Located in interior parts of Medak District, Shamshuddinpur is characterised by diversity-based dryland agriculture, both in the *kharif* (spring) and *rabi* (winter) seasons. Regardless of their socio-economic situation, virtually all farmers follow a mixed cropping system. *Jowar* (sorghum), the main crop, is grown in association with pulses like pigeonpea, greengram, blackgram, cowpea, fieldbean, chickpea and a range of dryland oilseeds including groundnut, mustard, safflower, linseed, and niger. Minor millets (foxtail millet, little millet, etc.) are also grown on very poor soils and commercial crops like sugarcane, ginger and green vegetables are cultivated on a handful of irrigated fields.

Irrespective of gender, everyone in Shamshuddinpur acknowledges the importance of crop diversity in meeting food, fodder and fuel needs, evading the risks inherent to dryland farming, optimising scarce moisture, and minimising costs of cultivation. Yet of all farmers, small women farmers are perhaps the most resourceful in making the most out of crop diversity on their land. They see a clear connection between crop diversity in their fields and grain diversity in their kitchen, a key asset in preparing nutritious meals, food offerings for the deities, festival delicacies, and herbal remedies. Although there is no outright rejection of marketable crops on women's part (cash crops like castor, coriander, chillies, bishop's weed or turmeric are grown in very small quantities by most families in Shamshuddinpur), there *is* a strong sense that these should not be grown at the cost of crops that meet more immediate and vital needs.

Intra-species diversity is still high in this part of the Deccan Plateau. In Shamshuddinpur, for instance, ten local varieties of sorghum, six of pigeon pea, and three of chickpea are still grown today. When opting for a given combination of varieties, women farmers call upon a great deal of know-how, planning skill and strategic thinking. Laxshmamma, from the village of Chillamammadi some 30 km from Shamshuddinpur, explains that by growing two or three varieties of chickpea or pigeonpea, she increases her chances of storing the harvest as foodgrains for home consumption. The underlying logic is that her husband is less tempted to go and sell small quantities of different varieties in the market than a larger volume of a single variety. Small women farmers, then, can take recourse to elaborate strategies in order to keep as much control as possible over food grains produced on their land. Yet overall, in Shamshuddinpur, men do not downplay the value of crop diversity as they do in other parts of Andhra Pradesh.

Satmoori and Pipri

In Gound adivasi (tribal) village of Pipri, in Adilabad district, there is a stark contrast in the depiction of farming practices by women and men. Men farmers eagerly speak of the cash crops that are now widely grown in the village, under rainfed conditions: hybrid cotton, hybrid sorghum, tomatoes, and chillies. The picture they convey is one of a largely commercialised agriculture, with inputs and outputs travelling in and out of the village. Women farmers, on the other hand, feel more inclined to speak about the food crops they grow on their land: pigeonpea intercropped with cotton, chickpea after a crop of rice, sesame on the border of sorghum fields, rows of fieldbean amongst sorghum plants.

Similarly, in Satmoori, an adivasi village in the same district, farming is based on a mix of food and cash crops with maize, sorghum (*jowar*) and cotton as the main crops (in terms of acreage). In 2001, a group of 22 women of all ages took part in a participatory exercise on the relevance of crop diversity to dryland agriculture (Table 1). Interestingly, the matrix they prepared reveals a very low consideration for cotton compared to all other crops on their part. Yet cotton is presently gaining ground in many parts of Adilabad District (as well as in other Deccan regions). Sorghum, considered by women farmers to be a crop of vital importance, is losing ground to the commercial crops. Men, being the main recipients of external advice, inputs and credit, are generally more inclined to expand the area under commercial crops; many women say that their husbands insist on moving towards cash crops.

Bhoraj

Agriculture in Bhoraj, a village located close to the town of Adilabad, constitutes yet another scenario. Cash crops like cotton and soybean dominate. Hybrid sorghum and pigeon pea are grown for direct consumption and for sale.

In this context of commercial agriculture, there is a clear demarcation between cash crops and so-called '*chillar pantalu*', meaning 'small change' crops, which do not bring in a sizeable income. These crops encompass most of the pulses (except pigeon pea) and oilseeds to which Shamshuddinpur and Satmoori women farmers attribute so much importance.

Although men openly discredit minor food crops in Bhoraj and in neighbouring villages, women have not entirely given up on them. One of their practices consists in going into cotton fields soon after germination, carrying seeds of field bean, green gram, black gram or roselle *(Hibiscus sabdariffa),* and sowing these wherever a cotton seed has failed to germinate. Even though crop diversity has been almost entirely sidelined in the present cropping pattern, women are not deterred in their determination to see pulses and oilseeds grow on their land. This is true not only of small women farmers, but also of large farmers. Gangamma, who belongs to a high caste family farming 30 acres, explains that she too tries to grow small amounts of green gram and black gram wherever she can. Yet, it is also significant that it took two hours of discussion for her to say that she was growing these crops and storing a few kilos of these seeds in small plastic bags. This would indicate that she had internalised the idea that it is worthless to grow ‘small change crops’.

Women and crop diversity

The demise of crop diversity can be seen as a metaphor for the marginalisation of women’s agenda in agriculture. “Small change” crops are suited to dryland conditions, grow without any extravagant need of inputs, and meet the food and fodder requirements of the household. As a woman farmer from Pipri said “If we only grow cotton, where is the fodder for our cattle going to come from?”. Yet, most agricultural extension officers, scientists, breeders, rural bank managers and even policy-makers pay no attention to the concerns of women, especially when they are ‘merely’ poor farmers. The entire agricultural support system is geared towards men farmers who can be more easily persuaded to adopt new seeds and technologies and to spend money on chemical inputs.

In the emerging paradigm of agriculture, which is spreading like wildfire in many parts of India, commercial crops are equated with modernity, and there is very little room for diversified cropping systems. As local dealers become the main suppliers of inputs, credit and advice, and the main outlets for the crop, women’s domain of expertise in agriculture drastically reduces. The recurring allegation made by men farmers that “Women don’t know anything about farming”, in villages like Bhoraj, is but one sign of this alarming trend.

Cosmetic changes in policy (like creating ‘niche areas’ for women, such as poultry-raising or sericulture) and initiatives that fail to address the contradictions of the dominant paradigm of agricultural development (like micro-credit schemes for poor rural women, that leave the problem of indebtedness via money-lenders unexamined) are not what is called for. A profound change of attitude towards women farmers is needed, and a shift in the way agricultural policies are conceived and implemented.

Finding out what women know about farming, and why their knowledge has been devalued, is a crucial step. There must be a sustained effort by extension workers, scientists and policy-makers to understand women’s practices and perceptions about agriculture, including cultural, social and symbolic dimensions.

In domains that are typically women’s responsibility, like seed saving, weeding, and cooking, it is vital that women’s concerns be allowed to emerge and inform policies. Small women farmers, for instance, have a preference for crop varieties that are suitable for mixed cropping, that can be saved as seed for next season, that require low levels of inputs and that produce enough fodder for their cattle. Unless these factors are given due consideration, there is a great chance that agricultural policies will continue to undermine women’s agenda instead of strengthening it.

Finally, issues of control and access to resources (e.g. land, water, and seed), credit and markets need to be scrutinised with a special attention to gender. Unless women’s control over productive resources is reinforced, through individual or collective approaches, it is doubtful whether women farmers will be able to continue contributing to agriculture with the same talent, aptitude and dedication that many Indian rural women still display today. ■

Had the women farmers whom I approached not shared their words, concerns and sensitivity with such openness and spontaneity, this article could simply not have been written. I wish to especially acknowledge the affection and inspiration received from a few vibrant women, farmers and cooks: China Narsamma (Pastapur), Samamma (Bidakanne), Kamlamma (Shamshuddinpur), Lakshmamma (Chillamammadi), Swarnamma and Cheichamma (Algole), Anjamma (Timmapur), Modhubai (Satmoori), Posani (Bhoraj). I also wish to thank Deccan Development Society (Medak District) and the Dhan Foundation (Adilabad District) for making this research possible.

Developing camel products

pastoralist women and PTD

Laura Lemunyete

Salato Juu and Salato Chini Women's Groups are sister groups operating in the Ngurunit area of Northern Kenya. The community of Ngurunit comprises Rendille and Samburu Pastoralists. Ngurunit's main economy is based on livestock production under the pastoralist system. Agriculture is very basic due to water constraints and very few alternative activities have been developed in the area.

Salato Juu/Chini Women's Groups consist of 104 members who formed together as sister groups in October 1995. Their main goal is to work together for the improvement of each member's life together with their families and wider community. Over the years Salato Women's Groups have been involved in a number of activities. These activities include making and selling handicrafts, running a tourist camp/conference centre, participating in making a calendar to raise funds for community preventive health projects as well as other activities that assist them to reach their goal.

Salato Groups' principle partner is PEAR Group (Participatory Education, Awareness and Resources Group), a Community Based Organisation operating in Samburu District. This organisation specialises in promoting, motivating and assisting in the implementation of community development projects.

The camel project

The main incentive for forming into groups was to increase food self-reliance through the implementation of a camel project. The groups started submitting proposals in 1996 and were successful in finding a donor through HPI (Heifer Project International). Activities started officially in January 1999. The project involves every group member acquiring a milking camel, as an ecologically sound livestock species suited to the Ngurunit area that is able to produce milk even during dry seasons. This aims at increasing each household's food self-reliance and possibility of income generation through the sale of camel products. Connected with this project are elements of livestock management training, encouraging ethno-veterinary knowledge through use of medicinal herbs and plants, group dynamics and leadership training, literacy promotion and environmental awareness raising and conservation. PEAR Group assists in the implementation and management of the camel project activities.

Through the camel project, the women of Salato Women's Groups received 103 mature female camels and 4 breeding bulls. The first lot was received in March 1999 and the last arrived in April 2000. By the end of that year, the camels were starting to give birth and many families started benefiting from the milk. Family nutrition improved and milk sale gave a bit of income. The group members were also seeking better ways to use the milk, both collectively and individually, as a source of income and increased food security. It was through this desire to increase the value of their product that they became involved in Participatory Technology Development (PTD) research on meat and milk preservation for food security and income generation. This PTD research is done at community level in co-operation with EU/ KARI (Kenya Agriculture Research Institute), and PEAR Group is involved in the project as facilitator.

The meat and milk preservation project is based on available academic research on this subject and, through the support of technical personnel and community facilitators, attempts to establish practical methods that local pastoralists can use for food security and income generating activities. Salato Groups were selected for the pilot phase of the project from February to June 2001. During this time they were able to start organising several preserved meat and milk product enterprises and start to explore the possible avenues of food security products such as camel milk cheese, dried milk and ghee (clarified butter).

From July 2001, the project continued in a more formal phase concentrating on infrastructure development (dairy and meat processing houses), marketing and continued product development for food security. More emphasis was also put on the health of the milking animal as it relates to milk production and dairy product quality. A dairy building was completed in April 2002 and a meat-processing house was finished in May 2002. KARI provided technical experts to work on the food security and health issues. Donors from the Finnish Embassy assisted the Salato Groups to equip the dairy with a solar system, a bag sealer and a cream separator. A refrigerator was also given that only needed some maintenance and repair. The

Group members, facilitated by PEAR Group, continued to adapt the technical processes and income generation products to their situation.

The project was renewed again for the year 2002/2003. The goal of this year is to establish regular markets for both milk and meat products, finish supporting infrastructure like fencing, water tanks and latrines, improve literacy and management ability of the group members, explore ways of adding value to animal products like the hide and to enhance the sustainability of the project to allow it to continue without external input.

Successes in the meat/milk preservation project

Through their involvement with the Meat / Milk Preservation Project, the members of Salato Groups have begun to see several positive changes start to take place in their abilities as members of a group, and as individuals, to improve their food security on a household basis and increase their income generation. Through the group dairy enterprise, a market has been created for individual milk sales. After processing the milk, the profits from the sale of the products, fermented milk, ghee, milk sweets and dried cheese, in turn are put into the group account and are available for grants and loans to the members for starting private business enterprises or assisting in educating their children.

The Participatory Technology Development side of the project has been successful in developing several important food security items that the group members are producing for household level use. The traditional method of extracting milk fat from cow milk does not work on camels because of the structure of camel milk. With the cream separator technology introduced, the production of ghee (clarified butter), which by the local methods for cow milk is very labour intensive, is made much easier and can be made without destroying the skim milk component. From the skim milk a dried, brined camel cheese or a processed milk sweet can be made. The cheese is easily stored for up to 6 or 8 months without spoiling and is added to maize meal porridge or maize as a very nutritious protein source. The milk sweet can be stored for up to 4 months and is added to tea or eaten alone. These products are made during the times of milk surplus and can be easily stored in local home conditions. These technologies go very far in providing alternative systems of food security by preserving a normally very perishable product.

Besides using it for their own income generation activities, the group dairy is also devising a way to provide this separation technology to the wider community during times of milk surplus, so that the fat can be stored for the dry season. So now, families that have camels as their source of milk can also benefit from making ghee.

One added benefit that the group members are realising from this project is through the creation of a fund from part of the income, to provide subsidised camel drugs for the group members when their camels require them. A major expense of owning camels is the high cost of drugs required to keep the camels healthy and productive. Many of the group members have very little cash income and find providing drugs for their camels a major constraint to their production. With the advent of the dairy project, the group members were able to set in place a system of milk donations on a weekly basis when their camels are lactating. The milk is then processed to improve the value and sold along with the other income generation products. The money from the camel milk sales is then put into the drug fund and used to buy drugs for the group camels. These drugs are provided to the members very cheaply, (less than 25 % of retail price), thereby assisting the group members to keep their camels healthy and increasing overall production.

Challenges for the Future

In terms of the meat side of the project, traditional methods of preserving the meat have been improved to create products that can be marketed for income generation. Tanning of the hides is also being explored so that a value-added product can be sold for more money than the raw skin can get. Some success has been achieved, but the PTD process is still going on to develop marketable products.

Marketing in general, of both the milk and meat products, is an ongoing challenge for the Group and the organisations working with them. While several markets have been established and several potential markets are in the process of being opened up, the women are still eagerly working on better, more marketable products that will enhance even further their income generation opportunities.

In terms of food security, the Salato Group members continue to raise awareness on the products that they have developed in the context of the project. While some of the group members have started to adopt the products on a household level, there is still a lot of work ahead for the group to spread the technologies to the wider community and other neighbouring communities. This challenge they are taking on with much enthusiasm and energy.

While the PTD methods have already resulted in several good products, the Salato Group members have learned that technology development is an ongoing process and they continue to seek new and better ways of preserving their meat and milk products. They have seen the positive outcomes of the project in increased income and other benefits like the camel drug fund and increased food security. This gives them the heart to continue in their search for ways to improve the lives of their families, their fellow group members and their community. ■

Gender mainstreaming
lessons from a Mexican NGO

Woman planting vegetables and herbs. She is participating in a project called "Manejo Integral del Solar" (integrated garden management) promoted by EDUCE. Photo: Maria de las Mercedes Rocha

Maria de las Mercedes Rocha, Teresa Munguía, Emma Zapata, Verónica Vázquez and Beatriz Martínez

In the 1970s, the relationship between gender and environmental issues began to receive increasing attention in the development context. The literature started to analyse the impact of environmental change on gender relationships, as well as the role of women in natural resource management. In 1984, these issues formally became part of the international agenda, when the United Nations Programme for the Environment supported a move to strengthen the participation of women in environmental planning. Likewise, both at the Earth Summit of Rio de Janeiro in 1992 and at the International Women's Conference held in Beijing in 1995, explicit references were made to the need to design environmental programmes with gender focus, in order to increase women's access and control over resources. Non-Governmental Organisations (NGOs) have played a very important role in the process of designing and implementing such programmes. Sustainable development with gender focus has become an important challenge for Latin American NGOs.

"Gender mainstreaming" means that all activities conducted by the NGO must have a gender dimension. In other words, every programme and project should be aware of different gender needs, and target them explicitly. For example, projects related to family health and nutrition are usually targeted at women, but with no consideration of their individual needs. Thus, the gender approach has been incorporated in a partial and fragmented way, if any, and the social transformations required to achieve gender equality are not encouraged. Women should not be seen as a resource for development, but rather as subjects of their own development.

EDUCE

EDUCE (Education, Culture and Ecology) was founded in Mexico in 1989 and was legally registered as an Asociación Civil (non-profit organisation) in 1992. EDUCE defines itself as a non-profit institution with no political affiliation, which is mostly devoted to the promotion of sustainable regional development. EDUCE works in several geographical areas of the country. In this article we will focus on the region of Los Chenes, located in the Municipality of Hopelchén, Campeche. This municipality has approximately 31,000 inhabitants, most of them Maya speakers. They are engaged in subsistence agriculture (corn and beans), domestic animal production, apiculture and the extraction of chicozapote latex (a resin obtained from the chicozapote tree *Manilkara zapota*, which has now largely been replaced by plastic).

EDUCE Campeche is formed by an interdisciplinary team, consisting of a group of specialists in the fields of communication, economics, rural development, agronomy, environmental studies, education, anthropology and accounting. Their goal is to foster regional development and to improve the quality of life of the local people through the implementation of productive, environmental and educational projects. The team uses a participatory methodology that promotes community involvement and project generation and implementation at grassroots level.

Working on gender issues

In Campeche, EDUCE has five programmes in 14 communities of the Municipality of Hopelchén. The projects resulting from the programmes are developed with the community through participatory methods. In some communities, there is more than one project. This article will discuss three of the five programmes that EDUCE operates in the region.

The first programme is Sustainable Management of Natural Resources (SMNR), which takes an agroforestry approach. The major purpose of this programme is to train and organise people for sustainable production, so that produce can be locally consumed or sold, thereby promoting regional development. 393 men from 13 different communities participate in this programme.

The second programme is called Integral Backyard Management (IBM). This programme has three components: vegetable (home gardens); animal (chickens and pigs); and technological (dry toilets and alternative water management systems). The programme is designed to encourage food self-sufficiency and contribute to disease prevention and environmental protection. Among the programme's specific objectives is the empowerment of women. 220 women from six communities participate in this programme.

Rural Agro-industries with Women (RAIW) is the third programme. It works with five groups of women, all at different stages in their training. These groups are engaged in honey production, bread making, preparing jams and marmalades, making handicrafts and handling a community corn mill. These projects have been designed to offer women some income-generation activities as well as productive, organisational, administrative and commercial skills. The programme also attempts to empower women through these activities. 34 women participate in these projects.

As can be seen, there is a clear separation between the projects involving men and those involving women. This separation reflects the division between the public sphere (the family plot) and the private sphere (the backyard). Similarly, the female income-generating activities promoted are an extension of traditional female roles, in that they involve the preparation of food. In other words, traditional views of men's and women's work have predominated in project design and implementation. According to the NGO personnel, these projects were developed through participatory methods and they reflect the gender division of labour that dominate in the region. Thus, EDUCE has found itself immersed in the dilemma of respecting the women's own processes and preferences which, from the institutional perspective, may reproduce gender inequality. This situation has arisen more than once in other parts of the world, and it is worth reflecting on ways in which NGOs can deal with it. EDUCE has responded with a variety of measures, which are described below.

Firstly, the NGO has not lost sight of the fact that the opportunities created by and for women, albeit traditionally female, also open the way to other types of processes. It is hoped that, as a result of their participation in these projects, women will become aware of their roles in society and their rights as women. In order to make this happen, EDUCE is combining the productive and organisational activities with gender awareness workshops, which focus on empowerment, citizen participation and female identities. Attendance at these workshops is voluntary. Approximately 55% of the women from the IBM and the RAIW programmes attend this type of training. The results will be described shortly.

EDUCE has also tried to involve the entire family in backyard activities and invite men to join IBM meetings. The strategy has generated greater awareness among women and some male participation. However, the idea still persists among the male population that working in and around the home is women's responsibility and that men have nothing to learn at meetings led by women. This situation has made EDUCE realise that male identities also need to be changed. This led to the organisation of a first workshop on masculinity issues, with EDUCE male personnel and community organisers. However, when similar workshops were held with community men, the process was halted by the groups themselves.

The creation of mixed groups (made up of both men and women) has also been part of EDUCE's strategy for changing the traditional sexual division of labour. However, in this case it is the women themselves who have refused to join a mixed group, because they have come to value only-women spaces. EDUCE has decided to respect such decision and allow the women themselves to come to the situation where they will be willing to join mixed groups, something which has already started to happen among community organisers. Similarly, some women's groups have moved from traditional female spaces towards the public sphere, by taking part in negotiations with the municipal government regarding a regional programme of sustainable development.

Women participating in a gender workshop of the project "Manejo Integral del Solar", promoted by EDUCE. Photo: Maria de las Mercedes Rocha

We now turn to the views of the Maya women themselves, on what working with EDUCE has meant for them. Those who have participated in gender awareness workshops in a regularly have started to see the workshops as a need because "they are very nice and we learn many things". These women are beginning to make decisions on their own and enjoy feeling confident in themselves. The most frequently mentioned workshops during the interviews were those dealing with women's rights and reproductive health; domestic violence; citizen participation; and self-esteem. Some of the women are clear about what they can achieve as women's collectives and are happy to know their rights: "Now we already know how to defend ourselves, (we know) that we have rights as women, we do value what we are, we know how far we can go".

It is hardly surprising, considering the working dynamics of EDUCE (where women have received gender awareness training and men have not), that the women show greater progress than their partners. This can be seen in the fact that the sexual division of labour inside the family has not been modified. In other words, the women continue to be responsible for all domestic work, despite their growing presence in income-generation activities and the public sphere. If women have to attend a meeting, their husbands will look after their children (something which men did not do previously), but they will not do any housework. However, in spite of their double working day, women hold on to their participation in public spaces. They also believe that productive and reproductive work should be shared by both men and women, although they have not been able to achieve such distribution of labour in their own homes.

Interestingly, women who do not attend the gender awareness workshops do not show any change in their perception of traditional gender roles. The differences between those women who attend and those who do not are clearly evident in their ability to express ideas. Those who attend the workshops demonstrate more ease in articulating themselves. This suggests that EDUCE is on the right track, but the need still exists to persuade more women and men to join this type of training.
In fact, of the 254 women who are taking part in the programmes, only about half are attending the gender awareness workshops.
If we add the number of men (393) participating, the percentage of people who have challenged the traditional gender roles is only 18.5%, and the vast majority is female.

Nevertheless, it is important to recognise the efforts being made by EDUCE to integrate the activities of women and men, as well as the success of the gender awareness workshops for some Maya women. More initiatives will have to take place along these lines in order to continue walking in this direction.

Women and livestock
Creating space and opportunities

Nitya S. Ghotge and Sagari Ramdas

In India almost 70% of the farming community are involved in livestock rearing, especially those living in the more ecologically and economically fragile areas of the country. In most communities, women are responsible for the day to day care and management of animals. The poorer the community, the greater their role; responsibilities naturally also increase in communities where women head households. While the activities performed by women may appear to involve very low skill levels, such as the cleaning of sheds, they are however most critical to the survival, health and production of the livestock. For instance, animals are more susceptible to diseases when housed in unhygienic, dirty sheds.

Despite this reality, livestock care is somehow considered a "male occupation". The work of women is seldom recognised and they are kept out of all important decision making processes, although the responsibilities ultimately impinge on them. To begin to truly understand the problems of rearing livestock in rural India, it is critical to begin to work with women.

Why gender matters

In a society as diverse and complex as India, the subject of women in livestock rearing could form the basis of many sociological studies. Traditional Indian society, with its complicated web of class, castes and communities, diverse livestock rearing and agricultural patterns, dynamics of access to resources and ownership of assets, all make for very complex interrelationships. At the same time, the rapidly changing environment impacts on local production systems and hence directly on communities, including both women and men. For example, the shift in agriculture from subsistence production to commercial production has meant that the role of women in agriculture has changed and many of the traditional jobs that women were once involved in, such as the post harvest processing of grains, are today being done by machines. Urban industrialisation has meant that men migrate to cities in search of jobs, leaving women to manage homes and farms in the villages. This has resulted in increased work pressures and work responsibilities for women. The rapid emergence of a disease like AIDS has also left many households bereft of the main earning member and forced women into a labour work force for which they are often not adequately prepared.

Development practitioners and policy makers often have fixed ideas on the role of women in livestock production. Policy makers tend to create uniform policies for the entire country, which prove ineffective given the diversity of situations. Policies are made for the more developed and accessible areas of the country, while the poor and remote areas, where women tend to have greater responsibility, remain marginalised. This can result in inappropriate schemes being thrust on women. One example is the Government of India goat distribution scheme for women below the poverty line in Maharashtra. This scheme largely failed because the beneficiaries were neither consulted nor trained before the goats were distributed to them. Most of the women beneficiaries had never raised goats before and within six months most of the animals had died.

Any work that aims at addressing the true needs of all the members of the community, must therefore begin by understanding the role of women in the production system of the community.

Action research in livestock production

Anthra is an NGO working with rural communities in India, trying to strengthen livelihoods by improving livestock health and productivity. To understand gender concerns in livestock management and in particular within indigenous knowledge systems, Anthra undertook a detailed study of the role of men, women and children in different livestock production systems. In most of the communities we worked with, women were responsible for 60% to 90% of the work related to livestock production, however there were distinct differences depending on the geographical area, caste, community and type of livestock reared. In some areas, such as the semi-arid regions of Latur, Medak and Ratnagiri, men and women equally shared responsibilities like cleaning sheds and milking. In the tribal communities in the Eastern Ghats, the work burden on women was considerably higher. Grazing responsibilities also differed from region to region. The one activity in which women always played a prominent role was in backyard poultry rearing.

With respect to indigenous knowledge, we found that women from Dalit communities, traditionally employed by wealthy farmers to weed their fields, are extremely knowledgeable about grasses and weeds for fodder and about the management of small ruminants. Conversely, women from prosperous traditional landed agriculture castes, who have been involved in dairying, are very knowledgeable on practices related to pre-partum, post-partum care and calf management. Women from other castes, who have never had dairying as a traditional occupation, do not have this knowledge. We also found that though women were knowledgeable about simple household remedies, cures and medicines for treating small ruminants, they have almost always been kept out of professional healing. Traditional healers were predominantly male, as knowledge was normally passed from fathers to sons and not to daughters.

Village women expressed a keen desire to have access to this specialised form of knowledge, which had been denied to them over the years. They also wanted to learn to recognise conditions that can not be treated with local remedies but need other kinds of treatment and care.

Women as Animal Health Workers

At Anthra, we took a conscious decision to ensure that at least 75% of all new animal health workers should be women, and that the women Animal Health Workers (AHWs) participate in all the healers meetings. The training did not merely focus on animal health issues, but also looked at women's health issues and gender questions in the larger context of sustainable development and natural resource use. The women AHWs were encouraged to work closely with other women in the village and share their knowledge in the village women's groups. These women have gained considerable recognition and respect from the rest of the community. They are now recognised as persons who possess specific skills and, very importantly, they are accessible to the villagers. Other women in the women's groups, who were previously entirely dependent on their husbands when the animals fell sick, have expressed that now they are able to get assistance and advice immediately from the women AHWs, who are always available in the village.

The women AHWs personally feel that they have become tremendously confident and can talk to others. Apart from their role as 'healers', they have also begun to take on leadership roles within the village women's groups and the community. They have become key persons who help resolve conflicts within families and mobilise others in the village to address gender issues that affect women: cases of violence against women, illicit brewing of liquor, and education of children, as well as other issues within the larger arena of natural resource management. They feel that by acquiring specific skills through this training, they have gained status in the family as well as in society. Interestingly, while we had anticipated resistance from the healers once the women AHWs began working, on the contrary they have been very supportive as they see this as an opportunity to sustain their knowledge. In many villages the women AHWs and the local healer work closely together.

Training programmes have also meant visiting other places, something most women say they had never even dreamed of. The training programme has meant forging new friendships with women from other regions -exchanging ideas, problems, and solutions and having fun together as well as singing, dancing and in other ways expressing their creativity. It has meant the breaking of traditional barriers of caste, class and gender, which are otherwise so predominant in rural India. Many have also acquired new skills such as literacy.

At the same time, the men must now recognise that women can successfully take on roles traditionally perceived as "male".

The way forward

It is not sufficient merely to work with or for women; it is also extremely important that gender concerns cut across all the activities of an organisation. To enable this process, we at Anthra have conducted several Gender Training workshops. Training is carried out by a team of resource persons, both men and women, drawn from Anthra and other collaborating organisations. Gender training is carried out in local languages and in English. So far, workshops have been conducted for the staff of Anthra and other NGO's, as well as for Animal Health Workers collaborating with Anthra and Veterinary Doctors and Livestock Assistants of the Animal Husbandry Department, Orissa.

Change on a larger scale, however, requires changes within the traditional agricultural institutions. One issue in this context is that the curriculum in agricultural universities does not consider gender issues important, and this omission is then reflected in the policies developed and implemented for agriculture. Engendering the curriculum is a necessary and important step forward for more gender sensitive policies and programmes in the livestock and agriculture sector. Anthra is participating in the effort to mainstream gender concerns into the agriculture curriculum of Indian Universities, initiated by the Gender Department of MS Swaminathan Research Foundation.

Concerns of rural women are not sufficiently addressed merely by resolving economic and livelihood issues. They also need to be addressed by enabling women to gain important social and political space, as well as being able to define and create new spaces within both the private and public domains. A considerable amount of work still needs to be done to achieve this, but our experience has shown us that little efforts do contribute significantly in raising gender questions, which had not been fully recognised or acknowledged earlier.

Bitter cassava and women:
an intriguing response to food security

Linley Chiwona-Karltun, Chrissie Katundu, James Ngoma, Felistus Chipungu, Jonathan Mkumbira, Sidney Simukoko and Janice Jiggins

Studies in Africa and South America show that cassava is regarded as two different crops, the bitter and the sweet. Bitter cassava provides the staple food, whereas sweet cassava is the vegetable, the snack or the thirst quencher. All cassava contains a certain level of toxic cyanogenic glucosides. Bitter cassava contains higher levels of these toxins, and is toxic if not processed.

A devoted couple processes their cassava for drying into makaka, for storing. Photo: Linley Chiwona-Karltun

The detoxification process involves a sequence of steps that have to be followed in order to create a safe food product. The methods are as variable as the desired end products, ranging from the most effective process of soaking, fermentation and drying of the roots, to grating, fermenting and frying, or simply drying the roots. The final results are flour, granular grits or pieces of dried roots that can either be stored as they are, milled/pounded into flour or boiled separately or together with legumes or vegetables. Sweet cassava can be eaten as it is, boiled, roasted or fried as the palate and resources dictate.

It has been observed and documented that farmers not only prefer, but also grow a higher proportion of bitter cassava cultivars than sweet cultivars. This fact continues to intrigue scientists, and we have been interested in understanding why farmers grow bitter and toxic cassava in Malawi. Our research uses a problem-based approach, and integrated methodologies that range from participatory research to natural sciences and emerging advances in biotechnology, in order to further understand the interactions between social and biological factors in farmer decision-making.

Bitterness – a reason for cultivation

The results of our research show that bitter cassava cultivars are highly preferred, particularly by women, because they provide food security - locally termed as kuvikilia. Bitter cassava cultivars provide food security in three ways:

1) the toxin deters foraging rodents and pests from feasting on the crop;
2) the need to process the tubers directly after they are harvested deters thieving from the field (processing is largely a women's domain); and
3) as the processing adds value in terms of time invested, the social obligation of sharing cassava with your neighbours is reduced.

These three factors are of major importance to women farmers, especially to women farmers that are, *de jure* or *de facto*, single.

The preference for bitter cassava is not a local phenomena restricted to resource-poor farmers in Malawi. Studies in other parts of the world confirm that bitter cassava cultivars are preferred because they have superior end-product qualities and because the toxin protects the crop from intruders of all kinds, man and beast alike. "*We grow bitter, toxic cassava because it gives a certain level of food security, kuvikilia. If we are to grow sweet cassava, look at our neighbours! Their whole field was harvested by thieves while they slept and now they have no food. Nobody wants to die from hunger*".

Processing - a drudgery for the poor?

Breeding for reduction or removal of the toxin has featured very high on the research agenda for cassava. Interestingly enough, the women that are the custodians of this crop do not perceive the processing or the toxin to be a problem. Their major problems are the lack of mills to reduce the drudgery of pounding, and the lack of simple technologies that can be locally produced and maintained, such as low cost equipment for peeling or grating the roots. There is also a lack of infrastructure and markets, be it local, national or regional, for their products. The toxin could simply remain in cassava.

"Cassava is a wholesome crop, a complete crop. On top it is the relish (the sauce), in the middle it is the planting material and at the bottom it is the staple dish (kondowole). We do not need fertiliser to grow it, nor do we need money to grind it at the mill, chigawo chilera balanda" (cassava nurtures the poor).

For research to be of any use to resource poor farmers we need to listen to the voices of the farmers themselves:

- Cassava is a hardy crop, tolerant to dry spells.
- Cassava yields something even in nutrient poor soils, a characteristic hard to come by with any other staple crop, especially maize
- Cassava is tolerant to vermin
- Although cassava is somewhat tolerant to certain pests and diseases, we need varieties that are even more drought tolerant, more adaptive to poor nutrient soils
- We need more varieties that are even better than the ones we have now, high yielding, bitter, early maturing, high dry matter content and good storage qualities.

Give us our daily maize

One wonders if the thievery is due to the current food crisis in Malawi. In part yes, it has been exacerbated by the food shortage. However, the main problem stated by farmers is that they have fooled themselves by believing that maize is their only staple crop. When subsidies for fertiliser and seed were easily available they neglected cassava. Now poor farmers in Malawi simply cannot afford the inputs required to grow maize. Even more distressing is the fact that farmers that are able to grow maize produce barely enough to last throughout the year. To feed themselves, many Malawians resort to casual employment or *ganyu*. Ganyu literary means food for work, and workers are paid either in money, or simply in food. However, this opportunity is very limited for women.

Today it is very difficult to find cassava-planting material in areas like Domasi, a modest trading and service centre along the Lilongwe – Zomba road in Malawi. People are hungry; last year's maize harvest rotted by excessive rain and this year's harvest is not enough. Even their stores of dried cassava are not enough. They are resorting to stealing fresh cassava roots (literally roots because they are not quite mature) from the fields. In normal times, the villagers would be out at night protecting their crops. This year, the villages are silent. The chiefs say that there's no point counting the number of hungry households any more. So many people are dead or dying from HIV/AIDS that every one who remains is hungry. There are households where only children remain, cared for by an elderly grandmother or a young girl.

Farmer to farmer cassava selection and multiplication

What Domasi and the hungry villagers all lack is access to stem cuttings and above all, stem cuttings with desirable characteristics, so that the acreage planted to desirable cassava varieties can be increased. Interaction with the farmers, mostly women, made us realise the need to include and involve farmers in the selection of new cassava cultivars. Exchange visits between farmers in different areas were arranged. In a relaxed, friendly environment, farmers could discuss their cassava cultivars with each other. The guidelines given for selection of the participants were that women and men should be equally represented; that literacy was not required but enthusiasm for and knowledge of cassava was decisive; and that a fair representation of the Cassava Clubs should be considered. Cassava Clubs have been established as a result of continued collaboration between the scientists and the farmers. Club members are usually not among the ultra poor or chronically food short, but form a somewhat homogenous class of poor smallholder farmers (0.2 – 0.5 hectares) who, in normal years, are potentially short of food (see UNDP 2001 for the classification of Malawi's poor and ultra-poor). The project has made a conscientious decision also to include the Village-to-Village movement in Domasi that is supporting HIV-AIDS affected households which fall into the ultra poor or chronically food short category.

Selection criteria for new cultivars

The farmers, together with scientists, have established local community multiplication fields in Domasi. Experience has shown that not just any cultivar is selected. Our preliminary results show:

- That whether woman or man, married or unmarried, the first question that farmers ask each other is: is it bitter or sweet? Although farmers in Domasi have almost exclusively grown sweet cassava, this preference is loosing importance. What these farmers wanted was mostly bitter cassava. Why? *"Look, look at our friends, they have so much cassava still standing in the field and all because it is bitter. If we had planted bitter cassava as we did in the past, we would also have food to eat"*. Simply put, food security.
- Secondly, the women were very interested in the starch quality of the tubers, as this was important in the preparation of the staple dish *nsima*, which is synonymous with food.
- Of equal importance was the yield, time to maturity and cooking time. These factors were equally important for both men and women.
- The men were more interested in the sweet cultivars, because the sweet cultivars have a well-established rural and urban market. Nevertheless, the very same men were just as interested in the bitter cultivars for ensuring overall food security.
- In the case of the Village-to-Village community-based NGO, all cultivars were of interest to meet the challenge of providing planting material, as well as food to the victims of HIV/AIDS and People Living With HIV/AIDS (PLWHA).

Most noteworthy

There was one aspect of the farmer-to-farmer selection that deserves extra mention. Women farmers that were single, *de jure* or *de facto*, were much more keen on selecting as many varieties as possible in order to minimise the risk for failure - what mattered was that they were bitter and that they were resilient cultivars with a reasonable yield. To put it in the words of one farmer during the exchange visit:

"We simply cannot boil away the fuel that brought us here, who knows when we will ever have the opportunity to travel, to see the unseen and to be hosted by other cassava farmers that have more cultivars than I have ever seen in my entire life. Madam, I want everything that we are allowed to take".

The community multiplication sites are carefully tended and guarded by the communities themselves with the aim of being self-sufficient.The multiplication sites established by women, especially single women, are undoubtedly in a head start position in terms of care.

The women were less concerned about knowing the names of the cultivars collected because they figured that with time they would learn to select those that best suited their environments. The men were very keen from the start to identify the new cultivars correctly, as it is important for the fresh sweet cassava market.

It is important to point out that although Domasi was traditionally a sweet cassava growing area before the dominance of maize, the knowledge of cassava processing still remains. Within this project we have made available simple processing peelers that are also used in the district where the farmers had the exchange visit. It is our hope that the local artisans will locally produce these peelers.

None of these community-based, women-to-women, women-to-men and men-to-men efforts will bring back those who have succumbed to the wrath of HIV/AIDS, but when and if they succeed, perhaps food security will take on a smiling human face in Domasi.

From Domasi, Malawi - the warm heart of Africa.

Women can move the earth

Experiences in working with Indian women farmers

Edith van Walsum

The Deccan Plateau is a drought prone region in South India covering substantial parts of Andhra Pradesh, Karnataka, Maharashtra and Tamil Nadu. 81% of this region is under rain fed farming. The Green Revolution has largely bypassed this area and there is a serious over-exploitation of the natural resource base. With the opening up of markets due to globalisation policies, the price of agricultural produce has crashed, poverty is increasing and male migration is on the rise. The number of *de facto* female-headed households is increasing, leaving women with the responsibility for managing their farms and ensuring food security - although they do not have the authority to make decisions.

Responding to a need

Realising the important role women play in the development process, NGOs started organising women's Self-Help Groups (SHGs) in the mid eighties. It quickly became clear that women's SHGs often functioned better than the men's groups. The focus of these groups has been on credit and savings, and today women's SHGs are receiving increasing recognition from governmental development agencies and the formal banking system. These developments have lead to a tremendous growth in women's individual and collective self-respect and their visibility in the community. This has had a positive impact on development in general, but the role of women as agricultural producers still remains largely unrecognised and has not been addressed.

Engendering organisations

Over the past eight years AME has engaged in comprehensive capacity building processes with NGO networks and farmers in South India. The focus has been on training NGOs and farmers to implement Participatory Technology Development (PTD) processes and Integrated Pest Management (IPM) Farmer Field Schools (FFS). Both approaches aim at experiential learning, through agro-ecosystem analysis followed by field level experiments and evaluation of the experiments. The aim of this capacity building process is that farmers are enabled to experiment with LEISA technologies so that they can develop and continuously adjust their own "package of practices".

AME has encouraged its partner organisations to look seriously at gender in agriculture. We have promoted a *household approach*, whereby a conscious effort is made to involve both women and men in the PTD/FFS processes. This is what we refer to as *gender mainstreaming.* The immediate objective of gender mainstreaming is that the PTD/FFS process itself will be more effective and its results more sustainable. The long-term objective is that gender mainstreaming should contribute to women's empowerment, by providing access to knowledge and institutions and giving an added impetus to ongoing processes of social organisation and empowerment.

Through this process, we have learnt that when there is involvement of both women and men, the quality of learning is greatly enhanced and so is the overall outcome of the PTD/FFS process. And once women are involved, they have a great energy to take the process further.

Why involve both women and men?

Women participated in a season-long training on Integrated Pest Management in cotton. In the course of the training process, they became confident that they could manage growing cotton without having to use pesticides. But at a critical stage their husbands, who had not participated in the training because they had gone to a nearby town for work, decided to intervene. They instructed their wives to apply pesticides, which - because it was done at the wrong time - lead to a reduction rather than an increase in the yield.

Methods used

There are no "unique" methods to ensure that gender is taken care of in a PTD process. In principle, all participatory methods can be used to address gender issues but they have to be used purposefully and systematically, with a clear gender focus in

mind. The gender analysis framework forms the basic reference for asking questions. This framework addresses three basic issues:
1) the gender division of labour;
2) the gender- differentiated access to and control over resources, and
3) benefits derived by men and women from the intervention/technology developed.

Training field staff in gender mainstreaming

WHAT:
Understanding gender division of labour, intra-household allocation of resources and benefits, communication and decision making.

HOW:
The use of gender analysis tools, PRA, interview techniques and focus group discussion techniques.

DESIGN STRATEGY FOR GENDER MAINSTREAMING:
Who should be involved in the PTD process; why, when and how?
How to identify gender specific constraints with respect to various technologies;
Women's constraints with regard to venues and time of meetings;
Strategies to enable women to benefit from PTD process and outcomes.

We use a combination of individual in-depth interviews, group discussions and observation to articulate the gender perspective in the PTD process. Discussions are held not only with the members of the groups, but also with their spouses and household members. Repeated interaction with both women and men in different contexts (individually, together, as single gender groups and as mixed groups) helps to strengthen the perspective. Most group discussions take place with women and men separately. On some occasions a few men take part in a women's discussion or vice versa. We use group discussions for problem analysis, to discuss learning points from the experiments, group organisational matters and group dynamics, and for the evaluation of the PTD process. Whenever relevant we use visualisation tools.

Women as well as men sometimes hesitate to talk about intra-household affairs in front of one another, especially regarding *decision-making and loans*. Therefore discussions on these issues are always held separately with men and women.

The use of PRA tools in a PTD process

- In the problem analysis stage, we use flow diagrams and seasonal labour calendars. The first reveals the resource flows as well as access to and control over the resources, and the second shows the gender division of labour and seasonal labour peaks.
- When identifying technological options (e.g. seeds or soil fertility improvement methods) we use pair wise and matrix ranking as tools to learn about women's and men's preferences and priorities, and the underlying rationale. Interesting differences can occur, which then can be taken up for further discussion.
- In the course of the experiments and during evaluation we ask men and women to draw maps of their farms. These show physical features of the farms and men's and women's perceptions of the same, which again can show interesting differences.

Stumbling blocks …

In our efforts to mainstream gender we have come across a number of stumbling blocks in the form of biased perceptions about women and men:

1) "Women do not have a say in agricultural decision making":
In spite of changing realities in agriculture many people, NGO workers, researchers and others, find it difficult to acknowledge the reality and to plan the PTD process accordingly.

2) "Participatory approaches are 'naturally' gender sensitive":
PTD, like any other participatory approach, provides no guarantee that women are also participants in the process initiated. Women's participation will not happen automatically, it needs to be facilitated.

3) "Trickle across: from men to women, from women to men":
Many extension programmes have been based on the incorrect assumption that information that reaches men automatically trickles across to women. We also see cases of "reversed" trickle across assumptions. Organisations have started to interact directly with women, but here the same problem on non-trickling or partial trickling across of information can be seen. There is also an additional problem: men are still the final decision-makers. This has lead to frustrating experiences for many women.

4) "Gender specialists take care of "the gender aspect":
It is often taken for granted that within development organisations, women will take care of 'the gender aspect' (whatever it is). The only way to overcome this obstacle is real teamwork and intensive gender sensitisation within organisations.

… and stepping stones

We have also experienced that PTD/FFS processes offer good opportunities for gender mainstreaming:

1) Understanding intra-household dynamics:
When interacting with farmers (men or women) we keep in mind that they are members of *households* and that 'our' farm experiment with them is only one of the many activities they are involved in. Other family members are likely to influence and be influenced by the PTD process. Once we succeed in developing an understanding of intra-household dynamics, it becomes easy to build up rapport with various members of the household and seek their active involvement.

We have seen that communication gaps within households can hamper the process of experimentation as well as the process of learning from it. We have also observed a clear tendency for women to get more deeply involved in the PTD process than men. Clarity about men's and women's stakes in the PTD process will help to guide the process in a meaningful direction, and to find an effective balance between women's and men's participation.

2) Learning with groups:
Groups provide the forum for learning, sharing, and disagreeing or agreeing on the merits and demerits of technologies and on the constraints and opportunities faced. Especially for women, the fact that they are members of a group has encouraged them to venture into trying out new things in agriculture.

Most women who got involved in the PTD process had already been functioning as a group for some time. This contributed to a rapid take-off. Adding PTD as a new function to an existing group gave it a new impetus. The fact that these groups had been involved in thrift and credit was very helpful, as they could take up the responsibilities of procurement and distribution of inputs among their members and manage a revolving fund to support these activities.

3) Learning from different NGO strategies:
There are so many NGOs, so many ideologies and so many approaches towards women and gender issues. Working together on PTD with a 'mixed' group of NGOs therefore poses its own challenges, **and** tremendous opportunities for learning. At different stages in the farming season, meetings are organised, wherein NGO staff and men and women farmers from different areas participate. These occasions provide opportunities to learn about how PTD processes work in different organisational contexts, and about conditions for successful gender mainstreaming.

4) Mobilising women's knowledge = empowerment:
Especially for women, more knowledge leads to greater self-respect and respect from others. Their mobility has increased; they decided to attend farmer's meetings and PTD review workshops that were 3 to 4 hours by bus away from their villages. It was primarily the group that gave them the confidence to do these things. Nowadays they visit agricultural knowledge and training centres and regional farmer meetings. In several cases, women have resisted pressure from their husbands to go back to chemical farming.

This process of mobilising knowledge also enables both women and men to improve the *quality of decision making*: 'best bets' regarding choices of technologies, how to allocate labour and money etc. become more focused and based on systematic comparisons. Last but not least, mobilising knowledge and putting it to new use is a joint learning process, which reinforces existing groups and helps to build new ones. This is what we believe *empowerment* is about, and this is perhaps the most important thing we saw happening in two years of 'PTD with a gender perspective'.

Women learning about insects for IPM. Photo: AME

Kadiri Women's Federation fuels PTD in groundnut

Kadiri is situated in drought-prone Anantapur District (Andhra Pradesh), the largest groundnut-producing district in India. Since the late 1960s, groundnut has gradually monopolised the farming system. Now, 85% of the drylands (about 850,000 ha) are under groundnut. Myrada, a large NGO, started working in Kadiri in 1982 with a focus on wasteland development, resettlement of the landless poor and participatory watershed development. Women's SHGs were established.

In 1997 the women's SHGs formed a Federation (Pragati Mahila Samakya) with the support of UNDP (United Nations Development Programme) and Myrada. Total membership was 2250 women. In the same year, erratic rainfall led to a shortage of seed. Mahila Samakya contacted the District Collector, who promised to help them but asked: "What will you contribute?" Within five days, the women remitted 7 lakh rupees into their collective account as assurance for seed repayment. This showed the emerging power of the Federation. District Authorities arranged for release of 3600 bags of groundnuts from the Andhra Pradesh State Seed Development Corporation (APSSDC). UNDP supported the effort by providing 8,5 lakh rupees worth of seed capital for Mahila Samakya. At the end of the season, the Federation repaid the groundnut seed to the APSSDC.

In the same year (1997) AME initiated PTD with one women's SHG, Venkateshwara Raita Sangha. The members tried out technologies for improving groundnut production. They identified three effective technologies: gypsum application, rhizobium and application of farmyard manure (FYM). Being convinced about the usefulness of these technologies, they decided to share them with other members of the Federation. Thus, Mahila Samakya became a platform for sharing information and knowledge on LEISA. On request, AME conducted training on LEISA technologies for groundnut for the functionaries of the Federation. They had formed their own training team that trained, in turn, the members of 45 SHGs and their families in PTD and LEISA technologies.

In 2001 and in 2002 two more women's federations were formed in Anantapur District. For the 2002 cropping season these three federations together placed an order for 1000 tonnes of gypsum. The first women's group started applying gypsum on an experimental basis in 1997 - with two tonnes of gypsum. Thus, the three federations ensured a scaling up of this technology by 500% in five years!

Women can move the earth, if given the space!

Lessons learned

LEISA technologies and Women's workload: Some technologies are labour intensive especially for women, e.g. bio-fertiliser and *mussoorie* phosphate application. Other technologies are big labour savers, e.g. in cotton IPM women are spared the work of fetching water for pesticide application, which can amount to 800 km walking with water per acre per cropping season.
We therefore cannot draw any generalised conclusion about whether LEISA technologies are "good" or "bad" for women. Women themselves are in the best position to decide. They take labour increase positively, as long as it is offset by benefits in terms of improved status and/or more say in decisions about the farm and money. Moreover, if they have a problem with a certain technology but also see its advantages, they will be inclined to find ways of making the technology more convenient. This is what happened when women experimented with the use of mussoorie phosphate. They found it dusty and slippery and therefore difficult to apply. They then started mixing it with farmyard manure and the problem was solved.

Health and nutrition have improved: The reduction in pesticide use leads to less health problems (notably reproductive health problems of women) and less medical expenses. Food tastes better and can be kept overnight because the storage capacity has improved. Skin rashes, loss of appetite, respiratory tract problems and reproductive health problems are frequently mentioned in connection with pesticides. These are other reasons why women are interested to learn more about LEISA technologies.

From cash crops to food security: Women have a direct interest in shifting from cash crops to food crops. Women farmers in Hosur shifted from groundnut to ragi (finger millet). They applied the experience gained in the groundnut PTD process on ragi. This interesting process was documented in a video film "Two fistfuls of small grains"(available from AME). Likewise, the farmers in Kadiri shifted from groundnut to bajra (pearl millet).

Increased involvement of women is part of a larger change process: In 1997, 30% out of 270 farmers involved in PTD/FFS processes were women, whereas in 2001, 65% out of more than 12000 PTD/FFS farmers were women. How do we look at these figures? They show that women are quite interested in learning new things about farming. They may also indicate an increased awareness on the side of institutions (NGOs and Departments of Agriculture) about gender issues. But, perhaps the most important reason for this increasing involvement of women is the fact that women are becoming the farm managers, as male migration increases. This is a tough situation for the women. In spite of increased responsibilities and an added work burden, they still have little control over resources and face several institutional gender biases. But there is also a silver lining. Women have found new and powerful ways of organising themselves into Self-Help Groups. And again these SHGs have organised themselves into Federations.

When implementing a PTD process, these factors have to be clearly kept in mind. Forgetting to do so may lead to ineffectiveness of the PTD efforts, and worse, it may lead to more problems for the women.

Gender in our own organisation

To be able to mainstream gender in our programs and projects, we needed to have a *gender sensitive organisation*. Although gender issues were given ample attention, inside the organisation we faced a number of dilemmas and problems.

Women in the organisation: Concerted efforts were made to identify suitable women for positions in AME. However, in reality there are comparatively few well-qualified women in AME's main professional areas who are willing to travel extensively and prepared to relocate to district towns. Also, retaining female staff proved more difficult than retaining male staff. Reasons for the higher turnover of female staff were primarily related to the personal situation (*gender specific*) of those concerned. Secondly, working in a male-dominated professional environment can sometimes be seen as a positive challenge, but it also leads to stressful and difficult situations.

Building a gendered organisational value base: Importance was given to gender sensitisation of the team. Though most team members responded positively, some found it hard to drop some strong and deeply rooted personal values, which were not well aligned with the principle of gender equity. This inconsistency between *strong personal values and organisational values regarding gender* sometimes manifested itself openly in conflicts between staff, but also in omission (intentional or unintentional), and a tendency to separate gender activities from other work (both by technical and social/gender persons).

Team-based structures and gender: AME's organisation structure has been designed in such a way that integration between technical and gender aspects is supposed to be taken care of by interdisciplinary teams in all programmes and activities. Even though these structural conditions for gender integration (and more broadly, for socio-technical integration) were created, in practice integration did not happen smoothly all the time. Time and again, there was the tendency to separate gender activities from other activities in AME.

Working together. Photo: AME

There is a long way to go, but...

Even though women play an increasingly important role in agriculture, this fact is yet to be reflected in more gender sensitive approaches in the majority of agricultural institutions - including our own. Many organisations *work with women*, but they are *not gender sensitive* and hence they contribute, knowingly or unknowingly, to increased physical and mental burdens for women. Still we are optimistic about the future - mainly because we have seen the tremendous energies of women. Once they have organised themselves, they cannot be stopped. They will demand that agricultural institutions become more gender sensitive.
It is up to all of us to respond!

The feminisation of agriculture and the implications for maize development in China

Yiching Song and Janice Jiggins

Research carried out in the mid-1990s highlighted the rapid socio-economic changes taking place in Chinese agriculture. International and national maize breeders, as well as to local authorities in Southwest China, began to consider the implications of these changes for the conservation, development and use of maize genetic materials.

The most profound changes were found to be in the structure of rural households and farming systems, and related changes in the role of women on the farm. These changes could be characterised as the 'feminisation of agriculture', which in China has multiple causes and effects. As the pressure increases on poor rural households to participate in the cash economy, men are migrating in ever-larger numbers to seek wage employment in cities, local industries, or irrigated agriculture in the lowlands. The bias toward male migration is formed in part by the patriarchal expectations of the family. The husband is supposed to provide for his family economically, guide the household's decisions, and mediate its relations with the outside world. Male migration is also favoured by gender discrimination in the wage labour market, which favours men over women in terms of job opportunities, and pays them higher wages even for the same work.

Women are thus assuming a larger and larger responsibility for meeting the household and food needs of the rural family, while the men seek to make their way in the modern economy, creating a system known as 'two households, one family'. Rural women are also assuming the costs of bringing up children, at a time when China's 'one child' policy has reduced the amount of household and farm labour available to support women's efforts. In the absence of their male relatives, women also are taking on unfamiliar roles in community leadership at a time when the certainties of government provision are giving way to the uncertainties and challenges of the market. The traditional division of labour between farm men and women, captured in the folk slogan 'the men till and the women weave', is surrendering to the new reality of 'women till and the men work in industry'. A survey of farmers has shown that, in selected areas of the three Southwest provinces of Guangxi, Yunan, and Guizhou, women comprise more than 85 per cent of the agricultural labour force. At the same time, the traditional expectation that 'men control the outside world, and women the inner world of the home', is giving way to the reality that women must stretch their 'inner world' to include farming and community responsibilities.

Two of the most difficult challenges that women face in their new roles at the head of farms were shown to be:
1) Accessing viable improved seed from the public sector agencies responsible for seed management, and
2) Maintaining a range of varieties that have the particular characteristics suited to women's preferences and farming conditions.

It was noted that two parallel seed systems were in place: one that is supported by the formal plant breeding and extension sector, and one that is maintained by poor farm women themselves. The formal sector is focussed on the breeding and dissemination of hybrid, high-yielding varieties, and is driven by the government's push to raise yields per hectare. In favourable conditions, these hybrids provide stable and high yields. However, many of the formal sector's hybrid products were the result of single crosses and lacked the buffering capacity to withstand environmental shocks or to sustain yields in the face of production constraints. In most smallholder subsistence farming areas in Southwest China, the conditions are not at all favourable, and women farmers also experience great difficulties in getting access to hybrid seed. Therefore, they rely upon exchanging the seed from their own harvests amongst themselves and on their indigenous maize breeding practices.

The formal maize breeding and seed supply system before the new seed law

From women farmers' point of view, the almost exclusively male networks of influence and communication in the formal system, which persisted up to the end of 2000, were impossible to penetrate. Women's specific needs, skills, and knowledge were largely ignored. The primary stakeholder in the formal plant breeding process was the Ministry of Agriculture. The Ministry in turn was linked to public service extension agents, so-called 'leading' farmers, government plant breeders and government-controlled seed companies. At the same time, the government's policy of increasing yields through the development and release of hybrids, failed to deliver products that were adapted to the real farming conditions in the smallholder sector.

There were also institutional problems. The breeders tended to blame the extension workers for not communicating the advantages of the modern varieties (MVs) strongly enough and hence not getting them into the hands of sufficient numbers of farmers. The extension workers blamed the farmers for the poor adoption of MVs in more marginal farming areas. Further, since extensionists working in these areas communicated almost exclusively with the minority population of male farmers, they provided distorted feedback to higher authorities regarding the changes taking place in the structure of farming and regarding farmers' needs. In addition, local governments, Ministry officials and seed companies were rewarded on the basis of the number of new hybrid seed varieties released and planted, which biased the formal system toward agricultural areas that were more favourable for the production of released varieties. Also around this time, some official voices began to express concern about the loss of biodiversity in the more favoured areas where the more genetically uniform MVs were displacing farmers' own varieties.

The tensions created by divergent interests, communication blocks and deteriorating institutional relations between the central and local authorities, began to threaten the continued functioning of the formal seed system. At the same time, the political authorities were concerned that millions of poor farmers remained beyond the reach of the formal system and at risk of hunger, while the scientific capacities of the formal system did not seem to be able to reconcile production and conservation goals.

The new Seed Law: opening to innovation

Toward the end of the 1990s, the government began moving to ease the situation by liberalising and privatising certain roles and functions. The People's Congress approved a new Seed Law that became effective December 1, 2000. It allowed the establishment of pilot schemes in order to test local options for a more effective seed system that might reconcile production and conservation goals, and to test ways to bring the formal seed system and poor farmers' seed systems into a mutually supportive relationship.

The opportunities that the new law opened up for local initiative, and the entry of new participants into seed production and exchange, can be illustrated by reference to developments in the state of Guangxi. Guangxi Maize Research Institute (GRMI) had formerly exercised a monopoly on maize seed production in the state. Under the new Seed Law, it was able, without reference to any other authority, to sign contracts with a 'seed production base' such as a village or farmers' organisation, for the production of new planting seed. The conditions of such contracts are that the seed production base must be ready and able to multiply the seed that GMRI develops, and to sell the seed harvest back to the GMRI for distribution to other areas. The villagers or farmers benefit by receiving twice the normal price for the new seed, in comparison with sales of unimproved maize seed to the government.

However, since the incentive price for maize seed remains lower than the market price, new tensions have developed between the GMRI and its suppliers. Meanwhile, since all of the early contracts were issued to 'seed production bases' controlled by men, and to units in the somewhat more favoured areas, at first poor women farmers continued to be excluded.

Women farmers as expert maize breeders

In the case study village of Wenteng, women farmers definitely preferred open pollinated varieties (OPVs) to hybrid varieties, for a number of reasons:

- The seeds can be saved and used again the following year, whereas hybrids lose their vigour after one cropping cycle;
- Farmers can manipulate the genetic material themselves to produce varieties that have desired characteristics related, for example, to yield, stress resistance, taste, storage, and cooking qualities, and to the intensity of crop management;
- OPVs offer the potential for continuing evolution at local level. The 1998 CIMMYT Impact Study was one of the first to document in detail the practices by which women acquired, maintained, and refreshed their preferred varieties through OPV hybridisation.
- OPVs can be crossed with materials brought into the farming system from elsewhere, including those obtained through the formal seed system. The word 'creolisation' is used in this context to refer to the processes by which farmers maintain and improve introduced cultivars.

Women who are known in the village to be expert maize breeders skilfully control the breeding process, from field design to seed selection through to pollination. The women claim that they have maintained their landraces (traditional varieties) through generations by separating the planting of landraces in space and time. The seed that is destined for the following year's planting is harvested, cultivar by cultivar, in a three-step process. The first step is to select the best plants from the middle of the field, that is, healthy, vigorous plants with big maize ears. Step two is to select the best ears based on cob size, length, and the number of seed rows. Step three is to select the best grains from the middle portion of each ear, based on kernel size, shape, quality, and colour.

The process of collaboration

Since the beginning of 2000, a Participatory Plant Breeding (PPB) project has been implemented in Guangxi province by the Center of China Agricultural Policy. The general goal of the project is to enhance the linkages and collaboration between the formal and farmers' systems. PPB and PVS (Participatory variety selection) field trials have been used as a platform for interaction and collaboration between the main stakeholders, i.e. women and men farmers, extensionists and breeders. Six Farmer Plant Breeding Villages were selected in the trial area to represent farmers' seed systems. They were selected on the basis of the previous research and through an analyses of local stakeholders, in order to represent a range of agro-ecosystems and socio-economic conditions, as well as a range of potential opportunities for institutional collaboration with women farmer groups.

Women farmers taking notes in a maize field. Photo: Yiching Song

In the beginning, it was something of a surprise to the scientists and extension workers to discover that men and women, the poorer and better off farmers, or farmers in different farming areas, can make different choices when selecting the varieties, and varietal characteristics that they prefer. Today, these actors are together learning, among other things:

- how to characterise the goals and needs of different types of farmers and of professional plant breeders, as well as the socio-economic environments in which maize is grown;
- male and female farmers' preferences, their indigenous practices and knowledge of plant breeding, seed selection and landrace maintenance; and
- to identify the genetic importance of existing landraces and other creolised local varieties.

The scientists are also trying to understand how farmers have used the genetic material introduced by the formal seed system to create creolised local varieties.

In the process, the male extension workers and scientists are beginning to recognise how women's preferences are linked to their roles in the household. For example, women consistently give a higher rating to 'cooking quality', and to their need to ensure food security even if planting seed cannot be purchased from the market. In contrast, men tend to give higher preference to characteristics that match the demands of the market, such as ability to yield well when grown together with other high value crops such as sweet potato. They are also realising that there are marked differences in the number and type of selection criteria that professional plant breeders consider important, compared to farmers. For example, six men and ten women farmers, three men and four women extension workers, and six men and two women formal plant breeders together examined maize trials during a field day held in June, 2001. The farmers mostly preferred improved varieties of established landraces and creolised populations over the 'superior' hybrid preferred by the formal breeders. The formal breeders assessed a variety almost exclusively in terms of yield and its value in the breeding programme, whereas farmers were also interested in a variety's performance during drought, or its ability to perform well even if fertiliser was not used, whether or not seed could be saved for the next year's planting, or the plant's shape, grain colour, and cooking quality.

In addition to the differences in the selections made by men and women farmers, the farmers from different villages also made different selections, reflecting the distinct climatic and other conditions of each village.

Conclusion

In all, the partners who work in the formal organisations are recognising just how heterogeneous farmers' needs and opportunities are, and that a 'one size fits all' approach will not assist China to develop its agriculture as efficiently and as productively as the authorities would like. Since the numbers of farmers and the areas to be covered are huge, this in turn is forcing an acceptance of a greater role for local organisations controlled by farmers and villagers themselves, as effective counterparts to the formal plant breeding and seed dissemination system.

The collaboration is leading to changes in the ways that plant breeders and extension workers think about their work and behave towards women and men farmers. Over time, the knowledge, skills, and attitudes of the breeders and extensionists, on the one hand, and the farmers, on the other, are drawing closer together, which strengthens all participants. ■

The feminisation of agriculture

Editorial

The majority of the world's agricultural producers are women. They produce over 50% of the food that is grown worldwide – more in most developing countries. In Sub-Saharan Africa, for example, women produce around 80 percent of food, both for household consumption and for sale. Women are usually responsible for food processing and also make a major contribution to food storage, transportation and marketing – although they seldom control the revenue generated. In almost all societies, rural women tend to work longer hours than men. Although the gender distribution of work and responsibilities varies with country, culture and situation, women are usually responsible for at least a large share of food production, preparation and processing, as well as the more fundamental roles of nurturing and caring for children and the elderly.

Despite these recognised facts and a considerable amount of development rhetoric about gender issues, women are still restricted in their role as farmers by unequal rights and unequal access to and control over resources, especially land. In India, Nepal and Thailand, for example, fewer than 10 percent of women farmers own land. In Kenya, although 98% of women work full-time in the agrarian sector, only 5% have land ownership titles (Schüssler p.28). Equal rights are internationally agreed upon in a number of instruments (see box), however this is slow to translate into practice.

In addition, women still carry out their work without much help from agricultural support mechanisms such as extension agencies, input suppliers and credit institutions. Women farmers receive less than 5% of extension services worldwide. The priorities of the woman farmer are rarely reflected in agricultural research or national policies, and when they are, this is often not translated into practice in agricultural development planning. Women, as producers, still remain largely invisible and unsupported. Mainstream investments and development interventions tend to focus elsewhere – and as a result, they are often ineffective.

So far, rural women have shouldered their burdens and often manage to cope. Modern times, however, have added to their load. In many parts of the world today there is an increasing trend towards what has been termed the 'feminisation of agriculture'. Men are becoming increasingly absent from farms and rural areas. In the face of economic change, men are migrating from rural areas to towns and cities, in their own countries or abroad, in search of paid employment. In addition, war, sickness and death from HIV/AIDS take a high toll on rural male populations. Women are therefore taking more and more responsibility for agricultural production, and there has been a great increase in the proportion of households headed by women.

Single: de facto or de jure?

A woman (or man) can be "single" in two different ways: de jure or de facto. If she is not married, or a widow, she is in fact and in the legal sense single – she is single de jure.

If she is married and her husband is alive, but for one reason or another is not living with her, she is considered single de facto. That is, she is not single in a legal sense but in practice.

It is an important distinction, as a woman's status and rights are often strongly dependent on her marital status. In particular, a woman's access and rights to productive resources, as well as the income from what she produces, is often strongly dependent on her civil status.

Ethiopian farmer and her ensete crop. Photo: Flemming Nielsen

One-third of all rural sub-Saharan African households are now women-headed. Women heads of household are often younger and less educated than their male counterparts, and have less land, less capital and less labour available to them. The land and other resources that they do use and have access to are usually controlled by the owner (often their husband) who also has the decision making power and retains it even if absent from the farm.

What can be done to support women farmers? The contributions of authors to this issue of LEISA cover a wide range of issues addressing the many facets of women's role in agriculture.

Different priorities, strengths, and needs

Women farmers often have different priorities to their male counterparts, and this can, in many cases, be related to their more direct role in feeding the family. Pionetti (p. 22) describes the stark contrast in the depiction of agricultural practices by women and men farmers in India. Men eagerly speak of their cash crops and commercialised agriculture, whereas women farmers speak about the food crops they grow, and value crop diversity. Chiwona-Karltun *et al* (p.14) describe how men are more interested in sweet cultivars of cassava, because they have a well-established market, whereas women prefer bitter cultivars for food security reasons, even though it takes more work to process.

In China, as in many other cultures, there is a traditional expectation that 'men control the outside world, and women the inner world of the home'(Song and Jiggins p.6). Such traditional perspectives can contribute to the lop-sidedness of "gender blind" information, collected by outsiders with the intention of helping a community. It is usually the men who provide information to outsiders, as such communication belongs in the "outside world". This means that women's priorities are often overlooked, unless they are specifically taken into account.

With the "feminisation" process, women must expand their world to include "outer world" aspects of agriculture and community responsibilities. Not taking women into account can mean ignoring not only the particular needs of women as opposed to men, but whole households headed by women who now have to take on double the responsibility.

The social effects of a changing economy

Economic change, driven by external forces, can unbalance gender relations and leave women with limited options. Lapoutre (p. 24) describes a process of community upheaval where rapid appraisal methods, which mainly focus on tangible information, were simply not sufficient to understand the processes of social change. By digging deeper and understanding the social dynamics of the situation, members of the community were able to relate the negative spiral of changing economic and social circumstances to changing cultural habits and preferences. Based on this understanding, it may be possible to rebuild a healthy community with space for women to develop, economically and socially.

Understanding the social aspects of economic change can also help to assess the merits of other options. Eisses and Chaikam (p. 26) describe the social benefits obtained by members of the Don Jieng Organic Farmers Group, who, after changing to organic agriculture, did not have time to work in the city, due to the increased labour requirements of organic production. Moreover, they no longer needed to work in the city to pay for agricultural inputs. The economic benefits of farming organically were not very different to the economic benefits of farming with inputs, but the social benefits of having the men in the village meant that membership of the organic farmer's group doubled within a year.

Access to and control of resources

Access to and control of resources is a power issue. In most developing countries, women's access to land and other resources is constrained as a result of cultural, traditional and sociological factors. This can also extend to agrarian reform. Schüssler (p.28) highlights the need to pay special attention to gender perspectives in all forms of land redistribution, entitlement programs and accompanying measures. This means not only making sure that women do not face active discrimination such as (in points-based land distribution schemes) awarding men higher points, but also compensating for indirect discrimination - such as awarding points for a higher education, in areas where women are discriminated against in the education system. Without a title to land, women have less control over their production and are often also denied membership of co-operatives and other rural organisations, and the accompanying benefits. Women have more and more responsibilities in the agricultural sector - they must also be allowed the power to effectively meet these responsibilities!

Mainstreaming gender considerations

Development organisations need to take gender considerations into account. Women have different needs and priorities, which are at least as important for food security as those of the men. "Gender mainstreaming" means that all activities conducted by a particular organisation must take into account different gender needs, and target them explicitly. De las Mercedes Rocha *et al* (p.18) and van Walsum (p.10) describe the importance of including both women and men in gender sensitisation - and how to bring it back into your own organisation.

Gender is the term for the socially and culturally defined roles for each of the sexes. Although women are women everywhere on earth and men are men, what is considered a "normal activity" for each of the sexes varies from place to place and from culture to culture. In one place it is normal for women to do most of the land preparation, whereas in another, it may be done exclusively by men. In one place it can be normal for women to do the fishing, whereas in another, fishing is reserved for men. The variation in these roles suggests that the different activities of women and men in practice have less to do with their biological sex, than with the social and cultural context in which they live. We talk about gender rather than sex because while a person's sex does not change, gender roles are socially determined and can evolve together with society.

Women's rights in international treaties – some examples

- Universal Declaration of Human Rights
- International Covenant on Economic, Social and Cultural Rights
- International Covenant on Civil and Political Rights http
- World Conference on Agrarian Reform and Rural Development 1979
- Convention on the Elimination of All Forms of Discrimination against Women
- Agenda 21 adopted at the Rio Summit 1992
- Vienna Declaration and Program of Action 1993
- Beijing Declaration and Platform for Action 1995
- Copenhagen Declaration on Social Development and the Program of Action of the World Summit for Social Development 1995
- Habitat Agenda adopted in June 1996 by the World Conference on Human Settlements (Habitat II)
- Commission on Human Rights resolution 2000/13 concerning "Women's equal ownership of, access to and control over land and the equal rights to own property and to adequate housing".

See www.ileia.org for links to many of these agreements on internet.

Simple technology to lighten the work

Women tend to work longer hours than men, and yet their needs and priorities are rarely considered in the research and development of agricultural technology. Simple labour-saving technologies can help women considerably in daily tasks such as food processing and storage, as well as food production and work related to water, sanitation, fuel and food preparation. Ross and Ross (p. 9) provide examples of several simple tools that can help relieve women's drudgery, such as wheeled hoes and broadforks. By taking women's needs into account in technology development, such simple implements can greatly increase women's quality of life - and the time available to do other work.

Never underestimate what women can do!

Where women are given space and opportunities, they can become tremendously valuable leaders in restoring community cohesion. Women Animal Health workers in India, for example (Ghotge and Ramdas, p. 16) apart from their role as 'healers', have also begun to take on leadership roles within the village women's groups and the community. They have been helping to resolve conflicts within families and to mobilise others in the village to address gender issues. These women feel that by acquiring specific skills through training, they have gained status in the family as well as in society. They work closely and in harmony with the village healers, who are usually men.

Women's groups involved in participatory technology development (Van Walsum, p.10 and Lemunyete p.20) have developed many successful technologies and these groups have even, in some cases, formed their own teams to train other groups and their families in the technologies developed.

The solution to the problems posed by the feminisation of agriculture is not simply a matter of recognising the value of women in a static sense. Rural communities are changing, and the role of women must be seen in the context of their role in community development. One fact becomes very clear, on reading the contributions of authors to this issue of LEISA: Women are the primary supports of the community. Food security, as well as the social health of the community, depends on including them in the development process. ■

CONTENTS

Many farmers not only prefer, but also grow a higher proportion of bitter cassava cultivars than sweet cultivars - despite higher levels of toxins and more work required to process the bitter cassava. Women in particular prefer the bitter cassava cultivars, despite the additional processing work, because they have superior end-product qualities and because the toxin protects the crop from intruders of all kinds, man and beast alike. This article looks at the difficulties faced by farmers in Malawi, where the dominant maize crop does not provide food security. The farmers were having problems in obtaining cassava stem cuttings with desirable characteristics, and gender-balanced exchange visits between farmers in different areas were successful in helping to address this problem. The needs of women farmers that were single, *de jure* or *de facto*, became clear in these visits - they were keen to select as many bitter cassava varieties as possible, in order to minimise the risk of crop failure.

"Small change" crops are suited to dryland conditions, grow without any extravagant need of inputs, and meet the food and fodder requirements of the household. As a woman farmer from Pipri said "If we only grow cotton, where is the fodder for our cattle going to come from?". Yet, a majority of agricultural extension officers, agricultural scientists, breeders, rural bank managers and even policy-makers pay no attention to the queries and concerns of women, especially when they are 'merely' poor farmers. In domains that are typically under women's responsibility, like seed saving, weeding, and cooking, it is quite vital that women's concerns be allowed to emerge and to inform policies. This article looks at the difference in women's and men's perceptions, and the need for a sustained effort on the part of agricultural extension workers, scientists and policy-makers to understand women's practices and perceptions in agriculture, including cultural, social and symbolic dimensions.

ILEIA is the Centre for Information on Low External Input and Sustainable Agriculture (LEISA) in the tropics. ILEIA seeks to promote the adoption of LEISA through the LEISA Magazine and other publications. It also maintains a specialised information database and an informative and interactive website on LEISA (**http://www.ileia.org**). The web site provides access to many other sources of information on the development of sustainable agriculture.

LEISA is about Low-External-Input and Sustainable Agriculture. It is about the technical and social options open to farmers who seek to improve productivity and income in an ecologically sound way. LEISA is about the optimal use of local resources and natural processes and, if necessary, the safe and efficient use of external inputs. It is about the empowerment of male and female farmers and the communities who seek to build their future on the basis of their own knowledge, skills, values, culture and institutions. LEISA is also about participatory methodologies to strengthen the capacity of farmers and other actors to improve agriculture and adapt it to changing needs and conditions. LEISA seeks to combine indigenous and scientific knowledge, and to influence policy formulation in creating an environment conducive for its further development. LEISA is a concept, an approach and a political message.

28 Land in the hands of women?

Renate Schüssler

Land issues are issues of power. This is apparent not only in the unequal distribution of land between large commercial plantations and small farmers, but also in the inequities between men and women in terms of access to land. In this article, Schüssler looks at gender balance in the context of agrarian reform, including examples from around the world. To achieve greater gender democracy, it is important to pay special attention to gender perspectives in all forms of land redistribution, entitlement programs and accompanying measures. Under conditions of structural injustice, justice cannot be introduced by mere equal treatment – compensatory measures are necessary.

20 Developing camel products: pastoralist women and PTD

Laura Lemunyete

Members of Salato Women's Groups have been successful in developing several important food security items that group members are now producing for household level use. While the PTD methods have already resulted in several good products, the Salato Group members have learned that technology development is an ongoing process and they continue to seek new and better ways of preserving their meat and milk products. Positive outcomes of their work have included increased income and other benefits - from a camel drug fund to greater food security.

DEAR READERS

There seems to be general agreement on the fact that in many parts of the world, women are taking on an increasing responsibility for agricultural production, as men are becoming increasingly absent from farms and rural areas. The reasons behind this trend are many - including factors such as low prices for agricultural produce and the need to increase cash income, leading to male migration to urban centres in search of work; and the AIDS epidemic, which is increasing its toll on the most productive generation, leaving older women and children behind with the task of supporting themselves. So what are the responses to this trend? How does the formal agricultural system tackle the challenge of supporting women and children with appropriate technologies and supportive measures such as credit?

These were the issues we wanted to explore in this issue, and we tentatively called the theme the "Feminisation of Agriculture". Unfortunately, we quickly became frustrated. We simply could not find good examples of practical solutions. We found lots of studies about the problems and constraints women farmers face and about how important they are as food producers. But almost nothing on how to assist them. We started to wonder if we were looking in the wrong places. Surely, after thirty years of gender focus in development co-operation there had to be something positive happening for the women involved in agriculture?

After a lot of searching we compiled the material that you will read in this issue. It is less practical and offers fewer solutions than we had hoped - instead it provides an understanding of the challenges that women farmers face and of how important it is to understand the gender dimensions in agriculture if you are hoping to change things for the better.

However, we are not satisfied with this. We are still hoping that we have actually missed lots of interesting and useful approaches that benefit women farmers. Please get in touch with us if you have good experiences to share!

Experiments with spiders, ants and other indigenous practices

Some tribal communities are using social spiders (Stegodyphus sarisinorium) to control stem borers in paddy fields. Photo: K.J.N. Gowtham Shankar

K.J.N. Gowtham Shankar

IDEA is a NGO working with tribal people in the northern Ghats in India. IDEA is a partner organisation in the COMPAS Programme for Endogenous Development (see LEISA Magazine Vol. 17, No2, p15).

During documentation of tribal indigenous knowledge in 1992, we found that some tribal people use spiders to control stem borers in paddy fields. This was interesting but needed further analysis. We identified the spider as *Stegodyphus sarisinorium* - a social spider. The spider is called differently in the local languages - *Patmakidi* in Oriya, *Salepurugu in* Telugu, and we call it *Bulu*. We also found that using spiders for pest control is an age-old practice of a specific tribal community - *Nooka Dora* - of Andhra Pradesh and Orissa, border villages in the north eastern Ghats, India. However, the knowledge was almost dying out as only 5-6 families were practising it in a remote village and that too only in paddy fields. We stimulated some young tribal farmers and senior farmers to conduct several small and simple experiments in the research centre of IDEA, which proved to be very effective. Based on the results, we did further experiments together with farmers in different villages for validation by the community. These were also successful. Then, we designed a systematic process for participatory action research and started studying various aspects of this spider - its habitat, feeding habits, breeding biology etc.

Simultaneously, we experimented with Bulu on horticulture crops (guava and pomegranate), vegetable crops (brinjal, ladies finger, cabbage, cauliflower and chilli) and floriculture crops (roses). We found out that this spider can successfully control fruit borers and mites in these crops.

This study helped us to disseminate the knowledge gained among more tribal communities and farmers. We developed training material on the experimentation and propagation techniques of Bulu and provided training to more than 500 farmers for conducting further on-farm experiments on different crops in their villages together with other farmer families.

The knowledge vested with just 5-6 families of a single community has now spread to more than 2000 farmers of 6-7 communities. It is spreading further to other areas due to regular farmer network interactions and farmer-to-farmer knowledge exchange, which we are facilitating through ongoing projects.

Control of black ants with domestic red ants

We also found that some of the *Konda dora* tribal farmers control black ants with tiny domestic red ants in their *Jawor* fields. Mountain farmers face a severe threat from black ants, which eat away the tender *Jawor* grains and damage the crop. Some of the senior farmers collect these domestic red ants from their houses and drop them in the fields affected by black ants. These red ants eat the eggs of black ants laid around the *Jawor* plant roots and attack the black ants. The black ants leave the fields within hours. We found this particularly simple technique of using red ants to control black ants very effective.

IDEA's research staff further tested this with other farmers for validation in different villages. The results were successful. We have systematically documented this knowledge and trained farmers in promoting it widely in other areas. Now, many farmers in the mountain villages are using this technique to control black ants in their *Jawor* and maize fields.

Experiments with botanical pesticides

We also did several experiments with indigenous knowledge of tribals on botanical pesticides. Thus, we have revived the use of many of these botanical pesticides.

■

Our tribal farmers' networks would like to interact with farmers of other countries for mutual exchange of information on indigenous knowledge and endogenous development approaches. We will be happy if you send your comments and suggestions to the following address

Issue 19.1, March 2003

Farmer Field Schools - emerging issues and challenges

The Farmer Field School (FFS) approach was first developed in the late 1980s for training rice farmers in Integrated Pest Management (IPM). The success of this discovery-learning approach based on the principles of adult education has contributed to its popularity. The FFS approach is now being applied and adapted in many regions of the world - Asia, Africa and Latin America. It is not limited to rice, but used in a variety of other crops and livestock. Farmer Field Schools are seen as entry points towards community strengthening and empowerment. As the FFS approach gains more ground, new issues and challenges emerge, i.e. maintaining quality in implementation, reflection of the core principles etc.
These issues and challenges will be the focus of the International Learning Workshop on "Farmer Field Schools - Emerging Issues and Challenges" to be held in Indonesia in October 2002. This issue of LEISA will include the findings of this workshop and highlight some of the interesting cases. We invite articles on experiences in applying/adapting FFS to various agro-ecological, socio-cultural and economic situations, monitoring and evaluation of FFS, upscaling FFS approaches etc. that would be interesting to field practitioners and add to the knowledge generated at this workshop.

You are invited to contribute to these issues with articles (about 800, 1600 or 2400 words + 2-3 illustrations and references), suggest possible authors, and send us information about publications, training courses, meetings and web sites. Editorial support is provided by ILEIA. Authors of published articles are entitled to a standard fee of USD 75,–.

Agroforestry species and technologies : a compilation of the highlights and factsheets published by NFTA and FACT Net 1985-1999
by Roshetko JM (ed.). 2001. 231 p. ISBN 1 57360 032 6. Winrock International, 38 Winrock Drive, Morrilton, AR 72110-9370, USA / forestry@winrock.org
Taiwan Forestry Research Institute. (TFRI Extension Series no.138).
This booklet assembles under one cover 97 factsheets and highlights published by the Forest, Farm, and Community Tree network (FACT Net) and its predecessor NFTA. These bulletins are concise summaries of important information on tree species and agroforestry technologies suitable for many environmental and socioeconomic conditions. A large number of nitrogen fixing trees and actinorhizal trees is discussed in alphabetical order. The publication provides a species index but this is disappointingly incomplete. Still the booklet is a practical reference tool for everyone involved in agroforestry.(WR)

Bridging human and ecological landscapes : participatory research and sustainable development in an Andean frontier by Rhoades RE (ed.). 2001. 368 p. ISBN 0 7872 8473 4 USD 40.97. Sustainable Agriculture and Natural Resource Management (SANREM) / www.sanrem.uga.edu ; anthro@arches.uga.edu. Kendall/Hunt Publishing Company, 4050 Westmark Drive, Dubuque, Iowa 52002, USA.
This book is a synthesis of the rich results of an interdisciplinary research programme on sustainable agriculture and natural resource management conducted in the mountainous landscape of Nanegal Parish, Ecuador. The major themes of the book, and its individual chapters, aim to show how people and the environment have engaged each other over time to create the human and natural landscape of Nanegal. The authors demonstrate that the landscapes are as much a medium of ideas and imagination of the people who live there as they are physical realities. The landscape pervades almost every aspect of daily life, and its pervasive quality derives not only from the natural lay of the land, but from the multiple ways farmers have encountered, constructed and represented it over time. By integrating these visions of the landscape, distinct but complementary, this volume provides a guide map to a sustainable future for people living in the mountains and hillsides of the world. Also available in Spanish, editorial@abyayala.org.

Reorientation of extension : a case study of participatory action research with a Non-Government Organisation in Northern Nigeria by Ehret W. 1997. 275 p. ISBN 3 8236 1279 4. (Kommunikation und Beratung, Sozialwissenschaftliche Schriften zur Landnutzung und ländlichen Entwicklung 17). Margraf Verlag, Postfach 1205, 97985 Weikersheim, Germany / margraf@compuserve.com.
In this book, the author documents a reorientation process of five years which he accompanied as a participative action researcher in a NGO in Nigeria. First the methodology of extension was changed, followed by a reorientation of the entire organization. The introduction of increased participation effects all three levels of extension services, the community, extension workers and organisation. In the communities the number of self-help activities, initiated and accompanied by the extensionists, increased significantly during the research period. For the extension workers it was diffecult to apply participative methods successfully in the beginning. It took at least three years of intensive coaching to get them used to these methods and to get them feel at ease applying these methods. However, at organisational level it was observed that the transformation towards participative concepts was difficult and that participative measures could only be introduced to a certain limit. The reorientation process revealed that achieving participation at the extension/client interface is easier than establishing participative management within an organisation. Also the specific situation of NGOs has been analyzed with the conclusion that NGOs lose their comparative advantages as they become bigger and, thus, more government-like.(WR)

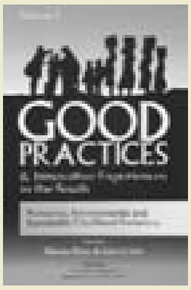
The living plateau : changing lives of herders in Qinghai : concluding seminar of the Qinghai livestock development project
by Wageningen N van, Wenjun S (eds). 2001. 96 p. ISBN 92 9115 376 1. International Centre for Integrated Mountain Development (ICIMOD), G.P.O. 3226, Kathmandu, Nepal / icimod@icimod.org.np / www.icimod.org.
The living plateau is about interventions by a development project for the improvement of the livelihood of sheep and yak herders on the Quinghai-Tibetan Plateau, China. The document takes stock of rangeland and livestock resources and describes the socioeconomic situation of herders. It summarises the outcome of field trials and technical interventions in the area of rangeland rehabilitation, the control of rodents, rangeland revegetation, seeded perennial forage and cereal fodders, the control of parasites in yak and sheep, and the control of young stock diseases. It further addresses the experiences of disseminating findings through extension services, and it reviews extension, including experiences with participatory rural appraisals. This small but concentrated document is a valuable information source because it contains the critically reviewed findings and lessons learnt from a large development project. (WR)

The real green revolution : organic and agroecological farming in the south by Parrott N, Marsden T. 2002. 147 p. ISBN 1 903907 02 0 EURO 12.- or downloadable. Greenpeace Environmental Trust, Canonbury Villas, London N1 2PN, UK / www.greenpeace.org.uk/realgreenrev.htm.
Greenpeace has launched an advocacy report for agroecological farming techniques, meant to contribute in the debate on the future of agriculture. The agricultural approach described emphasises the importance of using locally available resources and building agrobiodiversity to create productive and resilient agricultural systems. The report provides evidence from around the globe of the successes of the agroecological method: increased yields, enhanced food security and improved incomes. Recommended for policy makers and organisations involved in advocacy of sustainable agricultural development. This report is downloadable as html file from our website.(WR)

Ethnoagricultural development ; building on the strengths of indigenous beliefs and practices by Cooten DE van. 2001. 191 p. ISBN 1 876862 60 2 AUD 35.00. Kingdom Kookas Publishing, P.O.Box 133, Sanderson 0813, Northern Territory, Australia / winkent@optusnet.com.au.
Donald van Cooten has investigated the indigenous shifting, slash and burn agricultural systems in South Eastern Indonesia from a development point of view. In his book he concludes that ethnoagricultural development is the process of facilitating sustainable, agricultural development in the context of indigenous beliefs and practices. Agricultural development needs to proceed through the traditional religious leaders and bring about an indigenous enrichment movement. He sees the role of outside organisations in supporting and strengthening indigenous leaders and their communities.

This book provides necessary information on the indigenous people of the region and their sustainable, low external input agricultural systems. Agricultural development efforts should be aimed at ensuring sustainable production within the present systems. To make this possible studies like this one are needed, but a more participatory approach is also needed.(WR)

Securing tomorrow's food : promoting the sustainable use of farm animal genetic resources : information for action
by Geerlings E, Mathias E, Köhler Rollefson I. 2002. 89 p. League for Pastoral Peoples, Pragelatostrasse 20, 64372 Ober-Ramstadt, Germany / www.pastoralpeoples.org ; gorikr@t-online.de.
Farm animal diversity is vanishing at an alarming rate. As industrial livestock production expands, it is relying on fewer and fewer breeds. We are coming to depend on a livestock population with a dangerously narrow genetic base. Locally adapted animal breeds carry genetic material of immense value. These breeds must be conserved. The only realistic way to do so is by maintaining the production systems they are part of, by supporting the small farmers and pastoralists who manage these animals. The goal of this dossier is to stimulate policy makers, project staff and members of grassroots organisations to support, in their policies and actions, the sustainable use and community-based management of farm animal breeds. Important information, free available.(WR)



Good practices and innovative experiences in the south : vol 1 economic, environmental and sustainable livelihood initiatives by Khor M, Li Lin L (eds). 2001. 260 p. ISBN 1 84277 129 9 GBP 15.95.
Good practices and innovative experiences in the south : vol 2 Social policies, indigenous knowledge and appropriate technology by Khor M, Li Lin L (eds). 2001. 215 p. ISBN 1 84277 131 0 GBP 15.95.
Good practices and innovative experiences in the south : vol 3 Citizen initiatives in social services, popular education and human rights by Khor M, Li Lin L (eds). 2001. 260 p. ISBN 1 84277 133 7 GBP 15.95.
Third World Network, UNDP. Zed Books, 7 Cynthia Street, London N1 9JF UK / hosie@zedbooks.demon.co.uk.
United Nations Development Programme has collected a valuable number of case studies from developing countries all over the world. These case studies are gathered in three volumes of "Best Practices" for sustainable rural development. The aim of these books is to contribute to the exchange of these appropriate experiences between the different countries.
The described practices and experiences have been successful in solving environment, social and development problems. They cover the governmental sector as well as private and social institutions, NGO's and local communities. Each case study is extensively described, with detailed information on contact persons and background, mentioning the results and problems faced, and possibilities for upscaling.
The topics cover a variety of issues in policy, agriculture, economic, livelihood and gender. These books are recommended for everyone who is involved in sustainable development.(WR)

Ber (Ziziphus mauretania) by Pareek OP. 2001. 291 p. ISBN 854327525 GBP 15.- free of charge for developing countries. International Centre for Underutilized Crops, University of Southampton, Southampton SO17 1BJ, UK / A.Hughes@soton.ac.uk.
This monograph on the tropical fruit trees Ber and Chinese jujube, both Ziziphus species, provides thorough information on production, processing, marketing and utilisation of these species. Tropical fruit trees are important crops which can supplement and improve the quality of diets. Ber is a multiple purpose tree that produces non-food products like fuel, timber and leaf fodder together with a valuable fruit crop. Ber is cultivated all over the drier parts of the Indian subcontinent for its fresh fruits, which are rich in vitamins and minerals. It can be successfully cultivated even in the most marginal ecosystems of the subtropics and tropics. The tree propagates freely and greatly resists recurrent drought. It is thus an important tree suitable for integration into agroforestry systems of warm desert ecoregions. The tree can help in economic sustenance and insure against ecological degradation. Chinese jujube is cultivated in the drier parts of China; it can tolerate very low temperatures and is thus suitable for growing in colder regions.
This book is intended for researchers, students and NGO's. It is written in a rather scientific manner and completed with a list of "ber" experts and a seed suppliers directory. An extension manual for dissemination to farmers, field workers and policy makers is in preparation.(WR)

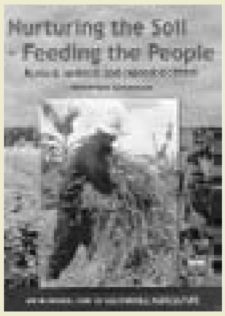
Participatory communication and adult learning for rural development by Coldevin G. 2001. 36 p. Food and Agriculture Organization (FAO), Sustainable Development Department, Extension, Education and Communication Service, Viale delle Terme di Caracalla, 00100 Rome, Italy / loyvan.crowder@fao.org.
Gary Coldvin has written this review paper on participatory communication and adult learning for rural development. The purpose of the publication is to provide an overview of the FAO Communication for Development Group's work as practitioner of applied communication for agricultural development over the past thirty years. During this period the role of communication has shifted from a one-way, top-down transfer of messages to a social process with a two-way sharing of information among communication equals, participatory communication. By seeking the views of the rural people themselves and involving them from the start of a project, participatory communication has become an important tool for successful implementing development initiatives. This paper provides a number of examples and cases drawn from FAO's field programmes and a lessons learned section.(WR)

Farmers and plant breeders in partnership
by Hanacziwskyj P (ed.). 2001. 28 p. Department for International Development (DFID), Plant Sciences Research Programme, University of Wales, Thoday Building, Bangor, Gwynedd LL57 2UW, UK / dfid.psp@bangor.ac.uk ; www.dfid-psp.org.
Participation allows plant breeders and farmers to learn from each other. In this paper of the Plant Sciences Research programme of DFID, advantages of the participatory approach are illustrated by examples of successful projects on participatory varietal selection and participatory plant breeding in Ghana, India and Nepal. In this research programme, farmers in developing countries are involved in the breeding, selecting and testing of new plant varieties. Such participatory crop improvement identifies or creates varieties to suit local needs, as well to marginal as to high-potential production systems.(WR)

Waste composting for urban and peri-urban agriculture : closing the rural-urban nutrient cycle in Sub Saharan Africa by Drechsel P, Kunze D. 2001. 229 p. ISBN 0 85199 548 9 GBP 45.- IWMI, FAO. CABI Publishing, Wallingford, Oxon OX10 8DE, UK / cabi-nao@cabi.org ; www.cabi.org.
Urbanisation has created a major challenge with regard to waste management and environmental protection. However, the problem can be ameliorated by turning organic waste into compost for use as an agricultural fertiliser in urban and peri-urban areas. This is especially significant in developing countries, where food security is also a key issue. This book addresses these subjects and is mainly based on papers presented at a workshop held in Ghana by the International Board for Soil Research and Management (part of IWMI) and FAO. Special reference is given to sub-Saharan Africa, with acknowledgement to experiences from other parts of the world. Contributing authors are from several European and African countries. This book provides a number of case studies, technical information and an analysis of constraints for the use and production of composted waste.(WR)

Vrkshayurveda : ayurveda for plants by Sridhar S, [et al]. 2001. 47 p. Centre for Indian Knowledge Systems (CIKS), No 30, Gandhi Mandapam Road, Kotturpuram, Chennai 600 085, India / ciks@vsnl.com ; www.ciks.org. (User's Manual-1).
This user manual on Vrkshayurveda is focused on certain aspects of plant nutrition and pest and disease management. Vrkshayurveda is an ancient Indian science dealing with all aspects of plant life. This booklet begins with an introduction to the subject. It lists certain important farmers' practices and provides a rationale for these practices based on the theory of vrkshayurveda. One section is devoted to specific recipes for disease treatment, for increasing general resistance to diseases and pests and seed treatments for increasing crop growth and yield. Use of specific growth regulators based on vrkshayurveda is also recommended. The recipes that have been recommended are based on field trials carried out by the Centre for Indian Knowledge Systems.(WR)

Participatory diagnosis of soil nutrient depletion in semi-arid areas of Kenya by Gachimbi LN, Jager A de, [et al]. 2002. 15 p. NUTNET programme International Institute for Environment and Development (IIED), Drylands Programme. (IIED Managing Africa's Soils, ISSN 1560 3520 ; 26). Drylands Programme, IIED, 3 Endsleigh street, London WC1H ODD, UK / drylands@iied.org / www.iied.org/drylands.
This paper describes the participatory diagnostic process undertaken as part of a 5-year research programme aimed at developing improved land and water management techniques in semi-arid areas of Kenya. The study indicates that farmers in the drylands of Machakos are well aware of the precarious condition of their soil resources. Soil sampling and nutrient monitoring activities jointly conducted by farmers, extension agents and researchers have increased their understanding of the causes of soil nutrient depletion, and farmers now recognise that soil quality is gradually declining because current farming systems do not use enough inputs to replenish nutrient stores in their soils. The results of the described diagnostic phase have been incorporated into a second programme in which the same group of participants test and evaluate new techniques. We look forward to the results of that project. (WR)



Nurturing the soil - feeding the people: an introduction to sustainable organic agriculture: revised, updated, and expanded edition by Scheewe W. 2000. 277 p. ISBN 971 23 2895 3. Rex Book Store, 856 Nicanor Reyes, Sr.St., Manilla, Philipines.
This is an expanded edition of the book "Nurturing the soil", which we reviewed in 1993 in the ILEIA Newsletter. It is nice that there is a renewed version of this book for all who are interested in an overview of concepts and ideas on sustainable agriculture. The book is written for extension workers and provides background information on soil management. The book helps to understand the important biological processes required in managing the soil sustainably. The author supposes that principles observed in nature can instruct farmers in the quest to improve farming practices. The book also provides basic information on agricultural practices that can improve the land, like mulching, composting, cover cropping, integrated pest management etc. The appendices contain important addresses and references for more detailed information. (WR)

An evaluation of strategies to use indigenous and imported sources of phosphorus to improve soil fertility and land productivity in Mali by Henao J, Baanante CA. 1999. 75 p.ISBN 0 88090 120 9. International Fertilizer Development Center (IFDC), PO Box 2040, Muscle Shoals, Alabama 35662, USA / general@IFDC.org ; www.ifdc.org.
This report is the result of a fertilizer research project conducted over several years in Mali as a collaboration between the government of Mali, through the Institute D'Economie Rurale, and the IFCD. Findings indicate that phosphate fertilisers are indeed needed for the production of food and cash crops and that Tilemsi phosphate rock is a suitable indigenous source of phosphorus for the sustainable production of important cropping systems in Mali.The report provides clear figures and a lot of data concerning soil fertility throughout the country, including economic evaluations. (WR)

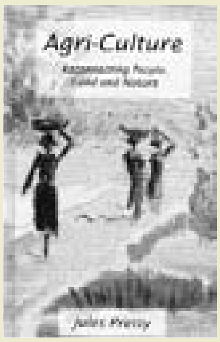
Soil conservation in organic farming : handbook 1 : green manure, green leaf manure, biofertilisers by Jayashankar M, [et al]. 2002. 30 p. Centre for Indian Knowledge Systems (CIKS), No 30, Gandhi Mandapam Road, Kotturpuram, Chennai 600 085, India / ciks@vsnl.com ; www.ciks.org.
During all stages, from seeds to harvest, agricultural crops take up a number of nutrients from the soil. The nutrients taken up by the plants during one season of cultivation should be replenished before the next sowing season. Only then can the nutrient level of the soil be maintained without depletion. Several practices are being followed to replenish these lost nutrients. This small manual gives an account of green manure, green leaf manure and the ways in which they could be used for increasing soil fertility. It also describes the different types of biofertilisers and their uses. The book ends with a list of Indian organisations supplying biofertilizers.(WR)

Dynamics and diversity : soil fertility and farming livelihoods in Africa : case studies from Ethiopia, Mali and Zimbabwe by Scoones I, (ed.). 2001. 256 p. ISBN 1 85383 820 9 GBP 16.95. Earthscan Publications Ltd, 120 Pentonville Road, London NI 9JN / earthinfo@earthscan.co.uk / www.earthscan.co.uk.
Ian Scoones is a well known expert in the field of soil fertility and small

scale farming in Africa. With this new book on the subject he adds another important work to his list of publications. This book is based on research carried out by teams of researchers from Africa and Europe over three years in a range of contrasting locations. The research results add up to a new approach for looking at soil management issues in Africa, with significant implications for development policy and practice. They suggest a more positive view of the prospects for sustainable agriculture in small-scale farming systems in Africa than the overridingly negative views of crisis and collapse which have dominated the policy debate. The research also points to the need for developing new technologies and management practices which are suited to the diversity of farmer needs and settings, when addressing the challenges of natural resource management. (WR)

Resource conserving technologies : transforming the rice-wheat systems of the indo-Gangetic plains : rice - wheat consortium, a success story by Gupta RK, et al. (eds). 2002. 42 p. Asia-Pacific Association of Agricultural Research Institutions (APAARI), FAO Office in India, 55 Max Mueller Marg, New Delhi 110 003 India, Rice-Wheat Consortium for the Indo-Gangetic Plains, (RWC) Campus, Pusa, New Delhi 110 012, India : rwc@cgiar.org, www.rwc.cgiar.org. (APAARI Publications 2002/1).
Rice and wheat are two major crops in the Indo-Gangetic plains of South Asia comprising of Bangladesh, India, Nepal and Pakistan. Following an eco-regional approach, the Rice-Wheat Consortium (RWC), convened by CIMMYT, has been operating farmer participatory research programmes from a perspective of system's ecology. These research and development efforts with a focus on resource conserving technologies are being practiced by a larger number of farmers, and a tillage revolution is emerging in South Asia. This booklet provides an account of useful and successful research and extension initiatives. Farmers are practicing zero- and reduced tillage in more than 250 thousand hectares at the moment. The ILEIA Newsletter 16.4 carries an article on the Rice Wheat Consortium. (WR)

Manual on integrated soil management and conservation practices 2000. 220 p. ISBN 92 5 104417 1 downloadable. FAO, Land and Water Development Division and Research, Extension and Training Division, Viale delle Terme di Caracalla, Rome 00100, Italy / www.fao.org. (FAO Land and Water bulletin, ISSN 1024 6703 ; 8).
This manual serves as a guide for technicians and farmers to jointly discover ways to solve the problems and the limitations posed by land degradation in Latin America and Africa. It has been put together with the aim of assisting diverse groups of people who are intervening in the conservation of the natural resources, particularly soil and water resources and in the context of each continent, country or zone. The publication brings together a collection of concepts, experiences and practical suggestions that can be of use for identifying problems and for formulating, executing and evaluating actions so as to benefit and to improve the productivity and conservation of soil and water resources. The manual is based on the training course for soil management and conservation, focused on efficient tillage methods for soil conservation, held in Nigeria in 1997. Available in English and in Spanish. (WR)



Agri-culture: reconnecting people, land and nature by Jules Pretty, 2002. Earthscan, London, earthinfo@earthscan.co.uk ; www.earthscan.co.uk .
'Agri-Culture' envisages the expansion of a new form of food production and consumption founded on more ecological principles and in harmony with the cultures, knowledge and collective capacities of the producers themselves. It draws on many stories of successful agricultural transformation in developing and industrialised countries, but with a warning that true prosperity will depend on the radical reform of the institutions and policies that control global food futures, and fundamental changes in the way we think. The time has come for the next agricultural revolution (author).

Information on soil micro-organisms

FAO Soil Biodiversity Portal

http://www.fao.org/ag/agl/agll/soilbiod/default.htm

This web page provides general conceptions on the meaning and significance of soil biodiversity, stressing the need for **integrated biological soil management.** It also provides a framework, under which soil biodiversity can be assessed, managed and conserved, showing examples of successful and unsuccessful practices that have been used in various regions of the world in managing soil biodiversity. Finally, an assessment of needs for further work, research, capacity building and policy and programme development is presented.

Worldwide portal to information on Soil Health

http://mulch.mannlib.cornell.edu/TSHomepage.html

The Gateway to Tropical Soil Health Information currently offers an extensive database of annotated resources on the World Wide Web, an on-line resource reference service, and classified resource listings for products, services, organisations, databases, literature and electronic discussion groups that have direct or indirect links to tropical soil health issues.

Information on Conservation Agriculture

FAO Conservation Agriculture Portal

http://www.fao.org/ag/agl/agll/prtcons.stm

This web portal provides an entry to the main information page on CA: "Intensifying crop production with Conservation Agriculture". Besides the introduction, it contains extensive information on the concepts and principles, on experiences from Latin America, Africa and Central Asia and on the environmental and economic impacts of CA. There are also web linkages to the main networks (e.g. on ACT. and RELACO see below), databases (e.g. CATechnology database see below) and organisations on CA as well as a report on the First World Congress on CA held in Madrid, October 2001. The information is available in English and Spanish.

Conservation Agriculture Technology database

http://www.fao.org/ag/catd/index.jsp

The CAT database lists commercially available equipment, which is specifically designed or is essential for the successful introduction of Conservation Agriculture. Special importance is given to small-scale equipment. The database addresses the needs of farmers, extension staff, technicians and others involved in Conservation Agriculture projects and anybody else interested in equipment for Conservation Agriculture, and where to obtain it.

ACT - African Conservation Tillage Network

http://www.fao.org/act-network/contact.htm

ACT Secretariat, c/o IES University of Zimbabwe, PO Box MP 167, Harare, Zimbabwe. Phone: +263-4-334395, Fax: +263-4-332853, Email: actsecre@africaonline.co.zw

The purpose of the network is to enhance the dissemination of conservation tillage in smallholder agriculture. Its main activities are: support to national networks; maintenence of an informative website and the ACT literature database; publication of an electronic newsletter "Act now" and a very good information series; organisation of topical working groups e.g. on green manure /cover crops, impact on soil quality, implements, dissemination approaches, curricula and training materials for farmers; workshops and pilot activities.

RELACO – Latin American Conservation Agriculture Network

http://www.relaco.cjb.net

Secretariat, c/o EPAGRI, Santa Catarina, Brasil. Email: relaco@epagri.rct-sc.br

The network links up persons interested in CA. It stimulates research and studies on CA and diffuses results. It organises seminars and training courses, stimulates activities of national networks and has published a wide range of documents and manuals on CA in Latin America. Its web site contains information (in Portuguese and Spanish) on important CA events and publications, and also its electronic circular. Information on RELACO in English can be found on the FAO Conservation Agriculture Portal (see above).

CD-ROM# 18 - Conservation Agriculture

This CD-ROM contains detailed information and literature on Conservation Agriculture that can help improve the knowledge base of those interested in this concept of sustainable agriculture. The CD-ROM provides technical staff as well as policy- and decision -makers with information and arguments for supporting, promoting and introducing Conservation Agriculture. For more information please contact: FAO, Land and Water (AGLL): **jose.benites@fao.org** or click **http://www.fao.org/landandwater/lwdms.stm#cd18**

Information on cover crops

TropSCORE The consortium for tropical soil cover and organic resources exchange

http://ppathw3.cals.cornell.edu/mba_project/moist/TropSCORE.html

The current members of TropSCORE are:

CIDICCO The International Cover Crops Clearinghouse, an NGO located in Tegucigalpa, Honduras. Operates in Spanish and English. **http://rds.org.hn/miembros/cidicco**

CIEPCA The Cover Crops Information and Seed Exchange Centre for Africa, a group hosted by IITA in Cotonou, Benin. Operates in French and English.

IDRC website on cover crops

http://www.idrc.ca/cover_crops/

IFDC-Africa has developed a decision support system for the use of legumes in West Africa: **Legumes, when and where an option?** Copies (in English and French) can be requested from the Programme for Integrated Intensification, IFDC-Africa, BP 4483, Fax: (228)2217817; Email: **ifdcafrique@ifdc.org**

Nitrogen fixation in tropical cropping systems

by KE Giller, 2nd edition, 2001. CABI Publishing, Wallingford Oxon OX10 8DE, UK, Email: cabi@cabi.org ; 425 pp. ISBN 0 85199 417 2 GBP 60, Euro 97.10

A fully updated and up-to-date standard work on nitrogen fixation by leguminous plants.

LEXSYS Cover Crop Database on herbaceous legumes
http://www.iita.org/research/lexsys.htm

Information Support Project for Soil Fertility and Improved Fallow Management
Institute of Biological Sciences, UP Los Baños, 4031 College, Laguna, Philippines.

ISP aims at providing an avenue for exchange of information on soil fertility, fallow management and shifting cultivation in the upland areas of Southeast Asia and the tropics.

Major activities include:
- publication of **Soil Fertility Matters**, a newsletters on soil fertility and fallow management
- development of databases, e.g. on contacts, fallow species, related references
- establishment and moderation of an electronic discussion list forum (**Fallow Net**)
- networking

The newsletter is available in printed and electronic forms. A free printed copy can be requested from macandog@pacific.net.ph .The on-line version and the other information can be found on **www.icraf.cgiar.org/sea/ifm**

Information on Integrated Soil Fertility Management

International Fertiliser Development Center
http://www.ifdc.org

IFDC's goal is to increase agricultural productivity in a sustainable manner through the development and transfer of effective, environmentally-sound plant nutrient technology and agricultural marketing expertise. Its web site provides information regarding IFDC's programmes and projects, services available, publications, events, news releases, newsletters, training courses, events etc. For information on ISFM you have to go the section on IFDC-Africa

FADINAP
the United Nations Fertiliser Advisory, Development and Information Network for Asia and the Pacific. **http://www.fadinap.org**

FADINAP provides assistance to developing countries in their efforts to increase food production by supporting the development of an efficient and effectively functioning fertiliser sector in Asia and the Pacific region. Its web site provides information on a wide range of fertiliser-related subjects: services, electronic newsletter, country gateways, market information and publications, among others on Integrated Plant Nutrient Systems.

Guidelines and reference material on Integrated Soil and Nutrient Management and Conservation for Farmer Field Schools
by Nabhan H, Bot A. and Roy RN. Publication Series: AGL/Misc/27/2000. Downloaded from

http://www.fao.org/landandwater/agll/oldocsp.jsp

These guidelines provide a basic conceptual framework and supporting reference material for assisting in the development and implementation of effective FFS focused on Integrated Soil and Nutrient Management and Conservation. They are intended for use by FFS facilitators with a background in agricultural extension, agronomy, soil science, plant nutrition, soil conservation or land husbandry and for the production of country or local specific manuals and curricula. These should be adapted to the agro-ecological environment, the cropping/farming systems, and the socio-economic conditions and educational level of the farmers in the areas where the FFS are to be implemented.

On-farm composting methods
by Misra RV and Roy RN, 2002, 26 pp. Can be downloaded from

http://www.fao.org/landandwater/ agll/compost/default.stm

This paper gives an overview of main composting methods used as a starter for the electronic conference on Organic Recycling conducted from May - August 2002.

DEVECOL a web-based information system for sustainable development
Development Ecology Information Service, 619 Upland Place, Alexandria VA 2301, USA / hansfree@comcast.net

http://www.devecol.org

Devecol is an information system and resource designed for field workers in sustainable development who want to take advantage of relevant experiences in comparable environments elsewhere in the world. The information resources consist of geo-referenced documents, base maps and thematic maps. The documents are site specific case studies, evaluations, surveys and research reports, which are full text available as pdf files. The maps show the climatic zones and soil conditions of the area where the studies are located.

At the moment a useful information tool for sub-Saharan Africa is under preparation. This will be ready in early 2003 with information on projects and case studies, which can be accessed from their map locations. FAO maps of soil associations and climate can be displayed under these locations.

The II World Congress on Conservation Agriculture: "Producing in harmony with nature"
Iguaçu Falls, Parana, Brazil - August 11-15, 2003.

This second Congress will call upon politicians, international institutions, environmentalists, farmers, and private industry to further support and develop the concept of conservation agriculture. Only with conservation agriculture techniques will we ensure the continuity of sufficient food production for an expanding population while maintaining environmental quality. This congress will build on the issues and lessons of the first World Congress which took place in Madrid in 2001. In line with the conference theme, keynotes and delegates will address the development of on-farm, practicable, farmer-originated and led, and scientist supported farming systems that develop towards more natural systems for the optimal use of the natural resources. Further information on the congress can be found on the FAO Conservation Agriculture web portal later this year.

Farmers develop new hand weeders in Sri Lanka to make SRI less labour intensive. Photo: Norman Uphoff

System of Rice Intensification gains momentum

Norman Uphoff and Erick Fernandes

Since 1999, the System of Rice Intensification (SRI), developed in Madagascar by Fr. Henri de Laulanié in association with the NGO Association Tefy Saina (ATS) and many small farmers in the 1980s, is spreading to many countries. Various articles and presentations on SRI at national and international fora, especially those by Dr. Norman Uphoff, Director of the Cornell International Institute for Food, Agriculture and Development (CIIFAD) at Cornell University in USA, have motivated many people to experiment with the approach and evaluate it for themselves.

SRI is a ‘system’ rather than a ‘technology’. It is based on the insights that rice has the potential to produce more tillers and grains than now observed, and that early transplanting and optimal growth conditions (spacing, humidity, biologically active and healthy soil, and aerobic soil conditions during the vegetative phase) can fulfil this potential. These principles are translated into a set of ‘baseline’ practices: transplanting of young seedlings, carefully one per hill, with wide spacing; no standing water during the vegetative growth phase; application of compost; and early and frequent weeding (see e.g. LEISA Magazine Vol.15, No.3/4, pp.48-49; Vol.16, No.4, p.12; Vol.17, No.4, pp.14-16). Practitioners of SRI are encouraged to vary and improve these practices, to see which can best give effect to the SRI principles in their specific situation.

The SRI approach has been tried in at least 17 countries under a range of climatic and other conditions. Farmers have worked with many different varieties (traditional, high yielding and hybrids) and soil fertility practices (organic, chemical, and a combination of both) and have developed several variants and improvements of the ‘baseline’ practices.

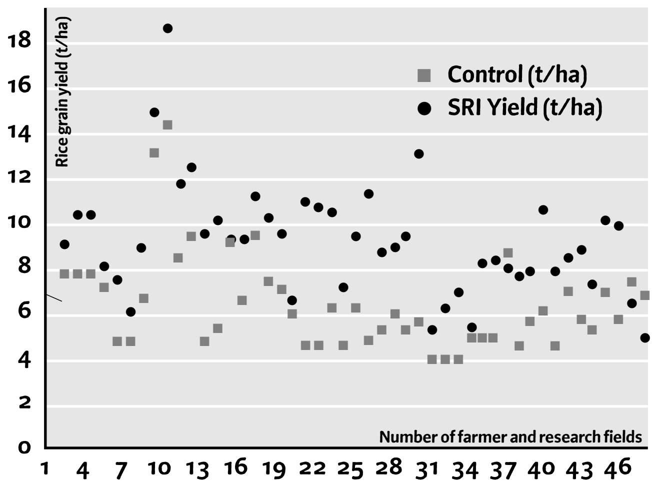

Figure 1: Comparative rice yields reported from cases where data were available on both actual SRI yield and comparison/control yield

First International Conference

As scientific validations of farmer and researcher experimentation have become available, it was timely to hold an international conference on the System of Rice Intensification. This was organised by CIIFAD and the China National Hybrid Rice Research and Development Centre, with co-sponsorship by ATS and the China National Rice Research Institute. It took place in Sanya, China, April 1-4, 2002. The objective was to better understand the variations in practices and the results that have emerged, and to establish means for communication that would facilitate evaluation of innovations from various sources and share them widely, so that farmers in many countries would have a longer “menu” of SRI practices to choose from.

Reports from China, Indonesia, Philippines, Cambodia, Laos, Thailand, Myanmar, Bangladesh, Sri Lanka, India, Nepal, The Gambia, Madagascar, Sierra Leone, Cuba, Peru, and the U.S.A. were presented at the conference. This article is a compilation of the main findings and comments.

Advantages

Numerous benefits associated with SRI practices were reported in the conference papers, the most important being an increase in

total factor productivity. Specific advantages included:

- **Higher yields:** increases of 50-200 %, with yields of 4-8 tons/ha common, but also yields above 10 tons/ha frequently reported (see Figure 1).
- **Increased returns to labour** with more production per day invested.
- **Water saving**: up to 50%, with higher productivity per unit of water applied.
- **Improvement of soil quality** and **increased efficiency of fertilisers**, both organic and chemical.
- **Reduced requirement of seed**: 5-10 kg/ha of seed is used, 5-10 times less than the quantity with the regular practice; this makes the use of improved and hybrid seeds much cheaper for farmers.
- **Less requirement of purchased inputs - water, fertiliser, seed and pesticides**, and lower costs of production contribute to **higher income** for farmers.
- **Higher seed quality:** SRI methods make it possible to increase considerably the yields for traditional rice varieties grown organically for which higher prices can be obtained; also, multiplication of 'breeder seed' can be faster as many more grains can be produced from a single seed.
- **Diversification of production**: less land is needed to produce the same amount of rice, freeing up land for producing green manure or crops with higher value.
- **Environmental benefits**, resulting from reduced demands for water and less or no use of agrochemicals.

The disadvantages reported included:

- **Requirement of good water control**, to be able to apply small amounts of water as and when needed to maintain soil moisture without saturation, rather than flooding fields continuously. Farmers who do not have such control or reliable access to water will get less or little benefit from SRI practices.
- **Requirement of more labour**, at least in the first year or two, as skills are learned for using the SRI practices quickly and confidently (see Box 1). This can be a barrier to adoption, even for poor households which are relatively more endowed with labour, if they need immediate returns from their labour to meet subsistence needs. At the present stage of development, SRI is mainly of interest to small farmers who have sufficient household labour. The challenge is to develop practices that make SRI suitable for situations where labour is more expensive and for larger-scale mechanised farming.
- **Drastic change of farmer practices** which is often not accepted by farmers, their communities, researchers and/or governments.
- **Requirement of greater skill** on the part of farmers, expecting them to adapt SRI practices to their own conditions based on their own trials and evaluations. This can, of course, contribute to human resource development, which is a benefit and not just a cost.

Box 1. Gender division of labour in SRI

We do not know how much SRI affects the gender division of labour within households, so this should be evaluated as a matter of some priority. Since SRI requires more labour per ha., at least initially, there is concern that this could increase the labour burden on women, who usually do the transplanting operation. Labour savings in terms of time spent on nursery construction and management with SRI would accrue usually to men.

However, conversations with women doing SRI transplanting in Sri Lanka indicated that they found SRI methods easier and quicker after the first year, once they became comfortable with handling tiny seedlings. Because lighter and fewer seedlings are transplanted, they reported that SRI transplanting had become quicker for them, and they found the technique more comfortable ("less backache").

In Madagascar, there are still complaints about the method taking extra time and effort, but the spacing for transplanting is still marked with ropes stretched across fields, rather than with a simple wooden rake that scores the surface of the fields with lines. With increased yield, women's burden at harvest time is probably increased, though a larger harvest helps maintain household food security, which is a major responsibility and burden for women.

Field experiences and observations

Using young seedlings. This is probably the single most important practice in SRI according to the factorial trial results in Madagascar, adding about 2.5 t/ha in this situation, other conditions being equal (Table 1). Some farmers have tried seedlings as young as 5 days; others have preferred older seedlings (3-4 weeks), e.g., because of slower growth in colder climate. Two evaluations in Madagascar have shown definite benefits from using younger seedlings. The advice to start by using 8 to 12 day-old seedlings remains sound, but decisions about seedling age need to match varietal and climatic differences.

Effective tillering. There is wide variation in tillering and the effectiveness of tillers. Sometimes there are up to 50% **unproductive tillers**, which cannot be explained very well. More often effective tillering is in the range of 60-80%, with some plots attaining 80-90%. How to optimise effective tillering is an important research question.

Quick and careful transplanting. Farmers have not found it difficult to transplant seedlings within 30 minutes, or preferably

Table 1. Factorial trial results, comparing yield responses on clay and loamy soils, Anjomakely, Madagascar, 2001

	CONTINUOUS FLOODING				SRI WATER MANAGEMENT			
	20-day plants		8-day plants		20-day plants		8-day plants	
	3 per hill	1 per hill	3 per hill	1 per hill	3 per hill	1 per hill	3 per hill	1 per hill
CLAY SOIL								
No Fertilizer	2.26	2.78	3.09	3.75	4.82	5.42	5.65	6.25
NPK	<u>3.00</u>	5.04	5.08	6.07	7.16	8.13	8.15	8.77
Compost	3.71	4.50	6.72	7.45	6.86	7.70	9.32	**10.35**
LOAM SOIL								
NPK	<u>2.04</u>	2.78	2.60	3.15	3.89	4.36	4.44	5.00
Compost	2.03	2.44	3.41	4.10	3.61	4.07	5.17	**6.39**

The yield figures reported (tons/ha) are each averages from 6 replicated trial plots. The average yield with conventional practices is <u>underlined</u>; that with all-SRI practices is **bold faced.** A traditional variety (riz rouge) was used for all trials, with soil type as one of the variables evaluated. These trials (N=240) were conducted in a village 18 km south of Antananarivo on the high plateau. More complete data from factorial trials conducted by Rajaonarison in 2000 and Andriankaja in 2001 are reported in the conference proceedings.

15 minutes or less, if they establish their nursery near the field. Farmers have found that using a trowel or other implement helps minimise trauma to the tender seedlings when they are uprooted from the nursery. Seedlings are sometimes planted in wooden or bamboo frames that can be kept in or near the house for protection and then carried to the field, so that seedlings are uprooted only at the time of transplanting.

Trauma during transplanting can be reduced by paying attention to the soil mixes used in the nursery and by appropriate water management practices. In Sri Lanka, for example, a nursery mixture of one-third soil, one-third sand, and one-third (chicken) manure has given very good results.

Traditional, improved or hybrid varieties. All varieties used so far have given higher yields with SRI practices, though not surprisingly, some varieties respond better than others, e.g., producing more tillers or giving better grain filling. It was observed that 120-140 day varieties responded most productively, but more evaluation is needed on this. The best SRI yields (up to 16 tons/hectare and higher) have been obtained with high-yielding or hybrid varieties, although traditional varieties, considered low-yielding, have also shown great yield increases. Since the latter are commonly preferred for taste and other qualities, and command a higher market price, they may regain popularity with SRI methods that increase yields up to 6-10 t/ha.

Seedlings per hill. 1 or 2 seedlings per hill can give good results depending on local conditions. Where soils are poor it may be better to use 2 seedlings per hill until soil quality is improved. There is enough evidence that 3 or more seedlings per hill retards growth due to plant competition below and above ground, and therefore does not need further experimentation. On good soil, single seedlings have been giving the best results.

Wide spacing. Some of the highest yields observed with SRI have come with very wide spacing, 50 x 50 cm, when soil quality is excellent. But spacing between plants is something to be optimised, not maximised, since one wants the largest number of grain-bearing tillers per sq. metre. This number is influenced by various factors (soil quality, variety) as well as by SRI practices, of which spacing is one. Most farmers are advised to start with 25 x 25 cm. Often 35 x 35 cm spacing has given the best results but on very poor soils 20 x 20 cm may be better.

Techniques of spacing. Instead of using strings to achieve desired and exact spacing, some farmers in Madagascar and Sri Lanka are now using wooden rakes with teeth (pegs) spaced at 25 cm, or wider, intervals to mark square grid lines on the muddy surface of their paddies. Farmers find that this speeds up the transplanting considerably (see Box 2).

Water management. There is plenty of evidence that in many conditions keeping the soil moist but unsaturated during the vegetative growth period is best. The SRI recommendation has been to add small amounts of water to the field daily, preferably in the late afternoon or evening (unless there has been rain during the day), and draining any excess (standing) water in the morning. This opens the soil to aeration and warming during the day. However, a large number of farmers, seeking to reduce their labour requirements, follow an irrigation schedule of alternate flooding and drying of their field instead of careful watering but not flooding during the vegetative growth period. It is not clear if this gives a higher yield but it does economise on labour. Certainly different practices are needed for clay vs. other kinds of soil. Further research is also needed to understand the implications of such changes at large-scale for water distribution and the environment.

Weeding. When fields are not kept continuously flooded to combat weeds, farmers have to use other practices. With SRI, early and frequent weeding is also important to aerate the surface of

Box 2. Adaptation and innovation of SRI practices in Sri Lanka

One of the reasons for fast dissemination of SRI in Sri Lanka is the enthusiasm and creativity of farmers to adapt and innovate SRI practices to resolve their field problems. The following are highlights:

- Various soil-enrichment practices have become part of the system including green manure (e.g. sunhemp), rice straw, chicken dung, and mixtures of certain green leaf extracts with cow dung. In this way farmers are improving soils degraded by conventional rice production practices without needing to transport huge quantities of compost to their paddy fields.
- Practical problems encountered in using the rotary weeder have resulted in alternative weeder designs to suit the specific conditions of different fields. Weeders are manufactured and sold by several farmer companies and private sector entrepreneurs. A motorised weeder is at the design stage in three locations and will be tested soon.
- To make transplanting easier, a rake was produced to draw lines in a square grid pattern on the ground. Seedlings are planted at the intersections of lines.
- A transplanter that can do careful planting of one seedling per hill in 6 rows at a time with required spacing has been developed.
- A seeder, which can drop one or two germinated seeds at the desired spacing has also been developed and is now in use.
- A foot-pedal water pump with sprinklers is being experimented with to ensure required moisture during the growth period and after panicle initiation. This is especially useful in drought periods when surface water is scarce, and also to ensure production of high-value organic rice for the export market.
- Many farmers are using different combinations of plant extracts, with or without ‘effective micro-organisms’ (EM), to avoid the use of chemical pesticides. They experiment with different plants available in highlands around the paddy fields. Some plant extracts are used not only as insect repellents but also as a source of nutrients.
- Farmers have stopped plastering their bunds and leave the grass cover on the bunds to protect the habitat of rice-pest predators. In this way they support biological pest control and microbial activity in the soil to improve soil health and biodiversity in the paddy fields. This saves money for plastering and pesticides and thus reduces production costs.
- SRI farmers experiment with different spacing and direct seeding. They also do careful time planning to prevent flowering during the full moon phase. They find that this reduces damage by insect pests.

The benefits achieved by farmers from SRI and other improved practices are attractive. Farmers have been able to at least double the yield they got from conventional practices while also reducing their production costs, often by half. They have become producers of quality rice earning a slightly higher income from sale as seed paddy. Biocide-free SRI rice fetches a higher price in the market, and the demand is increasing. Production of organic and traditional rice for export is increasing with one farmers’ group already obtaining certification for production of organic rice. In this way SRI is becoming a viable alternative for farmers cultivating small plots obtaining average yields of 8.5 tons/ha, achieving higher returns from reduced inputs, while increasing the productivity of land, water, labour and capital. Besides, SRI farmers produce clean and healthy rice through eco-friendly practices.

More information on the experiences in Sri Lanka can be found in Box 4 and in the Proceedings of the International Conference on SRI

Gamini Batuwitage, Additional Secretary, Ministry of Agriculture and Livestock, Govi Jana Mandiraya, Battaramulla, Sri Lanka. Email: batuwita@sltnet.lk

Training material used in Madagascar showing the steps involved in planting SRI rice.

the soil. SRI farmers could use hoes or weed by hand, but ‘rotary hoes’ or ‘cono-weeders’ are recommended. Access to mechanical hoes can be a bottleneck. Labour required for hand weeding can be as much as 20 – 25 days for one ha in Madagascar. Recently, SRI practitioners in Sri Lanka have developed a new design for a push weeder (see Box 2 and photo on p.24) which makes it possible to weed 1 ha in 3 to 5 days.

Soil and nutrient management. With SRI, the highest yields have been obtained with organic soil amendments, particularly compost. Research in Madagascar has shown that compost gives a considerable increase in yield compared to NPK fertiliser, especially for traditional varieties (Table 1). But it was also reported that most farmers are using neither compost nor NPK on their crop, and still getting yields with SRI methods that are twice as high as with standard methods. Participants wondered how this is possible, and for how long farmers can continue with such nutrient-depleting practices. At some point there may be soil nutrient constraints, e.g., P, that have to be alleviated by adding sufficient soil amendments. Often there are not enough organic nutrients available and chemical fertilisers are too inefficient to be profitable.

Better understanding of soil life and biological soil processes are needed to develop effective, efficient and sustainable soil fertility management strategies for SRI. There seems to be much scope for Integrated Soil Fertility Management (ISFM) practices. Green manure, composted rice straw, micro-nutrients and sprays of soil micro-organisms and plant extracts seem to be organic practices with good potential. Incorporation of a green manure crop either before rice (e.g., *Sesbania rostrata*, mung bean or bush bean) or after rice (e.g., jackbean) could work well with SRI. Researchers at the Tamil Nadu Agriculture University in India have good experience with sowing of green manure (*S.*

Box 3. SRI adaptation and diversification in Cambodia

After farmers gain confidence in SRI, they become interested in refining the ways of increasing rice production and diversifying rice-based farming systems. The following trends have been observed:

- Farmers modify the way that they transplant depending on their specific conditions, especially the age of seedlings and spacing. They are keen to assess appropriate practices in plant management for themselves through experimentation.
- It is much easier to talk to SRI farmers about integrating green manure after and before the rice crop, and they are more ready to invest in growing green manure.
- Some farmers are developing simple tools for weeding, like small hoes and harrows. The concept of soil aeration through weeding, which contributes to improved root growth, is now well understood by SRI farmers.
- This year, two farmers started with zero-tillage, and there are more farmers becoming interested in the practice. Zero-tillage is possible since SRI makes the cultivation of traditional rice varieties that produce a lot of biomass for mulching attractive again. So far, we observe that rice growing under zero-tillage is doing well, even better than the normal practices.
- When farmers see that their rice yield is increasing, they are willing to use part of their rice fields for growing other crops and for raising fish. We call this a multi-purpose rice field, or the System of Intensification and Diversification (SID) of rice production. Earlier, they would not consider diversification, as growing less of the staple food, rice, was unaffordable.
- Some SRI farmers return to practices of mutual help in transplanting, because those they would normally hire do not have the skills to transplant as required by SRI. By pooling their labour they find they can get good and quick results.

Based on our experiences, the SRI approach contributes significantly to increasing farmers’ innovative capacity, community learning and cooperation. Now, we see that ecological intensification of rice production through the small farmer group approach is a very good entry point to sustainable agriculture and rural development in Cambodia.

More information on the experiences in Cambodia can be found in the conference proceedings.

Yang Saing Koma, CEDAC, Email: cedac@camnet.com.kh

rostrata) within rows of rice plants and incorporating it into the soil with a cono-weeder, 30 days later. They have developed a special drum-seeder for this purpose.

With wide spacing of plants in SRI, broadcasting of fertiliser is less efficient. Application of chemical fertiliser granules (as successfully used in Bangladesh) or compost near the plants can be more efficient. Flooding and adding chemicals can have a strong negative impact on soil life and may affect crop production, but a lot remains to be understood. More ecological learning is needed to find the best soil management practices. Research presented to the conference from Madagascar indicated that crop responses to compost are non-linear, i.e., there may not be greater benefits from applying 4 or 6 t/ha compared to 1 or 2 t/ha, as the smaller amounts appear sufficient to "incite" the biological life of the soil and give good crop results.

Prof. L.P. Yuan of the Chinese National Hybrid Rice Research and Development Centre explaining his experiments on SRI using super hybrid rice varieties and inorganic fertilisers. Yields of 12 to 16 tonnes are expected. Photo: Coen Reijntjes

Land preparation. Good land levelling is important for getting best results from applying small amounts of water. At the same time, a proper drainage system for the field should be established so that alternate wetting and drying of the soil can be done effectively. With SRI, land preparation (puddling) does not differ from standard practices. There could be considerable saving of labour and energy by combining zero-tillage with SRI practice (both follow similar agroecological principles), but experimentation and evaluation on this remains to be done.

Raised beds, zero-tillage and direct seeding. One of the most promising adaptations of SRI appears to be the use of raised beds as being experimented with under the Rice-Wheat Cropping Systems Consortium in India and Pakistan (see LEISA Magazine Vol.16, No.4, pp.8-10). These beds are elevated 10-15 cm above the bottom of furrows in which irrigation water is intermittently issued. This can give water savings of 25-30%, with positive effects on yield due to soil aeration.

Some SRI farmers who have compared direct seeding with early transplanting found no difference in yield, but some saving of labour. Zero-tillage with mulching and direct seeding is practised with very positive results by farmers in, for example, Japan (Fukuoka), Sri Lanka (Nava Kekulama, LEISA Magazine Vol.13, No.3, pp.20-21), Nepal (LEISA Magazine Vol.16, No.4, pp.11), and Cambodia (Box 2). SRI was developed for irrigated lowland production, but some of its principles and practices could be extrapolated to rainfed areas. Some experiments in Madagascar, of direct seeding instead of transplanting, and using leguminous shrub cuttings as a mulch instead of mechanised hand weeding, have given good results (4 t/ha) in upland rainfed cultivation. This is a new direction for SRI research.

Ratooning. Some farmers in Madagascar let their SRI rice regrow after harvest for a second crop. The yields are not as high as the first crop, 60-70%, but this is profitable since it saves labour otherwise required for land preparation, sowing and transplanting. In Thailand, some farmers do a second ratooning.

Pest management. With SRI, rice plants are well developed and healthy due to organic soil management, high soil quality and deep rooting, which makes them more resistant to pest and disease attack and drought. Other traditional, organic or Integrated Pest Management (IPM) practices could help to make SRI rice production even more pest and disease resistant.

Diversification, from monocropping to integrated rice-based farming. Some SRI farmers who have discovered that they can produce the same amount of rice on less land have started to diversify their rice farming systems by growing green manure or higher-value crops and trees on the land no longer needed for rice production. This provides a higher income and has some advantages for pest and weed control and for soil fertility management. Integration of fodder crops and improvement of animal production can be a next step. In fact, SRI can be an important entry point for developing integrated rice-based farming systems that combine high production and profitability with high resilience and ecological sustainability.

Adaptation and diffusion

SRI is a complex system, which implies many drastic changes of current farmer practices. To train farmers in SRI is not so difficult, but there could be various difficulties in practising it. It is not just a matter of diffusing a few standard practices but rather of spreading a more holistic understanding of how rice plants can be grown more effectively. As adaptation to local conditions is needed, **farmer experimentation** is an essential part of any strategy for the dissemination of SRI.

From a scientific perspective, precise and well-documented comparisons are needed, both to convince scientists and to gain a better understanding of the potentials and limitations of SRI. Standard systems of evaluation and statistical analyses are necessary for scientific credibility. As this does not always combine well with a process of group-based farmer experimentation, effective **methodologies for participatory technology development and assessment** can be very helpful (see for example LEISA Magazine Vol.15, No.1/2).

Adaptation and diffusion of SRI is a very strategic process. It is important to convince **top-level government people** of the efficacy of these new methods and where possible to get policy-level promotion. **Political backing** for SRI will probably be gained most quickly and strongly where there are enthusiastic farmers who support the methods based on their personal experience and who are able and willing to lobby on its behalf. Successful SRI farmers will certainly be more effective in talking to politicians than researchers.

There should be special strategies to convince **professionals** in agriculture, who often find it hard to accept this new methodology. The mention of super-yields attained with SRI (e.g., 21 tons/ha in Madagascar) is seldom believed by researchers even when yield component information is provided, so it may be best to *stress average yields*, not those that can be attained with best SRI practices.

As long as governments do not accept SRI, there is a need for **alternative strategies** of dissemination. Even where there is government acceptance, multiple avenues for evaluation and dissemination can be complementary. So far, **NGOs** have been most active in taking advantage of SRI potentials, particularly attracted to SRI for its pro-poor, environmentally-friendly features. **Farmer groups** often are very interested in experimenting with SRI and in providing farmer-to farmer training to their colleagues.

SRI could be combined well with **Community IPM** and **Farmer Field School** (FFS) programmes on rice as the philosophy of experimentation and human resource development is common. **Credit facilities** may be needed for purchasing tools, in particular weeders. These can be very cheap, but for poor farmers even small expenditures like this may be a barrier. This, in fact, is the only area in which SRI requires credit.

Conclusions still provisional, further information on internet

As most of the knowledge about SRI is quite recent, conclusions about it must remain provisional for now, pending more years of experience and wider utilisation of SRI in a greater variety of circumstances. Much research is still needed to understand the ecological processes involved and to develop a variety of best practices. More insight is also needed in the applicability and limitations of the approach and the possible risks involved. The initial results are, however, mostly very positive and give reason to suggest that more countries and more farmers should have an opportunity to evaluate SRI for themselves.

The proceedings of the First International Conference on SRI, including all papers, contact addresses, training materials and illustrations are accessible on an SRI internet homepage: **http://ciifad.cornell.edu/sri/** Printed and CD-ROM copies are also available on request. The internet will also be used for follow-up information and discussions. Please send experiences, both good and bad, and comments too!! SRI networks have been established already in Bangladesh, Indonesia and Philippines and are being set up in China, Sri Lanka and elsewhere.

Box 4. Experiences with diffusion of SRI

Several participants reported on how the process of diffusion has proceeded so far in their countries. These experiences differed considerably from one country to the next:

- In **Madagascar**, SRI was introduced first by an NGO, Association Tefy Saina, through training and farmer-to-farmer extension, supplemented by booklets and radio. Subsequently there was also some involvement from the university and government. But most farmers have still been hesitant to try these radically new production methods, and the spread has been slow. No exact statistics are available on the number of farmers using SRI methods. This is at least 20,000, but the Ministry of Agriculture has estimated the number could be as high as 100,000 (10% of rice cultivators). Use is accelerating now that a larger and better-equipped NGO, Catholic Relief Services, is involved in SRI dissemination, with donor support.
- In **Indonesia**, dissemination is just starting after three years of evaluation by government researchers. SRI methods have been incorporated into a new official strategy for raising rice production (Integrated Crop Management) that is being supported on a national basis, expecting to make appropriate local adaptations. This country's IPM programme is also starting to work with SRI as this is very consistent with the agroecological approach and dissemination strategy used in its Farmer Field Schools.
- In **Sri Lanka**, SRI is reported to be spreading fast. Dissemination started with an article on SRI experiences in Madagascar printed in the Ministry of Agriculture's extension magazine in 2000 (30,000 copies were distributed). A researcher from Madagascar, Joeli Barison, had visited Sri Lanka to share his knowledge on SRI in January the same year. Agricultural officers and extension workers who tried SRI on their own accord got good results. TV and radio became interested, creating a process of dissemination that could not be stopped any more. Rotary weeders, since long forgotten, have been reintroduced, with fabrication instructions spread among local blacksmiths. One ecological rice farmer, Mr. H.M. Premaratna, became the leading SRI farmer, trainer and promoter, transforming his farm into a training ground (Nature Farming Centre) where more than 4,000 farmers have been trained. Unfortunately, some researchers in Sri Lanka have remained opposed to SRI, and official endorsement for dissemination has not been obtained yet from the Ministry of Agriculture. The previous Deputy Minister has been very supportive and has used SRI very successfully on his own farm (up to 17 t/ha yield). The present Minister has declared SRI to be an important cultivation practice especially suited for small farmers. A green light from the government is expected once there is more research results to confirm existing findings. Opportunities to export organically-grown rice that uses SRI methods have also helped to raise interest in SRI among farmers.
- In **Cambodia**, the NGO CEDAC has been working with farmers to disseminate and innovate the SRI approach since 1999. CEDAC helps farmers to understand the principles of SRI and to analyse the practices that keep rice from achieving its full potential. Now there are at least 2,000 farmers actively experimenting with SRI.
- In **Laos**, some small-scale NGO experimentation and evaluation with farmers has begun. The International Rice Research Institute (IRRI) programme in Laos has now taken the initiative to launch a national evaluation starting in June 2002. It expects to do three seasons of testing before making recommendations, but some farmers are likely to start using it more quickly if the initial results are good.
- In **Cuba**, some top-level officials became convinced about SRI at an early stage as it meets the country's needs to raise rice production without reliance on petrochemical inputs. Dissemination can go very fast here because of farmers' literacy and their need to find ways of raising rice production without expensive inputs. The first sugar cooperative to try SRI methods on one ha of land got a yield of 9.5 t/ha as opposed to the usual of 6.6 t. The next season, it got 11.2 t/ha from its SRI field, and is fully persuaded of SRI's merits, even though it was not yet using young seedlings or doing any weeding to aerate the soil. Just changing the regime of water management and using wider spacing with single seedlings made a big difference. In the current season, when 12-day-old seedlings were tried on a small plot, their superior growth after 40 days has persuaded farmers to start utilising the full system next season.
- In **China**, SRI evaluations have been done at various rice research stations. Chinese rice scientists are very interested in SRI methods as they can increase the already very high yields of super hybrid rice varieties. They have concluded that SRI is a good way to improve rice production in China, especially given the need to reduce water demands. But certain adaptations will be needed to suit Chinese conditions, where labour costs are high and organic fertiliser material is in short supply. A next step will be to encourage farmers to try SRI methods for themselves. In Sichuan province, researchers have taken SRI already to six different locations (agroecological zones). Many innovations being made in rice production, e.g. triangular planting system, seed inoculation, paper frames for transplanting, intercropping with glutinous varieties for pest control, could be useful outside China as well.

Wise lessons from Mother Nature

Ambarwati D. Rahayu and Rik Thijssen

Characteristics and processes of natural ecosystems can be used as the basis for designing sustainable farm systems. This is, however, conditional to proper observation and collection of information for learning about the beneficial features of nature, as well as in understanding the various natural processes. The international development organisation VECO collaborates in Indonesia with more than 40 local NGOs, spread over 7 provinces, on the development of sustainable agricultural systems that can help to alleviate food insecurity.

LEISA developments

In mountainous Indonesia, soil and water conservation is an obvious precondition for sustainable agriculture. Frequent losses by erosion not only oppose basic ecological principles of LEISA ("optimising nutrient availability and cycling") but also harm soil life and, therefore, affect the soil negatively, both quantitatively and qualitatively. When VECO partner organisations start a new agricultural programme with rural communities, soil and water conservation is, generally, a good starting point. After making an inventory of the local conditions during a PRA exercise, programme staff and farmers are 'fresh' and eager to get going, while the principles of building erosion structures are quite straightforward and, by now, understood by many. In this way some quick first results can be achieved which have an enormous impact on further LEISA developments.

Using the principles of agroforestry, shrubs and trees can be added to protect and stabilise man-made erosion control structures. However, in cases where soils are not deep and slopes rather steep, experiences from natural forests show that tall-growing trees can be a hazard, and are frequently the cause of landslides during the rainy season. Local farmers in the district of Mamasa, on Sulawesi, recognise this danger and, therefore, plant only shrubs on such slopes and frequently prune and lop the woody species, which tend to grow tall.

Cover crops are in most agricultural development programmes another means of curbing erosion. The soil-creepers, mostly leguminous plants, can also serve as soil fertility improvers. But what could be done in situations where soils are rather acidic and common cover crops do not grow well? Or in cases where cattle roam freely around and could destroy the cover crop by trampling or browsing?

Learning from local insights

Ethnobotanical surveys often provide important information and local insights with which such issues could be tackled. During an ethnobotanical study in the area of Balla Satanatean village in Mamasa District, an answer was discovered for the first question. Soils here are acid and farmers use lime to increase pH on their fields. The common, natural soil cover here is a creeping fern, *paken* (*Gleichenia linearis*), and large areas on slopes have been colonised by this "wire fern". Local *adat* (customary law) demands great respect for the functions of this plant and people will think twice before they do anything that might damage the protective 'blanket' formed by this fern. The soil-holding capacities of *paken* are so well understood that most farmers plant this species on dikes around their *sawah* (irrigated rice fields).

Farmers in Ngada District on Flores appreciate, already for a long time, the natural presence of the "weed" *putri malu* (*Mimosa diplotricha* or giant sensitive plant). This fast-growing species can provide a quick cover on fields between cropping periods or during a fallow. Covered with many small thorns, it is not a crop that invites animals, and people alike, to walk through. According to farmers it is not easy to clear *putri malu* afterwards, but they take that for granted since it is an excellent soil improver, cover crop and soil binder against erosion.

Another problem that many farmers on Flores face is very hard soils. Low in organic matter after continuous use, soil compaction makes it impossible to plough such soils. Women lament that they cannot grow vegetables or fruit trees near the homes because the soil has become as hard as a rock. Perhaps even worse, because in rocky places there are still some plants and trees that grow.

This last observation has been a challenge to the community. If plants can grow in the wild in places where there are only rocks, then why can plants not grow in their hard soil?

Pits of 30x30x30 cm have now been chiselled out and filled up with soil from other places mixed with organic material. Vegetables and fruit trees have been planted in this *olah lubang* (pit planting) system. The first results are promising and the hope is that by bringing back some life to this hard soil, the soil will eventually become healthy.

Maintaining soil fertility

To keep the soil in place is one thing. To keep soil fertility in pace with day-to-day agricultural requirements is another. Farmers in Indonesia are searching for alternatives to the chemical fertilisers they have been using since the Green Revolution started. Convinced that inorganic fertilisers have destroyed many of the qualities of their soil, and stressed because of the high prices of the chemicals since subsidies were abolished, farmers in the VECO programmes are, for instance, experimenting with liquid manure. This manure is made by fermenting large amounts of leaves of certain shrubs and trees in containers with water. After a few weeks, the concentrated liquid is diluted with water and used as a fertiliser on small rice fields, vegetable plots or young fruit trees. Reactions from farmers are all very positive. They observe good growth and more healthy plants. There is less damage by pests and products such as onions can be stored for a much longer period compared to produce from fields treated with chemical fertilisers.

During technical monitoring and evaluation meetings, the

Production of different crops using Urea (250 kg/ha) or compost (10 ton/ha)

Crop	Yield with Urea (kg/ha)	Yield with compost (kg/ha)
Rice	1,200	2,680
Maize	800	1,460
Groundnuts	975	1,125

Farmer innovation in compost-starters

During a study visit in 1998, to an extension institute in Bogor, the use of a commercial compost-starter EM4 ("effective microbes") was demonstrated to farmers from Bandungrejo village in Malang District, East Java. This technology, developed by a Japanese biotechnology professor, was, of course, tried by the farmers once they got home. The conclusion of the group was that the process of composting mixtures of rice straw and other organic waste was indeed accelerated by using EM4. Where it would take normally months for rice straw to degrade, the new technology took only few weeks!

However, the expenses of buying the litre bottles of EM4 were relatively high (about 25,000 Rupiah or US$ 2.80). One of the group members, Mr. Kusno, therefore decided to try to develop his own compost-starter. From their visit to Bogor, it had become clear what natural processes and components were important for a more rapid composting process. Mr. Kusno, who had ample experience with the fermentation of cassava roots to the local food product tape, reasoned that if the ragi ("yeast") used was able to make the hard cassava root soft, than maybe it would even be able to break down the fibres of the rice straw.

Using the ragi for making tape from cassava roots, they found it is possible to produce mature compost in only a matter of weeks. The compost was analysed by the Soil Laboratories of the Agricultural Department of Brawijaya University in Malang. A cost-benefit study was done and also proved very favourable - using compost could save almost 50% of expenses on chemical fertilisers. While it could even be lucrative to produce compost for selling, since production costs for 200 kg of compost was about 10,000 Rupiah, while compost was sold for 200 Rupiah per kg.

The results of the experimentation by Mr. Kusno and his farmer group has triggered off a complete new thinking about composting. After extension officers had shown them how to make the ragi themselves, farmers have also started experimenting with alternative ingredients to make effective compost-starters. While the ragi for cassava tape is based on micro-organisms from the roots of laos (Languas galanga), starters have now been developed using roots of other plants as well as over-ripe fruits.

Mr. Kusno died in 2000 at the age of 58 years. His work will always be remembered by the many farmers in Indonesia who implement 'his' technology under the name pupuk ragi Kusno (fertiliser from Kusno's ragi).

important soil processes concerning mineralisation and nutrient availability are explained and discussed. The accelerating effect that N and P fertilisers have on the decomposition of soil organic matter is always a hot item of discussion. Initially, a bonus effect is created by increasing the availability of macro and micro-nutrients to plant roots. On the longer term, this priming effect causes a larger fraction of the soil organic matter to be broken down annually. Arguably, this is the most important factor why the Green Revolution scored its early successes but finally caused serious problems for main soil qualities.

When confronted with this information, it is not so difficult for farmers to draw a parallel between the use of chemical fertilisers and the use of their liquid manure. Since the liquid fertiliser contains only water, nutrients and microbes, they can only agree that chances are high that similar priming effects could cause new problems, especially because of decreasing the content of soil organic matter.

Therefore, it becomes imperative that organic material of a certain quality is regularly added to the soil. The usual green manures are not applicable since research in alley cropping has shown that the easily decomposable leafy material from leguminous species contributes to a priming effect and does not add significantly to soil organic matter. Animal manure would be fine, but not all farmers keep animals while quantities of animal manure are often not sufficient. This leaves compost as the better option. Especially compost made out of fibrous material such as rice straw and alang-alang grass (*Imperata cylindrica*) could provide the necessary, long-lasting organic supplement for soils. Crop yields are significantly higher with the application of compost in comparison to inorganic fertilisers as seen in the table. Compost starters are popular amongst farmers and have become cheap and accessible due to farmer innovation (see box).

Conclusion

In order to imitate natural ecosystems in our pursuit of developing sustainable agricultural systems, we – development agents and the farming communities - should be prepared to observe well the many different components, and ingenious arrangements between components, that make up such a natural ecosystem.

Sustaining soil fertility: useful practices and methods in hill agriculture

FFS farmers' group discussing the quality of their soils. Photo: SSMP

Farmers in the hills of Nepal have, over the past centuries, developed complex farming systems based on a close integration of crop, livestock and forestry/grassland management. Manure derived from livestock is the main source of soil fertility management. About 32% of the fodder resources are derived from crop residues while the rest is derived from terrace risers, bunds and forests. Although fodder is in short supply and milk production is thereby reduced, farmers keep livestock partly for the purpose of manure production.

Farmers have constantly changed and adapted their farming systems over the past centuries as need and opportunities arose. New crops such as maize and potato entered the hills centuries ago and are now staple food crops contributing to food security. The expansion of fruit crops and vegetables is a more recent phenomenon improving food quality and farm income. At the same time, farmers have maintained traditional practices such as terracing, manure management, legume inter cropping, and mulching where appropriate.

Searching for innovation

The rapid intensification of land use, reduced access to biomass from public land, increasing access to input and output markets, new crops and cropping systems have exposed farmers to new challenges. Therefore, farmer-support organisations need to accelerate farmers' efforts to increase the productivity of the farming system with new practices and knowledge while maintaining its diversity and sustainability.

This article summarises experiences on the promotion of sustainable soil management of more than 50 governmental and non-governmental organisations under the common umbrella of the Sustainable Soil Management Programme (SSMP). More than 14000 households in 10 hill districts participated directly in project activities since 1999 through more than 1500 field trials or demonstrations per year. About 700 farmers participated in a recent evaluation of the programme. The major learning points so far are outlined below.

Technical opportunities for SSM

Various opportunities for improved soil management have been identified and confirmed with farmers over the past 3 years. For instance:

- ***Farm yard manure quality*** can be increased by better decomposition and the N-content can be increased by at least 2 to 3 times from about 0.5% N to 1.5% N through proper management of urine and manure. In particular, urine collection and the proper management of manure are new to most farmers, as many have initiated stall-feeding only over the past 1-2 decades. Previous recommendations for manure (use of starter, turning etc.) were derived from composting and proved to be too labour demanding and missed the importance of urine collection and N-preservation.
- ***Liquid manure*** can be prepared from urine and various plant extracts rich in minerals or secondary plant compounds. These "manure teas" were shown to be effective liquid fertilisers on crops such as vegetables and also for organic pest and disease management. Local marketing systems for such "manure teas" are emerging in some areas. The use of urea fertiliser declined in several areas due to liquid manure use.
- ***Increased fodder availability*** from fodder trees and grasses on private land has improved the fodder supply and quality for livestock. The quantity and quality of manure has increased (remember: about 80% of N in fodder is excreted through urine). Additionally the workload for fodder collection and transport, in particular for women, has been reduced.
- ***Legume cropping*** was not a successful intervention in many areas. However, it did expand considerably if the legume species was selected with farmers and well targetted to local ecological conditions and marketing opportunities. Groundnut has attracted, for example, the attention of farmers as a cash crop with local processing and marketing potential for women. Farmers have adopted Four-Season Bean, a climbing variety of *Phaseolus vulgaris*, as a vegetable and food crop.
- ***Multistorey Agroforestry*** systems have attracted farmers' attention in the case of inter cropping coffee (a new cash crop for most farmers), ginger, fruit trees, vegetable and fodder trees in the western and central region. Shade trees are essential for sustainable management of coffee plantations in minimising damage by stemborers, drought stress and low winter temperatures.
- ***High value crops with SSM*** such as fresh vegetables in areas with market access or ginger in more remote areas have stimulated farmers to care for their land and soil fertility. The initial doubt was whether short-cycle cash crops would contribute to an overexploitation of the soil and to a decline in soil fertility. However, field studies have confirmed that farmers increase their investment into soil fertility, if the information on the cash crop is delivered together with information on sustainable soil management. Fodder and manure production, for example, increased on these farms.
- ***Fertilisers*** may provide a response of at least 25-30 kg of additional maize yield per 1 kg of nitrogen applied if the fertiliser use is at low-moderate rates, correctly applied and well synchronised with crop demand. Farmers in accessible areas have started to complement manure with an inorganic fertiliser top-dressing. However, farmers' experiences on the correct type, amount, timing and placement of fertilisers in combination with indigenous organic manure management are still limited.

Technical challenges for SSM

Some major challenges remain to be addressed. We herewith invite readers to provide ideas and experiences on how to tackle the following challenges:

- ***Preventing the gradual acidification*** of soils is the most difficult challenge for sustaining soil fertility in the hills. At least one third of the soils have an inherent low soil pH and these soils will acidify further if inorganic fertiliser use expands and organic matter applications are reduced.
- ***Increasing phosphorous availability*** is another major challenge for SSM in the hills. Many soils have considerable P-reserves. A large part of the available P is linked to organic matter dynamics ("organic P") and the management of such P-pools, in particular in acidic soils, needs to be explored. Experiences with mycorrhiza application or P-mobilizing crops may be relevant.
- ***Organic pest and disease management,*** in particular of soil pests and soil-borne diseases, is required to manage soil fertility and soil health in an integrated approach. Experiences on the control of white grubs and red ant, in particular, and organic vegetable management in general are welcome.

Research over the past 5 years has confirmed the need for a combined use of different management practices to maintain or improve soil fertility under an "Integrated Plant Nutrient Management System" (IPNS). A joint effort between staff from the Nepal Agricultural Research Council, the Department of Agriculture, the Ministry of Agriculture and Cooperatives and various NGOs was initiated in 2001 to design and implement Farmer Field Schools on IPNS. Preliminary field trials indicate that the use of external inputs can be reduced to at least one half or can even be eliminated (using urine instead of urea) without yield reduction. More than 20 Farmer Field Schools on IPNS are under implementation in 2002.

Methodological opportunities

The promotion of SSM is not only based on technical interventions but is also a social process. Organisations working with SSMP use various approaches, methods and techniques in the promotion of SSM. Some have gone through a cycle of learning and improvements over the past years. This process continues, while the following conclusions can be drawn:

- ***Indigenous and new knowledge****:* Women and men farmers have confidence in their indigenous knowledge. New knowledge complements indigenous knowledge. Thus, methods of extension that build on discussion and interactive learning among farmers are most appropriate. Commonly known visual tools for soil characterisation (e.g. pH-paper, hydrogen peroxide, litter bags, erosion boxes) proved essential for stimulating discussion. The Farmer Field School approach for IPNS is centred around such a learning process.
- ***Soil fertility and land productivity:*** The farmers' concept of soil fertility is closely linked to land productivity as shown by various surveys. Farmers' interest in SSM-practices is much higher, if these are closely linked with complementary practices for increased soil productivity (e.g. vegetable plus better manure).
- ***Farmer-led experimentation:*** Farmers need to integrate new practices into their highly heterogenous hill farming systems. Methods of farmer-led experimentation were explored in 2000/2001 by some organisations. Simple experiments on inter cropping, crop arrangements, manure or urine use were most common. This proved to be effective in increasing farmers' role and commitment in the overall testing and diffusion process. Experiences were shared with others and over 30 organisations have started supporting farmer-led experimentation in 2002.
- ***SSM implications for women and men:*** Slightly more than 50% of all farmers participating in the field activities were women. However, this quantitative participation did not prove to be sufficient, particularly in more traditional communities. Thus, efforts were initiated to assess with farmers the implications of adopting specific SSM-practices for women and men farmers. This resulted in the identification of specific actions to address qualitative gender equity, which have become part of the strategy in a technically-oriented programme.

Methodological challenges

- ***Participatory planning, monitoring and evaluation (PPME):*** The introduction of new SSM-practices into traditional and complex farming systems is a gradual process of testing, adaptation and learning. Participatory surveys in project areas proved to be of a consultative character and were mostly dominated by staff of organisations. Additionally, surveys were quickly outdated by changes in opportunities and problems perceived by farmers. Thus, a regular process of PPME at the level of the farming community is considered essential to adjust projects to emerging needs and opportunities. SSMP supports this through annual work plans (Activity Proposals) and respective budget allocations to each project. However, the overall process of learning with farmers needs to be further strengthened. An exchange of experiences on PPME and on the integration of constant learning into project cycles would be appreciated.
- ***Farmer-to-farmer diffusion:*** As improvements of local SSM are a result of the integration of new and traditional knowledge and practices, experienced farmers turned out to be the best local promoters for SSM. Additionally, demand-led extension tends to be more effective and efficient than mandated extension. Thus, a new approach of farmer-to-farmer diffusion is under testing since 2001. The most experienced farmers received additional training so as to enable them to offer their services as local resource persons. A total of 400 farmers groups are expected to hire the service of these farmers with limited financial support by the projects. More needs to be learned about modalities to support demand-led farmer-to-farmer diffusion.

Governmental policies

Recent changes in governmental policies have in general been supportive of SSM. The termination of fertiliser subsidies, the recognition of organic amendments as fertilisers and the incorporation of IPNS into the Fertiliser Policy have set a new framework. The recognition and promotion of partnership between public and private organisations in agricultural development under various policy documents has set the stage for new institutional collaboration. Community forestry has strengthened the confidence in local management mechanisms. These changes were essential for creating a supportive environment. They coincided and were partly a response to a growing strength of civil society actors in the country. The gradual implementation and internalisation of such changes, however, does require continuous efforts and sometimes struggle.

Towards a holistic Farmer Field School approach for East Africa

James Robert Okoth, Godrick Khisa and Julianus Thomas

The Farmer Field School (FFS) experiential learning and self-help development approach has become very successful in Southeast Asia in improving irrigated rice production, even beyond Integrated Pest Management (IPM) for which it was initially designed (see LEISA Magazine Vol 17, No 3, pp 18-20). The approach is now also being used for IPM in many other crops (e.g. potato, see Sherwood et al, LEISA Magazine Vol 16, No 4, pp 24-25), for other focussed aspects of agricultural development e.g. Integrated Soil Fertility Management and even for more holistic community based rural development. It is spreading from Southeast Asia to South Asia and Latin America and, more recently, even to Africa. Adaptations of the approach are needed for each new purpose and each different situation. In 1999, the FAO Global IPM Facility launched an East African sub-regional pilot project for farmer field schools on Integrated Production and Pest Management (IPPM) in 3 Districts of Kenya, 3 Districts of Uganda and 2 Districts of Tanzania, to adapt the FFS approach to the East African context. In this article, the field coordinators of this programme report on the first experiences.

The specific context of East Africa

In East Africa agriculture is small scale and integrated, for both subsistence and market, combining multiple crops with several animal species and increasingly, with other economic activities. In the areas of Kenya, Uganda and Tanzania, where the programme is being implemented, rain comes in two seasons bringing between 600 – 2000 mm yearly. Maize, cassava, sweet potato, banana and beans are important food crops and maize, sugarcane, coffee, cotton and tea are the main cash earners. Most families keep some chicken, goats or sheep, and some have cattle. Population pressure is high, soils are increasingly depleted and eroded, and pests are very active. Economic opportunities outside agriculture are few and the HIV/AIDS pandemic is increasingly affecting agriculture. All this is putting a lot of pressure on farmers to find new sources of income and to adapt and intensify their farming practices.

