To install and maintain CHX/3694, the following hardware is required:

- An IBM 3694

To execute CHX/3694, the following hardware is required:

- An IBM 3694
- An IBM 3705, or equivalent integrated communications adapter (only required for communicating to a host computer)

For optional host machine readable material the following hardware is required:

- An IBM processor supporting operation of DOS/VSE, OS/VS1, OS/VS2 (MVS) and the 3600 FCS Host Support program.
- Sufficient direct access storage for the Subsystem Support Services (SSS) libraries to contain the CHX/3694 object modules and 3694 controller data.

CHX/3694 (cont'd)

- One magnetic tape drive unit for installation of the program product.
- One IBM 3694 or 3602 capable of creating an operational diskette image.
- IBM 3705 Communications Controller, or equivalent integrated communications adapter, with storage and features capable of supporting the 3600 Host Support Services diskette creation function.

CHX/3694 supports four levels of operational diskette, three for use on an IBM 3694 and one for use on an IBM 3602. The following chart specifies the four levels and the models supported, required features, optional features, user storage required and control storage required.

Operational Diskette Level	Models Supported	Required Features	Optional Features	Req'd. Addnl. User Storage	Req'd. Addnl. Control Storage
Standalone	All	None	Up to 9 DLPs; Aux. Diskt; DCA; 3262/37; Microfilm; 'PAID' stamp*	None	None
Basic	All	None	Up to 9 DLPs; SDLC Com.; Aux. Diskt; DCA; 3267/87; Microfilm; 'PAID' stamp*	None	None
Cluster	All	SDLC Com.; DCA; CAF; Aux. Dskt; 3262/3287	Up to 9 DLPs; Microfilm; 'PAID' stamp*	1 Incr.	1 Incr.
3602	1A, 1B	SDLC Com.; DCA; Aux. Diskt; FCA; 3262/87	None	3 Incr.	3 Incr.

* 'PAID' Stamp available only on 3684 mdl 2s, and requires Microfilm feature as a prerequisite.

Figure 1. Operational Diskette Levels Supported

Notes:

- 1-Incr. = Increment of Storage. For the 3694 Feature #1007 (Specify #9601 for Control Storage, #9602 for User Storage). For the 3602, storage features are dependent upon the machine configuration; refer to *IBM Finance Communications System Configurator (GA27-2762)*.
- 2-SDLC Comm = SDLC Communications, configuration dependent.
- 3-DCA = Device Cluster Adapter, Feature #3101.
- 4-CAF = Controller Attachment Feature, Feature #4401.
- 5-FCA = Fan Out Communications Adapter, and prerequisites.
- 6-DLP = Distribution List Printer.

To order one of the above pre-configured diskettes from PID, use the feature codes below:

Pre-configured Diskette	Feature No.
Standalone	#9445
Basic	#9145
Cluster	#9245
3602	#9345

To order optional source code for diskette creation together with a pre-configured diskette, select feature #7029 for 9/1600 M tape distribution, or #7031 for 9/6250 M tape.

To order optional source code for diskette creation without a pre-configured diskette, select feature #9001 together with #7029 or #7031 as appropriate.

User storage is used for various tables and user document edit routines required by CHX/3694 document processing functions. Sort pattern size is 7 bytes per routing - transit table entry. The maximum user edit

routine plus the maximum sort pattern size must be smaller than 10K bytes.

SOFTWARE REQUIREMENTS

For installation of the CHX/3694 diskette, or execution of CHX/3694, there are no additional programming requirements. The diskette received from PID is loaded in the primary drive, and the IML operation performed.

To implement a user validation exit routine for use by CHX/3694 during document processing applications, the user may employ the IBM 3694 Application Macro Expansions program product (5748-F56).

For creation of an operational CHX/3694 diskette from the optional tape, and for communicating to the host, the host system requires programming systems as follows: DOS/VSE, OS/VS1 (Release 7), or OS/VS2 (MVS Release 3.8) and subsequent operating system releases, unless otherwise identified. In addition, the following components are required:

- DOS/VSE (DOS/VS Extended).
Either
- ACF/VTAME (5746-RC7)
Or
- Advanced Communications Function for NCP/VS (ACF/NCP/VS), (5735-XX1) and ACF/VTAM Release 2 (5746-RC3)
- VSE/VSAM (5746-AM2).
- 3600 Finance Communication System Host Support Independent Release 7.0 (5747-BR1).
- 3694 Application Macro Expansions (5748-F56)
- OS/VS
- Advanced Communications Function for NCP/VS (ACF/NCP/VS) (5735-XX1).
- Advanced Communications Function for VTAM (ACF/VTAM), (5735-RC2).
- 3694 Host Support Independent Release 7.0 (5748-F56).
- 3694 Application Macro Expansions (5748-F56).

In addition, for creation of the operational diskette from the optional tape, Subsystem Support Services (SSS) is required.

COMPATIBILITY

For inbound (to the host) data transmission and outbound transmission of cycle sort, exception split and statement preparation tables, CHX/3694 is compatible with Check Processing Executive/Virtual Storage (CHX/VS). For outbound (from the host) data transmission, CHX/3694 is compatible with JES2, JES3 and VSE/POWER for the purpose of printing on either a 3287 or 3262 printer attached to a 3694 or 3602.

DATA SECURITY

While ultimate responsibility for security of MICR documents and captured data rests with the customer, CHX/3694 provides for the tracking of all item data changes and corrections, as well as all data transmissions on the 3694 master list printer. Operator identification is associated with all captured data for auditing purposes. Communication sessions may be validated at the CHX/VS processor location through the use of customer-written installation authorization exit routines (an ACF/VTAM facility).

PERFORMANCE CONSIDERATIONS

Document throughput of the 3694 under CHX/3694 control is dependent on the following:

- Operator keying rate.
- Operator document feeding rate.
- Number of out-of-balance conditions.
- Time required to resolve out-of-balance conditions.
- Length of documents (for automatic feed).
- Number of operator interventions due to items such as:
Pocket-full conditions,
Hopper-empty conditions,
Jams.

DOCUMENTATION: (available from Mechanicsburg)

General Information Manual

PROGRAM PRODUCTS

**CHECK PROCESSING EXECUTIVE/VIRTUAL STORAGE
CHX/VS REL.1 (5748-F54)****PURPOSE**

Check Processing Executive/Virtual Storage (CHX/VS) provides host support for transmission of document data captured at an IBM 3694 Document Processor. Additionally, CHX/VS provides a Cycle Sort/Statement Preparation Fine Sort interface to support the related application facilities of Check Processing Executive/3694 (CHX/3694).

CHX/VS may be used to communicate with CHX/3694 (5748-F53) operating in either individual 3694s or in a 3694 or 3602 operating as a cluster coordinator.

HIGHLIGHTS

CHX/VS provides for the receipt and acknowledgement of 3694-transmitted data streams and conversion to user input format.

Using the Virtual Telecommunications Access Method (VTAM), application data (images of documents captured at the 3694) are received, stored on the CHX/VS data base by run, and balanced. Balancing a run involves accumulating control totals during the transmission and comparing those totals to control totals sent from the 3694 in the input stream. An extract facility is provided to reformat captured run data into files comparable to the Input Create files produced by CPCS (5734-F11) and DOS/CHECK (5746-F12). A log file is maintained to provide reconstruction facility for the CHX/VS data base. CHX/VS prepares a network activity journal file which records online event information.

The Cycle Sort/Statement Preparation Fine Sort function provides an interface for user-written host application programs to provide Cycle Sort/Exception data and Statement Preparation Fine Sort data to CHX/3694. Data supplied in the specified format is processed by CHX/VS and the appropriate tables are transmitted to the specified 3694 or 3602 so that the Cycle Sort and Statement Preparation Fine Sort applications can be run.

CUSTOMER RESPONSIBILITIES

CHX/VS will usually be installed in conjunction with CHX/3694. *Program Reference and Operations Manual (CHX/VS)*, and *Program Reference Manual (CHX/3694)* should be read and followed during the installation. User programming may be required to conform to the CHX/VS cycle sort/statement preparation fine sort interface requirements. To operate CHX/VS at the host site, operations personnel should be thoroughly familiar with the *CHX/VS Program Reference and Operations Manual*.

SPECIFIED OPERATING ENVIRONMENT

CHX/VS is designed to operate in conjunction with the IBM CHX/3694 program product operating in an IBM 3694 or 3602.

HARDWARE REQUIREMENTS

The program product requires the following host system configuration:

- Any IBM system having the minimum requirements for DOS/VSE, OS/VS1 or OS/VS2 (MVS) and a virtual partition of 256K to support operation of CHX/VS programs, ACF/VTAM and VSAM.
- Any direct access storage device supported by DOS/VSE, OS/VS1 or OS/VS2 (MVS) for storage of application data.
- A magnetic tape drive unit for installation of the program product.
- IBM 3705 Communications Controller with storage and features capable of supporting ACF/NCP/VS or a comparable integrated communications adapter.
- Availability of a local or remote 3270 display for supervision/control function (CHX/VS does not require a dedicated CRT).

SOFTWARE REQUIREMENTS

CHX/VS requires the following programming systems. CHX/VS operates under DOS/VSE, OS/VS1 (Release 7), OS/VS2 (MVS Release 3.8) and subsequent operating system releases unless otherwise identified. In addition, the following components are required:

- DOS/VSE (DOS/VS Extended).
Either
 - ACF/VTAME (5746-RC7).Or
 - Advanced Communications Functions for NCP/VS (ACF/NCP/VS), (5735-XX1) and ACF/VTAM Release 2 (5746-RC3).
 - VSE/VSAM (5746-AM2).

In addition, the following must be available to prepare CHX/3694 user edit routines which CHX/VS will transmit to the 3694:

- 3600 Host Support Independent Release 7.0 (5747-BR1).
- 3694 Application Macro Expansions (5748-F56).
- OS/VS.
 - Advanced Communications Functions for NCP/VS (ACF/NCP/VS), (5735-XX1).
 - Advanced Communications Functions for VTAM (ACF/VTAM), (5735-RC2).

In addition, the following must be available to prepare CHX/3694 user edit routines which CHX/VS will transmit to the 3694:

- 3600 Host Support Independent Release 7.0 (5744-CA3).
- 3694 Application Macro Expansion (5748-F56).

DATA SECURITY

CHX/VS uses ACF/VTAM functions to communicate with the CHX/VS control terminal. The customer may provide an installation exit routine to ACF/VTAM to perform security/validation checking of the CHX/VS control terminal LOGON requests.

PERFORMANCE CONSIDERATIONS

The performance of CHX/VS is dependent on system resources that are available (including types and models of supported I/O devices, and telecommunication line speeds), paging characteristics, concurrent processing and the particular data being processed.

DOCUMENTATION: (available from Mechanicsburg)

General Information Manual

MVS SYSTEM INTEGRITY APPLIES: Yes

PROGRAM PRODUCTS

**3600 ADMINISTRATIVE APPLICATION SUPPORT
5748-F55**

DESCRIPTION

The IBM 3600 Administrative Application Support program product is a Finance Communication System (FCS) application program which executes in a 3601 or 3602 and provides field oriented operation on the 3604-7 or the 3278-2 attached via the Device Cluster Adapter (DCA 3278). The program supports SLU type 2 communication protocol (SNA 3270) and 3270 formatted datastreams to/from the user host application programs. Local print support is provided to allow printing the display image on a 3615 Administrative Printer.

Use of the 3600 Administrative Application Support program allows existing user applications written for the 3270 keyboard display under CICS/VS or IMS/VS to be implemented on a 3600 FCS without modification to host programs.

HIGHLIGHTS

The program uses the facilities of the Datastream Mapping Macros (DATSM) provided in the 3600 FCS Host Support Programs to provide the following functions:

- Simulate 3270 command orders received from the host.
- Simulate 3270 function keys.
- Simulate 3270 program function keys and program access keys.
- Simulate 3270 attribute byte processing.
- Maintain a screen image buffer.
- Provide the capability of displaying a datastream formatted for a device of one screen size on a device having different screen dimensions (windowing).

In addition to the 3270 commands and function keys simulated via the use of the DATSM macros, the following functions are provided:

- Print the screen image on an available 3615 printer.
- Position cursor to first unprotected field on the screen.
- Enter command processing mode.

The following standard command processing routines are provided:

- Change window parameters.
- Logon
- Logoff
- Send a message to another workstation.
- Enter date and time information.
- Return

The 3600 Administrative Application Support program may be tailored at assembly time by specifying the following options:

- Add user command processing routines.
- Modify message text produced by the program.
- Specify LOGON requirements.
- Define user fields, constants and equate values.
- Specify whether or not printer support should be available.
- Specify user exits.

User exits may be defined at appropriate points in the program to allow inclusion of user written routines to accomplish the following:

- Inclusion of constant data fields or format data into the screen image buffer from sources other than the datastream sent from the host.
- Editing of operator keyed data field.
- Verifying time and date entered by the operator.
- Verifying LOGON information.

CUSTOMER RESPONSIBILITIES

The user must provide host application programs written for SNA 3270s to interface with the 3600 Administrative Application Support program.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The minimum Finance Communication System consists of the following configuration:

- IBM 3601 or 3602 Finance Communication Controller with a minimum of 24K of user programmable storage.
- IBM 3604 Keyboard/Display or DCA 3278.

Primary keyboard/display support is for the 3604-7 or DCA 3278. Other mds of the 3604 are supported via the windowing facilities of the program.

The program product is designed to support one workstation (3604-7 or DCA 3278) in 24K bytes of user programmable storage. Each additional workstation will require approximately 6K bytes of storage. The screen image buffer (approximately 2K bytes) may reside in expanded user storage.

In order to create an operational diskette the following minimum host system is required:

- A S/370, 3031, 3032, 3033 or 4300 processor with at least 512K bytes of virtual storage for DOS/VS or 768K virtual storage for OS/VS1 or OS/VS2 MVS.
- A Direct Access Storage Device supported by DOS/VS, DOS/VSE, OS/VS1, OS/VS2 MVS, Subsystem Support Services and the Host Support for IBM 3600 Finance Communications System.
- A card read/punch device supported by DOS/VS, DOS/VSE or OS/VS
- One Magnetic tape drive unit for installation of the program product.
- An IBM 3704 or 3705 Communication Controller with storage and features capable of supporting NCP/VS.

SOFTWARE REQUIREMENTS

The 3600 Administrative Application Support program requires the programming systems listed below. To assemble and transmit the application program to the 3600 Controller, the user should have installed a current release of one of the following operating systems:

- Disk Operating System (DOS/VS) (5745-010)
- Disk Operating System Extended (DOS/VSE) (5745-020)
- Operating System (OS/VS1) (5741-VS1)
- Operating System (OS/VS2 MVS) (5752-VS2)

Additionally, the latest applicable releases of the following components at the time of availability are required:

DOS/VS or DOS/VSE

- Assembler - (5745-SC-ASM)
- Network Control Program/VS (NCP/VS) (5747-AJ2) or (ACF/NCP/VS) (5735-XX1)
- Virtual Telecommunications Access Method (VTAM) (5745-SC-VTM) or (ACF/VTAM) (5746-RC3) or (ACF/VTAME) (5746-RC7)
- Virtual Sequential Access Method (VSAM) (5745-SC-VSM) or (VSE/VSAM) (5746-AM2)
- Access Method Services (5745-SC-AMS)
- Host Support for IBM 3600 Finance Communications System (DOS/VS) (5747-BR1)
- Subsystem Support Services (SSS) (5747-CC6)

OS/VS1 or OS/VS2 MVS

- Assembler XF (5741-SC1-03 or 5752-SC1-03)
- Network Control Program/VS (NCP/VS) (5744-BA2) or (ACF/NCP/VS) (5735-XX1)
- Virtual Telecommunications Access Method (VTAM) (5741-SC1-23 or 5752-SC1-23) or (ACF/VTAM) (5735-RC2) or Telecommunications Access Method (TCAM) (5741-SC1-21 or 5752-SC1-21) (ACF/TCAM) (5735-RC3)
- Virtual Sequential Access Method (VSAM) (5741-SC1-DE or 5752-SC1-DE)
- Host Support for IBM 3600 Finance Communications System (OS/VS) (5744-CA3)
- Subsystem Support Services (SSS) (5741-SC1-SS or 5752-SC1-SS)
- Access Method Services (5741-SC1-DK or 5752-SC1-DK)

User written host application programs which interface with the 3600 Administrative Application Support program may execute under one of the following DB/DC program products:

- Information Management System (IMS/VS) (5740-XX2) with the DC feature
- Customer Information Control System (CICS/OS/VS) (5740-XX1)
- Customer Information Control System (CICS/DOS/VS) (5746-XX3)

COMPATIBILITY

The 3600 Administrative Application Program is compatible with the SNA 3270 SLU type 2 support provided by the following program products:

- Information Management System (IMS/VS) (5740-XX2) with the DC feature
- Customer Information Control System (CICS/OS/VS) (5740-XX1)
- Customer Information Control System (CICS/DOS/VS) (5746-XX3)

The user must provide host application programming to interface with the 3600 Administrative Application Support program. The program is compatible with the following IBM host application program products:

PROGRAM PRODUCTS**3600 Administrative Application Support (cont'd)****Customer Information Facility/VS**

Using CICS/DOS/VS (5746-XXS)
Using CICS/OS/VS (5740-XYC)
Using IMS/VS (5740-XYB)

User written VTAM or TCAM host application programs will interface with the 3600 Administrative Application Support program if the communication protocol and 3270 datastreams produced are equivalent to IMS/VS-MFS or CICS/VS-BMS implementation of SLU Type 2 (SNA 3270) support.

PERFORMANCE CONSIDERATIONS

The performance of a 3600 FCS application is dependent on the resources available in the controller such as number and speed of loops, host link speed, number of active workstations, etc. Performance will also be affected by the host application programs and the host system resources available.

MVS INTEGRITY

IBM will accept APARs describing any situation where the installation of the 3600 Administrative Application Support program causes an exposure to the system integrity of MVS. However, the 3600 Administrative Application Support program is not intended to run in an authorized state at any time and should therefore represent no threat to the system integrity of MVS.

DOCUMENTATION: (available from Mechanicsburg)

General Information Manual	(GH20-2414)
Licensed Program Design Objectives	(GH20-5052)

**IBM 3694 APPLICATION MACRO EXPANSIONS
VER. 1 MOD. LEVEL 1 (5748-F56)****PURPOSE**

This licensed program contains the 3694 Application Macro Expansions. These macro definitions can be utilized, in conjunction with the 3600 Finance Communications Assembler Language (through host processor assembly), in a user supplied application program to generate instructions which, when executed in the 3694 Document Processor mdl 1 or 2, perform the following document processing functions:

- 3694 Initialization.
 - High or low speed.
 - Autofeed or manual feed.
- Operational control.
 - Start/stop transport.
 - Pause/resume feed.
 - Clear transport.
 - Write indicators.
 - Dispatch/stop document control section.
- 3694 Document Control Section.
 - Logical and arithmetic operations.
 - Branch on condition.
 - Numeric base conversion.
 - Image matching.
 - Modulus checking.
 - Data movement.
 - Read document data.
 - Release document.
 - Scan a field on a document.
 - Search field for digit error.
 - Pocket selection.
 - Table lookup.
 - Chain for input data.
 - Wait for input data.
 - Write to Master list printer.

HIGHLIGHTS

Some of the application functions that can be performed using these instructions include:

- 3694 Full Function Path Operation (3694 mdls 1A-1D and 2A-2D).
 - Read the document (MICR) data input.
 - Read the keyboard data input.
 - Validate the input.
 - Perform inflight processing.
 - Create multiple output records.
 - Write to the master list printer.
 - Inscribe a document.
 - Endorse a document.
 - Item Identification control and printing.
 - Pocket selection.
 - Microfilming.
- High Speed Path Operation (3694 mdls 2A-2D).
 - Read MICR data input from document.
 - Validate input.
 - Inflight processing preparation.
 - Item Identification Control.
 - Pocket selection.
 - Microfilming.
 - 'PAID' Stamping.

CUSTOMER RESPONSIBILITIES:

The customer is responsible for installing the 3694 Application Macro Expansions licensed program product, and implementing appropriate security procedures through programming and physical control methods.

SPECIFIED OPERATING ENVIRONMENT**SOFTWARE REQUIREMENTS**

Host Programming Requirements: The 3694 Application Macro Expansions licensed program requires the same operating systems prerequisites and Host Programs which are required by the 3600 Independent Release 6.0 (IR/6.0).

In addition, the following are also required:

3694 Ind. Rel. 1.0

3600 Host Support Independent Release 6.0:

5747-BR1 DOS/VS (Version 6)

5744-CA3 OS/VS (Version 5)

PROGRAM PRODUCTS

5748-MS1 - INT. PROD. FAC. VM ENV. R3.0
INTERACTIVE PRODUCTIVITY FACILITY
VM ENVIRONMENT
RELEASE 3 Modification Level 0

PURPOSE

The Interactive Productivity Facility is designed to simplify the tasks and increase the productivity of those who use and manage IBM computer resources. Release 3.0 of Interactive Productivity Facility is specifically designed to assist users of the VM/SP System Installation Productivity Option/Extended (VM/SP System IPO/E) by providing the user a simplified and productive interface to VM/370 systems.

SPECIAL SALES INFORMATION

Release 3.0 of the Interactive Productivity Facility is designed to run in the VM/SP System IPO/E environment.

The Interactive Productivity Facility is included in the base of the VM/SP System IPO/E. It is recommended that it not be used outside this environment. However, if ordered independently, installation instructions are provided.

HIGHLIGHTS

- Interactive user interface with the system via display panels.
Using facilities of CMS in the VM environment, the Interactive System Productivity Facility provides a simplified interface to users. The interactive interface is provided via structured menu panels that guide the user in the selection of activities that lead to the execution of system functions.
- Prompting for input parameters.
Data entry panels prompt the user for the parameters required for the execution of system functions.
- Simplified procedures to invoke program products and product functions.
After prompting the user for the required parameters, the Interactive Productivity Facility transfers the prompted information into the appropriate system input format and invokes the necessary system functions.
- Interactive explain service.
To assist the new or infrequent system user, explanatory information is provided online.
- VM/SP System IPO/E Environment.
The Interactive Productivity Facility, a licensed program, is part of the VM/SP System IPO/E environment.

INTERACTIVE PRODUCTIVITY FACILITY CONTENT

The Interactive Productivity Facility is composed of the following components:

1. Dialog Manager
The Dialog Manager, running under CMS, provides the basic functions required to control the user interface and the execution of dialogs.
2. Executable Dialogs
Consisting of:
 - Menu, data entry, explain panels
 - Control statement files
 - Function routines that:
 - Display panels
 - Analyze user input
 - Invoke CP/CMS commands
3. EXECs to perform selected tasks are supplied by Interactive Productivity Facility for the following programs. See "Installation and Use Considerations."

A.	VM/SP System IPO/E Base Programs	Number	Rel. Level

Note: The above programs, referred to as Documented Support programs, have been installed and their IVPs are run as part of the overall VM/SP System IPO/E environment. However, they are ordered independently of the VM/SP System IPO/E.

4. User's Guide
Documentation, available in hardcopy, machine-readable form and microfiche that describes how to use the Interactive Productivity Facility in the VM environment.
5. Program Logic Manual
Documentation, available in microfiche form, that describes the function and interfaces of the Interactive Productivity Facility in the VM environment.

SPECIFIED OPERATING ENVIRONMENT

The following is the Specified Operating Environment for the Interactive Productivity Facility:

HARDWARE REQUIREMENTS

The Interactive Productive Facility is designed to operate with the following minimum hardware configurations when required for the full function offered by the Interactive Productivity Facility for all licensed programs supported:

- Processors:** IBM S/370, 303X, 4300 *, or 3081 supported by VM/SP that meet the minimum processor storage requirements described below.
- Terminals:** One IBM 3277-2 or one 3278-2.
- Printer:** One printer supported by the operating system.
- Tape:** One tape drive supported by the operating system.
- Reader:** None.

Processor Storage:	0.5MB *
DASD:	
3310	3
3330	3
3340	3
3350	2
3370 **	2
3380 **	4

* Installation of Interactive Productivity Facility on the .5 megabyte 4331 Processor requires the Control Storage Expansion optional feature (#1901). This requirements is based on the VM/370 minimum processor storage size of 384K bytes needed to IPL. If 3340 DASD devices are attached to the 4331 Processor, a minimum processor storage size of 1.0 MB is required.

** Indicates number of actuators.

PROGRAM PRODUCTS

**Interactive Productivity Facility VM Environment R3
(cont'd)****SOFTWARE REQUIREMENTS**

The Interactive Productivity Facility is designed to operate with the following products.

Program Name	Number	Rel. Level
VM/370	5749-010	6.0
VM/System Product	5664-167	
VM/IPCS Extension (Note1)	5748-SA1	2.0

Note 1: VM/IPCS Extension contains functions necessary to execute the problem reporting procedures generated by Interactive Productivity Facility.

INSTALLATION and USE CONSIDERATIONS

It is recommended that Release 3.0 of the Interactive Productivity Facility be installed and used in the VM/SP System IPO/E environment. The VM/SP System IPO/E provides an environment in which the device addresses and library and space allocation (system structure) are specified to conform with those that Interactive Productivity Facility functions expect. A description of this environment is found in the *VM/SP System IPO/E Planning Guide* (GC20-1874). If installed and used independently, the dialogs and EXECs dependent upon VM/SP System IPO/E structure may be invalidated unless the system structure is defined as found in the *VM/SP System IPO/E Planning Guide*. To use the Interactive Productivity Facility optional feature install function to install the licensed programs listed in 3B, those programs must be ordered in the VM/SP System IPO/E format.

DATA SECURITY

Customers using Interactive Productivity Facility can use the security facilities provided by CMS in the VM environment. The customer is responsible for the selection, implementation and adequacy of these facilities.

DOCUMENTATION
(available from Mechanicsburg)

PROGRAM PRODUCTS

**5748-MS1 - INT. PROD. FAC. VSE, VM/VSE R4.0
INTERACTIVE PRODUCTIVITY FACILITY
VSE ENVIRONMENT RELEASE 4.0
VM/VSE ENVIRONMENT RELEASE 4.0**

PURPOSE

The Interactive Productivity Facility Release 4.0 (VSE, VM/VSE Environments) is designed to simplify the tasks and increase the productivity of those who use and manage IBM computer resources. Release 4.0 of Interactive Productivity Facility is specifically designed to assist users of Release 3.0 of System Installation Productivity Option/Extended (VSE System IPO/E) by providing the user a simplified and productive interface to VSE systems.

SPECIAL SALES INFORMATION

Release 4.0 of the Interactive Productivity Facility (VSE, VM/VSE Environments) is designed to operate in the VSE System IPO/E Release 3.0 environment.

HIGHLIGHTS

- Interactive user interface with the system via display panels.
Using facilities of VSE/ICCF in the VSE environment, the Interactive Productivity Facility provides a simplified interface to users. The interactive interface is provided via structured visual display menu panels that guide the user in the selection of activities that lead to the execution of system functions.
- Prompting for input parameters
Data entry panels prompt the user for the parameters required for the execution of system functions.
- Simplified procedures to invoke products and product functions.
After prompting the user for the required parameters, the Interactive Productivity Facility transfers the prompted information into the appropriate system input format and invokes the necessary system functions.
- Interactive explain service
To assist the new or infrequent system user, explanatory information is provided online.
- VSE System IPO/E Environment
The Interactive Productivity Facility (VSE Environment), a licensed program, is part of the VSE System IPO/E.

The Interactive Productivity Facility is included in the base of each System IPO/E. It is recommended that it not be used outside this environment. However, if ordered independently, installation instructions are provided.

INTERACTIVE PRODUCTIVITY FACILITY CONTENT

The Interactive Productivity Facility has the following components:

1. Dialog Manager
The Dialog Manager, running under VSE/ICCF or VM/SP CMS, provides the basic functions required to control the user interface and the execution of dialogs. The dialog manager is shipped in the VM Environment and the VSE environment. The VM/VSE Environment in Release 4.0 is designed to run in conjunction with the VM Environment and to use its dialog manager.
2. Executable Dialogs
The executable dialogs consist of:
 - Menu panels that guide the user in selecting activities to be performed.
 - Data entry panels that guide the user in supplying the required information to execute system functions.
 - Explain panels that provide additional information for the new or infrequent user.
 - Skeleton JCL to which user-provided information is added for execution of system functions.
 - Function routines that:
 - Display panels
 - Analyze user input
 - Assign values to JCL parameters
 - Create executable JCL
3. Executable jobstreams to perform selected tasks are supplied by the Interactive Productivity Facility for the following products. Also, see "Installation and Use Considerations."

A. System IPO/E Base Programs	Number	Rel. Level
DOS/VSE SCP	5745-030	3.0

VSE/DITTO	5746-UT3	2.0
VSE/Fast Copy	5746-AM4	1.0
VSE/OCCF	5746-XC5	1.0
VSE/POWER/RJE	5746-XE3	2.0
VSE/POWER Shared Spool Feature	5746-XE3	1.0
VSE/VSAM Backup/Restore Feature	5746-AM2	2.0
VSE/VSAM Space Management for SAM feature	5746-AM2	Note 1

Note 1: There is no release designation for this feature.

4. Documentation

Documentation will be available in hardcopy, machine-readable, or microfiche that describes how to use the Interactive Productivity Facility in the VSE/ICCF and VM/SP CMS environments.

The following manuals will be available:

Name	Order Number
Interactive Productivity Facility General Information Manual	GH20-2492
User's Guide	SH20-5526
Reference Manual	SH20-2486
Program Directory	(shipped with product)
VM/VSE Feature Program Directory	(shipped with product)

A program logic manual will be available in microfiche form and hardcopy. It describes the function and interfaces of the Interactive Productivity Facility dialog manager in the VSE environment.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The Interactive Productive Facility is designed to operate with the following minimum hardware configurations when required for the full function offered by the Interactive Productivity Facility for all licensed programs. Additional requirements may exist for hardware system service.

- Processors
IBM S/370, 303X, and 4300 supported by VSE that meet the minimum processor storage requirements described below.
- Processor Storage

The minimum processor storage requirements are shown below:

	VSE Environment	VM/VSE Environment
B/I (1)	1.0 MB	1.0 MB (2)
DC (1)	1.0 MB	2.0 MB
DB/DC (1)	1.0 MB	2.0 MB

Interactive Productivity Facility -VSE, VM/VSE R4 (cont'd)

Figure 1. Minimum Processor Storage Requirements

Note 1: Batch/Interactive (B/I)
Data Communication (DC)
Data Base/Data Communication (DB/DC)

Note 2: ACF/VTAM or ACF/VTAME users who are running VSE as a guest machine under VM may experience performance degradation on an IBM system.

• Minimum DASD Requirements:

DASD Type	Environment	Minimum Spindles	Notes
3310	B/I	4	5, 6
3310	DC or DB/DC	5	6
3330	B/I	4	1, 5
3330	DC or DB/DC	5	1
3340	B/I	4	2, 5, 6
3340	DC or DB/DC	5	2, 6
3350	All	3	4
3370	All	3	3, 4

Figure 2. Minimum DASD Requirements.

The DASD requirements for VM/VSE are the sum of the requirements for the VM environment and the VSE environment.

Note 1: 3330 mdl 1 (3330 mdl 11s are treated as mdl 1s).

Note 2: 3340 mdl 70 or 70F or 3344 (one 3344 is equal to four 3340s).

Note 3: Actuators.

Note 4: The third spindle is required for verification.

Note 5: A fifth spindle is required for ACF/NCP.

Note 6: An additional spindle is required if using VM/VSE.

• Other hardware

The following minimum hardware is required for the Interactive Productivity Facility VSE Environment and VM/VSE Environment:

- One VSE-supported console.
- One local terminal which supports a 24 x 80 character screen format. This terminal must be supported by VSE, CICS/VS, VSE/ICCF, and the telecommunications access method selected by the user. In the VM/VSE Environment, this terminal must be supported by VM/CMS.
- One tape drive supported by the appropriate operating system.
- One VSE-supported printer.
- One VSE card image device (required for hardware system service) supported by the appropriate operating system.

SOFTWARE REQUIREMENTS

The VSE and VM/VSE Environments of the Interactive Productivity Facility are designed to operate with the following products:

Licensed Program Product Name	Number	Rel. Level
VSE/Advanced Functions	5746-XE8	3.0
DOS/VSE SCP	5745-030	3.0
VSE/ICCF	5746-TS1	3.0
VSE/IPCS	5746-SA1	3.0
VSE/POWER	5746-XE3	2.0
VSE/VSAM	5746-AM2	2.0
VSE/Fast Copy	5746-AM4	1.0
CICS DOS/VS	5746-XX3	1.5

ACF/VTAME		
VTAM SCP for ACF/VTAME	5746-CG2	1.0
ACF/VTAME for DOS/VSE	5746-RC7	1.0
Interactive Productivity Facility - VM Environment	5748-MS1	3.0
VM/SP	5664-167	1.1

Figure 3. Interactive Productivity Facility Environment.

INSTALLATION and USE CONSIDERATIONS

It is recommended that Release 4.0 of the Interactive Productivity Facility be installed and used in the VSE System IPO/E Release 3.0 environment. The System IPO/E provides environments in which the

device addresses and system structure (library and space allocations) are those that Interactive Productivity Facility functions expect. Descriptions of these environments are found in the *VSE System IPO/E Planning Guide* (GC20-1936) and the *VSE System IPO/E Reference Manual*.

If installed and used independently, the Interactive Productivity Facility dialogs and executable jobstreams dependent upon System IPO/E structure may be invalidated unless the system structure is defined as found in these documents. To use the Interactive Productivity Facility optional feature install function to install the licensed programs listed in the Interactive Productivity Facility Content section above, those programs must be ordered in the System IPO/E format.

Interactive Productivity Facility Tables: The Interactive Productivity Facility dialogs create tables based on input entered by the user. If a user of a prior release retains the same table data, Release 4.0 dialogs will continue to use the stored information. Where formats change from release to release, the Interactive Productivity Facility will convert the old format to the new format.

DATA SECURITY

Customers using Interactive Productivity Facility can use the security facilities provided by VSE/ICCF in the VSE environment or VM/SP CMS in the VM/VSE environment. The customer is responsible for the selection, implementation and adequacy of these facilities.

DOCUMENTATION

(available from Mechanicsburg)

The following documentation will be available concurrent with Interactive Productivity Facility availability:

- Interactive Productivity Facility Dialog Manager Logic Flow* (ZZ20-4611) ... Microfiche (LY80-2579) containing Interactive Productivity Facility Dialog Manager PLM, Panels, Skeletons, and Message File ... Microfiche (LY80-2580) containing Interactive Productivity Facility Dialog Manager source listings ... Interactive Productivity Facility Program Function Key Template for 3277 (SX20-2346) or 3276/3278 (SX20-2355) ... *Interactive Productivity Facility VSE Environment Licensed Program Specifications* (GH20-5527).

PROGRAM PRODUCTS

**5748-MS1 - INT. PROD. FAC. VM ENV. R4.0
INTERACTIVE PRODUCTIVITY FACILITY
VM ENVIRONMENT RELEASE 4.0**

PURPOSE

The Interactive Productivity Facility is designed to simplify the tasks and increase the productivity of those who manage, service and use VM/SP systems. Release 4.0 of Interactive Productivity Facility is specifically designed to assist users of the VM/SP System Installation Productivity Option/Extended (VM/SP System IPO/E) by providing the user a simplified and productive interface to VM/SP systems.

SPECIAL SALES INFORMATION

Release 4.0 of the Interactive Productivity Facility is designed to run in the VM/SP System IPO/E Release 2.1 environment.

The Interactive Productivity Facility is included in the base set of products for the VM/SP System IPO/E. It is recommended that it not be used outside this environment. However, if ordered independently, installation instructions are provided.

HIGHLIGHTS

- Interactive user interface with the system via display panels.
Using facilities of CMS and the Interactive System Productivity Facility (ISPF) in the VM environment, the Interactive Productivity Facility provides a simplified interface to users. The interactive interface is provided via structured menu panels that guide the user in the selection of activities that lead to the execution of system functions.
- Prompting for input parameters
Data entry panels prompt the user for the parameters required for the execution of system functions.
- Simplified procedures to invoke program products and product functions.
After prompting the user for the required parameters, the Interactive Productivity Facility transforms the prompted information into the appropriate system input format and invokes the necessary system functions.
- Interactive help service
To assist the new or infrequent system user, explanatory information is provided online.
- VM/SP System IPO/E Environment
The Interactive Productivity Facility, a licensed program, is part of the VM/SP System IPO/E environment.

DESCRIPTION

The Interactive Productivity Facility has the following components:

1. Executable Dialogs
Consisting of:
 - Menu panels that guide the user in selecting activities to be performed.
 - Data entry panels that guide the user in supplying the required information to execute system functions.
 - Help panels that provide additional information for the new or infrequent user.
 - Control statement files to which user-provided information is added for execution of system functions.
 - Function routines (EXECs) that:
 - Display panels
 - Analyze user input
 - Invoke CP/CMS commands
2. User's Guide (SH20-5583-0)
Documentation available from Mechanicsburg that describes how to use the Interactive Productivity Facility in the VM environment.
3. Dialogs that aid the user in installing and/or using the following programs which are included in the VM/SP System IPO/E Release 2.1. (See "Installation and Use" considerations.)

Program Name	Number	Rel.
Base Content:		
VM/System Product	5664-167	2.1
Interactive Productivity Facility	5748-MS1	4.0
ISPF	5668-960	1.0
VM/IPCS Extension	5748-SA1	2.0

Optional Features:

A Departmental Reporting System II (ADRS II) (with Bus. Graphics)	5796-PLN	1.7
APL/Data Interface II	5796-PNG	1.5

4. The Program Development environment dialogs are no longer shipped with the Interactive Productivity Facility Release 4.0. Examples of commands/EXECs providing similar function will be provided in the *Interactive Productivity Facility User's Guide*. An enriched Program Development dialog function is provided in the Interactive Systems Productivity Facility/Program Development Facility (5664-172) licensed program. ISPF/PDF is a recommended optional product of the VM/SP System IPO/E Release 2.1.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The Interactive Productive Facility is designed to operate with the minimum hardware configurations of the VM/SP System IPO/E environment.

The following chart summarizes the minimum hardware configurations for the VM/SP System IPO/E environment:

Processors:	One IBM processor supported by VM/SP Release 2.1														
Processor Storage:	1.0MB														
Terminals:	One IBM 3277-2, 3278 or 3279														
Printer:	One IBM Printer supported by VM/SP Release 2.1														
Reader:	None														
DASD Actuators:	<table border="1"> <tbody> <tr><td>3310</td><td>3</td></tr> <tr><td>3330</td><td>3</td></tr> <tr><td>3340</td><td>3</td></tr> <tr><td>3350</td><td>2</td></tr> <tr><td>3370</td><td>2</td></tr> <tr><td>3375</td><td>2</td></tr> <tr><td>3380</td><td>2</td></tr> </tbody> </table>	3310	3	3330	3	3340	3	3350	2	3370	2	3375	2	3380	2
3310	3														
3330	3														
3340	3														
3350	2														
3370	2														
3375	2														
3380	2														

For customers installing VM/SP System IPO/E on a 1 megabyte 4321 or 4331, the 'small CP' option should be specified. This option removes certain functions from CP. Refer to the *VM/SP Planning and SYSGEN Guide* (SC19-6201) for details. (Note: Multiple Interactive Productivity Facility users executing in a one megabyte processor can affect system performance.)

SOFTWARE REQUIREMENTS

The Interactive Productivity Facility is designed to operate with the VM/System Product (5664-167) Release 2.1 and the VM/IPCS Extension (5748-SA1) Release 2.0. VM/IPCS Extension contains functions necessary to execute the problem reporting procedures provided with the Interactive Productivity Facility.

The Interactive System Productivity Facility (VM/CMS) (5668-960) Release 1.0 is a prerequisite for the Interactive Productivity Facility - VM Environment.

Interactive Productivity Facility - VM R4 (cont'd)**INSTALLATION and USE CONSIDERATIONS**

It is recommended that Release 4.0 of the Interactive Productivity Facility be installed and used in the VM/SP System IPO/E Release 2.1 environment. The VM/SP System IPO/E provides an environment in which the device addresses, libraries and space allocations (system structure) are specified to conform with those that Interactive Productivity Facility functions expect. A description of this environment is found in the *VM/SP System IPO/E Planning Guide* (GC20-1874-4).

If installed and used independently, the dialogs, modules and EXECs dependent upon VM/SP System IPO/E structure may be invalidated unless the system structure is defined as found in the *VM/SP System IPO/E Planning Guide*. To use the Interactive Productivity Facility optional feature installation function to install the licensed programs listed in Item 3 above, those programs must be ordered in the VM/SP System IPO/E format.

DATA SECURITY

Customers using Interactive Productivity Facility can use the security facilities provided by CMS in the VM environment. The customer is responsible for the selection, implementation and adequacy of these facilities.

PROGRAM PRODUCTS

5748-MS1 - INT. PROD. FAC. VSE ENV. R4.1
INTERACTIVE PRODUCTIVITY FACILITY
VSE ENVIRONMENT RELEASE 4.1
VM/VSE ENVIRONMENT RELEASE 4.1
5748-MS1

PURPOSE

Release 4.1 of the Interactive Productivity Facility enhances the VSE System IPO/E Release 3.1. The Interactive Productivity Facility provides the intermediate system user with a simplified and productive interface to VSE systems.

HIGHLIGHTS

- Support for the addition of new products and new product releases.
- Full dialog support for 3375 DASD.
- Addition of VSE/OCCF verify dialogs.
- Dialog to support VSE/VSAM Backup/Restore feature.
- Dialog to support VSE/VSAM Space Management for SAM feature.

DESCRIPTION

- **Addition of Product Support**
 Two products are added as fully supported products for installation and service in this release. They are:
 - NPDA (Version 1) Release 2.1
 - NCCF Release 2.0
 The Software Product System Profile table has been updated to include information describing the added products.
- **3375 Support**
 All affected dialogs are modified to make the 3375 DASD a fully supported device. Support is provided for system and data files.
- **Dialog to support VSE/VSAM Backup/Restore feature**
 New panels, functions and job control skeletons are provided to prompt the user for the data required to generate the Access Method Services BACKUP and RESTORE jobs.
- **Dialog to support VSE/VSAM Space Management for SAM feature**
 The SAM ESDS file type is now supported by the Interactive Productivity Facility.
- **Addition of a VSE/OCCF verify job**
 Support is added to verify the installation of VSE/OCCF.
- **VM/VSE Environment**
 The VM/VSE Environment continues to support VSE/Advanced Functions Release 3 as a guest machine with VM/SP Release 1.1.

INTERACTIVE PRODUCTIVITY FACILITY CONTENT

The Interactive Productivity Facility has the following components:

1. **Dialog Manager**
 The Dialog Manager, running under VSE/ICCF or VM/SP CMS, provides the basic functions required to control the user interface and the execution of dialogs. The dialog manager is shipped in the VM Environment and the VSE environment. The VM/VSE Environment in Release 4.1 is designed to run with the VM Environment and to use VM dialog manager.
2. **Executable Dialogs**
 The executable dialogs consist of:
 - Menu panels that guide the user in selecting activities to be performed.
 - Data entry panels that guide the user in supplying the required information to execute system functions.
 - Explain panels that provide additional information for the new or infrequent user.
 - Skeleton JCL to which user-provided information is added for execution of system functions.
 - Function routines that:
 - Display panels
 - Analyze user input
 - Assign values to JCL parameters
 - Create executable JCL

3. Executable jobstreams to perform selected tasks are supplied by the Interactive Productivity Facility for the following products. Also, see "Installation and Use Considerations".

A. System IPO/E Base Programs	Number	Rel. Level
DOS/VSE SCP	5745-030	3.0
Device Support Facility	5747-DS2	5.0
VSE/Advanced Functions	5746-XE8	3.0
VSE/POWER	5746-XE3	2.0
VSE/VSAM	5746-AM2	3.0
VSE/IPCS	5746-SA1	3.0
CICS/VS	5746-XX3	1.5
DL/I DOS/VS	5746-XX1	1.6
VSE/ICCF	5746-TS1	3.0

B. System IPO/E Optional Programs	Number	Rel. Level
ACF/NCP/VS	5735-XX1	2.1
+ SSP for ACF/NCP/VS	5735-XX3	2.1
+ NCP/SSP SCP	5747-CH1	2.1
+ EP feature #6004	5747-CH1	3.0
ACF/VTAM	5746-RC3	3.0

VSE/VSAM Backup/Restore Feature	5746-AM2	2.0
VSE/VSAM Space Management for SAM feature	5746-AM2	**

* These products are returned to fully supported product status for installation and service in this release. These products are installed into the standard System IPO/E DASD space. The tapes for these products are distributed in the same format as ordered outside the VSE System IPO/E.

**There is no release designation for this feature.

4. **Documentation**
 Documentation will be available in hardcopy and microfiche that describes how to use the Interactive Productivity Facility in the VSE/ICCF and VM/SP CMS environments.

The following manuals will be available:

Name	Order Number
Interactive Productivity Facility	
General Information Manual	GH20-2492
User's Guide	SH20-5526
Reference Manual	SH20-2486
VSE Feature Program Directory	(shipped with product)
VM/VSE Feature Program Directory	(shipped with product)

Microfiche has been restructured as follows:

Interactive Productivity Facility	
Panels, skeletons, tables, messages for VSE Environment	LYB0-2579
Dialog manager source listings, PLM, and PLM TNLs for VSE Environment	LYB0-2580
Panels, skeletons, tables, messages	

PROGRAM PRODUCTS

Interactive Productivity Facility R4.1 (cont'd)

for VM/VSE Environment LYB0-2568
Dialog manager source listings,
PLM, and PLM TNLS for
VM/VSE Environment LYB0-2572

A program logic manual will be available in microfiche form and hardcopy. It describes the function and interfaces of the Interactive Productivity Facility dialog manager in the VSE environment.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The Interactive Productive Facility is designed to operate with the following minimum hardware configurations when required for the full function offered by the Interactive Productivity Facility for all supported licensed programs. Additional requirements may exist for system service.

- Processors
IBM S/370, 303X, 4300 supported by VSE or VM/SP that meet the minimum processor storage requirements described below.

- Processor Storage

The minimum processor storage requirements are:

	VSE Environment	VM/VSE Environment
B/I (1)	1 MB	1 MB (2)
DC (1)	1 MB	2 MB
DB/DC (1)	1 MB	2 MB

Figure 1. Minimum Processor Storage Requirements

Note 1: Batch/Interactive (B/I)
Data Communication (DC)
Data Base/Data Communication (DB/DC)

Note 2: ACF/VTAM or ACF/VTAME users who are running VSE as a guest machine under VM/SP may experience performance degradation on a 1 MB system.

- Minimum DASD Requirements for the VSE Environment:

DASD Type	Environment	Minimum Spindles	Notes
3310	B/I	4	5, 6
3310	DC or DB/DC	5	6
3330	B/I	4	1, 5
3330	DC or DB/DC	5	1
3340	B/I	4	2, 5, 6
3340	DC or DB/DC	5	2, 6
3350	All	3	4
3370	All	3	3, 4
3375	All	3	4

Figure 2. Minimum DASD Requirements.

The DASD requirements for VM/VSE are the sum of the requirements for the VM environment and the VSE environment.

- Note 1: 3330 mdl 1 (3330 mdl 11s are treated as mdl 1s).
- Note 2: 3340 mdl 70 or 70F or 3344 (one 3344 is equal to four 3340s).
- Note 3: Actuators.
- Note 4: The third spindle is required for verification.
- Note 5: A fifth spindle is required for ACF/NCP.
- Note 6: An additional spindle is required if using VM/VSE.

- Other hardware

The following minimum hardware is required for the Interactive Productivity Facility VSE Environment and VM/VSE Environment:

- One VSE-supported console.
- One local terminal which supports a 24 x 80 character screen format. This terminal must be supported by VSE, CICS/VS, VSE/ICCF, and the telecommunications access method selected by the user. In the VM/VSE Environment, this terminal must be supported by VM/SP CMS.

- One tape drive supported by the appropriate operating system.
- One VSE-supported printer.
- One VSE card image device (required for system service) supported by the appropriate operating system.

SOFTWARE REQUIREMENTS

Interactive Productivity Facility in the VSE and VM/VSE Environments is designed to operate with the following products:

Licensed Program Product Name	Number	Rel. Level
DOS/VSE SCP	5745-030	3.0
Device Support Facility	5747-DS2	5.0
VSE/Advanced Functions	5746-XE8	3.0
VSE/ICCF	5746-TS1	3.0
VSE/IPCS (Note 1)	5746-SA1	3.0
VSE/POWER	5746-XE3	2.0
VSE/VSAM (Note 2)	5746-AM2	3.0
VSE/Fast Copy (Note 3)	5746-AM4	1.0
CICS DOS/VS	5746-XX3	1.5
DL/I DOS/VS	5746-XX1	1.6
BTAM-ES (Note 4)	5746-RC5	1.0
BTAM SCP	5747-CG1	1.0
ACF/VTAM (Note 4)		
VTAM SCP for ACF/VTAM	5747-CF1	3.0
ACF/VTAM for DOS/VSE	5746-RC3	3.0
ACF/VTAME (Note 4)		
VTAM SCP for ACF/VTAME	5747-CG2	1.0
ACF/VTAME for DOS/VSE	5746-RC7	1.0
Interactive Productivity Facility - VM Environment	5748-MS1	3.0
VM/SP	5664-167	1.1

Figure 3. Interactive Productivity Facility Environment.

Note 1: VSE/IPCS contains functions necessary to execute the problem reporting procedures generated by the Interactive Productivity Facility.

Note 2: VSE/VSAM contains functions necessary to execute the following installation verification procedures: CICS/VS, DL/I DOS/VS, Data Dictionary and Sort/Merge II.

Note 3: VSE/Fast Copy contains functions necessary to execute, tailor and service procedures generated by the Interactive Productivity Facility.

Note 4: For VSE CICS/VS users, ACF/VTAM or ACF/VTAME is the recommended telecommunications access method together with the associated SCP code.

VSE users without CICS/VS must select and install BTAM-ES and its associated SCP code. The VM/VSE Environment does not require a telecommunications access method unless it is required by a support product.

INSTALLATION and USE CONSIDERATIONS

It is recommended that Release 4.1 of the Interactive Productivity Facility be installed and used in the VSE System IPO/E Release 3.1 environment. The System IPO/E provides environments in which the device addresses and system structure (library and space allocations) are those that Interactive Productivity Facility functions expect. Descriptions of these environments are found in the *VSE System IPO/E Planning Guide (GC20-1936)* and the *VSE System IPO/E Reference Manual*.

If installed and used independently, the Interactive Productivity Facility dialogs and executable jobstreams dependent upon System IPO/E structure may be invalidated unless the system structure is defined as found in these documents. To use the Interactive Productivity Facility optional feature install function to install the licensed programs listed in the Interactive Productivity Facility Content section above, those programs must be ordered in the System IPO/E format.

Interactive Productivity Facility Tables: The Interactive Productivity Facility dialogs create tables based on input entered by the user. If a user of a prior release retains the same table data, Release 4.1 dialogs will continue to use the stored information. Where formats change from release to release, the Interactive Productivity Facility will convert the old format to the new format.

DATA SECURITY

Customers using Interactive Productivity Facility can use the security facilities provided by VSE/ICCF in the VSE environment or VM/SP CMS in the VM/VSE environment. The customer is responsible for the selection, implementation and adequacy of these facilities.

DOCUMENTATION
(available from Mechanicsburg)

The following documentation will be available concurrent with Interactive Productivity Facility availability:

Interactive Productivity Facility R4.1 (cont'd)

Microfiche (LYB0-2579) containing Tables, Panels, Skeletons, and Message Files for VSE Environment ... Microfiche (LYB0-2580) containing Interactive Productivity Facility Dialog Manager Source Listings, PLM, and PLM TNLs for VSE Environment ... Microfiche (LYB0-2568) containing Tables, Panels Skeletons, and Message Files for VM/VSE Environment ... Microfiche (LYB0-2572) containing Interactive Productivity Facility Dialog Manager source listings, PLM, and PLM TNLs for VM/VSE Environment ... Interactive Productivity Facility Program Function Key Template for 3277 (SX20-2346) or 3276/3278 (SX20-2355) ... *Interactive Productivity Facility VSE Environment Licensed Program Specifications* (GH20-5527).

RPQs ACCEPTED: No

**5748-MS1 - INT. PROD. FAC. VM ENV. R5.0
INTERACTIVE PRODUCTIVITY FACILITY
VM ENVIRONMENT RELEASE 5.0
5748-MS1**

PURPOSE

The VM/Interactive Productivity Facility Release 5.0 is designed to simplify the user interface to the VM/SP System. VM/IPF communicates with the user through dialogs (panels) that support Administrative, Operations and General User functions, and thus can reduce the skill level required to use the system while improving user productivity. This offering enhances the user's capabilities in the Application Development, Information Center, and Engineering/Scientific environments in both autonomous departments and large establishments with distributed processing.

SPECIAL SALES INFORMATION

Release 5.0 of the Interactive Productivity Facility is designed to run in the VM/SP Release 2 and Release 3 environments and will be supported in the VM/SP System IPO/E environment.

OVERVIEW

Major enhancements/improvements to this release designed to support the System Administrator, Operator and General User include:

- Panel-Driven Directory Maintenance Functions
- A Problem Reporting and Management Facility
- Network Communications Support
- Accounting Function Support
- CMS File Communications Support
- Operator Panels
- A CP/CMS Command Entry Facility
- Indexing To Tasks
- Improved Human Factors of Panels and Documents
- System Tailoring Support
- New Task Structured Documents
 - General Use Guide
 - Administration Guide
 - Operation
 - Problem Control
 - System Reference

To assist the user in selecting tasks to be performed, a series of menu panels are available, and organized in a hierarchical structure. The user selects the desired task from the menu. This will lead to the execution of system functions. Through an indexing function, the experienced user can select the task directly, without the need to go through each level of the hierarchy.

Through Data Entry panels, the Interactive Productivity Facility prompts the user for information required to execute system functions. Using a 'fill-in-the-blanks' technique, the user supplies the necessary system parameter information, and the Interactive Productivity Facility transforms this into the appropriate system input format and invokes the necessary system functions.

For the new or infrequent user who requires additional information, most menu and data entry panels are supplemented with Help panels. Thus, the Interactive Productivity Facility is designed to relieve users from many tedious, error prone tasks and improve productivity.

HIGHLIGHTS

- **Panel Driven Directory Maintenance Functions**
Support is provided by panels for the Administrator to:
 - Work with a user's directory to enroll, change, remove users and change user's password or storage size.
 - Work with minidisks to add, change, extend, or delete them.
 - Provide directory status information by listing DASD space, checking directory integrity or checking status of users
 - Correct directory maintenance problems by rebuilding the directory from backup, initializing the directory or enabling a disabled directory
 - Use the CP directory map to create, browse, or print the directory map of DASD space
 - Perform general housekeeping functions
 Support is provided by panels for the General User to:
 - Change passwords, storage size, distribution codes and disk accessing
 - Display user's own passwords or modes
 - Establish/drop links to other users, control access by others to user's disks, and control auto-IPLs
- **Problem Reporting and Management Facility**
The Problem Control Facility (PCF) is a problem reporting and tracking facility used to report, answer, close and update problems and generate problem reports. The facility helps to correlate system dump problem reports with the user problem reports and can be used to control problem reports from multiple systems.

- **Network Communications Support**
Panels are provided to support the operator/administrator in the RSCS environment to initialize network(s), add/delete links and routes, and query networks for status.
- **Accounting Functions Support**
The user can, via panels, select accounting parameters for automatic execution by the VM accounting program
- **CMS File Communications Support**
Panel support is provided for the CMS communications EXECs: NOTE, TELL, DEFAULTS. A panel interface is provided for the EXECs: NAMES, SENDFILE and RDRLIST.
- **Operator Panels**
Panels are available to assist the user to attach devices, set logs, control spool files (rdr/punch/printer), query the system for status, and backup/restore data.
The operator can define a schedule for auto-backup of DASD volumes, or exercise this schedule, via panels at intervals of his choice. The saved data will then be available on tape in the event data recovery is required.
- **CP/CMS Command Entry Facility**
A facility is provided to allow EXECs and CP/CMS commands to be entered from the command line of most panels. This facility also:
 - Prevents certain machine-destructive CP/CMS parameters, commands or options from being executed from the command line if the user selects 'protective' environments
 - Re-displays unsuccessful/incorrect commands
 - Maintains a history of successfully completed commands for display/re-use
- **Indexing To Tasks**
The indexing facility provides the user the ability to select a function or task to be executed, from a table, without the need to progress through each level of the hierarchy.
- **Improved Human Factors of Panels and Documentation**
The panels and documentation have been structured to improve readability, eliminate unnecessary words, and use concrete words and phrases in place of complex or abstract terms.
- **System Tailoring Support**
Panels are provided to:
 - Specify when accounting reports are automatically printed
 - Add a real disk to DIRMAINT resources list
 - Initialize or label a real disk
 - Specify the default printer for automatic start at IPL time
 - Change FCB/UCS parameters and printer spool classes of the default printer.
 - New Task-Structured Documents
 Task-structured documents are provided for Administrators, Operators, and General Users. Task, versus function orientation, has been shown to increase usability and user acceptance.

DESCRIPTION

The Interactive Productivity Facility has the following components:

1. **Executable Dialogs (Panels)**
 - Menu panels that guide the user in selecting activities to be performed.
 - Data Entry panels that guide the user in supplying the required information needed to execute system functions.
 - Help panels to provide additional information for the new or infrequent user.
 - Control statement files to which user-provided information is added for execution of system functions.
 - Function routines (EXECs) that:
 - Display panels
 - Analyze user input
 - Invoke CP/CMS commands
 - Invoke applications
 - Service VM/SP System IPO/E feature products

PROGRAM PRODUCTS

Interactive Productivity Facility - VM R5 (cont'd)

2. Publications: To be available concurrent with program availability:

VM/IPF Rel. 5 Administration Guide	SC24-5230
VM/IPF Rel. 5 General Use Guide	SC24-5233
VM/IPF Rel. 5 Operation	SC24-5229
VM/IPF Rel. 5 Problem Control	SC24-5231
VM/IPF Rel. 5 Administration Messages	SC24-5234
VM/IPF Rel. 5 General Use Messages	SC24-5232
VM/IPF Rel. 5 Licensed Program Specification	SC24-5235
VM/IPF Rel. 5 System Reference	SC24-5228

may affect system performance. Further information on VM/IPF performance will be made available prior to General Availability.

RPQs ACCEPTED: No

3. Courses

Two courses are provided which teach how to use the VM/SP components EXEC2 and XEDIT. The IIPS program product must be installed to use these courses.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

VM/IPF is designed to operate on those IBM processors supported by VM/SP Release 2 or 3 with at least 1 megabyte of storage. Terminal(s) required are IBM 327X or equivalent.

SOFTWARE REQUIREMENTS

The Interactive Productivity Facility is designed to operate with the VM/SP (5664-167) Release 2 or 3, VM/IPCS Extension (5748-SA1) Release 2.0, VM/Directory Maintenance (5748-XE4) Release 2.0 and RSCS (5748-XP1) Release 3.0. The VM/IPCS Extension program product contains functions necessary to execute the problem reporting procedures provided with the Interactive Productivity Facility. The VM/Directory Maintenance functions and RSCS functions are implemented (and simplified) by a set of user panels.

The Interactive System Productivity Facility (ISPF, 5668-960) Release 1.1 is a prerequisite for the Interactive Productivity Facility - VM Environment.

CONVERSION

Several functions included in VM/IPF Release 4 have been restructured for VM/IPF Release 5 and some will not be included in this release:

- The System Utilities panels have been replaced by the General VM/SP Tasks.
- The Problem Management commands (SPROB and GPROB) have been replaced by Problem Control Facility functions.
- The OPTIMIZE command has been replaced by the XEDIT VMFOPT command.
- The MAIL facility has been removed and replaced by panel support access to the VM/SP Productivity Aids.
- The saving of Shared Systems and DCSSs has been modified and the panel now asks for a specific name to save.
- Documentation has been restructured and references to the VM System IPO/E removed.
- The stacked product tape installation function has been removed from the System Management panels and the INSTIPF (Exec) eliminated.
- The REVIEW command has been removed.
- Computer-Based Training courses supplied with VM/IPF Release 5 are limited to XEDIT and EXEC2.
- The ASSIST function has been modified. The ASSIST, ASSIST C, and ASSIST D commands, and Command Mode and General System Utilities via ASSIST are no longer available. The function System Help is not available from the General User panels.
- Panel access to the program product INFO/SYSTEM has been removed.
- The FLIST, BROWSE and MOUNT functions and associated CMS HELP can only be invoked from the command line. Panel support for these functions has been removed.

INSTALLATION and USE CONSIDERATIONS

VM/IPF 5 will be supported in the VM/SP System IPO/E environment but may be installed without the VM/SP System IPO/E. VM/IPF 5 functions require a specific system configuration (device addresses, directories, and space allocations). This system structure information is included in the installation instructions.

DATA SECURITY

VM/IPF runs as a virtual machine in VM/SP and is subject to the security facilities provided by CP. It is organized to provide for three types of users: General, Operator and System Administrator. Through use of standard CP Directory facilities, the Installation Manager can restrict access to each functional area. A user gains no additional VM/SP CP authorization capability from the use of VM/IPF.

Customer Management is responsible for the selection, adequacy and use of these features for the protection of their data.

PERFORMANCE CONSIDERATIONS

It is recommended that VM/IPF be installed on a 2 megabyte or greater processor. Multiple VM/IPF users executing in a 2 megabyte processor

VM PASS-THROUGH FACILITY 5748-RC1

PURPOSE

The VM Pass-Through Facility provides the VM/370 user with interactive remote access to host facilities that support the IBM 3271 and 3274 Control Units over BSC multi-point lines. This product supports connection to host systems such as OS/VS2, OS/VS1, DOS/VS, VSE and other VM/370 systems. Host applications supporting 3270 BSC remote displays such as TSO, CICS and CMS, may be accessed via the VM Pass-Through Facility. A user connected through the VM Pass-Through Facility interfaces with the host application, and the user's screen duplicates exactly what the host displays as though the 3270 were attached directly to the host system. When connected to a SNA host the VM Pass-Through user will have full 3270 BSC access to the SNA network. In this environment, VM Pass-Through can be used as the first step towards full participation in a SNA network.

HIGHLIGHTS

Release 2

- **DDP Support:** Support for the remote initialization and control of distributed IBM 4300 processors. Feature #9511 and appropriate 4331 and/or 4341 EC level changes are required. See 4300 Machine Pages for details.
- **3270 Printer Support:** Support for the IBM 3270 Information Display System printers from directly (or indirectly) attached subsystems such as CICS or TSO for printing at the Pass-Through node.

User Communication Services: The VM/370 user is able to gain remote access to interactive host applications through the VM Pass-Through Virtual Machine. The user may connect to this virtual machine from local or remote 3276, 3277, 3278 or 3279 display terminals.

User Selected Host: Once a user has connected to the Pass-Through virtual machine, the user may request connection to any host supported by the installation. The user is assigned to a free active logical port of the host connection. Once connection is made to the host machine the user is presented a logo from that system and is free to communicate to that system until session termination.

Selection Screen: A selection screen is available to assist the user in connecting to a host. The selection screen displays active and inactive nodes and allows the user to specify a session disconnect sequence.

Notepad Facility: The Notepad facility allows a CMS user to append a copy of the current screen image to a CMS file.

Message Facility: VM/370 users may send messages to other VM/370 systems and users.

Terminal Support: Users may gain access to Pass-Through services using IBM BSC 3276, 3277, 3278 and 3279 display terminals having a screen size of at least 24 x 80 characters. IBM 3279 displays are supported in base color only. Extended color, highlighting and programmed symbols are not supported. Once connected to the Pass-Through facilities, the user terminal is supported using the VM/Basic Systems Extensions Release 2, VM/System Extensions Release 2 or VM/System Product full screen support.

Up to 32 Ports Per Line: For each BSC leased line supported in 3271/4 emulation mode, VM Pass-Through will allow a maximum of 32 active display printer sessions to concurrently share that line. Users are connected by Pass-Through to logical ports associated with the line.

Communication Facilities: The VM Pass-Through Facility supports interconnection with other host systems. These hosts may include other VM/370 systems with or without the VM Pass-Through Facility program installed.

Multiple Host Nodes Supported: Multiple connections between the local VM/370 system with Pass-Through and host nodes are supported. Upon connection to the Pass-Through virtual machine the user selects which host node is required for the user's session. Upon disconnection from that host node another host node may be selected for another session.

327X Line Emulation: VM Pass-Through emulates a remote IBM 3271 or 3274 on a BSC multipoint leased line connection to another node which is programmed to support the remote 3270 (e.g., TSO, CICS and CMS). The local VM/370 system is transparent to the host node.

Pass-Through to Pass-Through Connection: VM Pass-Through supports interconnection to Pass-Through virtual machines executing in other VM/370 nodes.

CUSTOMER RESPONSIBILITIES

In addition to the responsibilities in the VM/370 section of the Sales Manual under the heading "Customer Responsibilities", the customer is responsible for ordering and installing the latest level of the VM/370 SCP and VM/System Product Release 2.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The VM/System Product is designed to run on the S/370 Models 135, 135-3, 138, 145, 145-3, 148, 155II, 158, 158-3, 158AP, 158MP, 165II, 168, 168-3, 168AP; on the 3031, 3031AP, 3032, 3033, 3033N, 3033S, 3033AP, 3033AP-2 and 3033MP Processor Complexes; and on IBM 4300 Processors; and requires VM/SP Release 2 to operate. See the pages for VM/System Product.

Real Storage Requirement: VM Pass-Through Facility, Release 2, in conjunction with VM/SP Release 2 requires a minimum user-accessible storage of 512K.

SOFTWARE REQUIREMENTS

The VM Pass-Through Facility, Release 2 is designed to operate with the VM/System Product, Release 2. IPCS support is designed to operate with the IPCS-E program product.

RPQs ACCEPTED: No

TERMS and CONDITIONS: See PP Index

PROGRAM PRODUCTS

**VM/INTERACTIVE PROBLEM CONTROL SYSTEM
EXTENSION
5748-SA1**

PURPOSE

IPCS is a software problem handling facility intended for use by customer personnel and, where appropriate, IBM Program Support Representatives (PSRs). IPCS will reduce the time, effort and expense required to resolve software problems by providing facilities for Problem Reporting, Problem Management and Problem Diagnosis.

DESCRIPTION

- **Problem Reporting** - Problem Reporting facilities standardize the problem reporting process, identify previous occurrences of the same problem on the system and allow faster and more specific identification of similar problems previously experienced by the entire VM/370 customer base. Duplicate problem recognition (1) reduces the amount and expense of unnecessary hardcopy documentation and (2) allows faster identification of available fixes that can be applied to the system.
- **Problem Management** - Problem Management facilities provide the capabilities of (1) updating the individual disk-resident problem reports and summary problem status reports, and (2) displaying and printing these reports. These facilities allow the customer and/or PSR to track and manage problems from their occurrence through their resolution.
- **Problem Diagnosis** - Problem Diagnosis facilities provide the capability to interactively view disk-resident problem data (i.e., CP and CMS ABEND dumps and all other dumps taken through the new VM/370 VMDUMP Facility. (See "VMDUMP" in VM/370 pages for further information on the VMDUMP facility available in VM/370 Release 6.) This capability allows the customer and/or PSR to interactively diagnose a dump-related problem from any VM/370 supported terminal, without the need for hardcopy problem data.
- **Remote Usage** - The VM/370 telecommunication capability enables the use of IPCS by customer personnel located remotely from the IPCS site. Use of IPCS in this manner is dependent upon the availability of appropriate customer-provided telecommunication facilities at both the IPCS and remote sites.

IPCS HIGHLIGHTS

Problem Reporting

- IPCS generates a disk-resident Problem Report for a software problem. The report contains specific symptoms of the problem as well as identification information such as time stamp, system level, etc. Optionally, the report can contain free-form descriptive information and/or identification of CMS files containing data related to this problem.
- IPCS provides facilities for printing Problem Reports or viewing them from a display.
- IPCS automatically extracts the appropriate problem symptoms from the dumps accompanying CP and CMS ABENDs. IPCS prompts the user for symptoms of other problems.
- IPCS automatically compares symptoms of the current problem with those of previous problems encountered at the installation and notifies the user of possible duplicates.

Problem Management

- IPCS provides facilities for updating the status of open problems from initial reporting through closing.
- IPCS provides facilities for displaying or printing the status of any, all or combinations of problems on file at the installation.

Problem Diagnosis

- IPCS provides a variety of dump viewing sub-commands which allow the user to interactively locate data, display data, print data or control the display screen for CP and CMS ABEND dumps, and any other dumps taken through the new VM/370 VMDUMP facility. (See "VMDUMP" in VM/370 pages for further information of the VMDUMP facility available in VM/370 Release 6.)
- IPCS provides facilities to print CP and CMS ABEND dumps, and any other dumps taken through the new VM/370 VMDUMP facility.

APAR Generation: An IPCS command, "APAR", will provide the facility for generating the hardcopy APAR and offloading problem data to tape or hardcopy for subsequent submission of the problem to IBM. This facility can reduce the turnaround time involved in problem resolution by providing more complete and accurate input to the IBM support organization.

General Problem Reporting, Tracking and Dump Viewing Support: IPCS will generate a Problem Report, track problem status and permit interactive dump viewing for all problems having a dump taken through the new VM/370 VMDUMP facility. (See "VMDUMP" in VM/370

pages for further information of the VMDUMP facility available in VM/370 Release 6.) The IPCS user can enter problem symptom information to be included in the Problem Report for any problem where this information is not automatically extracted from the dump.

By using VMDUMP, the operator of a guest virtual machine can make a dump of any user-detected software problem available for subsequent interactive dump viewing and dump printing through the facilities of the VM/IPCS Extension program product.

CUSTOMER RESPONSIBILITY

While IPCS is a powerful tool to assist the customer with software problem handling, it remains the responsibility of the customer to establish appropriate procedures for problem reporting, problem diagnosis and problem management.

IPCS requires no extraordinary installation procedures. Refer to the *General Information Manual* and the program directory shipped with the VM/IPCS Extension for the installation procedures required.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The VM/IPCS Extension Program Product is designed to operate on the IBM processors supported by VM/370 Release 6 with the VMDUMP facility.

SOFTWARE REQUIREMENTS

No additional system facilities are required over and above those required by VM/370 Release 6. See VM/370 pages for details. The VM/IPCS Extension program product can be operated with, but does not require, the following VM products and all the devices they support: (1) Release 2 of the VM/BASIC System Extensions program product, and/or (2) Release 2 of the VM/System Extensions program product. Additionally, Release 2 of VM/IPCS Extension program product can be operated with, but does not require, the following VM product: (1) The VM/System Product.

COMPATIBILITY

To implement the full capabilities of IPCS in the VM/System Product environment, and to correctly support the control block modified by the VM/System Product, installations should migrate to Release 2 of the VM/IPCS Extension program product.

CONVERSION CONSIDERATIONS

VM/IPCS provides a CONVERT command to reformat files established by the currently available VM/370 IPCS (Component 5749-DMM) to the format required by VM/IPCS Extension.

The facilities of Release 2 can be used with dumps previously processed by or files created by Release 1 of VM/IPCS Extension.

AIRLINE CONTROL PROGRAM/ TRANSACTION PROCESSING FACILITY ACP/TPF (5748-T11)

PURPOSE

ACP is a reliable, highly responsive, performance-oriented operating system for realtime transaction-driven applications. The ACP System provides the Multisystem Networking Facility within the framework of the Advanced Communications Functions (ACF) of SNA. The Multisystem Networking Facility is offered as a feature in a separately-orderable component called ACP/ACF. The ACP/TPF is a prerequisite to the ACP/ACF feature. The following is a description of the ACP/TPF Program Product and ACP/ACF feature when used in conjunction with the currently available PRPQ 5799-ACP Version 9 Release 2 (ACP 9.2).

DESCRIPTION

ACP systems are characterized by thousands of terminals dispersed over a large geographical area where each location may have from one to several hundred terminals. ACP provides realtime inquiry and update to a large centralized data base where message length is relatively short in both directions and response time is generally less than 3 seconds.

A key attribute of ACP is its reliability and availability. This is a result of a well managed operation and the use of the many support tools provided with ACP:

- Over 280 operator commands.
- 1- to 3-minute system restart.
- Online data base load/dump/copy.
- Online debugging aids and offline test tools.
- Dynamic system performance monitoring.
- Processor, line, and I/O error recovery and recording.

Applicability: ACP is applicable to any online transaction oriented application which requires fast message response time from a large number of terminals. Some examples of applications are airline seat reservations ... hotel reservations ... credit authorization/verification ... car rental reservations/billing ... police car dispatching ... electronic funds transfer switching ... teller memo post ... message switching ... loan payment processing.

SYSTEM SUPERVISOR

Work Management: Messages, entries, tasks and jobs are terms used to describe units of work in an operating system. The terms used in ACP are message or entry, both of which apply to the input characters that trigger a work unit.

At any one time, there are likely to be many entries in the system, each handling a unique unit of work. ACP will service existing entries which are ready to be processed before creating entries to service new input messages. The level of multiprogramming is controlled by the creation of entries, which is influenced by the amount of main storage available. Although entry processing may be deferred, the primary thrust is to speed an entry through the system.

Main Storage Management: The organization of main storage is one of the keys to the high performance of ACP. Part of main storage contains programs and data that are common to all entries and which remain in main storage. This portion is called fixed storage. Another portion, called working storage, is allocated to entries as required. Storage protection is used for fixed storage, inhibiting an application from illegally modifying the control program, core-resident application programs and critical data records. Working storage is divided into fixed size blocks. These block sizes are compatible over all levels of storage which permits the system to efficiently provide the application environment with the illusion of a single level of storage.

Program Management: Application programs are written in Assembler language and request control program services by means of system supplied macros. Programs may be allocated to fixed main storage or file storage. The main storage in which file resident programs must be placed in order to be executed is dynamically managed to eliminate redundant file accessing. The system uses a program sharing table to keep track of program segments that are currently in main storage. Through the use of system macros and system conventions all application program segments are re-entrant; therefore, one copy of the program may be shared by many entries at the same time.

Data Management: ACP considers the online files as a common data resource to be shared by the applications. An application may structure data to satisfy unique processing requirements, but the structuring is done within the context of the basic data structure supported by the system programs. The most primitive level of problem state data reference is done with symbolic addresses which supervisor programs use to locate a record on some physical storage media. Therefore, all problem state programs are independent of the physical residence of the data. The basic data structures are fixed, pool, tape, general file and general data set.

Fixed file records are records whose symbolic addresses are calculated by a system routine which uses a record type and an ordinal number. The record type identifies a set of data within the data base and the ordinal number identifies a relative record within the record type. The fixed file records appear as a sequential data structure to the application environment.

Pool records are records for which the system maintains an availability indicator for each record. When an application requests pool file space, ACP returns the symbolic address of one of the available records in the pool. When the application is finished with the record, the record associated with the address is marked available.

A common technique used by applications is to form data structures that use fixed records as indexes to pool records. The combination of fixed and pool structures provides the application designer with the tools to implement application oriented data management sub-systems in an ACP environment.

A number of important features are available to the user of fixed and pool structures:

Record hold is a method of reserving data records for the exclusive use of an entry during a record update. This feature prevents lost data when multiple entries are trying to update the same record.

Record duplication decreases the probability of losing critical data due to hardware failure and increases the accessibility of the records. If a record is duplicated, two copies, on separate devices, will be updated whenever file storage is updated. The additional copy reduces the probability that, upon retrieval, a record will be unavailable due to hardware failure. Most of the time both copies are available in which case the copy with the shortest device queue is used.

ACP has the capability of automatically logging all file updates to tape for selected record types. This function can be used for file backup.

File records with high reference frequencies may be selected for virtual file access (VFA). The main storage into which these records must be placed during application processing is managed to eliminate redundant file accesses. The system uses a record sharing table to keep track of records that are currently in main storage. VFA can potentially decrease the accessing requirements of the file subsystem.

The principle of a single level of storage keeps the devices on which the records are located completely transparent to the application. The file address reference which the Application Programmer references is completely independent of hardware characteristics. This device independence allows easy migration between file devices without application coding complications or modifications.

The organization of fixed and pool files distributes the records associated with a record type over physical file storage to reduce queuing time at the devices. Thus, when an application accesses successive records within a record type, each record may be obtained from a different physical component. The physical organization may be envisioned as a group of disk packs, each identical in format and type of contents. A record type forms equal layers on each pack. Each pack holds a portion of every fixed record type and every pool type included in the online files.

Tape files are classified into two categories, realtime and general. Realtime tapes are mandatory on a system and are used by ACP and applications for output critical to system operation and for testing. General tapes are treated as a sequential file and can be either written or read by the online system.

The records of a general data set are allocated sequentially within the same disk module. The allocation of a general data set to physical devices is done during online execution. The data set is dedicated to the entry requesting the use of the data set. The structure of the data within a general file or data set is application dependent.

Restart: ACP backs up critical data that resides in all levels of storage. The system data considered critical is grouped into special records called keypoints. In some cases, critical application data, backed up by the system, are grouped into records called globals.

Globals and keypoints are periodically written to different disk modules on a cyclic basis. In the event of a device failure from the primary back up device, the system can select an alternate disk module. A restart may be initiated automatically by ACP when it determines that such action is required, or by an operator taking a manual action. Restart time is usually one to three minutes.

Cohabitation: At other than peak periods, a relatively small amount of processor power is used by the ACP application environment. This available processor power is utilized by allowing OS/VS or an ACP test system to operate in the same processor with ACP. Cohabitation of ACP with OS/VS or ACP is accomplished with a software facility, known as the hypervisor, in conjunction with S/370 relocate hardware. The ACP hypervisor facility preserves the responsiveness of ACP applications by servicing ACP requests first. The Virtual Machine Assist (VMA) feature may be used to improve OS/VS performance, if it is

ACP/TPF (cont'd)

available on the processor. The ACP and OS/VS or ACP test systems are protected from each other such that failure of one will not adversely affect the other.

The hypervisor allows sharing of the system byte and block multiplexer channels, control units and main storage. While input/output devices can not be shared by ACP and OS/VS, their assignment can be changed from one system to the other by the operator. Main storage must be partitioned into two fixed size areas, one for each system, when the processor is initialized.

The hypervisor supports OS/VS1 or OS/VS2 (SVS or MVS) or ACP test system under ACP. However, ACP and only one other system may coexist between system restarts.

Operator Commands: ACP provides a complete set of operator commands and programs to allow the operator to control the system. The commands perform such functions as hardware reconfiguration, altering system tuning parameters, changing the current application program version to be used, starting OS/VS operation under the hypervisor and sending broadcast messages. In all, there are over 280 different operator commands available. These commands can be entered from up to ten selected terminals that function as operator consoles.

COMMUNICATIONS FACILITIES:

Both large terminal networks and computer networks are supported by ACP.

ACP's terminal environment consists of remote cluster controllers connected to the host system via medium speed communication lines using either Synchronous Data Link Control or Airlines Line Control.

ACP's computer network environment consists of remote central processing units connected to the ACP host system via medium speed communication lines using either Binary Synchronous Communication, Synchronous Link Control or Synchronous Data Link Control.

Extensive functional capabilities are provided in the area of message handling for long message input assembly and long message output transmission. Unsolicited message support allows the broadcasting of output from either an application or the computer operator. Application independence for the 3270 terminal is provided by the screen mapping and paging package.

Communications support functions include a comprehensive set of operator commands for network monitoring and control. Online utilities are provided to load and dump the programmable communications controllers (3705 and 3600). Reliability, availability and serviceability features include numerous communication trace functions as well as controller and link diagnostics.

Systems Network Architecture: ACP provides Systems Network Architecture (SNA) support for the 3600 Finance Communications System and for the 3270 Information Display System. The following functions are provided with SNA support:

- Distributed function of remote intelligent controllers.
- SNA and SDLC message integrity.
- SDLC line control efficiency.

In addition, the advanced communications function (ACF) provides for multi-system networking. The ACP/ACF feature supports cross system message routing, through which data may be transmitted across systems to its destination, without host intervention after initial session establishment.

ACP supports SNA interfaces with the SNA network via the 3705 Network Control Program (NCP/VS). The message protocol used by the 3600 application programs generated via the Program Customizer (PC3600) is supported by ACP.

Performance: SNA support is provided without compromise of the ACP high performance characteristics. For an inquiry message the instruction path is shorter than the performance oriented Airlines Line Control (ALC) path. This is primarily due to the line handling responsibilities assumed by the NCP/VS (i.e., polling, error recovery, translation).

In addition to the one input and one output message protocol used by PC3600, ACP provides support for attaching many terminals to a single SNA Logical Unit (LU) at a cluster controller. This feature is directed at the point of sale environment, where multiple terminals at the intelligent controller share a single SNA communication path to the host.

In any telecommunications system, the time required to perform a restart after a system interruption must be short. In keeping with the objective of less than 3-minute restart, the ACP SNA software does not automatically reinitialize the network on restart. Normally, the host and the cluster controllers will preserve message sequence numbers over a system interruption and no network initialization is required. However, following a 3705 failure, ACP performs the network start up function. This is performed in a fully parallel fashion to minimize the time required for network restart.

Application Interface: The ACP/application message processing interface consists of a parameter list with networking addressing formats used by system routines and a pointer to a main storage block containing the text of the message. This interface is common to all network components including those adhering to SNA protocols.

Message Integrity/Security: The complete message integrity capability provided in SNA by message sequence numbering is fully supported by ACP. The SNA sequence number of an inbound message is available to both the host and the cluster application programs. This number can be used for message recovery, audit trails and output reply correlation at the cluster controller.

As an optional feature, ACP provides a complete message recovery and reply tracking package. As each message is received in the host, it is analyzed by the application to determine if it is recoverable. ACP will write each recoverable message to the online disks and track the expected reply. When the reply is received from the application, it is written to disk and tracked until the positive response is received from the cluster controller. Recovery action is initiated if the application reply or the cluster response is not received within the specified time. In addition, ACP provides an application oriented recovery package which allows message recovery and data base recovery to be combined. This message recovery package can also be used by the application program to age messages sent to remote processors in the network.

ACP provides the support to encrypt and decrypt messages to or from the 3614 Consumer Transaction Facility. To facilitate the exchange of encrypted messages from any network end point (remote processors as well as 3614s), the encrypt/decrypt algorithm is provided as a supervisor call subroutine in ACP. Since this same algorithm is also provided in the 3600 software, all messages in the SNA 3600 network may be encrypted for maximum security.

Message Handling: ACP provides broad functional support in the area of message handling. Major areas of support include:

Long Message Assembly - Long messages sent from the remote controllers are segmented for transmission to the host. These segments are assembled on disk by ACP before presenting the entire message to the application program.

Long Message Transmission - Long messages sent by the application are segmented and queued on disk by ACP for transmission to the remote cluster controller. For 3600, these segments are transmitted using SNA pacing to protect against overloading the cluster controllers and the 3705. For 3270 these segments are collected by ACP and transferred to the NCP in a continuous data stream.

Unsolicited Message Transmission - An unsolicited message is an output message without a corresponding previous input. At the request of the application program, ACP queues unsolicited messages on disk by destination address. Prior to transmission, permission to send is requested and a positive response from the terminal or logical unit triggers the transfer.

Bulk Data Transfer - ACP provides specialized SNA support to facilitate the transfer of bulk data to and from the remote cluster controllers. Transmission of negative credit files and off-host authorized transactions are two examples of bulk data. On interactive transaction messages, the application is shielded from the details of the SNA message protocol by ACP. However, during long transmission the host application must establish meaningful checkpoints to minimize retransmission time in the event of a failure. For defined batch transfer logical units and application programs, ACP allows the application to receive, decode and send SNA responses. The normal long message assembly and transmit support is used in handling multiple segment output for the batch logical unit.

Screen Mapping - The application program achieves 3270 device independence by using the ACP screen mapping package to edit, construct and format 3270 data streams. Input messages originating at the terminal contain field oriented data consisting of device dependent control characters and message text. ACP deletes the control characters and presents the text to the application as a set of variable length data fields. This process is controlled by a predefined screen map. In the outbound direction, ACP constructs the terminal dependent data stream from the application provided data fields and the screen map.

3270 Scrolling and Paging - When a display message is greater than the screen size, it is either handled as a continuous scroll or as pages in a book. The application provides the display message as a long output message. After the first page is displayed on the screen, the terminal operator controls the screen with page or scroll commands. Scroll commands reposition the screen image a line or group of lines at a time. The entire process is controlled by the screen map which defines the page or scroll size. This feature facilitates split screen operation.

1980/ALA (Alternate Line Attachment) - Consumer Finance accounts have existing networks which include 1980 terminals. Support for the 1980/ALA RPQ, which allows non-SNA terminals to be attached to a 3601-3 Finance Communications Controller, permits the use of a single host connection for 1980 terminals and the standard 3600 SNA devices.

ACP/TPF (cont'd)

Support Functions: The supporting functions provided with the ACP SNA capability include the following:

Operator Commands - These commands give the ACP computer operator the ability to control the SNA network. The status of an NCP, a line, a cluster controller or an individual logical unit may be displayed at the console. The operator may also stop or start any portion of the SNA network and may alter the frequency for host selection of the NCP.

Online 3705 load/dump - The 3705 may be loaded or dumped online in parallel with realtime operation. The OS/VS provided NCP generation process is used offline to create 3705 load modules. These load images are then stored in the online disk files and are transferred to the 3705 on command from the ACP operator. Dump images are temporarily accumulated online for later spooling to tape and offline printing in standard format.

Online 3600 load/dump - The 3600 and 3614 may be loaded online in parallel with realtime operation. The OS/VS provided Subsystem Support Services package is used offline to create remote controller load images. The load images are stored in the online ACP disk files and are transferred to a 3600 or 3614 on command from either the ACP operator's console or from the remote cluster. Dump images are temporarily accumulated online for later spooling to tape for offline printing in standard format by Subsystem Support Services.

3705 and SDLC Link Diagnostics - ACP provides for concurrent maintenance of the SNA network with online 3705 diagnostics. These 3705 resident diagnostics are activated from the ACP operator's console and perform data path tests in parallel with normal message flow in the NCP. The link test transmits a test message and receives an echo on the SDLC link without disturbing the normal message traffic on other lines connected to the NCP.

Line and Message Trace - ACP provides extensive communication trace facilities at a link and NCP level. These trace functions are initiated from the ACP operator's console and the output is written to a log tape for offline printing. All messages sent to and received from the NCP can be traced. Link trace is performed in the NCP with accumulated trace data forwarded to ACP for logging.

Line Fallback - In the event of a permanent SDLC failure, the host operator can perform link fallback by manually dialing the cluster controllers on the failing link. Normal message flow is resumed by an ACP operator command which makes the necessary control block adjustments. The application program is unaware of the address change that has taken place.

Performance Measurement - This package performs online gathering of raw measurements for the offline data reduction package. The reduction programs produce reports which can be used to determine input loads, output loads, message rates, message processing characteristics, line occupancy and response time. SNA communication statistics are compiled and presented at varying levels of detail, extending from the system as a whole to an individual logical unit. Since the host system is not fully aware of the line traffic in an SNA environment, statistics online occupancy is not possible for all SDLC lines.

Network Generation - A single SNA network definition (NCP system generation input) is used to create both the NCP and the ACP network tables. The ACP SNA table generation program runs independently of the ACP system generation. This facilitates network configuration changes and growth without requiring a new ACP system generation.

Binary Synchronous Communications: ACP provides Binary Synchronous Communications (BSC) support using standard point-to-point and multipoint data link protocols (for details see the *General Information - Binary Synchronous Communication Manual (GA27-3004)*).

ACP supports BSC line protocol with non-IBM as well as IBM systems.

Data Link Operation: The ACP support of BSC links is characterized by the following operational attributes:

Transmission code - To provide more general usability, ACP handles BSC lines operating with either EBCDIC or USASCII transmission code. EBCDIC transparency is optionally provided to allow the transmission of binary data between computers.

Blocked transmission - Long messages consisting of multiple message blocks can be received and sent by ACP. There is no limit to the total message size in either the inbound or the outbound direction.

Send limit control - To balance line utilization between input and output, ACP limits the number of output messages sent between input operations. The send limit is defined at network generation time and can be altered online by the ACP operator.

Master/Slave contention priority - BSC point-to-point message protocol allows each end of the line to contend for transmission time. When both ends bid for the line simultaneously, the contention is resolved by a master/slave relationship. ACP may be either master or slave. This attribute is defined by line at network generation time and can be changed online by the ACP operator.

Control or tributary multipoint support - The control station on a BSC line either polls or selects the tributary stations. Polling invites the tributary to send data. Selection requests permission to send from the control station to the tributary station. ACP may be either the control or the tributary station.

ACP interfaces with the BSC lines via the 3705 Emulation Program (EP). When SDLC and BSC links are connected to the same 3705, ACP supports the Partitioned Emulation Program (PEP).

ACP BSC support provides least queuing by communication line. When multiple lines exist between two computers, output messages are queued to the line with the smallest message queue. This balances the line usage and promotes fast delivery of messages.

When multiple BSC lines exist between two computers, ACP provides alternate line routing in the event that one or more of the lines fail. ACP also returns undeliverable messages to the originating application when all lines to a particular destination are inoperative.

Message Integrity: BSC line protocol requires positive acknowledgment. In addition, ACP provides a generalized message logging and tracking mechanism which can be used by the application programs. Prior to transmitting a request to a remote computer, the application can request that ACP log the output with any associated data and activate a time out. When the data reply is received from the remote computer, the application can retrieve the log record and deactivate the time out. ACP ensures the integrity of the log over a system interruption.

Although 3614 encryption is provided with the SNA support, this algorithm can also be used to encipher and decipher messages sent and received over BSC lines.

Message Handling: ACP provides normal long message handling for both incoming and outgoing long multiple block messages.

Blocked input messages are assembled on disk before presenting the entire message to the application program. While input message size and block size is unlimited, message blocks which are compatible with ACP core blocks are handled most efficiently.

Long output messages are segmented on disk by the application and are queued by ACP on a line basis. ACP controls the transmission of each block and ensures that the entire message is sent successfully. Although output message size is unlimited, output message blocks must be 1020 bytes or less.

Operator commands - A complete set of operator commands are provided for monitoring and control of the BSC network. The status of each line and station may be displayed at the operators console. The operator may stop or start any network component, alter lines operational characteristics, load or dump the 3705 or initiate selected online link diagnostics.

Synchronous Link Control (SLC): SLC is a highly efficient protocol designed to control the interchange of messages on a point-to-point link between two processors. The link is synchronous on full duplex, private leased voice grade lines. Each link consists of up to 7 communication lines. The transmission load is balanced across the available lines (parallel transmission of data blocks). ACP supports SLC links with lines operating at speeds of up to 9,600 BAUD. All data messages are sequenced allowing each processor to detect missing or spurious messages and permit corrective procedures. The 3705 (EP), in conjunction with a prerequisite RPQ (see special RPQs/features), is used to attach SLC lines to the processor.

Airline Line Control (ALC): Airline Line Control was developed to satisfy the high speed communications requirements of airline reservation applications, but has since been adopted by other industries. ALC uses synchronous line transmission, full duplex, on dedicated communications lines. The lines may be either leased common carrier or private.

ALC characters are 6 bits in length, allowing for more efficient use of the line. Transmission integrity is maintained using cyclic checks. Terminal interchanges (e.g., 2,946, 2,948) and the S/7 when used as a line concentrator, use ALC.

Polling is performed using roll call or hub polling methods. Roll call causes each interchange/concentrator to be separately polled by the processor. In hub polling, the processor initiates the polling scan by sending a poll to the most remote interchange/concentrator. The poll message then ripples automatically down to the closest remote interchange/concentrator. This significantly reduces processor polling overhead and increases line efficiency.

Extensive management facilities are available to control the ALC networks and provide status information. Operator commands are provided to alter or stop polling, reconfigure and display the status of individual network components. Segmentation and reblocking of long messages, and the handling of unsolicited messages are performed by the ACP.

The 3705 in conjunction with the Emulation Program (EP) and a prerequisite ALC RPQ (see special RPQs/feature), is used to attach ALC lines to the processor. ACP provides load (IPL) and dump support for

ACP/TPF (cont'd)

the 3705 (EP). The Partitioned Emulator Program (PEP) is supported with the ALC RPQ for the 3705II with the type III scanner.

The S/7 (RMX S/7) is supported as a remote concentrator and provides the interface between line disciplines and the ALC functions in ACP. RMX S/7 can be used for the attachment of devices utilizing BSC and start/stop line disciplines (e.g., 3270, 2740). S/7 RMX utilizes standard software support (MSP 7 and TPMM) to provide the necessary line controls, translation, message queueing and processing functions.

Data collection counters are maintained in the RMX S/7 and, along with other data, are sent to the processor to facilitate the evaluation of the S/7 performance.

Screen Mapping/Paging functions, described earlier under SNA support, are also available to applications utilizing S/7 attached 3270s. The 3270 terminals can be logged onto a S/7 resident application. Log messages to non-S/7 resident applications are forwarded to ACP for processing.

Networking: ACP networking support provides the networking advantages of shared terminals, shared lines and reduced application/data base redundancy. Synchronous Data Link Control (SDLC), Synchronous Link Control (SLC) and Binary Synchronous Communications (BSC) may be used for intercomputer communication.

A *domain* within the ACP System in general, and SNA in particular, means a set of communication facilities (i.e., processors, channels, communications controllers, cluster controllers, lines, terminals and applications) identified to a single control point within a single S/370 processor for the purpose of establishing connections among the facilities. "Remote" domains may be identified to a given ("local") domain. This, in essence, extends the scope of connections permitted within a single domain by distributing the network identity to more than one processor. Establishing a connection between facilities in a remote domain within the framework of IBM networks always implies that the control information needed to establish the connection must at least flow through a processor, channel and communication controller in at least two domains. (This is not necessarily true for a domain identified in a non-IBM processor, i.e., the physical arrangement of the "processor" and the "communications controller" may be different than a S/370). Ordinarily, the control information to establish a cross domain connection will flow over an SDLC line, but cross domain connections may be established between two processor logical units attached via S/370 channels through the use of two channel adapters in the same communications controller.

The ability of *system supplied* programs to establish a connection on behalf of two facilities in different domains through the simple use of network names is called, for the purpose of describing ACP networking support, a *dynamic* interprocessor connection. In the ACP system, a dynamic interprocessor connection is characterized by the system supplied program called the Log Processor which is capable of interpreting a "Log In" (LOGI) message requesting a connection to a cross-domain resource. If special installation programs must be implemented to *establish* connections between communication facilities in different domains, then the connection is called a *relay* interprocessor connection. (Generally, relay applications define the remote processor to be a "terminal", or secondary SNA logical unit, and invent special rules or protocol to satisfy the unique connection.)

An ACP Message Router Package of the ACP Communications Control Program (CCP) supports dynamic interprocessor connections over BSC and SLC links. An SNA System Services Control Point (SSCP) component of the CCP supports dynamic interprocessor connections over SDLC links and uses the standard Advanced Communications Function (ACF) defined by SNA in support of Multisystem Networking Facilities. The SNA multisystem network support is simply called ACP/ACF. The ACP Message Router Package (support of BSC and SLC links) and ACP/ACF (support of SDLC links), both system supplied support for establishing dynamic interprocessor connections, are mutually exclusive.

However, an ACP System may be configured to use the ACP Message Router package for BSC and/or SLC dynamic interprocessor links which also uses the ACP support for SNA facilities in a single domain (i.e., not ACP/ACF). This simply means the SNA facilities in such an environment must use relay interprocessor connections to reach remote facilities. Alternatively, an ACP system may be configured to use ACP/ACF which implies that the non-SNA facilities must use a relay interprocessor connection to reach remote facilities. In an ACP/ACF environment:

1. A relay application, identified as a SNA Logical Unit (LU), may be used to support SDLC interprocessor connections between a non-SNA and a SNA facility.
2. A relay application must be implemented to support BSC or interprocessor connections between a SNA and a non-SNA facility.
3. A relay application must be implemented to support BSC or SLC interprocessor connections between two facilities both of which are non-SNA. Such a relay application can establish a connection

by taking advantage of a feature of ACP BSC support which associates network (application) names with BSC stations. However, the interprocessor connection cannot be established with the Log Processor.

The use of the ACP Message Router Package (BSC and SLC support) implies that each message that is routed through several domains must pass through a processor of each domain in the path traversed. The use of ACP/ACF means that after the interprocessor connection is established, the normal flow of a message routed through several domains need only pass through the communication controllers (3705s) of the path traversed. However, at least one of the end points in an SNA cross domain (dynamic interprocessor) connection must reside in a processor.

The ACP networking facility provides for terminal log-in, alternate line selection on errors and message least queueing for load balancing over multiple lines.

Terminals or SNA logical units may be either permanently logged into a fixed application or selectively logged in with a special terminal operator log-in message. The permanent log-in could be used for the point of sale environment, where many terminals share a single communication path to the host. The selective log-in provides more flexibility but still requires the terminal operator to input a special ACP login message.

Alternate line selection and least queueing are supported for SLC and BSC lines.

Alternate line selection is provided to ensure that messages are delivered to the addressed destination. If there are multiple lines to a remote computer and a line experiences a permanent failure, alternate lines may be used to transmit the message. If an alternate line is not available, the message is returned to the originator.

Least queueing is the selection of the communication line with the smallest queue for the transmission of output messages. This technique balances the communications load over multiple lines to a single destination and promotes prompt message delivery.

Application Interface: The networking interface is the common ACP/application interface used for communication with all network components regardless of line discipline or terminal characteristics. The message text and a small set of routing parameters are provided by ACP on initial entry to the application. On output the message text and associated routing parameters are returned to ACP. This interface also allows the application program to be independent of the computer which controls the terminals.

Support Functions: Networking functions include operator commands, network awareness, and network trace.

Operator Commands - Provide monitoring and control of the computer network. The status of the communications link (multiple lines) to a remote computer and of an individual application can be displayed at ACP operator's console. The capability to start or stop an individual application and a communications path is provided.

Network Awareness - When the status of an individual application is changed (stopped or started), this change is sent to all ACP systems in the network. In the event of a lost status change message, a complete status of all applications is sent on a time initiated basis. In this way, network awareness is maintained in the ACP components of the network.

Network Trace - Many terminals and applications may send a message to a single remote computer over one communications link. In this environment it is highly desirable to single out particular terminal or application traffic for tracing. ACP provides a network trace which allows console operator selection of specific network paths, trace points and trace data for collection.

SNA Restrictions: The following Advanced Communications Function (ACF) features as defined by SNA in support of Multisystem Networking Facilities are either not supported or are restricted by ACP/ACF.

- Resource takeover for Logical Units (LUs) controlled by another domain is not supported.
- Remote NCPs are not supported.
- Communication Controllers (3705s) shared among processors through the use of multiple channel adapters (multiple tails) within the controller *are* supported. However, if the SSCP of ACP/ACF is to own any logical unit (LU) in a node which is adjacent to the 3705 node and which is attached by an SDLC line, then it must own all such LUs.

SUPPORT PROGRAMS:

Support programs include those that help ensure against permanent loss of data records, programs that facilitate the expansion of file storage, programs that assist in maintaining system file storage integrity and programs used in the initialization, installation and performance measurement processes.

Capture/Restore: The constant availability of the online data increases the exposure of file storage to the effects of software and/or hardware

ACP/TPF (cont'd)

malfunctions. This exposure is minimized by ensuring that critical data can be replaced if necessary.

Maintenance of file storage copies on auxiliary storage media (disk packs, tapes, etc.) helps ensure against the loss of critical data. The process of copying file storage to auxiliary storage is called CAPTURE, and the process of restoring the capture to file storage is called RESTORE. The period of capture typically varies from one per day to one per week depending on user requirements.

One means of capturing file storage is to stop the system, then using standard OS/VS utilities, copy the storage to disk or tape. This procedure prevents the online use of the ACP system during a capture. A second method is to use the online capture supplied with the ACP system. This program captures the files during normal system operation, but during periods of low activity. Each file storage device is copied to magnetic tape. Simultaneously, a separate tape, called an exception tape, collects a copy of all records modified while the capture is in progress. The combination of the two sets of tapes represents a consistent, and static capture of the data base at the instant the online capture program completes processing. A significant advantage of the Capture/Restore feature is that it permits 24 hour operation of the system by performing its function while the system is operational.

Restoration of a full system restores the system to the time and date of the capture. Further programs or procedures may be required to reconstruct the files due to the activity between the time of capture and time of restore. Since the data is application dependent, the additional reconstruction is a user responsibility. A way of accomplishing the reconstruction is by using an ACP facility to log all file updates. These updates can then be applied to the restored module(s).

File Reorganization: Normal system growth usually dictates an increase in the number of file storage devices. Addition of new devices provides an increase in both fixed and pool areas.

A fixed file reorganization program is provided to accomplish this expansion. This program collects all records in the fixed area using the record types and ordinal numbers of the old system definition. The records are written onto the new system configuration by using the new system definition of file storage. Since application programs use a record type ordinal number to reference fixed file storage records, the reorganization is transparent to the application.

File Address Recoup: Application programs may fail to return pool addresses, in which case the record is lost for further application usage, which diminishes the number of available pool records. Correction of application errors eliminates the problem but the system must recover the records. Also, whenever the system encounters a catastrophic failure some records may be made unavailable. The File Recoup program is provided to recover lost pool records so they can be made available to the system for further usage. The Recoup program interfaces closely with the application environment to determine which records are valid. A useful by-product of the File Recoup program is information which identifies application programs which may have lost the file pool addresses. Another useful function is surveillance of the data base to discover potential deterioration such as broken chain structures.

Test Facilities: A comprehensive set of test facilities is provided for application development and maintenance.

The ACP test facilities provide:

- A check on violations (or possible violations) of programming conventions.
- An orderly progression from simple debugging through complex multiprogramming tests including the entry of messages from terminals.
- A uniform data definition and data base for use in all levels of testing.
- The ability to batch various test runs.
- A flexible method to specify and/or modify data for each test, including the facility to restore the test data base between individual test cases.
- A method of simulating unavailable programs.
- Flexibility in specifying the types of output desired.
- Online components to assist in the detection of faulty programs.
- Offline components to print the results of a test.
- Debugging Aids (traces, formatted dump, address stop).

The ACP test facilities are designed to be used at three major levels of testing:

Unit Testing: The independent testing of an individual program segment.

Package and Transaction Testing: Testing several programs together to check the validity of interrelated functions within a package of programs. This may include testing a complete transaction in a single

or multi-thread environment. Multi-thread means concurrent entries will be processed by the package. Thus, the reentrant programming conventions are verified.

System Test: Multi-thread test through a realistic simulation of the environment in which the programs will ultimately operate.

COMPONENTS OF THE ACP TESTING ENVIRONMENT

System Test Compiler (STC): Used to create a test data base, input test messages and control information for a test unit. STC runs offline under control of OS/VS and is the primary vehicle for test data preparation.

Program Test Vehicle (PTV): Creates a testing environment which runs under ACP. Interfaces between PTV and the control program are used to provide comprehensive checks on application programs. PTV can be best thought of as an additional program loaded with an ACP system. This program, when activated, controls the execution of test cases. Live terminals can be active simultaneously with PTV.

Real Time Trace (RTT): Used to monitor and record the activity of application programs in the ACP system. RTT can be run either in an operational system or when testing under the control of PTV. The output of RTT is a historical record of input message and control program macro activity. The level of output detail is controlled by option indicators in functional messages when used in an operation environment, and by control statements when used in a PTV environment.

Selective File Dump & Trace (SFDT) and System Test Post Processor (STPP): Writes specified file records to tape and, in conjunction with the STC post processor, formats all traces and printouts of main storage for ease of analysis. Key areas with symbolic names are labeled. Data blocks associated with each entry are grouped with that entry.

System Initialization Program (SIP): This package consists of documentation, macros and programs that are used to generate an ACP system. The generator of a system using SIP assigns variables, using terms that are common to the environment. SIP is designed to ensure that the assignment of variables is complete and that the variables are consistent with one another.

SIP permits the system installers to declare ACP system parameters through the use of macro instructions. These SIP macro instructions are used by the OS/VS assembly program to process parameters which are dependent upon a unique system configuration. SIP macro instructions are used to generate a portion of the configuration dependent data macros as well as keypoints. The SIP macro instructions also produce the OS/VS job control language (JCL) which is necessary to catalog ACP macro definitions and assemble the ACP programs.

The major output of SIP is:

- An OS/VS object library of all online and offline programs.
- An OS/VS Load Module Library of ACP programs.
- The System Allocator Table (as an OS/VS data set) which assigns programs to their storage locations.
- Formatted Loader File which includes the assembled IPL program which loads the ACP system.

System Performance Measurement: System performance functions (data collection/reduction) are designed to provide operational data on significant activities involved in processing messages. By analyzing the reports generated by this package, the user can determine how efficiently the installation is running, discover where the bottlenecks are, and what changes in system allocation (core, file, lines, terminals) could improve system performance.

The major functions of this program are to:

- Provide a tool that can be used during the installation and post-cutover periods to tune the system to peak efficiency
- Provide a means of periodically monitoring system performance.
- Provide sufficient statistics so that long-term trends can be observed from the runs, thus providing the base for predicting growth in system load and justification for future expansion.

Data Collection: Collectors are run in a continuous or sampling mode, allowing multiple types of data to be collected while avoiding significant interference with message processing. All collection programs write the data gathered to an online tape. No attempt is made to reduce any of the data online, as this would defeat the objective of causing a minimum impact on the system being measured. Data collection can be run to provide a history file of key system parameters such as milliseconds per message, file accesses per message, core usage per message, program calls per message, message rate and message length. The above information, plus the transaction history and trend, can be used to predict the need for more memory, channels, files, lines, or terminals or the need for more processor capacity.

PROGRAM PRODUCTS

ACP/TPF (cont'd)

Data Reduction: All data reduction associated with the system performance package is executed under control of an OS/VS system. The data reduction reports are designed to be used by an analyst familiar with ACP, but not necessarily a statistician. Frequency distribution reports including means, standard deviations and variations of each parameter are also available.

This program is written in PL/1 to allow easy tailoring for each installation.

DEVICE SUPPORT

Processors - S/370

- Model 135, 135-3, 138
- Model 145, 145-3, 148
- Model 158, 158-3
- Model 168, 168-3
- Model 195
- 3033, 3032, 3031 Processors

Channels

- 2860-1,2,3 Selector Channel
- 2870-1 Multiplexer Channel
- 2880-1,2 Block Multiplexer Channel

Direct Access Storage Devices

- 2305-2 Fixed Head Storage
- 2314 Direct Access Storage Facility (with Airline Buffer RPQ)
- 2319 Disk Storage
- 2835-2 Storage Control
- 3830-1,2 Storage Control
- 3880-1 Storage Control
- 3330-1 Disk Storage
- 3333-1 Disk Storage
- 3340 Direct Access Storage Facility
- 3350 Direct Access Storage Facility (Native mode only)

Integrated File Adapter for mdl 135, 138
Integrated Storage Control for mdls 145, 148, 158 and 168

Tape

- 240X Tape
- 2803 Tape Control
- 3420 Magnetic Tape Unit
- 3803 Tape Control

Unit Record

- 3211 Printer
- 3505 Card Reader
- 3525 Card Punch

Transmission Control Unit

- 2703 Transmission Control
- 2969 Programmable Terminal Interchange
- 3705-I, II Communications Controller (Locally attached)

Terminal Interchange/Control Units

- 1971 Terminal Control Unit
- 2946-4 Terminal Control Subsystem
- 2948 Display Terminal Interface
- S/7 (RMX/7) Remote Multiplexer
- 3271 Control Unit mdl 11, 12
- 3272 Local Control Unit mdl 1, 2
- 3274 Control Unit mdl 1B, 1C
- 3601 Finance Communication Controller (via 3705 mdl 1, 2A, 2B, 3A, 3B)
- 3602 Finance Communication Controller (via 3705 NCP) mdl 1A, 1B
- 3603 Terminal attachment Unit
- 7411 Terminal Control Unit
- 7441 Terminal Control Unit

Terminals

- 1977-1 Terminal Unit
- 1980-9 I/O Typewriter
- 1980-21/24 Terminal Printer
- 2740-2 Communication Terminal
- 2915-3 Display Terminal
- 3262 Printer
- 3268 Printer mdl 2
- 3275,77,78 Display Stations
- 3276 Control Unit Display Station mdl 11, 12
- 3284,86,87,89 Printers
- 3604 Keyboard Display mdls 1-6
- 3606 Financial Services Terminal mdl 1, 2
- 3608 Printing Financial Services Terminal mdl 1, 2
- 3610 Document Printer mdls 1-4
- 3611 Passbook Printer mdl 1, 2
- 3612 Passbook and Document Printer mdl 1, 2, 3
- 3614,24 Consumer Transaction Facility mdl 1, 2, 11, 12

- 3618 Administrative Line Printer mdl 1
- 3767 Communication Terminal (2740 Emulation)
- 4505 Video Display

Consoles

- 1052-7 Printer-Keyboard
- 2150 Console (with 1052-7)
- 3210-1 Console Printer-Keyboard
- 3215 Console Printer-Keyboard
- 7412 Console Console (with 3215)
- 3277 Display Station (with 328X Printer)

Features Recommended

- VM Assist
- Two Channel Switch
- DASD String Switch
- Tape Switching

RPQs/Special Features

3705 EP

Airline Line Control

- PRPQ #P85000 SABRE Line Control, one/3705 (3705-I only)
- RPQ #858655 SABRE Full Duplex Line Control, one/3705
- #4701 Line Interface Base, Type 1
- RPQ #858657 SABRE FDX Line Set, one/FDX line
- #1541 channel adapter type 1
- RPQ #858911 and #858912 3705-II type 3 Communication Scanner and type 4 channel adapter

Synchronous Link Control

- PRPQ #7S0003 Line Control FDX IATA, one 3705 (3705-I only)
- #1642 Communication Scanner, Type 2 only
- 4718 Line Set, Type 1H, 1/FDX Line

Binary Synchronous Communications

- #4714 Line Set, Type 1D, one/two HDX

System/7, ALC Line Control, BSC, 2740

Software

- TPMM 5799-WFG, MSP 7
- RMX/7

Hardware

- D08010 TP Multiplex Feature
- D08011 TP Multiplex Module
- D08123 TPMM Synchronous Direct Interface
- D08014 Interface Group
- D08015 Data Set Interface Cable
- 8K0703 3600 Alternative Line Attachment

CUSTOMER RESPONSIBILITIES

To successfully install and use ACP, the customer responsibility includes installing at least the minimum required machine configuration, communication equipment and appropriate communications lines. In addition, the customer must have installed the appropriate operating system as required by the ACP Support functions ... have a thorough knowledge of the ACP application ... train systems analysts, programmers and operators in ACP ... develop an implementation plan ... design and create a data base ... design terminal formats ... design and implement the ACP system ... prepare the physical site ... design and implement application programs using ACP macro instructions and the basic assembler language ... develop procedures to assure adequate security for data in the system ... develop appropriate backup procedures for the customer's application ... develop conversion procedures and schedules.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The minimum IBM hardware system configuration required for operating ACP.

- IBM S/370 mdl 135 - 512K bytes
- System Console (3215 or equivalent)
- Two IBM 3330, 3340 or 3350 Spindles
- Four IBM 3420 Tape Drives
- One IBM 3705 Communications Controller

Configuration Alternatives: System throughput is governed by the most restrictive system element and generally the processor instruction execution rate is the limiting element. Based upon this condition the communication and file subsystem should be designed to support the processor with the objective that they do not become the limiting system element.

PROGRAM PRODUCTS

ACP/TPF (cont'd)

SOFTWARE REQUIREMENTS

ACP requires OS/VS1 or OS/VS2 for offline batch utility functions. If support for the IBM 3600 Finance Communication System is used, ACP requires those versions of OS/VS1 or OS/VS2 which support Subsystem Support Services (SSS). See the appropriate 3600 SRLs for required configurations needed to support OS/VS1 or OS/VS2.

In addition, ACP is designed to operate with NCP/VS which resides within the 3705 Communications Controller supporting SDLC lines. Support for BSC is through EP/VS. Support of the Partitioned Emulator Program (PEP) is provided for configurations requiring both SDLC and BSC lines.

PROGRAM PRODUCTS

**AIRLINE CONTROL PROGRAM/
TRANSACTION PROCESSING FACILITY (TPF)
VERSION 2 (TPF2)
TPF2/ACF Feature - TPF2/HPO Feature
5748-T12**

PURPOSE

TPF2 is a high performance, high availability system for realtime applications. TPF2 systems are characterized by thousands of terminals dispersed over a large geographical area where each location may have from one to several hundred terminals. TPF2 provides realtime inquiry and update to a large centralized data base.

Key attributes of TPF2 are its reliability and availability. This results from a well managed operation and the use of support tools provided with the TPF2 system:

- 24 hour operation.
- Multi-application support and portability.
- Over 300 operator commands.
- Online debugging aids and offline test tools.
- CPU, line and I/O error recovery and recording.

The TPF2 program product is a system control program which has been designed for high performance and high availability as a transaction processor. The TPF2/ACF2 feature provides the facility for multi-system networking and distributed processing facilities at SNA3 levels. ACF2 is a prerequisite of the High Performance Option. The TPF2 HPO feature provides the ability to share a data base in a loosely coupled multi-processor environment.

HIGHLIGHTS of TPF VERSION 2

- Improved Recoup Capability - This enhanced utility has been integrated into the TPF2 program product. This program fulfills a need for a generalized utility for online pool record recovery and employs table driven descriptor records for ease of maintenance.
- Interactive Test Enhancements - The Interactive Program Test Facility (IPTF) is a tool to assist in the development and testing of TPF2 applications. IPTF supports interactive testing and debugging of TPF2 Entry Control Block controlled programs from a CRAS terminal. Test environments may be created, used for unit testing, saved, and reused for regression testing.
- Processor Support - TPF2 supports the 303X, 3083 and 4341 processors. The 3081 processor is supported in uniprocessor mode only.
- DASD Buffer - The typically high TPF message rate requires a very high data record retrieval rate. A 3350 DASD buffer is supported which reduces the impact of the data record retrieval rate by reducing channel and device utilization. This buffer has been made available by IBM as a hardware RPQ on the 3880 DASD control unit.
- 3705-80 Support - TPF Version 2 will support the 3705-80 Communications Controller.
- 3375 Support - TPF Version 2 will support the 3375 DASD Storage Device.
- Sabretalk Hooks - The capability has been added to TPF2 for executing programs which have been compiled by the sabretalk compiler, which may be used by some customers. This capability does not affect TPF2 performance.
- Functional Console - TPF supports Functional Consoles, a facility for distributing selected system messages to terminals which have been specifically enabled by the user.

HIGHLIGHTS of the HPO FEATURE

- Loosely Coupled Facility - Many larger TPF users have outgrown the largest uniprocessors. TPF2 offers these users a growth path for new application program development and growth of existing applications.

TPF2 extends the upper limit of TPF processing capability by supporting multiple processors which share a common data base. Up to four processors may share a common TPF2 data base. Processors may be added or removed from a TPF2 complex with minimal effect on system availability. Thus, the availability characteristics of a TPF system are enhanced in a TPF2 configuration using the loosely coupled facility. Functional console support improves the operability of a loosely coupled environment. Processors supported are the 3033 and the 3083J with requisite RPQs.

During periods of low activity, TPF2 processors may be removed from the complex and used for backup or other data processing requirements. These processors may be reintroduced during periods of high activity.

- Multiple data base function - TPF2, through support for Multiple Application Subsystems, permits concurrent processing of different

applications with separate data bases. TPF2 may support up to 64 discrete data bases, subsystems, each contained on different DASD devices. Each subsystem may present a unique perspective of the same data base to more than one subsystem user. Up to 128 subsystem users are permitted per subsystem with a maximum of 128 subsystem users in a TPF2 system.

A subsystem, or discrete data base, can be quiesced or moved to another processor without impacting other subsystems in the same processor. Applications using a data base operate independently and simultaneously with other subsystems, providing portability and individual control. New applications and equipment may be staged in a planned, orderly manner.

HIGHLIGHTS of the ACF2 FEATURE

- Network Participation - Through the facility of the ACF2 Feature, TPF2 provides support of SNA Advanced Communications Function (ACF) and Multisystem Networking Facility (MSNF). This support allows sharing of lines and terminals among multiple CPUs in an integrated network of computing systems. TPF2/ACF is a Cross-Domain Resource Manager (CDRM) and will communicate with the MSNF Facilities of ACF/VTAM, ACF/TCAM and other TPF/ACF CDRMs to control cross-domain session initialization, termination and recovery. The TPF2/ACF Feature supports cross system message routing. Through this facility data may be transmitted across systems to its destination without host intervention after initial session establishment. Also highlighted in the TPF2/ACF Feature is the support for Automatic Network Shutdown, Bi-directional Pacing, and Warm Start.
- The Network Extension Facility (NEF) - NEF, a PRPQ, enhances ACF/NCP/VS to allow 3705I and 3705II NCP management of Airlines Line Control (ALC) communication networks. This PRPQ (P09021) is supported by the TPF2/ACF Feature thus extending SNA-like benefits to ALC terminals.

APPLICABILITY

TPF2 is applicable to any online transaction oriented application which requires fast message response time from a large number of terminals. TPF2 is also applicable to users requiring high reliability and availability.

Some examples of applications are airline/seat reservations ... hotel reservations ... credit authorization/verification ... car rental reservations/billing ... police car dispatching ... electronic funds transfer switching ... teller memo post ... message switching ... loan payment processing.

DESCRIPTION

MAIN SUPERVISOR

Processor Resource Management: Shared resources, specifically a data base shared by several processors, is a facility which is offered with TPF2.

System Task Dispatcher: Messages, entries, tasks and jobs are terms used to describe units of work in an operating system. The terms used in TPF2 are message or entry, both of which apply to the input characters that trigger a work unit.

At any time, there are likely to be many entries in the system, each handling a unique unit of work. TPF2 will service existing entries which are being processed before creating entries to service new messages. The level of multiprogramming and the number of entries created is influenced by factors such as the amount of main storage available. Although entry processing may be deferred, the primary thrust is to speed an entry through the system.

Main Storage Management: The organization of main storage is one of the keys to the high performance of TPF2. Part of main storage contains programs and data that are common to all entries and which remain in main storage. This portion is called main fixed storage. Another portion, called working storage, is allocated to entries as required. Storage protection is used for fixed storage, inhibiting an application from illegally modifying the control program, core-resident application programs and critical data records. Working storage is divided into fixed size blocks.

The Virtual File Access (VFA) function retains high usage programs and data in main storage to reduce DASD accesses. TPF2 uses a record sharing table to manage records currently in main storage. VFA is application transparent.

Program Management: Programs may be allocated to fixed main storage or DASD storage. The system uses a program sharing table to keep track of programs currently in main storage. All application programs are re-entrant, therefore, one copy of the program may be shared by many entries at the same time.

PROGRAM PRODUCTS

TPF2 (cont'd)

Restart: TPF2 backs up critical data which resides on all levels of storage. System data considered critical is grouped into special records called keypoints. Critical application data is grouped into records called globals.

Keypoints are periodically written to different areas of DASD on a cyclic basis. In the event of a device failure from the primary backup device, the system can select an alternate disk module. A restart may be initiated automatically by TPF2 when it determines that such action is required, or by the operator when it is determined that such action is required.

DATA BASE SUPPORT

Data Management: TPF2 considers online files a common data resource to be managed by Subsystem. TPF2 achieves high performance through rigid disciplines, one of which is fixed data record sizes. Symbolic addresses are used to locate records on direct access storage media, thus application programs are unaware of the physical location of data. Data resources include fixed DASD records, "pools" of available DASD records, tapes, general DASD files and general data sets.

Fixed DASD records are retrieved by a program which calculates a DASD address from information (a record type and ordinal number) provided by the requesting program. Record type identifies a set of data records within a system data base and the ordinal number identifies a relative record within that set of data records. Fixed records appear to the application as sequential data which is also directly accessible.

TPF2 maintains data integrity through record duplication. Two copies of a record, on separate devices, may be maintained. The additional copy reduces the probability that a record will be unavailable due to hardware failure. This facility is transparent to the application program.

TPF2 supports the ability to share DASD records via a "pool" of available records. Pool records are controlled through the use of an availability indicator for each record. When an application requests file pool space, TPF2 returns the symbolic address of one of the available records in the pool. When the application is finished with the record, an indicator associated with the record address is again marked available. A data hierarchy of fixed and pool records, with the fixed records containing pointers to the pools, is a common technique in application data base design.

There are two categories of tape files, realtime and general. Realtime tapes are mandatory and are used by the TPF2 basic subsystem for logging information critical to system operation and for testing. General tapes are treated as a sequential file and are assigned to one entry at a time.

The records of a general data set are allocated sequentially within the same disk module. The allocation of a general data set to a physical device is done during online execution. General data sets are formatted as OS sequential data sets and dedicated to the entry requesting the use of the data set.

Data Set Services: Support programs, or system utilities, include those which protect against permanent loss of data records, facilitate the expansion of DASD storage and assist in maintaining DASD storage integrity. Programs, all of which are subsystem unique, which are used in the initialization, installation and performance measurement process include:

Parametric Recoup - Pool records are dispensed from a main storage resident control block. Some records are intentionally discarded on the occasion of system restart to avoid dispensing pool records already in use. Application programs may also, through error, lose pool storage records. The Parametric Recoup program determines which pool records are valid and which are not. Invalid or "lost" records are then recovered. The program functions concurrently with other system activity and does not affect system availability. Parametric Recoup employs table driven descriptor records for ease of maintenance. A useful output of the Recoup program is a report identifying application programs which may have lost pool references.

Capture/Restore - The TPF2 data base, typically operational 24 hours a day, must be protected from the effects of software or hardware malfunctions. Capture/Restore, a utility which runs concurrently with other system activity, copies DASD module storage to magnetic tape, thus ensuring that critical data can be replaced if necessary. An "exception" tape collects a copy of any record modified while the capture is in progress. The combination of the two sets of tapes represents a consistent, and static capture of the data base at the instant the online capture program completes processing.

Restoration is a reversal of this procedure. The reconstruction of a data base, a user responsibility, may be accomplished through the use of a TPF2 facility to log updates to tape. These updates are applied to the restored data base.

Data Base Reorganization - If it is determined that the DASD configuration is inadequate, a user may employ this utility to alter

his online DASD storage configuration. This program redistributes the TPF2 data base over more, or fewer, DASD devices. This reorganization is transparent to an application.

DATA COMMUNICATIONS SUPPORT

Data Communication Services: TPF2 includes an array of computer operator facilities for system and network management:

Operator Commands - TPF2 provides a set of operator commands and programs to allow the operator to monitor and control the system and the network. Status of an NCP, line, cluster controller, or logical unit may be displayed. The facility to start or stop an individual application and communication path is provided. Over 300 operator commands may be entered from up to 99 selected terminals which function as operator consoles. Functional consoles are supported. This is a facility for distributing selected system functions to specifically enabled terminal(s).

Network Generation - A single SNA network definition (NCP system generation input) is used to create both the NCP and the TPF2 network tables. The TPF2 SNA table generation program runs independently of the TPF2 system generation. This facilitates network configuration changes and growth without requiring a new TPF2 system generation.

Network Trace - Many terminals and applications may send a message to a single remote computer over one communications link. In this environment it is highly desirable to single out particular terminal or application traffic for tracing. TPF2 provides a network trace which allows console operator selection of specific network paths, trace points and trace data for collection.

Line and Message Trace - TPF2 provides communication trace facilities at the link and NCP level. These trace functions are initiated from the TPF2 operator's console and the output written to a log tape for offline printing.

Online 3705 and 3600 or 4700 Load/Dump - The 3705 and the 3600 or 4700 may be loaded or dumped online in parallel with realtime operation. NCP and 3600 or 4700 load images, generated offline, are stored on the online disk files and loaded to the devices on command from the TPF2 operator. Dump images are temporarily accumulated online for later spooling to tape and offline printing. Load image generation and dump formatting is provided by System Support Services (SSS) for 3600 and Host Support for 4700.

3705 and SDLC Link Diagnostics - TPF2 provides concurrent maintenance of the SNA network with online 3705 diagnostics. 3705 resident diagnostics are activated from the TPF2 operator's console to perform data path and link tests.

Performance Measurements - This package determines input loads, output loads, message rates, message processing characteristics, line occupancy and response time. Since the host system is not fully aware of the line traffic in an SNA environment, statistics on line occupancy is not possible for all SDLC lines.

Long Message Support - Segmented input messages are assembled by TPF2 before being presented to the application. Long output messages are segmented and queued on disk for transmission. For the 3600 or 4700 controllers, these segments are transmitted using SNA pacing. TPF2 provides specialized SNA support to facilitate the transfer of bulk data such as negative credit files to and from remote cluster controllers.

Unsolicited Message Transmission - An unsolicited message is an output message without a corresponding previous input.

Screen Mapping - An application program can achieve 3270 device independence by using the TPF2 screen mapping package to edit, construct and format 3270 data streams. This process is controlled by a predefined screen map.

3270 Scrolling and Paging - When a display message is greater than the screen size, it is either handled as a continuous scroll or as pages in a book. The entire process is controlled by the screen map which defines the page or scroll size. This function facilitates split screen operation.

COMMUNICATION FACILITIES

Both large terminal networks and multiple computer networks are supported by TPF2. TPF's terminal network consists of remote cluster controllers connected to the host system via communication lines using either Synchronous Data Link Control (SDLC) or Airlines Line Control (ALC). SDLC, Synchronous Link Control (SLC) and Binary Synchronous Communications (BSC) are supported for communication between processors.

Application programs are independent of the processor which controls the terminals. Message text and a small set of routing parameters are provided by TPF2 on initial entry to the application. Message text and associated routing parameters are returned to TPF2.

The TPF2/ACF Feature of TPF2 provides for multi-system networking. TPF2/ACF supports cross system message routing, through which data

PROGRAM PRODUCTS

TPF2 (cont'd)

may be transmitted across systems to its destination, after initial session establishment, without host intervention.

Systems Network Architecture (SNA): TPF2 interfaces with an SNA network via the 3705 Network Control Program (ACF/NCP/VS) and is compatible with ACF/VTAM and ACF/TCAM. TPF2 supports the attachment of the 3270 Information Display System and the 3600 and 4700 Finance Communication Systems. TPF2 provides:

Fast Network Restart - When TPF2 is restarted it will assume the network is still active. Error conditions such as NCP Slow Down, Automatic Network Shutdown, and lost input or output messages are handled as exception conditions by error recovery routines.

Application to application communication provided through Application Program Interface (API) extensions.

Support of inbound message traffic pacing between application programs or supported terminals - This support can help to avoid buffer overrun.

Support of 3705-I, 3705-II and 3705-80 multiple channel attachment capabilities through ACF/NCP/VS - This allows a single communication controller to be shared by several processors. A 3705-II can support a maximum of four host systems.

Network Operator Display Commands - A network operator may obtain more information about the status of network resources such as nodes, lines, terminals, logical units, physical units and application programs.

Capability for dynamic collection of tuning statistics - I/O interface data may be dynamically collected. Such data may aid a user in selecting optimum values for system parameters.

Extended serviceability through support of the ACF/NCP/VS capability to concurrently trace up to eight lines attached to a 3705.

Extended availability through improved line fallback support for SNA devices - This facility allows a cluster controller to use an alternate path to the host should the primary path become inoperable. Use of an alternate path is completely transparent to user applications.

Optimized management and control of a user's data communications installation - This support includes:

- Enhanced SDLC data link test.
- Terminal connectivity test.
- Intensive mode recording of SDLC data link errors.
- Dynamic display of ACF/NCP/VS storage.
- Dynamic dump of ACF/NCP/VS storage.
- Network operator control for session termination.
- Operator command enhancements.
- Display command enhancements.

The message integrity capability provided in SNA by message sequence numbering is fully supported by TPF2. Additionally, TPF2 provides the support to encrypt and decrypt messages to or from any device.

As a system generation option, TPF2 provides a Message Recovery package which ensures each input message is successfully processed and its reply successfully delivered. TPF2 also provides an application oriented recovery package which allows message recovery and data base recovery to be combined.

Multi-Host Networking - A multi-host network is created by interconnection of single host networks. This permits sharing of applications and terminals in any domain by any user in the multi-host network. TPF2 participation in a multi-host network requires the TPF2/ACF2 feature. Connection to a multi-host network is through ACF/NCP/VS (Release 3). Connection to another host may be through an SDLC communication line or a 3705 with multiple channel adapters. TPF2 multi-host network support allows communication with the following hosts:

- ACF/VTAM
- ACF/TCAM
- TPF2/ACF2

The key facility provided by TPF2 multi-host networking support is a Cross-Domain Resource Manager (CDRM). A CDRM establishes/terminates and maintains cross-domain sessions. Once a session is established, normal flow of data between end points is direct and host intervention is not required.

Cross-domain communication between non-SNA facilities (terminals and applications) or over non-SNA links requires a relay program to be implemented. This program may be used to support the following:

1. Cross-domain communication between TPF2 terminals and applications and a remote host over BSC or SLC communication lines.
2. Communication between non-SNA TPF2 terminals and applications and a cross-domain SNA host.

The following Advanced Communications Function (ACF) functions as defined by SNA in support of Multisystem Networking Facilities are not supported by TPF2/ACF:

1. Resource takeover for Logical Units (LUs) controlled by another domain.
2. Remote NCPs.

Binary Synchronous Communications (BSC): TPF2 provides BSC support using standard point-to-point and multipoint data link protocols (for details see the *General Information - Binary Synchronous Communication Manual (GA27-3004)*).

TPF2 interfaces with the BSC lines via the 3705 Emulation Program (EP). When SDLC and BSC links are connected to the same 3705-I or 3705-II, TPF2 supports the Partitioned Emulation Program (PEP).

TPF2 BSC support includes least queuing by communication line and alternate line routing.

TPF2 provides a generalized message logging and tracking mechanism which can be used by the application programs.

Synchronous Link Control (SLC): SLC is a highly efficient protocol designed to control the interchange of messages on a point-to-point link between two processors. The link is synchronous on full duplex, private leased voice grade lines. Each link consists of up to 7 communication lines. The transmission load is balanced across the available lines (parallel transmission of data blocks). TPF2 supports SLC links with lines operating at speeds of up to 9,600 BAUD. All data messages are sequenced allowing each CPU to detect missing or spurious messages and permit corrective procedures. The 3705 (EP), in conjunction with a prerequisite RPQ (see RPQs/Special Features), is used to attach SLC lines to the CPU. When SDLC and SLC links are connected to the same 3705, TPF2 supports PEP.

Airlines Line Control (ALC): This high speed, full duplex, synchronous line control provides:

- 6 bit line characters with cyclic check characters.
- Polling - roll call or hub.
- Operator commands for ALC network control.
- Unsolicited messages.
- Screen mapping and paging.

The 3705-I or 3705-II in conjunction with the Emulation Program (EP) and a prerequisite ALC RPQ (see RPQs/Special Features), is used to attach ALC lines to the CPU. When SDLC and ALC links are connected to the same 3705, TPF2 supports PEP. TPF provides load (IPL) and dump support for the 3705 (EP). The Partitioned Emulator Program (PEP) is supported with the ALC RPQ for the 3705-II with the type III scanner.

ALC lines are also supported through the use of the Network Extension Facility (NEF) PRPQ. This PRPQ which runs in conjunction with ACF/NCP/VS in the 3705 provides a bridge between ALC lines and SNA service routines which process and pass SNA messages to the host system.

The System/7 (RMX System/7) is supported as a remote communication concentrator. RMX System/7 can be used for the attachment of 3270 BSC and 2740 start stop devices.

SYSTEM INSTALLATION SUPPORT

System Initialization Program (SIP): The SIP package consists of programs, macros and documentation used in generating a TPF system. A user assigns values to macro parameters using terms which are self explanatory. SIP ensures that necessary parameters are completed and that parameter values are consistent with one another. SIP macros also produce batch job control language (JCL) which is necessary to catalog TPF macro definitions and assemble TPF2 programs.

SIP provides:

- An object library of all online and offline programs.
- A Load Module Library of TPF2 programs.
- The System Allocator Table which assigns programs to their storage locations.
- Formatted Loader File which includes the assembled IPL program which loads the TPF2 system.

PROGRAMMING DEVELOPMENT SUPPORT

A comprehensive set of test facilities is provided for application development and maintenance. The TPF2 test facilities are designed to be used at three major levels of testing:

Unit Testing - The independent testing of an individual program segment.

Package and Transaction Testing - Testing several programs together to check the validity of interrelated functions within a

PROGRAM PRODUCTS

TPF2 (cont'd)

package of programs. This may include testing a complete transaction in a single or multi-thread environment.

System Test - Multi-thread testing through a simulation of the environment in which the programs will ultimately operate.

TPF2 Facilities which support application testing include:

Interactive Program Test Facility (IPTF): Allows testing and debugging of TPF2 applications. A user may create the testing environment. This environment allows the programmer to dynamically build a test Entry Control Block, set up controls and stop the execution of the tested program at any point. The programmer may test, modify and retest without leaving a terminal. Test environments may be created, used for unit testing, saved and reused for regression testing.

System Test Compiler (STC): STC is used to create a test data base, input test messages and control information for a test unit.

Program Test Vehicle (PTV): PTV provides a testing environment running under TPF2 and controls the execution of test cases. Live terminals can be active simultaneously with PTV.

Real Time Trace (RTT): RTT is used to monitor and record activity of application programs in the TPF2 system.

System Performance Measurement: Collectors are run in a continuous or sampling mode, allowing multiple types of data to be collected while avoiding significant interference with message processing. All collection programs write the data gathered to an online tape. No attempt is made to reduce any of the data online, as this would defeat the objective of causing a minimum impact on the system being measured. Data collection can be run to provide a history file of key system parameters such as milliseconds per message, DASD accesses per message, core usage per message, program calls per message, message rate and message length. The above information, plus the transaction history and trend, can be used to predict the need for more memory, channels, DASD, lines or terminals or the need for more CPU capacity.

Data Reduction - All data reduction associated with the system performance package is executed under control of an OS/VS system. The data reduction reports are designed to be used by an analyst familiar with TPF2, but not necessarily a statistician. Frequency distribution reports including means, standard deviations and variations of each parameter are also available. This program is written in PL/1 to allow easy tailoring for each installation.

CUSTOMER RESPONSIBILITIES

To successfully install and use TPF2, the customer responsibility includes installing at least the minimum required machine configuration, communication equipment, and appropriate communications lines. In addition, the customer must have installed the appropriate operating system as required by the TPF2 support functions ... have a thorough knowledge of the TPF2 application... train systems analysts, programmers and operators in TPF2 ... develop an implementation plan ... design and create a data base ... design terminal formats ... design and implement the TPF2 system ... prepare the physical site ... design and implement application programs using TPF2 macro instructions and the basic assembler language ... develop procedures to assure adequate security for data in the system ... develop appropriate backup procedures for the customer's application ... develop conversion procedures and schedules.

TPF2 ACF FEATURE: Advanced Communication Function: TPF2/ACF provides the capability to link multiple processors through TPF2/ACF support of SNA Advanced Communications Function (ACF) with the Multisystem Networking Facility (MSNF).

This support extends to:

- Sharing of lines and terminals among multiple CPUs.
- Control of cross-domain session initialization, termination and recovery.
- Cross system message routing without host intervention.
- Multiple channel adapters.
- Automatic network shutdown.
- Bi-directional pacing.
- Warm start.

TPF2 HPO FEATURE: Loosely Coupled: The TPF2 loosely coupled facility extends the upper limit of TPF2 capability by supporting multiple processors which share a common data base. Up to four processors may share a common TPF2 data base.

TPF2 locks data at the record level. The "record hold" function which has been a function of TPF since its inception has been engineered into the 3830 and 3880 DASD control units through RPQs with supporting microcode. In a shared data base environment, failure of a control unit need not cause a system outage since locks maintained in a control unit may be moved to backup control units. The RPQ'd control unit, under

TPF control, restricts individual record access, for purposes of modifying that record, to one of the loosely coupled processors. This record hold facility is transparent to existing application programs.

Processors may be added or removed from a TPF2 complex using the loosely coupled facility with minimum effect on end user availability. Processors supported are the 3033 and 3083J with requisite RPQs. This approach provides favorable backup and migration options as additional processors may be added at any time for lateral growth.

To take full advantage of a TPF2 system, all components should be duplicated. Then a failure, hardware or software, on any system component will affect performance to some degree but would have no effect on availability. TPF2 enhances the already demonstrated reliability of TPF1.

The integrity of a shared data base must be maintained. Clock Synchronization is provided to provide the TPF2 loosely coupled complex with Time of Day (TOD) clocks which are driven from a single source. Maintenance of global system data presents a similar problem which is managed by Interprocessor Communication (IPC). IPC is affected through the use of a dedicated DASD control unit employing the Limited Lock RPQ and a single storage device.

During periods of low activity, TPF2 processors may be removed from the complex and used for backup or other data processing requirements. These processors may be reintroduced during periods of high activity.

Multiple Data Base: Users may opt to run, on the same processor, unrelated applications and data bases. This option, which may be elected at system generation time, is the multiple data base function. Multiple data base function provides significant data base flexibility, allowing for separate and portable application data bases and providing improved integrity and security of data. These discrete data bases, contained on separate physical devices, are isolated and protected from other such data bases. In this environment, new applications may be designed and added to TPF2 without impacting existing applications and data bases.

Each group of applications, sharing a data base, is treated as a unique TPF2 subsystem. Each subsystem provides for shared data base, file pool, globals and application programs. Subsystems are independent and protected from other subsystems, thus assuring that new applications and equipment can be assimilated in a planned, orderly manner.

A primary or basic subsystem is used for operational control of all TPF2 resources.

Each subsystem, including the basic subsystem, may have multiple subsystem users. Subsystem users perceive a subset of the subsystem data base. Data may be shared by subsystem users or may be reserved for a particular subsystem user. This function permits up to 64 subsystems and up to 128 subsystem users which may exist in any combination on a TPF2 system.

A major advantage of the multiple data base function is the ability to add and remove applications within a TPF system by adding or removing subsystems. Each subsystem assumes the characteristic of portability and may be invoked online or quiesced and removed while preserving a transparency to all other subsystems.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

IBM DEVICE SUPPORT

Central Processing Units

- 3031, 3032, 3033, 3033N, 3033S Processors
- 3081D Processor (uni-processor mode only)
- 3081K Processor (uni-processor mode only)

SOFTWARE REQUIREMENTS

TPF2 may be used alone or with the ACF Feature. The TPF2 HPO Feature facility requires the TPF2/ACF2 Feature as a prerequisite.

A TPF2 user is required to have an OS/VS1 or MVS system installed for offline batch and utility functions.

The Assembler H program product (5734-AS1) is required for TPF2 program assemblies. The PL/1 Optimizing Compiler (5734-PL3) is required for compilation of TPF2 Data Reduction programs.

If support for the IBM 3600 or 4700 Finance Communication System is used, TPF2 requires those versions of OS/VS1 or MVS which support Subsystem Support Services (3600) or Host Support Services (4700). See the appropriate 3600 or 4700 SRLs for required configurations needed to support OS/VS1 or MVS. The 4700 appears as a 3600 and is transparent to the TPF2 system.

TPF2 supports the protocol used by application programs generated by the program customizer, PC3600. TPF2 3600 Load/Dump accommodates the attachment of the 4700 system.

In addition, TPF2 is designed to operate with ACF/NCP/VS which resides within the 3705 Communications Controller and supports SDLC lines. Support for BSC, SLC and ALC is through EP/VS. Support of the Partitioned Emulator Program (PEP) is provided for configurations including both SDLC and EP-supported lines.

PROGRAM PRODUCTS

**OFFLINE IBM 3800 UTILITY PROGRAM PRODUCT
5748-UT2**

DESCRIPTION

The Offline IBM 3800 Utility program product provides the offline 3800 user with the same functional capability as is available to the online 3800 user. The utility, which is executed in an online S/360 or 370 environment, can be used to create control information and place it on magnetic tape which can be used to set up the 3800 for the printing of user data.

HIGHLIGHTS

The Offline IBM 3800 Utility:

- Provides the offline 3800 user with powerful utility control statements to achieve the full range of function available to the online 3800 user.
- Provides functions (graphic character modification, user-designed characters, national use graphics, copy modification, and user-defined character arrangement tables) not available through operator control or default selection.
- Promotes increased throughput and decreased risk of operator error by reducing operator intervention.
- Provides flexibility to place control files on the same tape volume as print files or on a separate tape volume.
- Provides operator communication via printed output on the offline 3800.
- Prints the contents of tape control files on an online system printer.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The utility operates on all IBM S/360s and 370s supported by the programming systems specified below.

The storage requirements for OS and OS/VS (real or virtual) are 64K bytes for program execution in addition to that required by the prerequisite operating system. An additional 8K bytes will be required if copy modification modules or graphic modification modules are loaded.

In order to operate the Tape-To-Printing Subsystem feature of the 3800, the utility output is written to 9-track tape with a density of 800, 1600 or 6250 bpi or to 7-track tape with a density of 200, 556 and 800 bpi, odd parity and the data converter feature.

SOFTWARE REQUIREMENTS

The Utility operates with OS/VS1 Release 6, OS/VS2 Release 1.7 (SVS), OS/VS2 Release 3.7 (MVS), OS/MVT Release 21.8 and DOS/VS Release 34. The Utility will also run under VM/370 Release 3 using one of the systems mentioned previously.

DISPLAY MANAGEMENT SYSTEM/3790 5748-XC2

[NO LONGER AVAILABLE, effective May, 1983.]

PURPOSE

This program product is a productivity aid for users of the 3790 Communication System that eases the design, coding, testing and support of the 3790 application programs. The DMS/3790 program product consists of a forms-oriented program generator for modules interfacing with the operator terminals, a teleprocessing interface program, and a set of macros to invoke functions, retrieve data, and manage the program's working storage.

DESCRIPTION

The DMS/3790 program product produces a class of programs referred to as screen handlers. The user defines the screen handler on a set of forms that is provided with DMS/3790. These forms allow the user to describe layouts (screen, line printer or 3793), input and output fields and the editing characteristics of these fields. In addition, the meaning of program function keys, program attention keys and selector pen detectable fields can be described. The output of the 3790 Program Generator will be programs which are ready for assembly. A facility is also available which will allow these forms to be prepared interactively under CICS/VS, TSO or VM/370.

DMS/3790 will provide the Communications Interface Monitor (CIM) as an optional feature. This feature manages communications between 3790 user application programs and IMS/VS or CICS/VS. CIM supports opening and closing of sessions with IMS/VS and CICS/VS, recovering from sessions that failed due to errors, sending messages to and receiving replies from the host system and storing replies in 3790 user buffers, indexed or relative data sets or work area files. CIM supports CICS/VS Release 1.3 and IMS/VS Release 1.1.4 host applications using VTAM. CIM will provide communications between DMS/3790 programs and IMS/VS via SLU type P.

DMS/3790 provides a Linkage Service facility which establishes standard interfaces and communication protocols between modules via a set of macros. Programmers can invoke application functions by names specifying only what data is to be operated on and where the result is to be stored. Linkage services locates the invoked function and, if at the host, CIM will transmit the data and store the reply in the specified location.

The Get Collection facility of DMS/3790 allows programmers to request inquiry data by name, specifying only a key field. Get Collection will permit inquiries against local or host resident files or files split between the 3790 and host systems. If the data resides on the host system, control will be given to the Communications Interface Monitor which will send the transaction to the host to retrieve the data.

The Work Area Management (WAM) facility of DMS/3790 provides temporary working storage for application programs. The WAM macros provide for high-level manipulation of this working storage, and symbolic addressing of storage. The Work Area is designed for storing terminal input data and passing data between modules on the 3790 and between the 3790 and the host.

HIGHLIGHTS

- DMS/3790 forms allow an application designer to describe the 3790 interface with the display operator. The forms provided are:
 - The Layout Form which defines:
 - Program information such as name, number and record layouts.
 - The screen format to be displayed to the operator.
 - The location of variable display and input fields on the display.
 - The meaning of PA keys, PF keys and selector light-pen attentions.
 - Special error messages that may be displayed to the terminal operator.
 - The Field Processing Form which defines:
 - Variable fields to be displayed to the operator.
 - Input fields to be entered by the operator.
 - Input field edits, including count, required or optional, type, selfcheck, picture, range and value.
 - Selector light-pen data.
 - The action that is to be taken if an edit detects an error.
 - The Buffer Description Form which defines the layout of fields in a record or buffer.
- Flexible panel definition provides for:
 - Field-by-Field Support.
 - Full Screen Processing Support.
 - Full 3277 Field Attribute Capability.

Extensive Operator Communications.

Deferred and Immediate Selector Light-Pen Support.

- Interactive Forms Preparation facility is a productivity tool that aids the designer in describing the interface with the display operator. It operates with a 3277 mdl 2 attached to the S/370 via a 3271 or 3277 control unit. This facility operates under TSO/TCAM, TSO/VTAM, CICS/VS and VM/370. This feature supports all the capabilities of the form plus:

Full screen entry of display and print layouts.

Left-right and up-down scrolling capability.

Automatic prompting for field attributes.

Restart capability.

Help panels.

- The Work Area Manager is a high function facility for temporary working storage.

It contains a two-level hierarchical structure. It provides for root segment and multiple dependent segment types, and multiple occurrences of each dependent type.

It is application oriented. The programmer assigns symbolic names to the root and dependent segment types. Using these names and flexible work area macros the programmer can easily add desired segments, add new occurrences of segments, insert segments at the start or middle of a chain and delete segments anywhere in the work area.

It provides for security checking.

The Work Area Manager performs all work area disk I/O for the program. If a segment has been updated by an application, the Work Area Manager automatically writes that segment to disk, eliminating the chance of losing the new information. The Work Area Manager controls record pools for allocation of work areas to programs and gives segments to all programs as needed.

- Get Collection supports distribution of inquiry data in the 3790 environment.

Inquiry data is requested by name, specifying only a key field. System-wide symbolic names are given to groups of related fields called collections. The programmer requests a collection by its symbolic name, specifying only the key of the collection.

A collection can be resident on the 3790, the host S/370 system, or distributed between the two systems. If it is 3790 resident, Get Collection will retrieve it from the local disk and present it to the program. If it is host resident, Get Collection will search the local disk to determine if it has previously been retrieved before requesting it from the host system. This reuse of data can improve response time to the user, and can minimize communications traffic and host processing overhead. If a collection can reside both locally and at the host system, Get Collection will search the local data set to see if it is residing locally before going to the host system. This allows the system designer to permanently store those collections that are most frequently used on the controller without limiting access to collections that are on the host system.

Location of collections is transparent to 3790 programs. Get Collection allows the system designer to change where collections reside without having to be concerned about the programs that reference them. A reassembly of these programs is necessary to allow them access to the moved collection. It is the user's responsibility to provide the necessary host application programs to transfer the collections.

Get Collection is transparent to the 3790 program because it automatically invokes the Communications Interface Monitor if the collection is located at the host system. When the program regains control, it looks as if the collection was resident on the local 3790 disk.

- Linkage Services supports the distribution of function in the 3790 environment.

Functions are invoked by name, specifying only the input and where to place the reply. A symbolic name is given to each function in the distributed system. The program invokes a function by this symbolic name, identifying the data that is to be passed to the function and where the reply is to be stored.

Linkage Services provides a set of standard data interfaces that can be used between 3790 programs. These interfaces identify the data that is to be operated on by a called function and where the calling function expects the reply to be stored.

Functions can be local or host resident. If a called function resides at the host, Linkage Services will invoke the communications facility to transmit the data to host system. When the reply is

PROGRAM PRODUCTS

DMS/3790 (cont'd)

retrieved, it will be stored in the area specified by the calling function.

Location of invoked functions is transparent to the programmer. Linkage Services allows the system designer to change where functions are located without being concerned about the programs that invoke them. Only a reassembly of the invoking programs is necessary to provide access to the moved function. It is the user's responsibility to write the application programs which perform the specific function.

- Communications Interface Monitor (CIM) is a separate feature of the DMS/3790 product.

CIM controls the 3790 side of the communications link. The session control functions performed include opening and closing of sessions, recovery from temporary errors, restarting and resynchronizing interrupted sessions and maintaining a log of communications errors.

CIM transmits requests to the host from the calling program's buffer, the calling program's work area, indexed records or relative records.

CIM retrieves replies from the host and stores them in the calling program's buffer, the calling program's work area, indexed records or relative records.

CUSTOMER RESPONSIBILITIES

To install and use the DMS/3790 program product the user must:

1. Acquire a knowledge of the functions provided by the different facilities.
2. Learn the new macros provided for implementing these facilities.
3. Learn how to prepare the forms provided for the screen handler generation.
4. Generate the necessary tables required at the host system for Linkage Services and Get Collection.
5. Provide the necessary data set and program IDs to be used.
6. Provide the necessary host application programs if the CIM feature is used.
7. Provide additional programming for the screen handler user routines if required for the 3790 applications.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

DMS/3790 requires the following system configuration:

- An IBM S/370 mdl 115 or larger for DOS/VS, mdl 135 or larger for OS/VS1 or a mdl 145 or larger for OS/VS2. The machine configuration for DMS/3790 varies according to the user's application needs. The requirement for operation under CICS/VS or IMS/VS is any IBM S/370 with enough real storage to meet the combined operating requirements of CICS/VS or IMS/VS, the host operating system, the appropriate access methods and other user-required applications. DMS/3790 requires 85K of virtual storage. The program operates in a virtual equals virtual environment.
- Depending upon the operating system used, any direct access storage device supported by the Virtual Storage Access Method (VSAM) and OS/VS1, OS/VS2 or DOS/VS.
- Any card read/punch and printer supported by OS/VS1, OS/VS2 or DOS/VS.
- Any magnetic tape drive supported by OS/VS1, OS/VS2 or DOS/VS (required for installation only.)
- A minimum of 1-3271 or 1-3272 and 1-3277 mdl 2 Display Station if the Interactive Forms Preparation facility is used.
- A 3704 or 3705 Communications Controller for online operations (if the 3790 is not local channel attached).

or

A 3747 Data Converter for offline diskette creation.

- A 3791 Controller, mdl 1A or larger.
 - 3791 configuration support feature #9431, #9165 or #9169. (CIM does not support feature #9431).
 - DMS/3790 will support only the following attached devices included in the above configuration:
 - 3793 Keyboard/Printer
 - 3277 mdl 1 or 2
 - A minimum of either 1-3277 or 1-3793 is required. In addition to above attached devices, the line printer (feature #4710, #4711 or #4715) is also supported.

SOFTWARE REQUIREMENTS

DMS/3790 is written in S/370 Assembler language, PL/S* and 3790 programming statements as follows:

- Interactive Forms Preparation - PL/S* and Assembler
- Screen Handler Generator - PL/S* and Assembler
- Get Collection - Assembler
- Linkage Services - Assembler
- Work Area Management - Assembler and 3790 Programming Statements
- Communications Interface Monitor (feature) - 3790 Programming Statements

* Programming Language/Systems (PL/S) is an IBM proprietary language.

Assembler language and 3790 programming statements source code is provided with the DMS/3790 program product.

Depending upon the host operating system used, the following programs are required:

OS/VS

	VS1	VS2
OS/VS Assembler XF	5741-SC1-03	5752-SC1-03* 5742-SC1-03**
Linkage Editor	5741-SC1-04	5752-SC1-04* 5742-SC1-04**

TSO Subroutines for TCAM	-----	5752-SC1-T8* 5742-SC1-T8**
TSO		
Data Management	-----	5752-SC1-T3* 5742-SC1-T3**
Scheduler	-----	5752-SC1-T4* 5742-SC1-T4**
Supervisor	-----	5742-SC1-T7**

* = MVS
** = SVS
*** Also applies to subsequent releases unless otherwise identified.

Note 1: VTAM or TCAM/NCP/VS Direct, NCP/VS and SSS are required for the transmission of programs from the host to the 3790. They are not required if the Batch Data Exchange facility is used to forward programs to the 3790.

Note 2:

PROGRAM PRODUCTS

DMS/3790 (cont'd)

VTAM, NCP/VS and CICS/VS or IMS/VS are required if the Communications Interface Monitor feature of DMS/3790 is to be used.

Note 3:

For the Interactive Forms Preparation facility CICS/VS or TSO with either VTAM or TCAM is required.

DOS/VS: Release 33

DOS/VS Assembler	5745-SC-ASM
Linkage Editor	5745-SC-LNK
Virtual Storage Access Method (VSAM)	5745-SC-VSM
Access Method Services	5745-SC-AMS
Sequential Disk IOCS	5745-SC-DSK
Virtual Telecommunications Access Method (VTAM)	5745-SC-VTM
Extended Telecommunications Modules (EXTM) with CICS/VS Version 1, Release 3.0	5746-XXB
3704/3705 Network Control Program/VS (NCP/VS) (if 3790 is not local channel attached)	5747-AJ2
Subsystem Support Services (SSS)	5745-SC-SSS
3790 Host Support	5747-BQ1
Customer Information Control System (CICS/VS) Version 1, Release 3.0 (and subsequent releases unless otherwise identified)	5746-XX3

Note 1:

NCP/VS, SSS and either VTAM or EXTM are required for the transmission of programs from the host to the 3790. They are not required if the Batch Data Exchange facility is used to transfer programs to the 3790.

Note 2:

NCP/VS and CICS/VS with either VTAM or EXTM are required if the Communications Interface Monitor feature of DMS/3790 is to be used.

Note 3:

For the Interactive Forms Preparation facility CICS/VS is required.

VM/370: VM/370 can be used for execution of the screen handler generator, for interactive forms preparation and for assembly of programs if a 3790 macro library is available. For validation and transmission of programs to the 3790 and for use of the CIM feature of DMS/3790, a DOS/VS or OS/VS system is required.

**DISPLAY MANAGEMENT SYSTEM/3770
(DMS/3770), RELEASE 1
5748-XC3**

PURPOSE

This program product is a productivity aid for users of the 3770 Communication System that simplifies the design, coding, testing and maintenance of the 3770 application programs. The DMS/3770 program product consists of an interactive or forms driven panel definition program, a screen handler program generator, a local data set access manager, a host communication access manager and an application function manager.

The 3770 programmable system is an operator oriented communication system that consists of an IBM 3774 or 3775 Programmable Communication Terminal and its attached devices. The operator terminal consists of the console keyboard, the 480 character gas panel display, the console printer and the 3278 Display Station mdl 2 RPQ #EJ2657 (3774 only). Support for the RPQ will be available in a later release. Records may be stored on one fixed diskette drive, and/or two additional diskette drives that are optional. Other devices supported are the 3501 Card Reader, the 2502 Card Reader and the 3521 Card Read/Punch.

Programs prepared on the host system are transmitted to the 3770 where they may be executed. These programs can operate in a stand-alone manner or with host communication.

The S/370 host system supports the 3770 under DOS/VS, OS/VS1, OS/VS2 and VM/370 (CMS). 3770 programs are created and tested at the host system and are transmitted by the user to the 3770.

DMS/3770 generates a 3770 application program which supports data collection and maintenance from the 3770 console. Local data sets may be either indexed or relative in organization. Host data sets may have any form of organization which the user-written host program will support.

HIGHLIGHTS

- Improved programmer productivity.
- The cost of maintaining 3770 application programs should be reduced because of system modularity and standardized documentation.
- Tedious aspects of 3770 programming are removed without prohibiting unique implementation via user exits.
- Distribution of function or data from the host system to the 3770 or vice versa.
- Application may be described on the Interactive Forms Preparation facility or by using the DMS/3770 forms.
- Full Screen Processing facility.

DESCRIPTION

- Field by field support.

The Interactive Forms Preparation Facility (IFP) is a productivity tool that aids the application designer in describing the interface with the display operator. This facility operates under TSO, CICS/VS and CMS. The IFP provides for online entry of the information necessary to generate screen handler programs by using a 3271 or 3272 and one 3277 mdl 2 Display Station or one 3275 Display Station (or equivalent 3274/3276/3278 combination). This facility provides the capability to improve productivity with functions such as:

- Full screen entry of display and print layouts.
- Left-right and up-down scrolling capability.
- Automatic prompting for field definitions.
- Restart capability.
- Help panels.

DMS/3770 forms allow an application programmer to describe the 3770 interface with the display operator. In order to use the screen handler function of DMS/3770 for specifying operator communications, certain forms must be filled out, keyed and input to the DMS/3770 screen handler generator. The forms are divided into two groups: (1) data definition and (2) screen handler definition. Data definition consists of the buffer definition form. This form allows the user to specify the formats of buffers or records. A DMS/3770 data definition processor edits this form and then generates, in card form, the appropriate 3770 code for the definitions. These definitions can then be added to a MACLIB or source statement library for reference at assembly time for the application.

There are two forms which provide for the screen handler definition. Contents of these forms allow input of basic program information of field editing characteristics.

The host communication function supports the BSC mode of line use. SDLC support is also available.

Five operational functions may be selected by the application programmer to be provided in the generated functional program:

- Add** --- Selected input data fields from the panel described by the application programmer are collected and arranged in the order specified by the buffer description and are stored in the local/host data sets selected by the operator.
- Display** --- Previously entered data is retrieved and merged with the panel described by the application programmer, and is displayed on the operator console of the 3770. A record may be retrieved by the operator by entering the key of the record, by entering the relative record number of the record, or by entering a null key which signifies "next record".
- Verify** --- Previously entered data is retrieved by key or by entering a null key ("next record"). The operator is supplied with the prompts from the application programmer specified panel and is required to rekey the entry values. If the existing data and the newly keyed data match, the next field is processed. Three attempts at each field are allowed before the new value is accepted in the case of mismatch. The original data is not shown to the verify operator to maintain keying independence. Indexed data sets include a verification indicator. The indicator will be changed to a "V" if the record was verified correct as is, and will be changed to a "C" if the record was altered during the verify operation.
- Update** --- Previously entered data is retrieved by key or by entering a null key ("next record"). The data is then merged with the panel described by the application programmer, and is displayed on the operator console one field at a time. After each input value is displayed, the operator is given the opportunity to alter it. After the last field, the record is rewritten to the source data set. If an indexed data set is being processed, the verification indicator will be changed to a "U" if a field is updated.
- Delete** --- The record is selected by the operator by key only, is merged with the application programmer specified panel and is displayed on the operator console. The operator is then prompted to continue or to abort the delete request. "No" implies abort, "yes" implies continue. The record is then removed from the data set by altering the key so that it is no longer selectable. (The deleted record may be returned to active status by the operator.)

Continuous running routines -- the operator has the option of performing a selected function in a continuous mode.

DMS/3770 requires at the host a number of input, output and work files to retain information as it is processing the various screen handler forms. These files are:

1. Input file.
2. Layout & field processing file (work).
3. Mapping file (work).
4. Generated output file.

CUSTOMER RESPONSIBILITIES

To install and use the DMS/3770 program product the user must:

1. Acquire a knowledge of the functions provided by the different facilities.
2. Learn the new macros provided for implementing these facilities.
3. Learn how to use the IFP facility or the forms provided for the screen handler generation.
4. Provide the necessary data set and program ID's to be used.
5. Provide the necessary host application programs and install CICS/VS or IMS/VS if host communications is used.
6. Provide any necessary user programming to perform functions not provided by DMS/3770. This may be done via user exits.
7. Provide the NCP/VS and Access Method Generations if online diskette transmission or DMS/3770 Host Communications is used.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

DMS/3770 requires the following system configuration:

- An IBM S/370 mdl 115 or larger for DOS/VS, an IBM mdl 135 or larger for OS/VS1 or an IBM mdl 145 or larger for OS/VS2 and comparable mdls of the IBM 3031, 3032, and 3033. The machine configuration for DMS/3770 varies according to the user's application needs. The requirement for operation under CICS/VS or IMS/VS is any S/370 with enough real storage to meet the combined operating requirements of CICS/VS or IMS/VS, the host operating system, the appropriate access methods and other

PROGRAM PRODUCTS

DMS/3770 (cont'd)

user-required applications. The DMS/3770 IFP facility requires 112K (code requirement) of virtual storage. The DMS/3770 editor and generator requires 48K (code requirement) of virtual storage. Depending upon the operating system used, any direct access storage device supported by the virtual storage access method (VSAM) and OS/VS1, OS/VS2, or DOS/VS is supported.

- Any card read/punch and printer supported by OS/VS1, OS/VS2 or DOS/VS.
- Any magnetic tape drive supported by OS/VS1, OS/VS2 or DOS/VS (required for installation only).
- A minimum of one 3271 or 3272 and one 3277 Display Station mdl 2 or one 3275 Display Station (or equivalent 3274/3276/3278 combination) is required if the Interactive Forms Preparation Facility is used.
- An IBM 3704/3705 Controller or ICA for online operations or an IBM 3747 Data Converter for offline diskette creation.
- An IBM 3770 Programmable Communications Terminal (3774 or 3775).
- DMS/3770 will support the following devices attached to a 3770:
 - Gas Panel Display.
 - Console Printer.
 - 3501 or 2502 Card Reader.
 - 3521 Card Read/Punch.
 - 3278 Display Station mdl 2 RPQ #EJ2657 (3774 only).
 - Diskette Drives (0, 1 and 2).

DMS/3770 supports all models of the 2314, 3330 or 3340 Direct Access Storage devices for its input and output files. In addition to a single disk, this program product also requires a Card Reader/Punch and a printer. A tape drive is required only for installation.

SOFTWARE REQUIREMENTS

3770 operates under OS/VS (SVS 1.7*) (MVS 3.0*), VS/1 (6*) DOS/VS (33*) and VM/370 (Release 5)/CMS. (* - and subsequent releases and modification levels unless otherwise stated.) The Sequential Access Method (SAM) and Virtual Storage Access Method (VSAM) are used for the input and output files. DMS/3770 is written in S/370 Assembler language, PL/S*, and 3770 programming statements as follows:

- Interactive Forms Preparation -- PL/S* and Assembler
- Screen Handler Generator -- PL/S* and Assembler
- DSURPRL1, 2, 3 Macros -- 3770 Programming Statements
- DMS/3770 supplied utilities -- 3770 Programming Statements

* Programming Language/Systems (PL/S) is an IBM proprietary language.
Assembler language and 3770 programming statements source code is provided with the DMS/3770 program product.

Depending upon the Host Operating System used, the following programs are required:

	OS/VS1	OS/VS2
OS/VS Assembler XF	5741-SC1-03	5752-SC1-03 (MVS) 5742-SC1-03 (SVS)
Linkage Editor	5741-SC1-04	5752-SC1-04 (MVS) 5742-SC1-04 (SVS)
Virtual Storage Access Method (VSAM)	5741-SC1-DE	5752-SC1-DE (MVS) 5742-SC1-DE (SVS)
IDCAMS (Access Method Services)	5741-SC1-DK	5752-SC1-DK (MVS) 5742-SC1-DK (SVS)
Sequential Access Method (SAM)	5741-SC1-DO	5752-SC1-DO (MVS) 5742-SC1-DO (SVS)

Customer Information Control System (CICS/VS) Version 1, Release 3.0 and subsequent releases and modification levels unless otherwise stated.	5746-XX3

Note 1: CICS/VS or CMS is required if the Interactive Forms Preparation Facility is used. CICS/VS is required if the programmable communication feature is used.

Note 2: If the 3278 RPQ #EJ2657 for the 3774 is installed, the appropriate levels of 3790 host support and engineering changes must be installed.

VM/370: CMS can be used for execution of the Screen Handler Generator and assembly of programs if a 3770 Macro Library is available. For validation and transmission of programs to the 3770 and for host communication, a DOS/VS or OS/VS system is required. Under VM/370 Release 5, the PA1 key function is not available for DMS/3770. PA1 is reserved for VM/370 usage. All IFP users under this release must use a 3270 display station having at least 12 PF keys.

COMPATIBILITY

DMS/3770, DMS/3790 and DMS/VS are similar in concept; however, because of the unique requirements of the individual systems, they are not compatible. The code generated by DMS/3770 contains 3770 unique macros. Therefore, the functional programs are not compatible with the IBM 3790 Communication System.

PROGRAM PRODUCTS

DMS/3770 (cont'd)

PERFORMANCE CONSIDERATIONS

Because of the variations possible with a communication terminal, it is difficult to predict performance. The performance of a DMS/3770 Generated Application Program executing on a 3770 terminal is highly dependent on the terminal resources available, data file placement and user written routines. Use of DMS/3770 generated programs should have a positive effect on the 3770 Programmable Communication Terminal performance. This is a result of the use of 3770 unique macro code as well as the structure of DMS/3770.

PROGRAM PRODUCTS

**DEVELOPMENT MANAGEMENT SYSTEM/
DISTRIBUTED PROCESSING CONTROL EXECUTIVE
DMS/DPCX (5748-XC4)**

PURPOSE

Development Management System/Distributed Processing Control Executive is a licensed program which offers productivity gains in the development of applications for the IBM 8100/DPCX Information System. Running a host S/370, 4300 or 3000 Series Processor, DMS/DPCX assists the user in complete application definition and subsequent maintenance.

The DMS/DPCX generated applications execute on 8100/DPCX systems. DMS/DPCX minimizes the data processing experience and aptitude required to generate new application programs. Programmers can use DMS/DPCX to develop application programs with a minimum learning period. Complete applications are generated into source code for the 8100/DPCX system. As application complexity increases, so does the requirement for DP expertise. DMS/DPCX is a member of the Cross System Generator Set of program products which also contains DMS/DPPX and DMS/CSP. Each of these program products share a common, proven architecture and all are highly compatible in their implementation. They are all intended to simplify application development and increase programmer productivity.

HIGHLIGHTS

- Provides a S/370, 4300 or 3000 Series online interactive preparation facility, which operates under VM/CMS, TSO or CICS/VS.
- Complete application programs are defined. Primary capabilities provided include display formatting, field editing, arithmetic operations, conditional processing, data definition and file read, write and update.
- Supports distributed data processing using the 8100/DPCX and the host system.
 - Enhanced Instructions.
 - Distributed indexed access method.
 - 32K task virtual storage and other symbolic machine enhancements.
 - Advanced function device support (large display screens and color).
- Resultant application programs that execute on the 8100/DPCX system may be either interactive or batch.
- Application programmers are shielded from SNA protocol and sequences.
- Manages communications between the DMS/DPCX user application programs and IMS/VS or CICS/VS. DMS/DPCX includes the DMS/3790 Communications Interface Monitor (CIM) feature, which assists the application programmer in the initiation and termination of host sessions.
- Self-teaching.
 - TUTOR mode for new users.
 - PROMPT mode for experienced users.
 - HELP facility.
- Application models may be defined, stored and subsequently customized to meet new requirements.
- Application definitions may be tested on the host before they are generated for the 8100/DPCX system.
- A utility is provided to assist in converting DMS/3790 screens to DMS/DPCX format.
- Utilities are provided which allow map, data and application definitions to be copied, renamed, deleted, printed and imported or exported between member specification libraries.
- A DMS/DPCX application may invoke user-written applications written in DPCX programming statements.
- DMS/DPCX supports all currently announced displays and display printers attached to the 8100/DPCX.

DESCRIPTION

The user at a display terminal is guided through the definition and generation of a complete application. The definition includes:

- Data formats.
- Screen formats (Maps).
- Editing.
- Use of program function and attention keys.
- Selector pen-detectable fields.
- File read, write, update.
- Table definition.
- Application logic and flow.
- Data manipulation.
- Inclusion of user code.
- Linkage to other programs.

The user can operate in either of two modes, TUTOR or PROMPT. A HELP facility is provided for use in both modes.

The user may test his application's logic on the host through the DMS/DPCX Interactive Test Facility. The Test Facility will support access to user-defined files of test data.

DMS/DPCX converts these specifications into source application programs that are assembled and validated on the IBM S/370 or IBM 4300 Processor with PVS. Resultant programs are distributed to the 8100/DPCX program library and execute in full screen processing mode or as a batch program.

DMS/DPCX also provides the DMS/3790 execution-time services on the 8100/DPCX system, which assist in the task of host communications and allow existing DMS/3790 applications to be run.

Use of DMS/DPCX can result in application programs that:

- Can be invoked by other programs.
- Execute interactively with an operator.
- Execute in batch mode.
- Can use a spooled printer.

This interactive facility runs under TSO/TCAM, TSO/VTAM, VM/CMS, or CICS/VS.

APPLICATION DEFINITION STEPS

Overview

- DMS/DPCX allows the user to perform application definition as independent steps. The user selects the application development facility (data definition, map definition or application definition) to be performed. The facility selected may be terminated at any time, and defined information will be stored for future reference.
- The information collected by each process is stored in the Member Specification Library (MSL). The user may then use the application generation facility to combine all the information about a given application from the MSL and generate the necessary DPCX programming statements to perform the given application. Since all definitions are stored on the MSL, they may be referenced or used by several applications without re-definition.

Step by Step

- **Data Definition** - Allows the definition of data format and characteristics including the length, data type and relationships with other data items in a record. Once the data is defined for a given file, the attributes of the data items will be automatically retrieved by DMS/DPCX if they are referenced during user program definition. This promotes consistent use of data items for all applications using DMS/DPCX.
- **Map Definition** - Allows the user to define the display format for the terminal or printer. Maps are defined interactively with the capability to specify editing criteria for each field.
- **Application Definition** - Allows the user to define the logic flow of an application. Arithmetic operations, process logic, data retrieval, and the flow of terminal displays and printers are defined during this step.
- **Application Test** - Allows the user to exercise an application under DMS/DPCX on the host. This interactive Test Facility will support access to test data files on the host. It allows the user to trace the execution of his program and thus follow and validate its logic before it is generated and transmitted to the 8100/DPCX system. The Test Facility also provides a pre-processor capability which checks the syntax and usage of DMS statements.

Application Generation - The data from the application, map, and data definitions are stored in the MSL. The generation step uses the data to generate a source program. During generation, the user is prompted to specify any unique 8100/DPCX information. The program is then compiled and stored in the S/370 and subsequently sent to the 8100/DPCX program library.

- DMS/DPCX operates in either of two modes, TUTOR or PROMPT. TUTOR mode is an instructional or teaching mode for users who have no previous experience using DMS/DPCX. PROMPT mode is an input assistance mode for an experienced DMS/DPCX user. A HELP facility is provided for use in both of these modes to assist the user in becoming more self-sufficient without referring to a manual.

The user may change between TUTOR and PROMPT mode any time during processing. This allows the user to receive either explicit instruction (TUTOR mode) or minimal instruction (PROMPT mode) on the information required to define and generate application programs.

- DMS/DPCX provides the facilities to create and maintain application models. An application model is a DMS/DPCX

PROGRAM PRODUCTS

DMS/DPCX R1 (cont'd)

definition of a program stored in the MSL. Models can be used directly or can be customized by an end-user to fit specific requirements. This technique offers the customer programming staff the ability to define an application program as a model and subsequently permit end-user departments to customize the models to suit their needs. Once a model has been customized, the user will execute the generation step of DMS/DPCX to obtain the source for the DPCX application program.

A data entry application model to aid in design, implementation, and maintenance, is provided with the DMS/DPCX program product.

- **MSL Utilities** - Allows the user to maintain interactively data, maps, and application definitions by listing, copying, re-naming, deleting, or printing. It also allows library members to be imported or exported between MSL.

EXECUTION TIME SERVICES

DMS/DPPX includes the execution-time services of DMS/3790. These are:

- **Communications Interface Monitor (CIM)** which manages communications between user application programs and IMS/VS or CICS/VS.
- **Work Area Manager (WAM).**
- **Get Collection.**
- **Linkage Services.**

CIM and Linkage Services functions are invoked in DMS/DPCX generated applications for the purpose of host communications.

When applications are defined using DMS/DPCX, some of the DPCX services and facilities that will be invoked at execution time are:

Data Set Services: Read, write and update access to indexed and relative data sets. This support will include DPCX/DXAM as well as existing 3790 data sets.

Transaction Services: Transaction services will allow for creation of transactions for subsequent batch transfer to the host system.

Queued Printer Services: Queued printer service to produce printer output. The printer output is spooled to disk. DPCX print facilities are used to print the output on any attached printer. Directly attached, tertiary printers may also be specified.

Panel Services: Panel services are used to retrieve full screen processing (FSP) panels to be used in mapping data to the display printer. These panels will be used with the DPCX presentation services.

Presentation Service: The DMS/DPCX screen handler will use full screen processing (FSP) to manage the user display screen. This will allow DMS/DPCX to take advantage of all of the functional capabilities of a display device.

Virtual Storage: DMS/DPCX applications take advantage of 32K task virtual storage to hold records from DXAM data sets and a working storage area.

CUSTOMER RESPONSIBILITIES

Installation

The installation process for DMS/DPCX is designed to require minimal system programming or system operator time.

DMS/DPCX installation is the process of building libraries received from PID on a magnetic tape. The installation must be accomplished using standard DOS or OS facilities before DMS/DPCX is initialized and made operational.

To install and use the DMS/DPCX program product the user must:

- Acquire a knowledge of the functions provided by the different facilities.
- Provide the necessary data set and program IDs to be used.
- Provide the necessary host application programs for the host communications function.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

DMS/DPCX requires the following systems configuration:

- An IBM S/370 model 115 or larger with a minimum of 192K or an IBM 4300 or 3000 Series Processor with enough real storage to meet the combined operating requirements of CICS/VS, the operating system and the appropriate access method.
- Depending upon the operating system used, any direct access storage device supported by the Virtual Storage Access Method (VSAM) and OS/VS1, OS/VS2 or DOS/VSE.
- Any IBM magnetic tape drive supported by OS/VS, DOS/VSE or VM/CMS.

- A minimum of one display terminal with 1,920-character screen and twelve program function keys.
- An IBM 8100/DPCX with feature #6001.

DMS/DPCX has no unique requirements for the 8100/DPCX systems.

SOFTWARE REQUIREMENTS

Depending on the host operating system used, the following programs are required:

8100	
DPCX (with feature #6001)	5761-DS1
OS/VS1 or OS/VS2	
Host Prep Licensed Program	5735-XR3

In addition, there must be an operational TSO or CICS 1.4.1 (or greater) system to execute DMS/DPCX. Further, there must be some system in place for transporting the DPCX programs from the host system to the 8100. This can include host transmission through DSX, SSS or a user-written program or it can be by using BDES.

DOS/VSE

Host Prep Licensed Program	5735-XR3
VSE/Virtual Storage Access Method (VSAM)	5746-AM2

In addition, there must be an operational 1.4.1 (or greater) system to execute DMS/DPCX. Further, there must be some system in place for transporting the DPCX programs from the host systems to the 8100. This can include host transmission through DSX, SSS, a user-written program, or BDE diskettes.

VM/CMS

VM/CMS can be used for execution of DMS/DPCX and for assembly of generated programs if an 8100/DPCX macro library has been set up. For validation and transmission of programs to the 8100/DPCX and for use of the Communications Interface Monitor of DMS/DPCX, a DOS/VSE or OS/VS system is required.

In order to execute DMS/DPCX under VM/CMS, one of the full screen interfaces is required. These are:

VM/System Product	5669-167
VM/System Extensions Program Product	5748-XE1
VM/Basic System Extensions Program Product	5748-XX8
Full Screen Console Interface PRPQ	5799-AWP

COMPATIBILITY and PORTABILITY

COMPATIBILITY with DMS/DPPX and DMS CROSS-SYSTEM PRODUCT: DMS/DPCX, DMS/DPPX and DMS/CSP are conceptually the same in the definition phase. However, DMS/DPPX and DMS/CSP offer functions that are not available with DMS/DPCX. Applications developed on DMS/DPPX or DMS/CSP which use these unique capabilities may require redesign or redefinition if the application is also to be generated for a DPCX system.

Applications defined using DMS/DPCX are portable to DMS/DPPX or DMS/CSP environments within previously published restrictions. For more information about DMS portability, see the *General Information Manual* (GH20-5555).

COMPATABILITY with DMS/3790: A conversion aid is provided to assist in conversion of DMS/3790 maps and data definitions to DMS/DPCX MSL format.

DMS/DPCX will not affect the execution of existing DMS/3790-developed applications. DMS/DPCX will include the execution-time services now provided by DMS/3790.

DATA SECURITY, AUDITABILITY AND CONTROL

DMS/DPCX will support features that assist in preventing unauthorized use of the 8100/DPCX including the following:

- Operator ID codes and password checking in application codes.
- Application program access level assignments.
- Isolation of program definition and execution.
- Supports use of predefined symbols for program auditability.
- Host environment security controls are available to the application programmer.
- Supports use of 8100/DPCX to control access to application programs.

The user is responsible for the selection, use and adequacy of these controls.

MVS SYSTEM INTEGRITY APPLIES: Yes

RPQs ACCEPTED: No

TERMS and CONDITIONS: See PP Index

5748-XE1 - VM/SYSTEM EXTENSIONS

PURPOSE

VM/System Extensions provides performance and usability extensions to VM/370 as described in the VM/370 SCP section. This support is recommended primarily for users running MVS, SVS or VS1 under VM/370, users with the 2305-II fixed head storage device for paging, and/or CMS intensive users on S/370 mdls 155II or above. VM/System Extensions Release 1 Modification Level 1 requires VM/370 Release 5 as a base. VM/System Extensions Release 2 requires VM/370 Release 6 as a base.

DESCRIPTION

Improvements in Resource Management: The functions of the VM/370 Resource Management PRPQ (5799 ARQ) are incorporated into the VM/System Extensions program product.

Throughput Improvements: Throughput improvements may be achieved in the following environments:

- Systems with real storage bottlenecks.

When a real storage bottleneck is indicated, the resource manager may reduce the effect and increase the level of multiprogramming. This is achieved through the use of improved scheduling and paging algorithms, which give rise to smaller working set size estimates and higher page steal ratios. The net result is that a given real storage size appears more able to contain the given load with improved throughput.

- Systems with many users logged on, some of which are idle.

The resource manager pages out swap tables and page tables of inactive users and frees up real storage for other purposes. This may increase the level of multiprogramming and improve throughput.

- Storage bound systems with long running non-interactive users and high multiprogramming levels.

Such systems devote a large part of their paging activity to swapping the long running users in and out of storage as each is given a timeslice. The resource manager reduces this paging overhead by swapping the longest running users into real storage less frequently but keeping them there for longer periods. This may lower the overall level of paging activity with accompanying reduction in supervisor overhead and some increased throughput.

- Systems that need more paging space than is available on preferred paging devices.

The resource manager maintains the active user pages on the high speed or primary paging devices using a page migration scheme. Pagewait due to slow access times of secondary devices is reduced and improved processor utilization and throughput may result.

Improved Response to Trivial Interactions: Improved response to trivial interactions may be achieved in the following environments:

- Terminal interactions occur for both single trivial commands and nontrivial transactions during terminal I/O.

The resource manager distinguishes between the two types of transactions by tracking the resource consumption rate and giving top priority to the smallest consumer.

- Transactions are characterized by a wide range of resource requirements.

The fair share algorithms of the resource manager, which are effective in both compute bound and paging bound environments, distinguish between the different resource requirements of the users. Consequently, a better interactive/noninteractive split is achieved with improved responsiveness to trivial transactions.

Installation Management Control: Installation management will have more control over the services provided in the following environments:

- Multiple users require a specified percentage of the processor.

The SET FAVOR command with percentage option may now be specified for more than one user.

- CMS batch facilities running non-interactively.

Directory priority controls may now be utilized to make CMS batch facilities either fully non-interactive to minimize impact on the system, or fully interactive to encourage its use.

- VM/370-ECPS

VM/370 on S/370 mdls 135-3, 138, 145-3 and 148 has been enhanced to accelerate the processing of the DIAGNOSE interface between a virtual machine and CP. Since CMS is a heavy user of DIAGNOSE, the CMS user may receive improved performance.

Shadow Page and Segment Table Maintenance: VM/370 will reduce the overhead associated with maintaining shadow tables used to run virtual systems.

Multiple shadow tables will be maintained to reduce the overhead associated with building shadow tables when a different address space within a virtual machine is dispatched.

Shadow table entries will be selectively invalidated when VM/370 steals a page from a virtual machine.

Shadow tables can be eliminated for V=R users running a production system.

Shadow table maintenance will be reduced for areas in a virtual system where the virtual address is equal to the real address.

Extended Support: VM/System Extensions will support operating systems that utilize the 370 Extended Facility of the 3031, 3032 and 3033 Processors, and the S/370 Extended Feature of the S/370 mdls 158 and 168 provided the host system has the S/370 Extended Feature installed. Thus MVS/Systems Extensions can be run on VM/System Extensions.

- **Dynamic SCP Transition To and From Native Mode:** An installation will have the ability to run another SCP in native mode on the same system used for running VM/370, with a minimum of disruption to the system's operation. It will be possible to switch from VM/370 to another SCP, run that SCP in native mode, and then switch back to VM/370 without IPLing the system. The other SCP must run in a V = R area. It can be MVS, SVS or VS1 in non-handshaking mode.

While running OS/VS in native mode, the installation is operating without VM/370. The performance of the OS/VS system will be equivalent to that OS/VS system running native with the same amount of storage and the same I/O configuration it was using in the VM/370 V = R area. When the installation again requires VM/370 services, the operator returns control to VM/370 and the installation again has all the advantages that result from using VM/370.

This will give an installation operational flexibility that it did not have before. It will be possible to run both VM/370 and OS/VS in native mode on the same system, without the disruption of an IPL when a switch is made between VM/370 and OS/VS. This capability will be valuable when running an application that cannot be shut down, such as DB/DC.

Note: This function is not supported for OS/VS2 on the 4331 or the 4341 Processor.

- **Single Processor Mode:** It will be possible to run VM/370 in Single Processor Mode (SPM). SPM will allow an installation to restrict VM/370 to a single processor of an AP or MP system, leaving the other processor for the exclusive use of a guest virtual machine running MVS. In SPM, when MVS is IPLed in a V = R area, MVS will initialize the other processor and run in AP or MP mode.

Using SPM, the throughput of MVS running on an AP system will be up to 1.65 times greater than without SPM. The throughput of an MP system will be up to 1.75 times greater.

With SPM, the Relative Batch Throughput of MVS on an AP system will be up to .75, and up to .85 on an MP system.

CMS Support of Labelled Tapes: CMS has been modified to process labelled tapes as follows:

VOL 1 Labels

- Processed by DOS or OS OPEN simulation routines.
- Processed by CMS TAPPDS or TAPEMAC Commands.
- Displayed or written by CMS TAPE command.

HDR Labels

- Processed by DOS or OS OPEN simulation routines: Exits are provided to allow access to user-written routines to process standard user (UHL) labels.
- Processed by CMS TAPPDS or TAPEMAC Commands.
- Processed by a new CMS Macro designed for use in Assembler language programs in conjunction with other CMS tape macros.

EOF/EOV Labels

- Processed by DOS or OS CLOSE simulation routines: Exits are provided to allow access to user-written routines to process standard user (UTL) labels.
- Processed by a new CMS Macro designed for use in assembly language programs in conjunction with other CMS tape macros.

Nonstandard Labels

- User exits are provided in DOS or OS OPEN and CLOSE simulation routines and in TAPPDS or TAPEMAC commands to allow access to user-written routines to process nonstandard labels.

Limitations: The following are not supported:

- Label processing for tapes which are read backwards.
- Multivolume files.
- ASCII labels.

VM/System Extensions (cont'd)

Spool Files To Tape: This support will provide Class D commands for the spooling operator which will enable him to store to, or retrieve from tape those unit record output files which he wishes to schedule for real output at some later time on his VM/370 system. The restored files will retain the same characteristics as the original file, but will be assigned new spool-ids to avoid duplicate identification within the spooling system. The spooling operator can store or retrieve spool files selectively (by class or spool-id) or completely. An option is provided to allow the operator to scan the tape.

Virtual Machine Storage Preservation: VM/370's control program will be modified so that during a VM/370 warm start or an abnormal termination by VM/370 of specified virtual machines, the user's virtual storage will be preserved. Specifically, virtual machine IPL will be changed so that it no longer uses a page of the user's virtual storage, and the V = R area under VM/370 will be preserved during VM/370 warm start. In addition, specific virtual machines can be identified such that at VM/370 abend, or when that virtual machine is abnormally terminated by VM/370, the registers and main storage for that virtual machine will be saved.