A broad approach needed

A mono-crop (rice) and mono-focus (pest management) of the FFS, as practised originally in Southeast Asia, would not work in East Africa. Depending on the local situation, farmers have different priority issues on which they would like to work in improving their livelihoods. With integrated production and pest management as the entry point, the FFSs in East Africa have included other aspects that have a bearing on production and livelihoods in general. At the onset of the FFSs, farmers undertake a participatory prioritisation exercise during which problems are identified and available resources are mapped out holistically. This forms the basis for relevant inclusions such as: HIV/AIDS issues, basic principles of nutrition, reproductive health care, immunisation, malaria control, environmental management, financial management skills, farming as a business etc. As a result the FFSs in the region have evolved to a forum where community livelihood issues are discussed.

The IPPM curriculum includes growing a healthy crop in healthy soil, conservation of natural enemies, regular field observation and empowering farmers to become experts. During the season-long, hands-on training process farmers are exposed to different soil husbandry and production practices, ecological pest management, post-harvest handling, value addition commercialisation and more importantly rational decision making as regards crop management.

Programme implementation

In the first phase of the programme, core facilitator field schools were created. Local governmental extension workers and NGO staff were trained as first-line facilitators accountable to the District Extension Workers. These first-line facilitators initiated Farmer Field Schools in the regions where they were based. Now, after many Farmer Field Schools have been started, more and more farmers are volunteering as second-line farmer facilitators. Their motivation coupled with a better understanding of the community makes them more responsive to farmers' needs. As the farmers take on the facilitation of FFSs, the role of extension workers is shifting to technical backstopping and linking the groups to services.

The FFSs are established following a foci model (growing outwards from a nucleus). This has increased the level of interaction among farmers, enhanced the flow of innovations across the project area and led to better co-ordination. The model has also increased community interest because impact is visible. As a result, farmers groups have established FFS networks to take on the organisational lead and advocacy role at regional and national levels..

In the FFS groups farmers learn to make an agroecosystem analysis, a crop management decision process, a participatory problem and needs assessment and how to develop a vision on improving their livelihoods. They also learn how to write grant proposals for the activities they select to work on. On acceptance of the proposals by the programme small grants are transferred to the bank accounts of the groups. With this money farmers are able to "hire" extension workers and other resource persons who can provide the information and skill training they need. Farmers are motivated to create a culture of saving to refund the working capital of their FFS groups.

A questioning, sharing and learning attitude is stimulated to enhance participatory farmer experimentation and innovation. Exchange visits link FFS groups with other farmer innovators who provide farmer-to-farmer training on their innovations.

First results

In this way more than 1000 FFS groups of 20 to 25 persons each have been started. They are now very coherent, empowered to request services and to start up commercial activities that are partly self-financed. Farmers, resource persons and facilitators have shared their indigenous and scientific knowledge which has increased the farmers' understanding on, for example, the impact of pesticides on human health, how to apply pesticides in a safe way, integrated pest management or on integrated soil fertility management

Earlier, farmers tended to keep their knowledge to themselves and did not share it with extension workers. As the attitude of extension workers has changed, from top-down teachers to equal partners, farmers have started to trust and appreciate them for their contributions and willingness in solving problems. Thus many more farmers have been reached.

FFS groups are also being used by other government services as platforms for diffusing of information, e.g. on malaria and AIDS prevention. There also have been Field Schools on food security and health. So, the initial narrow focus on pest management has widened to a broad problem solving approach, and the network of FFS groups and innovative farmers is growing fast.

Practical applications and future plans

Some groups are working on the 'push and pull' system as developed by ICIPE in Kenya (see LEISA Magazine Vol 17, No 4, pp17-18) to increase their maize and bean production. Small farmers who did not have animals were not willing to replace beans by Desmodium or to include Napier grass in the system. Adaptations were therefore needed.

Other groups are looking at the locally available sources of nutrients, improved fallow, the use of Mucuna as green manure and compost making. The soil is observed routinely, and soil, plants and animals are analysed as an interactive and interdependent whole.

Groups working on mitigating the impact of HIV/AIDS increased their awareness of the problem, the need to take care of the sick and available coping strategies. They have developed ways of farming with less labour, e.g. shifting from banana production to other crops. Women's groups have started to work together and indigenous farming knowledge is being transferred to orphans who are expected to take care of the family plots.

In Uganda farmers are working on the extraction of oil from sunflower seed with the use of hand presses. In the next programme phase, the business aspects of farming and marketing of surplus production will be given attention. Marketing groups will be started, market information exchanged and the quality of the products improved, among others, by reducing pesticide use. In this way, groups will try to get higher prices for their products.

Constraints

The FFS approach is very new in East Africa and there are still some serious constraints. The necessary attitudinal change takes time and many facilitators still have limited participatory skills. Process documentation necessary to improve the Field School methodology is time consuming and often is not given enough attention. Practical information for farmers is lacking and the internal information flow of the programme often does not reach the facilitators and farmers. When the relations within the groups are not good, groups do not function well.

Prospects

Training of the professional FFS trainers is expensive. But overall, the approach is relatively cheap and cost-effective as the farmer facilitators are basically volunteers. Compared to the ineffective old extension system the results of the FFS approach are much better not only in terms of the numbers of farmers involved and increased production, but also in terms of education of the rural population. The good results are being acknowledged and appreciated by the governments but they cannot afford the costs of 300 – 700 USD/ Year (2 seasons) necessary for each FFS group. External funding therefore is needed. With financial support from the World Bank, GTZ, UNDP and IFAD, the programme will now be extended to seven other Districts in Uganda, five in Tanzania and seven in Kenya.

Even after this short pilot phase, the experiences in East Africa show that, where funding is available, broad-based Farmer Field Schools certainly are a very promising approach for farmers in Africa to increase and improve their agricultural production and livelihood conditions. ■

Excellent groundnut growth around an eroding termite mound due to the much higher soil fertility. Photo: Joost Brouwer

Soil and crop growth variability can be an opportunity: examples from Niger

Joost Brouwer and Roelf Voortman

One of the most striking aspects of crop growth in the Sahel is its extreme variability. In one part of a field the millet or groundnuts may be lush and dark green. Only a few meters away hardly anything may grow at all (see photo). Is this good or is this bad? Or does it all depend on what you know as a farmer, and what you want, and what you are able to do?

We report here on a combined on-farm and on-station research programme at ICRISAT Sahelian Center near Niamey, Niger, that focussed on soil and crop growth variability. Many of the variability principles clarified in this research programme are also relevant to different parts of the world (see Brouwer and Bouma, 1997, a non-technical publication; Brouwer and Powell,1998; Voortman *et al.*, 2002).

Causes of soil and crop growth variability

Variability needs to be placed in the context of its environment. The overall slope of our terrain is only 1%. But the surface is covered with small rises and micro depressions, with short (2-20 m) slopes of up to 10%. Local soils, and thus crops, on these wind-blown sands in Niger are quite sensitive to periods without rainfall. Such intra-seasonal droughts are all too common during the rainy season, which lasts from June-September and averages 500 mm. The original vegetation was thorn scrub or very open woodland, which has now given way mostly to pearl millet fields and fallow. The millet is sown in pockets 1-1.5 m apart. Crop growth is also limited by the inherently poor soil fertility. Traditionally, the fertility of the millet fields closest to the villages was maintained through nutrient transfer: cattle, sheep and goats grazing in fallow and bush areas spent the nights on the millet fields, depositing their manure and urine. But there is no longer enough grazing land to satisfy the fertility requirements of the ever increasing number of fields.

In this setting, soil and crop growth variability plays a very important role. Physical causes of variability include micro topography, surface crusting and water availability, and the interactions of these aspects. Crusting affects seedling emergence, but also water availability: even on our very sandy soils, a slight slope with a slight crust can mean that as little as 30% of the rain infiltrates. A slight depression 5 or 10 m further on, and infiltration may be 300% of rainfall.

Needless to say, big differences in rainfall entering the soil cause equally big differences in leaching. In the depressions, soils are generally more acidic (pH-KCl of 4.0). On the small rises soil fertility is better, though still poor: the topsoil has about 0.3% organic matter, 120 ppm total nitrogen, 3 ppm available phosphorus and a CEC of about 1 meq per 100 g.

Both physical and chemical properties of the soil are influenced by biological factors: soil fauna and vegetation. Mound-building Macrotermes termites bring up less acidic and more clayey soil from lower layers to construct their mounds, and also incorporate plant and crop residues. Total nitrogen in the mound material can be as high as 3000 ppm, 25 times the content of the normal topsoil. Once the mounds have been abandoned, eroded and reworked by other termites, the crop growth on them can be spectacular (see photo). As much as 20% of a field had above average millet growth because of previous soil-enriching termite activity (Rotmans 1994). Trees and bushes also have their effects. Farmers in southwest Niger cut back *Guiera* bushes to reduce their water use and then sow millet more densely around the stumps, where the soil is more fertile. Under *Acacia albida* trees, which lose their leaves at the start of the rainy season, millet grows better because there is no competition for water, while shade from the bare branches lowers the soil temperature for sensitive seedlings. The trees can recycle nutrients from below the millet root zone, and manure left behind by livestock during the dry season also improves soil fertility. Indirectly, human activity can also contribute to crop growth variability: around wells and old dwelling sites soil fertility is relatively high.

What variability means to farmers and how they deal with it

Crop growth variability, much maligned in western agriculture, appears to have one great potential advantage to farmers in the Sahel: it can help stabilise yields (Brouwer *et al.* 1993). In years with good rainfall the best yields may be obtained on the higher, drier, but more fertile parts of a field. In years with poor rainfall, yields may be best on the lower, more leached but wetter parts of a field. Similarly, yields are usually higher on old termite mound sites and under *albida* trees. But as we have witnessed, the crop there may also develop too fast and wither during an intra-season drought, while the smaller millet plants in the open field survive and go on to produce normally.

Farmers react to spatial variability by differentiating their management. In better parts of a field the millet may be sown earlier and more densely, and certain parts of a field may be weeded first. The more demanding sorghum may be sown around termite mounds rather than millet. Sheep manure may be spread on eroded areas to help recover them. Branches may be placed on old termite mounds to speed up mound breakdown by attracting other termite species. Spatial variability may also be increased artificially, for instance by digging shallow holes to trap water. Small amounts of organic matter added as fertiliser also attract termites that improve soil structure ('zaï' technique).

Combining local and scientific knowledge

From what is stated above it might appear that farmers are already exploiting all locally available options for yield improvement. Indeed, there are those who say that the only way to improve agriculture in the Sahel is through external inputs. Such a statement ignores two facts:

- Firstly, for many farmers external inputs are unaffordable for the foreseeable future.
- Secondly, there are options that farmers do not know of yet, as they are based on processes they cannot observe, e.g. underground, or on ideas developed in other regions (Brouwer 1998). Here, scientists can assist farmers in making better use of their local resources. This may not result in enormous yield increases, but it can help buy time through small yield increases, thereby reducing pressure on the land. And that is an important aspect of sustainability: buying time so that one's options remain open for when circumstances change (Brouwer 2002). Besides, techniques that help make more efficient use of *local* resources can also help make more efficient use of *external* resources.

One of the things we found at Bellaré is that we are actually dealing with different wind-blown sand deposits (Voortman *et al.* 2002). The farmers already treat these deposits differently, for instance by sowing at lower density in part A. In part A soil surface sealing is a much bigger problem than in parts B and C. It may pay to look at ways of increasing infiltration there, e.g. chemically through addition of Ca or K, or with a grass mulch, making more water available for the millet.

On all three deposits there appears to be excessive manuring: more than 10 tons per hectare of manure plus urine are often found in the field, which leads to enormous annual leaching losses. Our findings suggest that it would be much more efficient to apply not more than 1.5 tons per hectare of manure, as evenly over the field as possible, every couple of years. This would allow regular fertilisation of a much larger area with the same amount of manure (Brouwer and Powell 1998, Voortman and Brouwer in press). In addition, in the relatively acidic depressions, cattle manure is quickly leached away and has almost no effect. It is better applied to the higher parts of the field. Sheep manure and urine, on the other hand, raise the pH of the soil in the depressions, and the slow breakdown of the manure pellets limits leaching losses. Our research suggests that spatial differences in effect and efficiency are also likely to apply to external inputs such as chemical fertiliser.

Ideas for the future

Our variability research has confirmed the rationale of certain current farmer practices in scientific terms, but it has also pointed to alternatives that deviate little from current practices and yet can improve efficiency of labour and input use. The challenge now is to take this further. If scientists know the locations in a field where nutrients are used most efficiently, can farmers devise ways to get them to the right place in the right amounts and at the right time? Knowing that young *albida* trees grow best near old termite mounds, can the survival rate of out-planted *albida* seedlings be improved? Knowing that mound-building termites can greatly improve soil fertility, can farmers and scientists together find ways of tilling the soil without discouraging the activity of these termites? And can they perhaps encourage these termites in areas where soil fertility is presently low? There are many ways in which indigenous farming systems may be fine-tuned, if farmers and scientists work together, really observe what is happening, and learn from each other. Only then can we truly understand how agro-ecosystems function, what role variability plays in them, and how productivity may be increased sustainably in the short term, even without external inputs.

Integration of Soil Management in Farmer Field School Programmes in Uganda

The demand from smallholder farmers for help in overcoming declining soil productivity and low yields is increasing. The programme for Soil Productivity Improvement, Conservation Agriculture and Nutrient Monitoring using the Farmer Field School approach (FFS) is a response to this demand. Its objective is to provide farmers, their communities and service providers with better rain-fed land management skills and decision-making capacity to overcome soil productivity limitations, and to develop and adopt sustainable and economically-viable land management practices.

The pilot programme is being implemented in Eastern Uganda during 2002-2003, through a partnership of concerned governmental, non-governmental, research and academic organisations. The Africa 2000 Network, a recognised NGO in the agricultural sector, is conducting the pilot activities in four districts with over 20 existing FFS groups set up for the IPPM programme (see p.18).

The FFS approach is being adapted for soil management issues. Training materials are being developed and resource persons of various service providers are being trained. Soil Productivity Improvement (SPI) is interpreted in the broader and more holistic sense of "Integrated Land Management". It embraces the management of soils, including soil biota, nutrients, water, crops, pastures, vegetation, livestock and other living organisms, tailored to a particular cropping and farming system, with the aim of improving and sustaining soil fertility and land productivity. Conservation Agriculture (CA) principles and monitoring activities are also being introduced as an integral part of the farmer-driven research and development process.

Integrated Soil Fertility Management

Opportunities for smallholders in West Africa

Henk Breman

Low soil fertility is the main reason as to why West African farmers deplete their soils. Integrated Soil Fertility Management (ISFM) provides a way to reverse this (LEISA Magazine Vol.16, No.1, pp24-25). ISFM aims at progressive improvement of soil quality and nutrient, water and labour efficiency through the combined use of soil amendments and inorganic fertilisers.

ISFM in practice

Experience shows that ISFM is effective in all climate zones having one or two rainy seasons, from the Sahel to Guinea savannah. In time, ISFM leads to improved agronomic efficiency of inorganic fertiliser, especially of N, but also of P. It usually takes 2 - 4 years or longer before this becomes visible to farmers in the form of increasing crop yields.

A three-fold increase of total millet biomass has been obtained in the Sahel, where five-fold fodder yield increases have been obtained. Similar fodder yield increases have been obtained in the Soudanian savannah. Maize yield increases due to ISFM are reported from the Soudanian, the Guinea and the Coastal savannah. While average farmer production is in the order of 1000 kg/ha, grain yields up to 6000 kg/ha have been registered with ISFM. Other crops that have reacted positively are sorghum and irrigated rice.

A whole series of soil amendments and related production systems in combination with inorganic fertilisers has been tested already. It concerns crop residues, manure, compost and household wastes, legumes and phosphate rock, agroforestry and perennial grass-crop rotations, leading to improved soil organic matter status. Part of the testing and validation is done in cooperation with rural development projects. An example is the use of a leguminous cover crop (Mucuna) in combination with local phosphate rock, to improve fertiliser use on a maize-cassava relay cropping system. An IFAD-funded project for village organisation and agricultural development in Southern Togo enabled IFDC to test and improve this ISFM option in 60 villages during 4 successive years. Such opportunities are exploited to develop and understand numerous options, to write and test technical advisory notes, and to develop a general guide on ISFM.

Strategic site selection

Three zones are distinguished in this context: 1 - zones where the use of inorganic fertilisers is already economically feasible; 2 - zones where the use of inorganic fertilisers can become feasible thanks to ISFM; 3 - zones where due to present fertiliser and crop prices, even ISFM cannot result in favourable cost benefit ratios for the use of inorganic fertiliser. Large parts of Africa comprise of marginal lands falling into zone 3.

For effective introduction of ISFM in zone 2, strategic site selection is a must. IFDC-Africa has developed two types of selection: Type I - for the choice of zones and villages, and Type II - for the choice of fields. Criteria for type I are the availability of inputs, relatively good production conditions, the accessibility of markets, and serious overpopulation with strong overexploitation of natural resources. The last criterion selects farmers with growing difficulties to make a living out of their land. Further resource depletion may be just enough for bare survival, but insufficient for courageous farmers seeking to improve their income and conditions. Such farmers are therefore very motivated to try new ways.

In West Africa, combinations of favourable conditions are found around cities with their market for cereals, fresh vegetables and fruits, in regions with intensive production of cash crops like cotton, and in regions with irrigated rice. Another example is regions with crop-livestock integration where intensification of animal husbandry through intensive fodder production is economically feasible. The Soudanian savannah, in particular, has strong comparative advantages for ISFM based crop-livestock intensification.

The IFDC-Africa approach exploits the opportunities created by favourable conditions within strategic regions, and aims for progressive inclusion of more marginal adjacent zones.

The second type of strategic site selection concerns the choice of fields at village and farm level. Practice shows that increasing cash income is the best stimulus for farmers to turn soil mining into sustainable production. Therefore, fertilisers and other external inputs have to be used on the best soils, not on the poorest or most depleted ones. Compound fields often offer the best chance of making fertilisers profitable. Farmers in Northern Togo succeeded in increasing maize production by almost 1000 kg/ha using 50 kg/ha of urea, while the same dose resulted in an increase of only 370 kg/ha on bush fields.

Participatory and holistic ISFM introduction

IFDC-*Africa* is introducing ISFM in a participatory and holistic way, working with farmers through NGOs, extension services and national research institutes. The process approach is indispensable: ISFM development can only take place through a careful integration of outside scientific knowledge and indigenous knowledge and experience, in particular where conditions are heterogeneous and the technology options are diverse and flexible. It is only by working together, evaluating progress and failures, and assuring that cooperation adds capacity to farmers and other stakeholders that progress can be made.

Investments are required to increase the capacities of farmers and other stakeholders, and to enable networking. Even for the relatively favourable strategic sites, ISFM can not be introduced without external financial support for credit, training and networking.

Opportunities and constraints for Conservation Agriculture in Africa

John Ashburner, Theodor Friedrich and José Benites

Farmers in Uganda evaluating an animal drawn direct seeder. Photo: Alexandra Bot

It is only recently that government services and development organisations in Africa have become interested in Conservation Agriculture (CA), having learnt of its successful application in Latin America. International organisations including the World Bank, FAO, GTZ, RELMA and Sasakawa 2000, started supporting initiatives to introduce CA in Africa in the late 1990s. Early experiences have been positive although CA has yet to be applied in a manner that encompasses all its aspects. But it is very clear that for CA to eventually be adopted in regions of Africa, it needs to provide sustainable solutions to the many urgent problems that African farmers are currently facing. These include soil degradation, loss of soil fertility, frequent droughts, labour shortages, declining yields and the general drudgery associated with human-powered agricultural production systems. This article discusses some of the opportunities and constraints involved with CA.

Africa's tentative experiences with CA

Many traditional farming systems in Africa have characteristics closely resembling CA systems. Tillage is often limited to planting in holes, mulching is practised (using weeds, crop residues, grasses or green manure), as is direct planting with a hand hoe and a wide diversity of crops and trees are grown. In many commercial agricultural exploitations, conservation (or reduced) tillage and direct planting, combined with the application of herbicides has been widely practised in Eastern and Southern Africa for some time (*Biamah et al 2000*). In Zimbabwe for example, about 75% of the commercial farmers practice some form of conservation tillage (but this may now be in the process of changing). One of the first "No Till Clubs" was formed by a group of commercial farmers in KwaZulu-Natal in South Africa back in the 1970s (*Fowler, 2002*). Cover crops have been the subject of research for many years, as have more suitable crop rotations and ways to better integrate crop and livestock production. However, the impact and the practice of these techniques by smallholder farmers in Africa are still very limited.

Labour saving practices needed

Increasingly, labour shortages are seriously affecting the availability of farm labour in Africa. In many countries, the rural population is steadily being reduced through migration to urban centres. This particularly concerns the younger male population, meaning that those with the best potential for heavy physical work are no longer working on the land. The situation is being further aggravated by the HIV/AIDS pandemic that is so tragically striking many parts of the African continent. As a result, many African households are now headed by women who are experiencing tremendous pressure as they have to not only care for the household and family, but run all the farm operations at the same time.

For these and other reasons, it is now becoming even more essential that farming methods that conserve resources, reduce human labour requirements and significantly improve food security be adopted. CA scores high on all these points, as is described in the previous pages.

Issues influencing adoption

Although there is much potential for the adoption of CA systems in Africa, there are also many issues that affect the feasibility of its introduction and how its principles can be translated into location-specific, agricultural production systems. Some of these are summarised below.

Awareness of the problem by a critical mass of stakeholders is a major precondition for change, particularly if the solution requires dramatic changes in behaviour or practices. The perceived problem must be serious enough to provide the pressure and incentive for change. This is not always the case and many extension services that are accustomed to promoting good ploughing practices are not yet ready to reverse their philosophy and deliver a message favouring direct planting.

A general lack of knowledge is a major constraint, particularly concerning how best to introduce CA techniques and the need for appropriate equipment and inputs such as cover crop seeds and herbicides. Fortunately, there is already a wealth of knowledge available in some parts of Africa, notably in Zimbabwe, Tanzania and Zambia as well as in various parts of Latin America. In addition, there is much that can be learnt from traditional African agricultural production systems, including water harvesting technologies, direct planting, indigenous crops etc. When one considers the present situation in Africa and the rapid advances of CA in Latin America, one cannot but note the excellent opportunity for the development of South-South exchanges.

Lack of a local infrastructure to support the manufacture and repair of CA equipment. A limited range of CA equipment is being produced in Zambia, Zimbabwe and recently in South Africa, with limited distribution. Hardly any CA equipment is available in other African countries and importation from Latin

Knife roller drawn by oxen is a popular tool on small to medium farms in southern Brazil. Photo: Alexandra Bot

America is not an option, due to the low purchasing power of smallholder farmers. Preparing the way for more widespread adoption of CA in Africa will consequently involve strengthening the private sector and provision of appropriate credit facilities.

Land tenure is a critical issue influencing the adoption of CA, as stakeholder commitment to land management is likely to be serious only if there is clarity concerning land titles and property rights. The need for a permanent soil cover can compete with traditional arrangements such as communal grazing of farmer's fields after harvest. Where communal grazing is practised, few crop residues remain and farmers are generally unwilling to invest in growing green manure or cover crops. Solutions to this typical African problem have to be found, preferably by analysing the issues with all the stakeholders concerned.

A permanent soil cover is an essential aspect of a sustainable CA system but the availability of sufficient biomass, both in quantity and throughout the year, can create a serious problem in Africa. The reasons are many. In humid conditions, the decomposition rate of the biomass is very fast. In contrast, a lack of rainfall may constitute a constraint for biomass production. And the available crop residues are needed for animal feed, fencing, fuel and a myriad of other uses. For CA to be successfully adopted in such a context, crop rotations and cover crops must allow production of enough residues to meet all these needs. To help achieve this objective, shrubs or trees can be included in the production system, inter-cropped or planted as living fences.

The integration of livestock into CA systems is very important in Africa, particularly when livestock constitutes a major component of the local economy. Uncontrolled grazing should in any case be avoided if animal nutrition is to be improved. The annual seasonal feed demands of the livestock must be integrated into the design and planning of CA rotations so as to ensure adequate supplies. Specific measures that can be adopted include controlled grazing, zero grazing, improved pastures, forage conservation, improvement of the cut-and-carry system, etc. (*Mueller et al., 2001*).

Organisation of stakeholders so as to improve public commitment is another important factor for the introduction of CA in Africa. Use should be made of existing groups such as Farmer Field Schools (FFS) and exchanges between farmers can usefully be promoted through publicity campaigns, inter-community exchanges and study tours.

Awareness creation

In recent years, a number of international workshops have been convened and pilot projects to create awareness of CA techniques are now being implemented in several countries. The most recent workshop was held at Jinja, Uganda, in May 2002, where amongst others, a range of CA equipment suitable for manual use, with draft animals and with tractors was exhibited (photo p.13).

Work is also commencing in Swaziland and 24 indigenous legume species have been identified already in the Lubombo mountain region and are being studied for their potential for use as cover crops. The first animal drawn knife roller to be constructed in the country was demonstrated in July 2002 and it is planned to demonstrate CA production systems on pilot plots over the coming months. Other CA equipment has also been fabricated in Ghana and Uganda. Awareness creation in CA is also being undertaken in Eritrea and Uganda, whilst additional projects are likely to commence within a few months in Kenya, South Africa, Mozambique and Tanzania. Requests for assistance have also been received from Lesotho, Ghana and Guinea Conakry.

The African Conservation Tillage Network (ACT) was founded in 1998 with the objective of promoting CA and exchanging experiences amongst African practitioners. For this purpose, a web site has been established through FAO (www.fao.org/act-network, see p.30). The Animal Traction Network for Eastern and Southern Africa (ATNESA) is also playing an important role in the development of animal drawn equipment for CA in Africa (www.atnesa.org).

CA - opportunities in Africa

There seems to be an interesting potential for the site-specific application of CA principles in different locations of Africa, both in the humid tropics and also in the more arid areas. A major opportunity arises from the time saving and reduced drudgery of field activities, given the "feminisation of agriculture" and the HIV/AIDS problem. Another opportunity arises from what is considered to be its better mitigation of drought and adverse climatic situations. CA can provide an entry point for arresting the loss of soil fertility through its characteristic of integrated soil fertility management. In this way, it can also contribute to improved yields and enhanced food security.

But the wide-scale adoption of CA in Africa is still in its infancy and its long-term adoption will depend heavily on the human factor and a general willingness for major stakeholders to change. It should not be considered as the only solution, but the authors are of the opinion that, over time, it can make a significant contribution towards improved food security in the continent. ■

The views expressed in these papers on CA are the personal opinions of the authors and do not necessarily reflect the official policy of FAO.

A farmer in the steep lands of southern Honduras using a planting stick to sow his maize in a mulch layer of fallow vegetation. Photo: Alexandra Bot

farmers produced more or less the same quantity as the year before.

Farmers are reporting increases in maize yield of a minimum of 60%. Even more important is that yields remain stable at a higher level for longer periods. The longest period fields have been under continuous maize production is seven years. These fields, with a slope of 35% and poor soil have an average production of 2.9 t/ha. Before, on the same fields, the best yield was 1.6 t/ha while the land had to be left fallow for several years after a two-crop cycle. Besides maize and sorghum the plot is providing the farmer with firewood and poles, which give an extra value to the production. Additionally, from the first year onwards, the farmer can rent his/her terrain for livestock grazing, because of increased stover production on the field. Usually this is done for two months. Efforts are still needed to integrate livestock production better into the system.

Rural development enhanced

The Quesungual system not only meets the household subsistence needs for fruit, timber, firewood and grains, but generates a surplus, which when sold on the market generates cash income. This change is just the beginning of a process of intensifying land use and increasing land and labour returns. Once the farmer feels comfortable with the enhanced food security (maize and beans), (s)he starts to diversify into crops for the local market or home consumption, soya, sugarcane, indigo, pumpkin etc., as well as small animals for the market such as pigs and chickens. Increased grain availability is accompanied by the improvement of the household post-harvest storage system. When basic grain security is assured, families begin to invest time in improving their living conditions and education, and devote time also to community organisation. Women's production cooperatives are now making dairy products. Farmer and trade organisations have also been established. The people themselves are now taking full responsibility for planning improvements in their communities.

Obstacles to adoption

This experience has generated great interest not only in Honduras but also in the region. The south of Lempira is now known as the region where farmers no longer burn - a label they are proud of. Nowadays, the Quesungual system is being adopted elsewhere in the country and is being adapted by farmers according to local conditions. The major obstacle to large-scale change from slash-and-burn to agroforestry is not the small farmer. They are well aware of the problems connected with slash-and-burn agriculture and respond rapidly to sustainable alternatives. It is the extensionists and their professional superiors who clinch to their production-based, single-crop focus and oppose a systems approach. It is their lack of training in demand-driven participatory extension and the still dominant paradigm of rural development projects with their focus on physical, supply-driven indicators. Although much is said about collaboration between local and professional knowledge systems, the practice is still in its infancy.

Experiences in El Salvador

Conservation Agriculture and rural development

Marcos Vieira and Jan Van Wambeke

Besides knowledge, technologies and supplies, adoption of Conservation Agriculture (CA) needs a favourable (policy) environment, motivation and participation of farmers and their communities. The presence of leaders and/or farmers' organisations is important for knowledge sharing and capacity building. The combination of all these parameters with CA at catchment level results in sustainable rural development based on the integrated management of natural resources.

Productivity and conservation

In Guaymango (El Salvador), about 85% of the land area is used for agriculture, and consists of small hills and slopes between 40 and 90%. Half of the agricultural land is used for pastures, the other half for crop production (mainly maize and sorghum). Monoculture, overgrazing, burning of crop residues and intensive tillage rapidly led to severe land degradation, low yields, poor nutrition and increased poverty in the early 1970s. Following the spread of the Green Revolution in wheat and rice, the thinking on research and extension in El Salvador was conditioned by traditional extension methods, combined with a "package" approach. The package disseminated by the Ministry of Agriculture, primarily during the late 1960s and throughout the 1970s, consisted of the following technology, according to Sain and Barreto (1996):

- use of hybrid maize seed,
- use of nitrogen and phosphate fertilisers,
- increased plant densities, through reduced row distances,
- application of herbicides and insecticides.

During a diagnostic appraisal that was held in the area of Guaymango in 1973, three major problems were identified: high poverty levels, food insecurity and recurrent health problems in the community. Based on this appraisal, it was concluded that low productivity of the agricultural system was one of the main causes of the high poverty levels found in the area (Calderon, 1973). Furthermore, it was concluded that the low quality of the soils caused by serious degradation in the area was the main reason for the low productivity of the agricultural systems. Based on these conclusions, an intensive programme was launched by the Ministry of Agriculture and several private and public institutions to increase maize and sorghum productivity and to improve soil conservation practices. A number of soil conservation measures were added on to the package mentioned above, based on zero tillage and improved crop residue management, and included the following components:

- no burning of crop residues,
- uniform distribution of crop residues over the field,
- use of living and dead barriers, and
- contour sowing.

The promotion of these measures was the starting point of a new phase in land management in the area, based on conservation tillage. Through this programme and later through land reform, farmers improved agricultural production, increased their net income more than 2.5 times and adopted "conservation" practices at the same time. Close collaboration between institutions and organisations participating in this programme was also an important factor, which has contributed to the successful adoption of Conservation Agriculture practices by farmers.

Integration of crop and livestock

The interaction of crop production and livestock within the agricultural production system is vitally important in understanding the adoption of conservation tillage practices by farmers. Livestock in the farming system is probably the most difficult challenge, particularly when there are other uses for crop residues than cattle feed, like mulching and soil improvement.

At the end of every crop cycle, the improved maize-sorghum system in Guaymango produces almost 10 tons of crop residue per hectare. At the end of the dry season, nearly 6-7 tons of crop residue per hectare remains for use as mulch. Compared to similar regions (2.3 tons per hectare) this is a substantially greater quantity and can be explained by three main factors:

- farmers here value the use of crop residue as soil cover more than elsewhere;
- the high economic importance of cattle in the farming system (number of cattle and duration of grazing period);
- the high degree to which a fodder market has been developed (trade of grazing rights).

The experience of Guaymango is one of the few that reports successful integration of the crop and livestock components of the farming system, without creating competition in the allocation of crop residues. The amount of residues produced by the system is enough to serve both the conservation purpose and as fodder for livestock (Choto and Saín, 1993). This is precisely why farmers do not sow hybrid varieties of sorghum in Guaymango, but local varieties that have a high straw/grain ratio (Choto et al., 1995) instead.

Farmers' perceptions

According to local farmers, the adoption of conservation tillage practices and the improved crop production technologies have induced a considerable change in their livelihoods. The most apparent differences are the increased yields - it has doubled and in good years even tripled; and the labour required for sowing has been reduced by 75%, which according to the farmers is because the soil has become softer and easier to work with. When residue burning was used to clear the fields, the soil was very hard and it took almost a day and 10 people to sow a hectare, compared to 5-6 people needed now in half a day.

The mulch effect of crop residues has additional advantages. According to the same farmers, it conserves more soil moisture, which allows them to harvest in dry years. It also prevents seeds from being washed away by rain showers, just after sowing, and facilitates rainwater infiltration. The decomposing mulch layer gives the soil a darker colour, which is usually an indicator of better soil fertility. The presence of more earthworms was mentioned as a positive change because 'their excrements are like fertilisers'. "Tilling the soil at this stage would mean destroying the existing fertility (residues and roots) and soil life", said one of the farmers.

After 25 years of managing crop residues optimally, some farmers are even applying less fertilisers to their maize fields than when burning residues was a common practice.

Pest and disease incidence has been reduced. One of the insect species, white grub ('*gallina ciega*') (*Phyllophaga* sp.), which was formerly reported as a pest in maize, is still present in the fields, but is no longer a problem. Farmers think that the larvae now feed on the roots and residues of the previous crop, instead of attacking the roots of the crops growing in the field. The mulch layer also prevents birds from feeding on recently sown seeds. The birds, which still visit the fields, are now a form of biological pest control, because they feed on caterpillars and larvae found in the crop residues or on the plants.

Full adoption after only ten years

The expectation of increased yields and the increased awareness of the value of appropriate crop residues management as a soil conservation measure are the main reasons given by farmers for not burning crop residues when preparing their fields. Although many farmers were initially sceptical about changing from burning crop residues to more conservation-oriented soil management, full adoption of the technological package was achieved in just 10 years. Both the successful agricultural extension programme and the link between practical recommendations, incentives and restrictions were key elements that induced this change in soil management. ■

The Quesungual system in Honduras

An alternative to slash-and-burn

Luis Alvarez Welches and Ian Cherrett

Slash-and-burn agriculture is an efficient system as long as population pressure is low enough to limit impact on the tropical forest. As the rural population grows the cycle of land clearing becomes shorter, leaving little chance for the vegetation and soil to recover. The lack of fertile land pushes subsistence farmers onto steeper hillsides and into the more humid forests. This leads to accelerated deforestation and environmental degradation and land use becomes increasingly unsustainable.

In Central America, and especially in Honduras, slash-and-burn agriculture has been 'technified'. In an attempt to modernise basic grain production by small farmers, projects and NGOs have promoted credit, fertilisers and other inputs without changing the production system. The result has been even worse for the small farmer and the environment: the rural population has become debt-dependent and the process of deforestation and degradation of land and water resources has accelerated further. This has increased the vulnerability of the countryside to natural phenomena such as hurricane Mitch in 1998 when many died and rural incomes dropped dramatically (see LEISA Magazine Vol.17, No.1, p.18-20).

The Quesungual system

In the department of Lempira, one of the poorest and most isolated regions of Honduras close to the border with El Salvador, small farmers cultivate their land (1-5 ha) on hilly terrain, 200 to 900 meters above sea level. Supported by the Lempira Sur collaborative project initiated by FAO, a massive shift to a new production system has taken place over the past ten years. This system is called "*Quesungual*", after the village in which it was first developed. It is a Conservation Agriculture system with a tree component which allows small farmers to cultivate their land on steep slopes continuously while regenerating it.

The Quesungual system is an adaptation of an indigenous agroforestry system, which can be found in the dry tropical forest ecosystem (140-800 masl). This system is characterised by three layers of vegetation: mulch, crops, and dispersed shrubs and trees. It usually combines grain crops with naturally regenerated trees and shrubs with high-value/ multipurpose timber and fruit trees. A typical plot has numerous pollarded trees and shrubs and about 15-20 large trees: timber and fruit species. The diversity of species in the system is high (see table 3).

Burning has been abandoned, vegetation and plant density are controlled by hand and in addition some farmers use herbicides prior to sowing. Maize is intercropped with sorghum and beans, using zero-tillage, mulching and direct sowing technologies. The natural vegetation is used as a cover crop, in between the grain crops.

In the dry season, the trees and shrubs are pollarded at a height of 1.5-2 m, in order to eliminate the branches and regrowth, and to provide light for the future crop. The pollarded material is used as mulch to cover the soil. The branches and trunks, which can be used as firewood and poles, are removed from the plot. In general, high-value timber trees and fruit trees are not pruned. Farmers achieve an ideal density through the management of the natural regeneration. Before sowing the second crop (often beans) the field is cleared a second time but trees and shrubs are not necessarily pollarded. Mineral fertilisers are expensive and thus used only when maize and sorghum are both grown as first crop. Only once during the cropping season, weeds are cleared either manually or by using a herbicide. The crops are harvested in the traditional way (FAO, 2001).

Impacts on resilience, natural resource base and production

For the farmers it is the moisture retention qualities of the system that makes it so attractive. The agroforestry system retains 15% more water in the soil in the driest month (April) than the slash-and-burn system (8% humidity in a traditional field and 23% in a Quesungual field). This difference is equivalent to 20mm of rainfall, which means that crops can be sustained 20 more days without rainfall. And it is this difference that counts for the success or failure of a crop in a climatic regime with irregular dry spells during the rainy season.

Besides better infiltration of rainwater into the soil profile through the soil cover, the increase in soil moisture can be explained by the increase in organic matter content of the soil. The organic matter content was monitored during four years, in three different places, and increased from 2.4% to 4.5%. At the same time soil erosion has been nearly stopped. The loss of nutrients through erosion has been estimated to be more than 10 times lower in the Quesungual system than in the slash-and-burn. Taking into account only the nutrients, these losses represent US$34/ha under the Quesungual system, instead of US$396/ha, in the slash-and-burn system.

The improved soil conditions make the system more resistant to climatic phenomena. Compared to farmers who remained with the old system of slash-and-burn, the Quesungual farmers didn't experience a total loss in maize production during the dry period of el Niño in 1997. Even in the following year, when hurricane Mitch passed over Central America resulting in excessive rainfall and many farmers losing their crop for a second time, the Quesungual

Planting concepts and harvesting good results

José Benites, Sandrine Vaneph and Alexandra Bot

In large parts of Latin America, Asia, Eurasia and Africa soil tillage by plough or hoe is the main cause of land degradation leading to stagnating or even declining production levels and increasing production costs. It causes the soil to become more dense and compacted, the organic matter content to be reduced and water runoff and soil erosion to increase. It also leads to droughts becoming more severe and the soil becoming less fertile and less responsive to fertiliser.

In the early seventies, farmers in Paraná, Southern Brazil, recognised that continuing soil erosion and declining crop yields were forcing them to abandon their land and move into a marginal existence. Their first attempt at changing this trend was to rigorously adopt conventional terracing systems. The mixed and often disappointing results led them to tackle the problem of erosion at its source, considering the direct impact of rainfall on the bare soil. They abandoned the plough, broke their compacted soils, introduced cover crops, stopped the burning of crop residues and developed cutting rollers to turn crop residues and cover crops into mulch. This mulch layer eliminated rainfall impact on the soil, reduced the speed and quantity of runoff and virtually eliminated soil erosion. It also significantly increased soil fertility and yields, and reduced the labour and cost of land preparation (Hercilio de Freitas 2000, see also ILEIA Newsletter Vol.11, No.3, pp.16-17).

This was in the early nineties, at the beginning of the Zero-Tillage (ZT) movement in Latin America. At that time '*conservation*'-, '*reduced*'-, '*no*'- or '*zero*'-tillage or '*direct planting'* in combination with herbicides was already being practised by commercial farmers, mainly in the USA. But it was only after ZT was combined with cover crops and crop rotation, adapted to tropical conditions, and improved herbicides and special equipment were developed, also for small farmers, that the tremendous benefits of this approach were widely appreciated and it spread faster.

At present, ZT is being practised on about 60 million ha, mostly in Latin and North America. In Latin America, particularly in Brazil, Argentina and Paraguay, some 25 million hectares have been converted to ZT in the past ten years. As the approach has become far more comprehensive than simply ZT, it is now being referred to as Conservation Agriculture (CA) by FAO and other organisations (see also LEISA Magazine Vol.17, No.3, p.22).

In Latin America, farmers, their organisations and networks took the lead in the development of CA. Government support was initially limited as ZT was not an officially recognised technology and researchers, extension agents, trainers and policy makers were reluctant to accept new ideas. Now, all this has changed and CA is developing fast due to effective collaboration between farmers, private enterprise, research and extension. CA has long passed the stage that it was only suitable for grain crops, like maize, beans and soy. Now, crops like sugarcane, cassava, tobacco, onion, tomato, cabbage and lettuce are all successfully grown under CA.

CA also fits into an increasing number of cropping conditions of large and small farmers in the humid and dry tropical, semi-tropical and temperate climate zones in Latin America, Africa, Eurasia and Asia. The FAO is playing an important facilitating role in promoting and further developing CA, among others, by its field projects, by actively supporting regional CA networks and by providing information on CA through its publications and web site. This article provides an overview of principles, practices, potentials, constraints and methodologies. The articles on p. 10 and 11 present two FAO-supported cases of CA in Honduras and El Salvador. The article on p. 13 discusses the perspectives of CA in Africa. Previous issues of LEISA Magazine have presented approaches similar to CA: New Kekulam zero tillage rice farming in Sri Lanka (Vol.13,No.3,pp.20-21); traditional mulch farming in Burkina Faso (Vol.15, No.2&3, p 37), traditional shifting cultivation and analog agroforestry (Vol.16, No.3); the Rice Wheat Consortium approach to CA in India and Pakistan(Vol.16, No.4, pp.8-10). Other cases can be found in (García-Torres, Benites and Martínez-Vilela 2001).

General principles of CA

Three technical principles are crucial in CA:

- ***No mechanical soil disturbance*** *– direct seeding or planting*
- ***Permanent soil cover*** *– particularly with the use of crop residues and cover crops*
- ***Judicious choice of crop rotations*** *– multiple cropping, agroforestry and animal integration*

The permanent soil cover provided by growing crops, crop residues or mulch not only protects the soil from the physical impact of rain and wind, but also stabilises the soil moisture and temperature in the surface layers. This zone thus becomes a favourable habitat for a number of organisms, including plant roots, worms, insects and microorganisms such as fungi and bacteria. This soil life uses the organic matter from the soil cover, recycling it into humus and nutrients, and contributes to the physical stabilisation of the soil structure, allowing air and water infiltration and storage. This process, which can be called "biological tillage", strongly enhances soil and water conservation and soil fertility. Mechanical tillage is avoided in order to maintain soil life and soil structure, and to reduce mineralisation of soil organic matter. A varied crop rotation is important to avoid pest and disease problems, improve soil conditions and make full use of the entire soil profile and the synergetic and complementary interactions between different plant species. Green manure/ cover crop species (leguminous and non-leguminous) that are part of the crop rotation are essential in building up the soil organic matter content. The soil cover also provides new habitats for natural enemies of pest and disease organisms. It provides a physical barrier to weeds and releases allelopathic substances that reduce weed germination. Thus a healthy soil which offers optimal physical, chemical and biological conditions for the growth and reproduction of plants is created.

Box 1. Key features of CA systems

- No ploughing, disking or seed bed preparation
- Green manure / cover crops are integrated into the cropping system
- Crop, weed and cover crop residues applied as mulch protect the soil permanently
- Direct seeding or planting
- No burning of crop residues or fallow vegetation
- No uncontrolled grazing
- Nutrient cycling through the biomass in and above the soil
- Surface application of lime and fertilisers
- Specialised equipment for seeding and mulch management
- Continuous use of cropland
- Crop rotations and cover crops are used to maximise biological controls

Specific practices

Many traditional shifting cultivation systems follow the above principles of slash and mulch. Uncontrolled burning (slash and burn) and grazing, however, works against these principles. There are no blueprints for the development of new CA systems and the general principles and key features (see box 1) have to be adapted to each specific agro-ecological, socio-economic and cultural context. The success of such a new system depends entirely on the creativity and flexibility of its practitioners in developing management practices suited to their particular situation and needs. Traditional practices and species, which are adapted to the local context, but abandoned due to reasons of low productivity, are often re-introduced with good results. Agrochemicals are not excluded, but low or decreasing quantities are used efficiently. CA often includes Integrated Soil Fertility Management (ISFM), Integrated Pest Management (IPM), Integrated Weed Management (IWM), agroforestry and crop/livestock integration, for which the three principles provide an excellent basis. The integration of trees and livestock into the system is especially important. CA can come close to or be completely organic.

Benefits are many

Permanent vegetative soil cover ***strongly prevents soil erosion*** and reduces the need for other soil and water conservation measures, bunding, terracing, etc. The increased soil organic matter content allows more water and nutrients to be stored in the soil profile, so ***more soil moisture and nutrients are available for plant growth***. The excess water filtrates to deeper soil layers, ***recharging groundwater supplies*** and reducing floods and sedimentation of waterways downstream. The water conserving effect of the soil cover and the increased organic matter result in an ***economisation of irrigation water***, as is shown in table 1.

With time, the accumulation of soil organic matter and the increased activity of soil micro-organisms lead to ***higher efficiency of organic and inorganic fertilisers*** and thus allow lower application rates. This saves costs and increases the profitability of in-organic fertilisers, thereby making them affordable to more farmers.

Increased soil moisture and soil fertility favours root penetration and development, which in turn ***boosts biomass production and crop yields***. CA is a successful strategy for ***ecological intensification,*** among others ***of shifting cultivation and slash and burn systems,*** which can evolve into permanent agroforestry systems, while burning is abandoned.

CA allows ***early and timely planting*** due to the absence of tiresome land preparation activities. The effects of the soil cover result in an agricultural system that is ***less vulnerable to drought, heavy rainfalls or other natural disasters.***

Also ***the risk, scale and frequency of weed, pest and disease infestation are reduced considerably***. Where chemical pesticides or herbicides are applied in CA, the amount needed often decreases with time as farmers gain skills and new ecological balances are established. Compared to conventional tillage, ***the use of chemical pesticides and herbicides is less*** in CA.

The improved workability of the soil and less agronomic activities during the production cycle ***reduce the labour requirement substantially*** (see table 4, p.12). This is especially important for those who rely only on family labour and in areas where labour is becoming a constraint because of deaths and diseases. The reduction in the on-farm labour requirement allows ***farmers*** to ***diversify their activities***, including processing of agricultural products, and thus improve their incomes. Besides the reduction in

Table 1. Economy of irrigation water through soil cover (Pereira, 2001).

Percentage of soil cover	0	50	75	100
Water requirement (m^3 ha^{-1})	2660	2470	2090	1900
Reduction in water requirement (%)	0	7	21	29
Number of times irrigated during season	14	13	11	10
Number of days in between irrigation	6	6	8	9

Table 2. Increase in yield and farm income (in monetary units; CA=Conservation Agriculture)

	Conventional Agriculture	CA Year 1	CA Years 2-4	CA Years 4-6	Year 6 and onwards
Gross output	2000	1800	2200	2300	2400
Total variable costs	1400	1300	1200	1100	1000
Gross Margin	600	500	1000	1200	1400
Total fixed costs	200	200	200	200	200
Net farm income	**400**	**300**	**800**	**1000**	**1200**

(FAO, in print. Conservation Agriculture. What you should know about... economic aspects of Conservation Agriculture. Training module. AGLL. FAO Rome.)

labour, the ***cost for land operations and maintenance of tools and equipment are also reduced***. Even where mechanical traction is used, CA leads to ***considerable savings in the use of fossil energy***. As CA also strongly contributes to carbon sequestration due to the increase of biomass in and on the soil, it could when applied at large scale, provide ***a major contribution in controlling global warming.***

All this contributes to ***increased and more stable yields and revenues*** (***up to double or even triple)*** which build up during a period of 2-6 years. Diversification of agricultural production also plays a role in ***improving the farmer's livelihood: less risks, increased income, improved diet, etc.***

CA provides a truly sustainable production system, not only conserving but also enhancing the natural resource base and ***increasing biodiversity*** without sacrificing yields at high production levels. Therefore CA is a major opportunity that can be exploited for achieving many objectives of the international conventions on combatting desertification, on biodiversity and on climate change.

Constraints and challenges

Conversion from conventional tillage to CA is not simple and poses many constraints that need to be resolved, demanding time, effort and money. It may include costs for purchasing specialised equipment and agrochemicals, possible temporary income decreases until the new dynamics are established, and a learning process by the farmer to acquire higher management skills. For many (small) farmers, a general lack of financial resources and lack of access to equipment, chemical inputs or green manure seeds can be serious limiting factors.

Tenure may also be a constraint in situations where most of the land is collectively managed and where land is accessible to multiple users often having contradictory interests in terms of land use, for example pastoralists and farmers. Farmers who have insecure tenure may be reluctant to adopt CA even though they see the benefits, because improving the soil productivity increases the risk of losing the land to more powerful persons in the society. This is a major problem for landless persons and female heads of households.

Pest, disease, weed or soil fertility problems could occur in the transition stage when the system has not yet stabilised ecologically. This may require the use of chemical pesticides, herbicides or fertilisers for which money could be a constraint. In moist areas for example, a major issue raised by the permanent soil cover could be pest and disease management. The crop cover may harbour small animals such as rats or snakes. In drier areas, the lack of biomass due to water or nutrient shortages and other uses of the biomass (livestock feeding, cooking) is often a major issue. Where population density is low and agriculture is marginal, availability and the cost of equipment and agrochemicals is a constraint. Social and cultural acceptability may also be a problem where CA differs substantially from the indigenous or conventional system.

Before starting with CA, it may be necessary to eliminate some major effects of degradation, such as compacted soil layers, plant nutrient deficiencies or heavy weed infestation. Subsoiling of compacted and degraded soils can, due to higher water infiltration, result in immediate yield increases of up to 30%, but may be too costly for small farmers.

Conversion from conventional tillage to CA calls for a drastic change of thinking. CA is based on agro-ecological processes and systems which require farmers to think in terms of ecological concepts such as soil as a living system, plant communities, nutrient flows, pest – predator and animal – crop – soil relations, etc. If farmers are unable to radically change their thinking and vision on farming, they will not succeed in making CA work effectively. This is not only true for farmers but also for technicians, extensionists and scientists.

Farmers who depend on their local resources may have a lot of traditional / indigenous knowledge that fits with CA. Often, extensionists and researchers find it difficult to accept indigenous knowledge and learn from and with farmers. For them, shifting to the concept of CA and a participatory way of working means a tremendous change. The resistance to change of researchers, academics and advisors can be much greater than that of farmers.

Box 2. "Friends of the Land" clubs in Brazil

In Brazil, the main obstacles for farmers in the adoption of Zero Tillage were the lack of knowledge, information and technical support. These obstacles were overcome through the activities of "Clubes Amigos da Terra" (CATs), non-profit, non-commercial and non-political farmer organisations. The operational basis of the CATs is farmer-to-farmer exchanges of experiences on a monthly basis and organisation of promotional events, such as field days and debates. CATs also organise on-farm research and pilot projects with the support of other organisations. An important factor for success has been the assistance which medium and large farmers, through individual CATs and the Brazilian Federation for Direct Planting, have provided to small farmers wishing to adopt ZT. Private sector support was fundamental to the expansion of ZT as well. In South Brazil, where ZT by small farmers is well developed, there are more than ten manufacturers specialising in ZT machinery for small farmers. Both in South Brazil and Paraguay, ZT systems that eliminate the need for herbicides have been developed, especially for small farmers.

Recently, the Landcare movement in South Africa adopted an approach similar to CAT in Brazil, advocating the establishment of local Landcare Groups which would conduct situation analysis, broaden their strategic understanding with a visioning process of CA, and then undertake participatory land use planning.

Farmer groups crucial for CA

Access to information, cover crop seeds, equipment, training and technical support is a prerequisite for successful conversion to CA. In addition, financial support, especially for small farmers, is often a major requirement to catalyse the conversion process. But, one of the lessons learned from Brazil is that new technologies spread fast only when farmers feel the need to change their practices and when they take the lead in technology adaptation and innovation. Simple extension of the message, even coupled with demonstration, usually will not suffice. Also, successful improvement of land husbandry depends not just on the motivations, skills and knowledge of individual farmers. The formation of farmer groups and associations or, even better, building on existing and active groups for testing and adaptation to local contexts and learning from shared experiences is crucial for CA to take off. In Brazil such groups have become action groups, transmitting the new ideas and technologies from farmer to farmer, stimulating and supporting members to make the change (see Box 2). In addition they have also become important local pressure groups, managing to obtain improvements at institutional and political level.

Strategies for conversion to CA

Specific conversion strategies are needed to make conversion to CA attractive and affordable to farmers. In Latin America, building up soil organic matter content in the soil with intercropped green manure / cover crops (associated with the normal cash or subsistence crops) over a period

Box 3. Principal mechanisms for mass conversion to CA

- farmer-to-farmer exchange
- extension activities
- commercial and NGO-sponsored events
- small farmer pilot projects
- technical assistance/promotion activities of private sector
- private and co-operative technical assistance
- NGO/government/private-sector publications
- press and television reports
- small financial inducements

of one to three years before moving to ZT is the strategy followed by most farmers. In this way the conversion takes place without loss in productivity, while costs (for tillage and equipment) already drop considerably (Rolando Bunch, Fallow Net email discussion on CA).

Farmers may have their own specific reasons for wanting to change their farming practices. These reasons can vary from community to community and from one social group to another within a community. This calls organisations working with farmers to offer specific entry points. Saving labour, increasing yield, reducing costs, drought proofing, improving health or the livelihood system in general can be appropriate entry points to start CA. It must be the farmers themselves who decide on trying out or transferring to CA and which entry point is most important for them. They should also decide on the use of external inputs: choosing between herbicides and mechanical weeding, and using fertilisers and lime to correct initial soil imbalances. Good information on potential benefits, opportunities and constraints is a prerequisite for farmers in making their choice.

Finding the right approach of facilitating a farmer-driven participatory conversion and technology development process while ensuring the communication of a very straight-forward technical message is challenging. It requires the support of convinced and capable extension workers and researchers. Often, low-cost or ecological options can be found for adaptation to the local context and resolving conversion problems, for example weed control with hand tools, cover crops and crop rotations; use of manure and biological nitrogen fixation; home-made "soups" for disease control; compost starters etc. (Barber 1999). Sometimes new innovations are needed.

CA started in many countries as a farmer-driven adaptation of a production system. But researchers and extension workers from both public and private sectors have played an important facilitating role in reaching a critical mass of farmers and generating knowledge and adaptations to the system as a whole or to equipment in particular. In addition the process has drawn sectors together and allowed the development of coherent integrated strategies and approaches (see Box 3) addressing crops, livestock, land and water resources, as well as infrastructure, marketing, education etc.

Involving the private sector

The large-scale shift to CA in Brazil and Argentina was possible among others due to close collaboration between innovative farmers and the private sector to develop and disseminate appropriate equipment. CA is challenging the existing private sector companies and local craftsmen/artisans to support the transition to CA systems. In particular, the testing, manufacturing and provision through local markets of required tools and implements. The same applies for cover crop seeds and associated herbicides plus spraying equipment, in case chemical weed management is chosen (see Box 4).

Exchange and networking

Access to information is very important in reaching a critical mass of CA practitioners, both within a country and between countries and organisations. Part of the information can be made available in the form of selected case study material describing CA experiences under different conditions. Researchers can gather in-country information on, for instance, validation of different cover crop species and testing and adapting of hand and animal drawn equipment.

The transfer of the concepts, principles and technologies of CA needs network interchange within and between countries, so as to facilitate sharing of known solutions to problems identified during the continual learning process. Such networks can accelerate the advancement of knowledge and techniques being steadily accumulated by both national institutions and community groups in their efforts to reverse land degradation on a global scale. For this purpose several regional networks -RELACO, ACT, SACAN and ECAN- have been founded in Latin America, Africa, South Asia and Central Asia (see Websites p.30) respectively.

Policy support

CA will only spread rapidly and widely when and where government policies, services and infrastructure facilitate the conversion to these systems. Policy support is needed to adjust legislation and to provide an enabling environment to meet the requirements and facilitate the initiatives of local groups and land users. This means an appropriate policy and institutional framework and the provision of incentives (pricing, markets, land reform, security, etc.). Existing incentives and subsidies should not jeopardise the implementation of the system. New incentive measures may be needed to encourage CA uptake, including the identification and multiplication of seeds and supply of equipment through public and private sector involvement. Financial support alone cannot boost a CA programme. It is essential to make the general public, decision and opinion makers aware of the social benefits of the adoption of these practices in order to gain the government's support for natural resource management initiatives of farmers.

Finally, international organisations such as World Bank and FAO, and OECD countries in their own right, should encourage a vigorous international and regional media campaign emphasising the importance and relevance of CA as an entry point to the process of rural poverty alleviation, food security, and environmental protection. Development of CA can only be achieved by integrated action at farm, community, national and international levels.

Box 4. Development of equipment for CA in small farms

Even in 1990, there were few small farmers working with CA in Brazil. Although the general principles were broadly applicable, the planting technology for manual and animal traction had not been developed. It was pioneer research and small manufacturing firms, which resolved the problems of adapting the planting technology in direct collaboration with farmers. Equipment for direct seeding in mulch (e.g. jab planter or animal driven direct seeders), management of vegetative cover (e.g. knife rollers and slashers), spraying of herbicides (e.g. adapted knapsack sprayer) and mini-tractors were thus developed for small farmers (see illustrations on cover, p.3,13,14). Collective purchase and use of such equipment was stimulated, as CA allows for greater flexibility in the time of sowing.

Living soil -basis for Conservation Agriculture

Editorial

Conservation Agriculture spreading fast

Thirty years ago it all started with herbicide-based Zero Tillage (ZT) for grain crops like maize and soybean. Gradually a much broader and ecologically sound approach evolved, which is now being called Conservation Agriculture (CA). CA is based on reduced or no tillage, direct seeding and crop rotation. The soil is covered with a mulch layer of crop residue, green manure or cover crop, and herbicides or mechanical or natural methods for weed control are used when required.

Presently, many crops, e.g. sugarcane, banana, cassava, tobacco, rice, onion, tomato, cabbage and lettuce, can be grown in CA systems in humid, dry and temperate climates. CA is practised widely: from commercial, large-scale, relatively simple mechanised systems using herbicides, pesticides and inorganic fertilisers to semi-subsistence, complex systems with integration of trees and animals replacing slash and burn (p.10). CA is challenging farmers to produce in a more integrated and ecological way by following Integrated Pest Management (IPM), Integrated Weed Management (IWM), Integrated Soil Fertility Management (ISFM) or Agroforestry, or even to go organic.

The potential benefits of CA - reduction of soil erosion, more efficient use of inputs, important savings in labour, fossil energy and total costs, and increase in production - are impressive. CA has become one of the fastest spreading approaches in agriculture, not only in the USA and Australia but also in Latin America, where millions of farmers are practising it (p.6). The CA movement in Latin America is an important breakthrough in the acceptance and development of agroecology / LEISA. However, in Africa and Asia, despite some initial successes, practitioners are still few and far apart.

Different actors working together

The past decade has witnessed important advances in herbicide technology and in the designing of special equipment for mulching, direct seeding and spraying. Also green manure/ cover crop (gm/cc) technology is developing fast. Larger and smaller farmers in Latin America now have a wide choice of herbicides, equipment and gm/cc species, both leguminous and non-leguminous.

In Latin America, development of CA is strongly site and crop specific and driven by farmers' organisations with participatory support from research and extension. Private enterprise is playing an important role as well, especially in development, production and sale of herbicides, equipment and gm/cc seeds. FAO and many other international development organisations are strongly supporting CA.

Also multinational companies like Monsanto are investing in the introduction of ZT approaches to increase their sales of seeds and agrochemicals. They propagate high-external-input ZT based on direct seeding, monocropping and hardly any mulching of crop residue. They seem to offer an attractive opportunity to farmers but not without hidden risks. NGOs and a small farmers' organisation in the Philippines point at the risk of upland farmers getting too dependent on these companies and their costly and health affecting agrochemicals. It may also mean that farmers loose their own local seeds and end up with the genetically engineered seeds propagated by these multinationals. It is not at all necessary to take these risks when organic- and traditional seed-based alternatives are available at low cost as in the Philippines (Biotechnology and Development Monitor No.46, June 2001, p.13). It is therefore important to establish a clear distinction between low-external-input based Conservation Agriculture and high-external-input based Zero Tillage.

Africa faces many constraints to CA

For many years, CA (or Conservation Tillage as it is called in Africa) is being practised by commercial farmers, e.g. in Zimbabwe and South Africa, but only by a few small farmers. Adoption of CA and gm/cc is hampered by many constraints including those related to soil, climate, free grazing of animals and lack of biomass for soil cover at the end of the dry season, availability and affordability of equipment and herbicides, availability of gm/cc seeds, labour migration, community land tenure and lack of information (p.13). Still, FAO staff is of the opinion that, over time, CA can make a significant contribution towards improved food security, also in the dryer parts of Africa.

Traditional Conservation Tillage - entry point for CA

The practices applied in CA (zero tillage, mulching, direct seeding, crop rotation) are not new; many traditional systems have similar characteristics. Some examples have been published in LEISA Magazine Vol.16, No.3. Traditional Conservation Tillage is practised by many small farmers in the humid as well as the dryer parts of Africa, but is now under pressure. *The immediate future challenge is to build productivity enhancing improvements into these systems without destroying their unique advantages* (Kayombo, Elis-Jones and Martin, see p.33). These traditional practices can be good starting points for the development of small farmer CA systems (p.10).

In the ILEIA Newsletter's special issue 'LEISA in perspective' Vol. 15, No. 2/3, pp37-39, Hien reported on an interesting Conservation Tillage/mulch farming case now spreading on the Mossi plateau in Burkina Faso. Here, traditional mulching is used in combination with other traditional water and nutrient management strategies (planting holes, stone and grass contour bunds) and increasingly with composting, tree planting, production of fodder and intensification of animal husbandry. Recent studies (IFAD/GTZ-PATECORE) found that this ecological intensification trajectory is leading to resource conservation, increased yield and income, and improved social conditions in the villages (Haramata No.41, June 2002, p.9-10). Such cases may provide important learning points for development of CA for small farmers in Africa.

Integrated Soil Fertility Management a new chance

Breman (p.15) stresses the importance of increasing soil fertility, as a first among other measures, in combatting poverty in Africa. And, according to him, inorganic fertilisers have a key role to play in this. The International Fertiliser Development Centre (IFDC) has concluded that the conventional way of using inorganic fertilisers is not profitable in most places in Africa. IFDC suggests that Integrated Soil Fertility Management (ISFM), also called Integrated Plant Nutrient Systems (IPNS) or Integrated Nutrient Management (INM)), combining locally available natural nutrient resources and inorganic fertiliser, can change this. ISFM can double fertiliser use efficiency and increase water use efficiency and fodder and cereal production 3-5 times. IFDC-Africa now follows a Farmer Field School approach for participatory development of ISFM in strategic sites where benefits from inorganic fertilisers are highest. This is mainly on compound fields, around cities with markets for cereals, fresh vegetables and fruits and in regions with intensive production of cash crops like cotton or irrigated rice, or where intensification of animal husbandry through intensive fodder production is profitable. ISFM and CA can support each other very well.

However, in large parts of Africa, even as part of an ISFM approach, inorganic fertilisers still may not be profitable. Only more efficient and creative use of the local natural resources and ecological processes can provide improvements in such regions, for which there are still many opportunities. Hien's case from Burkina Faso mentioned above shows that mulching alone increased sorghum yield by 50 –75%. Researchers and small farmers in these regions can work together to improve traditional biological soil management e.g. through enhancing the activities of termites (Brouwer and Voortman p.16).

Farmer Field Schools for more holistic development

FAO concludes that small farmers in Africa have complex systems and a wide diversity of needs and opportunities. And for this reason FAO has started a pilot programme in East Africa for developing a holistic Farmer Field School-based approach for agricultural development (p.18). In this approach farmers analyse their situation and decide which entry point - soil fertility, drought proofing, pest management, marketing or even health - they want to work on. A special sub-programme is working with farmers on development of the FFS approach for CA, including IPNS (p.17).

Soil micro-organisms increasingly popular in Asia

Also in Nepal, farmers, researchers and development workers are working closely together in a Farmer Field School approach to develop IPNS (p.20). Farmers have identified several possibilities for improving soil management such as improvement of manure quality, increasing fodder availability, legume cropping, agroforestry, growing high value crops and using inorganic fertilisers. Liquid manure teas are becoming very popular and in some places are replacing urea on the local market.

In Indonesia, farmers are discovering that Mother Nature still has many wise lessons for them, among others, the effectiveness of creeping ferns and leguminous weeds to maintain soil fertility. Also here, liquid manure, biological extracts, Effective Microorganisms and compost starters are becoming popular. These are effective innoculants and boosters of micro-organisms which can considerably increase the efficiency and effect of organic fertilisers. However, Rahayu and Thijssen (p.22) also warn that these technologies, on the long term, can break down soil organic matter if not enough organic fertiliser is returned to the soil. Compost starters based on micro-organisms (yeast) from the roots of *laos* (*Languas galanga*) and other plants or from over-ripe fruits have revolutionised compost technology in Indonesia. A next step and challenge for agricultural development in Indonesia could be to develop Conservation Agriculture.

Feeding the soil instead of the crop

The importance of soil micro-organisms (mycorrhiza, bacteria, yeast, fungi, termites, earthworms, etc) and the potential benefits of technologies that make use of these micro-organisms is being better understood. One of the main learning points of CA is that for efficient, productive and sustainable agriculture, farmers should create favourable soil conditions and feed the biological community in the soil instead of only the crop (FAO Soils Bulletin 78). FAO has an interesting web page on how soil micro-organisms can and are being used by farmers (see p.30).

Farmers and researchers should learn to think in terms of 'ecological soil management' instead of conventional nutrient management, which has proven to be unsustainable.

Rice farmers eager to reduce inorganic fertilisers

The experiences with the System of Rice Intensification (SRI) (p.24) are confirming this conclusion. Experiments in many countries have proven that rice has the potential to produce more tillers and grains than now observed, and that early transplanting and optimal growth conditions (spacing, humidity, biologically active and healthy soil, and aerobic soil conditions during the vegetative phase) can fulfil this potential. Researchers cannot explain how such high yields can be obtained and sustained with modest amounts of (organic) nutrients. Further research on 'ecological soil management' is therefore still needed. Farmers in many countries are actively trying to adapt the basic SRI practices to their conditions and are developing innovations to make application easier and more effective. In some countries, farmers are even experimenting with no tillage-based SRI.

Time for governments to change their policies

The adaptation, innovation and diffusion process of SRI could become very similar to the participatory development process of CA in Brazil. Also in SRI, participatory development of appropriate tools is very important. The active role of farmers in

Soil life in good hands with SRI farmers. Photo: H.M. Premarathna

the development of SRI and CA shows their eagerness to return to more natural and less costly ways of farming. Now, organisations like the FAO and World Bank are strongly supporting CA and are confirming the need for 'ecological soil management'. It may be time for governments to change their policies as well. Countries like Brazil and Costa Rica (CA), but also Indonesia and Sri Lanka (SRI) are already leading the way.

The experiences with CA seem to confirm what the famous Japanese conservation agriculturist / natural farmer Masanobu Fukuoka stated in 1975: ***"whether or not farmers spread straw over their fields may well decide the fate of the agricultural land"***.

C O N T E N T S

ILEIA is the Centre for Information on Low External Input and Sustainable Agriculture (LEISA) in the tropics. ILEIA seeks to promote the adoption of LEISA through the LEISA Magazine and other publications. It also maintains a specialised information database and an informative and interactive website on LEISA (**http://www.ileia.org**). The web site provides access to many other sources of information on the development of sustainable agriculture.

LEISA is about Low-External-Input and Sustainable Agriculture. It is about the technical and social options open to farmers who seek to improve productivity and income in an ecologically sound way. LEISA is about the optimal use of local resources and natural processes and, if necessary, the safe and efficient use of external inputs. It is about the empowerment of male and female farmers and the communities who seek to build their future on the basis of their own knowledge, skills, values, culture and institutions. LEISA is also about participatory methodologies to strengthen the capacity of farmers and other actors to improve agriculture and adapt it to changing needs and conditions. LEISA seeks to combine indigenous and scientific knowledge, and to influence policy formulation in creating an environment conducive for its further development. LEISA is a concept, an approach and a political message.

6 Conservation Agriculture: planting concepts and harvesting good results

José Benites, Sandrine Vaneph and Alexandra Bot

Tillage is one of the main causes of soil degradation and low yields. Conservation Agriculture (CA): zero tillage, direct seeding, mulching, green manure/ cover crop production and crop rotation, with or without the use of herbicides, has become an enormous success in the USA, Australia and Latin America in the past decade. It is now being introduced in Africa and Central, South and Southeast Asia with promising results. The articles on Conservation Agriculture (p.6-15) discuss the concepts of and experiences with this approach in Latin America and Africa.

36 Experiments with spiders, ants and other indigenous practices

K.J.N. Gowtham Shankar

IDEA is working with tribal people in the northern Ghats in India. During documentation of tribal indigenous knowledge they found that social spiders were used to control stem borers in paddy. This practice, which was still known only to a few families, has now been disseminated to many farmers in the region who are now using Bulu also for pest control in other crops. This is just one of the many indigenous pest management practices documented and shared by IDEA. The tribal farmers in the region invite the readers of LEISA Magazine to exchange experiences with them.

DEAR READERS

This issue of LEISA Magazine is focused on three important approaches in agricultural development: Conservation Agriculture (CA), Integrated Soil Fertility Management (ISFM) and System of Rice Intensification (SRI). All three approaches are deeply rooted in 'ecological soil management' and move towards LEISA, agriculture that makes optimal use of the ingenuity of nature. The articles prove that farmers, who work with nature instead of against it, can produce high and sustainable yields. The articles also demonstrate the creative and innovative force of farmer experimentation and participatory development processes. Especially the development of Conservation Agriculture in Latin America by millions of larger and smaller farmers is a break-through in the development of agroecology / LEISA.

Part of this issue has been produced in close collaboration with the Conservation Agriculture Working Group of FAO. Their support is very much appreciated by ILEIA.

Story of a tattered newsletter

Ann Waters-Bayer

The young man, a recent university graduate, has enthusiastically started his first job as agricultural advisor with a local NGO. He works "in the bush" (although there are precious few bushes there), in a dry and dusty area with no paved roads, no telephone, no short-wave radio. In the NGO office in the regional capital, there is a computer, but no modem.

He is based 350 km from the capital. After dark, he has electricity for five hours. It is hard to read the small letters of the newsletter in the dim light. Nevertheless, he continues reading, because the article is about farmer-developed methods of harvesting water, methods that would interest farmers in his area.

In one village is a youth group that is particularly keen on experimenting with new ideas. He lends the newsletter to the group leader. By the time the newsletter is returned, it has passed through several hands. Comments by the young people reveal that they have read not only the water harvesting article but also several others. The village has no library, no bookshop, no newspaper. They have nothing new to read, except this. The NGO advisor explains that the newsletter is available free of charge. The group would have to arrange that it be brought somehow from the post office in the capital, because there is no postal service to the village, but the NGO vehicle often comes from the capital, so that's a possibility.

In the Networking section of the newsletter, a website is mentioned. One of the young women had seen a website when visiting her sister, a secretary with an international aid agency in the regional capital. It took a long time until the colourful pictures appeared on the computer screen. But then they disappeared again. Her sister explained that it was difficult to "stay connected". The young woman couldn't bring the pictures back to show in the village. Something had been written with the pictures; she couldn't recall what. But she has read the newsletter twice, happy also to practise her English, and has discussed it with friends.

The youth leader shows the article to the village development committee. The committee head asks the NGO advisor if the work described in the article can be visited. The advisor says it is too far away, but a friend who also read this article knows of farmers in this very region who are doing something similar. Maybe the NGO vehicle could be used to take some members of the development committee and the youth group to visit these farmers.

Low-external-input technologies and farmer experimentation to adapt new ideas to local conditions are most needed in the more marginal and risk-prone areas of rain-fed farming. Information about such technologies and experiences can stimulate local innovation. When we in the North spend much of the day communicating with our computers, we can get carried away with the wonders of the new information and communication technology, like children with new toys. In large parts of Africa, when you leave the cities, when you reach the more remote areas, when you see a well-worn and well-read copy of an old ILEIA newsletter as I did recently in Ethiopia, you are brought down to earth.

This is a plea to all information and networking services and donors: in your enthusiasm to explore new paths in electronic communication, don't forget that a large number of people who are hungry for information still depend on the printed and spoken word. Please don't starve them.

Issue 18.4, December 2002

Feminisation of agriculture needs appropriate responses

The feminisation of small and marginal agriculture is increasing rapidly in many parts of the world due to processes such as labour migration, part-time farming, urban life focused education and HIV/AIDS. This has an enormous impact on women, their households, rural communities and farming. Supporting women in their role as farmers requires many changes and adaptations. These relate to property rights, access to productive resources as well as to adaptations, i.e. decision making, labour division, crop management, animal husbandry and production of tools. Also research, extension, information management, input supply, financing and marketing etc. have to become more women-focused and have to develop methodologies and procedures adapted to the specific conditions and needs of women. Often, women as the main managers of change have to cope with ecological degradation. What specific needs do women in such conditions have and what adaptations have been developed by women to cope with these processes? What are the experiences of participatory programmes that have been supporting women to cope with change? What are good examples of technologies and methodologies suited for use by and with women? We invite you to share your experiences on these and other relevant questions with other readers of the LEISA Magazine. First deadline for contributions 1st of September 2002.

You are invited to contribute to these issues with articles (about 800, 1600 or 2400 words + 2-3 illustrations and references), suggest possible authors, and send us information about publications, training courses, meetings and websites. Editorial support is provided by ILEIA. Authors of published articles are entitled to a standard fee.

Actor-led change for efficient agrifood systems : handbook of the participatory actor-based CADIAC approach by Bourgeois R, Herrera D. 2000. 136 p. ISBN 979 9317 10 X EU 22.87. Regional Coordination Center for Research and Development of Coarse Grains, Pulses, Roots and Tuber Crops in the Humid Tropics of Asia and the Pacific (CGPRT)
CIRAD, Avenue Agropolis, 34398 Montpellier Cedex 5, France / librairie@cirad.fr ; www.cirad.fr. (CGPRT Centre Monographs no. 39).
This book is intended as a practical handbook for scientists, analysts, and students working on the definition and implementation of policy changes that contribute to real economic and social agriculture-based development. The objective is to promote competitive and sustainable agrifood systems that broadly benefit society.

The commodity-chain analysis and action-oriented dialogue approach (CADIAC) is meant to be a tool to achieve policies, measures and actions that contribute to improving the competitiveness of agriculture. This handbook presents and describes the CADIAC method and ends with the formulation of concrete proposals. The book is also available in French and Spanish. (WR)

Land rights under pressure : access to resources in Southern Benin by Edja H. 2001. 23 p. ISBN 1 899825 82 7. International Institute for Environment and Development (IIED), London. GRET. (Land Tenure and Resource Access in West Africa). SMI (Distribution Services) Ltd, P.O.Box 119, Stevenage, Herfordshire SG1 4TP, UK / orders@earthprint.co.uk
This paper forms one of the four 2001 outputs of the series 'Land Tenure and Resource Access in West Africa'. The objective of this IIED series, jointly financed by DFID and GRET, is to enhance the research capacity of West African researchers and their institutes and to further the level of knowledge on land tenure and resource access issues in West Africa and their implications for policy and practice contributing to sustainable development. The French version of this series can be obtained GRET.

Rising population density and degradation of soils increase the pressure on land, which in itself often causes degradation, and is one of the main constraints in the West African region.

This report about Benin examines the diverse set of arrangements by which people gain access to land and trees, through a widespread system of rental, loans, sharecropping, mortgage and guardianship contracts.

The other three papers are about access to land in the cotton zone in Burkina faso, land management in Ghana, and share contracts in Ghana.(WR)

The Prosopis juliflora - Prosopis pallida complex : a monograph by Pasiecznik NM [et al]. 2001. 162 p. ISBN 0 905343 30 1. HDRA, the organic organisation, Ryton Organic Gardens, Coventry CV8 3LG, UK / kcadoret@hdra.org.uk
This is a manual with information and research on the Prosopis genus, and specifically on the two most widespread species in tropical regions, *Prosopis juliflora* and *Prosopis pallida*. The two species are covered together due to continuing taxonomic confusion, and similar biology, ecology and resource characters. Native to South America they are now widespread in many arid and semi-arid areas in Africa, the Middle East, Australia and Asia. Prosopis trees are a valuable source of fuelwood, timber, animal fodder, bee forage, medicines and other raw materials to local people.

The monograph is divided into five chapters. Chapter 1 - People and Prosopis, contains sections on Prosopis as a resource, the history of exploitation and world Prosopis distribution in the year 2000. Chapter - 2 The species, includes systematics and nomenclature, a description, biology, ecology of, and environmental requirements of the Prosopis juliflora - Prosopis pallida complex. Chapter 3 - The complex as a resource, provides information on Prosopis as a source of fuel and wood, fruit, foliage, plant extracts (honey) and other benefits. Chapter 4 - Husbandry and management, includes nursery propagation, field establishment, stand management, and exploitation of the resource. Chapter 5 - Recommendations, covers use of improved genetic material, improved management, development of processing technologies, commercialisation of Prosopis tree products. An extensive reference list is included.

The genus Prosopis : a reference database 2001. HDRA, the organic organisation, Ryton Organic Gardens, Coventry CV8 3LG, UK / kcadoret@hdra.org.uk ; www.hdra.org.uk.
The reference database is distributed with the monograph and contains 6443 non-abstracted references. It is the largest single collection of references covering the genus Prosopis. Each reference has been keyworded from a selection of 41 subject areas for ease of searching.

The above publications together are a useful resource to anyone working specifically with Prosopis, especially to research and development workers, students and land-users in the worlds arid and semi-arid zones.

Bamboo in the high forest of Eastern Bhutan : a study of species vulnerability by Messerchmidt D, [et al]. 2001. 32 p. ISBN 92 9115 314 1. International Centre for Integrated Mountain Development(ICIMOD), GPO Box 3226, Kathmandu, Nepal / www.icimod.org ; distri@icimod.org.np
This booklet is a clear case study from eastern Bhutan on how policies that ignore traditional forest and species management systems that have evolved, and worked well from generation to generation, do so at the risk of the disappearence of not only sustainable locally acceptable management and harvesting systems, but also at the risk of species disappearing. Bamboo is an important alternative forest resource harvested from the high forests of Bhutan. This study was conducted to determine the significance of bamboo in the local subsistance and commercial economies, with particular attention to factors affecting the risk of extinction of the species. (WR)

Ten million trees later : land use changes in the West Usambara mountains : the soil erosion control and agroforestry project in Lushoto district 1981-2000 by Johansson L. 2001. 163 p. USD 15: GTZ, Dag Hammarskjöld Weg 1-5, 65760 Eschborn, Germany / www.gtz.de
Can be ordered from www.maneno.net ; lars@maneno.net ; secap@tanga.net.
The first chapter can be downloaded from www.maneno.net
'Ten million trees later' tells the story of the SECAP project towards the background of dramatic land use change in Tanzania. It combines an account of project activities over a twenty-year period with a discussion of underlying theories and a critical analysis of the achievements. The book was written for two different kinds of readers: people who live, work or visit in Lushoto District, and as a case study for people who study or work with rural development. Most of the chapters can be read independently, which is why main ideas and conclusions re-occur in different forms. It starts with the description of the case study. The following chapters provide the historical context and describe

how the project changed over the years. Chapters five to eight discuss the different sectors and technical aspects for readers working with development or extension, like soil conservation, livestock and forestry. In the end, the author summarises the lessons learnt. This very interesting long-term case study is well illustrated with colour photographs, maps and charts, and written in an appealing style. However, it lacks an index and a list of references.

Water rights and empowerment by Boelens R, Hoogendam P (eds). 2002. 256 p. ISBN 90 232 37641 : EURO 25.00. Van Gorcum, PO Box 43, 9400 AA Assen, The Netherlands / assen@vangorcum.nl.

In the Andean region, most irrigation systems have been built by local users, organised into peasant or indigenous communities, who also manage their own systems under collective control and norms of their own.

This book emphasises the issues of internal water rights within irrigation systems, but since collective rights between irrigation systems or between these systems and other types of water users are becoming increasingly important, a chapter on collective rights within the context of water management in watershed or catchment areas is added. Further chapters reach beyond the system level: discussing the issue of local collective rights regarding other normative frameworks, regarding other groups of local, regional or national interest, within the perspective of national legislation. With this book the authors seek to contribute to the development of methodological proposals that strengthen local water control and empower peasant and indigenous communities. Recommended. (WR)

Review of the agricultural knowledge system in Fiji : opportunities and limitations of participatory methods and platforms to promote innovation development by Bachmann L. 2001. 275 p. ISBN 3 8236 1350 2. (Kommunikation und Beratung, Sozialwissenschaftliche Schriften zur Landnutzung und ländlichen Entwicklung 44). Margraf Verlag, Postfach 1205, 97985 Weikersheim, Germany margraf@compuserve.com.

The author describes the articulated agricultural knowledge system of the small island country Fiji. The focus of this study is the agricultural research and extension department of the Ministry of Agriculture. A participatory action research methodology was used to investigate the potential of participatory methods to improve information flows between farmers and the ministry, in order to achieve systematic user integration in the knowledge system. Furthermore, several project cases were analysed to investigate the potential of platforms, to bring together different actors, and to improve innovation development and diffusion. The book provides methodological tools for tackling the complex issue of agricultural development. By promoting multiple perspectives, better integrating farmers and their knowledge through participatory methods, and the use of platforms as joint learning opportunities for all relevant actors, the book highlights new ways for innovation development, and improves the chances for wider adoption.

Managing manure to sustain smallholder livelihoods in the East African highlands by Lekasi JK [et al.]. 2001. 32 p. ISBN 0 905343 336. Henry Doubleday Research Association (HDRA), Ryton Organic Gardens, Coventry, CV8 3LG, UK / kcadoret@hdra.org.uk
ILRI, KARI.

The scope of this research report on manure management in the central Kenyan Highlands was to evaluate manure management options that could best conserve nutrients and improve manure quality. Livestock make an important contribution to the sustainability of intensive smallholder farming through their contribution to soil fertility. This research shows that increases in crop yields on smallholder farms gained from simple techniques for better care of manure during collection and storage, can be substantial and enduring.(WR)

Negotiating poverty : new directions, renewed debate by Middleton N, O'Keefe P, Visser R (eds.). 2001. 239 p. ISBN 0 7453 1822 3. ETC International. Pluto Press, 345 Archway Road, London N6 5AA, UK / www.plutobooks.com

This policy document on global poverty provides a critical account of Western aid policies. With contributions from leading academics and activists who debated with the politicians, it offers a radical analysis of the real issues. The authors argue that before any effective strategy can be put into action, the poor themselves must be included in the debate. For those in the developed world, resposibility must be taken for contributing to the creation of poverty before it can effectively be eradicated. Chapters cover the aims and framework of poverty reduction; the role of the global market; the problems of employment; human security; environmental security; legal aspects; and the practical problems of implementation.

Paysans du sertão : mutations des agricultures familiales dans le nordeste du Brésil by Caron P, Sabourin E (eds.) 2001. 243 p. ISBN 2 87614 449 2 EU 39.03. CIRAD, Avenue Agropolis, 34398 Montpellier Cedex 5, France / librairie@cirad.fr ; www.cirad.fr

This book presents the results of a number of studies of the family-based agriculture in the northeast of Brazil. Though the agriculture in this region is generally considered unproductive, unadapted to liberalisation, and unable to innovate, these studies show that family-based agriculture in reality is undergoing drastic technical, economic and social changes. The authors analyse the role and the functions of development oriented research by looking at the results and the methods developed. Several examples of research and action operations are used to illustrate this: the implementation of a local credit system and support of municipal planning of rural development.(WR)

Handpump : operation, repair and maintenance by Kamble V, Pate G. 2001. 16 p. Rs 20.-. BAIF Development Research Foundation, BAIF Bhavan, Dr. Manibhai Desai Nagar, Warje, Pune, Maharashtra 411 029, India / baif@vsnl.com. (BIAF Barefoot Technician 1).

This small manual is an useful guide to handpumps, and provides proper instructions on handling. In many places, damaged handpumps have been abandoned due to lack of repair skills and the unavailablity of suitable tools. This manual explains the design and operation of the handpump. It provides guidelines to repair defects; causes and remedies for defects have been presented in the form of pictures and tables. The last part shows how to do repairs with the help of fishing tools. The drawings are meant to explain the method of handling tools. A clear and cheap publication.(WR)

WEBSITES

The World Bank ICT Department
http://info.worldbank.org/ict/
If you want an overview of donor funded ICT projects and ICT companies that are active in your country, this is a good starting point. For projects and companies basic information like objectives, size and contact persons is provided. In some cases the website also provides access to more comprehensive project documents.

National Community Radio Forum
http://www.ncrf.org.za/
This site is focused on South Africa but will be of interest for people from elsewhere who are interested in rural radio. It is an example of how the Internet can be used to support networks using other media – in this case radio that support the poorest of the poor. You can read their manifesto, see how they organise collaboration and the experience they have gained since their inception in 1993.

Developing Countries Farm Radio Network
http://www.farmradio.org/
Please read the article in this issue of the magazine for more information about the Farm Radio Network. On their website you can find scripts that are distributed to radio stations. If you are involved in rural radio broadcasting this is a site to check. They do not charge for their scripts and library services.

PEOPLink
http://www.peoplink.org/
This is another example of new opportunities provided by ICT. PEOPLink is a nonprofit marketplace benefiting grassroots artisans and their communities around the world. They manage to bring buyers in contact with producers in developing countries and involve many NGOs in promotion.

Digital Dividend
http://www.digitaldividend.org/
A website dedicated to exploring creative business approaches, public- private partnerships, and other sustainable ways to bridge the global digital divide.

Women in the Information Age
http://www.ksg.harvard.edu/witia/
This site, developed by the Women in the Information Age Project at Harvard University's John F. Kennedy School of Government, aims to address the gender issues in ICT.

Honeybee
http://csf.colorado.edu/sristi/honeybee.html
The Honeybee network of India is one of the pioneers in using ICT for capturing and sharing indigenous knowledge. On their website you can find research papers and a database with farmers' innovations.

The Association for Progressive Communications
http://www.apc.org/
The Association for Progressive Communications (APC) is an international network of civil society organisations dedicated to empowering and supporting groups and individuals working for peace, human rights, development and protection of the environment, through the strategic use of information and communication technologies (ICTs), including the Internet. The website has many resources for small internet service providers working with civil society. APC also develops free software.

Itrain Online
http://www.itrainonline.org/
ItrainOnline is a joint initiative of six organizations with expertise in computer and Internet training in the South. The website aims at being a single source on the web containing a selection of the best and most relevant computer and Internet training resources for development and social change. You can find practical information about anything ranging from "how to use Email" to how to do advanced programming for your own website.

OneWorld
http://www.oneworld.net/
OneWorld is a network of more than 1200 organisations focused on human rights and sustainable development. The website is a good entrance to information on these topics. Most of the resources consist of reviews of resources elsewhere on the Internet and is organised in "channels". There is for instance a channel named the "Digital Opportunity" channel that is good if you want to keep up-to date with ICT and development.

The African Virtual University (AVU)
http://www.avu.org/
AVU is an example of how ICT can enhance education. Since the launch of its pilot phase in 1997, AVU has provided students and professional in 17 African countries over 3,000 hours of interactive instruction in English and French. More than 24,000 students have completed semester-long courses in technology, engineering, business and the sciences and over 3,500 professionals have attended executive and professional management seminars on topics such as strategy and innovation, entrepreneurship and e-commerce. AVU provides students access to an on-line digital library with over 1,000 full text journals. Over 45,000 free AVU e-mail accounts have been created and the AVU website currently receives more than 1 million hits per month.

Bellanet
http://www.bellanet.org/
Bellanet is an international non-profit initiative focused on helping the international community to work together using ICT. Their website is an entry point to the activities of Bellanet that ranges from defining technical standards to compiling experience in knowledge management and web-to-email service as described in the centre spread of this magazine.

The International Institute for Communication and Development
http://www.iicd.org/
The International Institute for Communication and Development (IICD) assists developing countries to realise locally-owned sustainable development by harnessing the potential of ICT. On their website you can find many documents about the latest developments and experiences in ICT for development.

Visit our website: www.ileia.org

Free Software

Basic software applications for an office computer include: operating system (the main choices are Windows, Linux, or MacOS), word processor, spreadsheet, email client (to send and receive email), web browser, and *utilities* for file transfer (FTP), file expansion and compression (Zip) and viewing of PDF files.

Operating Systems: Linux or Windows?

The operating system (OS) is the software platform on top of which other applications run. The choice of OS determines to a great extent the applications that will run on a personal computer. Most of the products listed below are compatible with both Linux and Windows operating systems.

Linux (**http://www.linux.com** and **http://www.linuxiso.org**) is a free, reliable, and secure operating system that can be a good alternative to Windows, especially for those using older computer hardware. However, it is considered more difficult to set up than its main rival, Windows. Popular Windows applications such as Word and Excel will not run on Linux. For more information visit: **http://www.seul.org/docs/whylinux.html**

Windows (**www.microsoft.com**) is the most widespread operating system for personal computers worldwide. Microsoft's commercial dominance means that much of the world's software is designed for computers running Windows OS. Windows is not free, but free software *is* available for Windows users.

Office applications

OpenOffice (**http://www.openoffice.org**) is a free office suite that includes word processing, spreadsheet, graphics, and presentation applications. OpenOffice has every feature you could ever dream of. For basic word processing consider AbiWord (http://www.abisource.com/). It is free, fast on old computers and easy to learn.

Ftp

If you have direct access to the Internet and want to download computer programs and documents FTP (File Transfer Protocol) is often the fastest method. Most browsers have limited support for FTP transfers so it is better to use a dedicated FTP program If you make your own web pages you can also use FTP to upload them to an Internet server.

WS-FTP LE **http://www.ipswitch.com** is the classical FTP program. It is fast, small and efficient and includes a list of good ftp sites. You can buy a version with more features but don't worry; the LE version is more than enough for even advanced users. The download page is on: **http://www.ftpplanet.com/download.htm**.

Compression

Many files on the Internet are compressed so they can be transferred faster. To use them they have to be uncompressed. The most common method for compression is Zip. These files have a ".zip" extension and can be uncompressed with Winzip (**http://www.winzip.com/**) or "StuffIt Expander" **http://www.alladinsys.com**. Both programs also handle a number of less known compression methods.

PDF

Pdf (portable document format) is a popular format for distributing electronic documents. The advantage is that the layout is preserved, e.g. if you download an article from the LEISA Magazine as a pdf file and print it, it will look exactly as the printed magazine. The disadvantage is that pdf files are big and you need special software to view and print them. You can download the free pdf reader at: **http://www.adobe.com/support/downloads/main.html.**

Email

If you have Internet access you may chose to use the Email program in your browser. However, if you only use Email or if you want more features that the simple features in the browsers, then a dedicated Email program is worth considering.

Pegasus Mail (**http://www.pmail.com**) is a free electronic mail client that enables several people to maintain private accounts on the same computer. Pegasus Mail donates manual sets to non-profit organisations. Euroda light (**http://www.eudora.com**) is another free and feature-rich Email program.

Delete unwanted Email without downloading

Spam is the word for the unwanted advertising Emails that become still more widespread. If you don't want to waste time to download them to your computer you can check the subject and sender of the Emails and delete the unwanted ones on the server. With web based Email like Yahoo and Hotmail this is straightforward. However, if your Email uses the common POP3 protocol then you will need a program like "Harvester" (**http://spazioinwind.iol.it/neutronstar/mysoft.html**).

Check web-sites for updates

Some websites offer to notify you by Email when they change the content. However, if the site you are interested in does not offer that facility consider using a free utility like WebMon (**http://www.markwell.btinternet.co.uk/webmon/**). It can quickly check the sites you are interested in and tell you if they have changed. It is much faster than checking the sites manually.

Download websites and browse off-line

If there are many people accessing the same websites from the same computer it may be worth downloading the whole site and browsing off-line. In particular libraries and documentation centres can benefit from this. "Ttrack Website Copier" (**http://www.httrack.com**) can download whole websites. It rebuilds the web pages on your hard disk so all links will still work when you are off-line.

UNESCO Free Software Portal

http://www.unesco.org/webworld/portal_freesoft
UNESCO has collected a large number of links to free software for communication, library management, office applications, and science and education. The site also contains information for users who wish to understand and follow the Free Software movement, and for software developers themselves.

Nonags software

http://www.nonags.com/ is a software site with thousands of free programs well organised and described.

For French speakers...

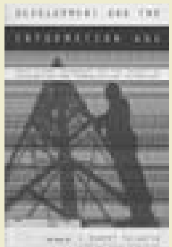
Boîte à outils du CIDIF is a CD-ROM containing over 150 free software programs for French-speaking computer users in the Caribbean, Eastern Europe, Africa, the Middle East, and the South Pacific region. For information contact: Centre international pour le développement de l'inforoute en français (CIDIF), 165, boulevard Hébert, Edmunston NB, Canada E3V 2S6.
http://www.naviguer.org/boite | **http://www.cidif.org**

Information Revolutions - How information and communication management is challenging the lives of rural people by Mundy P and Sultan J. 2001 234 p. ISBN 92 9081 2289CTA, Technical Centre for Agricultural and Rural Cooperation, Postbus 380, 6700 AJ Wageningen, The Netherlands. cta@cta.nl
This book could be called a tribute to several enterprising individuals and organisations in Africa, the Carribbean and the Pacific who have taken steps - some modest, some bold - to help revolutionise the management of information for agricultural development. CTA's intention in publishing these experiences is to raise awareness and thereby motivate others to follow these examples in the context of their own lives. The authors have done a wonderful job in selecting the best examples -those that are real local or national initiatives, having a proven track record and are sustainable. Approximately 40 of them are described in the book. The book has nine sections on radio and television, newspapers and newsletters, literacy and local languages, computers and telecommunications, farmers' groups and markets, farmers' knowledge, research and extension links, research networks and libraries. Written in a simple and straightforward style, the stories will certainly capture the attention of many and stimulate them to take on new initiatives - and thereby get them to communicate, without which development efforts are doomed to fail. (CW)

The appropriateness and effectiveness of drama as an agricultural extension tool by Munro J. 1998 30p. Occassional Publications Series No. 26, Network on Bean Research in Africa, CIAT, Kampala, Uganda
The Network on Bean Research in Africa serves to stimulate, focus and coordinate research efforts on the common bean. The network is organised by CIAT, International Center for Tropical Agriculture, which is one of the international agricultural research centers (IARCs). CIAT tries to find different ways of disseminating information on new technologies together with its partners. This paper is the result of a study of a project in Uganda that used drama as a method of technology transfer. The findings revealed that drama had been effective in communicating the message. Among those who had been at a performance and then interviewed, 68% had learnt something new from the drama, and 65% had made a change in their agricultural practice (i.e. planting beans, planting trees etc.) as a result of the drama. Apart from the success, the paper also covers the limitations of drama as a tool for extension and provides recommendations for overcoming these limitations. (CW)

Picture supported communication in Africa - Fundamentals, examples and recommendations for appropriate communication processes in rural development programmes in Sub-Saharan Africa by Hoffmann V. 2000 352p. ISBN 3 8236 1342 1 Margraf Verlag, PO Box 1205, D-97985 Weikersheim, Germany. CTA, Postbus 380, 6700 AJ Wageningen, The Netherlands.
This book is an English translation based on the second, updated and completely revised edition of the original version published as a habilitation thesis in 1990 by the author in German. What the author tries to examine quite thoroughly in this book is the perception that pictorial communication, which is omnipresent in industrialised countries, is a universal, language-independent and supracultural means of communication, particularly for development programmes in the Third World and for reaching people who are not literate. The book does have a lot of theoretical content, which is balanced with two extensive case studies from GRAAP in Burkina Faso and CFSME, Rwanda, both of which have used pictures as an aid to the African oral tradition through low-cost techniques such as flannelgraphs. In conclusion, the author gives some recommendations for the production of pictorial material, training of facilitators, use of media in different settings etc. This is a book that is suited to those who are willing to spend time in going deeper into communication practise. Also available in French. (CW)

ICTs in Developing Countries Crede A. and Mansell R. (eds) 1998 ISBN 90 804322 1 0 International Institute for Communication and Development (IICD), PO Box 11586, 2502 AN The Hague, The Netherlands.
A series of four booklets published by the IICD focuses on the significance of information and communication technologies (ICTs) for sustainable development. The first booklet titled "The importance for sustainable development" explains what ICTs are and why they should be considered very important for the sustainable development of developing countries. Two important issues in this context - building of human capacity and setting in place a policy framework - are discussed. Booklet II is called "Gaps in provision" and examines the major imbalances in the provision of ICT in developing countries, i.e. inadequate infrastructure, the urban-rural divide etc. Suggestions to overcome the ICT gap are presented. "The basis for a national policy framework", the third booklet, focuses on issues related to setting up a national policy framework for ICT, including policies for learning, funding etc. The fourth booklet contains case studies and is titled, "Examples of ICTs in practise" and covers six areas: education, health, commerce, public information, environment, agriculture and rural development. An informative series presented in a simple-to-read style. Get copies through information@iicd.org



Development and the Information Age - four global scenarios for the future of information and communication technology
Howkins J. and Valantin R.(eds) 1997 59 p. ISBN 0 88936 835 X International Development Research Centre (IDRC), P.O.Box 8500, Ottawa, ON, Canada, K1G 3H9.
The Information Revolution is producing astonishing transformation in virtually all spheres of human activity. But how can these technologies help to balance the scales of development between the countries of the "industrialised" world and those of the "developing" world? Will they narrow the existing gap, or will they widen it? These were the questions debated by many experts from around the world at a workshop co-sponsored by UNCSTAD (United Nations Commission on Science and Technology for Development) and IDRC in June 1996. The four scenarios envisioned are described in the book and offer a glimpse into the future of the information age, particularly on its impact on reaching the goal of global sustainable and equitable development.

Correction LEISA Magazine Vol.18 No.1 - Livestock: which way?
The e-mail address of the publisher of the book "Utilizing different aquatic resources for livelihoods in Asia: a resource book" mentioned under "Sources" on page 31 should read bookstore@iirr.org

Information villages:
Connecting rural communities in India

Katherine Morrow

The Information Villages project was started in 1998 in Pondicherry, South India, by the M. S. Swaminathan Research Foundation. The project links 10 villages near Pondicherry into an information network connected to the Internet. The goal is to develop community ownership and collective action around the use of new technologies, in keeping with a “pro-poor, pro-nature, pro-women” approach to development. M.S.Swaminathan, the chairman of the Foundation, is guided by an insight regarding technology dissemination that he puts in a nutshell, “From my long experience in agriculture, I find that whenever poor people derive some benefit from a technology, the rich also benefit. The opposite does not happen,” he says.

Pondicherry is a former French colonial area in southern India, on the Bay of Bengal. The main language of the rural people is Tamil. Almost a quarter of the families in this region earns less than a dollar a day. It is predominantly a paddy or sugarcane producing area.

Women have not been excluded from ICTs.

Hub and Spokes model

The Information Villages project has established a rural information network along a hub and spokes model. Ten villages constitute the network. In each village is a small, community-owned and operated Village Knowledge Centre, staffed by trained volunteers and equipped with several computers, printers, telephones, and Internet access. The centres provide supervised free access to those who wish to find information, learn about computers, search the Internet, communicate by phone or email, or use other services such as word processing, printing, and fax.

At the centre of the wheel is the project headquarters in the town of Villianur, where staff scour local sources and the Internet for information that is relevant and useful to the rural people of the region: information on agriculture, health, government policies, educational opportunities, the weather, and more. This information is put into a format that makes it more accessible to rural communities with a low level of literacy, translated into Tamil, and transmitted to the info shops electronically, via the network.

Technical infrastructure

With the help of committed volunteers, the villages around Pondicherry, beginning with Veerampattinam, were brought online starting in 1998. The near absence of a modern electrical and telephone infrastructure in the region led to some creative solutions: solar panels for electricity and wireless transmission systems where communication lines didn’t reach. Costs were minimised. The emphasis on low budget technologies undoubtedly enabled more villages to be connected, and freed up funds for a greater emphasis on training and evaluation aspects, which are often neglected in technology projects.

Building the network

Site selection was accomplished after a process of participatory rural appraisal in 13 villages. Villianur, a market centre and administrative node, well connected by roads, was chosen as the headquarters of the project and the hub of the information network. The Villianur hub is equipped with a computer, modem, telephone, a small telephone exchange, and wireless equipment. It is here that the project staff produce, translate, and update information that is fed into the network.

The “spokes” or sub-centres in nearby villages were chosen with care. In each village, participatory rural appraisal was carried out in order to identify an accessible rent-free building, electricity and volunteers. At each centre, the Foundation entered into a written agreement delineating the responsibilities of the Foundation to provide equipment, expertise and training, and the community to maintain and staff the site with volunteers, pay the telephone bills, and ensure prejudice-free access to all members of the community.

Each village is unique, and the project has experienced the closing of some centres and the opening of new ones. Some knowledge centres established in private homes were closed when they did not allow socially underpriviledged people to visit, and when the managers exhibited reluctance to share knowledge freely. These experiences made the project team realise how critical community ownership is to the success of each knowledge centre. The community as a whole must endorse the project so that it does not become associated with one group or caste.

Staffing and training

Staffing is by village volunteers identified by the community members. At least half of the volunteers must be women, under the terms of the agreement with the Swaminathan Foundation. The Foundation provides training in Windows 95/98, MS Office, web site construction, voice recording, file compression and wireless data transmission. The volunteers also learn to send and receive email and fax messages, and some receive training in desktop publishing, computer programming and design, which enables them to produce letterheads, posters, visiting cards and wedding invitation cards. The provision of such services is seen as one way in which the centres can generate an income.

Working with newspaper reporters, the Foundation is also providing journalism skills training to the volunteer knowledge centre employees in writing and presenting information clearly and crisply.

Mapping the rural information landscape

When the project began in 1998 there was almost no modern telephone infrastructure and a three-to five-year wait for standard telephone lines. A survey of 11 villages targetted by the project revealed two reading rooms, six post offices, 12 public telephones and 27 private telephones for 22,000 people. There were also 1,129 television sets, of which 424 were connected to cable TV broadcasting in Tamil.

Television and radio were generally regarded as sources of entertainment, not practical information. For useful information farmers turned to other farming families, local shopkeepers, and suppliers of farm inputs. They expressed a low opinion of local government functionaries.

There is high demand for agricultural information: the costs and availability of agricultural inputs, including seeds, fertiliser and pesticides, and grain prices in different markets throughout the Pondicherry area. 121 farmers interviewed in 2000 reported that grain prices are the most important piece of information they receive. *"Now that [villagers] have access to market rates, middlemen are not able to exploit the farmers or fishermen,"* says Raja Mohan, the head of the information technology hub in Pondicherry.

The knowledge centres provide detailed weather forecasts downloaded from the Internet in audio format and broadcast over a speaker system outside the knowledge centres. The knowledge centre in Veerampattinam downloads wave height predictions from the US Navy web site, which provides 12-hour predictions for wave heights in the Bay of Bengal. The centre prints out detailed maps from the site that are posted outside the centre, and broadcasts the information over a speaker system for the benefit of fishers who cannot read. The fisher families of Veerampattinam, most of whom use non-motorised catamarans, consider this information life saving.

Value Addition: local content is the key

Along with access, a key component of the project is "value addition" – collecting, creating and disseminating locally relevant information in Tamil. This activity mainly takes place in Villianur, the network hub. Recognition of the need for "intelligent intermediaries" based in the communities to interpret and package information for local use is seen to be one of the major success factors of the project.

Information compiled by community volunteers and provided in the village knowledge centres is locale specific. It relates to prices of agricultural inputs (such as seeds, fertilisers, pesticides) and outputs (rice, vegetables), market (potential for export), entitlement (the multitude of schemes of the central and state governments and banks) health care (availability of doctors and paramedics in nearby hospitals, women's diseases), cattle diseases, transport (road conditions, bus and train schedules, cancellations), weather (appropriate time for sowing, areas of abundant fish catch, wave heights).

There is growing evidence that farmers are using the information. For example, 14 farmers who had had their sugar cane crops devastated by "red rot" disease in two consecutive years were able to contact an entomologist through the knowledge centre. The preventive measures prescribed by him helped them save the sugarcane crop in 2001.

Farmers' Diary

Staff at Villianur have recently initiated a daily news item sent to the knowledge centres called "Farmers' Diary." The bulletin provides information on technologies and techniques relevant to agriculture and animal husbandry, with an emphasis on sustainable approaches such as Integrated Pest Management, Integrated Crop Management, and Integrated Nutrient Management Practices relevant to the main crops grown in the region: paddy, sugarcane, cotton, pulses, cereals and horticulture crops. The information comes from the agricultural university, magazines, individuals, research stations, and indigenous farming practices shared by the farmers in magazines. The diary for animal husbandry aims to give information on animal health practices suggested by Tamil Nadu Veterinary University, research stations and farmers' indigenous animal health practices. Project staff have so far developed 135 items related to agriculture and 59 animal husbandry health practices.

Linking with Extension

Greater cooperation with the Department of Agriculture is being discussed, and a partnership is taking shape. The Department wants to link their farm clinics to the Villianur hub so that extension staff can communicate more quickly with Departmental headquarters. Farm clinics in three villages will begin sharing agricultural information via the knowledge centre located in their assigned village. The Foundation is also developing a web site which will bring together all the relevant agricultural information in the region, including

- the schedules of Agricultural Officers and the training programmes they plan to conduct
- IPM methods developed in consultation with agricultural extension officers, university professors and people with indigenous knowledge

Village knowledge centres are run by community volunteers. Photo: M.S. Swaminathan Foundation

- Information on vermiculture, biopesticides, biofertilisers and bioremediation agents
- Crop and livestock integrated farming systems
- Conservation, sustainable use, and equitable sharing of water and the establishment of community water banks
- Government entitlements related to farmers.

Once the website is in place, it will provide a rich source of information to extension workers, other Department staff, members of the communities in which knowledge centres operate, and many others who have an interest or need for such information, in the Pondicherry region and elsewhere in the world.

Power and gender impacts

The Swaminathan Foundation and the project's funder, the International Development Research Centre, took great pains to ensure that the technology was not appropriated by the powerful to further exclude women, the Dalit caste, and the poor.

Unlocking information that was previously inaccessible to the rural poor can be threatening to those for whom knowledge is the key to exercise their power. Local bureaucrats are often reluctant to give up their monopoly on information, which can be a source of power.

Before setting up the knowledge centres, the Foundation required participating villages to agree to certain criteria. Each centre had to guarantee access to members of the Dalit population (formerly known as 'untouchables'), and ensure that at least half of the trained volunteer operators are women.

The key to success has been the integration of gender analysis and awareness at the earliest stages of project design, and making it a part of ongoing training, evaluation and monitoring. The knowledge centres track the number of men and women visitors to the centres on an ongoing basis, providing a changing picture of how rural women are using ICTs. Statistics kept by each shop indicate that between 34% and 50% of users are women, depending on the village.

The terms of the agreement with the Foundation that at least half of the volunteers must be women, helps ensure that women feel at home in the centres and continue to visit. The experience of handling and maintaining computer equipment and answering men's questions gives women new confidence and status in the community and helps ensure that technology is not thought of as "man's domain."

Photo: M.S. Swaminathan Foundation

Women primarily visit the knowledge centres to obtain information about family income supplements and public welfare schemes, low-cost insurance, and health issues, especially child bearing and rearing. Some women have also explored ways to start up new family enterprises. Grain price information is of interest to women agricultural workers who receive part of their wages in grain.

Lessons learned

Several constraints have been noted by project staff: lack of local language content on the World Wide Web, the weakness of both telecommunications and electrical infrastructure in the region and especially in rural zones, and the reluctance of local bureaucrats to give up their monopoly on information on government services and programmes.

In an earlier phase, project leaders Balaji and Arunachalam summed up the lessons thus: *"ICTs can make a positive contribution to improving the quality of life in ultra poor families in rural areas. It is essential that community ownership of ICT devices and training is established in the initial phase to prevent influential sections from appropriating all the benefits. Special efforts are needed to identify knowledge and information needs both of men and women. Local level "intelligent intermediaries" are an essential component in any such project. There is a need to maintain a continuous dialogue with the actual users to assess changing needs vis-à-vis the network derived information. A wide variety of access technologies are available now, and the emphasis should be on what is operable locally without cumbersome licenses or power requirements."*

Balaji and Arunachalam note, however, that direct economic benefits from this type of enterprise are difficult to quantify, although they certainly exist. They see potential for ICT to support micro credit and community banking. Empowerment of local communities can be seen in the increased level of awareness that rural families have about their rights and entitlements under publicly funded schemes, and the improvement in their bargaining power in the marketplace.

Sustainability through partnership

Sustainability of the network in a context where most users are below the poverty line is one of the most difficult hurdles to overcome. Most of the knowledge centres are partially self-sustaining, thanks to the efforts of volunteers. A key to sustainability is the fact that the centres are valued community assets. When repairs are needed, they are made, not always with external financial assistance.

The tangible social benefits of the project are compelling to the Indian government. The Department of Science and Technology wants to see the experiment replicated in most of the villages in Pondicherry, and is covering the cost of connecting five more villages through wireless technology. Other avenues to sustainability that are being explored are the sale of services such as desktop publishing and online banking, and partnerships with the departments of Education, Agriculture, Statistics, and the District Rural Development Agency.

The positive media attention the project has received since 1999 has helped to bolster the Information Villages Research Project. Internationally, the project received coverage in the Human Development Report 1999, the New York Times (May 2000) and in 2001 won the Stockholm Challenge, an award for pioneering ICT projects that benefit people and society.

Going Global?

The emphasis that the Information Villages Research Project places on community ownership and local content is reflected in an ambitious international initiative being undertaken under the auspices of the G8. The Open Knowledge Network seeks to build on the Pondicherry approach in order to create a global network of locally-based knowledge centres together with sectoral hubs, engaged in production and exchange of practical information for development. Oneworld International, a UK-based media organisation, is leading this experiment, which is currently at the stage of technical pilot. If successful, the Pondicherry approach will be the basis for expanding the reach of ICTs to rural communities in many parts of the world.

Using the Internet for advocacy: the ETC perspective

Katherine Morrow

For more than thirty years, Pat Mooney has worked with civil society organisations (CSOs) on international trade and development issues related to agriculture and biodiversity. The author of several books, he is co-founder and Executive Director of ETC Group (formerly Rural Advancement Foundation International - RAFI), a small international CSO addressing the impact of new technologies, especially biotechnologies, on rural communities. "Any major new technology introduced into a society that is not, by its nature, a 'just' society, will exacerbate the gap between rich and poor" is its position as stated in *The ETC Century.*

ETC Group is known for its hard-hitting critique of frameworks for technological innovation that put profit ahead of people. For this reason ETC Group is sometimes seen to be 'anti-technology', but the Group has appropriated information technology and has used it very effectively. The success of the Group's advocacy work depends on credible research, combined with effective and fast dissemination to the media, policymakers, and citizens at large. In addition to offering "cheap mail" for an organisation that consists of seven people located in three countries, information technology plays a key role in every aspect of the Group's strategy. The Internet helps researchers gather evidence and collaborate on papers. It also provides the dominant platform for research dissemination, and for the critical business of supporting the efforts of individuals wishing to voice their concerns in their own countries or at the international level.

In a recent interview Pat Mooney shared his views on information technology and the ways that ETC Group uses the Internet to disseminate research and conduct global advocacy on biotechnology issues. What emerges is a picture of an organisation that has wholeheartedly included the Internet in its communications toolkit, while remaining alert to the limitations of the technology and the problems encountered along the way.

Supporting citizen engagement

The interactive nature of the Internet, the way it enables people to instantly connect with each other, is perhaps its most significant characteristic. CSOs such as Amnesty International have pioneered the use of email and the web to promote citizen engagement through direct action. The Internet is an inexpensive and highly effective tool to support letter-writing campaigns, the gathering of signatures for petitions, donations, and online discussion forums. ETC Group uses basic web technology to help visitors to its website write letters (or emails) of concern to legislators and policymakers.

> MOONEY: *We started to use computers back in the early eighties, around 1982, when the first IBM-DOS computers came out. At the time, other groups were horrified that we were actually using computers. We got a lot of criticism for using this "obscene, dangerous" technology. But I think it's fair to say that advocacy organisations have been more effective in using the Internet and computers, than, for example, the corporate world. That may well change in the years ahead, but for the moment, at least, we've gained by it all.*
>
> *In our advocacy work, the Internet enables us to do things we couldn't do before, ways of creating interest, discussion and participation. In the 'Take Action' section of our website, we suggest ways that people can put their concern into further action, including model letters. It's been great to be able to say not only "here's some news", but also "here's what you can do about it."*

While dynamic websites undoubtedly enhance advocacy efforts, simple email offers a cheap, effective way to communicate directly with decision-makers. In the South, where web access is not widespread, email is more widely available and can be just as effective - when the right message reaches the right person.

> MOONEY: *I think many of our southern partners underestimate their capacity to use email to reach policymakers. Most policymakers and their staff have email addresses. They are seeking support and information. Email is a way to*

get critical information to them quickly, for example by sending information to the Agricultural Committee of the local congress or parliament. When a negotiator in an international meeting gets an email message from a CSO back home it counts for something. That message has more impact than if it came from us.

Using the web for publishing and research

Pat Mooney describes the central role of the ETC Group's website as a low-cost publishing tool for the group's research. Publishing on the web allows organisations to disseminate content in less time, and at a lower cost, than is possible with print publication.

Mooney notes, however, that as a tool for researchers, the web presents some drawbacks. One is the tendency of websites to keep only the latest information, discarding their archives. Another problem is that while the web presents a wealth of sources, it is often difficult to assess the quality and reliability of online information. These difficulties point to the need for organisations to put more time into quality control of their websites as well as the need for Internet users to develop specialized online research skills.

MOONEY: *The Internet has been a critical tool for getting information out about breaking issues and circulating it as fast as possible among our partners in the South. Virtually everything we publish is up on our website before it's available in paper.*

The web is critical for our research function, but whereas we felt pretty relaxed a few years ago, thinking "everything's on the web," we now realise that's not true. One of the shortcomings of the web is the lack of historical information. We've gone back to books and magazines to get a perspective on how things compare over time.

Measuring impact

Computers originated as number crunchers, and Internet-based tools offer a distinct advantage when it comes to tracking usage data. These data, when analysed, can provide organisations with very detailed quantitative measures related to their online audience.

MOONEY: *Web statistics allow us to know who is using our information, which is extremely important. We count on average 15,000 people actually downloading data from our website each month, with an even balance between corporations, academia, governments, and civil society groups. We also measure how many other websites link to ours, which I think is a pretty good indicator of impact. The Alta Vista search engine lists 1655 external links, which is high for a civil society organisation of our size.*

Reaching audiences in the south

Adopting the Internet as a primary dissemination tool cannot be done without taking into consideration extremely low rates of access in most of the developing world. Given ETC Group's mandate to address issues that affect farmers in the South, this is a major challenge. The Group frequently relies on telephone for communication with staff in the field, and makes use of Internet-connected partners in the South to relay information to and from the grassroots level. Many international efforts to "bridge the digital divide" give specific priority to improving Internet access and providing technology training to nongovernmental actors working in developing countries, in part due to the critical role these organisations play in ensuring that the concerns of local people are heard internationally.

MOONEY: *We don't use the Internet as effectively as we could, but that's at least in part because it's much harder to work online if you're in Chiapas, or rural Zimbabwe, or even in the middle of a UN meeting in Rome! In the South it's still hard to get online and download information. We depend on our partners in the South to download, print, and disseminate our material. We also encourage them to adapt the material, to make it locally relevant. We don't copyright any of our information. People can take it and use it as they want, translate it and pass it around.*

Information overload

MOONEY: One of our frustrations is that the speed of communications cuts into our ability to do research. What's dragging us down, of course, is the amount of email we get. We get hundreds of requests a week. Responding to everyone means less and less time to do research. All of us are cutting back on the number of listservers we're on, preferring to communicate one-on-one and by phone. We've had to develop form responses to email queries; otherwise we'd spend our entire lives answering emails. We have a form letter that says, "Go to our web site and look for these keywords."

Working with the media

No matter what the issue, in order to reach a wide audience it is essential to reach the media. This means developing a relationship of mutual respect and trust with journalists reporting on agricultural and development issues. ETC Group's experience points to the limitations of email in communicating with journalists. Email, an exchange of text between people, lacks the subtlety and richness of face-to-face and telephone interaction. Some situations simply demand more interpersonal contact than email can provide; communicating with journalists seems to be one of them. However, email and the web play an important role in making these relationships more productive by supporting the exchange of background material and the dissemination of press releases.

MOONEY: *The press rely on one-on-one contact by phone with key parties. We talk to three to five journalists a day, sometimes more. Journalists have to know that they can rely on us for accurate information and good quotes. It's a combination of accurate information, good quotes, and being known in general, not just on the Internet. The more you have that combination, the more they contact you, so success in working with the media is cumulative over time.*

Technology concentration

The ETC Group's broad premise is that it is not technology itself that poses a risk, but the concentration of power over its development and application in society. We asked Pat Mooney to reflect on this premise as it applies to information and communication technology, now and in the future.

MOONEY: *As time goes on, we see the issues surrounding technology as issues of governance more than anything else. And governance means who controls the media and communications technologies. We are seeing what we describe as the merger of conduit and content. The hardware conduit services of informatics are merging with the content side, so that you have concentration of providers of both the substance and the technologies for communication, for example the AOL-Time-Warner merger. We think that monitoring this is extraordinarily important for the future of good governance and democracy, and for the preservation of dissent.*

Radio browsing the Internet: an option for rural communities

Modern information and communication technologies (ICTs), more specifically the Internet, has the potential to offer a new generation of tools for rural development. However, it requires special efforts to create appropriate access models for those who can neither afford internet access nor have the language capacity to understand the content. The purpose of the Kothmale community radio internet project was to test and demonstrate an access model that could overcome these barriers and make information accessible to otherwise marginalised communities in rural areas. UNESCO implemented the project in collaboration with the Sri Lankan Ministry of Posts, Telecommunications and Media, Sri Lanka Broadcasting Corporation, Sri Lanka Telecommunication Regulatory Commission and the University of Colombo.

Kothmale community radio

The Kothmale community radio station is located in the central hill region of Sri Lanka and serves a population of 200,000. The area of coverage includes around 60 villages with an average of 400 residents and three rural towns with around 175,000 residents. The station began broadcasting in 1989 and in ten years has become an integral part of the community and the most popular FM radio in the area. Currently, it has morning and evening broadcasts; the morning broadcast is commercialised and the revenue generated covers 75% of the station's operational costs.

Combining Internet with radio

The community radio internet project introduced three features, which combine new information technologies with conventional radio.

a. ***"Radio browsing the Internet" programme*** The radio station broadcasts a daily two-hour programme during which broadcasters supported by resource personnel browse the internet on-air together with their listeners and discuss and contextualise the information in the local language. Listeners direct queries to the station (in person, by mail or by telephone), and the broadcasters surf the Internet on their behalf and transmit the information. Resource persons (agricultural extensionists, doctors) who are invited as studio guests help to put the information in context.

b. ***Provision of internet access*** Besides its own internet café, the station's server provides free internet access at two nearby public libraries. This is quite attractive to people who cannot afford the facilities of a computer and are unable to pay for long-distance telephone calls. Trained volunteers take turns to assist the visitors in using the computer facilities.

c. ***Development of a community database*** The community radio develops its own information database based on the requests of listeners. This database attempts to package information that meets the needs of the rural population in the local languages on the Internet. In addition, the station provides skills to help the community to develop their own web sites and encourages them to produce content for the Internet.

Successful initiative

The project has succeeded in accomplishing its goals - it has brought the benefits of ICTs to a rural population. Many people are benefiting from the increased access to information and the examples are as diverse as the users. A local farmer has obtained information on organic farming of tomatoes and improved storage methods. Another farmer was delighted with the housing diagrams and feeding information for geese he gathered from the Internet. A group of local producers of "*jaggery*" (sweet made of palm treacle) found markets for their product. A group of youth used internet sources to network with other organisations in setting up an environmental NGO. Having mobilised resources, they have launched a reforestation programme in their community. A local health worker was able to find information on mosquito-borne diseases directly relevant to her work.

The project has led to an increased awareness on the benefits of ICTs within the community. Many within the community have opened e-mail accounts to keep in touch with their relatives working abroad. Younger members of the community are enthusiastic users of the computers and the internet facilities at the radio station. Many of them have gained computer literacy and are a bridge for the rest of the community in the learning process.

Apart from expanding the knowledge base of the people, it is also contributing to increased participation of the community in economic and social development.

Keeping it going

The Kothmale project was implemented with an initial grant of US$ 35,000, which covered project management, costs for internet connectivity, equipment and installation, training, research and workshops for project partners. The existence of a well-equipped radio station in Kothmale reduced the setting up costs significantly.

With the UNESCO funding coming to an end, the future of Kothmale internet community radio depends on whether it can finance itself. The station would have to generate an additional US$ 1000 per month to maintain the present activities. Many income generating options are being tried out. Already work has begun on hosting a number of commercial web sites on the station's internet server. The local youth have been trained to design and develop web sites for the private sector. The server can provide seven additional access points, which the station intends to rent to government or non-governmental organisations. The "radio internet browsing" programme is expected to increase the volume of radio advertising. Listeners, who have formed an Internet listeners club, are raising funds to support the facility.

Meanwhile, UNESCO is developing a global programme drawing on the experiences of Kothmale. This programme on community multimedia centres offers a global strategy to address the digital divide in the poorest communities of the developing world.

Communicating innovation: the 'In the Field' project

Monica Janowski and Kaz Janowski

Under an apple tree in our garden in 1998, we talked about innovation and communication. Monica is a social anthropologist at the Natural Resources Institute (NRI) of the University of Greenwich, whose staff need and want to communicate the results of ground-breaking projects to a wider audience who are not scientists or specialists. Kaz is a radio producer at the BBC, which needs depth and really good content in programmes. We decided that there was potential complementarity there; and that we would try to make something happen.

Two years later, after discussions within NRI and between the NRI, the BBC and the UK Department for International Development (DFID), we succeeded in getting a series of 12 programmes commissioned by the BBC World Service, and in getting funding from DFID to support NRI's part in the collaboration. We called the series `In the Field', with the subtitle 'Exploring Innovative Improvements to Livelihoods around the World'.

Making 'In the Field'

Building on earlier discussions, Monica put out the word at NRI asking for researchers to volunteer their projects as topics for programmes. The idea was that the researchers themselves, where possible, would act as 'barefoot reporters' and would carry out the interviews themselves, with villagers and local researchers in their project sites. At the core of each programme we wanted to have local people telling their own stories and talking about their feelings about the particular problem they had faced and how this had been tackled.

To act as reporters, NRI researchers needed practical training in using the equipment and in face-to-face interviewing skills.

Programmes in the "In the Field" Series

- The Buabeng-Fiema monkey sanctuary, Ghana
- Tree pods - a new way of feeding goats, India
- The need for agricultural land in the city, Ghana
- Stepping off the pesticides treadmill, India
- Vegetable gardens in the city, Zimbabwe
- Farmers who just don't farm, Poland
- Introducing ethical trade, UK and Ghana
- Different ways of understanding ethical trade, Ghana and UK
- Fighting the rat problem using new traps, Mozambique
- Alternatives to "slash and burn" agriculture, Bolivia
- Trading cocoa fairly, Ecuador
- Training "barefoot vets" to treat village animals, Indonesia

We arranged this at the BBC. The training was enjoyed by all; BBC staff found the topics of the research projects very interesting and the researchers were excited at the prospect of communicating their results to a wider and more general audience through their input to the programmes.

Once the researchers returned from the field, we used excerpts from the interviews, local music and sound effects to make the programmes, held together by a script read by a presenter. Where voice-overs in English were necessary, we used people from the countries concerned, so as not to distance them from the interviewees themselves. We also interviewed the researchers and included excerpts from these interviews in the programme, so that the researchers became `characters' in the story too. Topics covered in the programmes were wide-ranging, both geographically and in terms of subject matter, from tackling the rat problem in Mozambique to trading cocoa fairly in Ecuador (see box on this page).

We worked closely with the NRI researchers, and through them their local research partners, to ensure that they, and local informants, were happy with what went into the programmes. We decided that this was very important since researchers told us that that in the past when they had been in touch with the media, whether print or broadcast, their work had often been misrepresented.

The 'In the Field' booklet and websites

To partner the radio series, we produced a booklet with the aim of consolidating what was in the programmes and to raise other related issues. The booklet was funded by DFID, and was sent out by the BBC free of charge to listeners, who were prompted to write in.

We tried to make the booklet as attractive and engaging as possible, with photographs of many of the villagers who talk to us in the programmes and of the villages they live in and maps showing the location of villages. The double page spread for each programme is separated into sections for ease of reading, entitled 'Setting the Scene', 'Defining the Problem', 'Taking Action', 'Global Relevance', 'Cast and Key Quote' and 'Thinking Points' (see example on p.24). There are also two double page spreads looking at cross-cutting issues related to tackling livelihood problems. To ensure that the text for the booklet was accessible, we brought in a popular science journalist to work with Monica on it.

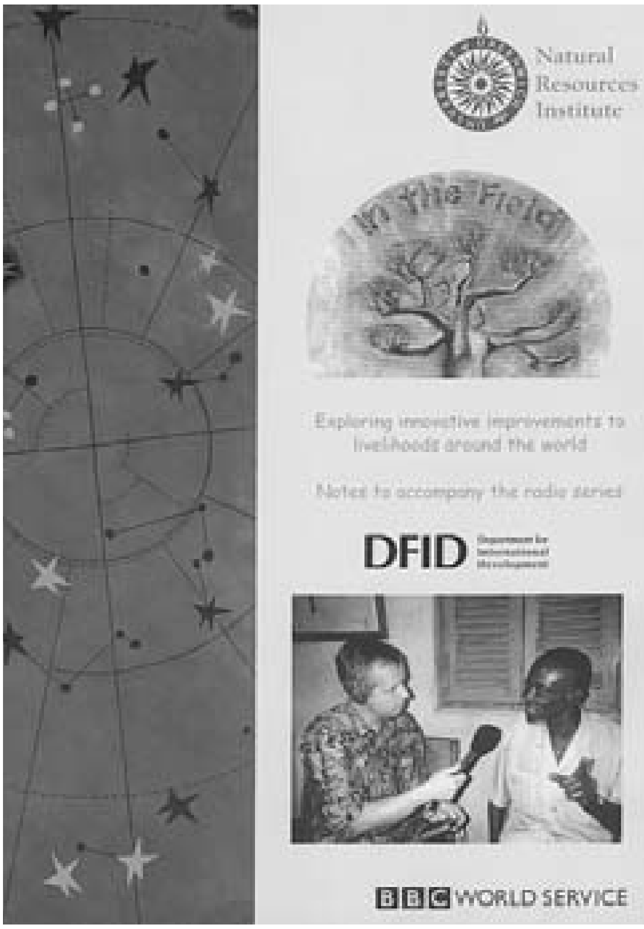
In addition to producing the booklet, we presented the text, photographs and maps in downloadable form on a series website at the NRI (*http://www.nri.org/InTheField/)*. The audio of the programmes is on a series website at the BBC (*http://www.bbc.co.uk/worldservice/sci_tech/features/field/index.shtml)*.

The series was first broadcast on the World Service between January and March 2001. It went out for the second time between January and March 2002.

Who was listening and what did they think?

Our hope with the series was to increase appreciation of the common issues and problems affecting people in different parts of the world, and how these can be tackled effectively. We also hoped that this would stimulate and encourage local initiative to tackle problems of this kind.

Our potential audience for these programmes was very wide, since they were going out through the BBC World Service, which has a diverse audience all over the world, ranging from



opinion leaders to people at village level in countries where English is spoken as a second language. To find out whether we had been successful in our aims, we wanted first of all to try to find out who was listening to the programmes, who was writing in for booklets and what they thought about the series, website and/or booklet. We were particularly interested to know whether people at village level were listening to the programmes and writing in for the booklet.

Since we didn't have funds to do research locally on response to the programmes, we relied on response to the booklet, with which we enclosed a feedback form. In this we asked listeners/readers to let us know something about who they were, how they might use the material and what they thought of it. We had a healthy response, from all over the world, to the offer of the notes, both on the feedback form and by email. The initial print run for the booklet was quickly exhausted and a reprint was arranged in early 2002, in time for the second transmission of the series in January that year.

We have had a number of requests from people at institutions who see the material as a valuable resource for teaching and for teacher training, both in the South and in the North. This includes teaching in schools, at university level and teaching extension workers at village-level.

We have also had many responses from people who were interested on a personal level in the programmes. These demonstrate the chords which the programmes seem to have touched in relation to individual work and also in relation to interest in how people live in other parts of the world, and how these parallel respondents' own experiences. For example, a comment from Chun-Quan Meng in X'an in China: *'I enjoyed 'In the Field' very much. It is an interesting and practical agricultural programme. On January 30th's programme you review vegetable farming in Harare. It is a wonderful topic. It reminds me of my farming activities in the 1970s when I was a farmer at a small mountain village about 140 km SW of X'an. At that time I grew vegetables for making money. Nowadays I usually grow vegetables on the balcony of my house for enjoyment. Anyway, I love looking at and caring for vegetables.'*

Another from Huthyfa H. Mohammed in Baghdad, who has 'an interest in global issues and self-improvement': *'I am enormously grateful and thankful for the significant help you afford me throughout your fundamental informative programmes broadcasted by your unique World Learning. In the Field, one of these lively and provoking programmes to which I keep listening intensively, since it enhances my knowledge and invigorates my experience as long as I live in the modern world'.*

From Anish Damodaran a livestock inspector from Kerala in India, who was attracted by the programme on paravets in Indonesia: *'I have been working in villages as a livestock inspector for about 5 years. I will try to become a barefoot vet. This article has been a great source of inspiration. This has been an idea I have been keeping for a long time. At some point in my life I will go back to teaching. Then these notes can be a study material. I will share these notes with anybody who is interested to do first aid for animals, to love them or as a hobby'.*

An educational role for 'In the Field'

Because we received so many responses from educational institutions saying how much they liked the programmes and notes and that they were already using the booklet in teaching, we decided that it would be worthwhile to formally pilot the use of the notes and radio programmes in teaching.

We have therefore set this going in a number of institutions around the world, both in the North and in the South. We identified schools, colleges and universities to pilot the material both through the responses which the BBC received from listeners and through contacts which the NRI has with institutions around the world.

As well as making class sets of the booklet available to teachers piloting the material, we wanted to make it possible for them to use the radio programmes themselves in teaching. Although the radio programmes are posted on the BBC series website, it is not always easy for institutions, particularly in the South, to play these in a classroom. We have therefore produced cassettes containing the radio programmes, which we are sending out free of charge to educational institutions involved in piloting.

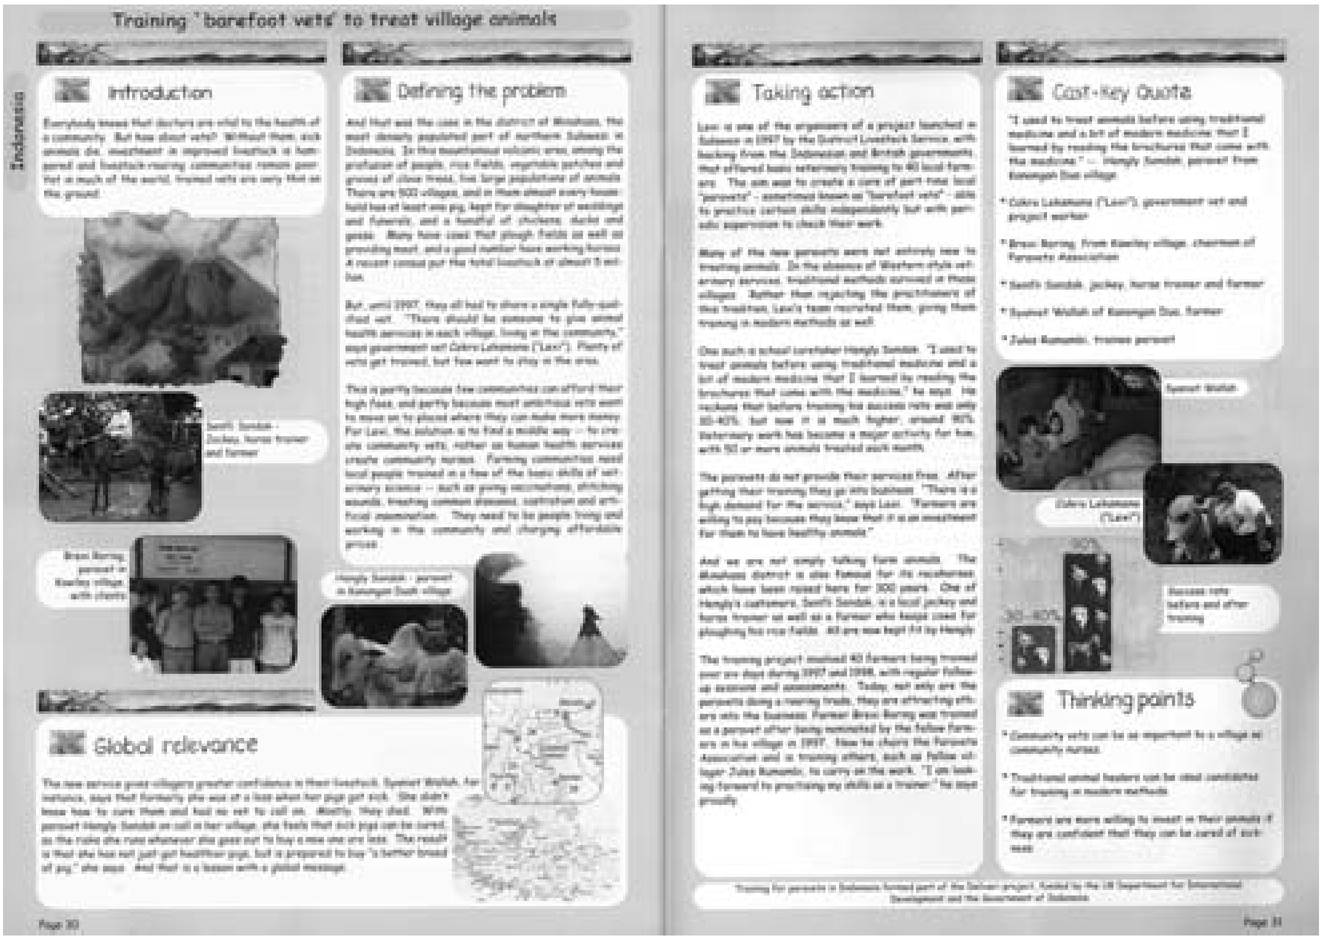
Reaching down to village level

We haven't heard as much as we would like from listeners right down at village level, although most of our correspondents seem to have close contact with villages either personally or professionally. In order to ensure that we are succeeding in reaching into villages, we are hoping to go more local through rebroadcasting. We have received several requests to allow rebroadcasting of the series on local radio stations, which the BBC allows free of charge.

We are particularly interested in an initiative in Zambia, where rebroadcasting is being combined with setting up Listener Groups to discuss the programmes at village level, whose members use wind-up/solar-powered radios.

Conclusion: the benefits of partnership and the future

We feel that the 'In the Field' collaboration between the BBC and the Natural Resources Institute has been a great success. The two sides brought very different backgrounds, skills, and networks to the table, and we found that these were complementary in many ways. From the BBC's point of view, the collaboration with the NRI has meant access to a network of knowledge and village-level research; from the NRI's point of view, the BBC has access to a wide audience of people in all walks of life, also at village level, far beyond the NRI's project areas.



Crucially, as far as the NRI is concerned, the BBC has the ability to make interesting and lively programmes that have a wide popular appeal, translating the findings of research projects into something that is human and accessible. This is something which NRI scientists do not have experience in, and consequently it is difficult for them to communicate the findings of their projects directly to the people they most want to reach – potential beneficiaries of their new knowledge at village level around the world.

The fact that the programmes have been transmitted on the BBC World Service all-English stream is both a help and a hindrance to communication. A major plus is that programmes can be made which are listened to around the world, and that the drawing of parallels between problems and solutions in different places is encouraged in a way that would not be possible through a purely locally-focused series. However, most people in most countries do not understand English and they can have access to the programmes only through an intermediary. We hope that in many countries where English is a second language there will be at least a few people in each village who will listen to the programmes and tell others about them. However, we do have concerns about the exclusion of many people because the means of communication is English. Rebroadcasting in languages other than English, maintaining the original interview village-level extracts and translating the script and voice overs, is a way of overcoming this problem.

The feedback forms and emails we have received are only partial commentaries on response to the material. We do not have very much information on the kinds of people who are responding in this way, and on the responses of groups of people, in particular within communities at village level. It would be very useful to be able to carry out research at village level in conjunction with local broadcasting of 'In the Field' through a local radio station. This would enable us to make an assessment of the responses of different categories of people – for example young/old, women/men, poorer/better off – within communities.

This in turn would allow us to begin to see how this kind of approach, combining broadcast information with printed information, can be used at village level to disseminate information on useful technologies and to stimulate debate on important topics. A particularly exciting idea would be to set up links between discussion groups and/or interest groups (with, for example, the same technical problems) in different parts of the world through an initiative where the same material is used in different places. This could potentially be linked to the connection of villages to the internet which is developing in different parts of the world.

"In the field" will be transmitted for the third time on the BBC World Service in mid-October 2002

Radio brings information to many rural communities worldwide. Photo: Danielle Baron, JHU/CCP

Connecting farmers worldwide through radio

Nancy Bennett

Radio has long been used as a tool for learning and community adhesion. Particularly in remote regions without telephones, people use radio to announce arrival dates, funerals and weddings. People learn about their government's policies and plans on radio, and hear about events and issues in their communities. They also use their local or community radio stations to voice their own views.

Radio network for Canadian farmers

In Canada, with thousands of communities isolated by the vast distances between them, radio has been an important tool for rural development. National public radio, the Canadian Broadcasting Corporation (CBC), was formed in the first half of the 20th century to strengthen the nation. Canadians needed a way to get Canadian perspectives about Canadian and international issues, especially because of their proximity to the powerful and far-reaching media networks of the United States.

In the 1950s, the CBC launched a new programme that was intended to specifically address the needs of farmers who were spread across the country. The National Farm Radio Forum was an interactive programme that brought farmers together on Monday evenings to listen to the weekly broadcast. In groups, in the kitchens or living rooms of their neighbours, farmers discussed the programme and answered questions in a workbook that was distributed to these organised groups. Their answers, and their questions, were then sent to the CBC office to be used in the following week's programme.

By the 1970s, the CBC's farm radio programmes no longer included the Forum – but the daily farm reports were still immensely popular and important to rural listeners, and CBC's farm programming had gained international renown.

Taking the experience beyond Canada

In 1974, CBC farm commentator George Atkins was invited as a resource person to a conference in Zambia for African farm broadcasters. There, the idea for Developing Countries Farm Radio Network was born. Speaking with his African colleagues, Atkins was struck by their need for practical, relevant information for their radio programmes. Without a variety of reliable information sources, African broadcasters were dependent on the brochures of commercial agricultural suppliers – often biased to promote sales of products that their listeners could neither use nor afford. Without accurate and appropriate information sources, how could the broadcasters provide popular, important programmes?

On his return to Canada, Atkins devoted his efforts and time to his idea of a network of farm radio broadcasters – a new kind of forum that would enable them to exchange information that was useful to their listeners, and that would support the development of viable and environmentally sustainable agriculture. With start-up funding from Massey Ferguson, Atkins enlisted 36 participating broadcasters in 24 countries. Soon, agriculture researchers and extensionists joined the effort by providing information that was relevant to small-scale farmers in Africa, Asia and Latin America. By the 1980s, Atkins had left the CBC and was working full-time to achieve his vision of farm radio broadcasters working in concert for rural development and food security. The radio programmes and scripts developed and distributed by the Toronto office, based on contributions from the field, was limited only in number, due to limited finances – never by information, ideas or energy.

Worldwide radio network

Today, five hundred radio broadcasters, stations, and training organizations in almost 100 countries participate in Developing Countries Farm Radio Network. Almost one-half of participating stations is in Latin America and the Caribbean; one-third is in sub-Saharan Africa. Their programmes are heard from the Andean mountains to the African savannah in 300 languages, and are changing farm practices all over the world. A community garden in South Africa experimented with a bamboo irrigation system developed by a farmer in Thailand after hearing about it on a local farm radio programme – and has improved its management of a scarce resource. This kind of success is repeated over and over – a testament to the value of information, communication, and networks.

Keys to success

The success of any network is based on the participation and skills of its members, and Developing Countries Farm Radio Network is no exception. Indeed, we refer to our members as our partners in recognition of the contribution they make. Network partners must regularly assess the needs of their listeners and develop radio programmes that respond to those needs. They are responsible for finding and filtering appropriate information for their programmes, often translating it into the local language of broadcast, and producing entertaining and informative programmes that attract listeners. They take a globally-relevant topic (such as pest management, or soil conservation) and add local information and perspective to make it understandable and practical for the farmer tending her small plot. In a world that is increasingly complex and interconnected – even small-scale farmers are affected by international agreements and protocols – the demands on farm radio broadcasters are daunting.

Changing with the times

In response to the increasing and evolving role of radio broadcasters working for rural development, Developing Countries Farm Radio Network is changing. We continue to provide reliable and relevant information – in the form of scripts, stories and programme ideas - to broadcasters who have limited resources for local research and production. Many of our partners are community or small local radio stations operating with volunteer labour, basic equipment and shoestring budgets. They do not yet have regular access to the Internet.

We also provide custom research services to our partners who are preparing programmes about specific issues or are responding to listener enquiries. In the 25 years we have been gathering information, we have built up a library that we believe is unique in the world. With contributions from the 1000 extensionists, educational and research institutions, NGOs and others – mostly in developing countries - with whom we have established regular contact, we have a collection focused on small-scale (usually tropical) agriculture, practical approaches, experimentation and innovation. We hope, one day, to make our catalogue available on-line and our library services available to others working for food security and rural development.

Building the skills and capacity of partners

Increasingly, our programme aims to develop the skills and capacity of our partners to understand and respond to local needs. This means that the scope of the information we deal with is broader than it was a quarter-century ago. Once focused on crop production, animal husbandry and nutrition, we now take a more integrated approach that includes, for example, how small-scale farmers can cope with HIV/AIDS, how to get and use information about markets, or how cooperative community models can improve rural incomes and quality of life.

Skills and capacity development also includes training. With each package of scripts and stories we share amongst our partners, we include training and professional development materials. Background articles sensitize broadcasters to issues affecting their listeners, and increase their comfort in covering these topics. Few journalists have in-depth subject knowledge and must be alerted to opportunities for new programming. We regularly make organisations and other resources on specific subjects known to our partners, both in our newsletter and on our web site. A current project in partnership with ISNAR (International Service for National Agricultural Research) aims to promote increased cooperation and collaboration between radio broadcasters and their national and local agriculture research services.

A women's listener group in India. Photo: JHU/CCP

Other training materials promote effective communication approaches, with an emphasis on involving the listeners as information providers as well. While many people think of radio as a one-way medium, we encourage broadcasters to begin with listening, and to provide forums - through panel discussions, taped community meetings, call-in shows, and even the on-air reading of listeners' letters – for public discussion and debate of issues of interest and importance in their communities.

Radio - unrivalled in its outreach to rural communities

Because of its unrivalled access and its low production costs, radio is the technology that best meets the information and communication needs of farmers, world-wide. At Developing Countries Farm Radio Network, we will continue to support radio broadcasters so that they can meet those needs, strengthening small-scale farming and rural communities as they work toward food security.

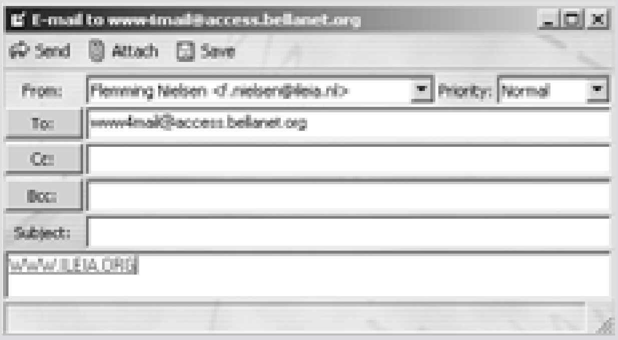
Accessing the Internet in the Sou

Web Access by Email

In most developing countries, access to the Internet is expensive, slow, or both. Very often, many people share a single Internet-connected computer. To surf the web in the conventional way requires a stable power supply and continuous Internet connection while the user visits one page after another. If this is not possible or practical, web access by email is a solution that allows you to access web pages using only email. You can prepare the emails before you go online to minimize the time you are connected.

What you need: Access to email, and a web browser such as Netscape or Internet Explorer.

1. Compose an email message addressed to **www4mail@access.bellanet.org**
   In the body of the message, type the address (URL) of the web page you wish to receive. Send the message.



Requesting a web page by Email

2. You will receive in reply an email message containing an attachment. Open the attachment in a web browser. The web page contains only the text, no pictures, because images on the web contain a lot of data and take longer for you to download.

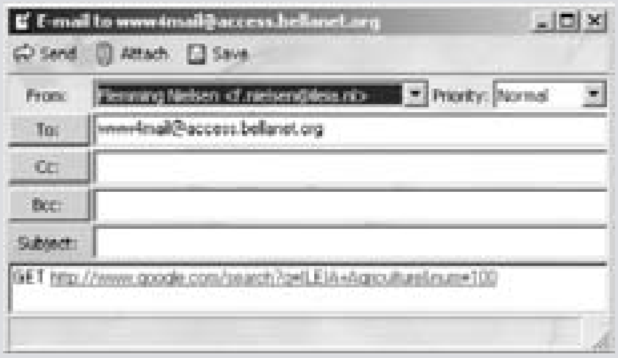
3 To follow the links, or request to see the pictures, just click in the boxes and press "send." Later on, check your mail and you will have received the requested pages.

Search the Web by Email

Send a message like the following:

To: **www4mail@access.bellanet.org**
Subject: [leave blank]
Body:
GET http://www.google.com/search?q=ILEIA+Agri culture&num=100

Try it, or replace 'ILEIA' and 'Agriculture' with your own keywords, as many as you like, separated by +



Searching the Internet with Email.

You can use a similar technique to search ILEIADOC, ILEIA's online bibliographic database:
As an example, send a message to:
www4mail@access.bellanet.org
with
http://ileia.cust.iaf.nl:8080/Ileiadoc.html?pg=q&q= sheep+goats
(replace 'sheep' and 'goats' with your own keywords) in the body of the message.

More on Web Access by Email

- Accessing the Internet by E-Mail: Guide to Offline Internet Access
- Full instructions on surfing the web by email, ftp by email, and much more. Available in many languages. By Bob Rankin and Gerald Boyd. To receive a copy, send a blank email to: **accmail-faq@expita.com**
- See also: How to Do Just About Anything by E-Mail, by Gerald Boyd **http://www.expita.com**

uth: some tools and techniques

Translation of Email by Email

Send an email as usual to a colleague in your own language. In the “Cc:” line, send a copy of the message to the Universal T-mail Translator. The way you format the address will determine how the message is translated.

The format of the cc address is: (Original language)-(Final translation)@t-mail.com, where the language codes can be: English (en or an), French (fr), German (ge or de), Italian (it), Spanish (sp or es), Portuguese (pt or po).

To get from an English to a French translation you would use cc: **en-fr@t-mail.com**

The person you mail to will receive both your original email and the translation.

Automatic translation of your Email using the free t-mail.com service

Reading and Converting PDF Files

Many scientific and other documents on the web are saved in Adobe PDF format. To read these documents you need the free software Acrobat Reader (See p.33 on how to get it) However, you don’t need to the PDF reader if you use the “PDF Conversion by Email”. This service allows you to convert PDF files to a plain text format that is easier to read and send by email using older computer technology.

You can receive pdf files from the Internet as text files. Here an article from LEISA magazine vol. 17, no. 4, page 6-8 is requested.

If the PDF is on the Internet (tip: the web address or URL ends with .pdf), mail the URL in the body of an email message to **pdf2text@adobe.com**. The converter will mail back the plain text of the file. If the PDF file is on a diskette or on your computer, send it as an email attachment to **pdf2text@sun.trace.wisc.edu**

Web-browsers

Most new operating systems (e.g. Windows) include a web browser. However, you may want to try one of the alternative free ones. Lynx (**http://lynx.browser.org/**) is a text-only browser that run fast on even the oldest computer. Since it ignores graphics you can surf very fast. It allows you download graphic files to you hard disk if you want but Lynx itself will not show them.

Opera (**http://www.opera.com/**) is a highly-rated free web browser Opera that is much smaller than other major browsers and includes an FTP client and Email program. A good choice for those using older hardware. The only problem is that the free version download adverts and thus keeps you online for a longer time.

Netscape Communicator (**http://browsers.netscape.com/browsers/main.tmpl**) Netscape’s web browser comes with a set of free tools: Netscape Mail (an email client), Netscape Instant Messenger, and Netscape Composer (for creating web pages).

Microsoft Internet Explorer (**http://www.microsoft.com/windows/ie/default.asp**) Microsoft’s IE web browser comes with a similar set of complimentary tools: free email client (Outlook Express), instant messaging, and web page editing. Outlook Express is frequently targeted by viruses and is not recommended as an email client.

Viruses

Viruses (and also Worms and Trojan Horses) are programs designed to harm your computer and spread from one computer to another. They will not destroy your computer physically but can change or delete software and your files so the computer becomes useless until the software has been installed again. It is wise always to keep backup on floppy disks or CDs.

Typically, you contract a virus by opening an email attachment from an unknown person, or by sharing computer diskettes with another person. The best way to protect against viruses is to install Virus protection software on your computer and to update it regularly. If you receive a file you did not ask for, especially with the extension .exe, it may contain a harmful virus. Infection occurs once you click on the file to open it. The best solution is to delete the file without opening it.

Free virus protection software include: “AVG AntiVirus” (**http://www.grisoft.com/html/us_downl.htm**) and VCatch (**http://www.vcatch.com/download.html**)

“Farmer to Farmer”: Participatory radio for Dekhon farmers in Tadjikistan

Armorer Wason

Farmers in Tajikistan have only recently begun to farm with a measure of independence from the state and collective farms of the Soviet era. They face enormous challenges: breakdown of the rural Soviet infrastructure, lack of effective structures to support private farming, lack of finance, endemic corruption, poor rule of law, and during 2000 and 2001 very severe drought. Moreover, there has been almost no discussion in the media of the real problems they face. Farmers do not have reliable sources of information, even on the most basic, uncontroversial, technical aspects of farming.

Farming in Tajikistan

Tajikistan is in a stage of transition from the Soviet economic model, with much of the economy still controlled by the state and most farmland under a high degree of state influence. Between 1995 and 1999, 120 (out of 600) state controlled farms were privatised, mainly into lease farms, joint stock companies and some private peasant ‘dekhon’ farms.

A ‘dekhon farm’ is generally either a small to medium-size family farm (2-50 ha.), or a large ‘collective dekhon farm’ or ‘dekhon association’ (50 to 500 ha.). Dekhon farms are created with a lifelong inheritable dekhon lease. From June 1999 land privatisation was accelerated, with a further 160 collective farms to be converted into private dekhon farms through the issue of land share certificates to collective farm employees. By November 1999 there were 13,000 dekhon farms.

The main priority for the Tajik Ministry of Agriculture is the revenue from the cotton crop, and it is almost entirely taken up with administering the production and delivery of cotton from large state farms through a modified form of central planning. Some of these farms have been nominally privatised, but in reality they are not free to make their own decisions: they must sell to the state at prices determined by the state. Cotton comprises 30% of exports and 30% of total state tax revenues, but the actual returns paid to producers, and the wages of much of the rural population working on the cotton-producing state farms, are close to zero. In lieu of unpaid wages, farms commonly “rent out” land to their workers.

Most of the rural population relies for its basic livelihood on self-production on household plots of land. These provide 45% of the total consumption of rural households. Households implement a complex form of integrated agriculture and land productivity is high. Vegetables are grown for market and for the household’s own consumption, and crop residues from the plots partially sustain small and large livestock.

Mass Media in Tajikistan

Upon independence from the former Soviet Union, Tajikistan descended into a civil war that claimed some 60,000 lives out of a population of 6.7 million. A power-sharing agreement concluded between the warring parties in 1997 established an uneasy peace. The short period of relative openness subsequent to independence from the Soviet Union is popularly believed to have been a major contributing factor in the outbreak of the civil war. The Minister of Agriculture expressed the opinion that giving information to farmers was a very dangerous thing to do, and that freedom of information was one of the causes of the war.

At present, there are no independent national television or radio stations in Tajikistan. There have been several attempts to gain licences for independent broadcasting projects, but no licences have been granted to transmit nationally. Tajik Radio is essentially an arm of the state, with no public service responsibility. There is no commitment to programmes that honestly reflect the preoccupations or concerns of audiences. The role of programme managers is to control programme content, while programme quality, especially in terms of relevance to audience concerns, is not considered important.

Journalists exercise significant self-censorship, as indeed they did in the Soviet era. Self-censorship is so effective that the people of Tajikistan survive with almost no detailed information beyond what government wants them to know. The impact of this is very deep: this is a society that does not have a dialogue with itself. As in Soviet times, the very act of asking questions becomes uncomfortable, even on the most uncontroversial themes.

“Farmer to farmer” radio series

The radio series *Farmer to Farmer* aims, despite the very considerable constraints, to respond to the concerns and questions of private dekhon farmers through interviews with farmers and a range of agricultural experts. It is broadcast once a week as part of Tajik Radio’s lunchtime programme for rural listeners, and then repeated in the evening. Initially, programmes were 15 minutes in length, but now run for 20-25 minutes.

Radio producer interviewing farmers in the Kulyab province of southern Tadjikistan. Photo: FAO

With support from the Swiss Agency for Development and Co-operation (SDC), the local office of the Food and Agriculture Organization of the United Nations (FAO) manages the production of the radio series. This is part of a larger project, based in the capital Dushanbe, which trains veterinarians, supports veterinary services, and distributes seeds. The Project Co-ordinator and national staff have close links with the Ministry of Agriculture, which supports the project.

The series is transmitted throughout the country by Tajik Radio. It is a significant departure for Tajik Radio, which has never broadcast an independently produced radio series before.

Implementation strategy

The FAO radio project required attention to four areas in order to be effective: a workable degree of control over production, participatory audience research, journalism training for the radio producers, and, at a later stage, a campaign to promote the series.

It was essential both to recognise the very real limits on the editorial independence of the radio programmes and to attempt to ensure that the project had as much influence as possible over the production of programmes. The agreement was that the radio producers recruited to the project would plan, record and script materials under the supervision of the FAO Project Co-ordinator, and then edit and mix the final programme at Tajik Radio. Inevitably, Tajik Radio managers would have an ultimate veto over programme content.

To meet the information needs of the target audience, to ensure the credibility and reputation of the programmes among farmers, and to stimulate and encourage farmers to work together to find solutions to their problems, it was essential to build the project on a solid basis of effective, participatory, audience research. In Tajikistan, however, it was clear from the outset that compromises would have to be made in order to protect both the programme producers and the project. It was decided that radio programmes should initially concentrate on non-controversial technical questions, and that gradually the programme producers would feel their way towards covering more difficult areas.

Focus groups were used to inform and mediate the agenda for the programmes and to fulfil two other invaluable functions. Firstly, they were to provide an objective process for evaluating the success of the programmes - an opportunity to test the extent to which farmers understood, liked and made use of the material. Secondly, the focus groups were intended as a powerful force to re-orientate the radio producers to a new view of their role. Programme producers in the former Soviet Union did not solicit the needs and concerns of their audiences and were not expected to take them into account. Their key function was not to ask questions but to give their audiences an officially sanctioned view.

It was clear that the radio project was a valuable opportunity to support the general development of good journalism practice in Tajikistan, in a relatively uncontroversial subject area. Apart from the two programme producers recruited to the project, training seminars on journalistic research were given to interested parties.

As the audience for Tajik Radio's programme for rural listeners is very small, it was evident that some effort would be needed to promote the radio series once it had achieved an acceptable standard.

Successful initiative

The arrangements for producing and transmitting programmes have been very successful. Programme scripts are finalised with the project coordinator before being edited at Tajik Radio. This has worked well, and there has been a steady improvement in both production values and journalism standards. Tajik Radio representatives welcomed the programmes and have appreciated the variety and new approaches they inject.

There has been valuable synergy in locating the series in an existing agricultural project. The agronomists and veterinarians have provided valuable background information, contacts and stories for the programme producers and have welcomed the radio producers on trips to rural areas. They have been extremely supportive in the research process and sensitive to professional and editorial boundaries.

The lack of journalism training and a decision to concentrate on 'safe' technical themes ensured that the early programmes did not pose a challenge for Tajik Radio. As the series has become established it has gradually become more adventurous thematically, and the questions put to interviewees are more focused.

The participatory audience research has been partially successful. The facilitation in some focus groups has been better than in others. The groups have been well attended, which could be an indication of the motivation of farmers. Participants generally felt that the programmes gave useful information, but that at times they lacked dynamism and did not always provide a rounded view of a subject. The groups stressed the need for appropriate technical information, i.e. plant and animal diseases, warnings of disease outbreaks, coping in drought conditions, assessing quality of livestock, sources of reliable seed material etc. There were also requests for information on the prices of produce, fuel, fertilisers, pesticides, and ideas for alternatives to increasingly costly pesticides, fertilisers and other inputs.

Broader subjects of concern included rights to land use and legal regulation, relationships with the collective farms, finance and credit etc.

It is clear from the programme scripts that the radio producers have endeavoured to adjust their work to respond to these constructive criticisms. There is no doubt that the radio producers were strongly affected by the experience of observing focus groups, and that they worked hard to meet the needs they heard expressed.

The agenda for the radio series clearly reflects most of the concerns of the focus group participants. Programmes have been made on all the technical subjects requested by the farmers, with close attention paid to ensuring that they are seasonally and regionally appropriate. Increasingly, the programmes are covering the frustration and problems faced by farmers, eg. taxation, corruption, credit, land registration. An excellent "Question and Answer" section in later programmes of the series has given clear and helpful answers to farmers on specific questions. It is very encouraging that the experience and voices of farmers themselves are at the heart of the programmes.

The radio producers have made significant progress in producing well-structured, clear, accessible materials and there has been considerable success in using new production ideas. The producers now have a far better grasp of the strengths and limitations of radio as a medium, and of how to ensure that listeners can take in the information that they seek to communicate.