This improved integrity of virtual storage is particularly beneficial to IMS/VS users running in a virtual machine who need to have storage preserved so that they can run a standalone program to recover IMS/VS log buffers. In addition, standalone dumps that are IPLed from an external storage device will now accurately reflect the user's virtual storage, because VM/370 will no longer use a page of that storage.

Spooling of Accounting Records: This support provides the installation with the ability to spool accounting data to a designated virtual machine with a designated class. The data can be spooled to provide punched output or spooled to a virtual machine's reader for additional processing. This eliminates the need to have a real card punch online at all times to get accounting records.

Virtual Machine Interface to Allow Programs To Use The Full Facilities of a 3270 Type Terminal: The diagnose interface has been extended to allow a virtual machine user to share a display terminal with CP. When the user has control of the screen he has available most of the facilities of the device.

Support for the 3262 Printer Models 1 and 11: The 3262 mdls 1 and 11 are, respectively, 650 and 325 line-per-minute printers.

Support For The Enhanced 3270 Display Terminals: The following enhanced 3270 terminals are supported:

3268/3287/3289 Printer (copy command support only)
3274 Control Unit mdl 1B, 21B (3272 compatible)
3274 Control Unit mdl 1C, 21C, 31C, 51C (TP - BSC only)
3274 Control Unit mdl 1D, 21D, 31D (3272 compatible)
3276 Control Unit/Display Station mdl 2 (1920 character screen)
3276 Control Unit/Display Station mdl 3 (2560 character screen)
3276 Control Unit/Display Station mdl 4 (3440 character screen)
3278 Display Station mdl 2 (1920 character screen)
3278 Display Station mdl 3 (2560 character screen)
3278 Display Station mdl 4 (3440 character screen)

This includes support for the 96-character set (94 characters plus space and null), and PF keys 13 through 24.

The following functions are only available in VM/System Extensions Release 2:

- **Interactive help facility under CMS:** The help facility is an informational, online display service available at the CMS terminal to guide the user in using CP and CMS commands and reacting to CP and CMS messages. As a result, the user can, in most cases, avoid referencing manuals during CMS sessions.
- **CMS file system enhancements:** The file system enhancements will provide the user with a more efficient and flexible file system. Specifically, the enhancements are:
 - Removal of the current limitations on the size of CMS-disks and the number of files per CMS-disk.
 - Support for physical block sizes of 800, 1024, 2048 and 4096 bytes.
 - Efficient handling of variable length files.
 - Selective directory updating.
 - (FBA) device type support.
 - Concurrent open for read and write of CMS files.
- **CMS tape command performance improvement:** A large blocksize (4K) is supported for tape dump/load to decrease overhead.
- **CMS/DOS uplevel to DOS/VSE:** The CMSDOS DCSS provides DOS/VSE support in CMS. This segment processes all DOS/VSE requests. Since the CMSAMS and SMSVSAM DCSS have been updated to depend upon the DOS/VSE SVCs and to support VSE/VSAM and DOS/VSE files on FBA devices, the CMSDOS DCSS has been updated to support these SVCs and devices.

- **CMS use of CP page management interfaces:** CMS now takes advantage of the existing page control interfaces to better communicate the true working set of pages to CP, thus better utilizing the page frame resources of the real machine.
- **CP performance improvements:** The CP changes are:
 - The storage management algorithm for returning free storage to the dynamic area has been modified. A check is now made every hour and upon a user logging off to determine if any dynamic area pages obtained for free storage purposes can be returned to the dynamic area.
 - The set favored command has been changed to accept a percentage specification of 100. This specification will be handled as a special case by the scheduler where the user will be kept at the top of the run list.
 - CMS disk I/O (Diagnose 18) has been modified to take advantage of ECPS:VM/370 for CCW translation.
- **Small CP option:** Small CP option reduces real memory requirements for CP which makes more pageable storage available to virtual machines.
- **Enhanced support for the 3270 Information Display System.**

APL Text Feature: The 3270 APL-TEXT feature provides the 3270 user with access to the full APL, TEXT and EBCDIC character sets. This makes it possible for the user to interact with the VS APL program product as well as text processing applications which run under CMS. This support extends the APL-TEXT function to users with 3274 Controllers and 3278 Display Stations.

Intensified Display: VM/370 will take advantage of the intensified display feature of the 3270 Information Display System as follows:

- 1) The "Current Line" of the CMS Editor will be intensified.
 - 2) All CMS Edit messages will be intensified.
 - 3) An application program may supply a 3270 Start Field order and an attribute byte in a DIAGNOSE 58, CCW Code 19 (Virtual Console Interface) data stream. This provides an application program with the ability to define a field as normal intensity, intensified or non-display.
 - 4) Messages from the system operator or other user will be intensified.
 - 5) The redisplay of user input will be intensified so that it may be distinguished from output. The SET command will activate or deactivate intensification of input redisplay.
- **Support for the 3289 Printer Model 4:** The 3289 mdl 4 is a 150 or 400 line-per-minute printer and functionally compatible with the 3203 printer mdl 4 (except in the area of UCS buffer load).
 - **Support for the 8809 tape:** The 8809 is a two speed tape drive (12.5 ips and 100 ips). It will be supported at 12.5 ips in VM. The standalone dump-restore utility (DDR) supports the device at 100 ips to provide high-speed backup capability when executing on a standalone processor.
 - **Support for the 3310/3370 direct access devices:** The 3310/3370 are direct access devices that use Fixed Block Architecture. The Direct Access Storage Compatibility feature (#7901) of the IBM 4331 Processor for emulation of 2314, 3330 and 3340 format data on the 3310 or 3370 is supported. VM/370 supports 3310 or 3370 volumes containing emulated data which are dedicated to a guest operating system other than VM/370 or CMS.
 - **Support for the 3880 Storage Control mdl 1.**

CUSTOMER RESPONSIBILITIES

In addition to the responsibilities described in the VM/370 SCP section under the heading "Customer Responsibilities", the customer is responsible for ordering and installing the proper level of VM/370.

To run SVS under VM/System Extensions Program Product PTF UY77568 must be applied to the SVS system.

ECPS:VM/370: VM/System Extension is designed to operate with VM/370 Release 5 and to utilize ECPS:VM/370 with the following ECs with REAs as indicated.

EC #149136 with REA 01-17926 for mdl 135-3 or higher EC level
EC #149136 with REA 01-17926 for mdl 138 or higher EC level
EC #356901 with REA 01-18431 for mdl 145-3 or higher EC level
EC #147710 with REA 01-18432 for mdl 148 or higher EC level
EC #276270 for 3031 or higher EC level

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

VM/System Extensions is designed to run on IBM S/370 mdls 135, 135-3, 138, 145, 145-3, 148, 155II, 158, 158-3, 158AP, 158MP, 165II,

VM/System Extensions (cont'd)

168, 168-3, 168AP, 168MP and on the IBM 4331, 4341, 4381, 3031, 3031AP, 3032, 3033, 3033AP and 3033MP processors. IBM S/370 mds 158MP, 168MP and the 3033MP Processor are supported in UP mode, in MP mode with I/O on only one side and in MP mode with I/O on both sides when Single Processor Mode is used. To install VM/System Extensions on a 4331, 4341 or 4381 Processor, the hardware configuration must include a DASD device that is supported by VM/370 Release 6. It requires a minimum accessible main storage of 384K. This Program Product is designed for MVS, SVS or VS1 users who run under VM/370 for testing, conversion or production; for those who use the 2305-II fixed head storage device for VM/370 paging; and for CMS intensive users on S/370 mds 155II or above.

VM/System Extensions supports a cardless operating environment. By using the facility to spool accounting records and altering the system generation procedures to use tape devices, the requirement for a card reader/punch can be eliminated. Specific details are contained in the TNL update to the *VM/370 Planning and System Generation Guide* (TNL order number SN25-0757). Specific details relevant to the minimum configuration required for hardware maintenance should be directed to Field Engineering.

Note: Users running VM/Systems Extensions on a 135-3, 138, 145-3 or 148 with ECPS for VM/370 will not realize the full benefit of ECPS because new shadow table maintenance algorithms will be used in preference to some ECPS algorithms.

For the 4331 Processor, it is possible to run VM on a configuration without a block multiplexor channel (the 4331 does not have selector channels) if the appropriate Tape and DASD devices are selected. The 8809 Tape, the 3340 DASD, the 3310 DASD and the 3370 DASD can be attached via adapters. These devices are supported in SEPP Release 2.

The configuration requirement for channels is that the configuration contain either the channels or equivalent adapters to which the required DASD and Tape devices can attach. For SEPP Release 2 this requires a selector channel, a block multiplexor channel or appropriate adapters.

PROGRAM PRODUCTS

**VM/DIRECTORY MAINTENANCE
RELEASE 1
5748-XE4**

PURPOSE

The manual procedures to maintain the VM Directory have been cumbersome, time consuming and error prone. The objective of the VM/Directory Maintenance program product is to provide efficient, easy-to-use, and secure interactive facilities to address these problems.

HIGHLIGHTS

- Directory changes are made interactively using a set of general user and system administrator commands.
- Security is enhanced through the ability to enforce regular password changes.
- Directory integrity is improved through ownership by a strictly controlled service virtual machine which uses automatic backup/restore and journaling. Protection against I/O errors is achieved through the maintenance of Directory entry checksums, which are logical arithmetic sums of each entry's contents.
- Directory availability is maintained through automatic virtual machine re-initialization should a program interrupt occur or should some other condition occur which would otherwise have resulted in a disabled WAIT state being entered.
- CMS file integrity is improved through automatic command driven allocation of minidisk space. This prevents inadvertent overlaying of existing minidisk extents with new minidisks extents.
- User efficiency is improved by allowing him to perform certain directory changes himself (thereby bypassing the usual administrative bottleneck). Some such changes can be put into effect immediately through an update-in-place facility, thereby improving system efficiency by avoiding repetitive use of the nontrivial DIRECT utility.
- Usability of the program product is emphasized through an integrated HELP facility, and the use of prompting and full screen 'menus' where appropriate. The full screen menu feature is only available when the VM/Basic System Extensions Program Product (5748-XX8), the VM/System Extensions Program Product (5748-XE1) or the VM/System Product (5664-167) is installed.

DESCRIPTION

Product Review: The Directory Maintenance program product functions are largely performed by a disconnected service virtual machine which has exclusive ownership of the VM Directory. The function provided is invoked through the use of four classes of commands:

- Commands which allow the general user to change some of the statements in his own directory entry. For example he may change his logon or minidisk passwords, his minidisk access modes, his automatic LINK requests, account number or distribution code.
- Commands which allow the system administrator to define new virtual machines in the directory or to change statements in any existing entry. For example, he may change the userid or the passwords, minidisk definitions (space is automatically assigned if the appropriate definition file has been set up), virtual device addresses and dispatch priority.
- Commands to monitor and control the directory management process. For example, commands may be used to start the system up or shut it down, to review minidisk space allocation (and possible overlaps) and free space, to turn on or off automatic minidisk extent verification and to suspend or restore the automatic or manual placing of updated directory source online.
- Commands to facilitate the maintenance of the directory system. For example, these commands may be used for loading and activating versions of the system or control files, for sorting or initializing the directory source, for taking dumps and for emergency rebuilding of the directory source from backup and for the requesting of transaction logging for possible debugging purposes.

Directory maintenance commands are issued from the user's virtual machine and are transmitted, via the CP command SMSG, to the directory service virtual machine for processing. The resulting transactions may be processed immediately or they may be queued if the virtual machine is already busy. Some transactions which simply replace existing statements in a directory entry may be brought online immediately through an update-in-place capability in the VM Control Program. More complex transactions requiring expansion or contraction of an entry may only be brought online when the standard DIRECT utility is run. It is possible through the use of a control file, to request periodic automatic executions of this utility. Also via this file, an installation may specify input for the use of certain standard features, such as how often backup is to be performed, or how often the directory is to be brought online using the DIRECT utility, or the installation may specify the use of optional features such as menus.

CUSTOMER RESPONSIBILITIES

In addition to the responsibilities of the VM installation as defined in the VM pages, the customer has the following responsibilities with regard to the Directory Maintenance Program Product:

- To install Release 6 of VM.
- To optionally install the VM/Basic System Extensions Program Product, the VM/System Extensions Program Product or the VM/System Product if the full screen 'menu' is desired.
- To provide sufficient DASD space to accommodate the needs of the program product.
- To train the system administrator to operate the program product.
- To educate the general user on how to use the program product.

SPECIFIED OPERATING ENVIRONMENT

The Directory Maintenance Program Product may be used in any VM installation where CMS is available.

HARDWARE REQUIREMENTS

The same IBM products as those announced for VM/370 Release 6 and VM/System Product. In addition, when running with the VM/Basic System Extensions Program Product, the VM/System Extensions Program Product or the VM/System Product, the 3310 and 3370 Fixed Block Architecture devices are supported and when running with the VM/System Product, the 3380 DASD is also supported. The directory maintenance virtual machine requires a minimum of 716K virtual storage size and the following three minidisks:

- Virtual disk 191: 8 cylinders of IBM 3330 mdl 11 space (or equivalent) for the programming system.
- Virtual disk 195 containing the directory source, control files, history and log files: Approximately 15 cylinders of 3330 mdl 11 space (or equivalent) plus 1 cylinder for every 100 users in the directory. This is based on the assumption that there are an average of 10 statements in the typical directory.
- Virtual disk 193 containing the directory backup source, the spooled console log and a few other working files. Space requirements are the same as Virtual 195.

SOFTWARE REQUIREMENTS

The Directory Maintenance Program Product is designed to operate with Release 6 (PLC4) of VM/370 as a base with APARs VM09879 and VM10286 installed. If the full screen 'menu' support for command processing is desired, there is an optional dependency on the VM/Basic System Extensions Program Product, the VM/System Extensions Program Product or the VM/System Product.

The VM/System Product is also required to use:

- Support for the 3380 Direct Access Storage.
- Support for specifying the 3279 Display Station screen attributes in directory entries.
- Support for specifying an alternate path to the CP directory.

In addition, APAR VM12034 must be installed on the VM/System Product to use the ability to make screen modifications to the directory entry effective immediately.

COMPATIBILITY

The Directory Maintenance program product is compatible with the existing manual methods of directory maintenance. An installation may at any time change from one method to the other, or use both at the same time.

DOCUMENTATION: (available from Mechanicsburg)

The following publications are available in support of this new product: *Licensed Program Design Objectives ... General Information Manual ... Licensed Program Specifications ... General User's Guide ... Installation and System Administrator's Guide ... Program Logic Manual.*

PROGRAM PRODUCTS

**VM/DIRECTORY MAINTENANCE
RELEASE 2
5748-XE4**

PURPOSE

The manual procedures to maintain the VM Directory have been cumbersome, time consuming and error prone. The objective of the VM/Directory Maintenance program product is to provide efficient, easy-to-use, and secure interactive facilities to address these problems.

HIGHLIGHTS

- Directory changes are made interactively using a set of general user and system administrator commands.
- Security is enhanced through the ability to enforce regular password changes.
- Directory integrity is improved through ownership by a strictly controlled service virtual machine which uses automatic backup/restore and journaling. Protection against I/O errors is achieved through the maintenance of Directory entry checksums, which are logical arithmetic sums of each entry's contents.
- Directory availability is maintained through automatic virtual machine re-initialization should a program interrupt occur or should some other condition occur which would otherwise have resulted in a disabled WAIT state being entered.
- CMS file integrity is improved through automatic command driven allocation of minidisk space. This prevents inadvertent overlaying of existing minidisk extents with new minidisk extents and inadvertent destruction of minidisk files.
- User efficiency is improved by allowing him to perform certain directory changes himself (thereby bypassing the usual administrative bottleneck). Some such changes can be put into effect immediately through an update-in-place facility, thereby improving system efficiency by avoiding repetitive use of the nontrivial DIRECT utility.
- Usability of the program product is emphasized through an integrated HELP facility, and the use of prompting and full screen 'menus' where appropriate.
- Commands which provide the installation with information relative to the status of its users and the DATAMOVE virtual machine, the facility to control the flow of messages from DIRMAINT, and a command interface to the DATAMOVE virtual machine.
- IPL Control Statement extension to allow the user to add a PARM option followed by up to 48 characters in a user's directory entry.
- RAS enhancements include improvements in TOD interrupt and new day detection, resolution of several ABEND conditions, and disk full recovery.

Product Review: The Directory Maintenance program product functions are largely performed by a disconnected service virtual machine which has exclusive ownership of the VM Directory. The function provided is invoked through the use of four classes of commands:

- Commands which allow the general user to change some of the statements in his own directory entry. For example he may change his logon or minidisk passwords, his minidisk access modes, his automatic LINK requests, account number or distribution code.
- Commands which allow the system administrator to define new virtual machines in the directory or to change statements in any existing entry. For example, he may change the userid or the passwords, minidisk definitions (space is automatically assigned if the appropriate definition file has been set up), virtual device addresses and dispatch priority.
- Commands to monitor and control the directory management process. For example, commands may be used to start the system up or shut it down, to review minidisk space allocation (and possible overlaps) and free space, to turn on or off automatic minidisk extent verification and to suspend or restore the automatic or manual placing of updated directory source online.
- Commands to facilitate the maintenance of the directory system. For example, these commands may be used for loading and activating versions of the system or control files, for sorting or initializing the directory source, for taking dumps and for emergency rebuilding of the directory source from backup and for the requesting of transaction logging for possible debugging purposes.

Directory maintenance commands are issued from the user's virtual machine and are transmitted, via the CP command SMSG, to the directory service virtual machine for processing. The resulting transactions may be processed immediately or they may be queued if the virtual machine is already busy. Some transactions which simply replace existing statements in a directory entry may be brought online immediately through an update-in-place capability in the VM Control Program. More complex transactions requiring expansion or contraction of an entry may only be brought online when the

standard DIRECT utility is run. It is possible through the use of a control file, to request periodic automatic executions of this utility. Also via this file, an installation may specify input for the use of certain standard features, such as how often backup is to be performed, or how often the directory is to be brought online using the DIRECT utility, or the installation may specify the use of optional features such as menus.

CUSTOMER RESPONSIBILITIES

In addition to the responsibilities of the VM installation as defined in the VM pages, the customer has the following responsibilities with regard to the Directory Maintenance Program Product:

- To install VM/System Product Release 1 or VM/System Product Release 2.
- To provide sufficient DASD space to accommodate the needs of the program product.
- To train the system administrator to operate the program product.
- To educate the general user on how to use the program product.

SPECIFIED OPERATING ENVIRONMENT

The Directory Maintenance Program Product Release 2 may be used in any VM installation where VM/System Product Release 1 or VM/System Product Release 2 is installed and where CMS is available.

HARDWARE REQUIREMENTS

The same IBM products as those announced for VM/System Product Release 1 or VM/System Product Release 2. The directory maintenance virtual machine requires a minimum of 716K virtual storage size and the following three minidisks:

- Virtual disk 191: 8 cylinders of IBM 3330 mdl 11 space (or equivalent) for the programming system.
- Virtual disk 195 containing the directory source, control files, history and log files: Approximately 15 cylinders of 3330 mdl 11 space (or equivalent) plus 1 cylinder for every 100 users in the directory. This is based on the assumption that there are an average of 10 statements in the typical directory.
- Virtual disk 193 containing the directory backup source, the spooled console log and a few other working files. Space requirements are the same as Virtual 195.

The DATAMOVE virtual machine requires a minimum of 512K virtual storage size and a virtual 191 disk with 5 cylinders of 3330 mdl 11 space (or equivalent) for its related files.

SOFTWARE REQUIREMENTS

The Directory Maintenance Program Product is designed to operate with either VM/System Product Release 1 or VM/System Product Release 2.

In addition, APAR VM12034 must be installed on the VM/System Product Release 1 to use the ability to make screen modifications to the directory entry effective immediately.

COMPATIBILITY

The Directory Maintenance program product is compatible with the existing manual methods of directory maintenance. An installation may at any time change from one method to the other, or use both at the same time.

DOCUMENTATION: (available from Mechanicsburg)

PROGRAM PRODUCTS

**5748-XP1 - VM/370 RSCS NETWORKING
VM/370 REMOTE SPOOLING COMMUNICATIONS
SUBSYSTEM (RSCS) NETWORKING**

PURPOSE

This product permits CMS users to transmit jobs to other systems for execution. Output may occur at the other system, or on the VM/370 System unit record devices. Remote users may transmit jobs for execution to a CMS batch virtual machine, and can specify that the output can be sent to any terminal or system defined on the network. This product can be used to submit jobs for execution in other batch systems (DOS/VSE, OS/VS) running in a virtual machine. If the other batch systems support the NJE/NJI protocol, output can be directed to any virtual machine or system defined in the network.

DESCRIPTION

RSCS is a multi-tasking supervisor supporting multiple concurrent remote spooling operations while running in a single VM/370 virtual machine. It is designed so that a separate task supports the specific characteristics of each remote terminal, workstation or node attached to the RSCS virtual machine via a teleprocessing line. The RSCS supervisor provides each task with a common access method to the VM/370 spool file system and an Execute Channel Program (EXCP) level interface for I/O to the teleprocessing line.

Printer or punch files that any VM/370 virtual machine user (e.g., a CMS user) wants to have transmitted to a supported remote destination need only be spooled to the RSCS virtual machine with the destination designated via the CP TAG command. The proper task for the remote destination will be initiated and the files will be sent. For file being transmitted from a remote destination, RSCS will read the data from the remote destination, produce a VM/370 spool file from the data and either forward it to another destination, spool it to a virtual machine's reader or spool it to the system depending upon what has been specified by the sender.

RSCS supports three general types of remote connections: NonProgrammable Terminal, Programmable Terminals and NJE/NJI systems.

RSCS provides asynchronous peer-to-peer communication capabilities between VM/SP systems. When used in conjunction with the programmable operator facilities of VM/SP Release 2, RSCS Release 2 or 3 provides communications capabilities for the remote operation of VM/SP systems in distributed data processing environments.

Nonprogrammable Terminal Support: RSCS provides support for the IBM 2770, 2780 and 3770 as a 2770. It also provides support for the IBM 3780 and 3776/3777-1 as a 3780 terminal. This support is provided through the IBM 3704/3705 Communications Controller in emulation mode, through the 2701 Transmission Control Unit, or through the Integrated Communications Adapter available on the IBM S/370 mdl 135, 135-3, 138 or the Communications Adapter on the 4331 processor. RSCS will also support the 2770, 2780 and 3780 terminal via the 2703 Transmission Control Unit.

RSCS provides support for 3270 Information Display System printers, which are either locally attached or on a remote cluster attached to the VM/370 processor on which this release is running. 3270 Information Display System printers are defined to be 3284, 3286, 3287, 3288 or 3289 printers attached to the appropriate 3271, 3272, 3274 or 3276 control unit. (The 3262 line printer, mdls 3 and 13 are compatible with the 3289.)

Programmable Terminal Support: RSCS supports communication with processors programmed to run as a HASP workstation. This includes the DOS/VS Job Entry Workstation Program (PRPQ WFO358). RSCS can assume the role of a HASP workstation and connect to any HASP, ASP, RES, JES2 or JES3 system running as a main processor. RSCS can connect to a VSE/POWER host system.

NJI/NJE Systems: RSCS supports communications to and from systems running NJI/NJE for JES2, RSCS Networking or the HASP, ASP or VM/370 Networking PRPQs over binary synchronous facilities or channel to channel attachment (CCA) using a common NJE protocol.

HIGHLIGHTS

The RSCS Networking Program Product is a superset of both the RSCS Component of VM/370 and the VM/370 Networking PRPQ. Significant new features as compared to the RSCS Component of VM/370 include:

RELEASE 1

Release 1 Networking: This product allows a VM/370 system to operate as a full member of an NJI/NJE job network. It includes those functions common to all NJI/NJE compatible systems such as:

Compatible Network Protocol - allows one system to transfer jobs and card or printer formatted data streams to another without requiring either system to assume a subordinate role.

Store and Forward Facilities - which complete transmission of a data stream from one node to another before any further action is taken on that data stream. As a result, the integrity and recovery facilities of each node's spool file system provides integrity and recovery of that file in the event of a network or system failure.

Routing - by means of destination tables, is provided by each node in the network. Until the node to which a spool file is directed is reached, each intervening node will enqueue the file for the link to the next node for proper routing to the specified destination. When the final destination is reached, the file is released to that system for processing.

Operator Commands - are provided to allow the network operator to reconfigure the network without interrupting normal networking operations.

Simplified and Improved System Operation: Additional operator commands are provided to make it easier for the RSCS operator to control the RSCS virtual machine operations. Note: The RSCS machine can run without operator intervention. The normal and recommended way to run an RSCS virtual machine is to run it disconnected (i.e., with no operator terminal) and to spool the console output.

VM/370 accounting records for each file transmitted or received are maintained. These records contain information that pertains to the origin, destination and record count of the file.

A simple EXEC function is provided that allows the RSCS operator to call out frequently used series of commands such as those needed to automatically start up communication links, or to automatically change a network configuration at a particular time of day.

A dynamic directory is provided that allows the RSCS operator to permanently update (add, delete, change) the RSCS link and route identifiers without having to re-sysgen RSCS. This directory can be changed by the RSCS operator using normal CMS editing facilities. The changes will take place at the next IPL of RSCS. Operator commands are provided to temporarily modify the link and route identifiers in storage so that changes can be made without having to re-IPL RSCS. These changes will only remain active until the next IPL of RSCS.

Files and jobs may be submitted through the VM/370 real card reader to RSCS for transmission. The data deck to be transmitted must be preceded by an ID card to direct it to the RSCS virtual machine and by a card that contain 'tagtext' to specify its destination.

CMS users can send special messages to the RSCS virtual machines requesting RSCS to send messages or commands to other nodes on the network.

DASD Support: The product supports the IBM 3310 and 3370 (Fixed Block Mode) DASD devices and the enhanced CMS file system, both of which are supported in the VM/Basic System Extensions Program Product Release 2.

Enhanced Coexistence: In addition to being able to communicate with NonProgrammable Terminals and Programmable Terminals, RSCS can now communicate with VSE/POWER, and can participate in NJE/NJI networks. This allows a VM/370 system running RSCS Networking to coexist and communicate with a diverse number of communications terminals and host systems as shown in the following chart:

Remote System Nodes

NJI/NJE Hosts:	NonNJI/NJE Hosts:
Any system capable of running:	Any system capable of running:
RSCS Networking	VSE/POWER
JES2 NJE	RES component of OS/VS1
VM/370 Networking PRPQ	JES2 component of OS/VS2

PROGRAM PRODUCTS
VM/370 RSCS (cont'd)
RELEASE 2

Release 2 includes all of the functions provided in RSCS Networking Release 1 plus the following:

- **Spooling of files to 3270 Information Display System printers.**
Files can be spooled to RSCS for printing on 3270 Information Display System printers which are either locally attached or on a remote cluster attached to the VM/370 processor on which this release is running. 3270 Information Display System printers are defined to be IBM 3268, 3284, 3286, 3287, 3288 or 3289 printers attached to the appropriate IBM 3271, 3272, 3274 or 3276 control unit. (The 3262 line printer, mdls 3 and 13, is compatible with the 3289.)
- **Transmission of Additional Spool File Attributes.**
Spool file attributes associated with the IBM 3800 Printing Subsystem in VM/370 Release 6, and new spool file attributes in the VM/System Product, will be transmitted and preserved when a spool file is sent between VM/370 (RSCS Release 2) nodes and non-VM/370 NJI/NJE nodes.
The RSCS command language is extended to allow the RSCS operator to change these spool file attributes for any spool file enqueued to the RSCS virtual machine.

RELEASE 3

Release 3 provides all of the functions of RSCS Networking Release 2 plus the following:

- **Virtual 3800 Support:** RSCS will support the networking and transmission of virtual 3800 printer files created on one VM/SP system to another VM/SP system for printing. These files may be transmitted through intermediate VM/SP systems that are using Release 3 of RSCS or through NJI/NJE systems.
- **Extended 3800 Support:** RSCS will accept for printing on a VM/SP Release 2 system, 3800 print files that were created on a non-VM NJI/NJE system, and which have multiple Character Arrangement Tables specified, and contain print control and table reference characters preceding each data record.
- **Authorized Operator:** The RSCS virtual machine or individual links can now be controlled by an authorized operator on another virtual machine or at another node in the network. This permits greater user flexibility in operating an RSCS network.
For example, since an authorized operator can now be specified for a particular link, an output-only workstation (such as the 3270 information display station printer) can be controlled from a terminal nearby the printer in a location that is remote from the central RSCS operator.
- **Improved Usability:** Installations may now specify that RSCS is to use the CP message No Header command to improve the readability of RSCS messages, by eliminating blank lines and CP message headers sent to a user on a local system. This option can be particularly useful when used in conjunction with the programmable operator facility of VM/SP Release 2 to eliminate unnecessary messages from the local RSCS machine to the remote operator of distributed machines.

When the new end user commands of VM/SP such as NAMES, and TELL are used, RSCS will become transparent to end-users. Users of these commands need no longer be aware of SPOOL, TAG, and PUNCH commands.

- **Improved Serviceability:** RSCS networking can now use the facilities of the VM/370 Interactive Problem Control System program product for RSCS problem determination and analysis. IPCS provides an interactive online facility for reporting and diagnosing program failures and for managing problem information and status.
To aid in resolving problems related to communications links, the capability of the RSCS TRACE command will be extended to print details of each transmission that takes place over the link, optionally including the complete contents of the data buffer. The log output may optionally be routed to another user or another node.
- **Workstation Forms Control Support:** An RSCS operator (or an authorized operator) can now specify which print spool files, based upon their form name, are to be printed on a particular remote workstation printer. The form name can either be selected manually for each type of form to be printed, or selected automatically by RSCS as a function of the files in the queue for a particular link. Optionally, the operator may request setup pages to be printed to aid in forms alignment.
- **Distributed Data Processing:** When utilized in conjunction with the programmable operator facilities of VM/SP Release 2, the VM/370 Pass-Through Facility, Release 2, RSCS can be used for the remote operation and control of multiple VM/370 systems

from a central site. RSCS networking provides the vehicle for the asynchronous transmission of programs, data, messages, and commands between VM/SP systems. The new end-user commands of VM/SP Release 2 provide the facilities of RSCS to non-DP end-users in a simple and straight forward manner. Remote initialization of 4300 processors requires the ROCF feature on the 4300 processors.

CUSTOMER RESPONSIBILITIES

The customer is responsible for installing this program product. In addition the customer is responsible for understanding the user interfaces to the systems and communications terminals that he wants to communicate with and with telling his users of these interfaces. The customer is responsible for assuring that all teleprocessing linkages are properly set up and is responsible for properly identifying links and routes to this program.

SPECIFIED OPERATING ENVIRONMENT

This product is designed primarily to allow CMS users and RJE users connected to RSCS to transmit jobs to other systems for execution with the output produced either at the other system or returned for output on the VM/370 system unit record devices. Additionally, remote users can transmit jobs for execution in a CMS batch virtual machine. Because of the flexible interfaces within RSCS and the VM/370 spooling systems, this product can be used to submit jobs for execution in other batch systems (DOS/VSE, OS/VS, etc.) running in a virtual machine. If the other batch systems support the NJE/NJI protocol, output can be directed to any virtual machine or system defined in the network. This product is very useful for sending messages and data streams to CMS users on VM/370 systems communicating with each other through this product.

HARDWARE REQUIREMENTS

Processors: RSCS runs on any IBM processor supported by VM/370 Release 6 and a virtual machine storage size of 384K or greater.

Hardware Configurations: The RSCS Networking program product is designed to run on the System/370 Models 135, 135-3, 138, 145, 145-3, 148, 155II, 158, 158-3, 158AP, 158MP, 165II, 168, 168-3, 168AP, and 168MP; on the 3031, 3031AP, 3032, 3033, 3033N, 3033S, 3033AP, 3033AP-2, and 3033MP processor complexes; 3081 and IBM 4300 Processors.

3270 Information Display System Printers: Release 2 supports the following 3270 Information Display System printers:

- IBM 3262 Printer mdl 3 or mdl 13 (IBM 3262 Line Printers mdls 3, 13 are compatible with the IBM 3289)
- IBM 3268 Printer mdl 2
- IBM 3284 Printer mdl 1 or mdl 2
- IBM 3286 Printer mdl 1 or mdl 2
- IBM 3287 Printer mdl 1 or mdl 2, mdl 1C or 2C Base Color Only)
- IBM 3288 Line Printer mdl 2
- IBM 3289 Line Printer mdl 1 or mdl 2

The above printers are supported when attached to the following control units:

- IBM 3271 Control Unit mdl 1 or mdl 2
- IBM 3272 Control Unit mdl 1 or mdl 2
- IBM 3274 Control Unit mdl 1B, mdl 1C, mdl 1D or mdl 51C (Base Color Only)
- IBM 3276 Control Unit Display Station mdl 1, mdl 2, mdl 3 or mdl 4.

SOFTWARE REQUIREMENTS

RSCS is designed for, and requires, VM/System Product (VM/SP). (For RSCS Release 3, the Extended 3800 portion of the 3800 printer enhancements requires Release 2 of VM/SP, but the remainder of the new functions in Release 3 will run with Release 1 of VM/SP.) In addition, the RSCS support of IPCS requires the latest release of the VM/Interactive Problem Control System Extension (IPCS) program product. VM/SP Release 2 programmable operation capabilities are supported under RSCS Releases 2 and 3.

Adequate CMS formatted disk space must be provided to contain the RSCS system disk, the RSCS text staging area, and the RSCS source staging area. The approximate amount of DASD space required is shown in the following table:

PROGRAM PRODUCTS

VM/370 RSCS (cont'd)

	SYSTEM	BASE TEXT	BASE SOURCE
DASD	DISK	STAGING AREA	STAGING AREA
2314	6 cylinders	7 cylinders	67 cylinders
3330	3 cylinders	4 cylinders	35 cylinders
3340	8 cylinders	9 cylinders	98 cylinders
3375	3 cylinders	3 cylinders	26 cylinders
3350/3380	2 cylinders	3 cylinders	18 cylinders
3310/3370	1536 blocks	1792 blocks	14592 blocks

COMPATIBILITY

RSCS Networking Release 3 is upward compatible with RSCS Networking Release 2.

Files can be successfully transmitted from an RSCS Release 2 system to a Release 3 system. However, when files are transmitted from an RSCS Release 3 system to either a Release 2 system or an RSCS Release 3 system that is running on VM/SP Release 1, any of the new spool file attributes that may be present will be lost. Virtual 3800 files cannot be successfully transmitted to an RSCS Release 2 system.

PROGRAM PRODUCTS

**5748-XT3 - SPF/CMS
VM/CMS - 3270 DISPLAY SUPPORT and
STRUCTURED PROGRAMMING FACILITY**

PURPOSE

VM/CMS - 3270 Display Support and Structured Programming Facility (SPF/CMS) is functionally equivalent to Version 2.2 of the SPF/TSO program. The two programs are fully compatible in display formats and operation, except for those features which are explicitly oriented to the VS2/TSO or VM/CMS environment. SPF/CMS also includes a utility which permits transfer of SPF program libraries from VS2/TSO to VM/CMS.

HIGHLIGHTS

SPF/CMS is a program development tool designed to take advantage of the characteristics of IBM 3270 display terminals, and to increase programmer productivity in the VM/CMS environment. SPF supports both structured and conventional programming techniques. It can be used either by an individual programmer, or by many programmers working together on a project. SPF features which increase programmer productivity and simplify operation include:

- Display presentations and menus which prompt the user, reduce keystrokes and minimize the opportunity for error.
- Support for multi-level programming libraries, automatic collection of library activity statistics and printing of library contents.
- Full screen, context editing which allows additions and changes to multiple lines in a single interaction.
- Simple one-character edit commands for inserting, deleting, duplicating or rearranging lines of source data.
- Forward, backward and sideways scrolling of source data or listings, plus the ability to locate information by character string or line number.
- Split screen, allowing two SPF functions to be performed independently on the same display terminal.
- Use of program function keys for frequently performed SPF operations and commands.
- Menu-driven utilities for specification, maintenance and current status display of libraries and files.
- Menu interface to standard language processors (compilers and assembler) for execution in the foreground or CMS batch machine.
- Document preparation support, including text editing features and a menu interface to the SCRIPT/VS Document Composition Facility.
- Hardcopy log summarizing significant user actions during the session.
- Online tutorial for instruction and reference - especially valuable for the occasional or novice user of SPF.

DESCRIPTION

SPF operates as a VM/CMS application and is invoked simply by entering the command "SPF". It operates on a 24-line, 32-line or 43-line IBM 3270 display station, equipped with either 12 or 24 program function keys.

DISPLAY FORMAT: SPF uses four basic types of display presentations:

- **Option Selection Menus** - where the user selects from a list of options by typing a number and pressing the ENTER key.
- **Parameter Entry Menus** - where the user supplies parameters by filling in labeled fields. In many cases, SPF displays default values, based on what the user last entered. The user may overwrite the displayed defaults.
- **Member Selection Lists** - for displaying a list of members in a MACLIB or SPF library. The user may select a member by entering a one-character code in front of the appropriate member name.
- **Data Displays** - for displaying source code or listings for editing and browsing. The first two lines of the display include a title, message area, command input field and scroll amount field. The remaining lines contain the data.

PROGRAM ACCESS AND FUNCTION KEYS: The program access (PA2) and the 12 or 24 program function (PF) keys are used to request commonly used or special SPF operations, including:

- **RESHOW** - to redisplay the contents of the screen.
- **SCROLL** - to move the screen window up, down, left or right by the amount shown in the scroll amount field.
- **SPLIT SCREEN** - to enter split screen mode or to adjust the locations of the split based on the current cursor position.
- **PRINT** - to obtain a hardcopy snapshot of the current screen image.
- **HELP** - to obtain additional information about an error message or general information about SPF commands and options.

- **END** - to terminate the current operation and return to the previous display or menu.

Users may rearrange the assignment of SPF-defined PF key functions, and may equate additional PF keys to edit and browse commands.

MAJOR FUNCTIONS: The major functions provided by SPF are:

- **SPF PARMS** - to specify terminal type and user options.
- **BROWSE** - to display source data and output listings.
- **EDIT** - to create or change source data.
- **UTILITIES** - to perform SPF utility functions.
- **BACKGROUND** - to compile, assemble or debug.
- **BATCH PROCESSING** - to compile or assemble via a CMS batch machine.
- **CP/CMS** - to enter a CP or CMS command, or EXEC.
- **TUTORIAL** - to display information about SPF.
- **EXIT** - to terminate SPF.

SPF PARMS: The SPF parms function allows the user to specify terminal type, mono/dual case, number of program function (PF) keys, default options for list and log files and PF key definitions.

BROWSE: The browse option allows the user to display source programs, output listings, test data, etc., stored in SPF libraries, MACLIBs or DASD resident sequential CMS files with the following characteristics:

- Fixed or variable record formats.
- Records with or without printer control characters.
- Records with logical record length up to and including 32,767 bytes.

The screen window for browsing is 22, 30 or 41 lines deep depending upon terminal type. (Two lines are reserved at the top of the screen for title information, messages, command entry and display of the scroll amount.) Four-way scrolling is available via the scroll PF keys. In addition, FIND and LOCATE commands may be used to scroll to a designated character string, line number or symbolic label.

EDIT: The edit option allows the user to create, display and modify source data (program code, test data, documentation, etc.) stored in SPF libraries or DASD-resident sequential CMS files with the following characteristics:

- Fixed or variable record formats.
- Records with or without printer control characters.
- Records with logical record lengths of up to and including 255 bytes but not less than 10 bytes.

The edit display is similar to browse except that each line consists of a six-column sequence number field followed by a 72-column data field. Four-way scrolling is available via the scroll PF keys.

To modify information on the screen, the user simply moves the cursor to the desired location and enters the new information. Several lines may be modified before pressing the ENTER key. Lines may be deleted, inserted, shifted left or right (for indentation changes), duplicated or rearranged by overtyping the sequence number fields with line commands consisting of one or two characters (e.g., D for delete, I for insert, M for move). In general, several line commands as well as data modifications may be typed before pressing the ENTER key.

In addition, primary commands may be entered at the top of the screen to find and change designated character strings, to control sequence numbering and character translation, to submit the data to the job stream, to save the edited data or to cancel without saving.

UTILITIES: The SPF utility function allows the user to select one of the following options:

- **Library Utilities** - to compress a MACLIB, to print a file or to delete, rename or print selected members of a MACLIB or SPF library.
- **File Utility** - to specify a new SPF library, to rename or delete a file or SPF library or to display file or library information.
- **MOVE/COPY** - to move or copy an entire file or selected members of a MACLIB or SPF library.
- **Project Utility** - to print or display information about SPF libraries.
- **Reset SPF Statistics** - to create, update or delete statistics for an SPF library, and optionally reset sequence numbers.
- **Hardcopy Utility** - to initiate printing or punching of a sequential CMS file or member of a MACLIB or SPF library.

PROGRAM PRODUCTS

SPF/CMS (cont'd)

- Retrieve Utility - to transfer SPF libraries which have been dumped to tape (via IEHMOVE) from SPF/TSO to SPF/CMS.
- SCRIPT/VS Utility - to allow formatting, displaying and printing of documentation maintained in SPF libraries or sequential CMS files. Use of this feature requires that the SCRIPT/VS Document Composition Facility be installed.

FOREGROUND PROCESSING: The foreground option provides an interface with standard language processors for foreground compilation, assembly, CMS loading or debugging of programs stored in SPF libraries.

BATCH PROCESSING: The batch processing option provides an interface with standard language processors for CMS batch machine compilation or assembly of programs stored in SPF libraries. For other batch machine jobs, the CP SPOOL and PUNCH commands or some EXEC may be entered via the CMS command option (primary option 6).

CP/CMS COMMAND: The CP/CMS command option displays a menu on which any CP or CMS command or EXEC may be entered without leaving SPF.

TUTORIAL: The SPF tutorial provides immediate online reference and instruction on how to use SPF. It may be viewed sequentially from beginning to end, or randomly by selecting topics from a table of contents or index. It may be entered from the primary option menu, or from another SPF option by pressing the Help PF key.

CUSTOMER RESPONSIBILITIES

The customer must have installed the prerequisite programs and the appropriate processing programs described under compatibility for use of the SPF foreground and batch processing functions.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

The computer system requirements are the same as needed for VM/370; that is an IBM S/370 mdl 135 and up with at least 384K real storage, or an IBM 4300 Processor.

The storage requirements for the user's VM machine will vary depending upon the size of the files being edited and the extent that "split-screen" will be used. The SPF programs are reenterable and should be placed in a discontinuous shared segment area. This will reduce the storage requirements for user machines and should also improve performance when there are multiple SPF users online.

The minimum virtual machine size is 512K if SPF resides in the discontinuous shared area. If SPF does not reside in the discontinuous shared area, a virtual machine size of 768K is recommended.

Terminals: SPF supports the following IBM 3270 Display Stations:

- 3275 mdl 2.
- 3276 mdls 2, 3 and 4.
- 3277 mdl 2 (local or remote attachment).
- 3278 mdls 2, 3 and 4 (local or remote attachment).

The following keyboards are supported:

For 3275 or 3277 display stations:

- 78-Key EBCDIC Operator Console (feature #4632).
- 78-Key EBCDIC Typewriter (feature #4633).
- 78-Key ASCII Typewriter (feature #4635).
- 78-Key EBCDIC Typewriter/APL (feature #4638 for 3277 only), when operated with APL switch OFF.

For 3276 or 3278 display stations:

- 75-Key EBCDIC Typewriter (feature #4621).
- 75-Key ASCII Typewriter (feature #4624).
- 87-Key EBCDIC Typewriter (feature #4627).
- 87-Key ASCII Typewriter (feature #4628).

The standard character set (94 graphics plus blank and null) is supported on 3276 and 3278 display stations.

The audible alarm (feature #1090) is supported, but not required. Installation of the audible alarm feature is strongly recommended to enhance usability. The alarm is sounded by SPF whenever a warning or error message is displayed.

SOFTWARE REQUIREMENTS

This licensed program is released to work with VM/370 Release 5 and subsequent releases and modification levels unless otherwise stated. Prerequisite is either the VM/ System Extension program product (5748-XE1) or the VM/Basic System Extensions program product (5748-XX8).

SPF/CMS is written in PL/S* and translated into Assembler Language.

*Programming Language/System (PL/S) is an IBM proprietary language.

COMPATIBILITY

SPF operates as a CMS command. SPF provides menu interfaces with the following IBM processing programs for foreground and batch execution:

VM/370 Assembler	
COBOL-OS/VS Compiler and Library	5740-CB1
COBOL Interactive Debug	
(foreground only)	5734-CB4
FORTRAN IV G1 Compiler	5734-FO2
FORTRAN Interactive Debug	
(foreground only)	5734-FO5
PL/I OS Checkout Compiler	5734-PL2
PL/I OS Optimizing Compiler	5734-PL1

All the program-numbered items above can be ordered separately under IBM program product licensing agreements. The appropriate processing programs must be installed to use the SPF foreground and batch processing functions.

SPF also provides a menu interface to SCRIPT/VS to allow formatting, display and printing of text maintained in SPF libraries or CMS sequential files. Use of this feature requires installation of the following IBM program product:

Document Composition Facility (SCRIPT/VS) (with the Foreground Environment Feature), 5748-XX9.

General Information Manual ... Licensed Program Design Objectives.

PROGRAM PRODUCTS

**DISPLAY MANAGEMENT SYSTEM/CMS
RELEASE 2
DMS/CMS (5748-XXB)**

[NO LONGER AVAILABLE, effective May, 1983.]

PURPOSE

The Display Management System/CMS program product provides new display oriented interactive function to the CMS user. DMS/CMS requires VM/370 Release 6 and VM/Basic System Extension, VM System Extensions or VM/System Product as prerequisites.

HIGHLIGHTS

Interactive Definition of Display Formats: Utilizing the herein listed Display Stations, an application programmer or application user may interactively format the screen image as it will appear to the end user. This design includes not only definition of constant data but user input fields as well.

Field characteristics are captured when the field is established during the screen design. Field attributes include: Protected/not protected, alphameric/numeric, normal/high/dark intensity, extended color, highlighting, light-pen selectable and may be changed after the screen is designed.

Editing commands provide functions such as:

- DELETE lines.
- DUPLICATE line.
- MOVE and COPY lines.
- Shift LEFT AND RIGHT.
- CENTER.
- Scroll FORWARD and BACKWARD.
- DISPLAY the desired screen.

HELP panels are provided to guide the designer in the use of the functions, and PF keys provide easy manipulation of the various panels.

Screen images are stored under a symbolic name in CMS files for later reference by CMS applications programs.

Communication/Manipulation of Display Formats

High Level Language: The current releases of the following languages can communicate with screen images that were designed and stored under DMS/CMS.

- COBOL/VS (5740-CB1 and (5746-CB1).
- PL/I (5734-PL3 and 5736-PL1).
- RPG II (5746-RG1) (see Note 1).
- VM/370 Assembler.

Note 1: The following functions and capabilities of DMS/CMS Release 2 cannot be used from an RPG II program:

- Selector Light-Pen Support.
- "Data Entry" Options.
- Improved Cursor Management Capability.
- Change Data Field Protection, Color and Highlighting.

DMS/CMS provides the application programmer with facilities to:

- Move data from program to display.
- Move data from display into program.
- Determine fields selected.
- Change highlighting, color, or intensity.
- Change field intensities.
- Manage a cursor.
- Add a comment to bottom line of display.
- Sound the audible alarm.

EXEC Language: The DMS/CMS EXEC2 and DMS/CMS EXEC support provides full screen function to EXEC users. EXECs can be written to communicate to the screen images developed by the DMS/CMS Panel Formatter. All functions of DMS/CMS Release 1 will continue to be available through the DMS/CMS EXEC support. The full capability of DMS/CMS Release 2 is available through the DMS/CMS EXEC2 support.

Support for Various Models of the 3270 Terminal Family: The following 3270 Display Terminals are supported:

- 3275-2 Display Station.
- 3276-2, 3, 4, Control Unit Display Station.
- 3277-2 Display Station.
- 3278-2, 3, 4, 5 Display Stations
- 3279-2A, 2B, 3A, 3B Color Display Stations.

CUSTOMER RESPONSIBILITIES

In addition to the responsibilities in the VM/370 pages under the heading "Customer Responsibilities," the customer is responsible for ordering and installing VM/370 Release 6, VM/Basic System Extensions, VM/System Extensions or VM/System Product.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

DMS/CMS is designed to run on any IBM processor that is supported by VM/370. In addition, at least one of the following terminals must be in the configuration:

- 3275-2 Display Station.
- 3276-2, 3, 4 Control Unit Display Stations
- 3277-2 Display Station.
- 3278-2, 3, 4, 5 Display Stations
- 3279-2A, 2B, 3A, 3B Color Display Stations.

SOFTWARE REQUIREMENTS

DMS/CMS is designed to operate with VM/370 Release 6 and VM/Basic System Extensions, VM/System Extensions or VM/System Product and subsequent releases of each, unless otherwise stated. To display panels on the 3278-5 or 3279-2B, 3B, VM/System Product is required. To display panels using the DMS/CMS EXEC2 support, VM/System Product Release 2 is required.

COMPATIBILITY

Panels created under DMS/CMS Release 1 can be used with Release 2. They may be reformatted to take advantage of additional Release 2 functions, or used without reformatting. Panels created under DMS/CMS Release 2 can not be used with Release 1.

Application programs and EXECs running under DMS/CMS Release 1 will run without recompilation or change under Release 2. Panels formatted with extended color and highlighting, or for wide screen, or using the autoskip option may be displayed by existing programs and EXECs. Use of selector pen fields from an EXEC requires rewrite to use the DMS/CMS EXEC2 support.

**VM/INTERACTIVE FILE SHARING
5748-XXC****PURPOSE**

VM/Interactive File Sharing program product is designed primarily for CMS users. It provides (1) the capability of sharing user VSAM data sets among multiple CMS virtual machines in a single processor and (2) significant usability enhancements for VSAM/AMS users. VM/Interactive File Sharing requires VM/370 Release 6, VSE/VSAM Release 1 and VM/370 Basic System Extensions Release 2 as prerequisites.

HIGHLIGHTS

VSAM Data Set Sharing: VM/Interactive File Sharing runs as a virtual machine which allows a user to define and build VSAM data sets and then manages multiple CMS application requests against these data sets. VSAM is used to manage the physical storage of data but the application programmer need not be trained in VSAM.

Access to VM/Interactive File sharing is via DL/I CALL statements and can be from the current release of the following languages:

COBOL/VS (5740-CB1 and 5746-CB1)

PL/I (5734-PL3 and 5736-PL1)

RPG II (5746-RG1)

VM/370 Assembler

The same capability should also be available for earlier releases of these languages, but has not been tested.

The CALL statements are interpreted by VM/Interactive File Sharing and expanded into the appropriate VSAM request.

Data set security is provided at two levels -- normal VSAM password protection and VM/Interactive File Sharing security via a USERID authorization list.

Exits are provided for user written journaling routines.

AMS Usability Feature: VSAM/AMS functions are available to VM/Interactive File Sharing users but they are presented in a much more usable manner through the use of special modules. These modules prompt the CMS user with simple questions about the function needed and the data set characteristics. The module then expands the answers into the necessary VSAM parameters, by providing the appropriate VSAM defaults.

Although designed for the CMS user, this VSAM usability enhancement may be used to establish VSAM data sets that will be accessed by other SCPs, running as guests on VM/370 or natively. This capability is limited to the compatibility provided by VSE/VSAM, when running in a CMS environment. Detailed information is provided in the VSE/VSAM and VM/370 documentation.

Support for New DASD: Since it utilizes VSAM, VM/Interactive File Sharing provides support for all DASD devices included in the VSE/VSAM Release 1 Program Product.

CUSTOMER RESPONSIBILITIES

In addition to the responsibilities in the VM/370 pages under the heading, "Customer Responsibilities", the customer is responsible for ordering and installing VM/370 Release 6, VSE/VSAM Release 1 and VM/Basic System Extensions Release 2.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

VM/Interactive File Sharing is designed to run on any IBM processor that is supported by VM/370.

SOFTWARE REQUIREMENTS

VM/Interactive File Sharing is designed to operate with VM/370 Release 6, VSE/VSAM Release 1, VM/Basic System Extensions Release 2 and subsequent releases for each unless otherwise stated.

PROGRAM PRODUCTS

5748-XXE - DOCUMENT LIBRARY FACILITY R1

PURPOSE

The Document Library Facility (the library) is a service program that supports the storage of text documents and other types of data. It operates in a batch environment under OS/VS2 (MVS), OS/VS1 or DOS/VS and uses the Virtual Storage Access Method (VSAM). When installed with Document Composition Facility (5748-XX9), it enables the SCRIPT/VS Formatter to run as a batch job in these environments. The Foreground Environment feature of the Document Composition Facility is not required.

HIGHLIGHTS

The library is a repository of data managed in a variety of methods according to the needs of the user.

- Data from many sources can be stored in the library, such as:
 - Text edited and prepared on interactive systems such as VSPC, ICCF, CMS or TSO. The batch job entry functions available with those systems are used to submit the document as part of the job which invokes the library.
 - Text prepared by ATMS-III using the library as an archive facility.
 - Text prepared and edited by the 3730 Distributed Office Communication System with Host Communication Support Feature (#9285) installed. Batch transmission of 3730 created documents between the controller and a host system is available using the 3730 Document Transmission Facility. User programming in the S/370 system is needed to communicate with the 3730 Document Transmission Facility, and to collect the data and generate the JCL which invokes the Document Library Facility. See the *3730 System Description Manual* (GA33-3022) for an overview of the Host Communication capability of the 3730 System.
 - Text prepared and edited using a magnetic card II typewriter or Office System 6, and transmitted using the remote job entry (RJE) capabilities of the host system. See the *Office System 6 Programmer's Guide* (G544-1003) for data conversion considerations.
 - Input to or output from application programs.
- Operation of the ATMS III Archive.

ATMS-III allows the user to archive documents into the Document Library Facility library. Several functions of the library have been enhanced to support this use and are also available to other users of the Document Library Facility.

- Document names can be up to 16 characters long and can contain any character.
- Passwords may contain any character.
- A content attribute defining the type of data in the document can be specified such that documents of the same name but different content (e.g., source and formatted text) can be stored in the library.
- A user identifier (name and/or number) for another system (e.g., ATMS-III) can be mapped to a different user number in the Document Library Facility library.
- Control Statements and input data can be mixed in the same Document Library Facility input stream.
- Documents as well as users can now be locked.
- A user and all the documents in his library can now be purged.
- A document's name and content attribute can be changed.
- Up to 50 characters of user-specified information can be stored with a document on IMPORT and can later be listed.
- Multiple storage data sets of different VSAM control interval sizes can be specified for storing a document in the library.
- User exits are provided for selected control statement processors.
- On IMPORT, a user-written attribute processing program can supply all of the input data.
- Attribute processing programs can be invoked when a document is EXPORTED from the library.
- Data in the library can be accessed by means of commands.
- When the Document Composition Facility is installed, the library can invoke SCRIPT/VS:
 - To process documents that have been prepared directly for SCRIPT/VS
 - To process documents that have been prepared for ATMS-II processing
 - To process documents that require a user-provided data conversion routine

– As a subroutine of a problem program.

Data Security: Data stored in the library is protected by:

- VSAM data set password protection.
- A library structure which distinguishes private, project, and public libraries, by assigning different levels of document sharability.
- Passwords assigned to user libraries.
- Passwords assigned to user documents.

Document Archiving: Documents can be archived in a sequential data set for storage outside of the Document Library based on the document's content attribute, version number, user number, and date of IMPORT into the library.

Version Control: Multiple versions of the same document can be retained in the library.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

Processors: The Document Library Facility operates on all S/370 mdls 125 and above, the IBM 4300 processors, and the IBM 3031 and above Processors, supported by DOS/VSE, OS/VS1, or OS/VS2 (MVS). Floating-point hardware is required for library operation.

Direct-Access Storage Devices: The library uses VSAM to access data in its library and SAM to read or write to external data sets. Any direct-access devices supported by these access methods are supported by the library.

Storage Estimates Guidelines

Real Storage: The Document Library Facility uses the paging facilities of the operating system to run in less real storage than the amount of virtual storage required. The factors determining how much real storage they require are numerous and dependent on the installation. Therefore, no precise statement of real storage requirements can be made. The system programmer responsible for installing the programs will determine the amount of real storage to be used.

All storage estimates shown are in addition to that required for the prerequisite System Control Program.

Virtual Storage: When the Document Library Facility is used, 200K bytes of virtual storage is required. When SCRIPT/VS is used with the library, 215K bytes of virtual storage is required for the library.

Direct-Access Storage: The library load module requires 21 tracks of 3330 direct access storage. Additional storage is required for any data conversion routines, the exact amount required being determined by the individual program. The amount required for document storage is determined by the user. **SOFTWARE REQUIREMENTS**

The Document Library Facility can be installed to be used in the batch environments of the following virtual storage operating systems:

- OS/VS1 Release 7
- OS/VS2 (MVS) Release 3.8
- DOS/VSE.

In order for the library to be installed, the Virtual Storage Access Method (VSAM) and Access Method Services must be installed. In DOS/VSE, VSE/Advanced Functions Release 2 (5746-XE8) and VSE/VSAM Release 2 (5746-AM2) are required.

Note: This program is designed to work in the specified release levels and any subsequent releases and modifications unless otherwise stated.

Source code language is Assembler and is distributed as optional material. The DOS/VSE user will require the OS/VS Assembler XF in order to assemble the optional material.

DATA CONVERSION

The Document Library Facility provides an interface for converting a document's processing controls before it is stored or processed by SCRIPT/VS. With this interface you can have:

- Documents with ATMS text processing controls processed by SCRIPT/VS.
- Documents with other text processing controls processed by SCRIPT/VS, provided that you have supplied a data conversion program to translate the other text processing controls to those that are recognized by SCRIPT/VS.

DOCUMENT COMPATIBILITY and CONVERSION

The FILE option in the Document Composition Facility Release 2 SCRIPT command is now mutually exclusive with the PRINT and TERM keywords (where the DEV option should be used). The '.UD' control word will cause only blanks not to be underscored.

Document Library Facility (cont'd)**MVS SYSTEM INTEGRITY/SECURITY**

IBM will accept APARs describing any situation where the installation of this program product causes an exposure to the system integrity of MVS.

In MVS, system security facilities are available through use of the Resource Access Control Facility (RACF), 5740-XXH. The RACF program product or equivalent function can be used to protect data outside of document libraries. Document protection provided by the Document Library Facility is effective only within the context of the Document Library Facility. In addition, RACF can be used, in MVS, for additional security in checking a user's authority to access the library.

PROGRAM PRODUCTS

5748-XXE - DOCUMENT LIBRARY FACILITY R3

PURPOSE

The Document Library Facility (the library) is a service program that supports the storage of text documents and other types of data. It operates in a batch environment under OS/VS2 (MVS) or VSE and uses the Virtual Storage Access Method (VSAM). When installed with Document Composition Facility (5748-XX9), it enables the SCRIPT/VS Formatter to run as a batch job in these environments. The Foreground Environment feature of the Document Composition Facility is not required.

HIGHLIGHTS

The library is a repository of data managed in a variety of methods according to the needs of the user.

- Data from many sources can be stored in the library, such as:
 - Text edited and prepared on interactive systems such as ICCF, CMS or TSO. The batch job entry functions available with those systems are used to submit the document as part of the job which invokes the library.
 - Text prepared by ATMS-III using the library as an archive facility.
 - Text prepared and edited by the 3730 Distributed Office Communication System with Host Communication Support Feature (#9285) installed. Batch transmission of 3730 created documents between the controller and a host system is available using the 3730 Document Transmission Facility. User programming in the S/370 system is needed to communicate with the 3730 Document Transmission Facility, and to collect the data and generate the JCL which invokes the Document Library Facility. See the *3730 System Description Manual* (GA33-3022) for an overview of the Host Communication capability of the 3730 System.
 - Text prepared and edited using a magnetic card II typewriter, 6580 Displaywriter or Office System 6, and transmitted using the remote job entry (RJE) capabilities of the host system. See the *Office System 6 Programmer's Guide* (G544-1003) for data conversion considerations.
 - Input to or output from application programs.
- Operation of the ATMS III Archive.

ATMS-III allows the user to archive documents into the Document Library Facility library. Several functions of the library have been enhanced to support this use and are also available to other users of the Document Library Facility.

- Document names can be up to 16 characters long and can contain any character.
- Passwords may contain any character.
- A content attribute defining the type of data in the document can be specified such that documents of the same name but different content (e.g., source and formatted text) can be stored in the library.
- A user identifier (name and/or number) for another system (e.g., ATMS-III) can be mapped to a different user number in the Document Library Facility library.
- Control Statements and input data can be mixed in the same Document Library Facility input stream.
- Documents as well as users can now be locked.
- A user and all the documents in his library can now be purged.
- A document's name and content attribute can be changed.
- Up to 50 characters of user-specified information can be stored with a document on IMPORT and can later be listed.
- Multiple storage data sets of different VSAM control interval sizes can be specified for storing a document in the library.
- User exits are provided for selected control statement processors.
- On IMPORT, a user-written attribute processing program can supply all of the input data.
- Attribute processing programs can be invoked when a document is EXPORTED from the library.
- Data in the library can be accessed by means of commands.
- When the Document Composition Facility is installed, the library can invoke SCRIPT/VS:
 - To process documents that have been prepared directly for SCRIPT/VS
 - To process documents that have been prepared for ATMS-II processing
 - To process documents that require a user-provided data conversion routine

– As a subroutine of a problem program.

Data Security: Data stored in the library is protected by:

- VSAM data set password protection.
- A library structure which distinguishes private, project, and public libraries, by assigning different levels of document sharability.
- Passwords assigned to user libraries.
- Passwords assigned to user documents.

Document Archiving: Documents can be archived in a sequential data set for storage outside of the Document Library based on the document's content attribute, version number, user number, and date of IMPORT into the library.

Version Control: Multiple versions of the same document can be retained in the library.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

Processors: The Document Library Facility operates on IBM S/370 mdls 138 and above, on the IBM 4300 Processors, and the IBM 3031 and above Processors, which are specifically supported by OS/VS2 MVS SP 1.3.0 and VSE AF3. Floating-point hardware is required for library operation.

Direct-Access Storage Devices: The library uses VSAM to access data in its library and SAM to read or write to external data sets. Any direct-access devices supported by these access methods are supported by the library.

Storage Estimates Guidelines

Real Storage: The Document Library Facility uses the paging facilities of the operating system to run in less real storage than the amount of virtual storage required. The factors determining how much real storage they require are numerous and dependent on the installation. Therefore, no precise statement of real storage requirements can be made. The system programmer responsible for installing the programs will determine the amount of real storage to be used.

All storage estimates shown are in addition to that required for the prerequisite System Control Program.

Virtual Storage: When the Document Library Facility is used, 200K bytes of virtual storage is required. When SCRIPT/VS is used with the library, 215K bytes of virtual storage is required for the library.

Direct-Access Storage: The library load module requires 30 tracks of 3330 direct access storage. Additional storage is required for any data conversion routines, the exact amount required being determined by the individual program. The amount required for document storage is determined by the user.

SOFTWARE REQUIREMENTS

The Document Library Facility can be installed to be used in the batch environments of the following virtual storage operating systems:

- OS: OS/VS2 MVS/SP Rel. 1.3.0
- VSE: VSE Advanced Functions Rel. 3 (5747-CC1) and VSE/VSAM Rel. 2 (5746-AM2).

In order for the library to be installed, the Virtual Storage Access Method (VSAM) and Access Method Services must be installed.

Note: This program is designed to work in the specified release levels and any subsequent releases and modifications unless otherwise stated.

DATA CONVERSION

The Document Library Facility provides an interface for converting a document's processing controls before it is stored or processed by SCRIPT/VS. With this interface you can have:

- Documents with ATMS text processing controls processed by SCRIPT/VS.
- Documents with other text processing controls processed by SCRIPT/VS, provided that you have supplied a data conversion program to translate the other text processing controls to those that are recognized by SCRIPT/VS.

DOCUMENT COMPATIBILITY and CONVERSION

Document Library Facility Release 2 is fully upward compatible to Document Library Facility Release 3 in the OS/VS2 MVS and VSE environments. The OS/VS1 environment is not supported in Release 3.

Release 3 of Document Composition Facility is required when formatting documents under Document Library Facility Release 3 in a batch environment. Document Composition Facility Release 2 is not supported under Document Library Facility Release 3, nor is Document

PROGRAM PRODUCTS

**DISTRIBUTED SYSTEMS EXECUTIVE
DSX RELEASE 2.2 (5748-XXG)**

[NO LONGER AVAILABLE, effective 11/83.]

PURPOSE

Distributed Systems Executive (DSX) is a set of programs and files that give 8100 Information System and 3790 network users a simple, comprehensive and effective means of data and network management. DSX combines, in one product, the host libraries, holding files and control files, and the transmission, formatting and reporting functions needed for library and transmission control in 8100 and 3790 networks.

DESCRIPTION

DSX consists of two major parts: Central Library Support and Transmission Control.

Central Library Support supplies the functions and facilities needed at the S/370 host to maintain an inventory of network and processor resources and to report on the status of these resources. Programs, panels, DSCBs (3790 and 8100/DPCX) and CLISTs (8100/DPPX) are maintained in two separate libraries; one for 3790 and 8100/DPCX resources, and one for 8100/DPPX resources.

Transmission Control supplies the functions and facilities needed to schedule and control the exchange of data between the S/370 host and one or more processors. These include:

Sending programs, panels, DSCBs (3790 and 8100/DPCX), CLISTs (8100/DPPX) and data sets (8100/DPPX).

Deleting programs, panels, DSCBs (3790 and 8100/DPCX), CLISTs (8100/DPPX) and data sets (8100/DPPX).

Sending messages, print data and file update data (3790 and 8100/DPCX).

Retrieving messages (3790 and 8100/DPCX), transactions (3790 and 8100/DPCX), programs, panels, data sets (8100/DPPX) and storage dumps.

Initiating execution of a user function at 8100/DPPX via CLIST sent from the host.

Sending power off commands (3790) to the clusters.

HIGHLIGHTS

Central Library Support: The DSX files contain complete 8100 and 3790 host libraries of programs, panels, DSCBs and command lists. The ability to assign version and modification levels to the 8100 and 3790 modules and flexible, accurate reports give a network administrator a means of eliminating redundancy and controlling accuracy in the 8100 and 3790 host libraries.

Network Management Assistance: Complete, orderly records of processor configurations, module assignments and session statistics, with automatic record entry and important cross-checks, plus records of problem incidents entered by the user at the hosts, give the 8100 and 3790 network administrators much of the information needed for effective network planning and control.

Problem Determination Assistance: Host access to dumps, and DPPX error logs, as well as information on other user-noted problems, helps in problem analysis.

Unified Approach: 8100 and 3790 users have a comprehensive set of effective data and network management functions in one IBM-supplied set of programs.

Flexibility: Users are given many options in scheduling the initiation of transmission by time, date, processor, groups of processors or combinations. Macros are provided for user-programmed reformatting of data.

Means of Controlling Change: With the network equipment and data resources defined in its files, DSX becomes a useful tool for controlling processor configurations and modifications. Since DSX checks the cluster master file before attempting transmission (to see if a program is assigned to a processor, for example), users are prevented from making some time-consuming mistakes. Study of system and user-noted problems occurring in the processors may help to identify and correct problems resulting from incorrectly assigned or implemented changes.

Reports On Demand: Users can obtain complete, current information on a specific processor, data library contents, scheduled transmission sessions, 3790 or 8100/DPCXabend dumps or recorded problems. Reports can be current summaries or full historical details. Reports are designed to be readable, useful and informative.

Technical Sales Information: This program is applicable to the 8100 and 3790 configuration #9431, #9165 or #9169 which have the capability to communicate with a S/370 host via SDLC communication lines.

CUSTOMER RESPONSIBILITIES

For the Cluster Master File, the customer must collect and load the required data, and set up a means within his organization to ensure that the information in this file is kept current and accurate.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

DSX may be used on any IBM S/370 mdl 125 or larger or 303x or 4300 processor capable of operating with:

OS/VS1 Release 7 with VTAM2 or ACF/VTAM and VSAM
OS/VS2 Release 3.8 with VTAM2 or ACF/VTAM and VSAM
DOS/VSE with ACF/VTAM or ACF/VTAME and VSE/VSAM
OS/VS1 Release 7 with TCAM 10 or ACF/TCAM and VSAM
OS/VS2 Release 3.8 with TCAM 10 or ACF/TCAM and VSAM

Minimum virtual storage requirements are 360K plus VSAM and VTAM requirements.

DSX can communicate with an IBM 3790 Communication System which must have one of the following feature codes:

#9431 (at EC 742035 or higher)

#9165 (at EC 742042 or higher)

#9169 (at EC 742051 or higher).

The host system must include IBM S/370 control units and features necessary for operation with the 8100 or 3790, as explained in the *IBM 8100 Installation Manual - Physical Planning*, (GA27-2877) and the *IBM 3790 Installation Manual - Physical Planning*, (GA27-2769).

SOFTWARE REQUIREMENTS

This licensed program is released to work with the following IBM programs and subsequent releases unless otherwise identified.

	Release	VTAM	TCAM	VSAM	S/370 Assem
DOS/VSE	-	*	-	**	X
OS/VS1	7	*	#	**	X
OS/VS2	3.8	*	#	**	X

* VTAM Support:

DOS/VSE: ACF/VTAM Version 1 (5746-RC3), ACF/VTAM Version 2 (5666-280) and ACF/VTAME (5746-RC7)
OS/VS: VTAM2, ACF/VTAM Version 1 (5735-RC2), ACF/VTAM Version 2 (5662-280) and ACF/VTAM Version 2 (5665-280)

TCAM Support:

OS/VS: TCAM 10 and ACF/TCAM (5735-RC1 and 5735-RC3)

** VSAM Support:

DOS/VSE: VSE/VSAM (Program Product 5746-AM2)
OS/VS: VSAM

Program Validation Services (PVS) is required for preparing 3790 or 8100/DPCX programs, panels and DSCBs for processing by DSX.

For DSX use with 8100/DPPX, sequential data sets may originate on S/370 or on an 8100/DPPX system. Programs and panels originate on an 8100/DPPX system.

This licensed program is distributed in S/370 Assembler language source, and in load modules assembled from those source programs.

COMPATIBILITY

Existing input from 3700 functions are compatible for 8100/DPCX and will be accepted by DSX for 3790 and DPCX functions.

DOCUMENTATION

(available from Mechanicsburg)

General Information Manual (GH20-2149).

Reference Materials: Pertinent publications addressing the 8100 Information System, 3790, OS/VS, DOS/VS and supported versions of VSAM, VTAM2 and ACF/VTAM.

MVS SYSTEM INTEGRITY

IBM will accept APARs describing any situation where installation of the Distributed Systems Executive (DSX) causes an exposure to the systems integrity of MVS.

RPOs ACCEPTED: No.

PROGRAM PRODUCTS

**GRAPHICAL DATA DISPLAY MANAGER (GDDM)
RELEASE 3
PRESENTATION GRAPHICS FEATURE (PGF) and
INTERACTIVE MAP DEFINITION (IMD)
5748-XXH**

PURPOSE

The term GDDM is used generically to include GDDM Base, IMD, and PGF, as appropriate. GDDM provides advanced function device support which reduces apparent complexity for the user who is creating screen and printer layouts.

OVERVIEW

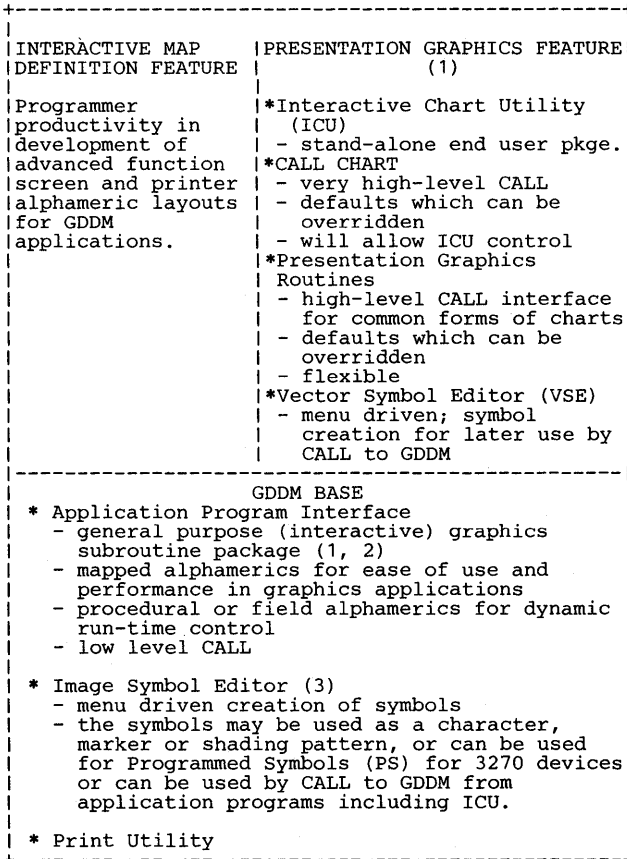

The USER may be either a programmer or (for certain interactive utilities) an end user or casual user, as appropriate.

The LAYOUTS can include color, text and simple schematics or more complex graphics; facilities include alphanumerics (either procedural or mapped), graphs and charts, special character sets, symbols, fonts and control of device attributes and partitions.

The DEVICES are those running on the 3270 extended data stream (the 3270 family including the 3279 color display, 3290 Information Panel, and the 3277 Graphics Attachment, and others such as 8775) plus system printers.

The SYSTEMS include most major programming system environments for S/370, 303X, 308X or 43XX.

Both GDDM Base and PGF (but not IMD) have multiple sub-components as illustrated in the following diagram:

- (1) Presentation graphics describes applications in which the programmer or end user does not interact directly with the displayed picture, but may interact with the application. Interaction is via menus or programmed function keys, program attention keys and the keyboard in ways which cause the application program to change the picture.
- (2) Interactive graphics describes applications in which the end user interacts directly with the system to change the picture, as in drafting. The end user enters graphic data using positioning devices such as light-pen, cross-hair control and cursor.
- (3) Image graphics is the building of pictures from non-coded information represented as a bit string or bit array. Support for this is limited. At execution time GDDM generates the device dependent data stream necessary to display the picture.

The application programmer is isolated as far as possible from the device and model characteristics of the display/printer for which the programming is being done.

HIGHLIGHTS of RELEASE 3

Interactive Chart Utility (part of PGF):

- The library management facility of the Interactive Chart Utility (ICU) allows the user to find out what charts and symbol sets are available, and to manage the charts and symbol sets that have been created. It is no longer necessary to exit the ICU and use subsystem facilities for this.
- In Release 2, the paired data facility was normally available only from applications that called the ICU. This facility is renamed free data, and is now also directly available to the end user.
- Scrolling on the ICU data panel now operates in steps covering four columns of data.
- The physical size and positioning of ICU printer output can be controlled by the end user.
- The ICU can use proportionally spaced symbol sets designed by the Vector Symbol Editor. Further, a given set can have some characters as filled (shaded) areas and some as lines (non-shaded).
- The 3277GA, with its high resolution and screen content, can be used advantageously with the Vector Symbol Editor to design symbol sets. The symbol sets can then be used with the ICU on 3278, 3279, 3290 and 8775 Programmed Symbol displays.

GDDM Application Programming Interface (API):

- The interactive graphics extensions cover two broad areas - handling operator input in terms of graphics constructs such as segments and world coordinates, and modifying the graphic output in response to operator input.
 - Logical devices for interactive graphic input on all GDDM-supported displays.
 - In GKS (Graphical Kernal System) terminology, this comprises CHOICE, PICK and LOCATOR input primitives working in EVENT mode.
 - Segment modification for Interactive Graphics:
 - A segment facility allows pictures to be sub-divided into parts. Segments may be created and deleted, and the segment attributes (intensity, position and detectability) can be dynamically modified.
- The functions are offered on 3278, 3279, 3290 and 8775, and permit a wide range of simple interactive graphics applications to be programmed.
 - Additional support is offered in 3277GA to take advantage of the cross-hair cursor, joystick and high screen resolution available on this terminal. This permits graphics objects to be built via GDDM on the 3277GA for use later in 3278, 3279, 3290 and 8775 applications. The GDDM Vector Symbol Editor is an example of using the 3277GA for this.
 - Operator feedback such as the cross-hair cursor position if LOCATOR is enabled, or the pick window if PICK is enabled.
- The run-time mapping extensions in GDDM Base permit the maps generated by IMD to be used by applications. Maps are out-of-line objects which can contain:
 - The size and position of the graphics field.
 - The size, position and field attributes of the alphanumeric fields.
 - Constant alphanumeric data.
 - Rules for sending or receiving variable alphanumeric data.

This information can often be changed without the need to edit and recompile the programs that use the map. Further, separate versions of a map can be designed to exploit properties of different devices without the programmer having to use the device-specific logic. Finally, the mapping calls use less computing resources than the corresponding GDDM alphanumeric field calls.

- Proportional spacing for vector graphic text on all graphic displays and printers.

Interactive Map Definition (IMD) Feature:

- Used during program development of the end user screens (maps) for applications which mix alphanumerics and graphics. Modern design concepts facilitate programmer productivity. Screen layouts can be tested prior to application program completion. IMD generates the data structure for the application program, linking program variables to screen fields.

PROGRAM PRODUCTS

GDDM V1R3 (cont'd)

Additional Device Support:

- 3277GA (Graphics Attachment) RPO 7H0284.
- 3290 Information Panel:

Support for large screen, partitioning and vertical scrolling. All GDDM Base, Interactive Map Definition (IMD) and Presentation Graphics Feature (PGF) alphamerics and graphics are available for the 3290. Enhancements have been added to allow full utilization of the 3290 Information Panel's functional capabilities. GDDM, including IMD, will allow an application to create and manage up to 16 partitions, each with its own cell size and scroll buffer. Partition management functions will allow an application to create and delete partitions and to modify viewports associated with partitions.

GDDM Release 3 supports graphical output to 3278-compatible screen size configurations of the 3290. Note that, via GDDM Release 3, the support of full 3290 function is also available in current host environments. 3290 zoom is restricted to alphamerics only.

- 4250 Printer:

GDDM Release 3 produces rastered graphics image which enables GDDM-created graphics objects to be rastered, and placed on a file as a Composed Page Data Stream which subsequently can be printed on the 4250 using the Composed Document Printing Facility (5668-997). Similarly, the Interactive Chart Utility (ICU) can be used to create charts that can be printed later on the 4250. GDDM Release 3 also provides the capability to separate multi-colored pictures created on the 3279 Color Display into several monochrome print masters for color printing using standard offset litho techniques.

GDDM Release 3 rastered graphics image creation is available under MVS/SP TSO and VM/SP CMS only.

Graphics objects can also be passed to GDDM Release 3 in GDF (Graphics Data File) format for rastering.

Document Composition Facility Release 3 (5748-XX9) will allow merging of the GDDM rastered graphics image as a page segment into a DCF document at printing time.

- 8775 Enhanced Function:

Validation and partitions are now supported by GDDM. Partitioning provides the ability to display data in up to eight user-defined rectangular partitions, and for the host or user to interact individually with the data within each partition. The Interactive Display Text Facility licensed program is not supported.

- Removal of any limit to the content (data stream length) of a picture which is to be saved.

Additional environments:

- Access from IBM BASIC (but no data structure is generated by IMD).

- MVS/XA:

GDDM Release 3 under MVS/SP 2.1.1 supports applications using either 31-bit or 24-bit addressing mode (including 31-bit applications residing above 16 megabytes) in the CICS/VS Version 1 Release 6 and TSO environments.

Under CICS/VS Version 1 Release 6, TSO and IMS/VS, most of the GDDM modules reside above 16 megabytes, giving significant virtual storage constraint relief to all CICS/VS Version 1 Release 6 users of GDDM, and to TSO and IMS/VS users of GDDM if GDDM resides in the link pack area.

Approximately 1.5 megabytes of GDDM and its features PGF and IMD reside above 16 megabytes. Of the Interactive Chart Utility and parts of GDDM required by the ICU, approximately 0.75 megabytes resides above 16 megabytes.

- TSO Background:

A background job running under the TSO terminal monitor program using the TSO Extensions (TSO/E) (5665-285), or TSO Command Package (5740-XT6), may use GDDM.

Print Utility Enhancements:

- All Systems

- Print files are now fixed length, 80-byte records.
- Page eject can be controlled

- TSO

- Availability of printers and GDDM's TSO print utility is improved. The utility can be started before a printer is activated. Further, if a printer becomes inactivated due to an error or due to operator action, the printer will automatically become attached to the utility when the printer is reactivated. In both cases, the utility

must be identified as the VTAM controlling application for the printer.

- Multiple instances of the utility can be run within one system or VTAM domain, provided that each has its own VTAM ACB and print request queue data set.
- The print request queue name is no longer pre-defined. It can be set in the defaults module or by DD card.
- All resources are closed/de-allocated when the utility terminates.

- VM/SP CMS

Facilities have been added to GDDM's VM print utility to allow installations to better integrate the utility with other printer support.

- The installation or VM user can supply an EXEC, ADMQPOST, which GDDM invokes on completing a print request. The EXEC could route the GDDM print file to another VM machine for processing. Via such an EXEC, the installation could centralize processing for several printers in one VM batch machine.
- The print utility can output a punch file rather than sending directly to the printer. Installations with other facilities for driving 3270 printers via SIO can use this to extend these facilities to handle GDDM output.
- Print files are now fixed-length 80-byte records to facilitate customer programming of the above. This change has been made in all environments.

Operational Enhancements:

- Symbolic trace.
- FSSHOR is an extension to FSSHOW which, in addition to displaying the saved picture, returns the identity of the key used to terminate the display.

National Language Support:

Help and Menu panels in the Interactive Chart Utility are available in French, German, Italian, Katakana and Spanish languages, as well as English. Most diagnostic messages presented to the Interactive Chart Utility users are also available in these languages. These languages are provided as separately orderable modules, and the local language can be readily invoked, replacing the English language Help and Menu panels with those in the selected local language.

HIGHLIGHTS of RELEASE 2

- Provision of GDDM/PGF functions to customers working with VSPC and IMS/VS environments.
- Provision of S/370 and 303X system printer support in all environments.
- Improved usability in combination with CICS BMS alphamerics.
- Reduced alphameric path length. For more detailed information, see Product Announcement Letter.
- Enhanced interactive chart utility function and usability.
- Support for SCS terminal printers.
- Enhanced presentation graphics routines and functions.
- Curve fitting routines are provided in all environments in the presentation graphics routines.
- Support is provided which permits a picture developed by a GDDM application to be outputted as a Graphics Data File. The format of this file is documented, thus permitting users to process the file to develop a data stream for devices such as plotters which are not directly supported by GDDM.

DESCRIPTION

GDDM Base

Hardware Functions

- Field and Character Highlighting
 - Blink
 - Reverse Video
 - Underscore
 - Color (Base or Extended)
 - Protected/Unprotected
 - Intensified
 - Light-pen Selectable
 - Programmed Symbols
 - Partitions

Software Functions

- Display or Printing of:
 - Lines
 - Arcs
 - Areas
 - Annotation

PROGRAM PRODUCTS

GDDM V1R3 (cont'd)

- Attributes
 - Line Type (e.g., solid, thick, dashed)
 - Color Shading (64 unique GDDM-provided hues)
 - Patterns (26 unique GDDM-provided patterns)
- Graphics function
 - World Coordinate system
 - Two-Dimensional Windowing and Clipping
 - Interactive Graphics

GDDM Base includes a utility, the Image Symbol Editor, which enables a user to create, edit and save sets of images of user-specified size suitable for graphical annotation, special fonts or specialized symbol sets. These symbol sets may be loaded via GDDM at run time into the specified terminal provided it is configured with the PS feature and the cell size of the symbol set matches that of the terminal. The Image Symbol Editor facilitates Symbol Set definition by virtue of the following interactive design concepts:

- Menu-driven processes.
- Help facilities.
- Data presentation (that is, a selected symbol from the set may be permanently displayed as a reference symbol while designing or editing new ones).
- Target presentation (that is, the new symbol may be shown "life-sized" during the editing process).
- Device dependent prompts (that is, special printer symbols for the 3287 with the Programmed Symbols feature are checked to assist in optimizing printing speeds).
- Symbol browse (the total new symbol set may be displayed "life-sized" during the editing process).

The functions above are limited where the characteristics of the using display terminal do not match those of the terminal for which the symbol set may be targeted. (In particular, a symbol set may be designed with color on a monochrome display.)

GDDM Base provides a Print Utility Function for the printing of both alphanumeric and graphic data. Two types of printing are available:

1. Complete Screen copy
The entire contents of the page as displayed on the screen are copied to equivalent positions on the printer page.
- 2) Graphics-only copy
Only the graphics field will be printed. It may be repositioned on the printer page and changed in size if desired.

Presentation Graphics Feature: The Presentation Graphics Feature (PGF) is an optional feature available with GDDM. PGF is comprised of a set of high level graphic subroutines that extend the ease-of-use of GDDM to the presentation graphics user. In particular, it provides a set of high level presentation graphics subroutines to minimize the programming of applications involving presentation charts (pie charts, line graphs, surface charts, Venn diagrams, histograms or bar charts). Like GDDM Base, PGF is comprised of a set of callable subroutines which are reentrant and reusable. The subroutines may be invoked from applications written in APL, IBM BASIC, COBOL, PL/I, FORTRAN and S/370 Assembler language.

The business charting functions are designed so that an application programmer may use extensive defaulting rules to minimize his programming effort. Alternatively a user has the flexibility, by the specification of attributes on these functions, to "tailor" the graphical presentation. The defaulting rules will automatically generate various shading patterns and color selections without programming specification. Alternatively the application programmer is provided with extensive capabilities to override these default rules and to specify uniquely designed shading patterns, line types, etc.

Interactive Chart Utility: PGF also includes an easy to use Interactive Chart Utility designed to allow the non-DP professional to develop presentation charts by entering menu responses and data via the display keyboard. This facilitates chart production by eliminating the need for application program development. Chart Formats and Data may be stored and recalled by the terminal operator by name; a powerful library facility is provided in Release 3.

The Interactive Chart Utility is menu driven and provides a "Help" facility to provide additional guidance to the user should it be required.

The menus lead the terminal user through the various presentation options. A standard presentation is used by the utility to display the chart. All charts created may be printed upon command.

Vector Symbol Editor: PGF also includes the Vector Symbol Editor which allows a terminal user to generate and save symbol sets in which the individual symbols are described in terms of vectors. These vector symbol sets provide a further means to annotate graphical panels. Vector symbol strings may be used by GDDM and may be scaled or rotated when displayed by the application program.

Overview of Mapping:

GDDM Release 3 introduces mapped alphanumerics as an optional alternative to the existing procedural or field alphanumerics (retained to allow fully dynamic run-time control). Mapping provides:

- High-level interactive screen and printer layout.
- Separation of layout and program logic.
- Removal of device dependence from the application to the map.
- General performance improvements.
- Value to graphics applications (e.g., presentation of alphanumeric menus).

GDDM provides as an optional feature Interactive Map Definition (IMD), a program development time component. This feature is an online programming aid, enabling the application programmer to create and update a library of maps containing alphanumeric layouts for display devices. IMD provides a full screen context editing capability, scrolling, menu-driven processes, HELP, restart, defaults and utilities, and requires GDDM Base. Following the creation or modification of a map by IMD, before it can be used by an application program and GDDM Base, a special IMD generate process must be invoked, the result of which is:

- The structure of the Application Data Area in the appropriate application language (COBOL, Assembler language or PL/I) placed on a "source copy library"
- One or more map objects placed on a "map object library".

At compile time, the Application Data Area definition is copied into the application from the source copy library.

At run time, the application issues CALL statements to GDDM passing the name of a map and an Application Data Area. The functions required by the application are defined partly by previously defined maps, and partly dynamically at the API (Application Program Interface) by setting fields in the Application Data Area and by control-function calls.

The key to the transfer of data between application and GDDM Base is the map which GDDM Base loads from the map object library, and which contains the following information:

- The structure of the input and/or output data record as viewed by the application.
- A definition of the constant data in the layout.
- The size and position (row, column or floating), within the page, of the layout.
- The relative position and length of fields within the layout, including the graphics field.
- Device attributes to be associated with the defined field.
- Device control information (e.g., alarm, free keyboard).

Maps are grouped together into a map group, containing information required for a complete page. The map group includes device dependent information including screen size. At any instant during run time, several map layouts may appear on a screen.

GDDM provides screen and printer support for advanced functions:

Extended field attributes, via maps or dynamically via the Application Program Interface (API)

- Highlighting.
- Programmed symbols.
- Extended color.
- Field validation (Trigger, Mandatory Fill, Mandatory Enter).

Character attributes dynamically via the API

- Highlighting.
- Programmed symbols.
- Extended color.
- APL character set.

The GDDM Mapping API may be used in concert with most other GDDM calls, for example:

- Partitions (or software-emulated partitions) with or without scrolling (hardware or software) may be defined to contain pages laid out using maps.
- Graphic pictures are defined within an area reserved within a map or adjacent to a map.
- Device control functions (e.g., alarm, reply mode, position of cursor) may be used to augment those defined in maps.

RELATIONSHIP between IMD and GDDM BASE

Programmer at terminal (program development time)

uses IMD (GDDM Base is pre-requisite)

to create	Map Specifications
to generate	Application Data Area structures on source copy libraries
and	Maps on map object libraries

PROGRAM PRODUCTS

GDDM V1R3 (cont'd)

uses an interactive editor (e.g., ISPF/PDF) to create Source Program

uses COBOL, Assembler or PL/I compilers with copies to create Source program input and Application Data Area Structure Program modules

End-user at terminal (application run time) invokes Application (program modules) which in turn call GDDM Base passing the name of a map and an Application Data Area

interacts with Application through GDDM Base map

Devices Supported By GDDM: All terminal protocol management and support for specific features (i.e., switched/nonswitched) is under the control of the underlying subsystems. Consult your IBM *General Information Manuals* for the subsystem in use in your installation for detailed information relative to the specific feature support provided.

GDDM supported devices attach to the following control units:

3271, 3272, 3274, 3276 and 8100DSC*

* Either DPPX or DPCX 3270 Data Stream Compatibility program product enables the 8100 to look like a controller to the host.

Some operating systems/subsystems may not support all models of the control units. Consult the relevant system/subsystem specifications for further details.

Not all devices attach to all control units; some are loop attached. Consult the relevant device specification to determine the control unit and model and configuration support for any particular device.

GDDM provides alphameric support for the following terminals:

Note: The small screen (less than 1,920 characters) 3270 devices are not supported by the interactive utilities.

- 3104 Display mdls B1, B2
- 3178 Display
- 3230 Printer mdls 1, 2 supported as a 3287
- 3232 Keyboard Printer mdls 1, 11 (output only)
- 3262 Line Printer mdls 3, 13
- 3268 Printer supported as a 3287
- 3275 Display mdls 2, 12
- 3276 Control Unit Display mdls 1, 2, 3, 4, 11, 12, 13, 14
- 3277 Display mdls 1, 2
- 3278 Display mdls 1, 2, 3, 4, 5
- 3279 Color Display mdls S2A, S2B, S3G, 3X, equivalent 8100-attached models
- 3284 Printer mdls 2, 3
- 3286 Printer mdl 2
- 3287 Printer mdls 1, 2, 1C, 2C
- 3288 Line Printer
- 3289 Line Printer mdls 1, 2
- 3290 Information Panel
- 8775 display, all models

GDDM Release 3 provides graphics support on the following terminals, provided (except 3277GA) they have the Programmed Symbols feature:

- 3277GA Graphics Attachment mdl 2 with RPQ 7H0284 (not supported under IMS)
- 3278 Display mdls 2, 3, 4
- 3279 Color Display mdls S3G, 3X
- 3287 Printer mdls 1, 2, 1C, 2C
- 3290 Information Panel
- 8775 Display mdls 1, 2, 11, 12

All these devices (except 3277GA) use the 3270 Extended Data Stream, or the architected extensions to SCS (SNA character string). GDDM Release 3 will run on any further terminal or terminal-attached printer and provide graphics function if it is upward compatible with a supported device.