Staff of the larger FAO project has actively promoted the radio series, distributing 1,500 promotional leaflets in rural areas in many parts of the country. Leaflets promoting the radio series were also sent to the international agencies operating in Tajikstan. However, there have been very few letters and telephone calls from farmers, and it is likely that audiences have remained fairly small in the absence of a structured mass media campaign to advertise the programmes.

The future

Tajik Radio is pleased with the project but like other governmental institutions in the country, they barely survive in economic terms. They have no resources to support the continuation of the project. Sustainability of the project inevitably derives from the availability of donor funding. If economic transition proceeds successfully it may be possible to achieve longer-term sustainability through private-enterprise sponsorship.

Through 'Farmer to Farmer' great strides have been made to improve the responsiveness and relevance of radio to farmers' needs and problems. This is a good beginning, given the constraints of the wider political context. But for farm radio in Tajikistan to be genuinely farmer led, the new programme approach will need to be matched by political change concerning the role of journalists.

■

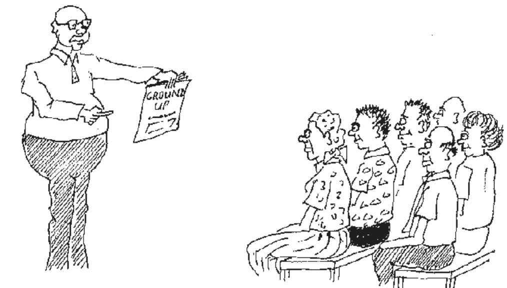
"Ground up": facilitating networking and sharing in sub-Saharan Africa

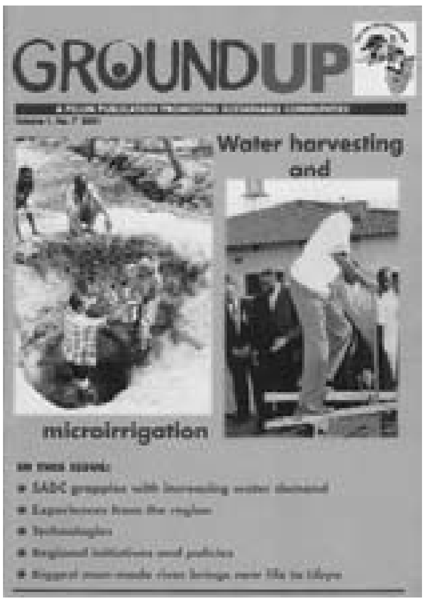
Parkie Mbozi



SOME MEMBER ORGANISATIONS USE GROUND UP IN COMMUNITY WORKSHOPS.

Participatory Ecological Land-Use Management (PELUM) Association is a regional network of 138 civil society organisations with over 15 development partners working in nine countries in eastern and southern Africa. They are Botswana, Kenya, Lesotho, Malawi, Uganda, South Africa, Tanzania, Zambia and Zimbabwe.

The members are involved in a wide range of activities in sustainable agriculture, food security, and natural resource management The activities include training, information dissemination (including gender, HIV/AIDS), drought relief, seed multiplication and delivery, financial support, advocacy and lobbying.



PELUM members have joined hands in forming strategic alliances to fight poverty and remedy other social injustices in the region, and to enhance capacity building. The PELUM mission statement reads in part: "We aim to build the capacity of members to respond appropriately to changes and challenges towards the empowerment of communities."

Launching "Ground Up"

PELUM Association launched its regional magazine, *Ground Up,* in March 2000, five years after the Association was formed. *Ground Up* was a response to the information needs of its members. They wanted a magazine, which would enhance their capacity to deliver extension messages through the sharing of experiences and information across the region. The magazine was to be a vehicle for networking in participatory ecological land-use management (pelum) across eastern and southern Africa and with like-minded partners and organisations beyond the region.

The magazine was also meant to fill a gap in development literature which focuses specifically on agriculture and environment at a Sub-Saharan regional level, and which is rooted in the region and looks at development from a southern perspective.

The specific objectives of the magazine are to:

- popularise the participatory ecological land-use use management (pelum) approach among communities in eastern and southern Africa;
- influence policy-makers to think pelum and to lobby and advocate for sustainable communities;
- provide a forum for critical analysis and evaluation of pelum approaches;
- share pelum approaches in the region and beyond and to promote networking;
- encourage research in the area of pelum; and,
- to provide a voice for the South, giving a southern perspective to development.

After a series of consultations, a feasibility study and a week long planning workshop, and armed with a dummy edition, we finally published the maiden issue in April 2000.

Ensuring sustainability

The planning workshop produced a five-year business plan, which projected that the magazine would attain financial sustainability by the third or fourth year of publication. While many development publications are given out free, we decided to take a different route: combining information service delivery with business. We wanted to look ahead to the time when donor support would fall away, particularly after the period of our current strategic plan (2000-2004).

In the firm belief that there was a niche for a regional development magazine, we planned for a commercial publication from the outset. We printed the magazine in colour, signed up designers, originators and printers, and went in search of subscribers, advertising agents, distributors and editorial contributors throughout the region.

The magazine sells at US$1.50 on the newsstands and at US$5 to subscribers, against a production and distribution cost of around US$2.7. This means that the difference of US$1.2 on the newsstand price is a subsidy to popularise the magazine.

The editing and printing of the magazine is done in Harare, Zimbabwe, the base of the regional office of PELUM Association. The magazine is then sent to country-level commercial distributors and bookshops and to country PELUM offices to be distributed through the PELUM network at a commission of 10% for members and 20% for country PELUM offices.

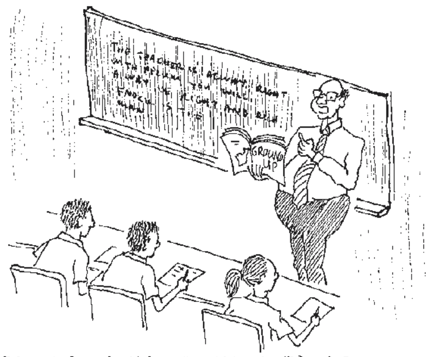
While we commission experienced journalists to write on given themes, we also encourage PELUM members to contribute their experiences, in line with our aim to "sing our own song" in the magazine. Ideally, the content should be dominated by contributions from the members. This is in line with PELUM principles and values and intends to give the members greater control of the magazine.

Realising that not many members have had journalism training, we have been running training courses in basic writing skills every year since 1999.

Content of the magazine

In deciding the themes for *Ground Up* editions we have been mindful of the core business of the members and partners, and problems specific to the eastern and southern African region. To make the magazines more relevant we ask the members to suggest themes, which reflect the information demands of the farming communities they work with. The previous issues of the magazine have, therefore, focused on:

- farmer innovations
- participatory methodologies and concepts
- seed security
- issues and experiences in advocacy and lobbying
- farmer-to-farmer extension
- organic farming and marketing
- micro-irrigation and water harvesting
- measuring impact of development programmes.



GROUND UP HAS BEEN USED AS LECTURE MATERIAL IN UNIVERSITIES.

For the rest of 2002 we will focus on mainstreaming gender in agricultural programmes, the World Summit on Sustainable Development, in particular the Farmers' Convergence which PELUM is organising, and biotechnology and food security. These themes are intended to fill information gaps and enhance the capacity of the members in those specific areas.

Achievements

Two years of publishing *Ground Up* has been a mix of opportunities and challenges. We have just over 100 subscribers at present and a little under 30% of the copies produced are sold through newsstands across the region.

We have some structural achievements in producing a regional magazine and in facilitating networking across the region and beyond. Firstly, the Association has gained invaluable experience in producing such a magazine, which can be shared with others in the region and beyond. This experience also adds to the learning and growing process of the Association.

Secondly, the magazine has managed to bring together experts with different backgrounds and has facilitated networking. To an appreciable extent, through the magazine, we have also managed to provide an avenue for linking experts with the communities on the ground and between policy makers and those affected or afflicted by those policies.

Through the magazine we have also created a pool of journalists and media who are friendly and sympathetic to the cause of PELUM and are now working closely with us on a number issues in sustainable agriculture. The journalists are paid US$60 for an article and US$10 for a photograph or cartoon used.

Testimonies of Impact

From the beginning, comments like the following have been received regularly: "*I realise the importance of the publication your organisation is producing. The magazine is very relevant and essential to my field of agricultural extension and rural development in my country. I am a civil servant in the Ministry of Agriculture in Ethiopia ...*" We realised that this type of feedback was not enough; we wanted some deeper insights. We decided to have a comprehensive external review of the magazine, which was carried out in Tanzania, Zambia and Zimbabwe in March and April this year.

From the preliminary results of the review we have deduced that the magazine has been instrumental in selling the PELUM values, principles and methodologies in sustainable agriculture. The Tanzania *Ground Up* review report reads, "*Ground Up successfully documents the achievements and constraints of various experiences, e.g. in micro-irrigation, thereby allowing farmers and development workers to share across the region.*" James Mwami, an extension worker in Uganda, says, *"I find Ground Up useful because it tackles grassroots mobilisation and participation. The magazine is proving to be very useful to our organisation."*

There is also a reported trickle-down and multiplier effect from *Ground Up*. Mark Maseko, the Zambian reviewer, reports that, "*Some member organisations use it (Ground Up) in community workshops while others use the information from the magazine to develop course materials for their community education projects. Worldwide Fund for Nature (WWF) and the Catholic Diocese of Lusaka reported this kind of utilisation of information from Ground Up." Ground Up* has also been used for compiling teaching material in universities. The School of Agriculture at the University of Zambia, for instance, has asked for back copies to distribute among its students. The magazine's use of research findings seems to be one of its major attractions among academic and research institutions.

Some members describe *Ground Up* as the flag-bearer for the Association and in campaigning, advocacy and lobbying. Through *Ground Up*, PELUM Association has raised awareness about the issues that need to be brought to the attention of politicians and policy-makers.

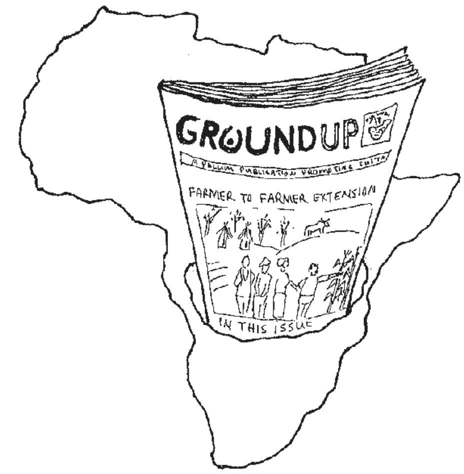
The magazine has also enhanced networking and the sharing of information and experiences throughout the region. A number of respondents state that they read the magazine specifically to learn about the experiences of other members or about organisations involved in similar work or facing a similar problem. Through *Ground Up* we have been able to link organizations and individuals wishing to learn from each other. For instance, a number of farmers wrote to us or directly to the International Development Enterprise inquiring about an innovative treadle pump, which we featured in Volume 1, Number 1.

The magazine has facilitated networking by providing sources of information and contact details of authors, individuals and organisations involved in particular areas of interest. One farmer reader based in Hurungwe, Zimbabwe, wrote, *"I was interested in the article about micro-irrigation technology for small-scale farmers (Ground Up, Vol. 1, No. 1). Please send more information about how I can get a quotation or terms of payment and the address of the agent of treadle pumps. I have been looking for this type of pump to boost my farming business."* The theme of organic farming in Vol.1, No. 6 was eagerly taken up among organic farmers, marketers and consumers in the region and beyond.

---- INCREASE THE MAGAZINE MARKET BASE AND MAKE IT MORE RELEVANT ON THE GROUND.

Challenges

Although it is evident that the magazine ranks highly among its readers, we still face a number of challenges. We are yet to expand the reach and penetration of the magazine in the region. Postal charges are prohibitive, and customs regulations differ from country to country. In some countries educational materials attract duty and value-added tax which cost as much as the price of a copy. These



THE MAGAZINE HAS FILLED A GAPING HOLE IN AFRICAN MEDIA

problems have restricted the number of copies sent out.

Being a relatively young publication, copy sales, subscriptions and advertising are still limited. We are also recognizing that development information and products do not sell as much, particularly in this part of the world where purchasing power is limited among households and development information is known to be free.

The less than expected number of contributions from members has also been a source of concern. We aimed to have at least 75% of the content from members of the Association. The best we have done is 50% with the rest of the articles coming from academics, researchers, journalists and partner organisations. We believe this reduces the extent to which experiences are shared among members of PELUM, though not necessarily between PELUM and similar organisations.

Our biggest challenge remains to be in assessing the impact of the magazine in the area of advocacy and lobbying and, more fundamentally, its impact on the livelihoods of farmers and farming communities.

The future

The Tanzanian reviewer of *Ground Up* writes, *"Despite some structural weaknesses, the magazine has filled a gaping hole in African media, and serves as a vital means of realizing the vision of PELUM and raising the Association's prestige and visibility. If Ground Up remains sensitive to the needs of its target group, and flexible enough to adapt its editorial policies, there will always be a need for such a publication. In terms of meeting market needs, Ground Up has good prospects."*

This is an encouraging observation. We intend to use the review to strengthen the magazine, particularly in marketing, distribution, advertising and member participation. We want the country desks to become more involved in the magazine and assume its ownership. Two country offices are already producing their own newsletters, largely inspired by, and learning a lot from, *Ground Up*. We would like to see such developments scaled up and replicated in the other countries.

One of our strategic priorities is enhancing the capacity of members, extension workers and farmers in the region to document their experiences for the magazine. This would facilitate not only the sharing of information and experiences but also increase the magazine's market base and make the magazine more relevant on the ground.

One major lesson we have learnt in the last two years is that it is not easy to attain financial viability of a development-oriented magazine. However, *Ground Up* being the only agriculture and environment magazine produced and circulated in the region currently is the magazine's greatest strength. We intend to capitalise on this strength to keep the PELUM flag flying.

Market rates flow out of the cradle of a telephone

Given the glamour of information technology, we are led into believing that costly hi-tech tools are essential for harnessing the power of IT. But VIIT (Vidya Pratishthan's Institute of Information Technology), a young engineering college in the small town of Baramati, India, has been working out a way of offering agricultural information via the much-overlooked phone.

Telephone - effective medium

VIIT recently has been putting together its interactive voice response (IVR) system, meant to benefit the rural population. This IVR system is meant for use in Indian conditions - where connectivity is often not available, computers are few, telephone lines could be noisy, and there is a lack of literacy among the rural population.

Phones have spread out to large areas of India particularly over the past decade-and-half. VIIT points out that telephone links today cover 70% of India's geographical area, and could, thus, play a vital role in ensuring that IT has a wider penetration across the many small villages that dot India.

The telephone is, in fact, the most penetrating medium of communication in rural India. "It can be used in conjunction with computers to provide updated information to the people who are not acquainted with the use of computers and IT," argues the VIIT. That's the solution they've tried to put forward.

Market rates by phone

"So far a voice engine in the regional language was not available," says the VIIT. Now, the system is being set up around the area of Baramati. It offers market rates of various commodities via the phone. The service is called 'aaj ka bazaar bhaav' (today's market rates), and is being used by the Baramati Marketing Society. Rates can be dynamically updated, and the user can choose the preferred language. This means that the information can be accessed via a normal phone line.

What are the advantages? Users can have instant access to the changing market rates at an affordable price, and in their own language. There is 'time management' on both sides. Resource-management is also stepped up. Besides, there is a report generation facility.

It works quite simply. For starts, the user dials into the telephone number of the Marketing System. The system - without human intervention - picks up the call and plays the welcome message; it then waits for the user's response. This done, the user has to dial the code for the category of information needed. The system then plays the rates of the required category. Then, the user has the option of dialling '0' to stop the conversation, or dial another code to listen in to more details. Following this, the system disconnects and gets ready for the next call.

IVR systems could be the way to revolutionise the access to digital information (across a context like India). It ensures availability of information, by investing limited resources. Once the framework is ready, it is easy to implement this system according to the need of the user in no time," argues Prof. Amol C.Goje, the Director of VIIT.

UNFFE: exploring new alliances in agricultural extension

Uganda National Farmers' Federation

In the ten years since its inception, the Uganda National Farmers Federation (UNFFE) has grown to become the main representative of farmers' interests in Uganda. Currently it has more than 100,000 members throughout the country. UNFFE works both at the farm level where it provides training, advice and inputs, but also at the policy level in realisation of the important role that agricultural policy has in improving farmers' livelihoods.

UNFFE – or UNFA as it was called until February of this year – has been at the forefront of the new trends in agricultural extension. Being the main farmers' organisation in Uganda, UNFFE plays an important role in the new government's plan for modernisation of agriculture (PMA).

The fast growth of UNFFE was facilitated by donor support, but self-sufficiency has always been high on the agenda. UNFFE is trying to bring both farmers' organisations and agricultural companies under one umbrella. This is an unusual alliance that many donors and governments hope will provide part of the answer to the funding crisis for public extension. The experience of Uganda's PMA - and UNFFE – is being watched carefully by other countries that are interested in seeing whether it can work before they decide to embark on a similar strategy.

Structure, goals and services of UNFFE

The Federation was founded in 1992 by farmers throughout Uganda in response to a need for better services for and exchanges between the farming community that comprises over 80% of Uganda's population. At the same time, it was to serve as an organised channel through which government or any other interested agency could extend services to farmers. The overriding objective was to mobilise the farming community into one independent umbrella organisation. Currently, 68 farmers' organisations are members of UNFFE, 56 of them are active.

Organisationally, UNFFE consists of three main organs, i.e. the Farmers' Council, National Executive Committee and the Secretariat. The major goals are:

- To improve farmers' incomes and welfare through increasing the quality and quantity of their production by providing services to members on demand and at cost. Sustainability and farmer empowerment is of major importance.
- To bring all farmers' organisations and agro-based industries under one umbrella organisation as a common front for the promotion, co-ordination and safeguarding of their activities and interests.
- To improve the environment in which farming activities take place through lobbying and advocacy.

Services to member organisations include the following:

- Providing agricultural advisory services.
- Providing agricultural and related information through the *Farmers' Voice* magazine, topical cassettes, brochures and other publicity material.
- Organising and conducting training programmes for farmers.
- Organising agricultural fairs.
- Mainstreaming gender in all aspects of the activities of the Federation
- Lobbying and advocating for farmer-friendly agricultural policies

History of agricultural extension in Uganda

UNFFE is one of the recent developments in the history of extension in Uganda that goes back to the days of British colonialism. Over the years, several disparate agricultural extension service systems have been introduced and practised.

In the colonial period, the extension service was a regulatory and enforcement body. It was organised like an army with the farmers being the soldiers on the ground who had to implement the orders from above. A series of regulations where designed to foster quicker adoption of new practices and crops.

Later extension work shifted from enforcement to education of farmers. During this period, the extension services were commodity-based with an emphasis on export crops like cotton and coffee.

Next came the community development – cum-extension approach, whereby the general agricultural officer was simultaneously charged with administrative duties, technical promotion, distribution of inputs, credit schemes and other ad-hoc assignments such as political mobilisation and census-taking. This wide-ranging set of duties usually resulted in low performance, discontinuity and demobilisation, with little organised technical work being effectively carried out.

The Project approach followed, whereby donors funded projects of their interest and staff were as such attached to various projects within the same office. This then gave way to the "Training and Visit System" that was implemented under the Unified Agricultural Extension programme. This management system provided for regular training of extension staff by subject matter specialists (SMS), and a regimented schedule of visits to farmers. Although this system of extension improved on the preceding one, it also had its limitations.

In spite of good intentions all of the above-mentioned approaches did not address directly the needs of the farmers. Over time, farmers' needs varied, marketing was liberalised, and so the need arose for setting up farmers' associations to address the problems that are unique to farmers.

UNFFE's demand-driven, cost-recovery agricultural advisory services

In 1995, UNFFE (at that time UNFA) started implementing a demand-driven and cost recovery agricultural advisory service in five pilot districts. In each of the five districts, one county was taken as a pilot area to implement the agricultural advisory service on the principle of demand driven cost recovery. This was a new concept, which was entirely different from the government approach.

The service was established with cost recovery as a high priority to ensure sustainability, and continues to run on voluntary farmers' participation as Extension Link Farmers (ELFs) and Contact Farmers (CFs). Farmers are organised into Special Interest Groups (SIGs) depending on the farming enterprise of their interest. Each SIG has a CF who should be a model/progressive farmer whose responsibility, among others, is to demonstrate new technologies and to encourage members to adopt them through the example of his/her practical experience. An ELF is basically a teacher and should at least have good communication skills and be innovative. The ELFs are regularly trained on the job by UNFFE's professional advisors at the district level and, in turn, provide training and advice to their respective SIG members through their demonstrations.

The procedure is that ELFs carry out a training programme by adopting an appropriate technology that addresses a major constraint in the local agricultural systems of their members.

The roles of the ELFs include: providing training and basic technical support to members of the SIG on farming techniques; encouraging other farmers to form SIGs; monitoring members' farms; collecting marketing information and assisting in the formation of marketing centres. ELFs also organise exchange visits among themselves.

The National Agricultural Advisory Services

In 2000, the Ugandan government launched the "Plan for Modernisation of Agriculture" (PMA). The PMA is meant to be a holistic strategic framework for eradicating poverty through multi-sectoral interventions enabling people to improve their livelihoods in a sustainable manner. The PMA has got seven priority areas for action, one of which is the National Agricultural Advisory Services (NAADS).

The NAADS aims to be an agricultural advisory service owned by all stakeholders, and to be an effective, efficient and sustainable organ, responsive to the needs of farmers. The programme aims at engaging farmers into critical thinking and discussions regarding their agricultural endeavours and the management of their farms as a business enterprise rather than simply delivering messages and inputs for their own sake. The underlying principle is to be responsive to the needs and demands as identified by farmers themselves, who then determine the work programmes and activities of advisors. In other words, the government has now moved away from service-driven extension to demand-driven extension services, just like UNFFE.

The role of UNFFE vis-à-vis government

The role of UNFFE is complementary rather than competitive. UNFFE has purposely recruited only a skeleton staff for co-ordination purposes, in order to also utilise the available government staff. Hence, in the implementation of UNFFE's advisory services, government extension staff has participated as subject matter specialists, resource persons, facilitators, and consultants. UNFFE, in turn, has also been used by government staff to mobilise farmers to benefit from government extension services.

UNFFE participated in the Task Force and was very actively involved in the formulation of the NAADS policy. Many of UNFFE's ideas were incorporated into the NAADS document. The NAADS is also working on the principles of being demand-driven and aiming for cost recovery. The only difference is that with UNFFE, individual farmers do the cost recovering while with the NAADS, farmers will cost recover as a group, sub-county and district.

UNFFE is a member of all NAADS institutions starting from the NAADS Board, the farmers' fora at district and sub-county levels, and in farmers' groups. UNFFE members and staff are members of the various committees and task forces of the NAADS. The federation participates in NAADS workshops and other extension service-related seminars.

The future as UNFFE sees it

Since its founding in January 1992, UNFFE has made steady progress. In its early years, UNFFE funded its activities using membership fees. From 1994, the federation started getting financial, technical and moral support from DANIDA (the Danish government's international development agency). This enabled it to acquire office premises, transport, office furniture and equipment. It also helped UNFFE to serve a growing farming community.

However, these days donor support is declining though demand for UNFFE's services is growing. The federation therefore needs to find ways to continue offering services to its members while keeping an eye on its cost-recovery plans.

Cost recovery is not easy in practice

Stephanie de Kool worked for some years as field level advisor for UNFFE. We asked her how cost-recovery for extension services works at the field level. Here is her reply.

UNFFE's structure and cost-recovery plan for its services appear to be the solution to guaranteeing a **demand-driven** (bottom-up) and **sustainable** agricultural advisory service. However, the cost-recovery of advisory services at the grassroots level of UNFFE district organisations has not been realised to the extent envisioned. Only a small percentage of the costs of extension services are actually covered by the farmers.

Lack of cost-recovery makes the district organisations dependent on donor funds. Besides this threat, the organisations are presently weakened because staff do not get the expected percentage of their salary out of cost recovery and are therefore underpaid.

There are several factors that seem to hinder cost recovery at the grassroots level in Uganda:

- In the first place, the economic situation of average Ugandan farmers is very weak. They use the small income that they earn from marketing their produce for basic household needs and school fees for the children, rather than for agricultural training and advisory services.
- Secondly, the level of education amongst the farmer community is low. As a result, it is likely that many farmers do not value knowledge as something that can improve their livelihood. Therefore, they might be less willing to pay for knowledge than they would for something tangible.
- Thirdly, the UNFFE district organisations are limited by funds and available manpower whilst attempting to serve and organise their members, who are spread over extensive rural areas. The organisational structure is, therefore, not well established everywhere. Yet, the organisational structure of Extension Link Farmers (ELFs) leading Special Interest Groups (SIGs) at the grassroots level, is a pre-requisite for realising cost recovery of the services.

Hopefully, the NAADS will result in a solution to the problem, since it provides funds that can be used by farmer communities to pay for the agricultural services they demand. The NAADS will, however, have to prove itself in the coming years. Its performance will depend to a great deal on the success of organising farmers at the grassroots level to function independently and on making the right decisions on the way funds are spent.

Will ICTs change the rural information landscape? Photo: ITU/Jean-Marie Micaud

The ICT agenda: global action plans and local solutions

Katherine Morrow

Information and Communications Technologies (ICTs) have brought issues of communication and rural access to information to the forefront of the development agenda. In this energetic atmosphere, experiments and pilot projects abound. People are forming new social networks, learning together and sharing knowledge across geographic and cultural boundaries. The context for this issue of LEISA is a global phenomenon: the growth of information and communications technology, a process that is both a product of, and a stimulus to, the parallel phenomenon of globalisation. Many see these changes as a historic societal transformation on a par with industrialisation, with the Internet as the harbinger of "perhaps the greatest revolution that humanity has ever experienced."

Whether or not this proves to be the case only time will tell. At the moment, computers and the Internet are becoming part of the daily life of millions in the North, giving them instant and largely free access to over 50 million pages of information on every conceivable topic (collectively known as the World Wide Web), and enabling them to use email and other computer applications to speak to each other and exchange written messages and pictures in a flash. The information networks that make this possible are formed by linking computers together into a global network of fibre optic cable, satellites and telephone lines, known simply as the Internet.

The digital divide

In the South, the situation is radically different. There are relatively few telephones, let alone computers needed to connect to the Internet. In terms of delivering information or communicating electronically, rural areas in the South are considered "the first mile of connectivity." For many LEISA readers and others, this mile, by and large, must be travelled using more traditional technologies: a magazine, a printed email message, a book, a cassette tape, a story or a song.

A fundamental issue is the poor state of rural electrical and telecommunications infrastructure in the South, causing a North-South disparity, termed "the digital divide". The lack of adequate infrastructure is only one aspect of the digital divide, however. Nor is it simply a North-South gap. When expressed in numbers, one in 15 people in the world counts as an Internet user. The figure for North America and Europe is one in two; for Africa it is one in 200 (Jensen, 2000). But these statistics do not take into account the even greater disparity between Internet access in urban vs. rural areas. Mike Jensen, an expert on ICTs in Africa, states, "No studies have been made in Africa of the number of rural vs. urban users, but it is safe to say that users in the cities and towns vastly outnumber rural users."

Global responses

Infrastructure and related policy issues are high on the agenda of various international bodies that have been convening global conferences, issuing statements, and drafting action plans regarding ICTs, the Information Society, and the digital divide.

The United Nations ICT Task Force was established in 2001, a forum for discussions on policy and particularly on how ICT can help to achieve the Millennium Development Goals. A similar initiative is the Digital Opportunity Task Force, created by the G-8 in July 2000. The DOT Force brings together governments, non-governmental organisations, experts and the private sector around initiatives focusing on different aspects of the digital divide, such as access, training, and support for locally relevant Internet content.

In his opening statement to the General Assembly plenary meeting on ICTs for development in June this year, the Secretary General of the United Nations, Kofi Annan, identified three areas of shortfall in the policy process at the international level:

- ***Top down, donor-driven:*** *"Our efforts must be based on the real needs of those we are seeking to help. They must be fully and genuinely involved. […] In particular, we must find* *better ways to ensure the participation of developing countries at all stages."*

- ***Lack of long-term commitment:*** *"Our efforts must be sustained over the long term. In recent years, we have witnessed a number of very promising initiatives that, regrettably, did not live up to expectations. The reasons were diverse, but one of the principal causes was insufficient long-term commitment on the part of initiators and sponsors."*

- ***Duplication of efforts:*** *"There is a real need for the many initiatives to come together, united by a common purpose and common determination."*

The latest milestone in the international dialogue around ICTs and development is the World Summit on the Information Society (WSIS), set to take place in Geneva in 2003 and Tunis in 2005. The Africa Regional Conference on WSIS concluded in Bamako, Mali, in May 2002, with a declaration calling for greater infrastructure investment and the removal of regulatory, political, and financial obstacles to the development of communication facilities.

The WSIS process is an opportunity to achieve greater coherence among international initiatives. A greater challenge will be in ensuring that the information society of the future is one in which cultural diversity and indigenous knowledge systems are genuinely valued and supported.

Back to the drawing board

The development impact of ICTs is notoriously difficult to capture. Development projects that set out to achieve specific goals through the introduction of ICTs, for example to enable farmers to access agricultural information, often find that the technology is being used in altogether different ways, for instance that local youth use the Internet to look for jobs outside the community.

Lessons learned from such experiments point to a need to apply the hard-won lessons of the past to the new technologies. Community-driven, participatory approaches tend to succeed; hasty, top down experiments tend to fail. A new focus on the communication role of ICT, local content, training and the use of simple ICT applications in combination with existing media such as radio is needed to support societies with low levels of functional literacy.

ICTs are proving their value in helping to deliver information to and from intermediary information providers such as universities, government offices, telecentres, NGOs and libraries. Some of the most successful ICT for development projects are focused on supporting the work of intermediaries who are relaying information to and from farmers and others at the grassroots level who do not themselves have access to the technology.

Many early efforts to introduce ICTs in village settings failed due to unrealistic expectations regarding people's ability to pay for the services offered. While many cities in the South have a thriving market for private cybercafes, in rural areas the "business case" for ICTs is much weaker. In the aftermath of these frustrating attempts, alternative, indigenous models of community access such as the Information Villages Research Project (p.28) are springing up, challenging the consumer-demand framework for technology adoption. It appears that, viewed as a community investment and a community asset, information technology will have to demonstrate its value in each local context, and if it is valued, it can be sustained.

The role of mediating organisations

In this respect the role of local "mediating organisations" is critical. Even with the community-owned model, ICT investments can fail to pay off because of a lack of training and technical support and the difficulty in finding relevant information in the local language.

Research by the Telecommons Development Group describes how "mediating organisations" – community development organisations that know how to use ICTs effectively – are linking local information and communication needs with technology, funding mechanisms, and policy arenas. Farmers' organisations, for example, are enabled to participate as stakeholders in international policymaking on issues that affect their lives. It is important that they do so, and as Pat Mooney of the ETC Group notes in p.26, such messages do carry weight.

Linking communities of practice

A major thrust of Bellanet's work with ICTs is in helping development workers use the technologies to engage in dialogues with each other (see also p.3). Participation in online communities doesn't require high-end technology; simple email is a powerful tool that enables users to connect with each other. For example, in partnership with the Technical Centre for Agricultural and Rural Cooperation (CTA) Bellanet hosts an online dialogue called AFAGRICT, an electronic discussion among people interested in the use of ICTs in agriculture in Africa. AFAGRICT is a community of practice linking researchers and practitioners in the North with those working in isolated rural settings. Such communities can be a valuable resource and source of moral support for extension workers and others working at the community level.

An important lesson that Bellanet has learned in its work with communities of practice is that networking is not about technology; it's about people connected through their common interest, sharing knowledge and working together toward common goals. The principles that underlie LEISA approaches also hold true for networks: their strength lies in diversity, and the best networks are organic, arising from the commitment and hard work of individuals. They are formed from the ground-up around practical issues, and they use technology in an appropriate and sustainable way.

Future opportunities

Widespread access to ICTs in rural areas is still several years in the future, but wireless technologies may eventually end the reliance of ICTs on costly telephone infrastructure. In Central America and many other regions, mobile telephones are increasingly affordable, helping to overcome rural isolation and enabling dispersed families stay in touch.

The challenge for those working at the grassroots level is to understand the choices offered to them by investment in ICTs and to make informed decisions. At this level, where information is scarce and communication difficult and expensive, ICTs have a lot to offer, but the high initial costs – not only in hardware, but in the cost of training and applying the technologies in day-to-day work – can be an insurmountable obstacle. We hope that this special issue of LEISA Magazine will help clarify some of the issues, offer some solutions, and perhaps inspire others to tackle the challenges and find their own way of travelling "the first mile." ■

Recent and future challenges in agricultural extension

John Farrington

Historically, many of the changes in agricultural technology have been viewed as "public goods". It was in the interest of the nation to ensure food production and develop agriculture, and therefore, government funding was often provided to work with farmers - often farmers' associations - in explaining and testing the new technologies. The private sector became important in Europe and the USA with the introduction of, first, mechanical and subsequently chemical technologies. Even so, the impact of public funded extension was undoubtedly significant.

Over the last 50 years, there have been a lot of changes in fashion in agricultural extension. Keeping in mind the basic distinction between the ways extension is *organised*, and what it does (i.e. its dominant *functions*), this article asks:

- What have been the main patterns of organisation and function?
- What has underpinned the transition from one pattern to the next
- What extension issues are currently most prominent on the international agenda, and why?

Dominant patterns during colonial times

Two patterns of extension provision were dominant in these times. One was for extension to be linked specifically to export crops extracted from the "colonies". Typical examples included such major commodities as tea, coffee and cotton. Cocoa and rubber, being regarded initially as "forest" crops, came under this system later. Extension services were generally organised by the private companies or parastatal marketing boards involved directly in the production (but more often in the processing or marketing) of the commodity. The services were paid for by a levy on the sales of the product, which was easy enough to collect where the product had to pass through a monopoly purchaser.

A second was for colonial governments to impose their concepts of "good husbandry" in relation to soil and water conservation. However, much of the activity here consisted of issuing orders, checking whether farmers followed these, and imposing fines or imprisonment where they did not.

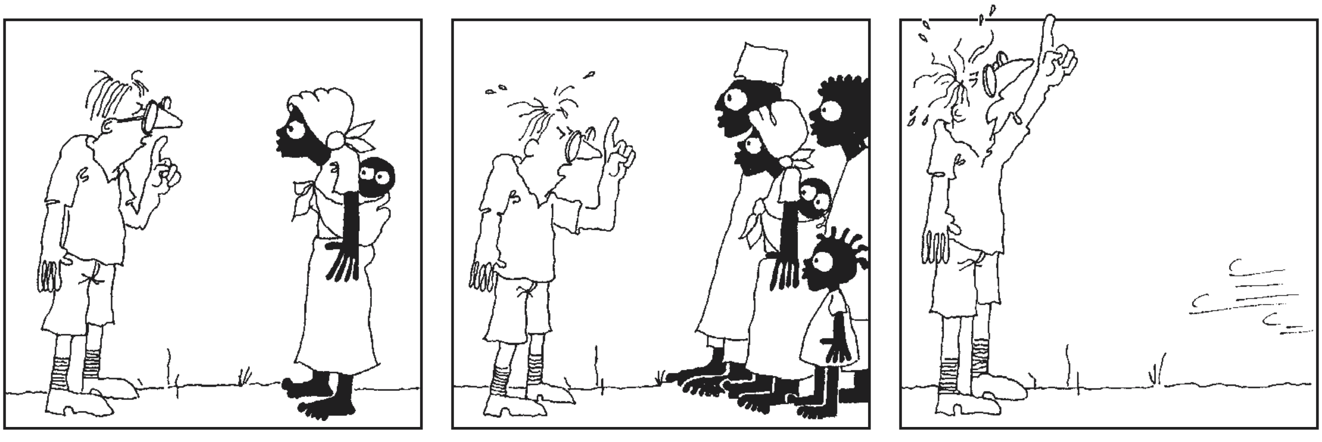
In both of these cases, the underlying concept is that technology has to be transferred, that recommendations have to be followed rigidly and that farmers who do not adopt are "laggards" in some way. Whilst technical specifications remain important for internationally marketed produce, outside of this context there has over the last 2 decades been a growing recognition of the validity of farmers' own knowledge and practice in such matters as varietal selection and soil and water conservation itself.

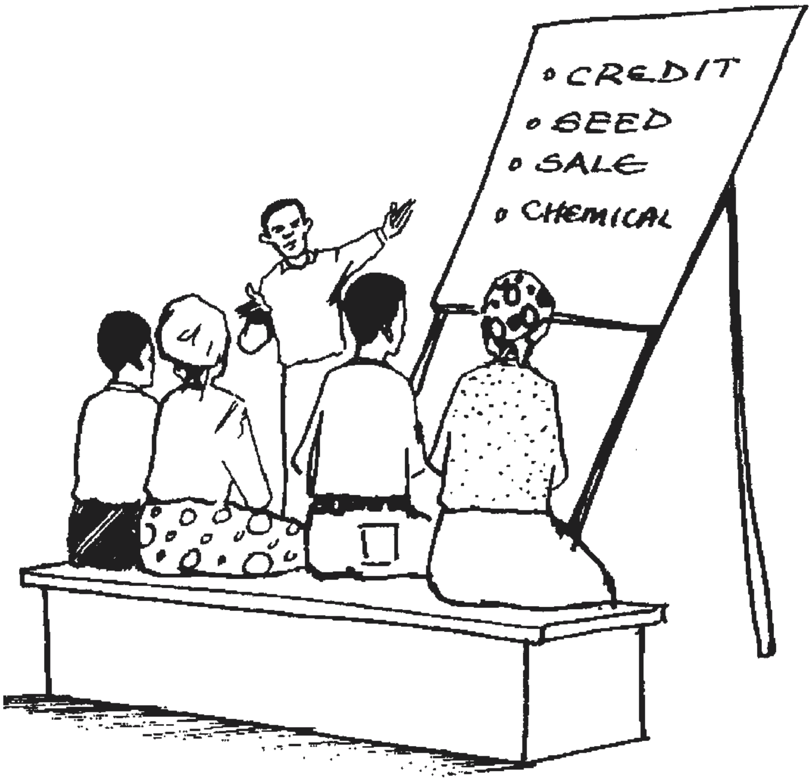
Post-Independence changes

One of the most pressing tasks facing newly-independent governments was to ensure adequate food supplies (which, incidentally, highlights the fact that food security is as much a matter of political self-determination as of economics – by contrast with the near-exclusive emphasis that neo liberals place on the trade economics of food security). Accordingly, they began to build up existing national agricultural research and extension services, or create new ones where these did not already exist. Research and extension were often run by separate departments. The interrelations between the departments were generally weak and dominated by researchers' perceptions that extension existed simply to disseminate the results of research. In other words, extension "existed to transfer new technologies to the masses". Others saw the potential for extension agents to carry out all manner of other activities, such as those relating to census and statistics, or even tax collection, so that in many cases they became distracted from their main purpose, and in some cases were even viewed by farmers with antagonism.

Two broad sets of efforts - both promoted by donors, but sadly, with little compatibility between them - were undertaken to strengthen national extension services in the 1970s and 1980s. One was the promotion of "systems" approaches. Approaches such as farming systems research focused on the understanding and improvement of existing systems instead of their wholesale replacement. These ideas were based on recognition that farmers had developed complex systems of managing crops and livestock in ways adapted to locally varying agro-ecological and socio-economic conditions. If options for technical change were to be developed which would be relevant to these farmers, it was essential to base them on good understanding of how farmers perceived and managed their farming systems. In this context, extension would not be restricted to dissemination functions, but would have a key role in feeding information on what innovations farmers adopted or rejected (and how and why) back into research systems. Whilst much of the philosophy of this approach remains relevant, in practice, it has been dogged by high cost, inability to shift "recommendation domains" onto a large scale, and resistance by many scientists to be drawn out of conventional modes of operation.

A second, starting in the 1980s, was the promotion, especially by the World Bank, of the Training and Visit (T&V) system. It is important not to lose sight of the immense scale of





this initiative: by 1992 World Bank and IDA had funded 602 projects with an extension component, almost all based on T&V, to a total value exceeding US$5bn. By the late 1990s, the pendulum had swung the other way - the World Bank lost interest in T&V, leaving numerous countries with T&V-based systems which were both costly and largely dysfunctional. T&V was intended as a system for managing public extension resources, but also had profound effects on extension methods and farmer-extension worker interaction (Garforth and Harford, 1995). It was developed and promoted in the belief that existing public sector services were overburdened with distracting tasks, poorly organised and inadequately trained. The main features of T&V are well known: it stripped away from extensionists such "extraneous" functions as promoting input subsidy schemes, or selling inputs themselves; it had a strongly hierarchical structure, with village workers backstopped by subject-matter specialists; it relied on strong technical "messages" reminiscent of "technology transfer" thinking; and it relied on local level dissemination through "contact farmers" – initially individuals and subsequently group approaches. There has long been widespread agreement on its shortcomings, which include its lack of flexibility of response in unstable, rainfed environments, its reinforcement of structural inequalities through the contact farmer approach, and its unsustainably high cost.

In retrospect, what also makes T&V look old-fashioned is its insistence that extension should be uniquely a publicly-funded, publicly-delivered service with no room for public/private partnerships of any kind, and, secondly, the insistence that extensionists should not take on any related activities such as the sale of inputs.

Privatisation and institutional complexity post-T & V

With the demise of T&V, the organisational landscape has become much more complex – in some ways, necessarily so. Some of these changes have resulted from the growth and replication of locally-based initiatives, such as the creation of local groups to test and exchange technologies, some groups being formed by farmers themselves, others spinning off from local institutions such as churches. Some of this complexity is the result of pressure from eg the World Bank and IMF towards economic liberalisation. Extension has not been spared from this "rolling back" of the state - "cost recovery" has been introduced for some aspects of what extension services did (eg. soil testing or livestock vaccination), or extension has been handed over entirely to the private sector for some categories of farmers (eg the more commercial) or categories of activity (such as veterinary).

This pressure has also accelerated trends that were established long before disillusion with T&V became widespread. These include:

- Efforts to build multi-agency partnerships in ways that (for the state) reduce costs, but also spread the reach of extension to areas where a purely public sector service is unlikely to be viable, and make it more responsive to local needs and opportunities. Such partnerships include service-providing non-governmental organisations, though much mutual suspicion needs to be overcome and these to some extent remain reluctant partners (Farrington and Bebbington, 1993)
- Efforts to build community-based organisations, such as farmers' associations, and to expand their capacity to make demands on technology systems and share new ideas, skills and approaches among their members. This approach has been pursued especially strongly, and with some success, in francophone countries
- Efforts to place funds in the hands of farmers so that they can "contract in" extension from whatever source they prefer. These include the voucher scheme operational in Chile for some time, and the channelling of extension funds to farmer groups via the Sub-Counties in Uganda following the NAADS Act (p.12).

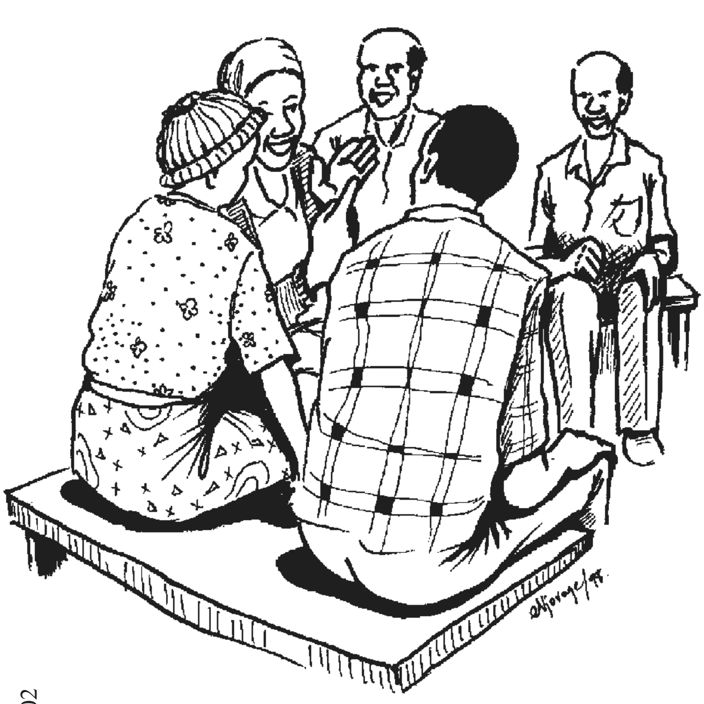
Emerging priorities

Two new sets of conditions have to be faced by developing countries and have important implications for extension. One is globalisation, especially in respect of trade in agricultural commodities. Many, especially in the North, overestimate the potential benefits for developing countries (especially landlocked countries in eg Africa) of globalisation, and underestimate the threats it poses. Where it does offer potentially new markets, the implication for extension is clear – all aspects of production, processing and marketing need to be driven by the requirements of the market, and extension guidance has to be tailored accordingly. This would not be much different from the approach pursued largely for export commodities and largely by extension agents employed within

large private companies in francophone countries. Where it poses threats, appropriate trade, agricultural and rural development policies need to be in place to meet such threats. In terms of agriculture, these will have to identify how internal markets and production systems can be supported and stimulated, and extension strategies designed accordingly.
The other change on the international landscape that affects extension is growing concern among donors that their support should be geared towards poverty reduction. This poses the interesting question of *whether* (not *how*) extension can contribute towards poverty reduction. A recent study (Farrington et al 2002) argues that it can, but only so long as poor people are seen to be not just farmers (or producers in general), but also labourers and consumers. Consumers can benefit through lower-cost food – and the extension implications of this are clear. The implications for extension of supporting the "poor as labourers" more than in the past are not so self-evident. Basically, little can be done unless agricultural policy in general (and technology policy in particular) bases itself on a fuller understanding of the labour economy – are wage rates stagnant, falling or rising, at what times of year and for what kinds of work (and worker)? when are particular kinds of workers relatively underemployed? What kinds of activity (within or outside agriculture) can be promoted to offer employment during these periods? It is only on the basis of questions such as these that extension can then be designed to offer what would be appropriate, check on its uptake, and make necessary course-corrections.

Changes in techniques and approaches

Our discussion up to now has focused largely on the question of how extension can best be organised. We now consider techniques and approaches – though these are not entirely unrelated to organisation: for instance, an organisational structure such as that of T&V which lends itself to linear, "transfer of technology" types of approaches is unlikely to be appropriate for more participatory types of approaches based for example on experiential learning.



Broadly, during colonial and early post-colonial periods, farmers were treated as passive recipients of technologies designed and delivered from scientific centres. Farming systems research, and growing interest in indigenous knowledge, prompted approaches which recognised the validity of traditional ways of managing farming, and appreciated that new technologies would have to be consistent with these if they were to have any chance of adoption. "Participation" by farmers in setting the agenda for research and extension therefore began to be advocated (Chambers et al, 1989). It was soon recognised that participation could take many forms, ranging from consultative approaches to make sure that extension recommendations were adequately targeted, to empowering approaches supporting the rights and entitlements of farmers as citizens, and therefore an end in their own right.

Many approaches to extension have been driven by the ethos of participation, and not all can be reviewed here. They include:

- Farmer-to-farmer approaches, in which farmers themselves are trained to promote learning among their colleagues, and to make demands on "external" systems (Scarborough et al (eds) 1997)
- Experiential learning approaches, such as farmer field schools. These emphasise the importance of learning in practical field settings instead of through didactic modes in classroom settings. They have been widely used with, for instance, integrated pest management.
- "Soft systems" approaches such as the Agricultural Knowledge and Information System (AKIS – Roling 1988) to think about the institutional framework supporting extension, and to identify the roles played by different kinds of actors in different settings.

The future?

The purpose of this article has been to set out a personal view of how and why patterns of extension have changed in the recent past, and fuller speculation on what the future holds is best left to others. However, it seems to me that extension will have a major role (but also many challenges) in the future in identifying how to bring together (on the one hand) the best that farmers can input into technology design, adaptation and dissemination, and (on the other) the best that technology systems themselves can offer. Nowhere will this be more difficult than in areas weakly-integrated into markets, where the majority of the rural poor still live (Farrington and Gill, 2002). These areas will be characterised by growing impossibility of recruiting and retaining conventional village-level public sector agents. This problem may be addressed by encouraging them to form small businesses involving for instance input supply, or generating the skills necessary to provide small business advice to local people. It might also be addressed by locating a strong cadre of extensionists and higher-level specialists in local towns, and increasing the capacity of people to draw on these – this will involve not only the logistic problems of getting them into towns, but also major psychological shifts on the part of public sector workers so that they welcome such "demand pull", visit the villages as necessary, and link closely with the private sector to generate advice appropriate to shifting market contexts. This is a complex agenda, but one which extension will have to take in its stride if it is to continue having an influential role in the future. ■

Changing information flows

Editorial

Access to information is one of the most valuable resources in agricultural development. Today, the demand for agricultural information is stronger than ever. The increased market integration that is experienced by even the most remote farming communities greatly increases the pace of change. Events and developments far away from home have profound effects on the livelihoods of farmers. Information is needed:

- to exploit opportunities in time – like the many emerging niche markets for organic products;
- to raise awareness about the potential negative impacts of current choices, e.g. embarking on the use of genetically modified crops when more and more markets don't want them
- to get to know about the experiences of other farmers in order to search for better opportunities and sustainable solutions, like the System of Rice Intensification that is improving the livelihood for many rice farmers

Today, the demand for agricultural information is stronger than ever. Photo: Bert Lof

The last decade has seen tremendous changes in information provision to farmers, resulting from policy changes, financial crises and revolutions in information and communication technology (ICT). In this issue we attempt to explore these changes and what they mean to small-scale farmers in rural communities in the South.

Public funded extension in crisis

Agricultural development has long been seen as a pre-requisite for economic development in the society at large and thus it made sense for governments to invest significantly in agricultural extension systems. Public funded agricultural extension was a corner stone in development policies all over the world.

In developing countries the 1970s saw the fastest growth in national extension systems – often they grew close to ten percent per year. However, in the 1980s the annual growth rate slowed down to a few percent and over the last decade stagnation or even dismantling of extension systems has been on the agenda. Farrington (p.6) provides more insight into the history of public extension.

The decreasing public support for agricultural extension is the result of many factors, among them:

- severe and repeated financial crises in most developing countries;
- a shift in preference for private enterprises over government intervention that is reflected in structural adjustment programmes imposed by international donors but also by national governments – it is believed that private companies are more efficient than the public sector in providing services;
- dissatisfaction with the perceived lack of impact by agricultural extension.

Today national extension systems are in dire straits with resources being cut to a minimum. Many extension workers have been laid off or have left for opportunities elsewhere and the ones who remain often lack the basics for their work like transport and access to information. Staff morale is often low due to the inability to perform their task well combined with continuous criticism from outsiders who often do not understand the impossible working conditions of the extension staff.

Exploring new ways to deliver information

For a long time nobody questioned the existence of public funded extension systems, so the focus was on efficiency within the extension system instead of alternatives. But the crisis in public extension services has led to a search for solutions and alternatives. No universal prescription to the "problem" of extension has emerged. Instead a pluralistic system is envisioned with many players selling extension services, including NGOs, private companies and extension departments. (Farrington, p.6) The thinking is that it will force every extension provider to maximise efficiency and to provide relevant extension.

The Uganda National Farmers Federation (p.11) is an example of such a partnership for agricultural extension. It is a young successful farmer organisation trying to provide extension services on a cost-recovery basis by building alliances with private companies and other actors.

There is much talk about the shared interests among the different actors in agricultural development, but very little about the conflicts. Will these new partnerships promote only high-input farming because the participating private companies can earn money on selling the inputs? Or will they promote self-sufficiency and low-input alternatives that may be in the interest of many farmers but undermine the private companies? Only time will tell, but it is important to be aware that these old conflicts do not disappear just because the different actors take on a shared identity.

Another trend is the attempt to shift the workload from public paid extension to farmers who have to do their own research and farmer-to-farmer extension. This can be empowering and can stimulate endogenous development, but too often the costs are not considered. It is important to remember that many farmers suffer under labour constraints that will limit their possibilities of running their own research and extension system and it does not solve the problem of getting required information from outside.

The current trends point towards the development of a dual system in which the farmers who can pay are served well whilst the poor farmers are left "empowered" to do whatever they want but with resources to do nothing. The many new unconventional partnerships between private, public and civil society will make it much more difficult to see what is really going on.

What can modern ICTs offer?

And it is in this context that information and communication technologies are seen as being able to change the landscape of rural information exchange. Most of the experience as of now relates to information delivery in the developed countries, which has been revolutionised over the last two decades through the widespread adoption of computers and Internet connection. Here, it is now common to have a computer at work and at least one at home.

The Internet spreads faster than almost any previous technology. It took radio almost forty years to reach an audience of 50 million and for the Internet just four. The amount of information available on the Internet is tremendous and growing fast. Many international and national organisations make almost all their publications available on the Internet. Publishing to the Internet is easy, quick and almost free. Advocacy organisations like ETC have been able to gain the benefits of ICTs as is seen in the interview with Pat Mooney on p.26.

Most information on the Internet is available at no cost so the user “just” has to find a way to get connected. This is easy and cheap in developed countries due to the well-developed infrastructure; not so in many developing countries. Computer equipment is expensive and reliable power supply and telephone connections are not readily available. When the computers break down, spare parts and qualified technicians are difficult to come by. There is also the problem of “computer literacy”. Computers are much more difficult to use than other technologies like radio, telephone, and fax, for which special training is required.

Thus it would be over-optimistic to think that everybody will soon have access to the Internet. There are plenty of limitations and obstacles to be overcome as pointed out by Morrow on p.9. However, there are some encouraging success stories like that of the village information centres in Pondicherry, India (p.28) and the Internet Radio project in Kothmale, Sri Lanka (p.25) Both these experiences have been used to develop larger, global initiatives for improving Internet access in rural communities.

Using all available means

Yet, for many farming communities in the South, modern ICTs are still a technology of the future. Therefore, it is important not to forget the “old” technologies and to use all available means in reaching people with the information they require.

Radio is one such technology, which has penetrated deep into otherwise inaccessible rural areas. Rural radio has a long and fine track record but is often overlooked because of all the attention paid to the Internet. Developing Countries Farm Radio, for example, broadcasts to nearly 100 countries in Latin America, the Caribbean and sub-Saharan Africa. (p.20). Its success has been in building a network of broadcasters, radio stations and training organisations, which has been able to keep pace with the changing times and provide their audiences with globally-relevant information in a locally-adapted form. The case of Tadjik Radio (p.16) is quite different. This article shows that it is not only technical obstacles that need to be overcome to facilitate the access of information; an attitude of participation and openness is also required.

Getting information to where it is most needed often requires creative partnerships. The “In the field” project on p.22 is a partnership between researchers of NRI, funders, people in the communities and broadcasters from BBC World Service. The series, broadcast twice in 2001 and 2002, has been immensely popular and has led to new partnerships: with schools in developing educational material and with local radio stations for re-broadcasting in local languages. The radio series was accompanied with a booklet, web site and a set of audiocassettes, thus combining media to get the best impact.

For some rural communities, like the one mentioned on the back page, a printed magazine is still the only shred of information they have access to. In places with no power supply, no computers and telephones, magazines or newspapers can still be read and passed around to others - information used and shared. And even in not so remote places, magazines have an important role to play as demonstrated by the “Ground Up” magazine of PELUM in Zimbabwe (p.13). It is popularising ecological land management approaches, influencing policy makers to take note of them, providing a forum for critical analysis of the approaches, encouraging research and giving a southern perspective to development.

The message is clear - use all the means available, both the new and the old, to change information flows and thus enable rural communities to access, share and exchange experiences in sustainable agriculture.

22 Communicating innovation: the "in the field" project

Monica Janowski and Kaz Janowski

The "In the field" series broadcast on the BBC World Service in 2001 and 2002 is an example of a fruitful partnership between researchers, broadcasters and funders in communicating innovations to a wider audience. It is also an excellent example of using different media to get the best impact - a radio series complemented by a website, printed booklet and audio cassettes. The 12 programmes in the series feature interesting initiatives in bringing about innovative improvements to livelihoods around the world. The response to the series and the requests for educational material is a good indicator of how useful the information is to the listeners. The follow up to the series in terms of rebroadcasting in local languages and development of appropriate educational material will not only ensure that the information reaches more people at village level, but also that it will be translated into action. Many more of such partnerships are needed to get valuable information to the people who need it most.

GROUND UP HAS BEEN USED AS LECTURE MATERIAL IN UNIVERSITIES.

13 "Ground Up": facilitating networking and sharing in sub Saharan Africa

Parkie Mbozi

Participatory Ecological Land-Use Management (PELUM) Association is a network of 138 civil society organisations working in nine countries in eastern and southern Africa. "Ground Up" is the magazine launched in 2000 by PELUM in response to the information needs of its members. The magazine is being used to share field experiences and to network with like-minded organisations in the region. It is also a tool for advocacy and a means of popularising participatory ecological land-use management. Just two years and 8 issues later, the impact of Ground Up as a source of information and inspiration is commendable. A recent evaluation of the publication is explicit in pointing out that the magazine has filled a gaping hole in African media.

ILEIA is the Centre for Information on Low External Input and Sustainable Agriculture (LEISA) in the tropics. ILEIA seeks to promote the adoption of LEISA through the LEISA Magazine and other publications. It also maintains a specialised information database and an informative and interactive website on LEISA (**http://www.ileia.org**). The web site provides access to many other sources of information on the development of sustainable agriculture.

LEISA is about Low-External-Input and Sustainable Agriculture. It is about the technical and social options open to farmers who seek to improve productivity and income in an ecologically sound way. LEISA is about the optimal use of local resources and natural processes and, if necessary, the safe and efficient use of external inputs. It is about the empowerment of male and female farmers and the communities who seek to build their future on the basis of their own knowledge, skills, values, culture and institutions. LEISA is also about participatory methodologies to strengthen the capacity of farmers and other actors to improve agriculture and adapt it to changing needs and conditions. LEISA seeks to combine indigenous and scientific knowledge, and to influence policy formulation in creating an environment conducive for its further development. LEISA is a concept, an approach and a political message.

28 Information villages - connecting rural communities in India

Katherine Morrow

The Information Villages project connects 10 villages in Pondicherry, India, through the use of modern ICTs. The project was started in 1998 by the Swaminathan Research Foundation and has gained international fame for its success in bringing the benefits of modern ICTs to the rural poor. Using a hub and spokes model, a central information centre (hub) is connected to the knowledge centres in the surrounding villages (spokes). In each village, volunteers selected by the community run the knowledge centres. The project's gender focus has ensured that 50% of these village volunteers are women, thus ensuring that women are not excluded. Prejudice-free access to the socially underpriviledged has also been ensured through the agreement between the project and the villagers. Training has been a major focus of the project enabling the volunteers to collect, create and disseminate locally relevant information in Tamil, and allowing the villagers to access useful information. The experiences of this project with its focus on community ownership and local content are reflected in recent initiatives to create similar networks elsewhere in the world.

DEAR READERS

BELLANET

Bellanet is an international not-for-profit organisation established to help the international development community to work together more effectively, especially using information and communication technologies (ICTs). Based in Canada, Bellanet is funded by the International Development Research Centre, the Canadian International Development Agency, the Swedish International Development Cooperation Agency, and the Royal Danish Ministry of Foreign Affairs - Danida.
www.bellanet.org

As an organisation involved in the collection and dissemination of information through the LEISA Magazine, ILEIA knows the value of information in improving the livelihoods of rural people. Every time you, our readers, give us feedback on how you use the information from the magazine - to try out new agricultural practices, to set up new enterprises, to build new linkages, to lobby for policy changes etc. - we are not only encouraged, but also convinced that our efforts bear fruit.

Of course, the printed medium, like the LEISA magazine, is just one amongst the many ways in which information can be communicated and exchanged. Eight years ago, the ILEIA Newsletter on "New ways of information" dealt with some of these methods. (March 1994, vol.10.1)

Much has happened since then. Public extension systems are being dismantled, giving way to other more creative alternatives, especially partnerships between different stakeholders. At the same time, modern information and communication technologies have progressed rapidly and are expected to drastically change rural information access. As such, we thought it appropriate to examine this theme again, particularly the changes that are taking place with the rise of modern communication technologies, and to call the issue "Changing information flows".

In doing so, we have been priviledged to collaborate with Bellanet in Canada, an organisation with a great deal of experience in harnessing modern ICTs for development. Special thanks are due to Katherine Morrow of Bellanet, who despite her hectic schedule, wrote up several interesting experiences, worked with us on the contents, put together some interesting tips for ICT users in the South, joined the hunt for an appropriate cover photograph and kept answering our endless questions.

We hope that you will enjoy this issue and be inspired to take up creative ways of sharing your knowledge and experiences with others.

Changing information flows

Networking for family poultry development

E. Fallou Guèye and K. van 't Hooft

Mr. Subramanium actively promotes indigenous chicken breeds. Photo: Bertus Haverkort

Around 80% of the world's poultry is managed in traditional poultry systems, consisting of chickens, guinea fowls, turkeys, ducks, pigeons etc. These animals, of a wide variety of indigenous breeds, play an important role in the family: as a small asset, as a source of food or for social and spiritual obligations. The importance of poultry as a tool for poverty alleviation has been long identified. Many projects have attempted to replace the local poultry breeds with exotic or cross breeds specialised in egg or meat production, whilst introducing the standardised conditions of more intensive systems. Success, however, has been limited. In the past few decades, family poultry projects based on local knowledge and the improvement of indigenous breeds of different fowl species under local circumstances have been developed. In this process, high mortality due to infectious diseases (especially Newcastle disease) as well as predators, theft, and seasonal lack of feed, had to be dealt with - a tough task under local conditions and policies.

Several networks have been established to exchange experiences and research results between people engaged in family poultry keeping in developing countries. Examples are the FAO programme to support family poultry production that works through the International Network for Family Poultry Development (INFPD) (www.fao.org/ag/aga/agap/lpa/fampo1/fampo.htm); the Network for Smallholder Poultry Development of the Royal Veterinary and Agricultural University in Frederiksberg, Denmark (www.poultry.kvl.dk); Fowls for Africa of the Agricultural Research Council of South Africa (www.arc.agric.za); and the Improvement in Rural Poultry in Developing Countries of the University of Queensland, Australia (www.vsap.uq.edu.au/ruralpoultry).

One issue that these networks have focused on is the development and testing of thermo-stable vaccines for the control of Newcastle disease under rural family conditions. Newcastle disease is capable of causing a 50 - 100% mortality in unprotected chicken flocks, and the impact and unpredictability of the outbreaks in rural communities have discouraged many families from investing in new animals. Vaccination is the only way of controlling this disease, both in industrialised and extensive systems. The commercial vaccines commonly available (La Sota, Hitchner B1 and Clone 30) are adapted to large-scale chicken farms; these require constant refrigeration and once opened need to be used on a large number of individual animals within a short time. These multi-dose vials of vaccine (minimum 1000 doses) are not suitable for village poultry systems.

The INFPD and the Australian Centre for International Agricultural Research (ACIAR) have supported projects in the development of vaccines suitable for use in village poultry systems. These do not require continuous refrigeration and give optimal effect when administered as eye drops, but can also be given as a food additive to animals that cannot be caught. The first of these vaccines (NDV4-HR), was successfully tested in Asia and Africa, and is now produced commercially. Another thermostable vaccine (I-2) developed later is free of commercial ownership. (for more information contact: Dr. John W. Copland copland@aciar.gov.au) It is available at no cost to countries that wish to produce their own vaccine; the simple techniques required for producing and testing the vaccine can be learnt in short workshops. It is now being produced in Vietnam, while it is currently being tested in several African countries. The outcome of this effort shows the potential and the importance of networking and research in optimising low-input livestock systems. ■

Theme for issue 18.4, December 2002

Feminisation of agriculture needs appropriate responses

The feminisation of small and marginal agriculture is increasing rapidly in many parts of the world due to processes such as labour migration, part-time farming, urban life focused education and HIV/AIDS. This has an enormous impact on women, their households, rural communities and farming. Supporting women in their role as farmers requires many changes and adaptations. These relate to property rights, access to productive resources as well as to adaptations, i.e. decision making, labour division, crop management, animal husbandry and production of tools. Also research, extension, information management, input supply, financing and marketing etc. have to become more women-focused and have to develop methodologies and procedures adapted to the specific conditions and needs of women. Often, women as the main managers of change have to cope with ecological degradation. What specific needs do women in such conditions have and what adaptations have been developed by women to cope with these processes? What are the experiences of participatory programmes that have been supporting women to cope with change? What are good examples of technologies and methodologies suited for use by and with women? We invite you to share your experiences on these and other relevant questions with other readers of the LEISA Magazine. First deadline for contributions 1st of September 2002.

You are invited to contribute to these issues with articles (about 800, 1600 or 2400 words + 2-3 illustrations and references), suggest possible authors, and send us information about publications, training courses, meetings and websites. Editorial support is provided by ILEIA. Authors of published articles are entitled to a standard fee.

The role of smallholder farmers in seed production systems report and recommendations of a study visit organised by the technical centre for agricultural and rural cooperation, Zimbabwe, 1999. 2000. 94 p. ISBN 92 9081 2176. Technical Centre for Agricultural and Rural Co-operation (CTA), PO Box 380, 6700 AJ Wageningen, The Netherlands / cta@cta.nl CTA number 965. 10 credit points.

This book reports about the CTA study visit to 19 seed supply projects in Zimbabwe by 16 seed supply experts from sub Saharan Africa. The visits focused on work with smallholder farmers and on small grain and other indigenous crops. The report details the visits, outlines the seed supply situation in participants' home countries, and explains the follow-up work upon returning home. The report provides a lot of technical information but also encompasses socioeconomic aspects in management decision making.

The availability of improved seeds holds a key to enhanced farm productivity and increased income generation. The formal seed sector has had an impact on the productivity of high-value crops. But high quality seed supply for smallholder farmers has often been neglected, though indigenous crops grown by small farmers largely contribute to household and national food security in most countries. It is the informal seed sector that supplies 90% of the seeds of these indigenous crops. This report provides recommendations to improve the informal seed sector. The participants in the study agreed that when the informal seed sector is given the resources it needs to generate high-quality seeds for the nearly 90% of farmers in Zimbabwe and neighbouring countries who presently rely on this source, it will have a huge impact on national food stocks and food security. (WR)

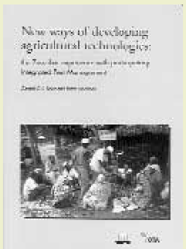
Global development : an experiment in rural development in Bolivia 2001. 83 p. Centre of Studies on Social and Economic Reality (CERES), Cochabamba, Bolivia. Simon I. Patino Foundation, 8, rue Giovanni-Gambini, 1206 Geneva, Switzerland.

From 1990 to 1995, the Simon I. Patino Foundation undertook an integrated development project in a peasant community near Cochabamba (Bolivia) with the objective of improving the quality of life of the population and halting the process of emigration, severely affecting the region at that time. The book describes the experiment from its inception, the handing over of responsibility to the community and the relative continuance of activities. In the first part of the book the agricultural site with its drought problems is discussed and the start-up of the project together with the organisation and the activities undertaken. The last part deals with relations within the community, the handing over of the project to the community and the causes and consequences of the interruption of most of the project activities. The text concludes with a more general reflection on the subject of development, for which the experiment under consideration serves as a starting point. (WR)

From indigenous knowledge to participatory technology development : soil and water conservation by Michael YG, Herweg K. 2000. 52 p. Centre for Development and Environment, University of Berne, Institute of Geography, Hallerstrasse 12, 3012 Berne, Switzerland / cde@giub.unibe.ch. Dr. Yohannes Gebre Michael, P.O.Box 33569, Addis Abeba, Ethiopia / Fax: +2511 518977.

This booklet on extension in soil and water conservation contains extracts from the detailed case studies Yohannes Gebre Michael carried out on different sites in Ethiopia, as part of his PhD. It is targetted at Development Agents of the agricultural extension service. The booklet helps the user to understand and respond to the diverse rural communities and landscapes, to see the needs and understand how indigenous soil and water practices work, to consider these indigenous practices as options for participatory technology development, and to integrate both indigenous and introduced know-how and practices for a more sustainable land management.

This booklet illustrates a procedure on how to learn about the prevailing natural and human settings in a rural area. It shows how to make best use of existing know-how through discussions with farmers, women, elders and leaders. Land users have most knowledge of their area, and development agents and experts should not attempt to do the farmers' job on behalf of them. Recommended. (WR)



New ways of developing agricultural technologies : the Zanzibar experience with participatory integrated pest management by Bruin GCA, Zeeman F. 2001. 167 p. ISBN 90 6754 624 0. Wageningen University and Research Centre, Technical Centre for Agricultural and Rural Cooperation (CTA), PO Box 380, 6700 AJ Wageningen, The Netherlands / cta@cta.nl.

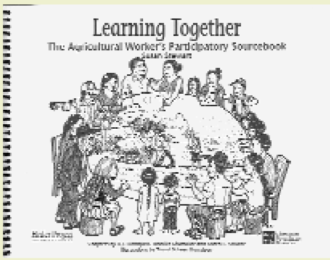
This book tells the story of an international collaboration in crop protection that evolved over sixteen years in Zanzibar. The project developed from a top-down activity focussing on the strengthening of a governemental plant protection organisation, to a successful process of bottom-up development in subsistence agriculture.

Experiences are decribed with the Farmer Field School (FFS) development on the islands of Zanzibar. The results in five different cropping systems are described, and general lessons are drawn from the successes and failures. Lessons include necessary adaptations of the FFS model, originally developed in rice agriculture in Southeast Asia, to the typical agro-ecological and socio-economic conditions of small-scale farmers in East Africa. By doing so the book addresses biological, ecological, social, economic, bureaucratic, and political dimensions of agricultural development.

The conclusions of this work show that FFS can work in an East African context if certain conditions are met. These conditions include raising awareness, creating mutual trust, developing new partnerships in research and extension, promoting conducive policies for FFS development, and mobilizing funds to make this happen. The good news is that the FFS way of working is capable of effectively mobilising people to collaborate in new and productive ways. However, this will not happen overnight and requires commitment of many stakeholders.

The international seminar on non-timber forest product : China Yunnan, Laos, Vietnam 2001. 187 p. ISBN 7 81068 271 7 RMB 40.-. Sino-Dutch Cooperation Forest Conservation and Community Development Project Office / hepikun@public.km.Yn.cn Yunnan University Press, 8 Jiaolin Road, Kunming, Yunnan 650031, P.R. of China.

This seminar aimed at increasing understanding about the role of Non Timber Forest Products (NTFP) in conservation and development in three countries - China, Vietnam and Laos. The report contains all the papers presented and summaries of the plenary discussions. Besides the plenary discussions, three parallel working group discussions tackled specific practical problems, in order to share and discuss experiences and lessons learnt. The three working groups were: NTFPs and forest conservation, NTFPs and community development, and NTFPs and marketing and processing. Papers addressing these topics with a lot of case studies and recommendations for sustainable use and management, participatory methods to determine the role of NTFPs in community's life, and marketing information are compiled in the proceedings. Useful information on forest conservation and sustainable development.(WR)



Learning together: the agricultural worker's participatory sourcebook
by Stewart S. 1998. 350 p.
ISBN 1 886532 10 9. Heifer project International, PO Box 808, 1015 Louisiana Street, Little Rock, AR 72202-2815 USA / www.heifer.org
Triops, Hindenburgstrasse 33, D-64295 Darmstadt, Germany / triops@net-library.de ; www.net-library.de.
Christian Veterinary Mission, 19303 Freemont Ave.N., Seatle, WA 98133 USA / www.vetmission.org. CTA no. 1045, 80 creditpoints

Learning together is a very rich resource book of excellent quality, meant for trainers in the field of agricultural and livestock development. It focuses mainly on trainers (both professionals or farmers) who are or will be training farmers in a participatory way. It is written by a variety of people working in agricultural development connected to a range of organisations. Drawing on the training experiences of practitioners from over 25 countries on 5 continents makes the book extremely practical. It offers a wealth of useful participatory methods, tools, techniques, games, energizers, etc. that can be used to improve on the quality of agricultural training.

It is designed primarily as a reference book. Users can pick out ideas from the sections related to the activity they want to undertake. The book is very comprehensive and includes all relevant topics, which are covered in a very practical way. The source book contains four sections: (1) How adults learn and effective learning techniques, (2) The steps in a training cycle, (3) Issues in agricultural and livestock training (gender, communication and IK) and (4) Reference section.

The book is rich in illustrations and the text is easy to understand. The approach to learning is very refreshing. Instead of the traditional form of theory followed by exercises, this book gives a lot of exercises through which reflection on the theory is stimulated. In short, this is certainly a book that will be frequently used and highly appreciated by every agricultural trainer who seeks to improve his or her training/facilitation skills. (WvW)

Urban Agriculture 2001. 45 min VHS PAL. ETC Netherlands/Resource Centre on Urban Agriculture and Forestry (RUAF), PO Box 64, 3830 AB Leusden, The Netherlands / www.ruaf.org ; ruaf@etcnl.nl.

This video on urban agriculture has been produced to facilitate a greater understanding of urban agriculture among policy-makers, urban planners, NGOs, sectoral organisations and other people who can make a contribution to the integration of urban agriculture into urban policies, plans and development programmes. It can be used in meetings, seminars, workshops, staff-training sessions, and initial phases of projects. The first part of the video shows the potential contribution of urban agriculture to enhancing urban food security, to poverty alleviation and to sustainable urban management. The second part of the video presents two examples of local processes of situation analysis, planning and action regarding urban agriculture - one example in Dar es Salaam, Tanzania, and the other in Cuenda, Ecuador. The video is also available in French and Spanish.

Ethical consumers and ethical trade : a review of current literature
by Tallontire A, [et al]. 2001. 34 p. ISBN 0 85954 527 X GBP 5.-. Natural Resources Institute (NRI), University of greenwich, Chatham, UK
DFID. (Policy series ; EP 12). NRI Catalogue Services, CAB International, Wallingford, Oxon OX10 8DE, UK.

This review examines both the nature of ethical consumerism and the characteristics of consumers themselves. The motivations of ethical consumers are varied, as is their willingness to pay an ethical premium on consumer goods. Ethical consumerism is a complex phenomenon and the experiences obtained within the fair-trade and organic movements are reviewed in an attempt to clarify issues determining its future potential. These conclusions are important both to the commercial sector and to development agencies concerned with trade with developing countries.

On-farm seed priming - a key technology to improve the livelihoods of resource-poor farmers in marginal environments by Harris D., 2001. 15 p. DFID plant Sciences Research Programme, Centre fro Arid Zone Studies, University of Wales, Bangor, Gwynedd ll57 2UW, United Kingdom.

Soaking seeds before sowing, or priming, is a technique that has been used by farmers for generations. However, it has been done mainly in times of drought to "catch up " on time lost, and the duration of soaking has been highly variable. This booklet documents the findings of participatory research undertaken by researchers of the Centre for Arid Zone Studies of the University of Wales and farmers in several countries in Asia, Africa and Latin America on seed priming as a regular practice. The findings prove that seed priming is a low-cost, low-risk technology ideally suited to the needs of resource-poor farmers in marginal areas of the semi-arid tropics. The booklet contains a lot of practical information on a range of crops that can be tried out and adapted by farmers. More information can be found on the web site www.seedpriming.org (CW)

The meat business : devouring a hungry planet by Tansey G, D'Silva_J (eds.). 1999. 249 p.
ISBN 1 85383 603 6 GBP 12.99. Earthscan, 120 pentonville Road, London, N1 9JN UK / orders@lbsltd.co.uk ; www.earthscan.co.uk.

This book tackles a fundamental global concern: how can we feed ourselves in the coming centuries, in a way that provides healthy and plentiful food for all people and yet is gentle on animals and on the environment? The papers of Compassion in World Farming's conference on Agriculture for the new millennium- Animal welfare, poverty and globalisation have been transformed into this book. The book is very informative and provides ethical consumers and campaining citizens with practical advice on how to achieve urgently needed reforms in agricultural practices. The exploitation of animals in factory farming is criticized. It says that cheap meat takes food from the mouths of the poor and creates degradation and pollution of the environment. The book contributes to the discussions on the need for a more sustainable agricultural system both in developed and in developing countries.(WR)

Milk south-north (Lait sud-nord) by World Herders Council (Conseil Mondial des Eleveurs), 2000. B.P.2453, 6002 Lucerne, Switzerland
http://www.condial.org/francais/fspublications.htm
The World Herders Council is an initiative of traditional herders of the Sahel. It is an international network of herders who are determined to stay and who have a concept of cattle breeding which includes a respectful attitude towards nature, towards animals and towards people. Their dossier Milk south-north, is a reflection on ethics for herding dedicated to milk, in which the discussion between herders from "the South" and European stockbreeders is paramount. The printed version of the dossier is in French and English and can be ordered via this web site.

Impact of changing agropastoral systems on agrobiodiversity: A case study of the Qinghai-Tibetan Plateau
an article by Wu Ning, 1998.
http://www.icimod.org.sg/focus/agriculture/agribio_bk/agrobio4.htm
This study describes the daily lifestyle of the pastoralists and discusses the economic progress and resultant pressure on the environment, particularly on the rangeland ecosystem and its biodiversity.

International Centre for Integrated Mountain Development (ICIMOD)
4/80 Jawalakhel, G. P.O. Box 3226, Kathmandu, Nepal.
icimod@icimod.org.np
http://www.icimod.org.sg/
ICIMOD's mission is to help promote the development of an economically and environmentally-sound mountain ecosystem and to improve the living standards of mountain populations in the Hindu Kush-Himalayan Region.

Farming Systems by International Institute of Tropical Agriculture (IITA), c/o Lambourn (UK) Limited, Carolyn House 26 Dingwall Rd., Croydon, CR9 3EE, UK. IITA@cgiar.org
http://www.iita.org/crop/farmsys.htm
IITA's mission is to enhance the food security, income and wellbeing of resource-poor people, primarily in the humid and sub humid zones of sub-Saharan Africa. It conducts research and related activities to increase agricultural production, improve food systems, and sustainably manage natural resources, in partnership with national and international stakeholders. Information on sustainable crop-livestock systems is available on this page. IITA also provides publications free of charge.

Integrated Crop-Livestock production for the slopelands of Asia, 1998, informative article to introduce a workshop on this topic.
http://www.agnet.org/library/article/ac1998d.html
Combining livestock with crops is a sustainable and profitable system of production for low-income slopeland farmers in Asia.

Low-cost livestock technology development by farmers, 1998.
http://www.agnet.org/library/article/ac1997f.html
This survey undertaken by the FFTC (food and fertiliser technology center) aimed at collecting and disseminating low-cost indigenous farming technologies related to livestock production. These technologies are described in the paper.

A knowledge link on livestock and rangeland systems, Work in progress 2002-1st edition. International Fund for Agricultural Development (IFAD), Via del Serafico, 107, 00142 Rome, Italy / livestockadvisory@ifad.org
This CD-Rom contains all the html available on the livestock and rangeland knowledge subsite of the IFAD website: **http://www.ifad.org/lrkm/index.htm**. It is based on case studies of a range of IFAD projects that support livestock production among pastoralists, agro-pastoralists and smallholders.

The Real Green Revolution
www.farmingsolutions.org
Farmingsolutions is a website jointly created by Greenpeace, Oxfam and ILEIA. The aim of the website is to bring forward successful experiences of ecologically-sound, socially responsible and economically-viable farming practices, and to demonstrate that this kind of agriculture can be successful in fighting hunger and malnutrition.

The website argues for a fundamental shift in agricultural production; from the present resource degrading, chemical-dependent, industrial agriculture controlled by corporations, to an agriculture suitable for small farmers and adapted to local conditions.

The web site is easy to navigate and has a lot of information on world hunger, agricultural production and successful agro-ecological approaches.

You are invited to contribute your own experiences and opinions to the site, please do!

www.farmingsolutions.org

Ethnovetweb, Evelyn Mathias, Weizenfeld 4, 51467 Bergisch Gladbach, Germany. evelynmathias@netcologne.de
http://www.ethnovetweb.com/
This website is about ethnoveterinary medicine, or how people around the world keep their animals healthy and productive, and how development can build on this information. The site provides information resources and publications, some in full text. A strong part of the website is the page with links and descriptions of other web sites on ethnoveterinary medicine and livestock development.

Livestock, Environment and Development Initiative (LEAD) is an inter-institutional project with the secretariat in FAO, Rome.
http://www.virtualcentre.org/selector.htm
The work of the LEAD Initiative targets at the protection and enhancement of natural resources as affected by livestock production while alleviating poverty. The website provides information in English, Spanish and French, about electronic conferences, online discussion forums, research and development and electronic newsletters on livestock production.

Centre for research on sustainable agricultural production systems - CIPAV, Cali, Colombia / lrrd@cipav.org.co
http://www.cipav.org.co/index.html
The CIPAV Foundation is a Colombian NGO founded in1986. The projects and programmes on which it focuses are alternative agricultural production systems. These systems promote the efficient and sustainable utilisation of the available human and natural resources, in harmony with the environment. Their experience in a wide array of ecosystems and social conditions can be summarised in a strategy for sustainable farming systems in tropical humid America. The site provides information on livestock research, the electronic journal Livestock Research and Development, conferences, publication lists etc., in Spanish and in English.

Animal production and health page of FAO, Rome Italy
http://www.fao.org/WAICENT/FAOINFO/AGRICULT/AGA/index_en.htm
Global livestock production is growing more dynamically than any other agricultural sector. Livestock are already the world's largest land user, and the livestock sector is predicted to become the most important agricultural sector in terms of added value by 2020. On this page FAO provides recent information on livestock production. A lot of publications are mentioned. Of particular interest is a series of practical publications especially meant for farmers.

International Livestock Research Institute (ILRI). ILRI-Kenya P.O. Box 30709, Nairobi, KENYA / ILRI-Kenya@cgiar.org
http://www.cgiar.org/ilri/research/prod-con.cfm
The International Livestock Research Institute works to improve the wellbeing of people in developing countries by enhancing the diverse and essential contributions that livestock make to smallholder farming. On this research page of ILRI, information on the production-to-consumption systems approach is to be found. Research to improve livestock productivity and sustainability in market-oriented smallholder systems will help ensure affordable balanced diets for the urban poor while reducing poverty and building assets for the rural poor. More information can be obtained from the newsletter of the Crop-animal Systems Research Network (CASREN) which is available in pdf format on the ILRI site.

Food and Fertilizer Technology Center: An international information center for farmers in the Asia Pacific Region fftc@agnet.org
http://www.agnet.org/
Asian countries are densely populated, and farms are small. The articles available on the site cover a wide range of policies, programmes and problems in Asian agriculture. Also information on FFTC seminars, workshops, training courses and special projects to collect and disseminate information about agricultural technology for small farms in Asia is provided. Free publications and other technical information, including low-cost technology for resource poor farmers is given.

http://www.icimod.org.sg/publications/imd/imd98-5.htm
The paper "Livestock Development in Mixed Crop Farming Systems 98/5" is found on this page. This paper reviews and analyses: 1) the temporal changes that took place over the past years in terms of livestock population and composition and 2) the institutional programmes for developing the livestock sector. Finally, it draws implications of these experiences for livestock planners and policy-makers and raises several research issues related to livestock sector development.

Primary Animal Health Care in the 21st Century: Shaping the Rules, Policies and Institutions

Mombasa, Kenya, 15-18th October 2002

From the 15th to 18th October 2002, the Community-based Animal Health and Participatory Epidemiology (CAPE) Unit of PACE/OAU-IBAR is organising an international conference in Mombasa, Kenya. The objectives of the conference are to:

- review progress with the formulation of supporting policies and legislation for primary-level animal health workers
- identify key lessons learned and make recommendations regarding future policy and legislative needs

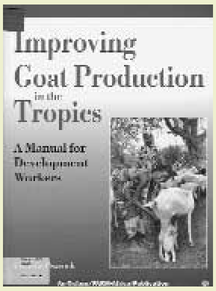
The conference, funded by DFID and CTA, will take the form of keynote presentations, submitted papers and posters and facilitated group discussions to arrive at recommendations regarding future policy and legislative needs.

Papers and posters are invited on the five themes listed below:

1. General policy, legislation and institutional issues
2. Financial sustainability and privatisation
3. Policies and Animal Health Research
4. Policy on training and learning issues
5. Policy on community-based surveillance

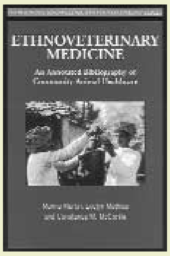
The venue for the conference is the Whitesands Hotel, Mombasa, Kenya. Accommodation will be available at the special conference rate of US$60 per single room on a full board basis. Sponsorship will be available for limited numbers of selected participants to cover the costs of travel and accommodation.

For more information and to register please contact: Dr Keith Sones, c/o CAPE Unit, PACE Programme, OAU/IBAR, P.O. Box 30786, 00100 Nairobi, Kenya. Fax: 254 2 212289 e-mail: ksones@net2000ke.com



Improving goat production in the tropics a manual for development workers by Peacock C. 1996. 386 p.. ISBN 0 85598 269 1 (pbk) : £ 14.95. FARM-Africa, 9-10 Southampton Place, London WC1A 2DA, UK. Oxfam, 274 Banbury Road, Oxford OX2 7DZ, UK.
This book is written both for livestock specialists and for development workers who do not have formal training in animal production. It explains the theory of goat-keeping, and how it can be used to design simple and cheap improvements in the nutrition, health, and breeding management of small or large flocks.

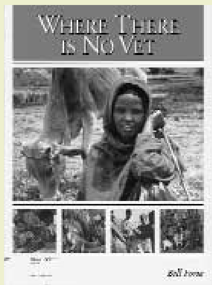
The role of forages in reducing poverty and degradation of natural resources in tropical production systems
by Peters M [et al] 2001 11 p. (Agren Network Paper no. 117) The Overseas Development Institute (ODI), 111 Westminster Bridge Road, London SE1 7JD, UK / agren@odi.org.uk
The paper reviews the role of forage crops in improving the productivity of smallholder farming systems and breaking the cycle of poverty and resource degradation. It reviews the contributions of forage crops to increasing farm incomes, intensifying farm production, and contributing to better human nutrition. Several case studies are presented including mucuna in Central America and West Africa, the forage peanut in Colombia, a forage legume in China, forage crops in Costa Rica and the production of forage crop seed in Bolivia. The paper also describes a strategy for farmer participatory research in identifying suitable forage crops in Southeast Asia.



Ethnoveterinary medicine : an annotated bibliography of community animal healthcare by Martin M, Mathias E, McCorkle CM. 2001. 611 p. ISBN 1 85339 522 6 : USD 45.00. (Indigenous Knowledge and Development Series). ITDG, Publishing, 103-105 Southampton Row, London WC1B 4HL UK, orders@itpubs.org.uk / www.itpubs.org.uk.
This bibliography with 1240 abstracts of documents on ethnoveterinary medicine covers 118 countries over the whole world and 25 livestock species including numerous breeds of cattle and sheep.

Forage husbandry by Bayer W, Waters-Bayer A. 1998. 198 p.. ISBN 0 333 66856 1. (The tropical agriculturalist / Coste R (ed.)). Technical Centre for Agriculture and Rural Cooperation (CTA), PO Box 380, 6700 AJ Wageningen, The Netherlands.
This book gives an overview of different aspects related to forage and livestock keeping, with an emphasis on pastoralists and smallholder farmers. Included are basic aspects of the farming systems, basic biology of livestock and forage resources, management of natural forage, forage as an auxiliary product from cultivated land, cultivated forages, and forage conservation and supplementation. The information explains the way pastoralists and smallholder farmers organise their lives, using livestock as part of their risk reducing and diversification strategies, combining livestock with crops and other - often non-farming - activities. In this sense not only technical and socio-economical aspects are taken into account, but also gender and other characteristics of the cultural dimension of livestock keeping. The last chapter gives an overview of the research and development approaches related to livestock keeping and forage production. This methodological guide includes a combination of traditional practices with outside ideas and technologies, according to the specific characteristics and needs of the farmers. Also available in french (KH)

The long dry season: crop-livestock linkages in Southern Mali by Ramisch J. 1999. 24 p. (IIED Issue paper no 88) International Institute for Environment and Development, Dryland Programme, 3 Endsleigh Street London WC1H 0DD, UK / drylands@iied.org
This paper investigates the interactions brought about by the co-existence of animal herds and agriculture in a village setting. It draws on PhD research that used soil nutrient balances to evaluate exchanges of animal manure and traction between owners and non-owners of livestock in Mali. The examples describe an agricultural sector undergoing an increasing level of intensification together with a growing number of animals. The challenge is to find ways of building on practices to intensify agricultural production further, while keeping at bay the risks of soil mining or widening inequality between different groups.



Where there is no vet by Forse B. 1999. 368 p.. ISBN 0 85598 409 0 : GBP 14.95. Oxfam, 274 Banbury Road, Oxford OX2 7DZ, UK.
Oxfam and CTA supported the preparation of this guide to first aid for animals. The author is a veterinary practitioner and farmer, and does a commendable job of explaining an impressive number of livestock diseases and their causes, symptoms and treatment. The numerous drawings make the text easy to understand. Although some information on care, feeding and handling of animals is given, the recommendations focus on curative measures. Important mechanisms of specific (often local) livestock species or breeds, such as tolerance or resistance to a particular disease, are mentioned only briefly. Although it is clear that a general book on simple veterinary medicine for the tropics cannot cover ethnoveterinary treatment in any detail, it would have been desirable if more emphasis was placed on local medicines which people can prepare themselves and which need not be kept cool. The book will be useful for field-based development workers, to guide them in making routine treatment and in handling emergencies. It frequently points to the limits of what can be done where there is no vet, requiring assistance from more experienced people. (AWB)

Managing mobility in African rangelands : the legitimization of transhumance by Niamir-Fuller M (ed.). 1999. 314 p.. ISBN 1 85339 473 4 GBP 17.95. Food and Agriculture Organization of the United Nations (FAO). IT Publications, 103-105 Southampton Row, London WC1B 4HH, UK / orders@itpubs.org.uk.
This book addresses one of the most important questions in range management in dryland areas of Africa: that of livestock mobility, which is still the most important economic strategy to deal with seasonal and inter-annual variation in forage and water availability in the rangelands. The book is divided into 11 chapters, of which 8 are case studies from countries in northern (Morocco), western (Mauritania, Mali, Niger), eastern (Sudan, Uganda) and southern Africa (Zimbabwe, Namibia). These cases cover the most important ecological zones for range management: arid, semi-arid, seasonally dry subhumid, in both lowlands and highlands. They deal in

some detail with current practices, their ecological foundations and problems, and issues of resource access and tenure. In the final chapter, key concepts related to livestock mobility are discussed: transience and flexibility, priority of use, managing uncertainty and risk, strengthening management regimes, managing key sites, law enforcement and mechanisms for conflict resolution. This book is a must for both policymakers and practitioners in range management and pastoral development. Moreover, in comparison with other technical texts, it is also reasonably priced. (AWB)

Agricultural services and the poor : case of livestock health and breeding services in India - summary by Ahuja V, [et al]. 2000. 148 p + 17 p. Indian Institute of Management, Vastrapur, Ahmedabad 380 015, India / www.iimahd.ernet.in The World Bank, Swiss Agency for Development and Cooperation.

This study on the delivery of livestock health and breeding services in three states of India attempts to develop policy recommendations for a more efficient and balanced system of delivering these services. The report with a seperate summary describes two field surveys. The first covered service provider units operated by various agencies like government, cooperative unions, private entrepreneurs and non-governemental agencies. The second study focused on the demand side of livestock service delivery. Its objective was to evaluate the potential impact of privatization and cost recovery on different categories of farmers. In the light of the findings of these two surveys, the study recommends a redefinition of the role of government in this sector by moving the curative veterinary and AI service into the realm of the private sector. (WR)

Capitalising on experience in Indo-Swiss cooperation in livestock development in India 2000. 50 p. free. Capitalisation of Experiences in Livestock Production an Dairying (LPD) in India project(CAPEX), Intercooperation, PO Box 6724, CH-3001 Berne, Switzerland / intercooperation@intercoop.ch; Swiss Agency for Development and Cooperation (SDC)/IC NRM Programme, Chandragupta Marg, Chanakyapuri, New Delhi 110021, India.

The main findings of the project Capitalisation of Experiences in Livestock Production and Dairying (LPD) in India -CAPEX- are presented in this booklet. This project reviewed the experiences of the Indo-Swiss Programme LPD in India, from its inception in 1963 to date, and formulated future priorities. LPD involved 8 projects spread throughout India. It also included support to developing a national livestock policy. Considering the wealth of experiences available after such a lengthy and large programme, the CAPEX-team choose 2 topics to focus on: 1. the evolution of a comprehensive LPD programme out of single projects and 2. selected technical issues in livestock breeding. The project is a nice example of the value of reflection on experiences! This booklet is a summary of a full version, also available at Intercooperation, as technical report no. 15. (IHG)

Politics, property and production in the west African Sahel : understanding natural resources management by Benjaminsen TA, Lund C (eds.). 2001. 335 p. ISBN 91 7106 476 1 GBP 18.95. Nordiska Afrikainstitutet, Uppsala, Sweden.

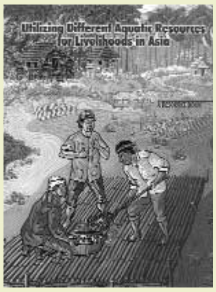
This collection of studies about Burkina Faso, Mali, Niger, Nigeria and Senegal presents natural resource management (NRM) for cropping, livestock husbandry and fishing in the context of political, economic and sociocultural processes. It shows that NRM is, above all, about relationships between people. It gives a glimpse into what is happening at local level while development agencies herald new programmes of decentralisation, democratisation, combatting desertification and participatory multi-stakeholder decision-making. Keen attention is paid to details of how local people decide about production and access to natural resources with a view to more than official policies, and often despite these. The studies reveal the need to look not only at the rules of the game but also at what people actually do. The book should not discourage interventionists trying to strengthen the rights of the marginalised, but does encourage them to become better aware of the tactics of the powerful.Nevertheless, the evidence of production by smallholders in the midst of environmental uncertainty, official and actual changes in property regimes, and political manoeuvring contradicts the alarmist cries of crisis in the Sahel. The book creates a modest optimism that people have a capacity for change and development with the right political environment, yet makes clear that there is no policy blueprint.

It is striking that only one of the 14 authors is African. Are African academics such a marginalised group? (AWB)

Corrections: LEISA Magazine Vol. 17 No. 4 - GM not the only option

The caption to the photo on page 27 should read, "P.V.Satheesh from the AP coalition in defence of diversity gives evidence to the jury. Photo: Agroindia"

The letter published on the back cover, "Using the poverty of the south to justify GM food to the north" was an initiative of Tewolde Berhan Gebre Egziabher of Ethiopia. He was awarded the "Alternative Nobel Prize" (Right Livelihood Award) for his international negotiations on behalf of the South.



Utilizing different aquatic resources for livelihoods in Asia : a resource book

2001. 416 p. ISBN 1 930261 02 0. International Institute for Rural Reconstruction, Y.C.James Yen Center, Silang Cavite, Philippines / jelmontoya@hotmail.com IDRC, FAO, NACA and ICLARM.

Natural resources, especially water resources, continue to be available to poor families in many parts of the world and poor families have demonstrated that they can utilise these resources in a sustainable manner.This resource book is a compilation of proven experiences from Asia that are totally field-derived, and is the result of a participatory workshop conducted in 2000 at the IIRR. With clear descriptions and nice illustrations, this book provides extremely useful information on aquatic resource management. Participatory approaches and extension strategies, community managed aquatic resources, freshwater systems, lake and reservoir-based systems and brackishwater and marine systems are the chapters dealt with.

The materials of the book can be used freely in advocacy, training and planning. The authors realise the value and need for upscaling their efforts in small-scale aquaculture. Especially recommended for development practitioners, local government officials and academic institutions.(WR)

Observations and farmer experimentation with predatory ants

Paul Van Mele and Vo The Truyen

Mr. Nguyen Van Cung cultivates one hectare of organic citrus in Giong Trom district of Ben Tre province in the Mekong Delta of Vietnam. He has nearly 40 years of experience with biological pest control. Mr. Cung fears that a lot of his experience will be lost because the new generation of farmers spends less time observing and 'experiencing' their crop. Whilst on a visit to his orchard, Mr. Cung shared with us some of his knowledge and experiences in keeping the weaver ant *kien vang (Oecophylla smaragdina)*.

Orchard diversity

Mr. Cung grows mainly lemon trees in his 1 ha. orchard as lemon tolerates the widely-occurring greening disease better than other citrus varieties. But we also came across trees of papaya, mandarin, king orange, pomelo, soursop (*Annona muricata*) and rose apple (*Syzigium* sp.) in his orchard. This he does to spread labour and get an income throughout the year. On an average he makes about 1000 US$ per month.

Moreover, Mr. Cung finds the latter three fruit species particularly useful for the weaver ant, because these trees have big and flexible leaves that are ideal for building nests. The density of the trees is such that the canopies touch one another, enabling the spread of the weaver ant throughout the orchard.

Farmer Nguyen Van Cong (left) and son Phong (second left) in the family orchard. Photo: Vo The Truyen

Benefits from the weaver ant

Protects fruit crops from pests
It is known that the weaver ant is a good predator on citrus and other trees such as mango, longan, lychee, cashew and coconut palm. A fruit crop not mentioned before in publications is soursop, which does not suffer from the fruit borer due to the weaver ant.

Protects annual crops from pests
Before Mr. Cung started cultivating citrus, he helped his father on the farm. With a rope the ants were guided from the trees towards the rice nursery beds and to the fields where pulses were grown. If left undisturbed ants even made nests by stitching the leaves of the leguminous crop together. Through experimentation they had found out that pests in these major annual crops could also be sufficiently controlled by the weaver ant that normally resides in the trees.

Deters rats
Besides insect pests, the weaver ant also attacks or deters a small type of rat that feeds on fruit in and around the orchard.

Increases mango fruit set
A major problem for mango production in the Mekong Delta is low fruit set, which is greatly improved when ants are present. Mr. Cung describes this as an indirect consequence of the ant preying on the mango flower hopper.

Improves citrus fruit quality
Mr. Cung says that mandarins grown without ants would be less sweet and juicy, and more granulous (*suong*). He also has a good citrus yield with the ants.

Provides a means of weather forecasting
The ants' behaviour helps him to predict the weather of the coming days. For instance, weaver ants sense oncoming storms. They become very active and move from the weaker to the stronger branches of the trees. This is a sign for the family to prepare for a storm.

Some observations on ant behaviour

The best time for making new nests is the beginning of the rainy season, as the trees produce new growth flushes. It is also a good time for introducing nests to new orchards as the ants are highly active. In the dry season there are more and smaller nests with a lesser number of ants per nest compared to the beginning of the rainy season when ants seem to join in larger nests.

During the cooler period of the year, from December to February, the nests are high up in the trees. At the hottest time of the year and during the rainy season from May to November, ants move to nests inside the canopy, to protect themselves from the heat and strong rains.

The Vietnamese word Mr. Cung uses to describe a colony or several nests that can live happily together without fighting is literally translated as ants 'from the same place' or settlement (*ô*). This can vary from nests in one tree at the beginning of colony establishment, to nests in one planting bed, one orchard or in neighbouring orchards. Mr. Cung's interventions to support the ants throughout the years have resulted in his colony covering more than 1 ha at present.

Weaver ant technology

Mr. Cung is often asked by colleague farmers to give advice on matters concerning the weaver ant. He was one of the first farmers who started converting paddy fields into orchards. Now, all citrus farmers of the village practice some level of ant technology. At social gatherings farmers discuss and exchange ideas about many things of their farm, including the ants.

Weaver ant colony establishment
Citrus farmers generally consider the black ant *kien hoi* a pest. Mr. Cung tells us that the black ant causes a lot of the citrus fruit to drop. He attributes this to the presence of sucking insects that are abundant when the black ant is present. As black ants and weaver ants fight each other, one of the first things before establishing a weaver ant colony is to get rid of this black ant.

(a)

(b)

(c)

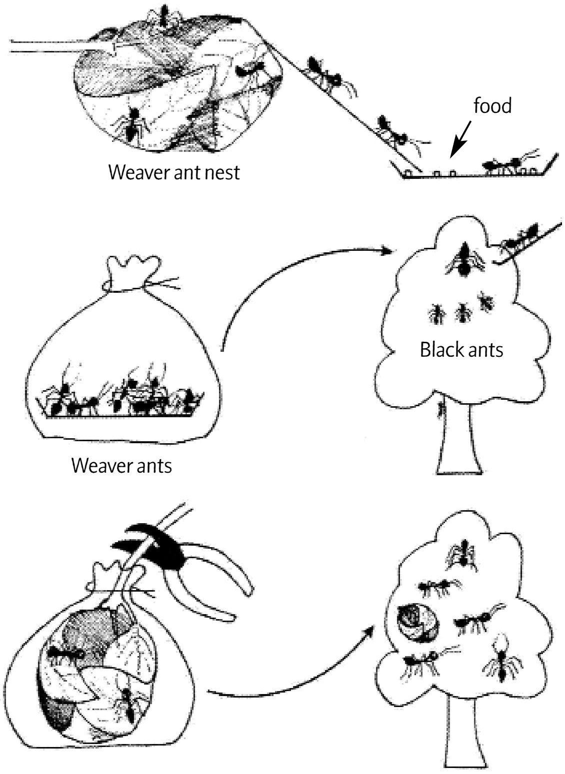


Figure 1: A good way to introduce a new weaver ant colony in case black ants are present as proposed by Mr. Cung. Drawing by Marcella Vrolijks.

Mr. Cung has developed a very successful strategy for this purpose as illustrated in figure 1.

The first step is to lure the strong soldier weaver ants by putting a rope from one of the trees with nests to a container with food such as shrimps (figure 1a). After the container is full of strong soldier ants you put a bag over it and transport it to the place where you want to establish a new colony. Once on the spot, you climb the tree all the way to the top where you then release the soldier ants (figure 1b). This approach guarantees better success than when you just release it at any other place in the tree. Once the black ants are defeated you then introduce a complete nest (figure 1c). The best time to do this is at the beginning of the rainy season (April/May) as ants are then very active.

Helping weaver ants to win from invading black ants

'To fight the black ant, you study its military strategy, and then you know how you can help the weaver ant to win the battle', Mr. Cung continues. One weaver ant can easily win from 5-6 black ants by cutting their bodies in half. However, when black ants become too numerous, the weaver ant gets tied down by the legs and finally killed. But it is not only numbers that matter.

Mr. Cung has observed that black ants sometimes attack established weaver ant colonies from several directions, simultaneously. When the weaver ants start running away, it is time to intervene so that they do not loose the battle. You have to trace down the soldier base of the black ants and cut their support line, for instance by pruning the branches along which they enter the tree. Black ants also have a kind of journalist ants or 'liaison officers' (*giao lien*) that report back to the 'base camp' (*can cu*) for more support. By cutting the line, this flow of information is also cut off.

But if the branches are bearing fruit, they cannot be pruned. Then a different intervention is required. Mr. Cung collects an 'aid force' (*luc luong ho tro*), a nest from the same weaver ant colony, and puts it directly in the base camp of the black ants. The fighting black ants in the tree are soon informed and return to their base camp. The weaver ants, which were disoriented, return and fight side by side with the ants of the aid force.

In the case of black ants attacking a newly introduced weaver ant colony, it is even possible to bring in an aid force from a different colony. This is the only time that weaver ants from different colonies do not fight each other, but join forces against a common enemy.

Mr. Cung has developed two different strategies to keep the black ant population under control. When the black ant becomes too numerous in the dry season, a rotten fish is crushed and spread over a small area of half a square metre in the orchard. This attracts many black ants, which are killed by burning the spot. In the rainy season, the black ants look for a dry place to build their nest. By hanging a bunch of dried leaves or grass in the tree, black ants are lured in and then removed and burnt.

Supplementary feeding

Mr. Cung has observed that weaver ants do not need supplementary feeding in the rainy season due to an abundance of food. He now feeds them moderately in the dry season with mainly fish and small shrimps. Although the ants can transport large pieces of food to their nest, he prefers to provide small pieces that can be carried by a single ant. The amount of food given determines for a great part the number of nests.

Reducing harm to both the weaver ant and farmer during harvest

To avoid the irritation of ant bites during harvest, Mr. Cung has developed a simple ant-friendly technique. When harvesting fruit he takes a bag of wood ash and spreads some ash on the branches he wants to climb. The ants retreat back to their nests. Once the wind or rain removes the ash from the branches, the ants return.

Conclusion

The knowledge and experience of farmers like Mr. Cung will be lost unless more efforts are undertaken to document and spread them to others.

Local livestock for empowerment of rural people

W.M.K. Warsi

Domestic animal diversity represents one of the most neglected as well as threatened aspects of biodiversity. According to FAO, one third of the world's estimated 4000 livestock and poultry breeds are in danger of extinction. In the South, these breeds are vested with traditional farming and pastoral communities, who manage them according to their indigenous knowledge and in tune with local ecological constraints. Causal factors for their extinction include political backing for cross breeding, loss of grazing land, globalisation of the economy, catastrophes, conflicts, legal restrictions on the marketing of their products etc. Many countries provide direct subsidies on feed and other inputs, which tend to favour exotic breeds and industrial animal farming.

Nevertheless, many local livestock breeds continue to represent the lifeline of rural populations. While they may not be able to compete with "improved breeds" in milk and meat yields, they fulfil a much wider range of functions and provide a larger range of products. Being able to thrive even with low fodder inputs, their maintenance is ecologically more sustainable, especially in marginal environments. Requiring lower levels of health care and management, they commonly entail a lower workload for women in comparison with exotic breeds. As is becoming increasingly clear, they often have scope for speciality products and can be essential to preserve habitats and cultures.

At the local level, the loss of a breed means the loss of a livelihood strategy and loss of indigenous knowledge. At the global level, it means decreased manoeuvring room for adapting to environmental and economic changes. The Convention of Biological Diversity (CBD) mandates maintenance of the remaining livestock genetic diversity. It also emphasises the need for the active involvement of indigenous communities and the role of local knowledge and institutions in conservation.

The LIFE Network

The League for Pastoral Peoples (LPP) and the Indian NGO Lokhit Pashu Palak Sansthan (LPPS) jointly organised an international workshop on "Local Livestock Breeds for Sustainable Rural Livelihoods" at Udaipur and Sadri, Rajasthan, India, in November, 2000. This workshop initiated the process of implementation of the Convention of Biological Diversity in regards to domestic animal diversity. It received an overwhelming response and a large number of participants from scientific institutions, universities, NGOs, governments and international donor agencies from Asia, Africa and Europe attended it. At the end of the workshop a joint declaration, known as the "Sadri Declaration", was signed by all the participants. Inspired by the response from the participants of the workshop and the Sadri Declaration, LPP and LPPS took the initiative to establish a network: LIFE (Local Livestock for Empowerment of Rural People).

LIFE aims at supporting and fostering the following activities:

- Study and document indigenous knowledge relating to livestock breeding and breeds.
- Make case studies of livestock breeds that are threatened and the social, economic and political factors involved.
- Exchange information between NGOs, pastoralists and farmers' associations, scientific institutions, policy makers and others through workshops and a mailing list.
- Build capacity of NGOs in the conservation and development of indigenous livestock breeds.
- Analyse the macro-economic and political factors driving the process of livestock genetic resource erosion.
- Lobby for more participatory orientation of research concepts in formal-sector organisations.
- Establish a network of organisations and individuals for community-based conservation of livestock breeds.

Membership of LIFE is not restricted to a particular geographic location. Any organisation or individual concerned for sustainable livestock development is welcome to join this network.

World watch list for domestic animal diversity

The increasingly grim outlook for indigenous livestock breeds – and for the farmers who depend on them – is detailed in the third edition of the 726-page volume of the FAO/UNEP World watch list for domestic animal diversity (WWL-DAD:3), released in December 2000. While local communities generally possess extensive knowledge of the observable characteristics of their breeds, there is negligible documented research data for about 85% of all breeds and even less sound breed comparison information for decision making on breed use. The real value of genetic diversity is not properly reflected in current choices of breeds and associated technologies. Breeds that utilise low-value feeds, or survive in harsh environments, or have tolerance to or resistance against specific diseases could be very beneficial in the future.

Indigenous breeds can be improved to provide better outputs
Opportunities for improvement of indigenous breeds have never been explored systematically. To help countries in improving the performance of indigenous breeds, the FAO's initiative for Domestic Animal Diversity (iDAD) is currently producing guidelines for identifying and achieving particular breeding objectives (more meat, milk, eggs, wool, etc.). In addition, iDAD supports the conservation of pure breeds, which is vital for maintaining genetic diversity and preserving the genetic material on which future agriculture may depend.

For more information visit the web pages of FAO's Domestic Animal Diversity Informati on System. www.dad.fao.org

Towards local resources-based integrated crop- livestock systems

T.R. Preston

The present livestock production systems in most industrialised countries are in direct competition with human needs. Livestock presently consume almost 50% of world cereal grain supplies. In the "intensive" large-scale production systems (Sansoucy 1998), increasingly promoted by corporate agriculture, livestock wastes contaminate soil and water resources, create less than favourable working conditions for the personnel involved in feeding and cleaning, and decrease employment opportunities. To meet food needs in 2050, it is necessary to develop livestock production systems, which do not depend on cereal grain.

In developing countries in the tropics, instead of grain-based livestock systems, alternative production systems must be developed which make optimal use of locally available resources, solar energy, soils, water and people for multiple end purposes. The challenge is to capture the sun's energy in systems of production and utilisation which at the same time will contribute to alleviation of poverty, creation of jobs, a more equitable life-style, protection of the environment and increased biodiversity. Close integration of livestock in the farming system, with recycling of all excreta, will be the basis of an agriculture which can be highly productive and also sustainable (Figure 1).

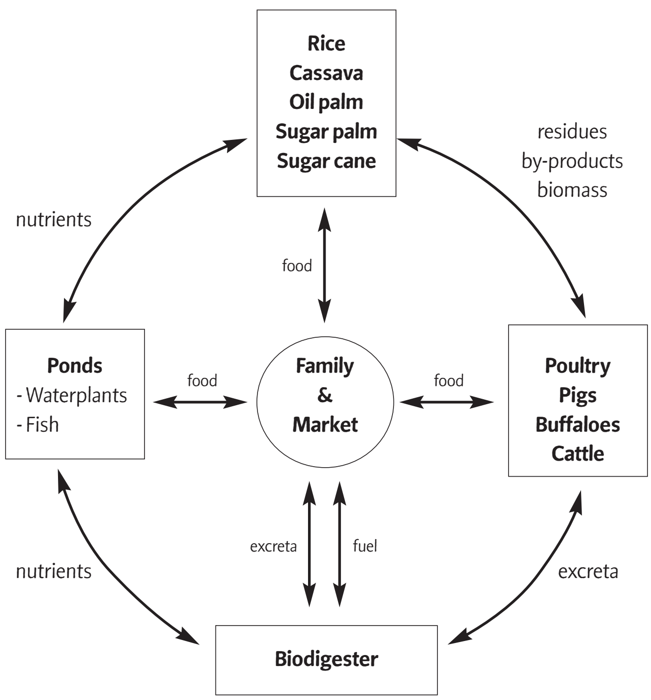

Figure 1: The integrated farming system

Energy crops
In tropical countries, especially in the humid zone, there are many crops and farming systems that considerably exceed the productive capacity of grain cereals. Key plants in this scenario are sugar cane, cassava, and the palm family, especially the oil and sugar palms.

The yield potential of the sugar palm (*Borassus flabellifer*) is extremely impressive. An annual average yield equivalent to 18 tonnes of soluble sugars per hectare has been documented in a study with 12 family farm households in Cambodia (Khieu Borin and Preston 1995). Despite this demonstrated potential almost no research is currently conducted to improve the technology of growing and using this tree, which is found throughout the SE Asian region.

Protein crops
There is an equally great potential to produce high yields of protein in the tropics. But this will be with trees, shrubs and water plants, rather than with soya beans. The *Lemnacaea*, of which "duckweed" is the most widely distributed, have a particularly important role to play in efficient resource utilisation because of their capacity to extract nutrients from water fertilised with wastes (excreta) from livestock and people. A specific feature of this plant is that its protein content can be manipulated according to the nutrient supply in the water. Values in the range of 35-40% protein in the dry matter can be attained when the nitrogen content of the water is in the range of 20 to 30 mg/litre (Leng 1999). Duckweed is easy to harvest and needs no processing prior to being fed to livestock. The protein is highly digestible and the excellent balance of essential amino acids makes it an ideal supplement for chickens, ducks and pigs. Average yields are in the order of 100g fresh biomass/m^2/day equivalent to 8 tonnes of protein/ha/year (Nguyen Kim Khang 2000).

The cassava plant (*Manihot esculenta*) can be managed as a perennial forage crop with repeated harvests of the foliage at 50-70 day intervals. The foliage yield increases over successive harvests (Preston, 2001) as the repeated cutting stimulates new growing points. Yields of 3-4 tonnes of protein/ha/year are possible with this regime. The fresh foliage is an excellent protein source for ruminants, while after ensiling (which converts the toxic cyanide into non-toxic cyanates) it can safely be fed to pigs (Ly and Rodríguez 2001). Cassava is an exploitive crop when grown in monoculture and on sloping land. Managing it as a perennial shrub / tree and associating it with N-fixing legumes, such as *Flemingia macrophylla* or *Desmanthus virgatum*, or fertilising it with heavy dressings of livestock manure or biodigester effluent, are ways in which it can be grown sustainably with enhancement of soil fertility (Preston et al 2000). The presence of cyanide components in the leaves may even serve as an "organic" pesticide, providing protection against a wide range of pests.

Changing the livestock system
The feeds derived from these "alternative" crops (juice from sugar cane and sugar palm, roots of cassava, fruit from oil palm, duckweed biomass and cassava foliage) do not lend themselves to "factory" farming systems which traditionally use dry feeds, easy to store, transport and mix into "least-cost" rations. The "alternative" feeds require "alternative" farming systems such as developed by CIPAV in Colombia (see page 14) which are now widely being adopted and adapted in, among others, Vietnam and Cambodia.

Dutch dairy farmers find own solutions to their environmental problems

Willem van Weperen en Henk Kieft

Farmer experimentation and innovation and farmer-researcher platforms for the development of low external input and sustainable agriculture are very successful not only in tropical countries. Also in the Netherlands, there are remarkable initiatives of farmers to develop alternatives to the unsustainable conventional dairy production model. Ten years ago, two environmental associations of dairy farmers, VEL and VANLA in the province Friesland, in the north of the Netherlands, started to experiment with nature and landscape management and integrated agriculture. Now, after several years of successful experimentation with environmentally-sound farming practices, this initiative is being taken up by several hundreds of dairy farmers in different parts of the country.

Fifty years of dairy development

In the '60s, the average Dutch dairy cow produced 4000 kg milk per year. In 2001, this was about 8500 kg. The average yearly increase of about 100 kg milk per cow was possible due to very successful technology development, enhanced by effective research-extension-farmer interaction, access to credit, and a conducive policy environment. Artificial Insemination and effective breeding policies increased the potential milk yield of dairy animals to levels that our grandfathers did not even dream of. Other important innovations were: the shift from rope-tied to free-roaming stables with sleeping cubicles and a much better ventilation system; disease control through effective vaccination; very high fertiliser application levels which boosted grass yields; mechanisation of fodder production; improved fodder conservation techniques and the introduction of fodder maize. The availability of ample high quality roughage, supplemented with high levels of protein-rich concentrates, made it possible to fully exploit the improved genetic potential of the dairy cows. But also, the low prices of these high quality fertilisers and concentrates were essential in achieving high milk production.

Increasing environmental problems

The recommended fertiliser application for pastures has gone up to 400 kg nitrogen (N) /ha. Presently, annual grass production on pasture land is 10-12,000 kg dry matter/ha. in 5-6 cuts. The low price and high status of mineral fertilisers made cow manure lose its importance and was used only as an extra, over and above the recommended fertiliser application. Until recently, the nitrogen present in manure was not even considered in calculations.

These high fertiliser applications increasingly led to serious environmental problems: leaching of nitrates from the topsoil to the groundwater negatively affecting the quality of the drinking water and high levels of ammonia emission from the cows negatively affecting the quality of nature in the surroundings of the farm. In the '80s, the Ministry of Agriculture had to introduce a series of 'restrictive' measures for dairy farmers to meet the environmental targets set by the European Union. Broadcasting manure on pasture land was banned and instead it was made compulsory to inject the manure as slurry into the soil during the growing season.

In the early '90s, a mineral bookkeeping system for dairy farmers was introduced and was tested as a voluntary management tool. Through simple accounting of mineral input and output at farm gate level, nutrient losses within the farming system were made evident. Ideally, inputs (concentrates and fertilisers) balance with the outputs (milk and meat) in terms of nutrients. However, losses of nitrogen occur in the cow and in the soil. This bookkeeping revealed that losses of N/ha in the conventional dairy system had become very high and hence N efficiency very low (<18% at cow level and <30% at soil level). See figure 1.

Animal health problems and consumer concern

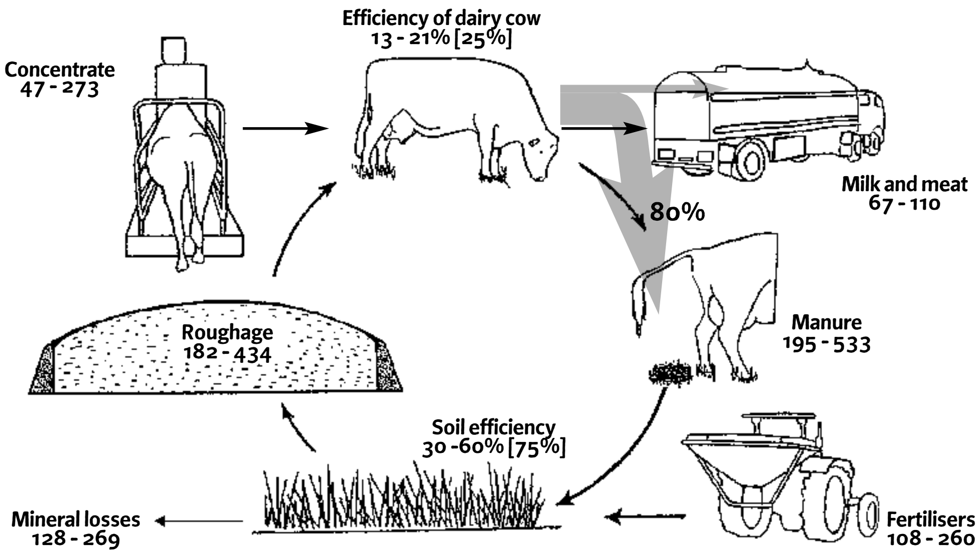
The high-input farming system led not only to environmental pollution but also to animal diseases:

- very high protein levels in the rations causing digestion problems and malfunctioning of the liver;
- high incidence of mastitis;
- animals becoming susceptible to hoof diseases;
- prolonged calving intervals due to fertility problems.

These health problems are increasing veterinary costs and decreasing milk production.

Consumers are showing increased concern with the (perceived) lack of animal welfare related to intensive production, and with human health in relation to cow-diseases like Mad Cow Disease (BSE). They have begun challenging the so-called "license to produce" of farmers. The Foot and Mouth Disease crisis of last year aggravated this feeling and exposed the vulnerability of the modern livestock production systems.

Figure 1: Nitrogen efficiency of Drenthe project farmers expressed in kg N/ha/year [ideal]



Two environmental associations start the process

Ten years ago, the two environmental farmer associations in Friesland were founded by farmers to regain control over their own future. They argued that by development of integrated agriculture, pollution control by conscious use of agrochemicals and plastics, and the management of nature and the many small-scale natural landscape elements (hedges, bunds, pools, etc.) on and between their farms, they could greatly improve the quality of their environment. These measures, they said, should not necessarily decrease their production and income, while certified quality products, landscape management and income from agro-tourism could provide new opportunities.

The philosophy of these dairy farmers, based on their 'gut feeling' and experience with the production system of their fathers, is that many relationships exist between the various components of the farming system, and that these relationships should be considered in all management decisions. For example, the way they feed their cows affects the quality of the manure. The quality of the manure affects the quality of the soil. The quality and fertility of the soil affects the quality of the pasture and fodder crops and hence the feed, which in turn affects the health of the animals and the quality and quantity of the products. All parts of the system as well as the whole are important! The quality and quantity of the dairy products (milk and meat) are improved by optimising the (biological) quality of all the different aspects (manure, soil, pasture, feed, animals, products) and the quality of the whole system. In conventional dairy production, the concept of system quality was lost because of the focus on the development of a high input - high output system. Through refocusing on quality, the system develops in the direction of a low input - high output system.

The farmers found that by reducing the amount of protein and increasing the amount of crude fibre (roughage) in the feed of their animals, the quality of the manure is much better than the slurry produced by conventional dairy farmers. They argue that this type of manure (with higher C/N ratio and relatively rich in organic N) is more beneficial to soil life and therefore more efficient in production of biomass. Consequently, N emission to the environment will be reduced. Broadcasting manure with these qualities is also less detrimental to the environment.

The approach builds, as much as possible, on farmers' knowledge and ecological regulating mechanisms found in nature. The farmers consider their experiences as added value to the conventional scientific knowledge as they also use practices and methodologies not accepted by conventional agricultural science.

Apart from system quality, the farmers also work on adapted animal breeding, new opportunities to diversify the local rural economy such as agro-tourism, and farmer cooperation to enhance processes of change.

The PMOV platform – taking it further

In the last 3 years, this initiative has been taken up other farmers and together with some researchers they have founded the PMOV platform to promote 'eco-technological' farming. Presently, the platform constitutes about 120 experimenting dairy farmers, two formal experimental research farms comparing integrated and organic agriculture and the two environmental associations of Frisian dairy farmers.

The network felt strongly that a link should be built with university research for two major reasons. The farmers, who rely on their own observations and incidental measurements, wished to get more insight into what ecological processes actually take place in their farming systems. Secondly, they wanted policy makers to understand their exploratory efforts and promising results, and adapt legislation towards objective-oriented regulations instead of instrumental ones. "Politicians should tell us what they want, but we will decide ourselves how to do it!" Initially, the Ministry of Agriculture was very reluctant to cooperate. The farmers were perceived as those trying to escape environmental legislation. Only with great difficulty could the farmers negotiate some legal space for their experiments which did not conform to Dutch law for manure application. After several years of good results some recognition for the value of these experiments is emerging, and money from the government has been allocated to facilitate further experimentation by a larger number of farmers also in other parts of the country.
Also in 2002, a grant is expected from formal Dairy Research to formulate a joint monitoring project to assess PMOV farm results and compare these with conventional farms. 'Joint' here means that farmers and scientists together design the project. Interest also exists to better understand the dynamics and decision-making logic of experimenting farmers, to make the sharing of their experiences to other interested farmers cost efficient. These farmers do not only perceive themselves as entrepreneurs, but also and often even more so, as 'stewards of complex agroecosystems'. They often feel the need to regain their 'license to produce' within society at large.

Management guidelines for dairy production

Based on the long years of experience of the farmers and the experiments carried out on the experimental research farms, the platform formulated some new management 'guidelines' for keeping dairy cattle in a more sustainable way:

1. Reduce the percentage of crude protein in the diet (from 18% to around 16 or 15%) and increase the crude fibre content;
2. Try to keep the OEB (Rumen Protein Balance) at zero;
3. Try to increase the C/N ratio of manure from 7 to around 10;
4. Feed concentrates to a maximum of 25 kg per 100 kg of milk;
5. Reduce the fertiliser applications on pasture stepwise with about 30 kg N/ha/year. Try to get it down until it is in balance with the permitted yearly losses (180 kg N/ha/year);
6. Distribute larger portions of the manure applications to the 1st and 2nd cut. Stop manure and fertiliser applications entirely after mid July.

Preliminary results

The results of the practical experiences indicate that it is possible to maintain the milk yield with lower costs due to substantial reduction in mineral fertiliser supply and concentrate feeding. The values of nitrate losses into the ground water and ammonia losses into the air were clearly below the set EU-targets. The health status of cattle on many PMOV farms has improved, adding significantly to cost reduction. The biological quality of milk, manure and soils is presently being assessed.

Beside these technical results, the farmers strongly value the benefits from improved social relations and collaboration within the working groups and their communities. As farming now is more in line with their intuition, farmers feel less stressed as well.

The techniques, ideas and experiences of the farmers and the two experimental research farms are shared through farmer-to-farmer meetings, newsletters, seminars and info-markets, lectures and excursions, farmer study-clubs and educational material.

The experiences show that these farmers are well able to resolve their own problems and make their farming systems sustainable to a large extent. Within the norms set by society, farmers should have professional freedom to find their own solutions adapted to local conditions.

Camelids are best suited to the conditions of the Andean highlands. Photo: AIGACAA

Improving llama production in Bolivia

Osman Rocha Ravollo

For over 6000 years the South American camelids have been a distinctive feature of the Andes region, both physically and culturally. Of the four existing camelid species, two have been domesticated: the llama and the alpaca. With the arrival of the Spaniards, these native animals and their breeders were forced to retreat to the highlands of the Altiplano.

Bolivia is the country with the largest number of llamas in the world. Almost all of the two million animals are bred in small family herds, grazing exclusively on wild pastures. The llamas are part of the life strategy of these poor peasant families; they are a means of transport, they provide meat, their manure is used as fertiliser and fuel, and their wool for garments and similar articles.

Llamas are intimately connected to the culture and cosmovision of the Andean indigenous people and play a central role in many of their rites and celebrations. For example, when a couple gets married, they receive several llamas from their parents, depending on the number owned by the parents. This inheritance is then carefully administered by the newlyweds. The common ritual known as *Rhuthucha* - 'first haircut' - takes place around the age of two; on this occasion, too, the child receives a couple of llamas from his or her godfather, as well as parents and other relatives. Although the parents take care of the animals, from that moment onwards the child has his or her initial asset called the *lacama*.

A llama breeding family

Señor Pánfilo Gerónimo is 55 years old and lives with his wife Damascena in the community la Rivera of the Oruro department. The couple has 6 children, some of them are still in school, and the others have migrated temporarily to work in Chile. The mountainous region where the family lives is situated at 3,800 m above sea level; its climate is harsh with frequent frosts. A small part of their land is used for crops, such as potatoes, *quínua* (local grain), barley and oats, while the rest is used for grazing.

Don Pánfilo explains, *"We have 180 llamas and 30 sheep. The whole family takes care of them, taking turns with herding. The sheep graze elsewhere and my wife takes care of them; we also have 5 donkeys. All decisions about the llamas or the sheep are taken together with my wife. We breed llamas to have meat ourselves, and also to sell at the Pisiga fair, some 40 km from here. The male llamas are also used as packers. The sheep are for our own consumption. We use the manure of the llamas and the sheep as fertiliser in the fields and sometimes as fuel for cooking."*

The family has learnt the art of breeding llamas from their parents and grandparents. They keep many traditions, such as the Wilancha ritual, alive. Don Pánfilo explains, *"This ceremony is performed to plead for the well being of the families, when a new task is undertaken, or in the hope of a good year for the animals. During the ritual a llama or a sheep is slaughtered at dawn. Blood is shed for the Pachamama* (Mother Earth) *and for the work that is about to be started. The meat of the animal is then cooked and all present are invited to the meal."*

Limitations

Over the past decades, the tendency has been to reduce the size of the family-owned llama herds in Bolivia. In the areas where camelids were predominant, people started to combine them with, or give priority to other species, particularly sheep. Economically, the main function of the llamas - transportation - was being taken over by engine-driven vehicles, while at the same time the prices of llama meat and wool were particularly low, due to the low quality of these products.

Llama wool is inferior to that of the alpaca as it contains a great deal of low-quality bristles. Therefore, in many areas, only 20% of the animals are sheared each year. Llama meat is consumed either fresh or as *charque* (sun dryed). The sale of fresh meat is limited and the prices are very low due to the presence of grain-like cysts of the parasite *Sarcocystis aucheniae* and *S. lamacanis*. Though this parasite does not pose a danger to human consumers, meat with a high degree of infestation is often confiscated. Therefore, it is usually sold through informal channels. The incidence of the parasite, which is transmitted by dogs, is approximately 90% in animals older than 2 years.

Other factors that limit llama husbandry are the degradation of the pastures, the lack of labour, external parasites, lack of shelter, and the degeneration of the animals due to inbreeding. Mortality rates are high, both in adults and offspring. Another problem is the lingering influence of the traditional authorities, which used to regulate the use of the communal pasture areas. All this, plus the fact that breeding takes place almost exclusively in areas of extreme poverty, has increased the cultural prejudices and lowered the status of breeding llamas.

Economic and ecological potential

Despite these limitations the llama is the species of highest potential in the Bolivian highlands, which explains why families have continued breeding it. On the one hand, the highlands comprise huge areas of natural pastures, especially suited to camelids. They are best adapted to this environment, being highly resistant to the effects of the altitude and climate, and – unlike sheep, goats and cattle – do not disturb the fragile ecosystem of the Andean mountains when they walk and graze. As such, the camelids play a fundamental role in recovering the large areas of degraded pastures.

Furthermore, as long as Sarcocystiosis is kept under control, camelid meat is excellent for consumption, with lower levels of cholesterol and fat than beef, pork or lamb. It is possible to reduce the mortality rate of the animals by controlling external parasites, improving shelter and nutrition; better quality wool – comparable to the alpaca – can be achieved by selective breeding programmes. Other potentials include the families' experience in llama breeding and their knowledge of wool processing – both of the fabric (the women) and of the loom (the men) – and other artisan products.

ASAR

ASAR (Asociación de Servicios Artesanales y Rurales) is an NGO, which has since 1995 been developing programmes for improving llama husbandry in 6 provinces of the Oruro and Cochabamba departments. After analysing the potential and limitations of llama breeding, they have worked towards organising the llama farmers, training them and letting them have a voice in the strategies of the project. In the training of livestock para-technicians, two participants were elected by each community. The methodology was directed at illiterate adults with a great deal of practical knowledge.

After several courses in organisation, llama breeding, transformation and commercialisation of products, the association ARPROCA (Regional Association of Camelid Producers) was established, drawing together the communities from the Litoral, Atahuallpa and Mejillones provinces. It managed to generate funds from UNEPCA (Executive Unit of Camelid Projects) in 1995. These funds were used as credit for the members of the association to buy selected llamas and to establish a special llama-slaughterhouse in Huachacalla to commercialise the venture.

Quality improvement and marketing of meat

In September 1997, this abattoir for camelids was ritually opened by the communities. Subsequently, courses on slaughtering and the preparation of dried meat were given. Several small solar drying units were built in the communities, to produce high quality *charque*. Once the abattoir was opened, it was also possible to collect data on the slaughtered animals, and monitor the effect of the actions taken to reduce the incidence of sarcocistiosis, by controlling the incidence of infestation in the dogs (periodic deworming) and by strategic grazing strategies. Between 1997 and 2000, sarcocystiosis in animals older than 2 years has been reduced from 90% to 54%. Thanks to these efforts, good quality fresh and dried meat is now sold in the established meat stores, and the producers fetch a better price. In the year 2000, ARPROCA was able to sell 35,687 kg of fresh meat and 480 kg of charque in local and regional markets. Likewise, a network of 12 veterinary community animal health workers has been trained to provide basic veterinary help to the families in the ARPROCA area. This has made it possible for families to increase the weight of their animals. The family income for each llama sold has increased by US$ 9.65 per adult animal and US$ 8.76 per young animal, between 1997 and 2000.

Llama wool and its market

Some llamas have high quality wool similar to alpacas. In the area of Calientes, a breeding programme for the genetic improvement of llamas was started in coordination with the Universities of San Simón, Bolivia, and Hohenheim in Germany. Groups of llamas were selected according to their wool or meat producing qualities, and three breeding centres of the ARPROCA now stimulate controlled breeding in the family herds , for either meat or wool production.

In December 1997, 23 people from 14 different communities belonging to ARPOCA were trained in classification, selection and spinning of the wool, and the weaving of carpets and fabrics. Currently, the crafts centre in Huachacalla employs 8 women and one man. The annual production of this centre is eight carpets of 3 x 2 m., 48 rugs, 200 m of woven cloth, 24 sweaters and 12 ponchos. Private companies, such as SARTAWI, COPROCA and LLAMACTIVA, pay the llama breeding families a good price for the wool as they have found international markets for these products.

Not marginal anymore

Thanks to these new possibilities in management and markets, the breeding of llamas in these areas has ceased to be a marginal activity. The families are now trying to increase the size of their llama herds, not only for cultural and ecological reasons, but also for the socio-economic advantages. Don Pánfilo explains: *"Earlier, it was difficult. Each year I could sell some 20 llamas of different ages at the fair. Each llama gave us about 30 kg of meat, 5 bolivianos per kg. Sometimes they didn't want to take it because of the arrocillo* (Sarcocistiosis)*. With the money I would buy groceries and bread to take home. I didn't sell the wool or the leather, because there weren't any buyers. Now, fortunately, the situation has changed. There is less arrocillo, the llamas are heavier and we can sell the meat at a better price. Also LLAMACTIVA buys our wool at a good price to export it to Peru. They also buy our leather as they have also found a market for this product. With all this we are certainly better off now than before!"*

The Cuban experience in integrated crop-livestock-tree farming

Fernando Funes-Monzote and Marta Monzote

For nearly 25 years agriculture in Cuba strongly depended on trade with socialist countries in Europe and the Far East. A few export products (sugar cane, citrus, coffee and tobacco) were exchanged for, among others, modern inputs to sustain the farming and ranching activities.

In 1990, this advantageous trading system collapsed. As trade was blocked also with the USA and other Western countries, import of inputs was not possible anymore. The ensuing economic crisis demonstrated the vulnerability of agriculture strongly dependent on imported external inputs. But agriculture in Cuba proved to be unsustainable, also due to the ecological and environmental problems it had created: soil degradation, deforestation, water pollution and loss of biological diversity.

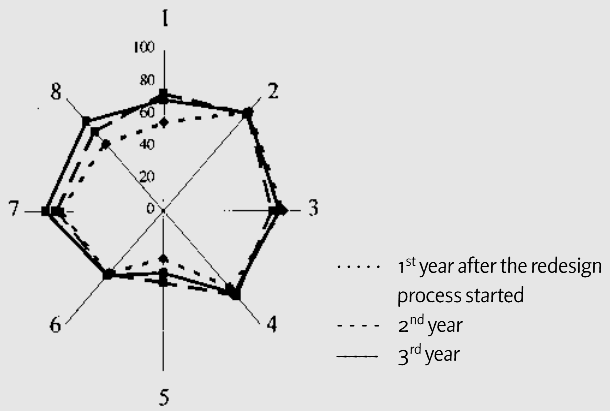

Figure 1. Evaluation of a farm through weighted indicators (% satisfaction) represented in a spider web

The challenge to transform agriculture

This crisis challenged Cuban farmers and the government to transform their export-oriented, large-scale, specialised production systems into diversified, integrated, self-sufficient, small-scale systems. Agricultural research started to experiment, among others, with local cattle and the development of integrated systems and management practices, and more sustainable feeding methods. Conversion of ranching systems into integrated crop-livestock-tree systems to reverse the economic and environmental crisis and to provide income and food security for producers was the focus, with efficiency as a key factor for success.

In 1994, the Cuban Grass and Forage Research Institute started a project to study, develop and promote integrated small and medium-scale crop-livestock-tree systems. The work included research on 14 experimental farms and a large outreach programme in the provinces of Havana, Sancti Spiritus, Camaguey and Las Tunas based on participatory extension for spreading the lessons (Monzote and Funes-Monzote, 2000).

Six years later, the project has shown that integrated crop-livestock-tree systems can be sustainable, efficient and productive alternatives to specialised, external-input dependent dairy farming. Researchers and farmers show that combining the components into a consistent whole brings better results in terms of total production, energy efficiency, recycling of organic matter and the use of available natural resources.

The experimental farms

The project converted 14 ranches into integrated farms. These farms cover a wide range of soils (alfisoles, mollisoles and inseptisoles) and climates (1000 to 1400 mm rainfall, nearly 80% during the rainy season). These rainfed farms, ranging from 1 to 20 ha. in size, had not used agrochemicals or imported animal feed in the four years before the project began. Eight of them were specialised ranching systems dedicated to pasture and milk production.

Each experimental integrated farm has its own unique combination of crops, livestock and trees (with 25 to 50% of crops integrated in the livestock system) which suits the local conditions: soils, topography, climate, natural vegetation, wildlife and farmer preference. Each farm has a crop production sub-system (areas of arable crops, perennial crops and vegetable garden) and an animal production sub-system (forest ranch land, pastures with a mixture of gramineous and leguminous species, fodder banks with e.g. Pennisetum, sugar cane, protein banks with leguminous fodder crops and trees such as glycine, kudzu, leucaena, and areas for small animals). Medicinal plants and fruit trees are distributed throughout the farms.

Each farm manager defined the process of redesigning the farm. Self-sufficiency in food, fodder and organic fertilisers, high production of biomass, diversification and integration were the leading principles. Strategies like the use of crop residues for animal feeding, functional biodiversity, reforestation of grazing areas, recycling of manure, composting of organic waste, soil regeneration and conservation were followed.

Table 1. Scores of the sustainability indicators in the experimental farms

Indicator	Range*
1 Milk production (tons/hectare)	1-3
2 Food production (tons/hectare)	1.9-6.1
3 Reforestation level (number of trees/hectare)	53-277
4 Diversity of wildlife (total number of species)	46-78
5 Food products (Number of edible products)	11-20
6 Production of organic fertilisers (tons/hectare)	1-2.8
7 Intensity of work (hours/day/hectare)	0.8-4.5
8 Energy efficiency (calories produced / calories invested)	4.5-10.6

* as a mean result of the 14 farms during six years

Evaluation of performance

Spider web diagrams (figure 1) were used to show the results of a large number of tests used to interpret the performance of the farms. Eight agroecological indicators were selected to evaluate the performance and sustainability of the integrated crop-livestock-tree systems. In milk specialised systems in Cuba the average yield is about 1 to 1.5 tons of milk per ha. Some of the integrated farms achieved 3 tons of milk and 6.1 tons in terms of total food production from crop and livestock (Tabel 1).

Diversification of production

The biodiversity in the redesigned farms had increased considerably in the three years. The number of trees per hectare had increased by 26 – 50% a year and the average number of food crops had increased from 14 to 17 to 20. The total biodiversity of wildlife had increased from 46 to 78 species per hectare, in addition to the increase in the diversity of soil life.

Reforestation is an essential activity in the transformation to integrated systems. But securing the survival of planted tress is a complex task on farms with livestock. Therefore, for each sub-system several strategies (see Table 2) were defined:

Table 2. Reforestation strategies

Reforestation	
Crop production sub-system	**Animal production sub-system**
• Around the fields • Within the cropping land (in strips)	• Within the pastureland (with protection) • Forest patches (segregation) • Fences (hedges) • Use of species that are not palatable for cattle

Organic fertilisers

A crucial question is where to obtain the organic matter and nutrients. One option is to import them from another farm, which is usually the case in market-oriented organic production.
The other option is to produce them on-farm. In this respect, Jeavons (1991) dismisses the former and stresses that organic fertilisers must be produced on the farm itself, recycling nutrients and maintaining the fertility of the soil by proper management. In balancing nutrient flows, long-term, nutrient losses by soil erosion, leaching, etc. have to be minimised and export of nutrients to the market has to be compensated by import of nutrients, e.g. as fertiliser or feed. The advantage of having cattle is that they produce considerable quantities of manure, which makes recycling of nutrients and organic matter easier.

The evaluation showed that it is possible to produce enough good quality organic fertiliser from the by-products available in the farms to fertilise both the ranch and crop areas at a rate of 2 - 6 tons per ha., depending on the design of the farm.
In addition, worm humus is produced in smaller quantities and green manure crops at a large scale. In this way the degraded soils are being regenerated into biologically active and nutrient-rich soils. Nevertheless, there may be a nett outflow of nutrients, which has to be compensated for on the long-term.

Multiple cropping

Designs for multiple cropping systems were made that are well adapted to the local conditions and with crops commonly used in Cuba: cassava, beans, groundnuts, soy beans, sesame, maize, sorghum, squash, melon, tomatoes, cucumbers and *vigna, mucuna* and *canavalia* etc. (as green manure) (see Figure 2). These systems resulted in high land use rates (LUR), proving the vast potential of multiple cropping for intensive land use.

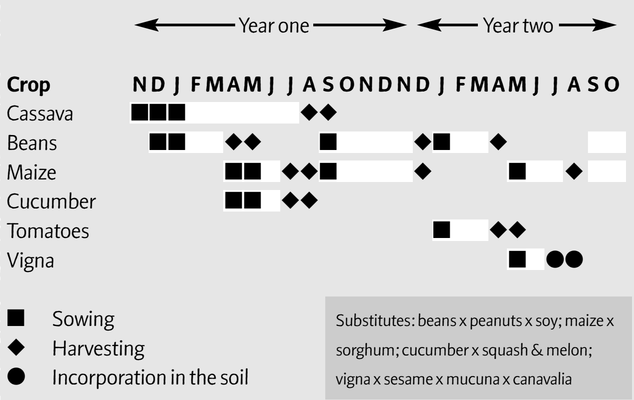

Figure 2. Sequence of rain-fed crops for 2 years

Biomass production and energy efficiency

The evaluation revealed the high productivity of these farms. The total biomass production was 3-9 tons of dry matter/hectare/year, of which 1-3 tons/hectare/year relates to the livestock system and the rest to crops, which corresponds with 3,000 - 10,000 Mcal/hectare of protein. The number of persons that can live from each farm varied from 4 - 10 persons and the sources of protein and energy are diverse (see Table 3). This shows the potential of integrated farms to produce a complete diet, food security for the family and a market surplus.

The energy balance of 4 - 10 calories produced for each calorie invested, shows the biological benefit and efficiency of these systems. In conventional livestock systems applied in Cuba during the '70s and '80s, this is normally in the order of 5 calories invested for 1 calorie produced (Funes-Monzote, 1998).

Table 3. Number of persons sustained on the monitored farms

Indicators	Range*
• People fed per hectare	4-10
• Sources of energy	4-9
• Sources of vegetal protein	3-10
• Sources of animal protein	5-12

* as a mean result of the 14 farms during six years

Final comments

This study showed the high potential in terms of production, sustainability and environmental care of integrated crop-livestock-tree farming built on agroecological principles.
The practical evaluation methodology based on selected sustainability indicators is appropriate for further defining of strategies, planning and research. The redesigned farms attracted a lot of attention from farmers, technicians, researchers and teachers; they provided training opportunities and led to the adoption of the approach by other farmers.

The agroecological concepts stimulate the creativity and enthusiasm of farmers, which leads to better decision making and performance of the farm. By incorporating crops and trees in their farming system, ranchers can become self-sufficient in food products and increase the amount of by-products available for animal feed and income. Recycling of manure, green manure crops and trees help to take care of the environment, whilst adding value to the production unit.

Promotion of crop-livestock-tree integration is important to change the farming mentality and to develop more efficient production practices based on the optimal use of locally-available resources and a fair and sustainable balance between nature and human beings.

Adaptation of the zero grazing concept by Luo farmers in Kenya

Nelson A.R. Mango

The National Dairy Development Project (NDDP) of Kenya was implemented by the Kenyan and Dutch governments with the main aim of increasing milk production for the market. In 1979, the NDDP introduced a dairy farm concept based on *zero grazing* (ZG) which involves confining of dairy cattle in a stall and the development of a cut and carry fodder system. When the project ended in 1999, it had covered a total of 25 districts throughout the country and over 10,000 farmers were involved in either ZG or semi -ZG dairy farming. Many of the Luo farmers of Siaya district embraced the project as they were attracted to the additional benefit of ZG, namely replenishment of soil fertility for crop production. However, they introduced a number of adaptations to the ZG concept to fit their needs and opportunities. The ZG concept and the adaptations made are discussed below.

Farmers saw many possibilities in the "zero grazing" approach. Photo: Willem van Weperen

The zero grazing concept

The research component of NDDP produced a technology package that aimed at addressing the constraints of smallholder dairy farming in Kenya: lack of grazing land, low productivity of dairy cows, low quality of fodder, prevalence of diseases and lack of financial means (Valk, 1990; Muma 1994). The package consists of several components:

Housing (the zero-grazing unit): Fig.1 shows the floor plan of a ZG unit building as proposed by the NDDP. In the ZG system, the cows are kept inside all year round to prevent tick-borne diseases and other health hazards.

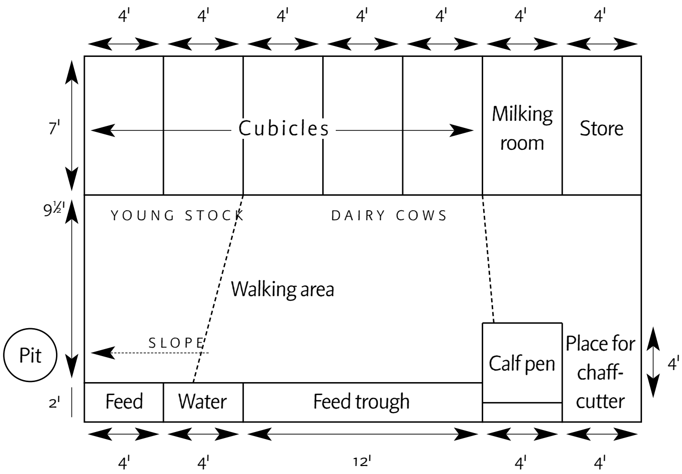

Fig.1 Floor plan of zero grazing unit

The introduction of improved dairy cattle breeds. The NDDP recommended that farmers stock their units with high milk yielding graded dairy cows. Graded cows, in this case, were not pure breeds, but animals with more than 50% 'exotic blood'. Exotics used for obtaining graded cattle were Jersey, Ayrshire, Guernsey, Friesian and Sahiwal.

Breeding and fertility: Farmers were advised to maintain the dairy breeds by upgrading their stock through artificial insemination using semen from a dairy bull.

The production of high-yielding fodder on-farm. In a ZG system all feed is brought to the animals, as they are not allowed to graze outside. Napier grass is the main fodder crop that the project recommended to the farmers. Its re-growth after cutting is rapid and establishment is relatively easy.

Utilisation of farmyard manure and artificial fertilisers to maintain soil fertility. To replenish soil fertility, NDDP recommended that farmers return all manure to the napier plot every 2 to 3 days. Farmers were also advised to apply 4 bags (@ 50 kg) of compound NPK fertiliser (20-10-10) per acre per year.

Feeding: The project advised the farmers to plant 0.75 - 1 acre of napier grass per mature cow and her offspring, and to cut it when approximately 60-90 cm long. Commercial dairy meal was to be given as the main protein concentrate supplement to the cows at milking time, the quantity depending on the production of the cow. Mineral salt lick was to be offered to the animals *ad lib* in the mineral box.

Introduction of the ZG concept to Luo farmers

Initially, dairy production with graded cows was developed in Kenya on large-scale European farms during the colonial period. Since the 1950s, it spread to African smallholdings as well. In Siaya, the first graded cows arrived in the early '50s. But, being settled pastoralists, the Luo people still highly valued its own breed of African Zebu cattle, which played an important cultural role, for example in wedding and funeral ceremonies. Free ranging animals were essential in providing manure for crop production. By bringing in nutrients and organic matter from a wider area to the cropped fields, soil fertility can be replenished. Being more expensive and needing more care, graded dairy cattle could not be used to perform these functions. As such, the Luo people did not accept these animals.

When the NDDP was launched in Siaya in 1987, farmers were actively seeking solutions for the problems they were facing: reduced land sizes, low incomes, loss of soil fertility leading to poor crop yields and market failures of cash crops like coffee, cotton and sugar. Some innovative farmers had already started with ZG, particularly after seeing its benefits in the neighbouring districts where it had been introduced much earlier. The Luo people were getting more integrated into the money economy and cash crop production. Their ceremonies were changing as well as their opinion about graded cows. Now, most farmers have adopted the ZG concept, because they were able to adapt it to their needs and opportunities.

Production of napier grass

Most ZG dairy farmers have an average of 2 to 3 cows, 1 or 2 heifers and 1 calf. Some have a young or full grown bull. The majority of farmers have only 0.4-0.6 acres of napier per cow and her offspring. Farmers do not find this a problem as they always supplement napier grass with crop residues such as maize stalks, sweet potato vines, banana leaves and stems, and molasses.

During times of scarcity, farmers are forced to feed the African Zebu cattle on the napier grass as well. This lowers the amount of napier grass that is available for the dairy cows. Then they harvest the napier grass even below 60cm in height. During times of plenty (wet seasons), the napier grass is allowed to overgrow as a lot of labour is required in the other areas of the farm. Farmers then cut napier grass only to feed the high-grade dairy cattle and not the African Zebu.

Replacing commercial concentrates

Most farmers use commercial dairy meal. They feed dairy meal to the cows at milking time at a rate of 2 kg per day or depending on productivity. Some farmers reduce this rate of dairy meal provision due to the availability of ample roughage. Several farmers in the district have come up with ‘home-mix’ dairy meal. Farmers who use this home-mix state that they get twice as much milk for the same amount of commercial dairy meal, which is sometimes adulterated with sawdust. A typical composition of a 100 kg of home-mix dairy meal is 40 kg sunflower cake, 40 kg maize grain, 10 kg sorghum, 5 kg soya beans and 5 kg dried cassava chips. The mixture is dried and milled.

Some farmers have embarked on using brewer’s waste (*machicha*) as a protein supplement. Farmers get their brewer’s waste from Kenya Brewers Limited some 40 km from Kisumu town. They find brewer’s waste cheap to buy even though its transportation is costly. Farmers mention that the use of brewer’s waste as a feeding supplement, *ad lib,* increases the milk production by 7 litres per day.

Other additional sources of protein are fodder legumes. Some farmers grow their napier grass mixed with *Desmodium spp.*. Apart from increasing the protein content of the feed, it also fixes nitrogen in the soil. Also, fodder trees like *Leucaena spp., Calliandra spp.,* and *Sesbania spp.*, are used to increase the protein content of the diet.

Use of manure and artificial fertilisers

Most farmers in Siaya do not apply fertiliser to their napier. Those who do, apply an average of 39 kg per acre per growing season instead of the recommended 100 kg. Figures on the amount of manure that is returned to the napier plot in Siaya are also much below the recommended amounts. A bag of fertiliser is quite an investment, which most farmers prefer to use on cash crops, food crops or vegetable crops instead of on the napier grass. Fertilisers are also not readily available everywhere in the district. There is an apparent competition for manure between the napier grass and cash crops, especially vegetables. Farmers with sufficient manure from their ZG units have expanded farming by growing high-value crops like vegetables (kale, cabbage and onions). Some farmers prefer applying the manure to their maize crops.

Farmer innovation in napier production

A group of farmers are now using a new method to grow napier known as *tumbukisa*. This method is a response to the high labour input required by the normal method of growing napier recommended by the NDDP at a spacing of 3 feet by 2 feet. With *tumbukisa*, farmers dig holes of 3 feet by 3 feet and 4 feet deep; they mix the topsoil with three wheelbarrows of compost manure from the dairy unit and use the mixture to fill the hole. About 10 cane sets are planted on top of the filled hole in a concentric manner. Top dressing with slurry is done every six months instead of 2 to 3 days. This method is labour intensive to establish, but requires far less labour to maintain as slurry application in only done twice a year. Since the holes are spaced 2 feet apart, some farmers plant sweet potatoes in between.

As applying slurry to the napier plots manually is labour intensive, some farmers have constructed furrow channels, that take the slurry by gravity from the unit into the napier plots, maize and vegetable fields. Some farmers just remove the dung manually from the unit and heap it somewhere to decompose and form farmyard manure.

Conclusion

Some farmers in Siaya adopted ZG with the aim of commercialising milk production. As a result of the project, they set up the Yala Dairy Co-operative Society for marketing their milk. The society also advances credit to its members to expand dairy farming. These farmers see ZG as an alternative to coffee, sugar and cotton that are now less successful in the area. ZG provides them another way to generate money for household requirements and to pay for their children’s education.

Farmers accepted the “zero grazing” approach but only after adapting it to their own situation. Photo: Willem van Weperen

Others adopted ZG in the first place to obtain manure for crop production. By buying nutrients as feed (napier grass, concentrates or other sources of protein) from outside the farm, the losses of nutrients due to soil erosion and export of products to the market, can be compensated. ZG makes it possible to still keep cattle where land is scarce. These farmers see ZG as a way of re-establishing the balance between livestock and crop production, which was largely lost due to reduction in the numbers of African Zebu cattle.

What happens when the river runs dry?

Viengsavanh Phimphachanhvongsod, Peter Horne and Werner Stür

Lao people say, "*When the river is in flood, the fish eat the ants. When the river runs dry, the ants eat the fish*". For many of the 80% of the Lao population who are rural, this saying encapsulates their deep connection with seasonal change and cycles of shortage and surplus. Shifting cultivation, the dominant farming system in the northern mountainous regions of Laos, is susceptible to the vagaries of climate, soils and steep slopes. In Xieng Khouang province, for example, where shifting cultivation is widespread, upland rice yields are among the lowest in the country (<1.2 t/ha), the average household size (6.5 – 8.1) is the highest in the country, female literacy rates are among the lowest in the country and 6 of the 7 districts have nett negative food balances (Sisouphanthong and Taillard, 2000).

The most pressing problem facing farmers in these areas is declining rice yields, due largely to declining soil fertility and increasing weed problems. Both of these are the result of shorter fallow periods (which averaged 12 years in 1981-2 but have fallen as low as 3-4 years in the more-intensively farmed areas). In the recent past, farmers were able to overcome occasional disasters in their rice crops by gathering forest products and hunting wild animals for home consumption and sale. These coping mechanisms have, however, rapidly diminished in the last 20 years, resulting in newly emerging poverty.

So, how do farmers cope with this increasingly vulnerable farming system? Many strategies are emerging depending on local and household opportunities. Some are robust strategies and are likely to persist, such as diversifying farm activities to reduce reliance on upland rice and concentrating labour and manure on the smaller areas of more fertile fields. Other strategies are short-term coping mechanisms that have developed in the absence of better alternatives, such as selling labour and growing cash crops in the hope that traders will come to buy them. But, the most widespread strategy, which is becoming increasingly important, is to raise animals. Livestock are the easiest way for most upland farmers to accumulate capital, (delivering a high return per unit of labour input) and they can be sold in a market environment where there is constant demand and stable prices (unlike most crops). Typically, the better-off farmers will have 5-10 cattle and buffalo whereas nearly all farmers raise small animals (chickens, pigs, ducks or goats).

The link between livestock and reducing poverty

A study by the State Planning Committee (SPC) in 2001 asked farmers across Laos to define poverty, identify its causes and prioritise the ways they would like to overcome poverty. Livestock emerged as the primary indicator of wealth, livestock disease ranked second as a cause of poverty, and livestock acquisition ranked second as a solution to poverty. This was particularly so among the ethnic groups which inhabit the remote mountain areas. Among the poor, women were, on average, worse off than men. The raising of small livestock is typically women's work. At certain times of the year (especially at the start of the wet season) they spend 30-50% of their working time collecting feed for pigs. These small animals are particularly susceptible to catastrophic disease epidemics and, when disease strikes, "the loss to the family is every bit as traumatic as the collapse of a bank in which all of one's savings were held".

The need for new options in smallholder livestock production

The strong emphasis placed by smallholder farmers on livestock as a "stepping-stone" out of poverty has encouraged government and non-government organisations throughout the country to work on improving smallholder livestock systems. In an earlier article in LEISA Magazine (Vol.16, No.3, pp.26-27) we described research that is being done with farmers in the northern mountainous regions of Laos to identify forages (both grasses and legumes) that can help minimise some of the livestock feeding problems. In this first year, working with 222 farmers in 18 villages, the most promising forage technologies that have emerged are those which:

- help farmers overcome seasonal feed shortages (such as the grass *Panicum maximum* "*Simuang*" for cut-and-carry feeding of cattle and buffalo when they are sick, working or penned)
- help reduce labour requirements in looking after animals (such as the legume *Stylosanthes guianensis* CIAT184 which can be grown near pens as a source of high quality feed for pigs) and,
- can provide feed at particular times of year when traditional feed resources are in short supply (such as *Brachiaria brizantha* "*Marandu*" for providing green feed to cattle and buffalo in the dry season)

The most promising varieties for Southeast Asia and their potential impacts on smallholder farmers (based on field experiences of over 5 years) have been described in two books that are available in English and five regional languages (Horne and Stür, 1999, Stür and Horne, in press).

Forages will, however, only ever be one component of livestock feed resources and, especially for small animals, new supplementary feed resources are needed. To provide an energy source for their pigs, for example, Hmong women in the remote district of Nonghet grow maize. They have two traditional varieties but neither satisfies their needs. We are now expanding our work in partnership with such farmers to evaluate and develop other feed resources (especially new legume, maize and sweet potato varieties) to help them diversify their livestock feed resource base.

In the study by SPC about 70% of the villages surveyed identified livestock disease as an urgent and high priority problem. Epidemic diseases (particularly fowl cholera and Newcastle disease in chicken, swine fever in pigs and the parasite *Toxocara vitulorum* in buffalo calves) can cause annual losses of 80% or more. *Haemorrhagic septicaemia* results in occasional major losses of cattle. Two complementary approaches are being developed to deal with these disease problems. The first is to build a national network of Village Veterinary Workers who are linked to district offices, which can supply them with veterinary medicines. This is a strategy that will have longer-term impacts but is dependent on the development of a supply chain that can deliver good-quality vaccines and veterinary chemicals to remote areas. In the shorter term, some organisations are working with farmers to develop livestock management and simple medication strategies that do not eradicate these diseases but limit the impact.

Where is this leading?

Working with upland farmers in Laos to improve livestock health, feeding and management strategies is likely to have major positive impacts on poverty in the short to medium term. Research and development like this is not, however, an "end-game" in which a solution is developed for a problem and that's the end of the story. For every solution there are new opportunities, problems and issues. In 25 years time, many farmers we are working with now may no longer keep livestock, but they have used livestock to build capital to allow them to take the risk of moving into new enterprises. The key to sustainable development in this context is the mentoring of groups of people at community, district and province-level who have the experience, skills, confidence and mandate to work together to resolve new problems (or take advantage of new opportunities) as they arise. In this sense, the **process** of research and development is as important as the technologies that are developed.

It is common for district officers to make trips to villages only when they are asked to collect data or when there is a technology package to be 'extended', often through the development of model farms. These unrelated village visits and the lack of adoption of 'tech-packs' by farmers develops an expectation among district officers that 'we cannot make a difference'. The general trend towards genuine participatory research that is happening throughout the world offers an alternative that empowers district officers to see that they **can** make a difference. We are assisting four districts in Laos to implement a new process in which the district officers, their institutions and farmers work through a series of steps in an annual process to find solutions to their livestock problems and capitalise on emerging opportunities (see Figure 1). Details of each step in the process are described in more detail in a book that will be published later this year (Horne and Stür, in prep). The key to the process is to encourage district officers to experiment and adapt the approaches to suit their needs. Working with farmers as active partners will be a learning experience for all concerned.