Hardware Features for Graphics

Device and Model	Feature
3274-31A, 31D, 31C, 51C	#9112 Configuration Support C
3274-41A, 41C, 41D, 61C	(Configuration Support D standard)
3277-2	RPQ 7H0284 Graphics Attachment
3278-2, 3, 4	#5790 Programmed Symbols
3279-S3G	
5279-3X	#5790 Programmed Symbols

- 3287-1, 2 #8750 Video Output
- 3287-1C, 2C #5781 Programmed Symbols - 2
- 3290 #5782 Programmed Symbols - 4
- #5783 Programmed Symbols - 4A
- Configuration D Support or Configuration T Support (T excludes 3278/9 graphics on the same controller)
- #5790 Programmed Symbols

GDDM supports the following system printers via system/subsystem spooling support for alphameric:

- 1403 Printer
- 3203 Printer mdl 5
- 3211 Printer
- 3262 Line Printer mdl 5
- 3800 Printing Subsystem mdls 1, 2
- 4245 Line Printer

GDDM supports the following system printers via system/subsystem spooling support for alphameric and rastered graphics image files:

- 4250 Printer

Accessory Support: GDDM will support the data streams from the Magnetic Hand Scanners and Magnetic Slot Readers attached to the 3278, 3279 and 8775 Display Stations.

CUSTOMER RESPONSIBILITIES

To install and use GDDM the user must:

- Acquire a knowledge of the functions provided through reading the various GDDM *Programming References* and *User's Guides*.
- Understand the use of the appropriate Application Program Interface in APL, IBM BASIC, COBOL, PL/I, FORTRAN or S/370 Assembler in order to invoke GDDM.
- Understand the GDDM initialization and customization processes described in *GDDM Installation and System Management* (SC33-0152).
- Carry out approved Problem Determination procedures before contacting IBM for program service.
- Install PTFs as appropriate.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The storage requirements of GDDM are dependent upon various configuration and workload parameters including device type, screen size, PS storage available at the device, message rates and the general processing environment.

GDDM will run on any IBM S/370, 303X, 308X or 43XX processor with sufficient storage to meet the combined storage requirements of the host operating system, access methods, DB/DC or Interactive Subsystem and GDDM.

The floating point feature is required for GDDM.

SOFTWARE REQUIREMENTS

GDDM applications execute under the control of the following IBM subsystems:

	SUBSYSTEM					
	CMS	CICS/VS	IMS/VS	ACF/TCAM	ACF/VTAM	VSPC
DOS/VSE with VSE/AF		X				
MVS/370		X	X(1)	X	X	X(1)
VS1		X	X(1)			
VM/SP	X(2)					

- (1) excluding IMD and run-time mapping.
- (2) excluding the CMS DOS environment.

In IMS/VS only, the output functions of GDDM are available, except for the interactive utilities ICU, ISE, VSE.

PROGRAM PRODUCTS

GDDM V1R3 (cont'd)

The table that follows lists the earliest Version or Release under which GDDM Release 3 may execute. The subsequent columns list any later level which is required for 3290, 4250, 8775 and MVS/XA.

System/ Subsystem Access Method	Minimum Level for GDDM Release 3 support				Additional Requirements for			
	Sys- tem	Sub- syst	A/M (1)	Other Notes	GDDM support of 3290 & 8775 (13)	GDDM support of CDPF files	CDPF support of 4250	31-bit support (MVS/XA)
DOS/VSE/AF	AF R2				-		AF R3	N/S
CICS/DOS/VS		V1 R5			(10)	N/S		
BTAM/ES			(2)		-			
ACF/VTAME			(2)	(3)	-			
ACF/VTAM			V1 R2		V2 R1			
OS/VS1	R7				-		N/S	N/S
CICS/OS/VS		V1 R5			(10)	N/S		
BTAM			(2)		-			
ACF/VTAM			V1 R2		V2 R1			
ACF/TCAM			V2 R4		-			
IMS/VS		1.1.6		(4,5)	-	N/S		
BTAM			(2)		-			
ACF/VTAM			V1 R2	(6)	V2 R1			
ACF/TCAM			V2 R4	(6)	-			
OS/VS2 (MVS)	R3.8				-		SP1.3	SP2.1.1
CICS/OS/VS		V1 R5			(10)	N/S		V1 R6
BTAM			(2)		-			-
ACF/VTAM			V1 R2		V2 R1			V2 R1
ACF/TCAM			V2 R4		-			-
IMS/VS		1.1.6		(4,5)	-	N/S		V1 R3
BTAM			(2)		-			-
ACF/VTAM			V1 R2	(6)	V2 R1			V2 R1
ACF/TCAM			V2 R4	(6)	-			-
TSO		As OS		(7)	-	-		-
ACF/VTAM			V1 R2		(8)			V2 R1
ACF/TCAM			V2 R4	(9)	-			-
VSPC		V2 R1		(5,11)	-	N/S		N/S
ACF/VTAM		V1 R2			V2 R1			
VM/SP	R1				-		R3	N/S
VM/CMS		As VM		(12)	-	-		

Key to additional requirements:

- : Function supported without additional requirements.
- N/S : Function not supported.
- (blank) : Function not applicable.

Notes:

1. Later levels of access method other than those quoted may be necessitated by operating or subsystem requirements. Consult the specification for these programs for further details.
2. As required for CICS or IMS.
3. 3270 Extended Data Stream (Graphics, Color, etc.) is supported by ACF/VTAME for SNA devices only.
4. IMS does not provide a direct interface to a terminal. Instead, it uses message queues. This imposes a number of restrictions, described in *GDDM Installation and System Management*.
5. No mapping or IMD support.
6. Support for local or SNA devices only.
7. Either the MVS TSO Command Package (5740-XT6) or TSO Extensions (TSO/E.5665-285) is required for batch support.
8. ACF/VTAM V2 R1 and PTF UZ90213 are required for extended 3290 function on TSO/VCAM.
9. PTFs UZ90256, UZ90257, UZ90258 for APAR OZ69872 are required for support of GDDM in TSO/TCAM.
10. CICS/VS V1 R6 is required for full 3290 support. Under CICS/VS V1 R5, GDDM support of 3290 is limited to logical terminal definitions without partitions and with screensize less than 4,096.
11. PTF UP90038 is required for support of GDDM on MVS/VSPC. PTFs UP20877, UP28224 are required for correct operation of GDDM Release 3 chart enhancements.
12. No support in the CMS DOS environment. Where applicable, the VM/High Performance Option (5664-173) reduces the system overhead of the GDDM shared segment.
13. The 8775 requires downstream loading in order to support Enhanced Function, Enhanced Function with Magnetics, or Multiple Partitions and Scrolling. This loading can be performed by DPPX or DPCX (if attached via 8100), or by the Downstream Load Utility (DSLU, 5668-006) which is supported on DOS/VSE, OS/VS1 and OS/VS2 (MVS). Consult the specifications of this program for further details.

The use of certain features of displays or printers may also require later levels than quoted above. Consult the specifications for these products for further details.

Programming Languages: GDDM function is accessible via a standard OS/370 CALL interface from application programs using the following languages and compilers:

- S/370 Assembler language.
- PL/I (DOS and OS Optimizing Compilers and Libraries).
- COBOL (DOS/VSE, OS/VS, ANS Version 2, 3, 4 Compilers and Libraries)
- FORTRAN (G, H, VS and VSPC Compilers). (CICS/VS and IMS/VS do not in general support applications written in FORTRAN. GDDM IMD does not generate Application Data Structures in FORTRAN; this does not preclude use of mapping by FORTRAN applications where programmers create their own data structure.)

Other languages or environments do not support the direct use of the GDDM routines. In these environments, the products concerned have provided native interfaces to GDDM.

- VSPC provides access to the GDDM subroutines via the Foreground Processor interface. Some of the programs operating under VSPC allow their users access to this interface, and thus GDDM, excluding alphameric mapping.
- IBM BASIC in the VM/SP CMS environment provides a CALL statement which can be used to call GDDM. GDDM IMD does not generate Application Data Structures in IBM BASIC; this does not preclude use of mapping by IBM BASIC programs where programmers create their own data structure.
- VS APL Release 4 can utilize GDDM in CICS/OS/VS, CICS/DOS/VS, VM/SP CMS, VSPC and TSO environments to communicate with advanced function displays and printers; see APL documentation for the level of GDDM function supported. GDDM is prerequisite for:
 - The VS APL Session Manager under CMS and TSO (and optionally under CICS).

PROGRAM PRODUCTS

GDDM V1R3 (cont'd)

- The VS APL Session Manager Command auxiliary processor (AP120) under CMS and TSO (and optionally under CICS).
- The GDDM auxiliary processor (AP126) which gives full screen control and allows access by APL programs to the full functional capabilities of GDDM Base and PGF.
- The GRAPHPAK workspace which provides extensive support of graphics including functions for plotting, curve fitting, and drawing bar-charts, pie-charts, and histograms. Output can take advantage of color and GDDM functions.
- A workspace that uses AP126 to provide full screen support and takes advantage of GDDM including color on the 3279.
- IBM 3270 printers under VM/SP CMS.
- National Character Set support for Katakana and Canadian French under CICS, CMS and TSO.

GDDM IMD does not generate Application Data Structures for APL.

GDDM Base is a prerequisite for either or both of PGF and IMD.

COMPATIBILITY

Application programs written for use with Release 2 of GDDM Base and PGF will run under Release 3 without modification, but they must be link-edited again; it is not anticipated that this re-linkedit will be necessary for future releases. Data streams, chart formats and data, and symbol sets (but not print files) created under Release 1 and 2 can be used with Release 3.

Data streams, chart formats and data, print files and symbol sets created under Release 3 cannot be used with Releases 1 or 2.

CONVERSION

GDDM may be used in conjunction with most of the application support routines from the 3277 Graphics Attachment Support (GAS) program (5799-AXX PRPQ P09013). In particular, the subroutines for analytical geometry, three dimensional transformations, polygonal clipping and curve fitting may be used.

The GDDM interface, although functionally equivalent to the PRPQ interface, is syntactically different and therefore the transfer of application programs written for the PRPQ to GDDM will require structural changes to the program.

Note that the GAS PRPQ is a special purpose program and therefore has performance advantages over the more general GDDM, but applications written to the GDDM interface have more flexibility in terms of migration to other devices.

DATA SECURITY

GDDM does not depend on, augment or interact with, nor impede or detract from the security functions available in IMS/VS, CICS/VS, TSO (ACF/VTAM or ACF/TCAM), VSPC, VM/SP or other IBM programs. GDDM uses the system services within the subsystem in which it is invoked. Customer management is responsible for the selection, application and adequacy of such functions for its environment.

PERFORMANCE

For details of response time characteristics, see *GDDM Installation and Systems Management* (SC33-0152).

GDDM Release 3 continues to consolidate the performance improvements introduced in Release 2. Specific areas affected are:

- GDDM data streams for graphics output.
 - The average data stream for a range of 29 pictures has been reduced by 13%.
 - Graphic data stream structure has been changed and an average reduction of 10-20% in 3274 processing time is likely.
- GDDM data streams for procedural alphas output which contain pad characters have been reduced, improving applications like APL and the Interactive Chart Utility.
- Using procedural alphas, the GDDM path length to create and display some 50 to 200 fields is reduced in the range 40-80%.
- The ICU: Measured in a VM/SP CMS environment, a benchmark having 26 user interactions with the terminal (resulting in 5 graphic and 21 alphas displays) showed the following changes compared with GDDM Release 2:
 - Total GDDM and CMS CPU utilization down 20%.
 - Total GDDM data stream length down 16%.
 - Total number of GDDM calls to output screen I/O down 16%.
- Alphanumeric mapping: Reduces CPU requirements at run time, e.g., 75%-85% reduction of the path lengths to produce the same benchmark using procedural calls on GDDM Release 3.

- To take full advantage of improvements, some installations may find an increase in main storage is required to compensate for the increase in the reference set of 10% to 20%. This is especially true for environments where the level of paging contributes significantly to total performance costs. (The reference set is the number of different pages actually referred to during execution.)

PROGRAM PRODUCTS

**SQL DATA SYSTEM (SQL/DS)
VERSION 1 RELEASE 2
5748-XXJ**

PURPOSE

SQL/DS provides relational data base management facilities for customers executing in the VM/SP Release 3, VSE AF Release 3, and SSX/VSE Release 2 environments. SQL/DS provides multi-user read/write sharing of a data base. It also provides online query/report writing facilities, and operates with, and extends the capabilities of IBM's data systems offerings.

Release 2 contains all of the functions currently available in Release 1 (which executes in the native VSE environment). See the *SQL/DS Concepts and Facilities* publication (GH24-5013-1). All functions (unless otherwise noted) will be available in all supported environments.

Users are provided a non-procedural language called SQL (Structured Query Language) with which they access and query the data. SQL is also the language used to define and manipulate the data which is maintained by SQL/DS in a relational format. SQL requests can be entered through an IBM-provided facility (ISQL) as input to the SQL/DS Data Base Services utility; or can be imbedded in application programs written in COBOL, PL/I, FORTRAN or Assembler.

SQL/DS supports multiple, concurrent access from CMS virtual machines, batch virtual machines or VSE partitions, online transactions, and interactive program execution environments. SQL/DS will typically operate in multiple user mode and will reside in a separate partition or virtual machine from the user's application. Security and authorization control facilities are included in SQL/DS to allow users to manage and control access to the data. Backup, restart and recovery, and inline catalog capabilities are an integral part of SQL/DS. The underlying data base manager is relational.

SQL/DS also provides a DL/I extract facility. This enables users of DL/I to selectively copy data from a DL/I data base into SQL/DS. The commands describing the extract request are entered interactively through the SQL/DS terminal.

DESCRIPTION

SQL/DS offers customers on intermediate processors a full function data base management system with a query and report writer capability. Existing DL/I DOS/VSE customers can use the extract facility to access the DL/I managed data. In addition, SQL/DS is an end-user-oriented data system using the relational storage concept. The major advantages of SQL/DS are:

- It provides an ability to begin to develop answers to a problem before all of the requirements are known, or before all of the data is defined and organized. When the data organization is evolving or unsettled, this often causes high maintenance activity. SQL/DS will minimize such activity because one can dynamically extend the tables without affecting existing applications. One can implement, test and change both the data structure and applications online.
- Much of the SQL language used can be learned and applied quickly. Data requirements can be defined with a minimum of preplanning. This allows the non-DP professionals to quickly implement solutions to many of their information needs.
- Many information needs can be satisfied by the SQL/DS ISQL query/report writer capability, thus eliminating the need for those "select, sort, report" types of application programs. Since both programmers and non-programmers can use ISQL, there should be a reduction in the application program backlog.
- Users can enhance the performance of both unplanned and preplanned applications by defining indexes while the data remains online and available to other users. Indexes are used only to improve performance; they are not necessary to provide alternate access paths to the data. Index creation and use can be performed outside of (i.e., independent of) the application program.
- Data access is independent of the physical organization of the data stored, the sequence of records, and the order of data elements within a record.

Typical Uses of SQL/DS Include:

- Unanticipated queries of the data, for example, retrieving all records satisfying certain conditions; finding the minimum (maximum, average, sum, count) of selected data elements; grouping or sorting the records.
- Reports, complete with user designated titles, formats, subtotals, and totals.
- Management of departmental or individual (as contrasted to corporate) data bases. This data may be manipulated in a variety of ways, often in a "one-time", iterative problem solving mode.
- Users may 'model' the eventual production system on SQL/DS. They could first use ISQL to develop the data structure and various approaches of organizing and presenting the data. After evaluating these different approaches, they could then implement the desired

data structure and solution in the formal corporate information system.

Coexistence: SQL/DS and DL/I DOS/VSE are complementary products designed to provide solutions to different customer needs (query data and operational data). Some customers will select DL/I, others SQL/DS, and still others, both DL/I and SQL/DS.

1. DL/I DOS/VSE is a fully supported DPMS program product for structured, operational applications. DL/I is particularly applicable to those environments requiring high performance and having very large stable data bases.
2. SQL/DS can be used both as an end-user query/report writer product for the DL/I DOS/VSE user, and as a separate query data base for non-DL/I data. With the extract facility, authorized users can request that DL/I data be copied into previously defined SQL/DS tables. Outstanding extract requests may be executed according to the installation's conventions (e.g., either when DL/I is online or when DL/I is not being heavily used - such as during third shift). Subsequently, end users can query the data copied from the operational DL/I data base. SQL commands may be used to analyze the data without impacting high performance DL/I operations. SQL/DS is particularly useful for situations which are 'one-time' or unanticipated; require searching through the data; or 'n' when reports and inquiries are adequate. In addition, users can answer 'what if' type questions by modifying the data and then analyzing the new results without affecting operational data.
3. SQL/DS and DL/I coexist with each other, and with other Data Systems offerings (e.g., CICS/DOS/VSE).

RELEASE 2 HIGHLIGHTS

- **SQL/DS Relational Data Base Support for VM SP Release 3:**
 - Multi-User Data Sharing. Data stored in SQL/DS can be shared by multiple users concurrently. Uses native VM SP Release 3 services for managing the data, instead of DOS Simulation, or a VSE Guest, or VSE/VSAM. SQL/DS uses Inter-User Communication Vehicle (IUCV) to communicate between the SQL/DS virtual machine and user CMS virtual machines.
 - Data Integrity. Users and applications can not access the SQL/DS code and data except by using the defined interfaces. The SQL/DS data is protected from accidental damage by user machine.
 - Data Recovery. The SQL/DS data is protected from application, system, and DASD failures.
 - Data Security. The SQL/DS data can be protected from unauthorized access.
 - Data Base size. SQL/DS supports up to 64 billion bytes per data base, and up to 32 billion bytes per table.
 - Allows Multiple SQL/DS Virtual Machines in a VM SP Release 3 environment, each capable of serving multiple users.
 - Uses the new facilities in VM SP Release 3 for Overlapped Data Base I/O to support concurrent processing of multiple user requests.
 - Provides online query/report writing facilities for the VM/CMS users.
- **Application Development:**
 - SQL statements can now be used in VS FORTRAN programs to access SQL/DS data bases. The new extensions to the dynamic SQL programming interface have been used to provide a Pre-Processor for the VS FORTRAN language.
 - The Pre-Processors have been improved to allow user-specified options for controlling printing of the output. Additionally, users can now INCLUDE a VSE Source library member or a VM/CMS file into an SQL/DS application.
- **ISQL Enhancements:**
 - ISQL is available in both the VM/CMS and VSE environments. Its capabilities have been enhanced to provide support for terminal printers and large screen display terminals. Additionally, users will now have the ability to retrieve previously entered commands and alter them by overtyping.
 - For any query, ISQL will display information that allows a terminal user to estimate the approximate work required for the query. With this information, the user could decide to wait for the query to complete, or could cancel the request.
 - Functional and usability improvements include:
 - Saving of Format Information for some Modified or Parametrized Stored Queries

PROGRAM PRODUCTS

SQL/DS (cont'd)

- Multiple Operands in FORMAT, PRINT, LIST, SET and ERASE Commands
- PF Key Usage Enhancements
- Error Handling Options in Routines
- Stored Query Protection
- WAIT on a POWER Printer
- Data Base Services Utility:
 - The DBS Utility operates in both the VM/CMS and VSE environments. It has been extended to support zoned and double-byte character set data, and now has the ability to create sequential output files in both environments.
- Resource Control:
 - Installations can now control ISQL usage via user priority classes in the VSE/CICS environment.
 - Users will be able to CREATE tables even if they do not have Resource authority. The installation can allocate DBSPACES to users for this purpose. Users can now also change their own passwords.
- Operational Enhancements:
 - Installations may trace attempts to access data, acquire resources, or execute applications. The trace tape data created may be printed with an SQL/DS-provided FORMAT program, or loaded into an SQL/DS table for further analysis.
 - SQL statements and ISQL commands can be stacked in VM/CMS EXECs.
- Performance Improvements:
 - In the VM/SP environment, SQL/DS will use the new DASD Block I/O facilities in Release 3 which allow overlapped data base I/O in multi-user environments.
 - Improvements have been made in the utilization of system resources in the internal optimizer, index operation, and memory allocation components of SQL/DS.
- Relational Data Model: SQL/DS supports the relational model of data. Data is defined and accessed in terms of simple, easy-to-comprehend data tables and operations on data tables. The relational model consists of a 2-dimensional table with a fixed number of columns, and a variable number of unnumbered rows. The SQL/DS implementation of the relational model provides a high level of data independence. Applications are not dependent upon the physical relationships among the data elements. Views may be defined on tables such that user/application logical tables need not conform to actual stored tables. Views may combine data from several stored tables (or other views), and may subset tables by rows and/or columns.
- Structured Query Language (SQL): Data definition, access, manipulation, and control operations are supported by the Structured Query Language (SQL). SQL is a high-level, non-procedural data language available to users through an interactive facility (ISQL), a batch utility (DBS Utility), and imbedded statements in application programs. SQL statements consist of command verbs, one or more optional clauses, language keywords, and parameter operands. The structured use of verbs and keywords in the SQL syntax allows precise specification of data requests in a readable fashion.
- Interactive query support: All SQL statements and commands (except those that are application program specific) can be entered from a terminal for query operations without first having to write an application program. These statements and commands are processed by the Interactive SQL facility of SQL/DS, ISQL. Specific parameters may be inserted at execution time. Frequently used ISQL queries may be saved for later use. Format information on stored queries can be saved for all queries except those whose SELECT or FROM clauses are parameterized or changed. Users may RETRIEVE a previously entered statement or a data line into the command input area and alter it by overtyping. Also, the user may submit multiple operands in many ISQL commands. Any valid SQL Statement or ISQL command may be entered while viewing a query result. There are additional PF Key enhancements. Larger screen display terminals are supported.
- Optimizer Cost Estimate: For any query, ISQL will display information that allows a terminal user to estimate the approximate work required for the query. With this information, the user could decide to wait for the query to complete, or could cancel the request.
- Report Writing: SQL/DS will provide the end user the ability to develop basic reports without writing an application program. The user can specify titles, column headings, and totals and subtotals. He can also make format changes and preview the report on a display device before requesting the printed report. The ISQL results may be printed on any system-supported printer using VSE/POWER Release 2 (or later) in a VSE System. Any 3270 Information Display System terminal printer supported by the BMS facility of CICS/DOS/VS or by RSCS Networking Release 2 (or later) can print the ISQL results. In a VSE environment, the VSE/POWER RJE feature Release 2 is required for remote POWER printer support.
- Application Program Avoidance: Many information needs can be satisfied using ISQL without requiring an application program. For example, one may update, delete or insert data, retrieve calculated data using the arithmetic expressions, use the built-in functions (minimum, maximum, average, count and sum), or use the internal sort and Boolean logic capability. These capabilities, together with the query/report writing facility, may eliminate the need for a large number of application program requests.
- Routines: A user can create, save, update and later execute a series of commands and/or SQL statements stored in a routine. These routines can be user or installation defined and can be used to define the terminal environment, issue a stored query, and execute one or more stored reports. A user may specify error handling options in these routines. An installation may also specify, save, and modify a profile of default characteristics for each authorized user.
- VM/SP EXECs: An Exec may be written to Stack any SQL or ISQL command, and invoke ISQL to process these stacked commands. These commands may be parameterized, and current values entered at execution time.
- VM/SP CMS Subset: ISQL users may invoke the CMS Subset capability to execute selected CP and CMS commands and EXECs.
- Ease-of-Installation: Although individual results may vary, initial customer experience with Release 1 has shown that it can be installed within one day; no system generation is required. There are few system parameters, and most of these can either be defaulted or specified later with little impact on the system or user applications.
- SIPO Support: SQL/DS Release 2 will be available on the VSE/System Installation Productivity Options. SQL/DS is also installable in an SSX/VSE Release 2 environment

RELEASE 2 DESCRIPTION

SQL/DS supports multiple, concurrent access from CMS virtual machines, batch virtual machines or VSE partitions, online transactions, and interactive program execution environments.

SQL/DS will typically operate in multiple-user mode, and will reside in a separate partition or virtual machine from the user's application. There may be many different applications simultaneously interfacing with SQL/DS using the operating system's cross-partition or inter-user communication facilities.

The above mode of operation allows multiple users to share the SQL/DS code and data base, and controls concurrent access to the data base. For faster performance and less system overhead (with no concurrent access and no data locking), SQL/DS can be executed in single user mode with a dedicated data base.

Users are provided an easy-to-use language called SQL (Structured Query Language) with which they access and query the data. SQL is also the language used to define and manipulate the data which is maintained by SQL/DS in a relational format. SQL requests can be entered through an IBM-provided transaction (ISQL); as input to the SQL/DS Data Base Services utility; or can be imbedded in application programs written in COBOL, PL/I, FORTRAN, or Assembler.

Many end users will be able to manipulate the data, formulate queries, and generate reports using ISQL without the need to write an application program.

SQL/DS had its origins in a relational data base prototype (referred to in the IBM Systems Journal, Volume Sixteen, Number Four, 1977, as System R) which was developed at the IBM San Jose Research Center.

The relational model provides a simple tabular view of the data to an end user. This data view is independent of actual storage structures and access techniques. A user can enter queries, generate reports and write application programs to process SQL/DS data without specifying access paths or predefined relationships, because these are managed automatically by SQL/DS. Users need only specify what data they want to use, not how to get it.

Security and authorization control facilities are included in SQL/DS to allow users to manage and control access to the data. Backup, restart/recovery and catalog capabilities are an integral part of SQL/DS.

- SCP: VM/SP Release 3; DOS/VSE AF Release 3; SSX/VSE Release 2.
- User Environments:
 - CMS Interactive
 - Online transactions
 - Batch (single and multiple user mode)
 - Interactive program development

SQL/DS (cont'd)

- **Ease-of-Use:** SQL statements are used to define, describe and access data in interactive environments and in preplanned application programs executing in either batch mode or as online transactions. Although individual results may vary, customer experience has shown that enough of the SQL language can be learned within a day to enable programmers and other professionals to effectively and productively use the system.
- **Application Programming language interfaces:** COBOL, FORTRAN, PL/I, and Assembly. The SQL/DS precompilers can INCLUDE a VSE Source library member or a VM/SP CMS file into an SQL/DS application. The Precompilers will allow user-specified options for controlling the printing of the output.
- **Documentation:** Task-oriented manuals and online reference text.
- **Online Help:** Upon request, SQL/DS will provide online reference information. This includes end-user-oriented explanations of SQL statements, terminal commands, SQL/DS messages, system catalog tables, etc.
- **Performance:** SQL/DS utilization of system resources has been improved. Improvements have been made in the internal optimizer, index operation, and in storage utilization. In the VM/SP environment, SQL/DS will use the new facilities in VM/SP Release 3 which will allow overlapped data base I/O in multi-user environments.
- **Catalog Support:** SQL/DS provides online maintenance of control information. Most of the data definition, access, and control can be done by an end-user without interrupting SQL/DS operations. This control information is stored in system tables (called catalogs) which can be accessed by any authorized user.
- **Bulk Data Entry:** SQL/DS provides several options to enable users to enter multiple records of data from existing non-SQL/DS formats into an SQL/DS table. These include online entry using the INPUT or INSERT commands of ISQL; the SQL/DS DBS Utility reading data from any sequential file (including CMS files); and the SQL/DS DL/I Extract facility in the VSE AF 3 environment.
- **Interactive program development:** The facilities of ICCF or VM/CMS may be used for interactive program development, compilation, testing, and execution of SQL/DS applications.
- **Data Conversion and Migration:** Existing Release One SQL/DS data bases will not have to be converted to SQL/DS Release 2 unless the installation is also migrating from SQL/DS on VSE to SQL/DS on VM/SP Release 3 (which uses a different physical storage structure than VSE/VSAM). SQL/DS procedures and utilities will be available for this conversion.
- **Recovery:** SQL/DS provides full recovery from application, system and media failures in all supported environments. In the VSE AF3 and SSX/VSE environments, CICS/DOS/VS coordinates recovery among DL/I, SQL/DS, and other CICS/DOS/VS controlled files for transaction, system and subsystem failures. In the VM/SP environment, similar recovery capability is provided by SQL/DS.
- **Data Sharing:** Multiple SQL/DS users may share access to the same data base simultaneously for both development and production uses. In a VM/SP environment, SQL/DS supports more than one SQL/DS Data Base Machine. Each SQL/DS Data Base Machine will be able to service requests from multiple concurrent CMS user virtual machines. However, a CMS user virtual machine can access only one such SQL/DS Data Base Machine at a time.
- **Data Locking:** Is at the DBSPACE, page (default), table, or individual row level. Locking granularity is automatic, but may be user-specified.
- **Data Base Services Utility (DBSU):** All SQL statements (but not ISQL Commands, DL/I Extract Commands, or application program specific statement) can be processed by the DBS Utility. DBSU obtains its input from a sequential control file which may contain both input data and commands. The control file may be a CMS file or a VSE file. The following capabilities are provided by DBSU: Data base table or DBSPACE unload/reload support for DB reorganization; support for loading of the data base from a user-defined sequential file; support for unloading of table or view data into a user-defined sequential file; support for optional data conversion when processing to or from user-defined sequential files (including zoned decimal data); support for logical input data records consisting of multiple DBS control file records.
- **Data types supported:** Fixed- and variable-length character, packed decimal, binary, double-precision floating-point, fixed- and variable-length double-byte character set.
- **Double-Byte Character Set (abbreviated DBCS):** The data types supported in SQL/DS have been extended in Release 2 to include double-byte character set (DBCS) data. This allows fixed, varying, and long varying data to be encoded as 2-byte characters. DBCS data can be stored as column data in SQL/DS tables or used as host variable data in SQL/DS PL/I and COBOL application programs. This support is required for portrayal of data in languages such as Kanji which require a 2-byte-per-character representation. The ability to process double-byte character data does not include the capability of using ISQL for inserting, displaying, or listing DBCS data. However, the Data Base Services (DBS) utility will accept commands and data records containing DBCS data. SQL/DS tables containing DBCS column data can also be loaded, unloaded or prepared for listing using the DBS utility.
- **DL/I DOS/VS Extract Facility:** Specific DL/I segments and fields can be defined online to the Extract facility of SQL/DS. The DL/I data definitions are presented in table format to the query user. Authorized users can request, via SQL-like Extract statements, that DL/I data be copied into previously defined SQL/DS tables.
- **Security, Auditability, Serviceability:** Users may trace attempts to access data, acquire resources, or execute applications. These attempts are written to a trace tape which may either be printed with an SQL/DS-supplied FORMAT program, or loaded into an SQL/DS table for subsequent analysis using ISQL.
- **Dynamic SQL Extensions:** The dynamic SQL programming interface is extended for Assembler language programs. The extension allows assembler programs to create access modules, and dynamically store prepared SQL statements in them. The extension also provides the capability to execute these stored SQL statements at a later time from other applications.

RELEASE 1 DESCRIPTION

SQL/DS is designed to provide ease-of-access to data for both the new end-user and the experienced data base programmer. It provides query, report writer, end user data base management, and a DL/I extract facility. SQL/DS had its origins in a relational data base prototype (referred to in the IBM Systems Journal, Volume Sixteen, Number Four, 1977, as System R) which was developed at the IBM San Jose Research Center. The relational model provides a simple tabular view of the data to an end user. This data view is independent of actual storage structures and access techniques. A user can enter queries, generate reports and write application programs to process SQL/DS data without specifying access paths or predefined relationships because these are managed automatically by SQL/DS. Users need only specify what data they want to use, not how to get it.

SQL/DS will typically operate in multiple-user mode. It typically will be in a separate partition or virtual machine from the user's application; there may be many different applications simultaneously interfacing with SQL/DS using the operating system's cross-partition or inter-user communication facilities.

The above mode of operation allows multiple users to share the SQL/DS code and data base, and controls concurrent access to the data base. For faster performance and less system overhead (with no concurrent access and no data locking) SQL/DS can be executed in a single user mode with a dedicated data base.

Finally, SQL/DS can operate in an interactive environment. Users can develop, compile and execute SQL/DS applications using the interactive program development capabilities of ICCF or VM/CMS.

The SQL/DS partition will contain the control facilities to allow users to access the data base concurrently. The control component will also isolate the other components of SQL/DS from the environment and from the SCP's communication facility. This will provide a high degree of data integrity, and will insulate other partitions from user programming errors. SQL/DS data support is summarized by the following list of key facilities:

1. Relational Data Model

SQL/DS supports the relational model of data. Data is defined and accessed in terms of data tables and operations on data tables. The 2-dimensional tables, which are a structured part of the relational model, normally have a fixed number of columns, and a variable number of unnumbered rows. The relational model can effectively support a broad range of user data requirements. Views may be defined on tables such that user/application logical tables need not conform to actual stored tables. Views may combine data from several stored tables (or other views), and may subset tables by rows and/or columns.

2. Structured Query Language (SQL)

Data definition, access, manipulation and control operations are supported by the Structured Query Language (SQL). SQL is a high-level, non-procedural data language available to users through an interactive terminal interface, a batch utility and application programs.

SQL/DS (cont'd)

SQL statements consist of command verbs, one or more optional clauses, language keywords and parameter operands. The structured use of verbs and keywords in the SQL syntax allows precise specification of data requests in a readable fashion.

SQL provides a set of statements which fall into four major categories: Query, Data Manipulation, Control and Data Definition. *Query* commands allow the user to retrieve data. *Data Manipulation* commands permit the user to insert, delete or update entries in the SQL/DS data. *Control* commands are used for transaction management operations such as restoring the contents of the data base to a previously-saved state. The *Data Definition* commands allow the user to create new tables, add columns to existing tables and create views. Also, SQL can be used to dynamically create indexes to provide quicker access to data.

3. Logical Storage Management

SQL/DS alleviates much of the preplanning and set-up required for data installation and maintenance by managing DASD storage in terms of logical space allocations (called DBSPACES). DBSPACES must be backed by real DASD space in the form of VSAM data sets, but this space need not be allocated until it is needed.

4. Terminal User Interface

In a CICS/DOS/VS or VM/CMS environment, a terminal user may directly interact with SQL/DS using an SQL/DS provided CICS/VS transaction ISQL (interactive SQL). The user can access data without writing an application program by invoking ISQL. ISQL utilizes CICS/DOS/VS or VM/CMS terminal control.

ISQL has user-oriented commands. The user enters both standard SQL statements to access the data base, or commands to control the terminal session. The SQL statements are passed on to SQL/DS for immediate compilation and execution. If the SQL statement is a query, the results of the query are immediately displayed at the terminal. Note that this facility allows the user to satisfy many of his information needs online, interactively, without writing an application program.

ISQL support allows terminal access for data administration and definition, data retrieval, data manipulation and data extraction from DL/I data bases.

There is an online help capability to assist the users in the use of the system and in error diagnosis. If errors are made, a more detailed explanatory text can be obtained. The user may request additional reference text regarding SQL/DS operations, SQL commands, etc.

ISQL provides a bulk online data entry capability. This allows the user to insert multiple rows easily into an existing SQL/DS table. Each input record must contain all the data destined for that row (null columns are allowed). Unless changed at insert time, the columns are entered in the order specified at table creation time. The user can save, cancel, end (commit), or reset (roll back to a previous commit).

PF keys are used for scrolling and shifting the display.

The user may save SQL statements and ISQL commands in an SQL/DS table. The user can create, store, recall, modify and execute sets of commands and statements as routines. Finally, the stored routines may be parameterized; the user can substitute at execution time variable information in a query routine which has been created to accept parameter input.

User profiles can be defined and saved. These describe the default characteristics (such as the decimal punctuation option for numbers).

5. Hard Copy Output

The user can issue simple and/or complex SQL statements via ISQL to retrieve columns or rows from an SQL/DS table. The result will be displayed on the screen. The user may then use ISQL commands to:

- Create report headings and footings.
- Change the column labels from the catalog to more descriptive labels in the report.
- Omit retrieved columns.
- Separate the query result into specified groups.
- Create subtotals and totals for all numeric columns, or for only those columns specified.
- Verify the format of the resulting report on the terminal prior to printing.
- Specify the output class, and number of copies.
- Request a hard copy print on the system printer or any system-supported printer. The date will appear on the top left, and the page number on the top right on every page.

- Save the ISQL commands and SQL statements in an SQL/DS table for later reuse and modification (as desired).

6. Extraction of Data from DL/I

The DL/I extract facility supports single processor operation. DL/I and SQL/DS must be licensed for the same processor. The DL/I data base may be offline when the user defines the desired DL/I data to the extract facility, and when an extract is requested. Both SQL/DS and DL/I must be active when the extract facility is executing.

The user may copy specific DL/I segment types and/or specific fields of a segment.

Execution of the extract request is asynchronous. Once the extract request is issued by an authorized user, he may perform other query operations (including "logging off" and "logging on" at a later time to get the results).

For more efficient operation, outstanding extract requests will be merged to allow multiple requests for the same PSB/PCB to be satisfied in a single pass through the DL/I data base.

7. Concurrent Access from Multiple Applications

SQL/DS will support concurrent access from multiple users and environments including CMS interactive, online transactions, batch, or interactive program development. SQL/DS will protect data access through internal locking mechanisms which prevent conflicting access from multiple users. Users need not explicitly issue lock requests.

Sharing of data is at the row level: Multiple applications can access data from the same table at the same time. SQL/DS will prevent application access to rows modified by other applications which have not completed. SQL/DS will also support protection of read operations, such that data read by one user cannot be modified by other users until the first one completes. Users may elect to explicitly acquire locks on data at the table or DBSPACE level.

In a VM/SP environment, SQL/DS will support a multiple virtual machine mode (MVMM) of operation. This will allow SQL/DS to be in one virtual machine, and user applications in other logical or physical machines. The SQL/DS Data Base Machine will be able to service requests from multiple concurrent CMS user machines. Multiple MVMM is also supported; that is, there may be multiple SQL/DS Data Base Machines, each machine sharing the same code, and each with its own data base.

8. Data Recovery Support

Data recovery facilities of SQL/DS help to protect data from three types of failure: User, system or media. All recovery is based on the concept of restoring data to a consistent state as defined by successfully completed logical tasks.

On user failure, SQL/DS is designed to isolate the work associated with the failing application and backout all uncommitted changes to data. This is done dynamically without impact to other activity on the system.

On system or SQL/DS failure, SQL/DS restart is designed to automatically restore data to a consistent state by backing out uncommitted changes and completely processing the committed changes.

SQL/DS supports media recovery by providing a data base archive facility and a recovery process which will restore a data base from this archive.

9. Data Security

There are two aspects of security; first a facility to control access to the SQL/DS system itself, and second, the facilities to control access to the data managed by SQL/DS.

a. System Access

SQL/DS provides flexible user-controllable security facilities. The SQL language is used to specify the authorization to the SQL/DS controlled resources (data, programs, etc.). The creator of the resource determines which users may access or change it. An application cannot access data that is beyond its authorized scope. Furthermore, non-authorized users can be recorded and audited.

Authorized passwords for SQL/DS usage are established by the installation and stored in the system catalogs. Once a user is verified by the terminal manager (CICS/DOS/VS or VM/CMS) then SQL/DS controls the access to its managed resources. Note that SQL/DS does not require an additional user-id and password for online access to it.

PROGRAM PRODUCTS

SQL/DS (cont'd)

b. Data Security

SQL/DS assists in providing data security by using a catalog mechanism for controlling user access to programs that access data. VIEWS can be used to subset a table of specific columns or rows or to combine parts of several tables. Authorization to data can be at the individual table, row, or column level. Also, data manipulation authority (INSERT, DELETE, etc.) can be separately controlled. The TRACE facility can be used to audit unauthorized attempts.

The security facilities are flexible in that security administration may be controlled by one individual or delegated to meet the needs of the customer installation.

User management is responsible for the proper selection, application, and adequacy of these controls and security features for his individual environment.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

SQL/DS is designed to operate on those IBM processors supported by DOS/VSE Advanced Functions Release 3 or later, SSX Version 1 Release 2 or later, and VM/SP Release 3 (see the VM/SP Release 3 Announcement Letter). The IBM CPUs must support conditional swapping, and extended precision floating-point. This, SQL/DS will not execute on IBM S/370 models 165, 155, 135 and models below 135. The minimum storage requirement is 2.0 megabytes for multiple-user mode operation. At least one 9-track tape drive is required for SQL/DS Trace or Archive facilities. SQL/DS will support all IBM devices supported by these operating systems through VSAM data management facilities (in VSE), or by VM/SP Release 3. Terminal support for preplanned SQL/DS applications will be provided through CICS/DOS/VS and VM/CMS. ISQL can be used with the following (or compatible) IBM terminals:

- a. IBM 3275 mdls 2, 12 CRTs
- b. IBM 3276 mdls 2, 3, 4, 12, 13, 14 CRTs
- c. IBM 3277 mdl 2 CRTs
- d. IBM 3278 mdls 2, 3, 4, 5 CRTs
- e. IBM 3279 mdls 2A, 3A, 2B, 3B CRTs

SOFTWARE REQUIREMENTS

In a VM/SP environment, SQL/DS is designed to operate with and requires VM/SP Release 3 or later. Neither DOS Simulation, nor VSE/VSAM nor a VSE Guest is required.

ISQL Results may be printed on any system-supported printer, using VSE/POWER Release 2 or later in a VSE system. Any IBM 3270 Information Display System terminal printer supported by the BMS facility of CICS/DOS/VS in VSE, or by RSCS Networking Release 2 or later in VM/SP Release 3, can print the ISQL results. In a VSE environment, the VSE/POWER RJE feature Release 2 is required for remote POWER printer support.

In a VSE environment, SQL/DS is designed to operate with and requires DOS/VSE Advanced Function Release 3 or later and VSE/VSAM Release 2 or later. The following related (or equivalent) products may optionally be used:

Component Name	Component Number	Release Level	Comment
CICS/DOS/VS	5746-XX3	1.5 or later	Note 1, 3
VSE/POWER	5746-XE3	2 or later	Note 1, 3
VSE/ICCF	5746-TS1	3 or later	Note 2
DL/I DOS/VS	5746-XX1	1.6 or later	Note 3

Note 1: For query/report writer, and for support of the IBM 3270 Information Display System printers.

Note 2: For interactive program development

Note 3: For extract facility

In an SSX environment, SQL/DS requires Version 1 Release 2 of SSX.

In a VM/SP environment, SQL/DS is designed to operate with and requires VM/SP Release 3.

COMPATIBILITY

SQL/DS Release 1 to Release 2:

A data base (and directory, log and system catalogs, etc.) generated under Release 1 will be supported under Release 2. The Release 2 installation process will support the installation of a system that already has a data base generated under Release 1.

Programs, access modules, stored queries and routines generated under SQL/DS Release 1 will be supported by Release 2.

DATA CONVERSION to SQL/DS FORMAT

Users will have several options to convert their data from their existing formats to SQL/DS. These include:

- VSAM AMS repro facility and the SQL/DS Data Load facility.
- Modifications to currently available user unload/reload programs.
- DBS utility to bulk load existing user-generated SAM files into SQL/DS tables.
- In the VSE AF 3 environment, the SQL/DS Extract facility will enable the user to copy selected DL/I data into SQL/DS tables.

MIGRATION of SQL/DS between VSE and VM/SP ENVIRONMENTS

Existing SQL/DS data bases (Release 1 level) will not have to be converted unless the user is converting from SQL/DS on VSE to SQL/DS on VM SP Release 3 (since VSE SQL/DS uses VSE/VSAM for DASD support, and VM SQL/DS does not). SQL/DS Archive and data unload/reload facilities can be used for this conversion.

PERFORMANCE CONSIDERATIONS

The primary objectives of SQL/DS are ease-of-installation and ease-of-use. SQL/DS provides the user an access language which eliminates the need to know the physical structure of the data base. This places additional requirements on the program product, which in turn may increase the system resource requirements processor cycles, real storage, I/O activity and DASD space). The increase in system resources should be compared to reductions in personnel effort. The relational model uses one familiar concept of tables; SQL/DS does not require a high skill level or extensive education in order to effectively use it. This situation is not dissimilar to the tradeoffs between the use of high level languages and assembler language.

The actual system resource requirements vary and depend on many factors (such as number of records searched, the complexity of the query and the availability of indexes). Response time and throughput depend on the allocated system resources, the priority of the executing task, and the nature of the transaction. An increase in the required system resources may be offset by the value of the increased function provided by SQL/DS, and reduced programmer effort.

1. Unplanned Environments

In the unplanned environment there are performance advantages due to the inherent nature of a relational data base system such as SQL/DS. A user may make many requests for data without having a detailed data processing background, knowledge of the stored data, or knowledge of the characteristics of the resulting answer. The basic SQL facilities for such requests can be easily learned and used, and can enhance end user productivity.

Using ISQL and the report writer capabilities, many of the one-time or simple application programs may be eliminated.

2. Pre-Planned Environment

Because SQL/DS allows reorganization of the data base, addition of new transactions or tables, and extension or deletion of tables without impacting existing application programs, a user can install the first application program without requiring that all pre-planning is complete. SQL/DS supports interactive addition, extension, or deletion of tables without requiring suspension of other processing or regenerating the entire data base. The pre-planned environment includes precoded online, shared batch, and single user batch application programs. These applications have varying performance characteristics. It is important to emphasize the following when comparing the SQL/DS performance relative to the other data base models.

In SQL/DS, the user only indicates *what* data is required. Because the user specifies less information (i.e., he does not indicate where the data is located) SQL/DS must determine where the data is before it can access the data. Consequently, it is not appropriate to restrict performance considerations to just system resources and throughput. One should also consider personnel productivity. This transferring of effort from the application programmer to SQL/DS can result in greater productivity for the person, at the potential expense of more system resources.

PROGRAM PRODUCTS

**5748-XXK - ELIAS-I/VM R1
ENTRY LEVEL INTERACTIVE APPLICATION
SYSTEM - ONE/VM RELEASE 1**

PURPOSE

ELIAS-I/VM is an interactive program which runs under the control of the Interactive Productivity Facility (5748-MS1). When correctly installed in its Specified Operating Environment (SOE), ELIAS-I/VM is designed to provide a system which is intended to facilitate the design, development and implementation of VSAM, DB, DC and/or DB/DC programs with CICS/DOS/VS, DL/I DOS/VS, and/or VSE/VSAM using COBOL or PL/I and, optionally, DMS/CICS/VS-DOS.

HIGHLIGHTS

ELIAS-I/VM provides:

- Interactive interface for definition of DL/I DOS/VS Data Bases.
- Interactive interface for definition of CICS/DOS/VS screens (using Basic Mapping Support or DMS/CICS/VS-DOS).
- Interactive program build facility for batch or online programs in COBOL or PL/I.
- Interactive facilities to enhance DMS/CICS/VS-DOS user exit programming.
- Data Base recovery and reorganization routines.
- Task-oriented documentation.
- Sample programs to illustrate how DB/DC programs may be structured.
- Ease-of-use for DB/DC programming.
- Dialogues and help functions available in the following languages: French, German, Italian, Katakana, Portuguese, and Spanish in addition to English.
- Standard program design and error recovery routines designed to provide easier and reduced maintenance.

DESCRIPTION

ELIAS-I/VM presents, via its optional documentation and with supporting education, a design methodology, especially oriented towards DB/DC applications, tailored to the user who is not experienced in DB/DC implementation and who has limited in-house skill. Hints and tips are provided to facilitate the use of improved programming techniques in the smaller system environment.

ELIAS-I/VM interactive procedures are designed to provide assistance with VSAM, DB, DC and/or DB/DC program implementation by providing a dialog capability for the programmer. ELIAS-I/VM bricks are also included in the product. These bricks are designed to be included in VSAM, DB, DC and/or DB/DC application programs and to provide assistance in utilizing standard CICS/DOS/VS and DL/I DOS/VS and VSE/VSAM facilities.

Procedures and bricks are provided for the following main functional areas:

- Assistance with DL/I data base definition. Procedures to generate DL/I nucleus, DBDs, PSBs, SSAs, and the associated VSAM files, together with the associated COBOL or PL/I structures. A procedure to transport ELIAS-I/VM defined DL/I control blocks and COBOL or PL/I structures into the DB/DC Data Dictionary DOS (5746-XXC) is provided.
- Assistance with PSB import. A procedure to make available to ELIAS-I/VM program generation procedure PSBs which have been defined without making use of ELIAS-I/VM facilities.
- Assistance with DL/I data base maintenance. A procedure for loading, reorganization and back-up/recovery of DL/I data bases.
- Assistance with CICS/DOS/VS screen map generation using BASIC Mapping Support. Interactive definition of application screens to ELIAS-I/VM design standards. These maps can be defined for use either with COBOL or PL/I application programs.
- Assistance with batch and online program creation and maintenance in COBOL or PL/I. Provision of skeleton programs with data areas, screen maps, linkage and error recovery code for DL/I (CALL or High Level Programming Interfaces), VSE/VSAM, and CICS/DOS/VS.

"Fetch a brick" capability for services requests related to DL/I (CALL or HLP interfaces), VSE/VSAM, and CICS/DOS/VS either in batch or online programs written in COBOL or PL/I. Simple use of full screen editor to enter user source statements and test the resulting program.

- Assistance for writing COBOL or PL/I user exits for DMS/CICS/VS-DOS (5746-XC4). For those customers who have DMS installed, ELIAS-I/VM provides support for writing user exits in either COBOL or PL/I, offering productivity improvements made available to the developers of traditional COBOL or PL/I programs.

- Assistance with "compile and link" jobstream creation. A procedure to generate a fully tailored jobstream in order to submit to batch for compiling and linking batch and/or online programs, as well as, CICS/DOS/VS screen maps.

ELIAS-I/VM has been designed to provide the maximum productivity benefits when used in a full DB/DC environment together with CICS/DOS/VS, DL/I DOS/VS, and either COBOL or PL/I and, optionally, DMS/CICS/VS-DOS.

CUSTOMER RESPONSIBILITIES

The customer should ensure that the functions of ELIAS-I/VM match their application requirements and that they have sufficient terminals and machine power to realize the benefits of an online programming environment.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

ELIAS-I/VM is designed to operate on any IBM S/370, 30X and 4300 processor supported by VM/SP.

ELIAS-I/VM runs under control of Interactive Productivity Facility, in a CMS machine with at least 1 megabyte of virtual storage allocated.

It requires a minimum of 4,000 CMS library blocks (1024 bytes) of auxiliary storage.

ELIAS-I/VM generated code supports the IBM 3310, 3330, 3340, 3344, 3350, and 3370 Disk Storage devices.

A typical minimum VM/VSE DB/DC environment where ELIAS-I/VM can be installed to support application programming development might be:

— IBM 4300 Processor: 2 megabytes of storage ... 3 spindles 3370 DASD* ... 1 Console 3278-2A ... 1 Printer 3211 or 3203-5* or 4245* ... 1 Card or Diskette Reader ... 1 Tape Drive 3420* ... 1 Terminal 3277-2 or 3278-2.

— IBM S/370: 2 megabytes of storage ... 8 Spindles 3340 DASD* ... 1 Line Printer ... 1 Card or Diskette Reader ... 1 Tape Drive ... 1 Terminal 3277-2 or 3278-2.

* = or equivalent devices supported by the operating system.

SOFTWARE REQUIREMENTS

This licensed program requires the functions provided by the Interactive Productivity Facility Release 3.0 (5748-MS1), running in conjunction with the following programs:

	Release
VM/370 SCP	5749-010 6.0
VM/SP	5664-167

The ELIAS-I/VM editors make use of the full screen editing facilities provided by the CMS editor of VM/SP. In addition, customers may want to install the Display Editing System Release 1.0 (5796-PJP), whose facilities can also be used by the ELIAS-I/VM editors.

The set of macros and application programs generated by ELIAS-I/VM may interface with the following programs:

	Release
VSE/POWER	5746-XE3 2.0
CICS/VS	5746-XX3 1.5
DL/I DOS/VS	5746-XX1 1.5
	ICR2
VSE/VSAM	5746-AM2 2.0
DMS/CICS/VS-DOS	5746-XC4 2.0
DOS/VS COBOL	5746-CB1 2.5
PL/I Optimizer Compiler and Libraries	5736-PL3 5.1
DB/DC DATA Dictionary	5746-XXC 3.0

Programs developed using ELIAS-I/VM can either be executed on a native VSE environment or on a VM/VSE environment.

MIGRATION FROM ELIAS-I/VM RELEASE 1

ELIAS-I/VM Release 1 is upward compatible with ELIAS-I/VM Release 2:

- Tables created by ELIAS-I/VM Release 1 can be used directly by ELIAS-I/VM Release 2 dialogs.
- Program skeletons generated using ELIAS-I/VM Release 1 facilities can be accessed by ELIAS-I/VM Release 2 editors.
- ELIAS-I/VM Release 2 bricks providing functions already existing in ELIAS-I/VM Release 1 can be included in any ELIAS-I/VM Release 1 generated programs, without regeneration of the framework.

Restriction: ELIAS-I/VM Release 2 editors can only use ELIAS-I/VM Release 2 bricks.

PROGRAM PRODUCTS

ELIAS-I/VM (cont'd)

COMPATIBILITY Between ELIAS-I/VM (5748-XXK) and ELIAS-I (5746-XXV)

ELIAS-I/VM is functionally equivalent to ELIAS-I. The data base definitions, structures, maps, and application programs created using the facilities of one of the products, are fully compatible with the related items created using the facilities of the other product. All bricks made available to the user are the same in both products. Therefore, all files generated by either of the two products are fully interchangeable.

DOCUMENTATION
(available from Mechanicsburg)

The following documents will be available at ELIAS-I/VM availability time:

Licensed Program Specifications (GH19-6187) ... Licensed Program Design Objectives (GH19-6205) ... General Information Manual (GH19-6157*) ... Application Design Guide (SH19-6158) ... COBOL Application Programmer's Guide (SH19-6159) ... PL/I Application Programmer's Guide (SH19-6160) ... System Administrator's Guide (SH19-6161) ... COBOL Samples Handbook (SH19-6162) ... PL/I Samples Handbook (SH19-6163) ... Program Logic Manual (LY19-6121) ... Reference Card (GX11-6065).*

* = will be available at announcement time

The Customer will receive all necessary instructions for installing ELIAS-I/VM on top of an installed system which contains the Interactive Productivity Facility Release 3.0, and the other prerequisite programs described under Programming Requirements.

RPOs ACCEPTED: No

PROGRAM PRODUCTS

**VS BASIC
5748-XX1**

DESCRIPTION

VS BASIC is a language processor which provides a problem solving capability in both interactive and batch environments. The BASIC language is relatively easy to learn and easy to use. Its simplicity has broad appeal to non-computer professionals (business analysts, engineers, scientists, students, etc.) as well as to the professional programmer. The language is widely used as a problem solving tool across a broad range of scientific and business oriented applications.

VS BASIC is designed to operate in virtual storage systems. It will operate in the time-sharing environments CMS (Conversational Monitor System) of VM/370, TSO (Time Sharing Option) under OS/VS2 (SVS and MVS) and VSPC (Virtual Storage Personal Computing) under OS/VS1, OS/VS2 (MVS) and DOS/VS. It also operates as a batch compiler under control of OS/VS1, OS/VS2 (SVS and MVS), DOS/VS and CMS Batch.

RELEASE 1 and 2 HIGHLIGHTS

- Arithmetic capability in short- and long-precision, permitting arithmetic operations on variables and arrays.
- Character facilities, enabling the user to define character variables of different lengths, to concatenate groups of character data items and to locate and extract substrings within character strings.
- Array handling operations for both numeric and character one- and two-dimensional arrays.
- Record-oriented file facilities that allow record processing in direct or sequential fashion.
- Input-output facilities that provide great flexibility in accessing input data and in formatting output data.
- A set of intrinsic functions performing often-needed arithmetic and character operations.
- User-defined functions that can be defined in one statement or over a group of statements.
- Program segmentation capability that allows more than one BASIC program to be executed in sequential order.

In addition, the VS BASIC processor under CMS and TSO provides an interactive debugging facility to permit the user to dynamically debug a program at the terminal. VS BASIC under VSPC does not provide the debug facility.

RELEASE 3 HIGHLIGHTS

Extended Input-Output Facilities: PRINT TO allows the user to direct terminal output to a file. This file can subsequently be printed at the terminal or at a system printer, if available to the host system.

INPUT FROM permits data to be retrieved from either the user terminal or a user file.

Additional Data File Support: The VS BASIC language has been extended to include support for direct files accessed via relative record numbers. Support of files in the VSPC library has been extended to include support of VSPC direct files. Support of VSAM data sets has been extended to include support of relative record data sets. VSPC files and reusable VSAM data sets can now be opened for reuse.

Program Error Handling: Through the use of CN statements and read-only variables, VS BASIC error handling facilities now control and identify many more errors occurring at execution time.

Operators/Mnemonics: The addition of the character mnemonics to the relational, logical and character operators extends the use of the operators to terminal keyboards without special characters. The special characters and mnemonics can be used interchangeably for the operations noted.

Buffered-Ahead Terminal Input: This facility enables a user to enter on one input line, data which will satisfy more than one INPUT request, thus providing the ability to override the prompt for each of the entries.

CUSTOMER RESPONSIBILITIES

Each customer installing, operating or maintaining VS BASIC must have a working knowledge of the applicable operating system (OS/VS1, OS/VS2 (SVS or MVS), DOS/VS, VM/370). No customer should attempt to install VS BASIC until the installation has achieved proficiency in the use of the operating system.

The customer is responsible for providing adequate protection against accidental loss or misuse of data. This includes an adequate review of the system's security provision by the user.

It is the customer's responsibility to make the changes in the customer program necessary to run under VS BASIC. It is also the customer's responsibility to ensure type compatibility when exchanging data with programs written in other languages while using VS BASIC under VSPC.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The VS BASIC processor is designed to operate in a virtual storage system, in both time-sharing and batch environments. It is a single-pass compiler, which accepts up to 1000 source statements and produces executable code that can be run immediately after compilation, or that can be stored as an object program and run at some later time.

Under VSPC, the VS BASIC processor is reenterable in the OS/VS1, OS/VS2 (MVS) and DOS/VS environments. Under OS/VS Batch, the VS BASIC processor is reenterable. Under TSO, the VS BASIC processor is reenterable except for the interactive debug module. Under DOS/VS batch the processor is reenterable except for the executor module.

If reenterable, the processor may be placed in the link pack area or the shared virtual area so that many users can simultaneously refer to them.

Under CMS, the interactive debug and executor modules are not reenterable.

Because all environments in which VS BASIC operates can be virtual, real storage requirements are largely a function of performance desired. Under VSPC, the virtual storage required to run VS BASIC consists of the VS BASIC specific requirements and the VSPC requirements. VS BASIC requires 128K bytes in addition to the VSPC interactive environment requirements. In OS/VS2 (MVS), 128K bytes per VSPC dependent address space is required. If VS BASIC is placed in the system link pack area, only 128K bytes are required.

Under CMS, VS BASIC requires 300K bytes of virtual storage without the interactive debug facility.

In other environments VS BASIC requires 128K bytes of virtual storage without the interactive debug facility and requires 256K bytes with the interactive debug facility.

SOFTWARE REQUIREMENTS

VS BASIC, which is written in Assembler language, is designed to operate in virtual storage environments. It will operate in these time-sharing environments:

- VSPC under OS/VS1, OS/VS2 (MVS) and DOS/VS.
- CMS under VM/370 Release 3.
- TSO under OS/VS2 (SVS and MVS).

It also operates as a batch compiler under OS/VS1, OS/VS2 (SVS and MVS), DOS/VS and CMS batch. Program compatibility is thus offered for users who may decide at some later time to change environments.

Record-oriented file facilities or VSPC stream or record facilities use VSAM (Virtual Storage Access Method). VS BASIC Release 3 provides access relative record capability under OS/VS2 (SVS).

COMPATIBILITY

Programs: VS BASIC Release 2 programs (for which object programs were saved) must be recompiled with the Release 3 Processor.

Those few user programs which depend upon a PRINT USING statement with a reference to an IMAGE to force the preceding data to be printed, will need to be modified. One way is through the addition of a PRINT statement which will then cause the preceding data to be printed.

All correct BASIC programs running under ITF: BASIC (5734-RC3, 5734-RC4 and 5736-RC2) will run under VS BASIC as long as the maximum literal pool size is not exceeded. Note: In Release 3, PRINT literals are no longer stored in the literal pool.

All correct BASIC programs running under the BASIC processor currently supported by CMS (CALL-OS BASIC, 360A-CX-44X) will run under VS BASIC after adjustment of file input/output statements. CMS editing commands can be used to change these statements to conform to VS BASIC syntax.

Additionally, under CALL-OS BASIC, if an OPEN statement is issued for a file already open, the file is repositioned to its beginning. Under VS BASIC, an OPEN statement for a file already open is ignored. CALL-OS BASIC programs containing such OPEN statements should be converted by adding a CLOSE statement before the OPEN statement.

All correct programs running under VS BASIC (nonVSPC) will run under VS BASIC for VSPC after adjustment of file input-output statements and program names in CHAIN statements. These changes can be made using the VSPC editing facilities.

The MAT ZER and MAT CON functions, which exist in earlier BASIC processors, are replaced in VS BASIC by the facilities of the MAT assignment statement. However, as a compatibility convenience, these functions are available in VS BASIC so that existing BASIC programs containing references to them will not require change in order to run under VS BASIC.

PROGRAM PRODUCTS

VS BASIC (cont'd)

Files: Files created under ITF: BASIC can be read by VS BASIC by specifying the filename in the form 'userid.DATA(name)', where name is the name of the file in input/output statements.

Files created under DOS ITF: BASIC must first be converted to conventional DOS files; the ITF CONVERT command may be used.

Files created under CALL-OS BASIC running under CMS can be used by VS BASIC after being converted to VS BASIC format.

NonVSPC VS BASIC files can be imported from sequential data sets to VSPC by using the VSPC service program.

DOCUMENTATION: (available from Mechanicsburg)

VS BASIC General Information Manual (GC28-8302) ... VS BASIC Design Specifications (GC28-8311) ... VS BASIC Design Objectives (GH20-9118).

PROGRAM PRODUCTS

**CHAINED FILE - DL/I BRIDGE
DOS/VS and OS/VS (5748-XX3)**

DESCRIPTION

The Chained File - DL/I Bridge provides assistance in converting data base applications to Data Language/I (DL/I) from current chained file systems which include:

- 1) S/360 Bill of Material Processor (360A-ME-06X).
- 2) S/360 Data Base Organization and Maintenance Processor (5736-XX4).
- 3) S/360 Data Base Organization and Maintenance Processor with the CICS Feature of DBOMP (5736-XX4).
- 4) Chained File Management System of OS/360 Requirements Planning System (5734-M51).

This program product supports conversion of:

- (1) and (2) to DL/I DOS/VS (5746-XX1).
- (1), (2), (4) and Bill Processor Systems - IMS/360 Bridge (5734-XX9) to IMS/VS (5740-XX2).
- (3) to DL/I DOS/VS (5746-XX1) and to CICS/DOS/VS (5746-XX3).
- (3) to CICS/OS/VS (5740-XX1).

The Chained File - DL/I Bridge provides the necessary logic to:

- Unload the user's current chained file system data base.
- Load the DL/I data base.
- Provide flexibility for data base reformatting and structuring.
- Interface existing programs to the DL/I data base, thus permitting them to operate with few or no program changes against the DL/I data base.
- Support low-level code and perform continuity checking.
- Execute batch application programs in a batch message processing region of IMS.
- Improve chain file maintenance by optionally using a fast batch capability.

HIGHLIGHTS

This program product can minimize the conversion effort required to migrate from chained file systems to DL/I DOS/VS or IMS/VS.

The bridge interface module which replaces the FILEORG and IOPROCESS modules of the existing chained file system is file and application program independent and, as a consequence, must be generated by the user only once.

The Chained File - DL/I Bridge users describe their existing chained file data base to the bridge with a subset of those parameter statements used to describe the data base to their existing chained file system.

The bridge description generator supports the migration to DL/I DOS/VS or IMS/VS by providing:

- An audit list including diagnostics.
- A report describing the chained file system data base as defined in the input.
- A structuring report describing the mapping of existing chained file system records to DL/I segments and fields.
- A report describing the DL/I segments for each chained file system record type.
- The input statements for the DL/I DBDGEN and PSBGEN utility programs required for bridge operation.
- Macro instruction card image output which is used to produce the user's bridge data base conversion modules and bridge program modules.

CUSTOMER RESPONSIBILITIES

Customers planning to use this program product must first install DL/I DOS/VS or IMS/VS, and if online processing, CICS/DOS/VS or CICS/OS/VS.

Users must assemble and link-edit the description generator program. It is then executed, using existing parameter statements plus user-prepared parameter statements. The file description report is used to verify the accuracy of the statements entered. The user must execute the DL/I DBDGEN and PSBGEN utility programs, using control statements created by the description generator. They must assemble and link-edit the control blocks produced by the description generator. The unload module is assembled and link-edited together with the user's chained file system input/output module(s) and executed to unload the chained file system files.

The load program is assembled, link-edited as a DL/I application program, using the output of the unload program to create the converted DL/I data base. The bridge interface modules are assembled and link-edited replacing the existing chained file system FILEORG and IOPROCESS modules to perform maintenance and retrieval functions. User programs may require some changes prior to recompilation, especially if the user is migrating from DOS to OS.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The amount of virtual and real address space required for the Chained File - DL/I modules is almost independent of the type and level of the operating system.

The address space requirements for the bridge modules, control blocks, and working storage vary with the number of chained file system files, the record length, and the extent of file structuring. For unstructured bridging of a chained file system data base consisting of an item master file, a product structure chain file, a routing chain file, and a work center master file with a maximum record length of about 500 bytes each, the required virtual address space for bridge modules, control blocks, and working storage is approximately (rounded to the next higher 2K value):

Program name	Bridge modules		Control blocks and working storage	
	Virtual address space req'd	Real address space req'd	Virtual address space req'd	Real address space req'd
Description Generator Program	70K	22K	30K	20K
Unload Program	20K	20K	4K	4K
Load Program	14K	14K	2K	2K
Interface	24K	24K	6K	6K

Tables used by the load program and the bridge interface module vary in size, depending on the number of chained file system files in the data base and the extent of structuring used.

Additional address space is required for an operational system as follows:

Program Name	Space must be added for
Description Generator Program	Operating System
Unload Program	Operating System; Chained File System or Bill Processor Systems - IMS/360 Bridge
Load Program	Operating System; DL/I DOS/VS or IMS/VS; VSAM
Interface (batch)	Operating System; DL/I DOS/VS or IMS/VS; VSAM; Application Program
Interface (online)	Operating System; DL/I DOS/VS or IMS/VS; VSAM; CICS/DOS/VS or CICS/OS/VS Application Program(s)

The peripheral equipment consists of:

- Disk storage facilities as required by DL/I DOS/VS or IMS/VS
- 9-track tape units, as required by DL/I DOS/VS or IMS/VS
- One card read punch
- One printer
- Terminals as supported by CICS/VS (optional)

SOFTWARE REQUIREMENTS

The program product operates in virtual storage under the IBM Disk Operating System/Virtual Storage (DOS/VS), the IBM Operating System/Virtual Storage 1 (OS/VS1), or the IBM Operating System/Virtual Storage 2 (OS/VS2). The unload program operates as an application program within the installed chained file system environment. The converted DL/I data bases are organized using the Hierarchical Indexed Direct Access Method (HIDAM).

Supported release levels of the operating systems are as follows:

PROGRAM PRODUCTS

Chained File - DL/I Bridge (cont'd)

Operating System	Type of Processing	Release Level
DOS/VS	Batch, online	31
OS/VS1	Batch	3.0
OS/VS1	Online	4.0
OS/VS2	Batch	1.6
OS/VS2	Online	3.0

Subsequent releases, versions and modification are also supported unless so stated in a future version of this document.

In the batch environment, the Chained File - DL/I Bridge requires DL/I DOS/VS (5746-XX1) Release 1.1, or IMS/VS (5740-XX2) Release 1.0. For online processing, this program product requires DL/I DOS/VS (5746-XX1) Release 1.1 and CICS/DOS/VS (5746-XX3) Release 1.0.1, or IMS/VS (5740-XX2) Release 1.0.1 and CICS/OS/VS (5740-XX1) Release 1.1. Subsequent releases, versions and modifications of the aforementioned program products are also supported unless so stated in a future version of this document.

The Chained File - DL/I Bridge will also run with the above systems under VM/370.

All chained File - DL/I Bridge programs are written in IBM S/370 Assembler language and one of the following Assemblers is required:

Program Number 5745-SC-ASM, for DOS/VS

Program Number 5741-SC1-03, for ZOS/VS1

Program Number 5742-SC1-03, for OS/VS2

Application programs being converted to the DL/I environment may be written in COBOL, PL/I or Assembler language.

The following must be used for COBOL programs: DOS Full American National Standard (ANS) COBOL Compiler Version 3 (5736-CB2) and Full ANS COBOL Library (5736-LM2), or DOS/VS COBOL Compiler (5746-CB1) or OS Full ANS COBOL Compiler Version 3 (5734-CB1) or Version 4 (5734-CB2).

DOS PL/I programs must be compiled by the PL/I Optimizing Compiler and Libraries (5736-PL3) or by the PL/I Optimizing Compiler (5736-PL/I) - PL/I Resident Library (5734-LM4), PL/I Transient Library (5734-LM5).

OS PL/I programs must be compiled by the PL/I Optimizing Compiler (5734-PL3) or by the PL/I Optimizing Compiler (5734-PL/I) - PL/I Resident Library (5734-LM4), PL/I Transient Library (5734-LM5).

All Assembler language programs must be reassembled. In the CICS environment, all COBOL and PL/I programs must be recompiled.

DOCUMENTATION: (available from Mechanicsburg)

General Information Manual (GH12-5116).

PROGRAM PRODUCTS

5748-XX8 - VM/BASIC SYSTEM EXTENSIONS

PURPOSE

VM/Basic System Extensions is designed for use by DOS/VS, DOS/VSE, VS1 and MVS users running under VM/370, and/or CMS users running on S/370 mdls 135, 135-3, 138, 145, 145-3, 155II, 158, 158-3, 158AP, 158MP (in uniprocessor mode and in MP mode with I/O attached to only one side), 165II, 168, 168-3, 168AP, 168MP (in uniprocessor mode and in MP mode with I/O attached to only one side), 3031, 3031AP, 3032, 3033, 3033AP and 3033MP (in uniprocessor mode and in MP mode with I/O attached to only one side) and on the 4321, 4331, 4341 and 4381 Processors.

HIGHLIGHTS

Improvements In Resource Management: A subset of the functions of the Resource Management PRPQ (5799-ARQ) is incorporated into the VM/Basic System Extensions program product. Specific improvements are:

Throughput Improvements: Throughput improvements may be achieved in the following environments:

- Systems with real storage bottlenecks
When a real storage bottleneck is indicated, the resource manager may reduce the effect and increase the level of multiprogramming. This is achieved through the use of improved scheduling and paging algorithms, which give rise to smaller working set size estimates and higher page steal ratios. The net result is that a given real storage size appears more able to contain the given load with improved throughput.
- Storage bound systems with long running non-interactive users and high multiprogramming levels.
Such systems devote a large part of their paging activity to swapping the long running users in and out of storage as each is given a timeslice. The resource manager reduces this paging overhead by swapping the longest running users into real storage less frequently but keeping them there for longer periods. This may lower the overall level of paging activity with accompanying reduction in supervisor overhead and some increased throughput.

Improved Response to Trivial Interactions: Improved response to trivial interactions may be achieved in the following environments.

- Terminal interactions occur for both single trivial commands and nontrivial transactions during terminal I/O.
The resource manager distinguishes between the two types of transactions by tracking the resource consumption rate and giving top priority to the smallest consumer.
- Transactions are characterized by a wide range of resource requirements.
The fair share algorithms of the resource manager, which are effective in both compute-bound and paging-bound environments, distinguish between the different resource requirements of the users. Consequently, a better interactive/noninteractive split is achieved with improved responsiveness to trivial transactions.

Installation Management Control: Installation management will have more control over the services provided in the following environments:

- Multiple users require a specified percentage of the processor.
The SET FAVOR command with percentage option may now be specified for more than one user.
- CMS batch facilities running non-interactively.
Directory priority controls may now be utilized to make CMS batch facilities either fully non-interactive to minimize impact on the system, or fully interactive to encourage its use.

Addition To ECPS: ECPS for VM/370 on S/370 mdl 135-3, 138, 145-3 and 148 has been enhanced to accelerate the processing of the DIAGNOSE Interface between a virtual machine and CP. Since CMS is a heavy user of DIAGNOSE, the CMS user may receive improved performance.

CMS Support Of Labelled Tapes: CMS has been modified to process labelled tapes as follows:

VOL 1 Labels

- Processed by DOS or OS OPEN simulation routines.
- Processed by CMS TAPPDS or TAPEMAC commands.
- Displayed or written by CMS TAPE command.

HDR Labels

- Processed by DOS or OS OPEN simulation routines: Exits are provided to allow access to user-written routines to Process standard user (UHL) labels.
- Processed by CMS TAPPDS or TAPEMAC commands.
- Processed by a new CMS macro designed for use in Assembler language programs in conjunction with other CMS tape macros.

EOF/EOV Labels

- Processed by DOS or OS CLOSE simulation routines: Exits are provided to allow access to user-written routines to process standard user (UTL) labels.
- Processed by a new CMS macro designed for use in Assembler language programs in conjunction with other CMS tape macros.

Nonstandard Labels

- User exits are provided in DOS or OS OPEN and CLOSE simulation routines and in TAPPDS or TAPEMAC commands to allow access to user-written routines to process nonstandard labels.

Limitations: The following are not supported:

- Label processing for tapes which are read backwards.
- Multi-volume files.
- ASCII labels.

CMS Unlabeled Tapes: CMS will process unlabeled tapes.

Spool Files To Tape: This support will provide Class D commands which enables the spooling operator to store to, or retrieve from, tape those unit record output files which he wishes to schedule for real output at some later time on the VM/370 system. The restored files will retain the same characteristics as the original file, but will be assigned new spool-ids to avoid duplicate identification within the spooling system. The spooling operator can store or retrieve spool files selectively (by class or spool-id) or completely. An option is provided to allow the operator to scan the tape.

Virtual Machine Storage Preservation: VM/370's control program will be modified so that during a VM/370 warm start or an abnormal termination by VM/370 of specified virtual machines, the user's virtual storage will be preserved. Specifically, virtual machine IPL will be changed so that it no longer uses a page of the user's virtual storage, and the V = R area under VM/370 will be preserved during VM/370 warm start. In addition, specific virtual machines can be identified such that at VM/370 abend, or when that virtual machine is abnormally terminated by VM/370, the registers and main storage for that virtual machine will be saved.

The improved integrity of virtual storage is particularly beneficial to IMS/VS users running in a virtual machine who need to have storage preserved so that they can run a standalone program to recover IMS/VS Log Buffers. In addition, standalone dumps that are IPL'd from an external storage device will now accurately reflect the user's virtual storage, because VM/370 will no longer use a page of that storage.

Spooling of Accounting Records: This support provides the installation with the ability to spool accounting data to a designated virtual machine with a designated class. The data can be spooled to provide punched output or spooled to a virtual machine's reader for additional processing. This eliminates the need to have a real card punch online at all times to get accounting records.

Virtual Machine Interface To Allow Programs To Use The Full Facilities Of a 3270 Type Terminal: The diagnose interface has been extended to allow a virtual machine user to share a display terminal with CP. When the user has control of the screen most of the facilities of the device are available.

Support for the 3262 Printer mdls 1 and 11: The 3262 mdls 1 and 11 are, respectively, 650 and 325 line-per-minute printers.

Support For The Enhanced 3270 Display Terminals: The following enhanced 3270 terminals are supported:

- 3274 Control Unit mdl 1B (3272 compatible)
- 3274 Control Unit mdl 1C (TP - BSC only)
- 3276 Control Unit/Display Station mdl 2 (1920 character screen)
- 3276 Control Unit/Display Station mdl 3 (2560 character screen)
- 3276 Control Unit/Display Station mdl 4 (3440 character screen)
- 3278 Display Station mdl 2 (1920 character screen)
- 3278 Display Station mdl 3 (2560 character screen)
- 3278 Display Station mdl 4 (3440 character screen)
- 3268/3287/3289 Printer (copy command support only)

This includes support for the 96-character set (94 characters plus space and null), and PF keys 13 through 24.

Interactive Help Facility Under CMS: The help facility is an informational, online display service available at the CMS terminal to guide the user in using CP and CMS commands and reacting to CP and CMS messages. As a result, the user can, in most cases, avoid referencing manuals during CMS sessions.

CMS File System Enhancements: The file system enhancements will provide the user with a more efficient and flexible file system. Specifically, the enhancements are:

- Removal of the current limitations on the size of CMS-disks and the number of files per CMS-disk.
- Support for physical block sizes of 800, 1024, 2048 and 4096 bytes.

PROGRAM PRODUCTS

VM/Basic System Extensions (cont'd)

- Efficient handling of variable length files.
- Selective directory updating.
- Fixed Block Mode (FBM) device type support.
- Concurrent open for read and write of CMS files.
- CMS may access one system disk and up to 25 minidisks concurrently.

A CMS Tape Command Performance Improvement: A large block-size (4K) is supported for tape dump/load to decrease overhead.

CMS/DOS Uplevel To DOS/VSE: The CMSDOS DCSS provides DOS/VSE support in CMS. This segment processes all DOS/VSE requests. Since the CMSAMS and CMSVSAM DCSS have been updated to depend upon the DOS/VSE SVCs, and to support VSE/VSAM and DOS/VSE files on FBM devices, the CMSDOS DCSS has been updated to support these SVCs and devices.

CMS Use Of CP Page Management Interfaces: CMS now takes advantage of the existing page control interfaces to better communicate the true working set of pages to CP, thus better utilizing the page frame resources of the real machine and improving performance.

CP Performance Improvements: The CP changes are:

- The storage management algorithm for returning free storage to the dynamic area has been modified. A check is now made every hour and upon a user logging off to determine if any dynamic area pages obtained for free storage purposes can be returned to the dynamic area.
- The set favored command has been changed to accept a percentage specification of 100. This specification will be handled as a special case by the scheduler where the user will be kept at the top of the run list.
- CMS disk I/O (Diagnose 18) has been modified to take advantage of ECPS:VM/370 for CCW translation. The improvement is available with the existing ECPS:VM/370 assist on the 3135-3, 3138, 3145-3 and 3148 Processors. The improvement is also available with the ECPS:VM/370 assist on the 4341 and 4381 Processors.

Small CP Option: Small CP option reduces real memory requirements for CP which makes more pageable storage available to virtual machines and is designed for the entry level system.

Enhanced Support for the 3270 Information Display System

APL Text Feature: The 3270 APL-TEXT feature provides the 3270 user with access to the full APL, TEXT and EBCDIC character sets. This makes it possible for the user to interact with the VS APL program product as well as text processing applications which run under CMS. This support extends the APL-TEXT function to users with 3274 Controllers/3278 Display Stations.

Intensified Display: VM/370 will take advantage of the intensified display feature of the 3270 Information Display System as follows:

- 1) The "Current Line" of the CMS Editor will be intensified.
- 2) All CMS Edit messages will be intensified.
- 3) An application program may supply a 3270 Start Field order and an attribute byte in a DIAGNOSE 58, CCW Code 19 (Virtual Console Interface) data stream. This provides an application program with the ability to define a field as normal intensity, intensified or nondisplay.
- 4) Messages from the system operator or other user will be intensified.
- 5) The redisplay of user input will be intensified so that it may be distinguished from output. The SET command will activate or deactivate intensification of input redisplay.

Support For The 3289 Printer Model 4: The 3289 mdl 4 is a 400 line-per-minute printer and functionally compatible with the 3203 Printer mdl 4 (except in the area of UCS buffer load).

Support For The 8809 Tape: The 8809 is a two-speed tape drive (12.5 ips and 100 ips). It will be supported at 12.5 ips in VM/370. The standalone dump-restore utility (DDR) supports the device at 100 ips to provide high-speed backup capability when executing on a standalone processor and 3310/3370 DASD.

Support For The 3310/3370 Direct Access Devices: The 3310/3370 are direct access devices that use Fixed Block Mode. The Direct Access Storage Compatibility feature #7901 of the IBM 4331 Processor for emulation of 2314, 3330 and 3340 format data on the 3310 or the 3370 is supported. VM/370 supports 3310 or 3370 volumes containing emulated data which are dedicated to a guest operating system other than VM/370 or CMS.

CUSTOMER RESPONSIBILITIES

In addition to the responsibilities in the VM/370 SCP pages under the heading "Customer Responsibilities", the customer is responsible for ordering and installing the latest level of VM/370.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

VM/Basic System Extensions Program Product is designed to run on IBM S/370 Processors 135, 135-3, 138, 148, 155II, 158-3, 158AP, 158MP, 165II, 168, 168-3, 168AP and 168MP and on the IBM 3031, 3031AP, 3032, 3033, 3033AP, 3033MP and 4331, 4341 and 4381 Processors. On MP mdls, it runs in uniprocessor mode and in MP mode with I/O attached to only one side. VM/Basic System Extensions is recommended for DOS/VS, DOS/VSE, MVS, VS1 or CMS users who run under VM/370 for testing, conversion or production.

VM/Basic System Extensions requires a minimum user available main storage of 384K, which will support a mixed-mode environment.

VM/Basic System Extensions supports a cardless environment. By using the facility to spool accounting records and altering the system generation procedures to use tape devices, the requirement for a card reader/punch can be eliminated. Specific details are contained in the TNL update to the *VM/370 Planning and System Generation Guide* (TNL order number SN25-0499). Specific details relevant to the minimum configuration required for hardware maintenance should be directed to the Field Engineering Division.

ECPS:VM/370 Support: VM/370 Basic System Extensions Release 2 is compatible with ECPS:VM/370 Level 19 on the 4331, 4341 and 4381 Processors. This support will be included in the initial shipment of the 4321, 4331, 4341 and 4381 Processors.

VM/370 Basic System Extensions Release 2 is also compatible with ECPS:VM/370 Level 18 on the 3135-3, 3138, 3145-3 and 3148 Processors. On these processors, the Level 18 support is the same as the support needed for Release 5 of VM/370. The appropriate ECPS:VM/370 support is provided by the following ECs:

- EC #149136 and later for the mdl 3135-3.
- EC #149136 and later for the mdl 3138.
- EC #356901 and later for the mdl 3145-3.
- EC #147710 and later for the mdl 3148.

VM/370 Basic System Extensions Release 2 will execute on these S/370 processors at other earlier EC levels, but the hardware assist will not be used.

SOFTWARE REQUIREMENTS

VM/Basic System Extensions Release 1 requires VM/370 Release 5 as a base. VM/Basic System Extensions Release 2 requires VM/370 Release 6 as a base.

RPQs ACCEPTED: No

PROGRAM PRODUCTS

5748-XX9 - DOCUMENT COMPOSITION FACILITY R2

PURPOSE

Document Composition Facility is a text processing application that promotes the use of computers in the preparation of printed materials. The Document Composition Facility consists of two parts: A formatter and general purpose document processor called SCRIPT/VS, and an optional feature called the Foreground Environment Feature. This optional feature enables the base program, SCRIPT/VS, to be used with the OS/VS2 (MVS) Time Sharing Option (TSO), the Advanced Text Management System-III Release 1.0 under CICS/VS, and the VM/370 Conversational Monitor System (CMS). The use of SCRIPT/VS in a batch environment requires the Document Library Facility program.

DESCRIPTION

SCRIPT/VS is a text processing program that provides for markup, full-page makeup, printing of text documents and a number of other document processing functions. It runs in several computer system environments:

- VM/370 CMS (Conversational Monitor System).
- ATMS-III Release 1.0 in CICS/VS.
- OS/VS2 (MVS) TSO (Time Sharing Option).
(TSO, ATMS-III and CMS operation require the Foreground Environment feature.)
- The batch environments of OS/VS1, OS/VS2 (MVS), and DOS/VS. (Requires the Document Library Facility program product 5748-XXE.) This environment can accept documents that have been communicated to the host system from standalone word-processing systems such as the Office System 6.

The text can be entered on terminals or displays using the editing facilities available for CMS, TSO, VSPC, ATMS-II, ATMS-III, ICCF or CICS systems. SCRIPT/VS can then be either run directly in the foreground environment of TSO or ATMS III or under CMS (with the Foreground Environment feature installed), or the text document can be submitted with JCL to invoke SCRIPT/VS in the batch environment of OS/VS2 (MVS), OS/VS1 or DOS/VS. In this case the Document Library Facility program product must be installed.

SCRIPT/VS formats text for printing on system printers such as the 3800 Printing Subsystem and on typewriter and display terminals with the Foreground Environment feature installed. With the 3800, SCRIPT/VS can format text in multiple character styles and sizes (called fonts). Thus, SCRIPT/VS provides flexible composition for printing on a computer printer as an alternative to using independent composition machines or sending composition jobs to an outside vendor.

SCRIPT/VS can also be used as a preprocessor to prepare documents for processing by other programs, such as formatters that support photocomposers.

SPECIAL SALES INFORMATION

The application area for these products is generally referred to as 'in-house publishing'. The type of users will range from end-users such as secretaries and problem solvers, to skilled DP users, to publications professionals. Many of these users currently handwrite their documents for secretarial typing.

For purposes of looking at how these different users may use the products, the application area of in-house publishing is described below in three segments which we have called: Application development documentation, office publishing and formal in-house publishing. The potential customer set in these three areas may overlap, but characteristics of each segment vary enough to warrant different approaches to marketing the Document Composition Facility and Document Library Facility program products.

Application Development Documentation: This segment represents the potential users of these products who are currently users of DP systems for either program development or problem solving purposes. Although they are using online terminals to interact with the processor for their current tasks, they often utilize offline secretarial typing services to document their programs or work. This documentation can now be produced effectively on the same system used for their online development work.

Potential customers include:

- Current users of SCRIPT/370 IUP (5796-PAF) or SCRIPT/370 Version 3 IUP (5796-PHL) in CMS, for whom SCRIPT/VS contains numerous enhancements.
- CMS users, especially the users of the Display Editing System for CMS IUP (5796-PJP), who will find additional benefit for text entry/edit by using full-screen 3270 support. The formatted text can be displayed back on the screen in either full screen or split screen mode.
- TSO users, especially those with the SPF (5740-XT2) or SPF-II (5740-XT8) full-screen editor program products, which ease the job of entering and editing the text document, and allow split

screen viewing of the formatted result along with the document source.

- VSPC users employing the VSPC editor facilities and the CICS users with the CICS Source Program Maintenance Online II FDP (5798-CFT) or ETSS/II FDP (5798-CLR) editor installed. They can enter and edit the document and then submit it with JCL to the Document Library Facility and SCRIPT/VS as a batch job. The formatted output can be directed back to the terminal for viewing.

In summary, the above mentioned interactive systems currently have editing facilities (some especially enhanced for text) making the users of these systems prime candidates to add document processing, complementing the other functions they are already performing on the terminal-based systems.

Office Publishing: There are a large number of potential users in office publishing who are generating pages for which SCRIPT/VS could be used. To identify these users is a little more time consuming than the application development documentation segment, because they may not be currently using their installation's DP equipment. Users of the ATMS-III (5740-XYL, 5746-XXU) program products can produce edited documents with ATMS and then invoke SCRIPT/VS directly, or submit the document to batch for formatting by SCRIPT/VS under the control of the Document Library Facility.

The current ATMS-II (5740-XXV, 5746-XXG) user may install SCRIPT/VS with the Document Library Facility in batch and send documents created on ATMS-II with its GML markup to SCRIPT/VS to benefit from the additional formatting functions and 3800 usage.

The other potential customers in this segment for these products are the users of word processing systems which can attach to the S/370 host computer.

One segment of potential users of these products are the 3730 Distributed Office Communication System customers. The 3730 System with Host Communication Support feature (#9285) provides support for a host-attached system that allows the 3730 System or 3730-3790 System to communicate with a user-written application program running in the host system. This application program can then invoke the Document Library Facility to store the document, and/or invoke the Document Composition Facility formatter to process the document. In this latter case, a document containing native Document Composition Facility controls will require some preprocessing by the user-written application. Documents containing other formatting controls (e.g., 3730 native controls) may require significant user-written conversion preprocessing. (See the *3730 System Description Manual* (GA33-3032) for an overview of the 3730 text controls.)

In addition, the Office System 6 or a Communicating Mag Card Selectric® typewriter can be used for standalone entry and edit of a document containing GML, and that document can then be submitted to the host (the IBM Office System 6 via RJE support and the CMCSST via direct 2741 attachment.)

Formal In-House Publishing: The 3800 Printing Subsystem installed and on-order base can be used to identify SCRIPT/VS candidates for this segment. Text processing with SCRIPT/VS further enhances the capabilities of the 3800. The 3800 can print multiple character styles, has some proportional spacing capabilities, prints at high speed, and with quality and appearance quite acceptable for many documents; every copy is an original. With the marketing support focus on benefits of using the 3800 as an output device, sell these customers on installing SCRIPT/VS. Usage of the 3800 is governed by the system control programming (SCP) present in the environment.

In addition, alternate interpretation of GML allows SCRIPT/VS to act as a preprocessor to another formatting program's controls. This allows SCRIPT/VS to be marketed to existing users of composition programs that drive photocomposers. These users can continue to utilize their composition programs for final copies, and yet use SCRIPT/VS for proofs and realize the benefits of GML for their document markup.

Application Benefits: For all of the applications in the preceding segments, the use of SCRIPT/VS has several advantages. These advantages are particularly evident in the following instances:

- When SCRIPT/VS is used with interactive text editors or word processing systems, manuscript preparation can be easier and quicker than it is with other methods, because these systems provide text entry, editing, and storage facilities. Revisions require minimal rework. Only affected portions of the source document have to be updated. SCRIPT/VS produces the new version with no need for additional layout work, retyping, page numbering, or proofreading.
- Once the text is in machine readable form, it is available for other applications. It can be duplicated, rearranged, and selected to produce a variety of reports and other output documents.
- Copies of the work can be made quickly at each stage of the process:
 - Review copies for the preparation of the manuscript.
 - Proof copies for evaluating the layout.

Document Composition Facility R2 (cont'd)

- Camera-ready copy for plate making (or multiple final copies, as printed by the computer).

The text originally entered in the computer with markup serves as the source for SCRIPT/VS preparation of printed output at every step of the process.

- When final copies as printed by the computer are used (for example, with the 3800 Printing Subsystem), copies can be printed in the precise quantities needed. In this case, the original quality is retained for each copy. Additional copies can be printed as needed, rather than stocked.
- SCRIPT/VS GML is helpful in publishing where consistency of publishing style is important. Besides standardization of style, these other GML benefits apply:
 - The ease and speed of marking up with GML.
 - The ready use of alternative sets of processing functions for producing copies for different purposes. For example, early review copies might be printed on an impact printer (or sometimes typed or displayed on a computer terminal), and proof copies and final copies might be printed on the 3800 Printing Subsystem, for use of different character styles and sizes.
- SCRIPT/VS itself can rearrange and select sections of a document for alternative outputs, when the document is marked up for conditional processing of the affected sections.
- Data from various documents can be included in one output document.

The various documents to be processed can be stored in the library of the system being used. They could also be stored using the Document Library Facility which provides document storage control and easy access by authorized users to the stored data.

HIGHLIGHTS OF DOCUMENT COMPOSITION FACILITY

The formatting functions provided by SCRIPT/VS include:

Page Layout: The user may specify page dimensions and layout through the use of the following functions:

- **Line Formatting:** The user may control how input lines are processed for output.
- **Vertical Spacing:** The user may control the amount of space left between output lines, including the reservation of space on the page.
- **Paragraphing:** The user may control the style of paragraphing (spacing between paragraphs and indentation).
- **Fonts:** When using the 3800 Printing Subsystem, the user may control which font is used for different portions of text, both in the body and in running headings and footings. Sixteen upper and lower case fonts including bold, italic and overstrike characters in different pitches are included with SCRIPT/VS on an "as is" basis.
- **Columns:** The user may specify, from 1 to 9, the number of columns as well as the size of each column and its placement on a page.
- **Margins:** The user may control the size of the top, bottom, left, and right margins. Title lines can be defined that will be put into the top and/or bottom margins.
- **Indentation:** The user may control indentation; for example, hanging indents, left or right margin indentation, and indent one line only. The indent left and right functions can be specified to take effect after a given vertical distance and remain in effect for a given vertical distance.
- **Headings and Footings:** The user may specify running headings and footings with or without page numbers and separate treatment for odd and even pages. Running headings and footings can be suppressed.