So what happens when "the river runs dry"? Poverty in Laos is not endemic and not generally synonymous with hunger, but farmers are susceptible to an increasingly risky environment. Livestock are an important insurance against calamity when "the river runs dry". Developing new technical options with farmers in a process that builds linkages and confidence between farmers and development workers is helping to build resilience into their farming systems.

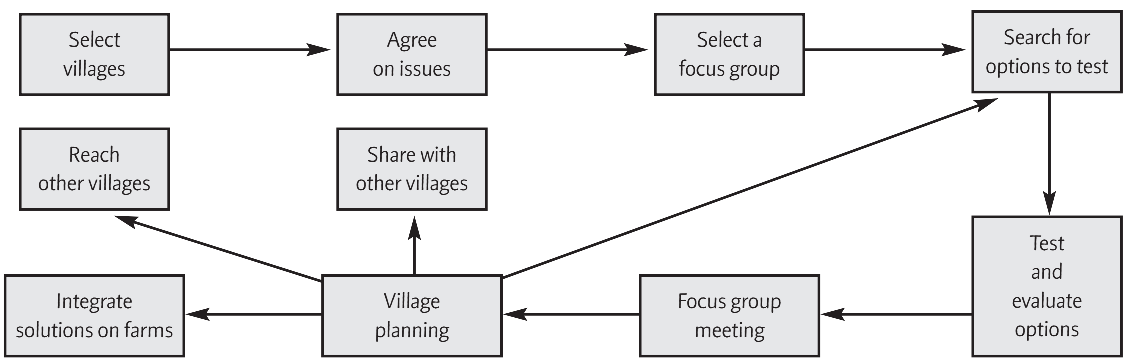
Figure 1: The process of finding solutions to livestock problems



The drawing provides an overview of the different components of an integrated system as developed by CIPAV.

Integrated systems: the experiences from CIPAV in Colombia

Enrique Murgueitio

In Colombia, inefficient extensive cattle ranching by 10% rich farmers occupies 40 million ha, 90% of agricultural lands. The 90% poor subsistence farmers have access only to about 10% of the land and must produce in an increasingly intensive way. Farming units smaller than 20 ha cover only 13% of the land but comprise 74% of farms. Permanent crops such as coffee, oil palm and sugar cane occupy 3 million ha and short-cycle crops, mainly cereals and tubers, around 2 million ha.

Since 1986, the Centre for Research on Sustainable Farming Systems (CIPAV) has worked in the south-west of Colombia, conducting participatory research studies with peasant farmers and entrepreneurial producers on different aspects of integrated systems. In recognition of the development and implementation of these systems in the humid rural areas of Colombia, CIPAV was awarded the ecological prize "Blue Planet Award" in 1995. Presently, much of the progress made in generating, validating and applying new know-how regarding these systems has been concentrated on issues such as agroforestry and silvopastoral systems, environmental adaptation of livestock, management of micro watersheds, water decontamination and production of healthy food products. In this article the author provides an outline of the basic models.

The basic components of the peasant systems

The small-scale integrated systems that have been developed with peasant farmers use highly productive annual crops, multipurpose trees and water plants as sources of biomass to provide feed for cattle and other animal species, food and fuel. The systems consist of several subsystems that can be introduced separately or as an integrated farm. These subsystems are: biomass production (crops), ruminants, monogastrics (poultry, fish, earthworms), water decontamination and biogas (see Figure p.26). This basic model is developed for small-scale farms but has been adapted to large-scale as well.

The system can be either based on a crop or on residues and by-products of processed tropical crops. Sugar cane planted at high density, oil palm, coconut palm, plantain, banana or cassava are a few examples of crops that can be used. In the case of sugar cane, the juice is fed as a complete replacement of cereals to pigs and ducks and supplemented with fresh water fern *Azolla filiculoides* and whole soybean grain. Local fodder tree species like *Gliricidia sepium, Trichanthera gigantea, Erythrina fusca, Erythrina peoppigiana, Erythrina edulis, Thitonia diversifolia, Morus alba, Leucaena leucocephala, Moringa oleifera, Cnidoscolus aconitifolius* or *Guazuma ulmifolia* are used depending on which adapts better to the local conditions. The tree foliage is harvested and the leaves are used as a source of protein to supplement sugar cane tops for feeding cattle. Trees are also used as sources of fruits, shade and nitrogen. Animals are partially stall-kept, allowing for easy recycling of their excreta by vermicomposting or through a biogas digester to provide fuel. Biodigesters are part of the treatment for decontamination of waste water from washing animal enclosures and coffee beans. The productivity of these intensive integrated farming systems is 3 - 10 times higher than of traditional farming systems. The system can be implemented gradually at a pace convenient for each farmer. Few farmers set up the whole system at once. Resources required are mainly manpower, manure and plants.

The "Productive Decontamination" subsystem

This subsystem consists of a plastic-bag biodigester of *continuous flow* (water and organic residues enter and escape continually at a constant rate), aquatic plant channels, fishponds and associated crops. Waste water goes into the biodigester to produce biogas from organic waste. The effluent is directed through zigzag channels with aquatic plants where suspended solids, phosphorus, nitrogen and heavy metals are removed by bacteria and the plant root systems. The channels have different species of plants that vary in their degree of efficiency to decontaminate (*Azolla filiculoides, Azolla sp., Lemna minor, Eichornia crassipes, Salvinia natans*). Aquatic plants and sediments from the channels are used to fertilise forage and fruit crops. Finally, the water can also be sent into a fishpond where plankton utilises the remaining minerals in the water to produce biomass to feed fish. Fish are produced in a system of multiple association of species (*Prochidolus reticulatus, Cyprinus carpio* and *Colossoma macropomum*). Pressed stalk and stems are also used as fuel. In this integrated system waste products are minimised and the local resources are efficiently used. Fuel production is an added benefit for the family and the environment. In small farming units biogas is used for cooking while entrepreneurial farms use it for warming piglets or generating electrical power in internal combustion engines.

Components of the commercial systems

In the larger-scale commercial systems, the biomass subsystem is divided into four components (sugar cane, silvopasture, grassland and aquatic plants). The cattle are of a dual-purpose type for both milk and meat production. The silvopastoral subsystem consists of grass (*Cynodon nlemfuensis, Panicum maximum* or any other Gramineae), associated with a legume tree like *Leucaena leucocephala* or *Erythrina fusca* (10,000 or more plants/ha). Grazing on these pastures allows the animals to freely browse on the fodder trees, which regenerate naturally. Grazing is rotational and pastures are fertilised with manure and effluent from the biodigester. Calves are kept under a restricted suckling regime supplemented with sugar cane tops, grass, urea-molasses blocks and a mixture of tree foliage and palm oil. Commercial feed has been completely replaced with excellent biological results. These systems eliminate the costs of nitrogen fertilisation, allow an increase in the number of animals per unit area up to 5 animals/ha (national average: 0.5/ha) and increase milk production above 12,000 l/yr. Given the fact that the system is environmentally friendly and highly productive, some areas of land can be freed for conservation.

Diversification in the use of sugar cane has resulted in the production of certified organic *panela* (dark sugar loafs) for export using animal manure as fertiliser and substituting herbicides with hair sheep and manual weed control. Sugar cane has also been used in steer fattening (stalks and tops) combined with tree forages such as *Gliricidia sepium* planted in densities between 10,000 and 20,000 trees/ha.

In commercial swine production, water is decontaminated using biodigesters that allow 20-25% reduction in the cost of electric power by using a mixture of biogas and fossil fuel (diesel or gasoline) in internal combustion engines.

The use of tractors for low-weight cartage is restricted through the use of animal draught, mainly buffaloes and mules, with a 50% reduction in the cost of these activities and environmental (emission reduction) and social (employment generation) benefits, while maintaining efficiency.

The approach is spreading in the humid tropics

The CIPAV system is ideal for the humid tropics in Central and South America and Southeast Asia, where biomass production is not a limiting factor but conservation of natural resources and the environment is a priority. For the last 10 years these systems have been tested, adapted and adopted (either all or some of the components) by small farmers in different climatic conditions in Colombia. Currently this technology is being transferred and adapted to the Philippines, Cambodia, Vietnam, El Salvador, Barbados, Trinidad and Tobago under FAO assisted projects. ■

Native tree species for silvopastoral systems

Currently, CIPAV is working with local communities in the central and western Andes of Colombia on the integration of native tree species in silvopastoral systems. Two examples of research on such trees are:

1. Nacedero *Trichanthera gigantea*

This species, native to the northern Andes, is traditionally used by rural indigenous and small farmer communities in Colombia and Venezuela. Its main uses are related to its medicinal properties and to increasing spring water. The water-attracting capacity has been mentioned by different authors but has not yet been proved through formal scientific methods. Researchers from CIPAV learned from the farmers how to use this species as a fodder plant. Since then participatory research has allowed for considerable gain of knowledge related to this species. Some important products and results of this research are:

- Intensive cultivation in protein banks in more than 20 departments in Colombia and 12 countries in Central America, the Caribbean, Venezuela and Southeast Asia
- Fast asexual propagation techniques
- Germoplasm collection in Colombia and Venezuela
- Inclusion in most Andean micro-watershed reforestation projects in Colombia
- Commercial products for natural medicine

2. Arboloco *Montanoa quadrangularis*

This is a tree species from the Andes of Colombia and Venezuela that grows fast in unforested habitats. For more than a century this species has been used for construction of houses and buildings, animal enclosures, coffee-drying sheds, corrals, furniture, fences etc. Its white pith is used in handcrafts.

Work done by CIPAV with this tree relates mostly to phenology, regeneration, growth, rehabilitation of degraded pastures, plantations and agroforestry systems. Young farmers trained to conduct rigorous periodic observations participate as co-researchers. In less than 5 years and with a limited budget these studies have benefited small farmers and institutions in the form of:

- Guidelines for the restoration of deforested micro-watersheds
- Plantations for the rehabilitation of degraded pastures
- Low-cost technology for establishing habitat corridors, live fences and tree-lines for erosion control.

The results of these research programmes have been presented in the electronic conference on 'Agroforestry for animal production in Latin America' organised and run by FAO and CIPAV (see http://www.cipav.org.co).

Animals need shade trees to feel comfortable. Photo: Ana Primavesi

Optimising climate-soil-pasture-cattle interactions in Brazil

Ana Primavesi and Odo Primavesi

In nature, nothing functions in isolation; everything depends on the other factors present. In animal production, to optimise the performance of cattle, it is very important that management practices try to enhance the ecological functioning of the web of living organisms within the production system - climate, soil and soil life, vegetation and cattle - by influencing their interactions. In this article we look at some of these interactions and how, in Brazil, they can be optimised in an ecologically sound way.

Adapting pasture to the soil and cattle to the pasture

Cattle breeding is a very expensive activity when the breed is selected first, then the pasture suited to that breed and finally the soil is corrected with lime and fertiliser to make the pasture grow. This order has to be reversed. The pasture has to be adapted to the soil and the cattle to the pasture, and all of it has to fit the climate. In the tropical climatic zone, European breeds should be used only for crossbreeding with zebu cattle. It is not the most productive breed that will give the best performance, but the breed that adapts best to the existing ecological conditions, climate, soil and pasture.

Increasing water availability for plant growth

Forage yields depend strongly on the availability of water. Especially in the dry areas of Brazil, improving permeability and the storage capacity of the soil can increase water availability. Covering soils with vegetation and its residues allows for better infiltration of rain water, improves the soil structure, and thereby increases its air and water circulation and storage capacity necessary for plant metabolism and efficient plant nutrition. In a well-structured soil, roots are able to explore a larger soil volume for more water and nutrients. Plants can, therefore, develop better and faster and will be less affected by drought. Integrating deep-rooting crops and trees into the pasture system will further increase the production of biomass and the overall performance of the system.

Plants absorb water from the soil and transpire it. When the air is saturated with water vapour, plants cannot transpire any more. But when the wind carries it away, they absorb more water from the soil and transpire more water into the air, thus drying up the soil. In Brazil, in one year, wind can carry away an equivalent of 750 mm of the total rainwater. Planting of shrubs and trees as windbreaks can strongly reduce the transpiration of pastures and hence increase the available water for plant growth.

Enhancing micro-climate for comfort

When the surface temperature of tropical soils is higher than 33° C, plants cannot absorb water and nutrients any more. Deep rooting trees can act as air humidity and temperature regulators, pumping water from the subsoil, and releasing it through transpiration. Therefore the shade of trees is cooler than for example, the shade of a dry leaf roof.

An animal is not a machine into which forage is put in and milk and meat comes out. It is a living being that needs to be comfortable to produce well. Shade trees provide comfort to cattle. In the colder season it is 3 to 4° C warmer under the trees and in the hot season it is 3 to 4° C cooler. Pastures with at least 50 shade trees/ha allow a yield increase of 15 to 30% milk and around 20% meat. It is not only the quantity of fodder quantity or the energy consumed or the digestibility of the forage that matters; it is also the comfort that makes cattle produce well.

In Brazil, there is an increasing tendency to establish wind shelters and small shade forests to avoid water losses by wind and to improve animal comfort. In extensive systems with *cerrado* (savannah) vegetation, the bushes and trees provide additional advantages, like the supply of forage and increase of biodiversity of forage species. This allows for better animal weight maintenance and even an increase, compared to monoculture grassland, also in the dry season. When new pastures are opened, with maintenance of bush and tree strips of the original "cerrado" vegetation, the grass grows faster and the productivity is higher, due to wind protection. *Embrapa Agrobiology*, the Brazilian research centre on agrobiology, near Rio de Janeiro, has developed an easy way to establish legume trees even on very degraded pastures, by inoculating the seedlings with *Rhizobia* and *Micorhizae* and adding a little phosphorus to the substrate. Organic matter production and accumulation in these soils is surprisingly fast. This works well as a pre-treatment for establishing forage plants

Grazing rotation instead of fire

The division of pastures into smaller sub-units for grazing rotation is fundamental to prevent grassland being destroyed by cattle. In native grassland, cattle always first eat the plants it likes most. The plants that are not eaten get old, hard and are not tasty. The eaten plants sprout again and are grazed on another time. This goes on until these palatable plants disappear. But the less appreciated plants continue to grow and multiply and with time the entire pasture gets hard, rough and has little nutritive value. Then the ranchers set fire to the pasture. Many plants die, and only those that can protect their growing points against fire survive. Thus the pasture becomes worse and the forage volume smaller. Eight consecutive years of burning, with one fire per year, is enough to decrease plant production to 25% of the initial. As only the hard, less palatable plants that cattle eat only when very tender are left, farmers burn the pastures up to five times per year. Thus all organic matter that nourishes soil micro-organisms is burned out, resulting in their death. The soil compacts, water runs off and the vegetation gets scantier.

All perennial plants need a rest period to recover the reserves in their roots, which are needed for re-sprouting. Forage plants and weeds recover their root reserves only when they bloom. Grasses need to bloom and form seeds once a year. This makes pastures more resistant to droughts and low temperatures and warrants vigorous re-sprouting. Ranchers say: "*rest for a pasture is as good as irrigation*". Forages cannot always be grazed when it is best for the cattle. Sometimes they have to rest to recover their forces. In Brazil, rotative grazing is getting more common under better-controlled conditions, using electrified fences, sometimes powered by solar energy.

Integrating leguminous forage plants

In Brazil, 70% of the pastures are of *Brachiaria (decumbens, brizantha* or *ruziziensis),* and 80% of the cattle are improved *Bos indicus,* this is zebu, mainly of the Nelore breed. *Brachiaria* is an African grass with very active *Micorrhizae* fungi on it roots which give it a high degree of adaptation, productivity and efficiency of phosphorus absorption and use. The main problem is that it is planted in monocultures. In more fertile soils, *Cynodon dactylon* cv. Coastcross and Tifton , and different cultivars of *Panicum maximum* (Tanzania, Tobiatan) and *Pennisetum purpureum* (Elephant grass) are used.

Grass-legume mixtures are rare because the tropical grasses are very aggressive when supplied with nitrogen. Pasture with soybean rotation is more common. After 3 to 4 years of *Brachiaria brizantha,* soybean is direct seeded into the desiccated pasture. The nitrogen input by soybean improves the growth of *Brachiaria* grass, allowing an increase of the stocking rate from the national mean of 0.5 Animal Units (AU)/ha up to 3 AU/ha. Nitrogen-fixing legume shrubs and trees like *Cajanus cajan* or *Leucaena leucocephala* and other fast growing species are introduced in semi-intensively managed pastures for protein rich forage.

Eliminate nutrient deficiencies

Tropical grasses have a very high biomass production potential, but need a good water and mineral supply. But cerrado soils, for example are acidic and poor, especially in calcium, magnesium, phosphorus and potassium. The major nitrogen sources are nitrogen-fixing leguminous plants, cattle manure and synthetic nitrogen fertilisers. Small doses of phosphorus (35 to 42 kg/ha P_2O_5) are needed to guarantee the development of forages. Phosphorous-deficient, decumbent grasses like *Brachiaria*, don't form stolons, have a shortened vegetative cycle, bloom early and produce little biomass.

Cattle also need phosphorus. Insufficient phosphorus in the pasture lowers milk and meat production and makes cows sick. It happens specially when pastures have old, dry forage, or when the soil is compacted by overgrazing and forage roots cannot penetrate the surface layer of the soil. It can be completely avoided by applying phosphate fertiliser or giving cattle mineral salts.

There also can be other nutrient deficiencies, which affect animal health, like that of calcium causing a kind of "grassland tetany". This can occur especially in *Brachiaria humidicula* pastures, but also in young, vigorously sprouting grasses or in very compacted soils.

Magnesium-deficient zebu cattle are very nervous and aggressive and the heifers do not develop well. Cobalt, extremely deficient in the Amazon region, is the mineral which is most lacking in Brazilian grassland. Young animals are meagre, gloomy, without appetite but gnawing at tree barks; they loose the hair from their tails and have a scrubby hide. In all cases mineral salts are very important to compensate for the mineral deficiencies and to keep the animals healthy.

Parasites and diseases

One of the biggest problems in tropical cattle breeding is parasites, mainly worms, ticks and bots. The horn fly becomes an increasing problem in flogs treated against parasites with injectable *Ivemectin*. This is because the beetle that eats the larvae of the fly in the cattle excrements is also killed. With rotational grazing and a pasture with 20-25 % legumes, the worm problem can be practically controlled. Tick attacks are mostly seen in European cattle that have a thinner hide. Zebu cattle are rarely affected. The problem of bots can be resolved by selecting the bot-resistant animals and selling the affected ones. Normally, "sweepers" (animals with no respect for fences, grazing anywhere) never have bots.

Towards "green meat" and "green milk"

To prevent 'global climate change' by 'greenhouse gases', it is important to reduce methane emission by cattle. This obliges farmers to speed up animal production per unit area and to reduce the slaughter age to get a lower ratio of kg methane/kg animal protein (meat). The use of grains for animal feed has to be reduced as well, giving priority to human consumption. This then increases the dependence on forage. But, as grass cellulose is the main source of methane emission, management practices that contribute to an increase of forage yield per unit area and maintain stocking rate without weight losses, all year long, are needed. Profitability, competitiveness and sustainability of the production system will be thus increased whilst reducing the negative impact on the environment.

Optimising livestock strategies in Bolivian mixed farming systems

Also for pigeons, there is a place on diversified Andean farms.
Photo: Katrien van 't Hooft

Katrien van 't Hooft

Most smallholders in rural Bolivian communities have developed mixed systems, in which the production of crops and the rearing of animals are combined with income-generating off-farm activities. The strategies vary a great deal from one family to another, and also within a family, depending on the time of the year, the age of the family members, or external circumstances. It has been calculated that 90% of rural families in central and south Bolivia earn more than 50% of their income through non-agrarian activities. (Jimenez Sardon, 1984)

Principle of diversification

The strategy used by rural families to counteract risks and optimise opportunities under changing and adverse circumstances is to diversify their activities. (Valdivia and Jetté, 1996). This principle of diversification also forms the basis of family-level livestock keeping in Bolivia, as in most parts of Latin America.

Each family has control over a couple of small plots of land, which are often on different ecological floors and from which they produce a variety of crops, thus minimising the considerable weather-related risks, and guaranteeing self-sufficiency for the family. The animals reared are poultry, guinea pigs, sheep, goats, pigs, cows, donkeys, llamas, alpacas and rabbits, and sometimes, depending on ecological circumstances, carp and bees. Women bear most of the responsibilities in animal care. Animals are an important part of the agricultural system and the culture of peasant families. Animal raising is embedded in Andean cultural values, such as solidarity and reciprocity, community organisation, and respect for *Pachamama* – or Mother Earth. Rural families perform, therefore, numerous rituals and festivals related to livestock throughout the agricultural cycle. The subject of livestock rearing by families is also closely connected to those of biodiversity, environment, gender, poverty and migration.

Livestock research and education

Despite massive investment in livestock research, the benefits to marginalised communities, where livestock is especially important to livelihoods has been very poor. In Latin America, as elsewhere, technologies were developed mainly for intensive and industrialised livestock production systems, assuming that the same technologies could be used to improve all livestock systems. This assumption turned out to be invalid. In fact, most modern technologies do not fit the reality of the low-input livestock system, while they have also enabled commercial producers to displace the smaller and less specialised producers.

Animal science as taught in Latin American universities and farming schools does not take into account the complexity of the context in which rural families rear livestock. Rather, attention is focused on reaching the maximum productivity per animal, limited to animal species used in industrialised livestock keeping, especially cattle, pigs and chicken. The absence of essential elements of family-level livestock keeping in the curriculum is reflected in the frequent failures of livestock projects.

Failure of livestock projects

Stimulating livestock keeping at family level is an objective of many livestock projects. It is at this level, though, that failures are most frequent and have harsh consequences. An analysis (Blackburn et al, 1992) of different livestock projects revealed that many were inadequately adapted to the social, economical and cultural reality of the families belonging to the target population. The projects intend to change the people's system of production, usually from a diversified low-input system to a specialised one, directed to a monetary market, without consideration of the social implications and risks that these actions pose to rural families. Many of these projects have not been preceded by a thorough analysis of the reality of the families, like their ways of seeing the world (or cosmovision), their survival strategies, the rationale behind their different productive systems, the role of animals within this reality and the way the families perceive projects. Moreover, a lot of information on the outcome of projects is shelved as work reviews, poorly accessible to students and other interested people. Thus, the same mistakes are repeated.

Two basic strategies

A wide array of livestock keeping strategies can be observed among rural families. Basic elements of these strategies are the use of various animal species, the flexibility to change from one species to the other, and the low-external-input nature of the management system. Most families base their livestock keeping on *diversified* husbandry practices: poultry and pigs scavenge around and do not require major labour or capital input, and *cuy* (guinea pig) are kept in the kitchen, fed on leftovers. Though there is high mortality amongst these animals, their output is produced against very low cost. In addition, one species, like for example milk cattle, may be managed under a more *specialised* system, requiring relatively high levels of capital and labour input, and depending on market sales. The logic behind this more 'specialised' livestock system is quite different to that of the 'diversified' livestock system.

Though all divisions are artificial and never reflect reality in all its complexity, we can use this division in the main strategies of family-level livestock keeping: diversified and more specialised management of animals (Table, next page). They have to be considered as the two extremes of a continuum, with many variations in between. It is helpful, however, to understand the basic idea and logic behind each of these livestock keeping systems, in order to find ways to optimise each of them.

Different ways for optimising

In general terms, under the conditions of diversified livestock keeping, it is not possible to increase profits by reducing the costs of production, because these costs are minimal. It is also not possible to aim for a major increase of productivity per animal, as that would require a large investment of cash and labour, which goes against the basic principle of this strategy. The

Table 1: Characteristics of the two basic livestock keeping strategies

CHARACTERISTICS	DIVERSIFIED LIVESTOCK KEEPING	SPECIALISED LIVESTOCK KEEPING
LABOUR	Mainly women and children - combined with migration	Usually the whole family, including men
RISK FOR FAMILY	Low, because of the different species used	High, dependence on (external) conditions related to one species
FUNCTION OF THE ANIMALS	Multiple: to be consumed by the family, to be sold, as a way of saving and reducing risks, to produce organic fertiliser and medicines, for cultural and spiritual reasons	Mainly for income generation
PRINCIPLES	The number of animals most important. Reduced investment and low output of traditional products (meat, milk, eggs, wool, fur), combined with the use of other products, like manure, bones, horns, blood, bladder.	Main focus on production level per animal. Large investment of money and labour to sell traditional products. Specialised keeping of one species is often combined with diversified keeping of other species.
MANAGEMENT	The animals are kept in many different ways. Temporary food shortages and disease risks are part of the system.	The animals are kept in a relatively uniform way, directed at optimal conditions throughout the year.
TYPE OF HEALTH CARE	Based on local practices and medicine (ethnoveterinary medicine), sometimes complemented with selected 'modern' practices. Veterinary care includes rituals and local practitioners.	Based on 'modern western' practices by field workers and veterinarians, complemented with selected ethnoveterinary practices of the owners. Limited consultation of local practitioners
FLEXIBILITY	High, it is easy so shift from one species to another	Low, due to high individual value of the animal and the specialised knowledge and network required

best way of optimising diversified livestock keeping, without veering away from its principles, is to *reduce the mortality rate* of the animals. Under normal circumstances, the mortality rate in diversified livestock keeping can vary from 40% to 80%. This is due to a variety of reasons, such as infectious diseases; theft, accidents and predators; food and water shortages; lack of shelter; internal and external parasites; lack of care during special moments such as parturition and disease; and inbreeding. The relative importance of each of these variables differs according to the animal species and the circumstances.

In more specialised livestock keeping the mortality rates are generally much lower than in diversified keeping, because of the extra attention given to feeding and care of the animals. The way to optimise specialised livestock keeping is by *reducing the costs of production* and *increasing the profit margin per animal*. This may imply, for example, improving feeding strategies throughout the year, or cross-breeding with exotic breeds. As this is also the basis of industrialised livestock keeping, plenty of documentation about these technologies is available. Stimulating the cooperation and organisation amongst families that produce a specific species can be a major starting point, to improve marketing and infrastructure, for example.

Niche for poverty alleviation

The measures taken to reduce the mortality rate in diversified livestock keeping should be based on the strategies, the practices and the knowledge of rural families, especially of women. These measures should be cheap and require little additional labour; the income earned in the short term as a result of these measures should be greater than the costs necessary to implement the change. Under these conditions, the measures can combine traditional practices with strategies of modern veterinary medicine, and include the training of community-based animal health workers.

Various projects have shown that it is indeed possible to reduce mortality rates under these circumstances, i.e. low-cost vaccinations against specific diseases such as Newcastle disease in chicken or hog cholera in pigs; protection of chicks from predators by confining them during the first 2-3 weeks of their lives; strategic parasite control in llamas and alpacas; selection and exchange of stock of indigenous breeds; and specific actions to counteract the worst effects of food shortages, such as supplying mineral salts and supporting traditional forms of feed supplements during the critical periods. Special attention and simple infrastructure during and after parturition, can drastically reduce the number of piglets crushed to death by the sow.

There is, however, a lack of knowledge generation, extension materials, research and education in this field, as most livestock development initiatives have aimed at changing the diversified systems into more specialised ones. Optimising the diversified system of family level livestock keeping within it's own context, and without changing the logic it is based on, is an under-utilised niche for poverty reduction. It implies a major challenge for projects, as well as for research and education in the livestock field.

The 'Livestock Revolution' and its impact on smallholders

Leah Garcés

Two-thirds of the world's livestock are found in 'developing' countries. Most farmers in these countries practise multiple-purpose, non-intensive methods of animal production. Animals are critical for their livelihoods, cultures and social status. Many of these animals graze areas not suitable for crops or scavenge freely, often consuming garbage and harmful insects. Small farms that combine livestock and crops use the land relatively sustainably: crop residues are fed to animals; manure provides good fertiliser and fuel; and animal draught power reduces the need for fossil fuels. Smallholder livestock production makes a substantial contribution to the economy.

In India, for example, livestock contributes about 30% of the total farm output, and 80% of livestock products come from small farmers with 3-5 animals and less than 2 ha of land (Rangnekar 2001). It is estimated that one-quarter of the world's total land area is being used for grazing livestock, including extensive grazing systems. A further one-fifth of the world's arable land is used for growing cereals to feed livestock. This makes livestock production the largest user of land in the world.

The 'Livestock Revolution'

But livestock production systems in these countries are changing fast, due to the so-called 'Livestock Revolution'. The global demand for meat is expected to more than double over the next twenty years, creating an increased demand for cereal feed. Southern countries are expected to become the main producers of meat and animal products for the rest of the world, with increasing dependency on imported grain. It is expected that there will be a shift from livestock being kept for multiple purposes and local food supply to animals being raised under factory farming conditions for export. Many small-scale farms will be out-competed and replaced by large-scale industrial farms (Delgado et al 1999).

This Livestock Revolution will provide new opportunities for agriculture in the South. But, who will benefit from it, what will be the cost to small farmers, food security, the environment, farm animal genetic diversity and farm animal welfare? Compassion in World Farming Trust (CWFT), a research-based farm animal welfare organisation that investigates the development of factory farming at an international level, recently studied the effects of the rise in factory farming on Southern countries, their farmers and farm animals (Gracés 2001; Cox and Varpama 2000). An overview of the results is given below.

Small farmers are loosing

The leading agencies working on hunger alleviation admit that rural small farmers are being pushed out of business by factory farming. Farmers in the UK, US and Europe have already experienced the painful consequences of the so-called 'vertical integration' of livestock production, in which specialised enterprises such as feedlot farms, animal feed traders, and meat packers, all merge under one giant company. This leaves very limited market opportunities for small, independent farmers, many of whom have been forced to leave the business altogether. According to the US Department of Agriculture, there were 5.7 million farms in the USA, in 1950. Today, the number has decreased to about 2 million farms.

This same pattern is quickly taking hold in Southern countries. Brazil's poultry industry is a good example. Between 1970 and 1991, Brazil's poultry industry grew from small backyard farmers to a multi-national mechanised industry, becoming almost entirely vertically integrated. Originally, small family farmers were given day-old chicks by major companies and were paid to raise them. Sadia is an example of a family-owned company, which employed 14,000 smallholder farmers to raise chickens on their mixed farms with a clear benefit to these farming families. The chickens were brought back to Sadia, who processed and distributed them to consumers.

Unfortunately, this system began to change four or five years ago, due to financial troubles of family owned companies, such as Sadia, which were taken over by financial interest groups and foreign companies. Now, Sadia is raising, providing feed for, and processing its own chickens in large production units. Certainly, most of the 14,000 mixed farmers, who once raised chickens for the Sadia industry, do not benefit from this new 'development' initiative.

Harm to import-dependent developing countries

There are many examples that support the view that the introduction of industrial livestock rearing not only harms the individual small-scale farmer but also the developing countries as a whole. As a consequence of industrial livestock rearing, these countries have become more import-dependent. Grains, tractors, fuel, fertilisers and special animal units and processors are required for intensive livestock rearing, none of which a developing country starts out by making itself.

Over the last decade, Asia has begun to import large amounts of grain to feed its industrially-produced farm animals. Likewise, machinery, oil and production units are being imported and subsidised by the government. The Asian economic crisis of 1999, that raised prices of imported feeds and depressed urban demand, proofed that being an import-laden economy can be disastrous and unsustainable.

Threat to food security

A *World Poultry* study (Gueye 2001) done in sub-Saharan Africa indicates the importance of family-level poultry rearing for food security, poverty alleviation, environmental health and genetic diversity. While the one or two breeds of broiler chicken used for chicken meat in factory farms are generally imported, 85% of rural families keep several species and breeds of poultry of indigenous types. The products of these local breeds are often preferred to those from exotic breeds by local consumers. Furthermore, the local breeds are better adapted to local diseases, pests and climate. Poultry are usually raised in extensive systems, while some families specialise in semi-extensive and small-scale intensive poultry systems.

In extensive production (backyard) systems, birds are reared with little land, labour or capital, can be accessed by even the poorest social communities in rural areas, and are of great importance for women, especially in female-headed households. The study indicated that an average flock of 5 chickens enabled a woman in Central Tanzania to earn an additional US$38 per year or a 9.5% increase in income. Poultry raising has contributed to the 'greater empowerment of women by improving their financial status, if socio-cultural and religious environments allow it'. As such, the loss of family farming to industrial farming could seriously affect women and children.

Effects on the environment

Factory farming was developed in Europe with the aim of ending food shortages after the 2nd World War. Science and technology were promoted, farmers were given subsidies to encourage production increases, and consumers were given cheaper food. But, these policies of production at all costs can no longer be supported. As far back as 1997, the chief of the FAO's Asian Pacific Regional Office declared that it was time to move away from the 'Green Revolution' livestock model, as the environmental problems of this approach were already obvious.

Industrial animal farming has proved to have detrimental effects on the environment both in the short and the long term (Haan et al. 1998). For example, the production of cereals for the livestock industry often takes place far away from where the animals are raised. This is leading to depletion of soil fertility where cereals are produced, and pollution at the other end of the trading spectrum where cereals are used for animal feed. Soya and maize are major products of the US supplied to industrial animal farms around the world. Such monoculture systems, though strongly promoted by governments, have unintended consequences for soil and water quality. Thirty percent of the total cropland in the United States is now eroding at excessive rates, according to the Soil and Water Conservation Society (http://www.swcs.org/).

Globally, farm animals produce 13 billion tonnes of waste per annum (Turner 1999). Animals on industrial farms consume high-protein feeds and produce waste that is extremely environmentally damaging. Industrial animal farming contributes 5-10% of the total of greenhouse gases in the world, accelerating climate change. Moreover, large amounts of water and fossil energy are required to grow, process and transport industrial farm animal feed and treat the animal waste (Pimentel et al.1997).

Loss of genetic diversity

The FAO (2001) reports that the greatest threat to the world's domestic animal diversity is the export of specialised breeds of farm animals from developed to developing countries. Crossbreeding with and eventual replacement of local breeds has resulted in a situation that around 1,350 domestic animal breeds (30% of all domestic breeds) are at risk of extinction. Every week, two breeds of farm animals disappear.

One of the greatest misjudgements of the 'Livestock Revolution' is to deny the importance of genetic diversity for food security. For example, in 1996, some 942,000 inseminations have been carried out in the Netherlands alone, with semen from a single Holstein Friesian bull, named Sunny Boy. In that period the Dutch dairy sector averaged 1.7 million milking cows! (Compas Magazine, Oct.1999, p.26.) Semen of this bull was also used in many other countries.

Nearly 12,000 years of domestication and breeding under different environments have resulted in some 4000 breeds of farm animals. The genetic diversity of these breeds has made it possible for humans to thrive in all corners of the globe, facing a range of environmental challenges including varied climates, diseases, parasites and pests. Unlike imported industrial breeds, local farm animals in given environments have developed resistance or adaptations to these challenges.

For example, in Rajasthan, India, non-industrial breeds of farm animals have benefited human food security even in a harsh desert climate, where temperatures can rise to 50ºC. This region counts 7 local breeds of cattle, 8 breeds of sheep, 4 breeds of goats, as well as camel and horse breeds. Through these local breeds Rajasthan significantly contributes to the national milk and wool output. Marginal lands can contribute to food security only by working with farm animals adapted to the local climatic conditions (Rathore et al. 2001).

Government interventions in Rajasthan have focused on 'improving' local breeds by crossbreeding them with exotic breeds from other climates. Not surprisingly, the crossbreeding of local sheep with exotic sheep has failed to achieve any improved yield, mainly due to high mortality and problems with feed supply. In the case of cattle, the government has realised the detrimental effects of crossbreeding, and in 1998 revised its policy to protect and improve local breeds.

Negative impact on farm animal welfare

Another negative impact of industrial farming is its impact on farm animal welfare. As recognised by the Treaty of Amsterdam,

Measures to benefit the poor to better compete with the livestock industry (LID 1999)

- Access to credit (to allow for the purchase of animals);
- Access to appropriate (community based) animal health services and simple preventive measures such as vaccinations and improved hygiene;
- Secure grazing rights and access to water;
- Access to markets;
- Trade policies and frameworks that allow smallholders and pastoralists to compete with industrial animal production. For example: support to cooperatives, levying taxes from animal producers based on their ecological and social impacts;
- Improve feeding to increase the performance of local breeds (Haan et al 1998);
- Support livestock production based on local resources (feeds, breeds, indigenous knowledge and institutions) and integrated farming systems;
- Stop subsidising intensive animal production in the North and the South;
- Stop export of subsidised products of the livestock industry to developing countries.

Local breeds of farm animals, such as these cattle in the Gambia, are better adapted to their environment than breeds imported for factory farming. Photo: CIWF

farm animals are living creatures capable of feeling pain and suffering. Industrial animal farming often closely confines the animals indoors, without light and with little or no exercise. This inhibits the natural behaviour of animals, and is known to create aggression, stress and injuries in animals. Industrial animal farming also carries out standard practices of mutilation: the hen is debeaked, so that she can no longer peck her cage mate, and the pig is tail-docked, so that his bored pen mates can no longer bite its tail.

The surroundings of industrial animal farms can be dirty and poorly ventilated, leading to poor animal health. Moreover, selected breeding for large muscles and fast growth, especially in pigs and chickens raised for meat, leads to leg problems, cardiovascular inadequacy, increased risk of mortality and poor welfare.

Learning from the mistakes of the North

In superficial economic calculations, industrial animal farming is considered the cheapest and most productive form of animal production. But, these calculations do not include the 'total costs' of this production system. Industrial animal production looks viable only when selected aspects of the production – consumption system is viewed. In reality, the hidden costs of industrial animal production for future generations are enormous. It is therefore very important that policy decision makers examine questions such as: Is it acceptable to cause job losses by putting small-scale farmers in poverty stricken populations out of business? Is it acceptable to cause ecological degradation, environmental pollution, climate change and increased ozone layer depletion? Is it acceptable to cause unnecessary pain and suffering to farm animals?

The UK, for example, has been struck by diseases such as foot and mouth disease and mad cow disease (BSE) that has brought the industrial animal farming system under serious questioning by the public. Food poisoning connected with eating animal products is also higher than it has ever been in the UK, leaving consumers to doubt the safety of industrial animal products. More and more consumers are turning away from the products of industrial animal farming towards the products of more sustainable systems such as organic and free-range. The governments in Europe are now beginning to recognise this situation and the value of more quality-driven livestock production. The Netherlands government, for example, has recently begun to subsidise organic pig production by 30%. An editorial comment in World Animal Review in 1998 raised an all-important question: "Should this type of livestock production continue to be encouraged globally, or should alternatives be sought?"

Policy makers must now support more sustainable and humane forms of animal farming and realise that industrial animal farming holds no future for Southern and Northern countries alike.

Livestock: industrial or integrated?

Editorial

Livestock production is important for the majority of farmers in developing countries, especially for small farmers in more marginal conditions where land cannot be used for other purposes. Smallholders keep livestock for food, fibre, fertiliser, fuel, draught power, as a buffer in case of crop failure, and also for social and cultural functions. Increasingly, livestock is also produced for cash, which is the main objective of specialised livestock production systems. This type of livestock production strongly depends on the dynamics of the global markets.

A team of researchers of the International Food Policy Research Institute (IFPRI) and the Food and Agricultural Organisation (FAO) produced an extensive report called: 'Livestock to 2020: The next Food Revolution' (see Garcés p.7). 'Livestock Revolution' was the term they used to describe the expected massive increase in livestock production in developing countries due to doubling of the demand for livestock products, especially in the North, over the next 20 years. Like the 'Green Revolution', this 'Livestock Revolution' involves the large-scale transformation and growth of production along the same lines as it has already taken place in many 'developed' countries. What will be the consequences of this development?

Painful experiences in the North teach us that this development towards 'factory farming' will put enormous pressure on natural resources, food safety, animal diversity and welfare, as well as threaten the income generating possibilities of small farmers. In reality these systems are very inefficient and the hidden environmental and social costs of the livestock industry are enormous (Garcés p.7). Also, to meet food needs in 2050 it is necessary to increase human food production considerably. But, the 'Livestock Revolution' will compete strongly with human food production. Presently, livestock already consumes almost 50% of world cereal grain supplies. It is therefore very important to develop livestock production systems, which do not depend on cereal grain (Preston p.26). The Animal Welfare Review in 1998, therefore, raised the all-important question: *"should this type of intensive livestock production continue to be encouraged globally, or should alternatives be sought?"*

Even without the 'Livestock Revolution', livestock keepers already have enough ecological problems, for example, due to overgrazing and burning. Research has developed technologies mainly for intensive and industrialised livestock production systems. But, many modern technologies do not fit the reality of low-input livestock systems (van 't Hooft p.10).

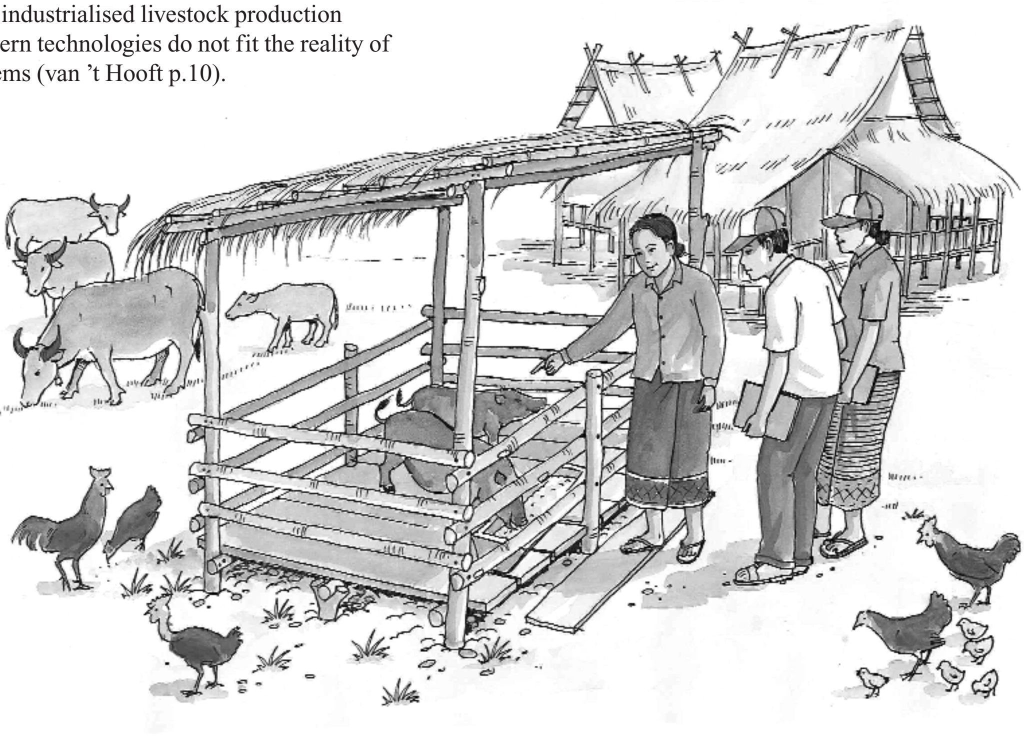
But what alternatives are available to farmers? The articles in this issue present some useful insights, practical suggestions and ways to achieve them.

Enhancing the quality of the whole system

To optimise the performance of farming, it is important that management practices enhance the ecological functioning of the 'web' of all living organisms within the production system by influencing the interactions between climate, soil, vegetation, animals and farmers (Primavesi and Primavesi p.12).

Traditional farmers often have mixed systems in which the production of crops, animals and natural resources are integrated, products are of multiple-use, and waste products of one sub-system are used as inputs in other sub-systems. Within this integrated system, depending on needs, opportunities and risks, farmers may follow different strategies: keep many different animal species under low-input management system, or combine this with the intensive production of one specific species (van 't Hooft p.10). Traditional systems can be relatively productive, while making optimal use of the available natural and human resources. Presently, influenced by modernisation and globalisation, most of these traditional systems are loosing their economic and social coherence.

The awareness that agro-ecological systems are complex and integrated, and that the quality of all parts of the system, including its social and cultural dimensions, is important to optimise the performance of the whole system, has been lost in more modern agriculture. Intensive livestock production in The Netherlands, for example, strongly focused on high input / high output relations and profit making and forgot about the environment. Two environmental associations of dairy farmers, rediscovered the importance of the quality of the whole system. They found that the quality of the cow manure influences the quality of the soil, which, determines the quality and quantity of the pasture and fodder crops, the feed for the animals, which is important for animal health and the quality and quantity of their products (see Figure 1 on p.24). They have developed a new way of feeding their milk cattle with lower protein and higher fibre contents by using less concentrates and fertilisers, which reduces nutrient losses while maintaining milk production at the same level. (van Weperen and Kieft p.24).



Presently, livestock research appears to show heightened interest in mixed or integrated farming systems going by the number of conferences that has dealt with this subject in Latin America, Africa and Southeast Asia (Sources p.30). Agroecological research in Colombia and Cambodia is working successfully on the development of integrated farming systems, with close integration of animals, recycling of all excreta, and the use of highly productive energy and protein crops, to improve productivity and sustainability of smallholder and commercial agriculture in the humid tropics (Preston p.26; Murgueitio p.14).

Integration of crops, grasses, trees and animals

Many of the authors stress the importance of diversification of agriculture. Van 't Hooft (pg.10) explains the importance of animal biodiversity in smallholder agriculture in the Andes. Primavesi and Primavesi (pg.12) report on the benefits of integration of leguminous crops and trees in pastures in Brazil. Funes-Monzote and Monzote (p.20) analyse the effects of integrating crops and trees in dairy farms in Cuba. Viengsavanh et al (p.16) explain how, in Laos, integration of specific grasses, trees and legumes help farmers overcome seasonal feed shortages for their animals, reduce labour requirements, improve animal health and performance in extensive systems. Murgueitio (p.14) points at the complementarity between ruminants, monogastrics like chicken, fish and earthworms, micro-organisms in biogas digesters, crops, grasses and trees to optimise the benefits of intensive integrated systems.

In tropical countries, especially in the humid zone, there are many crops and farming systems that considerably exceed the productive capacity of grain cereals. Key energy plants for intensive integrated systems are: sugar cane, cassava, the palm family (especially the oil and sugar palms). Key protein crops are: N-fixing legumes (trees and shrubs rather than soy beans) and water plants like "duckweed".The feeds derived from these "alternative" crops do not lend themselves to "factory" farming systems which traditionally use dry feeds, easy to store, transport and mix into "least-cost" rations. The "alternative" feeds require relatively small scale, diversified and integrated farming systems. The role of animals in these systems will be synergistic rather than as primary producers (Preston, pg.26).

In more marginal environments it is very important to integrate farm animals adapted to the local climate and forage (Primavesi and Primavesi, Pg.12). Indigenous animal species are often much better adapted to these conditions. Thriving even at low levels of fodder inputs, their maintenance is ecologically more sustainable. While they may not be able to compete with "improved breeds" in regards to milk and meat yields, indigenous animal species fulfil a much wider range of functions and provide a larger range of products. As is becoming increasingly clear, they often have scope for specialty products and can be essential to preserve habitats. Improved feeding can double the performance of local breeds (see box on p.9). But, according to FAO, one third of the world's estimated 4000 livestock and poultry breeds are in danger of extinction! The 'Livestock Revolution' will speed up the loss of indigenous animal biodiversity. Action is therefore urgently needed – an example of this is the LIFE project (Warsi p.27).

In addition, small animals and insects could have considerable potential to improve the integrated farming system. Poultry is an example of a small animal which plays a very important role in smallholder production and poverty alleviation. Earthworms (Murgueitio) and weaver ants (Van Mele and Vo p.28) are examples of very useful insects which could strongly enhance the overall productivity of integrated systems. And, of course, we should not forget the wide diversity of micro-organisms in the soil and the animals without which agriculture would not be possible.

Chain management and weak links

An increasing number of organisations are working on improvement of the whole livestock production chain, including aspects such as input supply, processing, marketing, transport and farmer organisation. Rocha (p.22) presents such an example. In the Andean highlands of Bolivia there is an enormous ecological and economic potential for llama production. However, llama production is strongly marginalised due to, among other factors, a parasite in the meat (Sarcocistiosis), which makes it less attractive for human consumption. Farmers, supported by a local NGO, have succeeded in reducing the prevalence of this parasite, improving market structures for commercialisation of this product, and undertaking other activities to revitalise family-level llama production, with positive economic, ecological and cultural effects.

Often there is a weak link in the production chain, which could strongly inhibit the overall performance of the system. Strengthening of weak links may have unexpected results. Unlike in the intensive systems in The Netherlands, mentioned earlier, in extensive systems, for example, animals often get too little proteins or lack specific minerals (e.g. phosphate, calcium, magnesium or cobalt). Integration of leguminous or other protein-rich crops and trees into the system and feeding of protein-rich concentrates with added minerals could contribute a lot to improve animal health and production (Primavesi and Primavesi; Preston; Viengsavanh et al).

In Kenya, Luo farmers had a lack of manure to fertilise their crops. By adopting 'zero grazing' they succeeded in strengthening the livestock component of their integrated crop-livestock system, which then brought the whole system to a higher level of production. However, intensification of indigenous farming systems, e.g. by introduction of zero grazing, has to fit local perceptions, needs and opportunities (Mango p.18).

Another example of a weak link is Newcastle disease in poultry production. Poultry networks are now testing new vaccines for control of Newcastle disease which can be produced locally and can be easily administered (van 't Hooft p.36).

Integrating researchers, policy makers and educators

By following a more holistic, ecological approach many farmers seem to come closer to their own 'gut feeling' of how they should manage their farm, which is also more in line with how their parents thought about it (van Weperen and Kieft, p.24). The problem is, however, to get other players such as researchers, policy makers and educators involved in this approach to form (inter)national networks and local platforms for change. Although, increasingly, these players are aware that there is something wrong with the conventional approach to livestock production, they have to make quite a change in attitude and thinking to take a different stand. For example, animal science as taught in Latin American universities and farming schools is focused on reaching the maximum productivity per animal, limited to the animal species used in industrialised livestock keeping, especially cattle, pigs and chicken. The absence of the essential elements of family-level livestock keeping and the basic principles of integrated, ecological livestock production in the curriculum is reflected in the frequent failures of livestock projects and the negative impact of livestock production on the environment.

Although integrated livestock systems have considerable potential to improve livestock production, the chances of small farmers competing with industrial livestock production will remain weak as long as research, policies and education systems do not change.

■

LETTERS

Dear Editor,

I agree entirely with your overall theme of issue 17.4 that GE is not the only option, but do also believe that your argument has been weakened in some of the articles which you included in that issue.

My fundamental concern is that in an edition dedicated to GM crops and smallholders there is no mention of China. The country claims that by 2010 up to 80% of the national area of cotton, corn, rice, soyabean and wheat will be planted to transgenic material (Chen Z.L. Transgenic Food: Need and Safety. OECD Edinburgh Conference on the Scientific and Health Aspects of GM Food 28th Feb. to 1st. March,2000).

On page 21 you state that "GM cotton is unlikely to have much appeal to small-scale cotton farmers" without providing evidence for the statement which appears to be contrary to the actual facts. Despite problems with seed supply small-scale cotton growers in China have gone to enormous lengths to obtain GM seed travelling hundreds of km. to buy it. The big attraction has been the reduction in the need for pesticide use with a reduction in average expenditure from RMB 1927 per ha. for pesticides on non Bt. Cotton to just over RMB 300 for the GM crop with no significant reduction in yield.

A striking result of this was that in 1999 only 4% of farmers using GM cotton had experienced any symptoms of pesticide poisoning as compared to 33% using conventional cotton. At the same time survey data revealed 23 beneficial insect species on Bt. cotton as compared to 5 on conventional.

The material on pages 6 and 7 also rings a false note. The great majority of the world's small-scale farmers live in Asia with a minority living in Sub-Saharan Africa. It is difficult to see evidence of "colonial land grabs pushing rural food producing societies off the best lands" in China, India, Bangladesh or Vietnam. It is equally difficult to accept that "healthy domestic markets will never emerge" in these countries. Even more surprising is the statement regarding lagging productivity in third world countries when average grain yields in the third world have risen overall from 1.2 to 2.52 tonnes per ha. over the past 25 years and average per capita food consumption has risen by 28% (FAO 2000).

Yours faithfully, **Stephen Carr**, Private Bag 5, Zomba, Malawi.

We agree that the GE experiences in China should have been covered. Unfortunately we were not successful in our search for a suitable contribution. If any one of you have first-hand information, please send it to us.

There is little doubt that there are farmers who have immediate benefits of switching to GE. However, like in all agricultural technologies and approaches it is important to look beyond the single farm and beyond the next harvest when assessing the value of GE. Our goal was to view GE in this broader perspective. It is also important to realise that GE is different from any previous agricultural innovation in that there is no way back when GE crops have been released: most of them have some biological advantages that will ensure the survival of their genes in nature. If problems show up we cannot get rid of the genes just by stopping the release of GE crops. This is particularly worrying in poor countries who do not have sufficient resources to remedy the situation.

We will take note of your comments on general statements (pag 6.7) in future articles.

Dear Editor,

I have something to say about GM crops, "Will GM crops feed the hungry and reduce poverty"? As these crops are created by private companies they are not introduced for reducing poverty or feeding the hungry. The question therefore must be, "Will GM crops bring profit for the companies"?

The problem of hunger is not productivity only, because in our time there are more than enough productive crops, which can feed the world. A fact is that not everybody can buy enough food. This is because some people are unemployed or do not have enough income to buy what is needed properly. GM crops will not help poor people.

Even in Ethiopia which is known as one of the poorest and the most drought affected countries there are always regions, which produce enough crops to feed the whole country. But there are always people who cannot afford to buy these food crops. For example, in 2001 the price of maize in Ethiopia dropped by 2.5 times and in some places by 5 times from the previous years due to mass increase in production. Until recently the government subsidised the price of fertilisers. But thanks to the World Bank and the IMF, the government eliminated subsidies to farmers. So farmers were obliged to sell their animals to pay their debt resulting from the price increase for inputs, even though they had harvested more than in the previous years. This resulted in even more hungry people who could not afford to pay the price of maize.

The introduction of new GM crops of which we do not know the future consequences is very dangerous. The example of Mad Cow Disease (MCD) may illustrate this. It is said that MDC may result from feeding cows meat and fish products. Cows are herbivores but we are trying to make them carnivores, without thoroughly studying the consequences. We change nature and have to pay for our carelessness.

In my opinion the GM crops and abundant use of fertilisers and pesticides are not necessary to feed the world. What is needed is sincerity in our work and ideas. So we have to think twice before we create new organisms on this small planet.

Yours, **Fekade Fullas**, P.O.Box 36, Bodity, Wolaita, Ethiopia

Dear Editor,

Congratulations on your recent special issue on biotechnology and GM crops. It had many very interesting and worthwhile articles that deserved to be widely read and discussed. However, we would like to correct an important misrepresentation. In the article by Mr. Peter Rossett (p.7) there is a photo with the caption: "Will the "super" rice presently being developed by the International Rice Research Institute (IRRI) meet the needs of small farmers?"

For the record, the "super" rice the article refers to is in no way genetically modified or engineered and so should not be included with the article. Known also as the "New Plant Type", this rice germplasm was developed over a 12-year period via traditional breeding methods. It is also incorrect to say it is "presently being developed" as last year it has been completed officially. Those readers who are interested to get the full story behind "super" rice can go to the following Internet address: http://www.irri.org/vis/prl1001.htm or contact my office directly. It should also be noted that the "New Plant Type" is not really a new rice variety as such. Instead, it is an advanced rice germplasm with better disease resistance and higher yield potential among its many improved features. As of last year, IRRI began sharing this germplasm with anyone (farmers, national systems, NGOs) who would like to use it in their traditional breeding programmes. Already, countries like China and India have started to include some of the NPT's improved qualities in its own new rice varieties for farmers.

Yours Sincerely, **Duncan Macintosh**, Spokesman, IRRI, Philippines.

CONTENTS

The authors of this article show how cattle farming in Brazil can be optimised in an ecologically sound way. They argue for management practices that influence the interactions between the different aspects of the production system - climate, soil and soil life, vegetation and cattle. Increasing the water availability for better plant growth, introduction of shade trees for enhancing the micro-climate, grazing rotation instead of burning pastures, integration of leguminous forage plants and elimination of nutrient deficiencies are some of the topics discussed. Towards "green meat" and "green milk" is what, according to the authors, animal production should strive for.

In 1979, the National Dairy Development Project of Kenya introduced a dairy farm concept based on zero grazing, with animals kept in stalls and a cut and carry fodder system. The article describes the main components of this ZG concept and how the Luo people of Siaya district have adapted it to suit their specific conditions. For instance, the Luo farmers do not grow napier grass as recommended by the NDDP as it is labour intensive; they have found a less labour intensive form which is called *tumbukisa*. Luo farmers have also found ways of adapting the feeding regime suggested by NDDP; instead of commercial feed, they have come up with a "home-mix" dairy meal and use brewer's waste as a supplement. For some farmers who aimed at milk production, ZG has become a viable alternative to coffee, sugar and cotton growing. For others, ZG is a way of re-establishing the balance between crop and livestock production.

ILEIA is the Centre for Information on Low External Input and Sustainable Agriculture (LEISA) in the tropics. ILEIA seeks to promote the adoption of LEISA through the LEISA Magazine and other publications. It also maintains a specialised information database and an informative and interactive website on LEISA (**http://www.ileia.org**). The website provides access to many other sources of information on the development of sustainable agriculture.

LEISA is about Low-External-Input and Sustainable Agriculture. It is about the technical and social options open to farmers who seek to improve productivity and income in an ecologically sound way. LEISA is about the optimal use of local resources and natural processes and, if necessary, the safe and efficient use of external inputs. It is about the empowerment of male and female farmers and the communities who seek to build their future on the basis of their own knowledge, skills, values, culture and institutions. LEISA is also about participatory methodologies to strengthen the capacity of farmers and other actors to improve agriculture and adapt it to changing needs and conditions. LEISA seeks to combine indigenous and scientific knowledge, and to influence policy formulation in creating an environment conducive for its further development. LEISA is a concept, an approach and a political message.

24 Dutch dairy farmers find own solutions to their environmental problems

Willem van Weperen en Henk Kieft

Dutch dairy farming in the last fifty years focused on increasing milk production through a variety of interventions that included technology development, effective research-extension-farmer interaction, access to credit, conducive policies etc. However, this development resulted in increased environmental as well as animal health problems. Many animal-related crises in the recent past has raised consumer concern considerably. Ten years ago, two environmental farmer associations in the Friesian province of the Netherlands began experimenting with environmentally-sound farming practices and integrated agriculture. Although these experiments raised suspicion within the authorities, initially, the results are gradually gaining recognition. Now, more than 120 farmers have taken on the initiative and together with researchers they have formed a platform called PMOV to take the initiative further. This experience shows that farmers are able to resolve their own problems and make their farming systems sustainable.

DEAR READERS

The 'Livestock Revolution', intensive industrial livestock production, is spreading fast to the South. In the North, it stands for loss of employment of many small farmers, environmental pollution, epidemic animal diseases (such as BSE and swine-plague), unsafe food and ill-treatment of animals. What alternatives do small farmers have that are competitive enough to keep them in business? In this issue of LEISA Magazine we have brought together a selection of articles which deal with improvement of livestock production by more holistic and ecological management and integration of crops, legumes, grasses, trees and other animal species. These integrated livestock systems seem to be more productive and better for the environment and the animals. But can smallholders and pastoralists really compete within the Livestock Revolution if politics does not make a conscious choice in favour of small farmers, the environment and animal welfare?

This issue has been conceptualised by the ETC livestock working group. Katrien van 't Hooft, a veterinarian with many years of experience with livestock farmers in the Andes (see page 10), who works as editor for the ETC Compas Magazine on endogenous development, was the guest editor for this issue. We are very appreciative of all the work she has put in.

Included with the LEISA Magazine is a special supplement on 'Ecosystem Disruption and Human Health', the result of a collaborative effort between IDRC, UNEP and ILEIA. IDRC holds the main responsibility for the content of this supplement, which is based on a consultation hosted by IDRC and UNEP in November 1999. Human health is an important issue that should become an integrated part of development efforts towards sustainable land use.

For those of you who have access to internet, we would like to mention that ILEIA together with Oxfam and Greenpeace are launching a campaign called *Farmingsolutions* on 8th April. The aim of this campaign is to show how food security can be achieved by innovative, ecologically and socially sound agricultural systems. The campaign is undertaken in preparation for the World Food Summit that is to take place in Rome, Italy, in June this year. The website **www.Farmingsolutions.org** gives easy access to information on world hunger, food production and innovative agro-ecological approaches. More information can be found on page 32.

On the request of many readers we have re-introduced a "letters" section in this issue. So please keep your letters rolling in and we will publish them.

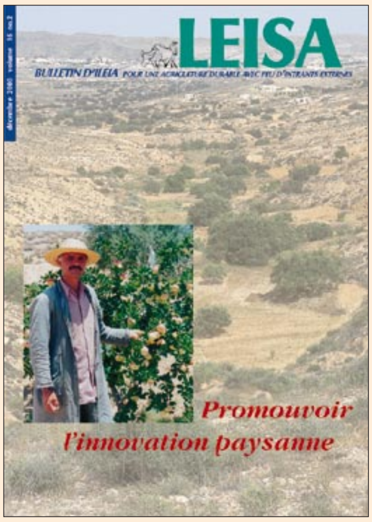
Livestock: which way?

The new ILEIA team

From left to right:
Lila Felipie (Secretary) - The Netherlands, **Ingrid Huibers Govaert** (Librarian) - The Netherlands, **Coen Reijntjes** (Content Editor) - The Netherlands, **Teresa Segura** (Subscriptions Officer) - Spain, **Flemming Nielsen** (Senior Researcher) - Denmark, **Anita Ingevall** (Director) - Sweden, **Chesha Wettasinha** (Intern in Editing) - Sri Lanka, **Wilma Roem** (Documentalist) - The Netherlands, **Bert Lof** (Deputy Director) - The Netherlands, **Marlies Marbus** (Office Manager) - The Netherlands, The inserted photographer is **Wilko Willemsen** (Information officer) - The Netherlands

After quite a while, the ILEIA team is once again at full strength. As you see, we have added some foreign flavour and made it a truly international team. With an abundance of new ideas and skills, we are energised and inspired to reach greater heights in championing the cause of LEISA in the coming years.

We wish you all a very challenging and rewarding year 2001!!



Promouvoir l'innovation paysanne

With financial support from the Technical Centre for Agricultural and Rural Co-operation (CTA) and the Indigenous Soil and Water Conservation Programme (ISWCP) the ILEIA Newsletter Vol.16, No.2 on "Grassroots innovation" has been translated into French. This special publication has been distributed, among others, to the subscribers of the ILEIA Newsletter in the French speaking countries of Africa. ILEIA hopes that this issue will lead to the initiation of a West African regional edition on LEISA at the end of 2001. Like the Latin American and the Indian regional editions, this edition will contain articles and information on LEISA and participatory development from the region itself, as well as a selection from the international ILEIA Newsletter translated into French. A regional editorial committee will be responsible for editing, publication and distribution. Readers interested in receiving the French West African edition, could request ILEIA to be put on the mailing list and receive a free copy of 'Promouvoir l'innovation paysanne'.

Themes for next issues

July 2001 Vol. 17-2
Globalisation challenged

Many farmers in the tropics are negatively affected by globalisation of the world economy and expansion of the consumer culture. To them, this is one step further on the road to economic and cultural marginalisation. In reaction, some farmers, communities and organisations have started to reconstruct traditional 'agri-culture', save indigenous seeds and breeds, or organise water harvesting. Others focus on development of the local agriculture based economy, local products, empowerment of local institutions or alternative education. Still others lobby for access to land, protest against genetically modified organisms or international agreements on intellectual property rights.
For this issue we invite articles on such reactions to globalisation, and on how local communities and farmer organisations can be strengthened to retain the right to their own futures. ***Deadline for contribution 1 March 2001***.

September 2001 Vol. 17-3
Going to scale

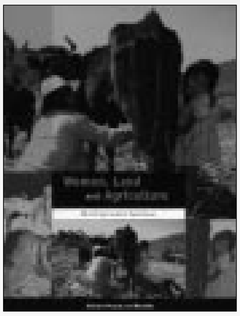
How do the benefits of innovations in agriculture and natural resource management spread to more people? What type of innovations do people prefer - when, where and why? How and when does spontaneous diffusion take place? What conditions can be created and what methodologies can be used to enhance or plan going to scale? What are the obstacles of going to scale, can they be overcome and how? What can we learn from case studies that analyse more or less successful experiences with going to scale? Going to scale has multiple dimensions, methodologies, players and contexts – spatial, temporal, technological, economic, ecological, social, gender, cultural, institutional, empowerment, capacity building, partnerships, communication, negotiation, financial incentives, etc. What role do these dimensions play in going to scale?
This issue will include and build on the results of earlier workshops on this theme. With some extra pages to spare and considering the complexity of the theme, some longer articles (up to 3600 words) may be accepted as well. ***Deadline for summaries of contributions 15 March 2000.***

You are invited to contribute to these issues with articles (about 1800 words + 2 illustrations), suggest possible authors, and send us information about interesting issues, publications, training courses, meetings, websites.

NEW IN PRINT

Small holding up *by Zarb J. 2000. In: The Ecologist, ISSN 0261 3131; v.30 no.9, p.40-44.*
In this article Dr. John Zarb, consultant researcher in sustainable farming, states that modern agriculture is in a crisis and that the alternative is: to move towards sustainable farming, not only in the "South" but also in the "Developed " world. He describes several examples in which the agroecological approach succeeded in developing a sustainable, self-supporting agricultural system using renewable resources. If sustainable technologies have brought significant improvements in agriculture under crippling economic, environmental and political conditions, then application in Europe or US, where structures like transport systems and markets already exist, should be successful. (WR)

Women, land and agriculture *by Sweetman C (ed.). 1999. 72 p. ISBN 0 85598 400 7 : USD 12.95. (Oxfam Focus on Gender). OXFAM Publications, 274 Banbury Road, OX2 7DZ Oxford, UK / bebc@bebc.co.uk.*
This book appears in the series Oxfam Focus on gender. It is composed of nine articles on agriculture, land rights and gender relations in countries in Africa, Asia and South America.

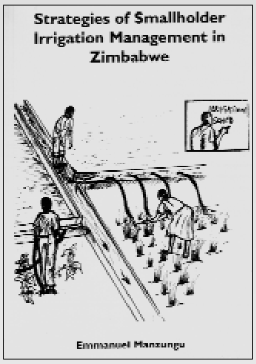


The articles assert that women's contribution to global agricultural production for food and for profit continues to be largely unacknowledged and undervalued, and that their ability to farm is constrained, because the resources they need are often controlled by others. Independent land rights, which enable women to decide on the use of land and keep the proceeds from such use, are still a dream for women in many countries, despite their increasingly central role in agriculture. Two articles shed light on methodological issues for development policy-makers and practitioners. Some tools have been developed to assist the process of integrating gender issues into planning and implementation. (WR)

Social responsibility in the global market : fair trade of cultural products *by Littrell MA and Dickson MA. 1999. 366 p. ISBN 0 7619 1464 1 (pbk) : GBP 18.99. Sage Publications, 6 Bonhill Street, London EC2A 4PU, UK / orders@sagepub.co.uk / www.sagepub.co.uk.*
This book is about fair trade from the angle of all the stakeholders: the producers or artisans, the alternative trade organisations and the consumers. Their needs, interests and preferences and business practices within the trade system are studied. There is a special focus on fair trade organisations that market cultural products from developing countries into the United States, but the themes covered (e.g. artisan empowerment and organisational sustainability) are of general interest. (IHG)

Policies for soil fertility management in Africa *by Scoones I and Toulmin C. 1999. 128 p. ISBN 1 899825 41 X. International Institute for Environment and Development (IIED), Drylands Programme, 3 Endsleigh Street, London WC1H 0DD, UK; Institute of Development Studies (IDS), University of Sussex, Falmer, Brighton BN1 9RE, UK.*
Fifteen case studies from 12 African countries (south of the Sahara) have been carefully analysed to: a) identify the key factors to explain patterns in soil management, b) give criteria for the need for public intervention and c) assess the options available for the determination of the intervention strategy. The conclusion presented is a very complex and diverse picture, which is in contrast to the generalisations often made in the international debate regarding the crisis in African agriculture. Recommendations are made to test ways to work with farmers more effectively, to promote a greater stakeholder involvement in discussions of policy options and the design of interventions aimed at generating a more sustainable agricultural sector. A thorough study that will take an important place in the African soil fertility management debate. (IHG)

Strategies of smallholder irrigation management in Zimbabwe *by Manzungu E. 1999. 200 p. ISBN 90 5808 145 1. Emmanuel Manzungu, 1606 Marapa Road, New Houghton Park, Harare, Zimbabwe.*
Emmanuel Manzungu presents a detailed study on operational irrigation management in Zimbabwe in accordance with his thesis in Wageningen University. This study seeks to understand the implied management problem in both government and farmer-managed smallholder irrigation schemes. Empirical evidence was gathered with respect to Mutambara,



Chibuwe and Fuve Panganai irrigation schemes, between 1994 and 1996 and included at least two wet and dry seasons. His major conclusions are that the state tended to administer rather than manage irrigation schemes. In contrast farmers easily engaged with operational aspects of irrigation management. Farmers, however, had their shortcomings in relation to extra-local factors. Emmanuel states: the beginning of management wisdom is the awareness that there is no one optimum management system. (WR)

Moving methodologies : learning about integrated soil fertility management in sub-saharan Africa *by Defoer T. 2000. 189 p. ISBN 90 58082 319 5. Royal Tropical Institute (KIT), PO Box 95001, 1090 HA Amsterdam, The Netherlands / kitpress@kit.nl, www.kit.nl/books.*
Toon Defoer, the first editor of "Managing soil fertility: a resource guide for participatory learning and action research, has written this book in accordance with his thesis in Wageningen University. The resource guide, volume 1 of the thesis has been reviewed already in ILEIA Newsletter 16(1) p.25. It provides user-friendly ways to gather, manage and analyse information, using participatory learning and action research. Moving methodologies is volume 2 of the thesis and describes the development of the participatory learning approach through the analysis of 3 case studies. Factors are analysed that have given direction to the adaptations and site specific configuration of the approach and applicable field tools. Two complementary interfaces are taken into account: the field teams interacting with farmers and the field teams as part of wider institutional settings. The book also deals with the impact of participatory action research in terms of changes in farmer learning, knowledge and innovation. The thesis concludes with discussing the major learning points in facilitating farmer learning and analysis of the major implications and issues in extending the approach. (WR)

How to convert sea water into drinking water : an easy-to-use manual *by Ryan F. 1998. 43 p. ISBN 81 87380 07 1 : USD 5.00. Books for Change, 28 Castle Street, Bangalore 560 025, India.*
This booklet is a handy guide for grassroot workers, trainers and the urban or rural poor to make healthy drinking water available in every home with little effort and almost no investment. Fourteen simple methods are explained with drawings and a clear description. Most methods described require only household utensils like pots, vessels and plastic sheets, and can be used for sea and brackish water, but also for tap water below the quality standard for human consumption. (WR)

Comics with and attitude... : a guide to the use of comics in development *by Packalén L and Odoi F. 1999. 96 p. ISBN 951 724 271 9. Ministry for Foreign Affairs of Finland, Department for International Development Cooperation, Kanavakatu 4-A, FIN-00160 Helsinki, Finland / kyoinfo@formin.fi.*
This book is meant as a source of inspiration for people searching for new cost-effective ideas to get the (development-related) message across. Comics draw the reader's attention, as they are a quick and easy way to tell a story in a

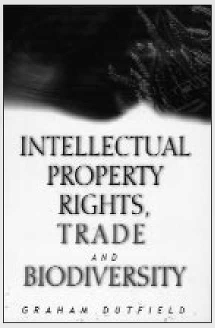
humorous or dramatic way. The author emphasises that comics should be simple, have a good story behind it and that the target group should be clear. Often, when local artists are involved the stories become more meaningful, and this book is full of such examples, ranging from campaign material on health, agriculture and environment to human rights, democracy and civil society. One chapter shows the complete procedure of making a comic with an attitude, of course in the form of a comic! At the end of the book references are given to more books and internet sites on comics. This book itself has an internet version on the internet site of the Department of International Development Cooperation of the Ministry of Foreign Affairs of Finland. (IHG)

●

Green beginning : joint forest management in Jhabua. *2000. 185 p. ISBN 81 85419 67 1. Tata Energy Research Institute (TERI), Darbari Seth Block, Habitat Place, Lodhi road, New Delhi - 110 003, India / mailbox@teri.res.in , www.teriin.org; SIDA.*
This book tells the rather successful story of the Jhabua forestry department in restoring land use possibilities in the Jhabua district in the state of Madhya Pradesh, India, with the use of a participatory approach: joint forest management and watershed programmes. The Jhabua district was suffering under frequent droughts and poor productivity of natural resources. The joint forest management program attempted to stop forest destruction, but also aimed at poverty eradication and generating employment to reduce pressure on natural resources. The history of the district and the whole process of implementing the programme is described in the book. Attention is paid to the role of women's self-help groups. What is achieved in Jhabua, so far, is that the district is green again and that the peoples income is raised. (WR)

●

Intellectual property rights, trade and biodiversity : seeds and plant varieties *by Dutfield G. 2000. 238 p. ISBN 1 85383 692 3 : GBP 35.00. The IUCN Project on the Convention on Biological Diversity and the International Trade Regime, International Union for Conservation of Nature and Natural Resources (IUCN). Earthscan Publication, 120 Pentonville Road, London N1 9JN, UK / orders@lbsltd.co.uk.*
Patents and intellectual property rights in relation to the biological diversity of seeds and plant varieties are critical issues in the controversy between interests of trade and environment. The book deals with this controversy, looking at all its different aspects and from all angles. International agreements such as the Convention on Biological Diversity, the TRIPS agreement of the World Trade Organisation, and the Convention of the International Union for the Protection of New Varieties of Plants (UPOV) are examined and ways of narrowing the gap between their interpretations are considered. Examples of genetic resource access and benefit sharing (ABS) laws, which



are being used by some countries to place conditions on the exercise of intellectual property rights are given, as well as examples of NGO initiatives to influence the international agreements. A very important book, balanced in its opinion and providing a complete update on the complex subject matter, including a very well annotated bibliography. (IHG)

Participatory forest management : implications for policy and human resources' development in the Hindu Kush-Himalayas. Volume I: workshop proceedings *by Bhatia A and Karki S (eds). 1999. 83 p. Volume II: China by Bhatia A and Ya T (eds). 1999. 65 p. Volume V: Nepal by Bhatia A (ed.). 1999. 41 p. ISBN 92 9115 970 0. International Centre for Integrated Mountain Development (ICIMOD), 4/80 Jawalakhel, GPO Box 3226, Kathmandu, Nepal / distri@icimod.org.np.*
These publications together are the proceedings of the regional workshop on Participatory Forest Management: Implications for Policy and Human Resources Development, held in May 1998, Kunming, China. The workshop brought together forest management personnel from various parts of the Hindu Kush-Himalayas. The basis of their discussions was the people-centered forest policies that have emerged in many countries of the region and their objectives of supporting and strengthening participatory forest management to ensure that the needs of mountain people receive the priority they deserve. Volume 1 is the workshop document, which gives an overview of the workshop and the participants. Volume 2 deals with China and concerns forest policies in China in general, and participatory forest management especially in Yunnan Province and in Tibet. Volume 5 deals with Nepal and describes the role of forests in the livelihood strategies of mountain people and the status of community forestry in Nepal. Volume 3 Eastern Himalayas, Volume 4 India and Volume 6 Pakistan complete the series. (WR)

Manual on contour hedgerow inter-cropping technology *by Ya T ; Pandey A (ed.). 1999. 29 p. International Centre for Integrated Mountain Development (ICIMOD), G.P.O. 3226, Kathmandu, Nepal / distri@icimod.org.np / www.icimod.org.sg.*
This easy to use manual on hedgerow intercropping explains the benefits of the system for the land and the farmer in an illustrative way. The technology for hedgerow planting and management is explained clearly and illustratively. Recommended for trainers, extension workers and farmers in mountain areas. The contour hedgerow intercropping technology is a soil-conserving technique. It involves planting double hedgerows of nitrogen-fixing plants along the contour lines of a slope at a distance of four to six meters. Space between the contour hedgerows is used for crops. The plants for the hedgerows are selected according to the needs for fuel or fodder, and also for their soil-conserving attributes. (WR)

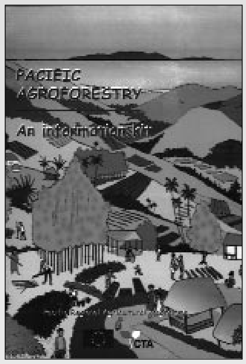
The participatory learning and action CD-ROM *is a new product from the Resource Centre for Participatory Learning and Action at IIED, the International Institute for Environment and Development, 3 Endsleigh Street, London WC1H 0DD, UK e.mail claudia.sambo@iied.org*
This new CD-ROM contains a database of 2000 bibliographic references on participatory methodologies and approaches, including a whole index of PLA Notes with abstracts.

●

Pacific agroforestry : an information kit *by Rogers S and Thorpe P (eds). 1999. 200 p. ISBN 982 343 038 1 : 40 credit points / CTA no.975. Pacific Regional Agricultural Programme (PRAP), Suva, Fiji Islands. Technical Centre for Agricultural and Rural Co-operation (CTA), PO Box 380, 6700 AJ Wageningen, The Netherlands.*
This information kit is the result of a workshop with agriculturalists from the different South Pacific Islands, for compiling their knowledge on agroforestry. As a farming system, the use of trees in farming has not been emphasised in this region until recently, although there is a great need for sustainable forms of agriculture in these fragile island ecosystems. The kit



proves that both indigenous and technical knowledge is (still) available, and that it is very timely for these agroforestry practices to be spread among a larger circle of extensionists. This glossy manual has a beautiful lay-out with a lot of instructive drawings and pictures. Technical information is interspersed with case studies, and the last chapter deals with ways to successfully promote agroforestry within the communities. (IHG)

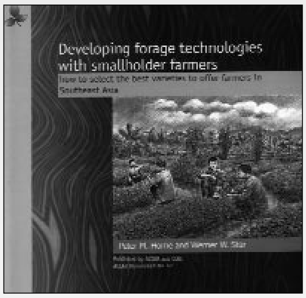
Capitalising on experience in Indo-Swiss cooperation in livestock development in India. *Capitalisation of Experiences in Livestock Production and Dairying (LPD) in India project (CAPEX), Intercooperation, PO Box 6724, CH-3001 Berne, Switzerland / intercooperation@intercoop.ch; Swiss Agency for Development and Cooperation (SDC)/IC NRM Programme, Chandragupta Marg, Chanakyapuri, New Delhi 110021, India. 2000. 50 p. free.*
This booklet presents the main findings of the project CAPEX, Capitalisation of Experiences in Livestock Production and Dairying (LPD) in India. The task of this project was to review the experiences of the Indo-Swiss Programme LPD in India, since its inception in 1963 to date, and to formulate future priorities based on its findings. LPD involved 8 projects spread throughout India and included support to developing a national livestock policy. From this wealth of experiences gained after such a lengthy and large programme, the CAPEX-team chose 2 topics to focus

on: 1) the evolution of a comprehensive LPD programme out of single projects and 2) selected technical issues in livestock breeding. The project is a nice example of the value of reflecting on experiences! This booklet is a summary of a full version, also available at Intercooperation, as technical report no. 15. (IHG)

Developing forage technologies with smallholder farmers : how to select the best varieties to offer farmers in southeast Asia *by Horne P and Stuer W. 1999. 80 p. ISBN 1 86320 271 4. Australian Centre for International Agricultural Research (ACIAR), GPO Box 1571, Canberra, ACT 2601, Australia / aciar@aciar.gov.au; Australian Agency for International Development (AusAID); CIAT Forages for Smallholders Project. (ACIAR Monograph ; 62).*
This booklet is based on the experiences of researchers and farmers working with the Forages for Smallholders Project in Southeast Asia.



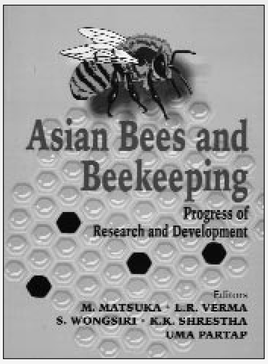
The manual can be useful for development workers in selecting appropriate forage options for farmers. It contains a list of forage species and varieties that grow in a wide range of conditions, and are either being used successfully by smallholder farmers or have significant potential in Southeast Asia. On many farms, feed resources for livestock are no longer plentiful, so farmers have to spend more time finding food for their animals. Planting forages can help to overcome this problem. (WR)

Natural crop protection in the tropics : letting information come to life *by Stoll G (ed.). 2000. 376 p. ISBN 3 8236 1317 0 : EUR 55.-. Tropical Agroecology Series. Margraf Verlag, PO Box 105, 97985 Weikersheim, Germany.*
This completely revised, enlarged and updated new edition of one of our most consulted books has been recently published. The first edition of Natural Crop Protection was published in 1986; though there were several updates, this revised edition is very welcome. The book presents practical information on natural crop protection techniques, already presented in former editions, combined with a number of case studies. By presenting both technical information and case studies on farmer participatory research, the book links information on natural crop protection with approaches and methodologies. Valuable suggestions are made for research to further improve engagement in developing natural crop protection practices for resource-poor and organic farmers. (WR)

The emerging alternative rice marketing system: selling high volume excellent quality rice : a preliminary study of an emerging alternative rice marketing system in Manila and Luzon provinces *by Miclat-Teves AG (ed). 1999. 100 p. Project development Institute, 3-B Mayumi St., U.P. Village, Diliman, Quezon City, Philippines; Center for Research and Information on Low External Input and Sustainable Agriculture (ILEIA).*
This study on alternative rice marketing has been prepared for the ILEIA Collaborative research program in the Philippines. Although it focuses on Luzon, its conclusions and recommendations are important for the development of alternative rice production and marketing in the whole country. Marketing of rice produced by small farmers' organizations, based on the principle of "fair trading" is studied. The low volume of the commodity is compensated by its high quality, and the marketing activity seeks to promote sustainable agriculture as well as to provide higher incomes for farmers. This alternative rice marketing system in which NGO's play an important role is compared to the mainstream rice marketing system. The book ends with a summary of problems, potentials and recommendations. (WR)

Agricultural Information Resource Centers - A World Directory 2000 *Edited by Johnson J.S., Fisher R.C. and Robertson C.B., 2000.752p. ISBN 0 9624052 2 1:US$105.00. IAALD World Directory, The Samuel Roberts Noble Foundation, 2510 Sam Noble Parkway, Ardmore, Oklahoma 73401, USA. pbrennen@noble.org*
Updated over the past five years, this third edition of the directory provides the most complete, up-to-date, single source of access to the world's agricultural information centres. Contains 3,940 entries from 189 countries, including contact details. The information is organised alphabetically first by country, then by city and parent institution. The key to acronyms and abbreviations that appear in the directory for databases, database vendors, institutions, institutions, and networks is an extremely valuable tool.

Asian bees and beekeeping : progress of research and development : proceedings of Fourth Asian Apicultural Association International Conference, Kathmandu, March 23-28, 1998 *by Matsuka M ... [et al.]. 2000. 274 p. ISBN 1 57808 084 3. International Centre for Integrated Mountain Development (ICIMOD), G.P.O. 3226, Kathmandu, Nepal / distri@icimod.org.np / www.icimod.org.sg . Science Publishers, PO Box 699, Enfield, N.H. 03748, USA / sales@scipub.net, www.scipub.net.*
This publication is an outcome of the knowledge and information shared during the conference and related workshops in Kathmandu, organised by the Asian Apicultural Association (AAA). The book presents an overview



of indigenous bees and beekeeping research and development in Asia, and highlights the issues related to conservation and management of the Asian hive bee, *Apis cerana*. In part one the authors advocate the need to conserve *Apis cerana* and suggest strategies for conservation of this indigenous bee species in the hindu Kush-Himalayan region. Part two explains new frontiers of bee biology research, especially of *Apis cerana* compared to the introduced species *Apis mellifera* (honey bee). There is a part on recent findings in bee diseases and pest control and on innovations in apiary management. A section on production, processing, properties, and marketing of different bee products- is also provided. In addition, new advances in crop pollination research through beekeeping and experiences in extension covering topics ranging from beekeeping needs and extension methodology in hills and mountain areas to the role of various institutions in promoting sustainable beekeeping are given in detail. The last part of the book provides information on traditional beekeeping methods and indigenous knowledge of beekeeping, and potential of beekeeping as a self-employment opportunity for women in hilly and mountain areas. (WR)

Roots and tubers for the 21st century : trends, projections, and policy options *by Scott GJ, Rosegrant MW and Ringler C. 2000. 64 p. ISBN 0 89629 635 0. The 2020 Vision, International Food Policy Research Institute (IFPRI), 2033 K Street, N.W., Washington, DC 20006-1002, USA / ifpri-info@cgiar.org; Centro Internacional de la Papa (CIP), Apartado 1558, Lima 12, Peru. (Food, Agriculture and the Environment Discussion paper ; 31). To order via internet or to download the complete paper, go to: http://www.cgiar.org/ifpri/pubs/catalog.htm#dp.*
This paper gives an overview of the most recent data and information on potato, sweet potato, yam and cassava and gives trends and projections towards the future per region. Research activities and organizations are also provided, with the objective of providing a vision for research on roots and tubers in the CGIAR. This publication provides a clear insight of the importance of roots and tubers in the food systems of developing countries nowadays, the role of which will remain important, and diversify increasingly in the future. (IHG)

Profit for the poor: cases in microfinance *by Harper M. 1998. 188 p. ISBN 1 85339 438 6 : GBP 12.95. Intermediate Technology Publications, 103-105 Southampton Row, London WC1B 4HH, UK.*
This book shows that there are many different ways of banking possible, which are rooted in the traditional methods of money-lending, local saving and credit groups. Fifteen case studies are presented, varying from well-known cases to more obscure ones, but they are all successful. Although sympathetic and accessible, the tone in the book is unmistakably that of a banking viewpoint. This does not have to be a disadvantage, as is said in the introduction: "micro-finance can offer a unique opportunity to combine genuine humanitarian aid for the poorest with good opportunities for trade and investment". (IHG)

The Center for Agroecology and Sustainable Food Systems of the University of California in Santa Cruz, USA. Its website www.agroecology.org is an information resource for developing sustainable ecosystems, emphasising international training, research and application of agroecological science to solving real world problems. The site provides information on related short courses and international events. An interesting series of practical case studies and a glossary of agroecological terms help understand the principles of agroecology as also explained in the textbook Agroecology: Ecological processes in sustainable agriculture by SR Gliessman (see next page). Very handy is the page on Agroecology Links www.agroecology.org/links.htm which makes it possible to make direct links to the main university, farmers and general sites on agroecology in USA.

Agroecology in action is the website www.cnr.berkeley.edu/~agroeco3/ of University of California in Berkeley, USA. This site gives access to the latest articles by Professor Miguel A.Alteiri and colleagues, among others, on agroecology and modern agriculture; agroecology and small farmers in the developing world; agroecology and biotechnology; agroecology and pest management (see next page). There is also a video on agroecology and biotechnology.

The International Maize and Wheat Improvement Center's website www.cimmyt.mx is quite elaborate and provides information on its worldwide programmes, contacts and publications. Information on the various resource conserving technologies that CIMMYT is developing together with wheat and maize farmers can be found on the site. CIMMYT's Natural Resources Group collaborates with national researchers, farmers and non-governmental staff in increasing and sustaining the productivity of maize and wheat systems while protecting resources. Some of this work is well described on the website.

Global Programme on Direct sowing, Mulch-based systems and Conservation tillage (GP-DMC) has been launched during the Global Forum on Agricultural Research, May 2000. In many countries DMC practices have fostered higher productivity, improved resource conservation, lowered food costs for consumers, and improved incomes for producers. The global-partnerships programme features a bottom-up process of learning and synthesis by analysing and comparing experiences with DMC in different regions. A facilitation unit is to be created. Stakeholders with relevant practical experiences are requested to join the open action group.

Further information: Larry Harrington, chair of the Interim Steering Committee, CIMMYT, Apdo. Postal 6-641, 06600 Mexico, D.F., Mexico. Fax: +52 5804 7558; l.harrington@cgiar.org

African Conservation Tillage Network launched

The purpose of the network (ACT) is to identify, disseminate and promote the adaptation and adoption of soil and water preserving tillage in Africa. The Network intends to create national networks for the exchange of information and experiences among researchers, extensionists and practitioners and to encourage farmers to experiment with the approach. A monthly, down loadable newsletter, Act Now, and training materials will be produced and pilot projects will be initiated to test and compare technologies. There will be an E-conference as well.

For more information: Edward Chuma, ACT Secretariat, IES/University of Zimbabwe, P.O. Box MP 167, Harare, Zimbabwe, Tel: +263-4-302603, Fax: +263-4-263433, Email: chuma@africaonline.co.zw and actnownews@africa.com

International Course on Integrated Pest Management will be conducted by The International Agricultural Centre from March to June 2001. The course deals with the effective implementation of IPM programmes, looking at technical as well as socio-economic aspects. It consists of 6 main modules: introduction; plant protection disciplines; development of IPM; pesticide management; IPM research, extension and implementation and IPM project proposal development.

More information and applications can be obtained from the IPM Course coordinator, International Agricultural Centre, P.O.Box 88, 6700 AB Wageningen, The Netherlands
Phone: (31)(0)317-495495
Fax: (31)(0)317-418552
e-mail: training@iac.agro.nl
website: www.iac-agro-nl

21st training in interdisciplinary team research for agricultural development will be organised by ICRA, International Centre for development oriented Research in Agriculture in 2002. It is a professional experiential learning programme in which participating researchers enhance their capacity to develop research proposals that meet the needs of clients and beneficiaries and contribute to sustainable development. Through workshops in the Netherlands and professional field work for a client agricultural research institute in the South, participants enhance their capacity to work in interdisciplinary teams, to use systems approaches for the analysis of agricultural change and to involve stakeholders in the planning and implementation of research. Course dates: January 17 – July 25, 2002 (English) and January 21- August 1, 2002 (French). Applications close 1 October 2001. Fellowships available.

Details and application forms: ICRA, P.O.Box 88, 6700 AB Wageningen, The Netherlands.
Phone: (31)(0)317-422938
Fax: (31)(0)317-427046

AREOL 13 - action research and evaluation on line is a free on-line course offered as a public service by the Southern Cross University, Australia. Beginning late February 2001, the course will run over 4 months on the theme, "Integration of effective change with rigorous research". The course will allow participants to understand some processes that combine action research, and can be used in practice. The course, however, does not attempt to cover all types of action research, nor does it analyse its philosophy.

More details and course materials can be found on www.scu.edu.au/schools/gcm/ar/areol

Centre for Alternative Agricultural Media, CAAM has been launched on 3 December 2000 in Dharwad, Karnataka, India. The first of its kind in the country, the centre's focus is on farmer friendly communication systems. Promoting alternative efforts in agricultural communication, encouraging self-help journalism among farmers, bridging the communication gap between farmers and scientists/ government, focusing on farmer innovations and pro-farmer issues feature among the centre's many objectives. Its website www.farmedia.org will focus on several aspects of alternative agricultural media. Regular e-bulletins will be released for networking with like minded individuals/ organizations engaged in innovative alternative efforts in the farm journalism sector.

For more information contact: Dr. Shivaram Pailoor, Director CAAM, Krishnalaya, 1st main, 4th cross, Narayanapur, Dharwad 580008, Karnataka, India. E-mail: caam@vsnl.net

International Society for Nature Farming (ISNF)

This society has as objective to promote teaching, research and extension activities of nature / organic farming. It creates awareness about the role of nature farming in sustainable and eco-friendly agriculture and encourages the adoption of the concepts. It also provides a forum for exchange of experiences and information and publishes two Newsletters: Prakritik Kheti (in Hindi) and Nature Farming (in English). The Society will shortly launch the 'Journal of Agriculture and Environment' and is organising, in collaboration with the Haryana Agricultural University, the International Conference on Nature Farming and Ecological Balance (ICN-FEB-2000), March 7-10, 2001 at Hisar, Haryana, India. At the same time there will be an electronic conference on the same themes:
Food production, quality and marketing; Land use planning and resource management; Organic farming systems and ecology; Indigenous knowledge and nature farming; Biodiversity and rural development; Government policies and extension programmes.

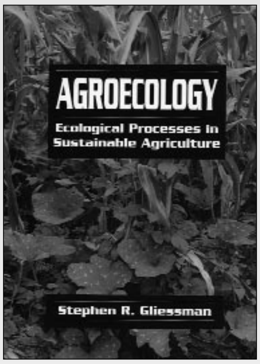
More information: ISNF, c/o Dr. IS Hooda, Dep. of Agronomy, CCS Haryana Agricultural University, Hisar – 125004, Haryana, India, icnfeb@hau.hry.nic.in
or www.geocities.com/icnfeb2001

Integrating Sustainability in Higher Agricultural Education. AFANet has developed a key activity to conceptualise sustainability in agriculture and to integrate it in the curricula of higher education in agriculture, forestry, aquaculture and the environment. AFANet, an EU SOCRATES Thematic Network, aims to stimulate co-operation in universities and colleges in Europe. The recently published book **Integrating concepts of sustainability into education for agriculture and rural development** edited by Bor, Holen, Wals and Filho, 2000, Frankfurt/M, Peter Lang Publishers (see ILEIA Newsletter Vol.16, No.3, p. 34), was the first main outcome of this AFANet activity. Part one of the book attempts to conceptualise the issues surrounding sustainability in higher agricultural education whilst part two provides case study examples from around the globe of the integration of the concept of sustainability into curricula. As a follow-up to the book, two dissemination activities were developed: an on-line discussion about the main outcomes of the book and an international seminar which focused on both the book and the results of the on-line discussion. The international seminar took place recently in Krakow, Poland, as part of the Euro-Eco 2000 conferences and was attended by university faculty members from 12 countries.
It was reconfirmed during the on-line debate and the Krakow seminar that the concept of sustainability is ill-defined. It should be realised, however, that this vagueness has an enormous strength if it is systematically used as an operational device to exchange views and ideas, and to make sustainability meaningful within a specific context.
Colleges and universities in the tropics could join this debate or start their own.

For more information: http://www.clues.abdn.ac.uk:8080/demeter/
The on-line debate can be visited on: http://www.lei.wag-ur.nl/sustainability/

IF YOU WANT TO KNOW MORE

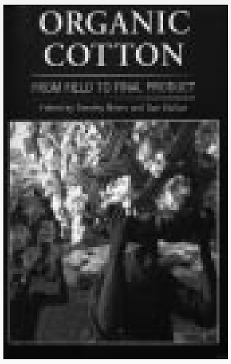
Agroecology : ecological processes in sustainable agriculture
by Gliessman SR. 1997. 357 p. ISBN 1 57504 043 3 : USD 49.95. Ann Arbor Press, 121 South Main Street, Chelsea, MI 48118, USA.
This basic textbook on agroecology is on the interaction of agriculture and ecology, purposes to promote a sustainable way of agriculture. It is divided into four sections. First it describes the concept of agroecosystems and why it is an answer to the failures of convential agriculture. Then subject-wise that



agriculture should be broadened to include the whole food system. This book is written in the first place for students, but offers everybody interested in agroecology a very complete picture in an attractive manner. Every chapter concludes with a list of recommended reading. By the many case studies it appears to be creative in a farmer's search for solutions. (IHG)

Agroecology : researching the ecological basis for sustainable agriculture *by Gliessman SR (ed.). 1990. 380 p. ISBN 0 387 97028 2. Sustainable Agriculture Information Project, Agroecology Program, University of California, Santa Cruz, Cal 95064, USA. (Ecological studies ; 78).*
This is an important overview of recent agroecological research in both the North and the South. Part 1 deals with basic ecological concepts in agroecosystems: Part 2 with agroecosystem design and management. The contributors (34 in all) are agronomists and ecologists who have begun to bring their respective strengths and approaches together to address the serious problems that test the world's ability to sustain its food production systems. Topics include research methodology, theoretical aspects of crop diversification and biological control, low-input ideotypes, analysis of traditional farming systems, and theoretical explorations of variability, stability and risks. Practical cases are reported from Mexico, India, Netherlands, USA, China and Thailand.
The book is presented just as a beginning. Agroecology is a field in its formative stages: it is more than ecology applied to agriculture, since it takes on a cultural perspective as it expands to include humans and their impact on farming environments. The book concludes by stating that it is one thing to express the need for sustainability and yet another actually to quantify issues such as nutrient cycling, energy flow, and population dynamics. There is a long way to go, and this book gives a challenging contribution along the way.

Organic cotton : from field to final product *by Myers D, Stolton S (eds). 1999. 267 p. ISBN 1 85339 464 5 : GBP 16.50. The Pesticides Trust, Eurolink Centre, 49 Effra Road, London SW2 1BZ, UK. Intermediate Technology Publications (ITP), 103-105 Southampton Row, London WC1B 4HH, UK.*
As cotton is one of the world's major cash crops, many farmers are confronted with the negative environmental impacts of its production such as reduced soil fertility, loss of biodiversity and especially the problems related to pests and pesticide use. Also further in



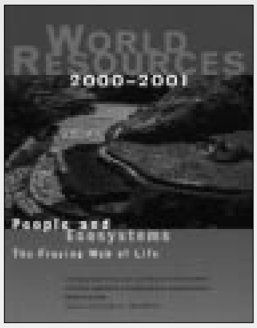
the processing chain pollution takes place, especially by bleaching and dyeing the cotton fabrics. This book describes organic cotton production and processing and is the first complete overview of its kind, since the first organic cotton was marketed some 10 years ago.
Still in a rather preliminary stage, there are signs that it is moving into a mass market. The book provides a very good and complete picture of the insights gained till now, and case studies from all over the world are compiled. Besides cultivation (including the growing of genetically engineered cotton) and processing, attention is paid to economic and marketing aspects, the conversion process, certification and support requirements for projects. Judging from the questions about environmentally friendly grown and -processed cotton that reached ILEIA in recent years, we predict this book will become a bestseller. (IHG)

Alternatives to conventional modern agriculture for meeting world needs in the next century. Report of a conference on Sustainable agriculture: evaluation of new paradigms and old practices, April 26-30, 1999, Bellagio, Italy. *Copies can be obtained from Cornell International Institute for Food, Agriculture and Development, Ithaca, NY 14853, fax: +1 607 255-1005, ciifad@cornell.edu. The full report can be down loaded from http://ciifad.cornell.edu/ciifad .*

The potential of agroecology to combat hunger in the developing world *by Miguel A. Altieri, Peter Rosset and Lori Ann Trupp. Available on: www.cnr.berkeley.edu/~agroeco3/*
The authors state that evidence suggests that the Green Revolution approach is unlikely to be the appropriate strategy to end hunger and that the agroecological approach offers several advantages. The principles of agroecology are explained and several examples from different parts of the tropics are given. Thousands of farmers are following the agroecological approach, thus showing its potential. The authors point at the necessity to increase investment and research into this strategy and to scale-up successful practices. (CR)

IRRI 1998-1999. *2000. International Rice Research Institute, MCPOBox 3127, 1271 Makati City, Philippines, irri@cgiar.org*

World Resources 2000-2001 People and Ecosystems: the Fraying Web of Life
World Resources Institute in collaboration with the United Nations Development Programme, The United Nations Environment Programme and the World Bank,2000. Paperback version 400p.ISBN 1 56973 443 7: US$27.00. World Resources Institute, 10G Street NE, Washington DC 20002, USA.
This millennial edition of the World Resources takes stock of the condition of the Earth's ecosystem and draws lessons from global experience in managing and protecting them. It focuses on five critical ecosystems that have been shaped by the interaction of physical environment, biological conditions and human intervention: croplands, forests, coastal zones, freshwater systems, and grasslands. Three steps to good management of ecosystems are proposed in the report. The first is to acknowledge the value of goods and services provided by these ecosystems and the tradeoffs that are often made among them. The second is to base decisions on current information about the capacity of ecosystems to continue



to provide goods and services. The final step is an "ecosystem approach" that explicitly recognises the interaction and tradeoffs among these goods and services, as well as the political and social context in which environmental decisions are made. Like the previous eight editions, this edition also presents an overview of current global environmental trends in population, human well being, food and water security, consumption and waste, energy use, and climate change.

Modern agriculture: ecological impacts and the possibilities for truly sustainable farming *by Miguel A. Altieri, Division of Insect Biology, University of California, Berkeley, USA. Available on: www.cnr.berkeley.edu/~agroeco3/*
The article discusses the development and impact of monocultures and the ecological problems they are creating. The author identifies an array of alternatives to conventional agriculture and discusses barriers for the implementation of alternatives. (CR)

Evaluating the sustainability of integrated peasantry systems
The MESMIS Framework

Santiago López-Ridaura, Omar Masera and Marta Astier

How can the sustainability of an agroecosystem be evaluated? How does a given strategy impact on the overall sustainability of the natural resource management system (NRMS)? What is the appropriate approach to explore its economic, environmental and social dimensions? These are unavoidable questions faced by any project dealing with complex agroecosystems. In Mexico, a number of development institutions, working on alternative agroecological strategies in a wide range of eco-zones, have joined forces to develop a Framework for Sustainability Assessment, the MESMIS framework.

The MESMIS project is an interdisciplinary and multi-institutional effort led by GIRA, the Interdisciplinary Group for Appropriate Rural Technology, a local NGO based in Western Mexico. The project originated in 1994 with the objectives of: a) developing an evaluation framework to assess the sustainability of alternative natural resource management systems; b) applying the framework to different case studies; c) training of individuals and institutions interested in the topic; and d) generating and disseminating materials to facilitate the application of the framework. Box 1 gives an example of how the Sustainability Assessment was put into practice by GIRA in the State of Michoacan, Mexico.

Sustainability evaluation

Most conventional evaluation approaches (e.g. cost-benefit analysis) are not always appropriate for addressing the challenges of analysing complex agroecosystems. A qualitatively distinct conceptual and practical approach is required. The MESMIS evaluation framework is such an attempt. It is a methodological tool to evaluate the sustainability of natural resource management systems, with an emphasis on small farmers and their local context (Masera *et al* 1999).

The framework is applicable within the following parameters:

1. Sustainability of NRM systems is defined by seven general attributes: productivity, stability, reliability, resilience, adaptability, equity and self-reliance.
2. The assessment is only valid for a management system in a given geographical location, spatial scale (eg. parcel, production unit, community etc.) and determined time period.
3. It is a participatory process requiring an interdisciplinary evaluation team. The evaluation team usually includes outsiders and local participants.
4. Sustainability is not measured *per se*, but is done through the comparison of two or more systems. The comparison is made either cross-sectionally (eg. comparing an alternative and a reference system at the same time), or longitudinally (e.g. by analysing the evolution of a system over time).

Figure 1. General Structure of the MESMIS. From Attributes to Indicators

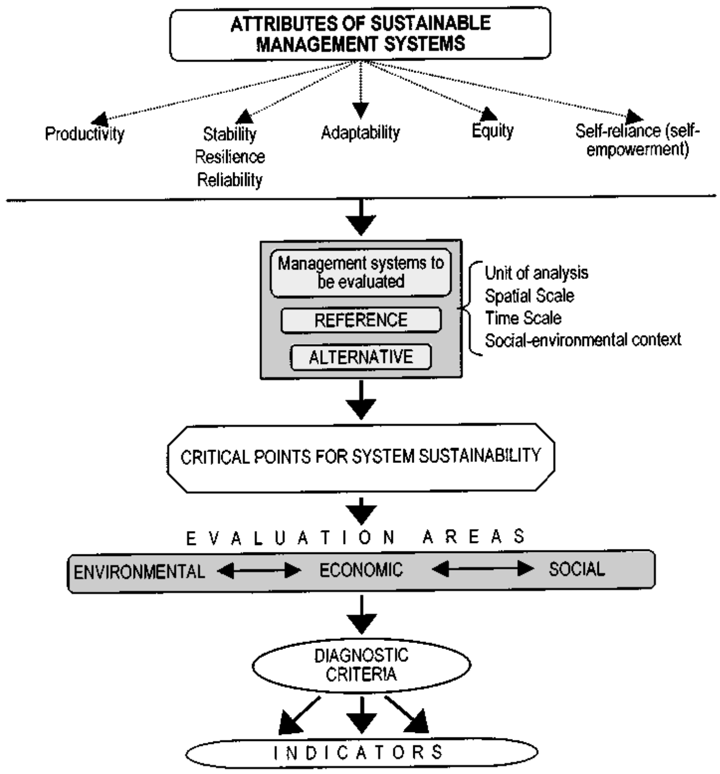


Figure 1 indicates the general structure of the framework. On the basis of the 7 attributes, a number of *critical points* for the sustainability of the system are identified, which are then related to three *areas of evaluation* (environmental, social and economic). In addition, for each evaluation area, diagnostic criteria and indicators are defined. This procedure guarantees a consistent relationship between the sustainability indicators and general attributes.

By providing an integrated strategy for sustainability assessment and evaluation, the MESMIS project has generated increased interest within academic and extension organisations. Several farmer organisations, research institutions and NGOs are currently using the MESMIS framework as a tool to evaluate sustainability. Since 1996 it has been applied in more than 20 case studies in Mexico and Latin America. It has also been used in more than 30 courses, workshops and seminars, and included in 14 university programmes in Latin America and Spain. The project has resulted in 15 publications, including one book on the MESMIS framework (Masera et al 1999), and another describing five case studies of sustainability evaluation within Mexico (Masera and López-Ridaura 2000).

Implementing the Framework

The operational structure of the MESMIS framework consists of an *evaluation cycle* of six steps.

Step 1 Definition of the evaluation object

In this first step, the evaluation team characterises the system under study (both reference and alternative), as well as the socio-environmental context and scope (spatial or temporal) of the evaluation. An accurate description should include: the components of the system (subsystems), the system's inputs and outputs, the main management and productive activities in each subsystem and the main social and economic characteristics of the stakeholders and the form of organisation they have.

Step 2 Determination of the critical points

The critical points of a system are the main features or processes threatening or

Figure 2. Characterization of Casas Blancas production unit.

strengthening the system's sustainability. Identification of the critical points will focus the evaluation process to the most important aspects of the system under analysis. Some key questions in identifying critical points are: What makes the system vulnerable? What particular problems are presented? What constitutes the strongest, most prominent feature? Examples of critical points are low yield and product quality (productivity attribute), soil loss, deforestation and pest damage (stability, resilience and reliability), or peasant indebtedness (self-reliance).

Step 3 Selection of diagnostic criteria and indicators
The diagnostic criteria elaborate on the seven attributes of sustainability. They represent a level of analysis more detailed than attributes, but less than indicators. Diagnostic criteria serve as a necessary intermediary link between attributes, critical points and indicators, enabling a more effective and coherent evaluation of sustainability. The set of indicators used in an evaluation process is specific for the system under analysis. They should be easy to measure, possible to monitor, derived from

Box 1 THE MESMIS FRAMEWORK IN PRACTICE
In the Casas Blancas *ejido,* an indigenous community in the Purhepecha Region of Michoacán State, GIRA has facilitated the development of alternatives for an agrosilvopastoral system. This was done by diversifying the cultivated plots (*milpa)* in order to obtain better stubble quality, avoid extensive grassing and control erosion. (Masera and López-Ridaura 2000).

The Casas Blancas *ejido* is representative of how many communities in the region manage their natural resources. Each farmer manages approximately 30 hectares - about 70% being forested (logging and reforestation) and 30% used for maize production and cattle raising. The agricultural management system, known as *año y vez,* consists of mainly maize production on one parcel for a year and a fallow for 1 to 3 years. In Casas Blancas, a *commercial* and a *traditional* strategy can be identified. They differ mainly in the type of fertilisation (inorganic or organic) and use of seeds (local or improved varieties), the type of traction (animal or tractor), the source of labour (wage or family), and the main objective of agricultural production (market or self consumption) (Figure 2).

A number of critical points were identified jointly by farmers and an external team through surveys, interviews and workshops. For each critical point, the evaluation team selected the diagnostic criteria and the indicators to be measured. Table 1 shows the critical points, diagnostic criteria and indicators used in this case study (Astier 2000). Figure 3 presents an AMOEBA diagram with the results from some of the indicators used.

The first evaluation cycle of the Casas Blancas case study helped in designing an alternative system, considering the strengths and weaknesses of the two different management strategies. The alternative system, now adopted by farmers is the focus of a second evaluation cycle, which proposes: a) the diversification of agricultural production by re-introducing amaranth and two edible leguminous species as intercrops, b) the use of organic and inorganic sources of fertilisation with special emphasis on phosphorus, c) the use of mixed traction for ploughing, and d) the introduction of leguminous cover crops and controlled grazing in the fallow parcel.

Table 1. Critical points, diagnostic criteria and indicators for sustainability evaluation in Casas Blancas Michoacán.

Attribute	Diagnostic criteria	Critical points	Indicators	AE[1]	MM[2]
Productivity	Efficiency	Low agricultural productivity	1 Grain yield	A	i,a
			2 Harvesting index	A	i,a
		Low animal productivity	3 Fodder availability	A	a,f
			4 Animal pressure capability	A	j
		Low profitability	5 Production costs	E	a,b,c
			6 Income	E	a,b
			7 Utility	E	k
			8 Cost/benefit ratio	E	k
Equity	Costs and benefits distribution	High costs for commercial systems adoption	9 Grade of adoption	S	g
		Limited basic grain supply	10 Grade of grain self-reliance	S	a,b,l
Stability	Resource conservation	High risk of erosion	11 Soil erosion control	A	m, d
		Soil degradation	12 Stability in nutrient balance	A	a,f,m
	Space and time diversity	Monocropping domination	13 Species diversity in parcel	A	a,f,b
Adaptability	Innovation capability	Failure of technological packages	14 Grade of technological innovation	S	a,b,e
			15 Permanence in technological packages	S	b,e
			16 Capability to adapt to environmental and political changes	S/A	a,b,m
Self-relianc e	Participation, control and organisation	Lack of co-operation among farmers	17 Participation in "ejido" assemblies	S	g
			18 Number of farmers in workshops	S	h

available and reliable information, and clear and simple to understand. E.g. A common diagnostic criterion for the stability attribute is *Diversity.* Indicators reflecting this criterion are the *Number of species* in the environmental area, or *Number of markets* in the economic area.

Step 4 Measurement and monitoring of indicators

This step includes the design of analytical tools and the methods of data collection. Indicators can be measured in a variety of ways. Methods that have been used in the MESMIS case studies include direct field measurements, setting-up of experimental plots, literature review, surveys, formal and informal interviews and participatory group techniques. Selection of the type of measurement depends on the availability of human and financial resources. A combination of direct and indirect measurement techniques is advised in applying the MESMIS framework. Here, farmer participation is important as has been proven by the great accuracy of the indicators selected and measured by them.

Step 5 Presentation of results

At this stage, the results obtained are summarised and integrated. Generally speaking, there are three techniques for presenting the results: quantitative, qualitative and graphical techniques. When properly designed, graphical techniques may provide the most effective way for identifying problems. In the MESMIS framework, an AMOEBA-type diagram is recommended. This diagram shows, in qualitative terms, how far the objective has been reached for each indicator by giving the percentage of the actual value with respect to the ideal value (reference value). This enables a simple, yet comprehensive comparison of the advantages and limitations of the system under evaluation.

Step 6 Conclusions and recommendations.

Step six recapitulates the results of the analysis. Firstly, the evaluation team appraises how the reference and alternative systems compare in terms of sustainability. Secondly, they discuss the main elements that enhance or inhibit the alternative system compared to the reference system. Based on these conclusions and considering the needs and priorities of all stakeholders, the evaluation team proposes recommendations to improve the system's sustainability.
Step six is also the phase for reflection upon the evaluation process itself, its logistical and technical aspects.

Making sustainability evaluation a permanent and cyclic process

An evaluation process is considered successful when it helps to improve the social and environmental profile of a NRMS. In other words an evaluation should aim not only at *qualifying* management options, but also at effectively helping to formulate an action plan geared towards improving the management system. Evaluating sustainability must be, ultimately, a *tool for planning and design.* Its success lies in its ability to be applied in the day-to-day activities of agroecological projects. Consequently, in the MESMIS framework, evaluation is not conceived as a linear process but as an iterative spiral. The conclusions and recommendations obtained form the starting point of a new cycle. ■

Mahaweli settlers in Sri Lanka diversify their farms using Farm Planning

Alice de Jonge

The Promoting Multifunctional Household Environments (PMHE) project, implemented by ETC-Lanka, was operational in Mahaweli System C in Sri Lanka, from 1991 to 2000. This article deals with Farm Planning for Sustainable Farming, an approach towards sustainable development of farms, initiated by the author and developed further in the project, which resulted in farmers moving away from a monoculture of paddy, to more integrated farming.

Photo: Alice de Jonge

Farm planning, a family affair

Paddy – main cash crop

Mahaweli System C is part of a large agricultural settlement scheme in the "dry" zone of Sri Lanka. Between 1980 and 1990 nearly 22,000 settler families arrived from various parts of the island to become paddy farmers. Each settler family was entitled to 1 ha of irrigated paddy land and 0.2 ha of highland for a homestead. The settler farmers were in turn supposed to transform Mahaweli System C into one of the key rice producing areas of the country. Agricultural extensionists of the Mahaweli Authority of Sri Lanka (MASL), were equipped to support farmers in cultivating rice.

Low profitability of paddy farming

After the first 2-3 years (5-6 seasons) of paddy cultivation, the majority of farmers began to see drastic yield decreases due to loss of soil fertility. Maintaining yields of around 4 to 5 tonnes per ha, much lower than the initial yields of 6 tonnes per ha, required application of increased quantities of inorganic fertiliser. With the price of fertilisers escalating steadily, the returns from paddy farming were marginal. Added to this was the lack of experience amongst farmers on how to maintain soil fertility under conditions that differed considerably from their areas of origin. The extension package offered by the MASL was hardly conducive in developing location specific farm systems suited to the different soil and water conditions in Mahaweli System C.

Finding alternatives to paddy

The deteriorating economic situation of the farmers, sub-optimal use of resources and degradation of the resource base prompted PMHE to consider principles of ecological farming and low external input and sustainable agriculture for developing alternatives to the existing farm system. Farm Planning for Sustainable Farming evolved through intensive interactions between farm families, MASL and PMHE extension staff and developed into a participatory extension methodology and a farmers' tool for resources management and farm development. (see box)

Farm planning helps farm families to search for alternatives and combinations of crops that would bring them more returns than paddy. It also helps them to find ways of utilising resources more efficiently. The families realise that bio-mass has to be created to make up for the nutrients that leave the field in the form of paddy grain.

Farm Planning and ecologisation

Farm Planning for Sustainable Farming is based on ecological principles (see box) and as such it contributes to develop a farm system in a more ecological way. In Mahaweli System C, it contributes, in combination and synergy with all of PMHE project activities, to the ecologisation of the paddy mono-crop in the irrigated tract. This is however inspired in the first place by an economic motive: how to get more returns from farming and how to reduce costs. Aspects of environmental conservation and health are of secondary importance. Based on ecological principles, Farm Planning enhances the awareness among farm families on the optimum, instead of maximum use of the environment.

A recent study shows a remarkable difference in ecological practices between farms of families practising Farm Planning and their neighbours without a Farm Plan. Almost 100% of the farm families involved in Farm Planning practise recycling of organic matter to improve the soil fertility of their paddy field - against hardly 50% of those not acquainted with it. Incorporation of paddy straw has become an established practice among farm planning families in place of the former habit of burning it. Banana, peanut and vegetables are being grown in the irrigated fields alongside paddy. Some families have successfully incorporated livestock in the farm system. Glyricidia is planted along the bunds of the paddy field to serve many purposes: fodder, green leaf manure, trails for climbing annual crops, firewood, etc. In this way certain needs of the farm are fulfilled by material produced on the farm itself, which reduces the cost of and the need for external inputs. A majority of the farm planning families considers soil fertility as the most important criterion for sustainability of the farm. Despite the home garden and paddy field being located apart, farm families bring surplus organic matter from paddy field to home garden and vice versa to improve soil fertility.

An important effect of Farm Planning is that the paddy land is observed and analysed: which parts are suitable for paddy cultivation and on which parts other crops or even perennials would do better? While diversifying the paddy mono-crop, the ecological principle of a site-specific choice of plant species is increasingly practised.

A young farmer's story

Mr. Jayasinghe, a young farmer from Mahaweli System C, changed his entire approach to paddy farming, remarkably, since he started with Farm Planning in 1996. After analysing the situation he improved the paddy field step by step. By levelling his land in a planned way over different seasons, he is now able to control weeds by flooding. He has planted a plot of about $\frac{1}{2}$ acre, less suitable for paddy cultivation, with banana, inter-cropping the young banana plants with vegetables at first. Gliricidia is being established on the bunds of his field. Jayasinghe uses the gliricidia leaves, together with the rice straw, to improve the soil fertility in poor plots. In the banana – vegetable plot he uses cow dung. He has also started to plant arecanut and coconut in his paddy land, thus diversifying his income and spreading the risk.

His external inputs have decreased considerably. " I use straight chemical fertiliser, which gives a good result in combination with the straw and leaves. Insecticides and herbicides are used only when necessary. I follow an IPM course with the extension officer", says Jayasinghe.

In the early years of settlement Jayasinghe sold his paddy crop directly from the field, like all his neighbours did at that time, and received the lowest price. In his Farm Plan he planned for storage of his paddy, to get better returns by selling it at the right time. Now he is a seed paddy farmer, delivering high quality seed to the South of Sri Lanka.

Jayasinghe is very clear about the benefits of Farm Planning for his farm and life: "After Farm Planning I have better results and I am more focused in my work. In the beginning, however, I had the feeling that I had lost my freedom, that I was trapped in a 'cage'. But now I have realised that it is my own plan, and that I can change it whenever I want."

Asked in which way his farm has become more sustainable, he answers: "When you plan your farm, you should use all your own resources first, before buying any inputs. I am now using all the crop and farm wastes, which I did not do earlier. I have been able to reduce my costs so much that I am no longer taking crop loans."

At the end of every season, the young farmer evaluates his well-kept records, to plan for the next season. "If you don't plan, you can't do all your activities in time, you miss things. It is also important to put your plans on paper, so that you can look at your objectives from time to time and build up your motivation". That maybe the reason why Jayasinghe has put his marriage into the plan for the near future: he has understood that Farm Planning is more motivating when it is a family affair.

Key elements of "Farm Planning (FP) for Sustainable Farming"

1. Learning from the forest for the farm.

Before starting a farm planning process in a farm, farm families and extension staff learn from the example of a natural forest as a sustainable environment. The most important ecological processes through which the natural forest sustains itself and creates a **balanced environment** are in brief:

- Bio mass production
- Diversity and Complexity (a web of relations in unity)
- Living soil as a major component of soil fertility
- Recycling of all organic matter
- Efficient use of all the resources
- Site specificity of plant and animal species chosen.

By discovering and analysing these processes and their linkages in a natural environment, families and extension staff draw learning points for sustainable farming. **Efficient resource use** serves as the starting point for FP. The **unity** in a natural forest environment as **a system with a web of interactions between its elements** is also important. Likewise, in FP the farm is considered in a holistic way, as a system with flows of material and energy between all the different farm enterprises.

2. Observation and analysis of the existing situation of the farm.

The planning process starts from the existing situation on the farm, which is carefully observed and analysed. How does the present farm **system** work and what are the available resources? The farm family members are the most important resource persons in the exercise of observation and analysis of **resources, processes, practices, opportunities and problems** in their own farm**.** Extension staff act as facilitators. Together they document the analysis of the farm system in maps, flow charts and written or "symbolised" text: this is the first part of the **farm document.**

3. Exposure visits to farm families who successfully developed their farms.

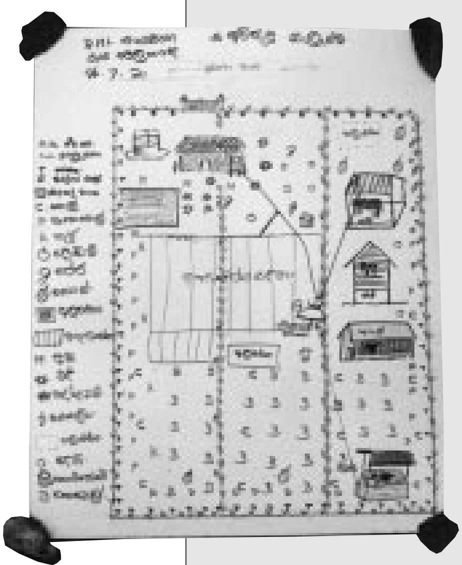
Groups of farm families who have mapped the existing situation of their farms visit others who are in the process of successfully developing their farms, and collect ideas for their own farm plans.

4. Planning for further development of the farm.

Before making the Farm Plan, farm families and facilitators discuss about planning in relation to needs, goals, dreams, and **vision on the future**. Planning starts with the 'here and now', the existing situation, and reaches a final goal. It describes changes and **improvements in different feasible steps**, keeping in mind the lessons learned from the natural forest environment and utilising **available resources** optimally.

In a Farm Plan this final goal, the more sustainable situation of the farm, is put on paper. Then, with the help of simple formats, often designed by the farm families themselves, the different steps of systematic development of the farm over several years, towards the desired situation, are chalked out: the **long-term plan.** The long-term plan is divided in **seasonal work-plans,** in which the activities for the season, the necessary resources and the expected returns are documented. This is the second part of the **farm document** made by the farm family.

This farm document, the Farm Plan, is not a blue-print but a **flexible framework for farm development**, which can be adapted to changing situations (e.g. weather conditions, availability of resources, changing views and priorities, new ideas, etc.). This makes Farm Planning an **ongoing process.**



Farm plan of a diversified home garden

5. Implementation of the Farm Plan.

Implementation of Farm Plans is the responsibility of the respective farm families. Their Farm Plan is a documented **commitment** to the systematic development of their farm. It increases the confidence of the farm families: "We can reach this goal on our farm with our own resources". At the end of each season the outcome of the **seasonal** work-plans is **review**ed and **new work-plans** are made, based on the results, and with reference to the long-term plan.

Farm Planning for Sustainable Farming is a **family affair**, involving women, men and children and their experience, knowledge and views of the farm. The planning process, the plans and their implementation are 'owned' by the family and facilitated by extension staff.

Farmer Field Schools for ecological potato production in the Andes

Stephen Sherwood, Rebecca Nelson, Graham Thiele, Oscar Ortiz

Various partners are working with farmers to strengthen local innovative capacity as a means of enhancing production and integrated management of potato in the Andes. Groups in Ecuador, Peru and Bolivia have used the Farmer Field School approach as a jumping-off point to tackle a range of challenges, most notably knowledge gaps and the devastating late blight disease.

Challenges to Andean potato farming

Although potato has been a staple crop in the Andes for millennia, modern population pressure has led to agricultural intensification and in turn to ecological disturbance and land degradation. Chemically intensive technologies have allowed for increased potato production in many areas, but at great costs to ecosystem health and also to farmers exposed to toxic substances. Modern market forces have contributed to the sharp reduction in potato varieties, and the trend is toward shortened fallow periods and monocropping. Mechanised tillage in many areas has contributed to physical soil erosion and compaction. High input requirements and market price fluctuations have led to significant loss of profitability.

The effects of ecological disturbance are acutely evident with late blight, a particularly destructive disease caused by a fungus-like microbe. Late blight contributed to the Irish potato famine of the 1840s when the pathogen arrived to Ireland from its centre of origin in Mexico. Since the 1980s, pathogen migrations have brought fungicide-resistant strains to South America. Management of late blight poses special challenges for several reasons: the high risk of crop loss, the invisible nature of the pathogen, the lack of natural enemies, and the small number of effective management tactics. As a result, it is difficult, in many parts of the Andes today, to grow the crop without regular fungicide applications.

Meanwhile, "modernisation" policies and structural adjustments have dismembered classical agricultural extension and research services in the Andes. The financial support to relevant public institutions has been severely decreased by full privatisation, as in the case of the national research institution in Bolivia, or semi-privatisation, as in Ecuador. This has transformed the roles of researchers and extensionists and placed greater responsibility on rural communities. While tremendously challenging for institutions, improving present-day agriculture will demand approaches that are more responsive and better suited to local agroecological and socioeconomic conditions.

Responding to collapse

The International Potato Center (CIP), the FAO's Global IPM Facility, and a diverse group of governmental and non-governmental organisations are working with Andean communities in Ecuador, Peru and Bolivia in responding to pressing potato-farming demands. Project partners are striving to enhance farmer understanding of agro-ecosystems and to strengthen local decision-making and technology development capacities for more productive and sustainable agriculture. Faced with tremendous pest problems and pesticide abuse, they are emphasising management-intensive approaches that require a good understanding of biology and ecology.

Beginning in the early 1990s, CIP began to work more closely with communities and other partners to strengthen potato IPM. Such collaborative arrangements have yielded diverse benefits. Communities gained new access to information and institutional resources, rural development agencies received increased technical support, and research organisations found brokers to mediate between their relatively narrow interests and the broader needs of communities.

The partners are building on this experience through a range of participatory extension and research models, in particular the Farmer Field School (FFS) methodology developed by the FAO in Asia, Local Agricultural Research Committees (CIALs) developed by CIAT, and Farmer-to-Farmer extension developed by World Neighbors and others in Central America.

Farmer Field Schools

From 1993-1996, CIP and CARE collaborated on IPM in the Peruvian Andes, working in community-based "pilot units" to validate and implement a series of management tactics for insect pests. Seeking sustainable mechanisms for participatory training and research, CIP and CARE began to test the Farmer Field School model in 1997.

CIP staff based in Peru, Bolivia, and Ecuador who were experienced with participatory methods, began to work with national counterparts to adapt the FFS approach to the diverse conditions of Andean potato farmers. The initial agronomic emphasis was on disease management, but now includes general pest and soil fertility management.

The Global IPM Facility led an intensive three-month training of trainers (TOT) in FFS for a group of 35 extensionists from the three countries, who have served as resource people for further developing national initiatives.

CIP's decentralised mode of operation has permitted semi-independent evolution of its national efforts. While each country promotes similar technical themes, such as agroecology, IPM and, in particular, late blight management, modalities and processes change depending on local needs and interests.

Ecuador: Community-based extension and pesticide reduction

CIP and the Ecuadorian National Institute for Agricultural Research (INIAP) collaborate with a large number of NGOs, in particular the Centro Julian Quito, the International Institute for Rural Reconstruction (IIRR) and World Neighbors, and with local municipalities to establish community-based extension systems in response to government restructuring. The FFS methodology strengthens extension approaches that previously centred on technology transfer modes of change. Early work centred on improving facilitation skills and independent farmer learning through self-discovery techniques. The partners now place emphasis on the training of farmer promoters and on linkages with farmer-to-farmer extension.

By the end of 2000, fifteen farmer field school courses would have been completed with the objective of helping farmers to fill knowledge gaps for better understanding of general agroecology and achieving more integrated (i.e., with less external input) management of production. Field school facilitators have shared endogenous know-how, such as a promising limited tillage system known as *wachu rozado*, and have introduced new technologies, such as late blight resistant varieties and insect traps.

As with the Asian experience in which FFS were organised for IPM in rice, the Ecuadorian field schools have used site visits between FFS groups and field days for exchange of ideas and raising public awareness. FFS graduates have expressed interest in follow-up activities, creating links with existing CIALs and establishing their own participatory technology development groups.

Bolivia: Decision support systems and resistance management

The Bolivian Foundation for Research and Promotion of Andean Products (PROINPA) had worked with farmers to develop and test improved simple decision support systems (DSS) for managing fungicides with resistant and susceptible varieties. Use of the DSS was seen to be highly profitable. The FFS approach was adapted as a way of teaching farmers about diagnosis, disease processes, and implementation of the DSS. Learning parcels in most FFSs contrasted the use of DSS with normal farmer practice, with three resistant varieties and one susceptible. ASAR, a collaborating NGO involved, added a change from inorganic fertiliser to manure and wider spacing, to look at the effects of cultural practices on disease development.

Farmer participants have also conducted trials of advanced clones with late blight resistance, where they evaluate varieties at flowering, harvest and after cooking. FFSs were conducted in seed producing communities located at altitude extremes, with the intention of generating seed flows from higher altitudes, where pests tend to be less problematic, to lower zones. As follow-up, a group is planting basic seed of three resistant varieties for seed consumers in the lower zone.

Peru: Capacity building and varietal selection

Since 1997, CARE and CIP have worked with farmer groups in Cajamarca, using the FFS approach to strengthen farmers' knowledge of crop management and to provide access to potato varieties and breeding lines with resistance to late blight. Initial work centred on disease management is evolving toward broader pest and crop management.

The first campaign involved a season-long training programme with four communities and included participatory experiments to test varieties and breeding lines under different fungicide regimes. The curriculum concentrated on disease processes, diagnosis, and management. In the field experiments, the yields of the moderately resistant varieties varied according to fungicide treatment, while the resistant varieties performed well even at low fungicide levels. Eight additional communities participated in the second season. Participants continued testing clones in their own fields, and CARE provided credit to allow larger-scale production of the most promising variety identified in the first years' FFS. Three breeding lines were released by other institutions based in part on the results obtained by the FFS groups. Qualitative evaluations show that farmers have enhanced their general IPM knowledge, particularly regarding late blight management.

The partners are currently facilitating 13 FFS in Cajamarca, with six more groups being led by new partner organisations. The basic curriculum now includes insect ecology and management, and each FFS group is conducting multiple experiments. One general problem is a tendency to design overly complex experiments. In future seasons, experiments will be tailored to the particular interests of the community.

Lessons and challenges

Introducing FFS to the Andes required more than just a re-writing of extension manuals. Local extensionists who agreed on the benefits of 'discovery-based learning', took to heart the re-design of their activities to create a new extension guide (see Pumisacho and Sherwood, 2000). Regarding the technical approach to IPM, extensionists generally favoured the less academic approach of the Asian FFS, which centred on the following principles: grow a healthy crop, conserve natural enemies, observe the crop regularly, and help farmers become experts.

Late blight in the Andes poses a special challenge to FFS and integrated disease management, and in particular to pesticide reduction. The disease's aggressive epidemiology has left farmers with few alternatives to fungicides. Consequently, FFS have had to emphasise not just capacity building, but also technology development in order to assist farmers in improving management of the disease and overall farming productivity.

Farmers and partner organisations have requested training in other components of Andean cropping systems, animal-pasture management, and greenhouse crops, requiring new institutional arrangements, curriculum development, IPM expertise and continued technology development. Further, communities in each country have solicited FFS in IPM for youth, so TOTs for teachers in technical aspects of IPM and FFS methodology are needed.

The FFS approach has been recognised as a highly flexible platform for bringing farmers, extension workers, and researchers together to improve potato production. Expanding and sustaining this work in an age of decreasing government support for agricultural development will require increased community leadership. The partners will be looking at "farmer-to-farmer" approaches that have proven so successful in Central America and elsewhere. National-level projects have recently been approved to expand FFS in Ecuador and Peru. They hope that these and similar initiatives in Bolivia will enhance community capacity to catalyse agricultural improvement in the region.

From sugarcane monoculture to agro-ecological village

Lindsey Mulkins and colleagues

The island of Negros is known as the sugar basket of the Philippines. More than half of the available agricultural land in the lowlands is devoted to sugarcane cultivation. The social and ecological problems associated with monoculture sugarcane production pervade the island. Negros became infamous in the 1980s when the collapse of the sugar industry led to the starvation of thousands of sugar workers and their families. Today, much of the landscape of Negros remains in monoculture sugarcane production under the control of wealthy plantation owners known as *hacienderos*. Many landless labourers continue to toil in the cane fields for 1.50-2 US$/day and are locked into a cycle of poverty, indebtedness and physically gruelling work.

For some of the sugar land communities of Negros, however, there is a positive transformation underway. One such community is the Flora community near Kabankalan in southern Negros Occidental. In 1997, through the Philippine government's Comprehensive Agrarian Land Reform Program (CARP), 76 hacienda workers and their families (approximately 375 people) were awarded an 87 hectare former sugarcane plantation, which they divided into individual farms of 0.82 hectares, and a collective farm of 17.7 hectares.

Photo: REAP-Canada

Conventional sugarcane production in the Flora community is now being transformed into sugar-cane trash farming

The Flora community has since diversified the former hacienda and is following an ecological approach to increase its food self-reliance and make more efficient use of its production capacity. To create a more organised and collective decision making structure, the community has formed a farmers association called PAGLA-UM. The community has also benefited from the presence of a number of organisations specialising in sustainable farming systems research and development. These include PDG, MAPISAN, MASIPAG, REAP-Canada and University of the Philippines in Los Baños, Department of Agronomy.

The Agro-Ecological Village

The Flora community's efforts to create internal food and energy systems are gradually resulting in a more ecological way of living. This approach, which emphasises community self-reliance, is called an 'agro-ecological village'. The general characteristics of agro-ecological villages are outlined and compared to conventional approaches in table 1. The community is using the approach to achieve empowerment, increase financial security, and minimise vulnerability to vagaries in the weather or fluctuations in the market. Sugarcane production has been reduced in scale and ecologised through the implementation of alternative production systems. It still remains a vital crop for the community, providing (outside) income, feed for 145 draught animals and organic matter to maintain soil fertility. In fact, sugarcane's capacity to produce large amounts of biomass for decomposition drives nutrient and organic matter cycles that are critical to the sustainable production of other crops like maize, grain legumes and vegetables.

Modified sugar production

The traditional form of cane production in Negros has led to serious environmental degradation. Sugarcane fields are frequently burned before or after harvest, resulting in reduced soil fertility. Between the early 1970s and 1988, soil organic matter declined by 26% in one of the main cane growing regions of Negros. Reduced soil fertility has led to lower cane yields, and consequently, higher application rates of fertilisers. Current estimates of sugarcane fertilisation levels in the Philippines are 209 kg N / ha, 55 kg P_20_5 /ha, and 74 kg K_20 / ha per year. Additionally, cane production in upland areas causes erosion, resulting in the siltation of water bodies. Ground water has also been contaminated by the high application rates of nitrogen fertiliser and persistent herbicides such as *simazine*. Trash burning has reduced biodiversity and is leading to respiratory ailments, eye disease and increased incidence of cancer among the people.

The alternative practice of pre and post harvest trash (crop residue) cane farming is beginning to be implemented in the Flora community. Three months before harvest, dead leaves are manually removed from the cane stalk (detrashed) and left to decompose on the soil. After harvest, the residual sugarcane biomass is maintained on the field. Through the decomposition process, the trash fixes nitrogen and increases soil organic matter content, reducing application rates of nitrogen fertiliser. Trash farming also enhances weed control, preserves soil moisture, minimises erosion, protects canes from lodging during typhoons, and significantly reduces harvesting time.

Trash farming is known to increase sugarcane yields, particularly those of ratoon crops (regrowth of cane after harvest). In Southeast Asia, yields increase on average by 5.8% in the planted crop and 21.1% in the first ratoon crop. Trash farming reduces the yield decline traditionally associated with ratooning, enabling sugarcane to be cropped an additional one to two ratoon cycles before yields become economically non-viable. If practised over a long time scale, sugarcane trash farming in communities such as Flora has the potential to create a positive feedback system where continuous improvements in soil fertility will lead to increased productivity, reduced input requirements and longer ratooning cycles. The Flora farmers are currently using less than half the amount of urea used by conventional sugarcane growers. However, with changing cultural practices, the optimal fertilisation level is yet to be determined.

The main disadvantages of trash farming are an increased risk of fire and higher labour costs. Cane trash is usually piled in alternate rows to minimise fire risks and enable cultivation between every other row. Labour costs of trash farming are offset by reduced input costs and increased cane productivity. Currently, average yields in the community are about 70 tonnes / ha.

Flora's production of rice and maize

The introduction of rice farming is central to the Flora community's move toward food self-reliance, enabling members to satisfy about 75% of their current rice needs with 3.8 ha of rice. The farmers have successfully implemented an organic rice farming system developed by MASIPAG (see ILEIA Newsletter Vol.14 3&4, p.47), the national ecological farmers' association in the Philippines. The MASIPAG programme emphasises the use of locally adapted varieties of rice selected under organic production systems, facilitating the management of rice without the use of synthetic fertilisers, herbicides or pesticides. Similar to sugarcane trash farming, Flora farmers maintain soil fertility in the rice paddies by mulching the rice straw back into the paddies after harvest. Whereas 90% of rice straw in the Philippines is burned, the mulching system has enabled the community to completely eliminate burning and inorganic fertiliser inputs, as the rice straw fixes nitrogen during decomposition. More nitrogen is provided by azolla, a nitrogen-fixing aquatic plant that grows during and after the rice harvest. Recycled rice hull ash from household cooking and mud press from sugarcane processing are also added to the paddies to maintain fertility.

In the MASIPAG system, the rice is transplanted in rows 30 cm apart. Farmers plough the ground deeply to help the rice crop form deep roots to improve nutrient uptake. Disease pressure is minimised by maintaining low plant density, wide row spacing, and planting disease and pest resistant rice varieties. Fields are planted in an east-west orientation to facilitate air movement through the paddies and minimise crop shading. A MASIPAG trial farm of up to 50 rice cultivars is maintained by the community each cropping season.

In Negros, the most serious pest problems of rice are black bug and golden snail. Black bug is managed by manipulating water levels at critical periods of rice development. Golden snail populations are controlled by maintaining low water levels after transplanting. They are also lured away from the rice seedlings by supplying taro leaves, a preferred food of the golden snail, for a period of 25 days after transplanting.

The Flora farmers intercrop glutinous and sweet maize with the sugarcane crop for home consumption and fresh market sale. To minimise competition effects, maize is harvested after 60 days and is only planted in alternate rows of cane. The community is currently testing alternative cropping systems for more ecological maize production, including intercropping white grain maize, pigeon peas and squash or sweet potato.

Vegetable Production

The Flora community grows a wide variety of vegetable crops for home consumption and fresh market sale, including eggplant (12 ha), squash (5 ha), daikon radish (2 ha), bitter gourd and peppers. The large production of vegetables not only serves the farmers by improving their diets and income levels but also increases the supply and affordability of vegetables in local markets.

Of all the crops grown in the community, vegetables are sprayed with the most pesticides. The farmers' lack of experience with larger scale vegetable production and the absence of locally adapted seeds have prevented the fully organic production of vegetables. Farmers are intensively experimenting with new vegetable varieties and alternative pest controls.

Social and Ecological Implications

Through modified sugarcane cultivation and crop diversification, the Flora Community is enhancing the quality of life of its residents, while reducing the environmental impact. The health of the community has improved as the people have secured a reliable and diverse source of food. The new approach has resulted in a system of labour that better matches the working capacity of the community. Since cane detrashing usually occurs during the rainy season when labour demand is low, it enables farmers to divide work throughout the year. Unlike sugarcane monocultures, the community's diversified agricultural production offers many more opportunities for the involvement of women in all aspects of food cultivation, including cane detrashing, seed collection, planting, marketing and value-added processing.

Sugarcane trash farming

In Negros, men and women who were once marginalised are becoming full participants in the region's economy. Rising income levels amongst the rural poor increase demand for basic consumer goods, and higher education for children. The combination of agrarian land reform and the ecologisation of monoculture production systems in Negros thus appear to have the potential to create socio-economic benefits beyond those at the farm production level. Although the Flora agro-ecological village is still evolving, it already seems to provide a promising model as a development strategy for communities dependent on monoculture agriculture systems.

■

Table 1. An agroecological approach to rural development in the Philippines

Activity	Agroecological system	Conventional approach
Approach	• Emphasises self-reliance and empowerment through optimal use of on-farm resources • Orientates market development towards import displacement • Minimises human impact on local environment and biosphere	• Emphasises development of export markets to pay for imported goods • Communities are vulnerable to external forces and loan-dependent • Degrades local natural resources and biosphere
Food Supply	• Internal and plant-based, on-farm production of seasonal vegetables, rice, corn, fruit, fish and eggs	• Much food imported, including rice, canned and dried fish, processed foods, livestock feeds
Soil tillage and on-farm hauling	• Carabaos (water buffalo)	• Tractors
Seeds	• Community seed banking of open pollinated seeds, new seeds assessed in trial farms, farmer driven participatory plant improvement	• No local adaptation trials, plant improvement or seed saving. Imported hybrid seeds dominate plantings
Soil Fertility	• Maintained through trash farming, nitrogen fixing legumes, azolla, mudpress, carabao dung, rice hull ash. Soil erosion minimised.	• Urea, phosphorus and potassium fertiliser
Insect and disease control	• Biological control strategies, resistant cultivars, balanced fertility	• Insecticides and fungicides
Weed control	• Mechanical weeding devices, crop rotation, good soil fertility management, trash farming	• Herbicides and tillage
Household cooking	• Use of rice hull cookers, efficient wood stoves, biogas, with all fuels farm-derived	• LPG fuel stove, open fire cooking, kerosene as fire starter
Marketing	• Emphasis of internal self-reliance and import displacement with value-added processing	• Monoculture production, products sold to distant markets

Conversion to Organic Farming

A project approach from China

Johanna Pennarz

The Organic Farming Development Project co-operates with advisory staff and experts from agricultural universities and local government to support farmers in converting to organic farming.

Initial situation

Following the high demand for organic products on the international markets, traders are the dominant actors in the organic farming movement in China. They try to identify farm products, which are on a low external input regime already and thus respond to the minimum requirements of international certification bodies. They are not interested in lengthy conversion processes and leave the solving of technical problems to farmers. There are no experts or technical staff specialised in organic farming yet. Staff who lack expertise in dealing with the highly diverse problems in organic farming, advice farmers to simply replace conventional inputs with biological ones. Farmers request blueprint solutions from experts and advisory staff and are not well prepared to start indigenous innovation processes themselves.

The project: conversion as a process

The project has introduced conversion to organic farming as a process in Yuexi, Anhui Province, with the following objectives:

- to develop an extension methodology on conversion, based on a participatory approach,
- to stimulate technical innovations in local farming systems,
- to organise smallholders for internal quality control, technical support and marketing, and
- to attract political support to organic farming.

Extension methodology on conversion

After the pilot villages in Yuexi county were selected, a first assessment of the potentials and problems for development of organic farming was conducted in 1998. This did not provide farmers with a ready-made solution, but proposed a number of options for conversion. The framework elaborated by the advisors made clear that the conversion would be a farmer-led process of gradually modelling the organic farming system by testing various options and possibilities.

At the time, the advisors could only refer to a few experiences in organic farming available in China. The first workshop, held in Yuexi in 1998, provided farmers with a basic understanding of the organic farming concept. It encouraged them to work on specific technical issues like inter-cropping, biological pest control, and green manure. A second training was held in 1999. Meanwhile, farmers fully understood the principles of organic farming and undertook organic practices. They selected the technical innovations they were going to try out during the coming season. A third workshop, held in early 2000, evaluated the experiences gained during conversion. Workshops served as focal points to summarise and exchange experiences and document the joint decisions made in the communities. Apart from these formal training workshops, the advisors have undertaken regular visits to the pilot areas to discuss the ongoing experiments and propose additional options. Through the process, they have developed methods to systematise information on local farming systems and feasible options for conversion.

Stimulating technical innovations

During the process of conversion, farmers have gained experiences with a number of organic farming techniques. They have become more self-confident and are willing to solve problems locally. Their production systems have improved significantly, and some innovations have already spread to their neighbours following conventional practices. In order to cope with the higher demand for organic fertiliser, farmers have increased their livestock production and integrated green manure into their annual cropping cycle. Green manure was common in traditional agriculture, but has been replaced by chemical fertiliser during the “green revolution”. As a result, traditional manuring techniques have fallen into oblivion and seeds of green manure plants have disappeared. Initially, some varieties were made available by the project, but then farmers started searching for seeds of traditional varieties from their region. Experiments with green manure have been very successful and others who wish to purchase seeds of green manure varieties are approaching the organic farmers now.

Even though the conversion process started just three years ago, farmers are already experiencing a visible improvement of the agro-ecological environment. They find that the biodiversity is enriched by beneficial organisms, which have returned to their gardens after a long absence: bees now replace the artificial pollination of the kiwi flower and snakes control the population of rodents. Farmers have become more aware of soil fertility issues. The project has introduced the spade analysis as a simple tool for monitoring processes within the soil, and farmers have learned that the texture and consistency of the soils under green manure has greatly improved within this short period.

Organising smallholders

In the beginning, conversion was confined to a demarcated area of land on which a single crop is converted to organic production. But, the project has encouraged a voluntary approach with only those farmers who are interested in organic farming participating. As a result, some farmers within the designated area have been sticking to conventional production, while others outside this area have converted to organic farming. Altogether, a higher number of farmers and a higher acreage have been converted to organic farming than originally planned. The voluntary approach with dispersed plots has placed higher demands on the organisation of the internal control and certification system.

Farmers in Yufan Village have established the first association of organic kiwi growers in China with the objective of providing technical support and information, and organising marketing of organic products. The kiwi farmers now plan to establish a direct marketing outlet in the provincial capital. The Organic Kiwi Association has put much effort in the development of their own requirements and in the internal documentation system. Each member keeps his own records on inputs and outputs. Recently, those farmers who have been participating in the conversion from the beginning received organic certification.

Attracting political support

The objectives and framework of conversion planning have been carefully communicated with the State Environmental Protection Administration (SEPA) in Beijing, which showed great support for the development of organic farming. The conversion plan resulted from a months-long communication process between project staff and the farmers. Finally, the conversion plan has been integrated into the master plan for ecological reconstruction of Yuexi. The political support has raised the significance of the conversion process for environmental policies and further motivated the administrative staff engaged in this process. At the same time, Yuexi has gained importance as a national pilot area for organic farming. ■

The Cuban response to scarcity of inputs
Crop associations

Maria de los Angeles Pino and Humberto Ríos Labrada

Until 1989, Cuba's agricultural system was characterised by its dependency on foreign external inputs. This system covered over 70% of the country's arable land. In some parts of the country, such as in the eastern region and in the western province Pinar del Rio, traditional agriculture still played a dominant role. It was official policy to reduce the land share of small farmers: producers had to either pass on their land to state farms or form co-operatives (Trinks and Miedema, 1999).

After the collapse of the socialist countries in 1989, the share of monoculture-based agriculture diminished drastically. The use of fuel, the main agricultural input, fell from 13.0 to 6.1 million tonnes in two years. In the same period, the amount of fertiliser used fell from 1.3 to 0.3 million tonnes and expenditure on pesticides from 80.00 to 30.00 million USD (Rosset and Benjamin, 1993).

At the same time, farmers and scientists in Cuba began to look for alternatives that would protect plants from biotic and abiotic stresses. They attempted to use the land efficiently and experimented with low input levels. In these experiments, farmers' knowledge, underestimated for so long, played an essential role once again.

Traditional crop associations, such as maize-beans and maize-pumpkin that had been used before by small farmers, became a common practice in large areas. At the same time, unusual crop combinations, such as carrot-cabbage, lettuce-cabbage, carrot-garlic, tomato-beans, sweet potato-pumpkin, maize-tomato, banana-beans, banana-taro-beans-maize, sugar cane-beans, began to appear in areas that had long been dominated by monoculture practices. Even though most of the work by formal research institutions was still directed towards monocultures, many areas started to produce food in a manner that remained invisible to formal statistics by the early 1990s.

In this new situation of virtually no external inputs, most of the new crop associations were found to be more productive than monocultures. Many farmers practising crop associations were able to obtain two or more crops on the same piece of land, previously monocropped. The different crop production schemes made it possible for farmers to operate in different ways: first, to produce and sell the entire harvest of the principal or "duty" crop to the state market at very low prices, as is obligatory; second, to produce and sell on the free market, with strong price incentives. For instance, in huge sugar cane tracts, one or two rows of beans or cowpea were planted between two rows of sugar cane. In this way, farmers who sowed beans at the start of the growing period of sugar cane could either be self-sufficient in beans or sell them on the free market. Thus, polycropping allowed farmers to produce one official crop, and at the same time secure an income through selling secondary crops.

Polycropping also led to better control of pests and diseases in the absence of chemical pesticides, to more efficient use of very scarce inputs and to higher economic profitability. The polycropping approach quickly spread all over Cuba as a way of alleviating the consequences of the external input crisis. Scientists joined the movement and started research on this method.

Tomato and maize: an unusual association

Tomato (*Lycopersicon esculentum* Mill) was a typical monoculture in Cuba before 1989. This crop requires a combination of temperature, radiation and relative humidity that is optimal between October 21 and December 20 in Cuba. Producing tomatoes out of season, though extremely lucrative, is very expensive, as the production should, ideally, be in greenhouses with high-energy consumption.

The solution to this problem was found in using maize as natural shade for tomato, and thus modifying the microenvironment favouring tomato production off-season. Different spatial arrangements of tomato-maize were tested under small farm conditions. Fertilisation was done with a combination of biofertiliser and 90 kg/ha of Nitrogen (120 kg/ha of Nitrogen being the normal recommendation).

The most productive spatial arrangement was three rows of tomato planted between two rows of maize (see Figure 1). Maize was sown 30 days before tomato was transplanted. Every row was oriented from north to south.

This spatial arrangement led to a reduction of the radiation intensity by about 25% and a temperature decrease of approximately 3°C. Yields of tomatoes produced under maize shade increased by 5-6 tonnes/ha in comparison with tomatoes grown as a monoculture. The tomato-maize association decreased adult white fly presence by some 24% and reduced virus infections by 6%. Fruit quality was found to be better.

The main advantage for farmers is in being able to plant before and after the optimum sowing period, allowing them to market fresh tomatoes off-season and thereby increase income. In the transition from tomato grown as a monoculture to the tomato-maize crop association, the benefit-cost ratio increased from 1.9 to 3 when sown after the optimum moment or from 2.4 to 3.5 when sown before the optimum sowing time. At the same time, some maize was produced for home consumption or sale on the free market. (Pino, 2000, in preparation).

The once unusual combination tomato-maize is becoming more and more common in small, private farms (with, on average, one hectare of land) of the San José de Las Lajas municipality. One of the principal obstacles to further spreading of this crop association has been the difficulty of mechanisation. It is interesting to note how quickly farmers have adopted this and other low input systems, in a setting where few Cuban functionaries realised the advantages of crop associations as a principal component of the new Cuban agriculture. In spite of the fact that such alternative practices in agriculture have contributed to a slight recovery of the Cuban economy and to higher food security, policy makers still advocate a backward move towards use of high external inputs. In order to avoid a renewed dependency on external inputs, the challenge now, for researchers and farmers alike, is to gather more evidence on successful crop associations.

The experience of family farmers from Tauá, Brazil

Organic cotton

Pedro Jorge B. F. Lima, Teógenes Senna Oliveira

Photo: Bert Lof

For more than two decades now, the so-called 'cotton crisis' strikes in the semi-arid Northeastern region of Brazil. This crisis has touched many sectors of the region's economy, but the burden lies mostly with the family farmers who usually plant cotton as their most important market crop. Since 1986, when the boll weevil (*Anthonomus grandis* Boheman) spread throughout the region, the crisis became even worse. The boll weevil was neither the only nor the main cause of the crisis, but it made the cultivation of traditional cotton crops (mocó, perennial cotton (*Gossypium hirsutum* L. r. *marie galante* Hutch) almost impossible.

In 1990, a local NGO, ESPLAR, began researching and developing agroecological alternatives for cotton cultivation in the semi-arid region. This was before the first demands for organic cotton in Brazil emerged. The initiative was a response to the demand of family farmers from two municipalities of the Ceara interior, in the Northeast of Brazil.

First steps

Between 1990 and 1996, ESPLAR carried out a Research & Development project titled "Ecological management of perennial cotton". Family farmers from different municipalities of Ceara took part in the discussions on what strategies for agro-ecological management to adopt and how to carry out the experiments. The management alternatives consisted of intercropping the perennial cotton, planting of an early maturing variety, removal of affected flower buds, and soil conservation measures.

The chosen alternatives found many barriers during experimentation. Farmers did not adopt all the recommended technologies, especially the removal of flower buds, which is crucial to the control of boll weevils. A long tradition of relatively extensive cultivation of perennial cotton made it difficult to cater to the additional labour needed.

However, in 1994, on the basis of the first results, diffusion of the proposed technologies took place. It was supported by a loan of US$150/ ha. 130 farmers cultivated almost 250 ha of crops. Although they did not reach the expected cotton production levels, the alternative management system resulted, in many cases, in the restoration of soil fertility, and in the continued maize and beans intercropping. Besides, substantial increases in the intercropping of Leucaena (*Leucaena leucocephala)* and the making of contour lines were observed (Sousa, 1999). It was the start of a gradual change of mind and an inversion of the predominant logic of many farmer-researchers.

Despite the limitations in production, the merit of this initiative was the exposure of ESPLAR and the farmers' organization of Tauá (ADEC) to the emerging market for organic cotton. Thus, in 1993 and 1994, ADEC sold 10.5 tons of cotton fibre, produced without any chemical input, for the production of organic cotton T-shirts for Greenpeace Brazil.

A new R & D project

In 1997, ESPLAR started a new project to develop cropping systems of both perennial (mocó) and herbaceous cotton on an agroecological basis. At that time there was deep discouragement amongst the farmers to continue growing cotton, due to consecutive crop losses.

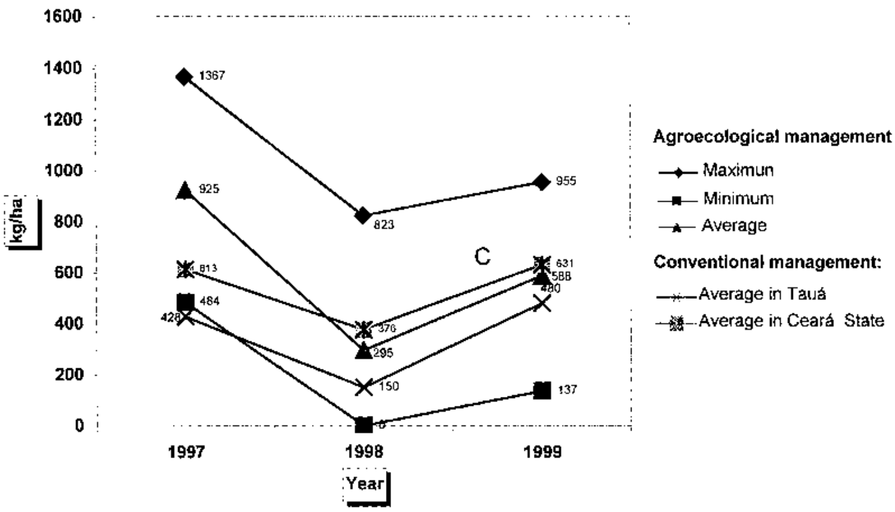
The new practices to be tested included planting of annual, herbaceous cotton at the beginning of the wet season, always in association with maize, beans and/or sesame, besides legumes such as *Leucaena* and/or *Cajanus cajan.* Cotton is planted in strips of 5 or 6 lines, alternated by strips of the other crops. Contour lines and other soil conservation practices are adopted where necessary. Fertilization is done with farmyard manure, depending on the quantity available to each grower, as well as with biofertilization of the leaves with fermented fresh manure mixed with other mineral, vegetal and animal components that are found locally. Pest management is based on the removal of flower buds affected by the boll weevil and on monitoring of the boll weevil population by means of pheromone traps. Moreover, farmers make use of *Trichogramma* spp. to biologically control *Alabama argilacea* and other harmful insects. Sprayings with Neem (*Azadirachta indica*) leaf extract are also used to control worms and as a repellent for the white fly. After harvesting, cattle graze on the crop residues in the fields. During the wet season the pruning of *Leucaena* is recommended for use as mulch.

In order to stimulate the farmer-researchers to apply most of the practices, ESPLAR has established a "risk contract", which gives each of them R$150 on a loan basis. After harvesting, the cotton goes to ADEC to be ginned and accounts are settled. The surplus is paid to the grower, but when the production value is lower than the debt, ESPLAR bears the loss.

Participatory research and extension: its results

Despite 3 consecutive years of drought, from 1997 to 1999, the number of growers using soil conservation practices, associated crops and ecological pest management in cotton production has increased considerably, from 4 to 154 in the year 2000. Some of them have been certified as organic cotton growers. All of them received technical support from ESPLAR. In the same period, the cultivated area increased

Figure 1 – Yield of herbaceous cotton with agroecological management in the experiments in Tauá and with conventional management in both Tauá and Ceará state, 1997-99.



from 2 ha to almost 180 ha, as is shown in Table 1. This indicates that the research strategy of associating participatory experimentation with the extension of the agroecological practices was successful.

The results obtained with the 4 original farmer-researchers in 1997, positively influenced dozens of other farmers. These farmers decided, often after years of abandonment, to start growing cotton again. In addition, the price for certified organic cotton, which reached a premium of 30% above the price of conventional cotton, was an extra incentive. Around 70% of the farmers indicated that they had been directly influenced by the 4 original farmer-researchers.

The average yields of the ecologically grown cotton in the experimental areas, during the 1997-1999 period, were always higher than the average yields obtained in Tauá for conventional cotton in monoculture (Figure 1). When compared with the yields of Ceará state, the experimental fields in Tauá were yielding higher in 1997, whereas the Ceará average surpassed the experiments in the two following years. It should be noted that due to intercropping, it was possible to harvest additional crops such as maize, beans, sesame and *Cajanus cajan.* They are, despite their small quantities, important contributions to the food needs of the farmer families.

In this organic cotton production system, boll weevil control is still a bottleneck, as there are no specific techniques on how to grow cotton together with the pest. Thus, in the dry years, 1997 to 1999, the recommended practices showed a relatively easy control of the insect. In a wet year with a much higher incidence, as in 2000, the control becomes more difficult.

Until now, the volume of organic cotton harvested has been relatively small, but has good market prospects with organic textile factories, both national and international. Several textile companies, from Brazil and abroad, have contacted ESPLAR for buying organic cotton. However, the current supply in Tauá is not enough to meet all the demands. Even if the potential to increase production in Tauá is considered, it will hardly exceed some tons of fibres per year. Nevertheless, Tauá is gradually becoming a reference point for organic cotton production in the semi-arid region of Ceará and the Northeast of Brazil. In 1999 ADEC made one more step ahead in aggregating value to the organic cotton, when it contracted the spinning of 3 tons of organic fibre.

Another relevant result of the research is related to the ecological control of the white fly (*Bemisia* spp.). The farmer–researchers are encouraged to carefully observe the interaction between insects, spontaneous and cultivated plants. In 1998 it was observed that the white fly strongly prefers sesame (*Sesamum indicum*). The infestation levels in sesame in 7 systematically monitored intercrops were 6 to 20 times higher than in cotton. It was also verified that two spontaneous plants with fuzzy branches and leaves, known as “gervão” or “rabo de raposa” (*Stachytarphetta cayenensis*) and “pega-pega” or “amor de velho” (*Mentzelia fragili*), attract and kill adult white flies. This opens up possibilities to effectively control this cotton pest by incorporating these plants in crop associations.

Progress, limitations and prospects

Research to design, test and diffuse agroecological alternatives for organic cotton growing, with the direct participation of family farmers in the semi-arid region of Ceará has faced serious difficulties. They are inherent to the environmental conditions of the region, to the poverty situation that excludes most of the population from formal credit, and to the unsustainable practice of traditional cotton production.

10 years later, it is observed that an increasing number of farmers are gradually adopting the agroecological practices. They are driven by the need to preserve the scarce natural resources and stimulated by the possibilities of an emerging organic market, offering higher prices.

Presentation of the results through the media and at several technical and scientific events, in and outside Ceará, roused the interest of many technicians, cotton growers, municipalities, NGOs and even the regional bank, in the organic cotton experience. This opened up the prospect of expansion to other states in the Northeast of Brazil. Furthermore, partnerships with official education and research and development institutions were established.

■

Table 1: Evolution of the number of family farmers adopting agroecological management with cotton consortia, according to certification results, Tauá - CE, 1997-2000.

Year	No of Farmers			Area (ha)		
	Total	Organic	In conversion	Total	Organic	In conversion
1997	4	4	0	2	2	0
1998	69	18	51	103	27	76
1999	104	42	62	144	57	87

Rice - fish integration increases production and income

Ecologising rice-based systems in Bangladesh

Marco Barzman & Luther Das

The Green Revolution in Bangladesh altered highly diversified agroecosystems that were strongly dependent on natural processes. A wide variety of vegetables such as lentil (*Lens esculenta*), eggplant (*Solanum melongena*), amaranth (*Amaranthus tricolor*), chilli (*Capsicum annuum*) and okra (*Abelmoschus esculentus*) were grown as field crops in the middle elevation areas between the homestead and the rice fields. Climbing vines such as bottle gourd (*Lagenaria siceraria*), bitter gourd (*Momordica charantia*) and country bean (*Dolichos lablab*) were grown in the highest elevations, using trees and houses as support. A wide variety of trees usually surrounded the homestead areas. Oxen, goats, and chickens were abundant. Irrigation networks covered only 15% of the country's cultivated land. A single annual crop of rain-fed rice was grown during the monsoon and rice fields were mainly confined to low-lying areas. Native wild fish and other aquatic organisms entered rice fields freely. The fish actively migrated and settled in the fields to breed. Rice farmers exploited this source of protein and made sure to open their dikes at the beginning of the monsoon. They also placed branches in their flooded fields to create a habitat more attractive to gravid brood fish. The use of composted cowdung and legumes such as *Sesbania rostrata* along with regular silt-laden floods maintained soil fertility. The absence of pesticides favored a balance between pests and natural enemies. These traditional systems provided a sustainable supply of fruit, vegetable, grain, meat, eggs, fish, fodder, fuelwood, construction material and animal power.

Green Revolution changes

Today, irrigation networks extend over 40% of Bangladesh's cultivable land. Rice areas have been gradually extended, two crops of rice per year is now the norm. Increased production is nearly meeting the needs of 130 million people. There have been, however, serious unforeseen agro-ecological consequences. Vegetable production for household consumption, now confined to the homestead, no longer meets the requirements of the rural population. The number and diversity of trees has reached catastrophically low levels generating a fuel crisis and a scarcity of fruit. With a scarcity of fodder, oxen are difficult to maintain and are increasingly replaced by mechanical tillers. The small quantity of dung still available is used almost entirely as cooking fuel, leaving little for organic fertilizer. Elevated roads, flood control, pesticide residues and eutrophication from fertilizers stopped the migration of fish from rivers to rice fields. Populations of native fish species (*Channa* spp., *Heteropneustes clarias*, *Anabas testudineus*) are now endangered and the traditional rice-fish systems have disappeared.

The system is already showing signs of unsustainability. Most rice farmers are dependent on insecticides for pest control. A 1995 CARE survey of rice farmers in Comilla district—a high-input use area—showed that 96% used insecticides during the dry season. But despite—or due to—the prevalence of insecticide use, old farmers report that insect pests are now more difficult to control than in their youth. They also report increasing fertilizer dosages for the same yields and are nearly unanimous in saying that their soils "are tired".

The decrease in the ability of rural households to produce vegetable, fruit, and high-protein food has contributed to an unbalanced diet, over-reliant on rice. The increased rice yields, on the other hand, have not translated into either improved nutrition or income.

CARE's Agriculture and Natural Resource sector realized that some of the elements of diversity and natural pest control from traditional systems could be restored to the intensive rice monoculture systems. The "ecologised" rice-based systems would help to increase the availability of diversified food while making the systems more sustainable. Using the Farmer Field School approach, the New Options for Pest Management (NOPEST) project introduced farmers to the ideas of integrating vegetables, fish and trees in their rice systems using a natural pest control approach. The "new-old" techniques have been widely adopted by more than 40,000 farmers without negatively affecting rice yields.

Reverting to natural pest control

Starting in 1995, the project promoted non-chemical means of pest control in rice. As a result, 85% of participating rice farmers completely left out the use of synthetic insecticides within a single season, and continued to practice natural pest control 5 years later. They rely on natural enemies

Table 1. Rice yield differences between users and non-users of insecticides.

	Dry season 1998 Mean rice yield (t/ha)	Monsoon 1998 Mean rice yield (t/ha)	Dry season 1999 Mean rice yield(t/ha)
Project participants using no insecticides	4.66 (n=134)	3.28 (n=172)	5.11 (n=114)
Non-participants using insecticides	4.18 (n=155)	2.73 (n=172)	4.71 (n=152)

Table 2. Rice yield differences between rice-vegetable and rice-only systems.

	Monsoon 1998 Mean rice yield (t/ha)	Dry season 1999 Mean rice yield (t/ha)
Participants' rice-vegetable	3.61 (n=13)	5.82 (n=10)
Participants' rice-only	3.66 (n=17)	5.16 (n=14)

Table 3. Rice yield differences between rice-fish and rice-only systems.

	Monsoon 1998 Mean rice yield (t/ha)	Dry season 1999 Mean rice yield (t/ha)
Participants' rice-fish	3.04 (n=35)	5.25 (n=35)
Participants' rice-only	3.66 (n=17)	5.16 (n=14)

Table 4. Rice yield differences between rice-fish-vegetable and rice-only systems.

	Monsoon 1998 Mean rice yield (t/ha)	Dry season 1999 Mean rice yield (t/ha)
Participants' rice-fish-vegetable	3.30 (n=3)	5.59 (n=10)
Participants' rice-only	3.66 (n=17)	5.16 (n=14)

and on the ability of the rice plant to compensate for insect damage, with no negative effects on their yields. The yields of project participants using no insecticide are consistently higher than those of non-participant insecticide users (see Table 1). Since the project participants also modify other practices, besides foregoing insecticides, it cannot be said that the yield increase is due entirely to the absence of insecticides. It does show, however, that insecticides are not needed to obtain yield increases. Project participants have higher net returns than insecticide users. In 1998, the average net return from the rice crop of participants, if they sold the entire crop, was Tk.5,373 (=US$107) per farmer per season, as opposed to Tk.3,443 (=US$69) per farmer per season of insecticide users.

Integrating vegetables

In 1991, a group of agronomists from CARE visited Sitakondo (Chittagong District), in the southeast of Bangladesh. They found what appears to be an indigenous dike crop system. Covering several kilometers, dikes between and surrounding rice fields are occupied by rows of country bean grown on simple supports. Local growers did not know the origin of the method and believed it to be ancient, attested to by the large number of country bean varieties in the area.

This system, along with experimental dike cropping systems from Indonesia prompted CARE staff to initiate a pilot project involving this technique. In 1995, the project began exposing men and women farmers to such cropping systems using the Farmer Field School approach. Since then, at least 40% of participating farmers are growing vegetables on the dikes of their rice fields, by elevating and widening their dikes. The most successful crops have been country bean, yard-long bean, bottle gourd and okra, all of which, except for yard-long bean, are traditional crops.

Data of 1998 and 1999 show either no difference or a slight increase in the rice-vegetable systems, in spite of the area lost to dike crops, i.e., the entire rice-vegetable field—the check plus the wider dikes—is producing at least the same total quantity of rice (see Table 2). The net returns from the vegetable crop that farmers would obtain if they were to sell the entire crop—they usually sell $\frac{1}{4}$ of the crop—is Tk.733 (= US$15) per farmer per season, an added value of 14% to the rice crop. Rice-vegetable growers eat vegetables more frequently and share the surplus with neighbours, friends and relatives.

Trees-on-dikes

The project also introduced the idea of growing trees on the dikes without affecting the rice crop, using cultural practices, such as periodical pruning of roots and branches. This type of pruning is perfectly appropriate to trees producing timber, cooking fuel and fodder. Now, 35% of project farmers are growing bokain (*Melia azidirach*), shishoo (*Dalbergia sissoco*), mahogany (*Swietenia macrophylla*) and acacia (*Acacia auriculiformis*), and continue to tend them long-term. Although it is too early to formally evaluate the benefits of this technique, the number of farmers planting trees on their dikes is growing and many have initiated small-scale tree nurseries to supply their community with planting material.

Integrating fish in rice-based systems

ICLARM and the Bangladeshi Government's Fisheries Research Institute were among the first to experiment with integrating fish in flooded rice systems in Bangladesh, but their ideas were not extended to farmers. In the 1992 dry season, CARE conducted pilot activities in which 180 farmers experimented with rice-fish using non-native fish species as common carp (*Cyprinus carpio*), tilapia (*Tilapia* spp.) and sharputi (*Puntius gonionotus*). These early trials showed that rice yields were increased by 16% with rice-fish relative to the previous dry season with rice-only, 6% of which was attributed to presence of fish in the rice field.

In 1998 and 1999, yield data of project participants practicing rice-fish compared to those practicing rice-only shows that rice-fish causes no significant decline in rice yields, and in some cases even an increase. The rice yields presented here are underestimated by about 5% because the ditch area in the rice-fish field was not taken into account when calculating rice yields (see Table 3).

The net returns from selling all the fish average Tk.7,354 (= US$147) per farmer per season. This is more than the returns from rice and it is perfectly compatible with rice production. Although not all rice fields are feasible for rice-fish systems, 30% of project farmers are practicing it and their numbers are constantly increasing. As with vegetables, rice-fish farmers eat fish more frequently and donate much of it to their social networks.

Integrating both vegetables and fish

Of course, both vegetables and fish can be integrated into the rice monoculture and we estimate that 18% of project farmers have done so. As expected, their rice yields are not inferior to those of farmers practicing rice-only (see Table 4).

In conclusion

Cereal crops are frequently considered to be obligate monocrops. Our experience, however, shows that there are many ways in which rice can become part of a more

Planting vegetables on rice bunds to improve nutrition and income

diversified agroecosystem. The "ecologised" monocrop becomes more productive, it offers more services to the farmer household, and the multiple ecological interactions within the system increase its sustainability. The successes we obtained in diversifying rice monocultural systems still represent the initial stages in making small-scale agriculture more sustainable. Areas that require future attention include use of native fish species, integration of livestock, interactions between the home garden and the rice field, and scarcity of organic inputs for soil fertility management in rice. In other words, there are probably still many possible beneficial options that could further diversify and "ecologise" these systems.

In defence of monocultures

David Wood

Crop monocultures are almost universally decried as unnatural, ecologically dysfunctional, and a threat to sustainable agriculture. At least part of this belief is based on the idea that all would be well if agriculture could mimic the structure of natural vegetation, which time has shown to be productive, stable and biodiverse. However, relatively complex natural vegetation - for example, tropical forest– is always suggested as a model for fields rather than simpler vegetation. Consequently, all prescriptions for ecological agriculture recommend between-crop diversity (polyculture), even to the extent of combining trees with crops (agroforestry). This diversity is thought to bring higher levels of productivity, stability, sustainability and equitability. This 'defence of monocultures' will question the *sole* reliance on complex models for *all* agriculture. In contrast, it will suggest that more appropriate models for a key section of farming - annual cereal cropping, now producing most of our food - can be found in vegetation dominated by single species, that is, 'natural monocultures'. Is there something that can be learned from natural monocultures that could be of value to sustainable cereal cropping?

Monocultures in nature

It has now been recognised by ecologists that monocultures exist throughout nature in a wide variety of circumstances, of which two could be of importance for sustainable agriculture.

***Marginal conditions**:* Firstly, natural monocultures are found in geographically marginal conditions, very commonly, between water and land. There are many familiar examples like the reed beds of *Phragmites australis* growing on the margins of fresh-water lakes in Europe. Such stands can have an age in excess of 1000 years. Salt marshes on the margin between land and sea in Europe and North America are often dominated by species of the grass genus *Spartina*. Net annual primary productivity of *Spartina alterniflora* marshes has been reported as up to 60 tonnes/ha, a figure close to the highest dry matter yields of intensively managed arable crops.

***Disturbed conditions**:* Secondly, natural monocultures are found in disturbed conditions as in the case of *Impatiens glandulifera,* a summer annual that colonises the margins of water courses in Europe. It has been argued that the objective of many forms of arable farming, especially cereal cultivation, is to achieve weed control by creating conditions in which the crop plant attains the dominant status. As in the example, dominance of a cereal crop depends primarily upon the synchronous germination of a high density of large seeds followed by the rapid development of a dense vegetation cover composed of a large number of plants of comparable age and maturity. More generally, the importance of cereals - that is, grasses - in food production may relate to the ability of grasses to resist disturbance, indeed to thrive under seasonally disturbed conditions.

Natural monocultures as models

***Rice**:* If there is a natural model for monocrop wet-rice production it should be found in a region of domestication of rice, in southeastern Asia, among wild relatives of domesticated Asian rice. The seasonally flooded rivers and deltas of the great silt-laden rivers draining the Himalayas seem to provide the ecological conditions for wild rice monocultures. The wild rice relative *Oryza coarctata* was the most common and plentiful grass species in the Sundarabans mangrove swamps of Bengal and: 'the first species to establish itself on newly-formed alluvial river banks, which are both marginal and seasonally disturbed by flooding.'

If early farmers chose swamps, first to gather, then to farm rice, they would be working in habitats where 'natural monocultures' are common. Single dominants are able to monopolise a swampy site to the virtual exclusion of any rival and any understorey. In addition, swamp vegetation has relatively high productivity, generally around 15-20 tonnes/ha/year. This is attributed to a plentiful supply of nutrients, due to flushing with nutrient-rich water, and low water stress for most of the year.

***Sorghum**:* Savannah grasslands worldwide are often dominated by limited numbers of species, often from the grass tribe *Andropogoneae,* a tribe which includes *Imperata*, but also *Sorghum* and *Saccharum* from which the crops sorghum and sugar cane were domesticated.The *verticilliflorum* race of *Sorghum bicolor* was identified as the progenitor of cultivated sorghums. It was found as the chief dominant, in enormous quantities, of the extensive tall-grass savannah of Sudan and Chad. Sorghum was domesticated somewhere along a belt south of the Sahara from Chad to western Ethiopia. The races *aethiopicum* and *verticilliflorum* of *Sorghum bicolor* are often dominant grasses in the northern savannah of Africa. These 'massive stands' of wild sorghum provide both an evolutionary and ecological pedigree for monoculture sorghum cropping.

***Wheat**:* Perhaps the strongest evidence of the importance of natural simple models for cereal agriculture comes from immediate wild relatives of wheat. These are found in the Near Eastern region of domestication, where there has been the most intensive research on crop relatives. Botanists and plant-collectors have repeatedly and emphatically noted the existence of dense stands of wild relatives of wheat. Wild einkorn (*Triticum monococcum* subsp. *boeoticum*) in particular tends to form dense stands, and when harvested its yields per square metre often match those of cultivated wheats under traditional management. Wild emmer (*Triticum turgidum* subsp. *dicoccoides*) grows in massive stands in the northeast of Israel, as an annual component of the steppe-like herbaceous vegetation and in the deciduous oak park forest belt of the Near East. The stand density of these wild cereals is comparable to cultivated fields, suggesting that these southwestern Asian cereals form the basis of modern monocrop agriculture.

Ecological determinants

Although the simple structure of natural monocultures may indicate a model for cereal cropping, a major question remains unanswered. What are the ecological determinants of natural monocultures, and can these be reproduced in sustainable cropping? Answering such questions would allow farmers not just to mimic the structure of natural monocultures, but also to mimic the ecological processes that maintain natural monocultures. Despite considerable recent research by ecologists on the role of species diversity, very little of the newer work takes up the question of why some ecosystems have more species than others. Yet some argue that low species diversity is characteristic of unpredictable and 'environmentally buffeted' environments, and that diversity is not correlated to environmental productivity, as in the case of salt marshes.

Natural flood and fire regimes are examples of environmental buffeting. At the time of transition between food gathering and cropping, early farmers would have been very aware of the impact of ecological determinants such as fire and flood on both productivity and the structure of natural cereal monocultures: human existence depended on this knowledge. A transition to farming that mimicked natural disturbance regimes in early fields would maintain the undoubted robustness of natural monocultures. For rice, the 'artificial swamp' of the field reduces competition from weeds and has allowed rice to persist in pure stands, as with many grasses in natural swamps. For the seasonally-dry grasslands which form a natural model for sorghum, and for wheat and barley fields, seasonal burning or grazing may be the 'fluctuating environment' that gives grasses the competitive advantage in annual seed production.

Diversity within monocultures

The level of within-species diversity in natural monocultures is also of direct importance for agriculture. Monoculture is defined by IBPGR (1991) as: '*the growing of a single plant species in one area, usually the same type of crop grown year after year*'. Nothing is said in this definition of variation within the crop species: complex varietal mixtures, as often found for example in common bean (*Phaseolus vulgaris*) under traditional farming, are monocultures by this definition. However, the term monoculture is now commonly used as a synonym for single-variety fields. Whatever the usage for fields, it will be important to know the genetic structure within natural monocultures and how it compares with the genetic structure of species found in more diverse vegetation. There are indications that some natural monocultures may be genetically uniform – for example, the many examples of aquatic plants, which spread vegetatively – with no intra-specific genetic diversity. It is commonly thought that such a low level of diversity is unsustainable in farmers' fields. How then does it persist in nature? In contrast, if natural monocultures of wild relatives of our cereals are found to be genetically diverse, then varietal mixtures could add sustainability to cereal cropping.

Crop-associated biodiversity

Concern over the ability of crop monocultures to maintain associated biodiversity may be misplaced. There is now substantial evidence that single crops such as rice have self-regulation through great crop-associated biodiversity. At higher trophic levels, including parasites and predators on the herbivores, there is yet more diversity. Management of the crop cycle to increase detritus from the rice crop could encourage detritus feeders and, in turn, natural enemies of rice pests, contributing to substantial biodiversity in a monoculture, and, under most circumstances, minimal pest damage. Indeed, the main problem with monocultures in Green Revolution agriculture could be the loss of associated biodiversity due to the use of agrochemicals, intensive tillage and the large-scale of production, rather than the monoculture itself. More information is needed from wild ecosystems to indicate how the biodiverse properties of natural monocultures can be maintained in agriculture.

Conclusions

Hitherto agroecologists have claimed that sustainability results only from complex polycultures, which mimic complex - and therefore stable - natural ecosystems. While this may be true for more equable tropical regions, it may not always apply to seasonally disturbed or marginal environments. Indeed, cereal cropping – producing most of our food - may be a close mimic of structurally simple but seasonally stressed and disturbed natural grassland ecosystems.

However, before simple natural models can contribute to sustainable farming, we need answers to many questions. There is an urgent need for research on natural monocultures – preferably on the close relatives of our most important cereals such as rice, wheat, and sorghum. We need to know:

- The genetic structure of natural monocultures: are they genetically uniform or diverse? What implications could this have for annual cereal production and could combinations of different varieties be more productive and sustainable than the present monocultures?
- How does the level of genetic diversity relate to persistence under pest and disease pressure and to short-term adaptation? Can this provide lessons for sustainable farming?
- What role does crop-associated biodiversity have in self-regulation of monocultures and what is its contribution to productivity and sustainability? What implications does this have for the technologies used in production of monocultures?
- What are the ecological determinants of natural monocultures? Does their ecology always include natural stress or disturbance such as burning or flooding that could provide models for field management? Are there lessons for zero-tillage systems?
- Finally, were natural monocultures an ecological pathway to domestication, skilfully managed by the first farmers and becoming our first fields? Or, have traditional monocultures always been mixed to some extent with other crops?

Pasture Cropping

Darryl Cluff and Col Seis have grappled for many years with the development of workable and regenerative solutions to the severe land degradation problems in the Birriwa-Gulgong area in central west New South Wales, Australia. In the 19th century, the perennial grasslands on the flat to undulating country, with an average but highly variable rainfall of about 600 mm, were very productive and ideal for raising livestock. However, the winter-active perennial grasses and palatable native legumes disappeared due to set-stocking and failure to reduce stock numbers during droughts. Since 1882 cropping became a major enterprise for most farmers. Traditional techniques, which involved the complete removal of all vegetation, resulted in vast tracts of bare ground both before and after the crops. Soil erosion and nutrient decline on arable land became extensive.

In 1995, they started to experiment with direct drilling of oat and wheat into native pasture. They direct drilled the grain into the permanent groundcover at 25-30 cm row spacing, using 80-100 kg seed and 210-330 kg NPS fertiliser per ha. The pasture cropping technique utilises a niche in the growth cycle of what remains of grasslands that have lost cool season perennials almost completely. Yields were similar to those from conventional farmers crops. But as the cool season annual cereal crops face little competition from warm season perennials they require no cultivation and little or no herbicides, and they improve the vigour and biodiversity of the grazed pasture and the condition of the soil.

They are now trying alternative crops such as lupins and are experimenting with resowing of native grasses with the crop seed to improve the pastures. Livestock is an important component of pasture cropping. Seis improved the gross profit on his sheep enterprise by using sheep to heavily graze pastures prior to sowing. Adaptation of machinery to the needs of pasture cropping was important in the creative innovation process.

'Only lack of imagination prevents us from growing productive healthy crops in sustainable biodiverse landscapes'.

How to grow winter wheat? The Fukuoka-Bonfils method

Winter wheat is normally sown in September-November and grows just a little before going dormant in winter. The winter cold triggers flowering. After the floral initiation in January, the plants develop a number of tillers and are finally harvested in August.

There are a number of drawbacks in growing winter wheat the conventional way. As the plants are still small at the onset of winter, soil erosion is high. Tillering takes place in February-March when temperatures are sub-optimal for this physiological stage of plant growth. The plants are vulnerable and require numerous treatments against weeds and fungi. The frequent tractor passes over the land lead to compaction and bad aeration of the topsoil.

Marc Bonfils' method

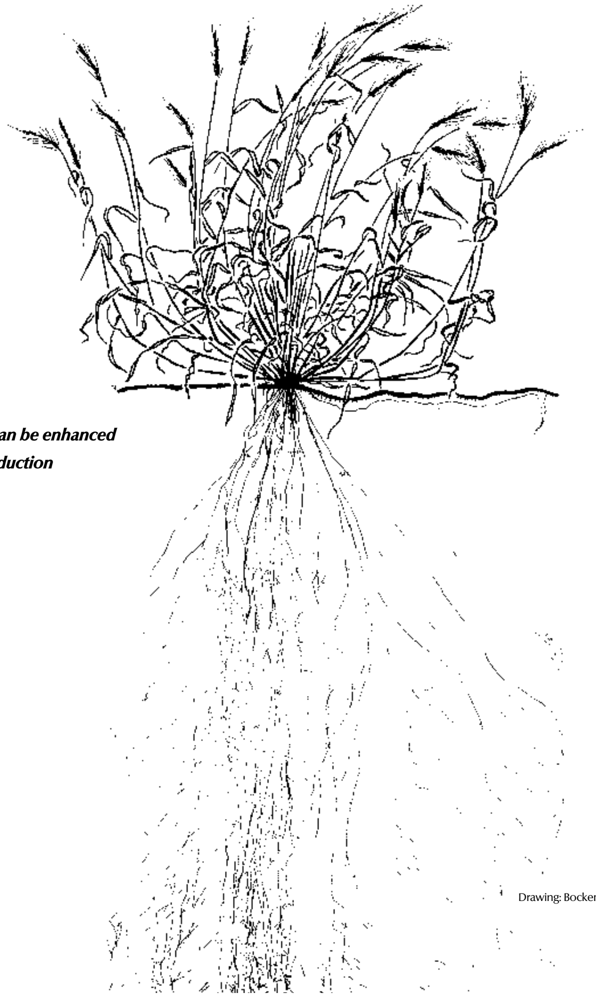
Is there an alternative? Can we regenerate our soils and still grow the food we need? Marc Bonfils has experimented with alternative cultural measures in the region of Beauce, France, for many years and has developed a system that embraces the general principles of permaculture. Although Bonfil's method is primarily for wheat, it is easily adaptable to other cereals. Bonfils found a way of growing food without ploughing in the European climate, as Masanobu Fukuoka did in Japan.

At the end of June – much earlier than in the traditional way - wheat is sown, or rather *pressed* into the soil at a spacing of 60cm, through the carpet of spreading perennial clover, previously sown in April. The clover cover assures Nitrogen fixation, better bacterial life, and development of algae that are also capable of fixing Nitrogen. During its long vegetative period the wheat plant makes deep roots before winter sets in, thanks to better availability of nutrients and greater bacterial activity. This gives the plants a head start for the next summer. Yields of over 15 tons per hectare (6 tons per acre) have been obtained in this manner. A comparison of some parameters:

	Conventional	Bonfils
Plants/m	350	1.5-4
Ears/plant	0-3	100-150
Earlets/plant	12-15	35
Grains/ear	20-30	40-60
Weight of grains	Low	High

Even before harvesting of the ears, the new wheat crop is already pressed in through the clover carpet amongst the maturing 'bushes' of wheat. Clover is a perennial: it is not sown each year but simply cut down at the beginning of the season, at a height that does not damage the wheat plants.

After harvesting in August, the straw and chaff are returned to the field. In this method, tillage is reduced to a bare minimum, avoiding practices like ploughing and compaction that retard the process of revitalising the soil.



Tillering in grain crops can be enhanced to increase production

Drawing: Bockemühl, 1980.

Advantages

The optimal temperature for tillering is 20-25°c. In Bonfils' method, unlike in the conventional, tillering starts already in August of the year of sowing, when temperatures are closer to the optimal. A better root system develops and a better plant stand is obtained, reducing leaching of nutrients in winter. These bigger plants appear to resist the cold better than young seedlings. With a wider stand, much more tillers are produced, each tiller leading to an ear. The tillering period starting in August is much longer than with the conventional winter wheat growing method.

Problems

The main danger lies in the wrong choice of variety: if a strictly winter variety is not used, then the plants will go to grain before winter, producing less than the standard methods. Most modern varieties, being hybrids between winter and spring or warm-climate types, have this tendency. Therefore, one should seek long-straw, traditional varieties, with strong vegetative vigour that gives plenty of side-shoots and dense foliage.

Mechanical harvesting constitutes a problem in the Bonfils method, as harvesting takes place amidst young, vulnerable seedlings. Cutting should be at least 5 cm above the soil.

A problem of the wheat-clover association is that the wheat grows too tall because of the richness in soil Nitrogen. Sowing wide, permitting maximum sunshine and thus reducing the risk of lodging of the wheat, can counteract this. ■

Update on the System of Rice Intensification

Photo: Association Tefy Saina

Well-developed SRI rice plant.

The ecological System of Rice Intensification (SRI) developed in Madagascar gives remarkably good results. Hundreds of farmers have increased their irrigated rice yields to 6–10 and even 15 tonnes. The main characteristics of the approach are: capturing full potential for tillering by early transplanting, planting one by one with wide spacing; providing full potential for root growth by creating aerobic conditions, alternative wetting and drying of the field, minimum irrigation and early and frequent weeding. A comparison of some parameters:

	Conventional	SRI
Seed requirement (kg/ha)	80 to 120	5 to 10
Transplanting after days	20 to 30	8 to 15
Spacing cm	10x10 to 20x20	25x25 to 50x50
Transplants per clump	3 to 4	1
Plants/m^2	75 to 150	4 to 25

A full description of the SRI approach has been published in the LEISA Newsletter Vol.15 3&4, pp.48-49, "Revolution in rice intensification in Madagascar", by Justin Rabenandrasana.

There is an increasing interest in the approach, as confirmed by Norman Uphoff of CIIFAD in a recent update on SRI trials, which states:

Madagascar: In January 2000, Robert Hirsch did a report for the French Development Agency, "*La Riziculture Malgache Revisitée: Diagnostique et Perspectives*, 1993-1999," He reported that over the period 1994-99, the average yields of farmers using SRI had ranged between 6.7 and 11.2 t/ha.

In contrast, the SRA system of rice improvement, recommended by the government and uses HYVs and fertiliser, produced average yields ranging from 3.12 to 4.92 t/ha in the same irrigation systems. Traditional practices averaged 2.78 t/ha.

China: The first willingness to test SRI outside of Madagascar was at Nanjing Agricultural University. Dr. Ding Yanfeng in the NAU Department of Agronomy set up SRI trials in June-October 1999. With plant spacing 25x25 cm and 20x30 cm, the yields were 9.5 t/ha and 9.2 t/ha, but with spacing of plants 30x30 cm, the yield was 10.5 t/ha. This is well above the current national average of 6 t/ha, but more important, it was obtained with about half as much water as usual. More trials are being undertaken during 2000.

Indonesia: During the wet season 1999-2000, Central Research Institute for Food Crops (CRIFC) conducted SRI trials at Sukamandi station, with a yield of 9.5 t/ha. Nearby farmers' yields with SRI methods were 5.9-6.9 t/ha. CRIFC now plans to conduct SRI trials at its stations throughout the country during 2000, if possible in all provinces, to assess any variations in ecosystem suitability.

Ivory Coast: The West African Rice Development Association (WARDA) conducted a series of tests during the 1999 season, which were characterised at first as "disastrous." Yields from two different varieties with SRI methods were only half as much as with WARDA varieties and methods.

However, WARDA conducted the trials without water control, so seedlings were inundated for much of their early growth period, nullifying the synergistic effects of SRI methods, which require well-drained soil.

WARDA has designed three sets of trials comparing SRI with conventional methods for testing in 2000.

Also in Nepal (CIIFAD), Cambodia (CEDAC), Sri Lanka (Ministry of Agriculture), Cuba (The Institute for Investigation of Rice), Sierra Leone (World Vision International), Bangladesh (CARE International), India (ActionAid), Colombia (CIAT), Honduras (Pan-American School of Agriculture at Zamorano), South Africa (Agricultural Research Council of the University of Pretoria) and Ghana (Ministry of Agriculture) trials have been or will be started.

Trials that we do not know about may be going on in other places, since papers on SRI have now circulated fairly widely. ■

Genetic diversity and disease control in rice

Scientists from the Philippines-based International Rice Research Institute (IRRI) have found a new way to control a major disease in rice without using any chemicals. By planting different types of rice alongside each other, they could almost completely control the spread of rice blast, a disease that can cost the rice industry millions of dollars a year.

A small scale experiment in 1997 suggested that interplanting could achieve 92 to 99% control of rice blast, as well as an unexpected double success by boosting farmers' yields by half a ton to 1 ton per hectare.

In 1998, 812 hectares were planted with hybrid rice and glutinous rice, four rows of one and one row of the other. The crop was sprayed with fungicide only once. Yields reached 9 tons of hybrid rice and nearly 1 ton of glutinous rice per hectare. Even more impressive was the fact that, within the interplanted crop, the incidence of blast fell to 5 percent from a common level of 55 percent and the yield loss dropped from 28 percent to nothing at all. In 1999, the area grew to 3,342 hectares, and the farmers involved boasted that interplanting was providing them with about US$150 more income per hectare. By the end of 2000, the IRRI-Yunnan research team plans to extend the scheme to cover up to 60,000 hectares and continue to expand it into the Philippines, Thailand, and other rice-producing nations.

IRRI's Director General Ronald P. Cantrell says, "The days of unsustainable high-input rice production are a thing of the past!"

No-tillage rice/wheat cultivation
The one straw revolution

Chris Evans

The natural farming rice-wheat no-tillage system was developed over 3 decades by Japanese philosopher and natural farmer Masonobu Fukuoka. His philosophy evolved as he saw the reductionist nature of modern science and the distancing of society from nature as root causes of humanity's many problems. This led him to search for better ways of farming that work more with nature, not against it. He realised that many of our current agricultural needs are met by too much hard work and high inputs. Instead, he reasoned that nature should be allowed to do more work in the farming system, which it has been "designed" to do anyway.

JPP Background
The Jajarkot Permaculture Programme is a grassroots NGO working in 4 districts of Nepal. As its name suggests, it is based on Permaculture, a technique of sustainable systems' design using the direct application of the principles of ecology. Thus its philosophy also embodies observation of and working with nature as the prime model of sustainability.

The JPP gained its first experience of no-till farming during a visit in 1988 by the author and co-founder of the JPP to Japan. After this trip, a trial plot was set up on JPP's Farm #2 Resource Centre (RC) in Jajarkot. The farm is about 1 acre of land consisting of irrigated rice-wheat and dry-land crops. Later a second trial was started at Sita Paila RC in Kathmandu.

The Fukuoka System
The plot was ploughed one last time, sown with wheat and white clover, then mulched with the straw from the previous rice crop. Weeding was necessary until the clover was established.

The wheat sprouts vigorously while the clover forms an undercover, acting as a green manure. This conserves moisture, fixes nitrogen and suppresses weeds - all needs, which the farmer normally tries to fulfil through labour and external inputs. By letting the clover and the straw do this work, inputs are lowered and the soil is not disturbed, allowing it to create its own system of fertility management, as in a natural undisturbed soil.

There is no further work until the wheat harvest the following spring. At this time, the wheat is cut, and rice is sown into the stubble and clover, with the wheat straw mulched on top. There is a risk that the clover smothers the young rice plants. Fukuoka floods his fields which weakens the clover and allows the rice to get away. After 1-2 weeks he drains the field allowing the clover to recover while the rice gains height. At farm #2 there was not enough water to do this; instead we grazed cattle on the clover briefly, a few days after the rice had been planted. At Sita Paila RC in Kathmandu, the clover was cut for rabbit fodder. Either way, the clover is controlled while the rice is given a chance to establish. For both rice and wheat, it is advised to coat the seed in a mixture of powdered clay and water to protect it from birds. When the straw is applied, it is possible to apply small amounts of well rotted compost (Fukuoka uses chicken manure) to help with its decay.

In this way, transplanting is completely eliminated, while weeding is reduced almost to zero. And there is no need for extensive flooding of rice paddies as its purpose in the traditional system is weed control.

Experience and lessons
The no-till system as adapted by the JPP has been extremely successful in that it really takes much less work to produce yields which are equal to and in some cases greater than the conventional/traditional methods. Because of the healthy soil, plants are robust and diseases are almost non-existent. It has worked consistently at Jajarkot's Farm #2 since 1989 and at Kathmandu RC since 1996. But the technique hasn't caught on by itself in the communities surrounding the RCs. This is partly due to the traditional use of straw as livestock fodder, and a lack of clover seed. Therefore, JPP has been reluctant to carry out extension of the method until sufficient alternative fodder can be obtained from agroforestry (AF) systems. Extension of AF thus takes priority over no-till, until the time is right for introducing the latter. The no-till method is so radically different that a major cultural shift is needed to enact it.

There are many ways of adapting the method, as JPP was able to do from the original system of Fukuoka. Timing of sowing is important, and it is possible to sow rice into wheat, and vice versa, when the previous crop is still standing. In Jajarkot we had a problem that the wheat ripened earlier than in surrounding fields, thus increasing its susceptibility to bird predation. The solution was found by either delaying sowing or using a longer rotation variety. Alternatives to clover need to be tried out – plants, which fulfil the same functions but are suitable to different environments, especially hot tropical/sub-tropical, which clover does not like. Perhaps vetches are a possibility. This method emphasises skill in observation of the crop and its environment, and ability to find plants and cropping systems, which mimic relationships and patterns found in nature ■

Sustaining the Green Revolution by resource conserving technologies:

The Rice-Wheat Consortium's example

Peter R. Hobbs, Raj Gupta, J.K.Ladha and Larry Harrington

The Indo-Gangetic Plains of Pakistan, India, Nepal and Bangladesh are endowed with plentiful natural resources, deep productive soils, sufficient good quality water, climatic conditions that permit multiple-cropping, high population densities and relatively good infrastructure. The Green Revolution (GR) of the 1970s and 1980s radically changed the traditional agricultural system of this region. Now, about 13.5 million hectares of land are in continuous rotation of irrigated rice and wheat, providing food and livelihoods for many millions. Between 1960 and 1995 rice yields increased from 1.55 to 2.66 tonnes/ha and wheat yields from 0.84 to 2.34 tonnes/ha.

The majority of the farm households have less than 5 ha of land, whilst a minority have more than 20 ha. All farmers use improved varieties of wheat with fertiliser. In rice, some farmers still grow traditional, fine quality varieties like *Basmati* as they fetch higher market prices. Mechanisation levels are high, especially in the western regions, with resource-poor farmers renting tractors and threshers for tilling and harvesting. Animal power is still common in the eastern regions, but farmers complain of the increasing costs of maintaining draught bullocks. Many farmers are moving to contract ploughing with tractors; dairy cows are acquired in place of draught bullocks.

Rice-wheat a safe system

The main factors for the initial success of the GR and the emergence of the rice-wheat system were the introduction of high-yielding, semi-dwarf varieties and chemical fertilisers. Pesticides, investments in irrigation infrastructure, political commitment and policy support played a lesser role. Free irrigation water, cheap agro-chemicals, subsidised power supply and low-interest farm credit were some of the crucial supports provided by South Asian governments that made intensive rice-wheat production profitable and a safe system for farmers.

Stagnation of production growth

However, in the past several years the productivity growth of wheat and rice has declined and the expansion of rice and wheat area has halted due to many reasons (Hobbs and Morris, 1996). Ecological degradation of the natural resource base has occurred as farmers using conventional technologies harvest up to 10 tonnes of cereal per year. Long-term rice-wheat experiments have shown that yield growth declines at constant input levels. Unbalanced use of fertiliser and delayed planting of crops are cited as major factors. Profitability has dropped as more inputs are needed to get the same yield. Input subsidies that favoured the GR have lacked farm-level incentives for efficient input use. The price of rice and wheat has declined steadily over the last 30 years. Partial removal of subsidies and ecological problems have put stress on the economy of farmers.

Ecological degradation

Resource degradation in the rice-wheat system can take many forms: loss of organic matter; mining of soil nutrients; build-up of weeds, diseases and pests; waterlogging, salinity and sodicity. Additional problems that reduce system productivity are: low nutrient and water use efficiency associated with delayed crop establishment, driven in turn by inappropriate tillage practices (delays in sowing wheat after rice can reduce yields as much as 1.5% per day); flat sowing and flood irrigation causing nutrient leaching; puddling leading to formation of a ploughpan, reduced soil permeability and enhanced soil cracking; and restriction of plant root and shoot growth and chlorosis due to temporary water stagnation. To compound these problems, *Phalaris minor*, the major weed in wheat has developed strong resistance to the commonly used herbicides and farmers have had to shift to new, more expensive herbicides. Excessive pumping from wells is leading to declining water tables in fresh water aquifer zones, while inadequate drainage is causing waterlogging and salinity in others. Many of these problems are interrelated and tend to be concentrated in areas where farmers practice continuous rice-wheat rotations (Pingali and Shah, 1999).

Rice at harvest time grown on beds in the Indian Punjab (9t/ha crop, 50% water savings)

The Rice-Wheat Consortium

The concern today is to continue the GR sustainably – to make agricultural practices ecologically sound and more efficient while increasing productivity and profitability, improving farmer livelihoods and reducing poverty. As population in the region swells, a yearly cereal yield growth of about 2.5% will be needed to meet food demands. The Rice-Wheat Consortium for the Indo-Gangetic Plains (RWC) is an institutional mechanism created to deal with these issues in SE Asia. It is a partnership of national programmes (Bangladesh, India, Nepal and Pakistan), international centres (CIMMYT, IRRI, ICRISAT, IWMI and CIP) and various advanced institutions (Cornell, CABI Bioscience, IACR, Rothamstead, and IAC Wageningen etc.). The RWC believes that the key to a sustainable Green Revolution lies in Resource Conserving Technologies (RCTs).

Participatory research

A stakeholder participatory approach based on strong partnerships is being used to develop and promote new technologies. Stakeholders include researchers, extensionists, local manufacturers, NGOs and farmers. Farmers experimenting with technical options are proving more successful than researcher demonstrations of "finished" technologies. With access to the necessary equipment, farmers are adapting practices to their own situations and providing valuable feedback to the other stakeholders. This approach required a change in paradigm that increased the mobility of stakeholders, decentralised decision making and allowed for strong partnership and trust building. The long-term implications of farmer tested technologies on the environment are being closely monitored by a team of scientists.

Promising technologies

Promising technologies to ensure timely sowing and good plant stands, crucial for rice-wheat system productivity and efficiency, are being tested. RWC scientists have developed new tillage and other resource conserving options, such as surface seeding, zero / reduced tillage, bed planting, mechanical transplanting, laser levelling, dry seeding rice, etc. These options have opened up "space" (time, labour, land and water) for farmers to experiment with more diverse cropping systems.

Sowing wheat before harvesting rice

Surface sowing of wheat on to unploughed, wet soil before or after rice harvesting is working well in heavy, poorly drained soils. This technique is particularly relevant to farmers with small land holdings and little or no power sources. In the 1997-98 wheat season, farmers in Nepal using surface weeding were able to get their crop planted on time, despite continued rain, and harvested an average of 4 tonnes/ha. Farmers who used traditional methods were unable to plant a crop at all.

Zero tillage and stubble sowing

Zero tillage and sowing of wheat in standing rice stubble using a seed drill, locally manufactured in India and Pakistan, is a key technology for farmers with access to tractors. This drill, a modified version of the local *rabi* drill, costs US$400. Resource-poor farmers are able to rent them. In a variant of zero tillage (reduced or minimum tillage) a rotovator stirs a thin layer of soil in a strip ahead of the seed drill. Although it delays planting by 4-5 days compared to zero tillage, reduced tillage may be the preferred system for areas with post-rice harvest weed problems. There is also a "strip-till" version that cultivates only the area where the seed is placed and not the entire area. Both 2-wheel and 4-wheel versions are available for these reduced tillage systems. Such technologies open the door to improvements in resource efficiency leading to timely sowing, water savings, higher fertiliser efficiency, reduced weed germination, less herbicide use, reduced residue burning, lower fossil fuel use, decreased air pollution – and higher yields!

Farmers are very enthusiastic about the technologies as they save money and increase production. For example, current land preparation practices for wheat after rice requires nearly 12 tractor passes, whereas zero-tillage only one. This saves up to 100 litres of fuel per hectare, approximately 1 million litres of irrigation water and wear and tear of tractor parts. This is roughly a US$50-60 or 30% saving in production costs per hectare while increasing production simultaneously. The acreage of zero-till has risen from a few hectares in 1996 to 10,000 hectares in 1999 and over 100,000 hectares in 2000 in NW India and Pakistan. The main constraint now is the availability of sufficient good quality seed drills.

RWC scientists and farmers are trying to cut down on the burning of crop residues, which amounts to nearly 10 tonnes/ha. Leaving the stubble on the field as straw mulch and seeding wheat into this residue, rather than burning it, could improve soil structure and fertility, reduce water use and create a habitat for beneficial insects. This technology, however, is still in the experimental phase.

Broadcasting rice seedlings

Raising of seedlings in beds and transplanting them into puddled soil is the predominant method of cultivating rice. Puddling destroys the soil's physical properties and gets more expensive as real rural wages increase. Direct sowing has system benefits and is an attractive option when the problem of weed growth is tackled. Research is underway to find integrated ways to control these weeds. Broadcasting of rice seedlings, a system common in China, reduces labour even further.

Modified bed planter

Traditionally, wheat is planted by broadcasting on flat land. Research has proven that this method is not ideal for enabling uptake of nutrients and controlling of weeds. Bed planting was introduced by scientists as an alternative, and is being used by farmers in Mexico on about 0.5 million hectares of irrigated lands. Here, a machine makes two beds of about 70 cm width. The technology has interesting advantages: it saves seed rate by about 40-50 %; saves water by about 30-40 %; gives higher yields; reduces lodging; enhances mechanical weeding; overcomes temporary water logging problems; promotes rain water conservation and allows subsurface fertiliser placement for reducing N losses in rice and wheat.

The technology is mainly used in wheat, but is being adapted to rice. Costs of making the beds after every rice harvest is to be reduced by permanent beds on which each successive crop will be planted on the previous residue. Bed planting would enable crop diversification in rice-wheat areas with the introduction of soybean, maize, cotton, mungbean, vegetables, and canola on beds. It also has great potential for expanding the acreage of hybrids with reduced seed rate. The latest – modified – version called the PAU bed planter is manufactured locally in Amritsar, Punjab, India at a cost of about US$ 425 *ex-factory*.
A similar model is available in Pakistan.
To help make seed drills, hand tractors, and tractor implements more widely available, RWC staff are linking with and advising farmer groups, local machine shops, and agricultural engineering specialists.

Integrated Pest Management

To minimise the use of chemicals, the RWC is developing integrated control measures for pests, weeds, and diseases in the rice-wheat system. Planting wheat in beds facilitates mechanical weeding and provides good weed control without the use of herbicides. In farmer-participatory trials, zero-tillage reduced *Phalaris minor* populations by two-thirds in the first year. Growing early planting varieties (late October) means that the wheat crop is well established and can suppress *P. minor* as it emerges in mid-November. Crop diversification with sunflower, sugarcane and other crops helps reduce losses to weeds. Stemborers survive in rice crop residue, but zero tillage practices actually help reduce this problem by leaving the rice stubble standing or as a mulch, providing a habitat for beneficial insects that control stemborers.

Photo: Rice-Wheat Consortium

Pau bed planter for no-tillage wheat production

Integrated Nutrient Management

Balanced and efficient use of organic and inorganic fertilisers is crucial in making the rice-wheat system sustainable and profitable. The reduced use of cattle manure over the years has resulted in a decrease of soil organic matter. The use of zero-tillage and the halt to burning of crop residues will improve this situation. Soil organic matter dynamics are being studied and monitored in fields with new tillage options, rotations and crop technical innovations. The RWC is also working on on-farm development of Site-Specific Nutrient Management. SSNM builds on: 1) crop nutrient requirements based on economically efficient yield targets; 2) estimation of potential soil supply of N, P and K; and 3) plant N-status during critical periods of growth. The technique permits an estimation of leaf nitrogen content at specific stages in plant growth by measuring leaf greenness. This gives farmers an idea of when to apply fertiliser and in what quantities. Simple colour charts that help better targeting of fertiliser applications are being introduced to farmers. (Ladha et al. 2000).

Biotechnology will be needed

Further increasing the yield potential of rice and wheat seems inevitable. This can be done by using hybrids, synthetics or improving the photosynthetic efficiency of crops. While traditional plant breeding has been effective in improving crop yields, biotechnology can make this more effective, e.g., through marker assisted selection. Biotechnology can play a role in providing needed resistance for various pests, diseases and other biotic stresses. Herbicide resistant crops may finally enable farmers to use direct seeded rice without weed problems. Insect resistant crops could help reduce the application of pesticide sprays. A combination of biotechnology and resource conserving technologies may give the best perspective on continuing and sustaining the GR. Although investments in biotechnology are increasing fast, major benefits for the rice-wheat system are still to come. Of course, any research and release of genetically modified crops should adhere to biosafety and bioethics standards, and must be acceptable to civil society.

Policies needed

Policies concerning pricing, incentives, research, agricultural education, funding etc. are essential if the efficient use of inputs and RCTs are to be enhanced. The case of the Indian Punjab demonstrates how the efficient use of water is hampered when farmers are given water free of charge. Such a subsidy should be more production oriented and linked to water saving practices. The same applies to pricing of fertilisers and other inputs. Fertiliser subsidies could be easily used to regulate fertiliser application, to encourage the switch from prilled urea to urea super granule (USG) or slow release forms, and to promote machines that help deep placement of fertiliser to reduce ammonia volatilisation and nitrogen leaching. Easier credit to purchase equipment would certainly be a better policy than subsidies on equipment.

Making the shift to resource conservation

A major bottleneck in large-scale adoption of RCTs is the mindset of farmers and other stakeholders on, for example, the age-old practice of excessive tillage. The shift to RCTs requires a reorientation and retraining of all stakeholders. Integration of RCTs into the respective curricula will enable extension workers, scientists and farmers to learn the benefits and needs of these technologies. Public awareness on the benefits of RCTs at the farm, village, country and global level is needed. Reaching out to more farmers requires innovative ways of scaling up RCTs based on participatory approaches involving all stakeholders.

Can we make it?

Farmers who have experimented with these technologies show tremendous enthusiasm in adopting it and sharing it with fellow farmers. The RWC believes that these technologies will become common place in South Asia in the coming years. Similar successes of farmer led technology adoption are seen in Brazil and Argentina where conservation tillage has been adopted on millions of hectares of land.
However, one note of caution needs to be made. Unless the population growth in South Asia is reduced in the next 2 decades, it will not be possible to produce sufficient food without degrading the environment. ■

Effective Micro-organisms Technology

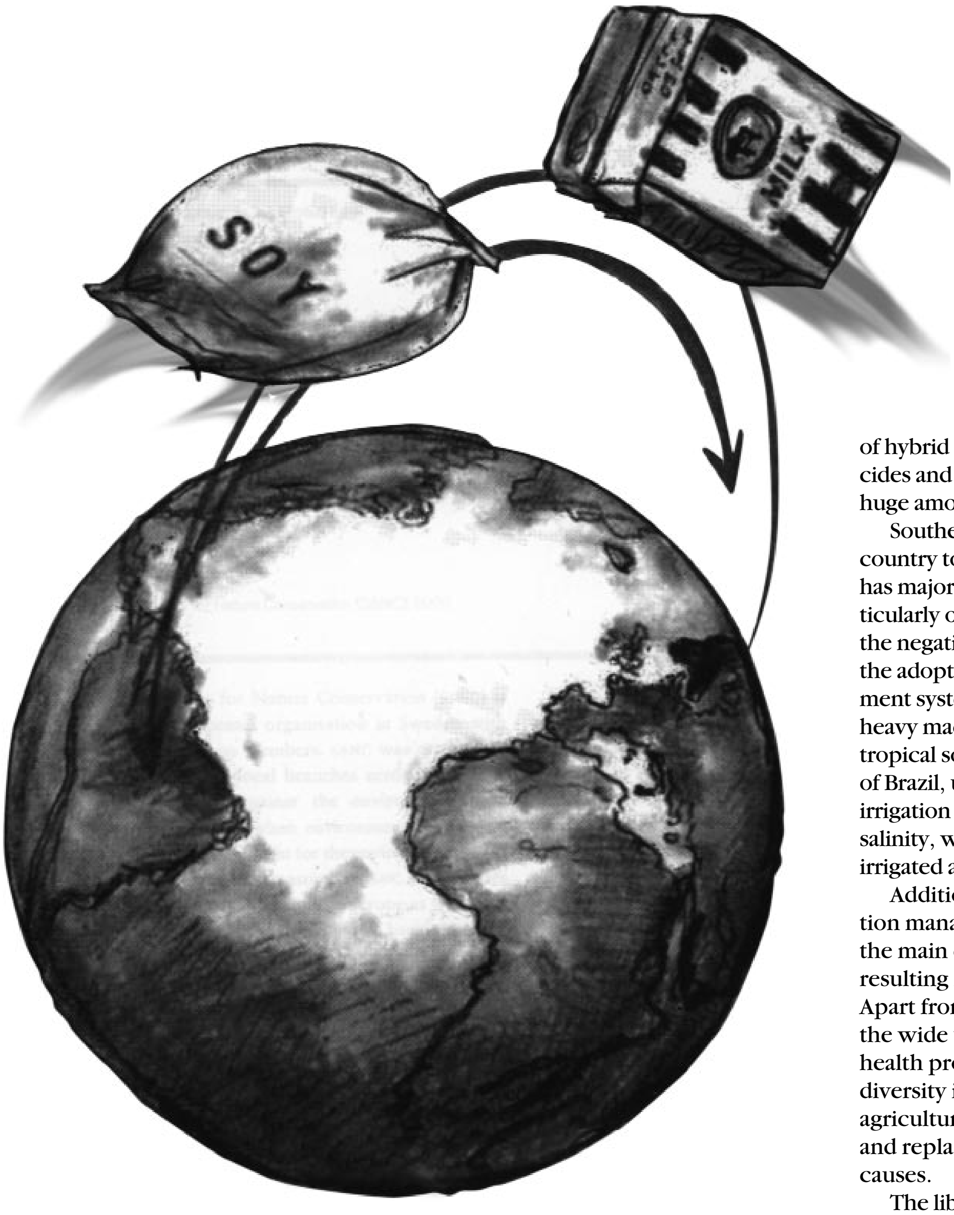
EM-Technology was developed by professor Dr. Teruo Higa in 1980 at the University of Rhyukyus, Japan. At the First International Conference on Nature Farming held in Tahialand in 1989, the Asia Pacific Natural Agriculture Network (APNAN) was formed. This network established an international programme for promoting research, education and extension of nature farming with EM-Technology.

EM contains photosynthetic bacteria (*Rhodopseudomonas spp*.), lactic acid bacteria (*Lactobacillus spp*.), and yeast (*Saccharomyces spp*.). It also supports the activities of other microbes. It is claimed that EM promotes germination, growth, flowering, fruiting, and ripening in crop plants. It enhances the photosynthetic capacity of plants and the efficiency of organic matter as fertilisers. EM develops the resistance of plants to pests and diseases and suppresses soil borne pathogens and pests. It can also be used in human and animal health care. A good introduction on EM-Technology can be down loaded from www.agriton.nl/higa.html

In Pakistan EM-Technology is being promoted by Nature Farming Research & Development Foundation (NFRDF) which set up the Nature Farming Research Centre and the EM-Technology Training Institute. In the last 8 years extensive experimentation has led to some important innovations in EM-Technology. Now a wide network of EM suppliers and technology transfer officers are available for the thousands of farmers who have begun using EM-Technology.

In January 2000, the **EM World Journal** (ISSN: 1562-255X) was launched by Nature Farming Research & Development Foundation, 41-X-101, Susan Road, Madina Town, Faisalabad, 38060 Pakistan. Fax: +92 41 613507; nature@fsd.paknet.com.pk

The Journal contains research articles on EM-Technology in agriculture and health. One of the articles: **Technology of Effective Micro-organisms as an alternative for rice and wheat production** in Pakistan by Tahir Hussain et al., reports on a long-term field experiment at Faisalabad, Pakistan, to determine the agronomic and economic merits of EM-Technology. Results were, among others: EM applied in combination with NPK fertilisers, Green Manure (GM) and Farm Yard Manure (FYM) caused significant increase in grain and straw yield and in nutrient uptake by the grain and straw of each crop following the order NPK+EM > GM+EM > FYM+EM. The GM+EM treatment produced grain and straw yields of each crop that approached those for NPK alone. A comparative economic analysis of the treatments showed a significantly higher net return due to EM. The average net profit from rice and wheat production using EM was US$44.90 / ha and US$62.35 / ha , respectively, compared to about nil for the conventional rice-wheat system with optimal fertilisation and management.



Soybeans for dairy products, a good deal?

The World Trade Organisation (WTO) makes claims for international liberalisation of trade in place of national protectionism. Countries are not autonomous any more; planning of the national economy is subject to international rules applied by the WTO. Even in remote rural areas the world market influences people's lives.

Brazil is the second largest soybean grower in the world, producing around 30 million tons per year. The European Union is the main importer of Brazilian soybean for its extensive dairy industry. In turn the EU exports large amounts of dairy products back to Brazil. In the past five years Brazil has had a negative balance of trade. Soybean is naturally seen as the crop, which can generate extra income for making up the trade deficit.

Specialisation in soybean and dairy is resulting in serious socio-economic and environmental problems in both regions, and is a good illustration of the "system error" that is inherent to the global system of agriculture. The challenge of implementing sustainable farming systems has become even greater in this context.

Angela Cordeiro, a Brazilian agronomist, was asked by the Swedish Society for Nature Conservation to undertake a study on how European agricultural policy affects Brazilian agriculture and vice versa. The report is being used in SSNC's campaign for sustainable agriculture. This article is based on the report.

Modernisation of agriculture

The modernisation of agriculture has been promoted by the Brazilian Government, since the 1970's, through the expansion of agricultural area, subsidised credit and educational, research and extension services oriented to promote "modern technologies". This process, aimed basically at the export market, relies on the intensive use of hybrid seeds, chemical fertilisers, pesticides and mechanisation, and consumes huge amounts of fossil energy.

Southern Brazil, the first part of the country to introduce the Green Revolution, has major problems of soil degradation, particularly on large farms. This is evidence of the negative effects of monocropping and the adoption of an European soil management system, use of chemical fertilisers and heavy machinery, which are not adapted to tropical soils (see Box 1). In the Northeast of Brazil, unsustainable management of irrigation has resulted in increased soil salinity, which at present effects 30% of irrigated areas.

Additionally, unbalanced plant nutrition management has been suggested as the main cause of pests and plant diseases, resulting in increased use of pesticides. Apart from water and soil contamination, the wide use of pesticides has become a health problem in rural areas. Loss of biodiversity is another negative impact of agricultural expansion, with deforestation and replacement of local varieties as main causes.

The liberalisation of the Brazilian economy in the 90's has resulted in further changes in land use.

Soybean - a foreign exchange earner

Current market theory states that comparative advantage provides better competitiveness on the international market. In the case of agriculture, it means that countries able to produce at the lowest cost are the most competitive. It is assumed that increasing scale is the best way to reduce costs. Geographic expansion of soybean from the South of Brazil to the Cerrado region followed this assumption. Therefore, soybean cultivation is now concentrated on farms larger than 500 ha. This is in contrast to 1985 figures, when medium and small farmers together produced almost 50% of Brazil's soybean production.

On the world market, demand for soybean is based on meat consumption patterns. According to market analysts, an increase in the global demand for meat is expected due to the market liberalisation. Consequently, there will be an increase in demand for soybean meal. Among other competitors, Brazil is in the best position to expand soybean production and potentially increase its market share. Therefore, soybean is seen as the "golden crop" of Brazilian agriculture, receiving special attention from Brazilian agricultural policies. The equation is simple: the country needs to achieve a favourable balance of trade, and agriculture is one of the main sources of income. Thus, soybean is seen as a foreign exchange earner that can boost the national economy and help the Government fulfil its commitments to the International Monetary Fund.

Dairy production – loosing out

Dairy production is another dramatic example of the impact of current agricultural policies. While Brazil is the second exporter of soybean and an important source of soybean meal, it is also one of the main importers of dairy products. As a result of opening up of the Brazilian market, liquid milk imports from the EU has risen from 19,435 tons in 1992 to 82,433 tons in 1997, causing serious damage to the domestic dairy sector. After the market deregulation in 1992, the Government did not control milk prices. Imports passed on to the hands of private industries that also took over the domestic dairy industry. With increasing costs of milk production and lowered revenue, many small farms are not able to continue with milk production.

However, milk production is a very important component of small farming. While EU, US and Argentina have 805, 105 and 22 thousand farms incorporating dairy production, Brazil has nearly 1.2 million of them. Around 40% are family farms below 50 ha. Over and above the continuous cash flow provided by milk production, cattle are an important element for the environmental sustainability of small farming. Crop rotation with forage legumes and the use of cattle manure in crops and vegetable production are ways in which animal and crop production coexist in diversified farming systems.

Hidden subsidies

These models are justified on the apparent competitiveness of soybean production in Brazil and dairy production in the EU. However, this competitiveness is not real as it depends on hidden subsidies, both in Europe and Brazil.

In the case of soybean, the cost does not include negative aspects such as the environmental impact of this crop on Brazilian ecosystems. For instance, the expansion of soybean to the Cerrado region led to deforestation and considerable loss of biodiversity. No mention is made of the cost of energy required for transportation of soybean to the main ports, thousand of kilometres away from the fields. The Government has given fuel subsidies to farmers and provided all types of facilities to make it feasible to grow soybean in the Cerrado. Actually, Brazilian society has paid a high cost to sustain this "false" competitiveness.

On the other side of the Atlantic, European society pays for the high competitiveness of its dairy sector. The low costs of dairy products are sustained by enormous government subsidies, creating a very artificial situation. Moreover, the intensive production system results in environmental problems, the costs of which are not considered. The high yields associated with artificial low costs disrupt the national production in countries where subsidies do not exist, creating a monopoly in European milk imports.

By analysing these cases it is easy to conclude that the production systems of Brazilian soybean and European dairy are interconnected and that the weaknesses of both systems sustain each other. Recognising this connection gives an idea on the complexity of building sustainable farming systems. However, from another perspective, it also shows the potential for building global alliances between farmers and consumers beyond national borders.

Fair trade essential

Fair trade is important for food security. Yet, how can fair trade be established, respecting social, environmental, economical and cultural diversity between nations? How can trade be built up so that benefits to developed countries do not imply exploitation of developing countries?

Interchange of experiences between local groups at global level could strengthen capacities for overcoming the technical, financial, cultural, political, and trade barriers to sustainable farming systems. The case of Genetic Modification (GM) is a good example of how local actions can have global influence. The European society reacted negatively to the introduction of this technology, because of possible negative impacts on health and environment. Thus, by refusing to buy GM products, European consumers created a pressure on retailers, which was transferred to food processors and food traders.

At the same time, civil society in Brazil campaigned against GM crops. As a result of European pressure and domestic campaigning, a court decision was taken against GM crops in Brazil until environmental impact studies were carried out. This delay in introducing GM crops to Brazil strengthened the European position.

Soybean for dairy products is portrayed as the type of exchange required in meeting the increasing food needs of a growing world population. But what should not be forgotten is that both soybean and dairy production depend on a natural resource base that is fast degrading due to modern agricultural practices. As such, sustainable farming systems are no more a luxury but a necessity.

Box 1. Ecologisation of soybean production

Can we 'ecologise' soybean monoculture? It seems that soybean monoculture begins with a monoculture of the mind, that is specialisation. We cannot change global politics in a short time, that is if we can change it at all. What can we do, technically, to make soybean production ecologically sound?

The first problem is that the technology being used in Brazil is from a completely different ecosystem, the temperate climate of Europe and USA. As a result, soils degrade and plants perform badly. Instead of building up biological soil life to enhance productivity, more fertiliser, irrigation, herbicides and other chemicals are applied. Ecologically sound management of soils is the basis for sustainable agriculture.

Tropical soils need protection from overheating, rapid drying and rain. This can be provided by closer planting, mulch, zero-tillage, cover crops, intercropping or even shade trees. A large quantity of organic matter is needed annually to recuperate the soil aggregates and the porous system. Soybean furnishes too little straw, decomposes rapidly as it is rich in nitrogen and poor in cellulose, and as such does not contribute to soil aggregation. In order to maintain the structure of the soil, crop rotation with maize, millet, or a similar crop is necessary. After a few years of continuous soybean production, especially when planted under zero-tillage, deleterious rhizo-bacterias including *rhizobios*, appear, and may kill the soybean plants. When alternated with maize, soybean yield increases by 20% already in the first year, and the need for agrochemicals goes down by 50%. When soybean is grown within a full crop rotation, using *soybean - groundnut - maize* in summer and *wheat - fodder turnip - black oats* in winter, there are practically no diseases and yields increase every year. The absence of wind break belts may lower the yields. In rotation with other food and fodder crops soybean does not have to be an anti-ecological and anti-social crop. However, adaptation of soybean varieties to Brazilian soil types and microclimate is still needed.

Bolivian Indians say," *Agriculture is a spiritual – social – material activity, and only when all these three factors are in harmony does she maintain life"*.
Only oriented towards the material aspect, agriculture will not work, and people will be sick, degenerate and die.

Monocultures towards sustainability

Editorial

The prevailing global trends - improvement of crop varieties, increase in the use of agrochemicals, mechanisation, liberalisation and globalisation of agricultural trade, national economic growth, increase in the use of fossil energy, agricultural policies and subsidies favouring production of main and export commodities, development of biotechnology, hybrids and genetically modified organisms, and privatisation of research and extension - support the growth of monocultures, which are often seen as unsustainable. The productivity and sustainability of annual food crops is of extreme importance for feeding an ever-growing world population. In this issue, we look at the negative impact of monocultures, especially of annual food crops, and the alternatives that are being developed.

Photo: PMHE project

Monocultures of the main annual food crops urgently need to be made more productive and sustainable.

Expanding monocultures

Whenever farmers focus on market production and adopt the agrochemical model, high-input monocultures become predominant. Not only the number of different crops and animals but also the genetic diversity tends to decrease. The increased use of agrochemicals seriously affects the natural biodiversity in and above the soil, on the farm and in the wider environment. Expanding scale and levelling of land leads to the loss of natural micro-environments and to a further decrease in diversity. In extreme cases this leads to large-scale farming with near endless high-input monocultures, year-to-year production of single crops on the same land, as in many Western and in some Southern countries like Brazil (soybeans, p.6), Philippines (sugarcane, p.22), Bangladesh (rice, p.16) and India (rice and wheat, p.8).

Political and economic forces are driving agriculture towards monocultures. Such systems are rewarded by economies of scale and contribute significantly to the ability of national agricultures to compete on international markets. The case study on soybean monoculture in Brazil (p.6) provides a good example of how international trade reduces biological and economic diversity, degrades natural resources and affects small farmers.

Serious consequences

Although this type of agricultural development made it possible to increase production in excess of global population growth, there is increasing evidence that if continued its negative impact on food security, rural poverty, and the conservation of natural resources will outweigh the benefits. For example (Torres et al, 2000; Altieri, 2000):

- Evidence from a number of experimental and field sites indicate declining growth of yields for the main 'Green Revolution' cereals under intensive cropping on some of the better lands, e.g. the Indo-Gangetic plains (p.8). In some places (e.g. p.6 and p.22), yields are actually in decline.
- Most large-scale agricultural systems exhibit a poorly structured assemblage of farm components, with almost no linkages or complementary relationships between crop enterprises and among soils, crops, and animals. Cycles of nutrients, energy, water and wastes have become more open which makes it increasingly difficult to recycle nutrients. Hence, these systems are very inefficient in the use of their resources.
- Higher primary production is obtained by increasing the use of external inputs and is leading to a decrease in their efficiency.
- Use of pesticides in the developing countries is increasing exponentially, just as is their negative impact on the health of people and the environment.
- As specific crops are expanded beyond their "natural" ranges to areas of high pest potential, or with limited water, or low-fertility soils, intensified chemical controls are required to overcome the limiting factors.
- High-input monocultures depend increasingly on fossil energy and lead to depletion of soil organic matter, which in turn contributes strongly to climate change.
- Lower prices of agricultural products were particularly beneficial to urban populations, but have not had the same effect in rural areas. On an average, around 50% of the rural population in many places remain to be poor. The most affected regions are Sub-Saharan Africa and South Asia.
- Dietary consequences of monocultures are substantial. Reduced crop and natural biological diversity has resulted in decreased dietary diversity. Eating more maize, rice or wheat has actually increased micronutrient malnutrition, especially in Green Revolution areas, termed as 'hidden hunger' (IRRI, 1999).

About two-thirds of the agricultural lands have been degraded to some degree in the past 50 years by erosion, salinisation, compaction, nutrient depletion, biological degradation, or pollution; about 40% of these lands are strongly or very strongly degraded. Unlike more complex agro-ecosystems, high-input monocultures are not capable of providing multiple functions of ecological and economic value. If we choose to continue the current patterns of resource use, we will be faced with the decline in the ability of agro–ecosystems to yield their broad spectrum of benefits – from clean water to stable climate, fuelwood to food crops, timber to wildlife habitat (World Resources Report, 2000).

Sustainable alternatives possible

In many places in the world it is already happening! Out of economic and ecological necessity, farmers and development supporters are trying to move away from high-input monocultures. Different approaches are being followed, e.g. Resource Conserving Agriculture, Evergreen Revolution, Agroecology, Permaculture, Regenerative or Organic Agriculture. There are important differences between these approaches but they all have a common denominator: resource conservation.

The transitions described in the articles lead to: reduced and more efficient use of agrochemicals, fossil energy, irrigation water and seeds; storage of carbon in soil organic matter and biomass (which reduces climate change); reduction of soil degradation. But at the same time they lead to higher production and lower costs and labour! This is true for zero tillage in rice-wheat production (p.8), ecological intensification of rice production (p.11 and 12), diversification of the production of rice (p.16), sugarcane (p.22), cotton (p.18) and maize (p.20), and is contrary to common belief!

Monoculture or polyculture?

But what type of biological diversity is needed for ecological sustainability? Wood (p.14) challenges polyculture as a means of sustainable production of annual cereals in the light of many natural grass monocultures. What can farmers learn from these natural monocultures to improve the productivity, stability and ecological sustainability of the present high-input monocultures? Wood states that single crops have self-regulation through high crop-associated biodiversity, in the soil as well as in the vegetation, in and outside the field. It is this associated biodiversity that is strongly influenced and reduced in high-input monocultures, due to agrochemicals, intensive tillage and the large-scale. The cases show that higher productivity and reduced losses and costs can be achieved by: combining different varieties of e.g. rice (p.12), intercropping, e.g. maize and tomatoes (p.20), rotation of soybean and wheat (p.7) or combining rice, fish, vegetables and trees (p.16).

It may also be possible to learn from the experiences of traditional and ecological farmers, e.g. how do they manage their annual cereals? Do they mimic natural monocropping or do they consciously combine annual cereals with other crops to enhance productivity, stability and sustainability? It may be interesting to look at these in terms of crop management, e.g. How do ecological farmers in Madagascar get higher rice yields than Green Revolution farmers? (p.12). Their System of Rice Intensification (SRI), is now being successfully tried out in many countries. Other cereals can be produced in a similar way, as in the example of the Bonfils/ Fukuoka approach for winter wheat (p.13). Clover or other leguminous cover crops used in wheat (p.13) and in rice-wheat production (p.11) may be an interesting additional element to zero-tillage, among others, in the Indo-Gangetic Plains (p.8).

Ecosystem approach needed

A shift to resource conservation requires, first and foremost, a reorientation on how we look at (agro-) ecosystems - we need to view their sustainability as essential to our own. Adopting an "ecosystem approach" means that we evaluate our decisions on land and resource use in terms of how they affect the capacity of ecosystems to sustain life - not only human well-being, but also the health and productive potential of plants, animals, and natural systems (World Resources Report, 2000). 'Agroecology' is based on a detailed understanding of ecosystems and the complex interactions of soil, water, plants, animals and farmers; it involves the whole farm and landscape system, and is far more holistic than the conventional crop ecology approach. This requires a scientific re-orientation as well.

In essence, the optimal behaviour of agroecosystems depends on the level of interactions between the various biotic and abiotic components. By assembling a functional diversity it is possible to initiate synergisms which support agroecosystem processes by providing ecological services such as the activation of soil biology, the recycling of nutrients, the enhancement of beneficial arthropods and antagonists, and so on. Today, there is a diverse selection of practices and technologies available, although they vary in effectiveness as well as in strategic value. (Altieri, 2000; Gliessman, 1999). Making monocultures sustainable is not just replacing chemical inputs by organic equivalents, but a systematic farmer-led conversion process. It requires gradual re-modelling of the agro-ecosystem by testing various options to improve ecological and economic performance as in conversion to organic agriculture (pg.21).

The design of farm implements adapted to ecological practices, such as zero-tillage (p.8) and polyculture is often very important, not only for conditions where mechanisation is needed, but also for those in which hand labour and animal traction prevail.

Old truths to be revised

The acceptance of the narrow scientific logic of conventional agriculture restricts the real possibility of implementing alternatives that challenge this logic. Some opposing practices are:

- Intensive seedbed preparation – zero-tillage (p.8).
- Use of herbicides – use of mulches and cover crops (p.11).
- Continuous irrigation – rice production in aerated soil conditions (p.12).
- Practices that inhibit tillering in cereals – practices that stimulate tillering e.g. in rice (p.12) and wheat (p.13).
- High density row planting in grains – low density planting e.g. in rice (p.12) and wheat (p.13).
- Use of agrochemicals to fertilise the soil and control pests and weeds – use of cover crops, mulches, and functional biodiversity (p.22).

The time is ripe to revise such old truths as the alternatives are resource conserving and have the potential to increase production in a competitive way. Yet, much remains to be learned about sustainable agriculture, thus further research is essential and urgent (Global Forum for Agricultural Research, 2000).

The experiences show that there is great potential in agriculture based on resource conservation and agroecology. Unleashing this potential may reduce the need to introduce genetically modified varieties, before taking the time to analyse and discuss possible risks.

Towards biodiversity based agriculture

Merely introducing alternative agricultural designs will do little to change the underlying forces that lead to high-input monoculture production, and will not improve the situation long-term. Ecological degradation is not only an ecological process, but also a political, economic and social process. Many national and international policy changes, e.g. regarding pricing and incentives, research and extension, agricultural trade and education are necessary to create favourable conditions for development of sustainable agriculture (Altieri, 2000).

Transforming monocultures needs large-scale and intensive involvement of all stakeholders. Participatory learning, research and extension programmes that can reach and mobilise large and diverse groups of farmers are needed. Supporting farmer learning and experimentation through, for example, Farmer Field Schools (p.24), Farm Planning (p.26), Sustainability Analysis (p.28), Participatory Research (p.8) and Farmer-to-Farmer approaches and the use of mass communication and information technology can be important elements of a large-scale, cost-effective strategy to make the shift.

A mass movement needed!

However, this cannot happen without a mass movement of farmers and consumers convinced of the dead-end road of high-input monocultures. Broad coalitions of development workers, researchers, policy makers and funders who support such a movement and create a critical mass against prevailing economic and conventional scientific forces are needed.

Dear Readers

This issue of the ILEIA Newsletter pays attention to high-input monocultures, especially annual commodity crops. It emphasises the experiences being gained with development of LEISA for these typical Green Revolution systems. Normally, the ILEIA Newsletter has a strong focus on smallholder farmers with one leg in self-sufficiency and the other in market agriculture, or even a third leg in other sources of income. But we assume that farmers with larger holdings, strongly specialised in commodity crops, have at least as many ecological sustainability problems. And it was for this reason that we intended to include a few articles on larger-scale farming in this issue. Although we got several interesting cases on 'ecologisation' and diversification of monocultures, most of these cases were, again, on smallholder agriculture. Could it be that besides IPM and zero-tillage, not much is moving towards LEISA yet in larger-scale high-input agriculture in the tropics, or is it that we just do not have the right contacts to get the information. Maybe this had to be so, considering the large number of small farmers trapped in monocultures. Hopefully, the articles and additional information will inspire many new initiatives towards LEISA.

As promised in the last issue, we are pleased to present the new ILEIA team on the back page. How do you like the picture? The team wishes you an inspiring, creative and resourceful year 2001!

Sustaining the Green Revolution by resource conserving technologies

Peter R. Hobbs, Raj Gupta, J.K.Ladha and Larry Harrington

Photo: Rice-Wheat Consortium

The Rice Wheat Consortium in South East Asia has joined hands with farmers in developing resource conserving technologies to improve production and ecologise the rice-wheat system in the Indo Gangetic Plains. Farmers are experimenting with new technologies like zero tillage, direct seeding, bed planting, Integrated Pest Management and Situation Specific Nutrient Management. Although the use of some of these technologies is spreading fast, much still has to be done to make the Green Revolution sustainable.

8

ILEIA is the Centre for Information on Low-External-Input and Sustainable Agriculture. It seeks to exchange information on LEISA by publishing a quarterly newsletter, bibliographies, and books. ILEIADOC, the data base of ILEIA's documentation centre, is available on diskette and on ILEIA's Homepage: http://www.oneworld.org/ileia. Back issues of the ILEIA Newsletter are also available on ILEIA's website.

LEISA is about Low-External-Input and Sustainable Agriculture. It is about the technical and social options open to farmers who seek to improve productivity and income in an ecologically sound way. LEISA is about the optimal use of local resources and natural processes and, if necessary, the safe and efficient use of external inputs. It is about the empowerment of male and female farmers and the communities who seek to build their future on the bases of their own knowledge, skills, values, culture and institutions. LEISA is also about participatory methodologies to strengthen the capacity of farmers and other actors, to improve agriculture and adapt it to changing needs and conditions. LEISA seeks to combine indigenous and scientific knowledge and to influence policy formulation to create a conducive environment for its further development. LEISA is a concept, an approach and a political message.

Mahaweli settlers in Sri Lanka diversify their farms using Farm Planning

Alice de Jonge

In the huge irrigated agricultural settlements of the Mahaweli in Sri Lanka, farmers are up against the ever-decreasing profitability of rice monocropping. Farm Planning for Sustainable Farming, introduced as a tool for better management of resources and sustainable farm development, has helped farm families to diversify their farming system and thereby increase their family income.

26

From sugarcane monoculture to agro-ecological village

Lindsey Mulkins and colleagues

Photo: REAP-Canada

The Flora community in Negros, the sugar basket of the Philippines, diversified the former sugarcane hacienda to become more food and energy self-reliant through its transition into an "agro-ecological village". Sugarcane production has been reduced considerably and supplemented with crops like maize, grains, legumes and vegetables. Trash cane farming, which recycles the residue by allowing it to decompose in the field, is replacing the traditional burning method that has led to serious ecological degradation. Farmers are experimenting extensively with new and old organic farming technologies.

22

Ecologising rice-based systems in Bangladesh

Marco Barzman & Luther Das

Farming in Bangladesh is increasingly showing signs of unsustainability. The New Options for Pest Management (NOPEST) project implemented by CARE-Bangladesh is following a Farmer Field School approach to introduce farmers to the ideas of reintegrating vegetables, fish and trees. Comparative data show that diversification of rice monoculture is beneficial.

Monocultures towards sustain-ability

Araurocária forest with maté shrubs

Photo: Paulo Petersen

From maté extractivism to the regenerative management of Araucária forests

Paulo Petersen, José Maria Tardin and Francisco Marochi

Extraction of maté leaves has always been an important economic activity in Paraná, Brazil. Now, improving the production of maté groves has become the entry point of a Regenerative and Analog Agroforestry (SAFRA) programme initiated by the Central-Southern Paraná Farm Workers Forum. Farmer experimentation, farmer-to-farmer exchange, technical training and multi-media communication are important methodologies in this programme which is now extending to value adding and marketing of other forest species, especially medicinal plants.

Historic development

The maté (*Ilex paraguariensis*) is a tree species native to the *araucária* (*Araucária brasiliensis*) forests in southern Brazil. It was used by indigenous peoples to prepare teas well before the arrival of the Portuguese, and afterwards was incorporated into the traditions of the European settlers. Its economic importance also dates back to pre-Colombian times, as we have historical records of bartering between Guarany Indians from southern Brazil and the Incas in Peru. Beginning in the late 19th Century, the central-southern region of the State of Paraná began its "maté cycle," during which the cultivation of maté became a major influence in determining the local landscape (Souza, 1998). Maté producers settled on small farms in a process that, together with the later arrival of European immigrants, contributed to the consolidation of a land-holding structure based on small-scale farming.

The faxinal system

During the consolidation of family farming in the region, agroecosystems were developed that combined multi-cropping with open-range livestock and the extraction of maté leaves. This latter activity was the main cash generator for farmers. With growing pressure on the land in several of the region's municipalities, the system could no longer support farming and open-range livestock raising. The pressure to separate these two activities led to the creation of "community ranges" in which both livestock was raised and maté extracted. This novel form of technical and economic organisation became a typical trait of family farming in several municipalities, and came to be known as the *faxinal* system (Chang, 1988). The maté-extraction activity was thereafter carried out both in livestock pastures – in the *faxinal* areas – and inside the *araucária* forest areas.

Today, although its relative economic significance for small farmers is much less, maté extraction is still a stabilising factor for family income, since it is less vulnerable to the ups and downs of weather and markets than other traditional crops such as beans and corn. It was the farmers' recognition of this strategic function that led them to preserve major areas of the native forest in their agroecosystems. This is why the central-southern region of Paraná has much more forest cover than neighbouring areas.

Intensification of maté production

Traditional maté-related practices are still largely based on extraction, and the adoption of measures to renew maté groves or revitalise their productive potential is not common. Due to the growing pressure to occupy forest areas caused by the fragmentation of farms as they are handed down from one generation to the next, this traditional system now faces a crisis of productive potential. Recently, in order to enhance maté yields, a few official programmes have disseminated the idea of intensification, by copying techniques developed in Argentina, based on open-field plantations where the forest once stood and the intensive use of soluble fertilisers and pesticides. Initial experiences in using this system in central-southern Paraná shown its incompatibility with local conditions, principally the exponential rise in production costs. These "modern maté groves" are not economically viable. They not only degrade the environment but also break down the farmers' cultural relationship with what is left of the forest.

Developing agroecological alternatives

The need to overcome this crisis led the Central-Southern Paraná Farmworkers' Forum (see Box 1) to develop and disseminate alternative maté-grove management approaches that are compatible with the social, cultural and historical process of maté extraction in the *araucária* forest and under the *faxinal* system. With technical and methodological assistance of AS-PTA (Consultants in Alternative Agriculture Projects), the Forum has promoted a process of experimentation involving local communities that try to adapt the "SAFRA" approach (Portuguese acronym

Box I. Farmers' organisations in central-southern Paraná

With 22 municipalities and a land area of 13,000 km², the population of the central-southern region of Paraná numbers 419,198, 65.6% live in rural areas. The area is set off geographically by its social and political forms of organisation. These were established historically by the farm workers' union movement in the 1980s and culminated in a regional coordination that aimed to plan and implement actions to defend the interests of family farmers through the Central-Southern Paraná Farmworkers' Forum. Unions from 15 of the municipalities participate actively in the Forum as do 200 community associations and informal groups. The Forum's overall activity guidelines are formulated during its bi-annual regional Congresses.

for Regenerative and Analog Agroforestry System) to their agroecosystems (see p14). This method works towards optimising environmental and economic aspects of agroecosystems as efficiently as possible. The approach is partly based on agroforestry practices developed by indigenous people from Asia, Africa and Latin America (Foresta, 1993; Götsch, 1995). Based on observations of species succession, this method seeks to reconstitute a productive forest, analogous to the original forest, through radical pruning to rejuvenate, revitalise and accelerate the system's natural succession process and through the introduction of native species, along with the densification of maté populations, in order to re-establish ecological conditions appropriate to greater production from the maté groves.

Social dynamics of innovation

To launch the process of adapting the SAFRA method to the region, half-hectare test plots were set up in 1995 on 15 farms in the municipalities of Bituruna and São Mateus do Sul, where the typical maté farming takes place both in the *araucária* forest and in *faxinal* areas. When the test plots were established, the areas were at different stages of plant succession: degraded by farming activities and colonised by grassy weed vegetation; fallow land colonized by short-cycle pioneer bush (*capoeira*); secondary forest growth; and *faxinal* areas (a combination of trees at various stages of succession, grassy weeds and domestic animals).

In addition to their experimental purposes, these plots were the bases for creating a broader technical-training programme in an interaction between farmers and the academic-based knowledge contributed by the AS-PTA consultants.

The 35 farmer-experimenters who participated most systematically in the tests were organised into two groups that met regularly at events designed to implement, manage and monitor the SAFRA approach in their respective municipalities. In addition to examining their systems, these events provided an extremely fertile setting for the technical and methodological training of the farmers' families, as well as for planning group activities. The two groups met together each year to exchange experiences and plan common actions.

The test plots did not make use of conventional experimental designs, since the objective was not statistical analysis. Monitoring the performance of SAFRA systems was based on easy to visualise qualitative criteria. This participatory monitoring process generated a large amount of data and information that has been valuable in teaching other farmers interested in applying the method on their own farms. Therefore, the test plots were part of a social dynamic supported by the farmers' organisations.

The process and results of the experiments and technical training activities have been systematised and communicated through on-site training events and visits, as well as to wider audiences through radio programmes, newsletters, videos and newspapers. In the programme's methodological strategy, therefore, experimentation, testing and communication are loosely connected.

Disseminating the process

In addition to spreading the SAFRA approach in the region, efforts were also made to spread the social process that has allowed it to be adapted to the ecological management of maté production. In this way it was hoped to ensure a sustainable social dynamic that would generate and exchange technical innovations. Three years after the tests began on 15 farms, the positive technical results and the social mobilisation achieved in support of the proposal has made it possible to implement a broad regional programme dedicated to training farmers in several of the region's other municipalities and communities. The farmer-experimenters in the programmes' initial groups have now become trainers, unleashing a horizontal, "farmer-to-farmer" based dynamic (see LEISA Newsletter Vol.16 No.2, p.26-27) .

The technical and methodological results accumulated through the experimental phase have been well used by farmers' organisations in their discussions with official agencies working in rural areas. The farmers' objective is to influence the formulation and implementation of public policies for regional agricultural development.

Towards forest management

In addition to expanding the scale of the SAFRA approach to maté production, the farmer-experimenters have recently taken on the study of other native forest species that might be of economic interest. Medicinal plants are particularly interesting here. Through a regional people's medicine programme based on phytotherapy – organised and maintained by the regional Forum of farmers' organisations – over 150 medicinal plants native to the *araucária* forest are now gaining greater cultural and economic value. In recent years, this programme has handled approximately 300,000 medical consultations for both rural and urban residents in the region.

In addition to the social and cultural revitalisation of the value of local biodiversity, the creation of this new front for technical experimentation has increased the economic value of the work done by rural women, since the management of medicinal plants within the farm family has traditionally been their responsibility.

The farmers' organisations involved in the programme are presently organising ways and means of processing and marketing the products of their SAFRA systems. Their development strategy in this sphere is once again based on the methods used to achieve technical innovation, namely to associate an experimental process in pilot projects with an ongoing exchange of knowledge between farmers and technical consultants. ■

Traditional slash and mulch in Guadalcanal

Tony Jansen and Roselyn Kabu Maemouri

The Solomon Islands are located in the Western Pacific Ocean. The main islands are volcanic in origin with mountains reaching 2400m. Climate is wet and tropical with an annual rainfall of 2500 to 6000mm. There is no distinct wet and dry season.

Most of the country is covered by rainforest and 80% of the population live in small isolated communities and practice shifting cultivation. Population growth, land degradation and cash cropping have resulted in shortened fallows that today vary from 5-7 years but which in some places are as short as three.

'Slash and burn' practices are the customary way of preparing garden sites but when we look more closely at traditional methods we find there are different approaches to the use of fire. Locally specific alternative practices have been documented. Some are in common use, others are on the verge of extinction. These traditional practices have been used to start discussions with farmers on the role of organic matter in soil fertility. Here, 'slash and mulch' will be discussed.

Yam and pana slash and mulch

Guadalcanal is well known for a 'slash and mulch' system of planting of yam (*Dioscorea esculenta*) and pana (*Dioscorea alata*) in which no fire or staking is used. The natural vegetation is usually mature forest or secondary forest. This is cleared leaving most of the trees standing. Vegetation is spread randomly over the site and yams are planted with traditional digging sticks. The leaves rot into rich organic material and trunks and branches form a mass of crossed 'stakes' that support the growing yams. Bananas and taro can also be planted in this system.

Tasimate slash and mulch

This is a similar method used in Tasimate. The difference is that it is applied with all food crops especially sweet potato and taro. This makes the results likely to be much more widely applicable.

Secondary forests are often dominated by stands of maturing pioneer species such as *Macaranga sp*. and trees with an understorey of soft ginger and banana-like plants. Undergrowth is cleared in a fallow of 4-6 years and the garden laid-out under the canopy of larger trees. The crops are planted in rows in a pattern depending on how the fallow trees that will be cut will fall on the land. After the plants are established, the trees are cut and branches and trunks are placed in wide rows across the garden. Soft leaves and stems are cut into thick mulch (5-10cm thick) and spread between the crop.

Sweet potato cuttings are planted farther apart than is usual in slash and burn systems and the vines grow over the thick mulch and rotting trunks. The first harvest comes from the mulched land, the second from the areas of sticks and trunks where nutrients are released more slowly.
Higher yields are obtained from this system than from other slash and burn systems practiced on similar soils in this area. Yields are also good with relatively short fallows. In fact these short fallow areas are preferred by farmers who practice this method.

Traditional knowledge has an important role in reinforcing sustainable management systems. It provides important links to move from the known to the unknown in development of new practices to cope with increasing land use pressure. ■

Tony Jansen and Roselyn Kabu Maemouri, APACE (Appropriate Technology for Community Environment), c/o DSE, PO Box 556, Honiara, Solomon Islands. Phone: +677 39551; Fax: +677 21339; Email: tonyj@welkam.solomon.com.sb

Themes for the ILEIA Newsletter

March 2001 Vol.17-1
Resilience of agriculture

How do farmers prevent disaster and react to the catastrophies of drought, flood, armed conflict, disease and economic crisis? How do farmers deal with variability and risk? How can the resilience of farming and rural livelihoods be improved? What impact does labour migration have on farming systems and gender roles? How can women best adapt farming in areas of labour migration and still optimise benefits and ecological sustainability? How can gender roles be renegotiated? How can women farmers best be reached and supported? How can farming by refugees be supported? ***Deadline for contributions 1 December 2000.***

July 2001 Vol. 17-2
Globalisation challenged

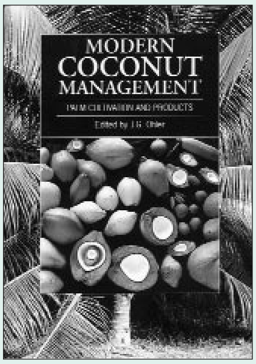
Many farmers in the tropics are negatively affected by globalisation of the world economy and expansion of the consumer culture. To them, this is one step further on the road to marginalisation. In reaction, some farmers, communities and organisations have started to reconstruct traditional 'agri-culture', save indigenous seeds or harvest water. Others focus on development of organic agriculture, local products, empowerment of local institutions or alternative education. Still others protest against genetically modified organisms and international agreements on intellectual property rights.
For this issue of the LEISA Newsletter we invite articles on such reactions to globalisation and on how local communities and farmer organisations can be strengthened to retain the right to their own futures. ***Deadline for contributions 1 March 2001.***

You are invited to contribute to these issues with articles (about 1800 words + 2 illustrations), suggest possible authors, and send us information about interesting issues, publications, training courses, meetings and websites.

Farmers' perceptions and sustainable land use in the Atacora, Benin *by Adegbidi A [et al], 1999, 49 p. GBP 5.00. Collaborative Research in the Economics of Environment and Development (CREED), Environmental Economics Programme IIED, 3 Endsleigh Street, London WC1H 0DD, United Kingdom; Institute for Environmental Studies (IVM), VU, De Boelelaan 1115, 1081 HV Amsterdam, The Netherlands. (Creed Working Paper series ; 22). IIED Bookshop, 3 Endsleigh Street, London WC1H 0DD, United Kingdom bookshop@iied.org.*
This paper documents part of a study on the farming systems in Atacora, North West Benin and is a contribution to the development of appropriate environmental policies for the area. In this survey farmers' awareness on soil fertility decline was examined, whilst an overview of the practices adopted for maintaining or restoring soil fertility was made. The traditional way to combat land degradation is to leave the land fallow, but due to land pressure these fallow periods are being shorter. Alternatives are known, but adoption rates are low. (IHG)

Integrating concepts of sustainability into education for agriculture and rural development *by Bor W (van de) ... [et al.] (eds). 2000. 329 p. ISBN 3 631 36425 3 : NLG 150.00. (Environmental education, communication and sustainability, ISSN 1434 3819 ; vol.6). Kniphorst Boekverkopers, Hoogstraat 49, 6701 BM Wageningen, The Netherlands.*
This publication builds on the proceedings of an international workshop held in August 1998 in Wageningen, the Netherlands titled,'' the Concept of Sustainability in European Curricula for Higher Agricultural and Related Sciences Education'' and expands on the subject with contributions from outside Europe. The target audience are those involved in curriculum development in higher agricultural and rural development education, and who want to integrate aspects of sustainability into teaching and learning. Issues such as biotechnology and market liberalisation demonstrate very clearly the need to deal with complexity and continue the discussion on interdisciplinary teaching and social and environmental impact. The book is divided into two parts: a discussion of conceptual issues and examples of institutions trying to integrate sustainability into their curriculum. The book gives a good overview of the issues involved and their complexity. It is encouraging to note that universities are recognising that they have a critical role to play in creating sustainable futures. (IHG)

Modern coconut management : palm cultivation and products *by Ohler JG (ed.). 1999. 458 p. ISBN 1 85339 467 X : GBP 45.00. Food and Agriculture Organization of the United Nations (FAO), Viale delle Terme di Caracalla, 00100 Rome, Italy; LEAD Progamme, Institute of Cultural and Social Studies, Leiden University, Leiden, The Netherlands. Intermediate Technology Publications, 103-105 Southampton Row, London WC1B 4HH, UK.*



This voluminous book provides a complete overview of all aspects of coconut management. Besides updated information on the general agronomic aspects, breeding and post-harvest treatment and processing, considerable attention is given to the role of coconut palm in intercropping systems and in combination with pastures and livestock. Appendices present an extensive bibliography and a register of institutions and experimental stations involved in coconut research. (IHG)

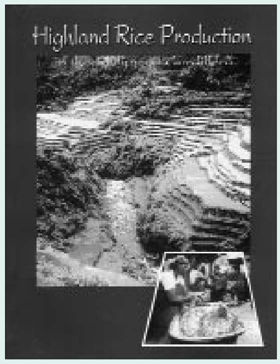
Soil Conservation and Watershed Management in Asia and the Pacific. *APO 2000. 261p. ISBN 92 833 2249 5 Asian Productivity Organization, Hirakawa-cho Dai-ichi Seimei Bldg. 2F, 1-2-10, Hirakawa-cho, Chiyoda-ku, Tokyo 102-0093, Japan. Fax (81-3) 5226-3950 Email: apo@gol.com*
The seminar on Soil Conservation and Watershed Management sponsored by the Asian Productivity Organization (APO) in November 1998 in the Republic of China was a means of addressing related issues in many Asia-Pacific countries. This publication contains the seminar proceedings as well as resource and country papers. Whilst the country papers review the current soil conservation and watershed management situation in the respective countries, the resource papers focus on specific topics such as planning for watershed management, integrated watershed management, soil conservation extension etc. The papers discuss the manner in which each country has tried to tackle the issue, the progress made and some of the bottlenecks encountered in the process. It is interesting to note that soil conservation and watershed management is a priority in each of these countries, and that it is supported by state legislation.

Learning from change – issues and experiences in participatory monitoring and evaluation *edited by Estrella M. with Blauert J., Campilan D., Gaventa J., Gonsalves J., Guijt I., Johnson D. and Ricafort R. 2000. 274 p. ISBN 1 85339 469 6: GBP8.95. Intermediate Technology Publications Ltd., 103-105 Southampton Row, London WC1B 4HL, UK.*
Bringing together a broad range of case studies and discussions between practitioners, academics, donors and policy makers, this book explores conceptual, methodological, institutional and policy issues in participatory monitoring and evaluation. It tackles the common themes and experiences in participatory monitoring and evaluation and shows the challenges – and far reaching benefits – of the approach. Interesting reading for all development professionals, including field workers, practitioners, researchers and policy makers.

Some successful indigenous technologies and practices for watershed management in Thailand *by Thongmee U., Phonpunpao P., Teerapon S. 1999. Royal Forest Department, Bangkok, Thailand/ ASIAN WATMANET/ Participatory Watershed Management Training in Asia (PWMTA) programme, Kathmandu, Nepal.*
Thai civilisation has evolved around sustainable forest, land and water management since ancient times. In the recent past, however, the principle of sustainability has been increasingly ignored. Highlighting indigenous watershed management systems in Thailand, this publication is a contribution to modern watershed management and conservation. It sets out to promote indigenous technologies and practices, particularly in the areas of water harvesting and upland irrigation, agroforestry, community forestry, forest conservation, agriculture and stock farming, and soil and water conservation.

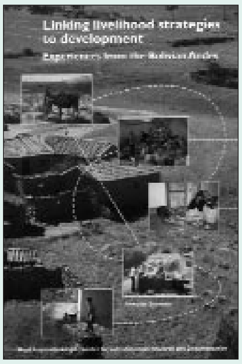
Fertile soil *by Misereor. 2000. 50 p. Misereor, PO Box 1450, D-52015 Aachen, Germany.*
This paper stresses the central role of soil conservation in rural development and gives a general overview of the subject. Causes of soil degradation and soil erosion are given, as well as ways to combat them on the basis of eleven Misereor project evaluations. Soil conservation is suggested as the basis for sustainable systems of land use. (IHG)

Highland rice production in the Philippine Cordillera. *CECAP and Philrice 2000. 213p. ISBN 97 19081 09 0 Central Cordillera Agricultural Programme (CECAP), Banaue, Ifugao and Philippine Rice Research Institute (Philrice), Maligaya, Munoz, Nueva Ecija, The Philippines.*



The Philippine Cordillera Administrative Region (CAR) is famous for its rice terraces – the eight wonder of the world. However, agricultural productivity, especially rice production, remains low. This publication consists of more than 52 field-tested and farmer-approved practices in the Philippine Cordillera. Easy-to-understand and fully-illustrated sheets show how to increase rice production, enhance traditional cropping systems, improve soil fertility and land productivity, construct efficient methods of irrigation, manage different kinds of pests and weeds, increase income through rice products, and many other traditional and alternative examples and practices in highland rice farming. This book is aimed at extension workers, farmers, community groups, NGOs, agricultural planners and researchers. It is also an invaluable resource for all those interested in farmer-tested methods to improve rice production in the highlands.

Linking livelihood strategies to development : experiences from the Bolivian Andes *by Zoomers A. 1999. 108p. ISBN 90 6832 125 0 : NLG 29.00. Royal Tropical Institute, PO Box 95001, 1090 HA Amsterdam, The Netherlands /* kitpress@kit.nl



Why have so many development initiatives failed to improve rural livelihoods in the ecologically culturally diverse *comunidades* of the Bolivian Andes? The book summaries the insights of a study - *Proyecto de investigacion sobre estrategias de desarrolla (PIED-Andino)* - that examined farmer and household livelihoods strategies, and village and intra-village relations over a 15 year period. The book sets out to explain that many development initiatives in the area have failed because they were based on an incomplete view of the local situation and because they assumed farmers were predisposed to resist change. *PIED-Andino* concluded that the significance of farmers multi-earning activities including off-farm employment was usually seen as a flight from poverty rather than as part of a multi-strategy response to environmental degradation. As a result development projects failed to build on farmers realities and livelihood strategies. Most evaluations of rural development projects were based on project goals not on the perceptions of farmers or the dynamic of the farm household. (MM)

Useful plants for land design *by Brazier A. 199?, 112 p. PELUM Association, PO Box CY301, Harare, Zimbabwe.*

This manual aims at the southern African region and describes plant species from the perspective of permaculture. It includes many multifunctional species and species that could be introduced more widely. The different sections deal with: climbing plants, cover crops, soil stabilisation species, shelter crops, pest control plants, dryland fruit trees and irrigated fruit trees. Besides general descriptions it also includes the local names and functions of each plant in the landscape (e.g. erosion control, windbreak etc.). A very well illustrated and functional workbook with spaces for readers' notes. (IHG)

Source book of sustainable agriculture for educators, producers and other agricultural professionals *SAN 1997. 136 p. ISBN 1 888626 03 8: USD 12.00. Sustainable Agriculture Publications, Hills Building, Room 12, University of Vermont, Burlington, VT 05405-0082, USA.*

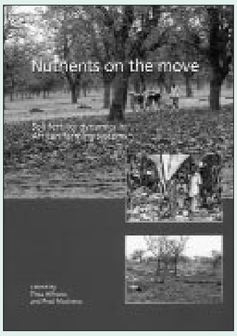
This book published by the Sustainable Agriculture Network (SAN) in the United States is a compendium of books, newsletters, conference proceedings, bulletins, videos, reports and web sites with information on agriculture and conservation. The subjects covered are agroforestry, animal production, cover crops, horticulture, grain production, marketing and farm profitability, nutrient management, soil quality and conservation, education and networking, and water quality and conservation. Each subject has its own icon, which allows for quick reference. The book features over 500 entries organised alphabetically by state, U.S. territory and foreign country. Each entry carries information such as title, author, type of product, abstract, date published, cost, how to order etc. SAN also invites readers to update or add an entry either by mail or through the web. Details are available at the end of the source book. Although most of the entries in the book are related to the U.S., the information can be equally useful to people interested in agriculture and conservation related issues in other parts of the world.

Rethinking soil and water conservation in a changing society – a case study in eastern Burkina Faso *by Mazzucato V. and Niemeijer D. 2000. 378p. ISBN 90 6754 596 1. Tropical Resource Management Papers, No. 32(2000)*

Soil and water conservation projects have had limited success in Africa despite various intervention approaches tried throughout the twentieth century. This study on eastern Burkina Faso, by two scholars from different backgrounds, argues that soil and water conservation is a complex issue in need of an integrated approach. It suggests that forms of intensification in African production systems can be best understood through analytical frameworks that focus on the interplay of social and environmental histories, rather than by assuming a simple trend towards increasing land degradation. The study offers an example of such an analytical framework and how it can be operationalized, leading to innovative perspectives on African land use systems.

From the roots up – strengthening organizational capacity through guided self-assessment *by Gubbels P. and Koss C. 2000. 184p. ISBN 0 942716 10 8. World Neighbours, 4127 N.W.122nd Street, Oklahoma City, OK 73120-8869, USA. Fax (405) 752-9700*

Guided self assessment is designed to help grassroots NGOs and community groups recognize their own potential, identify critical issues for programme and organizational development, and decide for themselves what actions to take, in relation to their purpose, context and resources. The process presented in this guide provides local organizations with the tools and perspectives necessary to strengthen their capacity by regularly reflecting on their performance, diagnosing internal strengths and weaknesses, identify priority capacity areas to be strengthened and designing action plans to improve effectiveness and long-term viability.

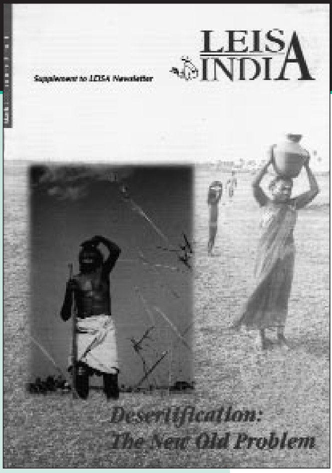


Nutrients on the move : soil fertility dynamics in African farming systems *by Hilhorst T. and Muchena F. (eds). 2000. 146p. ISBN 1 8 99825 56 8. IIED Bookshop, 3 Endsleigh Street, London WC1H 0DD, United Kingdom / bookshop@iied.org.*

NUTNET is a soil nutrient network made up of NGOs, universities, and national agricultural research institutes. Studies in six African countries were carried out with *NUTNET's* principal objectives in mind: to facilitate learning about soil fertility, stabilise soils and identify the conditions necessary for the sustainable production of food and other agricultural goods. In the countries studied agricultural production is in decline, stagnating or has an uncertain future. The *NUTNET* studies found that at farm and village level farmers were using a wide variety of strategies to cope with low levels of soil fertility. Farmers use indigenous knowledge to develop their own ways of conservation with the help of local NGOs and researchers. The editors stress, however, that it is important to study the full local and regional effects of farmers' initiatives. (MM)

Seeding solutions. Volume 1. Policy options for genetic resources : people, plants and patents revisited. *2000. 121 p. ISBN 0 88936 926 7. International Development Research Centre (IDRC)/International Plant Genetic Resources Institute (IPGRI)/Dag Hammarskjold Foundation*

This volume has been produced by the Crucible Group, a highly diverse body of people who came together after the 1993 Conference on the Environment and Development (UNCED) and in anticipation of the finalising of the General Agreement on Tariffs and Trade (GATT). They all shared a common concern for plant genetic resources and were alarmed that availability of these resources for world food security and agricultural development were being imperilled by proposed legislation. The present volume is an excellent source of information for policy makers and those requiring an up-to-date overview on the main issues related to the ownership, conservation and exchange of germplasm. The book begins by outlining the current struggle surrounding genetic resources and goes on to consider biodiversity and the issues of Intellectual Property Rights. Important here is the accelerated loss of bio- and cultural diversity, the commercialisation of transgenic crops and the implications for bioethics and social choice. Part Two discusses the various protocols that have been formulated in recent years including the Convention on BioDiversity and the Leipzig Global Plan of Action. The role of the CGIARs in facilitating access and exchange of knowledge is elaborated as is the role of World Intellectual Property Organisation (WIPO) in relation to knowledge policy making and the preservation of indigenous knowledge. In the final chapter the strategic role played by the World Trade Organisation in many of the issues raised in the book is discussed including the controversial role of the Trade Related Aspects of Intellectual Property Rights legislation commonly known as TRIPS. A second volume in this series dealing with the legal aspects of the debate is to be published later in 2000. (MM)



LEISA INDIA

The response to the integrated agriculture issue has been very encouraging and there has been a 40% increase in the number of contributors. In addition there is a growing diversity in geographical coverage as well as in the background of contributors. We have received contributions from all parts of the country from Assam in the east to Rajasthan in the west and from the northern, southern and central regions of India as well. Contributors include farmers, research students, senior academic, NGO project workers, extension officers, scientists attached to premier research institutions and senior bureaucrats. Presently, we are doing our best to select those articles that best share experiences gained in the different regions, practical field-based experiences and articles that report the successful use of technologies that our readers may also be able to try.

As a result of the LEISA India platform, there is already a lot of information exchange among the contributors and readers. For instance, Shri Narayana Reddi, a well known progressive farmer who contributes a regular column to **LEISA-India** was inundated with mail when he offered a specific seed variety. Similarly, there are a lot of exchanges on network experiences, especially on network models and on efforts to combat desertification and increase biodiversity. The number of subscribers is also steadily increasing and many new names are being suggested for inclusion.

The coming **LEISA-India** edition on Farmer Innovation will include: a report of a farmer innovators workshop (role models in the region); crop based innovations; process based and technological innovations; the philosophy and functioning of pioneering networks like Honeybee and regional partners like Hittalgida and the crusading spirit behind them.

As you know we have always distributed the ILEIA Newsletter and the LEISA India supplement separately. The Farmer Innovation issue will be the first time the two magazines will be brought together in a brand new regional magazine: **LEISA-India**. AME Bangalore will continue to handle its publication and distribution. ■

Those who are interested in **LEISA-India** may write to the following address. K V S Prasad, Coordinator, Info. Systems and Documentation, AME Programme / LEISA - India, 368, 4th cross, 3rd phase, J P Nagar, Bangalore - 560 078. India. email: amebang@giasbg01.vsnl.net.in

News from LEISA El Boletín for Latin America

Despite the changing political circumstances that threaten the stability of democracy and delay its consolidation in some of our countries, the willingness shown by peasant farmers, technicians and professionals in Latin America to search for alternative agricultural strategies continues to generate grass root innovations. However, these are still too few and dispersed to create the impact needed to reverse poverty among small-scale farmers or to stop the erosion of natural resources in many parts of Latin America. Nevertheless, the information being provided by our readers and the steadily increasing number of subscriptions shows that LEISA and Participatory Technology Development are making great strides on this continent. We can see that LEISA, *El Boletín de ILEIA* has come to play an important role in communicating information about sustainable agriculture and LEISA and complements the work of other communication efforts such as the Peasant-to-Peasant experience in Ecuador and Nicaragua, radio programmes and magazines. Although much remains to be done to ensure that *El Boletín de ILEIA* is viewed as the outcome of a truly participatory process, we are on the right track. We are getting increasing numbers of articles from readers based on their experiences, research work and other breakthroughs. Questionnaires asking for readers' opinions about the content and presentation of the magazine are often attached to *El Boletín*. Replies are mostly positive, although it must be said that only about 30% of our subscribers usually respond. Perhaps filling in questionnaires is not so effective in this day and age. We are therefore looking for more efficient ways of obtaining opinions in a situation where rural populations still have very limited access to electronic means of communication. Maybe our colleagues from *LEISA India* and those working on sustainable development magazines in other continents could help us out by suggesting ways in which we can keep in touch with our readers' opinions, so that we can include their criteria in the magazine. We are very grateful for any letters we receive, either via e-mail or by post.

In September 2000, we received more than 100 applications for new subscriptions. Many were from peasant farmers themselves including three peasants from Yucatan in Mexico. All the agro-ecological farmers from Ecuador, Bolivia and Peru who attended the Ecological Farming Meeting held in Lima in September 2000 requested a subscription to *El Boletin de ILEIA.* ■

Teresa Gianella-Estrems, Editor, estrems@amauta.rcp.net.pe

Energia

→ http://www.energia.org

ENERGIA is an international network on Women and Sustainable Energy, founded in 1995 to create an institutional base for galvanising action **to strengthen the role of women in the energy sector**. Energia is open to both men and women from the South and North interested in promoting its goal to "engender" energy and "empower" women, through the promotion of information exchange, training, research, advocacy and action aimed at sustainable energy development that is equitable for all.

ENERGIA News is produced jointly by Energy, Environment and Development (EED, Kurten, Germany), the Technology and Development Group (TDG, Enschede, the Netherlands) and ETC Energy (Leusden, the Netherlands). **The focus is on practice**, with a conscious effort to interpret and learn from this practice.

For more information: Email: ruaf@etcnl.nl Sheila Oparaocha ENERGIA News Secretariat c/o ETC Energy PO Box 64 3830 AB Leusden The Netherlands Tel: +31.33.4943044 Fax: +31.33.4940791

NETWORKING

The Forest Garden Initiative Programme supported by Counterpart International promotes and continues to work on the analog forestry model that fosters the restoration of degraded land through the development of family-owned forest gardens around the world. Community-based ecosystem management, certification and marketing of forest garden products are part of the Forest Garden approach.

For more information:
- Counterpart International, Inc., 1200 18th Street NW, Suite 1100, Washington, DC 20036, USA; Tel: +1 202 296 9676; Fax: +1 202 296 9679; info@counterpart.org ; http://www.forestgarden.org/
- International Analog Forestry Network: http://www.rcfa-cfan.org/
- The Forest Garden of Robert Hart: http://-www.globalideasbank.org/BOV/BV-314.HTML

Soil Fertility Research at Wye College, University of London, UK. The main focus of the research group's work is the legume/rhizobium symbiosis and its impact on nutrient cycling. Its web site provides information on such topics as improved fallows for Western Kenya, improved cropping systems, live-stock-based systems etc. The web site also provides information on the **Organic Resource Database** (ORD), a project initiated by the Tropical Soil Biology and Fertility Programme and Wye College. So far the main plant species covered has been tropical legumes. Decision tools to identify best use options are provided. The database addresses researchers, extensionists and NGOs.

It can be accessed free of charge and can be downloaded from the web site http://www.wye.ac.uk/BioSciences/soil/

Forest, Trees and People Programme (FTPP) supports rural populations participating in developing forest resources, and publishes the excellent periodical Forest, Trees and People Newsletter.

Address: FTPP Network, SLU Kontakt, Swedish University of Agricultural Sciences, Box 7034, 750 07 Uppsala, Sweden; Tel: +46 18 672001; Fax: +46 18 671980; FTPP.Network@kontakt.slu.se ; http://www-trees.slu.se/

Improvement and management of the fallow lands in West Africa is a research programme for the improvement and management of village fallow land. It aims at the intensification of the crop/fallow cycle. Research teams are based in Burkina Faso, Côte D'Ivoire, Mali, Niger and Senegal.

Further information (mainly in French): Institut de Recherche pour le Développement (IRD), B.P. 1386, Dakar, Senegal, Tel: +221 849 3535; Fax: +221 832 43 07 and http://www.ird.sn/act-rech/jachere/projet.htm .

Overstory is a free e-mail journal that serves people working in tropical agroforestry, forestry and sustainable development in 133 countries.

It is published by Permanent Agriculture Resources, P.O. Box 428, Holualoa, HI 96725 USA; Tel: 808-324-4427; Fax: 808-324-4129; E-mail: par@agroforester.com; Web site: http://www.agroforester.com. Past editions can be seen on: http://www.agroforester.com/overstory/osprev.html Some themes discussed are: Traditional agroforestry No.51; Non-timber forest products No. 53; The understory No.56; Value-adding No.63; Twelve tree myths No.68.

Rural Learning Networks in Community Forestry aims at improving farmers' livelihoods by facilitating farmer self-learning and information exchange on indigenous and locally innovated knowledge and practices, farmer-to-farmer exchange and communication. In community forestry, implementation of farmer-led research and extension approaches such as Farmer Field Schools is still in its infancy. The Forests, Trees and People Programme (FTPP) supports the initiation of the Rural Learning Network Approach.

New Forests Project (NFP) offers nitrogen-fixing tree seeds, technical information and training materials free of charge to groups worldwide.

Address: 731 Eighth Street, SE Washington, DC 20003, USA; Tel: +1 202 547 3800; Fax: +1 202 546 4784; icnfp@erols.com

New website on organic farming
CABI Publishing is pleased to announce the launch of a new organic farmingresearch internet site at http://www.organic-research.com The site contains the latest news on organic agriculture and information on events, research, education, legislation, jobs, network links and cases of organic farms in the North and the South. A search function is also available.

Trop SCORE

The Consortium for Tropical Soil Cover and Organic Resources Exchange, TropSCORE, is an association of regional and international members set up to collaboratively acquire, synthesis, exchange and disseminate information about low-external-input approaches for improving smallholder farming systems in the tropics and managing the natural resource base in a sustainable manner. The main focus is on cover crops, green manure and other organic means of managing tropical soils. Topic covered are of particular relevance to farmers in Africa, Asia and Latin America working in areas where resources are severely limited.

Members of the Consortium include:

CIDICCO, The International Cover Crops Clearinghouse, Honduras, Apartado Postal 4443, Tegucigalpa MDC, Phone: +504 232 3850; Fax: +504 239 5859; cidicco@gbm.hn ; http://www.sdnhon.org.hn/miembros/cidicco. Information, including Cover Crops News and several books, available is available in Spanish and English.
CIEPCA, The Centre for Cover Crops Information and Seed Exchange in Africa, Republic de Benin, 08 BP. 0932 Tr Postal, Cotonou, Phone: +229 350188; Fax: +229 350556; ciepca@cgiar.org . Newsletter and several publications available in French and English.
CIIFAD/MOIST, The Cornell International Institute for Food, Agriculture and Development working group on Management of Organic Inputs in Soils of the Tropics is based at Cornell University, 618 Bradfield Hall, Ithaca, New York 14853, USA. MOIST is an interdisciplinary working group that investigates and exchanges information on cover crops, green manure, managed fallows and mulches in tropical farming systems.
ECHO is a NGO resource centre and global bookstore: 17391 Durrance Rd., N.Ft. Myers, Florida 33917, USA; Tel: +1 941 543 3246; Fax: +1 941 543 5317; books@echonet.org ; http://echonet.org/ . ECHO provides international development resources including publications. It also makes seeds of under-exploited food, agroforestry, and soil-improving crops available on request free of charge.

Other services provided by TropSCORE include:

- TropSCORE Information Gateway Website, an international clearinghouse and search engine for TropSCORE internet resources on soil cover, organic inputs and tropical soil management.
- e-list of active electronic discussion groups in French, Spanish and English.
- print-to-web project providing internet access to "grey" literature and regional newsletters in order to scale up access to local information sources.
- Green Manure Cover Crops (GMCC) seed bank and on-line seed source database (planned for 2001).

For more information on TropSCORE contact: Lucy Fisher, CIIFAD/MOIST, Phone: +1 607 255 2920; lhf2@cornell.edu and http://ppathw3.cals.cornell.edu/mba_project/moist/TropSCORE.html

CAN YOU CONTRIBUTE

Information on Water Harvesting wanted

I am collecting and documenting success stories on traditional and recent methods of water harvesting, soil and water conservation and river-bank erosion control.
I am also collecting information on publications dealing with these issues and on organisations promoting water harvesting in other regions. I am keen to exchange info and photos with like-minded activists in other parts of the world. I would be grateful if there are readers of the LEISA Newsletter who can provide me information or send me the addresses of persons and associations involved in this cause. I am especially looking for cases of groundwater enrichment through reforestation and other in-situ methods. Such case studies are very important in today's context. The information collected in this way will be collected together and passed on to others via appropriate media.

Shree Padre, journalist, Post Vaninagar, Via Perla, Kerala-671552, India. spadre@vsnl.com

Second international competition on Grassroots Innovations

Any innovations attempted by farmers, artisans, fishermen and women, slum dwellers, workshop mechanics, primary or secondary school teachers or local communities on a wide variety of subjects are eligible for this competition. Suggested topics include, for example, managing natural resources, biodiversity, developing new farm implements, herbal pesticides, curing diseases, building houses, reviving culture and enrolling children or improving performance in primary education or any other field of human knowledge.
The award winning entries will be published in the Honey Bee Newsletter and included in the multi-media, multi-language database on Grassroots Innovations. Winners will also be invited to the Honey Bee network meeting in India in February, 2001.

You are invited to send your contribution including information on genesis, background, innovators/s, origin of idea, accompanied by photographs and/or video if possible, to:Prof Anil K Gupta, Coordinator, SRISTI and Honey Bee network, Indian Institute of Management, P.O. Box 15050 Ahmedabad 380 015 India. anilg@iimahd.ernet.in ; http://www.sristi.org
Last date for submission: December 30, 2000

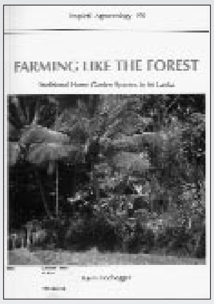
Best practices in shifting cultivation for sustainability and resources conservation in Asia
a resource book produced by the International Institute of Rural Reconstruction (IIRR), Y.C.James Yen Center, Silang, Cavite 4118, Philippines /iirr@cav.pworld.net.ph. Expected to be ready in December 2000 see p.2.

Analog forestry: an introduction
by Senananyake R and Jack J, 1998. Monash Publications in Geography Number 49, Monash University, the publications secretary, Dept. of Geography, Clayton, Victoria 3168, Australia, fax: +61 3 9905 2948, gary.swinton@arts.monash.edu.au ISBN 0 909685 58 4, Aus$ 33.00 + postage, pp.145.
This booklet explores the major ecological processes that underlie Analog Forestry. Much consideration is given to the inter-connectedness of functions within the forest over time and thus the importance of successsional changes and the adaptability of plants and other organisms of the forest ecological system. It postulates that much of the undervaluing of forests derives from an ignorance of the wide range of forest products, most of these from non-woody plants. In consequence the nature of forest products is dealt with in some depth. Much attention is given to the design of Analog forests. It is explained that in the design of Analog forests the strategies and values of indigenous people and the structures and functions of the relevant 'native' forest should be taken into consideration and that it should fit appropriately within the human and natural landscape of the region.
Case studies detail how the approach has been applied in Sri Lanka and Australia. Special attention is given to the possible contribution of Analog forestry to biodiversity conservation.
A challenging introduction to a knowledge intensive ecological approach to (agro-)forestry. (CR).

Farming like the forest: traditional home garden systems in Sri Lanka
by Hochegger K, 1998. Margraf Verlag, PO Box 1205, D-97985 Weikersheim, Germany, Fax: +49 79 348156; margraf@compuserve.com ISBN 3 8236 1293 X ; US$ 40.00
The *gewatta* or traditional home garden system is investigated and presented by the authors as a model for sustainable land use and biodiversity conservation. The forest-like gardens cover 14.5% of the island's total area. They offer a habitat for many plants and animals. At the same time they provide many of the daily needs of a growing population. Typical characteristics are a low need for external inputs and labour, minimisation of risks and a high adaptability to change. It has even survived the development of the monetary market by adding some cash-crop products.



Still further adaptations are needed to keep them attractive to farmers many of who also have jobs outside agriculture as well. To preserve the potential of these gardens more attention should be paid to education and training, the encouragement of local culture and establishing a research institute. This is very detailed and nicely illustrated case study, strongly contributing to better understanding of traditional agriculture. (CR)

Improving smallholder farming systems in Imperata areas of Southeast Asia: alternatives to shifting cultivation
by Menz K, Magcale-Macandog D. and Rusastra IW (eds), not dated. ACIAR Monograph No. 52, 280 pp. ISBN 1 86320 223 4. ACIAR, GPO Box 1571, Canberra, ACT 2601, Australia.
It reports on a research programme on the above subject. It discusses the problem of Imperata invasion, the research methodology followed and a number of case studies on alternatives such as tree planting, hedgerows, incorporation of livestock and fire management.

Imperata grassland rehabilitation using agroforestry and assisted natural regeneration *by Friday KS, Drilling ME, and Garrity DP (eds), 1999. ICRAF Southeast Asian Regional Research Programme, Bogor, Indonesia. ISBN 979 95537 0 9.*
A practical how-to-do booklet based on the above publication.

Fallow management systems documentation and participatory rapid appraisal methodology *by Magcale-Macandog DB et al. (eds). 1999. Workshop proceedings. Fallow Management Network – Philippines, secretariat DB Magcale-Macandog, NRMP – SEAMEO, Phone: +63 49 536 3459; Email: dmm@agri.searca.org*
A literature review and cases of fallow documentation are presented and experiences with different research tools are discussed.

Building upon traditional agriculture in Nagaland, India. *1999. 235 p. ISBN 0 942717 72 4. Nagaland Environmental Protection and Economic Development (NEPED), c/o Intern. Development Research Centre (IDRC), 208 Jor Bagh, New Delhi 110 003, India / mfaminow@idrc.org.in; Intern. Institute of Rural Reconstruction (IIRR), Y.C.James Yen Center, Silang, Cavite 4118, Philippines / iirr@cav.pworld.net.ph.*
One of the practical resource kits produced by IIRR with many very well illustrated practical how to do articles describing the indigenous land use system, farmers' best practices in e.g. crop, fallow, tree and agroforest management and biodiversity conservation. Also experiences with participatory development methodologies are included. Very readable and useful, also for people outside Nagaland (CR).

Kudzu-improved fallows in the Peruvian Amazon: a case study of the impact of technological change on deforestation *by Yanggen DR in: Angelsen A. and Kaimowitz D. (eds), 2000. Agricultural technologies and tropical deforestation. CAB International, Wallingford, UK. To be published in February 2001. ISBN 085199 451 2*
In this empirical research paper, based on a survey of 220 farm households, the economic reality of farmer management of fallow-based shifting cultivation is analysed. Costs and benefits of traditional and improved fallowing practices are compared and an assessment is made of how kudzu-improved fallow adoption affects deforestation in the lowland tropical rainforest areas surrounding the city of Pucallpa, Peru. It was concluded that, by reducing labour needs while increasing yield, kudzu-fallow adoption has been successful precisely because it fits the local economic conditions and is superior to traditional shifting cultivation. It is the land quality constraint and not the land quantity constraint that leads farmers to adopt kudzu fallows. Kudzu-improved fallows are not associated with the intensification scenario typical of land scarcity in the neighbourhood of urban centres. Farmers in older settlement areas may be particularly receptive to adopting improved fallows in order to conserve the remaining primary forest. (CR).

The Amarasi model: an example of indigenous natural resource management in Timor, Indonesia
by Nalan Yuksel, Ali Aoetpah and Imo, edited by Paul Burgers. ICRAF-SE Asian Regional Research Programme, Indigenous Fallow Management Network, Occasional paper 1999/1.
A systematic documentation of successful indigenous intensification of land use by shifting cultivators on West Timor, Indonesia. Beside their land use practices, the farmers changed their indigenous institutions and customary law. Very interesting reading (CR).

A natural ecosystem analog approach to the design of a successional crop system for tropical forest environments *by Hart RD. 1980. Centro Agronómico Tropical de Investigación y Enseñanza (CATIE), 7170 Turrialba, Costa Rica. In: Tropical Succession ; v.12 (1980) no.2 p.73-95.*
A succession crop system is described and compared with a conventional system showing the potential of the analog approach. Further scientific analysis of the approach provides evidence for the hypothesis that the agricultural viability of a particular crop system is directly related to the degree of similarity of that crop system to a natural plant system in the same environment.

Farming in nature's image : an ecological approach to agriculture *by Soule JD, Piper JK. 1992. 286 p. ISBN 0 933280 88 2 (pbk) : USD 19.95. Island Press, PO Box 7, Covelo, CA 95428, USA.*
In the first half of the book the authors analyse why there is a need for ecologically sound agriculture and, though very briefly, discuss experiences with and the benefits of "nature like" agriculture. The book really becomes interesting when the authors start to

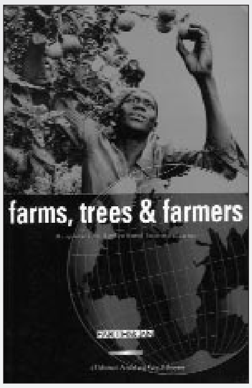
write about the research of 'The Land Institute' which specifically deals with developing agriculture modeled on native North American prairie. In this ecosystem model natural perennial grasses are replaced by perennial seed crops for human consumption. The research deals with basic questions such as: seed yields of perennials; over-yielding in perennial polyculture; the internal supply of fertility and the management of weeds, pests and plant pathogens. Though the research is an inspiring approach which provides hope for future success, a lot of work still remains to be done. A book for people interested in new concepts. (CR)

The forest islands of Kissidougou : social dynamics of environmental change in West Africa's forest-savanna mosaic *by Leach M, Fairhead J ; Millimouno D, Kamano M. 1994. 93 p. Institute of Development Studies (IDS), University of Sussex, Brighton BN1 9RE, UK.*
Kissidougou prefecture of Guinea is an example of West Africa's forest savanna transition zone, with dense forest "islands" encircling villages in the midst of savanna area. To analyse vegetation change during the last century, aerial photographs and remote-sensing, archives and methods for participatory environmental monitoring were used. In contrast with the general opinion of ecologists and policy-makers, the areas of forest and secondary forest vegetation proved to have increased since the turn of the century. People suggested that it was their work to intensify agriculture and encourage forest growth. Officials in the meantime instituted repressive laws to restrict local practices, as they thought the local resource management to be destructive. The authors analysed what happened and why there is a discrepancy between expert opinion and villagers' perspectives. (IHG)

***Sesbania sesban* improved fallows in eastern Zambia: their inception, development and farmer enthusiasm** *by Kwesiga FR et al. in Agroforestry Systems 47: 49-66, 1999. Kluwer Academic Publishers, The Netherlands.*
Several studies since 1987 have demonstrated the potential of two- or three-year sesbania fallows in restoring soil fertility and increasing maize yields. Analysis showed that these improved fallow systems were feasible, profitable and acceptable to farmers. The potential to increase maize production without applying mineral fertilisers has excited thousands of farmers who are enthusiastically participating in the evaluation of this technology. Presently, a strong network of institutions comprising government, NGOs, and farmer organisations is facilitating the adaptive research and expansion of improved fallow technology in eastern Zambia. The paper mainly focuses on the performance analysis of researcher-managed trials. Some attention is also given to farmer-designed and managed trials and partnerships.

Farmer experimentation and innovation : a case study of knowledge generation processes in agroforestry systems in Rwanda *by Biggelaar C (den) ; Hart N. 1996. 123 p. Forests, Trees and People Programme (FTPP), Swedish University of Agricultural Sciences (SUAS/IRDC), Box 7005, S-75007 Uppsala, Sweden. (Community forestry case study series, ISSN 1020 4466 ; 12).*
Active planting and management of woody species by farmers is relatively new in Rwanda. The farmers processes of generating knowledge about agroforestry, particularly their experimental methods, were studied. Locally identified tree experts had different knowledge about tree cultivation than local farmers. The latter had less land and were more likely to experiment with integrating trees in complex systems with field crops. It proved difficult to differentiate experimentation from normal farming practice, as each season is an experiment . Knowledge production by farmers was oriented to use but also to a future beyond the farmers lifetime. Considerable gender differences in knowledge about trees was found. Communication networks for knowledge sharing were weak and here more support it needed. Highly recommended reading for PTD practitioners. (AWB)

Farms, trees and farmers : responses to agricultural intensification *by Arnold JEM, Dewees PA (eds). 1997. 287 p. ISBN 1 85383 484 X (pbk) : GBP 16.95. Earthscan Publications, 120 Pentonville Road, London N1 9JN, UK.*
The uncertainties connected to tenure rights often lead to overuse of communal trees in open-access situations. In addition, serious deforestation has occurred in many places to satisfy the demand for fuelwood. This explains the dwindling number of off-farm trees. To make up for these losses, smallholders have planted trees in their fields or near their homesteads. Though these scattered trees cannot make up for the loss of biodiversity encountered in forests, the trees play an important, but relatively little-known, role in survival strategies of smallholders. In addition to supplying firewood, trees are used to complement otherwise monotonous diets, as windbreaks, to check erosion, and to supply a whole range of miscellaneous products. Many of the original projects that promoted tree planting on smallholders' farms were not very successful: they were triggered by the conviction that the energy shortage would automatically imply a need for more fuelwood. However, this did not take the whole complex farmers' perceptions into account in which decisions go well beyond the energy-from-fuelwood consideration.



More recent projects have showed a better approach. This is presented in this book through case studies from South Asia and Eastern Africa. The focus is on changes in tree management strategies over time and on farmers' decisions in the light of changing supply and demands. The case studies examine the relationship between tree management and subsistence needs, market opportunities and constraints, availability and allocation of land, labour and capital, and exposure to risk and risk management. It is the value of this book that it reveals the complexity of farmers' decision making processes. The book primarily addresses a scientific audience. (WB)

Batak resource management : belief, knowledge and practice *by Eder JF. 1997. 52 p. ISBN 2 8317 0366 2 : USD 12.00. IUCN Forest Conservation Programme, International Union for Conservation of Nature (IUCN), Strategies for Sustainability Programme, Rue Mauverney 28, CH-1196 Gland, Switzerland; WWF Forest Programme, World Wide Fund for Nature (WWF). (Issues in Forest Conservation).*
This report on the Batak of Palawan Island in the Philippines shows how, in practice, Batak belief and knowledge about the environment are inextricably bound up in the resource-use routines of everyday life. Systematic comparison of past and current Batak practices with those of lowland Filipino migrants show that the Batak approach to making a living remains consistently less destructive of the natural resources and ecological integrity of their forest environment than does that of migrant lowlanders. The report also looks at the weaknesses and strengths of the traditional Batak management system as a basis for future sustainable use. The author states that, given that lowland migrants and outside facilitating agents such as Haribon Palawan and IUCN bring additional, complementary strengths, there is considerable grounds for optimism about the future, assuming that significant political progress continues to be made in returning control over local resources to local people. For this continuous collaboration is needed. An interesting case study with a strong focus on non-timber forest products. (CR)

Agroforestry guides for Pacific Islands *by Elevitch CR, Wilkinson KM (eds). 2000. 239 p. ISBN 0 9702544 0 7 : USD 24.95. Permanent Agricultural Resources (PAR), PO Box 428, Holualoa, HI 96725, USA / guides@agroforestry.net; http://www.agroforestry.net.*
These guides written by and for agroforestry researchers, field-level extension workers and farmers provide a real clearinghouse on traditional and modern agroforestry not only for practitioners on the Pacific Islands but are also very useful in other regions. The separate sections deal with topics like multipurpose trees, non-timber forest products, understorey crops, tree integration, species selection, economics of farm forestry and multipurpose windbreaks. They include principles as well as practical implications and information on references, further readings, magazines, addresses, web links, organisations and resource persons. Aspects like forest ecology, indigenous fallow management, analog (agro-)forestry and ecological intensification are not yet included in the publication. (CR).

The full text of these articles can be requested from the authors or from ILEIA.

From slash and burn to slash and mulch

The Manobos and Mamanwas in the isolated Philippine island of Mindanao have traditionally used slash and burn techniques to open new swidden to produce sweet potato, upland rice and other crops. Most of their fields are on relatively steep slopes and average rainfall is above 4000 mm. The swiddens were often left fallow after only one year. Recently, forestry activity has put land for new swidden under pressure. Encouraged by the Tribal Filipino Programme *Surigao del Sur* (TRIFPSS), farmers have modified their practices. For several years they have been growing more vegetables and have planted fruit trees, coconut palms, bananas and abaca in multiple cropping. Today most farmers have replaced 'slash and burn' by 'slash and mulch'.

Local leaders have drawn up a management plan for the KALASAG Ancestral Domain. The farmers decided they would no longer open new swiddens but only cultivate those areas that had been opened up earlier. Fields planted with perennials like abaca, banana and fruit trees in combination with sweet potato are quite well protected. But, despite the practice of covering the soil with organic matter from previous crops, cut weeds and sweet potato vines, soil cover in most cases is not enough to effectively protect the soil. Considering that most fields are located on relatively steep slopes additional measures are necessary to control erosion and maintain soil fertility. The farmers have been reluctant to adopt the system of planting hedgerows along the contour lines of slopes in fields intended for the production of staples. The traditional beliefs and religious practices of the Manobos and Mamanwa reflect a deep respect for nature. The information about sustainable agriculture practices provided by TRIFPSS has blended well with these beliefs. Some leaders agreed with the observation, that if the indigenous people had acted like neighbouring 'Christian' colonist farmers, they would have already cut all the trees around their farms. Obviously the problems of agriculture and their solutions involve cultural and moral issues. For the communities in the KALASAG area, insisting on their specific culture has proven fundamental to their survival.

Indigenous Shifting Cultivation in Northern Western Ghats, India

In India shifting cultivation is practised in the Eastern Ghats and some parts of the Western Ghats. In the latter region it has yet to receive serious attention. A two-year study conducted by AERF revealed that most of the families practising shifting cultivation or *dongarsheti* are from low-income groups. At least one person from each family has migrated to cities for jobs or education. There is not enough manpower intensive *dongarsheti*. Moreover, the meagre income generated from inferior quality jobs is not sufficient to run a village household. Out migration is therefore responsible for both the maintenance of these traditional practices and the decrease in area devoted to *dongarsheti*. In 75% of the total number of villages surveyed, *dongarsheti* has been reduced almost to a demonstration scale and there are large tracts of mature fallows. In the more remote areas, however, *dongarsheti* is still the main livelihood strategy.

Assessing the shifting cultivation practices from this region on a larger scale is a matter of great urgency. Improved fallow management and marketing of local varieties could provide supplementary income for the communities.

Does intensifying pasture management in tropical Latin America protect forests?

This paper is based on data from the Tropileche research and extension consortium using results from three research sites in Colombia, Costa Rica and Peru and compare the adoption and effects of improved feeding systems for small-scale farmer milk and beef production. These systems were: a new Brachiaria grass variety, an association of Brachiaria with a legume called Arachis pintoi, and a cut-and-carry system with Cratylia, a leguminous bush that serves as a protein bank during dry months. To varying degrees in all sites, the improved forages increase both stocking rates and milk production. Although improved pastures require more labour to maintain them, the greatest obstacle to getting small-scale farmers to adopt them is their large initial establishment cost. Intensive pasture systems can be highly profitable but when capital is scarce or cannot easily be borrowed, they are not financially feasible.

Review of the evidence regarding the effect of improved pasture technology on forest cover led to an alternative hypothesis: forest scarcity is a prerequisite for technology intensification. It was found that, where markets modestly value forested land, as in the Peruvian Amazon, a private farmer's decision to raise cattle extensively by converting additional forest for pastures appeared perfectly rational. However, in more developed regions with older forest margins as in Costa Rica and to a lesser extent Colombia, farmers tend to produce livestock more intensively to avoid pasture degradation and the high cost of expanding into uncultivated land.

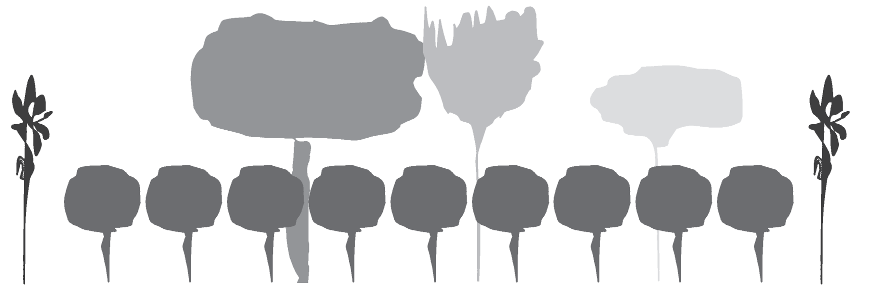
From: White D, Holmann F, Fuijsaka S, Reategui K, and Lascano C. **Does intensifying pasture management in tropical Latin America protect forests? Reversing the question.** In: Angelsen A. and Kaimowitz D. (eds). **Agricultural technologies and tropical deforestation.** CAB International, Wallingford, UK. To be published in February 2001. ISBN 085199 451 2.

Monoculture or polyculture?

Sabirin and Hamdan

North Sumatra is a province in the Indonesian archipelago. Its tropical rain forest has a rich natural biodiversity to which traditional swidden agriculture has contributed a rich agro-biodiversity. However, this richness is steadily being replaced by the monocultures of oil palm and subsidary crops such as cacao, rubber, tea, tobacco and sugar cane on the large governmental plantations (3,359,719 ha.), private estates (498,988 ha.) and smallholder properties (770,408 ha.). On a considerable part of the total land area (7,168,068 ha) the rich biodiversity is being constantly eroded.

Transect of planting structure:



Pinang *(Areca pinata)* as barrier — Petai papan *(Parkia spiosa)* — Kakao *(Theobroma cacao)* — Duku *(Lansium domesticum)* — Durian *(Durio zybetinus)*

Impact of monocultures

Natural vegetation is generally cut and burned to clear the land for plantation crops. This means that biomass and biodiversity of considerable economic value is lost and soil degradation, erosion, and air pollution becomes a problem. Monocultures require considerable amounts of chemical fertiliser and pesticides that also pollute the environment, and the large amounts of water needed for oil palm have created water scarcities. As moncultures destabilise the agroecological system many oil palm pests and diseases have emerged, including *Ganoderma sp*, fire-caterpillar and termite. The cacao moth has become a particularly serious pest in cacao plantations and is very difficult to eliminate. Monocultures have had a deep impact on social relations and culture as well. Traditional community spirit like *gotong royong (a system of mutual cooperation or community self-help)* has been weakened and traditional products like King Banana, *Sirih (Piper betle)* and economic activities like animal husbandry are disappearing. The products of monocultures cannot be used directly for home consumption or home industries. Older farmers find it hard to remain in the production system and the system itself cannot be adapted to the conditions and needs of the local people.

Development of polycultures

The Pesticide Action Network North Sumatra (PAN-NS) began to develop alternative agricultural models to counter the problems caused by monocultures. In this way they sought to generate higher levels of biodiversity and systems that were more environmentally friendly and delivered more economic benefit and profit. Since 1990, PAN-NS has been working with local farmers in different parts of North Sumatra to analyse and experiment with polycultures. Several polyculture models have been developed in which cacao (*Theobroma cacao*) plays an important role. Local trees like durian (*Durio Zybetinus*), duku (*Lansium domesticum*), petai papan (*Parkia spiosa*) or coconut (*Cocos nucifera*) are intercropped with cacao and pinang (*Areca pinata*) planted around the polyculture. In some places cattle can also be integrated into the system. Currently, PAN-NS is experimenting with local coffee as a main commodity crop.

The choice of trees to be interplanted will depend on whether the area is forest or cacao plantation. Banana (3x3 m.) can be planted as a pioneer crop on land where there are no trees. Local trees of economic significance can be planted in between the banana plants at spacing appropriate for the species concerned. In the second and third year banana plants will be replaced by cacao.

Sustainability analysis

The performance of a one hectare based polyculture model planted 10 years ago with 6 head of cattle integrated into the system has been compared to one hectare monoculture models of cacao and oil palm. Table 1 and 2 provide the economic data.

Based on these data and the ecological, social and cultural arguments mentioned above, it can be concluded that monoculture models are not as profitable as they seem and are ecologically and socially unsustainable. Although this is increasingly being admitted, it has not yet resulted in alternative development policies and practices. Sustainability has to be taken seriously in agricultural research and policy making in Indonesia.

Conclusion

Based on our experiences we conclude that small-scale polyculture is a very appropriate model for rural people, particularly in regions with high biodiversity. Polyculture is affordable, it does not need much capital for external inputs and only requires 2-4 hectares of land for each household. Although animal theft can be a serious problem, polyculture is a model for profitable, environmentally friendly and sustainable development. In addition, it is feasible for farmers and NGOs to adapt the *cacao* based polyculture model to other tree crops like coffee, if they are able to get the support of a funding agency through a revolving fund.

■

Table 1. Economic evaluation of the polyculture model

No	Cultivated plant	Plant/animal Population	Production year/unit	Cost/item (Rp)	Total income/ year (Rp)
1	Durian *(Durio zybetinus)*	36	.200	1,000	7,200,000
2	Duku	36	.500 kg	2,000	36,000,000
3	Petai Papan *(Parkia spiosa)*	36	025	1,500	1,350,000
4	Pinang *(Areca pinata)*	133	4 kg	3,000	1,596,000
5	Cacao *(Theobroma Cacao)*	800	2.75 kg	5,000	11,000,000
6	Cattle	6	6	1,000,000	6,000,000
				Total Rp	**63,146,000**

Covert to US$ 9,021 (1US$= 7000 Rp)

Livestock and forage management in stabilising shifting cultivation

Phengsavanh, Phimphachanhvongsod and Horne

While acknowledging the complexity and diversity of shifting cultivation systems, some generalizations can be made to illustrate the role ruminant livestock play in stabilising them. In the remoter areas of Northern Laos, rice shortages caused by frequent but irregular climactic catastrophes, are common. Such shortages can last for more than 6 months and have a serious impact on household security. Traditionally, farmers have dealt with these shortages by drawing on the natural capital of the forests, by hunting and gathering, growing less popular food crops such as maize and cassava, and by purchasing rice. Often, these farmers have little to sell but their labour, or opium, some forest products, medicine, herbs, and their livestock - cattle, buffalo, pigs, goats and chickens. The government discourages the production of opium and forest resources are decreasing as population pressure grows and villages are resettled away from their traditional forest resources. Gradually, farmers have become increasingly reliant on livestock for their cash income.

Benefits from livestock

There are a number of benefits in raising ruminant livestock:

- They have an assured market with relatively stable prices;
- They do not need transport: cattle and buffalo can be walked long distances. In one recent example, some H'mong farmers walked their 20 bulls 350 km from Xieng Khouang to market them in the capital, Vientiane;
- Provide a good profit for a relatively low input of labour;
- Are wealth that can be used in emergencies;
- Utilise natural resources (grass, rice straw, tree leaves) that would otherwise be wasted;
- The manure can be used to maintain the fertility of irrigated rice fields and home gardens. Some livestock owners sell manure to lowland farmers.

Serious problems offset these benefits including disease, limited fodder resources, and crop damage. However, the benefits are so substantial that, in almost all areas, farmers continue to raise livestock to help safeguard their livelihood.

Fodder scarcity

Factors that have contributed to the scarcity and degradation of traditional fodder resources include a growing livestock population and the over-utilisation of grassland, rice straw, and forest resources. The expansion of agriculture into traditional grazing land, the reforestation of grazing land, reduced productivity of native grasses and restricted access to forest grazing land are also serious problems.

Options for improvement

Shifting cultivators often have very few alternative ways of feeding their ruminant livestock. Alternative strategies include moving livestock between wet and dry season grazing areas; storing or reserving rice straw for dry season feeding; and cultivating grasses on fallow land to provide cut feed for penned animals.

The first two strategies are fairly well developed throughout the region and there is little potential for adaptation. However, the third strategy, managing forages, offers a promising possibility and can be developed in partnership with farmers. Villagers are most interested in cultivating forage species that can be given as cut feed to penned animals and improving the grazing areas used for community managed herds. Case studies have shown that farmers are particularly interested in having wet season supplementary feed for their cattle, dry season supplementary feed for buffaloes and cattle and more manure for their rice fields. They also want to control the amount of damage animal inflict on crops and minimise livestock losses.

In many cases, farmers are strongly motivated to manage feed resources, but their innovative capacity is constrained by a lack of information and planting material. The successful development of forage technologies, however, does not depend on the quantity of planting material distributed, but on carefully selecting farmers who acknowledge they have a real problem and who are prepared to seek solutions in co-operation with development workers. If this approach is combined with a broad range of robust technologies, the chance of successful adoption is much higher. For example, the upland areas of Bali are renowned for the widespread use of *Gliricidia sepium,* a shrub used as a living fence and source of dry season fuel. Yet this species was only introduced in 1970 in a "hundred cuttings" and owes much of its success to the fact that farmers were able to identify their problem and found the species appropriate, robust and easy to manage.

Forages that stabilise

In Northern Laos, farmers and development workers are exploring ways in which forage species introduced into the area can be integrated into technologies that will help stabilise shifting cultivation. This is being done in two ways. First, by comparing indigenous feeding strategies, such as cutting and grazing, using an introduced species. Second, they are developing new ways of incorporating introduced forages into existing shifting cultivation systems.

Regional evaluation of more than 70 forage species in five locations resulted in the identification of eight broadly adapted and robust species.

- *Brachiara brizantha* (currently cv Marandu with other lines soon to be tested),
- *Brachiara decumbens* cv basilisk,
- *Brachiara humidicola* CIAT6133,
- *Brachiara ruziziensis* cv Kennedy,
- *Andropogon gayanus* cv Kent,
- *Panicum maximilliani* T58,
- *Paspalum atratum* BRA9610,
- *Stylosanthes guianensis* CIAT184.

These species are now being evaluated for their potential in cut-and-carry or grazed systems by about 100 farmers in three northern provinces. At this stage, evaluations are informal and without replication, because the aim is to encourage a greater number of farmers to participate in farmer innovation. Should promising innovations emerge, they will be encouraged by farmer-to-farmer visits and studied in more detail in formal, replicated on-farm trials. At the moment, farmer-managed trials are either in progress or are just beginning. They will evaluate and adapt three potentially useful innovations suggested by researchers on the bases of experience gained elsewhere. These innovations are discussed below.

Forage trees and fences

Crop damage caused by livestock is a major and constant concern in the upland areas of Northern Laos. Farmers already use some living fences (mainly *Jatropha curcas*) either to keep animals in or out of fields. In some areas, especially those managed by H'mong people, enormous efforts are put into building solid, semi-permanent fences of wood, wire and bamboo. Living fences incorporating *Gliricidia sepium*, *Laucaena leucocephala* (on better soil) and *Calliandra calothyrsus* (in the higher areas) have considerable potential and can ease this burden as well as provide supplementary feed. However, the technical advantages and limitations of these trees need to be evaluated by farmers and development workers together and farmers' criteria for accepting or rejecting these technologies must also be carefully explored.

Oversowing upland rice.

Oversowing upland rice with *Stylosanthes guianensis* is not new but it is an innovation that has the potential to improve subsequent fallows and provide benefits such as reduced weeding and increased soil fertility. The use of forage legume species for fallow fields in shifting cultivation areas has been the subject of much detailed and promising research. Although the potential benefits such as reduced weeding requirements, improved soil fertility, easy establishment after a round of weeding and reduced risk of erosion, are well documented, farmers have been slow to adopt it. There are many reasons for this, but probably two are particularly important. First, most of the work done in Laos on *Stylosanthes guianensis* has been carried out on research stations or in researcher-managed trials with the expectation that the technologies can then be "extended" to farmers. There is a need to establish informal oversowing trials with farmers to discover what aspects of oversowing appeal to them and to see what treatments should be studied in subsequent formal trials. Second, sowing fallow fields with forages means they can be better protected from uncontrolled grazing. Fallow improvement with the farmers of Hoauy Hia village would almost certainly fail because of the lack of sturdy fencing. However, in H'mong areas where individual fallow fields are often sturdily fenced, the potential is much higher.

Informal and formal trials with farmers began with oversowing *Stylosanthes guianenses* CIAT184 in upland rice fields after the first round of weeding. The species has demonstrated particular potential. It was able to establish itself rapidly, had a low impact on rice yields if sown late enough, and is able to grow well on poor soils. Several other legume species are also being considered for this purpose.

Oversowing maize

In several areas of Northern Laos, farmers had complained about the burden of weeding maize fields. This is especially true in areas of poor soil where maize growth is slow and the crop cannot outcompete weeds. After the successes of farmers in Makroman village, Indonesia, several legume species, including *Centrosema pubescens, Stylosanthes guianensis* CIAT184 and *Chamaecrista rotundifolia* cv Wynn) were oversown into young maize and evaluated in informal farmer trials.

Conclusions

Farmers in the shifting cultivation areas of Northern Laos are strongly dependent on ruminant livestock for livelihood security. Diminishing feed resources have caused some farmer groups to take steps to manage feed resource, particularly through planting introduced forage species. Others recognise the problems but have not had sufficient access to information or planting materials to help them develop their own forage technologies. Both groups of farmers are prepared to work with development workers to explore ways in which local feeding technologies can be strengthening by introducing new, robust forage species, comparing them to existing species and evaluating new ways of incorporating them into existing farming system. ■

Peach palm (Bactris gassipaes) is a native Bolivian forest species with commercial potential. Here the palm is ready for harvest, with a cover crop (Canavalia ensiformis) sown between the rows.

Sustainable agriculture on the forest margin

Barry Pound, Morag Webb, Adalberto Flores, Benjamin Carreño and Rob Paterson

Slash and burn methods used by colonist farmers in Bolivia are unsustainable and degrade soil, forest and bio-diversity resources. In 1994, the Natural Resources Institute (NRI, UK) and the *Centro de Investigación Agrícola Tropical* (CIAT, Bolivia) tried to identify ways of making the present farming systems more sustainable and productive. Participatory on-farm trials combined with researcher-managed trials, case studies, participatory surveys and rural appraisals were used to validate technical options, including combinations of novel perennial crops, leguminous cover crops, agroforestry mixtures and small livestock. Effective technology options were developed but before resource-poor farmers could use them they needed information and technical support provided. In Bolivia, colonist farmers have very limited financial resources, infrastructure is rudimentary, and social cohesion is poorly. These factors hamper the dissemination and implementation of research results.

General situation

The practice of clearing forestland for agriculture is common in the humid tropics. Shifting cultivation, when practised by indigenous forest dwellers at low population densities can be ecologically sensitive and sustainable. At higher population densities the slash and burn methods used by colonist farmers in Brazil and Bolivia cause extensive degradation of soil, forest and biodiversity resources.

Smallholder colonist farmers in the tropical lowlands of Bolivia are extremely poor and have an immediate need for cash and food. While they often have plenty of land (30-50 ha), they have limited amounts of capital and labour and so use extensive farming methods that are wasteful of natural resources but require low levels of input. Forest biomass is used as fertility capital to produce a small range of subsistence and cash crops for one or two seasons. When accessible forest is exhausted, they cultivate in the bush-fallow (*barbecho*). Each successive cycle of slash and burn weakens the land leading to a "bush-fallow crisis". The farmer is then either forced to find new land, change to farming perennial crops (mostly citrus), or keep cattle on perennial grassland.

Farmers abandon their land when pernicious weeds increase and soil fertility declines (Webb & Gonzales, 1989, Barber & Diaz, 1994). The sandy soils are low in phosphorus and nitrogen is quickly lost through leaching and volatilisation. Nitrogen, sulphur and organic matter are lost through burning, and micro-nutrients soon become limited under acid conditions and low soil organic matter. On sloping lands, soil erosion is also a serious problem.

Slash and burn farm households manage several species of small livestock although productivity varies greatly between farms (Chamón *et al.*, 1999). Women and children are responsible for the chickens and guinea pigs raised for food and for the ducks and pigs sold for cash. Tropical hair sheep are also kept for household use and sale. All livestock, except guinea pigs, are free to scavenge for food and receive minimal supplements of grain, household wastes and crop residues. With no veterinary cost and no input apart from labour, the low level of production is almost entirely profit. Where markets are available, dairying is favoured. Profit margins are modest, but regular income from milk sales is important.

Ichilo-Sara project

The *Ichilo-Sara* project was developed by NRI and CIAT in the tropical eastern lowlands of Bolivia. It addressed three major development issues. First, the destruction of moist tropical forest by agriculture; second, natural resource degradation, and third, the lack of locally verified, sustainable agricultural systems suitable for smallholder farmers working in the forest margins.

An "adaptive research network" was set up with local NGO's to implement and evaluate an on-farm trial programme which would test 200 participatory on-farm experiments involving 30 novel cropping, agroforestry and livestock systems (see Figure 1). These trials were complemented by researcher-managed trials that dealt with problems requiring controlled conditions or used new technologies whose potential in local conditions had yet to be verified.

The project relied heavily on participatory methods. This made it possible to combine researcher, NGO and farmer knowledge and to empower farmers, NGOs and CIAT to carry out the type of research they thought to be relevant. Technologies were validated under farmers' conditions and the participatory approach ensured that information was disseminated during the research process.

Sustainability was a central issue in the *Ichilo-Sara* trials and on-farm and researcher managed experiments were designed with the following needs in mind.

- Reduce burning;
- Increase opportunities for perennial crops;
- Increase the efficiency and productivity of the fallow period;
- Develop technologies with low external input requirements;
- Integrate legume covers and green manure to maintain soil productivity;
- Diversify activities and income generating opportunities;
- Initiate a sustainable research effort based on participatory principles

Results

The project verified the local suitability of perennial species, and identified cropping systems and sequences that were economically viable for colonist farmers. The association of perennial tree crops, including citrus, peach palm, and tamarind with annuals, semi-perennials and legume covers proved that it was possible for small-scale farmers, with limited capital, to diversify into perennial systems. The annuals and semi-perennials offset establishment costs, and provide a source of income in the short and medium term. The legume covers prevent weeds building up and reduce the amount of labour needed for weeding. Trials also showed that the financial burden of establishing perennial systems could be overcome if the cultivated area was gradually increased and farmers used home-produced planting material. Experiments with intercropping and rotating rice with legume, food and cover crops proved that weed build-up and the cost of weed control could be significantly reduced. However, these systems did not halt the yield decline. Farmers also tested two novel agroforestry systems. The first was based on the enrichment of bush fallow with native fruit and timber species, while the second took cleared land through a sequence of annual, semi-perennial, and perennial species to a permanent, tree-rich system. After two years, results indicated that these options - whose components can be modified to suit the circumstances of individual farmers - were appropriate for those households that had a positive attitude towards trees and appreciated the income and environmental benefits they could bring.

Promotion pathways

The *Ichilo-Sara* project was designed to help resource-poor farming families living on the margins of the forest. By collaborating with institutions such as CIAT Bolivia and local NGOs it was hoped that experimental results would be widely disseminated. Results have, in fact, been good. Through collaboration, staff training and specially prepared materials the concepts, methods, systems and technologies investigated during the *Ichilo-Sara* trials have been widely adopted and the project has influenced other Bolivian projects and programmes.

The rate of adoption was monitored after 2-3 years (Warren, 1997), and at the end of the project (Pound et al, 1999). Among those farmers who had worked on the trials, adoption rates were found to be high. Adoption rates by neighbouring farmers who had not taken part in the project, however, were low partly because of a lack of community involvement in the way collaborating farmers were selected (Warren, 1997). When the project ended in 1998, high levels of adoption were still being recorded among collaborating farmers.

In 1996, farmers were tending to adopt single component technologies, rather than the complete systems being tested (Warren, 1997). This was a matter of considerable concern because the development and promotion of "sustainable systems" was a major objective. By 1998, the situation had changed and many farmers were including mixtures in their expansion plots. Cover crops were being integrated into perennial systems and perennials were being intercropped with annuals and semi-perennials. A high level of farmer-experimentation was also recorded. Farmers were modifying the components included in the original systems, and were comparing alternative management strategies.

Analysis

Several lessons can be drawn from the *Ichilo-Sara* trials. First, it takes time to clarify objectives with stakeholders, and to design a methodology that meets these objectives. It is important that all members of the research team - researchers, NGOs and farmers - understand the methodological and technical concepts behind the trials and training should be given if necessary. Experience showed that data collection should be limited to the needs of the project and that participatory research requires the same rigour and discipline as conventional research.

There is a potential contradiction between the collection of on-farm research results and providing farmers with an opportunity to adapt technologies. The *Ichilo-Sara* trials showed clearly that a balance must be found between these contrasting objectives.

The project concluded that the qualitative and quantitative information from participatory research can be successfully integrated but that an early feedback of results to collaborating institutions and communities is important. Projects should also plan a strategy to help farmers at the end of the project so they do not feel "abandoned".

Ensuring impact

Locally, the *Ichilo-Sara* project is regarded as having had an important impact. However, during the final project workshop (Pound *et al*, 1999) it was concluded that identifying potential alternative technologies is just one step towards achieving sustainable and stable systems. A co-ordinated strategy must also be identified and implemented to ensure that these technologies are adopted and utilised. Such a strategy might include the following elements:

- dynamic dissemination systems;
- technical assistance, especially for technologies that require long-term investment (e.g. fruit and agroforestry systems);
- accessible credit for small farmers with limited collateral;
- knowledge on adding value to primary products;
- appropriately structured and resourced community-based institutions;
- marketing information and structures;
- a policy environment conducive to sustainable land use.

The *Ichilo-Sara* project succeeded in using participatory methods to identify and validate sustainable technologies and disseminating them to the farmers in the project. Many of them are now using these ideas in their farming activities. CIAT is complementing "conventional" research methods with participatory methods and NGOs and extension projects in the area are promoting and adapting technologies identified by the project. However, further work is needed before small farmers can be assured of technology, resources and market access. ■

Technical areas addressed by the project
- Weed management
- Soil fertility maintenance
- Improved food security
- Income generation

+

Technical principles
- Improved availability of animal protein
- Development of sequences towards perennial-rich farming systems
- Maintenance of ground cover
- Reduction of burning
- Identification of cash generating opportunities
- Labour reduction
- Intensification of land use
- Diversity and integration of activities
- Simultaneous research and dissemination

Technical options pursued by the project
- Temporal and spatial integration of annual crops, perennial crops, cover crops and livestock
- Weed control using integrated manual, chemical and biological methods
- Agroforestry species for income and fodder
- Crop rotations/relay cropping/intercropping
- Introduction of locally novel perennial crops
- Cut and carry grasses
- Renovation of degraded pasture
- Enrichment of bush fallows with indigenous fruit crops
- Fast-growing forest species for wood, NTFP and fence posts (live or dead)
- Imperata control using cover crops
- Erosion control using live contour barriers and cover crops
- Improved husbandry of livestock

Figure 1. The development of technicaloptions

Marketing of forest and agricultural products from shifting cultivation

Artist: Ariel Lucerna

Madhav Karki, Rana B. Rawal and John Raintree

When shifting cultivation intensifies and the cash needs of producers and collectors increase, more agricultural and Non-Tree Forest Products (NTFPs) will reach local, regional, national and international markets. Some of these products have a high niche market potential because most shifting cultivation areas are rich in biodiversity and can produce high value speciality products. Good examples are red rice from Thailand and the Himalayan Morel Mushroom (*Morchella conica*) from Nepal. There is also a growing national demand for better quality products and, as globalisation intensifies, international traders are seeking new products to satisfy the international market. Marketing is therefore of strategic significance in sustaining shifting cultivation in the uplands of Southeast Asia.

Key characteristics of markets

Experience has shown that potential markets for the products of shifting cultivation have certain characteristics.

- Market demand depends upon the availability of a large range of products of good quality, in adequate amounts that are available at the right time and in convenient places;
- While attractive prices are the strongest incentives for producers, harvesters and processors to produce for the market, competitive pricing is needed to attract consumers to the market;
- Buyers of perishable products and industrial raw materials will invariably try to develop monopolies to avoid paying higher prices to producers, collectors and local traders;
- Sellers are often ignorant of markets, prices, and marketing strategies and do not have the necessary organisations, financial and infrastructure supports to avoid the trap of 'distress' selling;
- Government policies usually favour the traders and existing policies allow outsiders concessions to the forest and impose royalties and collection restrictions which poor collectors are unable to manage. Government officials feel more comfortable dealing with a few large traders than with a large number of small traders trying to market their forest products.