Head Levels: The user may specify up to seven head levels for distinctive formatting of headings for different levels of topics.

Table of Contents: The user may control optional generation of a table of contents and where it will be placed.

Back of the Book Index: Indexes can be automatically generated from index entries specified within the text at points of reference. Page numbers for these index entries are automatically generated.

Highlighting Phrases: The user may control how phrases are to be highlighted for emphasis.

Footnotes: SCRIPT/VS will save text which the user may designate as a footnote and will place it at the bottom of the page.

Hyphenation: The user may optionally cause words to be hyphenated at the end of output lines. SCRIPT/VS provides a dictionary of more than 10,000 American English words. Dictionary and stem processing support has been added for Dutch, French, German, Italian, Spanish, UK English, Canadian English, and Canadian French languages. Words

may be added to a supplementary dictionary for possible hyphenation in a particular document. In addition, users can now build their own dictionaries which can be catenated together with the base dictionary in user defined order.

Algorithmic Hyphenation: A user provided algorithmic hyphenation routine can be invoked if a word cannot be hyphenated using the base dictionary. An algorithmic hyphenation for American English words is provided with the product.

Printing of Portions of the Output Document: The user may control selective printing of formatted text.

Tab Handling: The user may specify the values of tabs. When formatting output lines, SCRIPT/VS tabs to the right to the prescribed tab stop. Up to 99 tab positions can be specified.

Box Drawing: Boxes can be constructed around text (which can still be formatted in the usual ways). The user may also draw boxes within boxes and vertical lines to separate columns of text within a box and horizontal lines to separate rows.

Keeping Text Together: SCRIPT/VS processing includes a way of keeping related pieces of text together to improve the appearance of output. The ability exists to specify floated text that may appear at the top or bottom of the specified page or column.

Use As A Subroutine: In a batch environment, with the Library installed with SCRIPT/VS, an application programmer may code programs to call SCRIPT/VS as a subroutine (for example, to format reports).

Production of STAIRS/VS Input: SCRIPT/VS can now produce formatted output suitable for input to the STAIRS/VS program products (OS-5740-XR1 and DOS-5746-XR4). It can then be indexed and retrieved with STAIRS inquiries. (Alternatively, this formatted output can be produced for proofing in a printed form).

Widow Control General Overstriking of Text: A string can be overstruck with a specified character or with itself.

Output lines can be numbered relative to the start of a page.

Character Translation: A single input character can be translated to a string.

Hexadecimal Character Processing: A hexadecimal character attribute allows the user to specify non-keyable hexadecimal characters for input to the formatter.

The user can stop the formatter and keep it from typing output until the user signals with the Attention key. (This is functionally similar to a mag card stop code capability.)

The general document handling functions of SCRIPT/VS include

Saving Input Lines for Subsequent Processing: The user may control whether certain input lines will be written to a data set or file.

Revision Codes: The user may control the placement of up to nine distinct revision codes in the left margin to indicate lines revised since a previous version of the document. (Revision codes may be used to flag lines for any reason.) The space available for the revision code can be controlled.

Spelling Verification: The user may control whether or not words are checked for spelling. SCRIPT/VS uses the same dictionary as for hyphenation. The additional words that can be specified for a particular document for hyphenation can also be used for spelling verification.

Imbedding of Separate Documents: The user may control how separate source documents are brought together for processing as a single document. Any number of source documents can be imbedded in the base source document.

Symbol and Macro Instruction Processing: The user may define symbols and macro instructions for substitution during processing. Symbols have many uses. For example, in tests for conditional processing, for cross-references to pages or figure numbers, for entering characters unavailable on the entry keyboard, and as abbreviations for lengthy, repetitive phrases.

Conditional Processing: The user may imbed controls within the document which will cause SCRIPT/VS to alter processing depending on the setting of the conditional parameters.

Destination of Output: The output document can be: (1) Stored as a file for possible later editing, printing, or as input to another program (for example, a formatter that supports a photocomposer) or; (2) printed on the device specified, which includes both impact and nonimpact system printers and with the Foreground Environment feature, display and typewriter terminals.

Tracing of Processing Actions: SCRIPT/VS formatter control words and each step of symbol and macro substitution in input lines can be traced.

Document Composition Facility R2 (cont'd)

GENERALIZED MARKUP LANGUAGE

To mark up a source document is to add information to it that enables a person or system to process it in some way. Facilities are provided to allow markup of the document with Generalized Markup Language (GML) and interpretation of that markup by SCRIPT/VS.

Document markup is the primary means of instructing computerized text processing systems, such as SCRIPT/VS, how a document is to be processed. A document can be marked up in two ways: With specific markup, which limits text processing to a particular application, or with generalized markup, which describes the structure and content of a source document, without respect to particular processing. The language used for generalized markup (GML) is descriptive; it provides the syntax and usage rules for developing the user's own vocabulary of tags for describing the parts of a document.

A starter set of GML tags is distributed with the Document Composition Facility program product on an "as is" basis to act as a sample and aid users in defining their own sets of GML tags for their installation's documents.

There are benefits of generalized markup when the only application will be text processing with SCRIPT/VS, and others when additional applications are anticipated.

Benefits of GML

Alternative GML Interpretation: A GML tag need not be limited to a single SCRIPT/VS interpretation. Each application could be satisfied by alternative GML interpretations, with no change to the source document or to the markup. The user controls the way GML is interpreted.

Ease of Document Markup: GML tags are easy to remember because they can consist of terms and abbreviations commonly used to describe a document. GML generally requires fewer characters than a corresponding complex sequence of control words. The result is faster markup and keying of the document.

Ease of Text Update: It's easy to update text marked up with GML. With GML, such things as the numbering of items in an ordered list is usually left to the formatter, which numbers the items automatically. Thus, when an item is inserted or deleted resequencing is automatic.

Uniformity of Formatting Style: Use of GML for all documents of a particular kind results in a single format for all those documents -- without the people who do markup even having to think about format. Similarly, a change in format for all the documents could be accomplished simply by changing the way GML is interpreted -- without anyone having to be retrained to do markup in a different way.

Alternative Text Processing Programs: SCRIPT/VS could be used to interpret generalized markup into the processing controls of text processing programs other than SCRIPT/VS. For example, they might be interpreted into the controls of another composition program which can produce output on a photocomposer.

Document Exchange: Documents with generalized markup can be processed by different groups or locations more easily than documents with the specific markup of a particular text processing program, because everyone might not use the same formatting style or output devices.

Data-base Applications: GML describes the contents of documents, so that programs can identify information in them. Programs could be written alone, or in conjunction with SCRIPT/VS processing, to extract information from documents for data base construction or to retrieve information for data base sharing.

Unique Customer Applications: Precisely because GML is general, it leaves the door open for numerous applications unique for a particular customer. GML designed for this purpose could, for instance, be used both for formatting printed output and for information retrieval.

HIGHLIGHTS of FOREGROUND ENVIRONMENT FEATURE

Terminal Support: After editing the document, the user may immediately invoke SCRIPT/VS and direct the output for immediate display at the terminal or to a file for later printing or editing.

Direct Interaction During Processing: In an interactive environment (CMS or TSO), the user may affect SCRIPT/VS as it processes by entering text and/or markup at a terminal. In effect, the terminal can be treated as an input file.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

Processors: In the interactive environments, Document Composition Facility with the Foreground Environment Feature installed operates under any IBM processor on which CMS, ATMS-III or TSO is installed.

In the batch environments with the Document Library Facility installed, the Document Composition Facility operates on all IBM S/370 mds 125 and above, 4300 Processors, and 3031 and above Processors. Floating point hardware is required.

Terminals: In foreground environments, SCRIPT/VS can accept input from or format output for the IBM 2741 and 3270 terminals, or terminals which are functionally equivalent at the data stream level that can be used with CMS, ATMS-III or TSO. The customer is responsible for establishing equivalency.

Printers: SCRIPT/VS output can be printed on the IBM 3800 Printing Subsystem with the multiple font capabilities.

Output can also be printed on the IBM 1403 Printer, 3211 Printer, 3203 Printer or any printer functionally equivalent at the data stream level to the above. The customer is responsible for establishing equivalency.

Storage Devices: The Document Composition Facility device support is provided by the environment in which it is operating.

Storage Estimates Guidelines

Real Storage: The Document Composition Facility uses the paging facilities of the operating system to run in less real storage than the amount of virtual storage required. The factors determining how much real storage they require are numerous and dependent on the installation. Therefore, no precise statement of real storage requirements can be made. The system programmer responsible for installing the programs will determine the amount of real storage to be used.

All storage estimates shown are in addition to those required for the system control programming and the particular online system.

Virtual Storage: Document Composition Facility requires approximately 220K bytes of virtual storage for the load modules. Since the code is reentrant, all users can share the same copy and therefore additional users do not require additional load module storage space.

Document Composition Facility also requires working storage to format documents. The actual size of working storage required depends on the complexity of the document to be formatted, but at least 60K bytes should be available.

Direct Access Storage: The approximate amount of direct access storage for the Document Composition Facility is shown below.

	CMS (Blocks)	Other* (Tracks)
Load Module Size	300	28
GML Macro Library	182	22
GML Profile	14	2
Hyphenation and Spelling Verification Libraries	780	72

* Estimates are based on a 3330-1.

SOFTWARE REQUIREMENTS

Document Composition Facility can be installed in:

- VM/370 CMS (Conversational Monitor System) Release 5.
- OS/VS2 (MVS) TSO (Time Sharing Option) with OS/VS2 (MVS) Release 3.8.
- ATMS-III Release 1.0 on CICS/VS Version 1 Release 4.

To run in these interactive environments, the Foreground Environment feature of Document Composition Facility is required.

The SCRIPT/VS Formatter of the Document Composition Facility can be installed with the Document Library Facility program product to allow batch formatting in the following virtual storage operating systems:

- OS/VS1 Release 7
- OS/VS2 (MVS) Release 3.8
- DOS/VSE

Note: This program is designed to work in the specified release levels and any subsequent releases and modifications unless otherwise stated. The 3800 Printing Subsystem requires the DOS/VSE 3800 Printing Subsystem Independent Release (5747-CC1) for operation with DOS/VSE.

Source code language is Assembler and is distributed as optional material. The DOS/VS user will require the OS/VS Assembler XF to assemble the optional material.

VSAM and Access Method Services are required when operating with the Document Library Facility.

DOCUMENT COMPATIBILITY and CONVERSION

Processing SCRIPT/370 Documents With SCRIPT/VS: Documents marked up for Installed User Program SCRIPT/370, Version 3 (5796-PHL), can be processed by the SCRIPT/VS formatter with little or no change to the source or in the output produced. If differences do occur, equivalent functions or results will usually be achieved by the use of user-written SCRIPT/VS macro processing functions. The long

PROGRAM PRODUCTS

Document Composition Facility R2 (cont'd)

form of SCRIPT/370 control words are not supported by SCRIPT/VS. EASYSCRIPT "tags" will be processed.

Processing ATMS Documents With SCRIPT/VS: Document Composition Facility contains a routine for converting documents in the Advanced Text Management System-II (ATMS-II) (5740-XXV or 5746-XXG), or ATMS-III Release 1.0 (5740-XYL, 5746-XXU) format for processing by SCRIPT/VS. The interface to this routine will be in the *Document Library Facility, which must be installed with SCRIPT/VS in a background environment for the routine to operate. The routine will convert most ATMS GML and control words into SCRIPT/VS GML, symbols and macros. The ATMS conversion macros are distributed on an "as is" basis.

Processing Release 1 Documents: The FILE option of the Document Composition Facility Release 2 SCRIPT command is now mutually exclusive with the PRINT and TERM keywords (where the DEV option should be used). The .UD control word will cause only blanks not to be underscored.

PROGRAM PRODUCTS

5748-XX9 - DOCUMENT COMPOSITION FACILITY R3

PURPOSE

Document Composition Facility is a text processing application that promotes the use of computers in the preparation of printed materials. The Document Composition Facility consists of two parts; a formatter and general purpose document processor called SCRIPT/VS, and an optional feature called the Foreground Environment feature. This optional feature enables the base program, SCRIPT/VS, to be used with the OS/VS2 (MVS) Time Sharing Option (TSO), the Advanced Text Management System-III Release 2.0 under CICS/VS, and the VM/370 Conversational Monitor System (CMS). The use of SCRIPT/VS in a batch environment requires the Document Library Facility program.

DESCRIPTION

SCRIPT/VS is a text processing program that provides for markup, full-page makeup, printing of text documents and a number of other document processing functions. It runs in several computer system environments:

- VM/370 CMS (Conversational Monitor System).
- ATMS-III Release 2.0 in CICS/VS.
- OS/VS2 (MVS) TSO (Time Sharing Option).
(TSO, ATMS-III and CMS operation require the Foreground Environment feature.)
- The batch environments of OS/VS2 (MVS) and DOS/VSE. (Requires the Document Library Facility program product 5748-XXE.) This environment can accept documents that have been communicated to the host system from stand-alone word-processing systems such as the 6580 Displaywriter.

The text can be entered on terminals or displays using the editing facilities available for CMS, TSO, VSPC, ATMS-II, ATMS-III, ICCF or CICS systems. SCRIPT/VS can then be either run directly in the foreground environment of TSO or ATMS III or under CMS (with the Foreground Environment feature installed), or the text document can be submitted with JCL to invoke SCRIPT/VS in the batch environment of OS/VS2 (MVS) or DOS/VSE. In this case the Document Library Facility program product must be installed.

SCRIPT/VS can format documents for the 4250 Printer. The full range of typographic fonts for the 4250 can be used to produce fully composed, camera-ready pages. Raster images (e.g., as produced by GDDM Release 3) can be included. Thus, SCRIPT/VS provides flexible composition for printing on a computer printer as an alternative to using independent composition machines or sending composition jobs to an outside vendor.

SCRIPT/VS formats text for printing on system printers such as the 3800 Printing Subsystem and on typewriter and display terminals with the Foreground Environment feature installed. With the 3800, SCRIPT/VS can format text in multiple character styles and sizes (called fonts).

SCRIPT/VS can also be used as a preprocessor to prepare documents for processing by other programs, such as formatters that support photocomposers.

SPECIAL SALES INFORMATION

The application area for these products is generally referred to as 'in-house publishing'. The type of users will range from end-users such as secretaries and problem solvers, to skilled DP users, to publications professionals. Many of these users currently handwrite their documents for secretarial typing. For purposes of looking at how these different users may use the products, the application area of in-house publishing is described below in three segments which we have called: Application development documentation, office publishing and formal in-house publishing. The potential customer set in these three areas may overlap, but characteristics of each segment vary enough to warrant different approaches to marketing the Document Composition Facility and Document Library Facility program products.

Application Development Documentation: This segment represents the potential users of these products who are currently users of DP systems for either program development or problem solving purposes. Although they are using online terminals to interact with the processor for their current tasks, they often utilize offline secretarial typing services to document their programs or work. This documentation can now be produced effectively on the same system used for their online development work.

Potential customers include:

- Current users of SCRIPT/370 IUP (5796-PAF) or SCRIPT/370 Version 3 IUP (5796-PHL) in CMS, for whom SCRIPT/VS contains numerous enhancements.
- CMS users, especially the users of the XEDIT or ISPF editors, who will find additional benefit for text entry/edit by using full-screen 3270 support. The formatted text can be displayed back on the screen in either full-screen or split-screen mode.

- TSO users, especially those with the ISPF full-screen editor program product, which eases the job of entering and editing the text document, and allows split-screen viewing of the formatted result along with the document source.
- VSE users employing the ICCF editor facilities. They can enter and edit the document and then submit it with JCL to the Document Library Facility and SCRIPT/VS as a batch job. The formatted output can be directed back to the terminal for viewing.

In summary, the above mentioned interactive systems currently have editing facilities (some especially enhanced for text) making the users of these systems prime candidates to add document processing, complementing the other functions they are already performing on the terminal-based systems.

Office Publishing: There are a large number of potential users in office publishing who are generating pages for which SCRIPT/VS could be used. To identify these users is a little more time consuming than the application development documentation segment, because they may not be currently using their installation's DP equipment. Users of the ATMS-III (5740-XYL, 5746-XXU) program products can produce edited documents with ATMS and then invoke SCRIPT/VS directly, or submit the document to batch for formatting by SCRIPT/VS under the control of the Document Library Facility.

The current ATMS-II (5740-XXV, 5746-XXG) user may install SCRIPT/VS with the Document Library Facility in batch and send documents created on ATMS-II with its GML markup to SCRIPT/VS to benefit from the additional formatting functions and 3800 usage.

The other potential customers in this segment for these products are the users of word processing systems which can attach to the S/370 host computer.

One segment of potential users of these products are the 3730 Distributed Office Communication System customers. The 3730 System with Host Communication Support feature (#9285) provides support for a host-attached system that allows the 3730 System or 3730-3790 System to communicate with a user-written application program running in the host system. This application program can then invoke the Document Library Facility to store the document, and/or invoke the Document Composition Facility formatter to process the document. In this latter case, a document containing native Document Composition Facility controls will require some preprocessing by the user-written application. Documents containing other formatting controls (e.g., 3730 native controls) may require significant user-written conversion preprocessing. (See the 3730 System Description Manual, GA33-3032 for an overview of the 3730 text controls.)

In addition, the 6580 Displaywriter, Office System 6 or a Communicating Mag Card Selectric® typewriter can be used for stand-alone entry and edit of a document containing GML, and that document can then be submitted to the host (the 6580 Displaywriter via 3270 emulation or via RJE support, the Office System 6 via RJE support and the CMCST via direct 2741 attachment.)

Formal In-House Publishing: Any customers using photocomposition equipment, or vending page make-up outside their company, are candidates for this segment. Use of SCRIPT/VS with the 4250 Printer will, in many cases, provide a cost effective alternative to in-house or vended photo composition. The ability to electronically merge graphic data in raster image form (e.g., produced by GDDM Release 3) will allow the user to avoid the traditional and costly cut-and-paste step.

In addition, the higher quality (240 pel) resolution of the 3800 Printing Subsystem mdl 3 (in compatibility mode) can be used for text-only page composition. The new fonts on the 3800 allow it to be used more effectively, either alone or with the 6670 Information Distributor, for high volume proofing of pages which might ultimately be printed on the 4250.

Application Benefits: For all of the applications in the preceding segments, the use of SCRIPT/VS has several advantages. These advantages are particularly evident in the following instances:

- When SCRIPT/VS is used with interactive text editors or word processing systems, manuscript preparation can be easier and quicker than it is with other methods, because these systems provide text entry, editing, and storage facilities. Revisions require minimal rework. Only affected portions of the source document have to be updated. SCRIPT/VS produces the new version with no need for additional layout work, retyping, page numbering, or proofreading.
- Once the text is in machine-readable form, it is available for other applications. It can be duplicated, rearranged, and selected to produce a variety of reports and other output documents.
- Copies of the work can be made quickly at each stage of the process:
 - Review copies for the preparation of the manuscript.
 - Proof copies for evaluating the layout.

Document Composition Facility R3 (cont'd)

- Camera-ready copy for plate making (or multiple final copies, as printed by the computer).

The text originally entered in the computer with markup serves as the source for SCRIPT/VS preparation of printed output at every step of the process.

Camera-ready masters can be conveniently produced (e.g., on the 4250) avoiding the more costly and time-consuming photocomposition step, and also avoiding the cut-and-paste step by electronically merging rastered graphics.

- When final copies as printed by the computer are used (for example, with the 3800 Printing Subsystem or 6670 Information Distributor), copies can be printed in the precise quantities needed. In this case, the original quality is retained for each copy. Additional copies can be printed as needed, rather than stocked.
- SCRIPT/VS GML is helpful in publishing where consistency of publishing style is important. Besides standardization of style, these other GML benefits apply:
 - The ease and speed of marking up with GML.
 - The ready use of alternative sets of processing functions for producing copies for different purposes. For example, early review copies might be printed on an impact printer (or sometimes typed or displayed on a computer terminal), and proof copies and final copies might be printed on the 3800 Printing Subsystem, for use of different character styles and sizes.
- SCRIPT/VS itself can rearrange and select sections of a document for alternative outputs, when the document is marked up for conditional processing of the affected sections.
- Data from various documents can be included in one output document.

The various documents to be processed can be stored in the library of the system being used. They could also be stored using the Document Library Facility which provides document storage control and easy access by authorized users to the stored data.

HIGHLIGHTS OF DOCUMENT COMPOSITION FACILITY

The formatting functions provided by SCRIPT/VS include:

Device Support for the 4250: New functions in the SCRIPT/VS formatter allow page layout and composition functions to take advantage of the all-points-addressable, multiple fonts, and raster image-merge functions of the 4250 Printer.

Page Layout: The user may specify page dimensions and layout through the use of the following functions:

- **Line Formatting:** The user may control how input lines are processed for output.
- **Vertical Spacing:** The user may control the amount of space left between output lines, including the reservation of space on the page.
- **Intercharacter Space Control:** On the 4250, the user can specify the amount of additional space to be placed between characters.
- **Word Space and Line Space Control:** The user can control the amount of space to be inserted between words and lines. The ranges for word and interline spacing, used by the Document Composition Facility for horizontal and vertical justification, can be specified by the user.
- **Explicit Inline White Space Generation:** Additional white space can be inserted into the formatted line. The white space is treated as a single required blank.
- **Explicit Baseline Positioning:** On the 4250, the baseline can be offset by a positive or negative value, for example, for superscripting, subscripting, or setting of fractions.
- **Paragraphing:** The user may control the style of paragraphing (spacing between paragraphs and indentation).
- **Fonts:** Any of the numerous fully proportional or monospace fonts available with the 4250 Printer can be used when composing a document. Users can specify the font library from which the fonts are to be selected. When using the 3800 Printing Subsystem, the user may control which font is used for different portions of text, both in the body and in running headings and footings.
- **Proportional Spacing:** On the 4250, both horizontal and vertical spacing are fully proportional. Character widths and heights will be measured during composition, and multiples of the device's space units will be used for justifying lines and/or balancing columns of text.
- **Columns:** The user may specify, from 1 to 9, the number of columns as well as the size of each column and its placement on a page.
- **Format Vertical:** Text within columns can be centered, top-aligned, bottom-aligned or justified.

- **Page Segment Inclusion:** On the 4250, when requested by the user, information is placed in the composed output which will allow merging of a rastered graphic image (e.g., created by GDDM Release 3) or other raster image into the document at printing time.
- **Margins:** The user may control the size of the top, bottom, left, and right margins. Title lines can be defined that will be put into the top and/or bottom margins.
- **Indentation:** The user may control indentation; for example, hanging indents, left or right margin indentation, and indent one line only. The indent left and right functions can be specified to take effect after a given vertical distance and remain in effect for a given vertical distance.
- **Headings and Footings:** The user may specify running headings and footings with or without page numbers and separate treatment for odd and even pages. Running headings and footings can be suppressed.

Head Levels: The user may specify up to seven head levels for distinctive formatting of headings for different levels of topics.

Input Line Prefixing: Individual input lines can be prefixed with control words, macros, or any string, depending upon control characters found at the beginning of the input line.

Named Areas: Specified named areas (for inclusion of text or raster segment) can be located anywhere on the page, relative to the page, body or current section. Areas can be added to the top or bottom of an area, they can be replaced, or they can be deleted.

Table of Contents: The user may control optional generation of a table of contents and where it will be placed.

Back of the Book Index: Indexes can be automatically generated from index entries specified within the text at points of reference. Page numbers for these index entries are automatically generated.

Highlighting Phrases: The user may control how phrases are to be highlighted for emphasis.

Footnotes: SCRIPT/VS will save text which the user may designate as a footnote and will place it at the bottom of the page.

Hyphenation: The user may optionally cause words to be hyphenated at the end of output lines. SCRIPT/VS provides a dictionary of more than 10,000 American English words. Dictionary and stem processing support has been added for Dutch, French, German, Italian, Spanish, UK English, Canadian English, and Canadian French languages. Words may be added to a supplementary dictionary for possible hyphenation in a particular document. In addition, users can now build their own dictionaries which can be catenated together with the base dictionary in user-defined order.

Algorithmic Hyphenation: A user-provided algorithmic hyphenation routine can be invoked if a word cannot be hyphenated using the base dictionary. An algorithmic hyphenation for American English words is provided with the product.

Printing of Portions of the Output Document: The user may control selective printing of formatted text.

Tab Handling: The user may specify the values of tabs. When formatting output lines, SCRIPT/VS text can be centered, right or character-aligned, as well as left-aligned, at specified tab positions within a line. Up to 99 tab positions can be specified.

Box Drawing: Boxes can be constructed around text (which can still be formatted in the usual ways). The user may also draw boxes within boxes and vertical lines to separate columns of text within a box and horizontal lines to separate rows.

Vertical and Horizontal Rules: Rules (of varying thickness on the 4250) can be defined for use with automatically-generated boxes, or for use as manually-placed horizontal and vertical lines.

Keeping Text Together: SCRIPT/VS processing includes a way of keeping related pieces of text together to improve the appearance of output. The ability exists to specify floated text that may appear at the top or bottom of the specified page or column.

Use As A Subroutine: In a batch environment, with the Library installed with SCRIPT/VS, an application programmer may code programs to call SCRIPT/VS as a subroutine (for example, to format reports).

Production of STAIRS/VS Input: SCRIPT/VS can now produce formatted output suitable for input to the STAIRS/VS program products (OS, 5740-XR1 and DOS, 5746-XR4). It can then be indexed and retrieved with STAIRS inquiries. (Alternatively, this formatted output can be produced for proofing in a printed form.)

Widow Control General Overstriking of Text: A string can be overstruck with a specified character or with itself.

Output lines can be numbered relative to the start of a page.

Character Translation: A single input character can be translated to a string.

Document Composition Facility R3 (cont'd)

Hexadecimal Character Processing: A hexadecimal character attribute allows the user to specify non-keyable hexadecimal characters for input to the formatter.

The user can stop the formatter and keep it from typing output until the user signals with the Attention key. (This is functionally similar to a mag card stop code capability.)

The general document handling functions of SCRIPT/VS include:

Saving Input Lines for Subsequent Processing: The user may control whether certain input lines will be written to a data set or file.

Revision Codes: The user may control the placement of up to nine distinct revision codes in the left margin to indicate lines revised since a previous version of the document. (Revision codes may be used to flag lines for any reason.) The space available for the revision code can be controlled.

Spelling Verification: The user may control whether or not words are checked for spelling. SCRIPT/VS uses the same dictionary as for hyphenation. The additional words that can be specified for a particular document for hyphenation can also be used for spelling verification.

Imbedding of Separate Documents: The user may control how separate source documents are brought together for processing as a single document. Any number of source documents can be imbedded in the base source document.

Symbol and Macro Instruction Processing: The user may define symbols and macro instructions for substitution during processing. Symbols have many uses. For example, in tests for conditional processing, for cross-references to pages or figure numbers, for entering characters unavailable on the entry keyboard, and as abbreviations for lengthy, repetitive phrases.

Conditional Processing: The user may imbed controls within the document which will cause SCRIPT/VS to alter processing depending on the setting of the conditional parameters.

Destination of Output: The output document can be: (1) Stored as a file for possible later editing, printing, or as input to another program (for example, a formatter that supports a photocomposer) or; (2) printed on the device specified, which includes both impact and nonimpact system printers and with the Foreground Environment feature, display and typewriter terminals.

Tracing of Processing Actions: SCRIPT/VS formatter control words and each step of symbol and macro substitution in input lines can be traced.

GENERALIZED MARKUP LANGUAGE

To mark up a source document is to add information to it that enables a person or system to process it in some way. Facilities are provided to allow markup of the document with Generalized Markup Language (GML) and interpretation of that markup by SCRIPT/VS.

Document markup is the primary means of instructing computerized text processing systems, such as SCRIPT/VS, how a document is to be processed. A document can be marked up in two ways: With specific markup, which limits text processing to a particular application, or with generalized markup, which describes the structure and content of a source document, without respect to particular processing. The language used for generalized markup (GML) is descriptive; it provides the syntax and usage rules for developing the user's own vocabulary of tags for describing the parts of a document.

A starter set of GML tags is distributed with the Document Composition Facility program product to act as a sample and aid users in defining their own sets of GML tags for their installation's documents. The GML starter set is now included in the program service coverage for the Document Composition Facility Release 3 product. This service applies only to the unmodified starter set. To simplify translation, all literal text strings inserted by the GML starter set into the document, and all messages, are each consolidated into a single macro.

There are benefits of generalized markup when the only application will be text processing with SCRIPT/VS, and others when additional applications are anticipated.

Benefits of GML

Alternative GML Interpretation: A GML tag need not be limited to a single SCRIPT/VS interpretation. Each application could be satisfied by alternative GML interpretations, with no change to the source document or to the markup. The user controls the way GML is interpreted.

Ease of Document Markup: GML tags are easy to remember because they can consist of terms and abbreviations commonly used to describe a document. GML generally requires fewer characters than a corresponding complex sequence of control words. The result is faster markup and keying of the document.

Ease of Text Update: It's easy to update text marked up with GML. With GML, such things as the numbering of items in an ordered list is usually left to the formatter, which numbers the items automatically. Thus, when an item is inserted or deleted, resequencing is automatic.

Uniformity of Formatting Style: Use of GML for all documents of a particular kind results in a single format for all those documents -- without the people who do markup even having to think about format. Similarly, a change in format for all the documents could be accomplished simply by changing the way GML is interpreted -- without anyone having to be retrained to do markup in a different way.

Alternative Text Processing Programs: SCRIPT/VS could be used to interpret generalized markup into the processing controls of text processing programs other than SCRIPT/VS. For example, they might be interpreted into the controls of another composition program which can produce output on a photocomposer.

Document Exchange: Documents with generalized markup can be processed by different groups or locations more easily than documents with the specific markup of a particular text processing program, because everyone might not use the same formatting style or output devices.

Data-base Applications: GML describes the contents of documents, so that programs can identify information in them. Programs could be written alone, or in conjunction with SCRIPT/VS processing, to extract information from documents for data base construction or to retrieve information for data base sharing.

Unique Customer Applications: Precisely because GML is general, it leaves the door open for numerous applications unique for a particular customer. GML designed for this purpose could, for instance, be used both for formatting printed output and for information retrieval.

HIGHLIGHTS of FOREGROUND ENVIRONMENT FEATURE

Terminal Support: After editing the document, the user may immediately invoke SCRIPT/VS and direct the output for immediate display at the terminal or to a file for later printing or editing.

Direct Interaction During Processing: In an interactive environment (CMS or TSO), the user may affect SCRIPT/VS as it processes by entering text and/or markup at a terminal. In effect, the terminal can be treated as an input file.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

Processors: In the interactive environments, the Document Composition Facility formatter (SCRIPT/VS) with the Foreground Environment feature installed operates under any processor which IBM has announced as specifically supporting ATMS-III, VM/CMS SP 1.1 or MVS/TSO SP 1.3.0.

In the batch environments with the Document Library Facility installed, the Document Composition Facility operates on IBM S/370 mdls 138 and above, 4300 Processors, and on the 3031 and above Processors, as specifically supported by OS/VS2 MVS SP 1.3.0 and VSE AF3. Floating-point hardware is required.

Terminals: In foreground environments, SCRIPT/VS can accept input from or format output for the IBM 2741 and 3270 terminals, or terminals which are functionally equivalent at the data stream level that can be used with CMS, ATMS-III or TSO. The customer is responsible for establishing equivalency.

Printers: SCRIPT/VS can format output for the IBM 4250 Printer taking advantage of its unique functions. SCRIPT/VS output can be printed on the IBM 3800 Printing Subsystem mdl 1 and mdl 3 (in Compatibility Mode under MVS only) with the multiple font capabilities.

Output can also be printed on the IBM 1403 Printer, 3211 Printer, 3203 Printer or any printer functionally equivalent at the data stream level to the above. The customer is responsible for establishing equivalency.

Storage Devices: The Document Composition Facility device support is provided by the environment in which it is operating.

Storage Estimates Guidelines

Real Storage: The Document Composition Facility uses the paging facilities of the operating system to run in less real storage than the amount of virtual storage required. The factors determining how much real storage they require are numerous and dependent on the installation. Therefore, no precise statement of real storage requirements can be made. The system programmer responsible for installing the programs will determine the amount of real storage to be used.

All storage estimates shown are in addition to those required for the system control programming and the particular online system.

Virtual Storage: Document Composition Facility requires approximately 245K bytes of virtual storage for the load modules. Each spelling verification dictionary included in the SCRIPT/VS load module increases its size by an additional 65K bytes. Dictionaries that are not included in the SCRIPT/VS load module are dynamically loaded as needed in all environments. Since the code is reentrant, all users can share the same copy and therefore additional users do not require additional load module storage space.

Document Composition Facility also requires working storage to format documents. The actual size of working storage required depends on the

PROGRAM PRODUCTS

Document Composition Facility R3 (cont'd)

complexity of the document to be formatted, but at least 100K bytes should be available.

Direct Access Storage: The approximate amount of direct access storage for the Document Composition Facility is shown below.

	CMS* (Blocks)	Other** (Tracks)
Load Module Size	450	45
GML Macro Library	400	65
GML Profile	75	20
Hyphenation and Spelling Verification Libraries	2,200	200

* Based on CMS 800-byte block formatted DASD.

** Estimates are based on a 3330-1.

SOFTWARE REQUIREMENTS

Document Composition Facility can be installed in:

- **ATMS** ATMS-III Release 2.0 with CICS/VS Version 1.5 under MVS and VSE.
- **CMS** VM/SP Release 1.1 (VM/High Performance Option, 5664-173 is required for hardware environments that required this extension to VM/SP).
- **TSO** OS/VS2 MVS SP Release 1.3.0.

To run in these interactive environments, the Foreground Environment feature of Document Composition Facility is required.

The SCRIPT/VS Formatter of the Document Composition Facility can be installed with the Document Library Facility program product to allow batch formatting in the following virtual storage operating systems:

- OS/VS2 MVS/SP Release 1.3.0.
- VSE/Advanced Functions Release 3 (5747-CC1) and VSE/VSAM Release 2 (5746-AM2).

Note: This program is designed to work in the specified release levels and any subsequent releases and modifications unless otherwise stated. The 3800 Printing Subsystem requires the DOS/VSE 3800 Printing Subsystem Independent Release (5747-CC1) for operation with DOS/VSE.

VSAM and Access Method Services are required when operating with the Document Library Facility.

DOCUMENT COMPATIBILITY and CONVERSION

Processing SCRIPT/370 Documents With SCRIPT/VS: Documents marked up for Installed User Program SCRIPT/370, Version 3 (5796-PHL), can be processed by the SCRIPT/VS formatter with little or no change to the source or in the output produced. If differences do occur, equivalent functions or results will usually be achieved by the use of user-written SCRIPT/VS macro processing functions. The long form of SCRIPT/370 control words is not supported by SCRIPT/VS. EASYSCRIPT 'tags' will be processed.

Processing ATMS Documents With SCRIPT/VS: Document Composition Facility contains a routine for converting documents in the Advanced Text Management System-II (ATMS-II, 5740-XXV or 5746-XXG), or ATMS-III Release 1.0 (5740-XYL, 5746-XXU) format for processing by SCRIPT/VS. The interface to this routine will be in the Document Library Facility, which must be installed with SCRIPT/VS in a background environment for the routine to operate. The routine will convert most ATMS GML and control words into SCRIPT/VS GML, symbols and macros. The ATMS conversion macros are distributed on an 'as is' basis.

Processing Release 1 Documents: The FILE option of the Document Composition Facility Release 2 SCRIPT command is now mutually exclusive with the PRINT and TERM keywords (where the DEV option should be used). The .UD control word will cause only blanks not to be underscored.

Processing Release 2 Documents: With Release 3 of the Document Composition Facility:

- Existing documents created for processing with Release 2 of SCRIPT/VS will, with few exceptions, produce comparable results when formatted with Release 3.
- The improved vertical distribution algorithm may cause differences in the placement of lines in a column.
- Documents created for processing with Release 1 of SCRIPT/VS may require markup changes when formatted with Release 3.
- The OS/VS1 environment is not supported in Release 3 of the Document Composition Facility.
- The algorithms for horizontal justification have been improved. This may cause differences in the placement of words on a line.

- Several restrictions regarding the use of widow zones with inline keeps and footnotes have been removed. This may cause differences in the placement of lines in a column.
- Changes to the logical device table (LDT) macro have resulted in a reorganization of the logical device table format. This requires users who have defined local logical devices to recode and recompile their logical device definitions.
- Trailing colons in SCRIPT/VS macro definitions should no longer be used when storing the definitions in a macro library. The extra colon will be treated as text.
- The DUMP option of the SCRIPT/VS command and the .ZZ control word are no longer provided.
- The .RD (Read Terminal) control word no longer performs a break or a section break.
- The .RH (Running Heading), .RF (Running Footing), and .FN (Footnote) control words no longer pre-execute any control words or tags when the running headings and footings and footnote leader are defined. Definitions are saved in their entirety and executed completely on each subsequent output page. Running headings and footings can include most valid control words, macros or GML tags. Under certain conditions, user-written macros with running headings and footings may need to be modified to support this enhancement.
- The .HY (Hyphenation) control word has new parameters whose defaults may disqualify hyphenation points that were used in Release 2. The same frequency of hyphenation can, however, be achieved in Release 3 with proper parameter settings.
- Reference numbers, as well as the UNFORMAT and NUMBER options of the SCRIPT command, are ignored on the 4250 Printer.
- The initial (default) values have changed for several existing control words relating to top and bottom margins, heading and footing margins, heading and footing space, and the binding margin.

IBM will accept APAR's describing any situation where the installation of this program product causes an exposure to the system integrity of MVS.

PROGRAM PRODUCTS

**8100 INFORMATION SYSTEM
DISTRIBUTED PROCESSING PROGRAMMING EXECUTIVE
DPPX ASSEMBLER
DPPX/ASM (5760-AS1)****PURPOSE**

DPPX Assembler is a licensed program that translates source programs written in DPPX Assembler language into 8100 Information System machine language and processes macro instructions, both user-written and those that are included with Distributed Processing Programming Executive (DPPX/BASE), Program Number 5760-010, or Distributed Processing Programming Executive/System Product (DPPX/SP), Program Number 5660-281.

HIGHLIGHTS

The input to the assembler is a source program that may be created by entering source statements either through the DPPX/BASE or DPPX/SP interactive editor or through a data set creation utility. Coding conventions for the assembler and the macro processor are similar to those of the S/370 DOS/VS assembler.

The output from the assembler is a relocatable load module suitable for link editing by the DPPX/BASE or DPPX/SP linkage editor.

The macro processor included with DPPX/ASM is a multi-pass interpreter that provides for macro definition, macro generation, and conditional assembly. System macros are included as part of the DPPX/BASE and DPPX/SP licensed programs. Approximately fifty system macros are available to support calls to facilities such as I/O services (for example: SEND, RECEIVE and CONNECT) and supervisor services (for example: GETMAIN, FREEMAIN and FETCH).

User-written macros may have as many as 50 symbolic parameters on a macro type. As many as 31 character positions in a macro instruction operand are available.

The assembler employs a multi-pass scanning process. In the first pass of the output of the macro processor, it collects symbol definitions in the symbol table and assigns a location address value to each instruction. The second pass creates the load module output, creates and lists the external symbol dictionary (ESD), and lists reporting options (for example, cross-reference report, relocation dictionary and diagnostic messages).

As many as 255 external symbol definition identification numbers (ESD IDs) are possible. There are 112 machine instructions that provide for arithmetic, comparisons, branches and jumps, shifting, logic (AND, OR, EXCLUSIVE OR, count leading zeros, test and set, etc.), and general control (store, load, control, etc.). Additionally there are 30 floating-point instructions for the 8140 mds A41 through A44.

The user invokes the assembler by using the ASSEMBLE command. Several optional parameters describe the assembler run (for example, creating and naming load modules and producing or suppressing assembler listings).

CUSTOMER RESPONSIBILITIES

Obtain formal education in Assembler language programming, if needed ... ensure understanding of the basic documentation for the DPPX/BASE or DPPX/SP and DPPX/ASM licensed programs ... ensure understanding of the DPPX licensed program installation process and install the DPPX Assembler licensed program ... provide sufficient storage and system capability to execute the assembler ... implement user applications ... carry out approved problem determination procedures before contacting IBM for program service ... update DPPX/ASM and DPPX/BASE or DPPX/SP with fix packages and service level updates as appropriate.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

DPPX/ASM requires DPPX/BASE or DPPX/SP for installation and use. DPPX/ASM also requires a minimum of 32K bytes of main storage during execution. This storage requirement is in addition to the DPPX/BASE or DPPX/SP main storage required for an application program. DPPX/ASM requires approximately 500K bytes of disk space for program load modules and other permanent data sets. In addition, disk space is required for licensed programs installed, for user-defined data sets, and for work space.

SOFTWARE REQUIREMENTS

DPPX Assembler runs under the control of the DPPX/BASE and DPPX/SP licensed programs. No other licensed programs are required for its use. This licensed program is written in Programming Language for Distributed Systems (PL/DS). When optional source code is ordered, it is distributed in DPPX Assembler language with most of the original PL/DS statements shown as comments.

COMPATIBILITY

Coding conventions are similar to those of the S/370 DOS/VS assembler, but the source code is not compatible.

PERFORMANCE CONSIDERATIONS

The performance of the assembler is affected primarily by the amount of storage available during an assembly, especially the amount of storage allocated for the symbol table manager.

**8100 INFORMATION SYSTEM
DISTRIBUTED PROCESSING PROGRAMMING EXECUTIVE
COBOL COMPILER and RUNTIME LIBRARY
DPPX/COBOL COMPILER (5760-CB1)
DPPX/COBOL RUNTIME LIBRARY (5760-LB1)**

PURPOSE

DPPX/COBOL offers a COBOL compiler and a runtime library containing reentrant routines which support arithmetic, logic, and data conversion, as well as input and output operations.

DPPX/COBOL Compiler is a key, but optional, complement to Distributed Processing Programming Executive Base (DPPX/BASE) and the Distributed Processing Programming Executive/System Product (DPPX/SP). In DPPX, the COBOL Runtime Library is also an optional licensed program. In DPPX/SP, the Runtime Library is an integrated component. COBOL has become the mainstay of commercial application development. DPPX COBOL provides the user a powerful programming language for application development. DPPX COBOL includes IBM language extensions which allow DPPX COBOL applications to utilize DPPX Data Base and Transaction Management System (DPPX/DTMS, 5760-TD1). Input/output subroutines are provided to allow interactive applications to use DPPX Distributed Presentation Services (DPPX/DPS) Version 1 or Version 2.

Operating environments which do not support compilation activities do not require the DPPX COBOL Compiler license. The DPPX/COBOL program can be compiled and linked on one system, and the generated modules may be executed on another system on which the DPPX/COBOL Runtime Library is installed.

HIGHLIGHTS

- Includes input/output subroutines to provide the facilities to pass data to DPPX/DPS, which offers device independence and format management facilities for interactive applications.
- Supports data base integrity features of DPPX/DTMS and DPPX/SP with IBM language extensions.
- Facilitates, through common COBOL source language, transfer of applications using DPPX or DPPX/SP indexed data sets to DPPX/DTMS. Data sets are simply redefined as DPPX or DPPX/SP/DTMS managed data bases.
- Produces sharable application programs, by creating reentrant code at user option.
- Includes IBM language extensions which allow the use of structured programming.

DPPX/COBOL simplifies the design and implementation of applications through IBM language extensions and input/output subroutines designed to utilize DPPX/DTMS and DPPX/DPS and the DTMS and FM components of DPPX/SP. In addition, the use of the COBOL language reduces the educational requirements for application programmers with COBOL programming experience on other systems.

Although some DPPX COBOL application programs which are initially implemented without DPPX/DTMS may execute in a DPPX/DTMS or DPPX/SP operational environment without change to the programs, other programs may need changes. In addition, some changes to fully utilize DPPX/DTMS or the DTMS component of DPPX/SP may be desirable. The indexed data sets of application programs shifted to DTMS can become resettable/recoverable data bases managed by DTMS. However, sequential and relative data sets accessed by the DPPX COBOL programs remain unchanged. Additional control over the synchronization of data recovery can be obtained by adding the statements COMMIT and ROLLBACK (IBM language extensions) to the application programs. The COMMIT statement commits changes to auxiliary storage when processing is successfully completed, and the ROLLBACK statement resets data to prior values when an abnormal condition occurs. If these additions are made, the programs must be recompiled for the DTMS environment, thus utilizing the data base integrity facilities of DTMS.

The user can specify that the object code generated by the DPPX/COBOL Compiler be reentrant. This reentrant code and the reentrant modules which comprise the routines of the DPPX/COBOL Run-Time Library can be shared by numerous application users, increasing the utilization of the main storage resource.

Implementation of the EVALUATE statement, the inline PERFORM statements, and the explicit scope terminators for conditional statements allows the implementation of structured programming. (These enhancements are included in the CODASYL COBOL Journal of Development language specifications.)

INDUSTRY STANDARDS

DPPX/COBOL is designed according to the specifications of the following industry standards, as understood and interpreted by IBM as of September, 1978: American National Standard (ANS) COBOL, X3.23 - 1974. ANS COBOL is identical to the International Organization for Standardization (ISO) 1989 - COBOL, approved by ISO in February 1978. The following ANS processing modules are included:

1 NUC 1,2	(Nucleus)
1 TBL 1,2	(Table Handling)
1 SEQ 1,2	(Sequential I-O), except the RERUN clause, STANDARD-1 alphabet-name referred to in the CODE-SET clause, and the optional words REEL and UNIT in the CLOSE statement (Relative I-O), except the RERUN clause and a data restriction*
1 REL 0,2	(Indexed I-O), except the RERUN clause and a data restriction*
1 INX 0,2	(Indexed I-O), except the RERUN clause and a data restriction*
1 SEG 0,2	(Segmentation)
1 LIB 0,2	(Library)
1 DEB 0,2	(Debug)
1 IPC 0,2	(Inter-Program Communication)

The first digit above represents the level of the modules included in the compiler; the second digit represents the lowest level in the American National Standard (0 implies that the module may be completely missing from some standard compilers); the third digit represents the highest level of the American National Standard.

It is anticipated that the DPPX/COBOL Compiler will meet the: December 1975 Federal Information Processing Standard (FIPS) PUB 21-1, low-intermediate level, with the exception of the following

RERUN clause
STANDARD-1 alphabet-name referred to in the CODE-SET clause
The optional words REEL and UNIT in the CLOSE statement
The FIPS flagger
A data restriction* for Relative and Indexed I/O

* Data restriction: The user of DPPX/COBOL cannot write a relative or indexed record with hexadecimal 'FFFF' in the first two bytes. DPPX/BASE access methods use this to indicate a deleted record.

CUSTOMER RESPONSIBILITIES

To install and use DPPX/COBOL the user must: Take education courses, as necessary ... Acquire a knowledge of the functions documented in *DPPX/COBOL Application Development Guide* and *DPPX/COBOL Application Development Language Reference*. ... Understand the DPPX installation processes, described in *DPPX Installation: Guide*, as they relate to DPPX/COBOL ... Provide disk storage space for the DPPX/COBOL Compiler object code ... Install the DPPX/COBOL Compiler ... Provide for adequate DPPX/COBOL Compiler disk storage work space ... Become familiar with DPPX/COBOL operating procedures ... Become familiar with the facilities provided by DPPX/DPS and DPPX/DTMS and DPPX/SP, if they are to be used with DPPX/COBOL ... Design and implement user applications ... Carry out approved problem determination procedures before contacting IBM for program service ... Install fix packages and service level updates as appropriate.

Additionally, for the DPPX/COBOL Runtime Library, the user must: Provide disk storage space for the DPPX/COBOL Runtime Library ... Install the DPPX/COBOL Runtime Library.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The DPPX/COBOL Compiler operates under the control of DPPX/BASE or DPPX/SP. The DPPX/COBOL Compiler requires DPPX/BASE or DPPX/SP for installation, and support the IBM I/O devices supported by DPPX/BASE. For information concerning IBM 8100 Information System configurations see *DPPX/BASE General Information (GC27-0400)*, *DPPX/SP General Information (GC23-0600)* and *IBM 8100 Information System Configurator (GA27-2876)*.

The DPPX/COBOL Compiler requires a minimum of 40K bytes of main storage, excluding storage required for DPPX/BASE or DPPX/SP for environment overhead. (For further discussion of the storage requirements for the DPPX/COBOL Compiler, see *Distributed Processing Programming Executive COBOL Application Development Guide SC26-3922*.) Application programs generated by the DPPX/COBOL Compiler will require approximately 16K to about 34K bytes (typically around 28K bytes) of main storage for DPPX/COBOL Runtime Library routines. The required storage is dependent upon the functional content of the application program. The DPPX/COBOL Runtime Library routines may be shared by DPPX COBOL application programs executing in other DPPX/BASE or DPPX/SP user environments at the user's option.

The DPPX/COBOL Compiler requires approximately 850K bytes of disk space for program load modules and other permanent data sets, and the DPPX/COBOL Run-Time Library requires about 150K bytes.

In addition, disk space is required for any other licensed program installed, for user-defined data sets, and for work spaces.

PROGRAM PRODUCTS

DPPX/COBOL (cont'd)

SOFTWARE REQUIREMENTS

The DPPX/COBOL Compiler and the DPPX/COBOL Runtime Library routines are written in Programming Language for Distributed Systems (PL/DS) and in DPPX Assembler language. Source code is available on magnetic tape and program listings on microfiche as related optional material. They are distributed in DPPX Assembler language with most PL/DS statements included as comments.

The following licensed program is required:

DPPX/BASE		5760-010
-----------	--	----------

DPPX/COBOL has been designed to operate with and complement the following licensed programs although they are not required:

DPPX/SP		5660-281
---------	--	----------

or

DPPX/DTMS		5760-TD1
-----------	--	----------

DPPX/DPS V1		5760-XR1
-------------	--	----------

DPPX/DPS V2		5660-264
-------------	--	----------

DATA SECURITY

DPPX/COBOL provides an application programming language compiler and runtime library for applications which run under control of DPPX/BASE or DPPX/SP. Data security is provided by DPPX/BASE or DPPX/SP and/or DPPX/DTMS.

PERFORMANCE CONSIDERATIONS

The performance of the DPPX/COBOL Compiler and the generated object code is very much a function of program size and application program content. Beyond this, throughput is affected by system configuration and processing activity from sources of concurrent workload.

**8100 INFORMATION SYSTEM
DISTRIBUTED PROCESSING PROGRAMMING EXECUTIVE
PARAMETER TABLE GENERATION FACILITY
FOR THE 3644 AUTOMATIC DATA UNIT
DPPX/GEN3644 (5760-ED1)**

PURPOSE

The DPPX Parameter Table Generation Facility (DPPX/GEN3644), executing on an 8100 Information System with the Distributed Processing Programming Executive Base (DPPX/BASE) or Distributed Processing Programming Executive/System Product (DPPX/SP), provides an efficient means for customizing the 3644 Automatic Data Unit. This customization consists of selecting 3644 functions and specifying the initial values of stored data items. DPPX/GEN3644 translates the customization data (developed on worksheets) into the format necessary for transmission to the 3644. Translation is performed by editing the source data and converting it into a parameter table format for loading into the 3644. The resulting parameter table works with the 3644 microcode provided by IBM.

DPPX/GEN3644 also produces a listing of the source data entered by the user. Extensive edits are performed both on a record basis and on an overall table basis. In most cases, editing continues despite errors, but the parameter table is not usable if any errors are found. Errors noted on the 3644 program listing are corrected by changing the original input and resubmitting the job.

The output of DPPX/GEN3644 is a sequential file containing the parameter table load (PTL) data as required for transfer to the 3644. The records on the sequential file are 256 bytes long.

HIGHLIGHTS

Worksheets are used to guide the customer through the procedure of defining the 3644 PTL. The worksheets are distributed as a set of reproduction masters for use in the customer's office copier or similar equipment.

Messages identify errors encountered during the processing of the source statements.

Symbolic naming of 3644 channels and common data items is supported.

A program listing is produced in a format similar to the source worksheets.

A parameter table load (PTL) is produced that is usable with the IBM-supplied control storage load (CSL) to customize the operation of the 3644.

The PTL is placed in a relative sequential data set. The plant communication support of the DPPX/BASE or DPPX/SP licensed program can be used to transfer both the CSL and PTL to the 3644 at the required times.

CUSTOMER RESPONSIBILITIES

The customer is responsible for installing the DPPX/GEN3644 licensed program.

The customer is also responsible for creating and managing the libraries of source statements and parameter tables for the 3644 through the use of DPPX or DPPX/SP system facilities. The source statements must be sorted into ascending sequence based on columns 1 to 9.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

DPPX/GEN3644 is designed to operate on the IBM 8100 Information System. The minimum configuration must include an IBM 8100 Processor with a disk, diskette, and console. A printer is recommended. The minimum real storage size required by DPPX/GEN3644 is 45K bytes.

SOFTWARE REQUIREMENTS

The DPPX/GEN3644 licensed program is designed to run with the DPPX/BASE and DPPX/SP licensed programs.

DPPX/GEN3644 is written in DPPX Programming Language for Distributed Systems (PL/DS). When optional source code is ordered, it is distributed in DPPX assembler language with most of the original PL/DS statements shown as comments. Source code is available on magnetic tape with program listings available on microfiche as related optional material.

The following components of the DPPX/BASE and DPPX/SP licensed programs and other licensed programs can be used in conjunction with DPPX/GEN3644:

- Entry of source statements from the worksheets: The interactive editor of the DPPX/BASE or DPPX/SP licensed program.
- Sorting of source records (if required): The DPPX Sort/Merge licensed program or the Sort component of DPPX/SP.
- Printing of the program listing and error messages: The printer sharing component of the DPPX/BASE and DPPX/SP licensed programs.
- Transfer of the PTL (and the CSL) to the IBM 3644: The plant communication support of the DPPX/BASE and DPPX/SP licensed programs.
- Control over the 3644 PTL preparation procedure: The command facility of the DPPX/BASE and DPPX/SP licensed programs.

COMPATIBILITY

The input source statements (from the worksheets) and the output PTL records of the DPPX/GEN3644 licensed program are compatible with the input and output of the 3630 Plant Communication System - 3644 Translation Services system control programming when the two programs are at the same functional level.

PROGRAM PRODUCTS

**8100 INFORMATION SYSTEM
DISTRIBUTED PROCESSING PROGRAMMING EXECUTIVE
FORTRAN COMPILER and LIBRARY
DPPX/FORTRAN COMPILER (5760-FO1)
DPPX/FORTRAN LIBRARY (5760-LM1)****PURPOSE**

DPPX/FORTRAN is a high-level mathematically-oriented programming language suited to manipulations of numerical data and formatted input/output operations on the 8100 Information System with Distributed Processing Programming Executive Base (DPPX/BASE) licensed program or DPPX/SP. DPPX/FORTRAN provides high-level language support for scientific and engineering applications. DPPX/FORTRAN can also be used in a wide range of other application areas for general problem solving.

The DPPX/FORTRAN language is supported by two licensed programs:

- DPPX/FORTRAN Compiler (5760-FO1), which performs syntax checking and compilation of FORTRAN source programs.
- DPPX/FORTRAN Library (5760-LM1), which provides data handling, data conversion, mathematical and system service subroutines to support the execution of FORTRAN application programs. The library may be used on the same system as the compiler or may be used independently on a non-development system to support FORTRAN program execution.

HIGHLIGHTS

DPPX/FORTRAN is designed according to the specifications of American National Standard (ANS) Basic FORTRAN, X3.10-1966, as understood and interpreted by IBM as of July, 1978. DPPX/FORTRAN is also designed according to the specifications of ANS FORTRAN, X3.9-1966, as understood and interpreted by IBM as of July, 1978, except for the following language elements:

- Adjustable (object-time) dimensions.
- G edit descriptor on FORMAT statement.
- Nesting of groups in format specifications.
- Complex numbers.
- Reading of format specification at execution.

DPPX/FORTRAN provides the following features not included in either standard:

- Direct access I/O statements - READ, WRITE, DEFINE FILE, FIND.
- ENTRY and PROGRAM statements.
- IMPLICIT statement.
- Length specifications on INTEGER (2 or 4 bytes), REAL (4 or 8 bytes) and LOGICAL (4 bytes) statements.
- PAUSE statement with a character constant.
- Alternate return (RETURN i).
- DEBUG, AT, UNIT, TRACE ON and TRACE OFF statements.
- Character constants.
- Hexadecimal constants.
- Z edit descriptor on FORMAT statement.
- Mixed-type expressions.
- END= and ERR= in READ statements.
- ERR= in WRITE statements.
- List-directed I/O operations.
- 7-dimensional arrays.
- Multiple exponentiation in expressions.

DPPX/FORTRAN Compiler: The DPPX/FORTRAN Compiler checks source program statements written in the DPPX/FORTRAN language for proper syntax, and translates the statements into machine language. As a part of compilation, the compiler allows the programmer to specify options that affect certain compiler operations, the content of the listing produced by the compiler, and the machine instructions generated by the compiler. Two of these options are:

- The compiler can be directed to generate either real or simulated floating-point machine instructions. Therefore, floating-point hardware is not required for arithmetic with real numbers.
- The compiler can be directed to generate a reenterable object program.

DPPX/FORTRAN Library: The DPPX/FORTRAN Library is designed according to the specifications of American National Standard (ANS) FORTRAN, X3.9-1966, as understood and interpreted by IBM as of July 1978, except for those elements dealing with complex numbers. Many additional functions are provided that are not specified by the standard. All routines in the library are reenterable. Included in the library are the following functions and subroutines:

- Data type conversion functions.
- Mathematical functions: Truncation, nearest whole number, nearest integer number, absolute value, modulo arithmetic, transfer of sign, positive difference, choosing largest and smallest value, square root, exponential, natural log, common log, sine, cosine, tangent, arc sine, arc cosine, arc tangent, hyperbolic sine, hyperbolic cosine and hyperbolic tangent.
- Service subroutines: Overflow, divide check, fetch, call command, time and date.
- Bit manipulation functions.

In addition to functions and subroutines, the DPPX/FORTRAN Library contains routines necessary to execute a FORTRAN program. For example, it contains routines that are automatically invoked to execute READ and WRITE statements.

The DPPX/FORTRAN Library may be installed on a DPPX or DPPX/SP system along with the compiler for the execution of programs on that system, or on a system without the compiler for the execution of programs that were compiled on another DPPX or DPPX/SP system.

CUSTOMER RESPONSIBILITIES

Obtain formal education in FORTRAN programming, if needed ... ensure understanding of the basic documentation for the DPPX/BASE or DPPX/SP and DPPX/FORTRAN licensed programs ... ensure understanding of the DPPX or DPPX/SP licensed program installation process and install the DPPX/FORTRAN licensed program ... provide sufficient storage and system capability to execute DPPX/FORTRAN ... implement user applications ... carry out approved problem determination procedures before contacting IBM for program service ... update DPPX/FORTRAN and DPPX/BASE or DPPX/SP with fix packages and service level updates as appropriate.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

Both DPPX/FORTRAN licensed programs can be used on the minimum IBM hardware configuration supported by DPPX/BASE or DPPX/SP licensed programs.

The DPPX/FORTRAN Compiler requires a minimum of 24K bytes of main storage in addition to the main storage occupied by the DPPX/BASE or DPPX/SP and any other licensed programs or application programs resident in main storage at the time of execution of a DPPX/FORTRAN compilation.

The DPPX/FORTRAN Compiler requires approximately 275K bytes of disk space for program load modules and other permanent data sets, and the DPPX/FORTRAN library requires approximately 450K bytes.

In addition, disk space is required for any other licensed programs installed, for user-defined data sets and for work space.

SOFTWARE REQUIREMENTS

The DPPX/FORTRAN licensed programs are written in assembler and Programming Language for Distributed Systems (PL/DS) source code.

Executing the DPPX/FORTRAN Compiler requires an installed and running DPPX/BASE or DPPX/SP licensed program. Executing compiled DPPX/FORTRAN programs also requires an installed DPPX/FORTRAN Library.

COMPATIBILITY

DPPX/FORTRAN can be run in the same environment as other DPPX or DPPX/SP licensed programs, if sufficient storage is available.

A very large set of FORTRAN language elements is accepted and processed consistently by the DPPX and OS/VS FORTRAN compilers and libraries. Source programs written for one of these systems will need little revision in order to compile and execute successfully on one of the others if the following restrictions are taken into account:

- DPPX FORTRAN does not contain all the elements available in OS/VS FORTRAN. For example, DPPX FORTRAN does not allow complex numbers.
- OS/VS FORTRAN products do not contain all the elements available in DPPX FORTRAN. For example, the OS/VS FORTRAN

PROGRAM PRODUCTS

DPPX/FORTRAN (cont'd)

products do not support the PROGRAM statement, bit handling functions, or two-byte intrinsic function arguments.

- There are some differences in compiler-defined limitations. For example, the number of nested expressions allowed in an assignment statement differs between the DPPX/FORTRAN compiler and the OS/VS FORTRAN compilers.

Differences are documented in *DPPX/FORTRAN Programming: Language*.

PROGRAM PRODUCTS

**8100 INFORMATION SYSTEM
DISTRIBUTED PROCESSING PROGRAMMING EXECUTIVE
PL/I COMPILER and LIBRARY (DPPX PL/I)
DPPX PL/I COMPILER (5760-PL1)
DPPX PL/I LIBRARY (5760-LM2)**

PURPOSE

DPPX PL/I offers a compiler and library to support the use of the PL/I language with 8100/DPPX or DPPX/SP.

PL/I is a programming language designed for applications that involve the manipulation of numerical and non-numerical data.

The program compiled by the DPPX PL/I Compiler and the DPPX PL/I Library routines they invoke are reentrant, and can be used with other DPPX or DPPX/SP programs to give access, for example, to interactive, data base, and presentation services provided by DPPX program products.

HIGHLIGHTS

The main features of DPPX PL/I include the following:

- DPPX PL/I offers a large selection of American National Standard (ANS) PL/I language elements.
- Program modularity is provided by the PL/I block structure and scope rules.
- Extensive input/output capabilities are provided.
- STATIC, AUTOMATIC, and BASED storage class attributes are supported, giving the programmer control over storage usage.
- Data manipulation capability is provided by a comprehensive set of operators and built-in functions.
- Program checkout facilities are available, including ON-units and condition built-in functions.
- Separately written PL/I code can be included from a PL/I source statement library into the source program at compile time (%INCLUDE statement).

DPPX PL/I Compiler features include:

- Extensive syntax error diagnostics and support for execution-time error diagnosis are provided.
- More than one PL/I source program can be compiled with one invocation of the compiler.
- The DPPX PL/I Compiler can optionally generate floating-point machine instructions for 8100 Information Systems with floating-point support. If this support is not installed on the system on which the program will execute, the compiler is designed to generate code that simulates the hardware instructions for floating-point operations.
- Data mapping is compatible with S/370 OS PL/I and DOS PL/I, provided that compatible data types and access methods are used.
- Object modules are reentrant (to improve storage usage during execution).

DPPX PL/I provides the capability to access DPPX or DPPX/SP facilities and programs. These capabilities include:

- Library routines and/or object programs can be loaded into shared storage.
- Library routines and other programs can be invoked, even though they are not link-edited with the program.
- DPPX/Data Base and Transaction Management System (DPPX/DTMS) and DPPX/Distributed Presentation Services (DPPX/DPS) are supported.
- DPPX PL/I programs can interface with non-PL/I routines.
- Sort user exit programs can be written in PL/I.
- DPPX PL/I programs can issue DPPX or DPPX/SP commands.
- Return codes can be set and tested.

Compiler and Library: DPPX PL/I consists of two products:

- The DPPX PL/I Compiler, Program Number 5760-PL/I, which performs syntax checking and compilation of PL/I source programs.
- The DPPX PL/I Library, Program Number 5760-LM2, which contains reentrant routines that manage the execution environment, handle input/output operations, perform data manipulation, and provide mathematical functions.

These products enable the user to designate one DPPX or DPPX/SP system as a programming development center, while other DPPX or DPPX/SP systems may be devoted to running the programs developed at the center. Both the compiler and the library would be installed at the programming development center. Processors at the other locations need have only the library to be licensed and installed for execution of the program compiled at the development center.

DPPX PL/I programs are compiled and executed under the control of the Distributed Processing Programming Executive Base (DPPX/BASE) or DPPX/SP. DPPX/BASE or DPPX/SP provides program development and execution facilities in interactive or batch environments. It can be configured as part of a distributed processing system or as a stand-alone data processing system.

INDUSTRY STANDARDS

DPPX PL/I is designed according to the specifications of the following industry standards as understood and interpreted by IBM as of January 1981: American National Standard (ANS) PL/I, X3.53-1976, which is technically identical to ISO 6160-1979 (International Organization for Standardization), and ECMA-50 (1976) (European Computer Manufacturers Association).

CUSTOMER RESPONSIBILITIES

In order to install and use DPPX PL/I successfully, the customer must have DPPX/BASE or DPPX/SP installed. The DPPX PL/I Compiler and Library are each distributed on separate diskettes. These program products will be installed according to the DPPX or DPPX/SP procedure for program products (see *DPPX Installation: Guide* or *DPPX/SP Installation*).

SPECIFIED OPERATING SYSTEM

HARDWARE REQUIREMENTS

The DPPX PL/I Compiler and Library are designed to operate under DPPX/BASE or DPPX/SP for the IBM 8100 Information System processors.

A floating-point processor is not required, but can be used if available.

Storage Requirements: When *compiling*, the DPPX PL/I Compiler requires the following storage:

- A minimum real block limit (RBL) of 66K bytes. Programs with many distinct names for variables and constants need more than the minimum RBL to compile. Providing more storage (for example, an additional 30K bytes) will enhance compiler performance.
- A minimum of 150K bytes of auxiliary storage for compiler workfiles.
- The DPPX PL/I Compiler requires 1,000K bytes of auxiliary storage for residence.

When *executing*, the system requirements are as follows:

- Processor storage for the application program. The amount depends on the size and contents of the source program.
- Processor storage for the DPPX PL/I Library routines invoked by the application program. The amount of storage required will vary from one program to another, depending on the function used. For example, a program for a commercial application might need between 20K and 40K bytes of storage for library routines. The most commonly used library routines would normally be in shared storage.
- A floating-point processor is not required, but can be used if available.

Auxiliary storage must be provided for the residence of the library routines (600K bytes for the total DPPX PL/I Library).

Note that the storage requirements for the compiler and library are in addition to the storage required by DPPX/BASE or DPPX/SP and any other programs the customer may use together with DPPX PL/I.

Device Support: The application program can make use of input/output devices for which DPPX/BASE or DPPX/SP provides device-independent support.

SOFTWARE REQUIREMENTS

The DPPX PL/I Compiler is designed to execute on an installed and running Distributed Processing Programming Executive Base, Program Number 5760-010, or Distributed Processing Programming Executive/System Product (DPPX/SP), Program Number 5660-281.

To execute compiled DPPX PL/I programs (including any DPPX/Sort exit routines written in PL/I), an installed DPPX PL/I Library is required.

PROGRAM PRODUCTS

DPPX PL/I (cont'd)

DPPX PL/I can be used with other DPPX program products, for example:

- DPPX Data Base and Transaction Management System DPPX/DTMS, Program Number 5760-TD1).
- DPPX Distributed Presentation Services, Version 2, (DPPX/DPS V2), Program Number 5660-264, is required if DPPX/DPS is to be used by PL/I programs.
- DPPX Sort/Merge, Program Number 5760-SM1, service level available at general availability of DPPX PL/I is required.

COMPATIBILITY

A large common set of PL/I language elements is accepted and processed consistently by the DPPX PL/I Compiler and the OS PL/I compilers. Source programs written for the DPPX PL/I Compiler will in most cases need some revision in order to compile and execute successfully on the OS PL/I compilers. The following are the main areas of difference between OS PL/I and DPPX PL/I (for more details, refer to *DPPX PL/I Compiler and Library: General Information* (GH19-6081):

- Language differences:
DPPX PL/I follows the rules of ANS PL/I, which differ in some areas from OS PL/I.
- DPPX PL/I does not contain all the language elements available in the OS PL/I Optimizing Compiler.
- Differences in implementation-defined limits (for example, the maximum length of an EXTERNAL identifier is 8 in DPPX PL/I and 7 in OS PL/I).
- Access to DPPX or DPPX/SP program products and to certain DPPX/BASE or DPPX/SP facilities is implemented in a system-dependent manner which cannot be transferred directly to OS/VS.
- In addition, there are differences in the ANS implementation-defined items (for instance, ENVIRONMENT option).

Data mapping of all data types supported by DPPX PL/I is identical to that in OS or DOS PL/I.

DATA SECURITY

DPPX PL/I provides an application programming language compiler and a library for applications that run under control of the DPPX/BASE or DPPX/SP program product. Data security function is provided by the DPPX/BASE or DPPX/SP program product and/or the optional DPPX/DTMS program product.

PROGRAM PRODUCTS

**IBM 8100 INFORMATION SYSTEM
DISTRIBUTED PROCESSING PROGRAMMING EXECUTIVE
DATA STREAM COMPATIBILITY
DPPX/DSC (5760-RC1)**

PURPOSE

This DPPX licensed program allows certain keyboard/displays, printers and selected controllers and communication systems attached to the IBM 8100 communication system with Distributed Processing Programming Executive Base (DPPX/BASE) to communicate with S/370, 303X or 4300 hosts as though they were directly attached by data link to the host processor.

Keyboard Displays and Printers: The Data Stream Compatibility licensed program supports both SDLC and BSC line control disciplines between the 8100 processors and the host system. When using an SNA access method, the 8100 appears to an application program as an IBM 3276 Control Unit/Display Station. In this case, transmissions from Data Stream Compatibility can share the same data link with transmissions from other 8100 applications. When communicating over a BSC link, the 8100 appears to S/370 and 4300 application programs as an IBM 3274 Control Unit or 3276 Control Unit/Display Station.

Selected Controllers and Communication Processors: The DPPX Data Stream Compatibility licensed program supports the SDLC line control discipline between the host system, the 8100 Information System and the controller or communication processor. The sessions supported by Data Stream Compatibility can share the same host data link with transmission from other 8100 Information System applications.

The 8100 Information System can be installed as a distributed processor while permitting existing host system applications to run with current controller or communication processor applications. DPPX Data Stream Compatibility provides a pass through function for existing applications and is a transition aid while new and additional distributed applications are developed and tested.

HIGHLIGHTS

Keyboard Displays and Printers

Data Stream Compatibility accepts input from:

- IBM 3104 Display Terminal.
- IBM 3232-1, 11 Keyboard Printer Terminal.
- IBM 3276 Control Unit/Display Station.
- IBM 3277 Display Station.
- IBM 3278 Display Station.
- IBM 3279 Color Display Station.
- IBM 8775 Display Terminal.

Data Stream Compatibility creates the necessary data stream for host communication.

The following printers are supported by Data Stream Compatibility:

- IBM 3230 mdl 1 on direct attached loop. IBM 3230 accepts SNA character string LU1 data only.
- IBM 3262-2,-12 on direct attached loop. IBM 3262 accepts SNA character string LU1 data only.
- IBM 3268 mdl 1 on direct attached loop. IBM 3268 mdl 1 accepts SNA Character String (LU1) data only.
- IBM 3287-11,-12 on direct attached loop. IBM 3287 accepts SNA character string (LU1) data only.
- All printers attached to a 3274 Control Unit.
- All printers attached to an IBM 3276 Control Unit/Display Station.
- All printers attached to the IBM 8101 Storage and Input/Output Unit via Display/Printer Attachment.

When Data Stream Compatibility is used on an 8100 connected to a S/370 or 4300 via a BSC data link, the printers that accept only SNA character string (LU1) data are not supported. When the connection is via an SDLC data link, the printers that accept only SNA character string (LU1) data are not supported for host applications sending LU3 data streams.

Host initiated copy is supported from:

- IBM 3277 to printers attached on the same Display/Printer Attachment.
- IBM 3278, 3279, or 3276 to printers attached to the same IBM 3230 or 3274 or 3276.
- IBM 8775 mdls 1, 2 and 3104 to printers on the same or another loop. Copy of programmed symbols and APL from the IBM 8775 to an IBM 3230 or an IBM 3287 is not supported. If utilizing host initiated copy from the IBM 8775, the associated

IBM 3230 or 3287 printer must be dedicated for host initiated copy.

Local copy is supported from:

- IBM 3278, 3279 or 3276 to printers attached to the same IBM 3274 or 3276.
- IBM 8775 mdls 1, 2 and 3104 to printers on the same or another loop. Copy of programmed symbols and APL from the IBM 8775 to an IBM 3230 or 3287 is not supported.

Printer and display assignments for copy are defined statically and can not be changed from a S/370 or 4300 program.

Advanced functions such as extended color and programmed symbols (PS) that require the 3270 extended data stream are supported by Data Stream Compatibility for SDLC host connections only.

A request for connection can come from the S/370 or 4300 (SDLC only) or from the keyboard/display. Data Stream Compatibility builds two active sessions for each user, keyboard/display-to-Data Stream Compatibility and Data Stream Compatibility-to-host.

The IBM 8100 Information System can be installed as a distributed processor while permitting most existing 3270 applications at the S/370 or 4300 host processor to run with little or no change. While the displays are in session with the host programs, the connection through the 8100 is not apparent to the user. When the displays are not in session with the host programs, they can be used by the 8100 for interactive work. Data Stream Compatibility provides a transition aid for existing applications while new and additional distributed applications are developed and tested.

Selected Controllers and Communication Processors: Data Stream Compatibility allows the following products with their application programs, when attached to the 8100 Information System to communicate with S/370, 303X or 4300 host application programs as though they were attached by SDLC data link to the host processor.

3601, 3602	Finance Communication Controller
3605	
3651	Store Controllers
3684	Point-of-Sale - Control Unit
4701-1,-2	
8130, 8140	Information System Processors with
DPCX	Distributed Processing Control Executive applications including DPCX/DOSF Distributed Office System Facility

The communication links between the 8100 DPPX/DSC system, the S/370, 303X or 4300 host and the downstream product must be SDLC.

The request for connection can come from the S/370, 303X or 4300 host (SDLC only) or from a program in a downstream controller or communication processor. DPPX/DSC builds two active sessions for each user, controller or communication processor-to-DPPX/DSC and DPPX/DSC-to-host.

APL SUPPORT

Data Stream Compatibility will accept input from the IBM 8775 with APL feature (#1120) and create the necessary data stream for S/370 and 4300 communications. The IBM 8775 is addressable from a S/370 or 4300 program using LU2 or BSC data streams. Data Stream Compatibility APL keyboard characters support is provided to the following host environments:

- OS/VS1 VSPC Release 2.0
- OS/VS2 MVS VSPC Release 2.0
- OS/VS2 MVS VS APL for TSO (See Note)
- VM/370 BSEPP/SEPP

Note: Changes to the VS APL for TSO Installed User Program (5796-ALB) to support the APL keyboard characters are described in a technical newsletter distributed to users of record.

In the above environments the then most current release of the VS APL program product (5748-AP1) will support, on the IBM 8775 with the APL feature (#1120), the same characters as are currently supported on the IBM 3274 with the APL/Text Control Function selectable during the customization of an IBM 3274 mdl 1A, 1C or 1D.

Support for the APL keyboard characters will be provided by Release 2 of the TSO Session Manager program product (5740-XE2).

Support for the complete APL Feature will be provided for use by suitably modified user application programs in the following environments.

- DOS/VSE
- OS/VS2 (MVS - including TSO)
- VM/370 BSEPP/SEPP

PROGRAM PRODUCTS

DPPX/DSC (cont'd)

The release of DOS/VSE, OS/VS1 and OS/VS2 (MVS) current at the time of hardware FCS applies.

CUSTOMER RESPONSIBILITIES

The customer must install DPPX/BASE and provide sufficient real storage for the Data Stream Compatibility environments. In addition the customer must define the tables that associate displays and printers for local copy.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

Data Stream Compatibility will operate on an IBM 8100/DPPX system with sufficient real storage to satisfy the combined requirements of Data Stream Compatibility, DPPX/BASE, and other customer required programs. Storage requirements are discussed below under "Performance Considerations".

The configuration must include sufficient I/O devices to support the requirements for system output, system residence and system data sets.

SOFTWARE REQUIREMENTS

This licensed program is designed to work with the DPPX/BASE licensed program.

Data Stream Compatibility is written in Programming Language for Distributed Systems (PL/DS). When optional source code is ordered, it is distributed in DPPX assembler language with most of the original PL/DS statements shown as comments. Source code is available on magnetic tape with program listings available on microfiche as related optional material.

Host Software: Displays and printers connected to the Data Stream Compatibility licensed program in the IBM 8100/DPPX processor may communicate with the following host systems and facilities and all subsequent releases and modification levels unless otherwise stated:

SDLC or BSC

VTAM applications under DOS/VS(E), OS/VS1, OS/VS2 MVS.
TCAM applications under OS/VS1, OS/VS2 MVS.
IMS/VS - 1.1.4 under OS/VS1, OS/VS2 MVS.
CICS/VS - 1.3 under DOS/VS(E), OS/VS1, OS/VS2 MVS.
TSO/TCAM or TSO/VTAM under OS/VS2 MVS.
VSPC under DOS/VS(E), OS/VS1, OS/VS2 MVS.

BSC Only

BTAM applications under DOS/VS(E), OS/VS1, OS/VS2 MVS, VM/370.

SDLC requires VTAM (VTAM2, ACF/VTAM Version 1 or ACF/VTAM Version 2 or ACF/VTAME) or TCAM (TCAM10, ACF/TCAM).

Note that S/370 and 4300 programming service is available only for current releases of S/370 and 4300 programming.

COMPATIBILITY

Most existing application programs written to the IBM 3276 BSC, or SNA interfaces of the above host software will run with little or no change when using the 8100 and Data Stream Compatibility.

Data Stream Compatibility has the following restrictions:

- Character sets are limited to EBCDIC only.
- The data stream to Display/Printer Attachment attached devices are MINIBASE.
- BSC dial is not supported; the only switched link support is SDLC auto answer to S/370 and 4300.
- Display to display copy is not supported for Display/Printer Attachment attached displays or the IBM 8775 display.

For downstream control units, the following functions will not be supported or may require modifications to host or controller programs:

- Remote Power Off capability is not supported.
- LAST/NOT LAST option for session termination; DPPX/DSC will not support "LAST" and will assume "NOT LAST" is specified.
- BIND parameter with a MAX RX U '00' will not be acceptable and will require a bind image.
- Remote diagnostics and application fixes are only available when supported by active DSC sessions.
- The PU services available are those supported by the current level of DPPX.
- Threshold and Remote Analysis (TARA) support is not available for 3600 control units attached to an 8100/DPPX system.
- Advanced Communication Function (ACF) Enhanced Recovery Capability (ACTPU/ACTLU) is not supported.

CONVERSION

No host software upgrade is necessary. The customer with an installed SNA S/370 or 4300 that is using RU sizes greater than 1024 bytes may have to regenerate his host CICS system if utilizing 8775 as his target display. The same is true for those users with IBM 3277 as the target display who use RU sizes greater than 512 bytes.

In addition, the customer who is installing control units or 8100 Information Systems downstream from an 8100 will be required to regenerate his NCP system.

PERFORMANCE CONSIDERATIONS

All DPPX licensed programs are designed to execute in an 8100 Information System that includes the DPPX/BASE licensed program (5760-010).

The Data Stream Compatibility support provides the appearance of a 3276 to a S/370 or 4300 or, in the case when a controller is supported by Data Stream Compatibility, an application interface. The user should expect that response times will be longer when using Data Stream Compatibility than when terminals or control units are directly attached to S/370 or 4300.

The minimum storage required for Data Stream Compatibility supporting one display terminal via an SDLC connection to a S/370 or 4300 is 16K bytes. Each additional terminal supported requires 3K bytes.

The minimum storage required for Data Stream Compatibility supporting one display terminal via a BSC connection to a S/370 or 4300 is 25K bytes. Each additional terminal supported requires a minimum of 4K bytes.

Storage required for DPPX/BASE and related I/O buffers are not included in the above figures.

The Data Stream Compatibility licensed program requires approximately 130K bytes of disk space for program load modules and other permanent data sets.

In addition, disk space is required for any other licensed program installed, for user-defined data sets, and for work spaces.

PROGRAM PRODUCTS

**8100 INFORMATION SYSTEM
DISTRIBUTED PROCESSING PROGRAMMING EXECUTIVE
DPPX SORT/MERGE
DPPX/SORT (5760-SM1)**

PURPOSE

The DPPX Sort/Merge is a sort product for the 8100 Information System that runs under control of the Distributed Processing Program Executive Base (DPPX/BASE) and provides users with facilities for extracting data from their data sets and sequencing it. It is designed to address the users' needs not only for straightforward sorting and merging of records of a single type but also for related tasks such as selecting certain records from one or more files and handling multiple record types (records which do not have their fields - for instance their sort keys - in the same position) as well as ordering according to user-specified collating sequences.

HIGHLIGHTS

- **Sort or Copy a Data Set:** DPPX Sort/Merge addresses the users' basic needs for extracting data from one data set and creating a new file, with or without changing the sequence of the records.
- **Copy, Sort, or Merge Multiple Data Sets:** DPPX Sort/Merge will also extract data from multiple input data sets to one output data set and, at the same time, optionally resequence the records or merge the data set records if already in desired order. One invocation of the program can handle up to seven different data sets (data sets on direct access storage devices can each have up to four extents, but must be contained within one volume).
- **Select a Subset of the Source Data:** While performing above operations, DPPX Sort/Merge can compare fields in records to constants and select records based on the result of the comparison(s).
- **Process More than One Record Type in the Same Application:** DPPX Sort/Merge can handle different record types concurrently; records are of different types if their significant fields, for instance the sort keys, are not in the same position.
- **Use Flexible Control Fields:** DPPX Sort/Merge can order records on a major control field and multiple minor control fields (keys). Defined control fields, and other fields, can be anywhere within a record (contained entirely within the record) and can be contiguous or noncontiguous. The complete "control word", constructed by the DPPX Sort/Merge program based on the user's key field specifications, can be as large as 512 bytes.
- **Process Multiple Data Types:** DPPX Sort/Merge control field data types can be either character, signed decimal, decimal zoned, signed decimal packed, or number fields in the standard DPPX format for numeric information. The latter type, number fields, can be up to four bytes long; the other four types can be up to 255 bytes long.
- **Sequence Data with Flexible Collating Rules:** DPPX Sort/Merge can, as mentioned above, sequence records based on the value of multiple control fields (sort keys). It does order each individual field in ascending or descending sequence. Character type fields are ordered in accordance with the EBCDIC collating sequence, the ASCII collating sequence, or a user-specified collating sequence (see next paragraph). Numeric (noncharacter) type fields are ordered numerically, all zero fields being treated as equal regardless of their sign.
- **User-Specified Collating Sequence:** DPPX Sort/Merge allows users to modify, through the use of a subcommand, the standard EBCDIC collating sequence. Users will take advantage of this when they have special requirements such as the correct ordering of data containing characters not included in the English alphabet.
- **Record Lengths and Block Sizes:** DPPX Sort/Merge handles records with a length of up to 4086 bytes minus the length of the "control word" for sort applications. In all other applications the maximum record length is 4096 bytes. The input and output block sizes may both be up to 4096 bytes.
- **Input Sources and Output:** DPPX Sort/Merge can read input from and write output to any input or output device supported by the DPPX/BASE device independent SEND/RECEIVE macros, provided the records are in relative sequential data sets (RSDS). The records in a DPPX/BASE indexed data set, or in a data base managed by the DPPX Data Base and Transaction Management System (DPPX/DTMS), can, in addition to normal RSDS, be input to the DPPX Sort/Merge because the records themselves are in RSDS. However, indexes are not created or updated for any data sets, and DTMS managed data sets must be deactivated by the DTMS user, using established DTMS procedures, if the user wishes to allow DPPX/SORT to access them. Input to DPPX Sort/Merge can also be provided by an application program (input procedure), and records sequenced in the desired order can be given to another application program (output procedure).
- **No User Work Space Allocation:** DPPX Sort/Merge copies and merges data sets and, provided the records can be contained in

available primary storage, sorts data sets without using any auxiliary storage. When work space is required, any direct access device that is supported by DPPX/BASE can be used. If enough free space is available in the SYSCAT catalog - subject to an installation specified limit - DPPX Sort/Merge can take full responsibility for allocation of sort work space and the user will not be required to supply specifications for it. (If enough such space is not available, the user will have to specify, in a subcommand, the work space to be used.)

DESCRIPTION

DPPX Sort/Merge is designed primarily to address the users' needs to extract data from their data sets and sequence it. The input may come from multiple data sets or from an application program, it may be selectively extracted, and the output written to one data set or given, one record at a time, to an application program.

DPPX Sort/Merge runs as an application program under control of DPPX/BASE and uses standard DPPX/BASE protocols, commands, return codes, and message formats.

DPPX Sort/Merge contains more function than straightforward sorting and merging, and it can be considered as a set of generalized DPPX application programs.

A DPPX Sort/Merge process consists of two stages, a definition stage in which the application is defined based on the user specified SORT command and its subcommands, and an execution stage in which the defined application is executed. The execution stage performs the actual processing of data; reading, selecting, sequencing, writing, etc. It carries out those tasks based on what the definition stage indicates; which functions to perform, in which order, and how. The definition stage, in order to be able to indicate the exact application the user wants executed, processes a SORT command and its subcommands, checking their syntax and logic, informing the user of errors and inconsistencies, and, when it finds an application definition to be free of error and complete, passes control to the execution stage.

The definition stage can receive the user specifications - the SORT command and its subcommands (SOURCE, TARGET, OPTION, FIELD, CHANGE, ORDER, SELECT, CANCEL, DEBUG and END) in three different ways:

- Conversationally, with prompting for the subcommands, and with the ability for the user to correct and reenter subcommands found to contain errors or inconsistencies.
- For immediate execution of a predefined application, by entering a CALL.CLIST command specifying a previously prepared command list containing the SORT command followed by subcommands.
- For batch queue execution of a predefined application, by entering a SUBMIT.BATCH command submitting a previously prepared command list containing the SORT command followed by subcommands.

The execution stage can receive control only from the definition stage as described above.

CUSTOMER RESPONSIBILITIES

To install and use the DPPX Sort/Merge licensed program the user must:

Attend classes as appropriate ... Acquire knowledge of the functions as documented in *DPPX Sort/Merge User's Guide* and *DPPX Sort/Merge Reference* ... Become familiar with the commands and their uses as documented in *DPPX Sort/Merge User's Guide* and *DPPX Sort/Merge Reference* ... Become familiar with the facilities of DPPX/BASE ... When necessary, if the "program input/output" facilities are to be used, become proficient in an appropriate programming language and the use of the program interfaces to DPPX Sort/Merge as described in *DPPX Sort/Merge User's Guide* and *DPPX Sort/Merge Reference* ... Install DPPX Sort/Merge according to directions and guidance given in *DPPX Installation: Guide* and "Memo to Users" ... Carry out approved problem determination procedures before contacting IBM for program service ... Install fix packages / service level updates as appropriate.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

To Install the Program

- An IBM 8100 system operating under DPPX/BASE.
- A diskette containing the DPPX Sort/Merge object code in standard DPPX distribution format.

To Use the Program

- An IBM 8100 Processor Unit with Device Attachment Unit(s) and provisions for attachment of required input/output devices.

DPPX/SORT (cont'd)

- Any input/output device supported by the DPPX/BASE device independent interface - for input to and output from the DPPX Sort/Merge program - if not handled from other DPPX programs.
- Any IBM direct access storage device supported by DPPX/BASE - for DPPX Sort/Merge work storage - if any larger sort applications than those that can be contained in primary storage will be executed. When such auxiliary storage is required, it must be sufficient to contain all input records, plus the total sort key for each record, plus ten bytes for internal pointers in each auxiliary storage block.
- A minimum of 28K bytes of main storage for the DPPX Sort/Merge program plus main storage for input/output buffers (depending on block size). This does not include DPPX/BASE main storage that may be required for an application program.
- Main storage for input and/or output procedures - when the "program input/output" facilities are being used.
- Any IBM terminal supported by DPPX/BASE presentation services - if DPPX Sort/Merge invocation from a terminal is desired.

SOFTWARE REQUIREMENTS

DPPX Sort/Merge operates under control of DPPX/BASE and uses facilities provided by DPPX/BASE.

Prerequisite Program: DPPX/BASE (5760-010)

DPPX Sort/Merge is distributed in DPPX assembler language. Source code for DPPX Sort/Merge is available on diskettes, and the program listings on microfiche, both as related optional material.

If the user wishes to enter the input records via a program (input procedure) and/or accept output records in a program (output procedure), routines in DPPX assembler language, or an appropriate high level language, for instance DPPX/COBOL, which are otherwise not required, must be developed.

PERFORMANCE CONSIDERATIONS

The performance of the DPPX Sort/Merge licensed program is dependent on the system resources available, the programs that operate concurrently and their relative priorities, and system and data set placement. Performance for a specific DPPX Sort/Merge application is also dependent on factors such as number of records in the input file(s), number of records selected for output, block size, record length, total sort key size, degree of sequencing already existing in the input file, amount of main storage available, placement of work space (when required), type of input/output data sets and devices, hardware configuration, whether or not all the DPPX/BASE routines required by the program are resident, and other options selected for the execution. For specific application performance and response time needs, attention should be given to ensuring that adequate real resources such as primary storage and direct access device work space are available, that input/output data set block sizes are not too small (number of accesses to the data sets are not too large), and that applications are not designed so that an unnecessarily large amount of data has to be processed.

PROGRAM PRODUCTS

**8100 INFORMATION SYSTEM
DISTRIBUTED PROCESSING PROGRAMMING EXECUTIVE
DATA BASE and TRANSACTION MANAGEMENT SYSTEM
DPPX/DTMS (5760-TD1)**

PURPOSE

Distributed Processing Programming Executive Data Base and Transaction Management System (DPPX/DTMS) is the data management and transaction management system that provides ease-of-use facilities for the IBM 8100 Information System application programmers and system programmers in the online transaction-oriented environment. DPPX/DTMS operates under the control of Distributed Processing Programming Executive Base (DPPX/BASE). The facilities provided by DPPX/DTMS are designed to enable the programmers to concentrate on application system program development, rather than data and transaction management.

The following paragraphs contain general information pertaining to DPPX/DTMS. A section beginning on page 3 (TD1.3) covers follow-on Functional Enhancement Package (FEP) highlights.

HIGHLIGHTS

- Handles concurrent requests with effective use of main storage. DPPX/DTMS allows several terminal users to effectively utilize DPPX/DTMS controlled storage areas called subenvironments. DPPX/DTMS also provides for data base buffer pooling, and will allocate or deallocate data buffers to the pool as system workloads vary.
- User ability to prioritize transactions. High priority transaction definitions may be designated by the user to reside in main storage, enabling execution to be initiated quickly.
- Facilities to assist in the development and testing of user programs. Users can operate in test mode, which allows programs to process production data bases, with no permanent change to the data bases. Online DPPX/BASE debugging services are supported.
- Ease-of-migration. Previously running DPPX programs may execute as DPPX/DTMS transactions, with no source or object code change. Existing DPPX indexed data sets can be defined as DPPX/DTMS-managed data bases with no physical change to the data.
- Provides security facilities. Specific user authorization requirements can be associated with transactions or data bases under control of DPPX/DTMS. DPPX/DTMS verifies that users have the proper credentials.
- Controlled sharing of data with full integrity.
- Automatic reset of an active DPPX/DTMS data base, if:
 - User program abnormally terminates
 - DPPX/DTMS abnormally terminates
 - DPPX/BASE abnormally terminates
- Re-creation facilities which allow for full recovery of DPPX/DTMS-controlled data bases, if the data has become invalid.
- Supports DPPX/COBOL and DPPX Distributed Presentation Services (DPPX/DPS). DPPX/DTMS has been designed to operate with and complement other products such as DPPX/COBOL and DPPX/DPS, although they are not prerequisites. DPPX COBOL programs can be written to utilize and access the DPPX/DTMS facilities, without the requirement for DPPX assembler language subroutines. DPPX/DTMS supports DPPX/DPS if present in the system, and uses it for work invitation and message displays.
- Ease-of-installation. No system generation is required. DPPX/DTMS as supplied from PID may be tailored by replacement of default values and environmental information. Data bases and transactions are defined through DPPX/BASE-like commands.
- Data base utilities, which reorder the data for more efficient sequential processing.
- Deadlock detection for shared data bases. When DPPX/DTMS detects a potential deadlock, it rejects the request that would have caused the deadlock. The rejected transaction program can request restart.