Best practices in market promotion

Certain principles should be followed when promoting the marketing of this type of product. These can be summarised as follows:

- Land and tree tenure rights should be unambiguously handed over to a designated local community with detailed management guidelines. National forest laws should be amended, if necessary, to prohibit proprietary rights, such as resource access and exclusive rights to transport and markets being granted to outside concessionaires;
- Collectors and growers should be provided with credit, storage facilities and transport subsidies;
- Fixing the minimum floor price of major marketable products can provide a strong incentive for collectors and growers because it assures a certain level of income when they sell them. Where 'niche' market products are concerned, however, producers and collectors should be allowed to capture the maximum profits possible because this type of product usually sells at the upper-end of the market;
- Developing markets for raw and finished products can contribute to the over-exploitation of resources, especially NTFPs. Governments should therefore take a strategic approach and maintain the balance between backward and forward linkages;
- Governments should not ban the export of raw materials from areas of shifting cultivation. A good example of the negative consequences of such an approach was the Indonesian government's ban on the export of raw rattan. The ban helped powerful local furniture manufacturers and big traders get greater control over the rattan trade and industry and keep the price of the raw material low. It also seriously set back attempts to mobilise local communities in sustainable forest management because local communities felt they had lost control over NTFP resources.

Market support services

Local communities and local traders find it difficult to get reliable market information. At the local level there is often little understanding of market dynamics and trends and resources and capacities at the local level are often grossly inadequate in this respect. The development of a suitable market support service is therefore essential to the sustainable development of forest communities. The development of marketing infrastructure, including basic communication facilities, simple storage, and primary processing facilities, can help local traders and enterprises to market their products profitably.

Communities of shifting cultivators who sell to the market also need outside support in building up a minimum amount of working capital to cushion them financially against 'distress selling' and to help them establish small and micro enterprises that can provide a guaranteed market for their products. NGOs and donor agencies can play a major role in developing local marketing capacity and facilitating the marketing process in the uplands.

Conclusion and implications

Markets and marketing can provide upland farmers with the chance of earning cash incomes and adding value to their traditional knowledge. However, in the current world of marketing green products, there is not only a lack of transparency, equal opportunity and incentives but powerful local and outside traders have also distorted markets.

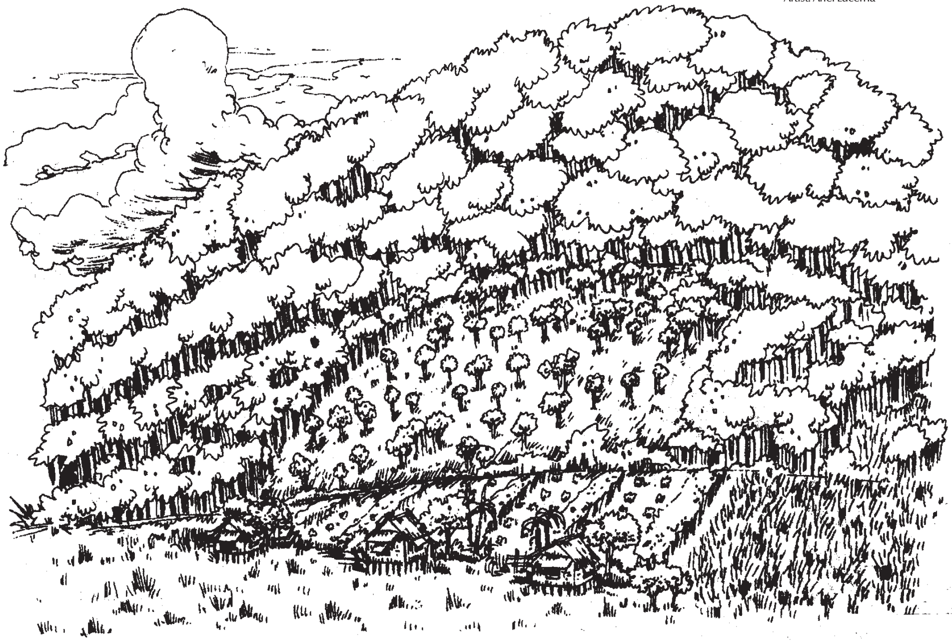
The Ikalahan: towards sustainable forest use

Delbert Rice

Artist: Ariel Lucerna



The Ikalahan (*Kalanguya*) inhabit the upper, forested regions of the Cordillera and Caraballo Mountains of Northern Luzon in the Philippines. Traditionally they are shifting cultivators, primarily focused on the staple food crop *obi* (sweet potato *Ipomoea batatas)*. Recent developments, however, forced them to take action to conserve their natural resource base and think of additional livelihood strategies. By enriching fallow vegetation they have succeeded in halving the traditional fallowing period and using 'Forestry Improvement Technology' they have increased the benefits derived from the forest while improving its biodiversity.

To obtain legal control of their ancestral domain and negotiate effectively with the Philippines government, the Ikalahan set up a legal corporation, the Kalahan Education Foundation (KEF), a procedure that eventually led to the creation of the Kalahan Reserve, in Nueva Vizcaya. An area of 14,730 ha has been set aside for about 2500 tribes people. This heavily forested area lies at an altitude of 600 to 1700m. Rainfall is high with 3000 mm falling annually between June and November.

The Kalahan Education Foundation is managed by a Board of Trustees consisting of 13 tribal leaders chosen by the people themselves. The KEF employs about 40 people, all of whom are Ikalahan, as teachers, processors, foresters and development workers. The Ikalahan have established a Kalahan Food Processing Center, the Kalahan Academy (a High School), the Shalom Bible College and several other community welfare programmes.

Fallowing

Although the soils of the Kalahan Reserve are shallow, they have adequate nutrients. However, when used for crop production, heavy rains tend to leach out the bases more rapidly than they leach out the acids. When this happens, the soil becomes highly acidic and the phosphorous in the soil is bound to aluminium and other metals, making it unavailable to the plants. The production of *obi* tubers is greatly affected by this lack of phosphorous and farmers know exactly when they need to let a field go to fallow.

Artist: Ariel Lucerna

The forest being trucked away by loggers

The traditional way of fallowing was to leave a field alone until grass, shrubs and trees had regenerated. After about 15 years the trees would be as big as a man's leg and the field would be ready for cultivation. First, the farmers would cut down the grass, bushes and trees and after the vegetation had been dried, it would be burned in a controlled way. Great care was taken to ensure the fire would not spread and damage any other standing trees or bushes. The ash produced in this way neutralises the acid in the soil, phosphorous is released from its bound form, and is available to the plants once again.

Shortening of the fallow

Recently the Ikalahan started planting small alder seedlings (*Alnus nepalensis)* in the *obi* fields. By the time these fields are ready for fallowing, the tree seedlings are already waist high. The alder trees enrich the fallow vegetation. In this simple way, the time needed for fallowing is reduced from 15 years to 7, thus doubling the amount of agricultural land available. Because the Ikalahan farmers do not need that much agricultural land, these "extra" pieces are allowed to revert to orchards or forest. Other mountain farmers in the region are now imitating this simple technique.

The *obi* cultivation cycle

Several varieties of *obi* are planted in each field. The different varieties probably have different nutritional requirements. Mixing and rotating them helps to preserve soil productivity. Planting is usually done in May or June. The first weeding is done about two months later.

Once the tubers begin to reach maturity they are harvested when needed. Both tubers and leaves go straight from the field to the kitchen. The Ikalahan never harvest an entire field at once. Defective tubers are not wasted because they are cooked and fed to the pigs, which are invariably a part of each Ikalahan household.

Gengen

After about four months of harvesting, tuber production may start to decline. The woman responsible for the field will choose an area of about 10 m.[2] and remove the entire crop: vines, leaves and tubers. The best vines are separated out and left in a shady place to sprout.
All other vegetation, including weeds, is buried in contour trenches across the slopes at about 8 m. intervals. The area is then replanted.

The hump over the contour line of *in situ* composted material is able to catch any soil eroded during the six weeks the newly planted vines take to mature. When one square is finished, the farmer repeats the process in an adjacent area. This cycle continues until the entire field has been cleared. A field is seldom more than two-thirds of a hectare in size. This system is known locally as *Gengen.* It may be repeated two or more times during the life of the field, depending on the circumstances.

Forest management

Besides providing sites for shifting cultivation, the forests are also a source of materials for domestic use, food and products for sale. As hunters and gatherers, the Ikalahan know that logging is not a sustainable way of extracting forest wood. They have, therefore, developed Forest Improvement Technology (FIT) to help them manage the forest and harvest its products in a sustainable and profitable way.

Community forestry

Community forestry is the best way to implement this technology. The forest farmer will probably know which trees should be removed to improve the forest; but it is still wise to have a forester help him to be sure that his choice will truly benefit the forest and not only his pocket. One forest farmer could not raise enough money to pay a forester's salary. A community, however, could easily afford to have one of its own members trained in forestry to serve the community as a whole.

Community land use plan

Community members can make a "community land use plan" to ensure they are all working together in the same way. *Unib*, a community near Santa Fe made such a plan and decided that each family should have a plot of about 8 ha extending from the river up the mountain slope. The flatter lands along the river would be used for rice and vegetables. The gentle slopes above these areas would be used for swidden farms to provide food for the family. Small orchards could also be developed near the swiddens if the family wanted to supplement its food supply or have fruits for sale. On the higher land, each family would have a family forest where timber and other building materials could be harvested for their own use or sale.

The family forests do not reach the top of the ridge. The *Unib* have set this aside as a sanctuary for wildlife. The wildlife could also use the family forest and they would be protected there as long as the swidden farms remained undamaged.

Finding the proper niches

Once the Ikalahan had established control over their resources in the Kalahan Reserve, they started to take measures to protect them. Over a period of several years many experiments were carried out. Everyone agreed that this was an impor-

Forest Improvement Technology

The goal of FIT is to improve the forest, rather than simply improve the short-term income of the forest farmer. In the long run this will lead to more sustainable increases in income. Trees are cut continuously in small amounts rather than all together every thirty years. In this way the forest ecosystem can be maintained.

Each year the forest farmer makes a selection of trees to be cut. He checks the forest for crooked, damaged or crowded trees that need to be removed to improve the forest. When these have been removed, they are sawn into lumber. It may not be first-class wood but it can be used or sold. Simple equipment is used and the sawdust, tops and branches are left to rot because they restore fertility to the forest soil and help maintain biodiversity. The forest farmer does not separate the potential crop trees from the other trees because he knows that all trees have a role to play in the forest.

In natural forests there is a continuous process of rejuvenation. Trees die or are felled by storms. In this way the canopy is opened and, because the microclimate is not damaged, young seedlings get a chance to develop. FIT follows this natural process. Mature trees that have stopped growing are removed to create favourable conditions for forest rejuvenation. If this is done every year, the forest will continue to develop and improve. The removal of individual trees does not hurt the forest or its environment and provides first class lumber.

If there are large open spaces, a forest pioneer species will be planted first. Agricultural crops are not planted between the trees because they would bother the other plants that need to grow to make a good forest. The population of one or two species of large or small plants can be increased by enrichment planting. This can be very favourable as long as the forest is not turned into a plantation.

As the forest grows, biodiversity will continue to improve and many species of insects, small animals, grasses and other plants will move in. This is good because all of these species help each other and the improved biodiversity will encourage the forest to grow faster and become more healthy. The forest farmer will only cut a small amount of growth allowing the forest to improve each year.

The growth-rate presently expected in Philippine forests is about 4.5 cubic meters per hectare per year. Under proper management, using FIT, the forest can produce as much as 15 - 20 cubic meters per hectare per year. Such an analog forest still retains the characteristics of a natural forest. It is not a plantation. It still has high bio-diversity and is an effective watershed with a high percolation rate. It will also provide a sanctuary for many kinds of wild orchids, animals, birds and insects.

If each forest farmer cares for 5 hectares of good forest, he may harvest up to 80 cubic meters of first class lumber every year without damaging the forest. That would provide him with a higher cash income than many professionals and he would still have plenty of time to produce his own food on the farm. Once the forest has developed, it can be sustained indefinitely.

Artist: Rolly Nicart

Sweet potato vines start to cover the field

tant step in developing new sources of livelihood. In the beginning, people had a vague vision of their goal, but not much idea of how it could be achieved. Now, after more than two decades of struggle, they describe the process quite simply: *Homo sapiens*, like all other species, must find its own sustainable niches in some part of the ecosystem and do this without trying to dominate the entire system.

The Ikalahan have been looking for resources in the forests that can be used benignly and sustainably while encouraging the forest to go on performing its other functions. In this they follow the basic principle of ecological balance and biodiversity. *Homo sapiens* should not limit themselves to a single niche but should try and make use of as many different possibilities as they can. Therefore, beside lumber, they have developed several new niches.

Wild fruit

For ten years the Ikalahan have been harvesting wild fruit from the forests and processing them into jams, jellies and marmalades. Their products are sold under the trade mark "**Mountain Fresh**" in all the better supermarkets in Metro-Manila. Some of the fruits they use, such as guavas and *santol* (*Sandoricum koetjape*), are quite well known to the customers. Others, such as *dagwey* and *dikay*, are completely new and the customers have to develop a taste for them before they start to sell well. This is quite a difficult job.

In some cases farmers were forced to plant more trees or vines in the forest because there was not enough wild fruit. Today, farmers can obtain a significant income from selling fruits to the Kalahan Food Processing Centre and there is no reason why they should cut down wild plants and replace them with field crops.

Orchids

In the Kalahan Reserve there are more than 70 species of wild orchid. In the past Ikalahan would gather wild orchids and sell them to outside buyers. This practise was, of course, unsustainable because orchids in the wild do not multiply rapidly. Now the Ikalahan use their forests as a gene bank. They gather a few orchid plants to serve as mother plants, propagate them, and sell their offspring to local farmers who raise them in "backyard forests". The Reserve also has a few very rare species and the Kalahan Educational Foundation is trying to develop propagation techniques that will enable them to sell these species in the same way.

Mushrooms

Several of the more valuable mushroom types are choosy about where they grow and like the cool moist climate the forest provides. At least one of those species, shiitaki, commands a very high price but it prefers a substrate of either oak or alder. Oak takes a long time to grow, but the Ikalahan have large quantities of alder and this grows very quickly.

Other promising niches

Other promising niches are wild meat, organic vegetables, and ecological jewellery. The Ikalahan are presently working on the technologies needed to electroplate leaves and other natural products with gold and silver to make jewellery. This could be combined with the polishing of some of the more attractive stones to be found in the riverbed.

Value adding for employment

The Ikalahan do not want to sell guavas - they want to sell jams and jellies. They do not want to sell lumber - they want to sell tables, chairs and other finished products. Every community has children. These children grow up and many of them go on to college and develop advanced skills. If the communities sell off all their raw materials to the city, the educated youth will be forced to follow the raw materials and find jobs in the urban areas. Therefore, the Ikalahan decided to develop ways of processing raw materials into finished products themselves. They also founded their own Academy because they did not feel that lowland education suited to the needs of forest people. In this way they created a situation where their children can chose to stay at home, become educated, manage local enterprises and later become the leaders who will take care of the community's future.

The experiences of the Ikalahan show that it is not necessary to eliminate swidden farming from the list of forest niches. However, care, ingenuity and patience is required if it is to remain the basis of a sustainable livelihood.

Community land use planning

Catalysing innovation in culturally conservative communities

John Raintree

"The livelihood of the Tagbanwa is swidden, no other. For a Tagbanwa there is no way to get food except swidden. This is the 'office' of the Tagbanwa. Every year you make swidden until you die. Passed down from generation to generation since the time of our ancestors – swidden, no other".

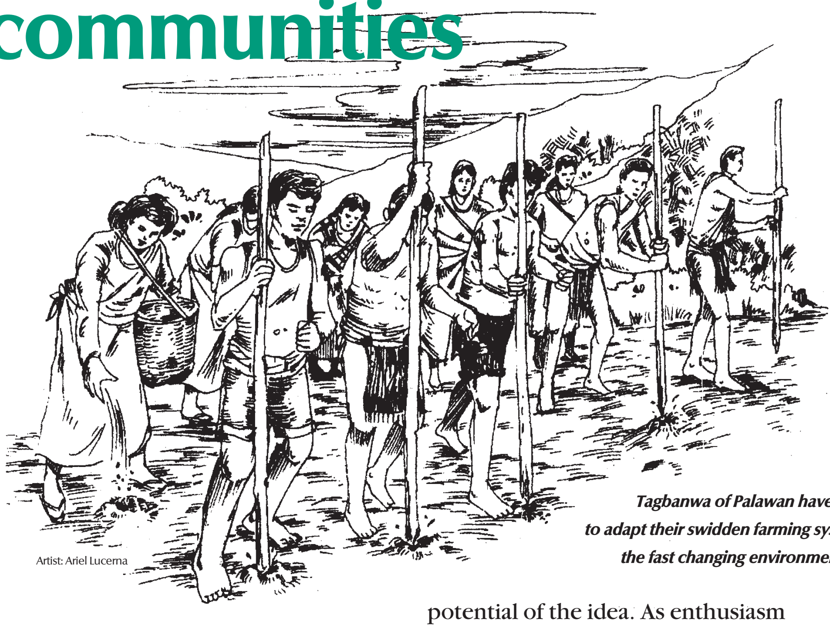
People who work with shifting cultivators are often struck by their dedication to traditional ways. This cultural conservatism often expresses itself as resistance to technological change, even when the old ways of swidden livelihood are no longer sustainable and some kind of adaptive change is necessary. The nature of this resistance must be understood if these communities are to be helped.

Understanding conservatism

Anthropologists see cultural conservatism as a community's way of defending itself against disruptive change. They do this to preserve the core values of their cultural identity and avoid the risks they believe change brings. External factors such as uncertainty about the right to use resources, hostile government policies, feelings of cultural inferiority or military oppression can undermine self-confidence and make people less open to change.

No culture exists in a vacuum and a community's viability depends on its ability to adapt in changing conditions. All viable cultures maintain ways of overcoming their conservatism through appropriate innovation. How these two opposing tendencies are resolved is a fundamental problem intrinsic to the self-regulation of living systems.

Every cultural community has its own particular set of defense mechanisms and external constraints. During my stay with the Tagbanwa, shifting cultivators in a remote area of the Philippines, I observed several mechanisms including low cultural value and lack of incentives for innovation; low self-estimation of ability of individuals to innovate, due to lack of custom; social constraints on the flow of information within the community; traditional technology strongly embedded in spiritual rituals, cultural values and ethnic identity; strong identification with own technology, new technology identified with other ethnic groups and therefore not acceptable; ethnic boundary constraints on access to information outside the community.
There are also important internal constraints on information flow.



Tagbanwa of Palawan have to adapt their swidden farming system to the fast changing environment.

Local knowledge may be difficult to access. People normally don't talk about how to do things, they learn new skills by watching others. Other constraints include functional fixedness: new functions inconceivable until demonstrated; aversion to didactic communication in egalitarian societies ; politeness - people don't normally volunteer unsolicited information and deep technical knowledge may be the preserve of specialists who might keep it secret for prestige or economic reasons. Most perceived strains in swidden life are minor, immediate and social, rather than major, imminent and ecological: discussing major problems is often met with resistance.

Under normal conditions these constraints might not pose problems for cultural viability. But if the whole system is in crisis and under pressure to change in order to avoid the continued degradation of its natural resources, then such defense mechanisms can inhibit innovations that might help the culture survive.

Facilitating innovation

Development catalysts not only facilitate local access to potentially useful information from within and outside a local system, they can also help get information across the barriers presented by automatic defense mechanisms and ensure that the local community is able to assess it in a fair and well-informed way.

The development catalyst must, therefore, tap into the indigenous tradition of shifting cultivation and experimentation. New ideas close to existing practices are introduced to small groups of interested farmers so that connections can be made between old and new ideas. By playing around with the new idea in a model or small-scale experiment a better feeling can be obtained for the real meaning and potential of the idea. As enthusiasm grows, the idea can be discussed and explored further and comparative experiments can be carried out in real life conditions. Each step creates a context for public participation, processing information, and debate. The community uses its own criteria to assess the idea and accommodate it to their own cosmovision. It may even have to modify its perception of how reality functions. The result is a well-thought out community decision in which the idea is adopted, adapted or rejected.

Much of the resistance to adaptive change in conservative communities is semantic in nature. The work of a development catalyst in such circumstances is to find ways to make communities conscious of these structures and encourage enough flexibility to ensure new innovations are evaluated with the insights of local experience and given a fair trial.

Learning to innovate

Overcoming cultural conservatism takes time. This may partially explain why shifting cultivators continue with often contra-productive farming practices. However, once the process of cultural adaptation has gone through the first cycle of innovation, the innovation process may become much easier. The ultimate value of this approach is not what is learned about any specific innovation. It is rather that the community is exposed to the experience of learning how to deal with new information and to innovate within their land use system so they can survive in a rapidly changing world. ■

Farmers in Camamu, Bahia prefer analog agroforestry as it gives higher income and helps sustainably.

Regenerative analog agroforestry in Brazil

Patricia Vaz

In 1985, Ernst Götsch started a cacao plantation in the south of Bahia, Northeast Brazil. The land was in very poor condition. After 40 years of slash and burn agriculture the soil was depleted and the wells had run dry. Five years later the land was covered by a young but productive agroforest and water was flowing again. This was the result of the system of ‘regenerative analog agroforestry’ developed by Götsch and known in Brazil as SAFRA.
The original vegetation in the region was Atlantic rainforest, but now only a few stands remain after years of timber exploitation and slash and burn agriculture. The average rainfall is about 1400 mm with average temperature of 25°C in January and 20°C in July. Soils are poor acidic oxisols and ultisols and classified as being unsuitable for cacao production.

However, as early as 1996, a year in which agricultural productivity in general was low, Ernst Götsch was getting yields of 5000 kg cacao per hectare on parts of his farm, 1400 kg more than average for south Bahia (Penereiro 1999). From the mid-nineties an incurable disease caused by *Crinipellis perniciosa* had been ravaging the cacao plantations in the region, and production had declined dramatically. The disease damaged the cacao trees on neighbouring farms but did not affect Ernst Götsch’s ‘analog agroforestry’ system.

This article will look at the principles and practices behind ‘analog agroforestry’, a remarkable approach that has been used successfully to regenerate abandoned pastures whose soils had become completely degraded. Within a period of 5-8 years they were supporting diverse agroforests and had become highly productive again. These results were achieved without the use of chemical fertilisers, herbicides, pesticides or heavy machinery.

Basic principles

Natural species succession

In essence analog agroforestry attempts to imitate nature. In nature, plant and animal species live in consortiums with other species because they need these species for optimal growth and reproduction. Each consortium creates the conditions for a new consortium with a different composition. Hence, each consortium is determined by the preceding one and will determine the following one. The different consortiums succeed one another in a dynamic, ongoing process called natural species succession.

Species succession is the natural process of quantitative and qualitative accumulation of soil fertility, diversity, complexity, energy and vitality that gradually transforms the colonist consortium into a climax consortium. In nature, pioneer species that are capable of growing in poor soils colonise open spaces. These pioneers, mostly grasses, herbs and shrubs, improve the soil and create the conditions in which secondary herbs, shrubs and tree species can grow. The secondary forests undergo several cycles, during which the life span of the dominant species gradually increases from 3 to 15 to 30 and up to 80 years and their demands on the quality of the environment become more and more specific. The secondary forest species create soil conditions conducive to the growth of primary forest species whose life cycles can be as long as 200 years.

Analog species

Analog agroforestry also identifies natural species, consortiums of species and successions of consortiums. To produce optimal benefits for the farmers, some of the natural species are substituted by more beneficial ‘-analog’ species that occur in similar natural conditions and succession phases. The local natural forest and traditional farming systems are analysed in order to identify situation-specific natural species, consortiums and preferred analog species. The life processes are optimalised to stimulate the greatest possible biodiversity by adapting the vegetation to all micro-environments. This may lead to many different combinations of species. Ernst Götsch, for example, planted pioneer species such as elephant grass, manioc, pineapple and *coarana* to improve the soil and secondary forest trees like Jangada preta, Inga, and many primary fruit-, nut-, and timber species to achieve a prosperous agroforest and secure high, medium, and long-term yields.

It is difficult to design an optimal consortium of plants taking all parameters into account. Help comes from the wild annual and perennial species, often called ‘-weeds’, that establish themselves spontaneously on the plots. These fill in many of the niches that have not been occupied by cultivated plants.

Optimal timing and density for planting is identified so that each species can have optimal conditions to establish itself, grow and contribute to the succession process. It appears that the timing of how plants are introduced into the succession process

Succession of plant consortiums in an analog agroforestry system

is a particularly critical factor in how they establish themselves and develop.

Natural rejuvenation

A degree of stress occurs as different vegetation phases succeed each other. Initially pioneer vegetation dominates because it develops faster than the other species. As the pioneers mature and age, the secondary vegetation is ready to take over but only after the whole system has stagnated for a while. The ageing plants suppress the development of 'young' vegetation. When storms, lightning or floods damage aged or diseased vegetation, the secondary vegetation reacts with accelerated growth and development.

Selective weeding and pruning

In analog agroforestry, the selective weeding, pruning and removal of plants replaces natural rejuvenation. Drastic pruning accelerates the growth of the system as a whole because it increases the amount of light and nutrients available to future generation of plant species. It serves as an instrument to manage species succession by making it possible to influence each plant individually as far as access to light, space and leaf area is concerned. Periodic rejuvenation by pruning, for example, prolongs the lifetime of short-lived pioneer species, and makes them better able to improve the soil. It can also encourage fruit trees to come into flower.

If farmers want to produce annual food crops on a regular basis, it is possible to return to the pioneer succession phase by drastic pruning and (partially) clearing of larger fields when a higher consortium comes to the end of its life cycle.

Soil regeneration

In nature, depleted soils may take many years to regenerate. However, in analog agroforestry the process is much quicker. Critical factors are:
- plant community composition and density;
- order in which species appear;
- timing of when species appear;
- interaction with micro-organisms and wild animals;
- (micro-)climatic factors.

Permanent soil cover

In analog agroforestry leguminous and non-leguminous pioneer species are used to regenerate soils. In addition, the organic material obtained from weeding, pruning and removing plants is used as mulch to protect and fertilise the soil. To enhance soil life and maintain a constant flow of nutrients, rapid and permanent soil cover and regular applications of organic material of different composition and decomposition rates are needed. Under these conditions it is not necessary to plough the soil.

It appears that the critical factors determining growth rates, the health of plants and the productivity of the system, are not the initial fertility of the soil, but rather species composition, planting density, and timing and succession management by selective weeding and pruning.

Analog agroforestry in practice

Preparation

To design an analog agroforestry system farmers analyse the farm system and the wider environment with the help of an experienced technician and then define their needs and objectives. Ideally the system should include species that regularly produce food in the short-, medium- and long-term and others that are capable of rapidly producing soil cover and high amounts of biomass. There should also be species that have multipurpose functions and produce mulch material, firewood, timber, fruits and medicines. Farmers must therefore select a combination of annual and perennial species that can be harvested at different phases of the succession.

Pioneer vegetation has to fit the succession phase of the original vegetation and at the same time species must also be introduced that have a similar function but are adapted to the next succession phase.

Between the species of the first consortium the farmer can introduce other species with longer life cycles and higher demands, although there is the risk that they may be pushed out of the system because they belong to a later phase of succession.

Farmers have different needs and objectives and start work in a wide variety of conditions such as depleted grassland, bush fallow vegetation, mature forest vegetation, fertile alluvial valley soil and eroded upland soil. There are no blueprints for species selection. It is important that the system is seen as a whole; the different phases of the succession process recognised and any gaps that threaten the succession/production cycle are tackled. To do this farmers need considerable knowledge of the species concerned as well as its functions and environmental needs.

Establishment

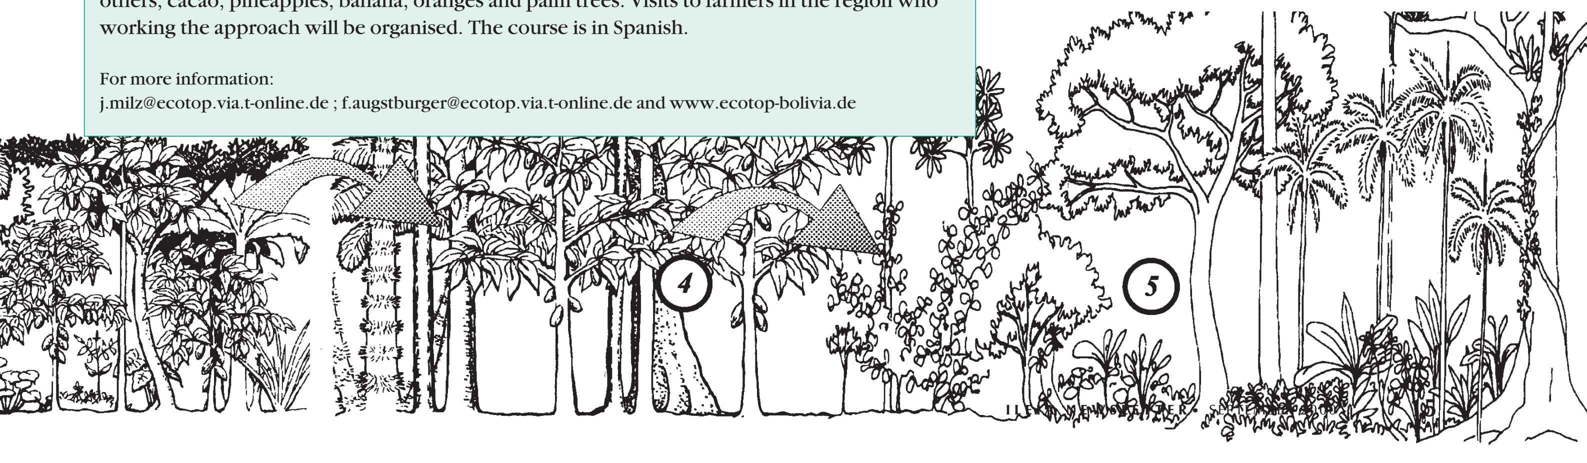
First, existing vegetation has to be synchronised. This means that, in a given field, all ageing plants will either be removed completely or, if they still have vigour, coppiced. Pruning brings the vertical structure of the vegetation into equilibrium. A week is taken to plant or seed the selected species. If more time were taken the system, which has to develop as one organism, would no longer be synchronised. This means that nearly all pioneer, secondary and higher species are planted

Training course on Analog Agroforestry

A training course on Analog Agroforestry (or Succession Farming as it is called by the organisers) in the humid tropics will be organised by Ecotop Consultants in Sapecho, Alto Beni, Bolivia on 15-29 July 2001. This course, meant for agronomists and practitioners, will combine theory and practice. Important topics are:
- The principles of species succession
- Management of agroforestry systems to enhance species succession
- Management of pests, diseases and other system damages
- Design of analog agroforestry systems
- Quality control for organic products certification

Demonstrations and practical exercises will be organised in agroforestry systems with, among others, cacao, pineapples, banana, oranges and palm trees. Visits to farmers in the region who working the approach will be organised. The course is in Spanish.

For more information:
j.milz@ecotop.via.t-online.de ; f.augstburger@ecotop.via.t-online.de and www.ecotop-bolivia.de



at the same time. Because the same planting distances are kept for each species as in monoculture cultivation, the overall plant density will be very high.

High densities and possible competition can easily be kept under control by pruning or by eliminating the plant completely. It is questionable to what extent there is really competition between plants. Experience shows that plants that function in different succession phases do not compete. Also species that grow at varying rates and end up in different layers of the vegetation do not compete, even if they come from the same species consortium and have similar demands.

Management

If there is good species planning, it will be possible to harvest products at each intervention. In this way, for example, it would be possible to harvest radish, then beans and maize, and subsequently animal fodder, pineapple, banana and later timber, resin and other non-timber products.

At the same time, the system is synchronised again by weeding, pruning and eliminating ageing and diseased plants. Older herbaceous plants are weeded, then fodder grasses are cut, and finally trees and shrubs are pruned and felled.

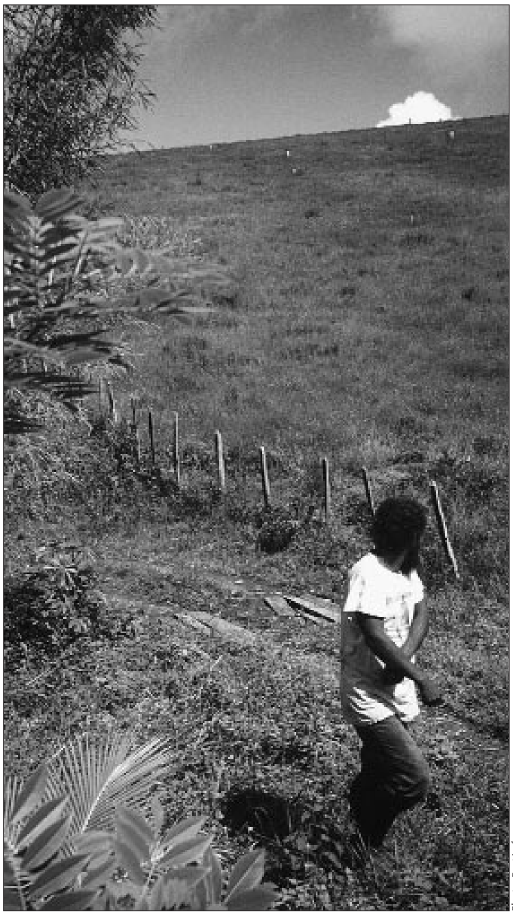


Photo: Bert Lof

Why not change this degraded rangeland into a diverse and productive agroforestry system?

Pruning is an art. Correct pruning requires that the farmer bears in mind particular factors including the characteristics of the plant and the environment in which it grows. There are some basic principles but the uniqueness of each situation has to be taken into account. In general the farmer must take into account:
- the capacity of the species for coppicing;
- its physiological age;
- its place in the succession process and the vertical stratum;
- whether it threatens the development of any higher plant
- any damage being inflicted by predators or parasites

A sustainable system

There are important similarities between indigenous forest farming (see Box p13) and analog agroforestry. Both imitate nature by using analog species and species succession. In traditional shifting cultivation fire is often used for natural rejuvenation. However, where fallow periods are short, natural succession may be halted in the pioneer phase and there will be no increase in soil fertility, diversity or vitality because too much valuable organic matter, plant nutrients and soil and plant life is lost. In modern agriculture chemical fertilisers, herbicides, pesticides and machinery have replaced natural processes. Slash and burn agriculture and modern farming are evolving in ways that lead not only to depleted and degraded soil and loss of species diversity but also to simplified natural environment and decreasing productivity and sustainability. The strength of analog agroforestry and indigenous forest farming is that it is sustainable because it improves agricultural productivity and the environmental health of the production system.

Research results

Penereiro (1999) compared the analog agroforestry system on Götsch's farm with a 12-year-old, natural succession bush fallow. The vegetation in the agroforestry system was more diverse and better balanced and the succession in the system was more advanced. In the analog agroforestry system the topsoil had a high soluble phosphate content. In the top 5 cm layer there was 7 times more phosphate and between 5 and 20 cm there was 4 times as much. At the 40–60 cm level the phosphate content was about the same. These concentrations can be explained by the combined effect of nutrient pumping by deep rooting trees and the effect of soil microorganisms stimulated by pruning and the permanent organic mulch layer.

Spreading the approach

Spreading analog agroforestry concepts requires a different approach to that used when passing on technologies via extension services. The construction and organisation of knowledge plays an important role. Initially, there must be an intensive exchange of knowledge between farmer and technician in order to create a common understanding of how people interact with nature. The older members of rural communities and small-scale traditional farmers know a lot about the species native to their area and are well aware of the interactions that take place between the various plants. Farmers still know how these plants were used for food, medicine and other domestic purposes.

This common understanding can be used to improve the system through continuous farmer experimentation. Several groups in Minas Gerais, Espírito Santo, Paraná (see Petersen et al p17), Rio Grande do Sul, São Paulo and Bolivia are experimenting with anolog forestry. Some farmers will not commit themselves to the whole system and their results are, therefore, limited. Others are wholly committed to the approach and have developed creative solutions that meet local needs and conditions.

Centro Sabiá in Pernambuco, in Northeastern Brazil is one of many organisations working with analog forestry. Here there is farmer to farmer exchange, experimentation and some farmers are being trained on Ernst Götsch's farm. Demonstrations are also held on the farms of particularly successful farmers. Several farmer promoters have been selected from this group and they distribute information on analog agroforestry. These initiatives should be intensified in order to provide an alternative to the present dominant but unsustainable production model.

Analog forestry:
An alternative to 'clear and simplify'

Ranil Senanayake

Modern agricultural and forestry practices have devastated many natural and traditional ecosystems and their diverse flora and fauna, replacing them with monocultures designed for maximum short-term production. The resulting highly simplified ecosystems are unstable and unsustainable and often require considerable external inputs. It is not only the poor who have ravaged local forest ecosystems, modern development agriculture and silviculture are often more destructive than 'slash and burn'.

The NeoSynthesis Research Center in Mirahawatte, Sri Lanka has examined alternatives to modern forestry and has developed a strategy to intensify agriculture in an ecologically sound way. Twenty years of field experimentation has lead to an approach that tries to work according to nature's designs. The system is known as Analog Forestry (Senanayake 1987). The Center's work proves that moving towards ecologically designed tree crops brings back economic and ecological stability.

Forest home gardens

Forest home gardens are a traditional form of cultivation in Sri Lanka and they are also common in other tropical areas. Forest gardens are patches of cultivated land dominated by trees and perennial shrubs and have a forest-like system appearance. The gardens are usually located close to farmers' homes and provide a wide variety of food, fuel, fodder, wood and medicinal crops. They also provide a cool and pleasant living environment. The composition of tree species varies with climate and elevation and is a product of generations of farmer experimentation, cultural and spiritual beliefs, and economic necessity.

Analog forestry in Sri Lanka draws on the strengths of this traditional paradigm. Many forest home gardens mimic the natural species succession found in local forest vegetation. The use of succession stages of natural ecosystems to design a cropping system was first reported by Hart (1980) who saw this as an analog to natural processes. He recognised the fact that a forest progresses from grassland to climax forest over time and that all of the organisms, from grass to tree represent the forest.

Analog forestry design

The trees and plants in an analog forest will be similar to those in native ecosystems. They will provide food or microhabitat for native species, but can also supply human needs. This requires a careful selection of analog species. In designing the analog forestry system it is important to keep in mind that, because of natural species succession, this will be a dynamic system and one that will mature. Therefore, a dynamic approach to management is needed as well as an understanding of how maturity can be used as a performance indicator. It is also important to identify opportunities for microhabitat creation. Protecting 'keystone' species becomes easier if the farmer develops this knowledge. Planning an analog forest is highly situation specific and will often entail different designs reflecting the characteristics of the local ecosystems. As the system matures it will create production opportunities and maximise species diversity.

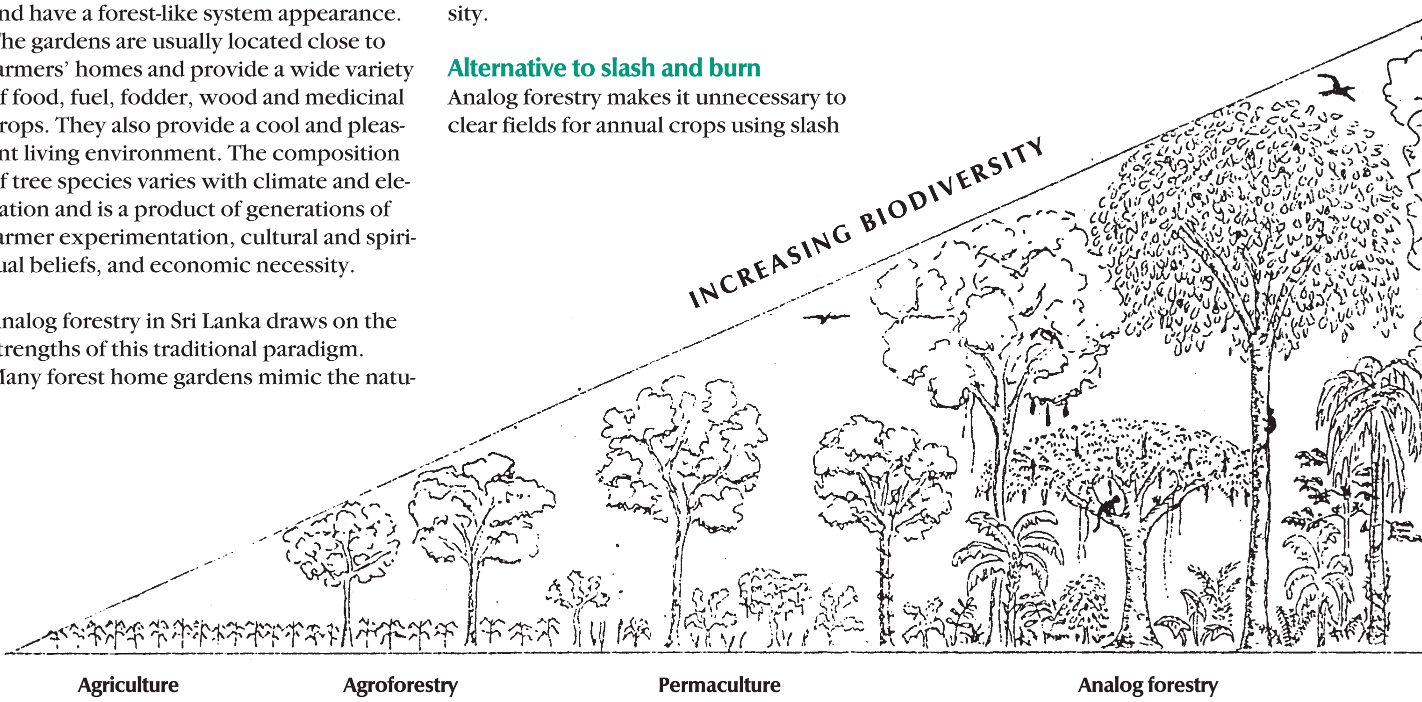
Alternative to slash and burn

Analog forestry makes it unnecessary to clear fields for annual crops using slash and burn techniques. The shade factor provides good conditions for shade loving crops such as cardamom, cloves, nutmeg and pepper which give the farmer more earning potential than annual crops. Once shade cropping has been established, farmers are reluctant to open the canopy because a return to 'slash and burn' will destroy the potential offered by these valuable crops. Increased crop diversity - tree crops included – brings other social and economic benefits, reduce the risk of glut and increase the demand for skilled agricultural labour.

This community of trees promotes environmental stability, conserves biodiversity and facilitates the production of clean water just like a forest. Recognising these functions is an important feature of analog forestry. It has been demonstrated that the environment created by this type of silvicultural system increases biodiversity and ecosystem stability within production systems. In Sri Lanka, records show that many species of flora and fauna have returned to farms with established analog forests.

Biodiversity conservation

While conservation is the ideal way of maintaining original levels of forest biodiversity, resources are too limited to purchase or schedule protected areas.



Establishing protected areas and private reserves is not enough to ensure the sustainability of many native species. In May 2000, a workshop hosted by the Ministry of Forests and a local NGO - Rainforest Rescue – held in Quito, Ecuador made clear that many areas currently described as having 'no forest' on the national forest map, actually contained a very high percentage of forest patches and corridors. In some regions the local NGO reported that forest cover extends over more than 50% of farm area. If the management of forest patches and the extension of corridors are not addressed urgently, the current policy of treating these areas as devoid of forest will become a self-fulfilling prophecy. Analog forestry projects in this region have show how effective reconnecting patches through an 'analog corridor' can be.

In order to re-establish components of natural biodiversity, analog forestry design often goes beyond the farm boundary and farmers are encouraged to think in terms of off-boundary effects, and the continuity of corridors and drainage systems.

Natural forest ecology

Critical elements

Programmes using analog forestry, such as the Forest Garden Programme of Counterpart International identified several factors that were critical in its work in Sri Lanka, Philippines and Mexico.

- A network of local seedling nurseries and community seed banks to provide a diverse range of seed stock and seedlings of plant species to rural farmers wanting to expand subsistence and cash crop tree gardens, wood lots and local tree belts.
- A 'seed and tools fund' to help rural farmers to buy the materials they need to improve their agriculture and land management capacity.
- Technical assistance and training to help farmers design, plant and maintain their analog forests, wood lots and buffer forests.
- Rural education materials adapted for local use and which foster improved farming, farm-based enterprise, community nutrition, family health and the management of the local environment.
- To get better prices extension officers should work together with distributors of niche products to foster national, regional and international markets for the products of 'Forest Gardeners' around the world.
- Certification that guarantees all products have been produced according to organic principles and in systems that benefit rural environments.

Forest Garden Products Certification is a system that sets standards for the certification of crops grown under analog forestry design. This national certification system has been running in Sri Lanka for over twelve years and is presently under international management. There are good markets for forest garden products such as tea, syrup and cashews in Australia and Japan.

The International Network

The International Analog Forestry Network (IAFN) has active members implementing projects in eight countries. Analog forests are being established in Sri Lanka to add value to local products and facilitate landscape management. In Mexico they are seen as an extension of the traditional Mayan land use system. In Colombia analog forests are being used to recover mine tailings left after the destruction caused by gold mining. In Ecuador they have been introduced to stimulate a change in the way cattle-dependent *campesinos* use their land and in Peru they are enhancing the gardens of indigenous peoples in Amazonia. In Canada analog forestry has increased crop diversity and biota in woodland while in Australia it is seen as a component of farm planning. It is clearly a viable approach with a wide applicability.

Box I. The frijolar, an indigenous example of the use of species succession

The frijolar system was developed and is being used by the indigenous descendants of the Mayas, in Central America. It is a system where beans – sometimes together with maize – are cultivated near a huge primary forest tree, *Ceiba pentandra*, which is considered sacred. This tree is 70 m tall and has a crown of about the same diameter. Where this tradition is followed, a plot with a dense stand of fast growing leguminous species will be found under the crown of the *Ceiba* tree, all of them showing signs of heavy pruning. Up to 40% of them can be *Inga sp.* a tree that can grow in stormy places or where flooding is frequent.
The ground layer is formed by herbaceous species, mainly *Piperaceaes*.
In the latter half of the rainy season, when the *Ceiba* tree loses its leaves, beans and maize are broadcast on the plot. At the same time, the herbaceous vegetation is moved and all the twigs of the adult fast-growing leguminous trees are cut off. The organic material obtained is cut into small pieces and distributed evenly over the soil. Beans and maize grow vigorously and cover the thick mulch layer within a few weeks. The trees that have been pruned react with a profuse flush of new twigs and leaves within 5-6 weeks. Weeds are unknown in this system. Two months after seeding, at the beginning of the dry season, the *Ceiba* tree renews its leaves. Three or four weeks later the beans are ready for harvest. Two weeks later the maize begins to ripen. Yields of about 2100 kg of beans and 1430 kg of maize per hectare have been recorded. This is quite good when compared to 800 kg of beans and 1000 kg of maize in slash and burn systems in the same region and on similar sites. In the slash and burn system weeding is done twice and only one crop is possible on the same place every 10 to 12 years.

Research by the International Centre for Research in Agroforestry (ICRAF) in Kerinci, West Sumatra, Indonesia identified a flexible system in which a complementary relationship had developed between indigenous forest management strategies and agriculture. Understanding the dynamics of this relationship at household level provides us with insights into how far such integrated agroforestry systems can be promoted among households in the forest margins to help secure rural livelihoods.

Photo: Paul Burgers

If coffee prices are high, coffee trees will be kept on the field.

Options for sustainable agriculture in the forest margins?

Indigenous strategies

Paul Burgers and Dede William

In most of the humid and tropical parts of Indonesia, farming communities have built strong links with the money economy and urban centres. Investments in agriculture, improved access to education, health, agricultural services and entertainment have meant that farm households need a source of cash income. On-going research into the dynamics of these indigenous systems has shown that villagers have been extremely innovative in the way they have applied indigenous strategies to intensify fallow management to balance immediate subsistence needs with long-term ecological sustainability.

Shifting cultivation in Gunung Raya

Gunung Raya is a sub-district on the edge of the Kerinci Seblat National Park. For decades, households in this part of West Sumatra have grown irrigated rice and relied on the surrounding forest for the products they ate and sold. However, in recent years, population growth, the development of the National Park, and improved access and links to urban areas and services, have changed local needs and aspirations.

Farming households in Gunung Raya have developed a highly efficient and productive multistorey tree-cropping system (agroforest) in mutual relationship with wet rice cultivation. Commercial annual crops are rotated with coffee and cinnamon. A “fallow period”, the period when the cinnamon trees are developing towards maturity, allows soil fertility to regenerate. Because of the similarity between these practices and shifting cultivation and the high percentage of commercial crops, these farming practices are often referred to as “commercial shifting cultivation systems”.

In Kerinci, farming households secure an adequate livelihood by consciously integrating forest management with agriculture to produce a combination of local and exotic crops and tree species. They carefully plan how resources of land, labour, capital and time can be optimally divided between these different crops. This results in several management phases of varying intensity.

High management or annual crop phase

This cycle generally begins with the rejuvenation of coffee either by planting new seedlings or coppicing (resprouting) old coffee stumps. Coppicing leads to an earlier closure of the canopy. At the same time, households cultivate commercial crops such as groundnuts, chili and potatoes. These annuals can be grown for about two years or until the density of the coffee canopy hinders growth. This is the time when farmers plant cinnamon trees in between the coffee.

Medium management or coffee phase

The coffee harvest will continue for 2 to 3 years depending upon whether the cinnamon trees have been coppiced or new seedlings are planted. Once the cinnamon canopy has closed, coffee will be unable to produce berries although the bushes themselves will not die. During the cinnamon harvest the farmer can either cut down the whole cinnamon tree or can harvest a number of branches to meet the families immediate cash needs. The farm household will usually decide to cut down the coffee bushes before the cinnamon harvest. If the household expects high coffee prices they may choose to keep the mature coffee trees in the field. After the cinnamon has been felled coffee will produce again a year later. Annual crops can be planted in the open spaces between the coffee trees until the canopy closes again. In this way the farmer can go on maintaining his coffee trees for many years or he can allow the cinnamon to take over. These differences in tree management are the result of a complex decision-making process, in which households try to balance the benefits of annual crops, coffee and cinnamon.

Low management phase or fallow phase

The closure of the cinnamon canopy marks the beginning of a “fallow-phase”. The invasive fallow species *Austroeupatorium* is allowed to establish itself under the coffee and cinnamon. The farmers use this species to increase soil fertility so they can grow annual crops without having to use fertilizers. Some households actively spread the seeds to ensure thick growth.
The length of the fallow period varies considerably. Cinnamon bark is harvested when the household needs large sums of money such as to meet the cost of a wedding or to pay hospital bills. Trees are usually harvested within 6 to 12 years.

Integration with the rice crop

Households in the research area have not only been innovative in choosing perennial species to suit the available resources. They have also capitalised on the fact that they can chose between a short-term high yielding rice variety and a longer-term indigenous variety. This gives a certain degree of flexibility when deciding how resources should be allocated between the management of the rice crop and the agroforest. Chosing to cultivate the high-yielding rice variety means that the farm family is fully engaged in the rice field for four months till the rice can finally be harvested. This is affordable when the agroforest has entered the medium or low management phase and does not need much attention. During the high management phase when the management of the agroforest needs full attention, households often decide to grow the indigenous variety that matures in 9 months. Labour requirements for this variety are more or less evenly spread throughout the growing season.
If the work load becomes a problem, tasks are divided and the women usually continue to work in the rice field while the men concentrate on the agroforest.

Lessons learned from the villagers

This highly complex and precise planning developed by villagers gives us an insight into how more sustainable, integrated farming systems can be developed. Understanding the household economy within a socio-economic, political and environmental context helps us understand the opportunities and limitations confronting farming households when they must decide between developing such integrated systems or focus on food cropping alone. The following key issues have to be considered.

Indigenous strategies

The success of multi-phase agroforestry depends on how it fits into local biophysical and multi-level socio-economic conditions. What is the balance between short-term livelihood security and long-term sustainability and how flexible is the system when local production conditions change. The dynamics of indigenous strategies give us vital information about whether or not sustainable solutions are being developed in changing contexts and the process this involves. Many farmers explained their objectives and management strategies for indigenous agroforestry systems to us. From their experiences we concluded that any development of such systems was dependent on certain opportunities and constraints.

Satisfaction of needs

Households often focus on the satisfaction of needs rather than profit from the crop they chose because of distortions in the wider economy. Households may reject technically feasible, yield increasing, highly profitable innovations because they involve greater specialization, and raise costs and risks. In Kerinci, during the monetary crisis in Indonesia, the price of cinnamon bark rose sharply. Households were expected to cut down large amounts of cinnamon and earn a huge profit. However, there was no large-scale harvesting, on the contrary, farmers argued they now needed to cut only a few cinnamon trees to satisfy their needs.

Flexibility

Usually, indigenous strategies are of a resilient nature. This enables adaptation to change, through a flexible use of resources, land, labour and time. Besides resource use, other components in the total farming system (like coffee and cinnamon in the above system) can be flexibly managed and harvested. These flexible components seem to be crucial for the establishment of multi-phase agroforests, in particular in areas where agroforests add to labour pressure within the total farming system.

Low-input versus high input

Indigenous strategies have evolved with low cost and in most cases with little or no expensive outside technologies or capital. Crops which require relatively high inputs nevertheless may be a viable option if initial investments are quickly repaid. A mixture of higher input short-term output crops with longer-term low input crops may combine well. They can also make multi-phase agroforests a profitable and sustainable option for livelihood security when population pressure intensifies.

Harvest security

Closely related to land availability is the tenure system, which legitimises access to land. Depending on the local situation, land security may or may not be a prerequisite for long-term investment options. The research showed that harvest security of tree crops is a crucial factor for planting trees. Rich households often use sharecroppers to establish the agroforest for them. The arrangements normally last for only one cycle, but since sharecroppers are sure of the harvest, they are willing to set up an agroforest. In fact, these arrangements are quite common in Southeast Asia and have often contributed to the establishment of reconstructed forests.

Box 1: An agroforest is like a championship team in soccer

The preconditions for establishing an agroforest with good prospects of economic, social and ecological sustainability were described by one of the farmers in Kerinci, Mr. Rustam. He compares his agroforest with an "unbeatable" soccer-team.

"A good soccer team has pillars that can be relied on," he says. "They keep our interest in the team. First, we have our attackers, who regularly try to "score goals", and keep our attention. These are our annual crops - groundnuts, chili, and potatoes. We plant them when we begin developing our agroforest and they provide us with an immediate and regular source of income: they score goals for us at regular intervals.
But we must also have a reliable defense for when the "game" starts getting difficult. This is coffee. Although we cannot harvest coffee so often it usually gives us a higher income. There are times though when this defense is not enough and then we have to rely on our goalkeeper: the cinnamon tree. From cinnamon bark we can be sure of a flexible income. If we need small amounts of cash we harvest a few trees or branches. If our needs are greater we will cut down all trees at once."

Lower investment costs

Systems, which include perennials that can be coppiced after "harvesting", result in a decrease in burning of fields. In Kerinci, only small patches of collected biomass are burned, as burning the whole field will destroy the ability of trees to coppice. Coppicing trees save the cost the labour needed for controlled burning and makes these systems more profitable.

Supportive policies

Enabling and guiding such management flexibility by farmers themselves is a challenge for policy makers and scientists who must learn how farming communities are trying to cope and adapt to outside pressures in a sustainable way.

Buhid shifting cultivators adapt land use

Chris Erni

Photo: Chris Erni

Shifting cultivation is still the main source of livelihood for most upland communities in Southeast Asia. Annual cropping is inter-linked with other complementary livelihood activities like animal husbandry, hunting, fishing, gathering, crafts and wage labour. These indigenous communities have co-existed with their natural environment for centuries, each transforming the other in a dynamic process of change.

Over the last 30 years, the Buhid of South central Mindoro in the Philippines have adapted their shifting cultivation practices considerably. In the upper Fay valley, which is several hours walk from the nearest road, this has led to more intensive and careful land-use practices. These have made it possible to sustain the livelihoods of a growing population on their old ancestral lands. This article looks at the process of land use intensification among the Buhid.

Scarcity of swidden

Traditionally, the Buhid have been highly mobile and a family's response to scarce resources was to move elsewhere. With rich resources, a rather opportunistic shifting cultivation strategy prevailed. Forest and other resources appeared unlimited; only a few permanent crops were planted and little attention was given to preventing invasions of *imperata* grasses and outbreaks of fire in fallow and grassland.

As options to move elsewhere became fewer and fewer some communities developed other responses. The process of adaptation was hastened by an increasing scarcity of swidden land caused by a rapid rise in population. Families evicted by cattle rangers had migrated into the area and laid claim to Buhid ancestral land. There was also some natural population growth. Slash and burn practices had led to large areas of former forest being converted into unproductive grasslands; shortened fallow periods and badly managed fallow land further worsened the situation. While the initial expansion of grasslands created more favorable conditions for some animals, like the deer traditionally hunted by the Buhid, it also attracted the interests of cattle rangers who, until the late 1980s, controlled large areas of Buhid land.

> The Buhid refer to a newly cut and burned field as a *námay*. It remains a *námay* until the cereal crop, rice or maize, is harvested. Although they have more specific terms for the subsequent stages, fields are generally classified as *talun*. This includes fields that are dominated by a crop such as sweet potato (which may be called *talun kamotehan* – from *kamote* for sweet potato), for example, right through each subsequent stage of fallow vegetation to mature secondary forest.

Intensification of land use

A few families were able to create paddy fields but, for most, intensifying land use meant more intensive forms of shifting cultivation. Conscious fallow management has been adopted in which the growth of woody vegetation was encouraged and efforts were made to stop the spread of fire to fallow land.

Furthermore, a more intensive cropping pattern was practiced. The cropping period was extended, new crops introduced and agroforests started to contribute significantly to both food self-sufficiency and cash income.

Three factors contributed significantly to these changes:

- The climatic conditions in the central and eastern uplands with almost year-round precipitation allowing almost continuous root-crop production;
- Flexibility regarding crop preferences. With the absence of a culturally prescribed rice-preference, crops better suited to prevailing conditions could be introduced. The bulk of calorie intake comes from root crops and plantains. Rice for ritual and social purposes is purchased from other farmers with more suitable soils or from the lowland markets.
- Access to new crops and a keen interest in experimenting with them.

The differences between the extensive and intensive forms of swidden farming that has evolved during the last three decades can be summarized as follows:

Fallow management

Fallow is an intrinsic part of shifting cultivation. But for many decades, outside observers, even trained agronomists, have misunderstood its function and value. Fallow land was often seen as "abandoned land". The cultural bias of foreigners or "lowland people" obscured the fact that its function could be compared to a clover crop on a former maize field.

Fallow has the following important effects:

- Eradicates weeds;
- Restores soil fertility and brings back soil-life;
- Provides forage land for livestock;
- Is a source of domesticated, semi-domesticated or wild food plants, and of protein from large or small wild animals;
- Is a source of herbal medicine, raw material for all kinds of domestic tools, crafts and other products of potential commercial value.

Since Buhid shifting cultivators usually create one or more new fields every year, a household usually possesses a number of fallow fields of different ages and at different stages in the natural succession of the forest community. Thus, the diversity of available useful resources is very high, probably even higher than in an undisturbed forest. This has a lot do to with the fact that the fallow vegetation is being "managed". A fallow field is anything but "abandoned". In addition, most shifting cultivators in Southeast Asia have relatively poor upland soils and cannot draw on the type of nutrient stocks available to farmers working on relatively rich alluvial lowland soils. They are therefore strongly dependent on the ecological processes involved in the species succession of fallow vegetation. Good fallow management, therefore, is vital to them.

Management of species succession

The Buhid consciously influence the pattern of species succession in fallow vegetation. In the second or third year of a new swidden cycle plantains, Tania (Cocoyam, *Xanthosoma sp.*), and fruit trees (mainly Jackfruit) are planted. The shady and moist environment that is created in this way helps the preferred fallow plant community, vines, herbs, shrubs and trees to germinate and establish themselves. In this way the fallow is enriched with domesticated plants, its productivity is extended and invasion by *imperata* grasses is halted. Tania, fruit trees, plantains and bananas continue to be productive although this will decline as nutrients decrease.

In the early growth stage, when the field is weeded regularly, species succession is managed quite intensively. As the vegetation becomes more mature, the degree of management is reduced until finally human intervention may be confined to an occasional clearing of competing vegetation to enhance the growth of a fruit tree, or to maintain a banana or plantain patch.

The enrichment of fallow vegetation and intensive management motivate farmers to protect their valuable fallow from fire.

Crucial crops

Crucial for the more intensive planting of perennials was the introduction of a very productive and at the same time hardier variety of plantain, called *sab-a*. This variety can tolerate the presence and shadow of trees and is therefore very suitable for enrichment planting in fields that are left fallow.

Tania was planted for the first time about 30 years ago and spread rapidly among the communities living in the higher and moister parts of Fay creek. Tania is a perennial plant and produces starchy tubers that have become an important part of local diet. It tolerates semi-shadow and is therefore often planted in the forest alongside creeks. But it is mainly planted in swidden fields during the later stages of cropping and is sometimes combined with plantains and fruit trees.

Agroforests

More recently, some Buhid farmers have transformed their swidden fields into agro- or analog forest. This is a form of *talun* that results from progressive species succession management on a swidden field. Eventually the original natural forest is entirely replaced by a man-made forest. Such a *talun* provides food (Tania bulbs, plantains, fruits) but also the much cherished betel nut, coffee and other cash crops such as cacao and bamboo.

Since the Buhid diet is heavily dependent on highly productive root crops and plantains and since some fields have been transformed into agroforests, smaller amounts of land have to be slashed annually for new fields. Today, the Buhid in the Fay valley usually cut only two small fields that measure about 0.3 ha per household.

Land tenure

The development of improved fallow management and the establishment of permanent agroforests was accompanied by changing land rights. Over time, there has been a move from weakly defined communal land rights that approximated an open access regime to individual rights. Intensive fallow management will only work if others can be prevented from using the land while it lies fallow. The increased investment involved in planting perennials was both a reason and a means for transforming traditional land rights. According to traditional law, individuals do not own land: they own the plants on the land. Planting perennials was, and still is used as a way of establishing indirect control over land since swiddening a piece of land with young perennials requires the permission of the owner.

The concept of individual land holdings eventually prevailed. In the early 1990s, there was considerable competition between new and traditional concepts of land rights and there were many disputes. In most areas, individual land rights over swidden land are now fairly well established and is the result of a process that has taken place within the context of indigenous law over the last 30 years.

Outsiders are contesting land resources in the Buhid ancestral domain. The Buhid have managed to retain or regain large parts of the land that had fallen under the control of pasture leaseholders. Some areas in the plains and foothills, however, have been lost to settlers. Since June 1998, the Buhid have a Certificate of Ancestral Domain Claim (CADC) for the entire 94,000 ha ancestral area and have applied to have it turned into a Certificate of Ancestral Domain title. Unfortunately, this has not yet been granted and as long as access to natural resources remains uncertain, it is very difficult to further intensify land use.

■

	Extensive form	Intensive form
Cropping pattern and sequence	1) Maize or rice 2) Sweet potatoes, some vegetables and other root crops 3) Fallow	1) Maize or rice 2) Sweet potatoes, vegetables and other root crops 3) Colocasia, plantain, banana or fruit trees 4) Fallow or transformation of fallow into agroforest
Perennials	Some bananas, plantains and fruit trees are planted in settlements	Some fallow fields are transformed into agroforest plots, with a mixture of perennials, amongst others coffee for cash
Subsidiary activities	Hunting, fishing and gathering of wild plants are important	Hunting less important; fishing and gathering of wild plants important
Animal husbandry	Extensive pig and chicken husbandry	Extensive pig and chicken husbandry

The evidence collected by the Indigenous Fallow Management (IFM) Network (see p.5) and the Consortium for Tropical Soil Cover and Organic Resources Exchange (TropSCORE) (see Box 2 on p.6) makes clear that it is time to change our scientific understanding of soil fertility management in the humid tropics.

Conventional scientific thinking is that if farmers apply enough chemical fertiliser and the soil has sufficient capacity to bank accessible nutrients, their land will be fertile and productive. In practice, these fertilisers are often not very effective and between 40 and 70% of the nitrogen applied is lost to the environment (FAO, 1990). On sloping and acid soils worked by shifting cultivators, these losses are probably even higher and make chemical fertilisers uneconomical.

Artist: Rey Cuevas

Nutrient banks or nutrient access

Rolando Bunch

Building up a large stock of nutrients in the soil is often of little value in the tropics. Rather, what is important and often done by farmers, is to maintain a constant, well-balanced supply of a minimum amount of nutrients and ensure that crop roots have unobstructed access to them. This will ensure that even if farmers have very poor soils and the flow of nutrients at any moment is very low (this can be even less than 20% of recommended fertiliser rates), they can still produce good yields.

Farmers' strategies to enhance soil productivity can be described as follows:

- ***Maximum organic matter production***. Frequently farmers can increase the amount of organic matter they produce in their fields while maintaining or even improving their yields. There may be a slight increase in cost but not necessarily. In fact many gm/cc and agroforestry systems increase over-all organic matter production while reducing the amount of labour required for controlling weeds.
- ***Use of natural processes*** like nutrient mobilisation and accumulation, N-fixation, nutrient cycling and species succession. These processes make nature (e.g. soil micro-organisms, plant roots, predator insects, and micro-climate creators) work for farmers and provide free inputs.
- ***Soil cover***. Soil exposed to the tropical sun produces more weeds. These reduce yield and increase the farmers' workload. Unprotected soil also becomes very hot making it difficult for soil life and plant roots to function well. Mulching and shade can provide soil cover.
- ***Zero tillage***. If there is little organic matter, zero tillage systems rapidly become unproductive. But if there is plenty of organic matter, these systems can remain productive for decades saving farmers both expense and work. By using zero tillage instead of ploughing, soil structure and soil life can be maintained and enhanced. The use of herbicides in zero tillage systems should be avoided as it affects soil life. If a sufficient layer of mulch is provided herbicides are unnecessary.
- ***Maximum biodiversity*** is important because it helps reduce the number of diseases and insects attacking crops and will, over the years, help maintain a good balance of available nutrients.
- ***Multifunctionality***. If farm organisms used for the above practices combine different functions, for example, soil productivity management with soil and water conservation and production for home consumption and market, the system will become more resilient and farmers will accept these organisms more easily.
- ***Fertilisation through the litter layer***. If farmers apply enough organic matter and use zero tillage, they will have a litter layer in their fields similar to that found in a forest. This layer will supply nutrients to the crops. In very acidic soils that have too much aluminium and very hard layers, the litter layer is particularly important. Roots have a hard time growing in these soils and therefore it is better for the plants to get their nutrients from the litter. Crop plants, like forest trees, can form a very closely woven root mat just under the litter layer to access nutrients and humidity. If phosphate fertiliser is required, it can be applied most effectively to the litter layer. If further intensification is needed than can be obtained through ecological strategies alone, organic or small amounts of appropriate chemical fertiliser can be applied through the litter layer.

The documented experiences of shifting cultivators and other smallholder farmers in the humid tropics suggest that if their colleagues were to follow their example and adopt the nutrient access approach, their situation would be far less hopeless.

Innovation in shifting cultivation in Asia:
Indigenous Fallow Management

Dennis P. Garrity and Chun K. Lai

In Asia and other tropical regions shifting cultivation, characterised by the sequential rotation of forest vegetation and cultivated food crops, was the first form of agroforestry to be widely practised. Shifting cultivators normally use slash-and-burn methods to clear primary or secondary forest to prepare the land for food crops. They alternate fallow periods of either natural fallow vegetation or 'managed' fallow with food crop cultivation in order to suppress weeds and restore soil fertility. Staples such as maize, rice, cassava, and taro are typical of crops grown in this way in upland Asia. In the past, a relatively low population density and abundant forest cover provided optimal conditions for sustainable shifting cultivation practices in which long fallow periods of between 10 and 50 years were not uncommon.

Diversity and change

Shifting cultivation continues to be the economic mainstay of upland communities in many parts of the Asian-Pacific region. It has been estimated that 15% of the region's population, or some 450 million people, depend on the forests for their livelihood. Among these are forest-dwellers whose lives depend on a combination of shifting cultivation and hunting and gathering and those who live outside the forests but rely on them for food, domestic resources and trade goods. Today, the conditions that sustained rotations with long fallow periods have almost disappeared and it has become necessary for many communities to evolve more intensive forms of land use. Population growth and the immigration of 'colonist farmers' have led to a decline in the amount of farmland available. Forests are under increasing pressure from logging, mining, plantation companies and the activities of slash and burn immigrant farmers. The creation of protected areas and parks with their resettlement programmes have added to the pressure on land. At the same time government policies are actively encouraging sedentarised agriculture and discouraging the use of fallow and fire.

Examples of successful, top-down technical approaches to stabilising and improving the productivity of shifting cultivation systems are difficult to find. However, there are many compelling examples of shifting cultivators who are successfully managing local resources to intensify land use. It is therefore important to understand the forces behind change in the Asian uplands and how these should be handled. Among the factors that have had the deepest impact on shifting cultivation are: evolving legislation and policies on land use and rights, particularly those that affect ethnic groups practising shifting cultivation in mountainous and forest areas; trends toward decentralisation of governance and the empowerment of local organisations; the push toward market- and export-oriented commodity production; the effects of globalisation, trans-boundary trade and new information channels; population, migration and employment patterns; trade-offs, tensions and conflicts between upland and lowland watershed users.

Shifting cultivation sustainable?

The annual cycle of slash and burn that characterises land preparation in shifting cultivation systems has often been criticised for being inefficient and causing tropical deforestation. Governments generally consider shifting cultivation to be 'unsustainable' and 'primitive'. To them it is a system that should be 'sedentarised' and 'modernised.' However, most of the policies, strategies and programmes that government agencies have designed for the Asian uplands have been based on lowlander perspectives and solutions.

Detailed anthropological studies, starting with the work of Harold Conklin in the Philippines, provide us with a more positive assessment of shifting cultivation. They present evidence of a rational farming system that has evolved to meet the constraints and opportunities inherent in remote upland areas and, by stressing its long history, give us evidence of its sustainability.

Box 1. Spectrum of fallow management strategies used by shifting cultivators in Southeast Asia

- **Burning** of vegetation for easy clearing and nutrient activation. Also used to rejuvenate rangeland vegetation.
- **Slash and mulch** of fallow vegetation as an alternative to slash and burn to start a new production cycle. (for example, see p36).
- **Green manure / cover crops** for inter- and relay cropping and seasonal fallows in annual systems to improve soil productivity: viney and non-viney legumes, compositae and others (see Box 2).
- **Improved fallows:**
  - **Accelerated fallows**: natural fallow vegetation improved with (N-fixing and non-N-fixing) trees, shrubs, legumes, and others to improve soil productivity.
  - **Enriched fallows**: natural fallow vegetation improved with trees and shrubs of economic value.
- **Interplanted fallow**. N-fixing and non-N-fixing trees or shrubs for soil productivity improvement inter-planted in annual or perennial crops, for example, dispersed trees, alley's, bushes, field borders in 'cut and mulch' or 'cut and carry' regime (with Alder trees, for example, see p.20).
- **Intercropping economic trees** (timber and non-timber) with annual crops or shrubs for cash, shade or increased soil productivity, for example, taungya and other systems.
- **Analog (agro)forestry**, consciously making use of the ecological processes involved in natural forest regeneration such as natural species succession and natural rejuvenation: annual crops, economic shrubs and trees, introduced pioneer (fallow) vegetation (N-fixing and non-N-fixing) and natural fallow and forest vegetation (for example, see p.14).
- **Managed and enriched fodder fallow** to intensify livestock production: trees, shrubs, legumes and grasses. (for example, see p.26 and p.10 for further examples).

(Adapted from the **Spectrum of indigenous approaches to modify fallow vegetation in Southeast Asia**, ICRAF, IFM Programme. This spectrum provides a schematic overview of many examples of IFM strategies, names of species as well as how these strategies are being used.
Source and further information: Indigenous Fallow Management Network ICRAF-Southeast Asia

These studies argued that shifting cultivation is a land-use practice that is based on indigenous knowledge accumulated through centuries of trial and error. In maintaining the intricate balance between product harvest and ecological resilience, the shifting cultivator often succeeds in maintaining an impressive degree of agrodiversity. It is far from being a practice that involves destroying the forest.

Work by the Alternatives to Slash-and-Burn Consortium (ASB) has shown that a remarkably wide-range of smallholder land use options is agronomically sustainable. However, whether or not these options remain sustainable in the present, rapidly changing economic context or are suitable for other farmer communities has yet to be seen. It is clear that the simple dichotomy sustainable/unsustainable is too crude.

Recent studies have identified the custodial role played by shifting cultivators in preserving forest ecosystems and natural species and the close link between biological and cultural diversity. It is unlikely that these two extreme views on shifting cultivation will be reconciled in the near future. It is therefore essential to reframe the debate and move forward to identify research and development interventions that do not only stabilise forest agroecosystems threatened by degradation but that can also improve the standard of living of marginalised, shifting cultivator communities.

Indigenous pathways

A major challenge is to document and evaluate indigenous strategies for intensifying shifting cultivation through research and development. This process involves identifying promising indigenous practices and understanding them in the context in which they are used. Their utility must be validated and the possibility of employing them in other areas must be explored with the farmers concerned.

Strategies used by farmers to intensify their system of land use centre on strengthening the different functions of fallow:

The ecological function – improving the regeneration of soil productivity and the ecological control of pests and diseases, e.g. by introducing leguminous trees, shrubs, or herbaceous vegetation that improve soil productivity and enhance biodiversity. This ensures that the same or greater production benefits are secured in less time.

The economic function – improving direct economic benefits by adding value to the fallow by introducing valuable perennial species of timber, fruit, and fodder trees.

Combinations of the two – both ecological and direct economic benefits can be obtained, e.g. by introducing trees for wood fuel, improving soil productivity, and introducing legumes for green manure and fodder. Effective strategies usually combine the economic and the ecological function.

These strategies may lead to different systems:

- Annual cropping systems in which the ecological function of fallow vegetation is emphasised;
- Agrosilvipastoral systems where livestock is significant;
- Agroforestry systems which alternate annual cropping with annual and perennial fallow and economic shrubs or trees;
- (Agro-) forest systems in which the phase of clearing of forest vegetation and cultivation of annual crops is foregone altogether, as the farmer chooses to focus on producing valuable perennial vegetation, allowing it to develop into permanent (agro-)forests.

It is important to understand the many farmer-generated solutions that have successfully allowed shifting cultivation to be intensified in the face of growing pressure on land use. Unfortunately, these indigenous innovations are little documented, generally unobserved and often misinterpreted.

The IFM workshop in Bogor

Case studies of these practices were collected for discussion in a regional workshop on Indigenous Fallow Management (IFM) organised by ICRAF in Bogor, Indonesia in June 1997. Proceedings from this workshop - **Voices from the Forest** (Cairns, in preparation) - contain a large and fairly comprehensive review of many of these systems. A CD Rom version of the proceedings is expected to be available at the end of 2000.

An overview of IFM strategies was prepared for the workshop on the basis of these cases. An adapted version is presented in Box 1. Follow-up work will explore the value of this indigenous knowledge for researchers and policy makers. This will contribute to strengthening the argument for empowering local communities and enabling them to manage their own natural resources.

Building on the momentum of the workshop, a regional IFM Network was formed as a forum for collaboration and sharing experiences.

Box 2. Green manure/cover crop systems are surprisingly common and varied

Green manure (gm) and cover crop (cc) systems are now widely used throughout the world. We listed more than 140 different documented gm/cc systems involving 41 different gm/cc species being used by farmers in 23 nations in the tropics. But farmers around the world, shifting cultivators included, use many more systems. For instance, in the very small state of Santa Catharina alone, over 125,000 Brazilian farmers use some 60 different species of gm/cc with dozens of different cash crops. Yet only 11 systems from Brazil are mentioned in our list.

Among the listed systems, more than 60% have been developed by farmers themselves. This gives us a clear impression of how appropriate these systems are for rural households and how interested farmers have become in finding, adopting, and adapting gm/cc's to improve their farming systems.

Gm/cc's are extremely multi-purpose. They are cultivated to enhance soil productivity, provide human food, animal feed, cash income and firewood and are used to help control erosion, regenerate waste lands, conserve water, combat plant disease and control pests.

The most common species used world-wide are:
Scarlet runner beans (*Phaseolus coccineus*). A legume grown by hundreds of thousands of farmers in the highlands of Latin American. They are usually intercropped with maize and the beans are harvested and eaten.
Pigeon peas (*Cajanus cajan*), common beans (*Phaseolus vulgares*), soybeans (*Glycine max*) and oats (*Avena spp.*) are more widely grown than any other gm/cc species.
Velvet beans (*Mucuna spp.*), undoubtedly the most widely grown gm/cc species introduced by development programmes. In Central America, Brazil, and West Africa, this species has been very successful. In many countries in Southeast Asia it is a traditional crop. Here the most common gm/cc's are probably from the family *Vignas*, which includes **mung beans** or **green beans** (*V. radiata*), **cowpeas** (*V. unguiculata*) and **rice beans** (*V. umbellata*). These species are all tasty, easy to grow, and drought resistant.
Jack beans (*Canavalia ensiformis*) is probably the second most widely introduced gm/cc species. They are very useful because most varieties are not such aggressive climbers as the velvet bean. Jack beans are capable of surviving and growing well in very poor conditions. Often, shifting cultivators plant it (or **Tephrosia candida**) in fields soon to be fallowed and after two years the soil is ready for rice cultivation. Furthermore, since jack beans are capable of fixing up to 240 kg/ha of Nitrogen, do not climb and can withstand heavy pruning, they can be intercropped quite easily with many different crops, such as maize, cassava, sorghum, tomatoes, and chili.

After: Bunch R, (2000). **A proven technology for intensifying shifting agriculture: green manure / cover crop experience around the world**. IIRR Resource Book (see p.30)

Intensification of shifting cultivation

Editorial

Shifting cultivation unsustainable?

Shifting cultivation using 'slash and burn' practices is often seen as unproductive and outmoded, destroying forest resources, and causing air pollution, soil erosion and floods. It is clear, forests are being destroyed at a terrifying rate. But are swidden farmers really responsible? What about logging and mining companies, large-scale plantations and ranches (p5) and the destructive impacts of ploughing and monoculture (p.12)?

Indigenous people have practised shifting cultivation or swidden agriculture, as it is also called, for centuries. There is considerable evidence showing extensive nomadic and even more intensive settled shifting cultivation can be sustainable and enhance bio- and agrodiversity. Indigenous people have rich reservoirs of site- and culture-specific knowledge and they use it to maintain a balance between cultivation and their forest's ecosystem.

Generalisation not possible

But, shifting cultivators with site-specific and ecology-sensitive knowledge are often heavily outnumbered by colonist farmers bringing different farming traditions and values. Population growth, land competition, the creation of plantations and nature reserves, and hostile government policies make it difficult to maintain long fallow periods and shifting cultivators are forced into more settled forms of agriculture. Many are unable to intensify land use in an ecologically sound way and adopt destructive practices to produce cash crops. Others decide to leave shifting cultivation and go outside the forest in search of work (Godbole & Sarnaik p.29). It is impossible to generalise about the sustainability or the unsustainability of shifting cultivation and situation specific approaches are needed to enhance the sustainable use of forests and forest margins.

Indigenous fallow management

Considerable energy has been invested in trying to intensify shifting cultivation. But as Garrity and Lai of ICRAF (p.5) complain, there are few examples of successful top-down technical approaches to stabilise and improve the productivity of shifting cultivation systems. However, compelling examples have been documented of shifting cultivators successfully managing local resources to intensify land use. Scientists have ignored the way shifting cultivators manage fallow land. Fallows were often seen as unproductive or unused areas and there was little understanding of their importance in the regeneration and intensification of shifting cultivation. In this issue (see p8, p10, p20 and p36), convincing examples of indigenous intensification using improved fallow management are discussed. In these examples, 'slash and burn' is little used in opening up new fields.

The Indigenous Fallow Management Network (p.5), initiated by ICRAF-Southeast Asia, has documented and analysed many cases and scientists are embarking on similar studies in other parts of the world. The international Consortium for Tropical Soil Cover and Organic Resources Exchange (TropSCORE) (p.6; 32) has identified many successful cases of ecological intensification. Bunch (p.7) concludes that it is high time the scientific approach to soil fertility management in the humid tropics will be revised. Experiences with analog agroforestry (p.14) support his opinion.

Analog agroforestry

Effective approaches to forest farming are being developed in many parts of the world on the basis of indigenous fallow management and the natural processes found in forest ecosystems. (see pps.12, 14, 17, 20). These experiences with 'analog (agro)forestry' demonstrate the potential of ecological soil and vegetation management to regenerate forests and increase their productivity in a sustainable way. Participatory methodologies (p.17& 24) are needed to develop site specific ways of applying these ecological approaches particularly in drier areas.

Livestock can play an important role in shifting cultivation. Improved fallow management can also be effective in intensifying livestock production in shifting cultivation as we see from the Laos example (p.26). These approaches to intensify land use probably only work in situations where ecological regeneration and intensification are absolute necessities and where they can provide attractive alternatives in terms of labour productivity and costs (White p.29). Today, rising fossil energy prices create economic and political conditions that make such ecological alternatives more attractive.

Value adding and marketing

Adding value to and marketing timber and non-timber forest products such as wild fruits, orchids, mushrooms (p.20) and herbal medicines (p.17) are ways in which shifting cultivators can earn money, especially if sustainable production can be guaranteed (p.12). But conditions for marketing forest products are often unfavourable (p23) and considerable policy reform and support from development organisations is often necessary. Market information, communication facilities, storage, processing, credit and training in the skills of managing small and micro enterprises are particularly important here.

Political and cultural processes

However, intensification means more than ecological vegetation, soil management and improving market opportunities. Poorly defined land use rights (p.8), lack of political recognition for the rights, skills, and knowledge of indigenous people as well as a lack of self-confidence and cultural conservatism are all serious constraints. Rice (p.20) describes the self-confident and independent approach of the Ikalahan in the Philippines to sustainable land use and cultural self-expression. Also Erni (p.8) and Scheewe (p.29) report on the pride of indigenous people who have succeeded in intensifying shifting cultivation in a sustainable way using their own indigenous knowledge, values and skills. Modern education and urban migration erode indigenous cultures and knowledge. Therefore, the Ikalahan founded their own academy and started processing and marketing their forest products. They wanted to make it possible for their children to stay in their own villages and culture if they choose. Raintree (p.19) reports on the difficult process of helping culturally conservative communities to innovate and renew their culture and shifting cultivation.

But it is not only shifting cultivators who have to make a mental shift. If the sustainable use of forest land is to develop further, researchers, policy makers, colonist farmers and consumers will also have to change their approach.

The editors have taken every care to ensure that the contents of this Newsletter are as accurate as possible. The authors have ultimate responsibility, however, for the content of individual articles.

The editors encourage readers to photocopy and circulate Newsletter articles. Please acknowledge the ILEIA Newsletter and send us a copy of your publication.

FUNDING
The ILEIA programme is funded by Sida, NOVIB and ICCO.

Dear Readers

In this issue, indigenous shifting cultivators and ecological farmers from South & Southeast Asia and Latin America challenge readers to revise their concepts on 'Farming in the Forest'. We did not receive articles from Africa but, probably, similar experiences can be found there as well. The sections 'Sources' and 'Networks' may provide some entry points for further information and discussion.

*This issue has not been produced in the same way as your usual LEISA Newsletter. The articles from Southeast Asia are the harvest of a writers workshop set up to produce a resource book on **'Best practices in shifting cultivation for sustainability and resources conservation in Asia'** that was held in the Philippines from 14–28 August this year. The workshop was a collaborative effort of the International Institute of Rural Reconstruction (IIRR), International Fund for Agricultural Development (IFAD), International Centre for Research in Agroforestry (ICRAF), International Development Research Centre (IDRC) and the Cornell International Institute for Food, Agriculture and Development (CIIFAD). Some 30 participants from China, Honduras, India, Indonesia, Laos, Philippines, Nepal, Solomon Islands, Thailand, United States and Vietnam took part. Together they shared 65 papers on many aspects of shifting cultivation and went on to discuss, improve and revise them in direct interaction with editors, desktop publishers and artists. Many of the drawings that accompany the articles in this issue of the Newsletter were originally made for the resource book which will be published by IIRR in December 2000. Details on how to order can be found on p.30.*

We are glad to be able to tell you that after a productive period of transition we are nearly back to full strength. Anita Ingevall, our new ILEIA Director started work in September. In the next issue we will introduce you to our new team!

The editorial team

Buhid shifting cultivators adapt land use

Chris Erni

Photo: Chris Erni

Over the last 30 years, the Buhid of South Central Mindoro in the Philippines have considerably adapted their shifting cultivation practices. This has led to more intensive and careful land use practices making it possible to sustain the livelihoods of a growing population on their ancestral lands.

ILEIA is the Centre for Research and Information on Low-External-Input and Sustainable Agriculture. It seeks to exchange information on LEISA by publishing a quarterly newsletter, bibliographies, and books. ILEIADOC, the data base of ILEIA's documentation centre, is available on diskette and on ILEIA's Homepage: http://www.oneworld.org/ileia. Back issues of the ILEIA Newsletter are also available on ILEIA's website.

LEISA is about Low-External-Input and Sustainable Agriculture. It is about the technical and social options open to farmers who seek to improve productivity and income in an ecologically sound way. LEISA is about the optimal use of local resources and natural processes and, if necessary, the safe and efficient use of external inputs. It is about the empowerment of male and female farmers and the communities who seek to build their future on the bases of their own knowledge, skills, values, culture and institutions. LEISA is also about participatory methodologies to strengthen the capacity of farmers and other actors, to improve agriculture and adapt it to changing needs and conditions. LEISA seeks to combine indigenous and scientific knowledge and to influence policy formulation to create a conducive environment for its further development. LEISA is a concept, an approach and a political message.

Regenerative analog agroforestry in Brazil

Patricia Vaz

Analog agroforestry is an approach to sustainable 'farming in the forest' which builds on the principles of indigenous fallow management and natural species succession. It is being developed by different organisations in the humid tropics, among others in Sri Lanka (p.12) and Brazil. Remarkable results were obtained by Ernst Götsch, who started with analog agro-forestry in Brazil. Starting from completely degraded soils, above average yields of cacao were obtained and biodiversity increased remarkably within 5-8 years. Patricia Vaz explains the principles and practices of this approach which is now being used by a rapidly growing group of farmers (p.17).

The role of livestock and forage management

Phengsavanh, Phimphachanhvongsod and Horne

In Laos, shifting cultivators have become increasingly reliant on livestock for their cash income. Scarcity of fodder has raised their interest in collaborative efforts to improve fallow management by introducing forages such as grasses and leguminous fodder and tree species. The autors report on the experiences of the Forages for Smallholders Project.

26

Indigenous Fallow Management

Dennis P. Garrity and Chun K. Lai

Examples of successful, top-down technical approaches for stabilising and improving the productivity of shifting cultivation systems are difficult to find. However, there are many compelling examples of shifting cultivators who are successfully managing local resources to intensify land use. The Indigenous Fallow Management Network, initiated by ICRAF-SE Asia, has documented and analysed many such cases.

How communities assess local innovators

Yohannes GebreMichael

As part of my doctoral research I studied indigenous soil and water conservation (SWC) practices in Northern Shoa and Southern Wello in Ethiopia. The study covered six rural communities with either high or low levels of government extension support in SWC. A total of 371 household heads (including 10% women) were asked to name at least three local farmers who were innovative in SWC and to explain why they had chosen them. In the survey, an "innovation" was defined as something new, started within the farmer's lifetime - either a completely different way of doing something or a modification of an existing technique. A farmer innovator is not necessarily a "model" farmer. He or she creates or tries new ideas without these having been recommended by extension.

Top innovation

More than 70% of those interviewed thought that, nowadays, every farmer was an innovator, in the sense of trying out something new. When a farmer innovates, the basic idea may no longer be new to the community, but it is new to that farmer, who experiments with it to adapt it to the specific conditions of his or her farm. Less than 5% of the interviewees could not identify any innovative farmers in their community.
In each community, 5-10 outstanding innovators were named. Most were mentioned by several farmers in the same locality. The interviewees said these farmers were chosen because they had:

- few gullies in their plots
- well arranged and integrated physical and biological SWC techniques
- good-quality SWC work, requiring little maintenance
- safe drainage of excess water so that it did not damage neighbouring plots
- a healthy crop stand.

More innovators were identified in the areas with low compared to high extension inputs. This was probably because the government campaigns introduced standardised SWC techniques and did not encourage adaptation to different conditions.

Characteristics of innovators

Most innovators were elderly (over 50 years). Some middle-aged innovators were ex-soldiers who had been resettled in the area. Their exposure to other parts of Ethiopia possibly gave them ideas to try out in their new surroundings. The level of formal education was not correlated with the degree of innovativeness. Family size was also not decisive. Many innovators were single or had only small families. They did their SWC in a way that did not demand a lot of labour at once. They spread it over several months or years. The farmer innovators were ranked locally as "rich" (46%), "medium" (33%) and "poor" (21%) on the bases of their livestock and land holdings. Some farmers explained that the rich can innovate more because:

- they have their own draught oxen and can release family labour for SWC work;
- they can use manure from their stock, adding to the positive effect of the SWC work;
- they are usually elders, more experienced in experimentation and better able to assess the potentials and limitations of SWC techniques;
- they have many plots with different agro-ecological conditions, demanding different innovations.

All interviewees agreed on two basic features of innovators: they work hard at farming as a full-time job, and they have an ethic of devotion to the land.
Many of the innovators' plots were located on steep slopes, at run-on sites, in depressions and near big gullies, i.e. at critical sites where physical SWC structures are indispensable. Land security had little influence on the propensity to innovate. At such sites, short-term survival would be impossible without good land care because the seed would be washed away. It was in the farmers' immediate interest to minimise erosion in the current year, no matter whether the land would be theirs in future years.

Innovators and community values

Farmers who had innovated in ways that could harm the community were not socially recognised. For example:

- In one village, the community criticised some young farmers who planted marginal hillside plots with eucalyptus trees. From past experience, the farmers feared that re-afforested land would be re-claimed by the government.
- In another area, a middle-aged farmer had increased his yields by using fertiliser and imported seed but was criticised through the *Edir* (a traditional institution) because other farmers did not want his success story to be used as a reason to force them to buy inputs at high interest rates - a current government policy.

Only about 4% of those interviewed said they did not know of any innovative farmer in their community.

Photo: Martin Moll

It can thus be seen that farmers were assessing local initiatives according to their value to the community. Research and development agents often assess innovations according to the yield increase they bring to individuals. It was obvious from this study, however, that community members have other criteria.

The challenge ahead will be to bring researchers, development agents and women innovators together to explore new ways

Women challenge cultural norms

Mamusha Lemma, Fetien Abay and Ann Waters-Bayer

Tensue Gebre-Medhin is a 30-year-old woman who farms at an altitude of some 1500 m in Central Tigray, Ethiopia. Annual rainfall is about 650 mm and falls mainly between May and August. She has 5 dependants and about 1 ha of land on which she grows sorghum, teff, maize and barley.

Ploughing with two oxen is a centuries-old tradition in Ethiopia, but has always been the domain of men. In 1981 the agricultural section of the TPLF (Tigray People's Liberation Front) trained Tensue in oxen ploughing. While her husband was still alive, she did not have the chance to apply what she had learned. After his death she had only one ox and followed the tradition of sharecropping with a man who also owned an ox. This meant she had to give half her harvest to the man. Moreover, for every two days the man ploughed his land, he ploughed only one day on hers.

A donkey-ox draught team

Tensue therefore decided to plough by herself. Her father was not happy to see her do this, because it was against the local culture. Nevertheless, he complied with her request to lend her a donkey to pair with her ox. In addition to breaking the taboo against women ploughing, Tensue thus introduced the idea of a donkey-ox draught team. This was a new system in the area, but she saw certain advantages. Oxen cost at least three times more than donkeys to buy. Donkeys are easier to manage and can live on poorer-quality feed. A donkey can be used as a pack animal to generate income by carrying goods to different markets for petty trading.

In her innovation, Tensue encountered some technical problems but found her own solutions. A donkey has no hump and is smaller than an ox. To keep the yoke in balance and to fix it securely, she put a pile of old rugs over the donkey's neck. The rugs also prevent the donkey being injured by the rubbing yoke. Another problem was that the two species do not understand the same commands. She therefore had to use different words when speaking to the donkey and the ox.

Growing acceptance

When Tensue started ploughing, many people laughed at her and some cursed her, calling her an evil wisher. Because the practice had not come from the ancestors, many villagers criticised Tensue. However, the local development agent defended and encouraged her. Confident in the value of her innovation, Tensue continued practising it, despite what others said. Last year, some women asked Tensue to train them to plough. She has even been asked to plough the land of families whose men have gone to war. The community is starting to accept her as a farmer and innovator in her own right.

Potential for poorer households

Women's innovations often indicate how local resources can be used more intensively, especially by poorer households. In addition to spreading women's innovations and encouraging others to innovate, researchers and DAs could help women improve and spread their innovations. In Tensue's case, researchers could help develop appropriate implements and equipment for donkey traction. DAs could stimulate community discussion about the pros and cons of ploughing with a pair of donkeys, a mixed donkey-ox team or a pair of oxen.

The challenge ahead will be to bring researchers, DAs and women innovators together to explore further the avenues that women are already opening up for the development of smallholder farming in marginal areas.

Themes for the ILEIA Newsletter

December 2000 Vol.16-4
Ecologisation of monoculture

How can monocropping systems and monolivestock systems be made more sustainable? Can they be transformed into integrated systems? How can the quality of the production chain be improved? Articles are invited on interesting examples of: ecological intensification and diversification of mono-cropping; integrated soil fertility management; ecological pest management; product development, adding value to and marketing new products.

Deadline for contributions 15 September 2000.

March 2001 Vol.17-1
Resilience of agriculture

How do farmers prevent disaster and react to the catastrophies of drought, flood, armed conflict, disease and economic crisis? How do farmers deal with variability and risk? How can the resilience of farming and rural livelihoods be improved? What impact does labour migration have on farming systems and gender roles? How can women best adapt farming in areas of labour migration and still optimise benefits and ecological sustainability? How can gender roles be renegotiated? How can women farmers best be reached and supported? How can farming by refugees be supported?

Deadline for contributions 1 December 2000.

You are invited to contribute to these issues with articles (about 1800 words + 2 illustrations), suggest possible authors, and send us information about interesting issues, publications, training courses, meetings and websites.

EL BOLETIN DE ILEIA

It is surprising what human links can be established when the results of Participatory Technological Development (PTD) experiences are made known. Recently, for example, ***El Boletin de ILEIA*** received several letters from readers in reaction to "Finding Common Ground"
(***El Boletin de ILEIA* Vol 15-1/2**) which reported the results of the ILEIA Research programme. *Shipita* was the subject that generated the most interest. Having read about the way the value and use of s*hipita* has been rediscovered in the Central Andes of Peru readers wanted to contact the researchers who had documented and systematised the related PTD experiences. As editor of *El Boletin* I was happy I could help them get in touch with each other. We have also had letters from readers in Costa Rica, Cuba and Nicaragua who were stimulated to write about their own research experiences.
During the LEISA International Editorial Committee meeting (Bangalore, March 2000) plans were made for ***El Boletin de ILEIA,*** **LEISA India** and the **LEISA Newsletter** (from 1September 2000 LEISA International) for the coming year. It was decided that ***EL Boletin*** should have more secretarial support. This means that we can now devote more time to building up a LEISA readers' network in Latin America. So keep sending us your information, enquiries, comments, requests, opinions, complaints and, of course, congratulations!! But don't forget we need your articles, book reviews, news (for our networking page) and other contributions as well. Each issue of ***El Boletin*** is the product of a participatory
process and reader's opinions play an important role in the decisions we take. ■

Teresa Gianella, PO Box: 18-0745, Lima 18, Peru,
E mail: estrems@amauta.rcp.net.pe

Editors appologise for the fact that in two recent ILEIA Newsletters the names of the authors of the following articles were unfortunately omitted. **Vol 15.1/2:** ILEIA Collaborative Research Programme (p.4 - 8); Stakeholder Concerted Action for LEISA (p. 77-80); Stakeholder Assessment of LEISA alternatives (p. 81-83) were written by Peter Laban, Bert Lof and Coen Reijntjes. In **Vol 15.3/4**: Recent initiatives (p.42-43); CGIAR: Towards gender sensitive research (p. 46) were written by Wietse Bruinsma. In **Vol 15 1-2** photos on pages 27, 28 and 29 were provided by Kalikasan; page 72, 76 and 81 photos by AME; page 79 photo by Markus Staub.

Photo: Coen Reijntjes

Farmers present their innovations to fellow farmers and researchers at the Farmer Innovators Workshop held in Doddaballpur, India, March 2000.

LEISA INDIA

In March 2000 the Editors of the **LEISA Newsletter, LEISA India** and ***El Boletin de ILEIA*** met in Bangalore, India. AME (Agriculture Man and Ecology), the organisation responsible for the production of **LEISA India**, subsequently arranged a field trip that included participation in a farmer innovators meeting. Faced with declining yields and environmental and health problems, innovative farmers had started to develop their own ways of ecological farming inspired by traditional knowledge and the creativity of nature. Some of these farmer innovators are true philosophers and through the attention paid to them by the press, radio and television they have become role models for many others.

AME has identified many such farmers in the Southern Indian states of Tamil Nadu, Karnataka and Anadhra Pradesh and has been working with them for the last fifteen years. This latest workshop was held on the farm of a legendary farmer Narayana Reddy of Doddaballapur near Bangalore city. Twenty innovative farmers from the three states gathered to share their experiences and develop strategies that would encourage innovation. Farmer innovations presented included ecological friendly landscaping, soil conservation, water harvesting, crop rotation, pest, disease and weed management and animal husbandry.

Mr. Tangaswamy, for example, specialises in agroforestry. He grows 60 varieties of fruit trees on his 10-acre farm and plants black gram, finger millet, sebania and paddy. He experiments continuously with new species of trees, crop rotation and weed management and each season brings new discoveries.

Mr. Ganapathi gradually has reduced the use of chemicals on his farm to zero and has developed his own natural ways of fighting pests and diseases in crops, animals and fish. He has increased productivity, profitability and the quality of the food produced on his farm.

Farmers attending the workshop suggested developing a network of innovative farmers in each state. This network would stress active participation of women and young people, facilitate exchange between members and train farmers interested in ecological practices.
The farmer innovators felt there was a need to document and codify innovative practices and make them more accessible to farmers. Publishing this information in **LEISA India**, local farming magazines and

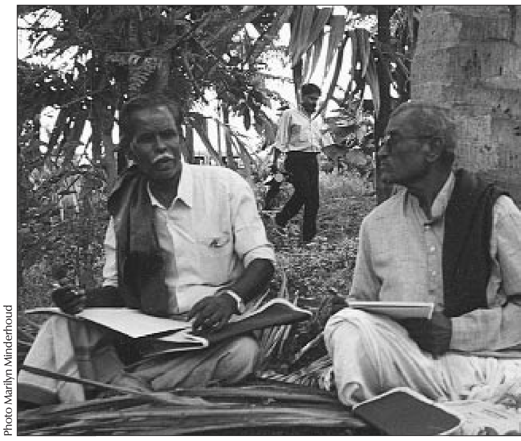

Photo Marilyn Minderhoud

Exchanging experiences during the Farmer Innovator Workshop organized by AME and held in Doddaballpur, India, March 2000.

translating them into local languages would make this possible. Farmers felt that organisations such as AME and ILEIA should pass on the LEISA perspective to educational institutes as well. ■

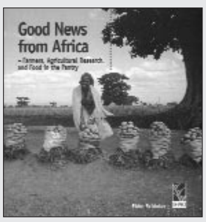
NEW IN PRINT

Participatory extension : insights from three agricultural development projects in Africa *by Schmidt P, Etienne C, Huerlimann M. 1998. 120 p. ISBN 3 908001 77 3 : SFR 25.00. Swiss Center for Agricultural Extension (LBL), CH-8315 Lindau, Switzerland.*
From an analysis of 3 agricultural development projects in Africa, this study tries to identify the main principles of effective participatory extension, as well as practical methods that can be used to implement this approach. Going beyond the field implementation, the study also addresses the wider institutional context.

Innocent farmers? *by Put M. 1998. 427 p. ISBN 90 5538 028 8 : USD 28.50. Thesis/Thela Publishers, Prinseneiland 305, 1013 LP Amsterdam, The Netherlands.*
A comparative evaluation of the "Transfer-of-Technology" and "Farmer First" extension approach as followed in the Maheswaram watershed project implemented by the Andhra Pradesh (India) government and a watershed project implemented by AWARE, a NGO in the same state.

The new middlewomen : profitable banking through on-lending groups *by Harper M. [et al.]. 1998. 124 p. ISBN 1 85339 431 9 : GBP 12.95. Intermediate Technology Publications (ITP), 103-105 Southampton Row, London WC1B 4HH, UK.*
The book describes how banks, alone or in collaboration with NGOs, can organise groups of people into 'micro-banks' that can act as independent banking intermediaries. This is a unique approach to the delivery of financial services to poor people.

Good news from Africa : farmers, agricultural research, and food in the pantry *by Schioler E. 1998. 72 p. ISBN 0 89629 700 4. International Food Policy Research Institute (IFPRI), 2033 K Street, N.W., Washington, D.C. 20006, USA.*



This booklet describes how agricultural research is achieving valuable results by propagating new varieties of grain that have led to greater yields on African farms.

Avoiding the shortcut : moving beyond the use of direct incentives. A review of experience with the use of incentives in projects for sustainable soil management *by Giger M. 1999. 61 p. ISBN 3 906151 32 8. Centre for Development and Environment (CDE), Inst. of Geography, Univ. of Berne, Hallerstrasse 12, 3012 Berne, Switzerland. (Development and Environment reports ; 17). Spanish and French editions are planned.*
A comprehensive contribution to the debate about the use of direct incentives. It reveals that most development projects still make employ direct incentives, even though they produce disappointing results. The objective of this study is to help change this situation.

Good practices in drylands management *by Oygard R, Vedeld T, Aune J. 1999. 116 p. Noragric Agricultural University of Norway, PO Box 5001, N-1432 As, Norway. World Bank, 1818 H-Street, N.W., Washington D.C. 20433, USA.*
The booklet looks at "good practices" in the management of rangelands and dryland farming, pastoral development, community-based natural resources management, and drought preparedness. It points to many possibilities for increasing the productivity of drylands while reducing ecological degradation.

Combatting desertification : conservation and development of dryland resources. *FAO 1998. CD-ROM. ISBN 92 5 004217 5 : USD 50.00. Secretariat of the Interdepartemental Working Group on Desertification, Sustainable Development Department, Food and Agriculture Organisation (FAO), Via delle Terme di Caracalla, 00100 Rome, Italy.*
This CD-ROM is the second edition of the Multimedia collection on desertification, which is to be issued regularly and updated on the occasion of future conferences organised by the parties to the Convention to Combat Desertification. It provides a complete and comprehensive collection of materials offering bibliographies, field photos, videos and an extensive selection of FAO full text publications relating to the sustainable development of human and physical resources in drylands. It can be used on both Windows 95/98/NT and Macintosh.

Trading places, trading ideas: "Dare to share fair" on participatory development approaches *by Posthumus B. 2000. 26p. "Dare to share" Fair committee, c/o ETC Ecoculture, PO Box 64, 3830 AB Leusden, The Netherlands (Postage and handling charged)*
In October 1999 a "Dare to share fair" was organised in the building of the Netherlands Ministry for Development Cooperation. Over 40 organisations, mainly from the South, participated and presented and shared their experiences. This report gives an impression of what transpired during these two days.

Forage husbandry *by Bayer W, Waters-Bayer A. 1998. 198 p. ISBN 0 333 66856 1. (The tropical agriculturalist / Coste R (ed.)). Technical Centre for Agriculture and Rural Cooperation (CTA), PO Box 380, 6700 AJ Wageningen, The Netherlands. Also available in French, ISBN 3-8236-1309-X.*

This interesting book gives an overview of different aspects of forage and livestock husbandary with particular emphasis on pastoralists and smallholder farmers. Included are basic aspects of the farming systems, basic biology of livestock and forage resources, management of natural forage, forage as auxiliary product from cultivated land, cultivated forages, and forage conservation and supplementation. The information explains the way pastoralists and smallholder farmers organise their lives, using livestock as part of their risk reducing and diversification strategies, combining livestock with crops and other - often non-farming - activities. In this sense not only technical and socio-economic aspects are taken into account, but also gender and other characteristics of the cultural dimension of livestock keeping. The last chapter gives an overview of the research and development approaches related to livestock keeping and forage production. This methodological guide includes a combination of traditional practices with outside ideas and technologies, according to the specific characteristics and needs of the farmers. The suggestions for participatory approaches combined with the clear language, practical explanation of technical aspects, and the examples from all over the world make this book a valuable asset for anyone working with livestock and resource poor farmers throughout the world.

Research partnerships: Issues and lessons from collaborations of NGOs and agricultural research institutions. *IIRR, 1999. ISBN 0-942717-73-2. International Institute for Rural Reconstruction, Y.C. James Yen Center, Silang Cavite 4118, Philippines. Fax: +63 46 414 2420; Email: iirr@cav.pworld.net.ph*
The workshop recognized that collaboration has been limited and documentation of efforts in research partnerships has been poor. However, successful initiatives do exist, and twelve cases form Asia, Africa and Latin America formed the basis for drawing up lessons in research partnerships. Analysis focused on the collaborative dimension – the partnership process.

Environmental indicators for agriculture. *OECD 1999. Volume 1: Concepts and framework. 45p, ISBN 92-64-17134-7. Volume 2: Issues and design. 213p, ISBN 92-64-17041-3, FF 240. Organisation for Economic Co-operation and Development, OECD Publications, 2, rue André-Pascal, 75775 Paris Cede 16, France. Also available in French. Volumes 3(Methods and Results) and 4 are expected to be ready in resp. 2000 and 2001.*
The OECD is making a major effort to develop a set of policy-relevant indicators to assess the harmful and beneficial impacts of agriculture and policy measures on the environment. The first volume describes the main environmental concepts and the indicators that need to be calculated: the use of nutrients, pesticides, water; land conservation; water and soil quality; greenhouse gases; biodiversity; wildlife habitats; landscape; and environmental impacts related to farm management practices, the availability of farm financial resources, and rural socio-cultural issues. Volume two is on the results of the OECD York Workshop attended by leading experts. It discusses the identification and design of suitable indicators, the methodology to be used in their measurement and issues relating to interpretation. On the basis of practical experiences, there is also a discussion about how indicators can be used for policy purposes.

PROLINNOVA (PROmoting Local INNOVAtion)

Ann Waters-Bayer

Promoting farmer innovation was one of the main themes at the recent Global Forum on Agricultural Research (GFAR) held on 21-23 May 2000 in Dresden, Germany. Over 400 participants from farmer organisations, NGOs, national and international research centres, and private industry concluded that a participatory approach to innovation development in agroecology should be widely promoted. Over the past year, NGOs from both developing and developed countries had discussed by Email and met in Rambouillet, France, to draw up a concept paper for a programme to promote innovation by farmers and their communities. This paper was enhanced further by incorporating comments solicited from various other NGOs by Email. The revised paper served as basis for discussion in Dresden.

A learning network

The main objective is to strengthen research and development partnerships and methods to promote local innovation in ecological agriculture and natural resource management (EA/NRM). A long-term aim is to institutionalise Prolinnova approaches into national programmes of research, development and education. The programme is envisaged as covering six major components:

- Identifying and documenting local innovations and innovation processes related to both agroecological techniques at field/farm level and institutional innovation in collective management of natural resources at landscape level
- Promoting farmer-extensionist-scientist partnerships to further develop local innovations and to scale-up innovation processes
- Training potential collaborators in these participatory approaches and methods
- Promoting the incorporation of Prolinnova into the teaching and research activities of institutions of higher learning
- Jointly analysing the approaches and methods used in the above-mentioned processes and their impacts
- Promoting regional and global R&D networks and the sharing of information on EA/NRM based on local innovation in similar agroecological zones or similar types of techniques or institutions.

Most activities will be implemented through national and regional sub-programmes, defined semi-autonomously and directly funded by different donors. These sub-programmes will be linked at a higher level, using mechanisms for sharing and mutual learning, such as web-based databanks, E-conferences, workshops, exchange visits and publications. Prolinnova will be essentially a learning network.

Apart from encouraging the launching of new programmes to promote farmer innovation in the various regions, Prolinnova will also seek collaboration with relevant existing programmes, databases and publications, e.g. Honeybee, ILEIA, ISWC, PFI, PRGA, and encourage their active involvement in the network.

Links with InterDev and PolicyNet

The Prolinnova initiative has been developed along with two other initiatives:

- InterDev, aimed at developing an internet-based system for documenting and sharing local innovations, initiatives and practice-proven techniques of EA/NRM; and
- PolicyNet, aimed at addressing policy and institutional issues to support local innovation processes, by way of relevant research and information dissemination.

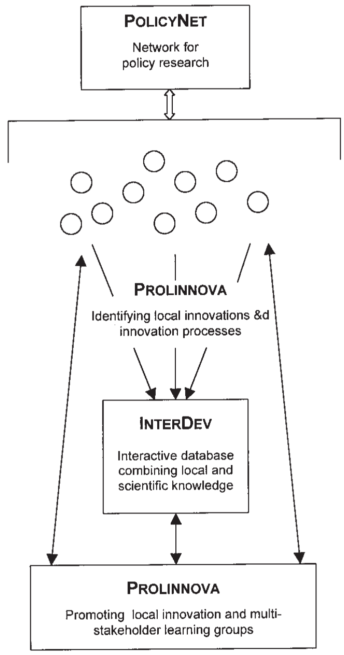

Figure 1: Mechanisms of knowledge management to promote innovation in ecological agriculture and natural resource management

InterDev will be an important platform for collecting and making available the lessons from Prolinnova, while PolicyNet will be vital for creating the political and institutional "space" to allow Prolinnova to blossom.

Initial inventory and consultation

The Rambouillet Group is currently developing an action plan to put the concepts into operation. Start-up activities include an inventory of existing programmes and databases on local innovation in EA/NRM and a consultation process with potential partners to review relevant experiences, analyse these jointly and identify gaps where supportive mechanisms can be introduced or strengthened. On this basis, partner institutions will design a more detailed Prolinnova programme.

This issue of the *ILEIA Newsletter* has already moved ahead in compiling experiences of discovering and promoting innovation by farmers. In the context of InterDev, ILEIA is setting up a website for continued documentation and discussion of relevant methods and processes. ■

All organisations interested in being actively involved in PROmoting Local INNOVation in AE/NRM are invited to contact Laurens van Veldhuizen, ETC Ecoculture, PO Box 64, NL-3830 AB Leusden, Netherlands (l.van.veldhuizen@etcnl.nl).

Advancing PTD: a study and workshop

A growing number of organisations have become engaged in agricultural research and extension that involved farmers at all stages in the process and that are designed to strengthen local capacities to experiment and innovate. Many have developed variations on the "classical" PTD approach: using novel entry points (e.g. indigenous innovators), trying to speed up the process and developing new methods. Some promising efforts have been made to institutionalise PTD within large research, extension and training organisations.

In view of the heightened interest in promoting local innovation (Prolinnova), it is high time to document, compare and analyse these experiences, and to learn from them. The proposed study during 2000/2001 will culminate in a workshop in late 2001.

The organisers – IIRR (Philippines), CIIFAD (USA), ETC (Netherlands) and tINNOVATEc (Switzerland/Germany/Netherlands) – are keen to learn of advances in PTD that help advance the development and scaling-up of PTD. We are seeking new cases from people who have learned from and improved the PTD practices pioneered in the 1980s and early 1990s. Cases should cover several years' experience, and can come from both the South and the North.

If you would like to join this learning activity, please contact ETC Ecoculture, expressing your interest and including a short abstract of the case you would like to contribute. Contact: Ellen Radstake, ETC, POB 64, NL-3830 AB Leusden, Netherlands (office@etcnl.nl).

Promoting Farmer Innovation

Will Critchley and Verity Nyagah

The objective of the "Promoting Farmer Innovation" (PFI) programme is to help formulate a radically new research methodology, while demonstrating the developmental benefits of improved land husbandry in dry areas. The programme began in 1997 in Kenya (Mwingi District), Tanzania (Dodoma Region) and Uganda (Soroti, Kumi and Katakwi Districts).

PFI has been working to establish partnerships of governmental and non-governmental agencies that will focus on farmer innovation. The programme is managed by the UNSO-UNDP Office to Combat Desertification and Drought and is linked to the Governments' National Action Programmes (NAPs), which have been developed under their commitment to the Convention to Combat Desertification (CCD) (see *LEISA Newsletter* 16.1 pp 6-7). PFI has turned out to be a classic case of learning by doing and consists of tailored training accompanied by fieldwork. A "10 steps" framework (Figure 1) was drawn up to guide field activities.

First lessons

On-the-ground identification of farmer innovators (FIs) by extension workers was surprisingly quick and easy. Forming clusters of FIs has proved a good way of organising interaction between innovators and providing a focal point for activities. There is a growing awareness, however, of the potential problem of creating exclusive clubs of "favoured" farmers. PFI is not primarily a programme to help innovators themselves; it's about stimulating innovators to share ideas with their fellow farmers.

Another lesson from the field is that many innovations are already good enough, and attractive enough, to be spread. Other farmers quickly take up these "best-bet" innovations. Thus, joint experimentation by farmers and researchers and adding value to innovations is not necessary in all cases. After all, farmers are the best judges of what is useful to them. If they find an original innovation interesting they will accept or modify it further themselves. Under PFI, certain innovations have spread rapidly (types of compost making; deep-pitting systems for planting sugar cane and cassava, etc) and have outstripped the programme's capacity to technically validate these techniques.

Documentation

A regional review workshop held in Dodoma, Tanzania, early last year in Dodoma, brought together policy makers, extensionists, researchers and innovators from all three countries. The issues debated and experiences analysed were captured in a book that has proved a remarkably useful awareness-raising tool and reference document on innovation. A professional video on the programme is serving the dual purpose of being a "virtual field visit" and raising awareness at all levels. English and French versions are currently in use; a Swahili version is being prepared.

Challenges ahead

There are immediate, and longer term, challenges for PFI:

- More attention should be given to *monitoring and evaluation* (M&E) at innovation level, and to develop such systems with farmers. M&E systems that both farmers and technical staff are comfortable with and that simultaneously yield user-friendly and functional data are not easy to design.
- The second main challenge is to bring *research agencies* more fully into the picture, to complete the farmer-extensionist-researcher triangle, and to strengthen the processes of innovation validation and joint experimentation.
- The third challenge, *impact assessment*, relies very much on the previous two. The impact of the programme must be assessed in the light of cost effectiveness.
- The fourth outstanding issue is how to *involve more women* (and youngsters) in the programme. Initially, there was a strong focus on male farmers. After a sequence of gender studies and sensitisation workshops, more innovations by women farmers were identified.
- Another set of challenges relate to investigating issues such as: ***What stimulates "innovativeness"*** the best? and ***How can we enhance this process?*** These are central to any innovator programme.

Institutionalisation

The ultimate challenge is institutionalisation, both through vertical integration into Government (and NGO) policy and by horizontal integration through partnerships on the ground. Institutionalisation is, encouragingly, well underway. For example in Kenya, PFI now has a formal alliance with FAO's Farmer Field Schools (FFS) programme, entitled "PFI-FFS". In Uganda, the FI methodology has been made explicit in the government's budget policy statement. In Tanzania, Dodoma's Regional Commissioner has given farmer innovators a key role to assist Government extension agents as resource persons. Institutionalisation, however, must be achieved in a non-threatening way: not by hard selling, but by gentle persuasion based on achievement and credibility.

Harnessing and supporting farmer innovation is no panacea, but few can dispute its place in building a better and more productive rural environment.

Innovation by Tunisian women in dryland farming

Noureddine Nasr, Bellachheb Chahbani and Ali Ben Ayed

At the beginning of the Indigenous Soil and Water Conservation (ISWC) project, training was given in Participatory Rural Appraisal and Participatory Technology Development (PRA/PTD) in different regions to facilitate identification of farmer innovators, men and women. One-day workshops were also held at the Ministry of Agriculture's regional department headquarters. Some 160 staff members took part. After these workshops, most of the innovators identified were men.

Identifying women innovators

In the local culture, it is difficult and often unacceptable for men to talk with village women. The ISWC team at the Arid Zones Institute consisted of men, so 15 women were recruited and trained to make a special study. These included teachers and students returning to their villages for the summer holidays. They collected data on women's role in farming and food processing and identified 31 women innovators. Most were found in Gafsa and Sidi Bouzid regions, where population density is highest and agriculture diverse and intensive.

The 31 women were all married and between 23 to 84 years old. Most were in their 30s and 40s and had little formal education. Most came from mountainous areas where, until recently, there were few opportunities – especially for girls – to go to school. Over 70% (all those over 40) were illiterate. However, with the recent spread of electricity and education in rural areas, the women have more contact with a new culture through radio, TV and their school-going children.

Spheres of women's innovation

The women innovate in activities that concern them directly. The main economic activity of all but one of the 31 women was farming, especially livestock keeping. Most also practise handicrafts. Women were innovating in animal husbandry (11 women), cropping (7), handicrafts (6), use of medicinal plants (3), efficient use of energy for charcoal making and improved stoves (2) and processing sheep and goat milk (2).

Handicrafts include making carpets and other products out of wool and weaving mats and other household items from alfa grass. Natural dyes are extracted from leaves, roots and bark. The oldest innovations – in handicrafts and medicines – are rooted in local knowledge but adapted (in design, materials, use) to the new socio-economic context.

The crop-related innovations include fig-pollination techniques and using plastic bottles for irrigation. Mrs Rgaya Zammouri in Médenine region, over 70 years old, uses 1.5 litre bottles to irrigate watermelons and melons. She buries each bottle upside-down in the soil. The cork has tiny holes in it made with a needle and the water infiltrates slowly near the roots of the plant. She fills the bottles from a cistern fed by run-off rainwater.

Hatching eggs without a chicken

Eleven women (35%) innovated in livestock keeping, specifically with sheep and goat feeding, and poultry, rabbit and bee keeping. For example, Mrs Mbirika Chokri, a 70-year-old farmer in Gafsa region, specialises in poultry and incubates chicken eggs in dry cattle dung. She puts the eggs with some straw in plastic bags to preserve humidity. Each bag has 16-20 eggs. She puts the bags in small holes dug in the manure and covers them with cardboard and a thin layer of manure. Each day she opens the bags to check the temperature of the eggs and to turn and aerate them. From day 20, the eggs start to hatch. She puts the chicks into a box to protect them from the cold and feeds them couscous, vegetables and bread. The idea came 5 years ago when one of her chickens, with eggs about to hatch, suddenly died. She put the eggs into a dung pile and they hatched after a few days. She decided to repeat this technique till she mastered it. She did not share her idea with neighbours, but accepted the ISWC team's request to present it in the "Agriculture and Innovation" programme on Gafsa regional radio and later on television. It aroused widespread interest among other farmers.

Potential for spread

Livelihood systems in central and southern Tunisia have changed radically in recent years. New production systems have replaced the traditional pastoralism and links between the countryside and urban markets are much closer. Rural women need more cash to satisfy new needs. Women innovate both to increase their income and to reduce their workload. For example, economising on water for irrigation reduces the time and energy needed to fetch water. Several women stated that their innovations came from their own idea or a chance discovery. Often, their innovations are practical and low-cost, and have good potential for spreading.
More Tunisian researchers, development agents and policymakers at regional and national level are coming to recognise women's innovation. In 1999, researchers and several women innovators began collaborating on experiments. The challenge is to improve and expand this approach in Tunisia and beyond.

Upright stones in 'devil's tie': local innovation for riverside terracing.

Devil's tie bedevils water: an Irob innovation

Asfaha Zigta and Ann Waters-Bayer

Irobland lies on the steep mountainous escarpment that descends from the plateau of Eastern Tigray (2500 m) to the Danakil depression (-100 m). In Yohannes' home near Alitena, annual rainfall is 300-400 mm, from mid-June to mid-August. The area is rich in rock. Alitena is situated beside a river that flows year-round and carries soil-laden water from the plateau. In the 1960s, Yohannes started building a stone wall in one of the curves in the river parallel to the riverbank, to divert water and soil into the space behind the wall. He saw this as a way of creating and irrigating land. In this 800 m² river plot he grew fruit trees (mainly orange), vegetables (mainly cabbage) and maize.

When Yohannes first tried to claim land from the river, he made a wall like the wall of a house and used large flat stones piled on top of each other (see illustration). But when the river flooded, the water lifted the stones and washed them away. He tried again, and the same thing happened. Then he thought if the water lifts the stones, I can try to set the stones upright before the water mets them. He chose a rocky outcrop in the steep wall of the riverbank as a starting point for building an upright line of heavy flat stones, one standing against the next with larger and smaller stones alternating with each other. He wedged more upright stones in a second storey above the first line, until a small wall was built. He did this as an experiment, to see what the floodwater would do with the wall. He observed that the water roared over the top of the stones but did not dislodge them; Yohannes had outwitted the river by using the force of its own water to push one stone against the other and, in effect, tie them together through pressure. This type of riverside wall became known locally as *seytan madewa* (devil's tie), named after the complicated tie, very difficult to open, that closes the goatskin bag that contains the precious gifts intended for an Irob bride.

Yohannes' field protected by the devil's tie was close to a major long-distance footpath. Over the years, many farmers passed by and saw what he had done. If Yohannes was in the field when they stopped, they sometimes asked him to explain what he had done. The principles were immediately obvious to most farmers, who were accustomed to working with stone to manage soil and water.

In the 1970s, a church-based project deliberately built on the techniques and innovations of the Irob. Yohannes was given the responsibility of supervising community work in building footpaths, wells and check dams around Alitena. When building a large check dam he noticed that floodwater poured over the top and undercut the dam. He suggested using a devil's tie to prevent this. At the point where the water hit the soil below the dam, large flat stones were pounded in upright, slanting towards the top of the dam. The stones broke the force of the descending water and dispersed it, so that some remained in the field while the rest flowed over the next dam down the valley.

Whenever Yohannes supervised teams of community members working on check-dams, he advised them to build the devil's tie wherever appropriate. Many started using the same technology for their own smaller check dams on the terraced fields near their homes. People in nearby villages also observed this technology and use of the devil's tie not only in riverside walls but also below dams spread throughout Irobland.

The devil's tie is an example of indigenous engineering that could stimulate similar innovations in other parts of Ethiopia. In less mountainous areas, it may be difficult to find a rocky outcrop to support the downstream end of the wall of upright stones and other means, such as a cement block, may have to be used. If creative farmers trying to claim land from rivers in other areas met with Irob experts in building the devil's tie, ideas for appropriate adaptation would doubtless emerge. Development agents could help by bringing such farmers together. Also formally-educated engineers could benefit from studying the technical aspects of this ingenious innovation.

Tragically, two years of war has destroyed much of what Yohannes and his fellow farmers painstakingly built up over decades. After the land mines have been cleared, the Irob will have to summon all their creativity and strength to pick up the pieces and reconstruct.

Unleashing the creativity of farmers

The editors

Farmers adapt their farming systems as conditions and needs change. They try out new ideas they have seen or heard about from other farmers, visitors or extension agents, put their own ideas into practice and sometimes work on innovations that have arisen "by accident". Innovations often arise out of necessity, others are born of curiosity. An innovation can be a practical technique or a different way of organising things, like when a farmer makes new arrangements about how land should be used with a neighbouring farmer.

With little or no support from outside – particularly if they live in areas where extension services are poor (p17) – farmers try to solve their problems by putting their trust in their own skills. For example, more than ten years ago, peasant farmers in Central America created the *Campesino a Campesino* (CaC) movement to develop a sustainable agriculture that would make optimal use of local resources by drawing on indigenous knowledge and values (p26). As many articles in this Newsletter show, farmer experimentation and innovation is deeply rooted in the daily struggles of small-scale farmers. Many innovations, especially those made by women, are hidden or isolated but there also can be close connections between them. These connections could be better used to stimulate a continuing process of innovation (p14). There can be serious constraints to farmer experimentation and innovation. Several articles stress that it is important that the community recognises local innovators. Women in particular often have difficulty in winning this recognition (p40).

Widening interest

Farmer innovation is not new, it has always been an essential part of agriculture. Drawing attention to the importance of farmer innovation is not new either. In recent years many books and articles have appeared on local innovations in such magazines as the *ILEIA Newsletter*, *Honeybee* (p5), and *Enlace* (p28). Despite this, formal research and extension has paid little attention to farmer innovation. Now, the tide seems to be turning. Some development programmes have started to go beyond participatory research on techniques originating in formal science. They are deliberately using indigenous innovation as an entry point into joint experimentation to further develop "home grown" ideas. These initiatives involve local innovators, neighbouring farmers, development agents and sometimes even research scientists. International and national research and development organisations are now considering how farmer innovation can best be supported especially for development of ecologically sound agricultural and natural resource management practices suitable for diverse and specific sites (p35).

Seeking complementarities

Ways are being sought to trigger participatory innovation processes in which the knowledge and experiences of small-scale farmers and external advisors are combined in a "learning dialogue" (Hocdé et al., p28). Research scientists have important tasks to play, by bringing in information, methods and analyses which complement what farmers already know and can do themselves. The evaluation of the CaC movement in Nicaragua (p26) revealed that more systematic learning, rigorous comparison of options, and insights from outside are needed to make farmer experimentation more effective. As argued by Braun et al., (p33), seeking complementarity in methodologies could also enhance local innovation processes, e.g. the approach of experimental learning-by-doing (a strength of Farmer Field Schools) could be combined with systematic comparison (a strength of PTD) and with wider sharing (a strength of CaC).

Enthusiasm and ownership

Supporting farmer innovation involves a variety of interlocking activities, as discussed on page 9, 25 and 28. The articles from Latin America in particular stress the importance of "farmer promoters" in facilitating innovation. Farmer promoters help farmers realise that they are capable of recognising and offering solutions, doing experiments and communicating options to others. Promoters can help farmers bring out their ideas and guide them in designing their own experiments. The goal is to promote a culture of enquiry and experimentation among farmers which helps build enthusiasm, self-confidence, pride and hope for the future (p26). Magazines, video, radio, television, fairs, workshops and farmer congresses (pages 18, 28 and 39) have proved to be effective tools for identifying, sharing and analysing local innovations and for stimulating further experimentation. As Hocdé et.al. (p28) observe, the important thing is that innovators do these things for themselves and take pride in them. In Costa Rica, innovating farmers took the initiative to found a committee of farmer experimenters and representatives from the public and NGO sector to support and plan participatory innovation development at regional level that put farmers' organisations in charge of research (p28).

Re-orientation needed

The articles included in this Newsletter make it clear that there are two major preconditions for supporting farmer innovation. First, empowering farmers to take the lead in experimentation, communication and organisation; and second changing the attitudes and roles of researchers and development workers so that they recognise farmer innovators as equal partners, with experiences and skills different to their own. Only then can they facilitate processes of participatory innovation and provide the complementary inputs needed.

Re-orientation is also needed in policy-making from the local to the international levels. The experiences of the CaC movement (p26) and in Tanzania and Ethiopia (p9, p23) show how vital it is to involve all stakeholder groups (farmer organisations, research and extension institutes, universities, development agencies, ministries, banks and the private sector) in platforms for dialogue. This should lead to change in policy relating to research, extension, education, land tenure, trade and many other factors that can stimulate or constrain farmer innovation.

The ultimate aim, as so aptly expressed by Braun & Hocdé (p33), is to stimulate social processes that unleash the creative skills of people and their organisations in order to create a permanent movement of innovation driven by the rural population. ■

Indigenous agricultural revolution *by Richards P. 1985. 192p, ISBN 0-09-161321. London, Hutchinson & Co.*
The author demonstrates that many of the most successful innovations in food-crop production over the last fifty years or so have indigenous roots. There should be less emphasis on '-teaching' farmers how to farm and supplying 'improved' inputs, and more emphasis on how to foster and support local adaptation and inventiveness.

Farmer experimentation and innovation: a case study of knowledge generation processes in agroforestry systems in Rwanda *by Biggelaar C den. 1996. Community Forestry Case Study 12. Rome: FAO/FTTP.*
A study of how farmers conduct their own experiments and generate know-

ledge related to tree growing. Knowledge production by farmers was oriented to its immediate use but also to a future beyond the farmers' lifetime.

Soil recuperation in Central America: sustaining innovation after intervention *by Bunch R & Lopez G. 1995. Sustainable Agriculture Gatekeeper Series 55. London: IIED.*
This study shows that aiming to ensure the sustainability of specific technologies may be counterproductive. Much more relevant to farmers' well-being is an attempt to sustain the process of innovation. Productivity will climb only if local-level innovation continues.

Farmers developing technology: the researcher's role revised *by Lopez G and Bunch R, ILEIA Newsletter Vol.16, No.1, p.22-23.*
In Central America farmer experimenters are taking over some of the roles conventionally associated with researchers. The authors have been facilitating farmer experimentation in the hope of finding profitable ways of using micro-catchments for water harvesting. On the basis of these experiences they challenge researchers to support the farmer experimenter movement and adapt their roles.

Traditions and innovations in land husbandry: building on local knowledge in Kabale, Uganda *by Critchley W, Miiro D, Ellis-Jones J, Briggs s & Tumuhairwe J. 1999. Nairobi: RELMA.*
Describes the process and results of a 4-year participatory research programme on soil and water conservation in Uganda. The approach evolved from studying local practices to collaboration between farmers and researchers in developing and disseminating innovations.

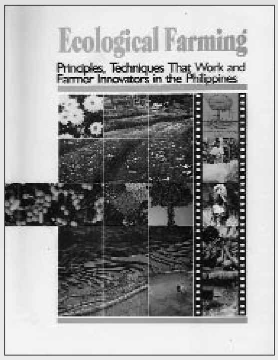
Client-driven change and institutional reform in agricultural extension: an action learning experience from Zimbabwe *by Hagman J, Chuma E, Connolly M & Murwira K. 1998. Agricultural Research and Extension Network Paper 78. London: ODI.*
Describes the ongoing institutionalisation of a participatory approach to innovation development and extension in Zimbabwe. The process requires far more than simply training staff in participatory methods. It needs also commitment from all actors, sound strategies, flexible methodologies, a conducive atmosphere for learning, and a focus on human relationships.

Participatory innovation development and diffusion: adoption and adaptation of introduced legumes in the traditional slash-and-burn peasant farming system in Yucatan, Mexico *by Guendel S. 1998. 133 p. ISBN 3 8236 1292 1. Margraf Verlag, PO Box 105, D-97990 Weikersheim, Germany. (shorter version available from GTZ Tropical Forest Research Project, TOEB@gtz.de).*
Mayan peasants in Yucatan face decreasing productivity in their slash-and-burn (*milpa*) farming system and lack alternative income sources. A system of green manuring with legumes (*mucuna, canavalia*) had been successfully introduced elsewhere in Central America and appeared suitable for the Mayan farmers, but few had adopted it. Sabine Guendel explored reasons for this lack of adoption in three case studies, in which intervening organisations took different strategies to promote the innovation. Her methodology facilitated analysis by the farmers of the functions and potential roles of cover crops within the *milpa* system. A clear picture emerges of how the historical *milpa* system changed in the last century to the current "traditional" one. The comparative analysis revealed that, when farmers were given the opportunity to experiment with an innovation and incorporate their local knowledge, they developed ways of increasing the innovation's contribution to food security and income generation. The methodology of participatory innovation development by farmers, NGOs and researchers is described in four phases: appraisal, convergence, experimentation and reflection. Farmer-to-farmer diffusion of new ideas was found to be much more difficult within communities than between them. The book gives little information about the status of the innovators in their community and their relationship with other community members, which may have helped explain the differences in their behaviour. The research gives considerable weight to local perspectives: farmers' assessments of the process and results of innovation development are often expressed in their own words. This gives the text a particular liveliness. (AWB)

The new frontier: farmers' responses to land degradation *by Amanor K. 1994. London: ZED Books/UNRISD.*
West African farmers faced with land degradation as a result of monocropping made adjustmenst by experimenting with regenerative technologies in agroforestry and managed fallow. Argues for a new structure of R&D that seeks to strengthen the independent research capacities of farming communities.

Farmer participatory extension training workshop: summary of workshop contributions and outputs *edited by Koma YS, Seng S, Solieng M, Shams N, Samram T, Brouwer H. & Bunna K, 2000. 108p. Centre d'Etude et de Développement Agricole Cambodgien (CEDAC), PO Box 1118, Phnom Penh, Cambodia. Email: Cedac@camnet.com.kh*
The first documented discussion on experiences with agricultural extension in Cambodia and the concepts and global experiences of farmer participatory extension.

Ecological farming: principles, techniques that work and farmer innovators in the Philippines *by Padilla HJ. 1999. AGTALON, Nalsian, Manaoag, Pangasinan, Philippines.*
In the introduction the author explains how farmers in the humid tropics can



collaborate with nature. The main body of the book is on farmer-proven ecological farming techniques from Luzon, Visayas and Mindanao. The practical cases on farmer innovations deal with many different topics such as nutrient, water and pest management, integrated farming, vegetable growing, forced feeding technology, herbal veterinary remedies, etc. The book is a strong testimony of the creativity of farmers. (CR)

From process to innovation: land use intensity practices among smallholder rice farmers in eastern Nigeria *by Igbokwe EM. 1999. Indigenous Knowledge and Development Monitor 7 (1): 3-7.*
Examines how smallholders select components of technical packages from extension to use in their own experimentation. Farmer innovations included yam/rice rotation and making mounds to incorporate organic matter in rice fields. Argues that the contact-farmer approach of the T&V system overlooks local innovation.

Farmer First: farmer innovation and agricultural research *edited by Chambers R, Pacey A & Thrupp LA, 1989. 218p, ISBN 1-85339-007-0. London: Intermediate Technology Publications.*
Starting with farmers' own capacity for innovation, contributors from the agricultural and social sciences, ecology, economics and geography, make the case for a farmer-first mode to complement the traditional 'transfer of technology'. One of the classical books on farmer innovation and participatory development.

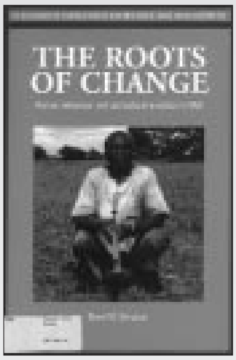
Women's role in technical innovation *by Ilkkaracan I & Appleton H. 1995. New York: UNDP/ITDG.*
A source book on women and innovation in food technology: 23 case studies address women's IK, innovation by women's, and collaboration between women and outside agencies supporting technology development.

Farmer innovators in land husbandry. *ISWC/PFI. Newsletter available from: Chris Reij, CDCS, Free University Amsterdam, De Boelelaan 1115, NL-1081 HV Amsterdam, Netherlands Email: cp.reij@dienst.vu.nl*
Joint newsletter of the action-research programmes "Indigenous Soil and Water Conservation in Africa" and "Promoting Farmer Innovators", reporting on the methods used and the experiences in the 8 countries involved. Includes also articles describing individual farmer innovators and their innovations.

Looking for innovation: post-war agricultural change in Niassa Province, Mozambique *by Levin S. 1996. Wageningen Agricultural University.*
Based on a 3-month study in a remote area of Mozambique, this highly readable thesis clearly explains methodological constraints to systematically documenting indigenous experimentation and innovation.

The neglected uplands: innovation and environmnetal change in Matalom, Philippines *by Anna Lawrence 1995. Working paper 95/11, 33p. Agricultural Extension and Rural Development Department, The University of Reading, PO Box 238, Earley Gate, Whiteknights Road, Reading RG6 6AL, UK.*
The study found that over recent decades farmers have begun to plant more trees, contour the cultivated slopes, and burn fallow less than previously. Information from nearby projects has been very important in stimulating these changes, but the relative isolation of the farming communities has also led to considerable experimentation and innovation on their own. Ecological education by the farming systems research institute has resulted in farmers more motivated to make improvements for ecological reasons rather than profit.

The roots of change: human behaviour and agricultural evolution in Mali *by Simpson BM. 1999. London: Intermediate Technology Publications.*
This study of how change occurred in farming systems in south-western Mali shows that local farmers' creativity, reinforced by social interaction, has



been the major force in the development of local production systems over the last 30 years. Explores patterns of behaviour of individual farmers and groups of farmers in generating, adapting and spreading new agricultural practices, and suggests how the creative potential of farmers and fieldworkers can be stimulated.

Joint learning for change: development of innovations in livelihood systems around protected tropical forest areas. *LISTRA. 1997. Eschborn: GTZ.*
Takes the concept of PTD beyond farm-level experimentation to the participatory development of social, organisational and technological innovations in NRM. All stakeholder groups are involved in analysing visions, problems and potentials for improving, compensating or replacing specific ways of using resources that have been restricted for conservation reasons. Options are screened in workshops, and multi-stakeholder teams experiment with new ways of ensuring a livelihood for people living around protected forests.

Issues in the utilisation of indigenous knowledge in agroforestry research *by Nielsen F. 1998. Thesis, University of Copenhagen.*
In three cases in Uganda, key issues of integrating IK into formal research are investigated. These include: farmers' knowledge generation and experimentation, farmers' networks as sources of inspiration and inputs, and the dynamic nature of IK. In farming systems involving slow-growing and space-demanding trees, farmers generated knowledge through unplanned collective experimentation.

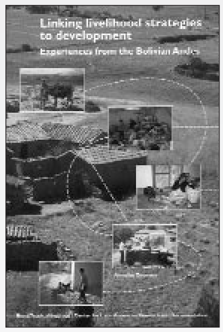
The spirit of innovation: a key to the future: experience of the Campesino to Campesino program (PcaC) in the buffer zone of the BOSAWAS Reserve *by Rivas Espinoza A & Zamora Gonzalez E. 1998. Forests, Trees and People Newsletter 35: 14-19.*
Near a large rainforest reserve, farmers learned from other farmers how to test new crop combinations, including "fertiliser beans" as cover crops. This stimulated innovation that evolved into collection of forest seeds, community forest management and income generation from forest products.

Farmers' experiments: creating local knowledge *by Sumberg J & Okali C. 1997. 178p, ISBN 1-55587-674-9. Boulder: Lynne Rienner Publishers, Inc.*
Critical analysis of Farmer Participatory Research based on a wide literature review and a search for experimenting farmers in Ghana, Kenya and Zimbabwe. The rapid field-work revealed no evidence of research-minded farmers or informal R&D systems. Farmer experimentation could not be differentiated from farming practice. It is argued that farmers need, above all, an increased supply of "raw material" (new seed, ideas and so on) with which they can experiment with their own.

Best practices on indigenous knowledge *by Guchteneire P. de, Krukkert I. & Liebenstein G. von (eds), 1999. 183 p., ISBN 90-5464-031-6. UNESCO-MOST / Nuffic-CIRAN, PO Box 29777, 2502 LT The Hague, The Netherlands. Email: ciran@nuffic.nl ; Website: www.nuffic.nl/ciran/*
This Best Practices Database, available as booklet and on internet, is on programmes working with indigenous knowledge (IK) in natural resource management in Africa, Asia and Latin America. The focus of the database is not on the details of the IK itself but in the ways it has been adapted, applied, and disseminated. The aim of the database is to encourage researchers and policymakers to incorporate IK into their project proposals, feasibility studies, implementation plans and project assessments.

Farmers' research in practice: lessons from the field *by Veldhuizen L van, Waters-Bayer A, Ramírez R, Johnson DA & Thompson J, 1997. ILEIA readings in sustainable agriculture. 285 p. ISBN 1 85339 392 4, London: Intermediate Technology Publications.*
Several cases of farmer-led research show how farmers develop and adapt innovations, try them out in different settings, assess their value for improving farm systems, and spread the new ideas and ways of experimenting to other farmers.

Linking livelihood strategies to development: experiences from the Bolivian Andes *by Zoomers A. 1999. 108 p. ISBN 90-6832-125-0. Royal Tropical Institute, KIT Press, PO Box 95001, 1090 HA Amsterdam, The Netherlands. Email: kit-press@kit.nl ; Website: www.kit.nl*
The author argues to go beyond agriculture and to start development interventions from the indigenous livelihood strategies. Farmers often carry out multiple income-earning tasks in addition



to farming, combining and recombining and renewing these tasks in a diverse and dynamic response to ever-changing conditions. An extensive analysis of information provides the background for far-reaching recommendations about how development interventions can be better linked to the livelihood strategies – the reality – of farmers.

Innovation for development *by Engel PGH & Salamon M. 1996. Amsterdam: Royal Tropical Institute.*
This is about managing agricultural innovation processes through facilitation: creating favourable conditions plus an understanding of social and institutional learning processes. Introduces "RAAKS", a participatory methodology for enhancing innovation.

Complementary platforms for farmer innovation

Ann R. Braun, Graham Thiele and María Fernández

The essential factor in strengthening farmer innovation capacity is not technology *per se* but the construction of social processes supportive of experimentation and learning (see Braun and Hocdé, *in press*; Braun et al. 2000). This means going beyond individual experiences to diverse forms of experimenter groups using different approaches. Several experiences coexist along the farmer-led/interactive research continuum, inviting a multi-tiered approach in which networks of rigorous farmer researcher "experts," less rigorous community-based research networks, and large-scale individual, informal experimentation are integrated.

Complementary approaches

In Latin America coexisting platforms include Campesino-a-Campesino (Hocdé et al, p), DIP, PRIAG (Hocdé et al, p), CIALs and Farmer Field Schools (FFS). Until recently there has been little interaction among them. However practitioners have begun to exchange and collectively analyse their experiences. This article focuses on FFS and CIALs, two platforms that have begun to operate within the same geographic areas, often facilitated by the same organisation. Farmers, researchers and extensionists are asking how they relate to each other and what are their comparative advantages. This article compares their essential characteristics and explores how these can best be articulated.

Local Agricultural Research Committees
A CIAL (*Centro International de Agricultura Tropical*) - originally developed by CIAT-Colombia - is a permanent research service operated by a rural community. Volunteer farmers apt at experimentation make up the research team. The CIAL links farmer-researchers with formal research systems. It increases local capacity to make demands on the formal system and to access useful skills, information and research products.

CIALs have four elected members and a facilitator. Facilitators are trained agronomists from supportive research centres, universities, extension services or NGOs. They can also be trained farmers who have been CIAL members. Facilitators play a key role in developing the CIAL's research competence and they feed back farmers' priorities and research results to formal research and extension services.

Building research capacity

Facilitators visit the CIAL regularly until the CIAL can manage the process alone. The facilitator helps the farmer research team conduct experiments that compare alternatives with a control treatment and with replicating experiments. Training familiarises farmer researchers with terminology that gives results credibility with formal researchers. Training also focuses on planning, management, the running of meetings, monitoring and evaluation, record-keeping and basic accounting. Working in and with CIALs means that profound changes in attitude and relationships are required on the part of farmers, rural communities and agricultural professionals.

The facilitator begins by inviting the community to a meeting where the purpose of the CIAL is discussed. Farmers are invited to analyse what it means to experiment with agricultural technology. They discuss local experiences and experimental results and the possibility of accessing new technologies from outside the community. A committee is elected if the community decides to form a CIAL.

The research fund

Research risks are absorbed by a CIAL fund owned by the community. Usually seed money is a one-off donation, but it may originate from a rotating fund managed by an association of CIALs. The committee uses the fund to acquire inputs for experiments and to compensate members for losses. When an innovation proves successful, the CIAL may add to the fund by selling the harvest or research products (eg seed). As the fund grows, the CIAL can expand its research, share earnings with participants, invest in new equipment or services, or launch a small enterprise.

The research process

An open meeting is held to determine the research topic. The first question is "What do we want to investigate?" The community prioritises topics based on the likelihood of success, who benefits, and the estimated costs.

Facilitators help the committee obtain the information required to plan experiments. Other farmers and staff of formal research and extension services are often consulted. Facilitators work with the CIALs to formulate clear objectives for each experiment. The CIAL then decides what to compare, how and when to evaluate, experimental variables, criteria for evaluating results, data needs, and measurement units.

After the experiment is completed, the CIAL draws conclusions and presents the results to the community. Analysis includes the question: "What have we learned?" Analysis of the process is especially important when an innovation is unsuccessful, or when there are unexpected results.

Three types of experiments

Facilitators guide the CIALs through three successive experiments. An "exploratory" trial when innovations are tested on small plots possibly with several treatments, such as different crop varieties, amounts and types of fertiliser, sowing dates or densities. Exploratory trials help eliminate options that are unlikely to succeed under local conditions. Promising treatments are tested on larger plots in a second experiment. Finally, two or three top-performing choices are planted over a still larger area in the third experiment, often called the production plot.

A small-scale beginning is essential. Small plots provide experience with applying new concepts, such as replication and control. They allow the CIALs to gain confidence before moving to larger and riskier scales. Facilitators gradually reduce the number of times they visit from two per months to once every three or four months as CIALs become more proficient. They visit mature CIALs for feedback on research priorities and results, and to provide information on technology under development by formal research services. Five years ago most CIALs were experimenting with crop varieties. Now small livestock, and pest, disease, soil, water and nutrient management are also being included.

Farmer Field Schools

FFS were initially designed to address problems of pesticide dependency and to develop location-specific management expertise independent of the formal research system. "Classical" FFS for integrated pest management (IPM) of rice is now used for other crops and topics.

Developing agroecosystem management expertise means building up an understanding of ecological principles and processes and the impact of farmer management decisions. FFSs provide an opportunity for learning-by-doing based on principles of non-formal education. Extension workers or trained farmers facilitate the learning process, stimulating farmers to discover key agroecological concepts and develop management skills through self-discovery activities practised in the field

FFS involve 20-25 participants from an existing farmer group or a community. This group forms the basis for collective action and follow-up activities after the school ends. FFS hold regular meetings throughout the crop cycle. Improved decision-making emerges from an iterative process of *agroecosystem analysis* (AEA), making and implementing decisions accordingly, observing outcomes, and evaluating overall impact. This is combined with experimentation aimed at understanding agroecosystem patterns, interrelationships and structure as the basis for problem-solving and decision-making. Observation, evaluation of context, and identification of interactions among different elements in the system are fundamental to FFS experimentation. FFS farmers use drawings and other visual methods to help them understand key self-regulating feedback mechanisms. The FFS approach assumes farmer innovation is constrained by a lack of agroecological knowledge and by erroneous information produced by poorly focused extension programmes and agrochemical distributors.

FFS and CIALs compared

FFS and CIALs share underlying principles. They see farmers as experts, stress respect for local values and knowledge, build capacity through hands-on experience. Both recognise and attempt to reduce the risk associated with learning and research. Outputs are seen as public goods.

Although organised differently, they have several processes in common. Facilitation styles and the role of motivation are similar. Both aim to strengthen farmer experimentation and innovation, but in different ways. CIAL experiments are relatively formal: most are controlled comparisons involving several technological options. Evaluation methods have been adapted to local levels of literacy, using symbols and simple classification and tabulation procedures. Farmers set their own evaluation criteria without influence from professional researchers.

To ensure systematic evaluation of technological options, CIALs are made up of a small group of specialised farmer-researchers, chosen for their reputation as experimenters, and trained to further develop their research skills. FFS unlike CIALs do not focus on identifying solutions from a range of technological options. They develop the communities capacity to better manage ecological relationships. FFS are not directed at a specialised group of farmer-researchers, but try to ensure a permanent learning process by targeting a relatively large and heterogeneous group.

FFS have been effective in addressing problems in agroecological systems that are well understood (eg. irrigated rice in Asia). Where understanding of system components and interrelationships is less developed (eg in the case of non-native crops which lack systemic self-regulation mechanisms), local capacity to evaluate different management options (technologies) is important, and controlled experimentation necessary. The demand for technological options implies the need for strong links with formal research. Here CIALs have a comparative advantage. In line with this demand, second generation FFS have begun to include controlled experimentation, the evaluation of technical options and have established ties with formal research.

Complementarity and synergy

FFS focus on agroecological education while CIALs concentrate on establishing a community-based research service linked to the formal research system. FFS are limited in time to one or two cropping seasons; CIALs are permanent. FFS experimentation is mainly qualitative while CIALs concentrate on experimentation through controlled quantitative comparisons. FFS build agroecological knowledge that could make CIAL research more meaningful. CIALs can generate locally adapted technological options to strengthen the FFS. Both can be established in the same area or community, although the sequence of establishment and linkages should be carefully planned (Braun et al. 2000).

Combining FFS and CIAL

In many countries the value and relevance of agricultural R&D for small farmers is being questioned. FFS and CIAL promote closer engagement with rural society, building local institutional structures and processes for agricultural development. They make R&D more relevant by putting farmers at the centre of development processes and make possible fundamental transformations in agricultural R&D systems. Financing and implementing organisations increasingly see them as viable new alternatives. Under these circumstances we believe that there is considerable potential for making wider use of both platforms and encouraging further evolution and synergy of both.

"This is my own innovation": the history of Limpo grass

Henri Hocdé and Mauricio Chacón

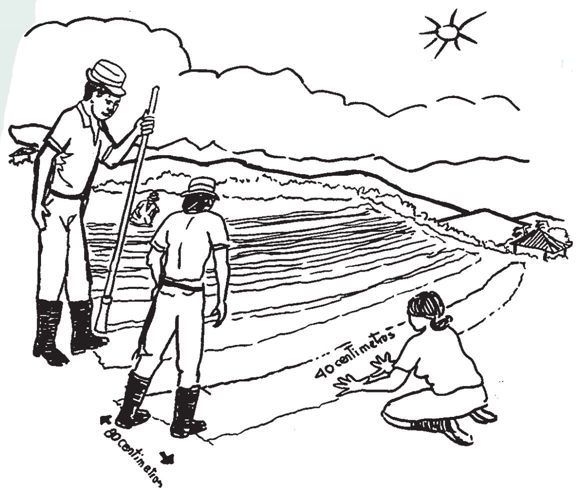
Livestock keeping is important in the Huetar Atlantica region among large- medium- and small-scale farmers and began 40 years ago with the felling of primary forest. Pasture soils are generally shallow with low fertility and farmers have suffered several setbacks in recent years. One of these was the introduction of Ratana (*Ischaemum indicum*). This "improved" variety is now the main grass in the region but it has turned out to be unproductive and low in quality. It is also coarse, resistant to humidity and difficult to eradicate from pastures.

A new grass takes root

During the 1970s, a local farmer brought a new grass from the United States and cultivated it on his farm for 3-4 years without anyone noticing. He then gave up farming and gave samples of the grass to a nearby Experimental Research Station. Here it was tested and eventually discarded in 1982. In 1981, a technical advisor from the Ministry of Agriculture (MAG) took a small sample of this grass to Pueblo Nuevo and handed it to Mr. Nardo Herrera who, having planted it on a damp part of his farm, prepared to test it in his own way. William Ratana, a neighbour who bred and fattened cattle, watched how this grass grew. He noticed that it never disappeared and that it could withstand flooding. He liked it and, in 1992, he invited a recently arrived technical advisor to his farm and asked his opinion.

Limpo grass

The extensionist had never seen anything like it. He took the sample to the university for classification. Researchers discovered that its scientific name was *Hemarthria altissima* or *Moralta vigalta,* it came from Africa and grew in humid areas. The extensionist passed on this information to William Ratana who decided to plant the Limpo grass on a hectare of flood-prone land, near a road, where Ratana had been grown and which was nearly always covered with weeds. Today, he grows 7 hectares of Limpo and is satisfied with the results. *"I watched the Limpo grass covering the ground aggressively, the cows producing more milk, calves growing fatter, the Ratana disappearing and the cultivated area increasing."*



Innovating farmers' workshop

In 1995, MAG staff organised the "*First innovating farmers' workshop on grassland of Huetar Atlantica*". Eighty farmers participated and six gave talks on their experiences as innovating farmers. William Ratana presented his Limpo Grass experience as "his own innovation". The extensionist helped him prepare his presentation. Willam showed photographs of the grass at different stages of growth, in different fields and of pastures developed under different management regimes. Above all, he spoke of the benefits of the grass as he saw them and had no difficulty in communicating his experiences to the workshop even though he had never spoken in public before.

William Ratana distributed the sack of Limpo planting material he had brought with him to the farmers attending the workshop. Neither his neighbours or the other farmers there had heard of the grass before. He is now testing five other grass varieties on his farm: *Briachiaria brizanta, B. dictyoneura, B. radgans, B. humidicola and Panicum maximum*.

Comparing and sharing experiences

In July 1999, technicians held another farmers' meeting to discuss Limpo grass. Twenty-farmers who had experimented with it attended and they told how they had used it in their own specific agroecological situation (altitude, fertility, size and type of farm). They reviewed their 4 years of experience in the context of plagues, diseases, acceptance by the cattle, deficiencies and tolerance. This information will be used to prepare a practical manual.

Fast dissemination

Local farmers are generally hesitant to introduce new grasses because of the high investment involved (about US$200/ha). Nevertheless, Limpo grass is spreading fast. It can be found in livestock farms from the San Juan River in the northern part of the country to Talamanca in the

south. It has partly replaced Ratana. It is good for producing milk and meat and although it responds well to chemical fertilisers, it can also be grown without them. It recovers quickly from flooding and prefers damp, fertile soils although it cannot withstand acidity or permanent flooding.

What did scientific research bring?

From 1987 to 1996, 250 types of grass and 204 varieties of legumes were subject to scientific screening at the Experimental Research Station. They were examined by local experts and researchers from prestigious international centres and all varieties were evaluated by technicians and researchers. The two that proved to be the most outstanding were *Brachiaria brizantha* and *Arachis pintoi*. The former cannot resist humidity and is eliminated by fungus; the latter spreads very slowly. Most of the FEs in the region knew about this collection but, according to them, all planting material of these species had been lost.

Farmers use other indicators

When evaluating the different materials, researchers in the station placed priority on biomass production and resistance to plagues and diseases. The livestock-keepers, on the other hand, take more than ten factors into consideration: resistance to humidity; yield; rusticity, hardiness; duration; resistance to diseases, plagues, rains and drought; ability to recover after cutting; aggressiveness and competition with weeds; sowing facility; propagation; acceptance by different animal species and the capacity to cover the soil.

The research station probably had promising varieties that might interest livestock-keepers. How many varieties were lost because of mistaken research and extension strategies? How much was invested in pasture research that had no positive result?

Growing benefits

Livestock-keepers in the region benefited little from the research stations work. However, through the tenacity of an experimenting livestock-keeper reenforced by the vision and creativity of an extensionist worker, Limpo grass - that had been present in the research station for nearly a decade and finally discarded - was introduced onto some 300 ha. Limpo grass can support twice as many livestock as Ratana and as a result farmers have been able to double their meat production and make a profit of about US$ 200/ha. Annual profits equivalent to US$ 60,000 are already being made throughout the region as a result of the knowledge of Limpo shared at the first FEs workshop. How many benefits to-morrow?

Supportive technical advisors

The moment when Limpo grass began to spread in this area is well defined. The starting point is precise, the names of the responsible livestock-keepers are well-known, and working mechanisms implemented by extensionists very clear. Rapid dissemination was boosted by agents who encouraged the monitoring of farmer experimentation, organised a second farmers' meeting and promoted farmer cross-visits. These extensionists fought against the guiding principles of their institution. They stopped giving talks on grasses and started to organise events at which farmers were allowed to talk and discuss their doubts, achievements, results and misgivings with extension workers.

Change in working methods

As a result of these promising experiences, the group of extension agents began changing their working methods. First of all, as professionals, they understood the need to document these types of activities. Second, as they become convinced that farmers form part of the chain that creates knowledge, they are reversing the conventional research organisation system. Gradually, they started to encourage farmers in the region to use their ability to observe, experiment and share, and to form groups of FEs. Third, they have started to gain more confidence in the value and usefulness of exchanging knowledge between livestock-keepers, technical advisors, public and private researchers and academic centres, in order to promote local innovation.

Farmer experimentation: a challenge to all!

Henri Hocdé, David Meneses, and Byron Miranda

PRIAG or the Regional Program for Reinforcing Agronomic Research on Basic Grains in Central America was an European Union-funded regional collaborative project between EU and the six countries of Central America (1991-1999). Its mandate was to improve the efficiency of the national research and extension systems and make them more responsive to farmers' needs.
It built on an approach known as 'farmer experimenter' (FE) in order to strengthen farmers' capacity to investigate and innovate at the local level, and to enhance their capacity to dialogue with researchers and extension agents. In this way they could create their own specific space and role in the research-extension-farmer chain. By strengthening farmers' capacity to produce, identify, obtain, modify, adapt, share and use information, agricultural technologies can be developed and spread.

PRIAG had teams (researchers and extension workers) in Panama, Guatemala, El Salvador, Nicaragua, Honduras and Costa Rica. Annual work plans were negotiated between farmer experimenters (FEs), formal researchers and extension agents and PRIAG also helped farmers organise, communicate and facilitate their experimentation. For PRIAG, farmer experimentation is a combination between experimentation, communication and organisation.

The first condition to secure this goal is to establish a climate of confidence between FEs and professionals and make it possible for farmers to speak for themselves. PRIAG devoted considerable attention to ensuring there was effective communication among FEs. This articles demonstrates this development in a Central American perspective and goes on to discuss the scaling-up of the process.

Farmers' testimonies

For several years, the Ministry of Agriculture (MAG), Costa Rica assisted by PRIAG has promoted a "Farmer Experimenter" project in two regions, Brunca and Huetar. In 1998, it decided to publish on this process both to reveal farmers' innovating skills and to show how the extension agents involved were willing to change their working methods and to see farmers as producers of technological innovation and agents of dissemination.

With this in mind, it was proposed to draw up a document that would contain the technical and economic results of farmers' experimentation and their views on their role as FEs. The important thing was to give them a chance to speak for themselves.

Field agents in the lead

The task was not entrusted to researchers from universities or foreign research centres. Despite their limited writing skills, grassroots extension agents working directly with the FEs were given the task.

In both regions, local MAG staff set up preparatory 2-day workshop attended by 20 field agents from the region and some interested researchers. Participants began by discussing the implications of the task before them, discussed how they could best help the farmers in their area to write up their own testimonies as FEs, and explored how this should be organised. They all agreed that the final text should be short -between 4 and 6 pages- illustrated, and pleasant to read. Each testimony should have the same structure, but individual style and creativity would be encouraged. The PRIAG facilitator proposed a structure for the testimonies. Field agents set guidelines for interviews and the order of the final text. These focused on four aspects:
My life. Who are we, my family and I? Where did we come from? Why and how did I become involved in experimentation?
My experiments. What am I proving? How did I design my experiments? What do I observe and measure?
The benefits of experimentation. What did my family, association and community gain from being a FE?
Dissemination of results. What would I recommend to other FEs from my area, my country and Central America?

Not an easy task

Each agent chose one or two farmer experimenters from their own area. They were free to choose their own way of obtaining information from the farmers in order to document experience. Some made long interviews, others made three or four visits and tape recorders were also used. Some presented the guidelines, explained the reason for the work and left the tape recorder with the farmer until the recording was ready for transcription. They used their own creativity to decide on the most appropriate method. The work aroused considerable interest among most FEs. The confidence established over the years between the farmers and the field agents was a crucial factor for success.

The field agents were enthusiastic about the task, but faced many difficulties. They realised that it was not enough simply to gather information during an initial interview. They had to complete and enhance farmers' statements, refresh farmers' memories, ask relevant questions, find the best illustrations, identify the titles that would most appeal to readers and highlight the main ideas. Most of the field agents confessed that this was far from an easy task.

Farmers found it fascinating to talk about their origins and were very voluble in this respect. Obviously, it was difficult for them to analyse their own experiments and the future of these initiatives. The field agents were amazed to learn what farmers thought about them and to see it written forthrightly in black and white. *"Previously we had no interest in technical advisors, we thought they were lazy and that their experiments were a waste of time ... now we understand the meaning of the experiments and have no desire to see our advisors go away."*

My life

FEs describe themselves as humble men and women working in adverse situations, risking their fragile economies, but eager to move forward to create a new and better future. Some regard themselves simply as curious, experimenting observers who talk about their observations and in this way get ideas for future experiments. Others see themselves as being disseminators or as being more interested in organising farmer experiments.

The bulk of these testimonies show clearly that the farmers live a very hard life. They relate how farming was introduced on this young frontier less than 50 years ago. They tell of migration, the number of farms they farmers went through before they established themselves on their present holding, the impressive size of their families (as many as 19 siblings) and the desolate state of the roads. In just a few pages readers get a clear picture of the true circumstances in which farmers live and work and can be brought close to the way farmers feel. Technical documents, reports and socioeconomic studies are unable to provide this sense of immediacy.

Through these testimonies, one realises that farmer experimentation is deeply rooted in the daily struggles of small-scale farmers. They reflect the reality of all FEs in Central America, and confirm the latest document published by the *Campesino a Campesino* Programme in Nicaragua (UNAG, 1999).

My experiments

It is evident that, in the eyes of the FEs, farmers' experiments go beyond setting up trial plots and studying and interpreting concrete results. The FEs stress the process as a whole and the impact it generates: creating an atmosphere of confidence between each other, generating a community movement, even though they still do not know where it will lead. *"FEs have become personalities"*, said one. They have acquired tremendous self-esteem and fuller awareness. They insist on the fact that they can now teach their neighbours and their children. They feel useful and the meetings, workshops and exchanges have broken their isolation.

Finally equal

The climate of confidence also had a positive effect on MAG field staff, researchers and others involved. Farmers who had previously tried to avoid them because they felt they were wasting their time now extended their friendship and sought their help. Relationship were now 100% better.

The oddest thing was the difficulties encountered in launching the task of getting testimonies. The approach provoked amazement. The testimonies were a sharp rebuke for those who felt there was no need to interview farmers because field agents had been working in this area for the past 10-15 years. They proved the farmers' force, conviction, faith and high sense of commitment to building a better world. They also showed the limits and bias in the knowledge of many MAG staff.

PRIAG financed the publication of some of these testimonies and delivered them to the farmers personally. The farmers use these documents as instruments to encourage others to accept the challenge to innovate. They had to try and find solutions to their problems themselves because they could not expect the solutions they needed to come from outside. They were proud to see their names and photographs in a book and to feel that, at long last, they were on an equal footing with the researchers who visited their farms.

Communicating innovation

Exchanges between FEs, local, regional and national meetings, fairs, congresses for FEs, written or visual testimonies (photos, TV, videos), regularly published magazines, local radio programmes, calendars, almanacs, T-shirts, caps and specific training workshops reflect the unlimited types of actions being invented and implemented in Central America to disseminate information on farmer innovation. There are many interesting examples.

Radio broadcasting

Panamanian FEs got involved in a radio programme in which they transmitted the results of their experiments themselves. In addition to their role as FEs, some of them have taken on the responsibility – together with MAG agents - of becoming radio correspondents. Equipped with a portable tape-recorder provided by PRIAG, they record their stories and send them to the main town in the region for the Sunday radio programme.

Filming own experiments

Farmers became involved in producing a video of their experiences. The idea originated in the Baja Verapaz region of Guatemala, where a group of 60 FEs attending a training workshop had just watched a technical film. When it came to analysing the film, several of them diplomatically stressed the importance of what they had just seen, but expressed concern about always having to watch the experiences of others. They suggested talking about their own experiences as FEs. They were then invited to answer the following question: "What images of your own activities as FEs would you like to see on the screen? Explain your reasons and argue your point." This was a long task that required several sessions, but a script was produced, the desired pictures were decided upon and filming dates were set. This resulted in the videos mentioned below.

Publications

In Nicaragua, many valuable experiences regarding the work of FEs are worth recording and making available to others. The monthly magazine Enlace, published by SIMAS (Central American Information Service on Sustainable Agriculture), has been reporting the history of one or several innovations in each of its issues since 1990. SIMAS also made up a "methodological basket" and distributed the publication to a large number of organisations and peasant outreach workers in the country. Its objective was to offer as many of the methodologies used by various Central American outreach workers as possible in the interests of promoting farmer experimentation.

Exchange fair

In 1997, the *Campesino a Campesino* Programme of UNAG in Nicaragua organised an "experience-exchange market" involving farmers and indigenous peoples in agricultural frontier areas. This was a meeting point for 140 innovating farmers from Central America. For two days, the participants displayed their work, using panels of photographs they had taken themselves. Each participant offered and asked for information as if they were actually in the main marketplace.

Television

Groups of FEs supported by the NGO Unicam in northern Nicaragua are also great believers in photographs seeing them as a practical and inexpensive way of showing their work to neighbours. As they become more involved in communicating their innovating activities, many farmers lose their fear of speaking in public and, every so often, they surprise others by appearing on television in Esteli, the region's capital city. *"Are these farmers really capable of standing in front of 150 people and talking about their experiences, using numbers, drawings and everything?"*

Farmers' diary

For the past few years, the National Extension Bureau of the MAG in Costa Rica has been publishing and distributing a type of log-book to farmers. Known as "My farm book", it enables farmers to keep daily records of their activities and to calculate their costs at the end of each month. Inserts with stories of innovative projects undertaken by farmers in different regions are interspersed throughout the book.

Ownership essential

Documenting and distributing information is one thing, but the use made of these documents is something else. A well-worn photograph much used by the innovating farmer is worth much more than a video of impressive quality that is confined to an air-conditioned room, a thesis containing congratulations from the awarding committee or a published article shelved by readers. The important thing is for innovators to do things for themselves and to be able to boast about their actions: *"I took these photos, I showed the video of our experience, I distributed primers, I handed out our testimonies…."* and so on. Ownership is an essential part the sharing, experimentation and communication that characterised all farmer innovation activities.

Broadening the process

In 1994, the Huetar Norte Regional Office of the Ministry of Agriculture and Livestock (MAG), assisted by PRIAG, introduced its technical advisors to a new working method with the aim of improving services and establishing closer relationship between advisors and farmers. A team of farmers and advisors set out to identify FEs, explore their innovating skills and to find out about their experiments. The team then went on to evaluate the impact of these innovations and experiments on production costs, pesticide use and environmental and soil degradation. Workshops were held for FEs and technical advisors. Experiments, results and experiences were discussed and plans made for further experimentation.

To broaden the scope of farmer experimentation, the working models were put into practice throughout the region Huetar Norte. The First Regional Congress for Innovating Farmers in the Huetar Norte Region was organised in August 1999. At the end of the event, the eighty participant FEs elected a regional, legal and permanent committee with the clear mandate to reinforce the research capacity of farmer organisations. It calls itself the Regional Committee of FEs of the Northern Zone (-CRAEZN). The Committee comprises five representatives of farmer organisations and two agronomists (one representative from the public sector (MAG), and one from the NGOs). An advisor from CIRAD supports the group.

A clearly defined mandate

The following mandate was given to CRAEZN:

- promote the creation of a Technical Experimentation Committee (comprised of FEs) in grassroots organisations
- negotiate and obtain economic and other resources in order to encourage and support the experiments conducted by farmer organisations, and create sustainable self-financing mechanisms to improve farmers' experiments
- draw up a regional farmer experimentation programme
- design projects that combine farmer experimentation with agro-industries and other economic activities
- provide training on farmer experimentation to farmers and agronomists
- organise the negotiation, collection, processing, management and dissemination of information on farmer experimentation
- promote the exchange of experiences between producer organisations through, e.g., discussion fora, field trips and local, regional and national congresses
- identify all farmers who are conducting experiments.

A significant step forward

Although this new initiative can be considered a continuation of other activities carried out in Costa Rica in the last decade, it is a significant step forward in qualitative terms. First of all, it was designed by the farmers themselves, representatives of producers' organisations and experts from the public and NGO sectors of the Huetar region. Second, in order to put farmers in charge of research and technology development, it focuses on farmer research methods and research financing controlled by producers' organisations rather than agricultural support services. Consequently, it is supposed to get more capacity to solve problems and influence public policies.

A challenge for all!

This new situation poses a challenge for researchers and technical advisors because it demands a radical change in their working methods. It means they will have to be more creative, communicative, tolerant, patient and capable of listening and sharing information and knowledge and apply these same values in drawing up and designing projects and realising their joint ideas and dreams. Field agents and researchers have to become facilitators committed to the educational process, combining the knowledge and experience of farmers and field agents in a ***learning dialogue***. This involves moving from a linear pattern of communication to a relationship of mutual cooperation where the contributions of each actor in the knowledge system are clearly acknowledged. ■

Towards a social movement of farmer innovation: *Campesino a Campesino*

Henri Hocdé, Jorge I. Vasquez, Eric Holt, Ann R. Braun

The "*Campesino a Campesino*" (CaC) or Farmer-to-Farmer programme was founded in Nicaragua in 1987 by the National Farmers and Cattle Ranchers Union (UNAG). It started with exchange visits between farmers from Nicaragua and Mexico in order to promote and diffuse appropriate technologies among poor farmers. The programme was a reaction to the top-down transfer-of-technology model that prevailed in Nicaragua during the 1980s promoting expensive technology packages involving improved varieties, irrigation, imported chemical fertilisers, pesticides and agricultural machinery. The programme sought to improve soil fertility, productivity and living standards, while reducing production costs and external dependency. The method has taken root throughout Central America and is applied by many NGOs and in some R&D projects. Over 10,000 farmers identify in one way or another with CaC and thousands more have been influenced by it (Holt-Giménez 2000), as they believe that farmers are capable of developing their own sustainable agriculture.

Farmer promoters

The key elements in the CaC approach are the "farmer promoters" and the mechanisms of communication used (Hocdé *in press)*. Farmer promoters are volunteers who conduct experiments in their own fields and share their knowledge and experience with others. Each takes responsibility for guiding a group of experimenting farmers from his/her community and visiting them regularly to help with planning, implementing and interpreting their experiments. They also organise exchanges between farmers and give training on topics determined by their own accumulated experience and concrete results that range from soil conservation, cover crops, husbandry, forestry and organic agriculture to cropping systems and diversification. Farmers themselves define the research agenda, manage the experiments and assess the results, either individually or in groups. Generally, they do not apply formal scientific methods such as the use of control plots or replications. Today, there are 700 farmer promoters working throughout Nicaragua in a wide range of agro-ecological and socioeconomic contexts.

Experimentation and communication

The farmer promoters' basic functions are to find technical solutions to problems in smallholder agriculture and to communicate them to neighbouring farmers who are also seeking solutions. In order to have credibility as communicators, promoters need to have tested recommendations on their own land. The two functions and processes -experimentation and communication- are therefore interdependent. Promoters do not recommend technical recipes or packages, but rather give suggestions and ideas to stimulate experimentation by others. A promoter's main tool for convincing others is through mentoring and setting an example rather than through the organisation of workshops or training events *per se*. The goal of CaC is to promote a culture of enquiry and experimentation among smallholder farmers.

Enhancing sharing and dissemination

Sharing and disseminating knowledge horizontally is a central responsibility of each promoter. Each communicates intensively with other farmers as well as with other promoters using traditional communication media such as sociodrama, theatre, poetry and music. A diversity of mechanisms such as fora and exchange visits are used and a wide variety of Participatory Rural Appraisal tools are used.

Exchanges are visits organised by promoters involving farmers, promoters and communities. They may involve small or large groups and may last between one and several days. In this way, farmer experiments are exposed to the critical eye of a variety of people, each with his or her own perspective. These are intensive training and learning opportunities and their pedagogical content can be considerable. During exchanges, participants explain and discuss results, methods and procedures, often amid criticism, argument and debate. Each participant analyses the strengths and weaknesses of his or her ideas and results before the group. The atmosphere of mutual reinforcement and encouragement permeates these events and helps motivate farmers to continue experimenting. Learning from mistakes is encouraged, as is the idea that each person follows his/her own problem-solving path. The art of facilitating these situations consists not only of creating a constructive and productive atmosphere, but in helping to bring out these ideas and synthesise them in such a way that the design of new experiments is oriented and guided . This requires that promoters be highly skilled in facilitation techniques.

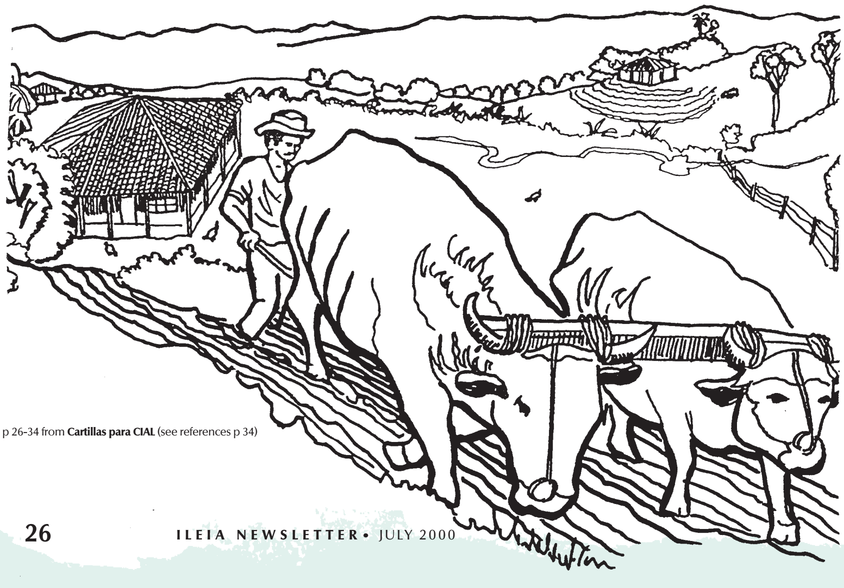
Radical changes

The CaC process can result in a radical change in the mental map farmers' have of their role in the process of technology generation and diffusion. Through involvement in the programme, farmers realise that they are capable of experimenting, offering solutions, communicating and transmitting technological options to others (Merlet 1995).

The CaC process builds enthusiasm, self-confidence, pride and hope for the future (*Programa de Campesino a Campesino* 1999). Motivation grows as creative capacities are tapped, and the attitude of dependency on external actors diminishes as farmers begin to identify themselves as experimenters. The most radical of the farmers involved in the programme view it as a way of breaking the monopoly of technology-development process held by agricultural professionals.

Technological lessons

The following lessons were derived. Farmers' research themes tend to concentrate on agronomic, animal husbandry and technical issues, not on socioeconomic aspects. In some cases, the advent of a



Drawings p 26-34 from **Cartillas para CIAL** (see references p 34)

We still have much to learn!

While more than 10,000 farmers and dozens of NGOs are part of the *Campesino a Campesino Movement*, hundreds of thousands more are not. The question is if CaC works so well, why hasn't it spread more? A recent, region-wide, participatory study (Holt, 1999), involving 40 institutions and 2,000 agroecological and conventional farmers, concluded that the obstacles for scaling up agroecology or 'sustainable agriculture' have less to do with technologies and methodologies than with national policy contexts and institutional behavior. But to further "scale out" sustainable agriculture, it also needs to be "scaled up" into existing agricultural policy frameworks. Some important constraints for up-scaling are:

- There has been little documentation and *systematization* done in a way that actually provides feedback to practicing technical advisors, promoters and farmers. This limits institutional learning, resulting in many projects "re-inventing the wheel". Furthermore, lateral learning by government and private sector institutions is generally poor and inconsistent, resulting in little headway for CaC outside of the informal social networks connecting remote villages and the NGO world.
- Not only is most formal agricultural research largely out of touch with sustainable agriculture and the farmers who actually practice it, comparatively few professionals are being trained in agroecology or in working with small farmers. This limits their ability to address agroecological problems, design effective on-farm agroecological experiments and accompany farmer innovation.
- Many NGOs adopted CaC participatory methodologies. However, this has not always led to greater farmer input or control over the program itself neither has farmer-led development necessarily become a guiding approach for NGOs. NGOs are still primarily accountable to donors, and few of them have direct mechanisms for accountability to farmers. The combination of "participation" and one-way accountability prevents clear strategies for farmer organization and empowerment.
- Despite its important program presence in one of the largest farmer's union in Central America, CaC has not been very successful in scaling-up its agenda within national and regional farmer organizations. Basically, promoters from CaC have been unable to penetrate decision-making circles dominated by medium and large-scale producers interested primarily in conventional agriculture. CaC remains a "special project" directed at smallholder clients, not a policy-setter or decision-locus for organizational policy.
- There are many policy mechanisms that could be brought in to improve conditions for sustainable agriculture and farmer-led development. However, the lack of effective political will on the part of governments and research centers makes this a remote possibility. Developing this political will depends largely on pressure from civil society. Unfortunately, the trans-institutional nature of CaC has not lent itself to forms of organization that could exert pressure on governments or research centers. NGOs are organized to implement projects not pressure governments. Farmer organizations can and do put pressure on governments, but not for policies that favour sustainable agriculture over, or even as much as, conventional agriculture.

Perhaps the most pressing lesson is simply that agriculture in general will change not only when farmers change, but when farmers and their allies are capable of changing the institutions that hold change back. We still have much to learn about just how to do that.

Adapted from: Holt-Giménez E. **Scaling-up sustainable agriculture: lessons from the Campesino a Campesino Movement in Meso-America.** Paper for workshop on "Going to scale" 10-14 April 2000, IIRR, Silang, Cavite, The Philippines.
- Holt-Giménez E, 1999. **Measuring farmer's agroecological resistance to hurricane Mitch in Central America.** In: Changes in the thought and practice of rural development in Central America, San Jose, Costa Rica. Free University of Amsterdam.

solution generated by promoters leads to excessive promotion of the technology over an ongoing search for solutions to other limiting factors. The strong emphasis on low-external-input techniques can be a barrier that dissuades some farmers from participating in the CaC movement, thus impeding its growth. More systematic agroecological learning and information on experiences from outside the farmer community, e.g. innovations developed by farmers operating in similar conditions or from scientific research, could provide new options for experimentation.

Methodological lessons

Farmers' concepts of the experimental process are different from those of formal researchers. For example, farmers may not limit what they regard as experimentation to plots specifically designated for that purpose.
The relationship between CaC initiatives and the formal research sector have traditionally been limited, with a few notable exceptions. Opponents of CaC approach contend that most formal researchers consider the experiments conducted by farmer promoters as an extension mechanism rather than as bonafide research. Advocates of the CaC approach complain that promoters have found few useful elements in the technical solutions offered by formal research. Overcoming the mutual reservations between promoters and researchers would undoubtedly constitute a leap forward, thereby improving and enriching the work conducted by both. Potential gains from the joint development of realistic solutions to concrete problems in farming lie not only in the better design and management of experiments, but also in the increased diversity of options that would become available.

Historical significance

Beside the technical and methodological limitations, Eric Holt-Giménez also mentions important policy and institutional constraints (Box). Despite all these limitations, the CaC experience constitutes an important reference point for both the farmers themselves and the formal agricultural services, in terms of demonstrating the potential of smallholder farmers as researchers and communicators. This approach is of historical significance, because it made a significant break with the conventional models of knowledge and technology transfer, rejecting passive knowledge banking in favour of active knowledge acquisition and generation.

Towards a social movement

A number of initiatives in or outside of Nicaragua are supposedly applying this approach. Innovation processes are social and collective actions. They are stimulated when a group of people share the same sense of purpose, learn to manage hazards and uncertainties, apply resources to develop their creative skills and socialise their results. The experience in Central America clearly shows that the old myth about creativity and innovation being a special gift reserved for geniuses has been overcome. The results reveal that we (all of us, not only farmers) are capable of being creative. The key factor is to support social processes that unleash the inventive skills of people and their organisations in order to create a permanent movement of innovation driven by the rural population.

Bringing Farmer Innovation to policy levels

Lobbying for policy support to local innovation

Photo: Will Critchley

Mitiku Haile

In 1996, the "Sasakawa Global 2000" campaign was launched in Tigray. This offered farmers a package of external inputs on credit and has focused on the better-watered areas. More and more farmers are being drawn into this scheme. Some farmers observed yield increases, especially in the initial years when rainfall was favourable.

Many farmers, however, are withdrawing from the scheme. They found that inputs were too expensive given uncertain rainfall and yields, and the lack of transport and marketing facilities. Some farmers question the suitability of chemical fertilisers for their conditions and want to use manure and other organic resources to enhance soil fertility. In pest management, many farmers find that Global 2000 methods ignore their indigenous techniques. The development agents (DAs) working directly with these farmers and Mekelle University, which offers development-oriented training began to recognise that farmers want extension to consider their own knowledge and creativity in land husbandry. It was evident that the approach to extension needed to be re-considered.

Research disregards potential partners

Agricultural researchers in Ethiopia usually set their own agenda on the basis of their own assumptions. With the recent decentralisation of research, the scientists were supposed to focus on alleviating the constraints to agriculture in their particular region and to solve local problems. However, no consideration was given to the fact that farmers might want to take part in the search for local solutions. Farmers have, of course, been experimenting on ways to manage soil, water, plants and animals for centuries, long before formal research began. They have developed an intimate knowledge of their environment and found new and better ways to manage local resources. Any research on agricultural intensification needs to consider this local knowledge and innovation.

Biased agricultural training

Agricultural education in Ethiopia, with few exceptions, has paid little attention to local knowledge. Course content and structure have been based on western concepts and large-scale commercial systems of production. The Ethiopian agrarian system is, however, highly fragmented and dominated by smallholders who are orientated mainly to subsistence. Education and training need to be transformed to reflect this reality and raise admiration for the farmers' abilities to produce under adverse conditions.

ISWC-Ethiopia recognised the need for policy change so that local knowledge and innovation would become the basis for formulating agricultural extension, research and training programmes. Therefore, besides identifying farmer innovation, extending promising local innovations and promoting participatory research to validate and develop them further, ISWC-Ethiopia tried to influence relevant policies.

Several targets

Different activities in lobbying for policy change were targeted at various levels of decision-making in several institutions:

- ***Baito*** (local council) The *baito* is the lowest level of government and together with the community it determines land use and management. ISWC-Ethiopia works closely with the Tigray BoA in organising village-level workshops, in which *baito* members become aware of the importance of farmer innovation.

- **Extension agents, specialists and supervisors** Through training sessions, field-level seminars and dialogue, extension staff in various positions are shown the processes and dynamics of local innovation. They are led to recognise innovations in their extension areas and the contribution of innovators to improving land husbandry. They are encouraged to integrate innovators into their extension work.

- **Research scientists and policy-makers** Researchers from Mekelle University, Mekelle Research Centre and the Ethiopian Agricultural Research Organisation and policy makers from BoA and the Ministries of Agriculture (MoA) and Education (MoE) are exposed to local innovation in land husbandry. They are drawn into discussing their policies on research and education.

- **The media** Representatives from the mass media are approached to spread information about innovative farmers and about promising innovations to a wider audience.

Strategies to invite policy dialogue

The major strategy is to arouse curiosity and enthusiasm among DAs, researchers and policy makers about local innovation.

DAs in particular have been quick to recognise innovators and invite them to be partners in extension. Researchers are challenged by DAs and farmer innovators to look more closely at certain innovations and, together with farmers, to work on them further. Policy makers are stimulated to recognise the importance of local knowledge and innovation in strengthening the extension system and in guiding research to help farmers improve what they already know.

ISWC-Ethiopia decided to pursue Participatory Technology Development (PTD) by introducing the concepts and spirit gradually on a wide front. Progress is slower than would be possible by focusing on a pilot area, but we will not face the problems of trying to scale up from a few isolated experiments. We do not impose PTD. Instead, researchers are challenged to open dialogue at every possible opportunity. We emphasise forging a functional link between researchers, DAs, *baitos* and innovators.

This emphasis has guided the choice of members in the ISWC-Ethiopia Steering Committee, which discusses and approves the annual project plans. Influential and committed persons were chosen who could foster partnership between stakeholders. The members include the Head of the BoA and individuals from research institutes and NGOs who have long experience in land husbandry research and development.

Examples of lobbying activities

Various types of activities were designed to influence policy either directly or indirectly. For example:

- **Network shops** bringing together researchers, DAs, policy makers and innovators have been organised at Regional, Zonal and District levels, and a national workshop is being planned; field trips to innovators are included;
- **Media coverage** the TV, radio and press are invited to make the achievements and aspirations of innovators more widely known; recently, journalists have, on their own initiative, visited innovators and interviewed them in their villages and at village-level workshops, as well as at fairs and conferences, such as the Anglophone Africa workshop on farmer innovation held in Mekelle earlier this year;
- **Newsletters** dealing with farmer innovation and written in the local Tigrigna language are produced twice a year for the farming communities, *baitos* and DAs;
- **Research reports, proceedings and journal articles** are written and distributed to researchers, BoA and MoA staff and policy makers;
- **Personal visits** are made to Government Ministries, Embassy officials and NGO heads to brief them about project approaches and activities;
- **Travelling seminars** bring farmer innovators, DAs and researchers to the sites of innovation and give innovators a chance to interact with village-level policy makers.

Some signs of change

Thus far, three years after the programme started in Tigray, we see signs that local innovation in land husbandry is being recognised and promoted.

Integration into BoA activities. Village-level seminars, during which villagers assess local innovations, are now being organised as part of BoA extension activities. Views of innovators are taken into account during land-use planning at village level. The BoA now organises awards not only for Global 2000 farmers but for local innovators (often, farmers who do not accept Global 2000). Innovators are involved in regional field days to show what they have achieved on their land and so gain recognition by researchers, DAs and policy makers. This encourages the innovators, creates opportunities for them to disseminate their innovations and stimulates discussions between different actors in agricultural development.

Increased openness in extension. Extension approaches and packages are becoming more open to local knowledge. DAs are recognising - and some are even documenting - farmers' informal experimentation in land husbandry. Concerns raised by farmer innovators are no longer hushed-up but brought to higher levels by DAs and the innovators themselves e.g at conferences. In the past, only farmers involved in the Global 2000 scheme were invited to regional farmers' conferences; now farmer innovators are invited too.

Official support to local initiatives. The BoA supports local initiatives, such as the activities started by communities to divide up rights to sloping land among community members. *Baitos* have responded to innovators' concerns about their rights to use improved land (see Box).

Change in attitude of researchers. Some researchers recognise that farmers do experiment and can be partners in research. A few are exploring farmers' innovations further in technical terms and are arranging PTD experiment with farmers. However, this aspect moves very slowly.

Incorporation into university teaching. A module on PTD has been incorporated into the "Research Methods" course given to all students of agriculture at Mekelle University. Several national and international MSc and PhD students are making field studies on farmer innovation and experimentation. Students doing their compulsory 5-month practical attachment are increasingly interested in documenting indigenous knowledge. In-service students from the BoA, NGOs and development projects are keen to continue examining local innovation when they return to their posts. Some of them even use their own resources (time, energy and material) to document innovations.

Local innovation for food security. Particularly in the drier areas of Tigray, farmers and DAs are criticising Global 2000 technology and find it unsuitable. DAs in southern Tigray actually challenge the targets being set for bringing farmers into the scheme. Now the Integrated Food Security Desk is exploring the potential of farmer innovation in identifying appropriate technologies for the 16 most drought-prone districts of Tigray.

How we influenced policy: testimony of a woman innovator

During our travelling seminar, we visited a fellow farmer in Southern Tigray in Raya Valley, where there was a very big and wide gully. It was not considered useful land during land allocation. A farmer had worked on the gully and made it productive, but when he started to grow crops there, the *baito* took the land over, saying he had enough land and that this reclaimed gully should be distributed to others. We saw this problem during the seminar and discussed it. The *baito* in Raya Valley reviewed the mistake it had made and gave the land back to the farmer. This is how we influenced policy.

Ms Leteyesus Gobena, ISWC Anglophone Workshop on Farmer Innovation in Africa, February 2000, Mekelle, Ethiopia

What next?

The various activities have been documented and a database of farmers' innovations has been established. However, it is still necessary that the documented observation be critically analysed in the field. This will help identify successful innovations that can already be disseminated and promising innovations that could be improved. It will be especially important that more researchers are attracted to support experimenting farmers in assessing and further developing their own innovations. It is our challenge now to maintain the dynamism of the process and to move into PTD on a broad basis.

Three models of extension by farmer innovators in Burkina Faso

Aly Ouedraogo and Hamado Sawadogo

Farmers in the Sahel zone of Burkina Faso have developed a method of rehabilitating degraded land. It is an improvement on the traditional planting pits known as *"zaï"*. On barren land, the farmers hack holes into the hard soil surface, fill the holes with organic matter and sow a few seeds of grain. A specific type of termite may be transferred to the pits, to speed up the decomposition of organic matter. Sometimes a tree seedling is planted or a tree seed is directly sown in the middle of the cereal plants. When the grain is harvested, the stalks are cut off at a height of about 1 m and this protects the tree seedlings from grazing animals. Over the years, this locally-improved traditional technique has led to the establishment of well-wooded farmland (Photo 1).

Many farmers have experimented with variations on the *zaï* theme, trying out different techniques to improve soil fertility and trying out various crop varieties and woody species to take advantage of the better conditions. A few farmers have taken the initiative to promote the spread of *zaï* and its various improvements. Here, three "extension models" developed by farmer innovators are described. These models are, in themselves, local innovations.

"Market-day" model

In the village of Gourga, 4 km west of Ouahigouya, the capital of Yatenga Region, Yacouba Sawadogo uses a "market-day" model to promote the spread of the *zaï*. He started improving the traditional planting pits around 1980. The *zaï* have since become recognised - also by scientists - as the most cost- and time-efficient technique in the Sahel for rehabilitating strongly degraded land.

Since 1984 Yacouba has been organising market days to share his experiences with *zaï*. These started as small events, but now each market day involves representatives from more than 100 villages. The events are organised twice a year. The first market day is held shortly after the harvest, and the farmers bring samples of the crop varieties (millet, sorghum, cowpea and maize) they have cultivated in their *zaï*. Yacouba stores this seed on his farm. The second market day is organised just before the rainy season. Farmers can then select the species and varieties they would like to plant in their *zaï*, taking into account the improved growing conditions.

Each market day has a specific theme. For instance, during the last market day, the accent was on growing sesame. An earlier theme was the use of *zaï* for growing trees through a system of direct seeding. At each market day, there is also a display of the local tools used to dig the *zaï*. This allows farmers from outside the region to see for themselves which tools can be used and to find out where they can buy them.

Yacouba receives many visitors. This costs him a substantial amount of time. The solution he has found to this problem is to request something from each visitor. People who come from abroad are asked to plant a tree, and groups of farmers from elsewhere in Burkina Faso or West Africa are requested to dig some *zaï* on his land. This works out as a sort of on-the-job training. The main problem, and one that has yet to be solved, is that Yacouba does not have very good seed storage facilities.

"*Zaï*-school" model

In the village of Somyanga, Ousseni Zoromé initiated the "*zaï*-school" model. In 1992 he started training some local farmers in how to make a good *zaï*. He chose the poorest possible site, immediately next to a major road between Ouahigouya and Ouagadougou, the capital city. The farmers managed to achieve a millet harvest of 400 kg per hectare on this very poor land. Anyone travelling along the main road saw this immediately, because it was a year of extreme drought and many crops had failed. The Minister of Agriculture also saw the plot and called in a team from national television to film it. Ousseni Zoromé, who had received no external support except some fuel for his old motor cycle from the regional department of agriculture, began to create new groups, which he calls "*zaï* schools". Each group has to collectively rehabilitate a piece of degraded land. In this way, all participants are trained on-the-job. There are currently 21 *zaï* schools with a total of more than 1000 members, and their numbers are increasingly rapidly.

The *zaï* schools are now organised into a regional union and Ousseni is seeking external support to expand and improve them. Each group has to pay a contribution of 5000 FCFA (US$8) to become a member of the union.

"Teacher-student" model

In the village of Gourcy, Ali Ouedraogo, a very experienced farmer innovator, has invested heavily in improved traditional

Yacouba Sawadogo has used the zaï to directly seed the trees and shrubs he wants on his fields.

Photo: Chris Reij

planting pits (*zaï*) in combination with compost production, tree planting and the protection of naturally-regenerating trees and shrubs. He is training individual farmers in five villages around Gourcy and visits them regularly, showing them how things should be done, giving them advice and exchanging ideas with them. His "students", in turn, train other farmers in improved *zaï* techniques.
Some of the students do not simply adopt what Ali suggests, they go on to adapt and experiment with his original ideas. For example, one farmer felt that the *zai's* Ali made were extremely large and required a great deal of work and physical strength to develop. Not everyone was able to this. The farmer therefore started to modify the layout and dimensions of the *zaï* to suit his capacities.

Voluntary extension

One interesting fact is that these farmer-led extension models were all developed on the initiative of the farmer innovators mentioned above. These farmers receive no remuneration for their time. At the most, they receive some limited external support for travel from local NGOs and individuals. Yacouba, for example, received a small, new motorcycle through his "Association for the Promotion of *Zaï*" (consisting entirely of farmers) so he could reach more villages. These farmers have no links with the government extension service, with the exception of Ousseni Zoromé's regional union that did receive some organisational suppport.

Moving towards wealth

The farmers in Yatenga Region and also in other parts of the densely populated Central Plateau of Burkina Faso are becoming increasingly interested in *zaï*. Under such dry conditions, this is not surprising. The pits collect and concentrate runoff water, and they allow farmers to use small quantities of manure and compost very efficiently.
All three of the above-mentioned farmers have many more trees on their fields than they had 20 years ago. Yacouba Sawadogo has used the *zaï* to directly seed the trees and shrubs he wants on his fields. In this way, he has created a forest of 12 ha with a considerable diversity of woody species. Since he can now feed his entire family even in drought years, Yacouba has shifted the accent from growing cereals to growing trees. When Ousseni Zoromé started to reclaim a large expanse of barren land in1983, there were only 9 trees remaining in these fields, now there are at least 2000. Ali Ouedraogo grows trees mainly alongside the stone bunds on the contours and in this way he has created windbreaks in his fields.
The use of *zaï* allows farmers to expand their resource base and to increase household food security. These three farmer innovators developed their own extension models because they are keen to share their experience with other farmers who, in turn, are keen to learn.

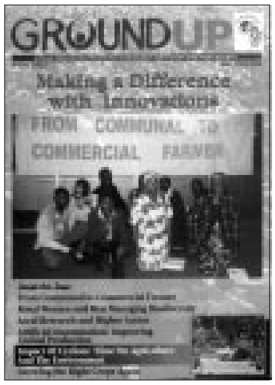
Pelum Association

GROUND UP

PELUM is a network of civil society organisations operating in East and Southern Africa. Pelum members work to facilitate learning, networking and advocacy in sustainable agriculture, natural resource management and household food security in order to secure community development amongst small holder families in the region. Members learn through linking their experiences of alternative approaches to agriculture and participatory development.



PELUM'S key startegies are information sifting and distribution, networking, short- and long-term training , off-farm seed saving and advocacy. It runs workshops, trains community development workers, identifies and distributes good books and articles and facilitates networking within the Association itself and among like-minded organisations.
PELUM has just begun producing a quarterly magazine **GROUND UP**. The latest edition is entitled **MAKING A DIFFERENCE WITH INNOVATIONS** and focuses on the theme of "sharing innovations". As the editorial reminds readers farmers have been innovating since time immemorial and today they are no less innovative than in the past. They contribute to innovations both as the sole creators of a final innovation and as contributors (often undervalued and unacknowledge) to improved innovations of researchers and inventors. Farmers are often the source of the (raw) information - derived from their indigenous knowledge and experiences - used by "outside" researchers, engineers and inventors in the process of developing "new" technologies. PELUM argues for a strengthening of partnerships between farmers and researchers making sure that farmers' contributions are openly acknowledged.

GROUND UP can be ordered from: The PELUM Associatin, Box MP 1059 Mt Pleasant, Harare, Zimbabwe. Subscriptions cost US$20 per year.

Local innovation and wider development in Tunisia: Gafsa regional radio

Noureddine Nasr, El Ayech Hdaidi and Ali Ben Ayed

The Indigenous Soil and Water Conservation (ISWC) project in Tunisia is coordinated by a team from the Institut des Régions Arides (Arid Zones Institute), a research organisation working in central and southern Tunisia. Here there are regional radio stations in the cities of Gafsa, Tataouine and Gabès.
The project selected Gafsa for two reasons. First, two-thirds of the innovators identified live in the zones covered by this station and second, the new programme "Agriculture and Innovation" could replace a programme on "Agricultural Extension".

The new 2-hour programme went out on the same day and at the same time as the old one and the presenter of the earlier programme (El Ayech Hdaidi) took over responsibility for the new one, which helped to maintain the link with listeners. A sociologist from the Arid Zones Institute worked with him.

Bringing stakeholders together

When "Agriculture and Innovation" started in March 1999, it was itself an innovation. It was the first time that a radio programme in Tunisia systematically invited farmers to present their knowledge and experience. Usually it was researchers and technical advisors who passed on information and recommendations to farmers. Agricultural extension in Tunisia meant teaching and training farmers, not listening to and learning from them.
The radio programme not only invites farmers to present their innovations. It also involves researchers, training specialists and development agents in debates about the innovations. Sometimes, these stakeholders in development sit together in the studio, but specialists can also call in by phone. This means that innovators do not need to travel long distances to the radio station to share their ideas with others. Several radio programmes were presented in this way from a distance. Sometimes, innovations from different regions were presented in the same broadcast. Innovators and listeners with telephones can take part in the debate from anywhere in the region. To stimulate the participation of as many listeners as possible, the contents of each programme is announced in the weekly magazine of the National Union of Agriculture and Fisheries. The Arid Zones Institute also makes sure that all regional Departments of Agriculture in central and southern Tunisia know what will be in the next programme and invites staff to take part.
In its first year, 100 farmers (85 men and15 women) presented a wide range of innovations, including economising on water use in cropping, soil fertility management, fruit-tree husbandry (grafting fruit trees on the root system of a shrub which indicates good soil fertility and soil humidity), small livestock rearing, breed improvement, and bee and poultry keeping.

Prizes for good listeners

To encourage the listeners to follow the programme closely and to get some feedback, a system of prizes was introduced. Once every two weeks, a prize of 50 Tunisian dinars (about US$ 45) is awarded to a listener who has responded by mail to a question posed by the presenters. The questions are usually about the innovators and innovations. Sometimes, listeners are invited to report on new innovations. This has proved a good way of identifying additional innovative farmers, both men and women. The prizes are provided by the project and by research and development institutions and local organisations.

Letters to the radio

After each broadcast, the radio station receives 20-30 letters from listeners, mostly from rural areas and especially from women (90%). In the case of the older, usually illiterate women, the letters have been written for them by their school-going children or by younger women in the village. The letters include:

- answers to the presenters' questions about the innovations discussed;
- information from listeners about new innovations, often asking if they can be described on the radio. Innovations

identified in this way include techniques for planting cactus and fig trees, local remedies for diseases of fowl and small livestock, and managing rainfed vineyards to produce table wine;
- requests for more details about specific innovations, because the listeners want to try them out;
- descriptions of how listeners tried out innovations presented on the radio; these include hatching chicken eggs in piles of dry manure, grafting prunes and peaches on the roots of jujubier (*Zizyphus lotus*), planting olive trees on cactus paddles, and drip-irrigation using plastic bottles;
- suggestions of new topics for the radio programme, such as pruning fruit trees, growing early crops under glass, artificial insemination, milk production, and keeping poultry and rabbits;
- congratulations and encouragement to the presenters;
- proposals of field visits or interviews.

Some listeners have suggested starting a parallel TV programme to show the best innovations.

Impact of extension by radio

A survey was made to evaluate the impact of the radio programme. The mail received was analysed for content. The men and women who had presented their innovations on the radio were visited to find out whether they had continued to develop their innovations and whether other farmers or extension agents had visited them. The listeners who had received prizes were visited. Farmers in villages along the Gabès-Gafsa and Gafsa-Maknassy-Mazouna roads were interviewed at random in places where farmers frequently meet, such as shops, reforestation sites and local extension-service offices. The programme had four major types of impact.

Provided incentives for innovators to continue innovating

For most of the men and women farmers who had presented their innovations on the regional radio, the experience had been an important social incentive. After the broadcast, several innovators continued to develop their innovations or started to develop new ones. For example:

- Mr Béchir Nasri, an innovator in Médénine Region (Nasr et al. 1999), invented a new system for pumping water from cisterns and a new technique for conserving wax honeycombs in beehives; he is now working on a technique to filter sediment from runoff water in order to avoid deposition in cisterns;
- Mr Khlifa Dadi, an innovator in Mareth Region (Chahbani & Nasr 1999), developed new irrigation techniques which economise on the use of water. These are adaptations of an innovation he saw during a visit to another innovator featured on the radio;
- Mrs Mbirika Chokri and Mrs Naziha El-Fahem (Chahbani & Nasr 1999) have increased their production efforts since they were on the radio. Mrs Naziha produces chicks and supplies them to about 10 other women who want to raise poultry using a micro-credit scheme developed by a project in Mazouna as a result of her radio presentation.

Encouraged visits to innovators

Since speaking on the radio, most innovators have been visited by other farmers and agricultural technicians. During his presentation, one innovator who distils cosmetic plants made an appeal to other farmers to grow these plants on a contract basis. A few days later, he was visited by a group of farmers. This visit was organised by the Presidential Pilot Project on Agricultural Extension based in Gafsa, which records all broadcasts of "Agriculture and Innovation" for use in their extension workshops. A few months later, when the farmer was interviewed on radio again, he mentioned that he had already signed production contracts with 20 farmers. Four innovators (including one woman) were visited by the Director of the Gafsa Regional Department of Agriculture. These visits were incentives to both the innovators and the extension agents, and indicate that new relationships are developing between farmers, development workers, research scientists and policymakers.

Adoption and adaptation by listeners

Analysis of the survey results and of the letters to the radio station showed that several listeners had adopted and, in many cases, adapted the innovations presented on the radio. For example, more than 50 men and women farmers were trying out the bottle-method of drip irrigation, and 5 women were hatching eggs in manure.

Changed attitudes

The radio broadcasts have also started to influence the attitudes of researchers and development agents. When the ISWC programme started in Tunisia in August 1997, the approach of seeking out local innovations as stimuli for rural development was strongly criticised and some research and extension staff even ridiculed it. After the first innovators had been identified and particularly since the radio programme started, it is evident that there is growing positive interest in this new approach.

Mass media and innovation

Listeners request that the regional radio programme be continued and extended to other regional stations and to national radio. This can be done only when development agencies and, in particular, farmers' organisations accept responsibility for and "ownership" of these radio programmes by making contact between local innovators and the radio station, encouraging farmers to listen to the programme, and so on. It is important that other mass media (the press and TV) also be used systematically to convey the message that men and women farmers are taking initiatives in developing useful technologies and improving their livelihoods.

Urban Agriculture Magazine

→ **http://www.ruaf.org**

Growing cities and populations are one of the big challenges of the future. The importance of Urban Agriculture (UA) in sustainable urban development is growing. **The Resource Centre on Urban Agriculture and Forestry (RUAF-) Programme** was developed to fill this information gap. The **Urban Agriculture Magazine (UA-Magazine)** is one of the ways the RUAF project intends to facilitate the flow of information and discussion on the actual and potential roles of intra-urban and peri-urban agriculture. The first issue of the UA-Magazine gives an overview of UA concepts and cases, and discusses UA as a mechanism applied by disadvantaged families to secure their livelihood under adverse conditions. The UA Magazine is **published on the RUAF web-site and in hardcopy form**. The RUAF web-site also provides reviews of recent publications, databases of institutes and persons and an bibliographic database.

Innovator Samuel Toh explaining the night paddocking technic to a radio agent during a study tour in Babanki. The paddock has just been tilled. A visiting farmer listens attentively and makes notes.

Chains of innovation by farmers in Cameroon

Paul Tchawa

Samuel Toh's farm in Upper Babanki is almost 2000 m above sea level and receives about 1500 mm of rain each year between May and September. Population density is about 150 persons/km². The "grassfields", where Bororo Fulani pastoralists keep their cattle, lie above the farming areas. In the early 1980s, Toh saw that his soils were becoming poorer and that, with population growth, there was less space for traditional long fallow to restore soil fertility. Bororo cattle grazed in the surrounding hills and he began to collect manure and transport it in jute sacks to his field. As this was strenuous work, he decided to build a fence around his field and to ask a Bororo herder to bring his cattle there each night for about a month. Afterwards he cultivated the fertilised area and the bumper crop he was able to harvest showed him that his new system worked. Over time, Toh improved his system. For example, he noticed that the animals tend to concentrate in one corner of the field and the manure was not well distributed. He subdivided the paddock, and the cattle were moved each night to different subdivisions.

Toh's innovation met with extraordinary success. One plant in particular is grown regularly after manuring: black nightshade or wonderberry (*Solanum nigrum*). Its leaves are eaten like spinach and are highly appreciated in Northwest Cameroon and in the cities of Yaounde (Central Province), Kumba (Southwest) and Douala (Coastal). Almost all farmers in Upper Babanki (more than 500 families) have adopted the night-paddock system, and a stream of traders in "bush taxis" weave through the villages to collect the leaves and take them to the city markets. Usually, the farmers grow nightshade for two years and then maize for another two years. The cattle then return and the fields are manured again.

New harvesting tool

Besides bringing direct benefits in terms of income, the innovation has borne other fruits as well.

With better soil fertility, farmers had five times as many nightshade leaves to harvest several times per season. It is hard work to break off the stems by hand. In the early 1990s, another local farmer, Phillip Ndong, tried to harvest with a knife but it was not sharp enough. Moreover, because the women and children were involved in harvesting several knives were needed and this was expensive.

He then tried using a razor blade held directly with the fingers. This cut the stems better, but also often cut into the fingers. He therefore took a piece of bamboo about 20 cm long and attached the razor blade to the end. After trying out several types of blade, he settled on one with three holes, which could be fixed firmly to the bamboo with thread. With this tool, which costs less than 25 FCFA (FF 0.25 or US$ 0.04), the price of a razor blade, the nightshade leaves can be cut quickly and efficiently and, because the stems are not damaged, leaf re-growth is stimulated.

Neighbours were sceptical at first, but now all nightshade growers in the area use Ndong's innovation. It spread spontaneously. Then another farmer in Babanki, Christopher Vitsuh, noticed that market demand for nightshade leaves was not being satisfied in the dry season and the price therefore increased threefold. This inspired him to develop a system of irrigation by gravity, so that he could produce nightshade leaves in the off-season.

Market demand

Since the 1960s, small canals have been dug in the Babanki area to conduct water towards brick-making yards. In 1986, Vitsuh thought of using the same technique to lead water to his farm. The night-paddock system had greatly increased nightshade leaf production in the wet season and the fertility could still be used in the dry months if there was water. Vitsuh started a small irrigation system, that expanded as additional families wanted to be connected to it. In 1999, the system was irrigating more than 10 ha to the benefit of some 40 farm families.

When Vitsuh had first thought of this idea, he contacted some advisors in water engineering. After examining the site, these experts estimated it would cost six million FCFA (60,000 FF) to set up the system. As Vitsuh could not afford this, he had the choice of giving up the idea or working out something himself. He did the latter and his initial network of 5 km of canals cost him only 110,000 FCFA (1100 FF).

To begin with, Vitsuh identified streams that could be diverted into canals. Depending on the location of the plots of the other farmers involved, the most

Participatory research on night-paddock manuring

A team composed of members of ISWC Cameroon, CIPCRE (a local non-governmental organisation), the University of Dschang, the Institute of Agricultural Research for Development (IRAD) and farmers has been formed to examine the production of nightshade (*Solanum nigrum*) in Babanki. The village lies
30km from Bamenda on the road to Nkambe. Here, market gardening is an important income-generating activity,and nightshade is the major crop.
Farmer innovators and the ISWC coordinator organised a workshop in June 1999 to identify priorities for joint experimentation. About 50 men and women farmers met at the palace of the traditional chief (Fon). During this workshop, the farmer innovators said they knew that the researchers' priorities differed from their own, but stated clearly: "Let's work first on our priorities; then we can help you with yours". They specified which aspects of the night-paddock system they wanted to address.
The farmers were paddocking 50 head of cattle overnight for one month, but suspected that these plots were being too well fertilised, while manure was needed for other plots. They wanted to know how many cattle should be kept in a paddock and for how long to ensure the best level of soil fertility, and what was the best crop succession to follow after manuring. The researchers agreed that they would address these questions first. During a second workshop in July 1999, details of the experiments were discussed and everyones task was defined. The researchers were so impressed by Samuel Toh's analysis and presentation at this workshop that they gave him the nickname "The Professor".
The experiments were carried out on the fields of four farmer innovators. They make their own recordings although this does not mean that they are the only ones involved in experimentation. They receive considerable support from the Fon and the villagers.
After they have dealt with the issue of maximising the benefits of manure, the researchers were keen to address their own priorities, such as examining the nutritional quality of the nightshade leaves, studying how increases in the cattle population was affecting the environment, and evaluating the forage species available to cattle. As long as farmers are also interested in these questions, participatory research can continue for the benefit of both local farmers and the larger world of research and development.

Paul Tchawa, Chris Reij and Ann Waters-Bayer, ISWC Programme

appropriate routes were chosen. As the land is prone to erosion and the canal sides could cave in, the farmers planted live hedges to stabilise them. When they had to cross a deep gorge or major watercourse, they used hollowed-out logs as pipes to link the two steep banks.

Community control

The new technology also led to social innovation. A management committee was set up in the community to arrange the distribution of the water to the different plots and to solve possible conflicts. Water is distributed on the basis of strict rules set by the farmers themselves. If the rules are not respected fines are levied. Farmers who have not contributed to digging the canals must give the management committee 20 litres of palm wine, a basket of maize flour and a cock if they want to irrigate their plot.

This innovation is characterised by people coming together because of a certain problem, the simplicity of the means used and a great potential for improving income. There was no outside intervention in building and managing this new irrigation system. Farmers in other parts of the village still seek the innovator's support to be linked to the network. Vitsuh conveyed this request to the Indigenous Soil and Water Conservation (ISWC) programme. As a result, a geometrician joined Vitsuh, helped survey the entire system and helped him improve and extend it.

Mutual inspiration

This case shows that, as isolated as some farmers' innovations may seem at first glance, there may be close and logical connections between them. In Babanki, one innovation triggered a series of innovations. The explosion in nightshade production led to a high demand for cattle manure and a more than two-fold increase in the number of cattle kept in the area. To reduce the cost (in terms of materials and time) of enclosing the animals overnight, some farmers have begun to experiment with live fencing. Under the in contract with the herders, the farmers have to feed the cattle for one month and some have started to plant fodder grasses.

Chain of innovations

Babanki farmers developed a chain of innovations:

- Night-paddock system
- Contracts between farmers and herders
- New harvesting tool
- Irrigation system
- Live fences for paddocks
- Growing fodder grasses

The relationships between the sedentary farmers and the mobile Bororo herders used to be tense, because the cattle sometimes damaged the crops and farmers expanded their fields into grazing areas. The contracts between the Babanki farmers and the Bororo for enclosing the cattle overnight on farmers' fields for a month each year has improved the relationships between the two groups.

It is also interesting to note that the links between innovations also link innovators, and they admire and respect each other. The development and mastery of an innovation by one person stimulates others. As a farmer in Babanki said: "After fertilising a patch of ground, you lose a lot if water cannot reach it". The farmers obviously do not regard these innovations as isolated developments. It is therefore not surprising that Samuel Toh, Phillip Ndong and Christopher Vitsuh support each other actively in developing their innovations.

Digging the pit

Sowing maize in pits: farmer innovation in Tanzania

Anderson Temu, Zacharia Malley, Salome Mwigune and Norsis Kinabo

Wilbert Mville, a 34 year-old farmer, lives in Itulike Village in Njombe District in the Southern Highlands of Tanzania. This is an area of sloping and undulating land at an altitude of between 990-2200 m. Temperatures range from 13 to 18ºC, and annual rainfall (November-April) varies with altitude from 600 to 1500 mm. The dominant soils are red kaolinitic clays with moderate natural fertility and medium to high water-holding capacity. Under continuous cropping, they degrade quickly through compaction, and plant rooting is shallow.

Research-minded farmers

In these and similar areas of southern Tanzania, the Indigenous Soil and Water Conservation Programme (ISWCP) set out to identify farmer innovators. This was the first step in establishing a process of Participatory Technology Development (PTD). Researchers and extensionists were trained in tools for farmer-led analysis and experimentation, an approach very different from the scientist-led research that dominates the official level in Tanzania.

Two PTD training workshops in March 1998 and April 1999 were crucial to changing the attitude and behaviour of researchers and extensionists from a conventional transfer-of-technology approach to a more participatory one. Workshop participants learned about innovation and informal experimentation by "research-minded" farmers. It was stressed that these should not be confused with "progressive" or "contact farmers" who had the resources to adopt techniques suggested by extension officers. Farmers who are less responsive to such messages often have fewer resources, but may still be very active in trying out new things in their farming system (Veldhuizen et al. 1997).

Locally-developed LEISA

A field trip during the 1998 workshop in Njombe exposed researchers to farmer innovation. Godson Lupenza, a village extension officer (VEO) in Njombe who had seen Mville's maize pits, suggested that a field-work group should visit him. The group members marvelled at Mville's willingness to speak, listen and answer questions, and his amazing knowledge. He had developed several innovations, e.g. different ways of planting maize, a pipe system to distribute water and cattle urine to his fields, a tree nursery and fish ponds. The scientists were keen to analyse these innovations and start joint research with Mville, who had already – on his own initiative – outlined topics for experimentation:

- comparing maize yield from large and small pits;
- trying bigger pits, each seeded with up to 30 plants, without thinning;
- sowing on raised seedbeds in old pits (from the previous season) to observe yield response to residual fertility;
- using compost instead of manure and crop stover as organic fertiliser;
- one top dressing of slurry compared with three top dressings.

Closer look

When two of the researchers (Temu and Malley) visited Mville again in February 1999, he explained that his ideas came from seeing that extension officers recommended sowing 2-3 seeds together in rows if there were enough nutrients (organic or inorganic). He reasoned that it must be possible to sow many more seeds in a pit that was rich in organic matter and still obtain a good yield. Since the soils on his farm are exhausted and because he had enough farmyard manure (FYM), plant materials and animal feed refuse, he set about designing the pit method. A year later, in 1997, he tried it on a small scale and modified it in 1998.

His technique involves digging pits 60-120 cm in diameter, 30-60 cm deep and 75-100 cm apart. Crop residues and manure (one bucket of 20-litre) are put into each pit and mixed with topsoil. 20-25 maize seeds are then sown in each pit and later thinned to 15-18 plants, depending on the size of the pit. He top-dresses the maize with a mixture of manure slurry from the kraal floor and urine collected with his piped system, diluted 1:1 with water. On each of three consecutive days, he applies about 2 litres of this mixture per pit. The following season, he makes new pits on the undisturbed soil between the previous season's pits. In this way, he hopes eventually to saturate the field with organic manure and thus improve the soil. Mville noted that he harvested 20 bags/acre (5 t/ha). When he planted in rows his yield was less than 5 bag/acre (1.25 t/ha).

Mville's wife works with him and has introduced her own experiments. For example, after the maize was harvested, she planted leafy vegetables irrigated by the pipe system to see how residual fertility could be used.

Technical staff

In the 1998/99 season, Mville began a trial to compare the effect of pit size on maize yield, a topic he had mentioned during the first workshop. He and his wife jointly monitored the trials, and she kept the records. A neighbouring farmer, Rose Kitamkanga, saw what Mville was doing and decided to experiment on her own to find out whether pit planting with manure produces more local maize than conventional row planting. The technical staff (researchers and extensionists) joined these experimenting farmers in the middle of the growing season. We had still been trying to work out mechanisms for participatory research, so the farmers started their trials without us! We helped them identify simple assessment criteria so that, at the season's end, they could use them to interpret the results. The farmers were able to record many parameters, the researchers only had to record a few including pit dimension, grain yield and soil analysis. Grain yield was measured at harvest in the presence of the innovators, VEOs and researchers.

Results

The results of these two trials, plus more from other farmer innovators, were presented in two farmer experimentation workshops held in November 1999 in Iringa and Mbeya Districts. Assisted by researchers and VEOs, the farmers used flipcharts to present their data to the other innovators. Results were discussed in a plenary session.

Farmers' comments

Mville and his wife noted that the larger pits produced better results than the smaller ones (8.8 compared to 3.6 t/ha). Rose noted that the maize yield from pits was 50% higher than from rows. The other farmers made the following comments on the trials and the results:

- the plot size for large pits was smaller than for small pits;
- the exact amount of FYM in Mville's trial was not known;
- the fertilisation schedule differed in the comparison of row and pit planting;
- the amount of urea applied was not specified.

Table 1: Results from Mville's experiment, using introduced maize variety

	Size of pit	
Parameter	Large	Small
Area of maize plot (m^2)	28	100
Number of pits	8	56

Grain yield (t/ha)	6.0	4.0

Observations

It was interesting to note that farmers saw the need to standardise non-experimental factors so that fair comparisons could be made between treatments. During the workshops, researchers guided farmers to brainstorm about other rules that could improve experiments in the next season. The importance of design, replication, randomisation, controls and plot area for trials, for example, were discussed. We all agreed that these principles would be put into practice when joint experiments were conducted in the 1999/2000 season.

Innovation spreads

The pit-planting technique spread quickly and was made known through:

- visits by individual farmers (mainly neighbours) to Mville's farm;
- farmer-exchange visits facilitated by the ISWCP;
- farmer-innovator and farmer-experimentation workshops;
- publication in the Swahili newsletter *Pambazuko* produced by a national farmer network (MVIWATA);
- presentation by Mville at the NANE Annual Agricultural Show in Arusha in August 1999;
- publicity through church congregations.

A quick survey made in Itulike and Wikichi Villages in Njombe District in June 1999 found that 71 farmers had already adopted or were adapting the innovation. Three farmers in Iringa District, who had seen it during exchange visits were trying out pit planting for themselves. However, while farmers are keen on the technique, it was agreed during the farmer-experimentation workshops that the innovation will be studied again in the 1999/2000 season and that the rules of experimentation decided upon in the workshop should be applied. Initially, only two treatments were selected: row vs. pit planting. We agreed on factors to be kept constant and data to be monitor. There are 11 farmers (replicates) doing the trial in Njombe and 3 in Iringa District. The trials are being closely monitored by farmers, extensionists and researchers.

Advantages to explore

Mville's data suggest that his technique may be a promising alternative to conventional row planting. However, labour input comparisons are needed. Pit planting cannot be easily mechanised; it may therefore be more suitable for farmers who cannot afford mechanisation. From our point of view, the advantages of this innovation appears to be:

- improved soil productivity over time;
- simpler weeding, as weeds only need be hand-pulled from the pits;
- reduction in labour for field preparation, because tillage is minimal: only in the pits;
- less erosion, as less soil is detached from non-pitted area;
- the pits collect runoff, allowing it to infiltrate and be conserved in the spongy organic fraction of the soil in the pits;
- concentration of nutrients in the pits and looseness of the soil favour maize root growth and nutrient absorption.

After analysing the results of the initial PTD trials, we will start working with the farmers on further studies to explore the potentials of this local innovation.

Forging partnerships with innovative farmers in Tanzania

O.T. Kibwana

New ideas are the key to agricultural development. In today's dominant model, researchers develop and test new ideas, extension agents package them into "messages" and farmers are told what to do. A very specific status hierarchy is perceived by all the actors. While the ineffectiveness of this linear model is now recognised, the question of how researchers find out the relevance of innovations at field level remains open. Mechanisms have been introduced to feed back farmers' opinions via the extension system to researchers, but they have done little to change the assumption that new ideas originate from experts working at a superior level.

The Indigenous Soil and Water Conservation Programme (ISWCP) in Tanzania (see Box 1) recognises that such experts are an important source of new ideas. But it also believes and has concrete evidence that farmers are very resourceful in generating and testing new ideas.

Agricultural development demands continual innovation. All farmers innovate in their struggle to make a living from the soil. However, not all farmers innovate to the same extent. There are always those who lead the way. ISWCP's challenge was to identify these farmers and to forge a genuine partnership between them, and researchers and extension agents.

Before ISWCP began there had already been interactions between these actors, and the attitudes, behavioural patterns and role definitions that had developed were being taken for granted. To change these attitudes meant creating a "new order". ISWCP tackled this task in the following way.

Breaking the ice

One of the first activities of ISWCP was to bring together researchers and extension agents in a **Joint research-extension workshop on PTD**. "Experts" in agriculture believe they are more open to new ideas than farmers, and see themselves as "Agents of Change". The workshop aimed at getting researchers and extension agents to agree on a new concept of farmer innovation (as they were still thinking of "innovators", "adopters" and "laggards" in the terminology of transfer-of-technology extension), and at introducing and offering training in participatory methods. A longer-term objective was to nurture a working relationship between research and extension. The workshop gave participants the opportunity to understand and appreciate each other's roles and points of view, and led to the setting up of mixed teams to identify farmer innovators.

Opening eyes

Farmer innovators and innovations had to be identifying and analysed. ISWCP began by selecting two or three divisions within each district according to the extension staff's evaluation of the general level of innovativeness in the area and whether village-level extension staff who had attended the PTD workshop were based in the division.

Research and extension teams were formed. These consisted of the divisional extension officer (DEO), selected village extension workers (VEWs) and a researcher from one of the two research organisations in ISWCP-Tanzania's National Steering Committee (NSC). As only one researcher works in each region, that researcher takes part in all the divisional research-extension teams in that region. VEWs were selected according to their interests, capabilities and disposition to regard farmers as creative. Team leaders were people from above the divisional level who were known to be interested in participatory research and extension.

The different approaches adopted in identifying innovators reflected the composition and orientation of each team. In some areas, the teams asked the local VEWs to identify local innovators. Others asked the VEWs to convene a meeting of community leaders to discuss the general topic of farmer innovation and experimentation. Community leaders were then asked to identify local innovators. In Njombe, for example, 12 innovators were identified in this way.

The teams visited the farmers identified as innovative and saw and documented their work. In the case of the more technically-oriented teams working through VEWs, the teams screened which innovations were interesting to document. Where community leaders were involved in identification, they met with the identified farmers and the research-extension team to discuss techniques and distinguish between innovations and traditional practices.

Innovator Profiles

The VEWs, assisted by the researchers, created innovator profiles using a format provided by the ISWCP. Profiles consisted of bio-data, economic status, social influence, neighbours' perceptions and motives for innovation. They found that:

- Most innovators had responded to problems they faced during their daily work, i.e. their motivation was to solve problems;
- Most innovators were middle-aged men with families, but the more striking

Photo: Laurens van Veldhuizen

Farmers discussing their experiences of "partnerships"

Partnership in action: planning future activities.

Photo: Laurens van Veldhuizen

innovations were undertaken by males in their early 30s;

- Some of the older male innovators held official positions in their localities; the younger ones were seen as being wayward. One was nicknamed "Pwagu", a popular character in a radio play who is always trying out new ideas but with little success;
- Better-off innovators embarked on more expensive innovations requiring purchased materials and hired labour, the poorer ones on simpler, less resource-demanding innovations; however, many who started resource-poor became richer through their innovations;
- Fewer women were identified as innovators, and their innovations tend to be homestead centred (e.g. mixing urine with manure from stall-fed cattle);
- Most innovators claim to have been inspired by their own ideas and curiosity; few admit to having been inspired by other farmers or extension agents; only later did it become possible to trace the origin of any particular innovation.

Let's get together

Parallel workshops for farmer innovators were organised at regional level (Iringa, Mbeya and Ruvuma), bringing together farmer innovators from several districts The general design of the workshops was made by a researcher, a PTD trainer and a woman who heads the national farmers' organisation. The main objectives were to provide a forum for exchanging experiences and to stimulate networking among the innovators. This was important because innovators often felt isolated within their own communities and unappreciated by the "experts" in research and extension services. The facilitation team for each workshop included a researcher, a PTD trainer, an extension agent and a farmer.

The farmer innovators greatly appreciated the workshops. For many, it was the first time they had travelled across district boundaries and their first opportunity to explain to others what they were doing. They exchanged seeds and planting materials as well as ideas. During the workshops, participants examined some innovations in the field and assessed their strengths and weaknesses. New friendships were made and innovators were enthusiastic to learn more from each other.

Farmers learn from farmers

Cross visits were organised in two stages. First, farmer innovators from one district visited others in the same district for three days and each group member played host in turn. Then, a group of innovators from one district visited innovators in another district within the region. VEWs accompanied farmers on their intra-district visits and the DEO went with them on inter-district visits.

The cross visits took place in December 1998. After each visit, group members evaluated what they had seen and identified the ideas to try out at home. In April/May 1999, teams of VEWs visited the farmers involved to see what they had put into practice. Farmers had been very active. The newly acquired seeds and planting materials had been tested. Some of the innovations had also been adopted, the most striking being the sowing of several maize seeds in a pit, the idea of Wilbert Mville in Njombe (see Temu et al., p.12). Seventy-nine farmers trying out this technique were identified in Njombe District alone. No wonder one farmer commented that "Learning from exchange visits is better than being visited by a VEW".

Agreeing on topics

Researchers and farmers often have different ideas about what problems should be studied first. Negotiations are needed to reach consensus on the relative importance of problems. Only then can joint action start. This process requires that each stakeholder group has the capacity to express its own position. Preparatory work is needed if fair negotiations are to take place. ISWCP tackled this on two fronts: by confronting the "experts" and addressing the farmer innovators. A series of workshops were held to help experts appreciate the farmers' potentials. Meanwhile, the process of identifying innovators, regional workshops and cross visits had served to strengthen the position of the farmers, who had became more confident, assertive and better able to argue their interests.

Negotiating priorities

Once these two parallel processes had matured, priorities could be set for joint experimentation building on local innovations. Multidisciplinary teams consisting of researchers (agronomists and soil scientists) and the VEWs visited individual farmers and discussions took place in the fields. Clusters of innovations were identified, for example:

- mixed cropping involving food crops and fruit trees;
- agroforestry systems;

- replenishing soil fertility with organic materials;
- testing different sowing systems;
- tapping underground water for irrigation;
- diverting waterways and managing the water;
- harvesting run-off water;
- production of agricultural tools.

Results were summarised and presented at a research-extension workshop for further negotiation. Finally, the proposals were reviewed by the NSC, which monitors the general orientation of the action research. The woman representative of the farmers' organisation had a special responsibility for ensuring that the farmers' agenda was maintained.

Learning together

During the first cropping season, a few farmer-experimenters were identified in each action area. Research teams consisting of a farmer-experimenter, the local VEW and a researcher were formed. The general framework for sharing responsibilities had already been agreed upon during the earlier workshops, but the teams still had to work out the details to fit their own situation.
Most experiments involved crops and some had been set up after the growing season had begun. In order to improve research in the next season, a workshop was held for the farmers, researchers and extension agents involved in the first experiments. The main aims were:
- to review the process of joint experimentation: How was it planned? How was responsibility shared? What happened?
- to derive lessons learnt so far: What went well? What problems had there been? How were these dealt with? What should be done differently next time?

Generally, participants and especially the farmer experimenters were satisfied with the process. For them, the most gratifying part of the experience was that they had been treated - at long last - as partners and equal to the "educated elite".
Of course, some problems were also identified. A major one was that it had been assumed that, simply by dividing responsibilities, the partners would be able to play their roles effectively. As it turned out, even in cases where the partners were clear about what they were supposed to do, they were not always prepared to do it. The participants therefore requested that, in each district, practical "hands-on" training be given. This should focus on the tasks that the farmers, researchers and VEWs should undertake in the next cropping – hence, experimenting – season. These workshops would also serve as planning sessions for the next season – a good way to complete the reflection-action-reflection loop.

Just catch words?

Participation, stakeholder involvement, empowerment are concepts that have gained popularity, but there is a danger that they become catch words. ISWCP-Tanzania is being implemented by partners – including research institutions and extension agencies, both governmental and non-governmental - who have claimed from the beginning that they believe in participation. However, experience shows that old habits die hard. Deliberate efforts have to be made to achieve a common understanding of the vision, philosophy and strategies of genuine participation. The terminology used must have a clear and shared content. Mutual trust is also critical in genuine partnership. You trust people whom you respect and understand. The mixed workshops were powerful tools for building trust, but it is wise to remember that farmers are old hands at uncovering deception. They may decide to keep quiet. And this would be a very dead end.

O.T. Kibwana, National Coordinator, ISWCP Tanzania, Cooperative College Moshi, PO Box 474, Moshi, Tanzania (iswcp@form-net.com).

Box 1: Indigenous Soil and Water Conservation in Africa (ISWC II)

The first phase of ISWC focused on indigenous knowledge (IK) in land husbandry. The second phase (ISWC II) focuses on dynamics in IK: discovering and promoting farmer innovation. The programme operates in Burkina Faso, Cameroon, Ethiopia, Tanzania, Tunisia, Uganda and Zimbabwe. The main objectives are:
- to improve the effectiveness of ISWC practices and innovations through joint experimentation by farmers, researchers and extension agents
- to initiate research on ISWC, spread research results, and create lobbying platforms to show policymakers that building on ISWC practices and innovations is an effective option for development.

Local innovators, who develop new ideas without direct influence from formal research and extension, are often overlooked as a source of inspiration for development. Innovators already in the midst of informal experimentation can be entry points into a process of Participatory Technology Development (PTD). The major components of ISWC II are:
- identification and analysis of farmer innovators and innovations
- networking between farmer innovators
- participatory research involving men and women farmers to develop improved land-husbandry technologies and systems
- setting up farmer-based monitoring and evaluation systems
- dissemination of tested technologies through farmer-to-farmer visits.

In each country, researchers and extension agents are trained in PTD methods. The researchers' role is to support experiments by farmers. Extension agents participate in planning the experiments. They help the farmers to monitor them, and organise farmer-innovator workshops and farmer-to-farmer exchange visits.

In each country, a government agency or NGO concerned with agricultural research or development acts as the lead agency. It establishes links with other local research, development and teaching institutions interested and experienced in participatory approaches to improving land husbandry. A National Coordinator in the lead agency manages programme activities. A National Steering Committee, involving representatives of the collaborating organisations, approves plans and evaluates the activities.

Annual review meetings and regional workshops in Anglophone and Francophone Africa bring national programmes together. An informal newsletter (*Farmer Innovators in Soil and Water Conservation*) also allows exchange between the participants. Advisory support is provided by a European consortium involving the Centre for Development Cooperation Services (CDCS), Free University of Amsterdam; International Institute for Environment and Development (IIED) Drylands Programme, Edinburgh, Scotland; Institute for Development Studies (IDS), University of Sussex, UK; and ETC Ecoculture, Leusden, Netherlands.

Funding is provided by the Directorate General for International Cooperation (DGIS) of The Netherlands Ministry of Foreign Affairs. Each partner country manages its own fund for activities such as training in PRA and PTD, farmer-innovator workshops, participatory research and farmer-to-farmer exchange visits.

Pacific Islander agriculture is dominated by root crops such as taro and yams and islanders face many problems with their cultivation. In Samoa, the introduction of leaf blight disease in 1993 devastated taro production and caused a dramatic decline in supplies of this staple food and export commodity. In Tonga, yam anthracnose continues to be a major problem. Island farmers, however, are important innovators and experimenters when it comes to solving the production problems associated with these crops. In Samoa, farmers have used their own innovations to ensure the rapid multiplication and availability of disease tolerant taro varieties, while in Tonga farmers have devised ways of minimising anthracnose disease and ensuring the vigorous growth of yams.

Farmer Innovation in the South Pacific

Steve Rogers, Tolo Iosefa, Taniela Hoponoa, Steve Hazelman and Danny Hunter

In 1996, the Samoan Ministry of Agriculture identified and released PSB-G2, a leaf blight tolerant taro variety from the Philippines. In general, taro is propagated vegetatively, and headsetts (also called tops) or large suckers are the best planting materials. However, the multiplication of PSB-G2 is enhanced because this variety also produces runners (stolons). The runners can be left attached to the mother plant to produce multiple suckers or cut and subdivided into pieces about 10 cm long. These are raised in nursery beds until they are ready for field planting (Figure 1). In Samoa, farmers received planting materials from the Extension and Research Divisions of the Ministry of Agriculture or from other farmers. Because there was a limited supply of planting material, most farmers received about 25 tiapulas (headsetts or tops) each.

Successful multiplication

In 1998, the European Union - Pacific Regional Agriculture Programme (EU-PRAP) Farming Systems Project and the University of the South Pacific (USP), in conjunction with the Research and Extension Divisions of the Ministry of Agriculture, carried out an impact assessment into the multiplication and distribution of PSB-G2. In the two-year period following the release of PSB-G2, the survey recorded an almost 75-fold increase in numbers with some farmers achieving a 700-fold increase. Although they had been provided with basic information on using runners for multiplication, the survey found that several farmers had been particularly successful at multiplication by innovating and adapting the above methods.

The innovations of Tauvela Suafoa

Reverend Tauvela Suafoa from Malaemalu village in Falealili district is an excellent example of a farmer who developed his own approach to multiplying and growing the new taro. He only received 50 *tiapula* in May 1997, yet in less than a year he had more than 3000 mature plants. Reverend Tauvela attributes this success to his mulching methods and sheer hard work. He described his method as follows:

- Remove the taro runners and cut them into node sections of about 5 to 10 cm long.
- Place node sections horizontally on a prepared nursery soil bed and cover with a thin layer of soil.
- Cover the nursery bed with a thin layer of cut *Erythrina* leaves. Good shoot growth will appear after 3 to 4 weeks.
- When the shoots are 25 to 30 cm long, transplant them to the field plot and mulch with “Samoan Manure”. This consists of a layer of cut banana leaves and a layer of *Erythrina* leaves and lawn cuttings, followed by another layer of banana leaves and a final covering of coconut fronds.

Reverend Tauvela has also experimented with the spacing of the new variety. Instead of the traditional spacing of 100x100 cm, he recommends a closer spacing of 50x50 cm. With this spacing he observed that PSB-G2 grows well and produces more runners. This means that more taro can be grown on a small area with less mulching material. Moreover, he not only succeeded in getting more taro plants, he also noticed an increase in the size of his Sunday congregation. This he attributes to his Sunday *To’onai* feast where he serves up *faalifu talo* and *luau* (taro corms and leaf in coconut cream). The Minister and his congregation all agree that the new variety has an excellent taste.

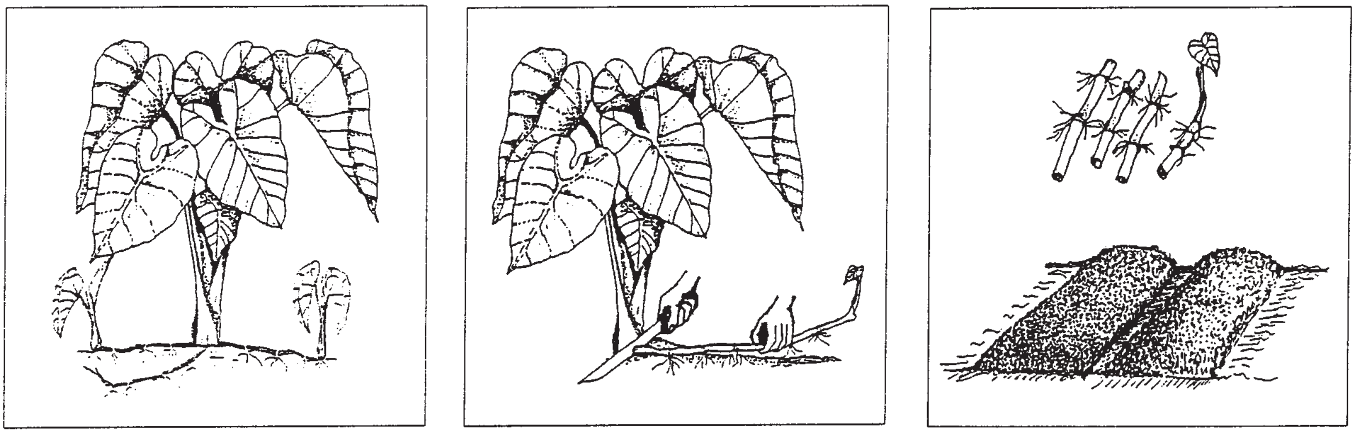
Food security increased

Farmer innovation in multiplying taro has meant a considerable increase in the availability of planting materials for other farmers. Because the area under taro cultivation - mostly using PSB-G2 – is increasing, there is more taro on the local market and at cheaper prices. This is great news for Samoa. For the first time since 1993, more people have the opportunity of eating their favourite food on a regular basis. Farmers are now selling planting material for half the price it was two years ago. Today, the Ministry of Agriculture estimates that there are about 10 million *tiapula* available in the country.

Superior yam planting materials

In Tonga, during on-farm yam trials to investigate ways of managing yam anthracnose, considerable variation in plant growth was observed. This was the result of non-uniform sprouting. Discussions between farmers and researchers resulted in the identification of local techniques for preparing and multiplying superior yam planting materials that could ensure a uniform vigorous growth and minimise anthracnose disease

Figure 1



Runners left intact on mother plant.

Runner removed from fully grown taro plant.

Runners cut into single or double nodes and planted in nursery.

problems. The expertise of Tevita Tui, a prominent yam grower and experimenter from Ta'anea village was a major input and other farmers cooperating in the on-farm trials also provided information.

Selection improved

Farmers identified five selection steps to ensure that superior planting materials are used:

- Select disease-free plants that are growing vigorously. Before reaching full maturity, cut off and remove the whole shoot to ensure the tubers remain disease-free.
- After harvest, select the best tubers. Keep the tubers separate from the rest of the yam and store to avoid further disease infection.
- When yams are in storage make a further selection and remove tubers with undesirable characteristics.
- Only prepare mini setts when yams have reached optimum dormancy time. This can be tested by cutting off the end of sample tubers and placing these horizontally on the floor overnight. If no fluid comes from the cut surface the tuber is said to be dried (*matu'u*) and ready for cutting. Setts with discolouration or signs of injury should be discarded. Many growers see this as the final step before yam setts are planted in the field. However, Tevita carries out a further innovative step that improves the selection of planting material.
- Incubate setts in a circular pit (*tanu*) until they are uniformly sprouted. This can take up to 2 months. Place setts horizontally in the pit up to three layers deep. A dried stick of 5 to 10 cm diameter and 100 cm long should then be placed in the centre of the pit. This stick is often referred to as the "nose" for it ensures ventilation. Tevita recommends that there should be no more that 200 setts per pit. Several dried sticks (*fetaki*) can be put across the top of the pit to ensure proper ventilation. Finally, dried banana leaves should be placed on top of the pit and covered with loose soil (Figure 2).

Multiple benefits

The *Tanu* method provides the following benefits for Tevita and other yam growers:

- sett size can be reduced to one quarter of that normally used for field planting without sacrificing crop yield. This means that more tubers are available for home consumption and sale;
- uniform crop growth can be achieved by selecting pre-germinated mini setts and eliminating diseased setts;
- one or two months of early field weeding can be avoided by germinating the setts in the Tanu pit;
- setts can be kept in the pit during periods of unfavourable weather.

Tevita has freely shared his knowledge with other farmers and extension staff. His enthusiasm and skill in giving practical demonstration of his innovations have encouraged other farmers and several Ministry staff to try these methods for themselves.

Important resources

Farmer innovation, and the knowledge and skills generated, are important resources in agricultural development. Ways should be found to build on these resources in national research and extension programmes. The innovations described in this article have formed the basis of farmer-to-farmer training and extension programmes to provide community-based training opportunities. This has led to a wider adoption of innovations and has also encouraged other farmers to experiment and innovate in a similar way. ■

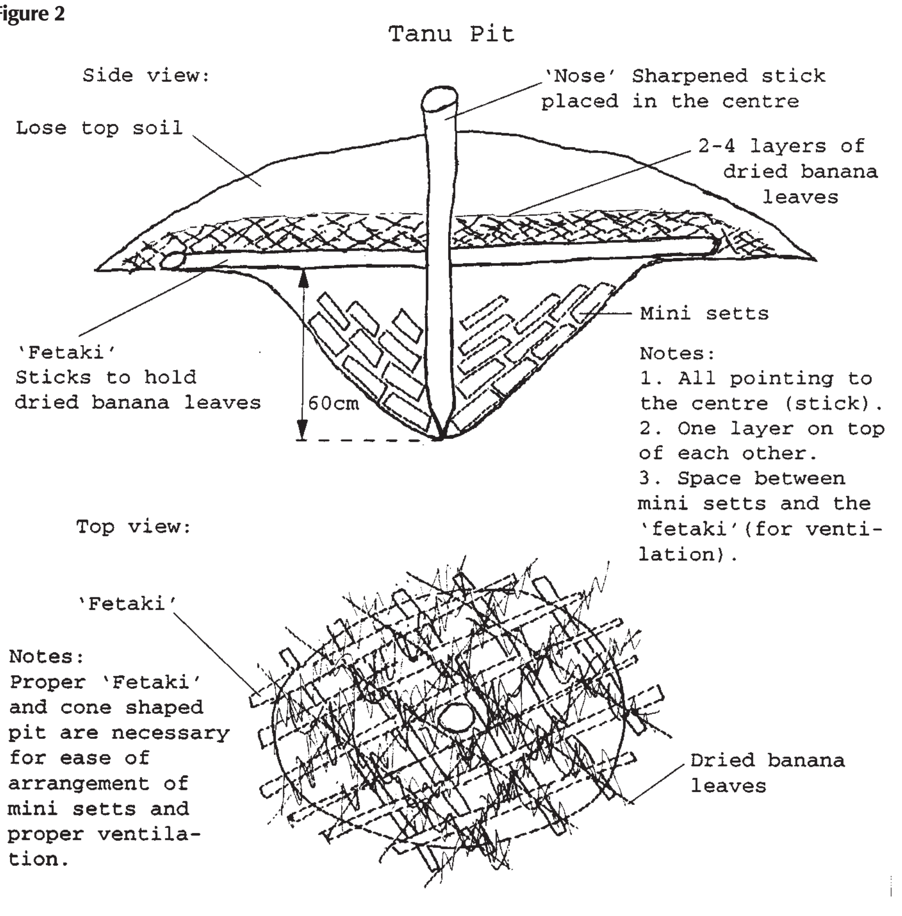
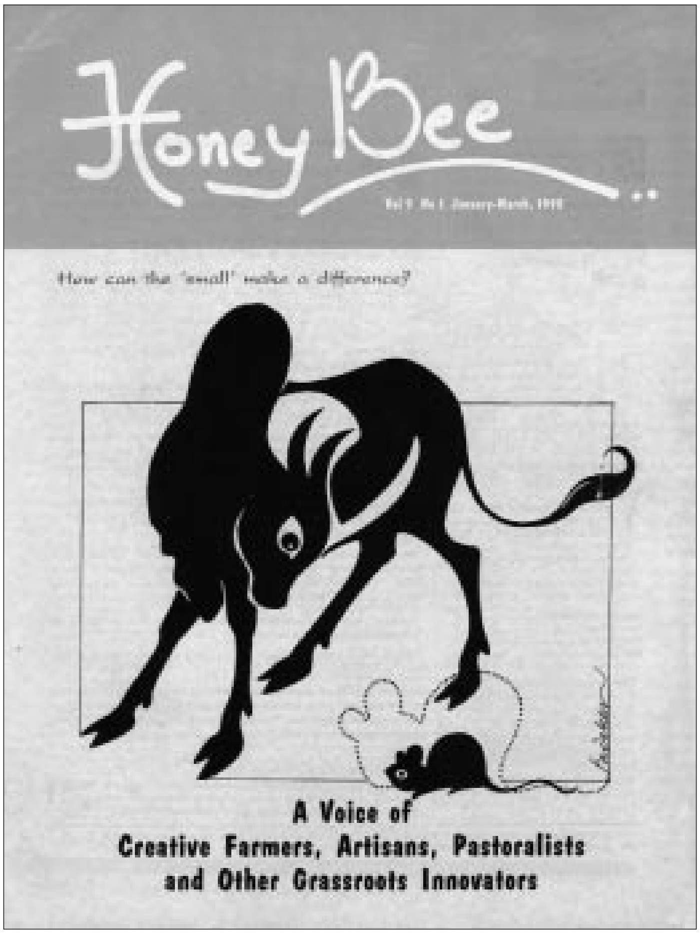
Figure 2





Grassroots innovations for survival

Anil K. Gupta

Although participation is much discussed, poor people rarely get the opportunity to develop their own agenda and vision or set terms for the involvement of outsiders. The entire participatory paradigm illustrates that people are participating in plans and programmes that we – outsiders – have designed. Not only is there little opportunity for them to articulate their ideas, there is also seldom an institutional space where their ingenuity and creativity in solving their own problems can be recognised, respected and rewarded.

Poor people must be inventive to survive. However, sometimes their coping strategies are inadequate and then they have serious difficulties in meeting their basic needs, educating their children and generating sustainable employment opportunities. Nevertheless, there are clear signs that within their local knowledge they have a tremendous potential for restoring the economic and ecological balance.

The Honey Bee network

Ten years ago, this awareness motivated me and some of my former students and colleagues to set up the Honey Bee network. Metaphorically the Honey Bee represents the ethical and professional values that most of us often neither profess or practise. A honey bee does two things that we intellectuals often fail to do: it collects pollen from the flowers and they do not complain, and it connects flowers in pollination. In the Honey Bee network, it is a matter of principle that we always credit the knowledge we collect from people and we share any benefit that arises from this knowledge fairly with them. We insist that this knowledge is transmitted in vernacular languages thus ensuring people-to-people communication. Honey Bee is a knowledge centre/network pooling solutions developed by people working in different sectors from all parts of the world. It creates links not only between people but also between formal and informal science. Honey Bee has collected over 10,000 examples of contemporary innovations and outstanding examples of the use of traditional local knowledge in the sustainable management of natural resources. These innovations are shared with local communities and individuals in over 75 countries through the Honey Bee newsletter which is issued in eight different languages (English, Spanish, Hindi, Gujarati, Tamil, Kannada, Pahari, and Telugu. SRISTI (Society for Research and Initiatives for Sustainable Technologies and Institutions), a global NGO based in India, was set up in 1993 to provide support to the Honey Bee network.

Of course, people cannot solve all their own problems and sometimes the solutions they find will be inadequate. Often there is scope for adding value and improving efficiency and effectiveness. However, it is clear that a development strategy that does not build upon what poor people are rich in, their knowledge, institutions and creativity, will never be ethically sound, professionally accountable or efficient.

Finding the odd balls

Our local innovation database has been developed using methods and approaches that people can use without much difficulty. We believe that learning has to be mutual and patient. The categories used must be those that people work with in defining their worldview. What Honey Bee has done is quite simple. During their summer vacation we ask students to help us find the odd balls, the farmers in the villages who are experimenting and doing things differently. Many of these farmers have found very creative and innovative solutions to their problems. The unusual thing about these innovations is that they remain so localised that even farmers in the same village sometimes do not know about them. However, this lack of diffusion does not mean these innovations lack validity.

We use several other methods to scout out innovations including competitions among functionaries of agricultural departments, NGOs, and educational institutions and information stalls in cultural and agricultural fairs. 'Shodh Yatras' or walks through the villages are organised every year in summer and winter for ten days to identify as well as honour the innovators and traditional knowledge experts at their doorstep.

We have come across technological, socio-cultural, institutional and educational innovations that contribute to the conservation of local resources, generate additional income and reduce or prevent losses. Farmers have developed unique solutions for controlling pests or diseases in crops and livestock, conserving soil and water, improving farm implements, various kinds of bullock carts for performing farm operations, storing grains, conserving land races and local breeds of livestock and conserving aquatic and terrestrial biodiversity. Below are some examples.

Strip-sowing equipment

Amrutbhai Agrawat, an artisan, makes farm implements in Pikhor Village, Junagadh District, Gujarat. He had developed several innovative farm implements including a wheat-sowing box and a groundnut digger. In most sowing equipment, the seeds fall on the ground through the lowest pipe-shaped portion. The spacing devices are located in the seed box. In dry windy regions, lodging can be a problem in irrigated fields. Amrutbhai devised a box that spreads the seeds in a strip. While the seed rate remains constant, the distance between the seeds is increased and they do not fall on one another. With better root growth, there is more efficient nutrient uptake and the crop does not lodge. With a stronger root network, the crop is better able to withstand water stress and also does not lodge. Similarly, the groundnut digger was designed with the help of a flexible blade hoe that allows the distance between the two rows to be changed and the depth at which the hoe enters the soil to uproot the groundnut pods to be adjusted.

Venture capital

Amrutbhai also tackled another centuries old problem. On most tropical plains, farmers cart farmyard manure to the field. They have to spread the manure by carrying it by basket to the right place. This demands much time and labour. By modifying the bullock cart Amrutbhai created a cart that the farmer could easily tilt so he could gradually distribute manure single-handed over the entire field. He discussed the idea with us and defined the risks. This was an idea worthy of the support of Venture Capital Fund (VCF). There are many programmes on micro-finance but no program on micro-venture finance. SRISTI recognised the gap and, with the support of a grant from the International Development and Research Centre (IDRC) and using its own resources, decided to experiment with the VCF idea. A proposal was prepared and reviewed and the cart was developed through a small risk-taking venture of Amrutbhai and SRISTI.

Later, this innovation received support from the Technoprenurial Promotion Program (TePP) of the Department of Scientific and Industrial Research through the efforts of Gujarat Grassroots Innovation Augmentation Network. GIAN helped in filing the patent on behalf of the innovator and in licensing the innovation to three entrepreneurs for five districts and for five years netting about US$ 2,000 as a license fee to Amrutbhai.

Many other ideas and inventions remain undeveloped or inadequately developed because there is no VCF to support them.

Cross-cultural exchange

This knowledge has great potential for generating cross-cultural and regional linkages. For instance, pastoralists in Mongolia make an animal lick out of onion leaves with wheat germ, sodium bicarbonate and dried milk. This lick is rich in selenium. Selenium deficiency, for example, can cause young calves to die prematurely. When the Honey Bee network idea was discussed with Akwasasne people in Canada it emerged that they had a livestock problem which could be traced to selenium deficiency. This shows the potential of the Honey Bee network: a practice in Mongolia, documented by a professor in Scotland and published in Honey Bee, was made available to indigenous peoples in Canada and provided a possible solution to local problems.

Rewarding creativity

The intellectual property rights of local communities and individuals have often been usurped by national and international corporations and professionals without any regulation or restriction. Not only were the contributions of local knowledge not recognised but when profits were made nothing was shared with the people. An example of unfair extraction: about 70% of plant-derived human drugs are being used commercially in the same way as they were used by the native people who discovered them. What modern science did was to improve the method of extraction or develop a synthetic analogue of the compound. The basic R&D was done by the people but they were never compensated.

There is a clear need to correct the unfair and unjust system of extracting local knowledge from people for corporate benefit. It should be noted, however, that many local communities do not necessarily seek material rewards but this is no reason for keeping people poor.

International registry

At present, any innovation once published comes into the public domain and becomes non-patentable. At the same time, people-to-people networking requires dissemination of ideas in numerous different languages to promote learning and experimentation. An international innovations registry INSTAR (International Network for Sustainable Technologies Application and Registration) was set up to prevent conflict developing between the need to protect intellectual property rights and dissemination for people-to-people networking. This registry, like the ISBN number for books, can provide a quick and inexpensive way of gaining some protection (say for ten years) for innovations. Later, with the help of an international fund for promoting sustainable technologies, more detailed patent applications could be filed on behalf of the innovators. Securing benefits also may raise the interest of younger people in green technologies, which may help this knowledge system not just survive but grow.

Recently, the Government of India has set up the National Innovation Foundation to make a national register of innovations, help link innovations with investment capital and enterprises, and to forge links between formal and informal science. Perhaps the time has come for setting up a Global Innovation Foundation as well.

Restructuring required

For most marginal communities in fragile environments, the standardised solutions developed for high-potential "green-revolution" regions are unworkable. However, in general there are no organisational arrangements that provide incentives to encourage scientists to work with the people to develop technologies that limit the potential for diffusion. Restructuring of international and national research organisations is required if technology development and diffusion is to become relevant and meaningful for marginal environments and disadvantaged communities. The Honey Bee network, with its limited resources and experiences, has demonstrated that such a transformation is feasible.

EL BOLETIN DE ILEIA
The Spanish version of the ILEIA Newsletter can be ordered from ETC Andes – Perù, ap. Postal 18-0745, Lima 18, Perù. E-mail: ‹estrems@amauta.rcp.net.pe›

LEISA INDIA INLAY
The LEISA Indian Inlay, a supplement to the ILEIA Newsletter was first published in March 1999. From July 2000 it will be printed as a separate magazine by AME, Bangalore India and contain a selection of articles from the ILEIA Newsletter together with articles of more regional and local interest. LEISA India can be ordered from AME, PO Box 7836, Bangladore 560 078, India.
E-mail: amebang@giasbg01.vsnl.net.in

EDITORIAL TEAM
This issue has been compiled by: Nourreddine Nasr and Ann Waters-Bayer (guest editors), Marilyn Minderhoud-Jones, Ingrid Huibers-Govaert, & Coen Reijntjes.

ADMINISTRATION
Lila Felipie, Nicole Kunz

SUBSCRIPTIONS
Nicole Kunz, E-mail: subscriptions@ileia.nl
The ILEIA Newsletter is published 4 times a year. Subscriptions: Individuals and organisations in North America, Europe, Japan, Australia and New Zealand: EURO 25.00 or US$25.00. Others: EURO10.00 or US$10.00. Those who currently receive the Newsletter free of charge will continue to receive it free until arrangements have been made for them to pay a local rate in their own currency.

DESIGN AND LAYOUT
Jan Hiensch, Leusden

PRINTING
Koninklijke BDU Grafisch Bedrijf B.V., Barneveld

COVERPHOTO
The cover photo shows W/ro (Ms) Tsige GebreAbezgi who lives in Central Tigray, in the small hamlet of Adi-Nefas, in the village area Maybrazio. The Latin name of the local plant Da"kuia in the picture is not known. She introduced this wild species to protect her fruit trees from termite attack.

The editors have taken every care to ensure that the contents of this Newsletter are as accurate as possible. The authors have ultimate responsibility, however, for the content of individual articles.

The editors encourage readers to photocopy and circulate Newsletter articles.

ISSN: 0920-8771

Dear Readers

This is a special on 'farmer innovation'. In earlier issues, innovations developed by creative farmers without the support of development programmes have been regular features. But never have we devoted an entire issue to farmer innovation. Having often experienced that conventional research does not 'deliver the goods' for smallholder agriculture, an increasing number of farmers and development workers are building on local innovation, experimentation and communication.

This issue bears witness to the creativity of farmers. It also shows how they can be inspiring communicators using different media. Participatory Technology (including institutional) Development, Farmer Field School and Farmer-to-Farmer approaches are presented as powerful complementary ways to enhance farmer innovation and, thus, to develop Low-External-Input and Sustainable Agriculture. Readers are invited to support this ongoing process through regional farmer-to-farmer movements and international exchange of practical information on local innovation.

The theme of this issue was suggested by members of the Indigenous Soil and Water Conservation (ISWC) programme working on farmer innovation in several Anglophone and Francophone countries in Africa. Two members of this network, Nourreddine Nasr of the Institut des Régions Arides in Gabes, Tunisia, and Ann Waters-Bayer of ETC Ecoculture in the Netherlands, are guest editors. Beside the regular English and Spanish editions, there will also be a French edition.

The next issues of the ILEIA Newsletter will focus on intensifying agroforestry (deadline 15 August), ecologisation of monoculture (deadline 15 September) and resilience of agriculture (deadline 1 December). For further information, please turn to the back cover. Your contributions are most welcome!

The editorial team

ILEIA is the Centre for Research and Information on Low-External-Input and Sustainable Agriculture. It seeks to exchange information on LEISA by publishing a quarterly newsletter, bibliographies, and books. ILEIADOC, the data base of ILEIA's documentation centre, is available on diskette and on ILEIA's Homepage: http://www.oneworld.org/ileia. Back issues of the ILEIA Newsletter are also available on ILEIA's website.

LEISA is about Low-External-Input and Sustainable Agriculture. It is about the technical and social options open to farmers who seek to improve productivity and income in an ecologically sound way. LEISA is about the optimal use of local resources and natural processes and, if necessary, the safe and efficient use of external inputs. It is about the empowerment of male and female farmers and the communities who seek to build their future on the bases of their own knowledge, skills, values, culture and institutions. LEISA is also about participatory methodologies to strengthen the capacity of farmers and other actors, to improve agriculture and adapt it to changing needs and conditions. LEISA seeks to combine indigenous and scientific knowledge and to influence policy formulation to create a conducive environment for its further development. LEISA is a concept, an approach and a political message.

Grassroots innovations for survival

Anil K. Gupta

Honey Bee

The Honey Bee network has collected over 10,000 examples of innovations and examples of traditional local knowledge in the sustainable management of natural resources. These are shared with farmers and scientists through the Honey Bee newsletter. The author presents some of these innovations. Given the unjust practice of extracting local knowledge from people for corporate benefits the author stresses the need for an international registry of farmer innovations and the restructuring of international and national public research.

Forging partnerships with innovative farmers

O.T. Kibwana

The Indigenous Soil and Water Conservation Programme (ISWCP) focuses on discovering and promoting farmer innovation in Burkina Faso, Cameroon, Ethiopia, Tanzania, Tunisia, Uganda and Zimbabwe. Kibwana discusses the different steps involved in ISWCP in Tanzania in which governmental and non-governmental research and extension organisations participate. Awareness among participants was raised, innovations were identified, analysed and documented and a start was made with Farmer-to-Farmer exchange and Participatory Technology Development

Gafsa regional radio

Noureddine Nasr, El Ayech Hdaidi and Ali Ben Ayed

Photo: Chris Reij

18

By early 1999, a growing number of innovators in dryland farming had been identified by ISWCP in Tunisia. Visits of farmers to innovators were organised, and some of these were broadcast on national TV. However, the major strategic activity was a weekly regional radio programme on "Agricultural and Innovation". This radio programme not only invites farmers to present their innovations for farmer-to-farmer exchange. It also involves researchers, training specialists and development agents in debates about the innovations to create links between farmer innovators and formal research and extension.

Farmer experimentation: a challenge to all!

Henri Hocdé, David Meneses and Byron Miranda

Since 1994, PRIAG in Central America has facilitated and strengthened farmer innovation through documentation, participatory experimentation, communication and organisation. By describing some of the practical approaches of the programme the authors show how farmers are being empowered and take the lead to develop topical and regional networks for farmer-to-farmer exchange, farmer experimentation, communication and planning. This approach is a real challenge for all as it requires new working methods for a 'learning dialogue' between farmers, scientists and the other stakeholders involved.

From the regional newsletters

LEISA INDIA INLAY

The second issue of **LEISA India Inlay** ***Stakeholders in research*** reported on experiences with low-external input-practices and research. It complemented the India section in the ILEIA Newsletter 15.1/2 *Finding Common Ground.* **India Inlay** contributors from a wide variety of backgrounds focused on the various stakeholders in research. The initiatives reported were essentially collaborative efforts between institutions, NGO networks and farmers. Articles covered farmer-centred PTD; the structure, functions and ideologies of the large Tamil Nadu LEISA network; farmers experimenting with methods to achieve sustainable groundwater usage; three cases of collaborative PTD in the field; participatory technological innovations, such as the development of seed drills, and a column by a well-known organic farmer discussing the role of livestock in sustainable agriculture.

The response to the **Inlay's** research issue has been encouraging. This has been reflected in the specific responses received as well as a steadily growing number of subscribers. Formal research organisations too are showing increasing interest in the **Inlay's** content.

New website: For readers interested in the environment and development debate in India there is the new **Centre for Environment Education** site: www.cee.envirodebate.org

El BOLETIN DE ILEIA

On the western slopes of the Andes and in other dry and semi-arid areas of Latin American, water scarcity is a daily challenge. Desertification in this part of the world is the history of how large areas of dry forests became desert and how agricultural soils have been eroded. The main and most intensive cause of desertification is the misuse of natural resources. Inappropriate settlement patterns and methods of production - both rural and industrial –have deliberately disregarded the insights and experiences of indigenous and local knowledge on conserving water in dry regions.

Desertification is largely a problem in the South. Here LEISA can contribute to reducing its risks.Through El Boletin, international and regional experiences of working to combat desertification are being exchanged. Indigenous wisdom and local scientific knowledge is being shared to the benefit of stakeholders in comparable agroecosystems. El Boletín editors are anxious to receive news and personal experiences from our readers in Latin America and other continents. Recently we received a letter from Abdella Dawuo Yusief of Ethiopia, who is interested in sharing and receiving information on animal breeding and particularly the production of cattle and poultry in dry areas. Readers who would like to exchange experiences with him should write to: Babile Agricultural Development Office, Abdella Dawuo Yusief, Babile past. Agent Babile - Eastern Hararge, Babile, Ethiopia.

One of readers has written to tell us that he has included an article from **El Boletin** in his doctoral thesis (Agricultores e investigadores en camino hacia el manejo integrado de los nutrientes, Laming, J. et al p6-8). We are delighted to share information and knowledge on low-external-input and sustainable agriculture in this way. You can contact Dr Olman Quirós Madrigal, an agroforestry expert at: Dirección Regional Central Sur, Ministerio de Agricultura y Ganadería, Apdo. 85-6000, Puriscal, Costa Rica, E.mail: upap@grecia.infoagro.go.cr.

For more information on El Boletin contact:
Teresa Gianella-Estrems, LEISA El Boletin de ILEIA, c/o ETC Andes, PO Box 18-0745, LIMA 18, Peru.

E.mail: estrems@amauta.rcp.net.pe

Themes for the ILEIA Newsletter

June 2000 Vol.16-2.
Farmer innovation
Second deadline for contributions 1 April 2000.

September 2000 Vol.16-3.
Integrated agriculture
How can unsustainable slash and burn systems evolve in more sustainable and permanent integrated systems? How can such an evolution process be supported and what are the economic and social preconditions for developing integrated systems? Articles are invited on: eg examples of (indigenous) strategies to intensify agroforestry systems; the spiritual, cultural and social dimension of indigenous integrated agriculture; role of animals in integrated systems; value adding and marketing of indigenous or new crop, tree or animal products; economic comparison of the performance of integrated systems.
First deadline for contributions 1 May 2000.

December 2000 Vol.16-4.
Monoculture systems
How to make monocropping or monoanimal systems more sustainable? How to develop them into integrated systems? How to improve the production chain? Articles are invited on interesting examples of: ecologisation and intensification; diversification; integrated soil fertility management; ecological pest management; processing; input supply; product development and value adding; marketing. Deadline for contributions 1 September 2000.

March 2001 Vol.17-1.
Resilience of agriculture
How do farmers prevent disaster and react to the catastrophies of drought, flood, armed conflict, disease and economic crisis? How does this influence their farming and livelihood strategies? How do farmers deal with variability and risk? How can the resilience of farming and households be improved? What impact does labour migration have on farming systems and gender roles? How can women best adapt farming in areas of labour migration and still optimise benefits and ecological sustainability? How can gender roles be renegotiated? How can women farmers best be reached and supported? How can farming by refugees be supported? Articles dealing with such questions are invited. Deadline for contributions 1 December 2000.

You are invited to contribute to these issues with articles, suggestions for possible authors, and information on interesting issues, publications, training courses, meetings and Websites. An ILEIA style guide available on request or at www.oneworld.org/ileia. Please do not wait until the last minute to send in your contributions. Send them as soon as possible! Accepted contributions will be published in the ILEIA Newsletter or on the ILEIA Website.

A-WEEK COURSE: PARTICIPATION IN LOCAL DEVELOPMENT

Date: 5-9 June/11-15 December 2000
Location: Nijmegen, The Netherlands

Agromisa is a knowledge centre for the south, focusing on small-scale sustainable agriculture. Agromisa has been organising a course on Participation in Local Development since 1994. The A-week is an intensive five days course which aims to give an introduction to Participatory Approaches that can be used to facilitate local development. Topics that will be treated during the course are: RAAKS (Rapid Appraisal of Agricultural Knowledge Systems), PTD (Participatory Technology Development), PRA (Participatory Rural Appraisal), Theatre for Development, Monitoring and Evaluation and Intercultural Communication.The role of a development worker as a facilitator and the cultural problems that can be encountered will be highlighted. There will be group discussions and practical exercises. Applicants invited from those working in development programmes who have as yet little experience in using participatory methods. The course will take 20 participants and is conducted in English. The A-week is held twice a year. This year the course will be given from 5-9 June and from 11-15 December.

Fees: NLG 2950.00 or US$1500 for institutions; NLG 940.00 or US$470.00 for individuals. (Fees include meals, accommodation and course materials.) Local tailor-made courses can also be given on request.

For more information: Agromisa, P.O. Box 41, 6700 AA Wageningen, the Netherlands, tel. (+31) 317 412217, fax (+31) 317 419178, E-mail: agromisa@wxs.nl

AGROMISA QUESTION AND ANSWER SERVICE

Land degradation concerns

Agromisa has received many questions on problems of land degradation. Soil and wind erosion, soil depletion, watershed management and water harvesting are issues that effect the sustainability of farming communities throughout the world. UNEP estimates that, every year, nearly six million hectares of previously productive land in arid, semiarid and dry sub-humid areas loose their capacity to produce food (Atlas of Desertification, UNEP, 1992).

The question

Last year, for example, we received a detailed six-page request for advice from a non-profit technical centre in Malawi. The centre provides practical knowledge and skills on different aspects of land use to small holders (including women groups). Soil erosion, declining soil fertility, inappropriate soil use, and food insecurity were becoming major problems. Due to a decline in soil fertility, the expense of chemical fertilisers and pesticides, yields from maize, beans and sweet potatoes, the three main crops, were in decline. Forested areas were shrinking as the villagers' demand for agricultural land, poles, fuel wood, and timber for sale increased. In the absence of adequate reforestation and regeneration plans, soil erosion and a falling water-table were becoming serious issues.

The Answer

Agromisa's advisors prepared detailed replies on each of the issues raised. From the letter it was clear that crop rotation was not common in the area. Adequate crop rotation to assist soil fertility and help against pests was there fore stressed. It was suggested that some catch crops and biological pesticides like fish bean, effective against caterpillars, should be used. When maize is harvested substantial amounts of nutrients are removed (especially nitrogen). It was suggested that a nitrogen fixing crop like beans should be used before maize was planted.

Strategies for increasing self-reliance were recommended such as reducing dependence on high-cost inorganic fertiliser inputs, for example. Composting, agro-forestry and promoting soil fertility were offered as alternatives. Organic farming and agro-forestry are indispensable techniques for small-scale farmers in the tropics. The main goals of organic farming are to keep the nutrient-cycle in equilibrium and to maintain soil fertility. Adding chemical fertiliser to the soil year after year has a negative effect on soil structure because soil organic matter declines. Agromisa's advice stressed the importance of soil organic matter; increasing water-holding capacity, the release of plant nutrients, the better storage of nutrients and improved soil workability. A good topsoil cover is important to minimise the loss of external inputs. Uncovered dry soil can be blown away by the wind or washed away during rain. Soil cover can be provided by a crop or by crop stubble and residues. Farmers working on steep slopes were advised to use crops, shrubs and trees along the contour lines to reduce soil erosion. To benefit from the crops used, legumes (nitrogen fixation) are recommended as contour planting.

In March 2000 Agromisa will join forces with several other Question and Answer Services to increase the number of experts available to answer your questions. More about this next time. The next issue of the ILEIA Newsletter looks at **Farmer Innovations** (see p36). If you have questions on this subject, please write to us at: Agromisa, Postbus 41, 6700 AA Wageningen, Fax: + 31 317 412 217, E-mail: Agromisa@wxs.nl

Agrodoks on problems of land degradation

The demand for information on desertification or land degradation related topics has been such that Agromisa has developed a set of practical booklets in its **Agrodok** series.

- Agrodok 2 **Soil fertility management,** Laura van Scholl, 1998
- Agrodok 8 **The preparation and use of compost,** M.Inckel et al, 1998
- Agrodok 11 **Erosion control in the tropics,** Hil Kuypers et al, 1999
- Agrodok 13 **Water harvesting and soil moisture retention,** J. Anschutz et al, 1997
- Agrodok 19 **Propagating and planting trees** , H.Schreppers et al, 1999

NLG65 or US$32 per set. NLG13.00 per copy from Agromisa (inc. postage).

TO ILEIA SUBSCRIBERS

Privacy of information

ILEIA sometimes gets requests from local NGOs, publishers and other concerned with sustainable development issues for the names and addresses of those Newsletter subscribers who might be interested in working with them or receiving information from them. In principal ILEIA wants to encourage this sort of networking and we would like to put people in touch with one another. At the moment, we work within the laws governing the privacy of personal information and we do not pass on the names and addresses of our subscribers to third parties. However, we want to encourage the flow of information and experiences on LEISA whenever possible. We would therefore like to have your permission to make your name and address available to selected organisations involved with LEISA and sustainable agricultural issues when the occasion arises. If you object to us passing on this information please let us know by 1 June 2000. If we do not hear from you, we will assume you have no objection to us passing on your name and address.

Address to contact is: subscriptions@ileia.nl or ILEIA Foundation, PO Box 64 3830AB Leusden, The Netherlands, or phone +31 33 4943086

New subscription policy

ILEIA's has a new subscription policy. From 2000 a yearly subscription will cost EURO 25.00 or US$25.00. Organisations and individuals in the Third World EURO10.00 or US$10.00. Those who currently receive the Newsletter at a concessionary rate will go on receiving it free of charge until arrangements have been made for them to pay a local rate in their own currency.

For further information about subscriptions please contact Nicole Kunz, Subscriptions, E.mail Subscriptions@ileia.nl; ILEIA PO Box 64 3830AB Leusden, The Netherlands

Websites on desertification: What can they offer?

Internet is promoted as being able to bring a solution to all the problems we have in technology development as far as information is concerned. Indeed, the seemingly free access to information offers tremendous scope. In practice, however, Internet has a relatively short history and many organisations possessing highly relevant subject matter information on combating desertification have not been able to put it all on their Website. The issue of copyright also plays a role. In the past, information had to be bought in the form of documents or advice, and provided a source of income for the owner or producer. Procedures and tools for buying information on Internet are steadily developing in the commercial sector. However, the non-commercial sector is still hesitating about investment. Website development is time consuming and funding is not always easy to acquire. As a result, there is a tendency to feature general information. To get detailed information direct contact must be made with the organisation concerned. Some websites resemble bulletin boards. Their announcements include documents on the texts of treaties and conventions, agendas and minutes of meetings, special events, addresses of relevant organisation including links to other sites. Most websites allow the downloading of relevant documentation. This can contribute to the improvement of the exchange of information between interested parties.

Only a few sites contain databases. Some databases, mostly national or international public organisations or organisations sponsored by international donors, require that users be registered but do not demand payment. However, it often takes considerable time to find data that fit ones requirements. Down-to-earth information for practitioners at the local level is often poorly represented. The problem of information management was specifically recognised by the third Conference of the Parties (COP) to the Convention to Combat Desertification (CCD) held in Recife October 1999.

Beautifully styled sites and animated applications are often a hinderance because they slow down access and use. This is particularly so for those working with older and slower computers and/or confronted with an expensive and perhaps unreliable telephone infrastructure as is often the case in developing countries.

A selection of websites relevant to desertification is presented below. They have been chosen for their accessible, search capacity and possibilities for further linking.

Club du Sahel:
http://www.oecd.org/sah/
The Club du Sahel, a forum for reflection and dialogue of the Organisation for Economic Cooperation and Development (OECD) was set up in the 1970s after the great droughts in the Sahelian zone of Africa. The site is accessible in French and English. The site focuses on cooperation and exchange possibilities, and some links to more practice-oriented organisations are displayed.

Convention to Combat Desertification (CCD):
http://www.unccd.ch/
This easily accessible website is well documented and provides details on the convention, the secretariat, signatories and ratifications, official documents of the Conference of the Parties (COP) and Committee on Science/Technology, recent conferences, list of meetings, public information (eg. the CCD Newsletter and specific fact sheets can be downloaded) and links to other sites.

Center for International Earth Science Information Network Columbia University (CIESIN):
http://www.ciesin.org/
If you want to directly access the site in a text only version to save time and costs:
http://www.ciesin.org/index_text.html
CIESIN was established in 1989 as a non-profit, non-governmental organisation to provide information that would help scientists, decision-makers, and the public better understand their changing world. CIESIN specialises in global and regional network development, science data management, decision support, and training, education and technical consultation services. CIESIN is the World Data Center for Human Interactions in the Environment.

An interesting and easily accessible site although somewhat USA in focus. The site highlights links to other interesting sites and interactive databases on important development issues in the South. It also provides extensive information on desertification.

ELDIS:
http://www.ids.ac.uk/eldis/eldis.html
This is a gateway to online information on development in countries of the South funded by DANIDA. Coverage includes social, economic, political and environmental issues. ELDIS makes a qualitative selection of materials and structures it for easy access. Its comfortable search function makes it a powerful site and one worth starting with. It providing access to many relevant document and organisation sources.

Office of Arid Lands Studies (OALS):
http://phylogeny.arizona.edu/OALS/oals/oals.html
The OALS is a multidisciplinary teaching, research, and information unit at the College of Agriculture in the University of Arizona, in Tucson, USA. OALS conducts interdisciplinary programmes that address local, state, national, and international problems related to understanding, regenerating, and managing the world's arid lands. It runs the Arid Lands Information Center
http://ag.arizona.edu/OALS/oals/alic/resources/resources.html
which publishes the Arid Lands Newsletter (can be downloaded), maintains a specialised 30,000-item document collection and provides links to a good number of interesting relevant organisations. This site is worth a visit.

International NGO Network on Desertification or **Réseau International des ONG sur la Désertification** (RIOD):
http://riod.utando.com/
The RIOD network was set up in November 1994 by the NGOs that were involved in the negotiations towards the Convention to Combat Desertification, It was felt that NGOs and Community Based Organisations would be more effective in fighting desertification if they could exchange of information, experiences and ideas more easily. RIOD requested UNSO to provide assistance to strengthen the efficiency of the network. The global focal point is at the Environment Liaison Centre International (ELCI) at Nairobi. The whole site is in English and contains interesting links. Visiting recommended not only for those with an NGO orientation!

REDESERT:
http://www.mma.gov.br/ingles/SE/redesert/hdeserti.html
The site of the Desertification Information and Documentation Network in Brazil, it can be accessed in Portuguese and English. It describes amongst other things the CCD in relation to the Brazilian programme to combat desertification. It also gives information on other relevant institutions in Latin America and provides links to other sites. Apart from one reference to RIOD it has a strong emphasis on government institutions.

UN Development Programme, Office to Combat Desertification and Drought (UNDP/UNSO):
http://www.undp.org/seed/unso/index.htm
The UNSO is responsible for UNDP's work in desertification control and dryland management. Based at UNDP headquarters in New York, the UNSO team of specialists works within the Sustainable Energy and Environment Division (SEED). Interesting site with easily accessible and well-presented information on concepts, National Desertification Funds (for local level initiatives), an Environmental Information System, Drought Preparedness and Mitigation, the National as well Subregional and Regional Action Plans, publications and contacts and links.!

EarthAction:
http://www.earthaction.org/index.html
and its resources and links on
http://www.earthaction.org/en/resources.html
Because environmental destruction, hunger and war are global problems, there are some areas of policy-making where simultaneous, world-wide public pressure is urgently needed. EarthAction wants to generate the political will to solve them. Interesting site for those who involved with the policy and politics of successful environmental management. It contains interesting links to other useful sites.

ELDIS Conflict Guide:
http://nt1.ids.ac.uk/eldis/conl/cfl.htm
Informative site with many links to other sites with interesting information on conflict resolution.

Swiss Peace Foundation (SPF):
http://www.swisspeace.ch/
Interesting site for getting information on conflict resolution models as well as some links to other sites involved in conflict management.

The World Bank:
http://www.worldbank.org
A site with an enormous amount of information on a wide variety of development issues, eg environment, sustainable agriculture, dryland and water management, community-based natural resource management, decentralisation & local development, empowering producer organisations, WTO 2000 negotiations, etc. The site gives access to World Development Sources, the World Bank Publication Catalogue and the World Bank database JOLIS with information on publications, research, projects, policies, conferences and case studies. Links are only made to partner organisations.

Partnership in the elaboration of the National Action Plan

Juan Luis Merega

The development of partnership between governments and NGOs, a relatively new phenomenon in Argentina, is the result of increasing democratisation following the fall of dictatorship, fifteen years ago. However, the process of participation has not yet reached all levels. Not all areas of government have put into practice the widely proclaimed participation and partnership between government and civil society.

Reasons for success

In elaborating the National Action Plan against Desertification, the Argentine Government, working through the Soil Conservation Directorate has adopted an open and receptive attitude towards NGOs from the beginning of the process. The NGOs, for their part, have proved to be reliable actors and have been able to offer considerable help without compromising their own positions. This experience has been a success because of three positive factors:

- The Argentine NGOs were able to achieve an efficient mechanism for representation and organisation through the Argentine Chapter of the '*Reseau International de ONG sur le Desertification*' (RIOD-Argentina). The result has been that the participation of NGOs has not been limited to one or two privileged institutions. On the contrary, the structure of the network with the democratic election of representatives at national (Asociaci'on Civil Los Algarrobos), subnational (CENEP, FUNPROVE, AMAD and Fundaci'on Patagonia Natural) and provincial level has made it possible to develop a transparent structure that has integrated some thirty institutions. In this structure each of the parties is entitled to speak for all in the different consulting instances.
- Conservation Directorate consistently accepted suggestions and proposals from NGOs. It has discussed these openly in many different formal and informal situations. Partnership is not synonymous with equality, but the commitment of working together and preserving the peculiarities and contributions that each can offer has made it possible to enrich the whole process.
- The United Nations Convention to Combat Desertification (CCD) has had a catalysing effect on the Argentine process. Not only because the Convention promotes participation and partnership, but also because the Intergovernmental Negotiation Committee sessions provided a framework that motivated the beginning of collaboration.

The process

The Argentine National Action Plan process was implemented through a participatory methodology involving a significant number of people dealing with the management of natural resources. Farmers, agricultural producers, indigenous communities and technical experts from NGOs worked together with scientific researchers, professors, state officers and political leaders. Thirty preparatory meetings and regional workshops were held in the period 1996-1997. More than 2000 people, representing national, provincial and local government, NGOs, universities, research centers and producers' unions participated actively. The result of this process was a draft document that was discussed at a national plenary meeting where the final text was ratified.

Preconditions

As far as the NGOs were concerned, this process involved some special features.

- In the first place, the political will of the Soil Conservation Directorate should be emphasised. This political will proved essential to obtaining concrete and continuous results.
- Second, the NGOs had the capacity to prepare feasible proposals that avoided sterile rhetoric.
- Another important element is institutionalisation. In the Argentine case, this institutionalisation was achieved through the presence of NGOs in the National Plan Committee. Recently, this institutionalisation has been increased, as NGOs have accepted positions on the commission that monitors the development of the Programme.
- Finally, it should be emphasised that the partnership between government and NGOs should not be reduced to participating in a couple of plenary meetings once or twice a year. The process shows its real potential in informal and permanent contacts, in consultations on both sides, in the revision and preparation of combined documents and in mutual support.

Only the beginning

It is clear that the work is not over. On the contrary, it is only the beginning and there is still a lot to do. Perhaps the most important thing needed now is time. Time for this partnership to evolve and consolidate, time to face new challenges. But above all time to ensure that today's political will becomes tomorrow's effective state policy. There are still many difficulties that government and NGOs will have to face.

Undoubtedly, the government should take the actions needed to institutionalise the process without delay. In particular the National Desertification Fund should be implemented. This should be an agile mechanism at local level capable of mobilising and channeling enough resources from the national budget. It should also be able to activate international cooperation.

Pending matters

NGOs have still many matters to attend to. Perhaps the most important is to increase the participation of community based groups and poorest farmers and to reinforce public awareness. However, in spite of the fact that there is still much to be done, Argentine NGOs are determined to face the future with hope. The work that has been done so far has allowed us to lay the foundations for a solid collective structure that should enable us to achieve the sustainable development of the drylands.

The United Nations Convention to Combat Desertification

The Convention to Combat Desertification (CCD) is a UNCED convention. Unlike the Convention on Biological Diversity and the Framework Convention on Climate Change, the CCD is still low on the political agenda. Its potential and importance for sustainable development is generally underestimated.

The term 'desertification' falsely evokes the image of advancing deserts. While a desert is a unique ecosystem, desertified areas are not: they are disrupted ecosystems. Desertification means land degradation, loss of soil fertility and structure as well as the erosion of biodiversity in drought prone areas.

When the negotiations for the CCD started in May 1993, little was known about the dynamics of desertification and the social, political and economic aspects of desertification were poorly understood. Major causes of desertification are unsuitable, poverty-induced agricultural practices; monocultures; the use of agrochemicals; the neglect of traditional knowledge; overgrazing; deforestation; over-pumping; salinisation and climate change, resulting from the greenhouse effect. Land degradation in dryland areas results in increasing amounts of unproductive land. At the socioeconomic level social and cultural structures deteriorate, food security is lost, migration becomes prevalent as incomes prove increasingly inadequate and debts grow. All these factors undermine a community's capacity to exert self-determination and control over its own resources.

The CCD came into force in December 1996 and has been ratified by more than 150 states. Considerable research, awareness raising, monitoring, lobbying and finance will be needed before it is possible to implement it.

Some strong characteristics of the CCD are:

- participatory, bottom-up approach
- integrated approach and gender sensitiveness
- addressing global dimension of desertification
- linking environment and development
- partnership building between stakeholders
- linking to other conventions and relevant agreements to create synergy.

National Action Programmes

Those taking part in the CCD are obliged to make a National Action Programme (NAP) along the lines laid down in the Convention. In November 1999, the third conference of participants took place in Recife, Brazil. African countries reported on their progress in developing and implementing NAPs. Although all African parties had started on NAPs, only 10 had reached the implementation stage. Donor countries also reported on their activities in support of NAP at the conference. Their reports showed the difficulties of putting the concepts and policies of the CCD into practice. Major bottlenecks to the participation of local communities in the NAP process were shown to be inappropriate and unfavourable laws and regulations at state level, a lack of funding, experience, expertise and the necessary political will. Monitoring progress provides countries with the opportunity to correct the way NAPs are developing.

Argentina (Merega p7) is a good example of how raising awareness on gender issues has influenced the NAP. A few years ago, the NAP process in Argentina was not gender sensitive. Today, Argentina strongly supports the incorporation of gender issues into the NAP.

The International NGO Network RIOD

NGOs have been taking part in the negotiation process that lead to the CCD and have contributed positively and strongly to the text and content of the convention. In November 1994, NGOs established RIOD (a French acronym for the international NGO network to combat desertification), a network to enable the international exchange of information, the raising of awareness and to encourage learning from experience as well as North-South cooperation and joint activities. NGOs have been instrumental in initiating and setting up consultative structures at country and (sub-) regional levels. They have helped raise awareness, involve local communities and create links with local and national authorities, institutions and donors. Many NGOs have contributed research and capacity building to participatory methods.

In August 1999, five years after it had been set up, the first RIOD general meeting was held to review the objectives and structure of the network. One of the conclusions of this review was that as the constraints to implementing the CCD became more visible, it was necessary to emphasis lobbying, campaigns, the creation of synergy and international political action to compel the creation of more favourable environment for combatting desertification.

Structurally changes are being made to improve efficiency at regional level. In the past RIOD had national, sub-regional, regional and global focal points. In the new structure there will be more emphasis on focal points at the national level. Fifteen regional representatives will form a Global Coordination Committee (GCC) for international coordination.

The NGOs in RIOD have recognised that although activities to combat desertification are not new, the CCD approach has great potential. By putting the people of affected areas at the centre of the process and pushing for an enabling environment at the national and (sub-) regional levels, it may be possible to boost those development processes that create more sustainability in environmental, social, economic and political terms.

However, there are many pitfalls. The dangers that the CCD will become just another time-bound document slowly moving from the desk to the bookshelf or that it will turn into a talking circus are very real. There is also the problem of hidden agendas. It is therefore necessary to mobilise and join forces and take action when necessary. There is too much at stake to allow this opportunity to slip by.

Farmers, NGOs and lighthouses: learning from three years of training, networking and field activities. *1998. 74 p. Sustainable Agriculture Networking and Extension (SANE), 201 Wellman Hall 3112, Berkeley, California 94720, USA.*
This report brings together the findings of the first phase of SANE, a network of regional and local NGOs in nine countries, all utilising an agroecological approach to assist small, resource-poor farmers in the establishment of sustainable farming systems. Central to the SANE programme is the "lighthouse", the concept of the agroecological sound farm or project, which serves to demonstrate the viability of the concept and spread the approach more broadly up to watershed, region or even country level. This diffusion was supported by the SANE programme by the training of NGO technicians in agroecological concepts and technologies, the strengthening of local institutional capacities and the establishment of new agroecological lighthouses. An overview of the first three years of this process is given and described in depth for the continents and countries involved in Latin America (El Salvador, Cuba and Peru), Africa (Senegal, Uganda, Cameroon and Mali) and Asia (Laos and the Philippines). A clear and open description of a difficult but valuable approach. (IHG)

Farming like the forest: traditional home garden systems in Sri Lanka *by Hochegger K. 1998. 203 p. ISBN 3 8236 1293 X : USD 40.00. (Tropical Agroecology ; 9). Margraf Verlag, PO Box 1205, D-97985 Weikersheim, Germany.*
Karin Hochegger presents a detailed study of the forests gardens of Kandy in central Sri Lanka. She first examines concepts of nature and conservation within the context of the beliefs of the inhabitants. She then traces the history of Sri Lankan agriculture before, during and after the colonial period, and the important role that the traditional home garden continues to play in ensuring family food supply. Most of the book is devoted to a detailed ecological study of 158 gardens: floristic composition, ethnobotany, structural features, nutrient cycle and wild fauna. Hochlegger emphasises that "farming like the forest" maintains harmony between nature and mankind. The gardens had an amazing biological diversity: 640 species were identified in the 158 gardens. In three gardens in which the efficiency of production was examined, inputs were found to be extremely low (mainly labour for harvesting) and the various outputs provided most of the family's subsistence needs. She predicts that additional off-farm earning opportunities would give the traditional home gardens a chance to continue to survive in their full richness. If, with their increased consumer demands, farmers would want to live from income derived from the farm, they would have to devote more land to cash crops, and intensify gardening by using fertilisers and pesticides. The book is very much focused on botanical knowledge, both of the farmers and of scientists, and has several line drawings of plants by Shanta Jayaweera. This will be of particular interest to those interested in botany and natural farming. (AWB)

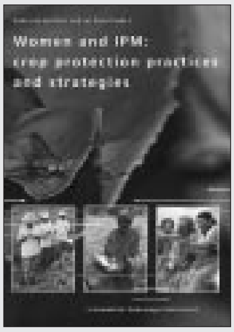
Women and IPM: crop protection practices and strategies *by Fliert E (van de) and Proost J (eds). 1999. 108 p. ISBN 90 6832 710 0 : DFL 29.00. Royal Tropical Institute (KIT), PO Box 95001, 1090 HA Amsterdam, The Netherlands, e-mail: kitpress@kit.nl; Intermediate Technology Publications (ITP), 103/105 Southampton Row, London WC1B 4HH, UK, e-mail: itpubs@itpubs.org.uk.*
This book builds on the different contributions made to the symposium on Gender Issues and Crop Protection, which was part of the 13th International Plant Protection Congress held in 1995 in The Hague, The Netherlands. On that occasion for the first time the importance of gender issues in crop protection was acknowledged. It soon became clear that most contributions related to integrated pest management (IPM) and that was probably not by chance. It is common



practice for women to do most of the day to day crop management, so the close monitoring required by IPM takes place quite naturally. IPM practices mean direct health benefits to the whole community, as the women, who prepare the food and bear the children, are protected against toxic pesticides. IPM cases from Bhutan, Vietnam, Indonesia, Costa Rica, Honduras, Zanzibar and Ghana are presented and other chapters deal with pesticide hazards and the role of women in the new agricultural economy in Russia. From the contributions it becomes clear that the IPM extension and training programmes should be made more accessible to women and they advocate the continuing support for IPM. The concluding chapter provides a broader view on the presented cases, including a plea for a new kind of external structuring of decision making, using mechanisms such as Farmer Field Schools. (IHG)

Participatory rural appraisal and planning : workbook *by Selener D, Endara N and Carvajal J. 1999. 146 p. ISBN 9978 40 814 2 : USD 25.00. International Institute of Rural Reconstruction (IIRR), Apartado Postal 17-08-8494, Quito, Ecuador / daniel@iirr.ecuanex.net.ec.*
Guia practica para el sondeo rural participativo *by Selener D, Endara N, Carvajal J. 1999. 132 p. ISBN 9978 40 248 9. Instituto Internacional de Reconstrucción Rural (IIRR), Casilla Postal 17-08-8494, Quito, Ecuador / daniel@iirr.ecuanex.net.ec.*
This work book contains valuable experiences with the use of PRA tools in Latin America. It draws on the fieldwork of IIRR staff involved in participatory rural development activities, notably their activities related to participatory planning. The particular value of this workbook lies in the fact that it focuses on the action part of PRA, rather than the usual appraisal. That is why the authors refer to PRA as Participatory Rural Appraisal and Planning (PRAP). The book was written for technical staff of development organisations and for community leaders. The language is easy to understand and the wealth of practical experiences compiled in this book makes it a great asset to all development practitioners interested in the use of participatory methods. The book contains a general section explaining the concept of PRAP and its guiding principles and gives an overview of the results obtained by applying PRAP. It also indicates what the limitations are and discusses who, where and with whom PRAP should be applied. Time requirement for PRAP application and gender aspects are also treated in this section. In section two the PRAP tools are discussed in more detail. The information gathering and analyses tools are clustered according to their suitability; for collecting spatial information, time information, socioeconomic information, production and technical information, identifying problems and solutions, project planning. All tools are treated in a fixed format: What sort of tool is it, What are its uses; what kind of information does it contain and how is the tool applied? Apart from PRA tools, tools from other (project planning) methods are included as well. The last section contains two case studies, illustrating the process of problem identification and project planning in detail. The two examples give good insights and lots of ideas about how participation in the planning process can be enhanced. This is done by looking at crucial factors like process design, profile of participants/stakeholders and actual PRAP application. Each case concluded with a summary of the main lessons learned. Where there is no vet *by Forse B. 1999. 368 p. ISBN 0 85598 409 0: GBP 14.95. Oxfam, 274 Banbury Road, Oxford OX2 7DZ, UK.*
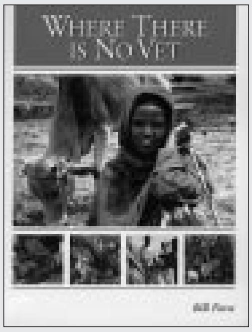
Oxfam and CTA supported the preparation of this guide to first aid for animals. The author is a veterinary practitioner and farmer, and does a commendable job of explaining an impressive number of livestock diseases and their causes, symptoms and treatment. The numerous drawings make the text easy to understand. Although some information is



given on care, feeding and the handling of animals, the recommendations focus on curative measures. Important mechanisms of specific (often local) livestock species or breeds, such as tolerance or resistance to a particular disease, are mentioned only briefly. Anyone wanting to use the information provided in this book would need a good pharmaceutical kit and cooling facilities, as frequent reference is made to antibiotics, which have to be kept cool. If the antibiotics work, they can indeed lead to the animals making a spectacular recovery. However, their frequent use can stimulate the development of the disease agents resistant to antibiotics. This danger is not stressed sufficiently. Although it is clear that a general book on simple veterinary medicine for the tropics cannot cover ethnoveterinary treatment in any detail, it would be desirable if more emphasis were placed on local medicines which people can prepare themselves and which do not need to be kept cool. The book raises ambiguous feelings. On the one hand, it is desirable to have a reference work that deals with so many diseases and possible cures. On the other hand, it proposes diagnoses and treatments that require specific tools, such as microscopes, and treatments such as intravenous infusions, which require substantial skill and special materials. Where there are microscopes and infusion solutions, a vet is probably not too far away either. Despite these critical remarks, the book will doubtless be useful for field-based development workers, to guide them in making routine treatment and in handling emergencies. It frequently points to the limits of what can be done where there is not vet and where assistance from more experienced people is necessary. I hope that future editions will correct some of the errors that slipped through the proof reading, eg. in the illustration on page 297, the "zebu" cow has a conspicuously straight back, whereas the "N'dama" cow has a hump! (Wolfgang Bayer)

Searching for women's voices in the Hindu Kush-Himalayas *by Gurung JD (ed.). 1999, 407p. International Centre for Integrated Mountain Development (ICIMOD), GPO Box 3226, Kathmandu, Nepal. E-mail distri@icimod.org.np; Web http://www.icimod.org.sg ISBN 92 9115 855*

This book contains 11 case studies carried out in villages in the Hindu-Kush Himalayas. The research was an ICIMOD initiative implemented under its Gender and Development 2000-2002 programme. ICIMOD set out to gain a deeper understanding of the views held by women living in the mountainous area that stretches from China to Alfganistan. The information collected was intended to facilitate more gender sensitive and constructive development planning in the region. Previous research had been conducted by 'professional researchers' who did not speak the local languages. This made it difficult for them to access the private lives and economic and civic position of the women in the various mountain communities. In this sense the ICIMOD research is unique. The women who conducted the three month study and the subsequent desk reviews of local and national policies not only spoke the local languages, but had grown up in mountain communities. They had gone on to further education and were now active in gender and development programmes in the area. As the editor admits, it was difficult to find researchers with this type of background. The book proceeds from the assumption that mountain women, although often more autonomous than women from the lowlands, are the main agents in resource management, yet they are socially, politically and economically disadvantaged and ignored. The book draws attention to the important role women play in the management of natural resources in the mountains and the impact their management practices have on lowland economies and natural resources. The book also stresses how their rich fund of local and indigenous knowledge can, if accessed, be of great value to those concerned with the development of the 140 million people who inhabit the Hindu-Kush. In many countries in the region the political status of women is uncertain. This is graphically illustrated by the editor who observes that data collection on women in Alfganistan was luckily completed before the Taliban took over. Such research by women on women would certainly never have been tolerated by such a regime. This is an accessible, factual and committed introduction to a little known region. This book provides a well-annotated and referenced introduction for those who wish to know more about the development problems of the Hindu-Kush and its women. (MMJ)

Information exchange in networks: analysis of individual communication behaviour and communication structure *by Weiligmann, B. 1999. 211p, ISBN 3 8175 0288 5, DM63.00 Institut fur Landwirtschaftliche Betriebslehre der Rheinischen Friedrich-Wilhelms-Universitat, Bonn; Arbeiten zur Agrarwirtschaft in Entwichlungslaendern, Wissenschaftsverlag Vauk, PO Box 4403, D-24043 Kiel, Germany, www.vaux.de*

The reader will quickly realise that this book is an unedited thesis. Its subject matter is particularly interesting for those in development organisations who are part of, or responsible for, information networks. In development work, networks play an important role in facilitating the circulation of information and experiences. Weiligmann studied the Tanzanian Vegetable Production Network (TVPN) to establish the reasons for its success, stability and effectiveness. The TVPN is typical of a network in a developing country. Great distances and poor communication infrastructure are major problems in Tanzania yet the TVPN, set up in 1993 by the Tanzania Government and GTZ, has been able to improve communication flow in the horticultural sector. It now includes all the important opinion makers in Tanzanian horticulture and its members have been able to enlarge their contacts with many different types of people. Weiligmann's study shows that, to be successful, a network should be able to offer its members widely accepted, concrete targets; incentives to contribute information and be able to stimulate a sense of trust. TVNP invested much effort in arranging meetings, workshops and presentations where members could meet each other face to face. Working in an environment of information scarcity the greatest incentive to participate in the TVPN was this type of contact and exchange. The personal information networks of TVPN members who had studied, worked or had contacts outside the country were particularly valued. Weiligmann's study comes to two instructive conclusions. First, it seems that direct contact made at TVPN meeting and workshops often facilitated the acceptance of technological change. Second, in constructing networks in situations of poor infrastructure and over great distances, consideration should be given to emphasising small, subnational/regional networks rather than networks at national and international level. The book contains a useful bibliography on communication and agricultural innovation with particular reference to Africa. (MMJ).

Organic cotton: from field to final product *by Myers D and Stolton S (eds). 1999. 267 p.ISBN 1 85339 464 5 : GBP 16.50. The Pesticides Trust, Eurolink Centre, 49 Effra Road, London SW2 1BZ, UK. Intermediate Technology Publications (ITP), 103-105 Southampton Row, London WC1B 4HH, UK E-mail itpubs@itpubs.org.uk.*

As cotton is one of the world's major cash crops, many farmers are confronted with the negative environmental impacts of its production such as reduced soil fertility, loss of biodiversity and especially the problems related to pests and pesticide use. Along the processing chain pollution also occurs, especially during the bleaching and dying of the cotton fabrics. This book describes organic cotton production and processing and is the first complete overview of its kind, since the first organic cotton was marketed some 10 years ago. Still in a rather preliminary stage, there are signs that it is moving into a mass market. The book provides a very good and complete picture of the insights gained up to now and it draws from case studies from all over the world. Besides cultivation (including the growing of genetically engineered cotton) and processing, economic and marketing aspects, the conversion process, certification and support requirements for projects are also discussed. Judging from questions about the environmentally friendly cultivation and processing of cotton that have reached ILEIA in recent years, we can predict this book will become a best-seller. (IHG)

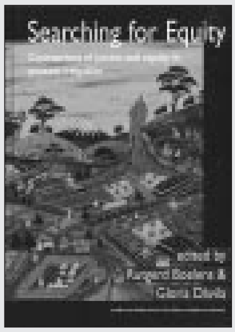
Searching for equity : conceptions of justice and equity in peasant irrigation *by Boelens R and Dávila G (eds). 1998. 472 p. ISBN 90 232 3385 9: USD 27.00. Van Gorcum, PO Box 43, 9400 AA Assen, The Netherlands. Buscando la equidad : concepciones sobre justicia y equidad en el riego campesino by Boelens R and Dávila G (eds). 1998. 506 p. ISBN 90 232 3386 7: USD 27.00. Van Gorcum, PO Box 43, 9400 AA Assen, The Netherlands*



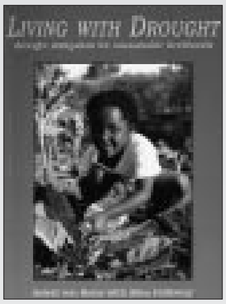
This book is about equitable water distribution and appropriate water management in irrigation. In the field of irrigation it is the indigenous populations in particular who, although most involved, are losing control over the process of water management, as national policies and development interventions decide what should be done over their heads. So, the intricate diversity of equitable rules and practices grown in history and culture are pushed aside, resulting in an often less sustainable and more unequal water tenure. In the first part of the book many viewpoints related to equity, justice, power and peasant rights with regard to irrigation are presented. The second part goes into detail with a wealth of examples from the Andes. Fascinating reading, although the addition of some photo-material would have made it more tangible. (IHG)

●

Manure management in the Kenya Highlands: practices and potential *by Lekasi JK [et al.]. 1998. 35 p. ISBN 0 905343 255. Henry Doubleday Research Association (HDRA), Ryton Organic Gardens, Coventry, CV8 3LG, UK.*

Description of a survey among 60 farmers cultivating high potential land in the Central Province, Kenya for their manure management and their perceptions of manure quality. Their livestock is traditionally kept in permanent confinement allowing the easy collection of excreta. Manure is highly valued as the crop cultivation is intensive and the purchase of artificial fertilisers is limited, due to the high costs. The purchase of stall-feed however, is common. This study reveals that due to the continuous intensification the need to enhance the nutrient turnover will become more important. Suggestions for improvement are given. (IHG)

'Participation villageoise au développement rural'. *'Réseau Africain sur les Approches Participatives'. 1999. KIT/World Bank, ISBN 90 6832 131 5. Distribution: ANANDER, BP V 183, Abidjan, Cote D'Ivoire; DIFOV, 03 BP 0712, Cotonou, Benin; DVA, BP 257, Antananarivo (101) Madagascar; DVA, BP 7018, Ougadougou, Burkina Faso; IER, BP 258, Bamako, Mali; IRAG, BP 1523, Conakry, Guinnee; Royal Tropical Institute (KIT) (contact: Aad Blokland), PO Box 95001, 1090 HA Amsterdam, The Netherlands; World Bank (contact: Jan Weetjens, AFTAI1), 1818 H Street, N.W. Washington, D.C. 20433, USA. An English version,* **Village participation in rural development,** *is expected to be published in May 2000. This publication can be ordered from KIT and World Bank.*
This is a Tool Kit for participatory rural community development consisting of a handbook, a set of 18 coated files with methodological tools and a trainers guide. The first part of the handbook explains the principles and steps of a participatory development process at community level. For each step methodological tools (eg mapping, semi-structured interview, transect, village history, seasonal calendar, visualisation and discussion of sensitive problems, problem tree, analysis of objectives and opportunities) are provided which help communities to better understand their situation, problems and opportunities, set priorities and objectives and plan effective actions. The diagnosis is at a general level giving space to whatever problems are being experienced by various groups of the population. Attention is also given to analysis and strengthening of institutions at community level in order to assist in the coordination of the implementation, monitoring and evaluation of planned activities. The second section of the book discusses the role of each actor, training needs and the necessary coordination and support required from the upper hierarchy. The last section discusses the consequences of the approach at the level of the national institutions involved in rural development. The objective of the trainers guide is to help trainers to design a participatory training programme to increase the skill of development agents to implement a community-based participatory development process and to use methodological tools. The training modules presented can be combined in various ways depending on need.
The Tool Kit is well designed, very readable and based on practical experience. Further development of the Tool Kit can be expected from the international support teams. For specific problems (eg health, water, soil fertility, soil conservation) additional, more focused learning tools are needed. (CR).



Living with drought : drought mitigation for sustainable livelihoods. *Learning pack comprising: a book and a video with three films: Letsatsi le eme (The sun is standing still), Banga dam and Mooka granaries by Kotze A (von); Holloway A. 1999. 206 p.; 29 min., 18 min., 14 min.; PAL. ISBN 0 86486 388 8; ISBN 1 85339 470 X : GBP 19.95. Disaster Mitigation for Sustainable Livelihoods Project (DiMP). David Philip Publishers, 208 Werdmuller Centre, Claremont 7708, South Africa, e-mail: dpp@iafrica.com; Intermediate Technology Publications (ITP), 103-105 Southampton Row, London WC1B 4HH, UK, e-mail: itpubs@itpubs.org.uk.*
The pack is a combination of participatory learning activities and written and visual case studies from 5 countries in southern Africa. The pack is the result of a participatory process that involved many different people from the region. The primary aim is to stimulate participants' thinking around issues of relief and development, and enhance their understanding of drought mitigation. The perception that drought is a disaster that ends with the next season's rains is challenged. As drought is a recurrent event in southern Africa sustainable development can be achieved only if drought mitigation is an integrated part of development practice, education and policy. The pack is intended for training of extension workers as well as for those involved in the participatory development of sustainable agriculture and in disaster management. It has been designed to be flexible, and to meet a wide range of training, education and facilitation needs. Users are assumed to have basic knowledge of the participatory learning processes.
The participatory learning process followed introduces learners to the terms and concepts of drought mitigation, understanding of vulnerability and risk including impact on women and children, and planning and implementation of community-based strategic drought mitigation. Practical options as well as institution-building, negotiation and policy advocacy are included as well as practical training materials. A very practical, participatory and user-friendly publication. More attention could have been given to assessment of traditional and recent indigenous strategies on coping with drought. (CR).

Farmer Field School on Integrated Soil Management, Facilitator's manual. *Produced by Farmer-centred Agricultural Resource Management (FARM) Programme 1998. FAO-RAP (ask the Regional Soil Management and Fertiliser Use Officer), Maliwan Mansion, Phra Atit Road, Banglumpoo, Bangkok 10200, Thailand, Phone: +66 2 281 7844; Fax: +66 2 280 0445; Email: FAO-RAP@fao.org*
The Farmer Field School (FFS) approach on Integrated Soil Management (ISM) has been successfully experimented with at field sites in China, Philippines, Thailand and Vietnam. This facilitators' manual was developed on the basis of these experiences. The objective of the manual is to assist facilitators by providing a basic framework and materials on FFS-ISM. The farmer field school aims to build each farmers' capacity to analyse their soil and other related crop management practices, to identify the main constraints, and to test possible solutions to their field problems, eventually identifying and adopting the practices most suitable to their farming system. The training materials help farmers to make their own decisions, to organize themselves and their communities, and to create a strong working network with other farmers, extension workers and researchers. The manual is meant for field-based extension officers, farmers' leaders and field-level development workers and their trainers and coordinators. It contains a large number of FFS-ISM exercises on general FFS related topics and a selected range of soil management topics.
Although the approach focuses mainly on fertility management, indigenous concepts of soil management are not well integrated (eg completely overlooking farmers own soil classification system) and linkages to related issues (eg. water, crop, livestock, credit) are few, the manual provides a very useful, instructive and flexible set of learning modules and reference materials. (CR).

Learning together through participatory extension, A guide to an approach developed in Zimbabwe *by Hagmann J, Chuma E, Murwira E and Connolly M. 1998. Harare: AGRITEX/GTZ/ITDG, 59 p. Order against mailing costs from: Universum Verlag, Germany, Order No. A-021-E, Fax: +49 611 9030556; Email: horst-dieter.herda@universum.de*
Learning together through participatory extension, A video to an approach developed in Zimbabwe. *Producer/director John Riber, executive producer Jürgen Hagmann. 1998, 42 min., English. Media for Development Trust, 135 Union Ave, POB 6755, Harare, Zimbabwe, Fax: +263 4 729066; Email: MFD@Mango.zw*
This booklet, written for field staff and middle-level extension managers, describes a community-oriented approach to rural extension based on farmer experimentation and learning. The action-learning cycle integrates four main phases: social mobilisation through a situation analysis carried out jointly by insiders and outsiders, community-level action planning, implementing of activities and farmer experimentation, and monitoring and evaluation through sharing experiences and ideas. A major focus is on local institutional development. The process in practice - with all its steps - is described and clarified through examples from the field.
The video shows the steps taken by a development agent in practicing a participatory extension approach (PEA) with farmers in Zimbabwe. The agent and the farmers together learn and develop innovations in technical and social fields. The video can be used to create general awareness of PEA or as an aid in facilitating training/learning programmes for extension agents.

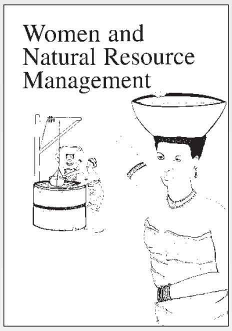
Holistic management: a new framework for decision making *by Savory A and Butterfield J. 1999. 616 p. ISBN 1 55963 488 X : GBP 24.95. Island Press, Washington, DC. Center for Holistic Management, 1010 Tijeras, NW, Albuquerque, NM 87102, USA. Fax: +1 505 843-7900; Email: center@holisticmanagement.org ; Website: www.igc.org/holisticmanagement.org*
This is the revised and updated version of the first edition of Holistic Resource Management published in 1988. The experiences of the many thousands of people now practicing Holistic Resource Management have strongly

enriched this second version.
The framework developed by Allan Savory intends to help people and communities to make better decisions on how to use their natural resources based on the perception that humans, their economies, and the environment are inseparable. The people involved start with defining all their resources under management and a common vision that reflects what they genuinely value and hope to accomplish. At the heart of the approach lies a simple cyclic testing process that enables people to make decisions that simultaneously consider economic, social, and environmental realities, both short- and long-term. A number of critical tools and management guidelines have been identified to influence ecosystem processes in such a way that optimal win-win results can be expected. Originally the framework was developed for holistic herd and range management in semi-arid regions for which Allan Savory had developed a challenging new approach. In this second edition of the book ideas for environmentally sound crop management are presented. Much attention is given to the holistic planning of land and financial resources. The use of the holistic management model is now being expanded to business and policy as well. The book presents a creative, practical and holistic approach to the development of sustainable resource management. Holistic Management has become very popular in the USA but is now re-discovering its roots in Southern Africa. By merging Holistic Resource Management framework with the participatory approaches for development of sustainable agriculture – livelihoods both could benefit considerably. (CR)

Changing views on change: participatory approaches to monitoring the environment *by Abbot J and Guijt I, 1998. SARL Programme Discussion Paper 2. International Institute for Environment and Development (IIED), 3 Endsleigh Street, London WC1H 0DD, UK. Email: bookshop@iied.org £8, available in English, Portuguese and Spanish.*
The booklet is a review of participatory approaches to tracking biophysical changes in projects focusing on environmental regeneration and draws on published literature, interviews with practitioners and experiences of action-research project in Brazil. It examines the roles of different stakeholders at each stage of the monitoring process. Wide interpretations of these roles and diverse purposes of monitoring have led to many forms of participatory monitoring. Compromise is inevitable when stakeholders with different expectations come together. Supposed trade-offs, eg. between scientific rigour and maintaining local participation are discussed. The book describes methods 1) based on visualisation techniques of PRA, 2) that use oral testimony to understand patterns of environmental change, and 3) that adapt methods of ecological assessment for use by local people. Ten experiences of monitoring are compared in terms of the role of local people in the process. The review highlights several areas for future research and improved practice in the participatory monitoring of environmental change (IHG).

Microplanning manual for joint forest management areas *B Singh & Varalakshmi (eds.). 1998. 112 p. ISBN 81 85419 45 0. TERI, New Delhi 110 003, India.*
The leading concept of this book is that local communities can effectively exploit forests while maintaining the regenerative capacity for sustained production. Genuine involvement of all (groups of) people concerned at the level they can practically manage, is seen as the key condition for success. In addition to the need for changing the roles and attitudes of extensionists (from conveying messages to facilitating communal processes), the basic tools for the different phases of participatory diagnostics are described including PRAs, transect walks, village profile or ranking. Special attention is given to different types of maps for resource use, forest conditions, forage conditions, soil erosion, command area for water harvesting purposes. The final outcome of the diagnostic exercise is the management map visualising the ideas for the agreed intervention. The appendices providing details of various formats used in specific cases, serve as practical examples to be used and adapted by the reader in other situations. (KM)

Capacity building: an approach to people-centered development by *Eade D. 1997. 226 p. ISBN 0 85598 366 3 (pbk) : USD 14.95. Oxfam. Oxford OX2 7DZ, UK.*
This book builds on the experiences gathered in Oxfam's numerous projects and programmes in analysing capacity-building issues. Thus, capacity building should start from essential principles such as people-centeredness, acknowledgement of human rights, empowerment and participation, interdependence between people and societies, sustainability and the acceptance that social change may involve risks. The book goes on to elaborate consequences for the orientation, contents and methodology of investments in people, organisations, and networks. The special chapter on capacity building in crisis situations introduces the concept of "capacities and vulnerability analysis" stressing the necessity to carefully balance the complexity and extent of intervention activities with the existing capacity in the societal groups concerned. Worthwhile reading if you are motivated by the "why to" question and involved in the debate (either individually or with other people) on the potential role of capacity building towards genuine development. (KM)



Women and natural resource management: a manual for the Africa region *C Jackson, McCracken J, Kabutha C and Ogana W. 1996. 176 p. ISBN 0 85092 465 0. Commonwealth Secretariat, London SW1Y 5HX, UK.*
The four sections of this training module subsequently address general introductory issues, lessons learned from rural women, women's organisations for conservation and conservation techniques. The book does not aim to be a cookbook that has to be followed precisely. It gives ideas, proposes methods and depicts specific tools but always invites adaptation and experimentation. Section two of the book contains the central message and provides an explicit and elaborate account of ways and means to learn from rural women. The third section describes in detail six case studies for different agroecological zones in Anglophone Africa. Because it depict many farming techniques rather succinctly, Section Four somewhat underplays possible limitations. The special notes for trainers at the end of each chapter provoke reflection on how to set up relevant training in the different fields. Even though it is a reprint of a 1992 manual, much of the information is still valid. (KM)

Africa's valuable assets: a reader in natural resource management *by Veit P (ed.). 1998. 447 p. ISBN 1 56973 258 2: USD 40.00. World Resources Institute, Washington, D.C. 20006, USA.*
A sociopolitical perspective on the state of Africa's natural resource management. Optimistically highlighting the availability of resources and the opportunities for future use. It analyses in generic terms basic aspects of development over the past decades and definitely contests the view, often adhered to in America as the authors state, that Africa is far from being a flourishing continent. Large amount of national data on economic indicators, development aid, population dynamics, education, health, land use, ratification of international conventions as well as human rights are presented to support the analytical chapters. The latter cover a wide range of issues such as participation, ownership and accountability, roles of GOs and NGOs, legislation and the mutual relationships between global agreements and national development priorities. Improved communication, nationally and locally but also through electronic networks, is seen as an essential element for the continuation of positive impacts. All chapters end with conclusions and/or recommendations which, by the nature of the Sub-Saharan focus, are somewhat general. Recommended if you are interested in the political dimensions of natural resource management. (KM)

Participatory forestry: the process of change in India and Nepal *by Hobley_M, 1996. Rural Development Forestry Study Guide 3, 337 p. ISBN 0 85003 204 0 : GBP 14.95. Overseas Development Institute (ODI) Regent's College, Inner Circle, Regent's Park, London NW1 4NS, UK.*
This publication analyses the historical evolution of forest management in India and Nepal from colonial exploitation to participatory forestry. Although there are many positive developments, Community Forestry and Joint Forest Management (JFM) have not been successful everywhere. To analyse the constraints the author raises the question of 'who benefits?' A multi-stakeholder and multi-resource approach needs joint micro-planning and innovative management. The complexity of the problems related to joint forest management are discussed from a technical and institutional perspective including scenarios for the future. Appendices are included describing exercises for use in training courses as

well as useful video material on the subject. (IHG)

Shared management of common property resources in the Sahel: a regional action-research programme

The SMCPR programme aims to research and identify how common property resources in the Sahel (eg community forests, rangeland) can be managed in an equitable, sustainable and peaceful way by the many people who rely on them for their livelihoods. It was developed in response to difficulties expressed by many projects setting up natural resource management systems where resources are important to both nomadic and sedentary groups. Mobile groups, and transhumant herders in particular, often depend on "village lands", "community forests" and other strategic resources, but their rights of access are being reduced. This is threatening their livelihoods, the sustainable use of the resource, and is contributing to conflict between different user-groups.

The programme works with seven operational projects in Niger, Mali, Sudan and Ethiopia. Four of these are forest-resource management projects, two are working specifically on pastoral development and one is working more generally on natural resource management in the context of decentralisation in Mali. All are working in areas used by pastoral and agricultural communities alike. The programme will research and identify natural resource management systems which take mobility and multiple user rights into account, and which reinforce local people's capacities to manage common property resources in an equitable, peaceful and sustainable manner.

A six-monthy Newsletter 'Browse' is being published to inform partners and other interested persons on the advances of the programme. A first issue has been published in September 1999 (CR)

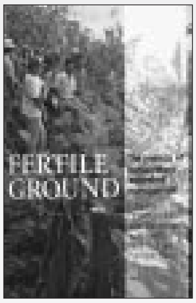
Alternative irrigation: the promise of runoff agriculture
by Christopher J Barrow, 1999. ISBN: 1 85383 496 3 (pbk) : GBP 15.95, 172 p. Earthscan Publications Ltd., 120 Pentonville Road, London, N1 9JN, UK. Fax: +44 171 278 1142; Email: earthinfo@earthscan.co.uk ; http://www.earthscan.co.uk

Runoff agriculture, the practice of concentrating surface runoff for cultivation, forestry, livestock or other human use, is being re-discovered as an alternative to conventional irrigation. Traditionally, this type of water harvesting has been widely used in drought-prone regions but due to changing economic, institutional and cultural conditions it fell into disuse in many places. This book gives an excellent presentation of the wide variety of techniques developed by farmers over thousands of years. A distinction is made between soil and water conservation techniques, runoff harvesting & storage techniques and flood water farming. Special attention is paid to the breakdown of traditional runoff agriculture (with an overview of the actual situation by country) and the opportunities and constraints for rehabilitation and expansion. The value of runoff agriculture and water harvesting in general have been widely demonstrated. Given the expected increase in drought and water shortage the relevance of runoff agriculture and this publication can be expected to grow.

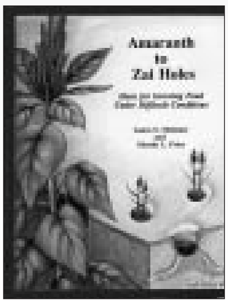


Fertile ground: the impacts of participatory watershed management
by Hinchcliffe F, Thompson J, Pretty J, Guijt I and Shah P (eds.). 1999. 385 p. ISBN 1 85339 389 4 : GBP 15.95. IT Publications, London WC1 4HH, UK.

This collection of case studies provides a wealth of information on different approaches and techniques in watershed management. The book covers resource conserving technologies and practices, enabling government policies, NGO led actions and institutional aspects. Concrete examples from all over the world illustrate the principal issues at stake in effective resource management aiming at long-term sustainability such as integrated soil fertility management, biodiversity management, scaling-up from village to higher levels, supportive policy measures, possible incentives and participation of all relevant actors in decision making. The cases do not present ready made solutions but provide informative insights into successful processes and techniques (as well as the necessary conditions for their application) which can support both GO and NGO initiatives in their endeavour to plan the proper management of watersheds and thus to avoid desertification. (KM)

Options for soil and farmer friendly agriculture in the Highlands of Northern Thailand
by Keer K (van), Comtois JD, Turkelboom F and Ongprasert S (eds.). 1998. 184 p. ISBN 3 9806467 0 X : DM 20.00. GTZ, 65726 Eschborn, Germany.