DESCRIPTION

DPPX/DTMS is designed primarily for processing online, commercial transactions. Two distinct but related functional areas are supported:

- DPPX/DTMS data base manager provides the management and control functions required for controlled intra-system sharing of data. Data integrity is maintained, both during normal program execution and after abnormal termination.
- DPPX/DTMS transaction processing manager provides transaction processing facilities in support of online applications and shared data. Concurrent requests from a number of terminals are resolved through management of system resources.

The most significant data management services of DPPX/DTMS provide for controlled shared access to data, data recovery, and re-creation of damaged files. The transaction processing component manages the use of processor resources while responding to concurrent requests. The data manager component and the transaction processing component are capable of operating independently of each other, allowing for more effective use of main storage since both programs need not be in main storage simultaneously.

The Data Base Manager

The extended data management services of DPPX/DTMS assist the user in: Definition of sharable data bases ... Controlling shared access to data ... Recovery and reconstruction of data ... Reorganization of data ... Data security ... Avoidance of deadlock.

Sharable Data Bases: Using the DPPX/DTMS commands supplied, the customer defines the characteristics and structure of each controlled data base. The resulting profile contains information such as blocking, record and field descriptions, numbers of buffers to allocate during processing, file security and authorization details and level of recovery and re-creation protection, as well as information relevant to one or more key sequences of the data. These profiles are external to application programs. They exist as stored data themselves, and are referenced by DPPX/DTMS when it is processing access requests for application programs.

Controlling Access: Multiple application programs executing in DPPX/DTMS, DPPX/BASE interactive, or DPPX/BASE batch environments may be scheduled simultaneously against the same data base. When an application program is updating a record, other programs are prevented from accessing the record being updated until the updating program has completed its entire update procedure or reached a point of synchronization. If the updating program, DPPX/DTMS, or DPPX/BASE terminates abnormally prior to completion of the update procedure, the updates it has made can be, under user option, backed out of the data base to the last point of synchronization. This process ensures that all of the data accessible to a given application represents the results of successful, completed transactions.

Recovery, Reconstruction, Reorganization: An optional logging facility allows data changes to be journaled to an independent data set for later use if reconstruction of damaged data bases becomes necessary. Data base unload, reload, and re-create utilities provide for the coordination of backup files with the journaled data changes, during reconstruction. These same utilities can be used to reorder a given file to optimize physical storage sequence according to new user processing needs.

The data bases managed by DPPX/DTMS are DPPX indexed access method data sets that have been defined to DPPX/DTMS. A record contains a fixed number of fixed length fields, at least one of which serves as a key. Up to eight key indices are maintained per data base. Access to records is by reference to an index.

Data Security: DPPX/DTMS, in conjunction with DPPX/BASE facilities, provides for data security through a combination of user identification, password, and authorization categories. Security checking is done by DPPX/DTMS, to verify that a user requesting access to a protected data base has the appropriate credentials. If not, the request is denied.

Avoidance of Deadlock: A deadlock situation occurs when two or more programs are waiting for each other for access to data records. In such a waiting situation none of the programs can continue. DPPX/DTMS recognizes these potential situations before they happen, and rejects the request that would have caused the deadlock. The rejected transaction program is notified, and can elect to restart or bypass this particular request.

The Transaction Processing Manager

The transaction processing services of DPPX/DTMS provide:

- Application-independent terminal management.
- Effective use of storage.
- Input/Output message routing.
- Conversational/Interactive application support.
- Transaction-initiated work requests.
- System command and control facilities.

To use the DPPX/DTMS transaction processing facilities, a terminal user may logon directly to DPPX/DTMS. A security check verifies the user's password, and the user may then request execution of any transaction processing programs for which he is authorized.

Application-Independent Terminal Management: Specific application-oriented transactions are written by the customer, and defined to DPPX/DTMS through command facilities. Each transaction definition contains security authorization information, priority level, transaction

PROGRAM PRODUCTS

DPPX/DTMS (cont'd)

owner, application program name, and the transaction name or identifier. Users then request execution of a given transaction by indicating, at the terminal, the name of the transaction they wish to invoke. Transaction definitions can only be altered or deleted by the transaction owner or an authorized operator.

Effective Use Of Storage: The transaction processing manager of DPPX/DTMS makes effective use of storage by allowing several terminal users to share DPPX/DTMS-controlled subenvironments. When a user requests a transaction to be run, the transaction occupies a subenvironment only for the time required for execution. The subenvironment storage is made available for use by other users between transactions or while the user is entering data for the next transaction.

Input/Output Message Routing: After the user initiates a transaction request and enters the relevant data, DPPX/DTMS loads the user's transaction program and makes the data available to it. Thus the application program is relieved from the necessity of actually reading directly from the terminal, since the data is available to it when it begins execution. The program can also create a message for DPPX/DTMS to route back to the terminal when this transaction is complete, eliminating the need for explicit terminal output statements and freeing the subenvironment without waiting for the writing of the message to end.

If a customer has DPPX/DPS installed, DPPX/DTMS supports its use in conjunction with the DPPX/DTMS terminal input/output operations. Users can take advantage of the facilities offered by DPPX/DPS when combining its use with DPPX/DTMS.

Conversational/Interactive Application Support: Transactions may be logically chained together, such that a program that looks like a single conversational program to the terminal operator may really consist of several one-step programs. This allows program storage to be freed for use by other transactions during user think time or input entry time.

Continuous conversational applications are supported by DPPX/DTMS as well. However, since the program is in control of the terminal input/output, the transaction stays resident until the entire conversational transaction is complete.

Transaction-Initiated Work Requests: Application programs themselves, whether running under DPPX/DTMS or not, can ask DPPX/DTMS to create a work request for a transaction program. The work request may be associated with the originating terminal, with other user terminals, or with devices such as terminal printers.

System Commands and Control: DPPX/DTMS allows user control over the operating environment through a collection of monitoring and tailoring facilities. Inquiries may be made concerning the current availability and status of the DPPX/DTMS components, such as the transaction processing or data management components themselves, as well as the data bases and transactions defined to DPPX/DTMS. Current operating status, such as identification of current online users, names of transactions being executed, data bases opened, and pending transactions can be displayed.

Data bases may be dynamically defined and brought online or offline, and subenvironments for transaction processing can be added or deleted through operator control, without interrupting transaction processing. The transaction processing manager and the data base manager can be brought up and shut down independently.

CUSTOMER RESPONSIBILITIES

To install and use DPPX/DTMS the user must: Attend classes as necessary ... Acquire a knowledge of the functions as documented in *DPPX/DTMS Administration: Guide* and *DPPX/DTMS Reference* ... Become familiar with the facilities of DPPX/BASE ... Understand the DPPX/BASE installation processes described in *DPPX Installation: Guide* as they relate to DPPX/DTMS ... Understand the customization procedures as documented in *DPPX/DTMS Customization: Guide* ... Become familiar with operating procedures as described in *DPPX/DTMS Operation: Guide* ... Become proficient in an appropriate programming language such as DPPX/COBOL, and learn the specific program interfaces to DPPX/DTMS as described in *DPPX/DTMS Application Development: Guide* ... Design and implement the specific user system, including the creation of transaction definitions and programs as well as the definition and construction of DPPX/DTMS-controlled data bases ... Become familiar with the facilities of DPPX/DPS and DPPX Presentation Services for IBM 3640 terminals (DPPX/PS3640) if these are to be installed ... Carry out approved problem determination procedures before contacting IBM for service ... Install fix packages and service level updates as appropriate.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

DPPX/DTMS hardware system configuration requirements (except for storage) are consistent with those of the DPPX/BASE licensed program.

The following table specifies the minimum real storage requirements for DPPX/DTMS, excluding initialization. Since either the data base manager or transaction processing manager may function independently, storage is shown for the three configuration variations.

The minimum storage requirements for the Data Base Manager alone assume a single DPPX/DTMS data base, requests from a single batch or DPPX interactive command facility user and no audit file. Data base reset is assumed.

The minimum storage requirements for Transaction Processing Manager Alone assume a single terminal and support for a single transaction subenvironment.

The minimum requirements for full DPPX/DTMS, Both DBM/TPM, assume a single DPPX/DTMS data base, a single terminal, and support for a single transaction subenvironment.

Data Base Manager Alone	Transaction Processing Manager Alone	Both DBM/TPM
30K bytes	32K bytes	48K bytes

Storage required for DPPX/BASE, user programs and data, and optional but related coexistent products such as DPPX/DPS and DPPX/COBOL, are not included in the above figures.

System Operator Console: Same as DPPX/BASE requirements.

Direct Access: For system libraries, any appropriate IBM devices supported by DPPX/BASE are allowed.

For DPPX/DTMS user data storage and DPPX/DTMS system data sets, at least one disk storage unit is required. It may be the same device as required for DPPX/BASE system operation.

The DPPX/DTMS licensed program requires approximately 1.2M bytes of disk space for program load modules and other permanent data sets.

In addition, disk space is required for any other licensed program installed (such as DPPX/COBOL), for user-defined data sets, and for work spaces.

Tape Units: Although not required, one or more IBM 8809 Magnetic Tape Units are recommended for use with DPPX/DTMS data logging facility. Data logging can also be directed to disk storage, or not done at all.

User Terminals: Users may establish sessions with DPPX/DTMS (through LOGON or AUTOLOG) with all devices supported by the DPPX/BASE line/page presentation services classified as Keyboard/Displays, Keyboard/Printers, or Printers. In addition, customers with the DPPX/DPS licensed program installed may use all devices supported by DPPX/DPS classified as Keyboard/Displays or Printers.

SOFTWARE REQUIREMENTS

The user may write DPPX/DTMS transactions and DPPX/BASE interactive and batch application programs in DPPX assembler language, PL/DS or DPPX COBOL. DPPX FORTRAN may also be used, but will require DPPX assembler language subroutines to access many of the DPPX/DTMS facilities.

DPPX/DTMS works directly with DPPX/DPS, if available. It is recommended that DPPX/DPS be used in conjunction with DPPX/DTMS, to maximize programmer productivity.

Since DPPX/COBOL has IBM language extensions for DPPX/DTMS, it is also recommended for use with DPPX/DTMS to provide the advantages of this high level language to the DPPX/DTMS programmer.

DPPX/DTMS is written in Programming Language for Distributed Systems (PL/DS). When optional source code is ordered, it is distributed in DPPX assembler language with most of the original PL/DS statements shown as comments. Source code for DPPX/DTMS is available on magnetic tape and program listings are available on microfiche as related optional material.

DPPX/DTMS requires the Functional Enhancement Package 1 (FEP1), or later, level of the DPPX/BASE licensed program (5760-010) for installation and execution.

DPPX/DTMS has been designed to operate with and complement the following licensed programs, although they are not required:

DPPX/COBOL Compiler	5760-CB1
DPPX/COBOL Run-Time Library	5760-LB1
DPPX/DPS	5760-XR1
DPPX/PS3640	5660-267
DPPX Assembler (DPPX/ASM)	5760-AS1
DMS/DPPX	5760-XC2

CONVERSION

Indexed data sets, created and operable under the basic DPPX/BASE facilities, may be placed under control of DPPX/DTMS with no change or movement to the physical data sets. Minor command list (CLIST) changes are required, as well as the redefinition of the data sets to DPPX/DTMS data bases.

Existing DPPX conversational and batch programs may also execute as transaction programs, to be run under the control of DPPX/DTMS. No revision or recompilation is required, although it may be desirable in

PROGRAM PRODUCTS

DPPX/DTMS (cont'd)

order to take advantage of the unique facilities provided by DPPX/DTMS.

Existing DPPX programs which access Indexed Access Method files which will be defined as DPPX/DTMS data bases may also execute unchanged, although there are a few differences which may make recompilation or reassembly necessary. For example, data bases can only be accessed through the device independent SEND/RECEIVE macros (READ/WRITE statements), not through the lower level (EXCP) macro type interfaces available with the indexed access method. Also, there are such items as additional return codes, CLIST considerations, and differences in data record locking which may be the basis for minor program changes.

PERFORMANCE CONSIDERATIONS

The performance of DPPX/DTMS is highly dependent on the system resources available, the programs that operate concurrently and their relative priorities, and system data set and data base placement. Performance also depends on specific options selected by the customer, including data base buffer pooling, the number of transaction subenvironments, storage resident transaction definitions and/or transaction programs, level of security protection, extent of data recovery facilities, selection of DPPX/BASE and DPPX/DTMS modules and buffers, storage resident scratch pad data areas for inter-transaction communication, and the DPPX/DPS and DPPX/PS3640 licensed programs.

HIGHLIGHTS of FEP 1

The DPPX/DTMS functional enhancement package 1 (FEP 1) provides additional capabilities in availability, performance and usability and also may be used with the 8101 File/Tape Switch RPQ.

AVAILABILITY

FULLY QUALIFIED DATA SET NAMES: This enhancement allows the user to define system data sets SYSAUDnn, SYSDBPL, SYSPRODS, SYSRDS, SYSRIDS and SYSTPL in any volume catalog or user catalog (as well as the master catalog) and permits DTMS to access them in their user-defined location. This will allow a user with the File/Tape Switch RPQ the ability to switch a data base file from one 8100 processor to another without losing these system data sets. For customers not using the File Switch RPQ, Fully Qualified Data Set Names is useful for greater operational flexibility and recovery purposes, allowing the DTMS data sets to be placed on volumes other than the system residence volume. Previously, the system data sets were required to be defined in the master catalog.

RELOAD to DIFFERENT VOLUME: This enhancement will allow a data base to be recreated and renamed on a volume different from the original. This enhancement increases the flexibility of recovery for all DTMS users and can enhance system availability in the event of the loss of a disk volume. The Reload to Different Volume enhancement will add volume serial and data set name parameters to the RELOAD.DB, RECREATE.DB and ALTER.DB commands. Previously, when a data base was reloaded or recreated, DTMS required that the data base be rebuilt on the volume on which it originally existed. Even though the data to rebuild the data base existed elsewhere, the data base could only be rebuilt on the original volume. If the original volume was unavailable due to a disk failure, for example, the customer could not recreate the data base.

Fully Qualified Data Set Names and Reload to Different Volumes were shipped to customers in Fix Package 0499 in January, 1982.

PERFORMANCE

MULTIBLOCK I/Os to the AUDIT FILE: DTMS will now read and write to the audit file with multiple logical blocks instead of one block at a time. The audit file buffer will be written whenever it is full or when a data base containing data in the audit file is committed. Audit file reads during recovery of a data base will be for multiple logical blocks instead of one block at a time. I/O operations to the audit file will therefore be significantly reduced.

MULTIBLOCK WRITES to SYSRIDS: Multiblock writes to the reset information data set (SYSRIDS) will be done through a buffer so that data to SYSRIDS can be written with fewer I/O operations than was previously required. Often, only one I/O operation will be required.

FAST UNLOAD/RELOAD: The Unload and Reload services are changed to improve the performance of data base recovery. Target and index data set images are saved during unloading and then restored during recovery operations, thus eliminating the need for rebuilding the indexes.

USABILITY

READ ACCESS to LOCKED RECORDS: This enhancement allows the user to specify the READLOCKED operand on the ASSOCIATE.DB command, thus allowing read access to records locked by another user.

RECREATE.TSE COMMAND: A new command permits the user to cause one or more transaction subenvironments (TSEs), either specifically by name or by profile name, to be recreated. This enhancement makes it

easier to re-execute the TSE initial CLIST and therefore re-establish connections or implement other changes in that CLIST.

AUTOMATIC RECOVER.DATA: DTMS will automatically recover certain internally used DTMS data sets when DTMS is restarted after a failure. This will eliminate the need for the user to both keep track of which data sets need to be recovered and to issue RECOVER.DATA commands during a DTMS restart operation.

SYNCHRONOUS DEACTIVATE.DB COMMAND: A new parameter will be added to the DEACTIVATE.DB command to provide for the command to operate synchronously. Users will now be able to deactivate and unload a data base from a single command list (CLIST). Previously, DEACTIVATE.DB operated asynchronously and it was not possible in a CLIST to follow a DEACTIVATE.DB with a command (such as UNLOAD.DB) which depended upon the completion of the DEACTIVATE.DB command.

PERFORMANCE CONSIDERATIONS

DTMS online systems with high recreatable or resettable data base activity will experience fewer system I/Os to the audit file and SYSRIDS. As a result of this reduced I/O, these systems can experience a general improvement in performance.

In addition, the number of I/Os used by the Unload/Reload facility is significantly reduced and will result in a performance improvement when using this function.

COMPATIBILITY

DPPX/DTMS FEP 1 is upward compatible with earlier service levels. Program products supported on earlier service levels will be supported on FEP 1.

PROGRAM PRODUCTS

**8100 INFORMATION SYSTEM
DISTRIBUTED PROCESSING PROGRAMMING EXECUTIVE
REMOTE JOB ENTRY WORKSTATION FACILITY
DPPX/RJE (5760-XC1)**

PURPOSE

DPPX Remote Job Entry Workstation Facility (DPPX/RJE) permits the 8100 Information System to function as a multi-leaving or multiple logical unit remote job entry workstation for submitting jobs to a host S/370 or 4300 for execution under OS/VS, DOS/VS, DOS/VSE and VM/370 operating systems with a job entry subsystem installed.

SPECIAL SALES INFORMATION

8100 Information System customers can benefit from DPPX/RJE in several ways. Those who previously utilized RJE terminals will be able to install an 8100 and become productive quickly by utilizing existing RJE host programs until other applications are developed. Those installing a distributed system, where RJE has not previously been an application, will be able to extend the effective processing power of the 8100 through the use of DPPX/RJE.

DESCRIPTION

DPPX/RJE executes under Distributed Processing Programming Executive Base (DPPX/BASE), sharing system resources with other DPPX application programs. DPPX/RJE will support the definition of multiple workstations within one 8100. The limitations on the number of physically unique and separately controlled workstations is determined by the available system resources and required performance.

The host connection may be established for SNA/SDLC over a point-to-point switched or multipoint nonswitched line (for details on communication lines supported by 8100/DPPX, see DPPX/BASE pages). Both BSC and SNA/SDLC may connect over a nonswitched point-to-point line. SNA/SDLC utilizes multiple logical unit (MLU) support and BSC utilizes the multi-leaving protocols. Using SNA/SDLC discipline, the user may submit jobs to OS/VS operating system through the following:

RES (Rel. 6)	VS1 (Rel. 6.7)
JES (Rel. 4.1)	MVS (Rel. 3.7)
JES/NJE (Rel. 2-3)	MVS (Rel. 3.7)
JES3 (Rel. 3)	MVS (Rel. 3.7)
POWER/VS	DOS/VS (Rel.34)
VSE/POWER with RJE feature	DOS/VSE (Rel. 2.0)

Using the BSC discipline, the user may submit jobs to OS/VS operating systems above, and additionally through:

RSCS	VM/370 (Rel. 5.0)
RSCS Networking	VM/370 (Rel. 6) VM/SE (Rel.2) VM/BSE (Rel. 2)

Host S/370 or 4300 RJE programming support is generated by specifying the 8100 as an SNA terminal under the SNA/SDLC protocol or as a S/360/370 multi-leaving workstation (Mdl 25) under the binary synchronous communication line control discipline.

DPPX/RJE allows multiple groups of I/O devices, either physically adjacent to or physically remote from the 8100, to be designated as independent SNA workstations. Each workstation is controlled independently by its own RJE console and each can use the DPPX session log facility.

A collection of I/O devices, which is defined at the host entry system as one workstation, need not be physically adjacent. This enables the customer to distribute subsets of that collection of devices to different remote locations, thus providing the appearance of multiple remote workstations under the control of one console.

DPPX/RJE, executing under DPPX/BASE, affords the properly authorized RJE operator access to other DPPX facilities (utilities, interactive editor).

The data editing functions used to create RJE input files can be performed outside the control of DPPX/RJE by a DPPX editor.

DPPX/RJE provides capabilities to:

- Support multiple concurrent SNA input/output sessions up to the maximum dictated by the installation's resource and performance requirements or by the host job entry subsystem.
- Support multiple input and output data streams under the multi-leaving binary synchronous communication (BSC) line control discipline.
- Process commands entered at the workstation and transmit host commands. The local commands enable the workstation operator to:
 - Control the operation of the workstation.

- Invoke other DPPX facilities concurrently with DPPX/RJE operation.
- Dynamically reconfigure a workstation connected to the 8100 if the operator has the proper authority and if the reconfiguration is a subset of the total workstation defined to the host job entry subsystem.

The host commands enable the workstation operator to submit and monitor jobs being processed at the central complex. Messages received at the workstation are displayed on the console. Once displayed, the messages can be logged in an operator's log. Each workstation is controlled by its own separate console and can have its own separate log.

- Perform intermediate data storage (SNA/SDLC only) of RJE output.
- Control printer forms by specifying forms control locally or from the host S/370 or 4300.

Initialization of DPPX/RJE is performed by an authorized operator logging on to the DPPX/BASE command facility and execution of commands that initialize DPPX/RJE and establish communications to the host. Access to DPPX/RJE is controlled through the DPPX/BASE security facilities.

Multiple logical unit (SNA)/Multi-leaving (BSC) provides, in a general sense, a fully synchronized, pseudo-simultaneous, bi-directional transmission of a variable number of data streams between two or more systems.

HIGHLIGHTS

Multiple logical unit support (SNA) - Provides for support of multiple logical units up to the maximum number of logical units dictated by the installation's system resources and performance requirements or by the host job entry subsystem.

Multi-leaving support (BSC) - Provides for support of a variable number of bi-directional data streams between the host S/370 or 4300 and the 8100 and its attachments.

Customizable user interface - Through the capability to customize the DPPX/BASE command interface, DPPX/RJE commands may be tailored to more closely resemble a variety of desired user interfaces.

Non-dedicated workstation - Input/Output devices are not dedicated to the RJE function. They may be reassigned to other systems or user tasks before or after assignment to the RJE function.

Reconfigurable workstation - The workstation configuration (i.e., readers, printers, etc.) can be dynamically modified to be a subset of the host's definition of the workstation

Intermediate output data storage (SNA/SDLC only) - RJE output may be printed or punched or routed to disk for future printing or punching. With a user-written installation correlation table, output can be directed to one of multiple output classes according to the output parameters specified. Jobs are then submitted to the DPPX/BASE printer sharing facility for output. The operator may view or cancel jobs scheduled for printing.

Forms control - Locally cataloged forms control blocks can be specified for loading into the printer when the print function is started. Additionally, for SNA/SDLC, forms control may be accomplished automatically as specified by the host S/370 or 4300.

Prestored job control commands - Sequences of job control statements may be pre-stored at either the workstation or the host S/370 or 4300 location for concatenation to their appropriate data files.

Data concatenation - DPPX/RJE supports the concatenation of multiple cataloged DPPX data sets which can be transmitted as RJE jobs to the host. The data sets may contain data with or without job control statements or job control statements alone.

Direct card input (hot card reader support) - Multiple jobs can be input from the card reader for immediate transmission to the host without RJE operator intervention between job streams.

Unattended operation - A user-written programmed operator routine can be used to minimize the need for an RJE operator.

Device Support

Console: IBM

- 3232-1, 11 Keyboard Printer Terminal
- 3276 Control Unit Display Station
- 3277-1, 2 Display Station
- 3278 Display Station
- 3279 Color Display Station
- 8775 Display Terminal
- 3767 Communication Terminal

PROGRAM PRODUCTS

DPPX/RJE (cont'd)

2741 Keyboard Printer (not error checked)

VM/BSE (Rel. 2)

Direct RJE Input: IBM

- Disk Storage
- 3501 Card Reader (via 3289-3 Printer)
- 2502-A1 Card Reader (via 3289-3 Printer)
- 3521 Card Punch with read option (via 3289-3 Printer)
- Diskette Type 2D (must have the format created by DPPX data management -- it cannot be Basic Data Exchange format)
- 8809 Magnetic Tape Unit (data sets must be cataloged)

Direct RJE Output: IBM

- 3262-2, -12 Line printer
- 3289-3 Line printer
- Disk Storage
- 3521 Card Punch (via 3289-3 printer)

Printer Performance Considerations: The following system factors must be considered in determining anticipated printer performance:

For SNA/SDLC work stations:

- Host link speed.
- NCP pause value.
- RU size.
- Pacing values.
- Data set compaction/compression.
- Print line length.
- Disk block size on queued output data sets.

For BSC work stations:

- Host link speed.
- Host transmission block size.
- Maximum number of output buffers.
- Data set compression.
- Print line length.

In addition to the above, achieving rated printer speed for the 3262 mdl 2 may require that output be routed to intermediate disk storage on the 8100 for subsequent printing. This capability is available: SNA only.

CUSTOMER RESPONSIBILITIES

To install DPPX/RJE the customer must: Attend classes as required ... Become familiar with the facilities of DPPX/BASE ... Understand the DPPX/BASE installation procedures described in *DPPX Installation: Guide* and *DPPX/BASE Administration* as they relate to DPPX/RJE ... Understand the customization procedures as described in *DPPX/BASE Administration* ... Become familiar with the operating procedures as described in *DPPX/RJE Administration and Operation: Guide* ... Design and implement the specific DPPX/RJE system the customer requires (i.e., command synonyms, command lists, etc.) ... Create host applications for the RJE function ... Carry out approved problem determination procedures before contacting IBM for service ... Install fix packages and/or service level updates as appropriate.

To use DPPX/RJE the customer must: Attend classes as necessary ... Become familiar with the facilities of 8100/DPPX as they relate to DPPX/RJE (i.e., printer sharing, editor, etc.) ... Become familiar with the operating procedures as described either in *DPPX/RJE Administration and Operations: Guide* or as dictated by the customer personnel responsible for the specific customized version of DPPX/RJE.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The IBM host connection may be established for SNA/SDLC over a point-to-point switched or multipoint nonswitched line (for details on communication lines supported by 8100/DPPX, see DPPX/BASE pages). Both BSC and SNA/SDLC may connect over a nonswitched point-to-point line. SNA/SDLC utilizes multiple logical unit (MLU) support and BSC utilizes the multi-leaving protocols. BSC lines must operate in transparent mode: Non-transparency is not supported. Using SNA/SDLC discipline, the user may submit jobs to an OS/VS, DOS/VS and DOS/VSE operating system (and subsequent releases and modification levels unless otherwise stated) through the following:

RES (Rel. 6)	VS1 (Rel. 6.7)
JES2 (Rel. 4.1)	MVS (Rel. 3.7)
JES2/NJE (Rel. 2-3)	MVS (Rel. 3.7)
JES3 (Rel. 3)	MVS (Rel. 3.7)
POWER/VS	DOS/VS (Rel. 34)
VSE/POWER	
with RJE feature	DOS/VSE (Rel. 2.0)

Using the BSC discipline, the user may submit jobs to the OS/VS and VM operating systems (and subsequent releases and modification levels unless otherwise stated) through the above, and additionally through:

RSCS	VM/370 (Rel. 5.0)
RSCS Networking	VM/370 (Rel. 6)
	VM/SE (Rel. 2)

IBM host S/370 or 4300 RJE programming support is generated by specifying the IBM 8100 Information System as an SNA terminal under the SNA/SDLC protocol or as a S/360/370 multi-leaving workstation (Mdl 25) under the binary synchronous communication line control discipline.

DPPX/RJE will operate on an IBM 8100 Information System with DPPX/BASE installed, providing there is sufficient storage to satisfy the combined requirements of DPPX/RJE, DPPX/BASE, and other customer required programs.

The minimum processor storage requirement for DPPX/RJE operating under the SDLC protocol with one input or output device specified is 30K bytes. When using the system default values, which have been selected to provide performance for a typical SNA RJE user, 34K bytes of main storage is required with an IBM 3289-3 printer as the only active device. Each additional input or output device requires a minimum of 10K bytes.

The minimum processor storage requirement for DPPX/RJE operating under the BSC protocol with one input or output device specified is 48.5K bytes. When using the system default values, which have been selected to provide performance for a typical BSC multi-leaving RJE user, 54K bytes of main storage are required with an IBM 3289-3 printer as the only active device. Each additional input or output device requires a minimum of 7K bytes.

These storage requirements do not include processor storage required by DPPX/BASE for the RJE operator environment, or for the host link and the printer, or processor storage required by any other programs which may be used in conjunction with DPPX/RJE.

The configuration must include sufficient I/O devices to support the requirements for system output, system residence, and system data sets. Sufficient direct access storage must be available to satisfy the user information storage requirements and may consist of any direct access facility supported by 8100/DPPX.

Use of DPPX/RJE requires a keyboard/display or keyboard/printer supported as a DPPX/BASE operator's terminal to function as an RJE console. The DPPX/BASE operator's terminal may be used concurrently as an RJE console.

SOFTWARE REQUIREMENTS

The DPPX/RJE licensed program is designed to work with the DPPX/BASE licensed program.

This licensed program is written in Programming Language for Distributed Systems (PL/DS). When optional source code is ordered, it is distributed in DPPX assembler language with most of the original PL/DS statements shown as comments.

Source code is available on magnetic tape, and program listing on microfiche, as related optional material.

The following program is required:

DPPX/BASE, 5760-010

Use of DPPX Assembler (5760-AS1) to generate or modify forms control buffers (FCBs) may be desired, but is not required.

CONVERSION

Conversion from other IBM RJE products may require:

- Respecification of the 8100 to the host job entry subsystem.
- Specification of a DPPX environment and associated resources for execution of DPPX/RJE.
- Adjustment to the DPPX/RJE operating environment (commands, operator activities, etc.). The installation may utilize the command synonym and procedural capability to help minimize the effect of some differences.

PROGRAM PRODUCTS

**8100 INFORMATION SYSTEM
DISTRIBUTED PROCESSING PROGRAMMING EXECUTIVE
APL (DPPX APL)
5760-XR2**

PURPOSE

The DPPX APL program product provides the APL programming language for use on the 8100 Information System. DPPX APL supports application program development and personal computing in the distributed data processing environment. DPPX APL complements VS APL on the host with local APL processing of local data.

DPPX APL enables users to write, debug and execute APL programs - from informal casual programs to full size interactive application programs using local data bases.

HIGHLIGHTS

DPPX APL is an IBM program product that provides APL programming language for use on the 8100 Information System.

The following list summarizes how DPPX APL supports application program development and personal computing in the distributed data processing environment. DPPX APL complements VS APL on the host with local APL processing of local data.

The DPPX APL user can:

Write, debug, and execute APL programs - from informal casual programs to full size interactive application programs using data bases.

The DPPX APL language is designed to be compatible with VS APL, Release 4.0. DPPX APL includes the primitive functions and operators provided by VS APL, and the system commands, system variables, and system functions provided by VS APL, with a few exceptions. Terminal support and auxiliary processing used to access program services outside the APL environment are different from VS APL. APL support functions help to provide auxiliary processing compatibility.

Access screens defined through DPPX Distributed Presentation Services (DPPX/DPS) or the FM component of DPPX/SP. These screens can be used for interactive applications developed in APL. However, creation of maps (defining screens) is done outside the APL environment, using the IMD component of DPPX/DPS or DPPX/SP IMD. (Note: APL characters cannot be used in fixed fields.)

Access data stored in DPPX or DPPX/SP data sets and DPPX Data Base and Transaction Management Systems (DPPX DTMS) data bases.

Execute DPPX/BASE or DPPX/SP commands. These provide access to the input/output services and other services of DPPX/BASE.

Use support functions that help the user to set up interfaces to DPPX or DPPX/SP functions such as DPS and DTMS. The support functions provide a high-level interface, that is easier to use than the low-level interface to the DPPX APL Auxiliary Processor, through which all DPPX communication is performed using APL Shared Variables. These functions are coded in APL and supplied with the product.

Interface with programs written in other languages, provided they conform to DPPX or DPPX/SP linkage conventions. The interfaces must be defined to the DPPX APL Auxiliary Processor.

Interface with other APL sessions and workspaces on the same 8100 system. An application program can thus be structured using more than one working area.

Access a working area of approximately 60,000 bytes.

Format workspaces and APL objects for subsequent sending to VS APL on the host processor, and after receiving APL objects from VS APL. The VS APL workspace needed is distributed with DPPX APL.

CUSTOMER RESPONSIBILITIES

- Install DPPX APL.
- Obtain education in using the APL language, if needed.
- Obtain education in using DPPX or DPPX/SP, DPS AND DTMS, if needed for application development using APL.
- Carry out problem determination procedures before contacting IBM for program service.
- Update DPPX APL and related products with fix packages as appropriate.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

DPPX APL is designed to operate on the following IBM machines:

IBM 8130 or 8140 processor with 768K or more bytes of storage. Floating-point hardware (feature #3750, available only with 8140) is recommended for performance reasons.

The following IBM devices are supported:

8775 Display Terminal - mdl's 1, 2, 11, 12

3276 Control Unit Display Station - mdl's 11, 12, 13 14

3278 Display Station - mdl's 1, 2, 3, 4 (for attachment with 3274/3276)

3279 Color Display Station - mdl's 2B, 3B (no specific color support) (for attachment with 3274/3276)

3287 Printer - mdl's 1, 1C, 2, 2C (no specific color support) (for attachment with 3274/3276)

The corresponding APL feature must be installed on the above devices if they are to be used for editing APL functions or if the APL characters are otherwise required.

The following list gives the APL feature code and prerequisite feature codes for these devices:

Device	Feature #
8775	4626, 3905, 3624, 3622
3276	4626, 1120, 1067, 1068, 3610
3278	4626, 1120, 3610
3279	4626
3287	1120, 3610, 9082

STORAGE REQUIREMENTS: The minimum storage required for the APL environment is 230K bytes of real storage. The APL environment contains the APL interpreter and a minimum of one swap slot of 64K bytes for active workspaces.

Additional storage is needed for users logged on to DPPX APL. The minimum requirement per user is 12K bytes of real storage.

Additional storage may be needed due to application and performance requirements for APL and user environments. The maximum number of swap slots is four.

SOFTWARE REQUIREMENTS

The following programs are required for installation and operation of DPPX APL:

DPPX/BASE (5760-010) service level 0701 and subsequent service levels, unless otherwise stated by IBM, or DPPX/SP (5660-281).

DPPX/DPS V2 (5660-264) service level 0100 (Format Management) (feature #9520), and subsequent service levels, unless otherwise stated by IBM.

To use particular functions the following programs may be required:

DPPX DTMS (5760-TD1) service level 0303 and subsequent service levels, unless otherwise stated by IBM, for access to DTMS data bases.

Distributed Systems Executive (DSX) (5748-XXG) on a S/370, 4300 or 30XX host, for transfer of APL objects to and from the host.

DPPX/DPS V2 (5660-264) Interactive Map Definition (feature #6000), or DPPX/SP IMD for ability to define DPS maps.

CONVERSION and COMPATIBILITY

Existing VS APL functions, workspaces and applications may need conversion and restructuring before executing them on an 8100 system. The APL language differences are minimal; however, some system interfaces are different (such as I/O and DPS screen access) and maximum workspace sizes are different.

When converting from DPPX APL to VS APL, consideration must be given to functions provided in DPPX APL but not in VS APL, as well as to the above considerations.

PERFORMANCE CONSIDERATIONS

The performance of DPPX APL is dependent on the system resources available, in particular:

Floating-point hardware

Storage

Amount of storage available for system transient areas, and amount of resident code for DPPX APL

Do not reproduce without written permission

DISTRIBUTED PROCESSING PROGRAMMING EXECUTIVE
PERFORMANCE TOOL (DPPX/PT) MONITOR
WITH REPORTER FEATURE
DPPX/PT Release 2 (5760-XR5)****PURPOSE**

The DPPX/PT Monitor, together with the DPPX/PT Reporter feature, is a licensed program that monitors and reports on the activity of components of the Distributed Processing Programming Executive Base (DPPX/BASE), the Distributed Processing Programming Executive/ System Product (DPPX/SP), and DPPX Data Base and Transaction Management System (DPPX/DTMS) licensed programs. The DPPX/PT Monitor is a program which collects performance data. The DPPX/PT Reporter feature is a program that generates reports on the basis of the data collected by the DPPX/PT Monitor. The regular use of DPPX/PT can provide a basis for performance management of an 8100 DPPX or DPPX/SP system.

DOCUMENTATION

(available from Mechanicsburg)

DPPX/PT General Information (GH20-2155) ... DPPX/PT Program Reference and Operations Manual (GH20-2502) ... DPPX/PT Licensed Program Specification (GH20-5291).

SYSTEM INTEGRITY: Refer to section GI 23.2.

RPOs ACCEPTED: No

HIGHLIGHTS

DPPX/PT provides both general and detailed information to help manage the performance of a DPPX system.

- Processor Information.
 - Utilization by priority level.
 - Distribution of dispatch queue by priority level.
 - Utilization by environment.
- Real Storage Information.
 - Queuing for real blocks to back transient areas.
 - Range of real storage allocation.
 - Usage of transient modules.
 - Buffer and storage usage by environment.
- DASD Information.
 - Utilization by device.
 - Distribution of request queue by device.
 - DASD data set utilization.
- DTMS transaction statistics.
 - Number of transactions by type.
 - Time under DTMS control by type.
 - Time waiting for dispatch.
 - Time dispatched.

CUSTOMER RESPONSIBILITIES

It is anticipated that customer personnel will be able to install and run the DPPX/PT programs and that system programmers will be able to use the DPPX/PT reports after studying the DPPX/PT manuals.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

DPPX/PT is designed to operate on an IBM 8100 DPPX/BASE or DPPX/SP Information System with sufficient real storage to satisfy the combined requirements of DPPX/PT, DPPX/BASE, DPPX/SP and DPPX/DTMS when the DTMS option is selected, and other customer required licensed programs and applications. This must include storage for the software timer which is used by DPPX/PT and which must be available when running the DPPX/PT Monitor. The real storage required for basic measurements is 8.5K for the DPPX/PT Monitor and 13.5K for the DPPX/PT Reporter feature. Optional additional measurements require additional storage. See *DPPX/PT General Information Manual (GH20-2155)* for storage details.

An output device, either DASD or magnetic tape, must be provided. If the reports are to be printed locally, a printer is required.

SOFTWARE REQUIREMENTS

This licensed program is designed to work with the DPPX/BASE and DPPX/SP licensed programs. If data regarding DPPX/DTMS is desired, then the DPPX/DTMS licensed program is also required. No other licensed programs are required to use DPPX/PT.

DPPX/PT is written in Programming Language for Distributed Systems (PL/DS). When optional source code is ordered, it is distributed in DPPX Assembler language containing PL/DS statements as comments.

DATA SECURITY, AUDITABILITY, and CONTROL

DPPX/PT programs run under DPPX/BASE or DPPX/SP, and access to them may be controlled using DPPX/BASE or DPPX/SP facilities such as user authorization. Since the DPPX/PT Monitor program is privileged to run in master mode, access to it should be limited. User management is responsible for the selection, implementation, and adequacy of the security controls.

**8100 INFORMATION SYSTEM
DISTRIBUTED PROCESSING PROGRAMMING EXECUTIVE
DATA CAPTURE AND MANAGEMENT SYSTEM
DCMS/DPPX Release 1 (5760-XR6)**

PURPOSE

This licensed program is a data entry package for users of the 8100 Information System that simplifies the design, setup, and execution of the user's data entry applications. The DCMS/DPPX licensed program consists of an interactive job definition program, an online executor for data capture, and two batch utility programs for DCMX/DPPX local data interchange and statistical recording.

HIGHLIGHTS

- Provides online interactive definition of data entry unique requirements.
- Provides ENTRY, VERIFY, SCAN, CORRECT and BROWSE functions.
- Provides a comprehensive set of checks and edits and allows exits for user-defined checks and edits.
- Provides operator statistics, including: Batches completed, saved, cancelled; key strokes per hour (by processing function or mode); error counts and errors per batch per hour.
- Provides immediate availability of entered data to other DPPX application programs.
- Simplifies the setup of data entry jobs.
- Provides the capability to update (add or delete) data items in a record structure.
- Provides 8775 screen partition support in enter mode.
- Provides sub-batching support allowing multiple operators to process related data sets.
- Provides online batch management utilities.
- Provides online operator status utilities.
- Provides utilities to print copies of record and job procedure definitions.
- Provides the capability to restrict the terminal operator to access only authorized functions and data sets.

Five operational functions may be selected by the data entry operator:

- ENTER** -- Batched data may be entered into the system through enter mode. The data is checked and edited according to user specified edits as soon as the operator depresses the "ENTER" key. The operator may then correct any errors. Any data in error which cannot be resolved can be written to the file as a "marked" record to be examined later. Records may also be "flagged" to indicate some unusual condition noted by a terminal operator.
- VERIFY** -- Verify mode is used for checking the accuracy of the data which has already been entered. If the verify data does not match the previously entered data, the operator is required to resolve the conflicts. The level of verification is user selectable. The user may choose to verify every record, or only those which have been defined as "requires verification".
- SCAN** -- Scan mode allows any authorized operator to browse through the batch and examine and change any record. In scan mode an operator may insert, delete, mark or flag, and modify records. Any scan mode data modifications must pass the user-defined edits.
- CORRECT** -- In the correct option of scan mode, only records which have been marked or flagged are displayed to the operator. The operator may correct the records, delete them, or mark them again. Any modified data is edited according to user specifications.
- BROWSE** -- Browse enables a user to examine a batch file in read only mode.

DCMS/DPPX provides the following check and edit capabilities:

- Required field.
- Minimum length input.
- Alphameric.
- Alphabetic.
- Character (any EBCDIC characters).
- Numeric (signed or unsigned)
- Blank detection.
- Date check.
- Time and date insertion.
- Justify and fill (left or right).
- Automatic field duplication.
- Automatic field skip (entry, verify).

- Field verification required.
- Self check (mod 10 or mod 11, verify or generate).
- Table value substitution.
- Table validation (range checks and/or lists).
- Batch total accumulation and balancing.
- User-defined exits (field and record level).
- Constant insertion.
- Duplicate character (Type 3 map processing).
- Field resequencing.
- Field-to-counter arithmetic operations.
- Self check (user mod NN, verify or generate)

DCMS/DPPX requires a number of input, output, and work files to retain information as it is processing the various data entry facilities. These files are:

1. DCMS/DPPX job parameter table.
2. DCMS/DPPX journal file.
3. DCMS/DPPX error table file.
4. DCMX/DPPX profile file containing operator and batch records.

CUSTOMER RESPONSIBILITIES

To install and use DCMS/DPPX program product the user must: Acquire a knowledge of the functions provided by the different facilities ... learn how to use the definition facilities for unique information required by DCMS ... provide the necessary batch data sets to be used ... provide any necessary user programming to perform functions not provided by DCMS/DPPX. This may be accomplished via user exits. The customer may elect to write his own routines to be run by the DCMS/DPPX executor or DPPX/BASE or DPPX/SP batch facilities. This capability enhances the user's options for further checks and edits, file I/O, or other functions to be performed during execution time of the DCMS/DPPX product.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The minimum configuration for data entry definition and execution under DCMS/DPPX is:

IBM 8100 Information System with 512K bytes of processor storage and 23 or 29 megabytes of disk storage if using DPPX/BASE or 58 megabytes of disk storage if using DPPX/SP.

IBM operator console or terminal

IBM display terminal with 1920-character screen (can be operator console)

Processor: DCMS/DPPX and its generated job parameter tables will run only on an IBM 8100 Information System.

Main Storage: In an execution environment, DCMS/DPPX requires a minimum of 54K bytes of main storage for resident processing requirements plus an additional 6K bytes for non-resident processing. (Actual storage requirements may vary up to 78K because of unique application requirements and concurrent use of multiple modes and functions in a shared environment.)

Each operator requires an additional minimum of 6K bytes. The basic 6K byte user storage area will support a DCMS/DPPX job definition which includes a single map for a data entry application.

The amount of additional storage required by each operator is directly dependent upon:

- The number of maps and the number of associated entry fields.
- The number and size of user records.
- The size of user exit processing routines.
- The number and size of user validation services.

The above storage estimates do not include the storage required for DCMS/DPPX dependent products (DPPX/BASE, DPPX Distributed Presentation Services (DPPX/DPS), or DMS/DPPX).

As DCMS/DPPX uses DPPX/BASE and DPPX/DPS Format Management (FM) services for device access, the appropriate manuals should be consulted for the additional storage requirements. The storage requirements of the user's subroutines will depend on the facilities used and the complexity.

Disk Storage DCMS/DPPX operating environment requires disk storage space of approximately 6,000 blocks. Data

PROGRAM PRODUCTS

DCMS/DPPX (cont'd)

set space varies with the number of terminal types and size of procedures defined within DCMS/DPPX.

Peripherals For use of DCMS/DPPX in either a developmental or execution environment, a DPPX/DPS-supported display terminal with at least a 1920-character screen is required.

SOFTWARE REQUIREMENTS

DCMS is written in Programming Language for Distributed Systems (PL/DS). It is designed for execution together with DPPX/BASE.

For the development environment, DCMS/DPPX requires the following IBM licensed programs:

Program Name	Program #
DPPX/BASE	5760-010
DPPX/DPS V1 or V2	5760-XR1 5660-264
DMS/DPPX	5760-XC2

Note: DMS/DPPX is required for table definition. It is also recommended for map definition but not required. Map definition may be accomplished using DPPX/DPS-IMD.

For the execution environment, DCMS/DPPX requires the following IBM licensed programs:

Program Name	Program #
DPPX/BASE	5760-010
DPPX/DPS FM V1 or V2	5760-XR1 5660-264

Note: If the customer elects to write user exits, then the appropriate compiler is required for the development environment and the appropriate library is required for the execution environment.

DCMS/DPPX customers may use the following products:

Program Name	Program #
DPPX/ASM (Assembler)	5760-AS1
DPPX COBOL Compiler	5760-CB1
DPPX COBOL Library (required if execution of COBOL subroutines is selected)	5760-LB1
DSX (Distributed Systems Executive) Release 2 (may be used to transmit batch files to a S/370 or 4300)	5748-XXG
DPPX/RJE (Remote Job Entry Workstation Facility) (may be used to transmit batch files to a S/370 or 4300)	5760-XC1

PERFORMANCE CONSIDERATIONS

Because of the variations possible with an 8100/DPPX system, it is difficult to predict performance. The performance of DCMS/DPPX is highly dependent on the following:

- Size and complexity of the DCMS job definition
- Customer's use of user-written routines
- Amount of resources available - memory, disk storage, etc.
- Data file placement
- Number of batch or online users
- 8100 environment in which the DCMS product is executing

DOCUMENTATION

(available from Mechanicsburg)

DCMS/DPPX Licensed Program Design Objectives (GH20-5053)

SYSTEM INTEGRITY: Refer to section GI 23.2.

8100 INFORMATION SYSTEM DISTRIBUTED PROCESSING PROGRAMMING EXECUTIVE DPPX/BASE (5760-010)

PURPOSE

The following paragraphs contain general information pertaining to DPPX/BASE through the Functional Enhancements Package 5 (FEP 5) service level. A section at the end of these pages covers the highlights of later FEPs and service levels.

DPPX/BASE is a licensed program designed for distributed data processing applications running on 8100 Information Systems. It provides multi-programming, multi-user and multi-level system support for concurrent application environments. Interactive, batch, and plant floor applications are supported.

DPPX/BASE provides a variety of functions to communicate with S/370, 4300, other 8100 systems, and terminals. There are facilities to simplify installation, application design, program development and system operation. DPPX/BASE provides general usage system support which may be tailored or modified to suit unique requirements.

DPPX/BASE may operate alone or with the following related licensed programs (described separately).

DPPX Licensed Program

- Distributed Presentation Services (DPPX/DPS)
- Presentation Services for 3640 Terminals (DPPX/PS3640)
- Data Base and Transaction Management System (DPPX/DTMS)
- COBOL Compiler (DPPX/COBOL Compiler)
- COBOL Library (DPPX/COBOL Run-Time Library)
- FORTRAN Compiler (DPPX/FORTRAN Compiler)
- FORTRAN Library (DPPX/FORTRAN Library)
- Assembler (DPPX/ASM)
- Sort/Merge (DPPX/SORT)
- Data Stream Compatibility
- Remote Job Entry Workstation Facility (DPPX/RJE)
- Parameter Table Generation Facility for IBM 3644 Automatic Data Unit (DPPX/GEN3644)
- Development Management System (DMS/DPPX)
- Data Capture and Management System (DCMS/DPPX)
- Performance Tool (DPPX/PT)

SYSTEM/370 and 4300 Licensed Programs

- Distributed Systems Executive (DSX) Release 2
- Host Command Facility (HCF)
- Distributed Processing Development System PRPQ (DPDS) - with Programming Language for Distributed Systems (PL/DS)

DESCRIPTION

The major components of the DPPX/BASE licensed program are:

- Supervisor
- Command Facility
- Device Support
- Communication Support
- Data Management
- Interactive Editor
- Linkage Editor
- Interactive Debug
- Batch Capability
- Printer Sharing
- General Utilities
- Initialization, Customization and Service Functions
- Reliability, Availability, and Serviceability (RAS)

SUPERVISOR

The supervisor is a fundamental part of the DPPX/BASE licensed program. It provides the basic services to manage the resources of the system:

- Processor and error recovery management, which handle interrupts, and schedule and dispatch the units of work (threads) at each machine level in the system.
- Basic services, which manage queues, locks and timers. Queuing, locking and timer services may be used directly by user assembler language programs. Timer services provide a time-of-day clock and multiple logical interval timers.
- Storage and contents management, which keep track of the relationships among address spaces and other system resources.

- Initial Program Load (IPL) function, which permits any of several DPPX systems to be selected by the operator at IPL time.

Addressing Structure

- The logical addressing structure of the 8100 (4MB) allows DPPX/BASE to use any group of 2048 byte blocks of main storage to build an address space for the programmer, which appears as a single contiguous area.
- DPPX use of 8100 logical addressing provides:
 - Flexible allocation of main storage.
 - Storage protection, which may be used to protect DPPX from user applications and one user application from another.
 - A common area, which is available to all applications for shared programs and storage.

COMMAND FACILITY AND COMMANDS

A comprehensive set of commands are provided with DPPX/BASE to define system environments, initiate work, and manage the operation and resources of the system. Terminal users, user applications, batch programs, and operators communicate with DPPX/BASE using this single set of commands.

The command facility interprets these commands and invokes the interactive editor, interactive debug, linkage editor and the assembler and compiler licensed programs, as necessary, in order to execute commands.

DPPX can be customized dynamically. Using commands, new resources may be added to the system when they are acquired. Customization can be done interactively at a terminal. With commands, a customer can install, execute, and service DPPX. Included are commands to:

- Set time and date.
- Define, support, and delete resources (devices, adapters, network links, programs, data sets, commands etc.)
- Execute commands, command lists and jobs.
- Edit programs and data sets.
- Copy, move, index, print and display data and messages.
- Debug programs.
- Link edit programs.
- Service DPPX.
- Compile programs (if a compiler licensed program is installed).

Commands may be executed interactively by the terminal user or by batch methods. (Commands are available from DPPX/FORTRAN, DPPX/COBOL, and DPPX/ASM coded programs, by using a CALL statement.)

The user can write commands and command lists unique to the installation and define an application program that can be called by a command. Command names can be readily abbreviated or changed.

A command list is a series of commands which may be defined by the user or by IBM to perform a predetermined set of operations. A list can use substitution parameters and make unconditional branches forward as well as branch on return codes.

Individuals can be restricted to a subset of the command repertoire by using authorization profiles; that is, the customer may not permit all users to access all commands, particularly commands which could affect system integrity.

The command facility provides capability needed by the customer to write a program (in assembler language) to perform system operator functions. This program can provide a programmed series of predefined actions which will permit an 8100/DPPX system to run virtually unattended.

DEVICE SUPPORT

Overview: DPPX/BASE provides programming support for the many devices that can be attached to the 8100. For most devices the programmer may use the SEND/RECEIVE macros to handle logical records without concern for the physical device characteristics. Through the SEND/RECEIVE macros (and their equivalents in the DPPX COBOL or FORTRAN languages or PL/DS), the user can refer to data in a device independent manner. For example, a user program can communicate with a terminal, another user program (local or remote) or a pair of sequential data sets (one for input, one for output), without any change to the program. Since IBM licensed programs also use these macros, the 8100 user can readily substitute alternative devices. Depending on the device, this user interface may be supported by:

PROGRAM PRODUCTS

DPPX/BASE (cont'd)

- Sequential presentation services for disk, IBM Diskette Type 2D and tape.
- Unit record presentation services for input only or output only devices.
- Line/page presentation services for interactive devices and user applications.

Printer control characters may optionally be used with unit record presentation services. The IBM 3287 SNA Character String (SCS) Support Feature (#9960) is a prerequisite for presentation services support of the 3287 Printer mdls 1 and 2.

Lower level interfaces may be used to satisfy special requirements.

General Device Support: Programming support is available for the following devices: (IBM devices, unless otherwise indicated, and supported by both DPPX and DPPX/SP, unless otherwise indicated).

- 8130 and 8140 Processors
- 8101 Storage and I/O Unit
- Disk Storage (included in 8130/8140 and optionally in 8101)
- Diskette Storage Type 2D (included in 8130/8140 and optionally in 8101)
- 2502, 3501 Card Readers and 3521 Card Punch
- 8809 Magnetic Tape Unit

Printers

- 3230 mdls 1, -2
- 3262-2, -3, -12, -13
- 3268-1, -2
- 3284-1, -2
- 3286-1, -2
- 3287-1, -1C, -2, -2C, -11, -12
- 3288-2
- 3289-1, -2, -3
- 5210-E01, -E02, -G01, -G02 (DPPX/SP only)
- 6580 Displaywriter System (through 3270 Data Stream Compatibility licensed program)

(Note that keyboard/printers may be used as printers for most functions.)

Keyboard/Displays

- 3104-B1, -B2 Display Terminal
- 3178 Display Station
- 3274-41C Control Unit
- 3274-51C Control Unit
- 3274-61C Control Unit
- 3276-1, -2, -3, -4 Control Unit Display Station with SDLC/BSC switch set to SDLC
- 3276-11, -12, -13, -14 Control Unit Display Station
- 3277-1, -2 Display Station
- 3278-1, -2, -3, -4, -5 Display Station
- 3279-2A, -2B, -3A, -3B Color Display Station
- 3290 Information Panel
- 6580 Displaywriter System through:
 - 3270 Data Stream Compatibility (3278)
 - 3277 Device Emulation (3277)
 - 3277 Device Emulation/Document Transfer (3277)
- 8775-1, -2, -11, -12 Display Terminal

Keyboard/Printers

- 3232-1, 11 Keyboard Printer Terminal
 - 3767-1, -2, -3 Communication Terminal
 - 2741 Communication Terminal
 - Western Union Teletypewriter Exchange Services M33/35, or IBM 3232-51 or equivalent, for example, the IBM 3101 Display Terminal (Character Mode)
- (Note that data sent to or from the 2741 is not error checked.)

3640 Devices

- 3641 Reporting Terminal (Appears as a keyboard/printer)
- 3642 Encoder Printer (Appears as a printer)
- 3643 Keyboard Display (Appears as a keyboard/display)
- 3644 Automatic Data Unit (Appears as a keyboard/printer)
- 3645 Printer
- 3646 Scanner Control Unit (Appears as a keyboard/printer)
- 3647 Time and Attendance Terminal (Appears as a keyboard/printer)

Includes the following controllers supported as a keyboard printer:

- 3600 Finance Communication Controllers
- 3630 Plant Communication Controllers
- 3650 Store Controllers
- 3680 Point-of-Sale Control Unit

- 4700 Finance Communication Controllers
- 8100 Information System with DPCX

When a controller or communication processor is supported on a host via Data Stream Compatibility (DPPX/DSC), the PU services available are those supported by the then current level of DPPX/BASE.

User applications may appear as a keyboard/printer terminal to other user applications, and to certain DPPX functions. A DPPX/BASE function, remote intercommunication, is used to create this appearance.

Attachment of Specialized Subsystems

- 3270 Personal Computer Attachment
- 3640 Plant Communication devices for host communication via Data Stream Compatibility (DSC)
- 5150 Personal Computer
- 5280
- 6580 Displaywriter with Displaywriter 3270 Data Stream Compatibility (DSC)
- Series/1

BSC Protocol Support: DPPX provides specific support for the following BSC protocols:

- 2780/3780 line protocol on a point-to-point BSC line using the SEND/RECEIVE macros. This interface is supported for output only operations (as a printer) and for input only operations (as a card reader).
- 8100 as a 3271 attached to a S/370 or 4300 host on a nonswitched multipoint BSC line. (Used by DPPX/DSC.)
- 8100 as a S/360 mdl 25 MULTI-LEAVING RJE Workstation on a point-to-point BSC line to a S/370 host. (Used by DPPX/RJE.)

8775 Support

- Supported by DPPX/BASE line/page presentation services (SEND/RECEIVE macros).
- User programming or other DPPX licensed program can support 8775 advanced functions such as highlighting, multiple partitions and field validation.
- DPPX/BASE can accept and store diskettes containing 8775 functional support.
- DPPX/BASE loads the 8775 with the appropriate functional support when the device is activated.

Display Copy Support: The following support is available for operator initiated copy from a display onto a printer:

- 8775-1, -2 and 3104-B1, -B2 onto a loop attached 3268-1 or 3287-11, -12 or a 3230-1.
- The 3276, the 3278 and the 3279 may also copy onto 3276/3274 attached printers independent of DPPX/BASE.

COMMUNICATION SUPPORT

DPPX is designed for interactive operation in a host S/370 or 4300 controlled or DPPX controlled network. Communications support is an integral part of the DPPX/BASE licensed program support. It provides:

- Independence of Network Appearance.
The DPPX/BASE structure allows non-SDLC devices to be managed and to appear as similar SDLC devices, transparent to user applications or higher level DPPX functions.
- Link Independence.
User applications need not be concerned with the particular physical link to which devices are attached.
- Link Sharing.
SDLC links may be shared by many sessions. For example, DPPX/RJE and HCF can share a host link concurrently with a number of 3270 terminals.
- Multiple Host Links.
Multiple communication links between an 8100 and one or more S/370 or 4300 hosts allows, for example, DPPX/RJE to communicate with a S/370 or 4300 job entry subsystem, and DPPX/DSC, in the same 8100, to concurrently communicate with a S/370 or 4300 application in the same or a different host.

DPPX/BASE (cont'd)

- Device Independent Communications.

User programs which transfer logical records may, without change, communicate with a DPPX keyboard/display, keyboard/printer, a pair of data sets, or (using remote intercommunication support) a DPPX user application. The user program may be written in DPPX COBOL, FORTRAN (using READ and WRITE statements), PL/DS or Assembler language. All SNA terminals are supported in this manner as well as others, such as the 2741, 3232-51 and 2780/3780 BSC equivalent devices.

Logical record, device independent communications are supported, through the SEND/RECEIVE macros, by line/page presentation services for interactive devices, and by unit record presentation services for input-only or output-only devices. The logical record is broken into one or more lines and displayed. Similarly, a logical record is built from data entered from a terminal or unit record device.

- Remote Intercommunication.

DPPX/BASE remote intercommunication support allows communication between applications in two interconnected 8100/DPPX systems. (The systems are connected by a single link with no intervening systems). The applications communicate logical records with the SEND/RECEIVE macros (line/page presentation services) and may be written in DPPX COBOL, FORTRAN, PL/DS or assembler language. A user application can also connect to certain DPPX functions, such as the command facility or the DPPX/DTMS licensed program, which are written with these macros. The user application appears as a keyboard/printer terminal to these functions. Knowledge of node addresses is not required in the application, which refers to the destination symbolically. This symbol is resolved at execution time into the actual remote program and node names.

DPPX COBOL applications may communicate with a remote application or DPPX function. A DPPX system can form such sessions with several other systems. However, only one such session may exist between any given pair of systems.

DPPX assembler language and PL/DS may communicate with a local or remote DPPX application or function. Several sessions of that kind may exist within or between systems.

- Adjacent Node Terminal Communications.

Adjacent node terminal communications complements remote intercommunication described above. It supports networks of IBM 8100s by permitting SNA terminals and supported 3640 devices attached to an 8100 node to establish, via SDLC links, sessions with applications in adjacent 8100 nodes. Thus, such a terminal connected to an 8100 can access function in another 8100 connected to the first via an SDLC link (the ability to service 8100 systems using DSX and HCF requires the 8100 to be S/370- or 4300-connected). This facility includes capabilities for:

- A terminal at an 8100 servicing another 8100 system,
- A terminal at an 8100 getting transaction processing performed on a connected 8100,
- All program development being located at one 8100 while still having the capability available on a connected 8100,
- A terminal at an 8100 system communicating through DPPX/DSC, with a host S/370 or 4300 connected through an intermediate 8100, (similar to a terminal at a S/370 or 4300 communicating through HCF with 8100s connected through an intermediate 8100).

- Host Transaction Facility.

Allows DPPX/DTMS applications (written in DPPX COBOL, PL/DS or DPPX assembler language) and S/370 or 4300 IMS/VS and CICS/VS applications to communicate via SNA. The host transaction facility (HTF) uses host presentation services to handle host communication protocols. The host presentation services function is also available to the customer. HTF can be used by DPPX/DTMS applications to send transactions to and receive replies from IMS/VS (transaction dependent terminal response mode) and CICS/VS applications. Data base inquiry, update, and message integrity are supported. HTF requires the transaction processing manager part of the DPPX/DTMS licensed program and supports DPPX/DTMS applications written in DPPX COBOL, PL/DS and DPPX assembler language through a simple CALL statement. HTF thus provides a transaction management level of function for host communication.

HTF is designed for use with CICS/VS 1.4 and IMS/VS 1.1.4 or subsequent releases.

For CICS/VS, host transactions may be sent with or without an expected reply message.

A variable number of host sessions may be active concurrently, permitting the user to trade off link performance against processor and storage utilization.

HTF sessions and transactions are initiated at the 8100/DPPX node.

HTF support includes standard DPPX/DTMS transactions that display replies to transactions to the originating terminal and log unsolicited messages. The user may replace these transactions (for example, to route unsolicited messages). For solicited replies to transactions, the CALL statement and an HTF routing profile provide flexibility in specifying the program which is to process a transaction reply. The program (user or IBM supplied) which processes the reply runs as a DPPX/DTMS transaction and may use DPPX/DTMS facilities, such as the data base manager. It may also send a message to the requesting terminal.

Separate user transactions initiate the host transaction and process any reply. The DPPX/DTMS "scratch pad" may be used to save data for the reply transaction running under DPPX/DTMS which may itself initiate another host transaction. The DPPX/DTMS applications, however, are not part of a single DPPX/DTMS recovery scope.

- Host Presentation Services.

The host presentation services allows DPPX assembler language or PL/DS applications to communicate with host IMS/VS and CICS/VS applications and SNA over an SDLC link. The host presentation services provide an access method level of function for host communication. A header precedes all data and is used to communicate information between the host presentation services and the user, such as SNA sequence number handling and whether or not replies are required. The host presentation services also provide the communications protocol handling for HTF. The host presentation services use SLUTYPEP support in IMS/VS (IMS/VS 1.1.4 or subsequent releases) and the 3790 Full Function Logical Unit support in CICS/VS (CICS/VS 1.4 or subsequent releases). For host presentation services use with CICS/VS running under TCAM, note that CICS/VS contains no unique device support for TCAM. It is the responsibility of the TCAM programmer to provide support. DPPX documentation will describe the specific functions and capabilities of the host presentation services in relation to IMS/VS and CICS/VS.

- Communication Services.

The communication services provide a general set of SNA functions and protocols which are used by other DPPX components, services and licensed programs. The interface to communication services is referred to as the data stream interface and is available to Assembler language programs for specialized network communication. It permits DPPX assembler language or PL/DS applications to communicate with TCAM or VTAM applications or subsystems or with any SNA cluster or device. The Communication Services provide function analogous to the VTAM Application Program Interface (API).

- Transform Services.

Provided to integrate selected non-SDLC devices into the DPPX SNA network. For example, the BSC 2780/3780 is managed in this way.

- EXCP BSC Interface.

DPPX/BASE includes a basic set of BSC functions for direct control of BSC links and devices. These functions are available through the EXCP macro. BSC devices and protocols can be supported in this manner. Four modes of BSC operation are supported:

- Point-to-point primary.
- Multipoint control.
- Point-to-point secondary.
- Multipoint tributary.

Specifically excluded are the following:

- ASCII.
- Switched operation.

Specific testing and higher level function have been provided for the following BSC protocols:

- Multi-leaving BSC on point-to-point lines (for the DPPX/RJE licensed program).
- Appearance to the host as a BSC 3271 on a multipoint line (for the licensed program).
- Attachment of 2780/3780 compatible devices.

Two features of the DPPX structure can simplify the attachment of BSC devices:

DPPX/BASE (cont'd)

- The use of transform programs to manage and integrate non-SNA devices into DPPX as similar SNA devices.
- The isolation of specific device support from higher level components. For example, the DPPX/DTMS licensed program and the DPPX/BASE command facility are not concerned with whether the terminals in session with them are 2741 or 3767 terminals or whether the links are start/stop or SDLC.

• Link Support.

- Direct attached loop.
- Data link attached loop via the 3842/3843.
- Nonswitched point-to-point and multipoint SDLC links.
 - Cluster appearance of 8100/DPPX to a host.
 - DPPX systems to a controlling DPPX system.
 - Terminals connected to an 8100/DPPX system.

Includes the following controllers on nonswitched multipoint SDLC links:

- 3600 Finance Communication Controllers
- 3630 Plant Communication Controllers
- 3650 Store Controllers
- 3680 Point-of-Sale Control Unit
- 4700 Finance Communication Controllers
- 8100 Information System with DPCX

When a controller or communication processor is supported on a host via Data Stream Compatibility (DPPX/DSC), the PU services available are those supported by the then current level of DPPX/BASE.

Note that switched facilities may also be used to simulate a nonswitched line by manually establishing the connection. Switched network backup can also be accomplished in this manner.

- Switched SDLC link.
 - DPPX auto answer to S/370 or 4300.
- Nonswitched multipoint BSC tributary to S/370 or 4300.
- Point to point BSC 2780/3780 links.
- Nonswitched 2741, 3232-51 and Western Union Teletypewriter Exchange Services Model 33/35 or equivalent, start/stop links.
- Other BSC links and terminal types. The user is responsible for programming support for the particular BSC protocol, using basic BSC functions provided by DPPX.
- DPPX/BASE supports direct attached loops at 9600 and 38.4K bps, data link attached loops at 2400 bps, and communication links at up to 56K bps (SDLC) and up to 9600 bps (BSC) on an 8140, and up to 9600 bps (SDLC or BSC) on an 8130. See the machine pages for details.

DATA MANAGEMENT

A single data organization, the Relative Sequential Data Set (RSDS) is used to organize, access and catalog data sets in the 8100/DPPX.

Access Methods: Data management provides two access methods, relative sequential and indexed.

The Relative Sequential Access Method (RSAM) provides the following capabilities:

- Direct access to records using a relative record or block number.
- Sequential access to records.

Indexed access to records using the Indexed Access Method:

- Up to 8 indexes, each accessing the data set with a different key, may exist concurrently.
- Indexes and the corresponding data records are maintained in separate data sets.

Direct and indexed access methods apply only to disk and IBM Diskette Type 2D storage. Sequential access may be used for most supported devices through the SEND/RECEIVE macros.

RSDS Structure: RSDS organization provides a common method of organizing data with the following characteristics:

- Records may be any size from 2 up to 4096 bytes for disk and diskette.
- Records may be any size from 18 up to 4096 bytes for tape.
- For disk and diskette storage, logical blocks may be any multiple of 256 bytes up to 4096 bytes. For tape, logical blocks may be any size from 18 bytes to 4096 bytes.
- All records in a data set must be the same size.

- All logical blocks in a data set must be the same size.
- At the user's option, locking is performed at the logical block level.

System Catalog

- The system catalog contains profiles of all data sets catalogued on the system residence volume, as well as all user and volume catalogs known to DPPX.
- Utilities are provided to list and modify the system catalog.

User Catalogs

- Multiple user catalogs may be created and updated.
- Utilities to list and modify the user catalogs are provided.

Volume Catalogs

- Provides capability of exchanging data between DPPX systems using diskettes as transporting media.

Tape Labels: Tape labels compatible with S/370 and 4300 are supported for tape processing. The DPPX/BASE licensed program provides support for tape label processing for IBM 'standard' labels, 'non-standard' labels, 'standard user labels' and unlabelled tapes. The label processing capability allows tape interchange with other systems using IBM-defined labels and allows the user the flexibility of establishing unique label formats for use within a customer enterprise.

INTERACTIVE EDITOR

The interactive editor is an editor for entering and editing data (character and hexadecimal internal formats). It operates as a line editor from keyboard/printers and keyboard/displays, or as a full screen editor (using the DPPX/DPS licensed program) on displays. It may be used to enter and edit source programs written in any DPPX programming language. The interactive editor can also be used for subsequent updating and reformatting.

LINKAGE EDITOR

The linkage editor supports the language translators by combining and linking object procedures (output of the language translators) into load modules. The linkage editor can also be used for module editing, to reserve storage for common areas and to build overlay structures.

It has options for special processing and produces output reports and diagnostics.

INTERACTIVE DEBUG The interactive debug facility can be used with any of the languages offered by DPPX. A simple command set allows the programmer in a terminal session to:

- Invoke a program to be tested.
- Place break points in the program at which execution is to be suspended, and display or alter any areas or registers within the program.
- Invoke dump facilities.

BATCH CAPABILITY

Batch processing is provided via the DPPX SUBMIT.BATCH command. The user enters "SYSIN" records into a data set either interactively, using the interactive editor, or via tape, diskette, disk or card reader. The SUBMIT.BATCH command is then issued to enter the job into the batch queue.

The batch processor, when active, will scan the job queue for "jobs" and will initiate them.

PRINTER SHARING

Printer sharing allows multiple users to write output to a print data set rather than directly to the printer. Printer sharing permits multiple interactive application programs, batch programs, utilities, and RJE "SYSOUT" to share the system printer facility by spooling output to the disk. Multiple printers are supported up to a maximum of four printers.

GENERAL UTILITIES

The utilities offered in DPPX are data management oriented. They include:

- Volume initialization for tape and disk storage.
- Copy data function.
- A utility to build indexed data sets.
- Commands to list catalogs.
- DEFINE, ALTER and DELETE data set and catalog commands.
- A stand-alone disk storage DUMP/RESTORE.
- A system trace to assist in analyzing and debugging the system.
- A stand-alone processor storage dump.
- Utilities to format and print storage dumps.

DPPX/BASE (cont'd)

- Ability to read or write basic data exchange from or to an IBM Diskette Type I or IBM Diskette Type 2D on an IBM Diskette Type 2D Drive.

ACCOUNTABILITY

DPPX provides the customer with tools, facilities, and options for a level of protection at each node of a distributed system.

Authority: For each object known to DPPX (people, programs, data sets, commands, physical devices, logical devices), there is a DPPX structure known as a profile -- a list of descriptors of the object. The profiles for people, programs, data sets and commands include authorization descriptors called credentials; the credentials of all of these objects attest to the authority they have to make use of other controlled objects. These credentials are known as authority credentials. Objects usable by others also have requirement credentials stating what authority is needed in order to use them. For one object to use another, the authority credentials of the first must include at least the requirement credentials of the second.

Requirement credentials and authority credentials are compared by the command facility in behalf of data set commands, the linkage editor, the interactive editor, and the interactive debug facility. This verification routine may be replaced by the DPPX/BASE user.

Password Protection: The profile for a user has a field for a password. When a user logs onto DPPX/BASE, the password contained in the profile must be supplied or the user will be rejected. Rejections result in a message to the system operator and can be journaled. Passwords may be changed by personnel with proper data set access privilege.

Isolation: A person can function as if he alone were using the system. Isolation (user/user, application/application, user/system, application/system) is achieved in DPPX by the environment structure, private address spaces, four levels of privilege for instructions, and eight levels of priority for interrupts. (This latter isolates program checks to the level to which they occur.) Storage protection is another facility used.

Cryptography: Cryptographic protection over a communication link, other than loop, is provided by the IBM 3845 and 3846 and is used to encrypt/decrypt at each end of the line. (Certain diagnostics must be bypassed.) A S/370 or 4300 host with ACF/VTAM Encrypt/Decrypt Feature (#6010), 5735-RC2, and the IBM Programmed Cryptographic Facility licensed program, 5740-XY5, can communicate cryptographically with a 3276 mdl 11, 12, 13, or 14 Control Unit/Display Station or a display station connected to a 3274 mdl 51C Control Unit with the Encrypt/Decrypt Feature (#3680) if the DPPX Data Stream Compatibility licensed program is installed on the 8100 system.

Physical Security: An optional three position keylock is provided for the operator's control panel. It limits panel use to off/on only, or to no use at all, and is not removable in the full use position. Keylocks for the covers and mechanical locks for the access doors to the diskettes are available. (Communications connectors are located inside these covers.)

Installation: The installation of 8100/DPPX is a flexible process, designed to minimize customer effort. DPPX initialization consists of a system residence device initialization and an initial program load (IPL). Performing these tasks requires only the setting of a mode switch, depression of the IPL button, and response to several prompts through the Basic Operator Panel. The customer has the option of accepting defaults or providing the responses in the manual mode of operation.

During the DPPX initialization phase, a data set of operational parameters (System Parameter List) is automatically accessed by DPPX to provide information about the operational environment (interrupt levels, activate lists, etc.). A default list is shipped with each DPPX system and a system parameter list accompanies each preconfigured definition (PCD) provided with the DPPX system. The customer can select the default list or a PCD system parameter list and use it as is or the lists can be modified using the interactive editor and the ALTER.SYSPARMS command. The customer can also create his own unique list.

The final phase of system installation consists of defining and activating the hardware configuration to the DPPX system. This customer process is performed interactively through the command facility. Data sets of define and activate commands are stored as a command list (CLIST) and invoked to perform the hardware/licensed program configuration matching. A CLIST data set will accompany each PCD. The customers may use the CLIST as is, modify it, or create their own. Default CLISTs will be shipped with each DPPX system which will allow a system operator console to be identified to the system.

RELIABILITY, AVAILABILITY, SERVICEABILITY (RAS)

DPPX has the following RAS features:

Integrity: Integrity features allow the system to protect itself from damage that might be caused by user errors.

DPPX is designed to use the integrity features designed into 8130/8140 processors, which provide:

- Storage access control codes: INVALID, READ, READ/WRITE, READ/EXECUTE and READ/WRITE/EXECUTE.
- Address space control to preserve integrity of control and application code.
- Control mode state use restricted to prevent unauthorized use of privileged processor instructions.

Data Set Access Credentials - Insure a user has authorization to access a data set, alter a data set profile or delete a data set.

Function Access Credentials - Commands received by the command facility are checked, at the command processor level, to ensure that the command is valid and that the user has the authorization to issue that command. Program access can also be restricted.

Availability: DPPX availability functions enhance the capability of the system to continue to provide the services demanded by its users during failure occurrence.

Error Exit Routines - Provides the application or DPPX component with the ability to effect a recovery suitable to each step of the application or component.

Resource Recovery - Resource managers attempt to recover resources when an environment is terminated to prevent contention because of resources not freed.

Printer Sharing - Allows several programs to share the same printer by scheduling printer output in data sets.

Auto Re-IPL - A re-IPL of the system occurs automatically when power resumes after a power outage.

Return Codes For Errors - For an unsuccessful operation, the return code defines the module of DPPX code that was unable to complete its requested function.

Stop Function - Allows an application to be terminated by the system operator.

Disable Failing I/O - When a physical link has an unrecoverable physical malfunction, the error is logged and application programs connected to terminals on the failing link are notified, enabling them to deactivate the resources.

Serviceability: DPPX serviceability can facilitate the service of failing components.

Error Logging - Incidents and related information are recorded in the error log to assist in problem determination. An interface is provided for customer developed programs to enter incident records in the error log.

Error Log Summary and Archive - Formats, summarizes and stores error log data in an archive data set.

System Messages - When an operator needs to be informed of an incident or of an action to be taken, a message is sent to the console. These messages describe an error, an action to be taken by the operator, or a recovery executed by DPPX.

Standalone Dump - Provides a capability to dump the registers, segment space, storage space and selected parts of control space of the processor if DPPX cannot be operated. Output is written to a data set on diskette.

Formatted Dump - Prints or displays, in readable format, the results of a standalone dump.

Message Log - Messages sent to or received by a particular terminal operator may be optionally logged for subsequent examination.

Interactive Debug - Allows online debugging of user environments. A set of commands allow the user to display, dump, and modify addresses and registers.

System Trace - Allows the operator to control a trace operation. Trace output may be directed to a data set.

Notification of Failing Network Component - When an SNA station, a link, or a physical unit incurs an unrecoverable physical error, a message is sent to the operator and the error is logged.

Distributed System Environment Test - May be invoked interactively to verify DPPX operation.

Service Level Update Management - The DPPX/BASE INSTALL.PROGRAM command is used for both initial installation and subsequent application of service level updates for 8100/DPPX licensed programs other than DPPX/BASE. Initial installation and service level updates of DPPX/BASE are handled via the initialization/customization functions of DPPX/BASE. In general, customers who apply fix packages as they are made available will not require service level updates.

APAR Create - An interactive aid which gathers pertinent information required to solve programming problems and outputs this data to a diskette.

PROGRAM PRODUCTS

DPPX/BASE (cont'd)

Fix Install - Allows a customer to apply fixes which are provided on a diskette.

Interactive Editor - Used to apply temporary fixes (patches) to load modules, or to modify records in sequentially accessed DPPX data sets.

Dump Manager - Provides a dump of a failing thread with its associated processes, control blocks and environment.

Initial Error Detection Under DPPX - Provided by ROS (Read Only Storage) tests during IPL (Initial Program Load). These tests include the processor circuitry, arithmetic operations, basic I/O, storage, disk and other functions.

Offline diagnostics are also available to service hardware components.

With the exception of offline functions (e.g., standalone dump, IPL, DPPX/BASE service level update), most of these functions are accessible from a S/370 or 4300 terminal using the Host Command Facility licensed program.

CUSTOMER RESPONSIBILITIES

To install and use DPPX/BASE the user must:

Attend education courses, as necessary ... Acquire a knowledge of the functions documented in the DPPX/BASE customer publications ... Understand the management and control of the design, installation and control of the DPPX/BASE system as described in *DPPX Administration* ... Understand the DPPX/BASE initialization/customization processes as described in *DPPX Installation: Guide* ... Install DPPX/BASE on the 8100 system ... Become familiar with operating procedures as described in *DPPX Operation* ... Become familiar with the facilities provided by other DPPX licensed programs. Add these optional licensed programs to the DPPX system ... Design and implement user applications ... Carry out approved problem determination procedures before contacting IBM for program service ... Install service level updates and fixes as appropriate.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The minimum DPPX/BASE system requires the following configuration:

- 256K IBM 8130 or 256K IBM 8140 processor with 256K bytes of processor storage, disk file and diskette drive.
- IBM 3276 Control Unit Display Station - connected via direct attached loop, or
- IBM 3274 Control Unit with a display station, for instance, an IBM 3278 Display Station - connected via direct attached loop, or
- IBM 3104 Display Terminal - connected via direct attached loop, or
- IBM 8775 Display Terminal - connected via direct attached loop, or
- IBM 3277 Display Station mdl 1 or 2 - directly attached via an IBM 8101 Storage and Input/Output Unit.

Additional keyboard/displays and an IBM 3262, 3268, 3287 or 3289 printer and/or communication link may additionally be attached where required.

- The DPPX/BASE licensed program requires approximately 15.5M bytes of disk space for program load modules, macros, catalogs, command lists, and other permanent system data sets.
- In addition, disk space is required for any additional licensed programs installed (such as DPPX/DPS and DPPX/ASM), for user-defined data sets and for work spaces.

The design objective of this system configuration is to support any of the following interactive or batch applications:

- Interactive command facility.
- Interactive editor (Line/page mode).
- One or more user-written assembler application.
- Multiple terminal interactive assembler application (number of terminals is dependent on size of user application).
- Printer sharing.
- Batch processor.
- Data set utilities.
- Stand-alone dump utility.

Not all the terminals and attachments in this configuration are necessarily active at the same time during the course of execution of the above applications. Devices may be activated and deactivated based on the sequence of the applications being executed.

The available storage for concurrent application processing is dependent upon the number of concurrent applications and the size and complexity of the user applications. A storage analysis should be made to determine which of the above applications and

functions can be run concurrently. Additional storage beyond the minimum storage required can be utilized by DPPX/BASE to improve performance and system throughput.

SOFTWARE REQUIREMENTS

DPPX/BASE can operate either standalone or connected via selected communications facilities to S/370 or 4300.

- When connected to S/370 or 4300 or 30XX via SDLC communication facilities, the following operating environments apply:

- SNA Communication Services.

VTAM (VTAM2, ACF/VTAM Version 1 or ACF/VTAM Version 2, VTAME) or TCAM (TCAM 10, ACF/TCAM), and subsequent releases and modification levels unless otherwise stated, operating under DOS/VSE (VTAME only), OS/VS1 or OS/VS2 (MVS).

- Host Presentation Services.

CICS/VS 1.4 and IMS/VS 1.1.4 (and subsequent releases and modification levels unless otherwise stated) operating under the S/370 or 4300 or 30XX programming supported by CICS/VS and IMS/VS, respectively, and supported by the DPPX/BASE SNA communication services (described above).

- Host Transaction Facility.

CICS/VS 1.4 and IMS/VS 1.1.4 (and subsequent releases and modification levels unless otherwise stated) operating under the S/370 or 4300 or 30XX programming supported by CICS/VS and IMS/VS, respectively, and supported by the DPPX/BASE SNA communication services (described above).

- When connected to S/370 or 4300 or 30XX via BSC communication facilities, the following operating environments apply:

- EXCP BSC interface.

- BTAM, VTAM, VTAME and TCAM under DOS/VSE (except TCAM), OS/VS1 or OS/VS2 (MVS).

- VM/370.

Note that S/370, 4300, and 30XX programming service is available only for releases of S/370, 4300 and 30XX operating systems and subsystems designated as current for service purposes.

This licensed program is written in Programming Language for Distributed Systems (PL/DS). When optional source code is ordered, it is distributed in DPPX assembler language with most of the original PL/DS statements shown as comments.

PERFORMANCE CONSIDERATIONS

DPPX performance depends upon a number of factors such as the system configuration and the system resources available, the number of concurrent user programs and their associated workloads and relative priorities, the user data set characteristics and access method.

The DPPX Storage Configuration option of ANDPPX can assist in determining main storage needed to support the required configuration and application programs.

DPPX Administration contains considerations which can be used in designing, coding and installing DPPX systems.

DOCUMENTATION

(available from Mechanicsburg)

DPPX/BASE General Information (GC27-0400) ... *DPPX Installation: Guide* (SC27-0401) ... *DPPX/BASE Terminal Operation* (SC27-0402) ... *DPPX/BASE Administration* (SC27-0403) ... *DPPX/BASE Commands: General Use* (SC27-0404) ... *DPPX/BASE Programming: Guide to System Services* (SC27-0405) ... *DPPX/BASE Programming: Using DPPX Program Listings* (SC27-0408) ... *DPPX/BASE Programming: Macro Reference* (SC27-0413) ... *DPPX/BASE Programming: Adding Communication Support* (SC27-0415) ... *DPPX/BASE Commands: Configuration and Operations* (SC27-0511) ... *DPPX/BASE Licensed Program Specifications* (GC27-0512) ... *8100/DPPX Library User's Guide* (GC27-0522).

HIGHLIGHTS OF FUNCTIONAL ENHANCEMENT PACKAGE 6 (FEP 6)

FEP 6 contains the following new and extended support:

IBM 8140 Model C support provides DPPX system users with the capability to take advantage of the performance improvements available in this model of the 8140 series. FEP 6 will support the following expanded storage capacities available in the 8140 Model C:

- Real storage of up to 2 megabytes.
- Logical storage of 16 megabytes.
- Additional shared storage (CASS). This provides the user with the capability to share more programs and can thus reduce the total storage requirements for multiple, concurrent applications.

PROGRAM PRODUCTS

DPPX/BASE (cont'd)

- Increased message throughput of up to 60 percent for the same response time. Specific performance information is covered in the performance section.

X.21 switched upstream support conforms to the International Telephone and Telegraph Consultive Committee (CCITT) recommendation X.21 on data transmission over public data networks. This recommendation defines a circuit switched protocol for synchronous operation between Data Terminal Equipment and Data Circuit-terminating Equipment. The switched connection capability allows for more flexible configurations than with leased connections, and also provides auto answer and auto call capability. FEP 6 provides the capability for the 8100 Information System to communicate with a host S/370 via public data networks employing the X.21 protocol.

Improvement to Availability

- Automatic re-IPL capability will be optionally available depending on the specific system wait condition. Unattended remote 8100 sites can benefit from the improved availability potential offered by this enhancement.
- Printer sharing will not terminate the printer environment on an inoperative condition and will automatically restart the printer when the printer is re-activated. This recovery is applicable when the printer (loop attached only) is deactivated, powered off or reset.
- An option is provided in printer sharing to specify initial setup and/or restart without prompts for alignment, etc.
- An option is provided in printer sharing to define the cancel key on the printer as cancel without restart.
- Printer sharing now supports up to 12 printers. Depending upon configuration, a user may not be able to drive all printers at rated speed simultaneously.
- Catalog Directory Compression.
 - Using this facility, DPPX/BASE will automatically attempt to recover from instances which previously resulted in an out-of-space condition in a catalog directory. This facility can also be requested by using a command.

Performance and Usability Improvements:

- The system will now be more self-tuning and it will no longer be necessary for users to provide load lists for LET (Linkage Effector Table) creation at IPL time.
- Expansion of a system parameter (SYSPARM) will occur automatically the first time a user-specified value is exceeded. This enhancement will reduce unnecessary customer involvement and the potential for over-allocation of storage. This applies to those parameters which normally cause a wait condition when the parameter storage is exhausted.
- Users can now display network resources, how they are currently defined, and determine current status. Information is supplied on links, physical and logical units, their active or inactive status, and sessions between logical units. This improvement is provided by the DISPLAY.NET command.
- Editor/Interactive Productivity Facility.
 - New local-line function to set up tab stops.
 - Hardware tabbing is now supported.
 - PF key assignments are now compatible with other IBM products.
 - Installing location can modify default PF key assignments.
 - Certain PF keys are displayed in a protected line at the bottom of the screen.
 - A separate line for messages.
 - The INCLUDE subcommand will now support included records shorter than the file being edited.
 - Repetitive subcommand entry.
 - Scroll backward and forward.
 - The DELETE and REPEAT subcommands allow a value up to 9999.
 - Variable length subcommand verbs and operands.
- Fewer system parameters required in ALTER/DISPLAY SYSPARMS commands.
 - Many parameters have been eliminated from the System Parameter Modules. These include ASEs and TCBS. There is no longer a need for user specification of these parameters.
- Enhanced CLIST Variable Substitution.
 - Named variables, available on a system-wide basis, are supported as substitution symbols in CLISTs.
 - New SET.SYSVARIABLE command to define and set a system level named variable.
 - New DISPLAY.VARIABLES command to display the value of the variables currently defined.

- Improved messages in catalog management and Host Data Transfer.
 - Improved message text.
 - Many messages self-explanatory.
 - Variable data supplied as needed.
- DISPLAY.COMMAND.
 - Provides the ability to display DPPX command operands, defaults and allowable values. The operator can then enter and execute the command from the same screen. (Requires DPPX/BASE Version 2 program product.
- Printer Sharing Enhancements.
 - The RESTART.PRINTER command is enhanced to support the cancel and hold options. These options allow the operator to cancel or hold a running job with one request and without stopping the printer.
 - Prompts now list valid replies.
 - A prompt is reissued after a reply error.
- Additional tuning information from the DPPX Performance Tool program product.
 - DPPX at FEP6 level with the DPPX Performance Tool will provide information on the use of the Dynamic Resident module for both resident and non-resident modules. The DPPX Performance Tool program product fix package 0206 is required to obtain the additional tuning information
- New Option for the RECOVER.DATA Command.
 - The "Subset" option is added to the RECOVER.DATA command to provide for faster data set recovery in situations where 1) there is sufficient free space at the end of the data set and 2) the data set is used in a fashion where new records are always added to the next available free record. (This is consistent with all the DTMS-maintained data sets.)
- Improved Scheduling Algorithm
 - The DPPX scheduling algorithm has been modified to provide more equitable distribution of the processor among threads with equal priority.

Service Enhancements

- The selective backout feature of a fix package for a program product is supported. System catalogs will be restored to their original levels as part of the backout procedure. This enhancement applies where the Remote Service Distributed Option (RSDO) was not used to install the fix package.
- The CSP (corrective service package) log will now be automatically updated when a CSP is replaced by a permanent and complete fix package. The customer will no longer have to manually update the file on the system.

System Management Enhancements

- Data set spanning multiple diskettes.
 - A data set which exceeds the capacity of a single diskette can be saved onto and retrieved from multiple diskettes.

Problem Determination Aids

- System status dump.
 - Formats key problem determination information to create a problem determination subset.
 - Reduces print dump time.
 - Expedites finding "duplicate" problems.
 - Improves problem reporting accuracy.
 - Reduces problem determination analysis time.
- Error Log Data Analysis.
 - Display of errors by tape volume serial and/or 8809 address.
- New trace options.
 - Ability to trace request units (RUs) at various points in the DPPX I/O layer.
- New error log data.
 - New error log data includes certain SNA protocol error and standalone dump events.
- Debugging of USERLIB.
 - Debug is now available for transient programs in USERLIB.

DPPX/BASE (cont'd)

PERFORMANCE

FEP 6 and the 8140 Model C operating in dual mode introduce a new performance growth path for interactive 8100 users. They are capable of providing increased message throughput over a similarly configured 8140 Model B operating under DPPX/BASE FEP 5. An improvement in response time is also possible under certain conditions.

The following figure shows the performance advantage offered by an 8140 Model C (operating with FEP 6) for a specific, yet representative, DTMS "Order Entry" application.

For example, an 8140 Model C replacing an 8140 Model B with processor utilization of 65% results in:

- a. A 70% increase in message throughput for the same response time, or
- b. An improvement in response time for the same throughput rate.

Under certain conditions both response time and throughput improvements are achievable. (See Figure 1.) Because of the increased system load, additional resources like communication links, loops, disks, real storage, etc. may be needed to achieve the above results.

FEP 6 and the 8140 Model C do not offer any performance improvements for jobs using the Floating Point feature or standalone batch applications like COBOL compilations.

The throughput improvement actually achieved by an 8140 Model C operating with FEP 6 depends upon:

- Installed real storage.
- Input/output load.
- Configuration.
- Processor utilization.
- Application.

An application characterized by heavy communication traffic and/or DASD load may not achieve the full message throughput improvement shown in Figure 1.

Applications running on the 8140 Model C in single mode with DPPX/BASE FEP 5 will experience performance equivalent to the 8140 Model B. DPPX/BASE FEP 6 with storage available to accommodate additional function will run on the 8130 and 8140 Models A and B with performance equivalent to DPPX/BASE FEP 5.

Performance is dependent on many factors. Since the above figure pertains to a specific application environment, individual applications and configurations should be evaluated before any statement of expected throughput improvement is made.

COMPATIBILITY

FEP 6 is upward compatible with earlier service levels. Licensed programs supported on earlier levels will be supported by FEP 6. However, the latest service levels on some licensed programs, such as the DPPX/Performance Tool, will be required to operate with FEP 6.

When application programs written for earlier service levels are run on the Model C with FEP 6, some minor modifications may be necessary to programs using the processor mask functions.

FEP 5 will run on the Model C but without taking advantage of either the improved performance or the extended storage capabilities of the new processor. When pre-FEP 6 levels are run on the Model C, the real and logical storage amounts are 1 and 4 megabytes, respectively. For BSC operations with the Model C configuration, an 8101 containing a BSC communications adapter must be attached to the Model C.

FEP 6 will run on any 384K or more 8100 processor, providing the enhancements stated above, but the extended storage and performance improvements support only the Model C.

FEP 6 supports BSC operation on the 8101, 8130, and 8140 Models A and B. For BSC operation with a Model C configuration, an 8101 containing a BSC communications adapter must be attached to the Model C. When FEP 6 and the Model C run BSC with the 8101 attachment, only the extended storage capability (and not the performance improvements) of the Model C are made available (single mode). An IPL is required to change modes.

SYSTEM INTEGRITY

The system integrity features of earlier service levels are unchanged and apply to DPPX/BASE FEP 6.

DATA SECURITY, AUDITABILITY and CONTROL

The data security, auditability and control features of earlier service levels are unchanged and apply to DPPX/BASE FEP 6.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The minimum DPPX/BASE FEP 6 system requires the following configurations:

- 8130 or 8140 processor with a minimum of 384K storage, at least one disk file and a diskette drive.
- One IBM 3276, IBM 8775 display terminal or a 3274 control unit with an attached display station, connected via a directly attached loop; or a directly attached IBM 3277.

The storage available for applications is dependent upon the number of, and the size and complexity of the user applications. A storage analysis should be made to determine which applications and functions may be run concurrently.

FEP 6 Processor Storage Requirements: The various Functional Enhancement Packages (FEP) through FEP 5 provide significant enhancements to the DPPX/BASE program product that improve performance and provide functional and usability enhancements. Through FEP 5, processor storage has been managed to a consistent level which resulted in negligible storage growth.

The DPPX/BASE FEP 6 enhancements will utilize an additional 35K bytes of processor storage above FEP 5. Storage requirements should be re-evaluated to determine the impact of this increase. It is recommended that customers assume a storage increase of 60K bytes (which includes the above 35K bytes) to account for future enhancements in response to customer requirements and IBM maintenance activity. The additional enhancements described in this update are contained within the 35K bytes of processor storage above FEP 5.

Operation of FEP 6 is not supported on systems with less than 384K bytes of processor storage. Configurations with 384K bytes of processor storage may still be viable under DPPX/BASE FEP 6. Since systems with 512K bytes of processor storage are capable of supporting a wide range of applications and production configurations, 512K is recommended as the minimum processor storage for FEP 6.

The increase in processor storage applies to DPPX/BASE only and not to the other licensed program products. As in the past, they will continue to announce their storage requirements individually.

Software Distribution: When the optional source code is ordered, it is distributed in DPPX Assembler language with most of the original PL/DS statements shown as comments.

INTEGRITY: Refer to section GI 23.2.

RPGs Accepted: Yes

8100 INFORMATION SYSTEM
DPPX/BASE COMMAND FACILITY EXTENSIONS
FEATURE
Features #6005, #6006, #6007 (5760-010) §

PURPOSE

The DPPX/BASE Command Facility Extensions Feature is a prerequisite for the DPPX/Interactive Productivity Facility. It provides the logic, display and table management services for DPPX/Interactive Productivity Facility operation and use.

The DPPX/BASE Command Facility Extensions feature Level 2 will provide a dialog development facility which simplifies the development of dialogs and the installation of customer-developed dialog hierarchies. It is a prerequisite for DPPX/Interactive Productivity Facility Release 2. DPPX/BASE Command Facility Extensions feature Level 2 is a complete replacement of DPPX/BASE Command Facility Extensions feature Level 1 and will delete all Level 1 modules and catalogs. DPPX/BASE Command Facility Extensions feature Level 2 is intended for systems operations usage and is not designed for application development.

HIGHLIGHTS

The DPPX/BASE Command Facility Extensions feature provides support for the operation of the DPPX/Interactive Productivity Facility. The DPPX/BASE Command Facility Extension feature provides services for logic control, accessing and displaying pre-defined menu, data entry and tutorial panels of DPPX/Interactive Productivity Facility. It invokes DPPX commands and programs based on the logic of the DPPX/Interactive Productivity Facility scripts. It manages the retrieval, modification and display of internal DPPX/Interactive Productivity Facility tables.

The DPPX/BASE Command Facility Extensions feature Level 2 provides the following enhancements:

- Dialog development facility - Simplifies the development of dialogs by providing a step-by-step procedure which includes a series of full screen panels to lead the user through the development of menu/data entry panels, tutorial panels and dialog programs. Facilities are provided to test the dialogs online. Permits independent integration of dialogs into the DPPX system.
- Customized dialog hierarchy - Simplifies the development of dialog hierarchies. The customer need only specify the connection between menu panels and scripts.

CUSTOMER RESPONSIBILITIES

To install and use this licensed program, it is the customer's responsibility to:

- Become familiar with DPPX/BASE concepts and facilities.
- Use the installation process as described in the DPPX/BASE Command Facility Extensions Feature program directory.
- Carry out the problem determination procedures described in the *DPPX/BASE Command Facility Extensions Feature Diagnosis* guide before contacting IBM for program service.
- Install fix packages and service level updates.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The DPPX/BASE Command Facility Extensions Feature is designed to operate on an IBM 8130 or 8140 processor with 512K bytes of processor storage, with a diskette drive and with 58MB of disk storage capacity. Also required is a display supported by DPPX/DPS Format Management with a screen width of at least 80 characters and a depth of at least 24 lines. DPPX/BASE Command Facility Extensions feature Level 2 commands can be executed via program function keys if available on the display.

Storage Requirements: The DPPX/BASE Command Facility Extensions Feature storage requirements are dependent upon the various configuration and workload parameters. The parameters include: Device type, map size, message rates, number of resident maps and the number of processing environments.

The DPPX/BASE Command Facility Extensions Feature executes in a standard DPPX interactive command facility environment (approximately 48K bytes of processor storage).

The approximate processor storage estimates for the DPPX/BASE Command Facility Extensions feature Level 2 are:

Resident Programs (shared address space)	11,000 bytes
Control Blocks and Work Areas (user address space)	8,000 bytes
Dynamic Variables (user address space)	1,000 bytes
Total	20,000 bytes

Non-resident DPPX/BASE Command Facility Extensions Feature programs are invoked as required on a temporary basis and unloaded when no longer needed.

These programs utilize additional processor storage.

The DPPX/BASE Command Facility Extensions feature Level 2 object code requires about 2,500 256-byte blocks of disk storage space for programs and messages, and 60 256-byte blocks of disk storage space for display panel maps (*) in the System Program Catalog (SYSPGM).

(*) Blocks of disk storage space for display panel maps are required for each one of up to 14 selected device groups using DPPX/DPS Version 1 or DPPX/DPS Version 2.

The DPPX/BASE Command Facility Extensions feature Level 2 also requires 2,600 256-byte blocks of disk storage in three user catalogs, for dialog scripts, help panels and tables.

SOFTWARE REQUIREMENTS

This feature is designed to operate with the current supported levels of the DPPX/BASE (5760-010) FEP5 and DPPX/DPS FM Versions 1 or 2. All subsequent service levels are supported unless otherwise stated.

The DPPX/BASE Command Facility Extensions Feature is written in Programming Language for Distributed Systems (PL/DS). When optional source code is ordered, it is distributed in DPPX Assembler language with most of the original PL/DS statements shown as comments. Source code on magnetic tape and program listings on microfiche are available as optional material.

DATA SECURITY, AUDITABILITY and CONTROL

DPPX/BASE Command Facility Extensions Feature utilizes the system services of DPPX/BASE and therefore is governed by the security and auditability features within that environment. Customer management is responsible for the selection, implementation and adequacy of these features.

PERFORMANCE CONSIDERATIONS

Performance of DPPX with the DPPX/BASE Command Facility Extensions Feature and the DPPX/Interactive Productivity Facility depends on a number of factors such as the system configuration, the available system resources, the number of concurrent user programs and their associated workloads and relative priorities, user data set characteristics and access methods.

DOCUMENTATION

(available from Mechanicsburg)

DPPX/BASE General Information (GC27-0400) ... DPPX/Interactive Productivity Facility General Information ... DPPX/Interactive Productivity Facility Licensed Program Specification. Users of this licensed program are encouraged to order the Licensed Document, *DPPX/BASE Command Facility Extensions Feature Diagnosis.*

DPPX/BASE INTEGRITY

IBM will accept APARS where the installation of the DPPX/BASE Command Facility Extensions Feature introduces an exposure to the system integrity of DPPX/BASE. This program is intended to run authorized.

RPOs ACCEPTED: No

**5761-DS1 - DPCX V1 R 2.2, 3 and 4
DISTRIBUTED PROCESSING CONTROL EXECUTIVE
VERSION 1, RELEASES 2.2, 3 and 4**

PURPOSE

DPCX offers users a multi-application display oriented operating system designed for the distributed environment. It provides functions especially designed for combined text and data processing applications with local and host interactions. With up to 31 concurrent applications multiprogrammed by DPCX in Release 2 and 62 in Release 3, a wide variety of office needs can be satisfied. The user can start to use the system without user programming. Integral to DPCX are 3270 Data Stream Compatibility for access to existing host applications, online bulk print for outputting host data and a comprehensive RJE facility. A text system application program, the Distributed Office Support Facility (DOSF) is available which has extensive functions without the need for user programming. In addition, applications and procedures can be developed for both DPCX and DOSF expanding the usefulness of the distributed system. DPCX Release 2 has been developed specifically to extend DPCX Release 1 for both data processing and text applications. It includes all the functions of Release 1 and provides enhancements. Feature #6001 is available and is enhanced. In particular, the new functions provide the installation with the ability to better balance the system against the demands of multiple applications. DPCX Release 3 is designed to take advantage of the increased storage and performance improvements available with the 8140 mdl C processor. It also increases the allowable number of concurrent active user tasks from 31 to 62, providing improved system flexibility; supports data link attached loops and new printer functions; provides a new network installation management capability; and contains several usability and serviceability enhancements. Feature #6001 is integrated into Release 3, simplifying both the ordering and installation processes.

DPCX Release 4 provides support for the new 8130B and 8150B Processors. The Data Stream Compatibility function is more powerful and flexible. The number of user data sets is increased to 191. The 6580 Displaywriter may be attached to an 8100 DPCX system and used as a 3270 display. Enhancements have been made to network management, usability, and serviceability.

Note: All unique Feature #6001 functions listed below are part of the base DPCX Release 3 program.

HIGHLIGHTS OF NEW FUNCTIONS OF RELEASE 2 and FEATURE #6001

- Base for DOSF, a new text application program.
- Performance enhancements.
 - System balancing options designed to optimize storage and disk utilization.
 - Improved DPCX transient management to reduce disk accesses.
 - Additional data set placement options to optimize access time.
- Print spool (feature #6001).
 - Accessible to all applications including DOSF.
 - Available for display on any local or remote 1,920-character or larger display.
 - Printable on any local or remote attached printer.
- Procedure enhancements.
 - Capability for automatic initiation of procedures after IPL or operator log-on (feature #6001).
 - Facility to initiate a procedure as an application subtask.
- Additional Device Support.
 - Direct Attach 3732 Text Display Station.
 - Direct Attach 3736 printer (correspondence quality).
 - Direct loop supported 3262 mdl 2 and mdl 12 with print bands for text (feature #6001).
 - Direct loop-attached (9.6K bps only) 5210-E01,E02 Printer.
 - Communication port attached 6670 Information Distributor (feature #6001).
 - Direct loop and communication port supported 8775 with IDTF licensed program.

HIGHLIGHTS OF NEW FUNCTIONS IN RELEASE 3

- 8140 Processor model C supported
- Maximum number of concurrent active user tasks increased from 31 to 62.
- Data link attached loops supported.
- Network Installation Management supported.
- 5210-E01, E02 with EC #996869 supported, providing attachment to 38.4K bps loop and SNA LU Type 1 data stream capability.
- New Error Log and Summary Analysis function.

- Link Problem Determination Application (LPDA) supported.
- Several usability and serviceability enhancements.
- Feature #6001 integrated into the base DPCX program.

HIGHLIGHTS OF NEW FUNCTION IN RELEASE 4

- Support for the new 8130 and 8150 Processors.
- New Data Stream Compatibility function.
- Number of user and system data sets increased.
- Network Management enhancements.
- Connectivity enhancements.
- Usability improvements.
- Installation enhancements.

DPCX HIGHLIGHTS

- System Concept
 - Virtual storage management which features demand paging and swapping and allows:
 - Efficient real storage utilization.
 - Real storage space required for program execution is independent of application program size.
 - No overlays are required.
 - Program to program protection.
- Multiprogramming support for concurrent execution of up to 31 tasks in Release 2 and 62 tasks in Release 3. These tasks can be user programs and/or system-provided functions (e.g., 3270 DSC and RJE).
 - Dynamic DPCX assignment of dispatching priority to terminal oriented application programs.
- Batch transmission support for data exchange with the host:
 - Online exchange of data sets from host to 8100.
 - Batch data exchange (BDE) via diskette or tape.
 - RJE Workstation Package (WSP) and associated interactive package (SYSEdit) for creating and editing RJE input files and procedures.
- Includes support for access to host applications on S/370, 30XX and 4300 for 8100-attached 3270, 3104, 8775, Personal Computer, 6580 Displaywriter and Series/1 devices.
 - 3270 data stream compatibility (3270 DSC) for existing 3270 host DB/DC, VTAM, TCAM, TSO, and VSPC applications.
 - A bulk print function which offers online printing support for existing 3270 or SCS applications.
 - Base color support, extended color and highlight support, programmed symbols, multiple partitions, scrolling and field validation.
- User control of the placement of data on disk to optimize disk access time and data set availability.
- Interactive support for creating and editing input files (SYSEdit)

Application Development Facilities: A set of application services, accessible through programming statements:

- Transaction support.
- Queued printer support (spool).
- Message handling support.
- Panel generating and maintenance support.
- Application to application information transfer.

See the DPCX programming statements or Development Management System (DMS/DPCX) program product, for coding of 8100 applications programs including display and printer formats, data definition and processing sections.

- DMS/DPCX also provides:
 - Data location at 8100 or host can be transparent to the application program.
 - Applications written with DMS/DPCX can exchange application definitions with DMS/DPPX within the constraints of the target machine. See DMS/DPCX announcement letter for additional information.
 - Support for 3732.

Host Facilities and Control: Program preparation and validation is via OS/VS or DOS/VSE assembler, at the host.

PROGRAM PRODUCTS

DPCX V1 R2.2 & 3 (cont'd)

The Host Prep licensed program (5735-XR3) is required at the Host by the users of DPCX Feature #6001, or users who make use of the following functions:

- Support for creation of subcategories for disk space allocation.
- Support for receipt of the DPCX Release 2/3 stand-alone system dump, and its formatted printing.
- Text programming statements used with a 3732/8775 terminal.
- Online fix distribution support and remote problem determination support for 8100/DPCX via the Subsystem Information Retrieval Facility (SYSINFOREF) program.

If the above functions are not required, the Host Support SCP programs 5747-BQ1 (DOS/VS) and 5744-BZ3 (OS/VS) provide the required support.

Host Prep Release 4 is required for support of DPCX Release 2.0 and 2.1, Host Prep Release 4.1 is required for support of DPCX Release 2.2, and Host Prep Release 5 is required for support of DPCX Release 3. DPCX Release 4 requires Host Prep Release 6.

Central library support for the 8100/DPCX network is provided by the Distributed System Executive (DSX) program product or Subsystems Support Services (SSS).

The capability for Host connected displays to log on to the host resident Host Command Facility program product and subsequently sign on to DPCX to access DPCX services and application programs.

The capability for a host program to initiate a session with a DPCX application program.

Operator Interface and Procedures

- Basic operator interface for selecting any user written or IBM provided program.
- Command operator full screen interface that extends the basic capability to include use of command language and initiate user written procedures. With support available in Feature #6001, both prompt screens and descriptive help information are available to assist operators in entering commands.
- Journaling, resulting in hard copy output, is available for some operator actions such as, initiation or termination of programs or IBM provided functions, commands entered, command responses, or messages retrieved. Journaling can be invoked for specific operators or all operators.
- Procedures can be written to simplify and customize operations. These can be written at the Host or the 8100 site.
- Access codes may be used to restrict operator access to specific DPCX supplied commands and programs (Feature #6001).

RJE Work Station Support: The RJE support which operates in conjunction with the host RJE support (RES/JES1, JES2, JES3, POWER/VS, POWER/VSE) provides all functions necessary to generate jobs and data either via an 8100/DPCX keyboard display or via diskette, transmit the job to the Host and receive the output from the Host.

- User written procedures for simplifying and customizing operations.
- Output print stream can be compressed and compacted making efficient use of host and printer links.
- Output jobs on the print spool can be viewed at any display, 1,920 characters or larger which can often eliminate the need for printing.
- Printing multiple copies from spool eliminates need to send more than one copy from the Host.

Performance Options: There are many aspects of the design of DPCX that help performance such as virtual storage management, a preemptive time-slicing dispatcher, multi-use of real storage blocks and direct sector application paging.

The user has control of disk and real storage allocation that can have significant effect on the response time or throughput of the system. These include:

- The user can select the location of data sets and indices on disks to control access time. These can span disks.
- The user can optionally control the size of four DPCX real storage pools that can reduce I/O accesses and the I/O processing.
- The user can place applications in real storage eliminating demand paging from disk and related I/O processing and access time.

Disk File Access Methods: DPCX support four file access methods that provide a range of characteristics that can be used to match application and performance requirements. These are:

- Distributed Indexed Access Method, DXAM, (Part of Feature #6001) provides for records of up to 4096 bytes, up to 8 keys,

including duplicate key values, with random or collating sequential access by key. Read and locate instructions allow finding records by five compare operators, such as GREATER THAN OR EQUAL. Keys can be up to 64 bytes.

- Relative Sequential Access Method, RSAM, (Part of Feature #6001) provides for records of up to 4096 bytes with random access by relative record numbers, RRN, or sequential access. Read and locate instructions allow finding records by five compare operators, such as LESS THAN OR EQUAL. The user has the ability to use both DXAM and RSAM access to records. Changes made to the records via RSAM will automatically update the DXAM indices.
- Indexed data set provides for records up to 1,920 bytes, with one or two keys with random access by key.
- Relative data set provides for records up to 256 bytes with access by RRN.

Display and Display Printer Support Summary: DPCX supports many SNA members of the 3270 family of control units, displays and printers, the 3104 display terminal and the 8775 single display station. The support includes:

- Direct attachment, directly attached loop, data link attached loop, and communication port attachments. (The 3104 is loop attached only.)
- Display sizes include 1,920, 2,560, 3,440, and 3,564 characters. The 3104 provides 1920 characters only.
- 8775 with IDTF licensed program.
- 8775 features - Advanced Function (#3624) and Multiple-partitions and Scrolling (#5110).
- 8775 mdls 1, 2 and 3104 copy support can be to any loop attached or communication port attached printer except the 3289-3.
- Support for the 3178 Display Station, a lower priced member of the 3270 Information Display System, providing functions equivalent to the base functions of the 3278-2.
- 3290 Information Panel support, offering a single terminal providing:
 - A concurrent multiple screens capability.
 - A multiple screen-copy capability
 - A multiple interactive screen capability
 - A multiple partitions capability
- Base and extended color, extended highlighting and programmed symbols.
- View contents of the general spool file.
- Online with the Host:
 - 3270 Data Stream Capability including APL/TEXT Feature.
 - Online bulk print.
 - RJE online printing.
- User written programs executing on 8100/DPCX. This includes full screen processing (FSP) or field by field (FxF) display modes and full screen print (FS Print) for printers. Applications can also acquire a printer for exclusive use.
- RJE spool, Print spool output printing.
- 6580 Displaywriter attachment in 3270 Data Stream Compatibility Mode. DPCX Release 4 supports two additional attachment alternatives to the Displaywriter.
- Downstream attachment of Series/1 (as a 3274-51C, 3274-61C, or 3276).
- IBM Personal Computer, 5150, attachment with SDLC Communication Adapter.
- IBM Personal Computer, 5150, attached to 8100 via 7426 Terminal Interface Unit.
- 7436-1 correspondence quality printer RPQ #XC5575.

Printer Support Summary: DPCX supports, in addition to the display family printers (see table), 3736 via direct attach, 3230, 3262, 3268, 3287, 3289 and 5210 printers via loop and communication port attached 6670. These printers have nominal capability from 40 cps up to 650 lpm.

- The 3289-3 can be attached to 9.6K bps loops.
- The 3230, 3262, 3268 and 3287 printers are loop attached at speeds up to 38.4K bps.
- The 3262 and 3289 printers have decompaction and decompression capability, thus saving host link and loop transmission utilization.

PROGRAM PRODUCTS

DPCX V1 R2.2 & 3 (cont'd)

- Up to 24 3736, 3284, 3286, 3287 and 3288 can be directly attached to a system.
- The 5210-E01, E02 Printer without EC #996869 attaches only to a 9.6K bps loop. With EC #996869, supported only by DPCX Release 3, it may be attached to either the 9.6K bps loop or a 38.4K bps loop. With EC #996869 it also supports SNA LU Type 1 data streams.
- The 6670 is communication port attached at line speeds up to 9.6K bps.
- Support includes:
 - Online Bulk Print (not 3289, 3736, or 6670).
 - Online RJE printing (not 3736 or 5210).
 - General spool, RJE spool or print data set to printer.
 - Display copy - 8775 mdl 1, 2 and 3104 to 3230, 3262, 3268 or 3287.

RELEASE 2/3 - DESCRIPTION

The following describes the new functions available with DPCX Release 2/3.

DOSF System Application: DPCX Release 2/3 provides an operating system for the execution of data processing applications and text applications. Text applications are of two types, those provided by the DOSF program product and those that are user written to extend text functions. By providing the functions described below, the user has additional flexibility to balance the system resources by trading real storage allocation for I/O processing and disk access time. This function provides the capability to balance the system resources for a wide variety of application programs. In addition, DPCX Release 2/3 provides new functions that support text and data application such as, the general spool file and new command processing functions.

GENERAL SPOOL FILE (Part of Feature #6001)

Release 2/3 provides a common printer output storage facility on disk that combines all existing facilities for all applications called the general spool. This facility provides the ability to:

- Print any file or job or DOSF document on any printer attached to the system (within the ability of the printer to handle the character set requirements).
- Allow any file or job or document to be viewed by authorized terminal users on any 1,920-character or larger display attached to the system. Review of the data will often provide the information needed by the user, thus eliminating printing.

The data in the spool file is in SNA character string (SCS) format. Data in the spool file can result from:

- User written application programs.
- Batch operations with the host.
- RJE output (local or from the host).
- Batch Data Exchange via diskette.
- Tape Data Exchange via tape.
- DOSF input.
- DPCX System Services (e.g., SYSLDSA).

The spool is divided into a set of files containing one or more records. Each file is targeted for a particular printer set-up, and may contain a password required for access.

The number of files that can be in the spool data set is limited only by disk space availability.

Existing interfaces for application programs, and RJE, are maintained and additionally extended with new interactions. Thus, for example, from an application program viewpoint, the file has from 1-64 groups, each of which has records with a Print Sequence Number identifier. (Sum total of records for all groups is 65,535.)

Browse: Files in the general spool data set can be viewed from any display, 1,920 characters or larger, locally or remotely attached to the system. This facility allows the terminal user to review the contents of the file as it exists in the spool, ready for printing. These records cannot be changed by the display operator. The record content is formatted for the printer in SNA character set, (SCS), format.

When viewing a file, the display is divided into three areas:

- An area containing information such as, file name, displayed page number, top line number and left most column displayed.
- A frame area for displaying the spool file.
- A message area containing messages and commands.

Data in columns beyond the screen width is viewed by horizontal scrolling.

The operator has control of the display through commands that provide the following functions:

- File Selection.

- Vertical and horizontal scrolling.
- Capability to position to the top, end or page number, in the selected record.
- Locate a specific string of characters.

These commands can be entered either manually in the message/command area or by program function (PF) keys of the 3270, 3104 or 8775 displays. The 3732 and 8775 with IDTF licensed program have specific keys for many of these functions.

The data as displayed is normally the same, line by line, with the hard copy that will result from printing. There are a few exceptions resulting in multiple display lines, but in only one print line: For example, underscore, overstrike and boldface.

Printing: Data in the general spool file can be printed on any printer, locally or remotely attached to the system. When print data is added to the general spool, the system will dynamically use up to 2K of user space of Task Virtual Storage. The control of printing is through new commands for starting, restarting, stopping or cancelling print tasks and/or to modifying the formatting attributes. With the exception of the 6670, the restart capability permits starting at the top of the page where printing stopped or backing up from 1 to 5 pages. For the 6670, restart is under control of the 6670 and will be at the beginning of the document. A file can be erased by an authorized terminal user by command. An operator can also view the status (hold, complete or print) of a file.

Printing requires that there be a match between the printer and general spool file character set. Characters not supported will result in a unique character or print check depending upon the printer. Since print data in the general spool is already formatted, if multiple copies are required, format processing only occurs once saving system processing and I/O operations. (The internally controlled multiple copy capability of the 6670 eliminates the need for multiple transmissions of the print data to the 6670.)

When using the 6670 Information Distributor for printing, 6670 Operator Control Language (OCL), contained in the system Edit file, can be prefixed to the print data stream for control of printing individual documents.

PERFORMANCE

The following performance related changes exist in Release 2/3:

- Less Symbolic Machine Rolling.

The installation is given direct control over the amount of real storage that is devoted to the Symbolic Machine Execution Pool above the system base. In general, the larger the Execution pool, the less rolling will take place and, therefore, the better the performance. This trend will hold true up to the point that sufficient real storage is devoted to the execution pool to hold all of the Symbolic Machines. At that point, no rolling will take place.

- Less Transient Loading.

The installation is given direct control over the amount of real storage that is used for the system transient pool above the system base. In general, with a larger transient pool, there will be fewer disk accesses to load transients and, therefore, better performance will result.

DPCX also provides other user real storage options. 1) Placing entire application programs in real storage, thus decreasing application program paging, and 2) Increasing the size of the real storage pool used to process DXAM indices, user programs, user data set records, and page Task Virtual Storage areas, thus decreasing disk I/O operations.

- Less Disk Arm Movement in Data Operations.

The installation is given more control over disk space allocation via Sub-categories. Through this mechanism it is possible to control the placement of the indices for data sets, separate from the data and, therefore, the results can be reduced disk arm movement in indexed data set operations.

- More Efficient Transient Loading.

The disk addresses of all transients will be known to the system, eliminating index accessing. As a result, disk accesses can be reduced, and transients can be located faster. Eight blocks of a transient are loaded concurrently further reducing disk time.

There are two processing elements within the 8140 model C. One of these processing elements performs the same functions as the 8130 and 8140 A and B models while the other is restricted in that it does not directly attach channel logic or system control function. The normal mode of operation with both processing elements operating on the 8140 model C processor is called dual mode. The 8140 model C can also operate with a single processing element which is called single mode.

DPCX Release 3 and 8140 mdl C operating in dual mode, and the increase in the allowable number of active user tasks, introduce a new

DPCX V1 R2.2 & 3 (cont'd)

performance growth path for processor bound interactive and office system 8100 users. They are capable of providing up to 70 percent increased throughput over a similarly configured and heavily loaded 8140 mdl B operating under DPCX Release 2.2. In those cases where the processor was heavily utilized, an improvement in response time may be possible by going to the 8140 mdl C and DPCX Release 3 for the same throughput.

The throughput improvement actually achieved by an 8140 model C operating with DPCX Release 3 depends upon many factors, some of which are:

- Installed real storage
- Input/output load
- Configuration
- Number of concurrent active tasks
- Process utilization
- Application

Additionally, an application characterized by heavy communication traffic and/or DASD load may not achieve the full performance improvement potential. For example, RJE and DSC/DSFC would normally be communications-bound tasks. Large sorts and document archiving to and from diskettes would normally be DASD-bound tasks. Also, tasks utilizing all, or substantial portions, of the system resources will not experience performance gains.

The increased number of concurrent active user tasks provides improved system flexibility for accounts where sufficient processing capability exists.

Applications running on the 8140 model C in single mode with DPCX Release 2.2 or 3.0 will experience performance equivalent to the 8140 model B.

In Release 4, the 8130B and 8150B provide the following throughput improvements for the same or better response times compared to current 8100 processors:

- 8130B: Up to 1.4 times an 8130A
- 8150B: Up to 2.0 times an 8140C
- 8150B: Up to 3.2 times an 8140B

The throughput improvements are based on similarly configured and heavily loaded systems. Response time improvements for the same throughput will also be possible.

The throughput improvement actually achieved by the new processors depends on many factors, some of which are:

- Installed real storage.
- Input/Output load.
- Configuration.
- Number of concurrently active user tasks.
- Processor utilization.
- Application environment.

In addition, an application characterized by heavy communication traffic and/or DASD load may not achieve the full performance potential. For example, RJE and DSC would normally be communications-bound tasks. Large sorts and document archiving to and from diskettes would normally be DASD-bound tasks. Also, tasks utilizing all, or substantial portions, of the system resources will not experience performance gains.

Data Stream Compatibility - Extended: The performance of the DSC function currently provided in DPCX Release 3 remains unchanged in DPCX Release 4. Typically, the 8100 process time is very small for DSC (for example, a transaction every 45 seconds of 40 characters in and 800 characters out would use less than one percent of an 8140B).

The DSC-E facility in DPCX Release 4 which allows switching between a host application and a DPCX application will utilize between two and three times the amount of 8100 process time as the current DSC facility for identical operations. In the example above, the DSC-E user would utilize between two and three percent of an 8140B. The response time, however, should not change noticeably. The performance of the DSC-E facility when using the 'suspend/resume' function or invoking user programs to access screen data is dependent on the user functions and applications.

PROCEDURES

DPCX procedures can initiate other procedures or be initiated by an application program. Procedures can also be selected by an operator using the command interface.

Release 2/3 expands this capability in several ways: (Feature #6001 configured to use 32K task virtual storage and general spool)

- Application programs can now initiate procedures as a subtask.
- At the completion of IPL, a procedure can optionally be invoked.
- At the completion of an operator logon, a procedure can automatically be invoked.

The significance of these new functions is that the user has added capability and flexibility to tailor the system to the installation's unique requirements. Using procedures for repetitive operations can result in more consistent operations by simplifying the operator interface.

DPCX provides the ability to automatically invoke a user written procedure at the end of system IPL. This allows the user to establish the operating environment including such things as which terminals are enabled, enabling the host link, establishing hot printer queues, output standard reports, etc.

Post operator log-on capability allows a procedure to be called automatically to provide processing for the specific operator. Thus, the system could have several procedures available. The procedure that is invoked depends upon the operator's number. For example, DOSF could always be invoked for an operator.

Application programs can now initiate procedures as a parallel processing subtask. This provides the ability to have an application program initiate procedures that start system functions. For example, when an application has reached a certain point in execution, a procedure could be started that initiates printing.

RELEASE 4 DESCRIPTION

The following describes the new functions available with DPCX Release 4:

Support for the 8130B and 8150B Processors: DPCX Release 4 supports the new 8130 mdl B and 8150 mdl B Processors. These new processor models enhance the modularity of the 8100 processor family and provide increased performance, availability, and reliability for the 8100 DPCX user.

Support for the New 8130 Mdl B23 and B24: DPCX Release 4 supports the new 8130 mdls B23 and B24 which employ state-of-the-art technology and provide a new 32-bit central processing element. The following support is provided:

- Processor storage of up to 2 megabytes.
- Logical storage of up to 4 megabytes.
- Improved throughput of up to 40% compared to an 8130 mdl A.
- Attachment of up to three 8101 storage and I/O units.
- Field upgradable from an 8130 mdl A.
- Support for two high-speed ports.
- Direct processor support for the Display/Printer Adapter.

Support for the New 8150 Mdl B: DPCX Release 4 supports the new 8150 mdls B20, B40 and B60 which employ state-of-the-art VLSI processor technology. These new processor models provide the DPCX and DOSF users significant performance improvements over the 8140 processor models. The following support is provided:

- Processor storage up to two megabytes.
- Logical storage of up to four megabytes.
- Improved throughput:
 - 8150 mdl B: Up to 2 times that of an 8140 mdl C.
- Upward compatibility from the 8130 and 8140.

The following limitations apply to the DPCX support of the 8150 processors:

- I/O is provided on a single processing element of the 8150B.
- The configuration capabilities for DASD, communication ports, Display/Printer Adapters, and devices remain unchanged from the DPCX Release 3 support of the 8140 mdls B and C.
- 8150 keys and locks are not supported by DPCX.

New Data Stream Compatibility Function: Significant flexibility and functional capability are provided with a new Data Stream Compatibility - Extended (DSC-E) facility. While the functional capabilities of the DSC facility in DPCX Release 3 remain unchanged, the user may now optionally invoke the DSC-E facility which provides the following new functions:

- **A suspend/resume 'hot' key switch:** A user of DSC-E may now suspend his host application by pressing a single user-designated PF or PA key. When communication with the host application is suspended, all DPCX functions and applications (including DOSF) are available to the user. The user may then return to (resume) the host application by again pressing the same PF or PA key. A host session may be suspended any time the display keyboard is unlocked; a host session may be resumed any time the DPCX task is at a point where a command may be entered.

DPCX V1 R2.2 & 3 (cont'd)

- **A user exit capability:** When in DSC-E mode, the user now has the capability to invoke a user-written program to access and process/modify the screen data generated by the host application. The program can be invoked by a user-designated PF or PA key.

If the DPCX system has DOSF installed, a 'screen capture' capability is also provided that allows screens generated by host applications to be captured by DOSF and stored as documents.

When the DSC-E option is selected, two user tasks are always made active. This is independent of whether the 'suspend/resume' function is ever used. The current DSC facility continues to use only a single task.

It should be noted that the DSC-E facility cannot be initiated from the host. Any DPCX/DOSF display (except a 3732) can initiate DSC-E. Additionally, the local copy function on an 8775 is supported only if the printer adapter feature (#5580) is installed.

Command Interface for DSC and DSC-E: A single command is now provided for quickly and easily accessing the Data Stream Compatibility functions of DPCX. An operand of this command is used to specify if DSC or DSC-E is to be invoked.

Number of User and System Data Sets Increased: The number of data sets available for user-written function programs has been increased from 96 to 191. The number of system data sets has been increased from 32 to 64.

Enhanced Network Management:

- **Problem Determination Aid:** DPCX has the capability to notify the Host system when certain 8100 hardware errors occur which result in the loss of a critical resource in the 8100 DPCX system. Also, DPCX will pass through to the Host unsolicited alerts received from downstream nodes. This function works in conjunction with the Network Problem Determination Application (NPDA) and the Network Communications Control Facility (NCCF) to provide the user with the tools necessary to monitor errors and perform problem determination from a central site. NPDA and NCCF are licensed programs that run at the host system.

- **Error Log Summary and Analysis:** The Error Log Summary and Analysis (ELSA) tool has been expanded to display and process Type 2 and Type 4 Condition Incident Log (CIL) records which are generated as a result of system ABENDs. Records can now be selected by device adapter address. The Processing and Control Element number has also been added to the selection criteria. These two new selection criteria allow for a more precise sample to be taken.

To better monitor the Host link, all Host communication will generate Type 3 CIL records. Information added to the Type 3 records describes the error in more detail.

- **Network Installation Management:** Network Installation Management can support the transmission of the Interactive Display Text Facility (IDTF) program for DOSF users of the 8775 text terminals. The IDTF program can be loaded on remote-site 8100 from a central host site. Optionally, the IDTF program can also be installed at the remote 8100 from the central site.

- **System and Data Link Traces:** Users can specify that only those trace records generated during a certain time period be formatted or copied. By eliminating the extraneous trace records, the time required to format the records for analysis is reduced.

Connectivity Enhancements:

- DPCX Bulk Print support is extended to include the 5210 Printer mdl E1 or E2 installed with EC 996869. Host applications can use this printer when it is attached to the 8100 DPCX system as an SNA Character Stream (SCS) Logical Unit (LU) Type 1 SNA.

- DPCX Release 4 supports two additional alternatives to the 6580 Displaywriter:

- The Displaywriter can be directly attached to an 8100 via the Display Printer Adapter (DPA) using RPO #8D0098 and PRPO #P10074. With these features installed, the Displaywriter appears as a 3277 Display Station.

- A Displaywriter with feature #8332 can also be coax attached to a 3274 Control Unit or 3276 Control Unit Display Station which is in turn attached either to a local or remote 8100 loop or to an 8100 Data Link Adapter (DLA). Attached in this manner, the Displaywriter appears as a 3278 Display Station and, optionally, the Displaywriter printer appears as a 3287 Printer.

With these attachment alternatives, the Displaywriter may be used as a 3270 display. Both these attachments provide document interchange with DPCX/DOSF (see the DOSF Program Announcement dated June 22, 1983).

Usability Improvements:

- **Operator-Definable PF and PA Keys:** A new facility is provided to allow DPCX and DOSF users to assign a specified function to PF and PA keys. With this facility, frequently used commands, procedures, and programs can be invoked simply by pressing a single key.

Commands, procedure names, and user program names can be assigned to the Program Function keys (PF keys 1-24) or the PA1, PA2, and PA3 keys. The request may be invoked immediately or displayed in the command entry area, updated if needed and executed when the enter key is pressed.

A PF key may also be assigned the special function of recalling the last command entered on the command line, and redisplaying it on the command line for possible update and reentry.

Control Operator Functions:

- **Display Command Access Codes:** A new command is provided that allows a user to display and optionally print the access codes associated with any given DPCX or DOSF command. The use of the command is restricted to the control operator, or any operator designated by the control operator.

- **Spool File Enhancements:** A new command is provided that allows a user to list and perform maintenance functions in the spool file. The functions allowed are display, delete, browse, and print all, or a subset of the files in the the spool. This facility may be used only by the control operator.

- **Enhancements for Enable and Disable Commands:** When enabling or disabling a program, the user can now identify the program by program name. The ability to identify the program by program number is still available.

Reliability, Availability and Serviceability: DPCX Reliability, Availability and Serviceability has been improved in Release 4:

- Enhanced problem determination is provided for user applications with an FP trap function. The function is invoked with a TRAP command, with all options provided through a menu facility.

- DPCX now supports the type 2D diskette for the Stand-Alone Dump (SADUMP) and the Stand-Alone Save/Restore and Copy (SASRAC) functions. The type 2D diskette may be used to both contain the above programs and to capture the dump data set.

- A facility is also provided to copy SADUMP data from the 8100 system disk to a type 1 or type 2D diskette. This allows a DPCX user to take an SADUMP to the system disk in a matter of minutes, and then transfer the dump data to diskette at a more convenient time. This facility also allows for the viewing of the SADUMP table of content records. The data presented includes the component number, the size of the SADUMP in number of 256-byte blocks, and the number of type 1 and type 2D diskettes required for the data.

- Time can also be saved in invoking the SASRAC function with the ability in Release 4 to predefine default SASRAC parameters. This will allow SASRAC to be run with few or no operator prompts which reduces the potential for operator errors.

- For problem determination and fix verification on 5210 Printers, an online 'printer exerciser' function is provided. The function is invoked by a new PRINTEX command

Installation Enhancements: The Stand-Alone Save Restore and Copy (SASRAC) facility and the SYSCONFG system service have been enhanced in Release 4. The enhancements allow a Release 4 DPCX system to be restored on 8100 processor with a different disk model than that on the processor from which the system was saved. For example, a system crated on a processor with a fixed head disk can be restored on a system with a non-fixed head disk.

The processor on which the system is being restored must have the same or more disk surfaces as the processor on which the system was created.

SYSCONFG will also change or delete disk volumes on those systems using the system default categories.

The automatic system configuration can now be initiated from the SYSCONFG menu in addition to the processor control panel.

SYSTEM COMPONENTS

3732 Text Display Station: Provides a 1,920-character display (24 lines x 80 characters) designed specifically to provide text entry, revision and related document functions.

The top line of the display provides the user with horizontal positioning information such as a scale that indicates the margins, tab stops and current cursor position. With wide text line two is used to indicate screen position and column scale. The bottom line of the display provides the user with such information as page number and line width and depth settings.

PROGRAM PRODUCTS

DPCX V1 R2.2 & 3 (cont'd)

The keyboard is designed for text operations with keys for entry of data similar to a typewriter. In addition, there are function and control keys used during document creation, revision, formatting and printing.

The terminal is supported by DOSF, a text program product. DPCX support includes user written programs using a subset of Full Screen Processing support. Applications can be written, for example, for data capture and local and/or host inquiry and update including host communications. Most DPCX provided system services can be initiated and controlled via the 3732.

The 3732 display and keyboard are different than the 327X and 8775 displays. The keyboard does not have PA or PF keys, although alternative keys will provide the equivalent AID bytes. The character set has additional characters used for text. The 3732 does not support 3270 data stream compatibility.

The 3732 can be located up to 2000 feet from the 8100/DPCX system. Attachment to the 8100 requires a display and printer attachment port and 3732 with Specify Code #9610 for 8100 attachment.

3736 Printer: A bidirectional, serial impact printer with a speed of up to 55 characters per second. The 3736 prints on tractor-fed continuous stationery or on manually-loaded single sheets (cut forms), using interchangeable 96-character print wheel, 10 or 12 pitch. The character set supported is compatible with the 3732 and the 8775 with IDTF licensed program for document printing, including printing characters in superscript or subscript locations. Printing width is 132 characters using 10 pitch or 158 characters using 12 pitch. Film ribbons are used to provide correspondence quality printing. This directly attached printer can be located up to 2,000 feet from the 8100/DPCX system. Attachment to the 8100 requires a Display and Printer Attachment port.

3262 Printer: Provides medium speed line printing for text documents. Attached to the 8100/DPCX system via loops with speeds up to 38.4K bps. The printer is available in two models, 2 and 12, with nominal printing speeds of 353 and 125 lines per minute with a print band providing printing compatible with the 3732 and 8775 with IDTF licensed program input. Other functions not supported are superscript, subscript and boldface printing. Printing width is up to 132 characters.

5210-E01, E02 Printer: A correspondence quality, table-top, bidirectional serial impact printer with speeds up to 40 (model E01) or 60 (model E02) characters per second. The 5210 prints on tractor-fed continuous stationery, single sheets (cut forms) supplied from a two-drawer sheet-feed attachment or cut forms manually loaded. The character set supported is compatible with the 3732 and 8775 IDTF licensed program for document printing, including printing characters in superscript or subscript locations. Printing width is 132 characters using 10 pitch, 158 characters using 12 pitch and 198 characters using 15 pitch. The one million character ribbon is contained in a snap-in cartridge designed for ease of insertion and removal. The printwheel is contained in a drop-in cartridge and support is provided for changing printwheels while printing a document. The 5210 without EC #996869 attaches only to a 9.6K bps loop. With EC #996869, supported only by DPCX Release 3, it may be attached to either the 9.6K bps loop or a 38.4K bps loop. With EC #996869, it also supports SNA LU Type 1 data streams.

6670 Information Distributor: A high quality printer with communication capability. It can format and print documents received from DPCX or from magnetic cards. The printer consists of a laser print head, a magnetic card unit, a communication facility and a processor. It also serves as a convenience copier. The 6670 is attached to the 8100/DPCX system via the communication port attachment, supporting line speeds up to 9.6K bps. Data from either the DPCX general spool file or the DPCX/RJE print job stream (online from the host) can be sent to the 6670 for printing. 6670 Operator Control Language (OCL) commands and instructions can be defined through terminal input or user programming and prefixed to the DPCX print data stream or to the DPCX/RJE print job stream to control the printing of individual documents. A DPCX subtask initiation capability is also available to the 6670 user via magnetic card input.

3290 Information Panel: The 3290 is a large capacity flat plasma panel display. The characters are orange on a black background. It attaches to the 8100 via the 3274 Control Unit.

The 3290 is data stream compatible with all models of 3270 displays in alphanumeric application environments, and also provides new functions. Highlights of the new functions supported by DPCX are:

- Concurrent multiple screen capability.
- Multiple screen-copy capability.
- Multiple interactive screens.
- Multiple partitions.
- Coexistence of multiple Copy Screens with multiple Interactive Screens.

Not all 3290 functions are supported by DPCX. The following is a list of limitations applying when the 3290 is operating under control of DPCX in other than Data Stream Compatibility mode:

- No more than 8 logical terminals are permitted per 3274 Control Unit. (Each 3290 is capable of supporting up to 4 logical terminals.)
- No more than 8 partitions are supported per screen with a maximum partition size of 4K bytes.
- A default screen size of 1,920 bytes only.
- Screen sizes of 1,920, 2,560, 3,440 and 3,564 bytes only.
- Inbound chains of up to 2,500 bytes maximum.
- Customer-provided Programmed Symbol sets are required if Browse is used when the 3290 character cell size is smaller than 9 x 12 pels.
- The 'WRTDEV DISPLAY, COPY' programming instruction (used for copying a display to a printer) is not supported in partitioned state with an opened LU Type 3 printer.
- 14- and 16-bit screen addresses are not supported.
- The 3290 cannot attach to an ASCII system.

8775 with IDTF Licensed Program: Attaches either via a loop operating at speeds up to 38.4K bps or via a communication port. Provides an 8775 display function with text entry and edit capability. Two additional operator selectable, downstream loadable functions are also available: Enhanced Function (Feature #3624) and Multiple Partitions and Scrolling (Feature #5110).

The 87-key EBCDIC Typewriter/Text Entry and Edit Keyboard provides the characters and functions of the 87-key EBCDIC Typewriter Keyboard with additions for text edit and entry.

The terminal can be used for either text entry and edit or for data processing applications.

With the IDTF licensed program loaded, the 8775 provides functions similar to those available with the IBM 3732 Text Display Station, plus some text functions not provided by the 3732, while retaining the data functions of the 8775. Only a 1,920 character screen size is supported. The terminals operate in either text entry and edit state or in data state. Switching between the two states does not require a downstream load. It is performed automatically under DPCX program control, dependent upon operator-selected functions.

With the Enhanced Function (Feature #3624) loaded, highlighting, partitioning, field validation, programmed symbols and APL (display only) via host are supported.

With the Multiple Partitions and Scrolling function (Feature #5110) loaded, multiple partitioning and vertical scrolling are supported.

Each of the above three functions is downstream loaded from the 8100 using the appropriate 8775 terminal setup procedure and each is mutually exclusive of the other; therefore only one function at a time is allowed per terminal.

Other Printers: Provides the ability to print documents on any printer attached to the 8100/DPCX system. Some special characters are not supported on these printers and will be printed as a unique character or result in a print check depending upon the printer.

Printers attached to the system include loop attached 3230, 3262, 3268, 3287, 3289; direct attached 3284, 3286, 3287, 3288; and display control unit attached 3230, 3262, 3268, 3287, 3289 and 7436-1 RPQ correspondence quality printer, RPQ XC5575. Display control units can be either direct attached loop or communication port attached.

FUNCTIONS AVAILABLE WITH DPCX FEATURE #6001

- Display Support.
 - Large screen displays: 2560, 3440 and 3564 characters.
 - 3274-51C Enhanced Function: Extended color, extended highlighting and programmed symbols.
 - 8775: Feature #3624, Feature #5110 and the IDTF licensed program.
- Access Methods: DXAM and RSAM.
- Printer Support.
 - 3262 mdl 2, 12 with and without print bands for text.
 - 6670 Information Distributor for printing and DPCX subtask initiating capabilities.
- Programming Functions: 32K Task virtual storage, improved editing and data manipulation instructions.
- System Functions: Print spool including browse capability.
- Extended Command Interface: Extensions to user procedure capabilities and command interface.

PROGRAM PRODUCTS

DPCX V1 R2.2 & 3 (cont'd)

Note: DPCX application programs making use of these functions of feature #6001, must be prepared at the host with Host Prep licensed program Release 4.0, 4.1, or 5.0 (5735-XR3).

DPCX RELEASE 1 to RELEASE 2 TRANSITION

Application programs written for Release 1 with or without Feature #6001 function are both source code and object code upward compatible with Release 2 with or without Feature #6001 function respectively. No modifications are required unless new devices or new functions will be supported.

For example, application programs written for DPCX Release 1 that access the Print Data Set in sector mode must be modified to run on DPCX Release 2 if DPCX Feature #6001 general spool file will be used.

User written procedures written for Release 1 are upward compatible with Release 2. No modifications are required unless new commands will be supported.

Existing diskette and tapes supported by Release 1 are fully compatible with Release 2.

DPCX Release 2 can be update installed and uses Release 1 data sets and user entered information.

DPCX Release 2 requires an 8100 configured with 384K bytes of real storage. (DPCX Release 1 requires 256K bytes of real storage.)

DPCX RELEASE 2 TO RELEASE 3 TRANSITION

DPCX Release 3 requires an 8100 configured with 512K bytes of real storage. DPCX Release 3 is upward compatible with DPCX Release 2. The Release 1 levels of the command processor and the printer spool functions are not supported. DPCX Release 2.2 will run on the model C, but without taking advantage of the improved performance capability of the new processor.

INSTALLATION CUSTOMIZATION

DPCX as distributed from IBM includes all functions and capabilities announced. The customer will install using the prompt/response system service capability of DPCX to customize for the appropriate hardware/program configuration.

DPCX is released on a series of installation diskettes which are loaded by the control operator onto disk storage via the operator panel. The next step is the post-installation initial program load procedure which results in the loading of the starter system in real storage.

Then:

- Control operator invokes the interactive configuration service utility.
- Control operator enters configuration information from previously prepared work sheets.
- The input is edited and the configuration positively verified.
- Real storage required to support the specified configuration is assigned resulting in a defined system utilizing from 384K to 1M bytes.

The interactive configuration service then activates the configured devices and the control operator may exercise the report option to display the generated configuration. This completes the customization process.

The control operator then invokes the system installation parameter service to specify information relative to, for example, host communication, transaction data set and RJE.

An automated installation/customization facility, ASSIST, is available to DOSF users whose systems operate with at least 29 million bytes of disk storage. For users of DPCX releases prior to Release 2.2, there is a further restriction that their system must operate with no host communication, no user programming and only direct attached terminals and printers. This facility, an option of the installation program, simplifies the installation/customization process and the system is ready for use at the end of the procedure. Details are contained in the Installation Instructions which are provided with the system.

Network Installation Management Capability: The centralized control facilities of DPCX are enhanced to provide a Network Installation Management capability which allows the installation and customization of DPCX and DOSF at remote 8100 locations from a central site.

There are three elements required to do installation and customization from the host:

- A Source 8100 system at DPCX Release 3 level.
- A Host S/370, 30XX or 4300 system with appropriate programming.
- Destination 8100 systems at DPCX Release 3 level.

Once DPCX Release 3 is installed from diskettes at the remote systems, future installations, as well as configuration and customization functions, can be controlled from the host. Support is not provided for

the remote installation of the DOSF spelling dictionary and 8775 enhanced functions.

The host support required for the Network Installation Management function is provided by the Distributed System Executive (DSX) or can be provided by user-written programs.

SECURITY, AUDITABILITY, and CONTROL

DPCX is intended for business applications with customer management control of the 8100 processor. No facilities (e.g., source code, compiler or linkage editor) are available for modification of programs at the 8100 processor. These functions are performed at the host. This implementation and the facilities listed below provide for strong central management control of the system and applications.

- Program isolation through virtual resource management architecture.
- Program protection in both primary and secondary storage.
- Application program unmodifiable during execution.
- User identification and authorization through passwords.
- Host-to-DPCX authorization through passwords.
- Full control operator journaling on disk with hardcopy log output.
- Through user written procedures, added security functions, such as additional passwords, can be added to limit access to application programs.

USER MANAGEMENT RESPONSIBILITY

These features are intended for use in an environment where application development and control reside at the host. This is the frequently preferred environment for sensitive business applications. For applications in which sensitive data is sent over external communication facilities, user management may wish to augment these facilities with the application of cryptography.

Since security, auditability and control are application, price, environment and organization dependent, final responsibility for their adequacy must rest with user management.

8100/DPCX PRODUCT SUPPORT

See *DPCX General Information: Introduction: (GC27-9075)* for more information.

8100/DPCX supports the following features and devices:

8130, 8140 or 8150 Processor

- Storage size of 384K bytes to one megabyte (1,024K bytes).
- Storage size of 1,024K bytes to two megabytes (2,084K) for 8140 model C.
- Maximum of one diskette 2D drive (mandatory) with the following media format and capacity:

	128-BYTES	256-BYTES
DISKETTE 1	243K bytes	288K bytes
DISKETTE 2D	N/A	998.4K bytes

- Maximum disk capacity of 64.5M bytes for 8130 and 123M bytes for 8140 processors (approximately 8 megabytes of disk capacity is required by DPCX).

8101 Storage and I/O Unit: For up to 258M bytes of additional disk capacity to an 8130 based system for a total of 322M bytes, and up to 387M bytes of additional disk capacity to an 8140 based system for a total of 516M bytes, and additional communication adapters.

Magnetic Tape: 8809: A maximum of 4 drives are supported in 12.5 inch per second mode for Application Program Control of tape. The 100 inch per second capability is utilized by the stand-alone dump/restore utility.

Terminal Devices Supported

- Direct Attach with up to 24 of the following:
 - 3277 Display mdl 2, 3284 Printer mdl 1, 2, 3286 Printer mdl 1, 2, 3287 Printer mdl 2, 3288 Printer mdl 2, 3732 Text Display Station and 3736 Printer.
 - 6580 Displaywriter with the following:
 - Displaywriter-3277 Device Emulation RPQ #8D0098.
 - Displaywriter-3277 Device Emulation/Document Transfer PRPQ #P10074.

PROGRAM PRODUCTS

DPCX V1 R2.2 & 3 (cont'd)

The direct attachment to the 8100 Information System is via the 8101 Storage and I/O unit of 8140 Processor models B51 through B72, using the display and printer attachment, DPA.

Models of Devices Attachable: Loop or Communication Port

DEVICE	LOOP ATTACHED MODELS			COMMUNICATION PORT MODELS	
	Max No*	38.4K	9.6K	Max No*	Up to 9.6K
3104	20	B1, B2	B1, B2	--	--
3230	20	1	1	--	--
3262	20	2, 12	2, 12	--	--
3268	20	1	1	--	--
3274 (1)	5	51C, 61C	51C, 61C	5	51C, 61C
3276 (2)	5	--	12, 13, 14	5	12, 13, 14**
3287	20	11, 12	11, 12	--	--
3289	1	--	3	--	--
5210 (3)	5	E1, E2	E1, E2	--	--
6670 (4)	--	--	--	1	1, 2
7426	5	1	1	5	2
8775 (5)	20	1, 2	1, 2	10	11, 12

- * The maximum number in this table pertains to DPCX Release 2 and earlier only. See below for Release 3 capabilities.
- ** Also mdl 2, 3 and 4 in SDLC mode (cannot attach 3279).
- (1) 3274 supports base and extended color, extended highlighting and programmed symbols.
- (2) 3276 supports base color only.
- (3) 5210 EC #996869 is required to attach to 38.4K bps loop. 5210 with EC #996869 is supported only by DPCX Release 3.
- (4) 6670 mdl 2 required for 9600 bps.
- (5) 8775 supports IDTF licensed program, extended highlighting, field validation, programmed symbols, multiple partitions and scrolling.

DEVICES ATTACHED TO 3274 AND 3276

DEVICE	3274-51C, 61C MODELS	3276-12, 13, 14 MODELS
	Up to 8 Devices	Up to 7 Devices
3178	C1, C2	C1, C2
3230	2	2
3262	3, 13	13
3268	2	2
3278	2, 3, 4, 5	2, 3, 4
3279	2A, 3A, 2B, 3B	2A, 3A, 2B**, 3B**
3287	1, 2, 1C, 2C	1, 2, 1C**, 2C**
3289	1, 2	1, 2
3290	1	--
7436*	1 (RPQ)	1 (RPQ)
6580***		

- * RPQ XC5575.
- ** Supported with base color only.
- *** A 6580 Displaywriter attached to the 8100 through the 3274 Control Unit or the 3276 Control Unit Display Station with the Type A Terminal Adapter must be installed with the following:
 - Displaywriter-3270 Attached Workstation licensed program (5608-SR9).
 - Displaywriter-3274/3276 Attached Workstation Adapter, feature #8332.

Up to three single lobe direct-attached loops are supported, of which two can be high speed of 38.4 bps. A loop can have up to 20 stations of the combinations shown above and in addition, one 3289 mdl 3 printer.

Up to five communication ports are supported with speeds up to 9.6K bps in a multipoint (max 10 stations), point-to-point or point-to-point direct connection without modems. See table above for number and type of devices.

Release 3 Configuration Changes: The data link attached loop is supported in Release 3. With this enhancement, any currently supported loop attachable device, whether for data processing or text applications, is available for use at any location, regardless of distance from the 8100. At the remote site, a 3843 Loop Control Unit provides the interface between the data link and the attached loop. The 3843 runs at the speed of the attached modems (up to 9.6K bps).

For configuration purposes, devices attaching to a data link or a loop are viewed as either small stations (1 device per station), such as the 5510, 6670 and 8775, or large stations (up to 8 devices per station), such as the 3274 and 3276.

Up to 11 stations can be attached per data link, and they may be either small or large. (An exception is the attachment of the data link attached loop; only one 3843 may be attached per data link and no other devices may be on the same link.)

Up to 26 stations can be attached to a directly attached loop. Of the 26, up to 5 may be large stations. (If no large stations are used, all 26 may be small stations.)

Up to 10 stations can be attached to a data link attached loop, and they may be either small or large.

There are no maximum number restrictions requiring the attachment of any specific type of device in Release 3.

Host Link (SNA/SDLC)

1200 to 56K bps

- Switched with 8100/DPCX Information System Auto-Answer (1200 to 9600 bps)
- 8130 transmission Speed: 1200 to 9600 bps.
- 8140 Transmission Speed: 1200 to 56K bps.
 - Nonswitched - Point-to-point or multi-drop (1200 to 9600 bps).
 - Nonswitched - Point-to-point or multi-drop, half or full duplex (56K bps).
 - 1200 to 56K bps point-to-point direct connect (without modem).

CURRENT RELEASES AT DPCX AVAILABILITY OF:

PROGRAM PRODUCTS

DPCX V1 R2.2 & 3 (cont'd)

Sending to the 8100/DPCX Systems: Application programs, relative and indexed user records, display panels, data set, control blocks, messages, print data and commands for data to be sent to the host.

Receiving from the 8100/DPCX Systems: Transaction data, messages and application program dumps.

DSX does not support subcategory definitions or data for DXAM/RSAM access methods, transparent data or larger symbolic machine dumps.

ASCII Support: ASCII support is available in the United States and Canada only. Specify #2990. **SPECIFIED OPERATING ENVIRONMENT**

HARDWARE REQUIREMENTS

Minimum Configuration Supported

- 1 8130 with 512K bytes processor storage
- 1 3277-2 or 3732 direct attached to an 8101

Minimum Configuration 2

- 1 8140 with 512K bytes processor storage
- 1 direct attached 3277-2 or 3732

Minimum Configuration 3

- 1 8130 or 8140 with 512K bytes processor storage
- 1 direct attached loop or communication port
- 1 3274 with a 3178, 3278, 3279, or 3290; or 1 3276; or 1 8775; or 3104

Maximum Configuration Supported

Maximum Configuration 1

- 1 8130 or 8140 model B with 1M bytes of processor storage
- 5 Disks with an 8130 base system, 8 Disks with an 8140 based system
- 4 Tape drives
- 24 3277-2 and/or 3732 displays; and/or 328X and/or 3736 printers
- 1 Host Link with up to 56K bps
- 5 Communication ports with appropriate displays/printers (Maximum of 11 stations per communication port)
- 3 Direct attached loops with appropriate displays/printers (Maximum of 26 stations per loop)

Maximum Configuration 2

- 1 IBM 8140 model C with 2M bytes of processor storage
- 8 Disks
- 4 Tapes
- 1 Host Link with up to 56K bps
- 5 Communication ports with appropriate displays/printers (maximum of 11 stations per port)
- 3 Direct attached loops with appropriate displays/printers (maximum of 26 stations per loop)

SOFTWARE REQUIREMENTS

No additional programs are required to run DPCX on the hardware described.

DOCUMENTATION
(available from Mechanicsburg)

DPCX Licensed Program Summary (GC27-0557) ... DPCX General Information: Introduction (GC27-9075).

RPQs ACCEPTED: No

PROGRAM CURRENCY

IBM Program Services previously announced for DPCX Release 3 will be available until February 1985.

LICENSED PROGRAM MATERIALS AVAILABILITY

Restricted Materials: No. All modules of this licensed program will be available with source licensed program materials.

PROGRAM PRODUCTS

**5761-XR1 - DOSF R2, 3, 4
DISTRIBUTED OFFICE SUPPORT FACILITY
for the 8100 INFORMATION SYSTEM
RELEASES 2, 3 and 4**

PURPOSE

DOSF is a DPCX system application designed to provide automated office support for principal, professional, clerical, and secretarial users. DOSF provides facilities for document creation, revision, formatting, storage, retrieval, printing and host transfer. It also offers a file folder organization, and the capability to manage 'work in process' to fulfill company-wide requirements for enhanced professional and secretarial productivity. DOSF supports the development of office correspondence, business related documents and automated text generation using local data. DOSF along with the other components of the Distributed Office System provides a host document data base with search, retrieval and archiving capabilities; and document exchange capability with other host text processing programs. An easy-to-use Data Stream Compatibility function allows display screens generated by a host application to be captured and used as DOSF documents. In addition to these comprehensive functions available without user programming, the user can write text application programs to enhance capability. DOSF executes with the DPCX operating system which provides extensive data processing and I/O device attachment capability. Thus, DOSF is a component of a distributed system ready to meet today's office needs in text and data processing.

RELEASE 2 HIGHLIGHTS

With the 8100/DPCX/DOSF system, terminal users are able to do the following:

- Create documents rapidly using the 3732 Text Display Station or the 8775 with the IDTF licensed program.
- Let the system automatically determine line and page endings during creation, revision and formatting.
- Use special commands and keys to create and revise wide documents and manipulate columnar text.
- Store frequently used text for later use in other documents resulting in less repetitive keying.
- Use the 327X/8775 display terminals to produce customized form letters, browse thru formatted documents, process completed documents and invoke many DOSF functions.
- Use Automated Text facilities to create documents from pre-formatted patterns which can be personalized via any 1920 character or larger display with information from files, programs, other documents or the keyboard.
- Generate mass mail documents using the DOSF provided function.
- Use the Spelling Verification and Assistance facilities to check the correct spelling of a single word, or all the words in a page or a complete document, and to assist in correcting words found in error.
- Use Records Processing facilities to perform such functions as selecting records or fields from a text created file that meet specific criteria and sorting records or fields in a text created file.
- Perform arithmetic operations on data contained in documents.
- Initiate automated office practices thru DOSF user written cataloged procedures.
- Initiate user written application programs that extend the functions provided by IBM.
- Use queued access functions for printer, diskette and host communications.
- Send documents to the host for storage in the document data base provided by the Distributed Office Support System.
- Send requests to DISOSS for the search, retrieval or deleting of documents.
- Exchange documents via the Document Interchange Facility, with other host text programs that use the Document Library Facility, such as ATMS-III and Document Composition Facility.
- Protect documents from unauthorized users by use of passwords, access codes, delete codes and user profiles.

RELEASE 3 HIGHLIGHTS

DOSF Release 3 is enhanced by:

- Support for 8140 model C Processor.
- DPCX Data Link attached loop support.
- Additional automated text function.
- Automatic hyphenation support for additional languages.
- Several usability enhancements.

- DISOSS/8100 Support
 - Printing of Displaywriter documents.
 - IBM Scanmaster I support.

RELEASE 4 HIGHLIGHTS

DOSF Release 4 is enhanced by:

- Editable interchange between 6580 Displaywriter and 8100/DOSF documents.
- Editable document interchange with 6580 Displaywriter via DISOSS/370 Version 3.
- 6580 Displaywriter cluster controller support:
 - New 6580 Displaywriter attachment support.
 - Document interchange capability.
- Enhanced professional office support:
 - Menu interface to text commands.
 - Text editor enhancements.
 - Enhanced document file management.
 - Quick access to multiple documents.
 - 'Work in process' capability.
 - Automated annotate capability.
- Permanent store security enhancements.
- New Data Stream Compatibility function.
- 6580 Displaywriter document view.
- Automated text enhancements.
- Records processing enhancements.
- Archiving enhancements.
- Spool file list processing.
- Usability improvements.

RELEASE 4 ENHANCEMENT HIGHLIGHTS

- 3278 with 3270 Personal Computer Attachment support.
- File exchange between DPCX/DOSF and the 3278 with 3270 Personal Computer Attachment.
- Storing and processing IBM Personal Computer files in DOSF permanent store.
- DOSF list processing enhancements including support for IBM Personal Computer files.
- Enhanced DOSF permanent store search functions.

DESCRIPTION

Note: The following description is of DOSF at the Release 4 level. For details as to release-dependent functions, refer to the sections describing individual releases, located further in these pages.

Documents created on the 3730 Distributed Office Communication System can be exchanged with the DOSF/8100 system via the Distributed Office Support System (DISOSS) or diskette. These documents are upward compatible. DOSF/8100 documents can be exchanged with a 3730 system via DISOSS or diskette provided the document text controls are supported by the 3730 or the document does not contain wide text. See section on "Document Exchange".

The 8100/DPCX system provides text users with processors with up to 2M bytes of real storage and disk capabilities up to 500M bytes, satisfying a wide range of text system requirements.

Thus, DOSF, as a component of the Distributed Office System, is part of the offering that provides the capability to help manage office information.

INTRODUCTION

Overview: DOSF provides facilities for document preparation from creation through to archiving. The process of developing a document consists of three steps; creation, editing and formatting. Thereafter, the document is usually handled as an entity for printing, distribution, storing or archiving. A document, for example, can be a single or multiple page letter, a report or a manual.

3732 Text Display Station: To create and manipulate the document content, the user uses the 3732 Text Display Station attached to the 8100/DPCX with DOSF. The operator is provided with an 80 character wide by 24 line display. The top line of the display provides the operator with horizontal positioning information such as a scale that indicates the margins, tab stops and current cursor position. The bottom line of the display provides the operator with such information as page number, line width and depth settings. When text width is

DOSF R2, R3 & R4 (cont'd)

greater than 79 characters, the second line is used to indicate screen position via a scale and column number.

The main part of the keyboard resembles that of the normal typewriter and has function and control keys used in document creation, editing, formatting and printing. In addition, the keyboard has function keys. These keys and a number of commands are used to enter, edit and format text, to control documents and to position the operator's view of the document. Some commands affect the document as displayed, while some affect the document when formatted just prior to printing.

The 8775 with the IDTF licensed program loaded provides functions similar to those available with the IBM 3732 Text Display Station, plus some text functions not provided by the 3732, while retaining the data functions of the 8775. The terminal can, therefore, be used when there is a need for both text and data processing applications. It is primarily intended for personnel whose normal tasks involve data applications and who have an occasional need for text functions.

A document created on an 8100/DOSF system via a 3732 Text Display Station or 8775 Display Station with IDTF (Interactive Display Text Facility) can be edited by a user on a Displaywriter workstation. Likewise, any document created on a Displaywriter can be edited by an 8100/DOSF user via a 3732 or 8775/IDTF workstation. Documents exchanged between the two systems must be converted to the receiving system's format for subsequent editing. This conversion occurs within the 8100/DOSF system.

Working Store: Is a facility provided by DOSF for each operator. It contains the current document that is displayed on the 3732 under operator control. Documents retrieved from Permanent Store including a concatenation of documents or subdocuments can also be placed in Working Store. Working Store contents can be sent to Permanent Store, or can be printed via the PRINT key. Up to seven work stores may be active at a time. A menu interface is provided to allow easy movement among these working stores.

Permanent Store: Is a DOSF facility provided for each operator, that is used to store documents. Documents stored in Permanent Store come from Working Store, from archive diskettes, from the 6580 Displaywriter or from the host. Application programs can also process these documents.

In permanent store, documents can be assigned to folders. The user is given the ability to list folder names, select a specific folder, and list the documents contained within that folder. The user can then select and edit any document listed in that folder. This facility allows the user to organize and work on his documents as he does today.

Access to user documents can be defined at the operator number level. The document accesses supported are get, add, delete, replace and list. Operators can now be grouped by departments, so that they share documents pertaining only to their department

BASIC TEXT FUNCTIONS

Document Creation: Provides the facilities for entering documents into the system using the text display station. This operation is similar to typing, with the function keys and commands to help increase productivity. Functions include:

Settings for tab stops and page width and depth.

The operator need not slow down or look at the screen to decide line endings (adjust mode) since words are automatically spilled to the left margin of the next line.

Text can be entered in free form (typewriter-like) with the operator being responsible for line endings. A signal sounds when the cursor is at 5 character positions from the right margin (no adjust mode).

The left margin can be temporarily moved to the right; this automatically causes the text that is subsequently entered to be indented. Additional temporary margins can be used to provide other indentations.

Commands and keys provide the ability to do functions by character, word, line, sentence, column or block.

Text can be defined to be:

- Printed, highlighted or underscored to attract the eye.
- Included or excluded from a copy.
- Defined as superscript or subscript.

Columnar data can be entered row-by-row or column-by-column.

When text entered by the operator is to exceed 79 characters in width, a wide text mode is invoked. The operator can retain a portion of the text as a reference window to be used as a guide for entry. Words are automatically spilled on line boundaries when the ENTER key is used. DOSF allows wide text up to 255 characters, however, printed output is limited to the available printer widths.

The operator's view of the document allows both vertical and horizontal screen scrolling. By positioning the cursor, the screen scrolling can be as fine as a line or character position.

Other controls allow the operator to display the top or the end of the document or to scroll by page.

When creating a new document, the operator can use existing documents providing increased accuracy and throughput. For example, existing documents can be:

A document that contains text ranging from a phrase to an entire subdocument.

One or more documents can be concatenated to form a new document.

Documents created by different operators can be brought together into a single document.

Documents used only to predefine headings and footings or tab stops, page width and length. This allows a variety of predetermined formats to be readily available.

After entry, the operator may use the ADJUST key to have the system format the document into pages. The operator can review the page breaks to determine if further action is required.

Document Editing: Provides the facilities for making changes, additions and deletions to documents stored in the system. Functions include:

Locating and displaying that part of the document where editing is required, via scrolling, or using commands to find a page or string of text.

Making corrections in both columnar and horizontal text using insert, copy, move, find/change and delete functions.

To assist in reviewing, a document can be printed with line numbers and/or revision indicators in the margin and with selected line spacing.

Records Processing: Provides the ability to process documents that contain structured data (text created files) such as lists and tables. Processing includes the ability to establish criteria for selecting records and to sort based upon the contents of one or more fields.

Record selection provides the ability to describe fields within records and use qualifiers such as "equal to" or "more than" to select records within the documents. These qualifiers can be combined with "and" or "or" to form more complex selection criteria.

Sorting can be done based upon one or more fields with a total maximum length of up to 60 characters and is done in ascending or descending order.

Text Arithmetic: Provides a means for an operator to add, subtract, multiply and divide single numbers, or rows or columns of numbers. It also provides the capability for complex arithmetic operations which can be retained in the text both as a record of what was done and as a means to minimize re-keying for repeated calculations.

Spelling Verification and Assistance: Used to check the spelling of a single word, or of all the words in a page or a complete document, and to assist in correcting words found in error. This function uses an IBM-supplied dictionary which is comprised of approximately 100,000 general English language words, 40,000 medical terms and 30,000 legal terms. The dictionary can be extended with a user-supplied list of words, limited only by the amount of storage the user wishes to allocate for this purpose.

Document Formatting: Provides the facilities for detailed page layout of the document. Includes such functions as:

Automatic or manual hyphenation.

Specifying at entry time centering, headings, footings, page numbering, page ending, annotation, text to be kept together and spaces for graphics.

Formatted documents in the general spool file can be viewed on any 1920 character or larger display locally or remotely attached to the 8100/DPCX system. (DPCX function)

Document Printing: Enables documents to be queued for printing by the 3732 PRINT key or via commands. A range of printers are available for printing draft or final copy either locally or remotely attached to the 8100/DPCX system. The print request is placed on a DOSF queue which has specific characteristics for printing. These include margins, length and width, and the code of the paper to be used. The operator, in addition to line spacing, selects the print format such as:

Justified ... where the right margin is aligned by adding spaces to each line where required.

Formatted ... where the line endings are with "ragged right" endings.

As entered ... where most of the commands that control the formatting are printed but are not executed.

When justified or formatted printing takes place, the document is printed in final format including, for example, headings, footings, centering and page numbering. When the operator uses the PRINT key, a menu is displayed allowing the operator to proceed using

PROGRAM PRODUCTS

DOSF R2, R3 & R4 (cont'd)

predefined parameters or to make changes. Documents to be printed are formatted before being placed into the general spool. Thus, when more than one copy is required, the processing load will decrease since formatting will only need to happen once rather than once per copy.

Printer drawer selection can be specified for printers which have a multiple sheet-feed capability.

Support is provided to allow the user to change the type style used when printing on a printer with multiple type style capability. For example, a word can be italicized in the middle of a sentence. This change can take effect at any point in the document and can apply to as little as a single character or as much as the rest of the document.

HELP Facility: Provides the operator with a menu driven capability invoked via the HELP key when immediate assistance is needed. HELP provides explanations of functions and commands. During command input, invoking HELP will provide additional operator guidance.

Other Operator Functions: Include the ability to list all the documents in permanent storage, send messages to other operators on this 8100 system, (can be sent to other 8100/DOSF and 3730 systems via DISOSS) view messages sent from other operators, remove documents from a print queue and stop the printer.

With a single operation it is possible to process a group of documents as an entity. This function helps to increase the accuracy and ease of operation, and includes deleting, sending or retrieving and placing on a print queue. For example, retrieve all documents not already in permanent store that were ordered between two specified dates.

Queue list processing allows the operator to change requests on queues and to display queue contents.

Journaling, (a DPCX function) resulting in hard copy output, is available for some operator actions.

PRINCIPAL/PROFESSIONAL OFFICE SUPPORT: DOSF includes significant office support for the principal and professional, as well as for the secretary.

Menu interface to text commands: DOSF learnability and usability are aided with a menu interface for a number of DOSF text commands and immediate commands. The strength of this menu interface is that it allows the new or occasional user to quickly become productive with DOSF while still providing the power of commands to the experienced user. For example, to create a centered heading, the user selects the heading option from the menu and completes the prompts. He then keys in the text. The appropriate DOSF text commands will be automatically placed in the document.

Text editor help: The DOSF editor provides text command identification via cursor pointing. This aids the occasional or new user in revising a document.

Document file management: DOSF has the capability of organizing documents into file folders. Documents can now be assigned to folders. The user is given the ability to list folder names, select a specific folder, and list the documents contained within that folder. The user can then select and edit any document listed in that folder. This facility allows the user to organize and work on his documents as he does today.

Easy access to multiple documents: Up to seven working stores are available to the user. A menu interface is provided to allow easy movement between these working stores. This function allows a user to automate the way he handles documents today. For example, a user might view a letter in one working store. That letter may reference another letter, causing the user to put aside the first letter and get the referenced letter into a second working store. The user may then create a response to the first letter in a third working store.

Work in process capability: If the user is interrupted in a work session, all currently active working stores can be suspended and the group of working stores be given a name. When the user wishes to resume the work session, he can then recall this group and continue working as before. A menu interface is provided to manage the suspended groups.

Automated annotate capability: An automated annotate capability is available to allow the user to add notes at any point in a document which is being viewed in a working store. The user indicates where he wants the annotation to appear in the document and keys in the text. The system automatically frames the note, and includes the author's name, date and time. This function becomes invaluable when documents are passed for review within a department or organization. Likewise, a principal could add instructions for a secretary to take special action on a document before distributing it. The document can be printed with or without the annotations. This facility is available on a 3732 Display or an 8775 Display with IDTF.

AUTOMATED TEXT FUNCTIONS

Automatic text functions enable the users to accurately and simply produce standard business documents, such as contracts or agreements, and repetitive documents such as confirmation or marketing letters. The capability provided includes:

Generating a standard business document from prestored text. These standard texts, (i.e., contract phrases for example) are used unchanged for more than one document and are protected from operator change. They are called out in sequence by the operator. There may be places within the text for the user to enter data. Thus, the end result is a unique document.

Using a pattern document previously entered on a 3732 or 8775 with IDTF licensed program terminal, a user at any 8100/DPCX or host attached via the Host Command Facility display that is 1920 characters or larger can cause the creation of a personalized document. The unique data for the pattern document can be from the keyboard, a stored document, a text created file, a DPCX user data set, or a program. The invoking operator can control the number of copies and printing format. Once the input has been completed, the operator is free to do other work while the system completes the letter.

Preprinted forms can be personalized in the same manner as described above using a pattern document.

Mass mail can be generated by using a pattern document with name and address inserted from a file. Mass mail processing takes place as a background job, freeing the operator to do other work.

User written text application programs can be written to meet specific organizational requirements beyond those described above.

327X/8775 (without IDTF licensed program) Text Capability: The general purpose display stations attached to the 8100/DPCX system are primarily used for data processing applications. DOSF in conjunction with DPCX provides support for these terminals (1920 character or larger) in a number of important ways:

- Ability to browse thru a formatted document on the DPCX general spool file.

- Ability to invoke a pattern letter, key in the keyboard input(s), specify the variable field source(s) and to initiate the processing.

- Initiation of DOSF procedures and applications specifically written for these terminals.

- Ability to process documents such as placing a request on:

- A local queue for processing such as archive, printing or deleting.

- DOSF archive queue for subsequent host processing by DISOSS, Document Interchange Facility, user written application.

- To initiate DOSF functions related to its operation such as:

- Define parameters (host sessions, operator profiles ...) initiate functions (host sessions, printing ...) control the system (queues, terminal access, operator access ...) send broadcast messages, receive messages create and update the data dictionary,

Host attached displays via the Host Command Facility and DPCX can do all the functions described above.

In addition, 327X/8775 terminals via DPCX and Data Stream Compatibility, have access to host based text and data processing programs. Text programs include ATMS, STAIRS, Document Library Facility and Document Composition Facility.

PROCEDURES AND APPLICATION PROGRAMMING

Tailoring of the system is provided thru the use of user written procedures. Procedures can be used for example, to simplify repetitive operations, decrease operator errors, increase the uniformity of operations and to provide unique commands. Procedures can be invoked at different points in systems operation such as, at the end of DPCX IPL, after operator log on, thru an operator entered command or by an application program. Procedures can contain commands, keyboard entries, DPCX commands, and can invoke both DOSF or DPCX services. Procedures are entered as a document, and then transferred to the procedure library.

Application Programming: Provides the ability to extend the IBM-provided functions. It can be used for example, to implement more advanced automated text functions, office management facilities, and to access host or local data bases. Programs can be interactive with an operator or once initiated, be completely independent of the operator. Text applications have the ability to use both text and data processing programming statements including most DPCX functions and access methods.

DOSF applications are written using programming statements that have been designed specifically to support text functions. In addition, DPCX programming statements can be used. Programs are written using Host Prep licensed program and/or host support (SCP) that executes on the S/370, 303X or 4300 systems. This provides facilities for program compilation, in conjunction with the Assembler. Programs are then placed on a VSAM data set. DSX, the Distributed System Executive, can be used to store and distribute programs. Program testing via SYSDEBUG, is available on the 8100/DPCX System.

PROGRAM PRODUCTS

DOSF R2, R3 & R4 (cont'd)

HOST SUPPORT

Host Interface: Host interface includes the ability to use IBM-provided functions or to use user written programs to send or receive host documents or transactions.

DOSF provides a document transmission facility (DTF) to send or receive documents between the 8100/DPCX system and host programs such as DISOSS or user written applications. The host applications can be in environments provided by VTAM, ACF/VTAM, ACF/VTAME TCAM, ACF/TCAM, CICS/VS or IMS/VS.

Both DISOSS and the Document Interchange Facility interface into DOSF with programs that reside in the 8100/DPCX system to provide additional capability without user programming. This includes sending or receiving documents. With DISOSS, there is additional ability to send commands for archive, delete, search, retrieve and optional features to print at the host, directly view on a 3732 display or send to STAIRS/VS. DISOSS support can either be interactive or batch.

User written programming capability includes the ability to communicate with host applications interactively or batch. This includes the ability to use IMS/VS and CICS/VS transaction and mapping support.

SECURITY of DOCUMENTS

Access control is by means of hardware keylocks, operator passwords and operator access codes. In addition, documents have additional control fields. Documents have a name which can be up to 15 characters in length; subdocument names are up to 8 characters. To process a document from Permanent Store, this name must be entered. When a document is to be stored, the operator has the ability to specify an up to 5 character GET CODE, and an up to 5 character DELETE CODE. Thus, to obtain a copy of a document or to delete it, these codes must be known.

Further protection is provided by specifying in each operator's profile, ability to obtain, delete, list or store documents in another operator's Permanent Store. A specific operator's Permanent Store can be protected by prohibiting all other operators from access or listing contents except the controlling operator.

For applications in which sensitive data is sent over external communication facilities, user management may wish to augment these facilities with the application of cryptography. This is a user responsibility.

Backup and Recovery: Provides ability to recover from both operator errors and disk errors. Operator errors include loss of data from, for example, altering a profile, or deleting documents before archiving. Disk errors can result in the loss of operator profiles, DOSF environment information, queue IDs and characteristics, and etc.

The controlling operator can take checkpoints of the data stored in the system to be used to reestablish the lost information. This can at times result in only partial recovery, depending upon the time since the last checkpoint.

Document Exchange: Documents created on a 3730 system can be sent to a DOSF/8100 system via DISOSS or diskette. These documents are upward compatible with the DOSF support. Documents containing 3730 wide table text commands will automatically be converted to DOSF wide text when retrieved from permanent store.

Documents created on a DOSF/8100 system can be sent to a 3730 system via DISOSS or diskette. These documents are compatible with the 3730 system provided the text commands contained within the document are supported by the receiving 3730 system. DOSF text commands that must be excluded include, for example, blind text, block overstrike, boldface printing, line numbered output, variable hyphenation, revision indicators or documents containing wide text. See *DOSF General Information Manual: Introduction* (GC27-0546).

DISOSS support for DOSF documents includes store, retrieve, delete and search. Excluded are the optional features of DISOSS - i.e., host printing, direct viewing on a 3732 and formatting for STAIRS/VS - when these documents contain DOSF text commands not supported by DISOSS. Refer to the current *DISOSS General Information Manual* (GH12-5124) for details.

DOSF also provides DISOSS/8100 users support for the printing of final form documents created on a 6580 Displaywriter. The documents may be distributed from the Host Document Library or between the systems through the network document distribution facilities of DISOSS. The interchanged documents must be printed on the 5210 with EC #996869 installed.

The Document Interchange Facility can exchange DOSF documents with the Document Library Facility. Not all DOSF text commands may be supported. Refer to the current *Document Interchange Facility General Information Manual* (GH20-2440) for details.

SYSTEM COMPONENTS

8775 with IDTF Licensed Program: Attaches either via direct attached loop operating at speeds up to 38.4K bps or via communication port. Provides an 8775 display function with text entry and edit

capability. Two additional operator selectable, downstream loadable functions are also supported: Enhanced Function (Feature #3624) and Multiple Partitions and Scrolling (Feature #5110).

The 87-key EBCDIC Typewriter/Text Entry and Edit Keyboard provides the characters and functions of the 87-key EBCDIC Typewriter Keyboard with additions for text edit and entry.

The terminal can be used for either text entry and edit or for data processing applications.

With the IDTF licensed program loaded, the 8775 provides functions similar to those available with the 3732 Text Display Station plus some text functions not provided by the 3732, while retaining the data functions of the 8775. Only a 1920-character screen size is supported. The terminals operate in either text entry and edit state or in data state. Switching between the two states does not require a downstream load. It is performed automatically under DPCX program control, dependent upon operator selected functions.

With the Enhanced Function (feature #3624) loaded, highlighting, partitioning, field validation, programmed symbols and APL (display only) via host are supported.

With the Multiple Partitions and Scrolling function (feature #5110) loaded, multiple partitioning and vertical scrolling is supported.

Each of the three functions is downstream loaded from the 8100 using the appropriate 8775 terminal setup procedure and each is mutually exclusive of the other; therefore only one function at a time is allowed per terminal.

3732 Text Display Station: provides a 1,920-character display (24 lines X 80 characters) designed specifically to provide text entry, revision and related document functions.

The top line of the display provides the user with horizontal positioning information such as a scale that indicates the margins, tab stops and current cursor position. With wide text, line two is used to indicate screen position and column scale. The bottom line of the display provides the user with such information as page number and line width and depth settings.

The keyboard is designed for text operations with keys for entry of data similar to a typewriter. In addition, there are function and control keys used during document creation, revision, formatting and printing.

The terminal is supported by DOSF, a text program product. DPCX support includes user written programs using a subset of Full Screen Processing support. Applications can be written, for example, for data capture and local and/or host inquiry and update including host communications. Most DPCX provided system services can be initiated and controlled via the 3732.

The 3732 display and keyboard are different than the 327X and 8775 displays. The keyboard does not have PA or PF keys, although alternative keys will provide the equivalent AID bytes. The character set has additional characters used for text. The 3732 does not support 3270 data stream compatibility.

The 3732 can be located up to 2,000 feet from the 8100/DPCX system. Attachment to the 8100 requires a Display and Printer Attachment port and 3732 Specify Code #9610 for 8100 attachment.

6580 Displaywriter: The 8100 with DOSF can be used as a 'cluster' or 'departmental' controller for the Displaywriter. This function provides document storage and printer sharing capabilities for the Displaywriter. Documents created on a Displaywriter can be filed on the 8100 and printed on a 5210 mdl E Printer with EC 996869 supported by the 8100. By making the 8100 disk storage available to the Displaywriter, the need for diskettes at the Displaywriter is greatly reduced. This also reduces the need to attach a printer directly to a Displaywriter. To meet the needs of users who have a variety of attachment requirements, DOSF Release 4 provides for additional ways to attach the Displaywriter.

The 6580 Displaywriter can be directly attached to an 8100 via the Display Printer Adapter (DPA) using RPQ 8D0098 and PRPQ P10074. DOSF will also support the attachment of a Displaywriter with feature #8332 and licensed program 5608-SR9 to a 3274 Control Unit or 3276 Control Unit Display Station attached either to a local or remote 8100 loop or to an 8100 Data Link Adapter (DLA). These attachment alternatives allow for the exchange of documents directly between Displaywriter and 8100/DOSF.

The Displaywriter can also be supported as a 3270 workstation in Data Stream Compatibility mode, but this attachment does not support document transfer.

5210 Printer: A correspondence quality table-top, bi-directional serial impact printer with speeds up to 40 (mdl E01) or 60 (mdl E02) characters per second. The 5210 prints on tractor-fed continuous stationery, single sheets (cut forms) supplied from a two-drawer sheet-feed attachment or cut forms manually loaded. The character set supported is compatible with the 3732 for document printing including characters in superscript or subscript locations. Printing width

DOSF R2, R3 & R4 (cont'd)

is 132 characters using 10 pitch, 158 characters using 12 pitch and 198 characters using 15 pitch. The one million character ribbon is contained in a snap-in cartridge designed for ease of insertion and removal. The printwheel is contained in a drop-in cartridge and support is provided for changing printwheels at any point while printing a document. The 5210 without EC 996869 attaches to DPCX only via a 9.6K bps loop. With EC 996869 (available July, 1983) installed, it attaches via loops operating at speeds of up to 38.4K bps. The proportional spacing capability of the 5210 is not supported by the DOSF formatter.

3736 Printer: A bidirectional, serial impact printer with a speed of up to 55 characters per second. The 3736 prints on tractor-fed continuous stationery or on manually-loaded single sheets (cut forms), using interchangeable 96 character print wheel, 10 or 12 pitch. The character set supported is compatible with the 3732 for document printing, including printing characters in superscript or subscript locations. Printing width is 132 characters using 10 pitch or 158 characters using 12 pitch. Film ribbons are used to provide correspondence quality printing. This directly attached printer can be located up to 2000 feet from the 8100/DPCX system. Attachment to the 8100 requires a Display and Printer Attachment port.

3262 Printer: Provides medium speed line printing for text documents. Attached to the 8100/DPCX system via direct attached loops with speeds up to 38.4K bps. The printer is available in two models, 2 and 12, with nominal printing speeds of 253 and 125 lines per minute with a print band providing printing compatible with the 3732 input. Functions not supported are superscript, subscript and boldface printing. Printing width is up to 132 characters.

Other Printers: Provides the ability to print documents on any printer attached to the 8100/DPCX system. Some special characters are not supported on these printers and will be printed as a unique character or result in a print check

Printers attached to the system include direct attached loop 3230, 3262, 3268, 3287, 3289; direct attached 3284, 3286, 3287, 3288; and communication port attached 6670; display control unit attached 3262, 3268, 3287 and 7436-1 RPQ correspondence quality printer, RPQ #XC5575. Display control units can be either direct attached loop or communication port attached.

INSTALLATION

All customers receive the same set of diskettes. These are read into the system by DPCX and then DOSF is customized to satisfy the specific site requirements. This customizing includes setting a unique DOSF identification, setting normal operator entry parameters, setting disk storage allocation and operator access to functions.

An automated installation/customization facility, ASSIST, is available to users whose systems operate with at least 29 million bytes of disk storage. For users of DOSF releases prior to Release 2.1, there is a further restriction that their system must operate with no host communication, no user programming and only direct attached terminals and printers. This facility, an option of the installation program, simplifies the installation/customization process and the system is ready for use at the end of the procedure. Details are contained in the Installation Instructions which are provided with the system.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS Minimum

1 IBM 8100 Information System configured to support the appropriate level of DPCX. See "Software Requirements", below.

1 IBM 3732 Text Display Station via direct attachment.

1 X 90K bytes real storage for DOSF

(Minimum Processor storage for DPCX/DOSF is 768K bytes. Enhanced configurability and performance can be realized by the addition of processor storage.)

1 X 4M bytes disk space for DOSF

SOFTWARE REQUIREMENTS

DOSF Release 2.0 requires DPCX Release 2.1 and DOSF Release 2.1 requires DPCX Release 2.2, both with the appropriate level of feature #6001 configured for DXAM/RSAM and general spool.

DOSF Release 3 requires DPCX Release 3. Printing of Displaywriter documents and Scanmaster I support is dependent upon DISOSS/370 Version 3 and DISOSS/8100 Version 1.1.

See *DOSF General Information Manual* (GC27-0546) and *DPCX General Information Manual* (GC27-9075) for additional information.

3730 COMPATIBILITY

Programs written for the 3730 system using the same or equivalent device type are upward compatible at both the source and object level to the DPCX/DOSF system, provided that there are no hard coded device addresses. User written application programs using 3730 wide table support executing on DOSF may have unpredictable results. 3730 documents are upward compatible to DOSF documents. They can be

transferred to DOSF via DISOSS or diskette. Documents using 3730 wide table support are converted to DOSF wide text support when initially retrieved from Permanent Store. See section on "Document Exchange" for added detail.

ASCII Support: ASCII support is available in the United States and Canada only. When specified for DOSF, it must be specified for DPCX also. Specify #2990.

RELEASE 2 CONTENTS

Revision indicators used to indicate document revisions.

Blind carbon copy used to identify text that will be included or excluded from a copy of a document when printed.

Find/change improvements that will allow locating and replacement of strings optionally interpreting capitalization, spacing, punctuation and underscoring.

Block underscore/deunderscore will allow the operator to define the block or column of the text and initiate the function. This can be from two characters to a whole document.

Block overstrike allows selection of a character or system default to overstrike text. The operator identifies a block of the text with imbedded text commands that are later interpreted before printing. This is used where the original text should not be deleted.

Bold face printing allows the operator to identify text; i.e., a character, word, sentence, phrase or block, that will be printed highlighted to attract the reader's attention. For example, on the 3736 printer, the character will be printed once, and then printed a second time slightly offset while on the 5210 the character is reprinted, but with no offset.

Automatic hyphenation can be specified by the user to have the system automatically insert hyphens in words that are found to cross the right margin of a page when adjusting a document. This function employs the dictionary used by Spelling Verification .

Variable hyphenation permits an operator to alter the system defaults used during the adjust with hyphenation function which can improve the appearance of printing.

Line numbering will allow an operator to have a document printed with line numbers in the margin to assist in reviewing. Numbering starts on each page and is by line or every five lines as selected.

Spelling Verification and Assistance is used to check the correct spelling of a single word, or of all the words in a page or a complete document, and to assist in correcting words found in error.

Text arithmetic provides a means for an operator to add, subtract, multiply and divide single numbers, or rows or columns of numbers.

Multiple sheet-feed support provides the user with the ability to specify drawer selection for printers with a multiple sheet-feed capability.

Type style change allows the user to change the type style used when printing on a printer with multiple type style capability.

RELEASE 2.1 CONTENTS

Records processing provides the ability to process documents that contain structured data (text created files) such as lists and tables. Processing includes the ability to establish criteria for selecting records and to sort based upon the contents of one or more fields.

Additional Automated Text commands allow the user to:

- Generate formatted reports from text created files stored in the system.
- Use text created files containing lists or tables as a source of imbedded data for documents or patterns.
- Insert a field from a file directly into a document in Working Store.

Additional Mass Mail commands provide a simplified means of merging data from a "master" document containing constant information and a "control" document containing variable information into a Mass Mail document using a technique of switch codes.

Alternate Working Store provides a means for an operator to interrupt work done on one document, and then return to the point of interruption on the first document. The system saves the contents of Working Store before "swapping" to the Alternate Working Store and restores them when "swapping" back.

Support for the 5210 enhances document printing flexibility and support by providing a loop attached printer and a capability to print documents at 10, 12 or 15 pitch. The 5210 also permits the user to use the DOSF multiple sheet-feed support and the type style change support when printing documents.

Support for the 8775 with the IDTF licensed program loaded provides functions similar to those available with the IBM 3732 Text Display Station, plus some text functions not provided by the 3732, while retaining the data functions of the 8775. The terminal can therefore be used where there is a need for both text and data processing applications.

PROGRAM PRODUCTS

DOSF R2, R3 & R4 (cont'd)**RELEASE 3 CONTENTS**

DOSF Release 3 complements the 8140 model C support provided by DPCX Release 3, and provides users with the capability to take advantage of increased storage and performance improvements available with this processor. This support, coupled with the DPCX Release 3 enhancement doubling the number of user tasks from 31 to 62 that can be active concurrently, offers improved system flexibility for accounts where increased processing power and additional storage is required, or where sufficient processing power is available but additional active terminal support is needed.

To meet the needs of users who have requirements for text capabilities at sites remotely located from the 8100 processor, DPCX Release 3 extends its configuration support to include data link attached loops. With this enhanced support, any loop attachable device, whether for data or text applications, is available for use at a remote location. With appropriately configured displays and printers, remote DOSF workstations are supported.

DISOSS/8100 users are provided with support for the Scanmaster I, as well as the printing of final form documents created on the IBM Displaywriter. DISOSS/370 Version 3 is also a prerequisite for this support.

The automated text facilities of DOSF are enhanced by the capability to insert fields from Relative Sequential Data Sets (RSDS) records into a document. The support is identical to that provided for index files, e.g., field lengths of up to 200 characters and record keys of up to 24 characters.

On prior releases of DPCX/DOSF systems, functional interfaces were provided through both DPCX and DOSF system services as well as commands. As a result, users had to decide which system service or command should be used to perform a particular function. DPCX/DOSF will remove many of these redundant interfaces and provide a single command processor interface for the desired function.

Support is provided to print documents at either 6 or 8 lines per inch on the 5210 printer. (Prior releases support only 6 lines per inch.)

The restriction of having a maximum of one text command in a line being processed by Find/Select or Sort/Select is removed. Processing will no longer be affected if a line contains multiple text commands as long as that line contains no other data.

A new option is added to SYSXFEA3 to provide a means to monitor disk space usage in the spool file.

RELEASE 4 CONTENTS

DOSF Release 4 complements the 8130 mdl B and 8150 processor support provided by DPCX Release 4, and allows users to take advantage of the increased performance of these processors.

Host or 8100/DOSF-attached 6580 Displaywriter users can edit documents created on an 8100/DOSF system via a 3732 Text Display Station or 8775 Display Station with IDTF (Interactive Display Text Facility). Likewise, any document created on a Displaywriter can be edited by an 8100/DOSF user via a 3732 or 8775/IDTF workstation. Documents exchanged between the two systems must be converted to the receiving system's format for subsequent editing. This conversion occurs within the 8100/DOSF controller.

Because they are created in different environments, the two forms of revisable form documents express common concepts in different ways, and each also has concepts that the other cannot express at all. Therefore, the conversion between these two forms of revisable documents is necessarily limited. However, many typical documents can be converted while still retaining their external format.

For planning purposes, the following list of 6580 Displaywriter text controls and functions are not handled when a Displaywriter document is converted to a DOSF document: Inhibit pagination, spell attributes text unit name, Reportpack shell documents, included text, right/colon tab alignment, justification, operator message, auto-outline, footnotes, insert escaped graphic, release left margin, begin/end column, set visual attributes, index, unit backspace, half-line spacing, proportional space management.

For planning purposes, the following list of DOSF controls and functions are not handled when a DOSF document is converted to a 6580 Displaywriter document: Annotation, arithmetic, blind text, column tabulate, deferred get, double strike, line numbers, imbeds, multiple-line records, revision indicators, subdocument, skip forward/diagram/line, begin/end centering, column tabs, margin text greater than 256 characters.

More detailed information regarding these incompatibilities is available in the appropriate product reference manuals.

Documents created on a 6580 Displaywriter can be filed on the 8100 and printed on a 5210 mdl E Printer with EC 996869 supported by the 8100. By making the 8100 disk storage available to the Displaywriter, the need for diskettes at the Displaywriter is greatly reduced. This also reduces the need to attach a printer directly to a Displaywriter. Because of differences in the internal structures of the documents, a

Displaywriter document will require more storage and take more time to format for printing than the same size DOSF document.

The Displaywriter can be directly attached to an 8100 via the Display Printer Adapter (DPA). It can also be attached through a 3274 Control Unit attached to a local or remote 8100 loop or an 8100 Data Link Adapter (DLA). These attachment alternatives allow for the exchange of documents directly between Displaywriter and 8100/DOSF. The Displaywriter can also take advantage of the 8100 system's file and printer services with these attachment alternatives. In addition, it is supported as a 3270 workstation without file transfer.

Users of host-attached 6580 Displaywriters can file and retrieve Level 3 DCA and final-form documents to and from the Host Document Library. Please note that a Displaywriter request to retrieve a DOSF-editable document will result in DISOSS/370 transforming the DOSF-editable document to a final-form document prior to transmitting the document to the Displaywriter.

DOSF Release 3 allowed DISOSS/8100 users to receive final form documents distributed from a host-attached 6580 Displaywriter. DOSF Release 4 enhances that support by allowing DISOSS/8100 to receive Level 3 DCA documents which have been distributed from a host-attached Displaywriter. When DISOSS/8100 receives these documents, they will be formatted into final form and made available for viewing or printing by the recipient. In addition, the existing DISOSS/8100 support for distribution of DOSF documents has been extended to allow distribution of Level 3 DCA documents which are resident in the 8100/DOSF permanent storage.

DOSF learnability and usability have been greatly enhanced with a new menu interface for a number of DOSF text commands and immediate commands. The strength of this menu interface is that it allows the new or occasional user to quickly become productive with DOSF while still providing the power of commands to the experienced user.

The DOSF editor has been extended to provide text command identification via cursor pointing. This aids the occasional or new user in revising a document.

A new concept of organizing documents into file folders is being introduced into the 8100/DOSF system. Documents can now be assigned to folders. The user is given the ability to list folder names, select a specific folder and list the documents contained within that folder. The user can then select and edit any document listed in that folder. This facility allows the user to organize and work on his documents as he does today.

An additional five working stores are being made available to the user, increasing the total to seven. A new menu interface is provided to allow easy movement between these working stores.

If the user is interrupted in a work session, all currently active working stores can be suspended, and the group of working stores be given a name. When the user wishes to resume the work session, he can then recall this group and continue working as before. A menu interface is provided to manage the suspended groups.

An automated annotate capability has been added to DOSF Release 4 to allow the user to add notes at any point in a document which is being viewed in a working store. The user indicates where he wants the annotation to appear in the document and keys in the text. The system automatically frames the note and includes the author's name, date, and time. This function becomes invaluable when documents are passed for review within a department or organization. Likewise, a principal could add instructions for a secretary to take special action on a document before distributing it. The document can be printed with or without annotations.

Permanent store security is enhanced to allow for document access to be defined at the operator number level. The document accesses supported are get, add, delete, replace, and list. Operators can now be grouped by departments, so that they share documents pertaining only to their department.

Significant flexibility and functional capability are provided with a new Data Stream Compatibility - Extended (DSC-E) facility. While the functional capabilities of the DSC facility in DPCX Release 3 remain unchanged, the user may now optionally invoke the DSC-E facility which provides the following new functions:

- A Suspend/Resume 'Hot' Key Switch: DSC-E allows a user to have an active host task and an active 8100 task simultaneously. The user may now switch between these two tasks by pressing a single user-designated PF or PA key. When communication with the host application is suspended, all DPCX functions and applications (including DOSF) are available to the user. The user may then return to (resume) the host application by again pressing the same PF or PA key. A host session may be suspended any time the display keyboard is unlocked; a host session may be resumed any time the DPCX task is at a point where a command may be entered.
- A Screen Capture/User Exit Capability: Display screens generated by a host application can be captured by DOSF and stored as a document. A user-written application may optionally be invoked to

DOSF R2, R3 & R4 (cont'd)

make any desired modifications to the screen before the document is created. The document resulting from a screen capture function is a DOSF document which can be edited, imbedded in another document, or printed. The screen capture function is invoked by pressing the user-designated PF or PA key.

When the DSC-E option is selected, two user tasks are always made active. This is independent of whether the 'suspend/resume' function is ever used. The current DSC facility continues to use only a single task.

It should also be noted that the DSC-E facility cannot be initiated from the host. DSC-E can be initiated by a user of any DPCX/DOSF display, except a 3732. When the DSC-E facility is used, the local copy function on an 8775 is supported only if the printer adapter feature #5580 is installed.

Also, a single command is provided for quickly and easily accessing the Data Stream Compatibility functions of DPCX. These functions can now be invoked by entering the LOGON command directly from the DPCX 'Enter Command' screen. The user can specify whether the current DSC or the new DSC-E function is to be invoked.

The DOSF facility for viewing documents formatted for printing has been enhanced to allow viewing of DCA Level 2 documents. Documents created on a Displaywriter and distributed to the 8100/DOSF DISOSS/370 can now be viewed by any 8100/DOSF system display. DOSF Release 3 allowed only for the printing of these documents.

As an aid to better managing Automated Text pattern letters, DOSF Release 4 provides a facility for listing and printing pattern letter specifications. The document created by this facility lists the pattern routing information and the specification information for each imbed in the pattern. The imbeds are grouped by type.

Pattern letters can now process numerical data without operator intervention. Automated text processing will now resolve all text arithmetic commands when generating documents. The arithmetic commands may be either in a pattern letter or in text brought into a document via Document Imbeds or Deferred Gets.

The repetitive letters facility has been made more flexible. Letters generated by the MERGE command will be put on a print queue only if the user requests. Also, the user can specify that the generated documents be either deleted from or retained in permanent store after they are printed.

DOSF will support the increased number of user data sets available in DPCX Release 4.

DOSF records can now contain text commands on the same line as data. This enhancement broadens the applicability of the DOSF records processing facility by lessening the distinction between text files and documents.

Select/Sort can now be done on an entire document without the operator being prompted for a target area.

Archiving reliability has been improved by the system immediately reading back each section written to diskette to ensure the data was recorded accurately.

The spool file list processing function provides the control operator the ability to list and process formatted documents in the system spool file. A new command, SPOOLPRC, will display a list of all or a subset of the documents in the spool file. The control operator can then select documents from the list to be either viewed, printed or deleted.

The following usability functions are included:

- Text commands can now be entered in either lower or upper case.
- The number of lines allowed in a heading or footing has been increased to 50. This provides more flexibility in the content and the placement of headings and footings.
- A new text command allows the user to specify the left margin at any point in the document. This command overrides the left margin characteristics specified in the queue definition.
- The text arithmetic facility has been enhanced to allow for processing to continue when a divide by zero situation is encountered. The current method causes processing to cease. A warning message will be issued, and the result of the calculation will be null.
- Three new system arguments have been added to the command procedure facility. These arguments provide access to the document name, get code, and operator number of the last document stored when the last STORE command was invoked. This new facility will add more power and flexibility to procedures which store a document using the prompt followed by a print request for a stored document.
- The Temporary Left Margin can now be set beyond position 79 and up to position 127.
- Multiple backspaces are now supported on the 8775/IDTF Display.

- Three lines of text will now be displayed when the tabrack is changed on an 8775/IDTF Display.

RELEASE 4 ENHANCEMENTS CONTENTS

The 3278 with 3270 Personal Computer Attachment is supported by DPCX/DOSF Release 4. The 3270 Personal Computer Attachment support is provided via the 3278 with 3274 Control Unit which may be attached to 8100 directly-attached and data link-attach loops and communication links. With this attachment capability, the 3278 with 3270 Personal Computer Attachment may be used in the following ways:

- **Personal Compute Mode:** Using the 3278 as the monitor and keyboard of the IBM Personal Computer, all Personal Computer functions can be performed.
- **Interactive Mode with DPCX/DOSF:** In this mode of operation, the 3278 operates the same as it did prior to the installation of the IBM Personal Computer attachment. The user can quickly change between DPCX/DOSF interactive mode and Personal Compute mode with the simultaneous pressing of two keys at the 3278 keyboard.
- **Interactive mode with an S/370 host via DPCX DSC:** In this mode of operation, the 3278 can appear as an S/370 attached display, again operating the same as it did prior to the installation of the Personal Computer Attachment.
- **S/370 Host File Transfer Mode via DPCX DSC:** The 3278 with 3270 Personal Computer Attachment provides a file transfer capability between the 3278 with 3270 Personal Computer Attachment and an S/370 Host system. This same file transfer can be accomplished with a DPCX-attached 3278 with 3270 Personal Computer Attachment via the DPCX DSC facility.
- **DPCX/DOSF File Transfer Mode:** This new facility in DPCX/DOSF is described in the following section.

File Exchange between DPCX/DOSF and the 3278 with 3270 Personal Computer Attachment: DPCX/DOSF Release 4 now supports the exchange of files between DOSF permanent store and a 3278 with 3270 Personal Computer Attachment. Any file resident on the 3278 with 3270 Personal Computer Attachment diskette may be transferred to the DPCX/DOSF system, and any member of DOSF permanent store may be transferred to the 3278 with 3270 Personal Computer Attachment.

To initiate the transfer of files, the 3278 with 3270 Personal Computer Attachment user must be logged on to DOSF, and be in a state where a command can be entered. A HOST command (or HOST-equivalent command in a customer program) must then be entered at the 3278 with 3270 Personal Computer Attachment to invoke a 3278 with 3270 Personal Computer Attachment using IBM Personal Computer Data Transfer Sample Application Program (or an equivalent customer-written program) that places the 3278 with 3270 Personal Computer Attachment in file transfer mode. The exchange of files is accomplished with a PUTFILE command to transfer files from the 3278 with 3270 Personal Computer Attachment to the 8100, and a GETFILE command that transfers files from the 8100 to the 3278 with 3270 Personal Computer Attachment. Parameters may be specified on the commands, or optionally a prompt screen is provided. The file name is the only mandatory parameter. Files may continue to be sent in either direction until the Sample Program in the 3278 with 3270 Personal Computer Attachment is terminated. While the Sample Program (HOST) is active in the 3278 with Personal Computer Attachment, other Personal Computer functions cannot be performed.

Storing and Processing PC files in the 8100: Personal Computer files that are transferred from the 3278 with 3270 Personal Computer Attachment to an 8100 DPCX/DOSF system are stored in DOSF permanent store. A CONVERT command may optionally be used to change the file to the DOSF format. Both versions of the file are stored in DOSF permanent store.

- **PC Files Converted to DOSF Documents:** A Personal Computer file that is converted to DOSF format and stored in DOSF permanent store may be processed in the same manner as other DOSF documents. This includes retrieval of the document at the 3278 with 3270 Personal Computer Attachment.
- **PC Files Stored as PC Files:** A Personal Computer file may be retrieved by any 3278 with 3270 Personal Computer Attachment in the same format in which it was originally created. The 3278 with 3270 Personal Computer Attachment user may also archive and delete the file, and if the file is in EDIT format containing ASCII data, it may also be printed at the DPCX/DOSF system. The same functions may also be invoked by any 3270-type device attached to the DPCX/DOSF system.

DOSF R2, R3 & R4 (cont'd)

DOSF List Processing Enhancements: Personal Computer files may also be processed via the document list processing function of DOSF. This function has been enhanced such that all saved Personal Computer files are identified as Personal Computer files. The 3278 with 3270 Personal Computer Attachment user can therefore list all Personal Computer files and select the following functions to be performed:

- Retrieve an IBM Personal Computer file to be sent to the 3278 with 3270 Personal Computer Attachment.
- Print a file as described above.
- Delete or archive a file.

Enhanced Search with Support for PC Files: The search function has been enhanced to be able to qualify the permanent store search by specifying the file type (e.g., Personal Computer). Additional enhancements also allow the searching for document/file names by prefix, suffix or character string within the name. The new search functions will use one or more '*' to indicate how the document/file names are to be searched.

PERFORMANCE CONSIDERATIONS

DOSF Performance: The performance of DOSF depends upon a number of interrelated factors. Those important to DOSF performance are the 8100/DPCX configuration, the number and characteristics of the concurrent applications, operator input and output rates, host link characteristics and the host application characteristics. Thus, the process of determining performance is complex and to ensure that each configuration is acceptable, that configuration and its characteristics should be carefully assessed.

Comparison of 8100/DPCX/DOSF Performance to 3730: It should be noted that the factors given below are generalizations and that some systems will get better or worse performance depending upon many variables. There is no warranty or guarantee that the performance factors given below will apply to a customer configuration.

The 8140 processor provides approximately 1.4 times more processing capability than the processor used in the 3730 system (3791) while the 8130 processor is approximately equivalent. The disk performance for both 8100 processors is about two times that of the fixed disk used in the 3730 system (3791), assuming random accesses over moderately loaded files.

With the structure of the DPCX operating system and the DOSF application program on a 768K byte or larger processor, the following may be expected for many systems:

- 8130 system to perform in the range of approximately 1 to 1.5 times the 3730 system.
- 8140 system to perform in the range of 1.4 to 2.5 times the 3730 system.

These above improvements apply to direct attached terminals interacting with local 8100 applications.

8140 Model C Performance: The 8140 model C is supported in DPCX/DOSF Release 3. There are two processing elements within the 8140 model C. One of these processing elements performs the same functions as the 8130 and 8140 A and B models, while the other is restricted in that it does not directly attach channel logic or system control function. The normal mode of operation with both processing elements operating on the 8140 model C processor is called dual mode. The 8140 model C can also operate with a single processing element which is called single mode.

DPCX/DOSF Release 3 and 8140 model C operating in dual mode, and the increase in the allowable number of active tasks, introduce a new performance growth path for processor bound office system 8100 users. They are capable of providing up to 60 percent increased throughput over a similarly configured and heavily loaded 8140 model B operating under DPCX Release 2.2/DOSF Release 2.1. In those cases where the processor was heavily utilized, an improvement in response time may be possible by going to the 8140 model C and DPCX/DOSF Release 3 for the same throughput.

The throughput improvement actually achieved by an 8140 model C operating with DPCX Release 3 depends on many factors, some of which are:

- Installed real storage.
- Input/output load.
- Configuration.
- Number of concurrent active tasks.
- Processor utilization.
- Application.

Additionally, an application characterized by heavy communication traffic and/or DASD load may not achieve the full performance improvement potential. For example, RJE and DSC/DSFC would normally be DASD-bound tasks. Also, tasks utilizing all, or substantial portions, of the system resources may not experience performance gains.

The increased number of concurrent active user tasks provides improved system flexibility for accounts where sufficient processing capability exists.

Applications running on the 8140 model C in single mode with DPCX Release 2.2/DOSF Release 2.1 or DPCX/DOSF Release 3 will experience performance equivalent to the 8140 model B.

8130 Model B and 8150 Performance: The 8130 B and 8150 B provide the following throughput improvements for the same or better response times compared to current 8100 Processors:

- 8130 B: Up to 1.4 times an 8130 A
- 8150 B: Up to 2.0 times an 8140 C
- 8150 B: Up to 3.2 times an 8140 B

The throughput improvements are based on similarly configured and heavily loaded systems. Response time improvements for the same throughput will also be possible.

The throughput improvement actually achieved by the new processors depends on many factors, some of which are:

- Installed real storage
- Input/Output load
- Configuration
- Number of concurrently active user tasks
- Processor utilization
- Application environment

In addition, an application characterized by heavy communication traffic and/or DASD load may not achieve the full performance potential. For example, RJE and DSC would normally be communications-bound tasks. Large sorts and document archiving to and from diskettes would normally be DASD-bound tasks. Also, tasks utilizing all, or substantial portions, of the system resources will not experience performance gains.

Data Stream Compatibility - Extended Performance: The performance of the DSC function currently provided in DPCX Release 3 remains unchanged in DPCX Release 4. Typically, the 8100 process time is very small for DSC (for example, a transaction every 45 seconds of 40 characters in and 800 characters out would use less than one percent of an 8140 B).

The DSC-E facility in DPCX Release 4 which allows switching between a host application and a DPCX application will utilize between two and three times the amount of 8100 process time as the current DSC facility for identical operations. In the example above, the DSC-E user would utilize between two and three percent of an 8140 B. The response time, however, should not change noticeably. The performance of the DSC-E facility when using the 'suspend/resume' function or invoking user programs to access screen data is dependent on the user functions and applications.

IBM TYPOGRAPHIC FONTS FOR THE 4250 PRINTER

- ITC Avant Garde Gothic ... 5771-AAA*
- Monotype Baskerville ... 5771-AAB**
- Monotype Bodoni ... 5771-AAC**
- Candida ... 5771-AAD***
- Monotype Century ... 5771-AAE**
- Monotype Century Schoolbook ... 5771-AAF**
- Excelsior ... 5771-AAG+
- Futura ... 5771-AAH++
- Monotype Garamond ... 5771-AAJ**
- Helvetica ... 5771-AAK+
- Optima ... 5771-AAL+
- Palatino ... 5771-AAN+
- Monotype Rockwell ... 5771-AAP**
- ITC Souvenir ... 5771-AAQ*
- Monotype Times New Roman ... 5771-AAR**
- Univers ... 5771-AAT+
- Typewriter and Pi ... 5771-AAW

APL Fonts

- The 132 APL characters in Light Italic at 10 and 12 characters-per-inch.

Pi Fonts

- Contains typographic, scientific and mathematical symbols with the upper and lower case Greek alphabet. There are 178 characters.
- Medium and Bold, Serif and Sans Serif typefaces in 4 sizes from 6 to 12 points ... a total of 16 fonts.

DESCRIPTION

Document processing and publishing applications require a large variety of typefaces in order to satisfy demands for aesthetics, variety of style, emphasis and readability. To provide these needs, IBM makes available a set of 17 program products containing 1,247 type fonts of graphic art quality in 22 distinct typeface families.

Intended for use with the 4250 Printer, the fonts consist of digitized alphabetic and other character forms in sizes ranging from 6 to 72 points (approximately 1/12" to 1") in height. Each character pattern is produced at a resolution of 600 x 600 dots (pels) per square inch, making it possible to reproduce faithfully the typeface designs. The results are letter forms of high graphic arts quality, style and variety. An international character set of 183 characters, satisfying the requirements of 11 languages, is provided in these 1,224 fonts.

In addition to proportionally spaced, typographic typefaces, 5 fonts in 3 mono-spaced, typewriter families are also offered. The character set combines the ICS with 34 additional characters for compatibility with system printer and SCRIPT/VS text character sets.

An extended character set is provided in Helvetica and Times New Roman for ease-of-migration to the 4250 Printer from system printers using TN, T11 or SCRIPT VS character sets.

Also included is the APL typeface family, which contains two fonts of 132 characters each. The other font families, called pi fonts, provide 16 fonts that contain a special set of the most commonly used mathematical, scientific and typographical symbols, together with the Greek alphabet.

Code page tables which associate each character name with its standard hexadecimal code point in each language, and a set of 'coded fonts', or table entries relating each code page with a font, completes each family package.

PURPOSE

Provides a wide selection of digitized, typographic quality fonts for use by the 4250 Printer. The typefaces included in each product are described below.

Family Name	Typefaces	
ITC Avant Garde Gothic	Roman & Italic - Medium, Bold	
	Monotype Baskerville	Roman & Italic - Medium, Bold
	Monotype Bodoni	Roman & Italic - Medium, Bold
	Candida	Roman - Medium, Bold, Semibold & Italic - Medium, Bold
Monotype Century	Roman & Italic - Medium, Bold	
	Monotype Century Schoolbook	Roman & Italic - Medium, Bold
	Excelsior	Roman - Medium, Bold & Italic - Medium
Futura	Roman & Italic - Medium, Bold, Semibold	
	Monotype Garamond	Roman & Italic - Medium, Bold
Helvetica	Roman & Italic - Light, Medium, Bold	
	Optima	Roman & Italic - Medium, Bold
Palatino	Roman & Italic - Medium, Bold	
	Monotype Rockwell	Roman & Italic - Medium, Bold
ITC Souvenir	Roman & Italic - Medium, Bold	
	Monotype Times New Roman	Roman & Italic - Medium, Bold
Univers	Roman & Italic - Light, Medium, Bold	
	Typewriter and Pi	Roman & Italic - and Bold Condensed
Prestige Elite	Roman - Medium, 12 pitch	
	Courier	Roman & Italic - Medium, 12 pitch &
		Roman - Medium, 10 pitch
Letter Gothic	Roman - Bold, 12 pitch	
	Light Italic	Italic - Light, 10 & 12 pitch
Pi Font Sans Serif	Roman - Medium, Bold	
	Pi Font Serif	Roman - Medium, Bold

Typeface names are registered trademarks of the following enterprises:

- * International Typeface Corporation.
- ** Monotype Corporation, Ltd.
- *** Ludwig and Mayer GmbH & Co.
- + Mergenthaler Linotype Co.
- ++ Fundicion Tipografica Neufville, S.A.

The typeface family names of these products are the trademarked property of the indicated licensors. Any document, including formal proposals, used to commercialize these products should indicate this fact.

HIGHLIGHTS

- **Print Quality**
 - Letter-forms of graphic arts quality digitized from the original artwork at 600 x 600 dots (pels) per square inch expressly for the 4250 Printer.
- **Proportionally Spaced Typographic Typeface Families**
 - 16 widely used families and their popular typefaces.
 - The 72 typefaces in these 16 families are each provided in 17 sizes from 6 to 72 points (approximately 1/12" to 1") ... a total of 1,224 fonts, each consisting of a multilingual, 183-character International Character Set (ICS).
 - An extended character set is provided for Helvetica and Times New Roman for ease-of-migration to the 4250 Printer from system printers using TN, T11 or SCRIPT/VS character sets.
 - Eleven Languages Supported - Danish, Dutch, English, Finnish, French, German, Italian, Norwegian, Portuguese, Spanish and Swedish.
- **Monospaced Typeface Families**
 - **Typewriter Fonts**
 - 5 fonts in 3 IBM typewriter families using an expanded set of 217 characters provide compatibility with standard IBM TN, T11 or SCRIPT/VS character sets, in addition to the ICS.

CUSTOMER RESPONSIBILITIES

The customer is responsible for:

- Adequate storage capacity
- Use of system utilities to load fonts to DASD devices.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

- An IBM 4250 Printer or functionally equivalent printer and its prerequisites.
- Processor storage as required by Composed Document Printing Facility licensed program (5668-997).
- Sufficient DASD storage for desired typeface families.
- Storage Requirements: DASD storage required for each product is shown below in megabytes.

Product	MB	Product	MB
5771-AAA	6.0	5771-AAB	6.2
5771-AAC	6.2	5771-AAD	8.0
5771-AAE	6.6	5771-AAF	7.0
5771-AAG	5.0	5771-AAH	8.2
5771-AAJ	6.2	5771-AAK	8.4
5771-AAL	5.5	5771-AAN	5.9
5771-AAP	6.5	5771-AAQ	7.0
5771-AAR	6.4	5771-AAT	12.0
5771-AAW	1.0		

SOFTWARE REQUIREMENTS

- The Composed Document Printing Facility licensed program (5668-997) and its prerequisites under MVS, VM and VSE.

DOCUMENTATION
(available from Mechanicsburg)

Composed Document Printing Facility General Information Manual (GC33-6133) ... Composed Document Printing Facility Installation and Operation (SC33-6135) ... IBM 4250 Printer, Type Font Catalog (G520-0004).

TERMINOLOGY

- **Point** - A typographer's measure approximately equal to 1/72 inch.

Typographic Fonts for the 4250 Printer (cont'd)

- **Baseline** - The line on which type appears to stand.
- **Size** - The distance specified, in points, between baselines when type is set solid, that is, with no additional interline spacing.
- **Font** - A set of characters in one size of one typeface. Example: Univers, Italic, bold, condensed, 12 points.
- **Typeface** - One variation of a character design style, independent of character size. Example: Univers, Italic, bold, condensed.
- **Typeface Family** - All typefaces of a single design style. Example: Univers.
- **Pitch** - Characters-per-inch.

**IBM PERSONAL COMPUTER MACRO ASSEMBLER
6024002****PURPOSE**

The Macro Assembler operates with the IBM Personal Computer Disk Operating System (DOS). Programs written in Assembler language are assembled into executable machine code that may run several times faster than equivalent high-level language routines. Additionally, the Assembler permits the programmer to design detailed program functions that are often impossible in a higher-level language. Assembler-produced programs, called "object" files, may be called from programs written from the following IBM Personal Computer languages: BASIC, Pascal, and FORTRAN.

HIGHLIGHTS

- Relocatable object modules
 - Definition of macros to generate commonly-used instruction sequences
 - Two versions: 96KB macro and 64KB subset
- Machine language of each instruction
 - Start and end addresses
 - Name, length, class of each segment
 - Public and local names and their attributes
 - Line numbers
 - Alphabetic cross-reference of variables
- Compatible with IBM Personal Computer BASIC, Pascal, and FORTRAN programs

The Assembler language program is created using a text editor such as the EDLIN utility program that is packaged with DOS, or a full-screen text editor such as the Personal Editor (6024051) which is a separate licensed program. The Macro Assembler is then used to assemble the program. Next, the DOS Linker translates the Assembler relocatable output into a load module, ready for loading and execution. While this process must take place on a 64KB or larger diskette system, the load module itself could be run on a diskette system with as little as 32KB memory. When a load module is designed for use as a subroutine of a higher-level language program (IBM Personal Computer BASIC, Pascal, or FORTRAN), the appropriate instructions must be included in the calling program.

Both versions of the Macro Assembler are co-resident on one diskette. A reference manual is packaged with the diskette.

CUSTOMER RESPONSIBILITIES

Customers are responsible for producing backup copies of the original diskettes when copying is permitted according to the terms and conditions of the IBM Program License Agreement and perform backup and recovery procedures for data diskettes.

BRANCH OFFICE RESPONSIBILITIES (None)**SPECIFIED OPERATING ENVIRONMENT****HARDWARE REQUIREMENTS**

An IBM 5160 Personal Computer XT or an IBM 5150 Personal Computer with at least 96KB of memory and one diskette drive. One of the following display options required for text entry:

- IBM 5151 Monochrome Display and the IBM Monochrome Display and Printer Adapter
- IBM Color Display and the Color/Graphics Monitor Adapter
- A 40- or 80-column black/white or 40- or 80-column color monitor with the IBM Color/Graphics Monitor Adapter

A minimum 96KB, one diskette drive system is required to produce an assembler language object module using the full Macro Assembler version. A subset version is provided to assemble programs on a 64KB system. This version does not support macros, repeat functions (REPT, IRP, IRPC), record pseudo-ops, or structure pseudo-ops.

SOFTWARE REQUIREMENTS

Both Assembler versions must be executed under control of the IBM Personal Computer Disk Operating System (DOS) Version 1 or subsequent versions or releases. When used with the IBM Personal Computer Disk Operating System Version 2.0, the Macro Assembler may reside on a fixed disk drive, and it may access fixed disk files. The DOS Linker program (on the DOS Diskette) is also required for the linkage editor process. A text editing program (EDLIN) for entry of the Assembler source program is resident on the DOS Diskette. If full-screen text editing is required, the Personal Editor is available as a separate product.

PACKAGING

IBM Personal Computer Macro Assembler Reference Manual - The correct procedures for writing, assembling, linking and running an Assembler program are described in the *Macro Assembler Reference Manual*. A complete instruction set reference is included. Details about the Linker program and EDLIN are included in the *IBM Personal Computer Disk Operating System Manual*.

**IBM PERSONAL COMPUTER BASIC COMPILER
6024003****PURPOSE**

With BASIC Compiler, programs written in IBM Personal Computer BASIC (Interpreter) may be converted to object code for improved run-time performance. Most functions supported by the Disk and Advanced versions of the BASIC Interpreter are also supported by the BASIC Compiler.

HIGHLIGHTS

Programs may be written and tested using the BASIC Interpreter and the BASIC program editor. Performance gains of several times over interpreter timings are possible (results vary by program). Object modules may be linked with subroutines written with the IBM Personal Computer Macro Assembler. Compiled programs may not be listed or modified, as source or BASIC Interpreter files can, thus providing some application security. Some double-precision arithmetic is supported by the compiler (trig functions, FOR-NEXT loop variables). The compiler checks every program statement for syntax errors during compilation. (BASIC Interpreter checks syntax of statements during program execution. It may miss errors in untested statements.) Demo program provided for training purposes. Compiler "metacommands" (directives) are available to control output formats and run-time options.

DESCRIPTION

The BASIC Compiler permits a programmer to convert an existing program written in IBM Personal Computer BASIC (Interpreter) to object code for a significant improvement in run-time performance. A high degree of compatibility between the interpreter and compiler has been maintained to minimize program modifications.

Each BASIC program to be compiled must be created as a source (ASCII) file using the BASIC program editor or an editor such as the EDLIN utility program on the DOS diskette. The compiler is then used to compile the program, producing a machine language file. Finally, a Linker program resident on the BASIC Compiler diskette is used to convert the machine language file into one that is ready for loading and execution (load module). The compiled load module contains some language functions that the interpreter has in the system unit's read-only-memory (ROM). For this reason, the compiled program may be larger in memory than the interpreter version plus the BASIC or BASICA (resident) Interpreter extensions.

CUSTOMER RESPONSIBILITIES

The customer is responsible for producing backup copies of the original compiler diskettes.

Application programs using compiled code may require licensed run-time libraries. Information concerning distribution *must* be obtained from IBM.

Usage of the run-time module is an option taken at compile time. Programs compiled without this option can be distributed with no additional considerations, but may require significantly more diskette space.

Since there are some minor differences between the language functions supported by the BASIC Interpreter and Compiler versions, the customer should be prepared to make changes to an existing interpreter program prior to compilation. These differences are summarized in the Compatibility section below.

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

A minimum 64KB, one-diskette drive system is required to compile a BASIC program, although the program itself may be executable on a smaller system (two drives are recommended for easier operation).

While the IBM Monochrome Display with the IBM Monochrome Display and Printer Adapter as well as the IBM Color Display with the Color/Graphics Monitor Adapter (40- or 80-column formats) are supported, 80-columns are recommended for displaying compiler messages and listings.

SOFTWARE REQUIREMENTS

The IBM Personal Computer DOS Diskette provides the necessary I/O routines and Linker. When used with DOS Version 2.0, the BASIC Compiler may reside on a fixed disk drive, and it may access fixed disk files.

COMPATIBILITY

	BASIC Compiler Differences
BASIC Interpreter Command, Function, or Statement	
LOAD, SAVE, AUTO, EDIT, LIST, ILIST, DELETE, MERGE, NEW, RENUM, CONT	Not supported on compiler. These commands are normally associated with program editing in the interpreter environment.
CHAIN, COMMON	Compiler function is a subset of interpreter. MERGE, DELETE and ALL options operate on lines in an interpretive program only. COMMON must appear in each program; variables must be listed in the same order in each program.
Commands referencing "CAS1:" (LIST, RUN, LOAD, SAVE, etc.) and MOTOR DEF FN, DEFINIT/SNG/DBL/STR, and DIM	Cassette operations are not supported. In a compiler program these statements must appear before functions or variables are referenced.
Dynamic array dimensioning and ERASE statement	Not supported.
Integer overflow error handling	Subset of interpreter function. /D compiler option available to provide additional support.
"Soft Key" support (default character strings assigned to function keys F1-F10)	Defaults are not supported. Programs may assign values using KEY statement.
String handling	Character-string length in interpretive BASIC is 256 characters; in compiled BASIC it may be up to 32,767 characters. The string descriptor (referred to by VARPTR and some assembler language subroutines) is three bytes long in the interpreter; four bytes in the compiler.
DRAW, PLAY	"X String" and "=variable" require use of VARPTR.
OPEN COM	LEN = number option must be added to support GET or PUT

DOCUMENTATION

IBM Personal Computer BASIC Compiler Manual.

The *BASIC Compiler Manual* should be used with the *BASIC Reference Manual* (6025013) and the *Disk Operating System Manual* (6172220). The *BASIC Reference Manual* contains additional cross-reference information to the compiler product, and will be shipped with new system units.

PACKAGING

The BASIC Compiler is resident on two diskettes. It is packaged with the *IBM Personal Computer BASIC Compiler Manual*.

VISICALC*
6024004**PURPOSE**

VisiCalc is an electronic spreadsheet application.

HIGHLIGHTS

- A "worksheet" of 254 rows and 63 columns
- Automatic recalculation of entire worksheet with new or changed data
- Automatic recalculation which takes care of the order of recalculation
- Step-by-step instructions with examples for all major features
- Quick Reference Summary card for easy reference
- Overlay of multiple worksheets to a single worksheet
- Variable column width
- Ability to view two parts of worksheet simultaneously
- Horizontal and Vertical dual-window synchronization
- Extensive functions and operators
- Fixed Title option for scrolling
- Replicate function for repetitive entries
- Transcendental functions
- Scientific notation available
- Communicates with other programs through the DIF** format

DESCRIPTION

VisiCalc is a program that creates worksheets in which a user can create dynamic tables of information. Each worksheet is composed of 254 rows and 63 columns which allow for 16,002 (254 X 63) unique locations or "cells". VisiCalc allows the user to perform processing in these tables by using algebraic formulas in cell locations in which the variables are other cell locations. When the value in one cell location changes, the entire worksheet including cell formulas is automatically recalculated. The display screen is called the window to the worksheet in which the resultant values (the result of calculating the formulas) are displayed. The formulas can be changed in place (edited), or moved or duplicated (by single cell or block of cells) to another location on the worksheet and saved on disk or diskette for later editing/processing. Two or more worksheets can be "overlaid", allowing for combination of data. Blocks of the worksheet can be saved in DIF** format which can then be read by applications supporting the DIF** format such as VisiPlot***, and Multiplan by Microsoft. DIF format does not include cell formulas, only the resultant values. This application is known also as an "electronic spreadsheet".

VisiCalc for the IBM Personal Computer is a unique tool which allows the businessman, the accountant, the analyst, and the planner an efficient way to solve their problems with no knowledge of a traditional programming language. VisiCalc combines the convenience and familiarity of a pocket calculator with the powerful memory and electronic screen capabilities of the IBM Personal Computer. Taking advantage of the tutorial nature of the documentation, new users will be able to build a spread sheet of numeric values easily, which they can then modify, causing the complete spread sheet to be recalculated using the new value or values entered.

Users can add labels, headings, and lines to their data to allow the printing of reports displaying the different "what if" situations which can be computed with the simple change of one or more of the data elements.

The VisiCalc program provides the facility to arrange data into a grid of up to 63 columns and 254 rows. Any element in this grid can be a numeric value, a label, or a formula. These formulas allow elements of the grid to relate to other elements, and have a wide range of flexibility. The formulas can also use the standard functions provided by VisiCalc. Some of these are: Summation, net present value, integer, and trigonometric functions.

CUSTOMER RESPONSIBILITIES

The customer must perform an initial setup procedure to format blank diskette(s) and copy portions of DOS onto the diskette(s). A specification file must be created for unique requirements; or, one of the sample files can be used. A DOS batch file can be prepared to automatically "boot" the emulation program at power-on time.

BRANCH OFFICE RESPONSIBILITIES (None)

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

An IBM 5150 Personal Computer with at least 64KB of memory, and one diskette drive or an IBM 5160 Personal Computer XT is required. In addition, one of the following 80-column display options is required:

- IBM 5151 Monochrome Display and the IBM Monochrome Display and Printer Adapter (1504900)
- IBM Color Display and the IBM Color/Graphics Monitor Adapter
- An 80-column black/white or 80-column color monitor with the IBM Color/Graphics Monitor Adapter

SOFTWARE REQUIREMENTS

IBM Personal Computer Disk Operating System (DOS) Version 1.1 or 2.0

The VisiCalc* program resides on diskette only. VisiCalc* data files may reside on diskette or fixed disk.

PACKAGING

VisiCalc is distributed with the following:

User's Reference Manual ... Quick Reference Summary Card ... one program diskette ... one backup program diskette

* Trademark of Personal Software, Inc.

** Trademark of Software Arts, Inc.

*** Trademark of VisiCorp.

EASYWRITER VERSION 1.1 6024005

PURPOSE

EasyWriter is a versatile and easy-to-use word processor featuring a menu-driven interface that allows users with varied skills to be productive quickly.

HIGHLIGHTS

- Full-screen editing
- Variable margin size
- Variable line spacing
- Insert and delete characters, words and lines
- Undelete (bring back) deleted characters and words
- Help menus on screen
- Automatic page numbering
- Search and replace
- Margin justification
- Tab set
- Titles and headings
- Block moves and copies
- Line centering
- Word count
- Linking and appending files
- VisiCalc* print files may be converted and merged into EasyWriter documents with the transfer program.

DESCRIPTION

EasyWriter allows users to write letters, reports, articles, even books. The text can be edited on the screen before it's printed, allowing the user to make changes, prepare personalized form letters, and much more.

Once EasyWriter is loaded into the computer's memory, EasyWriter displays the first of three system menus -- the File System menu. From this menu the user can save, revise, delete, link, protect, edit, append and format a file. The user can print a file from any menu. The Help menu describes options available to the user while text is being worked on. The Additional Commands menu allows the user to perform special functions such as setting margins and tabs as well as displaying the document in a print format.

All 12 fonts of the IBM 5152 model 2 Graphics Printer are available to the user. In addition, print files can be transmitted over the Asynchronous Communications Adapter to a serial printer.

The simple text entry and the full-function, full-screen text editor facilitate: Adding, inserting, deleting, and correcting of existing files; horizontal and vertical scrolling through text; and global selective search and replace. This is combined with the flexibility of formatting the output to the printer.

CUSTOMER RESPONSIBILITIES

Customers are responsible for producing backup copies of the original diskettes, when copying is permitted, according to the terms and conditions of the IBM Program License Agreement. Customers must install DOS on the EasyWriter program diskette according to instructions in the *EasyWriter Reference Manual*.

BRANCH OFFICE RESPONSIBILITIES (None)

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

An IBM 5150 Personal Computer with at least 64KB of memory and one diskette drive or an IBM 5160 Personal Computer XT is required. In addition, one of the following 80-column display options is required:

- IBM 5151 Monochrome Display and the IBM Monochrome Display and Printer Adapter
- IBM Color Display and the Color/Graphics Monitor Adapter
- An 80-column black/white or 80-column color monitor with the IBM Color/Graphics Monitor Adapter

The available work area in a Personal Computer with 64KB is 13.9KB. To avoid an out of space condition when running on a 64KB system, the user may split a large file into two smaller files. These may be linked together and treated as a single document. In a 96KB or larger system, EasyWriter supports a larger document size, up to a maximum of 24KB characters.

SOFTWARE REQUIREMENTS

IBM Personal Computer Disk Operating System Version 1 or subsequent versions and releases. The EasyWriter program resides on diskette only. EasyWriter data files may reside on diskette or fixed disk. Any DOS formatted diskette may be used for EasyWriter files.

PACKAGING

Reference Manual ... Quick Reference Summary card ... one program diskette

* VisiCalc is a trademark of Personal Software, Inc.

**IBM PERSONAL COMPUTER PASCAL COMPILER
6024010****PURPOSE**

The IBM PC Pascal Compiler operates with the IBM Personal Computer Disk Operating System (DOS). It provides the capability to compile Pascal programs conforming to ISO Working Draft #6 (with the exception of conformant arrays).

HIGHLIGHTS

- Generally conforms to ISO Draft (ISO/TC 97/SC 5 N595)
- Separate compilation of large program segments
- Object modules may be combined with subroutines written in IBM PC FORTRAN or Macro Assembler
- Variable length strings
- Super-array type supported
- Machine-oriented constructs
- Compiler Directives and Metacommands
- Flags for Jumps, Globals, Identifier level, Control level header, trailer, general listing format textual error and warning messages
- Extended CASE range
- Bitwise logical Boolean operators
- Extended Intrinsic
- Extended I/O

DESCRIPTION

The Pascal Compiler is available as an optional software product. The IBM Personal Computer Pascal version supports all of the facilities of the International Standards Organization (ISO) Working Draft #6, with the exception of conformant array parameters, which are instead provided by the "super array" type. Many additional features are also supported.

The Pascal program must be created as a source (text) file using a text editor such as the EDLIN utility program that is packaged with DOS on the DOS Diskette, or the Personal Editor, which is a separate IBM product. The Pascal Compiler is then used to compile the program, producing a machine language (object) file in relocatable format. Finally, the Linker program, packaged with DOS on the DOS Diskette, is used to convert the relocatable program into one that is ready for loading and execution at a specific memory address.

CUSTOMER RESPONSIBILITIES

The customer is responsible for producing backup copies of the original compiler diskettes. Since the reference manual does not provide a tutorial on the language, the customer should have some prior knowledge of Pascal.

BRANCH OFFICE RESPONSIBILITIES (None)**SPECIFIED OPERATING ENVIRONMENT****HARDWARE REQUIREMENTS**

An IBM 5150 Personal Computer with at least 128KB of memory, and two diskette drives ... one of the following display options required for text entry:

- IBM 5151 Monochrome Display and the IBM Monochrome Display and Printer Adapter
- IBM Color Display and the Color/Graphics Monitor Adapter
- A 40- or 80-column black/white or 40- or 80-column color monitor with the IBM Color/Graphics Monitor Adapter

The IBM 5152 model 2 Graphics Printer is recommended

SOFTWARE REQUIREMENTS

- IBM Personal Computer Disk Operating System (DOS) Version 1 or subsequent versions or releases
- If a compiled program performs diskette I/O, the IBM Personal Computer DOS must be diskette and memory resident.

PACKAGING

A *Pascal Compiler Reference Manual*. Since the Disk Operating System (DOS) is used during the program entry, compilation, linking, and execution phases, the *DOS Reference Manual* is required.

The Pascal Compiler comes on three diskettes.

**IBM PERSONAL COMPUTER COBOL COMPILER
6024011****PURPOSE**

With the COBOL compiler, programs may be written in ANSI standard COBOL. These programs are then compiled to an interpretive object code for execution on the IBM Personal Computer.

The COBOL compiler for the Personal Computer is designed according to the specifications for American National Standard (ANS) Programming Language COBOL (X3.23-1974) as understood and interpreted by IBM as of February 1982. American National Standard COBOL is compatible with, and identical to, ISO 1989-1978 standard of the International Organization for Standardization.

HIGHLIGHTS

The following functional modules are supported:

- 1 NUC1, 2 (Nucleus)
- 1 TBL 1, 2 (Table-handling)
- 1 SEQ1, 2 (Sequential I-O) except RERUN
- 1 REL 0, 2 (Relative I-O) except RERUN
- 1 INX 0, 2 (Segmentation)
- 1 LIB 0, 2 (Library)
- 1 IPC 0, 2 (Inter-program Communication)

Additional Features

- From ANS Level 2 Nucleus:
 - Level 88 conditions
 - AND, OR, NOT conditions
 - Nested IF statements
 - STRING and UNSTRING
 - PERFORM VARYING...UNTIL
- From ANS Level 2 Table-Handling:
 - SEARCH ALL statement
- From ANS Level 1 Debug (DEB 0,2)
 - SOURCE-COMPUTER paragraph WITH DEBUGGING MODE clause

Other IBM Personal Computer COBOL Features

- Object modules may be linked with modules produced by the IBM Personal Computer Macro Assembler
- ACCEPT and DISPLAY extensions for formatted screen handling
- CHAIN to other programs

DESCRIPTION

The COBOL compiler for the Personal Computer is designed according to the specifications for American National Standard (ANS) Programming Language COBOL (X3.23-1974) as understood and interpreted by IBM as of February 1982. American National Standard COBOL is compatible with, and identical to, ISO 1989-1978 standard of the International Organization for Standardization.

Each COBOL program must be created as a source (text) file using a text editor such as the EDLIN utility program that is packaged with the IBM Personal Computer DOS on the DOS Diskette, or the Personal Editor, which has full-screen function. The COBOL Compiler is then used to compile the program, producing an object file in relocatable format. Finally, the Linker program is used to convert the relocatable file into one ready for loading and execution using the COBOL run-time library.

CUSTOMER RESPONSIBILITIES

The customer is responsible for producing backup copies of the original compiler diskettes. Since the reference manual does not provide a tutorial on the language, the user should have some prior knowledge of COBOL. Programs may be written on standard COBOL coding forms.

The COBOL run-time library contains proprietary code. A distribution agreement between the customer and IBM is required before application programs can be distributed to others. For additional information, see the *COBOL Reference Manual*, or write to IBM, PO Box 1328-P, Boca Raton, Florida 33432.

BRANCH OFFICE RESPONSIBILITIES (None)**SPECIFIED OPERATING ENVIRONMENT****HARDWARE REQUIREMENTS**

An IBM 5150 Personal Computer with a minimum of 64KB memory and two diskette drives or an IBM 5160 Personal Computer XT is required to compile a COBOL program, although the program itself may be executable on a smaller system. An 80-column display is recommended for displaying compiler messages and listings. One of the following display options is required:

- An IBM 5151 Monochrome Display and the IBM Monochrome Display and Printer Adapter
- An IBM Color Display and the Color/Graphics Monitor Adapter
- A 40- or 80-column black/white or 40- or 80-column Color monitor with the IBM Color/Graphics Monitor Adapter

The IBM 5152 model 2 Graphics Printer is recommended.

SOFTWARE REQUIREMENTS

The IBM Personal Computer Disk Operating System (DOS) Version 1 or subsequent versions or releases is required. When the IBM Personal Computer Disk Operating System Version 2.0 is used, the COBOL compiler may be resident on a fixed disk drive and it may access fixed disk files.

PACKAGING

IBM Personal Computer COBOL Reference Manual. Since the IBM Personal Computer Disk Operating System (DOS) is used during the program compilation, linking, and execution phases, the *DOS Reference Manual* is required. If the Personal Editor is used to enter the programs, the *Personal Editor Reference Manual* is required. The COBOL Compiler is resident on two diskettes packaged with the *IBM Personal Computer COBOL Reference Manual*.

6024017

PURPOSE

The UCSD p-System consists of an operating system and either one or two languages for the IBM Personal Computer. The p-System provides the programmer with an extended Version IV.0 of the operating system, including a full-screen editor, program debugger, graphics support, an assembler, file handler, native code generator, and a print spooler. The system is available with either UCSD Pascal, FORTRAN-77, or both languages.

p-System with FORTRAN-77 - FORTRAN-77 Compiler

* UCSD p-System and UCSD Pascal are trademarks of the Regents of the University of California.

HIGHLIGHTS

- The p-System provides an excellent environment for program development.
- The language compilers generate "p-code", a portable, machine-independent format.
- A Native Code Generator may be used to convert p-code to efficient code for better performance.
- Machine-level reference and tutorial documentation is provided. FORTRAN-77 is ANSI-1977 level, supporting a wide range of engineering and scientific applications.
- It provides extensions to UCSD Pascal for development and commercial programming.
- Structured programming produces programs that are more efficient and easier to maintain.

DESCRIPTION

The UCSD p-System, with either UCSD Pascal or FORTRAN-77, is designed to run on an IBM Personal Computer with a minimum of 64KB and two diskette drives. A program is entered via the p-System's editor, then compiled to p-code and stored on diskette. The p-code version can then be executed as needed. The p-System filer maintains a library of user-written programs on diskette. For convenience, run-time or execution routines may be moved to an application program diskette.

CUSTOMER RESPONSIBILITIES

The customer is responsible for producing backup copies of the original diskette or for copying UCSD p-System files onto application program diskettes. Such copying is provided for convenience, but UCSD p-System resident diskettes may not be distributed to other users.

BRANCH OFFICE RESPONSIBILITIES (None)**SPECIFIED OPERATING ENVIRONMENT****HARDWARE REQUIREMENTS**

A minimum 64KB, two diskette drive system is required to run the UCSD p-System, although some application programs may execute in less memory.

Both 40- and 80-column display output is supported although 80-column displays (IBM Monochrome or Color Display) are recommended.

SOFTWARE REQUIREMENTS

Run-time routines may be packaged with application programs to provide the necessary execution prerequisites, although licensing of such routines is **required** for redistribution to others.

DATA SECURITY

The customer is responsible for the protection of data from unintended modification, destruction, or disclosure, and for the accuracy and integrity of the results.

DOCUMENTATION

Publications are packaged with diskettes for the products described above. They are:

Development (p-System)

Beginner's Guide for the UCSD p-System ... User's Guide for the UCSD p-System ... Internal Architecture Guide for the UCSD p-System ... Assembler Reference Manual for the UCSD p-System

FORTRAN-77 Compiler

FORTRAN-77 Reference Manual for the UCSD p-System

UCSD Pascal Compiler

UCSD Pascal Reference for the UCSD p-System

PACKAGING

The three major p-System components are the development (operating) system, FORTRAN-77 compiler, and UCSD Pascal compiler. They are packaged as four products on diskettes with related publications. They are available as the development system with a language. The second language is available with the development system or at a later time.

p-System with UCSD Pascal - UCSD Pascal Compiler

**MULTIPLAN by MICROSOFT
6024022****PURPOSE**

The IBM Personal Computer Multiplan is an advanced electronic spreadsheet for financial modeling and reporting.

HIGHLIGHTS

- Provides a "worksheet" of 255 rows X 63 columns
- Tutorial models on diskette
- Online help text
- Linking of active model to models on secondary (disk) storage
- Full support of IBM Personal Computer keyboard
- Full support of color capabilities
- Variable column width
- Natural language commands and variable (cell) names up to 8 display windows
- Extensive functions and operators
- Automatic recalculation which takes care of the order of recalculation
- Sorting of alphabetic or numeric data
- Cell protection
- Continuous formatting (allows entries across cell boundaries)
- Full-line (cell) editing
- Iterative solutions to simultaneous equations in more than one variable

User's Reference Manual ... Reference Card ... one program diskette ... one tutorial diskette.

- * Trademark of Software Arts, Inc.
- ** Trademark of Personal Software, Inc.

DESCRIPTION

The IBM Personal Computer Multiplan is a spread-sheet simulator which is applicable to many different kinds of numeric modeling and planning. It provides a framework for holding the relationships between constant and varying elements of a numeric model. This gives the user the opportunity to do projections, what-ifs, sensitivity analysis, budget and resource planning, scheduling, and a host of other applications that involve extensive manipulation of numbers and formulas.

The electronic worksheet is represented by a grid of cells. The user fills out the worksheet by entering words, numbers, or formulas into the cells. In this respect, the "electronic worksheet" is like a ledger with headings, values, and algebraic formulas filled via the keyboard, and the display screen provides a window to view the worksheet. Two or more completely different parts of the worksheet can be viewed through windows, or entire areas of the worksheet can be given a name which can be used in formulas and commands to refer to all the cells in the area. Cells may be "designed" (formatted) to further reflect the type of data they contain. For applications which require a "third dimension" (depth), Multiplan allows creation of more than one sheet. The active sheet may then refer to named-cells on different, inactive sheets.

After backing up the diskettes and transferring DOS to the program diskette, Multiplan is loaded by inserting the program diskette and turning on the computer. The user may obtain help at any time during the session by pressing "H" for help from the main menu or "?" from any sub-menu.

CUSTOMER RESPONSIBILITIES

Customers are responsible for producing backup copies of the original diskettes when copying is permitted according to the terms and conditions of the IBM Program License Agreement and perform backup and recovery procedures for data diskettes.

BRANCH OFFICE RESPONSIBILITIES (None)**SPECIFIED OPERATING ENVIRONMENT****HARDWARE REQUIREMENTS**

An IBM 5150 Personal Computer with at least 64KB of memory and one diskette drive, or an IBM 5160 Personal Computer XT is required. In addition, one of the following display options is required:

- IBM 5151 Monochrome Display and the IBM Monochrome Display and Printer Adapter
- IBM Color Display and the Color/Graphics Monitor Adapter
- A 40- or 80-column black/white or 40- or 80-column color monitor with the IBM Color/Graphics Monitor Adapter

The IBM 5152 model 2 Graphics Printer is required in order to print a worksheet.

SOFTWARE REQUIREMENTS

IBM Personal Computer Disk Operating System (DOS) Version 1 or subsequent versions or releases. When used with the IBM Personal Computer Disk Operating System Version 2.0, Multiplan may be resident on a fixed disk drive and it will support files on the fixed disk.

COMPATIBILITY

Multiplan can read DIF* files from diskette put there by Multiplan or any of the VisiCalc** series packages that support DIF* format. Note that DIF* format does not pass formulas - only constants and labels.

PACKAGING

Multiplan is distributed with the following:

PROGRAM PRODUCTS

**ASYNCHRONOUS COMMUNICATIONS SUPPORT
VERSION 2
6024032**

PURPOSE

This support allows users, with no additional programming, to use their IBM Personal Computers as asynchronous (start/stop) TTY ASR 33/35 terminals.

HIGHLIGHTS

- The user may interactively specify:
 - Bit rate (75 bps to 9600 bps)
 - Parity
 - Number of stop bits
 - Line turnaround characters
 - Local or host ECHO/no ECHO
 - XON/XOFF support
- Specifications for interaction with a particular host may be stored for later use, eliminating the need to respecify at each initiation.
- Programs and data may be sent from an IBM Personal Computer to a host system, or received from a host system and placed in an IBM Personal Computer file.
- Menu-selectable options:
 - Dow Jones News Service*
 - The Source**
- Files can be transferred between an IBM Personal Computer and most host systems.
- Binary files can be converted to ASCII format (or vice versa) using the utility program supplied.
- Either of two Asynchronous Communications Adapter ports can be used if two asynchronous cards are installed.
- While receiving from the host, there is an option to print data or store it on a file.

DESCRIPTION

Asynchronous Communications Support Version 2 provides improved ease-of-use, file transfer capability, and additional functions. Version 1 is no longer available.

In addition to supporting the system as an interactive terminal, the package allows the IBM Personal Computer to exchange program and data files with the host system with which it is communicating. The user has flexibility in specifying TTY ASR 33/35 terminal protocol, for attachment to a variety of host computers. It also provides for communication between two IBM Personal Computers for transferring program and data files.

Asynchronous Communication Support is designed to allow connection to most host systems which support TTY ASR 33/35 asynchronous terminals. Common settings such as parity, stop bits, and bps rates are specified interactively at program initiation.

CUSTOMER RESPONSIBILITIES

Customers are responsible for producing backup copies of the original diskette, when copying is permitted, according to the terms and conditions of the IBM Program License Agreement, acquiring the necessary communications modems, cables, subscriptions, and passwords.

BRANCH OFFICE RESPONSIBILITIES (None)

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

- An IBM 5160 Personal Computer XT or an IBM 5150 Personal Computer with at least 64KB of memory, one diskette drive, and an Asynchronous Communications adapter.
- One of the following display options is required:
 - IBM 5151 Monochrome Display and the IBM Monochrome Display and Printer Adapter
 - IBM Color Display and the Color/Graphics Monitor Adapter
 - A 40- or 80-column black/white or 40- or 80-column color monitor with the IBM Color/Graphics Monitor Adapter
- A customer-supplied full-duplex modem or direct cable connection to a local host computer
- A customer-provided EIA RS232-C cable for adapter to modem connection

SOFTWARE REQUIREMENTS

- IBM Personal Computer Disk Operating System (DOS) Version 1 or subsequent versions and releases IBM Disk BASIC.
- When used with the IBM Personal Computer Disk Operating System Version 2.0, the Asynchronous Communications Support

program may reside on a fixed disk drive and it can support fixed disk files.

PACKAGING

The Asynchronous Communications Support Program is resident on one diskette and comes with the following documentation:

Asynchronous Communications Support Program

* Dow Jones is a trademark of Dow Jones and Company, Incorporated.

** The Source is a service mark of Source Telecomputing Corporation, a subsidiary of The Reader's Digest Association, Inc.

**CP/M-86* OPERATING SYSTEM
6024035**

PURPOSE

CP/M-86 is a single-user operating system for the IBM Personal Computer. It manages information stored on diskettes and also provides an interface between a program and the IBM Personal Computer hardware.

HIGHLIGHTS

- Management of data files
- Cataloging
- Creating text and object files
- Copying files to diskette and other media
- Renaming and erasing files
- Verification of directory
- Write and run programs written in Assembler language.

Programming Interface

- Function calls for device handling and memory management
- Escape sequences for cursor and color control
- Light-pen input

Programming Utilities

- Line-oriented text editor
- Assembler
- Command-file generator
- Debugging program

Device Handling

- XON/XOFF and ETX/ACK protocols for Asynchronous Communications Adapter
- Selectable bps rate, parity, stop bits, and number of data bits
- Logical and physical devices
- Automatic Processing of Command Sequences
- Time-of-day and date
- Programmable function keys by using a utility or user program
- On-screen HELP function
- Status line displays user number, date, and time-of-day

Utilities and Commands

- ASM86 - Assembles INTEL 8088 source code into machine code
- ASSIGN - Assigns physical devices (e.g., printer) to logical devices (e.g., console-output)
- COPYDISK - Copies contents of an entire diskette to another diskette
- DDT86 - Allows monitoring and testing the execution of programs
- DIR - Displays the names of files cataloged in online directory
- DIRS - Displays the names of files cataloged with current user number and the SYS attribute
- ED - Allows editing of text files
- ERA - Removes files from the directory
- FUNCTION - Allows assignment of text and control characters to function and keypad keys
- GENCMD - Produces command (CMD) files
- HELP - Summarizes information for CP/M-86 commands
- NEWDISK - Formats diskettes and optionally transfers a copy of the operating system
- PIP - Allows copying, editing, combining, transmitting, and renaming diskette files
- PROTOCOL - Sets XON, ETX, NONE protocols
- REN - Changes the name of a file
- SPEED - Specifies bps rate, parity, stop bits, number of data bits, for Asynchronous Communications Adapter
- STAT - Gives statistical information about diskette files
- SUBMIT - Processes a file of commands
- TOD - Sets time of day and date
- TYPE - Displays text files on screen
- USER - Sets user number

DESCRIPTION

CP/M-86 is a single-user operating system for the IBM Personal Computer. It manages information stored on diskettes and also provides an interface between a program and the IBM Personal Computer hardware. Up to two physical drives or four logical drives are supported by utility programs that perform the following tasks: Formatting diskettes, copying files to other devices, and providing data about diskette files. Also supported by CP/M-86 are the IBM 5152 Model 2 Graphics Printer, the Asynchronous Communications Adapter, the IBM Monochrome Display, and the Color/Graphics Monitor Adapter (including customer-supplied light-pen) and the IBM Color Display. Dynamic memory management controls the allocation of memory and assigns specific memory areas to application programs. Program development utilities include an editor, an assembler, a debugging program, and a program to produce command files.

CP/M-86 may reside on its original (packaged) diskette, a copy, or as part of a diskette containing other programs. If any of these are present in Drive A when the computer is turned on, or whenever System Reset is performed, CP/M-86 will be loaded into memory. The operating system, or control program, is now ready to accept user commands to

run one of the CP/M-86 utility programs, execute a built-in command, or start a user program. Unless system I/O devices require reassignment (e.g., using the Asynchronous Communications Adapter for printer output), no configuration steps are necessary.

CUSTOMER RESPONSIBILITIES

The customer is responsible for producing backup copies of the original diskette. While CP/M-86 files may be copied to an application program diskette for convenience, such a diskette may not be distributed to other users.

BRANCH OFFICE RESPONSIBILITIES (None)

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

CP/M-86 requires at least one diskette drive and 32KB of memory. The DDT86 debugging program requires 48KB, while the ASM86 Assembler requires 64KB of memory. The operating system resides in 19KB of memory

One of the following display options is required:

- IBM 5151 Monochrome Display and the IBM Monochrome Display and Printer Adapter
- IBM Color Display and the Color/Graphics Monitor Adapter
- A 40- or 80-column black/white or 40- or 80-column color monitor with the IBM Color/Graphics Monitor Adapter

SOFTWARE REQUIREMENTS

CP/M-86 does not require as a prerequisite, nor is it compatible with, either the IBM Personal Computer DOS or the UCSD p-System**.

COMPATIBILITY

Application programs supported by other versions of CP/M-86 (e.g., CP/M-80) will run on the IBM Personal Computer after undergoing a migration process. This process includes transferring the original program source code from the other computer (usually via a communications link), modifying any program statements affected by language or hardware differences, and recompiling the program using an appropriate language compiler. Although CP/M-86 provides an 8088 Assembler, IBM does not offer CP/M-86 language compilers.

CONVERSION

CP/M-86 files on non-IBM computers must be "communicated" between machines to account for differences in diskette formats.

DATA SECURITY

The customer is responsible for the protection of data from unintended modification, destruction, or disclosure, and for the accuracy and integrity of the results.

PACKAGING

The CP/M-86 manual explains the use of the utilities and commands by giving examples and sample sessions.

CP/M-86 is resident on a single diskette, packaged with a *CP/M-86 Operating System Manual*.

* Trademark of Digital Research, Inc.

** Trademark of the Regents of the University of California.

**SNA 3270 EMULATION and SNA RJE SUPPORT
6024036****PURPOSE**

The SNA 3270 Emulation and SNA RJE Support Program provides significant connectivity enhancements for the IBM Personal Computer. These extensions provide additional flexibility for interactive and office system use of the IBM Personal Computer as an intelligent work station. Operating in SNA 3270 emulation mode, the Personal Computer appears to the host system as an IBM 3274 Model 51C.

HIGHLIGHTS

- Communications Interface
 - Supports IBM SDLC Communications Adapter
 - Both switched and leased line (including multipoint) support
 - Modem support
- EIA RS232-C Interface
 - Half duplex
 - External clocking
 - Up to 4800 bps
 - Constant request to send and line turn-around
- Online diagnostics with line trace, error logging, and analysis
- SNA 3270 emulation
 - The IBM Personal Computer appears to the host system as an IBM 3274 model 51C Control Unit.
 - The IBM Personal Computer uses the same screen formats as supported by the IBM 3278 Display Station, except for the status line. The following features are provided:
 - Logical Unit Type 2 (LU2)
 - 24 - 3270 program function keys
 - Local print key
 - Audible alarm
 - EBCDIC line transmission support
 - Keyboard numeric lock
 - 3279 base color mode support
 - 3279 Color Emulation
 - Status line messages
 - User-definable 3270 keys
- 3287 Models 1 and 2 printer emulation:
 - For local copy
 - Host-initiated screen print

The IBM Personal Computer will connect to host subsystems that support the above devices and features/options. A configuration utility to tailor the communications environment is supplied.

- SNA 3770 RJE support
 - The IBM Personal Computer appears to the host system as an IBM 3770 communications terminal with the following features:
 - Logical Unit type 1 (LU1)
 - FM Header Type 1
 - TS Profile 3 and FM Profile 3
 - Outbound from host compression
 - ASCII or EBCDIC line transmission support
 - Transparency
 - Device support for console, card/punch, and printer
 - The IBM Personal Computer will connect to host subsystems that support the above devices and features/options. A configuration utility to tailor the communications environment is supplied.
 - Transmit and receive source and object data in IBM Personal Computer DOS-compatible format
 - Formatted printing:
 - Channel control
 - Page size
 - Tab setting
 - Set line density (1 to 72 lpi)
 - Selectable diskette drives
 - Print to diskette or printer
 - End of job statistics
 - Multiple data set print/punch output
 - Multiple job file support from keyboard or diskette

DESCRIPTION

When used with the IBM SDLC Adapter, SNA 3270 Emulation and RJE Support licensed program permits the IBM Personal Computer to act as a terminal that can communicate with a host system in one of two modes, either supporting SNA 3270 or SNA 3770 RJE.

It includes access method software to support the IBM SDLC Adapter, with additional support to provide both SNA 3270 Emulation and SNA 3770 RJE interfaces to the user.

CUSTOMER RESPONSIBILITIES

Customers are responsible for producing backup copies of the original diskette, when copying is permitted, according to the terms and conditions of the IBM Program License Agreement, acquiring the necessary communications modems, cables, subscriptions, and passwords.

BRANCH OFFICE RESPONSIBILITIES (None)**SPECIFIED OPERATING ENVIRONMENT****HARDWARE REQUIREMENTS**

- An IBM 5160 Personal Computer XT or an IBM 5150 Personal Computer with at least 128KB of memory, and one diskette drive.
- One of the following 80-column display options:
 - IBM 5151 Monochrome Display and the IBM Monochrome Display and Printer Adapter
 - IBM Color Display and the Color/Graphics Monitor Adapter
 - An 80-column black/white or 80-column color monitor with the IBM Color/Graphics Monitor Adapter
- SDLC Communications Adapter (1502090)
- Communications Adapter Cable (1502067)
- Synchronous Communications modem with clocking up to 4800 bps on a switched or leased line
- Host Computer system with compatible IBM SNA 3270 Display System support

SOFTWARE REQUIREMENTS

- IBM Personal Computer Disk Operating System (DOS) Version 1 or subsequent versions and releases
- When used with the IBM Personal Computer Disk Operating System Version 2.0, the SNA 3270 Emulation and SNA RJE Support Program may be resident on a fixed disk drive and may access fixed disk files.

PACKAGING

The SNA 3270 Emulation and SNA RJE Support Program is resident on a single diskette which is shipped with a *User's Guide*.

PROGRAM PRODUCTS

**BINARY SYNCHRONOUS 3270 EMULATION PROGRAM
6024037****PURPOSE**

The Binary Synchronous Communications is a connectivity enhancement to the IBM Personal Computer. This extension provides additional flexibility for interactive and office system use of the IBM Personal Computer as an intelligent work station. Operating in BSC 3270 emulation mode, the Personal Computer appears to the host system as one of the following IBM 3270 BSC devices:

3271 mdl 2/3277 mdl 2	Leased line
3274 mdl 51C/3278 mdl 2	Leased line
3275 mdl 2	Switched and leased line
3276 mdl 2	Leased line

HIGHLIGHTS

- Communications Interface
 - Supports IBM BSC Communications Adapter (1502075)
 - Both switched and leased line support
 - Modem support
- EIA RS232-C interface
 - Half duplex
 - External clocking
 - Up to 9600 bps
- Constant line trace, error logging and communications statistics accumulation
- BSC 3270 emulation

The IBM Personal Computer appears to the host system as one of the following IBM 3270 BSC devices:

 - 3271 model 2/3277 model 2 (leased line)
 - 3274 model 51C/3278 model 2 (leased line)
 - 3275 model 2 (switched and leased line)
 - 3276 model 2 (leased line)
- The IBM Personal Computer uses the same screen formats as supported by the IBM 3275, 3276, 3277 and 3278 except for the status line. Only the following features are provided:
 - 12 program function keys
 - Local print key
 - Audible alarm
 - EBCDIC line transmission support
 - Keyboard numeric lock
 - IBM 3279 base color mode support
 - Status line messages
- Printer support
 - 3284 model 3 (when configured as a 3275)
 - 3284 model 2
 - 3286 model 2
 - 3288 model 2

The IBM Personal Computer will connect to host subsystems that support the above devices and features/options Configuration utility to tailor the communications environment
- Additional non-3270 functions provided:
 - User-definable 3270 keys
 - PRINT command allows users to route printer directed data to a file
 - SEND command allows ASCII file data to be written to the unprotected fields on the display for modification and/or transmission to the host
 - TRACE command formats and prints or displays the communications line trace
 - STATS command displays communications statistics

DESCRIPTION

When used with the IBM BSC Communications Adapter, the BSC 3270 Emulation licensed program permits the IBM Personal Computer to act as a terminal that can communicate with a host system supporting BSC 3270.

It includes access method software to support the IBM BSC Communications Adapter with additional support to provide BSC 3270 Emulation.

The *User's Guide* describes both installation and operation. A configuration program uses menus to prompt the user for various options available using default values for the most common configurations.

CUSTOMER RESPONSIBILITIES

Customers are responsible for producing backup copies of the original diskette, when copying is permitted, according to the terms and conditions of the IBM Program License Agreement, and acquiring the necessary communications modem, cables, subscriptions, and passwords.

BRANCH OFFICE RESPONSIBILITIES (None)

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

- An IBM 5160 Personal Computer XT or an IBM 5150 Personal Computer with at least 128KB of memory and one diskette drive
- One of the following 80-column display options:
 - IBM 5151 Monochrome Display and the IBM Monochrome Display and Printer Adapter
 - IBM Color Display and the Color/Graphics Monitor Adapter
 - An 80-column black/white or 80-column color monitor with the IBM Color/Graphics Monitor Adapter
- BSC Communications Adapter (1502075)
- Communications Adapter Cable (1502067)
- Synchronous Communications modem with clocking up to 9600 bps on a switched or leased line
- Host Computer system with compatible IBM 3270 Display System support
- IBM 5152 model 2 Graphics Printer

SOFTWARE REQUIREMENTS

IBM Personal Computer Disk Operating System (DOS) Version 1 or subsequent versions and releases ... when used with the IBM Personal Computer Disk Operating System Version 2.0, the Binary Synchronous 3270 Emulation Program may reside on a fixed disk drive and it may access files on disk.

DATA SECURITY

The customer is responsible for the protection of data from unintended modification, destruction, or disclosure and for the accuracy and integrity of the results.

PACKAGING

Personal Computer Binary Synchronous 3270 Emulation User's Guide (packaged with the diskette) ... this program is resident on a single diskette ... The user's guide is packaged with the diskette.

PROGRAM PRODUCTS

**IBM PERSONAL COMPUTER PEACHTREE BY
PEACHTREE SOFTWARE INCORPORATED
6024039****PURPOSE**

PeachText is a powerful word processor that can be learned quickly. Like other word processors, PeachText has the basic ability to prepare, revise and type a document. But PeachText can be used for much more than basic word processing. Through the use of logical commands (such as IF/THEN) and data that can change throughout documents (variables), PeachText can make decisions and pull information into appropriate places.

HIGHLIGHTS

- 80-column display of upper and lower case characters
- Full-screen editor
- Use of full function keyboard
- Online help text
- Ability to display and/or merge part of a second document while editing another
- Pauses can be built into a document to allow keyboard entry of variables while printing
- Use of conditional commands to retrieve and print data from a data file
- Display of document on screen allows user to view the print format of the document prior to printing
- Allows proportional printing on some specialty printers
- Global and selective search and replace
- PeachText creates DOS-ASCII files
- Automatically configured for the IBM Graphics Printer
- Word wrap-around and automatic carriage returns
- Special program utility mode for programmers
- Block operations
- Ability to use files larger than available memory work space by paging from diskette

DESCRIPTION

The PeachText program may be learned through a series of lessons in a tutorial format. This tutorial is friendly and easy to use and takes the beginner through the basic features of the program as well as the more advanced features. Error messages are clear and informative and provide the user with suggestions concerning the options which are available. The help screen provides information about function key usage and cursor movement activities, edit and print commands. The Edit Status Screen and Print Status Screen display information about the current activity, plus command options. The PeachText program operates in two modes, edit and print. Each mode has a command screen, from which the user can enter commands to manipulate text and/or format text. The user also has the option to enter imbedded commands which will be interpreted by the formatter at print time. The text can be printed to the display screen allowing the user to view the final format prior to printing.

CUSTOMER RESPONSIBILITIES

To successfully install and use the program, the customer should read the *User's Reference Manual* to understand the operation of the system, and perform the following tasks:

- Making a backup copy of the program diskette
- Completing the "Getting Started" chapter of the *User's Reference Manual*
- Performing backup and recovery procedures

SPECIFIED OPERATING ENVIRONMENT**HARDWARE REQUIREMENTS**

- An IBM 5160 Personal Computer XT or an IBM 5150 Personal Computer with a minimum of 64KB of memory and one diskette drive.
- One of the following 80-column display options:
 - An IBM 5151 Monochrome Display and the IBM Monochrome Display and Printer Adapter
 - An IBM Color Display with both the Color/Graphics Monitor Adapter and the Printer Adapter
 - A direct-drive 80-column black and white or 80-column color monitor with both the Color/Graphics Monitor Adapter and the Printer Adapter
- An IBM 5152 model 2 Graphics Printer

SOFTWARE REQUIREMENTS

IBM Personal Computer Disk Operating System (DOS) Version 1.1 or subsequent versions and releases. With IBM Personal Computer Disk Operating System Version 2.0, PeachText may reside on a fixed disk drive and may access fixed disk files.

PACKAGING

PeachText is distributed with the following:

User's Reference Manual ... one program diskette ... one demonstration diskette ... function key template ... Reference Card.

IBM 3101 EMULATION PROGRAM 6024042

PURPOSE

The IBM 3101 Emulation Program allows the Personal Computer to connect to another computer system as if it were an IBM 3101 Display terminal. This allows the user to access a host system for interactive applications residing there as well as the normal stand-alone processing which is available when the IBM 3101 Emulation Program is not executing.

** The Source is a service mark of Source Telecomputing Corporation, a subsidiary of The Reader's Digest Association, Inc.

HIGHLIGHTS

The 3101 Emulation Program emulates the IBM 3101 model 20, with some differences. Users may specify line characteristics and keyboard mapping. Sample specification files are provided for:

- VM/370, MVS/TSO
- IBM 7426 Terminal Interface Unit (TIU) for IBM 8100
- Yale IUP for Series/1
- 3101 Pass-through (PVM)
- Dow Jones News Service*
- The Source**
- Communications with another IBM Personal Computer

DESCRIPTION

The IBM 3101 Emulation Program, provides four main functions:

- Emulates the IBM 3101 Display Terminal according to user-selected options contained in specification files
- Provides several specification files as examples of popular 3101 configurations
- Transmits ASCII format files to and from host computer and local storage diskettes
- Converts ASCII format diskette files to and from binary format

The customer must perform an initial setup procedure to format blank diskette(s) and copy portions of DOS onto the diskette(s). A specification file must be created for unique requirements; or, one of the sample files can be used. A DOS batch file can be prepared to automatically "boot" the emulation program at power-on time.

CUSTOMER RESPONSIBILITIES

Customers are responsible for producing backup copies of the original diskette, when copying is permitted, according to the terms and conditions of the IBM Program License Agreement, and acquiring the necessary communications modems, cables, subscriptions, and passwords.

BRANCH OFFICE RESPONSIBILITIES (None)

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

- An IBM 5160 Personal Computer XT, or an IBM 5150 Personal Computer with at least 64KB of memory and one diskette drive
- One of the following 80-column display options:
 - IBM 5151 Monochrome Display and the IBM Monochrome Display and Printer Adapter
 - IBM Color Display and the Color/Graphics Monitor Adapter
 - An 80-column black/white or 80-column color monitor with the IBM Color/Graphics Monitor Adapter
- Asynchronous Communications Adapter
- User-provided, full-duplex modem or direct cable connection to a local host computer
- User-provided EIA RS232-C cable for adapter to modem connection

SOFTWARE REQUIREMENTS

IBM Personal Computer Disk Operating System (DOS) Version 1 or subsequent versions or releases is required. When used with the IBM Personal Computer Disk Operating System Version 2.0, the IBM 3101 Emulation Program may reside on a fixed disk drive, and may access files on the fixed disk.

COMPATIBILITY

Some IBM 3101 functions not supported are:

- Transparent mode
- Half-duplex modems
- Reverse channel and controlled request-to-send
- Non-EIA RS232-C interfaces
- Reverse video
- Non-blinking cursor
- Highlighting via color/graphics monitor adapter
- Program mode and ATTR keys
- Local mode
- Print line function
- Print and send message functions, and send mark function
- Foreign language features
- Dow Jones is a Trademark of Dow Jones and Company, Inc.

DOS VERSION 2.0

PURPOSE

The IBM Personal Computer Disk Operating System (DOS) provides the required support between the IBM Personal Computer hardware and an application program. It supports one or more 5-1/4-inch diskette drives, single- or dual-sided, and one or two fixed disks. In addition, DOS provides a user with the ability to display a diskette directory, and rename, erase, display, compare, or copy files. DOS also permits "chaining" a series of programs in a predefined "job stream". Either a job stream or a single program may be designated for automatic execution when the system is first turned on.

HIGHLIGHTS

- Supports diskette drives and fixed disk. Formatted capacity increased to 180KB for single-sided; 360KB for dual-sided diskettes
- Fixed disk initialization program for fixed disk support
- DOS can be started from diskette or fixed disk
- File space allocated dynamically as data is added
- Backup, restore commands to support fixed disk
- Tree-structured directories
- Command to display the directory structure
- Commands to create and remove subdirectories
- Sequential and direct access of data files
- File recovery utility
- Current date and time used in directory entries
- Supports "job stream" sequence of programs as batch files. Conditional (IF-THEN-ELSE) logic supported
- Automatic execution of program or job stream following power-on
- Graphics screen dump to printer
- Global filename characters for filename searches
- Multiple disk I/O memory buffers for improved performance
- Accepts commands entered in upper or lower case
- Line editor, debug, disk format, disk check, diskette copy, diskette compare programs
- Linker for language compilers
- User-installable device drivers may be added for new hardware support
- Optional verify after write
- Extended screen and keyboard controls
- Redirected I/O (example: Keyboard input and direct output to a file)
- Piping: Output from program "A" used as input to program "B"
- Divert parallel printer output to Asynchronous Communications Adapter (example: attach a serial printer)
- Background file print utility permits simultaneous file printing with other activity
- Extended device error trapping

DESCRIPTION

DOS provides an input-output interface for programs written for the BASIC interpreter or any high-level compiler language supported by DOS on the IBM Personal Computer. DOS provides line editor and debug utility programs to aid in program development. A linker program is provided to convert language compiler relocatable modules to executable load modules. DOS Version 2.0 offers function not available in previous versions (1.0 and 1.1) with a higher user memory requirement (DOS 2.0 is approximately 12KB larger than DOS 1.1). Where standard (documented) programming protocols have been observed, most DOS 1.0 and 1.1 programs should run under Version 2.0 without change. Examples of non-standard protocols are access of absolute memory locations where DOS resides and direct calls to the BIOS. Since DOS 2.0 uses more memory, some programs may no longer be able to fit in the same size machines. The program will still require the same amount of user memory - but with DOS 2.0 taking more memory, the amount remaining for the program will be less. In these cases, a program may have to be divided into smaller segments, or more memory may have to be added to the system. The IBM Personal Computer DOS resides on the DOS diskette. A second diskette contains the linker and the sample programs. If the DOS diskette is present in diskette drive "A:", or if DOS is resident on the fixed disk, when the system is started or restarted, DOS will automatically be loaded into random access memory. DOS can also be copied to any formatted diskette to provide the same function. If automatic program execution is not used each time DOS is initialized, DOS will ask the user for the current date and time. This information will be used to identify the most recent update to a file. If the AUTOEXEC option is used and "unattended" operation is desired, date and time prompting can be bypassed. DOS Version 2.0 uses approximately 24KB of random access storage. This is an increase over DOS Versions 1.0 and 1.1. On some systems, this means that additional memory may be required to permit an application program to be loaded and run. In general, 64KB is a minimum memory requirement for DOS 2.0 systems. The recommended memory for a system with a fixed disk is 128KB or more. Note: Prior to running a BASIC language program performing diskette I/O, one of the two language extensions, Disk BASIC or

Advanced BASIC, must be loaded into memory. See the section on IBM Personal Computer BASIC Language Extensions for additional information about memory requirements.

DOS Version 2.0 Functions

Note: (N) = new DOS 2.0 Function

DOS Command or Utility

Command or Utility	Function
ASSIGN	Substitute diskette drive assignments (N)
BACKUP	Backup fixed disk files to diskette (N)
BAT	Batch file support
BREAK	Check for Ctrl/Break Interrupt (N)
CHDIR	Change directory (N)
CHKDSK	Check diskette or fixed disk
CLS	Clear screen (N)
COMP	Compare files
CONFIG.SYS	Configuration File (N)
COPY	Copy files
CTTY	Substitute screen and keyboard (N)
DATE	Set date
DEBUG	Load, alter, display/execute files
DEL,ERASE	Delete files
DIR	List directory
DISKCOMP	Compare diskettes
DISKCOPY	Copy diskette
EDLIN	Line editor
EXE2BIN	Convert .EXE files to .COM format
FDISK	Initialize a fixed disk (N)
FIND	Search for string in file (N)
FORMAT	Format diskette or fixed disk
GRAPHICS	Graphics screen dump (N)
LINK	Link-edit a compiled program
MKDIR	Create a sub-directory (N)
MODE	Set display or printer options
MORE	Pause after displaying screenful (N)
PATH	Specify directory paths (N)
PAUSE	Remark within batch file, then wait
PRINT	Print files in "background" (N)
PROMPT	Change DOS prompt (N)
RECOVER	Recover file (N)
REM	Remark from batch file
RENAME,REN	Rename a file
RESTORE	Restore files from diskette to fixed disk (N)
RMDIR	Remove Directory (N)
SET	Set environment (N)
SORT	Sort data (N)
SYS	Transfer DOS to another diskette or fixed disk
TIME	Set time of day
TREE	Display directory path (N)
TYPE	Display file contents
VER	Display DOS version (N)
VERIFY	Write-verify data to diskette (N)
VOL	Display disk(ette) label (N)

BASIC LANGUAGE EXTENSIONS, VERSION 2.0

PURPOSE

The IBM Personal Computer BASIC Interpreter is structured in three functional levels: ROM Interpreter (Cassette), Disk, and Advanced. The Disk and Advanced BASIC language extensions are both resident on the DOS diskette. Version 2.0 of BASIC will only work with Version 2.0 of DOS.

HIGHLIGHTS

- Superset of function to many microcomputer BASICs
- Disk BASIC is a superset of Cassette-level BASIC, and Advanced BASIC is a superset of both
- Provides new graphics, music, and function key enhancements
- Reduces the need for special machine language subroutines
- Compatible with the IBM Personal Computer BASIC Compiler (6024003)
- Provides high-level communications support
- Advanced graphics supported: Paint, Circle, Get/Put display contents, Store and Draw line segments, line styling, tiling, viewports, windows
- Advanced light-pen and joystick support
- Event trapping of communications, function keys, joystick or light pen, music, and timer activity
- Path name support for tree-structured directories

DESCRIPTION

Disk BASIC and Advanced BASIC extensions are optional, and may be loaded into memory from the DOS diskette or from a fixed disk. Cassette BASIC provides the necessary cassette input/output instructions (the IBM 5160 Personal Computer XT does not support cassette attachment) as well as support for the display, keyboard,

**IBM Personal Computer DOS V2
BASIC Language Extensions V2 (cont'd)**

printer, light-pen, and joysticks. In addition, it provides a full complement of editing, logic, math, and string functions. Cassette BASIC is standard on the IBM 5150 Personal Computer and the IBM 5160 Personal Computer XT in the form of built-in read only memory. The Disk BASIC extensions to the language provide a full set of instructions, commands, and built-in function which support the Disk Operating System and add date, time of day, and communications capabilities. Advanced BASIC extensions include all Disk BASIC functions as well as enhanced display graphics, light-pen, and joystick support. Advanced BASIC includes both the Graphics Macro Language and the Music Macro Language (trademarks of Microsoft, Inc.). In addition, Advanced BASIC supports interrupts from the light-pen, game controllers, function keys, and communications adapters.

BASIC Language Extensions, Version 2.0 Functions

(N) = new function in Version 2.0

Disk Basic	Advanced Basic	Function
CHAIN	CHAIN	Chain to next program
CHDIR	CHDIR	Change Directory (N)
CIRCLE	---	Draw a circle
CLOSE	CLOSE	Close an I/O device
COMMON	COMMON	Pass variables to chained program
COM	COM	Enable communications interrupt
CVI,CVS,	CVI,CVS,	
CVD	CVD	Convert data from disk/diskette file
DATE	DATE	Current date
---	DRAW	Draw a predefined "picture"
EOF	EOF	End of file indicator
FIELD	FIELD	Define disk/diskette file records
FILES	FILES	Display disk/diskette directory
GET	GET	Read a random file record
---	GET	Read graphics image from display
INPUT#	INPUT#	Input from disk or communications
INPUT)	INPUT)	Input from communications
INP	INP	Input byte from external device
KILL	KILL	Delete disk/diskette file
LINE	LINE	Input variable length line from disk/diskette
INPUT#	INPUT#	
LLIST	LLIST	List a program on theprinter
LOAD	LOAD	Load a program from disk/diskette
		Return next disk/diskette file record number
LOC	LOC	Return count of characters in communication channel
LOF	LOF	
LSET	LSET	Move data into random file buffer
MERGE	MERGE	Merge a program from disk/diskette
MKDIR	MKDIR	Make directory (N)
MKI,MKS	MKI,MKS	
MKD	MKD	Convert data to random buffer format
NAME	NAME	Rename a disk/diskette file
	ONKEY	
---	GOSUB	Branch on function key
	On COM	
---	GOSUB	Branch on communications interrupt
	ON PEN,	
---	STRIG GOSUB	Branch on light-pen or joystick
---	ON PLAY	Continuous music during program run (N)
---	ON TIMER	Branch on time interval (N)
OPEN	OPEN	Open an I/O device
---	PAINT	Fill enclosed area with color
---	PEN	Enable light-pen interrupt
---	PLAY	Play predefined music
		Map an expression to relative or actual coordinates (N)
---	PMAP	
PRINT#	PRINT#	Write to I/O device in print format
PUT	PUT	Write buffer to a random file
---	PUT	Write graphics pattern to display
RMDIR	RMDIR	Remove directory if empty (N)
RUN	RUN	Run a disk/diskette resident program
SAVE	SAVE	Save a program on disk/diskette
		Read setting of joystick or enable joystick interrupt
---	STICK	
SYSTEM	SYSTEM	Return to operating system environment
TIME)	TIME	Time of day
		Number of seconds since midnight or system reset (N)
TIMER	TIMER	Memory address of file buffer
VARPTR)	VARPTR)	Define display viewports for graphics output (N)
---	VIEW	
WIDTH#	WIDTH#	Set width of data for device
---		Define logical limits for graphics output (N)
---	WINDOW	
		Write to a sequential disk/diskette file
WRITE#	WRITE#	

CUSTOMER RESPONSIBILITIES

The customer is responsible for producing a backup copy of the original DOS diskette, and for creating copies of DOS on other diskettes or fixed disk drives as required. All newly purchased diskettes must be initialized using the DOS FORMAT utility. Fixed disks must be initialized with both the FDISK and FORMAT utilities.

SPECIFIED OPERATING ENVIRONMENT

HARDWARE REQUIREMENTS

The IBM Personal Computer DOS Version 2.0 requires an IBM 5160 Personal Computer XT or an IBM 5150 Personal Computer with a minimum of 64KB and one diskette drive. A minimum of 128KB is recommended if a fixed disk drive is installed. Some user application programs may require more than the stated minimum amount of memory.

The IBM Personal Computer BASIC version 2.0 requires an IBM 5160 Personal Computer XT or an IBM 5150 Personal Computer with a minimum of 48KB of memory and one diskette drive. For most applications, however, 64KB or 96KB of memory will be required. Since BASIC does not address more than a 64KB workspace, more than 96KB of user memory is normally not used.

SOFTWARE REQUIREMENTS

The IBM Personal Computer Disk Operating System (DOS) Version 2.0 is a prerequisite to the use of the IBM Personal Computer BASIC language extensions, version 2.0.

PACKAGING

The IBM Personal Computer Disk Operating System Version 2.0 is resident on two diskettes. One diskette contains DOS and the BASIC language extensions. The second diskette contains the Linker program and sample programs.