This easily readable final output of a collaborative effort between the Catholic University of Leuven (Belgium) and the Maejo University (Thailand) describes the highlands, their people and the way they manage soils, vegetation and animals and defines the challenges ahead. Part II depicts in considerable detail the practical lessons and principal conclusions to be drawn from the management of forests, fallows, crop residues, soil use (erosion control, nutrients) and pests and diseases. At the heart is the optimal use of locally available and affordable resources and methods. Part III then portrays challenges for the future of highland agriculture. Although the conflicting roles of protection and production seem to complicate sustainable highland development, an opportunity for creating the necessary balance is sought in the full incorporation of the idea of diversity: the best approach is to mix and match several of the various agricultural, ecological economic, social and cultural options available. (KM)



Amaranth to zai holes: Ideas for growing food under difficult conditions *by Meizner LS and Price ML. 1996. 404 p. ISBN 0 9653360 0 X : USD 29.95. ECHO, North Fort Myers FL 33917 2239, USA.*

If you are working directly with communities and farmers in the tropics or subtropics, and if you are looking for practical livelihood techniques, this book is warmly recommended! It is based on fifteen years of experience published in ECHO's exchange bulletins and is a real gold mine of data on general growth conditions, and the way they can be adapted for a multitude of staple crops, vegetables, fruits, and pasture crops. Furthermore, it describes basic aspects of healthy soil and water management under dry land conditions, mainly focusing on small-scale situations. The chapter on animal husbandry emphasises animals that usually receive little attention such as camels, bees, local chicken, fish and rabbits. However, it is too brief to be used as a basis for experimentation. However, this deficit is recognised by the publisher and covered by interesting references. The wealth of ideas and references in to more in-depth documentation (including audio-visual materials) and/or contacts for information or training make this book a valuable resource kit for practitioners however much experience they may have (KM)

Land tenure and resource access in West-Africa: issues and opportunities for the next twenty five years. *IIED. 1999. 44 p. ISBN 1 899825 31 2. International Institute for Environment and Development, London WC1H 0DD, UK.*

This report is part of a programme by the British and French governments. It divides the region into four distinct zones, ie the Gulf of Guinea, the Atlantic forests, the land-locked Sahel and the Atlantic Sahel. Typical topics are the contradictions between customary and statutory systems, the implications of gender sensitiveness, the impact of migration and urbanisation trends, the role of pastoral management systems and the possibilities and drawbacks of irrigation. Special attention is reserved for resource conflicts, especially in peri-urban areas, wetlands and areas where arable crop farmers have immigrated in large numbers. Two crucial elements in the management of common property resources are at stake. First, how can different user groups agree on the management, the degree of exploitation and on cost/benefit sharing? Second, how can governments successfully devolve sufficient and adequate powers to these groups in negotiating and enforcing agreed terms for resource use and management? Based on local consultations the report identifies three critical leverage points for a way forward: decentralisation, clarification of customary and statutory tenure systems and encouragement of local debate (KM)

Analysis and planning using Strategic Environmental Analysis

Jan Joost Kessler

Given the growing need for systematic participatory environmental analysis, planning and stakeholder coordination of activities to combat poverty and land degradation, AID Environment and the Netherlands Development Organisation (SNV) developed the Strategic Environmental Analysis (SEAN) methodological tool kit. In this article, the main characteristics of SEAN are discussed, using its application in Atacora Province in Northern Benin as an example.

Photo: JJ Kessler

Active community participation in strategic environmental analysis and planning.

In regions with limited economic potential where there are environmental problems such as desertification, there is a growing need for systematic environmental analysis to answer such questions as:

- What are the insights and interests of different actors as far as the proper management of natural resources are concerned?
- What level of land degradation is acceptable and can be considered as reversible?
- How can coalitions of stakeholders be formed to deal with the root causes of land degradation?
- Are there any so-called win-win opportunities that can improve both the economic and environmental situation?
- How can environmental priorities be integrated with economic, social and gender priorities?

In many places the absence of a clear vision of the future has led to confusion, lack of coordination and the setting of incorrect development priorities. This is especially so when many activities have been undertaken by different actors. Poor experiences with national environmental planning have made clear that the analysis and planning of rural development must take place at sub-national level and actively involve the population. There is a need to pay more attention to root causes rather than symptoms and to make use of existing opportunities, ongoing changes and the promising initiatives being taken at various levels.

SEAN has been designed to meet these needs. It is a comprehensive and practical methodology with the long-term objective of including environmental issues in development planning. Concrete short-term objectives are:

- to analyse the environmental context of human development, its potentials and constraints,
- to integrate environmental key issues with economic, social and institutional aspects of sustainable development,
- to provide inputs for planning sustainable development policies and strategic action plans during the early stages of decision making.

SEAN aims to achieve these results by initiating and supporting a participatory process of mutual learning and by generating insights and creating transparency on the complex interrelations between the environmental context and other dimensions of land use.

Box 1: Some key underlying factors for the environmental problems in Atacora

- Increasing incidence of drought even in sub-humid zones
- High-level of seasonal rural emigration and lack of investments of revenues in the area of origin
- Low-level of education among rural farmers
- Poverty and poor access to credit
- Lack of organisation and power in civil society
- Predominance of traditional regulations of access and control of land resources
- Leveling, a strong social phenomenon discouraging private initiative (jealousy)
- Prevailing negative elements of local traditions
- Poor organisation of production sectors other than cotton
- Limited income opportunities outside the agricultural sector
- Non-application of organic fertilisers to improve soil fertility
- Absence of a good pastoral legislation and planning in which relevant actors have been involved
- Poor quality of urban development plans, poor management of urban wastes
- Poor agricultural extension services

Procedural and analytical principles

There are a number of procedural and analytical principles relating to the application of SEAN. First, there is need for broad participation, including actors from different institutional levels (vertical integration) and different interest groups (horizontal integration). Analytical principles include, for example:

- the multi-functionality of the environment: elements (fields, trees, etc) have multiple functions and attract varied amounts of interests from different actors;
- limitations to exploitation and the use of environmental elements;
- linkages between the different dimensions of sustainable development.

Box 2: The 10 analytical tasks of the SEAN methodology

Cluster I: Ecological system – human society context analysis
- **Task 1**: Identification of the main stakeholders within an area (including gender distinctions), identification of the main environmental functions (environmental production, carrier, regulation and cultural functions) upon which stakeholders depend, setting priorities among environmental functions and stakeholders.
- **Task 2**: Assessment of past and present trends in environmental functions (quantity and quality), using various types of indicators. Elaboration of environmental impact chains to clarify linkages between different environmental trends.
- **Task 3:** Assessment of the consequences (impacts) of current trends on stakeholders, as well as outside communities (off-site impacts), future generations (by extrapolating current trends) and natural values (eg biodiversity).
- **Task 4:** Defining the norms, standards and thresholds involved, to assess whether and when current trends may lead to the collapse of the environmental function, or to unacceptable change for certain stakeholders. As norms are difficult to assess, standards may be absent and thresholds not yet clearly defined. Generally qualitative assessments are made using insights and views from different actors involved.

Cluster II: Environmental problem analysis
- **Task 5:** Definition of the main environmental problems, using information from Steps 1-4 in a way that is as objective and specific as possible. This based on shared insights into the impact of current trends, a risk analysis and the type of stakeholder affected.
- **Task 6:** Listing the main causes and actors involved; analysing the underlying factors explaining actor's motivations. Underlying factors are mainly sociocultural, economic and/or institutional. This definition of underlying factors is essential if the root causes of environmental problems are to be tackled and key actors addressed. Priorities are set among those underlying factors identified.

Cluster III: Environmental opportunity analysis
- **Task 7:** The definition of main environmental opportunities is essential in order to look at the environment in a positive way. Opportunities occur in the ecological sphere (eg the potential for irrigation), economic (eg demand for certain products), institutional (eg new legislation), socio-cultural (eg women's potentials) and at the local level (eg an innovative community initiative). Priorities are set and packages are formed.
- **Task 8:** Analysis of the potential of opportunities to contribute to both solving environmental problems and solving or improving underlying factors ('win-win options') using insights from previous steps and a systematic approach (opportunity-impact matrix). Priorities are set on the basis of the potentials and constraints that surround realising opportunities in a sustainable way.

Cluster IV: Strategic planning and follow-up activities
- **Task 9:** Synthesis to define a vision and strategic priorities, defining inputs for strategic action planning, including both sectoral and inter-sectoral programmes. Operational plans based on the strategic plan can be worked out using a logical framework.
- **Task 10:** Formulation of a follow-up strategy, including issues internal to the implementing institution, establishment of an environmental monitoring system with indicators and procedures to adjust strategies or policies, external communication and capacity building.

The concept of sustainable development is made operational by long-term goals:
- ecological: stability and diversity
- socio-institutional: autonomy, health, security and equity
- economic: production and efficiency.

For each of these goals specific criteria are defined. These vary according to specific situations and context factors. SEAN takes the ecological dimension as its starting point for making the inventory and analysis of the potentials, constraints and risks. This starting point is justified by the need to overcome a historical and apparently intuitive human bias towards neglecting environmental issues in development planning. Second, it can be argued that environmental well-being is the basis for any sustainable socioeconomic activity. This is particularly important in many developing countries, where day-to-day life in the rural areas depends on the quality of the environmental resources in the immediate surroundings, and where, in urban areas there is considerable dependence on food supplies from the surrounding rural areas.

Objectives and participants

SEAN has been used in a number of countries. Each time the objectives are different. The objectives of applying SEAN in Atacora province were:
1. To analysis the problems and opportunities within the region;
2. Elaborate a vision and strategic orientation for sustainable development that integrates environmental issues with economic and socio-institutional issues;
3. Creating synergy and coordination between ongoing development projects and activities by involving local decision makers and other relevant actors;
4. Strengthening regional capacities as part of the decentralisation process;
5. Addressing the poverty and environmental fragility of the province.

Participants and parties involved were the following:
- *Funding agencies*: The 'Centre Béninois pour le Développement Durable' in Benin and SNV who runs several projects in the province.
- *Steering committee*: including representatives from the Ministry of Planning, Local Government and NGOs.
- *Owner of the SEAN process and outputs:* The elected '*préfet*' of the province.
- *Participants*: during workshops and field work representatives of local communities, projects, NGOs, local government, private sector, donors and central government were involved. Special attention was given to gender equity.
- *SEAN executive team*: a local moderator (GERAM Bureau d'Etude), two staff from local projects and 2 staff from provincial services, one SEAN expert (AIDEnvironment).
- *Technical advisors:* on an ad-hoc basis advice has been obtained from University experts.

In total, about 25 different organisations have participated, and several actors joined voluntarily. Participants were involved in workshops (debates), joint analysis and feed-back. These were used to set priorities.

The 5 phases of SEAN

The SEAN process has 5 phases. In Atacora they were applied in the following way:
1. *Preparation and initiation*: this critical phase included defining of objectives, lobbying at national level, the selection of participants, discussion on ownership and reviewing of relevant experiences.
2. *Scoping*: during this phase, a five-day workshop was held and existing knowledge was captured by going through the SEAN methodological steps with selected participants.
3. *Fieldwork*: fieldwork focused on increasing the level of understanding on a number of issues identified in the previous phase. Particular attention was given to women, pastoralists and children, to urban areas, and to critical issues such as soil fertility, migration patterns, trans-boundary pastoralist movements, agricultural extension and local traditions and views.
4. *Synthesis and planning*: this phase brought together the insights and views of the actors involved to define a common vision and 'strategic orientation' (Box 3) on sustainable development in the province.

5. *Follow-up*: this is an ongoing phase and focuses on supporting and strengthening the way the strategy is applied, working out of action plans, ensuring a feed-back of results to all stakeholder levels, and the setting-up of a monitoring system.

The 10 analytical tasks

The SEAN structure consists of ten distinct tasks within 4 clusters. These tasks are mainly used during the process Phases 2 to 4, to structure discussions, debate, field assessments and workshops. The ten tasks are briefly elaborated in Box 2. The SEAN toolbox has a set of guidelines, tips, tools and suggestions for each task that should enable potential practitioners to decide for themselves what task is relevant and how these can be worked out.

Some results in Atacora

SEAN has been applied in Atacora province in a very elaborate way. The process involving Phases 1 to 4 has taken almost 2 years. However, it has frequently been stated that processes that genuinely pay attention to participation and the objectives of interactive learning take a long time to mature. Some concrete results include:

- A diagnostic analysis of the situation including environmental, economic, social and institutional trends. These have been projected into the future; problems have been listed and causes identified. In Atacora, the main environmental problems are declining soil fertility; cotton production competing with the maintenance of food production; deforestation and the decline of urban living conditions (see Box 1);
- A vision for the coming 10 years has been developed for 4 distinct zones within the province.
- About 20 strategic areas were defined where improvements could be made. Objectives, development priorities and environmental and social criteria for designing integrated programmes were established and the implications for sector and territorial policies elaborated;
- Strategy for monitoring environmental change and progress developed together with impact indicators.

SEAN has succeeded in showing that an environmental analysis can help define relations with other dimensions of sustainable development during a participatory process. Considerable vertical and horizontal integration was achieved.
At national level, awareness of the importance of decentralised planning has increased and some key issues such as illegal gold exploitation were highlighted.

A flexible and holistic approach

SEAN is a holistic approach that can be called a 'sustainability analysis' (Dalal Clayton, 1993). It provides a logical structure for analysis and planning and can be used as local needs and experiences demand. It also has the capacity to guide processes involving long-term negotiation. SEAN has been effectively used in initiating negotiations, creating stakeholder platforms and to create transparency by setting objective criteria for establishing priorities and taking decision.

Marginal areas in complex and unpredictable situations need management systems that are adaptive, and that can respond quickly to new threats and opportunities. Planning in these situations has limited value because many unpredictable factors are involved. Such an adaptive management system should be based on a broad and accepted vision and strategic orientations, a monitoring (or early warning) system that focuses at key issues, and flexible institutions and planning systems. SEAN can be helpful in defining visions and strategic orientations, and in identifying which factors and actors to monitor.

The level of participation in a SEAN process can vary greatly. Donors and development organisations often want such processes to be finalised quickly and this can limit broad participation. In most cases SEAN is used for a period of six month, enough to achieve a limited level of participation.

In some situations there is enough general knowledge available and the emphasis is put on tools to analyse the links between environmental, social and economic issues. Even if this is done quickly at a workshop of key actors, for example, it can be an important added value. An outline for such 'quick scan' workshop setting has been developed.

Certain challenges remain.

- To establish more explicitly linkages between local level problems and constraints and opportunities at higher levels, including global markets and international policies;
- Policy analysis and institutional analysis (in principle, this is part of Task 6);
- Elaborating a monitoring system that is simple but able to address key threats and opportunities.

Documentation available

There is a reader on the SEAN methodology available in English, French and Spanish. A toolbox has recently been published in English. This is based on recent experiences and should allow potential practitioners to use SEAN with minimum external assistance. The toolbox consists of a presentation, educational cards on analytical tasks, the process phases and checklists, a SEAN case study and a booklet containing theoretical background. Price about US$50-. All publications can be ordered at SNV (E-mail: informatie@snv.nl). More information and order forms can be obtained from SEAN website (www.seanplatform.org) or with the author of this article.

Box 3: Some of the main strategic orientations resulting from SEAN

Each orientation has been worked out in detail and objectives, linkages with other dimensions, actors, opportunities and impact indicators are carefully defined.

Ecological orientations
- Maintenance and management of water balance
- Maintenance and management of biodiversity, plants and animals
- Maintenance of soil fertility
- Maintaining and improving the integration of trees in land-use systems
- Better control and management of grazing and livestock densities
- Improvement of urban living conditions

Social orientations
- Improvement of literacy rate
- Improvement of the level of education
- Control of the negative aspects and strengthening of the positive aspects of tradition
- Control of demographic growth and rural migration
- Promotion of gender awareness

Institutional orientations
- Support to existing structures and services to improve negotiation and communication capabilities
- Adaptation of current legislation on natural resources to prevailing socioeconomic conditions
- Support to decentralisation processes
- Support to NGOs and community-based organisations as intermediary structures
- Support to improve morality of civil society
- Improvement of means and systems of communication and information
- Technical and logistical support to existing services
- Improvement of technical and professional training

Economic orientations
- Development of promising markets and cash crops
- Promotion of off-farm income opportunities (eg. gold exploitation)
- Improvement of road system and opening up of remote parts of the department
- Improvement and adaptation of credit systems to improve access by all social groups
- Improvement and introduction of transformation, storage and conservation technologies
- Support to existing organisations and creation of cooperatives (economic structures)
- Diversification and promotion of renewable energy resources

National strategies for integrated soil fertility management in Africa

photo: J Lamers

The World Bank estimates that a 4% growth in agriculture is a precondition for rural development in Africa given it has a population growth of 3%. The International Institute for Soil Fertility Management (IFDC-Africa) believes that market-oriented agriculture and agricultural intensification based on the use of external inputs such as chemical fertilisers, improved varieties, integrated pest management, etc., is the only way to achieve development. However, in many regions in Africa the profitability of development packages based on external inputs is too low to attract farmers. Reasons include: the low efficiency of chemical fertilisers because of poor soils and unfavourable climates. Fertilisers and other external inputs are relatively expensive (eg., in 1997 the farm-gate cost of urea was US$ 350 in Burkina Faso compared to US$ 100 in India). Marketing of agricultural products is costly and difficult because local transport systems are poorly developed and the domestic market for agricultural products is of relatively small size. In addition, there is neither the buying power nor the capacity to develop a larger consumer market by creating jobs outside agriculture. Beside others, these factors contribute considerably to the stagnation of agricultural development in Africa.

Integrated soil fertility management

In nearly all African countries agricultural production is based on nutrient depletion, shows a negative nutrient balance, and is therefore unsustainable. In order for the yield-enhancing technologies to be applied in a profitable way, improvement of soil fertility management is necessary. Re-capitalising the soil by applying chemical fertiliser is not enough to improve soil fertility management. The efficiency of chemical fertilisers and their economy have to improve as well. This is possible by integrated use of soil amendments and chemical fertilisers. Different amendments exist, and their requirement depends on the need for improved soil organic matter status, improved P availability and/or improved pH. Lime and gypsum are the products most frequently used to improve pH; soluble sources of P and rock phosphate can be used to increase the availability of P. The more difficult challenge is to improve the status of organic matter in the soil. More and better organic manure is needed. However, it is difficult to get organic matter when inappropriate agricultural practices cause soil degradation and cost of organic matter transportation is high. A combination of chemical fertiliser with crop residue recycling, green manure, fodder crops or agroforestry can eventually improve the availability and quality of organic matter.

Zoning for strategy development

The viability of different options for soil fertility management depends on their economic profitability. Local agroecological and socioeconomic conditions make a considerable difference to the profitability of chemical fertilisers. This can be seen not only between regions but also between and within fields. A three-zone division can be made: Zone I chemical fertilisers are a profitable option; Zone II chemical fertilisers are only profitable after 'eco-intensification' through soil amendments as described above; Zone III chemical fertilisers even when combined with soil amendments cannot be used profitable. At present Zone II is by far the most prevalent in sub-Saharan Africa with high financial implications for moving towards zone I. The limits between zones can be influenced by agricultural policy and agro-technologies. Lower input prices, higher output prices and improved management, for example, can shift the cost-benefit break-even point between two zones to lower agroecological or socioeconomic conditions. Ideally, Zone I should be enlarged and Zone III should be eliminated to make market-oriented agriculture and agricultural intensification profitable for all farmers. To what extent this is feasible depends on the costs of support or subsidies necessary for the intervention.

In order to realize the same conditions in Zone II and Zone I at least temporary support has to be given. Support can be given in different ways including a temporary subsidy on local phosphate rock, materials and equipment to facilitate organic matter transport and management, and/or appropriate credit mechanisms. The cost of these socioeconomic measures have to be seen as an investment in the re-capitalisation of soil fertility in order to make the use of chemical fertilisers and agricultural intensification in the interests of rural development and food security feasible. Soil fertility improvement is not simply a technology. It requires profound adaptations of agricultural policies, stimulating farmers to invest in their soils and the private sector to invest in agricultural input and output market development. Such investments will be cheaper and better achievable than those in irrigation in most Africa (Breman 1998).

The 'Soil Fertility Initiative'

The Soil Fertility Initiative (SFI) was launched in 1996 under the aegis of the World Bank and in partnership with many institutions including IFDC during the world food summit in Rome. The SFI aims at helping sub-Sahara African countries achieve sustainable increases in agricultural production while preserving the environment. These countries have been called upon to elaborate national strategies and action plans to secure improvements in soil fertility. Burkina Faso and Ghana were the first countries to formulate National Action Plans (NAPs).

The National Strategy in Burkina Faso

The first step in the formulation of the National Strategy was the creation of a Soil Fertility Management Unit (SFMU) attached to the cabinet of the Ministry of Agriculture. The SFMU was assigned the following responsibilities:

- The promotion and creation of awareness of the need to create a favourable environment for investments in soil fertility;
- The elaboration of a national strategy for integrated management and the restoration of soil fertility;

- The elaboration of action plans to operationalise the strategy and
- The coordination of all soil fertility-related activities in Burkina Faso at national level.

The SFMU consulted extensively with the stakeholders (farmers, decision makers, input suppliers, agro-processors, transport operators, extension agents, researchers, development agents). A series of grass-roots workshops were organised during which discussions were held with stakeholders on the need and urgency for soil fertility restoration. These workshops provided the opportunity for developing a common understanding about the problems of soil degradation and for examining current practices in the light of what needs to be done. They also served as fora where ideas could be exchanged between research, extensionists, NGOs and others working on projects in the area of soil fertility maintenance. Awareness was also created through the publication of a bi-monthly magazine 'Sustainable Agriculture', which set out to inform stakeholders about soil fertility restoration. The SFMU also undertook a series of surveys to obtain information on farmers' strategies on soil amendments, accompanying technologies and developments in marketable products.

The process of sensitisation, inventorising the state of knowledge on soil fertility work in Burkina Faso, and setting up specialised committees to provide advice culminated in the creation of a national strategy. The process of the strategy elaboration was iterative and involved all stakeholders from the initial stages to its final adoption by government.

The strategy describes a vision and approach to restoring, improving and maintaining soil fertility. The action plans involved in the national strategy were as follows:

1. Action plan for the promotion of soil amendments
2. Action plan for the promotion of technologies that accompany soil amendments, and
3. Action plan for the development of input and output markets.

Action Plan 1 is based on the use of the rock phosphate and dolomite that occur naturally in Burkina Faso.

Action Plan 2 is based on available and proven technologies such as improved cultural practices with cereal-legume rotations, anti-erosion control techniques, the "zaï" traditional planting pits, mulching, use of organic and chemical fertilisers, crop-livestock systems, agroforestry and water retention.

Action Plan 3 aims at creating the conditions necessary for farmers to invest in soil fertility improvement. It includes actions that will raise the value-cost ratio of purchased inputs such as fertilisers. On the output side the action plan seeks to create effective demands for the products through agro-processing and value adding activities (Debrah 1998).

Lessons learned in Burkina Faso

In Burkina Faso experience reveals that the commitment of government, donors and technical assistance is extremely important in addressing the problem of soil fertility. The sensitisation, consultation and awareness creation process, although useful, was long, complicated and expensive. The large number of stakeholders involved made reconciling different positions and interests – including the role of SFMU vis-a vis the country's traditional soil research institute - difficult. Nevertheless the consultative and participatory approach to the formulation of national strategy was crucial. Many research and development projects designed to increase food production in SSA have failed because stakeholders were not involved in the process from start to final evaluation.

The Burkina Faso experience has shown that with the necessary elements in place it is possible, with consensus, to elaborate a concise strategy that provides an orientation for the regeneration of soil fertility. ■

Managing Soil Fertility: A Resource Guide for Participatory Learning and Action Research

Toon Defoer and Arnoud Budelman (Eds)

This resource guide is based on extensive work done in several African countries. It is intended to provide user-friendly ways of gathering, managing and analysing information and data by using participatory learning and action research. It suggests ways of using this knowledge to develop strategies for integrated soil fertility management.

The Resource Guide has been developed to provide broad-based support for analytical and experimental work with farmers. It focuses on understanding how farming systems work, and outlines frameworks for analysing diversity - and particularly resource flows - in agroecosystems. However, it is intended to be much more than an analytical handbook. Hands-on experience is one of the most effective ways for farmers to learn new approaches, so the Resource Guide also outlines tools and procedures for each step in participatory learning and action research.

The main aim of the Resource Guide is to give field workers practical advice on how to work with farmers to improve soil fertility management. It is intended as a source of inspiration and help to field practitioners working to facilitate positive changes in farming communities. One of the greatest challenges is the wide variety of ecological and socioeconomic conditions found in neighbouring sites. With this in mind the Resource Guide provides advice on efficient ways of managing all possible sources of soil fertility, in other words, integrated soil fertility management.

The Resource Guide consists of five parts:

Part 1 – Building common knowledge: A Textbook for Participatory Learning and Action Research (PLAR)
Part 2 – PLAR and Resource Flow Analysis in Practice: Case Studies
Part 3 – Field Tools for Participatory Learning and Action Research
Part 4 – The CD ROM: ResourceKIT (software package) and Detailed Field Tools (electronic version)
Part 5 –Detailed Field Tools for PLAR/User Guide to the ResourceKIT

The Resource Guide will be published by The Royal Tropical Institute in March 2000. Contact: Toon Defoer, Royal Tropicial Institute (KIT), PO Box 95001, 1090 HA Amsterdam, The Netherlands, Tdefoer@wanadoo.fr

Farmers developing technology: the researcher's role revised

Gabino Lopez and Roland Bunch

In Central America farmer experimenters are taking over some of the roles conventionally associated with researchers. COSECHA has been facilitating farmer experimentation in the hope of finding profitable ways of using micro-catchments for water-harvesting. On the bases of these experiences the authors challenge researchers to support this trend and adapt their roles to the farmer experimenter situation.

As the number of Central American farmer experimenters gradually grows into the thousands, certain questions have emerged. These can also be expected to arise in the future in other parts of the world. Most important among these questions are: 'What will be the role of professional researchers in the future?" and "How can farmer experimenters and professional researchers best work together?" Professional extensionists once feared they would lose their jobs if villagers became promoters. Now some researchers are also beginning to fear for their jobs because farmer experimenters are not only developing new technologies, but have proved themselves capable of both basic and adaptive research.

Experience shows, however, that in research and extension both villagers and professionals have unique contributions to make. Villagers are not learning how to experiment because they want to take over the job of the professional, but because they want to supplement and complement what professionals can do best. In this process the role of the professionals will probably change. The experience of COSECHA, a Honduran NGO, gives some insight into how this process may work in the future. COSECHA has been involved in the development of new water harvesting technology for small farmers.

Gabino Lopez convinced that water-harvesting in micro-catchments can make a return on costs.

Photo: Roland Bunch

Micro-catchments for water harvesting

Since the early 1980s, COSECHA personnel have been aware that the greatest need of villagers in semi-arid areas is to overcome the problem of deficient or irregular rains. In 1997, COSECHA decided to try and develop an inexpensive technology with which farmers could capture rainwater and hold it on their fields for up to six months. The water could be used for supplementary irrigation during the growing season and to extend the growing season by a few weeks if necessary.

Through its previous work, COSECHA had discovered that it was possible to dig 0.5 cu.m micro-catchments in the ground that would hold water for a number of days. However, we did not know how water could be kept for longer periods or how to do this at little expense. Experiments were carried out to find the size and shape of catchment farmers would be like best and how they would like to use the water. It was also important to find out under what conditions this technology could be economically feasible.

Preparing the technology for farmer experimentation. With most technologies, farmer experimenters can begin work right away. However, some technologies are less attractive to farmers in the beginning: they are too complicated; they are based on laboratory findings; the initial investment is too high; or they do not produce immediate economic benefits.

COSECHA did not know whether micro-catchments would be cost-effective. We made a series of micro-catchments of varying sizes and lined them with different materials (burnt clay, plastic, cement, and the sap from a local tree) and then tried using them to irrigate crops. They made a cost-benefit analyses of each alternative. We concluded that although eventually cheaper materials might be needed, the cost-benefit ratio for the farmers was attractive even if cement were used to line the catchments. The cement could easily hold 90% of the water for six months or more. It was decided to try two methods of lining the micro-catchments with cement. One using a mixture of cement and sand and another using cement, lime, sand and stones.

A small group of known experimenters were selected to begin the experimentation. COSECHA selected a group of 12 farmer experimenters from those interested in the catchment idea. These farmers were known to have considerable creativity, to have taken great care with their experiments in the past and to have benefited significantly from COSECHA's past PTD efforts. They would be able to take small risks without endangering their family's food security and were generally considered good farmer experimenters. An attempt was made to ensure that farmer experimenters would try out a reasonable number of alternative approaches and would be prepared to put in enough effort to maintain the catchments. The farmers selected were considered capable of recognising and collecting the necessary and relevant information and of promoting the water harvesting idea if and when the experiments were successful.

At first, we exchanged materials for information. Still farmers were reluctant to invest the US$15.00 to $20.00 needed to line the micro-catchments while there was no proof that the technology worked. COSECHA wanted to get as much information as possible for these experiments. Therefore it gave the experimenters cement, sand, lime and rocks and in exchange it was agreed that COSECHA would receive information on the problems, costs, benefits, and possible uses of the micro-catchments. In this way, COSECHA openly recognised the value of the farmer experimenters' research and the time they would have to spend recording information. Farmers felt more comfortable with the risk they were taking by participating in the experiments and the programme received a considerable amount of important information.

COSECHA maintained constant communication with the farmer experimenters. Constant communication with the farmer experimenters was very important. Discussions were held with farmers about aspects of the new technology and they were encouraged to try out potentially useful modifications. In doing so they were able to collect important data. It was found that farmers needed specific types of help. Some needed help to ensure they included all costs incurred in their reports while others needed help in keeping accurate records. Farmers also needed help in detecting sources of rainwater (eg from patios, footpaths, natural temporary waterways) and in recording how water was used. Sometimes estimating the size of the area that could be irrigated also presented difficulties..

Juan Atz, a farmer experimenter, lines a micro-catchment to prevent seepage.

Photo: Roland Bunch

COSECHA constantly promotes the cross-pollination of ideas, experiences and technological modifications among farmer experimenters. For example, one farmer experimenter tried using fill to support the downhill side of his catchment, but this caused the cement to crack. Another farmer experimenter found a very simple way of repairing small cracks. Many farmer experimenters decided they preferred 1-2 cu.m micro-catchments. More important still many farmer experimenters began to use water for their domestic needs and to fill backpack sprayers, for home construction and for watering animals and their perennial home gardens. These problems and ideas were immediately shared with the other farmer experimenters.

COSECHA is preparing to share the technology with farmer experimenters throughout Honduras. Now that micro-catchments have been found to be economically feasible for most crops and uses, several other NGOs in Honduras and El Salvador have begun promoting them. COSECHA has received a grant to maintain its work with farmer experimenters throughout the country, to organise conferences so farmer experimenters can share their new ideas with each other and document the results and to encourage water harvesting and other technologies being developed by farmer experimenters.

The future role of researchers

Because there are many potential farmer experimenters it is more than likely that they are carrying out most of the agricultural research in Guatemala and Nicaragua and that this will soon be the case throughout Central America. Nevertheless, this does not mean that professional researchers will have no work to do. On the contrary, farmer experimenters will be able to provide an important link with professional researchers and help ensure that their technology will be rapidly incorporated into the practices of village farmers.

As COSECHA's work with micro-catchments shows, professional researchers will still have plenty to do. Strategic activities include:

- Carrying out research that requires complicated theoretical understanding or laboratory equipment and research that farmer experimenters are not prepared to undertake eg research that is expensive or has doubtful or long-term paybacks,
- Organise groups of farmer experimenters to investigate different aspects or modifications of specific promising technologies, sometimes offering inputs in exchange for information,
- Carry out studies to explain the results and investigate the possible long-term impacts of farmer experimenter-developed technologies,
- Collect information and technologies developed by farmer experimenters and analyse them using systems such as "Modified Stability Analysis," computer software in order to establish the statistical value of the information collected
- Publish and disseminate information on particularly promising technologies developed by farmer experimenters through the traditional media as well as through events such as cross visits and conferences of farmer experimenters.

This brave new world of research has already arrived in Central America, at least as far as technologies such as green manures, natural pest control, and water harvesting are concerned. It will take some time before it reaches other parts of the world. But when it does, the chances of finding the technologies needed to maintain the multitude of low-input technologies desperately needed by the world's complex and diverse small-scale farms will increase substantially.

Water, first step towards combatting desertification

JA Soccal

Access to water is an essential condition for human development in the semi-arid zone and for combating desertification. Civil society in Brazil has successfully promoted some very inexpensive but effective technologies for water management. These are now beginning to be included in the federal public policies for the semi-arid northeast of the country. This article presents three of these technologies.

Photo JA Soccal

A plate cistern being built in Pedra Lavrada county, Paraíba, Brazil.

The Brazilian semi-arid zone

Brazil has a land surface of more than 8 million km^2, 980,000 of which are susceptible to desertification. Most of these areas are in the northeast of the country. Many of the rivers in this region are seasonal, groundwater reserves are scarce and water salinity is high. The climate is characterised by a short rainy season and total rainfall is less than 800mm. There is a period of drought every year that lasts from 7 to 9 months. Average annual temperatures vary from 23 to 27^{o} C and insolation is very high (2800 hours/-year). Since 1900 there have been fourteen serious droughts, each of which has lasted for several years. The consequences for the local population are extremely serious and many have left for the cities in search of work. Of the approximately 17 million inhabitants in the semi-arid zone, more than 10 million live in the rural area. The northeast has the largest rural population in the country and it is one of the most densely populated semi-arid regions in the world.

Causes of desertification

Approximately 180,000 km2 of Brazil are already seriously affected by desertification which has been caused by deforestation (for building, domestic and industrial fuel and agriculture), overgrazing and mining. The main causes of desertification, however, are structural. These include the concentration of lands, natural resources and income in the hands of a few people and the absence of development policy that focus on small producers and their working conditions. Behind these unfavourable structural conditions lurks a political elite, established in colonial times, that profits from the fact that the population is dependent on them particularly in dry periods. This structure, which has undermined the feasibility of any development in the region, is known as the drought industry. Traditionally, during times of drought, local political *honchos*, distribute water in trucks. This is an extreme *assistentialist* approach that can survive because of the strong feeling of gratitude so ingrained in the Brazilian people.

Technologies that work

Determined to break the chains that have held the strong and creative people of the northeast in dependence and underdevelopment for so long, the NGOs, CBOs (Community-Based Organizations) and Work Cooperatives active in the region developed simple, inexpensive and efficient technologies to address the problems of the area. These technologies - the plate cistern, the underground dam, and the pile driver well - have lead to the sustainable development of several communities and are beginning to be included in federal public policies for the region.

Plate cistern

This is a technology that can be used by a household to harvest rainwater for human consumption. It differs from traditional cisterns because it is relatively cheap. The model that is being spread throughout the northeast by civil society organisations has a capacity of 10,000 to 20,000 liters and costs less than US$ 150.00. It is easy to build because it is made of large cement plates, local sand and water rather than bricks.

The beneficiaries provide their own labour and materials are inexpensive. Some organisations such as PATAC (Programme for Applying Technologies Appropriate to the Community) and MOC (Community Organisation Movement) support a rotating credit system as a way of multiplying the number of these cisterns in the northeast at minimal cost.

These cisterns can ensure the supply of water for human consumption during the annual drought. The quality of the water is far superior to that provided by the water trucks. Trucked water is usually dirty because it often comes from weirs used by animals and is full of pesticide residues from plantations in the vicinity.

If we consider that a person uses an average of 4 liters of water a day for personal hygiene, cooking and drinking, a family of 6 people would use 11,000 liters in 10 months. Cistern technology has made a great difference to women who traditionally fetch water and it has proved to be an excellent way of dealing with the dry periods (Comunidade Solidária, 1999).

Underground dam

The underground dam is a technology that is more than 2000 years old. The idea is to build a semi-permeable wall, below and across the seasonal river bed or on the drainage lines (Figure 1). This allows ground water to be retained or accumulated closer to the surface. In this way it is made more available to plants and humans. Agricultural fields are created in the river bed or on the river margins and the dams are extremely useful for agricultural production - and even pasturing - during drought periods because it becomes possible to grow crops all year round.

On a smaller scale underground dams are used to provide water for human and animal consumption. Tubular pipes are inserted on the side of the dam. The NGO CAATINGA has considerable experience with dissemination of this technology and has developed a type of underground dam using local material and labour that, on average, costs just US$250.00. Compacted clay and stones are used to build a wall of about 2 meters (to the substratum), since the soils of the region are mostly shallow (Comunidade Solidária, 1999).

Pile driver well
This technology is not as widely disseminated as the cistern and dam already mentioned, but its has been very successfully implemented. Its use has spread throughout the municipalities of Sub-Mid São Francisco, and the states of Bahia and Pernambuco. It has a basic premise: to simplify modern systems for drilling wells, replacing motors by animal and/or human traction. With a simple system of pulleys and pipes with perforating blades to dig and remove the earth, wells are opened without the need to hire companies or spend money on machines and fuel. The communities of the region have an important asset when it comes to identifying the best location for drilling. The rural producer, Manoel dos Santos, director of the Syndicate Center (Pólo Sindical) of Sub-Mid São Francisco was trained as a water diviner (hydrostesys with aluminum rods) and has already successfully identified appropriate sites for opening more than 100 wells some of which have reached a depth of more that 100 meters. Mr. Santos also mobilises, organizes and trains communities in well drilling.

In 1996, when the pile driver well activity first began, the wells were opened and water removed by the system of pulleys and human or animal traction. Today, the system has been perfected and uses solar energy to remove the water. A pulley system operated by a stationary bicycle is used to reduce the effort needed to drill the well (Alves Júnior, 1999). It is an ideal system for arenite terrain (it cannot be used in granite areas) with good quality groundwater.

Reduced dependence
The in situ technologies for catching and using water described above represent a significant landmark in the history of Brazil's semi-arid communities because they break away from the traditional dependence on expensive technologies and traditional relationships. They should not be seen as an isolated event, but as part of a set of technologies developed and disseminated by organisation of civil society. These technologies include traditional, modern or alternative technologies for agriculture, ranching and agroindustry as well as approaches to management, capacity building and conquering markets.

Providing local communities with water without making them politically dependent is the key to developing technologies and approaches that promote local sustainable development. These technologies also promote the development of citizenship because the producer becomes responsible for the management of a scarce asset (water) and has greater responsibility for the development of his community because of such collective instruments as rotating credit, joint community actions and capacity building.

Plate cisterns have become particularly important because they have been incorporated into some federal and state public policies (Comunidade Solidária, 1999). They form a precedent for a more systematic implementation of other proposals put forward by civil society. This is decisive for the survival and development of the third sector in the semi-arid zone. Up to now its work has been restricted to a few communities and families. As its proposals are transformed into policies, activities may spread to more communities either in partnership with the private sector or government.

Chances for sustainable development
These experiences may also influence an old tendency within the Brazilian administration. Trying to solve regional problems by building enormous works at very high cost. In the semi-arid region, for example, huge weirs, dams and water mains have been built. They may have helped to solve part of the problem but they have also become a source of corruption and have lead to the concentration of resources in the hands of a privileged elite. They have also had far-reaching and dramatic environmental impacts.

At the same time, local works, smaller, less expensive and more accessible to the population have always been under-valued. With the success of the cisterns, the NGOs can expand the implementation of alternative technologies considerably not only in water works but also in sustainable development in general. These have a much greater chance of promoting the human development of the most needy sections of the population.

After an intense mobilisation before and during the Third Session of the Conference of the Parties to the Convention to Combat Desertification – COP3 in Recife, Brazilian civil society handed the Minister of Environment a document entitled "The Semi-Arid Declaration" in which all the proposals that had been discussed since the 1993 drought were brought together.

Orchard development gives tribal communities new chances

Sharad Mahajan, Madhuri Newale and Pratap Pednekar

In 1995, BAIF Development Research Foundation initiated the Adivasi Development Programme in Dharmapur, South Gujarat, India. The programme, which involved more than 11,000 families and 4000 ha of marginal land, is based on community-led participatory livelihood development. It seeks to promote horticulture, forestry species and crops. The WADI (orchard) model, as the approach is known locally, is becoming a very popular way of regenerating degraded lands and developing sustainable livelihoods for the rural poor. The programme has been selected for presentation at the UNDP Forum of Ministers on Poverty and Environment in New York, USA and EXPO 2000.

New economic perspective needed

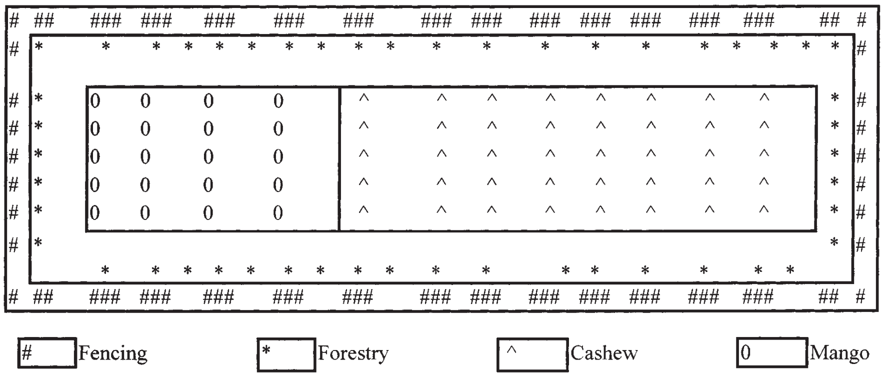
Dharampur is one of the tribal blocks in Valsad District, South Gujarat. Over 90 % of the population is tribal. Most of the tribals live in a forested hilly region. In former times there were dense teak forests but today tree cover has been reduced considerably and in the period 1986-1991 alone the forest was reduced by 8 %. Part of this area has been brought under cultivation and about a third has turned into wastelands or is being used for settlement.

In spite of high rainfall (about 2000 mm), there is a water scarcity each summer. Most of the rainwater disappears in unchecked runoff. Tribal families have marginal land holdings often less than 1 ha and cultivate only rainfed crops: paddy, coarse millets, pigeon pea and oil seeds. Productivity is low because they practice low input agriculture under unfavourable land and water conditions.

Poverty in India is closely linked to a degraded environment. This is especially true for tribals, as they have a symbiotic relationship with the forest. Increasing population and the fact that they had little or no stake in forest management has resulted in the depletion of forest cover and the further reduction of ground water levels and increased topsoil erosion.
As a result, food shortages are common and many people resort to labour migration leaving the area for nearby towns. Many loose hope and alcohol addiction is a serious problem. To provide tribal communities with more hope for a secure future a new, ecologically sustainable, economic perspective was urgently needed.

The Strategy

Land, Water and Manpower are the three major resources available in the area and an individual tribal family generates about Rs.6000 or US$120 each year by making use of them. This output is well below what families need to survive. Local people needed an assured income and livelihood. This could only be achieved by involving tribal families in the upgrading of their resources in an effective way.



Schematic layout of an orchard development plot

A three-pronged programme strategy was developed covering:

- Upgrading wastelands through orchard development
- Effective utilisation of available resources
- Involving and empowering people to manage their own resources

The orchard development programme provides long-term sustainable income for the family whereas effective use of available resources through soil and water conservation and crop cultivation provides the income needed to meet immediate demands. The programme aims to organise people and build-up their capacity for decision making and management. BAIF developed the basic concept underlying the programme during its work on the adjacent tribal block in Vaserda which started in 1982.

The Programme

- ***Upgrading wastelands through orchard development***
  The hilly terrain with limited water resources means that it is possible to develop either horticulture and forestry development on the tribals own land. A programme for individual families has been designed taking into account average land holding size and the minimum income needed for subsistence. Each participating family cultivates horticultural plants in particular mango and cashew - on 0.4 to 0.6 ha of land. Some 600-1000 trees are planted on the border of each plot. A mixture of species are selected. These include teak, bamboo, *gliricidia, Leuceana leucephala, Acacia auriculiformis* and *eucalyptus* to provide firewood, timber, fodder and green manure. The plot is protected by a live hedge of cactus or *Caesalpinia crista*.

- ***Effective utilisation of available resources.***
  Land development: Heavy rainfall and poor vegetation cause severe erosion. Therefore, orchards are protected by building slope-specific, soil conservation treatments. Trench-cum-bunds are constructed on land with slopes less than 15 %. Where slopes are more than 15%, trees are first protected by platforms and subsequently overall plot treatments such as trenching, gully plugging, and terracing are applied.

Water harvesting and utilisation

The area experiences two extreme situations - heavy rainfall during the monsoon and water scarcity during summer. Therefore, activities for harvesting available water and its efficient utilisation have been developed. These include:

- *Temporary check dams:* Immediately after the monsoon, the run-off water is harvested by constructing temporary check dams across the rivers and streams. These are constructed

Orchard trees protected by platforms.

Photo: Sharad Mahajan

Looking forward to a rich harvest.

inexpensively by using empty cement bags filled with sand and silt.

- *Spring development*: A number of well-dispersed perennial springs exist in the hilly areas. Though ground water resources are poor, the springs provide sufficient water to irrigate the orchards and cultivation of cash crops on a small scale.

- *Pot drip*: Pot drips are used in order to reduce the drudgery of irrigating orchards from head-loads of water and to reduce losses from evaporation and infiltration. The pot drip system consists of four clay pots dug in around the plant. The water in the pot diffuses into the soil through a hole in the bottom of the pot and in this way becomes available to the plant. This can result in water savings of over 50 %.

Water resources development and land shaping through soil conservation measures are also used to encourage the cultivation of additional crops. Improved crop varieties are used and participants are given both training and the necessary inputs.

The Effect

- *Development of marginal lands :* The programme operates in 133 villages in the Dharampur Block. The measures have helped to turn 4253 ha of marginal lands and wastelands into productive orchards. Over 200,000 mango and 400,000 cashew trees have been established. About 30 % of the plants have already started to produce fruit. At the same time the 5 million forest trees also planted are developing well.

  Soil conservation measures have started showing results and treated plots show less soil erosion, improved plant growth and a better conservation of soil moisture.

- *Effective utilisation of land and water :* 200-250 temporary check-dams are built each year. Spring development work is in progress and more than 1500 families have started to use pot drips.

  The effect of land and water resource development is clearly reflected in the changing cropping pattern of those participating in the programme. Rainfed cropping practices are now combined with irrigated cropping. The type of crops grown has also changed. Participants used to meet their basic food requirements by cultivating only paddy and coarse millets. Now, they cultivate wheat, groundnut, turmeric, onion, watermelon, bananas and vegetables for the market.

People centred approach

The programmes main entry point is *the people*. The approach aims to encourage:

- *Peoples participation* by generating awareness and motivation,
- *Peoples education* to stimulate thinking and training and
- *Peoples capacity building* to create a basis for making independent decisions and monitoring work.

It includes:

Farmer to farmer extension: Exposure visits are arranged so farmers can visit similar or new activities established by other farmers both within and beyond their region. This provides an opportunity for direct interaction with fellow farmers and also motivates participants by making them feel: *We can do this as well*!

Peoples choice first : The overall programme has been planned with full regard to the peoples needs. Peoples perceptions and choices are carefully considered when implementing the programme. Activities are selected or modified in the light of these requirements. Decisions relating to the selection of land for orchard development, the choice of tree species, the type of water resource development and soil conservation to be undertaken and the choice of crops to be cultivated are taken by all participants collectively.

Local resources development: Local resources have to be developed to ensure the success of the programme. In this context local youths have been trained as field guides (to provide agriculture- related services); technicians to repair hand pumps and engines; masons; barefoot accountants (for village-level record keeping) and health guides (to provide health services to the villagers).

Village planning committees: Village-level participant planning committees are formed to organise village-level activities and develop local leadership. These are representative bodies of participants set up to plan and review programme activities, identify participants needs and develop appropriate mechanisms to fulfill these.

Each planning committee has between 10 to 15 members and each member represents a group of 5 to 6 participants. The members of the committee are selected on the basis of specific criteria, such as having a good orchard or having a good rapport with villagers. In this way the right candidates are selected.

The committee holds monthly meetings to review ongoing work and plan work for the coming month. Village-level problems are sorted out and participants needs are discussed. Planning committees are in operation in all programme villages. All the programme work, from the selection of participants to providing them with credit is routed through these committees. Their range of activities now include the provision of inputs for inter-crop cultivation, grain bank development, the operation of Agro- Service Centers, and the collection and processing of cashew nuts. Members from all these committees meet once in a year to share the experiences and find new directions. The synergetic effects of these joint efforts are leading to sustainable development!

UHAI, a model for sustainable livelihood

CDK Muhia

UHAI in Kiswahili means livelihood. It is the name given to a "model" designed to empower people to manage their natural resources sustainably and to enhance their livelihood through dynamic people's forums. The approach was developed in the early 1990s by KENGO (Kenya Energy and Environmental Organisation) as an alternative to failing conventional development. Conventional approaches tend to over-emphasis economic development at the expense of indigenous culture, wisdom, spirituality and social values, knowledge, technologies, experiences, skills and aspiration of the people. The UHAI model has been established in 15 Kenyan communities both in rural and urban settings and has proved to be an effective approach to regenerating the natural environment and to controlling desertification. This article discusses the main elements of UHAI and the experiences gained using this approach in the community of Wamburi.

The rural base of many Africans implies that their livelihoods are directly supported by natural resources. The availability, access to and control of those resources are critical if these livelihoods are to be sustained. Sustainable livelihoods, however, also involve the relationship between people and nature. In most African societies culture and the environment were closely linked. Sustainable livelihood, in the UHAI approach, is seen as having its roots in the unique culture of the people. It focuses on the past, present and the future of life and it draws its strength from internal justice, morality, and collective community spirit and responsibility.

Culture central to development

The UHAI model argues that a people's culture must be at the center of development efforts. It recognises that authentic development springs from the collective visions, experiences, decisions and practical actions of the community. It seeks to empower local communities to take charge of their natural resources by using their indigenous systems, knowledge, wisdom and skills.

The UHAI model asks: "Why have many communities in Africa, at regional as well as at national level abandoned or look down upon their indigenous foods, mode of dressing, systems of reward and honor, engineering, education, art and music?" With consciousness about their traditional culture and historic development people are better placed to sustain their livelihoods and conserve their natural resources responsibly. The UHAI model will work in situations where this has taken place.

Guiding principles

To realise these ideals, the UHAI model offers certain guiding principles. These should form the basis of all relationships between people and the natural world. These principals include the recognition of:

- *The supremacy of nature:* Nature as the basis of life is supreme and all encompassing. All elements and beings must therefore recognize and respect it as a sacred endowment that should be conserved and sustained.
- *Peoples cultural heritage:* Culture defines the identity, dignity, pride and cosmology of a particular people. Therefore, its disintegration and disruption threaten the very existence of society. The cultural diversity and uniqueness of each ethnic nationality is the most valuable endowment of people throughout the African continent.
- *Eldership and sagehood:* Elders and sages are the keepers and custodians of knowledge, wisdom and the ethical dignity of human societies in Africa. Their wise council and vision should form the principal basis of moral guidance, local governance and stewardship of the society as well as the natural resource base.
- *Negotiation:* Any being that is primarily dependant on a particular resource for survival shall not be deprived of this livelihood. Man must, therefore, not only negotiate with man, but also with other creatures by studying, understanding and fully appreciating their source of livelihood.

By providing these principles, the UHAI model makes it possible to develop a framework that can restore respect for the values of natural resources and local culture.

The eco-cultural forum

The UHAI model seeks to restore and strengthen sustainable livelihood by reintroducing governance and decision making mechanisms. Through communal eco-cultural forums all stakeholders and resource-user groups within a community will have access to an open democratic space. Subsequently they will be able to directly influence decisions taken about the management of local natural resources. At the moment there is no such space at the level of community resource development.

The community eco-cultural forum consists of a council of elders, key resource-user groups (stakeholders), indigenous institutions and experts and representatives of facilitator (development) organisations.

The community eco-cultural forum takes on such activities as:

- Identifying and deliberating on issues, conflicts, opportunities and prospects relating to the utilisation, conservation and management of local eco-cultural resources.
- Defining, developing and evolving local solutions to the problems and conflicts that have been identified drawing on indigenous traditional knowledge as well as appropriate modern management systems and policies.
- Mobilising communities to undertake appropriate actions for the management of eco-cultural resources that can enhance their livelihood.
- Safeguarding the people's rights and access to resources in their struggle and search for nature conservation and a dignified livelihood.
- Monitoring the use and abuse of natural resources and advocating appropriate policies and actions.
- Researching and documenting past and present indigenous knowledge, skills, and technologies in natural resource management.

As an empowering model, UHAI tries to promote and invigorate the creative and innovative energies of the members of each community. The community must be able to create, innovate and develop new knowledge, skills, and techniques within its own environment. There must also be room to work towards achieving sustainable livelihood and efficient resources management systems. This is probably the most critical challenge of the UHAI model.

Wamburi community forum

Of the fifteen UHAI community forums, Wamburi is one of the best examples of a regenerated community and a regenerated environment. Wamburi is in the Nyika eco-cultural region. The communitty's catchment area includes the 200 households of Wamburi and Kithumba. These two villages lie between the Muojonzwe and Nthilani rivers and draw water from the Kyangeto. These rivers are subterranean for most of the year.

The natural resource base at stake

In the 1970s, villagers paid little attention to soil and water conservation. Their animals overgrazed the fields and bare, sun-baked soils were characteristic. Villagers ignored the importance of the sand basins along the rivers. These basins functioned as water reservoirs and prevented excessive evaporation. Soil erosion had silted up the only earth dam that had been dug in the late 1940s and had covered the water pipe and animal watering troughs. Lorry after lorry took sand away from these basins for housing projects in Nairobi and there was little understanding of the way they functioned in the local ecosystem.

Twenty years ago, villagers began to suffer food shortage, water was inaccessible and the number of livestock fell because there was little grazing. Rivers ran dry immediately after the rains ended and community life was out of balance.

From reflection to action

In 1990, having gone through several preparatory meetings and resource assessments, villagers decided to take the initiative to regenerate their communities and natural resources. Their first action was to stop sand collection and they threatened to burn any lorry coming to collect sand. Villagers went to the District Commissioner and asked for reinforcement. As a result five lorries and their crews were grounded for a week and were eventually forced to return to Nairobi empty.

Having organised themselves in the Wamburi Eco-cultural Community Forum the community acquired an identity. Operating as a forum, it identified training in soil and water conservation, agroforestry, natural resources management and wood energy conservation as urgent priorities. They selected key individuals for training and asked KENGO to provide it. During training, participatory exercises in resources mapping, strengthening group solidarity, and analysing strengths and opportunities were carried out. Plans were developed to build terracing to control runoff and a tree nursery was established by the dam site to provide seedlings (multipurpose tree species) for reforestation. River-beds were rehabilitated, the earth dam desilted and the cattle watering troughs renovated.

A project proposal was developed to support the desilting of the earth dam and to establish an improved stove production unit. Seedling production was improved by seed purchase and support was given to further encourage training in empowerment and capacity building. After the forum had been assessed, its programme was accepted for UNDP-GEF funding.

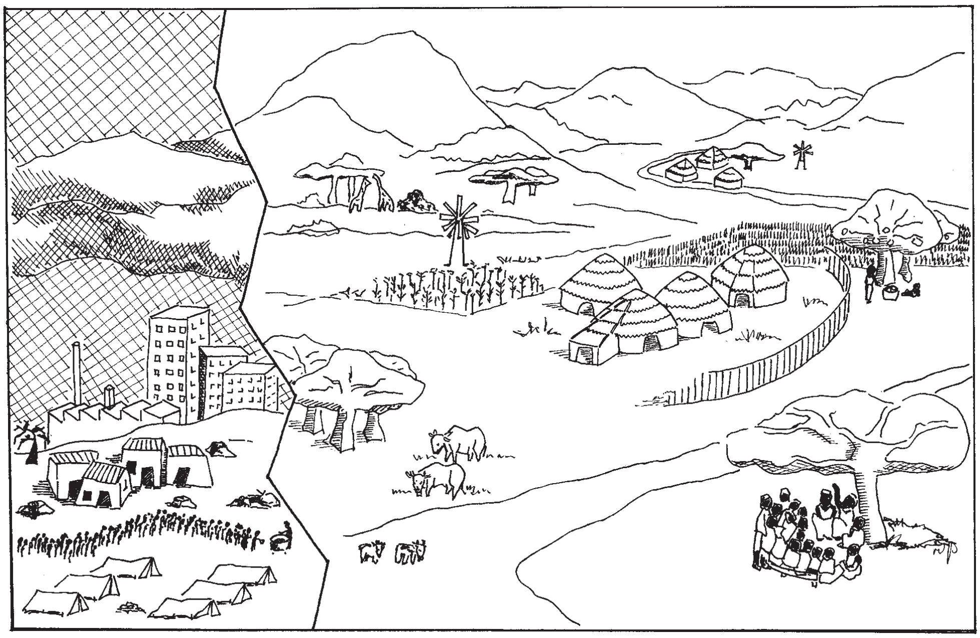
Impressive results

Within two years forum members constructed 10 kilometers of terraces, cut-off drains and bench-terraces in the catchment area. A tree nursery was established and members started to plant trees along the boundaries, terrace embankments and roadsides. Forum members made one of their experienced trainers a supervisor and bought him a bicycle to help him move around the area.

By 1996, the physical and human environment of the Wamburi catchment area had undergone a transformation. Members were heavily involved in food production, tree planting and the adoption of energy saving stoves. Most of the households had planted more than 200 trees, riverbeds had been rehabilitated after the construction of concrete tie-ridges that held sand and retain water over the dry period. The water stored behind the earth dam was now able to support an enlarged tree nursery (150,000 seedlings). In general there was more water available for domestic use and for livestock. Twenty percent of the households in the area have bio-intensive kitchen gardens and are self-sufficient in wood-fuel. Zero grazing is now a common farming practice.

Wamburi eco-cultural community forum is a source of strength to farmers in the area. Its members include professionals, retired chiefs, and working civil servants. Eighty percent of the membership is female. This explains why there is so much diversity in the food available in the community.

"Go and give these foods to your friends and tell them we have bid goodbye to relief food" villagers told me during one of my many training visits and offered me maize, beans, pigeon peas, millet, sorghum, onions, cowpeas and sweet potatoes. A neighbouring catchment is currently trying to copy Wamburi community as they try to regenerate the sunbaked patches that were formerly shambas (gardens).



Limitations

The UHAI model has its strengths and weaknesses. In Wamburi most of villagers were kinsmen and belonged to the same ethnic group. Trust was built up quite quickly. A common language and culture makes sharing and communication easier. If this is not the case it is much more difficult to create unity and agree upon a common action plan.

Promoting the participatory approach especially if it is being well articulated, is a time consuming business and makes the community preparation phase quite costly. In addition, cash benefit expectation in the short term can impair the implementation of the UHAI model. Donors for one reason or another, are not keen to give their support to community initiatives.

Patience and persistence are prerequisites for an effective facilitation of the UHAI model and for the participatory regeneration of the natural environment. Without a good facilitator participatory community development becomes impossible. This function, however, is not accepted by donors. Now the need for community participation is being recognised by the Convention to Combat Desertification and the National Action Plan, we hope the funding of participatory community development will become easier.

Shree Padre

In 1985, the Tarun Bharath Sangh (TBS), a conservationist orientated NGO, started an initiative in Alwar district to combat rural poverty. In the years that followed, they mobilised the rich experiences of traditional water harvesting and created one of the largest nature regeneration movements India has seen. Revitalising the water harvesting tradition and reforestation recharged wells. This set in motion a whole chain of economic and ecological improvements that created new hope for the local villagers .One of the results of this initiative was the transformation of local rivers from ephemeral monsoon waterways into perennial rivers.

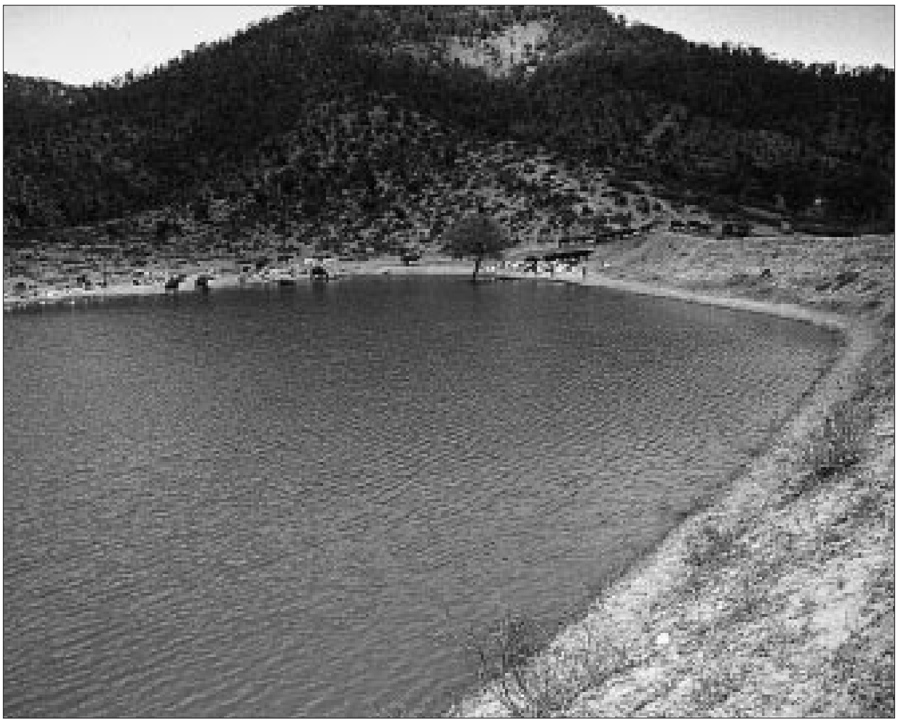

Photo Shree Padre

The Johad is a structure bound on three sides by the natural slopes of the hill. The fourth side, a mud wall - usually semi-circular in form – holds back the monsoon run-off.

Harvesting the monsoon: livelihoods reborn

Degradation and poverty

Alwar district lies in the Aravali mountains, 400km SW of New Delhi, in the Indian desert state of Rajasthan. The dense forests that covered this watershed were an integral part of the local rural economy until the 1930s when the colonial government abolished communal rights to forest land and allowed timber companies to exploit their resources. The hills were stripped of the timber that protected their thin soils from the fierce erosion of the annual monsoon. As water flowed away unchecked, rivers dried out, the ground water level fell, and the region's agricultural potential was seriously affected. When TBS first came into contact with the local population, villagers were living in poverty. Their main form of subsistance was small-scale herding and cultivating. Most men of working age had migrated to the cities in search of work and the women spent long hours walking to collect water. Community life was severely impoverished.

Gram Sabhas taking control

The TBS identified the lack of water as the major cause of poverty (Box 1). In their discussions with the villagers ways of tackling drought and erosion where explored. Regular village meetings or *Gram Sabhas* were established and each household sent its representative. During these meetings the elders described the water harvesting practices used in the past. Among these was the *Johad* (see Photo 1), a man-made tank built at strategic locations in the hills.

The TBS encouraged the re-establishment of such traditional techniques but it was also committed to waiting for the full participation and support of the local people before offering financial or material help. It was the villagers who had to decide whether or not they wanted to build and maintain *Johads* and check dams and they would only do so if they were convinced of the benefits.

The TBS worked towards developing a high level of understanding, commitment and participation.

Building a water harvesting structure like a *Johad* required cooperation and planning. The best location for catching the maximum amount of run-off had to be selected, soil characteristics studied and the relationship between the amount of water expected and the size of the *Johad* accurately assessed.

Once a village decided it would build a water harvesting structure with TBS help, it had to pay 25% of construction costs itself either in cash or in *Shramadan* (voluntary labour). Members of the *Gram Sabha* then made a list of the families most likely to benefit from the *Johad*. They were expected to provide the *Shramadan* and, if necessary, the land on which the *Johad* would be built. The TBS would then accept responsibility for providing external inputs such as tractors to trans-

Box 1. Tarun Bharath Sangh

Dr Rajendra Singh is head of Tarun Bharath Sangh. As a doctor practising in the ancient tradition of *Ayurveda* he was familiar with treating imbalances in the human body. As a farmer and conservationist he saw that imbalances in the way man used Nature's resources often lead to chronic poverty. In the drought-ridden district of Arwali he asked himself the most basic question: "Where is the water". The only water available was rainwater.

His interest in watershed development came from the people's need for water. If there had been no traditional water harvesting knowledge in the area, TBS would not have been successful in harvesting rainwater or in regenerating forest cover. The local elders, however, remembered the *Johad* and with the help of TBS volunteers and funds they were able to made successful use of the traditional knowledge that been ignored by government and western science.

An important element in the success of TBS's water harvesting efforts was the attitude of the villagers. They felt that the *Johad* was their own asset and that their future was linked to it. They were ready to struggle to re-establish their traditional ways of resource management and to draw up the regulations necessary to protect their environment and forests. The TBS supported the villagers with the funds it received from foreign contributions, assistance and volunteer labour.

port soil, diesel, cement, and the money to pay the masons. All other inputs had to be raised locally.

Once the *Johad* has been built, the members of the *Gram Sabha* discuss management and maintainance. *Johads* have a number of water outlets that enable villagers to regulate the flow of water to the fields and initially the fields closest to the village will receive the most moisture.

Jal-Jameen-Jungal

While the *Johads* improved water availability, the problem of erosive run-off continued and sediment gradually clogged up the new water storage space. The problem was taken up by the *Gram Sabhas* and, working with the conservationists of the TBS, villagers became increasingly more conscious of the relationship between *Jal, Jameen and Jungal* (Water, Land and Forest). This consciousness was further reinforced by the street plays and *Padayatras* (foot marches) that the TBS organised each year for those unfamiliar with the nature conservation movement.

The *Gram Sabhas* decided to raise a green cover and allow the forests to regenerate. Together with the TBS they tried to create conditions which would allow dormant root-stock and existing tree cover to re-establish itself and grow. Rules were established. The first step was to prevent camels and goats from grazing new growth. No one was allowed to cut live twigs and only dried branches and leaves could be sold. No living branches could be cut without permission from the *Gram Sabha* and penalties were strictly imposed. Villagers also expressed their common commitment through ritual, celebrating *Rakshabandhan*, for example, by tying a knot around trees and plants as a token of their commitment to protecting greenery. As a result of their efforts the proportion of forest cover on the Aravali mountains has risen to 40%, an increase of 34% in 15 years. Their target is 66% cover.

Rivers reborn

One of the most spectacular and unexpected results of this revitalisation has been the gradual return of water to the rivers in Arvari. The TBS did not start out with the aim of bringing perennial flow to dry rivers like the Aravati. When *Johads* were built and water run-off arrested, percolation gradually recharged underground aquifers and as these slowly filled up, excess water started to flow into the rivers. Traditional water harvesting techniques have realised the full, natural benefit of percolation from the catchment. In the 503 sq. km catchment of the River Aravati, for example, villagers built some 200 water harvesting structures over a ten-years period. As a result the river began to flow for longer and longer period each year until, in 1995, it flowed the whole year round, a phenomena that even took even the village elders by surprise.

But with the water came the bureaucracy. In 1996 the villagers of Hamirpura living along the Arvari were told that a contractor had been given a licence by the state government to start fishing in the river. Under law the river is the property of the government and now that there was water, the government was ready to take 'control' of its resource. But the villagers demanded a say in its management. Working with TBS they recently set up a River Parliament, locally known as the Arvari Sansad – an association of all the villages built along the river. They adopted a constitution to manage the river. If it succeeds this 'people's river parliament' will be an important example for the future (Mahapatra 1999).

Livelihood reborn

The ideas developed by villagers and the TBS have had considerable success. Now, more than 15 years later, 650 villages in the Alwar district have a *Gram Sabha* and 3000 water harvesting structures have been established. *Johads* have proved both durable and effective. In the floods of 1995/6, for example, villagers saw many government built dams being washed away while their carefully built *Johads* remained intact. Revitalising the *Johad* tradition and regenerating forest cover have brought many benefits. In 36 villages the water table has risen six metres. Wells have been recharged and moisture levels in the fields have been improved. Today, villagers no longer wait for financial support from the TBS: they take the initiative themselves and as their standard of living slowly improves, they are better able to meet the costs of building and maintainance themselves.

With water more readily available, buffalo breeding has received a new impetus. The supply of milk increased and regional milk products are again being offered for sale. Grain production is growing and the district which once imported grain now sells it to its neighbours.

One villager told 'Down to earth' magazine: *"Forests were cleared for the urban people. I lost my agriculture and had to slave for the same people who destroyed it. The freedom of the country doesn't mean anything to us. I became free in 1995, when I cultivated my land again for the first time. For villagers, freedom means freedom from poverty. This comes from self-sufficiency"*

Men who were pursuing menial jobs in the cities have started to return to their homeland. Women, freed from the time consuming task of fetching water, have more time to invest in community life and in one of the poorest states in India where the average literacy rate is 20%, more and more children are attending school. Along with these improvements came a renewed sense of 'self-respect'.

■

Box 2. Women at work

Women are often the ones most affected by a lack of water and TBS found that they were quick to respond to water harvesting ideas. Gyarsi and Phoola, for example, were the last two women in their village high in the Sariska hills. Together they set out to build a traditional water harvesting structure or *Johad*. They did all the physical work themselves and once every ten days they were visited by a TBS volunteer. Construction took them four months, but now water can be stored for longer and longer periods.

Women have taken outstanding initiative in water harvesting work.

Water harvesting: community-led natural resource management

Anil Agarwal and Sunita Narain

India is in water crisis despite its relatively high average rainfall. Water harvesting can offer a solution. If 5-10% of the land were used for rainwater collection there would be enough water for irrigation and household needs. Recent initiatives, both at community and government level, have made use of long-neglected water harvesting traditions. The results show that reviving water harvesting systems stimulate rural development and restores local ecosystems. This article discusses some of these initiatives and explores how community-led natural resource management can be facilitated.

Photo: S. Rajam / CSE

Tanks (eris) once watered one-third of the irrigated land in Tamil Nadu.

Water crisis

Forty percent of the world's population currently experience serious water shortage. India is one of the 80 countries bearing the heavy social, political, economic and environmental costs of this crisis. Water quality problems affect some 44 million people in the subcontinent and there is widespread pollution. Fluoride, arsenic and iron have entered the groundwater and seawater pollutes groundwater aquifers. In the summer when the situation is particularly acute, women and young girls have to walk long distances to fetch water. Wells are dug deeper and deeper lowering the groundwater table still further and gradually wells dry out. Fifty years ago there was twice as much water available per capita as there is today.

Water is not only vital for human survival, it is also essential for sustainable biomass-based economy. Although India has made substantial investments in an effort to exploit river and groundwater resources to service large-scale irrigation systems and urban water supplies, these systems have rarely reached the rural poor. Often large-scale water developments have led to inefficient and inequitable distribution of water resources and to forced re-settlement.

Decline of water harvesting

There are water-harvesting traditions in many parts of the (developing) world. India's traditional water-harvesting structures are treasures of ingenuity. Over the centuries, people in different types of ecosystems throughout India have used basic engineering skills to develop a wide variety of techniques to meet their water needs. Today, when the art and science of 'collecting water where it falls' is needed to help ensure an adequate, sustainable and equitable distribution of fresh water, it has become a dying wisdom. Serious efforts must to be made to combine water-harvesting traditions with the insights of modern science and technology (Agarwal and Narain, 1997).

Decades of British rule ravaged the peoples' water knowledge heritage. The consequence of British determination to maximise its exploitation of India's riches resulted in impoverished rural communities and the destruction of their resource management systems. Water management structures were also seriously disrupted.

Technological changes such as the introduction of tubewells put richer farmers in command of the tank area. Those who could afford to install these wells no longer have an interest in cooperating with the rest of the community in managing the tanks. Many central and southern Indian cities like Hyderabad, Chennai (Madras) and Bangalore grew up around traditional water harvesting systems. In the urban areas these systems have either disappeared because of pressure from real estate lobbies or have become heavily polluted. Today, traditional water harvesting systems are only important in remote areas such as the Himalayan states which are beyond the immediate reach of water bureaucracies.

Learning from experience

During the 1980s, several successful community-based resource management ventures emerged in response to the water management crises. Some of these are described below. They show the policies needed to turn ecological poverty into sustainable economic wealth. Today, these initiatives are particularly important because they have now matured. An advanced level of ecological succession has been reached and their economic impact is clearly visible.

Sukhomajri village

Sukhomajri, near the city of Chandigarh, is the first village in India to have income tax levied on earnings from the ecological regeneration of its degraded watershed. In 1979, when the nation was facing a severe drought, the villagers built small tanks to capture rainwater. They agreed to protect their watershed to ensure the tanks did not get silted up. The forest department's assurance that they would have the right to use forestland and its grass was a major incentive. The villagers had argued that they should benefit from the biomass

A bihar (rectangular catchment basin with embankments on three sides) still used by farmers in Bihar.

produced in return for protecting the watershed. The state forest department agreed to give the villagers these rights if they paid the forest department a royalty equivalent to the average income it had earned before the villagers started watershed protection.

The combination of public, private and community investments and the participatory efforts of the villagers have resulted in a rate of return of 19% according to one cost-benefit analysis. The tanks have resulted in a threefold increase in crop production. The amount of grass and tree fodder available to cattle in the protected forest has increased considerably and as a result more milk is being produced. As prosperity increases, Sukhomajri's economy has also changed. "Who could imagine that televisions, tractors and bicycles could be had for mere grass and water?" asks one of the villagers.

One of the most impressive results of the project is that the cost of desilting Lake Sukhna, which supplies water to downstream Chandigarh, has fallen dramatically. The inflow of sediment has been reduced by more than 90% saving the government Rs7.65 million ($0.2 million) each year in dredging and other costs (Chopra et al., 1990).

Ralegan Siddhi village

Ralegan Siddhi is a village in a drought-prone area of Maharashtra. The annual rainfall is between 450 mm and 650 mm. Villagers could never confidently rely on a regular harvest. In 1975, the village was poverty stricken and there was less than half a hectare of irrigated land per family. Krishna Bhaurao Hazare, a retired driver from the Indian army, began constructing storage ponds, reservoirs and gully plugs. Due to the steady percolation of water, the groundwater table began to rise. Simultaneously, government social forestry schemes were used to plant 300,000-400,000 trees in and around the village. Because of the increased availability of irrigation water, fallow land was brought under cultivation. The total area under production increased from 630 to 950 hectares and average yields of millets, sorghum and onion increased substantially.

The village made every effort to ensure equitable access to the resources generated. Water is being distributed equitably and only crops with a low-water consumption are grown. Today nobody in the village is dependent on drought relief. Incomes have increased substantially and income distribution is more even than in other parts of rural Maharashtra.

Ralegan put more emphasis on participatory democracy than representative democracy. The village created an impressive system of decision making and some 14 committees ensured that people participated in all decisions. A *Gram Sabha,* a participative democratic institution, was established to take community decisions and ensure that each household was involved in the development process. It was also able to exercise social pressure when necessary. (Mahapatra,1997).

A dead river back to life

Rainwater harvesting has brought the River Arvari in dry and drought-prone Rajastan back to life. (see Shree Padre p14). The river flows through a drought stricken region - villagers living on the margins of survival are desperately poor and find sustenance by migrating to cities to look for work. According to historical records of the region, the river Arvari used to provide groundwater recharge to wells in the area. But nobody can remember seeing it flow except during the short monsoon period. The river – in its 45km journey to its confluence in the reservoir of a dam on the River Sainthal – flows through about 70 villages. Its source lies in the degraded hills near the village of Bhaonta-Koylala.

In 1986, working with a local NGO, the Tarun Bharat Sangh (TBS), the villagers of Bhaonta-Koylala built a rain-water harvesting structure or *Johad* to trap the rainwater and use it to recharge the groundwater. Since then many more water harvesting structures have been built in the Arvani catchment. These small dams have helped to recharge the river and since 1995 it has been perennial.

Jhabua District

Transformation of rural ecosystems with people's participation, such as the cases described above, has remained isolated and scattered, and usually led by remarkable NGO leaders. Governement efforts in afforestation and watershed management have rarely been able to reproduce these successes. The problem is often that the devolution of power to local communities has been half-hearted and inadequate. People's participation has remained largely stuck in the 'you participate in my programme' mode.

In Madhya Pradesh, however, the government's watershed management programme (the Rajiv Gandhi Watershed Development Mission) has become an outstanding example of government interventions promoting public participation in environmental management. The statewide programme was initiated by the chief minister Digvijay Singh who was inspired by Krishna Bhaurao Hazare's work in Ralegan Siddhi. The programme is integrated and participatory in its approach. Today trees are flourishing in a district that 15 years ago looked like a moonscape and wells are literally overflowing with water in a place that was described as chronically drought-prone (Agarwal and Mahapatra, 1999)

The programme created several tiers of institutions: policy coordination at state level; implementation and coordination at the district and macro-watershed level, and work at village level to ensure that all villagers are involved in the effort. Some 1748 women's groups, for example, have been created in 374 villages in Jhabua and together they have 25,506 participants. Most important, however, serious efforts have been made to give local communities power over decision making and control over resources. Villagers play an active role in the management of watershed programme funds. Nearly 80% of the programme's funds are put in a bank account managed by Watershed Development Committees made up of village people. The Watershed Development Committee brings together the important interest groups in the village in a way similar to the *Gram Sabha*.

Eco-restoration is possible

These case studies show clearly that eco-restoration is possible even in highly degraded lands and that it can regenerate local rural economies and alleviate poverty in a sustainable and cost-effective way (Agarwal and Narain, 1999). In other words, helping the people to help themselves by improving their local natural resource base is a viable and effective strategy for poverty alleviation. The key to eco-restoration lies in good management and use of the local rainwater. This must be supported by community decision-making systems and institutions. There must also be legal and financial structures to enable and promote community action.

Examples such as those referred to above remain scattered because the governance system needed to foster people's control over natural resources does not exist. Locally-led instances have emerged despite and not because of the system. Effecting change at the micro-level requires enormous perseverance and effort on the part of an individual initiator especially if the governance system does not empower local communities to improve and care for their resource base. However, the government of Madhya Pradesh has now shown that the state can reproduce community-based efforts if there is adequate political will and pressure on the technical and administrative bureaucracy to deliver. The transformation of Jhabua is a fine example of the results that can be expected when a government seriously starts working with people.

Conclusions

The potential of water harvesting is enormous. The cases mentioned here show that improvements begin with increases in the quality and productivity of croplands as available water increases. This leads to better grass production from the local grasslands and slowly increased production of fodder and timber resources from tree and forestlands.

But for water harvesting to support sustainable rural development, there will have to be a change in the governance of water systems (Box 1). Decentralized systems of water management are needed. These in turn demand a community-based system of natural resource management. The only way this objective can be achieved is by deepening systems of participatory democracy and expanding people's participation at village-level. Every settlement must have a clearly and legally defined environment to protect, care for and use. It must also have an open forum in which all can get together to discuss problems and work to common solutions. By strengthening and emphasising the importance of open forums, common solutions and common natural resources, the developing world can make a determined bid to revive dying community spirit and to rebuild its devastated environment. ■

Box 1. Steps towards a community-based system of natural resource management

- *Maintain water as a community resource*. Water as a common property resource is the crucial link for improving the productivity of private croplands. It is vital to maintain the use of local water as a community resource and not allow water distribution to follow the inequity in land holdings.
- *Adopt an integrated approach to village resource development*. Current rural development efforts are extremely fragmented, focusing mostly on agriculture, and often efforts are contradictory and counter-productive. Yet the 'village ecosystem' usually consists of several integrated components: crop lands, grazing lands, forest and trees, local water bodies, livestock and various energy sources. What happens in one component invariably impacts on the others, and all is maintained in a delicate ecological balance. Thus development must focus on the holistic enrichment of the ecosystem, whereby attempts are made to increase the productivity of all components, from grazing and forestlands to croplands, water systems and animals.
- *Ensure people's participation in the regeneration of village assets*. All new plantations and grasslands have to be protected, but this will need the support of the people. Without this support the survival rates for village assets like check dams and tanks will be poor.
- *Strengthen village institutions to enable people's participation*. Rational use and maintenance of village land and water resources requires discipline. Villagers have to ensure that animals do not graze in their protected commons and that local water body catchments are conserved and properly used. They must also ensure that the common produce from these lands is equitably distributed within the village. Villagers can only achieve this if there is an effective village-level institution to give them an impetus and involve them in controlling and managing their environment. Deepening democracy at the grassroots is critical in the process of ecological regeneration and local water management. The village-level institution must work with a high order of democracy and transparency in decision-making in order to engender cooperation and discipline within the group members. In India, village-level institutions have worked best when they are built along the lines of the Gandhian concept of a *Gram Sabha*, a village institution that empowers the adults of the village to take decisions.
- *Promote decision-making forums*. Open public forums are more transparent and accountable and promote more confidence in community decision-making than small, elected village councils. Resolution of intra-village conflicts and coordination are invariably easier in open village forums where equitable community decisions can be taken than when organisations are closed and secretive.
- *Develop a legal framework that supports local rights to manage resources*. The Indian government owns a substantial portion of the land and water resources. As a result village communities are often alienated from their management or protection. This can lead to massive denudation of forests, overexploitation of grazing lands and neglect of local water systems. Laws dealing with natural resources like land, water and forests will have to be changed to give people the right to improve and develop the village natural resource base. The legal framework should encourage people to take the initiative to develop their natural resource base without waiting for government to act first.
- *Channel government funds directly to village institutions*. In the present system, various functionaries and agencies of the government control the finances upon which village development depends. Ultimately, only a small proportion reaches the community and it is often spent on projects over which the village has little control and which are not local priorities.

This article is derived from a study on the interaction between humans and their environment in the arid Sahel region of northern Senegal. It compares the pastoral community of Maka Ndandary to the sedentary agriculturists of Teud Bitty. Both villages are situated in the Pal-Mérinaguène sylvo-pastoral reserve, an area of declining rainfall. In the period 1931-1960 average rainfall was 473 mm. Twenty years later average rainfall had declined to 258 mm and was considerably more variable. The research was part of the Long-term Environmental Monitoring in Senegal Project and was carried out by EROS Data Center (EDC), the Centre de Suivi Ecologique (CSE), and two local NGOs. The study analysed information collected by remote sensing techniques (satellite and aerial photographs) and Rapid Rural Appraisals in both communities.

Photo: EROS

In Teud Bitty the landscape has become almost treeless.

Cattle and cultivators: conflicting strategies for natural resource management

Living side by side but following different livelihood strategies, the communities of Maka Ndandary and Teud Bitty come into increasing conflict over the use of the areas diminishing resources. The pastoral livelihood system is essentially conservationist in its approach to natural resources while the agriculturists of Teud Bitty employ more extractive methods. The different impacts these communities have on their environment is startling. The study focused on how the two communities managed their natural resources and examined the causes and consequences of recurrent resource conflict. It also examined the role played by the state.

.

The village of Teud Bitty

Teud Bitty was founded in the early 1900s by Wolof settlers and today has an official population of some 600 people. Only about 100 people actually live in the village all year round because at least 200 villagers are permanent labour migrants and the rest return to the village during the agricultural season but leave again when the long dry season begins. Migrants find work in the industrial rice, tomato, and sugar plantations along the Senegal River and take on any odd job they can find. Some are able to earn a reasonable livelihood in this way, the majority earn very little.

The social consequences of this seasonal out-migration are substantial. Family life is disrupted and the village is no longer able to engage in collective decision making and action. Out-migration also has several economic implications. The absence of labour has meant that certain activities like animal husbandry are no longer viable because there are not enough people left to care for them. Migrants usually take the family horse or donkey cart with them. This means there is no transport available to haul potable water to the village. The few with carts charge high rates for water transport thus impoverishing the rest of the village.

Resource management

The territory of Teud Bitty is organised along the lines of a classic Wolof village. The village is at the center of the territory and is surrounded by fields. These are in the form of two concentric circles, the smaller of which is immediately next to the village (*tooker* or house fields). The *tooker* is surrounded by the much larger circle of outer fields. Traditionally, *tooker* fields were the most intensively cultivated because they were well fertilised. Today, however, the village does not have enough animals to provide the necessary manure and the *tooker* yields little more than the fields in the outer circle where millet, cowpea, melon and groundnut are grown. In the past, when most of the villagers participated in farming, most of the land was cultivated every year. Now, because soil fertility is low and there is a lack of labour, a significant amount of land is left fallow.

Although the amount of cultivated land is falling, village fields are gradually extending over a larger and larger area. As traditional village fields are abandoned because of abysmal soil fertility, villagers seek to expand into new and more fertile areas. In many cases this has meant expanding into areas that were traditionally used as passageways by herds in the area.

Around the settlement are many varieties of trees which villagers use for shade, fruit and a variety of purposes. Trees within the village and *tooker* are generally protected and cannot be cut. The limits of these inner fields are marked by fences of live shrubs and trees and because these are close to the village and villagers work regularly in the vicinity they can be kept under rigorous surveillance. Beyond the *tooker*, however, there is hardly a tree to be seen. There are many inter-related reasons for the lack of trees. Many of the less drought resistant species died out progressively between 1945 and 1965, as rainfall slowly declined. A large number of trees also then died during the droughts of 1972-1973 and 1983-1984. Charcoal makers, attracted by the dead trees, set up kilns in the area but moved on when the supply of dead wood was exhausted. However, local families, whose agricultural output remained low after these droughts, began to turn to charcoal production, cutting live trees to supplement their income. Before long all the woody species disappeared because there were no rules to prevent villagers cutting trees on the outer fields.

The household economy

Average yields for millet in the region are less than 250 kg/ha and the study suggests that Teud Bitty's yields may be even lower. Residents estimate that the cereals produced by a "typical" family in a good year (two out of ten), will last about three months.

In the past, part of the deficit was compensated by the sale of groundnuts. Groundnut seed is now difficult to obtain, however, and yields (less than 300 kg/ha) are low. Much of the money earned from groundnut production is used to pay off the debts accumulated the previous year. What remains is used to pay taxes, medical expenses, clothes, and buy seeds for the next season. Most families maintain between 3-12 sheep and goats. Villagers admit that fattening one sheep is of more use to them than cultivating a field. The proceeds from the sale of one animal can generally purchase between 50 and 100 kg of grain. However, there are considerable constraints to keeping livestock. Villagers have difficulty in getting enough money together to invest in animals when the family is hungry for most of the year and there are the problems of poor pasture and maintaining herd size.

The money needed to feed the family for up to nine months of the year must therefore come from a patchwork of off-farm activities the most important of which is labour migration.

Lack of integration

The production system in Teud Bitty has always focused heavily on natural resource-based activities: growing crops, exploiting trees and raising animals. Yet there is little integration between these activities and each element of the production system is essentially extractive. At the moment there are no systematic ways of maintaining soil fertility and the cultivation of groundnuts has left the soil denuded and vulnerable to wind erosion further reducing soil fertility. As trees were cut and removed there was no longer leaf litter to replenish soil nutrients. In the past farmers made "fertilisation contracts" with pastoralist. Herders would tether their animals on particular fields at night in order to ensure the ground was well manured. This practice has now been abandoned because farmers claim that in years of very poor rainfall, fields that have not been heavily fertilised will produce better than those that have been intensively manured.

Livelihood strategies in Teud Bitty have become nothing more than a desperate attempt to squeeze what little remains from a depleted resource base. The population is aware that their current livelihood strategies are not viable. As one villager observed out-migration is destined to increase: "You see that few remain here now. We are afraid that even these last ones will soon have to leave."

The Community of Maka Ndandary

The residents of Maka Ndandary are Pulaars of the Wodaabe lineage. The first families settled in the area in the mid-nineteenth century. Today some 150 to 200 people live in the *hurum* (a settlement or 'that which is ours). Maka Ndandary is a scattered assortment of straw huts, animal enclosures, and pasture lands. Despite its apparently haphazard layout, Maka has a strong sense of community identity.

The population of Maka is proudly pastoralist. Nearly all families own cattle, sheep, and goats. Cattle herds can contain up to 60 animals although average herd size is about 25 animals. Sheep flocks vary in size from 10 to 80 animals. An average flock will have between 30 and 40 animals. Most families also have a few goats. Livelihood strategies are partly dependent on transhumance. Some of the *hurum* migrate seasonally with the community's livestock to find better pasture and water elsewhere. Each family also cultivates some crops and, as the study shows, they actually produce more grain than most of their Wolof neighbours.

Each household has a portion of land in the *hurum gese*. This is the most intensively used part of their territory and is roughly equivalent to the inner fields of Teud Bitty. This land is used for building houses and corrals for livestock and crops are planted in fields surrounded by hedges. The animal manure deposited at night in the *hurum gese* makes these lands particularly fertile. Families rotate their fields after five years, switching back and forth between two sites on either side of the homestead, a system that maintains soil fertility. The principal crop is millet. In addition, most families cultivate small quantities of beans, hibiscus, melon, squash, and a very small amount of groundnut for home consumption. The estimated average yield for millet was about 300-400 kg/ha, considerably higher than the 240 kg/ha considered average for the region.

Many families are able to produce enough grain to feed themselves for four to six months of the year. For six months each year they sell a sheep or goat once a week to buy food and other supplies. Even so they still manage to keep the herd size at between 30 and 50 animals. Cattle are only sold in case of emergency. There is hardly any economic necessity to look for work outside the *hurum*.

Resource management

Resource management practices in the Maka *hurum* have evolved progressively over the past 50 years. The rate of change has accelerated dramatically since the 1970s as environmental and human pressures began to increase significantly. From the mid-1950s Maka pastoralists began to be increasingly concerned about tree devastation in the areas where they pastured their

Photo: EROS

Participatory mapping combined with air photo's from earlier dates stimulate lively discussions on the evolution of land use

animals. They noticed that charcoal makers were coming into the area and beginning to wreck havoc with the vegetation. They also realised that there was no basis on which they could act to stop these incursions because they had no boundaries around a territory they could call their own. The heads of family gathered together to discuss the problem. They sent out a delegation to identify trees that would, in future, mark the boundaries of their *hurum*. In doing so, Maka became the first Pulaar community in the area to define its territory.

During the droughts of the 1970s, many Maka pastoralists left the arid north and moved their cattle further south. When they returned to their territory they were shocked to see the devastation that had taken place during their absence: many trees had been cut down by charcoal makers. Once again the community was galvanized into action and surveillance was intensified to control wood cutting. The residents decided that they would abandon the practice of moving entire families out of the *hurum* during transhumance. In future a few members of the community would stay behind with the explicit function of protecting the trees.

It was not only outsiders who were responsible for damage, but also some of the villagers themselves. Therefore, the community established a number of rules to control how the natural resources of the *hurum* should be used. No tree product, whether from live or dead trees, can be cut or collected in the *hurum gese* without the express permission of the land-holder. On the *hurum ladde* (outer pastures) people may harvest tree products for their own personal use, but they are prohibited from using them for commercial purposes. The same rules apply cutting grass because, in years when rainfall is low and fodder is scarce, there is a big demand for hay and outsiders come into the region with their carts searching for grass that they can cut and sell in the cities.

There are currently about 15 tree species found in Maka, considerably more than in neighbouring farming villages although far less than in the past when there were as many as 50 species in the area. Dense concentrations of trees are found in the *hurum gese* that occupies about a third of the *hurum* lands. Villagers patrol part of the outer pasture, the lesser *hurum ladde.* This has quite a few trees though not as many as the *hurum gese*. In the largest part of the outer pasture (the greater *hurum ladde*) there are significantly fewer trees, but there are signs of regeneration.

Conflicts over land and resources

Currently, depleted soils in the home territories of neighbouring villages are pushing Wolof farmers to expand onto new lands. Land in pastoralist communities such as Maka is relatively fertile which makes grasslands very attractive to neighbouring farmers. When pastoralists see a farmer cutting trees to prepare a field for crop production they try to reason with him to leave the territory. If the farmer will not leave voluntarily, the herder's only recourse is to ask the authorities to intervene. Maka residents report two cases where they notified the authorities and actually received a favorable ruling. However, the victory was illusory: the cultivators did not retreat and the authorities did nothing to enforce their ruling despite continued pressure from Maka residents.

While in these two instances State authorities did recognise the rights of Maka residents – at least in theory – they did so to avoid conflict between two neighboring communities. In general the State has cast a blind eye to the extension of cultivated land into Pulaar *hurum* grazing land. The authorities follow the principle that land should be allocated to those who will make it productive. "Productive land" is considered to be land that is cropped or planted with orchards…and does not include zones that are used for extensive grazing.

In fact, there are no plans for how land should be used in the area or what the rights of different populations and interest groups should be. Instead of managing the land, the Rural Community Council manages conflicts as they arise. Its main objective is to reduce the number and severity of disputes.

While the Maka residents have had only limited success in protecting their space from aggression by neighboring farmers, they have been substantially more successful in protecting the trees and grasses of their territory. They note with pride that when they confront someone found cutting a tree, the person almost always stops and leaves the territory without creating further disturbance. They feel that this is due to the fact that, for the last twenty years, they have systematically insistenced on their right to control the cutting of wood.

Pastoral livelihood threatened

The pastoralist livelihood system as practiced in Maka is essentially in harmony with its environment. This can be explained by two related factors. The first is the essential integration of all elements of the production system. Animals, trees, and crops are integrated in such a way that no resource is subject to sustained extraction without there being some compensatory input. The second ingredient is the explicitly conservationist approach of the local community. As the pressure on resources increases due to population growth, reduced rainfall, and a variety of other factors, these collective and protective strategies have become progressively more stringent and systematic. The aggressive and expansive use of land in neighbouring agricultural villages is currently threatening the sustainability of the system.

While the threat to the environment and to the pastrol livelihood is very real, it is not too late to put policies in place to improve the situation and protect the resources and the economic interests that depend on them. Time is running out, however, and only by a concerted effort that mobilises activists at the national, regional and community level can progress be made. The residents of Maka have not given up and those who share their concern for maintaining the fragile ecosystems of dryland northern Senegal should not give up either.

Kandia: threatened forest, threatened livelihood

by Freudenberger K, Hadj A, Ndiaye T and Trappan G. 1996. 43 p. Eros Data Center, Sioux Falls, South Dakota 57198, USA.

This study describes clearly the positive side of the forestry situation in the southern part of Senegal an area that receives between 800 and 1000 mm of erratic rainfall. The study used participatory methods to identify and quantify vegetation resources. Typical tools such as village mapping, wealth ranking and individual farm sketches, were checked with secondary data from existing soil maps and satellite imageries. Special emphasis was put on resource allocation and benefit sharing issues in relation to food security by applying a gender differentiated historical matrix on roles. Villagers gave considerable attention to the issue of burning vegetation especially with regard to control strategies and their implementation. Institutional aspects such as legislation, procedures and relationships with higher administrative levels were also being examined. The study provides an interesting framework for the implementation of inventories at village level, serving as an effective tool for the participatory establishment of elementary baseline data. (KM)

Communities combatting desertification: livelihoods reborn

Editorial

Desertification, better defined as land degradation, is of major and continuing concern to communities living in dry regions. It is the cause as well as the effect of poverty and endangers the welfare and livelihoods of future generations.

In 1993, the United Nations launched the 'Convention to Combat Desertification' (CCD) (p6). Most signatories to this convention are now formulating 'National Action Programmes' (NAPs) to deal with the problem in their own countries and some have reached the stage of implementation. The Convention sets out to address land degradation and its socioeconomic dimension - poverty - in an integrated and embedded way. It emphasises a "bottom-up" approach that sees civil society participating fully in decision-making and in doing so has raised hopes that concerted action will be possible.

Under the terms of the Convention, community-based organisations and NGOs are supposed to elaborate Local Area Development Programmes. These will subsequently form the basis of action plans at the national and regional level. Experiences with the formulation of NAPs indicate that some countries such as Argentina, for example, (Merega p7) have made an important break-through as far as the participation of people's organisations and NGOs are concerned. However, there are many countries where the lack of peoples' participation and the absence of planned integrated and concerted action and funding for such activities are major constraints. At the same time, unaffordable and non-sustainable technologies such as chemical fertiliser and large dams are still being recommended as solutions (Soccal p20).

This issue of the ILEIA Newsletter focuses on community action to combat desertification and on participatory methodologies to support communities in their efforts to devise effective ways of regaining their livelihood. What did we learn from the articles?

Causes of desertification

It is generally acknowledged that the causes of desertification are mainly human in origin. To combat desertification effectively, we need to understand these causes and underlying socioeconomic and cultural processes (Kessler p26). The articles offer significant insights.

Agarwal and Narain (p11) and Freudenberger (p8) point to colonial intervention. Foreign powers ignored traditional indigenous resource management, established the western concept of market agriculture, reoriented education and research and centralised state power. In the process community lands were expropriated and forests decimated. Most post-colonial government elites continued to operate with these foreign concepts and policies as they pursue the global 'development' dream.

- In the relatively fertile central region of Senegal, export-oriented groundnut monoculture has largely replaced traditional land-use practices. Forest, livestock and cropping are no longer mutually supportive. Pastoralism is increasingly difficult as the rangelands needed for transmigration in dry years are being taken over by sedentary farmers who have the support of government policies. At the same time traditional decision making, land tenure and management often lack the flexibility to adapt to new needs.
- In India, traditional water harvesting systems - once the backbone of Indian agriculture - have been replaced by deep wells. Rural communities and tribal people in particular have lost access to forest resources as most forests have been cut down and the monocultures of market-orientated agriculture have become common practice.

Such changes have resulted in the ecological degradation and poverty of local communities, important push factors stimulating a steady stream of outmigration. As Muhia (p16) stresses, combating desertification is more than a technical issue; it has fundamental political and cultural implications.

Opportunities recognised

Among the positive developments mentioned is the growing recognition of the need for cheap, ecologically sound technologies adapted to local conditions such as applying organic fertiliser and rock phosphate (p24) and using local materials to build water harvesting structures (Lopez and Bunch p22; Soccal p20). Traditional resource management strategies, such as those for rangeland management (Freudenberger p8), for example, are being re-valued because economically and ecologically they often prove more sustainable than conventional practices. Some governments have accepted policies that empower communities to manage their own natural resources (eg Joint Forest Management, p30). In addition, they increasingly disseminate technologies developed by NGOs and POs (Soccal p20) and enhance massive investment in watershed development (Agarwal and Narain p11).

There is growing awareness of the economic potential of ecologically-sound management and communities are starting to adapt their land use practices. Development workers, researchers and policy makers can strengthen such initiatives and create conditions favourable to local, natural resource management and farmer innovation. This may mean that professionals will have to reassess their conventional role. However, as Lopez and Bunch (p22) make clear, researchers who support farmer innovators need not be afraid of loosing their jobs. They are needed for the tasks farmers are unable to do themselves.

Communities recreate livelihoods

The contributors to this Newsletter describe successful community-led action where farmers have regained control over their natural resources and been able to recreate livelihoods.

- When Pulaar pastoralists in Northern Senegal became aware of the way their natural resource base was being degraded, they started to protect it against outsiders and those misusing it in their own community. This resulted in the conservation and regeneration of natural vegetation on which they depend for their livelihood (Freudenberger p8).
- Communities in dryland India, after becoming aware of the potential of watershed management to raise income and rebuild communities, have started to redefine rural development (Agarwal and Narain p11). Farmers in Rajastan, India, finally felt 'free from poverty' when conditions improved enough to allow them to return from the city to take up farming again (Shree Padre p14).
- Tribal communities in Gujarat, India, supported by BAIF, started to re-value their degraded forest land after achieving profitable, stable and sustainable livelihoods from growing fruit, fodder and fuel-wood trees (Mahajan p18).
- In Kenya, communities supported by KENGO are becoming more aware of their traditional cultural roots and values. This motivates them to regenerate the natural resource base which now provides them with sustainable livelihoods (Muhia p16).

Preconditions for regeneration

There are important preconditions for community-led regeneration of the natural resource base as the articles in this Newsletter show.

- Muhia (p16) refers to the importance of reviving traditional African values of respect for nature in order to motivate communities to regenerate their environ-

ment. However, he admits that without economic benefits motivation cannot be sustained.
- Affordable 'win-win' technologies that provide acceptable, competitive economic benefits and have positive effects on the environment should be available. Water harvesting is one such win-win technology. Information on indigenous and scientific win-win technologies must be accessible.
- Social unity and equity, strengthened by (traditional) social values and democracy are crucial to enhancing community action and peoples' participation. The benefits of regeneration should be shared and not reserved for the rich and powerful.
- Effective village institutions are needed to ensure full participation in decision making, coordinated community action, conflict resolution and access to governmental support.
- Legal frameworks and policies are needed that support the right of the local community to manage resources equally and that support participatory farmer innovation and the development of locally affordable solutions derived from indigenous and scientific knowledge.

Water and soil management

Although water management is crucial in combating desertification, soil management is equally important. This is particularly so where soils are poor and eroded, their organic content neglected and soil nutrients are exported without any compensation from external inputs of organic or chemical fertilisers (negative nutrient balance). All these factors undermine soil fertility. This situation is common in West Africa and scientists indicate that if no serious attention is paid to soil fertility management it will be impossible to halt land degradation and declining productivity and the poverty and communal disruption it brings. To break this vicious circle an international "Soil Fertility Initiative" has been launched which aims to facilitate the formulation of NAPs for Integrated Soil Fertility Management. Burkina Faso is one of the first countries that formulated – in a participative way - a national strategy to re-capitalise its soils (p24). Such strategies should be an integrated part of NAPs to combat desertification.

At farmer level further differentiation is needed to adapt soil fertility management to the specific local conditions. Resource Guides on participatory learning and soil fertility management (Defoer et al. p25; FARM p26) can be helpful tools in designing farmer-specific strategies.

Cartoon Anil Achar, India from **Comics to Combat Desertification**, Secretariat UN Convention to Combat Desertification, Geneva

Deforestation or making way for the camels

Balancing market and subsistence

Like the Soil Fertility Initiative, most (inter) national programmes to improve agriculture focus on developing market agriculture. It is assumed that this is the way to increase surplus production and raise the standard of living. *However, is it not time to officially admit that, in many economically marginal and ecologically vulnerable regions eg. in Africa, market agriculture based on external inputs is neither economically profitable nor ecologically sustainable and is often at odds with local culture* (Zone III, Breman p24). This may be the case even where investments in recapitalisation of soil fertility are being subsidised as in Burkina Faso. This also would mean admitting that agriculture in these regions should be based on the locally available resources, diversity and prevention of resource depletion - in other words, the basic foundation of traditional subsistence-oriented agriculture. This does not exclude new strategies for raising production and income. Selective production for market, labour migration or eco-tourism can be considered but only after a careful analysis has been made of what is ecologically affordable, culturally acceptable and economically feasible. The articles by Freudenberger (p8), Agarwal and Narain (p11), Shree Padre (p14) and Muhia (p16) provide examples of communities that are successfully building their future on their own traditional wisdom and experience in natural resource management. When external inputs become increasingly expensive and inefficient the need for this approach becomes even more apparent.

Conserted action needed

There are many organisations active in the broad field of combating desertification and stimulating rural development. An important aspect of NAPs should be the coordination of activities. Participatory environmental analysis and planning tools such as SEAN (Strategic Environmental Analysis) (Kessler p26) can help to reach a deeper understanding of the local economic and environmental situation. At the same time it can facilitate the development of strategies to reduce poverty, improve human welfare and regenerate the natural resource base and coordinate concerted action. In doing so, desertification can be combated in an effective and sustainable way.

■

Themes for the ILEIA Newsletter

You are invited to contribute to these issues with articles, suggestions for possible authors, and information on interesting issues, publications, training courses, meetings and Websites. The ILEIA style guide is available on request or at www.oneworld.org/ileia. Please do not wait until the last minute to send in your article. Accepted contributions will be published in the ILEIA Newsletter or on the ILEIA Website.

Photo: Ramprasad

March 2000
Vol.16-1
Desertification
Deadline for contributions 15 January 2000.

June 2000
Vol.16-2
Farmer innovation
How to support farmer innovators to enhance the adaptation of land use - agriculture to changing conditions and needs: e.g. innovator networks, farm radio, rural communication programmes, rural information centres, participatory technology development, platforms for innovation. How to create a social and economically benign environment for farmer innovation and farmer – researcher collaboration. How to enhance up-scaling of innovation. Interesting examples of innovations developed by farmers.
Deadline for contributions 1 March 2000.

September 2000
Vol.16-3
Integrated agriculture
How can unsustainable slash and burn systems evolve in more sustainable and permanent integrated systems. How can such an evolution process be supported and what are the economic and social preconditions for developing integrated systems. Interesting examples of: indigenous agroforestry systems and their evolution; indigenous or agroecological strategies to intensify agroforestry systems; the spiritual, cultural and social dimension of indigenous integrated agriculture; role of animals in integrated systems; value adding and marketing of indigenous or new crop, tree or animal products; economic comparison of the performance of integrated systems.
Deadline for contributions 1 May 2000.

December 2000
Vol.16-4
Monoculture systems
How to make monocropping or mono-animal systems more sustainable. How to develop them into integrated systems. How to improve the production chain. Interesting examples of: ecologisation and intensification; diversification; soil fertility management; pest management; processing; input supply; product development and value adding; marketing.
Deadline for contributions 1st September 2000.

January – March 2000
Vol.17-1
Resilience
How do farmers prevent disaster and react to the catastrophies of drought, flood, armed conflict, disease and economic crisis. How does this influence their farming and livelihood strategies. How do farmers deal with variability and risk. How can the resilience of farming and households be improved. What impact does labour migration have on farming systems and gender roles. How can women best adapt farming in areas of labour migration and still optimise benefits and ecological sustainability. How can gender roles be renegotiated. How can women farmers best be reached and supported. How can farming by refugees be supported.
Deadline for contributions 1 December 2000.

ILEIA Newsletter: new subscription policy

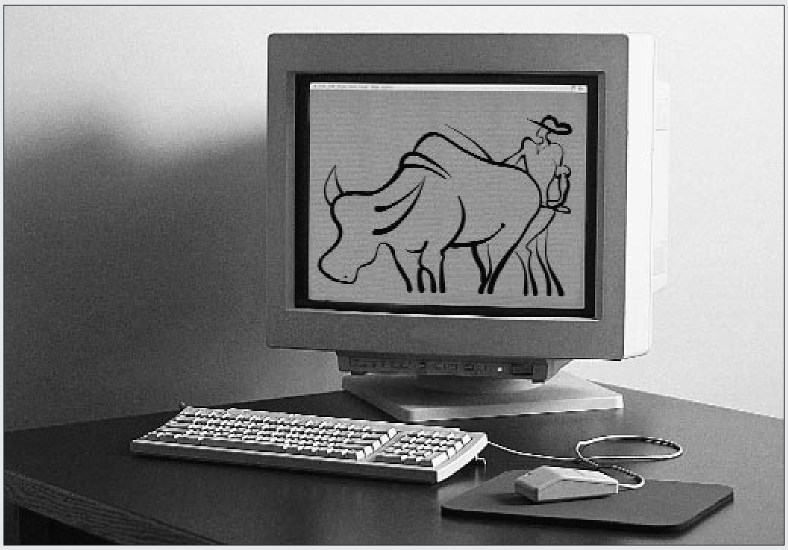
Bert Lof writes: A new institution dealing with sustainability has to ensure its own sustainability and financial future. The ILEIA Board has decided to change the Newsletter subscription policy. So far, 92% of all those who read the ILEIA Newsletter receive it free of charge, thanks to ILEIA's donors.

ILEIA will gradually introduce paid subscriptions at affordable rates. We are trying to initiate local currency payments in order to avoid heavy bank charges. When it becomes possible for you to pay in this way we will get in touch with you immediately and provide you with details about rates and method of payment. Those in developing countries who now receive the Newsletter free of charge will go on receiving it free of charge until paid subscriptions in local currency are introduced into their region.

We have set the yearly subscription for the quarterly Newsletter at EURO 10.00 or US$10.00 for organisations and individuals in the Third World and EURO 25.00 or US$ 25.00 for all other subscribers (or equivalent in local currency).

For further information about subscriptions and concessionary rates please contact Nicole Krutz, Subscriptions, E.Mail Subscriptions@ileia.nl, ILEIA, PO Box 64, 3830 AB Leusden

Building an Information Web



ILEIA is planning to develop its Internet Website into an interactive information and discussion platform on the development of LEISA. As the development of sustainable agriculture is a very broad subject and information management is a time consuming business, this will only be possible if ILEIA focuses its information gathering and distribution activities on specific themes. ILEIA will need to work in close cooperation with other information organisations that deal with specific aspects of sustainable agriculture.

ILEIA will specialise in particular themes relevant to sustainable agriculture but it will not loose its holistic perspective. Step by step, ILEIA will put information on these themes on the ILEIA Website. To maximise the efficiency of our work, the themes on the Website will be the same as the themes chosen for the ILEIA Newsletter. For example, the present issue of the ILEIA Newsletter is concerned with ‘agrobiodiversity’. An agrobiodiversity information platform will be opened on the ILEIA Website. The information published in the ILEIA Newsletter will be put, in full, on the Website; linkages with other sources of information will be made and additional information on agrobiodiversity will be added regularly. ILEIA will make use of the interactive potential of the Web to keep in touch with the agrobiodiversity debate. A monitored discussion site and links to established question and answer database will provide readers with opportunities for introducing new information and developing the issue further from their own perspective.

In the coming year, regional LEISA Websites will be established, beginning in Latin America. These, together with links to other sites and media, will speed up the process of assembling a growing body of information that can be used by farmers, extensionists and policy makers involved in the LEISA approach to sustainable agriculture. At the same time ILEIA will continue to collaborate with regional information centers to improve the two-way flow of information on LEISA between those involved in social, economic and political aspects of agriculture at regional, national and the global level.

The ILEIA Newsletter plans to deal with a series of thematic issues in this way. Each issue will be a springboard to constructing a new platform, the opening of new thematic dossiers, the building of another shelf in the LEISA virtual library, and creating more opportunity for online discussion.

‘Desertification’, ‘farmer innovators’, ‘integrated agriculture’, ‘monocropping systems’ and agrarian ‘resilience’ have been chosen as the themes for the next five ILEIA Newsletters. These themes are linked in many ways and can be approached from a multitude of perspectives. Keywords - ‘agroforestry’, ‘soil fertility’, ‘gender’ ‘groundnuts’ can provide entry points to the information, links and digitalised information that will be built up on the ILEIA Web. Gradually ILEIA hopes to develop platforms that will evolve into one international, multi-organisational and multi-entry-point information Web on the development of sustainable agriculture. Information that links ideas, stimulates action and supports policy.

ILEIA intends to build an information web that is as participatory and interactive as possible. Software for interactive information sharing is developing fast and ILEIA intends to use its experience with INTERDEV, a European initiative concerned with a broad range of development issues, to further consolidate its capacity to profile LEISA as a viable basis for rural and agrarian livelihoods. For those who have no access to Internet, CD Roms will be made available, and ILEIA will continue with its established publication and information services.

ILEIA Foundation: Forging LEISA

After 15 years of steady support from the Dutch Government the ILEIA project – initiated and guided over the years by ETC – has been transformed into the ILEIA Foundation. A new and challenging time lies ahead.

Since May 1999, the ILEIA Foundation has been able to continue the tasks of the ‘old ILEIA’ thanks to the generous support of the Dutch cofinancing organisation NOVIB, and a long-term commitment from the Swedish International Development Authority (SIDA). The ILEIA Foundation intends to further emphasis it role in collecting and systematising information on LEISA and to increase the scope of its regional programmes. The busy ILEIA offices will be staffed by many of the same experienced people already well-known to Newsletter readers. There will be new faces too. At the moment ILEIA is looking for a Director and, hopefully, in the next issue of the Newsletter, we will be able to introduce this new team member to you.

The Board of the new ILEIA Foundation has been “installed”. At the moment there are four members: Sunita Narain, Centre for Science and Environment, New Delhi, India; Professor Eric Goewie, Wageningen Agricultural University, The Netherlands and Dr. Stein W. Bie, Director General of the International Service for National Agricultural Research in The Hague. As well as ensuring continuity, their task will be to help chart an effective course for ILEIA in the coming years.

The ILEIA Foundation has already begun work on its new programme. In November 1999, the ILEIA Latin American regional programme got the go-ahead. This programme will include the further development of the Spanish language version of the ILEIA Newsletter and is supported by three Dutch cofinancing organisations - ICCO (lead donor), NOVIB and HIVOS. It is the first of some five or six regional programmes that ILEIA intends to implement. Other regional programmes are being developed for South Asia, Southeast Asia, West Africa, Southern Africa and the Middle East & Northern Africa. In these areas, regional editions of the ILEIA Newsletter will be produced. Regional Newsletters will carry some of the material published in the International version of the Newsletter but at least 50% of the contributions and information on publications and networking will come from the regions themselves. Regional editions in Arabic, French and other languages are a real possibility in the near future! A regional editorial committee will be responsible for producing these Newsletters locally.

If you would like to know more about ILEIA’s plans for the future have a look at our Website www.oneworld.org/ileia or get in touch with us here in Leusden.

Stein W. Bie
Chair, ILEIA Foundation

Bert Lof
Director ad interim

AGROMISA and ILEIA:
Your questions, our answers

Agromisa has come to the ILEIA Newsletter. In each issue, the Agromisa's Question and Answer team will deal with a selection of readers questions on themes planned for coming editions of the Newsletter. This year these include the relation between LEISA and the issues of desertification, farmer innovation and integrated farming as well as the problems associated with restoring ecological balance in areas of monocrop cultivation (see p64).

Introducing Agromisa

Agromisa's Agricultural Advice Service began in the mid-1930s and 65 years later it is still answering questions sent in by agricultural extensionist, rural community development workers farmers and training organisations. Agromisa focuses on issues that affect the sustainability of agriculture in the tropics and every year it provides detailed answers to many hundreds of questions from farmers and their organisations throughout the developing world. Questions are answered by a team of specialist volunteers made up of researchers, academics and agriculturalists. Once questions have been answered they are systematically classified and stored in a large and easily accessible database. The information provided gives a rich insight into the problems faced by small-scale farmers often working in economically and ecologically difficult conditions.

Biodiversity

This issue of the ILEIA Newsletter is concerned with biodiversity. Biodiversity is not a word often used by farmers. It is better suited to the desks and studies of researchers and policy makers. Agromisa has never received a question that directly refers to problems of biodiversity yet it does receive questions that can only be dealt with in the context of biodiversity.

In this first edition of the Agromisa column, we give one or two examples of the type of questions sent to us that concern biodiversity. Most of those we have received in the past have to do with maintaining plant vigour and preserving the potential for further strengthening and developing crops for a diverse and secure food supply. Some farmers want to know how new farming technologies can be combined with traditional practices "Can we combine hybrid seeds with our traditional seeds?' Others, more concerned with improving cultivation practices, ask how they can select seed with specific qualities (eg drought resistance). There are also farmers who admit they have lost touch with their traditional farming practices and need help to rediscover local resources and ways of propagating and storing local seed and plant material.

The ILEIA team hopes this column will generate a steady stream of questions to the Agromisa service and that we will be able to use some of them in the Newsletter. Each question we receive will be acknowledged. Questions selected for publication in the ILEIA Newsletter and those from individuals and organisations working with farmers at grassroots level will be answered free of charge by Agromisa's Question and Answer team. Questions from other organisations will be charged US$125.

Left to right: KVS Prasad and Chitrah Suresh (LEISA India Inlay) and Teresa Gianella (El Boletin) attending the international editors workshop in The Netherlands, March 1999

From the Regional Newsletters

Teresa Gianella *El Boletin*, Lima, Peru writes:

The theme of this Newsletter is of considerable interest to Latin American readers. They are well aware of the enormous genetic diversity within our native agriculture. Farming and livestock breeding practices in different Andean and Central American ecosystems made this continent one of the rich focal points from which food crops such as corn, common beans, sweet potatoes (Central America), potatoes, butter beans, peanuts (Andes) and cassava (Brazil, Paraguay) have spread throughout the world.

Today, however, just like small farmers in many other developing countries they are currently among the world's most poverty-stricken inhabitants. Their biodiversity is now at risk because they lack the political and economic power to challenge the powerful international consortiums of the biotechnological industry.

This double issue on Agricultural Biodiversity is the first of a new series of El Boletin de ILEIA. Over the next two years El Boletin will gradually become an independent regional Newsletter. One of its made objectives will be to foster the exchange of experiences of sustainable agriculture between the different countries of Latin America and other parts of the developing world. We plan to follow the concept for ILEIA regional Newsletters and carry both regional and international sections.

We invite our readers - and anyone interested in the ecological, cultural and economic viability of sustainable farming practices in Latin America - to write to us, and tell us what they think of this edition of the Newsletter. Please feel free to propose topics and make suggestions about language, text, design, illustrations, layout and anything else you think might improve El Boletin. Some of our readers have already written to us and we have a lively correspondence with Mexico, Cuba and Bolivia. As editors, we are very grateful for these comments.

KVS Prasad *LEISA, India Inlay* Bangalore, India writes:

The LEISA India Inlay, the first all India supplement to the ILEIA Newsletter, came out in March this year. It contained 16 pages of articles, news and information on the theme of marketing organic products in the subcontinent. The Inlay has received an enthusiastic response and circulation figures for the ILEIA Newsletter in India are climbing steadily toward the 4000 mark.

It looks as if the basic objective of moving the distribution and production of the ILEIA Newsletter to India as a first step towards developing an independent South Asian regional Newsletter has been a success. In line with the plans for other regional Newsletter's it is hoped that the LEISA India Inlay will eventually become an independent periodical publishing both international and regional LEISA articles and news of interest to readers in South Asia. Certainly, local distribution and publication activities have proved successful in attracting the attention of agricultural researchers, extensionist and community development workers.

The Inlay will publish articles on themes selected by the international editorial committee. This year these will be Desertification, Farmer Innovation, Integrated Farming, and an issue dealing with the problems associated with restoring ecological balance in areas of monocrop cultivation.

For more information or for a copy of the India Inlay:
KVS Prasad, PO Box 7836, Bangladore 560 078,
India. E-mail: amebang@giasbg01.vsnl.net.in

NETWORKING

4th National Congress on Organic Agriculture

17-19 May, 2000, Cuba. The congress will be organised by the 'Grupo de Agricultura Orgánica' of the 'Asociación Cubana de Técnicos Agrícolas y Forestales (ACTAF) in coordination with the 'Ministerio de la Agricultura' and the 'Asociación Nacional de Agricultores Pequeños' in EXPO-CUBA, Ciudad de La Habana. Main themes will be: Cuba in the world of sustainable agriculture; contributions to sustainable rural development in Latin America and the Caribe; from integrated production systems towards agroecology; contributions of small farmers to agroecology and food security; production potential and market opportunities of organic products; promotion of organic agriculture; economic assessment of agroecological technologies; conservation and regeneration of soil fertility; organic agriculture at the start of the 21st Century: the state of the art in Cuba. Study tours (10-16 May) and a training course (20-24 May) will also be organised.

More information: Marta Pérez Pérez, Secretaria Ejecutiva, Grupo de Agricultura Orgánica – ACTAF, Apartado Postal 4029 C.P. 10400, Ciudad de La Habana, Cuba. Tel/Fax: +537 845387; actaf@minag.gov.cu

Reconciliation and renewal: through collaborative learning

5th World Congress on Action Learning, Action Research & Process Management, 9th World Congress on Participatory Action-Research 10-13 September 2000, University of Ballarat Victoria, Australia. The Congress will deal with Reconciliation & Renewal in relation to: inequalities in global communities, the environment, the experiences of indigenous peoples, work, religion, the personal position in society, and diverse value systems. Participants are likely to be involved in: creating & facilitating change, creating reconciliation & renewal through participatory action learning & action research, developing alternative learning processes and new capabilities required in the global scene of the 21st Century.

More information: ALARPM/PAR World Congress Secretariat, c/- The Conference Organisers Pty Ltd, PO BOX 1127, Sandringham VIC 3191 Australia. Phone: +61 3 9521 8881; Fax: +61 3 9521 8889; conforg@ozemail.com.au ; www.conferenceorganisers.com.au

IFOAM 2000. The World Grows Organic

The 13th International Scientific Conference IFOAM 2000 will be organised by the Research Institute of Organic Agriculture (FiBL), 28-31 August 2000, Basel, Switzerland. IFOAM 2000 will explore ways in which organic agriculture can gain global momentum in production, processing and trade in the new millenium. The conference will be accompanied by seminars, exhibitions, excursions and public events.

More information: IFOAM 2000 c/o FiBL, PO Box, CH-5070 Frick, Switzerland. Fax: +41 62 865 7273; ifoam2000@fibl.ch ; www.ifoam2000.ch

Land conservation and food production in the third millenium

The 11th International Soil Conservation Organisation Conference will be organised by the National Institute of Agricultural Technology and the Faculty of Agronomy, University of Buenos Aires, Argentina. The ISCO 2000 meeting will be held October 22-27, 2000. Four main themes have been defined:
- Extension and intensity of land degradation processes. The challenge of the new causes of degradation.
- Scientific and technological advances for the protection of the environment and sustainable land use.
- Socioeconomic factors of human interventions and their consequences for food production and the environment.
- Policies for environment conservation. Scientific cooperation, education and extension.

More information: Secretaría Científica ISCO 2000, FAUBA, Av. San Martin 4453, (1416) Buenos Aires, Argentina, Tel/Fax: +54 11 4481 1688; isco2000@cirn.inta.gov.ar ; www.agro.uba.ar

Globalisation and local development: challenges to small-scale production

The International Farming Systems Association (IFSA) will hold the 16th symposium in Santiago, Chile 27–29 November 2000. Simultaneously, the 4th Latin America Farming Systems Research and Extension (IESA AL – IV) symposium also will take place. The main theme of these symposia is the interaction (conflicts as well as opportunities) between global and local processes, which are shaping the rural regions of the world and their relation to the impact on small farmers' production systems and their technical, social, economic and cultural behavior. Main themes will be rural poverty and food security; small farming systems, markets and competitiveness; environmental sustainability; institutional development. Spanish and English will be the official languages. Abstracts of contributions are due on 29 February 2000.

More information: IFSA/IESA, Casilla 228 Correo 22, Santiago, Chile. Phone: +56 2 236 4557; Fax: +56 2 236 4558; IFSA@rimisp2.cl ; www.rimisp.cl/ifsa_iesa2000.htlm

Cultures and biodiversity congress 2000

21-31 July, 2000 in Kunming, PR China. The specific objectives of the CUBIC congress are:
- To provide the opportunity for researchers to exchange experiences with each other, as well as with representatives of local cultures, policy makers and development staff, on the interactions of cultural values and practices and the management of biodiversity. What insights have been gained about these interactions and what impact do external forces have on these processes.
- To create a dialogue with one another and an image of the future that supports prosperous local cultures using and sustaining biodiversity in traditional and innovative ways. What do we think a better world would look like with regard to local cultures and the management of biodiversity?
- To develop appropriate approaches in which 'outsiders', government and non-government, can act differently and ways in which 'insiders' and local communities can be strengthened in their ability to govern their natural resources and secure their livelihoods.

The ten day programme will combine presentations, workshops, group work, field trips, arts and crafts.

More information: Therese Grinter: Xujc97@public.km.yn.cn or Xu Jianchu: CBIK@public.km.yn.cn

---

The International Agricultural Centre (IAC) is offering a two weeks course on: '**Plant variety protection**', 14-27 May 2000, 13-26 May 2001. Many countries are developing a legal framework for protecting plant varieties. The Uruguay Round of GATT gave an important impetus to this development. The execution of such a legal system requires sound procedures and profound knowledge of variety testing and variety registration. The course aims to assist emerging plant variety protection systems in their human resource development. The course focuses on legal, institutional and technical aspects of plant variety protection. The IAC has no funds for financing participants, funding must therefore be secured elsewhere.

More information: IAC, PO Box 88, 6700 AB Wageningen, The Netherlands, Phone: +31 317 495495; Fax: +31 317 418552; Training@IAC.AGRO.NL ; www.iac.agro.nl Closing date for application: 15 March 2000.

In April 1999 IAC has launched **a new information system, WISARD, on 'Agricultural Research for Development' on the WWW**. It contains information on research projects as well as institutes. It addresses the needs of organisations and networks in developed and developing countries to have updated and quick access to information on activities and potential partners searchable by country, keywords, institution etc. It is possible to enter and update information online.

More information: www.iac-agro.nl/wisard

Internet Conference: '**Material flow analysis of integrated bio-systems**' (March-Oct. 2000). The conference will be organised by the Institute of Advanced Studies of the United Nations University (Tokyo) (www.ias.unu.edu) and the UNU/IAS Integrated Bio-Systems Network (www.ias.unu.edu/proceedings/icibs/ibs/ibsnet) in cooperation with other organisations. The internet conference will focus on the analysis of material flows in integrated bio-systems. The organisers welcome abstracts of papers that can describe and quantify the flow of materials in existing and conceptual bio-systems under such themes as: Municipal biodegradable solid recycling and conversion systems., wastewater treatment and utilisation systems, integrated aquaculture systems, small-scale farming systems, large plantations, farms and feedlots, tools and methodologies for the design and analysis of integrated bio-systems.

More information: Mr. Jacky Foo foo@swipnet.se or www.ias.unu.edu/proceedings/icibs/ic-mfa/

SOLUTIONS TO POVERTY:

FROM MALTHUS TO BIOTECHNOLOGY

This year Zed Books published The Malthus Factor by Eric Ross. It is a major critique of the way Malthusian thinking has influenced capitalist development policy in modern times. Among other themes the book e xamines how the political economy of underdevelopment has been left unanalysed as public alarm focuses on the more visible effects of overpopulation.

Since the publication of Thomas Malthus's *Essay on the Principle of Population* in 1798, poverty, death and environmental degradation has been seen as the product of human population pressure on the means of subsistence. Malthus, writing in Great Britain at the beginning of the Industrial Revolution, suggested it was primarily the irrational reproductive and productive behaviour of the poor themselves that caused their material deprivation. He ignored the role of the economic system in the creation of poverty much as we in the North today ignore the role played by globalisation, trade liberalisation and the agricultural policies of leading industrial nations in entrenching poverty and food insecurity in the developing world.

In his book, **The Malthus Factor**, Eric Ross argues that Malthusian ideas have surfaced at critical moments in recent Western history and today they are being used to justify political and economic policies designed to promote the market economy. He questions, however, whether their objectives can ever provide the infrastructure necessary for building economically stable and socially just societies in the South.

Political instability, economic disorganisation and food security problems are frequently seen by international policymakers as the consequence of unwillingness on the part of developing countries to check population growth. Ross demonstrates that these problems are more often the consequence of social injustice and inequality in the distribution of resources.
It is in these terms that he introduces his analysis of the consequences of the Green Revolution. He argues that the transformation of labour-intensive peasant food production into capital-intensive commercial agriculture is regarded by some as a humanitarian response to the effects of supposed population pressures on food and income security in the Third World. A more realistic assesment would be that multinational companies and investors see the Green Revolution in more opportunistic terms.

Ross suggets, for example, that the Green Revolution was an integral part of a constellation of strategies that were intended to ensure the security of US interests worldwide. He suggests that the first targets of the Green Revolution were those countries where US strategic interests seemed most threatened by rural unrest: Colombia, India and the Philippines. In each, Malthusian arguments about the destalising effects of overpopulation comprised a major part of the rationale for why the livelihoods of peasants, dismissed as backward and unproductive, had to be subordinated to the interests of large commercial farmers. This despite widespread evidence that the latter actually tended to underutilise vast tracts of prime arable land, while peasant cultivators were often capable of extraordinarily intensive food production.

Ross concludes that the commitment to capital-intensive agriculture that the Green Revolution strategy involves ultimately undermines food security in developing countries, has displaced millions of peasants and driven many to become part of an international labour reserve army. Evidence suggests, he argues, that from its formal beginnings in Mexico in the mid-1940's, the Green Revolution was never intended to secure the subsistence of the rural poor, but rather to transform Third World agriculture in a way which would ensure its dependence on international capital.

The apocalyptic Malthusian scenarios that helped to secure such ends have persistently denied any real opportunity to consider alternative explanations - or solutions - for Third World deprivation. Yet, as Ross observes, the need for such debate may now be greater than ever. Prominent policymaking organisations, such as the International Food Policy Research Institute and the Council on Foreign Relations, are calling for a revival of the Green Revolution to combat the effects of the failure of developing countries to curb population growth. Multinationals such as Monsanto conveniently justify their business agendas on the grounds that an over-populated world needs all of their technical innovation. Such arguments, Ross concludes, once again obscure the reasons for Third World poverty. They chiefly address the current needs of global capitalism, rather than the interests of land-hungry and undernourished people in developing countries.
He sees the advocacy of increasing dependence on biotechnology as speeding up the decline of what is left of viable peasant communities. If unchecked this will consolidate the control of the world's food-production system in the hands of a few giant agro-industrial corporations.

New in print

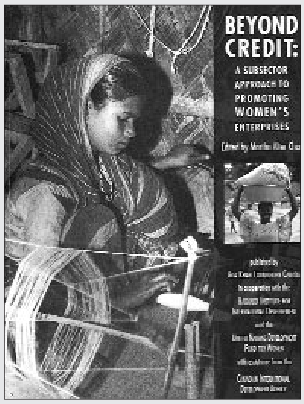
The seed keepers *by Shiva V. [et al.]. 1995. 156 p. Navdanya, Research Foundation for Science, Technology and National Resource Policy, A 60 Hauz Khas, New Delhi 110 016, India.*
This publication gives an account of the work of Navdanya, an Indian movement to conserve agricultural biodiversity by in-situ genetic resources conservation. By placing the farmer at the centre of the conservation, indigenous seeds as well as indigenous knowledge are conserved. The farmers involved in this program have often marginal resources, but also farmers disappointed with the green revolution technologies are very motivated. Individual farmers and their approaches are presented. A community seed register has been compiled and included, to facilitate exchange of organic seeds, and as a document of indigenous resources and knowledge. Besides, developing such registers across the Third World, could serve as a political tool against the privatisation of biodiversity. (IHG)

Creative training: a user's guide*. 1998. International Institute of Rural Reconstruction (IIRR), Y.C. James Yen Center, Silang, Cavite, Philippines.*
This is a very original manual on how to organise training courses. It is the outcome of a workshop that had as its objective the joint publication of a guide to creative training techniques that could easily be translated into local

media and languages and tailored to specific training purposes. A consultative and participatory process was used to develop the guide. The Philippine branch of IIRR had producing a number of successful training kits on a variety of subjects and it was against this background that the workshop took place. As the editors put it: this guide is not a recipe book, it is merely a selection of appetisers. After an introduction on basic facilitation skills, and evaluation techniques accompanied by exercises, come chapters dealing with specific issues. These include mind-mapping, timelines, map-making, producing & interpreting case studies, how to do action research, and conducting field trips. These are all useful skills valuable in a wide variety of situations. A very original book. (WB)

Farmer field schools on integrated soil management: facilitator's manual*. 1998. 218 p. Farmer-Centred Agricultural Resource Management Programme (FARM), FAO-RAP, Maliwan Mansion, Phra Atit Road, Banglumpoo, Bangkok 10200, Thailand.*
Farmer Field Schools (FFS) have had great success as a learning tool for the extension of integrated pest management techniques and approaches, especially so in Southeast Asia. The FFS approach in rice cultivation showed that farmers can become experts at ecosystem analysis and make informed decisions about necessary interventions. From there to applying the FFS concept to other realms as well seemed only a small step. This manual is about integrated soil management and relates the experiences of FFSs in China, the Philippines, Thailand and Vietnam. The publication has a practical approach with much detail on how to shape the courses. While this may be useful as a guide for many, the danger is that the course programme may be seen as a blueprint. It is difficult to judge the effect and the shape of the courses at a distance with only the facilitator's guide in hand. (WB)

Beyond credit: a sub-sector approach to promoting women's enterprises *by M Chen (ed.). 1996. 151 p. ISBN 0 969662 0 2. US$ 19.95. Women Ink., 777 UN Plaza, New York, NY 10017, USA.*
Explores interventions to promote enterprises amongst women in the Third World with low incomes that go beyond providing credit or financial services. Apart from insufficient access to credit facilities, women in developing countries, both in cities and in rural areas, are faced with many constraints when setting up businesses of their own. Micro-enterprise development programmes have tended to favour credit over technology and training or intervention policies. This is all the more so in development programmes targeting women. Women have turned out to be better at repayment than men and therefore, credit programmes that target women are expected to perform better. This publication reports on the experiences of two Asian NGOs that successfully supported the enterprises of low-income women: the Bangladesh Rural Advancement Committee (BRAC) and the Indian Self-Employed Women's Association (SEWA). Both are highly

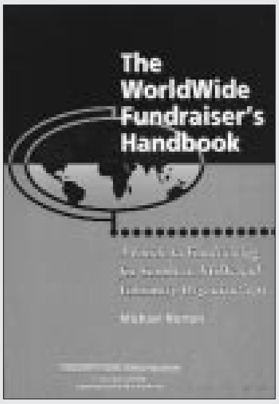


successful: BRAC administers a rural credit enterprise programme for over 800,000 poor women; SEWA developed a comprehensive employment-social security programme for over 100,000 self-employed women, both in the urban and rural areas. The publication looks at the reasons for these successes. The authors provide guidelines for an 'incremental and participatory subsector approach' to promoting women's enterprises. A key element is to undertake the mix of interventions demanded by the women themselves. Constraints are subsector-specific. The publication has a strongly educational focus. In appendices, practical, concise step-by-step tools are given for carrying out the analysis within the framework of the incremental and participatory sub-sector approach. Key concepts are presented as well as questionnaires, steps to follow and a framework for impact assessment. The book is accompanied by a 30-minute video that is frequently referred to in the text. A very practical, well laid-out publications and one that is important to those involved in providing support to women's enterprises. (WB)

Living farms: encouraging sustainable smallholders in Southern Africa *M Whiteside. 1998. 224 p. ISBN 1 85383 590 0. GBP 13.95. Earthscan Publications, 120 Pentonville Road, London N1 9JN, UK.*
Examines the agricultural situation in Southern Africa, where agricultural production has to cope with a population that doubles every 25 or 30 years. Production is often achieved at the expense of the environment and is, therefore, not sustainable. Much of the agricultural production is in the hands of smallholders, who have managed to maintain themselves despite harsh natural conditions and less than cooperative authorities. The author presents a wide variety of ways to encourage a more sustainable agriculture in Southern Africa that will be capable of playing a greater role in the eradication of poverty. The challenge is how to bring about this transition while supporting the basic needs of the population. Solutions must be sought in a skilful combination of resource-conserving technologies. So far, research into sustainable agriculture has been insufficient both in quality and volume and often those involved in research and extension are not well trained for the task. Finally, a great deal of present-day research is initiated by suppliers of external inputs who emphasise the use of bought inputs. All new technology development can only thrive in a local and national environment that provides incentives for sustainability. Appropriate state interventions and clearly defined property rights for natural resources are needed. States have to come to grips with the pressure being exerted on land and traditions. Communities have to be empowered, and new partnerships have to be created. This publication is primarily for policy makers and development professionals. The book includes a list of useful addresses and sources of information relevant for Southern Africa. (WB)

The worldwide fundraiser's handbook: a guide to fundraising for southern NGOs and voluntary organisations *M Norton. 1996. 270 p. ISBN 1 873860 75 7. GBP 12.95. Directory of Social Change, 24 Stephenson Way, London NW1 2DP, UK; International Fund Raising Group, 295 Kennington Road, London SE11 4QE, UK. Adapted from:* ***The complete fundraising handbook****, Sam Clarke (1992).*
This type of manual is hard to find and, therefore, very welcome. Fundraising is an extremely important part of an organisation's success and necessary if it is to survive, develop and reduce its dependence on any one source of fund. Fundraising is more than just getting money: it involves building a constituency and finding supporters with whom one can openly discuss both successes and failures. The author emphasises the need for a degree of humility and a sense of responsibility both when seeking

funds and when funds have been acquired. The book gives the reader a number of suggestions on finding donors. Many good ideas are never realised because those seeking financial assistance do not know how to identify or to approach the donor or how to properly 'package' their proposal. The main problem in fundraising is not so much the lack of opportunities but knowing where to start building a fundraising (or income generation) scheme. This book



provides ideas, techniques and the necessary skills to be successful. It shows readers how to set out a fundraising strategy and how to analyse and present their organisations to donors. Address lists of donors are included in the book. These have a certain anglophone and UK bias but it should not be difficult to substitute them with a more tailor-made selection. There is an important chapter on income generation. Many NGOs now find themselves in situation where this is essential in order to complement subsidies and project funding. Developing some sort of commercial enterprise, the profits of which are used to support the main work of the organisation, often requires a fundamental change in the attitudes of staff involved. An important book, strongly recommended. (WB)

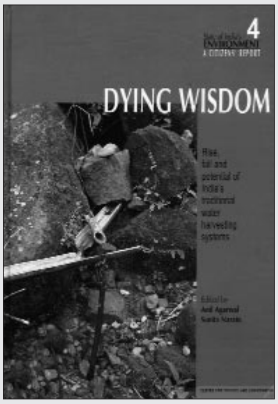
●

Village voices, forest choices: joint forest management in India *M Poffenberger & McGean B (eds). 1996. 356 p. ISBN 0 19 563683 X. US$ 28.80. D.K. Agencies, A/15-17, Mohan Garden, Najafgarh Road, New Delhi 110059, India.*

There is a global crisis going on in forest management that will produce major changes in the near future. This book examines these changes by describing the situation in India, a country that is of particular importance because the human-to-forest ratio there is one of the lowest in the world. In India, Joint Forest Management (JFM) programmes are a feature of the last few years and are based on the local management of forests. These programmes have led to the renewal of once badly degraded ecosystems, often without outside assistance. This has not been achieved without conflict. Those in control and commercial companies are not happy to give up power. Management by state forestry institutions is often based on techniques introduced in the last century from the temperate industrialised world. In order to understand these structures, the authors argue, one must look at the historical roots of deforestation. The key to management lies in the transition from open access to controlled access and in monitored utilisation through user group centred controls. As the authors put it: 'as tenurial rights and delineated responsibilities become vested in the user group, conflicts are reduced, communications improve, and local knowledge once again informs decision making'. JFM programmes involve a process of institutional capacity building. This goes beyond social forestry programmes that involve the local population but which do not necessarily lead to improving the condition of the nation's natural forest. How will management priorities change under community control? What are the daily practices within JFM programmes? The process is still not well documented as most of the data gathered concerns production figures. (WB)

●

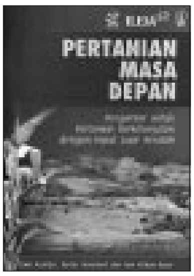
Dying wisdom: rise, fall and potential of India's traditional water harvesting systems *A Agarwal and Narain S (eds). 1997. 404 p. US$ 12.00. Centre for Science and Environment (CSE), 41, Tughlakabad Institutional Area, New Delhi 110 062, India. (State of India's Environment, a Citizens' report No. 4).*



Examines and documents traditional water harvesting systems in India. These are often centuries old. This monumental work is the fruit of a decade-long project by CSE. Material was collected during the course of many field trips, studies of historical documents, and was completed with input from a national workshop held in 1990. The undertaking, as the editors state, was triggered by the strong anti-dam movement in India. The question of whether there were viable alternatives needed to be answered. The book appears at a time when India faces the threat of serious water shortage. It will help to make people aware that a solution to this crisis may well lie in their own traditions. The greater part of the book is taken up by exhaustive descriptions. These are categorised into 15 major ecozones. An impressive number of pictures, drawings and tables help to guide the reader through this vast subject. The second part of the book is devoted to a minute description of the historical rise and fall of water harvesting in India, coinciding with the transition from community control to state intervention. The text offers much more than a technical description. Links are constantly being made with cultural beliefs and the way these express themselves in Indian society. Solutions centre on the (re)installation of a huge number of water harvesting systems including water diversion systems; hill slope rain water collection into ponds; diversion of springs and streams; rainwater retention; rainwater harvesting from rooftops; check dams and percolation tanks. There is a glossary, essential for non-Indians. The book ends with a statement of shared concern. A standard work. (WB)

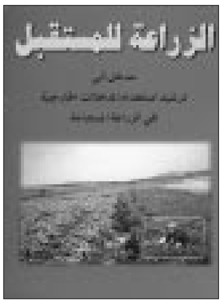
New→FFF in Bahasa and Arabic

The very successful ILEIA publication *Farming for the Future: an introduction to Low-External-Input and Sustainable Agriculture* by Coen Reijntjes, Bertus Haverkort and Ann Waters-Bayer is now available in Arabic and in Bahasa.



The Bahasa version, ISBN 979-672-453-7, can be ordered from KANISIUS, Penerbit – Percetekan, Kotak Pos 1125/Yk – Yogyakarta 55011, Indonesia. Fax: +62 274 563349; E-mail: office@kanisius.co.id ; Price: Rp 55,000

The Arabic version can be ordered from PARC, POB 25128, Shu'fat, The West Bank; Fax: +972 2 5831898; E-mail: pr@pal-arc.org
Contact person: Mr. Yahin abu Sharif



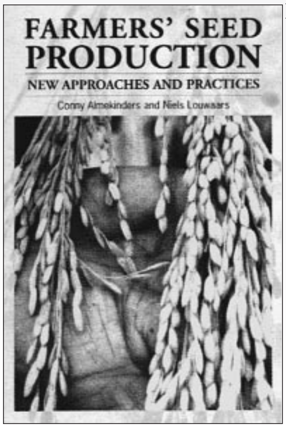
***Farming for the Future* provides an excellent introduction to the principles of low-external-input and sustainable agriculture based on making optimal use of local resources and indigenous - traditional knowledge and, where affordable, complementing this with modern ecologically sustainable technologies. It also provides a step-wise introduction to Participatory Technology Development, an approach for collaboration between researchers and farmers to strengthen local capacity to adapt and innovate agriculture. As the book contains many practical examples, references and the addresses of organisations where more information can be obtained it has become very popular with development workers, researchers and students.**

Farming for the Future is also available in English, French, Spanish, Portuguese, Chinese and Thai.

IF YOU WANT TO KNOW MORE

Encouraging diversity: a synthesis of crop conservation and development *WS de Boef & Almekinders CJM (eds). (forthcoming May 2000). Intermediate Technology Publications, London. 320 p. Price: 20-27 USD.*
Presents some 80 brief contributions with perspectives and experiences in plant genetic resources in the South and the North, from established institutions, researchers, pioneers and activists. These experiences illustrate the apparent conflict between crop conservation and crop development, and contribute to the understanding of opportunities that new approaches and activities in this field offer. There are similarities between problems in the South and the North. Experiences and perspectives of genebanks, plant breeders, seed programmes and NGOs involved in crop development and conservation are analysed and placed in the context of new approaches in local and global PGR management by the formal and informal sector. The latter part of the book takes the reader a step forward in the debate concerning PGR management. It discusses the implications of integrated and adaptive management approaches to PGR including concepts to be used and the institutional organisation required to bring about change. These must be able to stand up to the pressures being experienced by farmers and professionals in the PGR management.

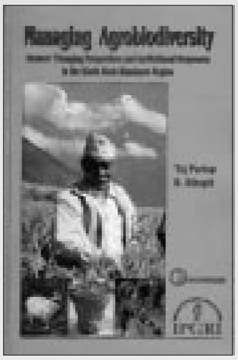
F-



armers' seed production: New approaches and practices
CJA Alekinders & Louwaars N, 1999. 290 pp. ISBN 1 85339 466 1, USD 29.95. Intermediate Technology Publications Ltd., 103-105 Southampton Row, London WC1B 4HH, UK, E-mail: orders@itpubs.org.uk
This handbook covers a whole range of theoretical and practical issues relating to improving the local seed systems of the main tropical food crops. It suggests and explains many approaches and methods to support local seed supply, conservation and improvement by small farmers in developing countries. There is a growing awareness of the fact that most seed is produced by farmers themselves and that new objectives and approaches are needed: taking the local seed system as starting-point, making use of farmers capacities and knowledge, linking farmers' seed system with the formal system, and selecting and adapting what is suitable from the formal system. Linking informal and formal seed systems and looking for complementarity between them offers challenging opportunities for overcoming the weaknesses of both systems. This approach makes the book a practical guide for participatory improvement of the local seed system, including participatory variety selection and plant breeding.

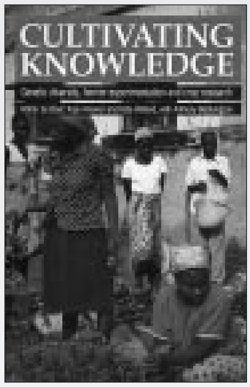
The book explains the informal and formal seed systems and the many technical and methodological issues in a very accessible, informative and extensive way and therefore deserves to become a standard work not only for those involved in the participatory development of small-scale agriculture but also for students and policy makers. (CR)

Technical and institutional issues in Participatory Plant Breeding - done from a perspective of farmer plant breeding
S McGuire, Manicad, C & Sperling, L. 1999. CGIAR Systemwide Programme on Particicipatory Research and Gender Analysis for Technology Development and Institutional Innovation (PRGA), Cali, Colombia. (Working Document No. 2). 88 p. (To request a copy contact prga@cgiar.org).
Gives a good overview of concepts, issues and farmer-led plant breeding. The last term covers a range of activities that have a strong basis towards drawing on farmers' capacities and initiatives to maintain and develop crop varieties. In contrast, in breeder-led approaches breeders take the initiative. The 11 cases described and analysed were all supported by NGOs or GOs in one way or other. Issues fundamental to PPB, such as local vs. broad adaptation, introgression and other forms of recombination, are briefly discussed. The publication has a number of well-structured sections, which certainly contribute to providing a good overview of the issues related to PPB. If it were only for the definitions and the reference list, this is a publication to have on hand. (Conny Almekinders)



Managing agrobiodiversity: farmers' changing perspectives and institutional responses in the Hindu Kush-Himalayan region *by T Partap and Sthapit B (eds). 1998. International Centre for Integrated Mountain Development (ICIMOD) & International Plant Genetic Resources Institute (IPGRI). ISBN 92 9115 841 0. 439 p. ICIMOD, PO Box 3226, Kathmandu, Nepal.*
Agriculture in the Hindu Kush-Himalayan region is in transition. Agrobiodiversity is adversely affected –although the exact extent is not known- by deteriorating economic and environmental conditions, especially habitat destruction, and by the adoption of new cash crops by farmers which replace the old ones. To fill the lack of information, ICIMOD and IPGRI have launched an initiative to document knowledge about agrobiodiversity in the region, both at species and agroecosystem level. Simultaneously, information was gathered and analysed about alternative strategies for the conservation and management of agrobiodiversity. (WB)

Technical and institutional issues in Participatory Plant Breeding – from the perspective of formal plant breeding. A global analysis of issues and current experiences *E Weltzien, Smith, M, Meitzner, M & Sperling, L 1999, CGIAR Systemwide Programme on Participatory Research and Gender Analysis for Technology Development and Institutional Innovation. (Working Document No. 3). Can be ordered from: prga@cgiar.org.*
This is a 'sister' paper to the McGuire, Manicad and Sperling publication and is a review of what has been done in PPB from the perspective of formal sector institutions such as national plant breeding programmes, CGIAR institutes, and extension services. It contains an inventory of 48 PPB cases from all over the world as well as detailed descriptions of a dozen illustrative cases, an analysis of key technical and institutional issues, and an assessment of the gaps in current knowledge in respect of PPB methods, organisation, and results.

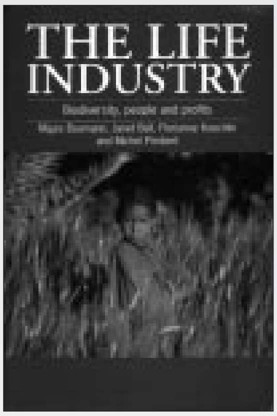


Cultivating knowledge: genetic diversity, farmer experimentation and crop research *W de Boef, Amanor K, Wellard K & Bebbington A. 1993. 206 p. ISBN 1_85339_204_9 (pbk). Centre for Genetic Resources (CGN), Wageningen, The Netherlands. Intermediate Technology Publications (ITP), 103-105 Southampton Row, London WC1B 4HH, UK.*
A collection of case studies that were originally presented at a seminar on Local Knowledge and Agricultural Research held in Zimbabwe in 1993. This seminar was the starting point of the Community Biodiversity Development and Conservation Programme (CBDC) described elsewhere in this issue. The papers address the relationship between farmers and researchers in local crop development from three perspectives. First, the socio-cultural environment in which local crop development occurs. Second, the biological and genetic rational underlying farmers resource use. Third, political frameworks in agricultural research and development. The case studies examine the importance of local knowl-

edge, documenting new approaches and methodologies that have been developed for building linkages between farmers and researchers. A number of cases deal with policy issues in relation to the expansion of agribusiness and its effect on small-scale farmers. This book has proven itself to be an important source for those interested in farmers' experimentation with regard to conservation and the development of local crops. (WB)

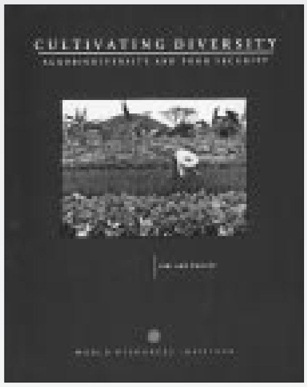
Farmers, gene banks and crop breeding: economic analysis of diversity in wheat, maize and rice
M Smale (ed). 1998. Kluwer Academic Publishers, Boston, 270 p. ISBN 0 7923 8370 2.
Series of papers based on presentations at a conference in Palo Alto, California 17-19 August 1997.

Biological and cultural diversity: the role of indigenous agricultural experimentation in development *by GD Prain, Fujisaka, S & Warren MD (eds). 1999. 218 p. ISBN 1 85339 443 2. GBP 16.95. (IT Studies in Indigenous Knowledge and Development series). Intermediate Technology Publications (ITP), 103-105 Southampton Row, London WC1B 4HH, UK.*
Farmers in developing countries do much to preserve diversity, even if it is not their first goal in farming. The role of indigenous knowledge and experimentation in agricultural development is now an accepted fact in development practitioners circles. With the advent of modern agriculture, much intricate traditional knowledge is disappearing. Likewise, biological diversity is seriously threatened although it has been high on policy and research agendas for a number of years now. This publication originated in the International Conference on Creativity and Innovation at the Grassroots, held at the Centre for Management in Agriculture, Indian Institute of Management, Ahmedabad, India, in 1997. Among the many papers presented there, this particular collection of papers emphasises the importance of indigenous agricultural experimentation in fostering biological diversity and cultural knowledge of that diversity. The fifteen papers describe a broad array of settings and experiences. They show the intimacy of the relationship between cultural and biological diversity. It is argued that farmer experimentation must not be regarded as a substitute for conventional on-farm research, but as a valuable approach to local knowledge creation through site-specific learning. Some authors believe there is little synergy to be had from linking formal research and farmers' experimentation more closely implying that farmers' participation has its limitations. (WB)



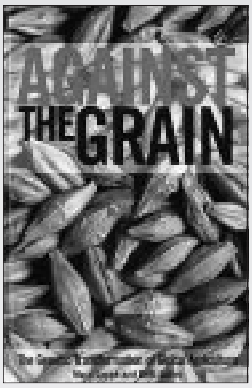
The life industry: biodiversity, people and profits *by M Baumann, Bell, J Koechlin F & Pimbert M 1996. World Wide Fund for Nature (WWF) & Swissaid. 206 p. ISBN 1 85339 341 X. Intermediate Technology Publications (ITP), 103-105 Southampton Row, London WC1B 4HH, UK.*
Contains papers presented at the international symposium 'Patents, Genes and Butterflies' jointly organised by Swissaid and WWF Switzerland in Berne, 1994. This book examines policy aspects of conservation of biodiversity. The commercialisation of biological resources poses a serious threat especially to smallholders in the South. A number of treaties have been concluded that protect their rights (see elsewhere in this issue) but their effect is questionable. The book examines the impact of current trends in legislation on the self-determination of peoples; biodiversity conservation; the relationship between science and society; the growth of the biotechnology industry; and development models in general in the North and the South. The challenge is to reconcile the conflicting perspectives of the various social actors. It has been written in three parts.
Part one examines 'the tools of control': uses made of genetic engineering, bioprospecting, biotechnology, and patenting issues. Part two looks at the thin line between bioprospecting and biopiracy. The contributing authors come from various organisations, including commercial ones. It is this openness that gives this book its weight. Part three looks at the future: 'Which way now?' Three main strategies are presented and compared: compensation or reward; intellectual property rights; or reclaiming the commons. The first two approaches imply working with the current system, adapting it to make it more equitable. The last strategy involves a rejection of existing mechanisms and advocating a much broader, stewardship-based approach to bioresource management requiring a more radical reversal of the existing approach to biodiversity management.
The problems associated with intellectual property rights mechanisms are enormous. Differences and implications are difficult to grasp and often fall in the juridical domain. This book succeeds in setting out these problems clearly. As such, it is extremely useful for those involved in policy aspects of biodiversity because it presents a wealth of facts and figures and many different opinions. (WB)

Culture, conservation and biodiversity; the social dimension of linking local development and conservation through protected areas *B Furze, De Lacy T & Birckhead J 1996. 269 p. ISBN 0 471 94902 7. GBP 55.00. John Wiley & Sons, Baffins Lane, Chichester, West Sussex PO19 1UD, UK.*
Even the most 'natural' habitats are in fact cultural habitats and created largely through human influence. Seeking to maintain these areas in their current state is a cultural response – a purposeful intervention by people to maintain something they value. Under the threat of an ever-increasing world population, dwindling natural resources and reduced maintenance budgets, modern management of protected areas must adapt, however threatening this may seem. The major issue is how to bring development and environmental protection together. Protected areas can no longer be development free zones, but must come to terms with ecologically sustainable development activities within and around them. The authors use case studies of local level participation in development activities within ecologically sensitive protected areas in different continents to illustrate that in sustainable environmental management environmental and economic goals can be integrated. For example, cultural attractions that show how people live among nature can be just as interesting for visitors as nature itself. The ultimate objective is to find the means to ensure that humans behave in ways that are consistent with conservation objectives. The challenge is to reach an agreement between the various stakeholders involved in defining the objectives for any particular area. Often, it will be a hard task to match all these interests and to choose the best option. The only chance of success is through participatory methods right from the start, through informed debate and a process of negotiation. Reading this book can provide many new insights in these problems. (WB)



Cultivating diversity: agrobiodiversity and food security
by LA Thrupp. 1998. 80 p. ISBN 1 56973 255 8. World Resources Institute, 1709 New York Avenue, NW, Washington, DC 20006, USA. http://www.wri.org/wri/
Gives a very complete picture of agrobiodiversity in a dense, but well laid out publication. After tracing the history and position of agricultural biodiversity, the author examines its benefits and importance and what its loss implies by using eloquent examples from the past. She argues that integration of agricultural development and biodiversity conservation is beneficial and even vital for food production, ecosystem health, and economically and ecologically sustainable growth. Apart from best practices, participatory approaches in ecosystem management, strategies to merge agriculture and habitat diversity, and *in situ* community-based conservation, the book describes in detail the policies and institutional

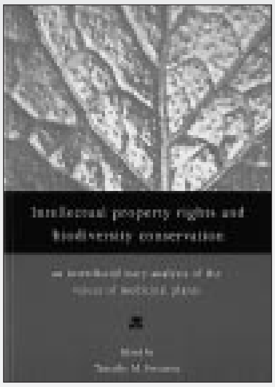
changes developed to confront the underlying causes of agrobiodiversity loss. The book is packed with information and especially useful for those interested in the policy aspects of biodiversity. Boxes, tables and figures help the reader to keep track. (WB)



Against the grain: the genetic transformation of global agriculture *M Lappé & Bailey, B 1998. ISBN 1 85383 576 5 GBP 15.99. Earthscan Publications, 120 Pentonville Road, London N1 9JN, UK.*
A valuable, politically oriented contribution to the debate about biotechnology, genetic engineering and transgenic crops and animals. The book examines new developments and their implications, looking in particular at developed countries. The achievements of commercial science have penetrated into our lives at an enormous speed and on an extensive scale, whether we like it or not. This publication helps to shape our viewpoint by thoroughly analysing the situation. Contains a glossary of terms, very useful in this difficult field.

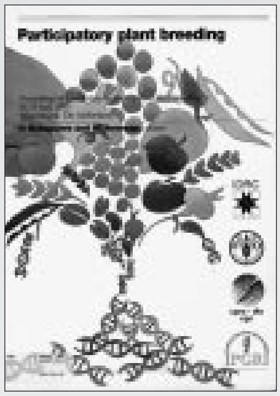
Seeds of choice: making the most of new varieties for small farmers *JR Witcombe, Virk DS & Farrington J (eds). 1998. 271 p. ISBN 1 85339 447 5. NLG 65 (approx. US$ 32.50). Krishak Bharati Cooperative (KRIBHCO), Indo-British Rainfed Project West, A8-10 Sector-1, Noida 201301, Gaziabad UP, India. Intermediate Technology Publications (ITP), 103-105 Southampton Row, London WC1B 4HH, UK.*
A compilation of experiences from the All-India Coordinated Crop Improvement Projects of the Indian Council of Agricultural Research from about 1990. These projects have provided experiences for a number of researchers who have catalysed advances in the field of participatory breeding. The experiences show the limitations of present practices of diffusing breeding varieties. Also, constraints of the regulatory framework are demonstrated, for example, the way variety release is organised in India. One conclusion is that the state-wise and centralised procedures for the testing and release of varieties do not adequately identify those that are useful for the diversity of farming conditions in India. A variety that is successfully released in one state may not be released in another with similar conditions. The book also presents cases in which farmer participation in setting goals, testing varieties and selection for location-specific adaptation has proven very successful. Suggestions for modifications to the system are formulated on the basis of these experiences. Variety release might benefit from information on similarity between agro-ecological conditions in different states. The upscaling of the results of Participatory Plant Breeding (PPB) and Participatory Variety Selection (PVS), and the role of seed diffusion and NGOs in this upscaling, is addressed in the last part of the book. The book contains an impressive amount of information on variety testing, diffusion and adoption in India and methodologies for acquiring this information. For people interested in PPB the experiences are very relevant, and for breeders in South Asia this book is a must. For others, the book provides insights in the multitude of factors that play a role in PVS as far as the formal sector is concerned. (Conny Almekinders)

Recent policy trends and developments related to the conservation, use and development of genetic resources *SH Bragdon & Downes DR. 1998. (Issues in Genetic Resources No. 7, June 1998). International Plant Genetic Resources Institute (IPGRI), Rome. 42 p. ISBN 92 9043 380 9. (Downloadable version: www.cgiar.org/ipgri/policy/ipr7.htm).*
A comprehensive, clearly written overview and analysis of the rapidly evolving policy and legislative issues related to the management and control of (plant) genetic resources. The publication first outlines the history and essence of the various treaties and fora: CBD, WTO and TRIPPS, International Undertaking, UPOV, WIPO and the UN Working Group on Indigenous Populations. It goes on to describe the issues that have emerged and that relate in different ways to the various treaties and fora: farmers' rights, interests of indigenous and local communities, benefit sharing, patenting and *sui generis* protection of plant genetic resources. This publication is an important support to policy makers in understanding different objectives, interests and key decision points. It is a valuable and readable introduction for anyone who wants to get a better understanding of the discussions surrounding the legislative aspects of conservation and the use of plant genetic resources. (Conny Almekinders)



Intellectual property rights and biodiversity conservation: an interdisciplinary analysis of the values of medicinal plants
TM Swanson (ed.). 1995. ISBN 0 521 47112 5, Cambridge University Press, The Edinburgh Building, Cambridge CB2 2RU, UK.
Argues the need for biodiversity conservation drawing on information on the use of medicinal plants in the pharmaceutical industry. Two papers deal with the issue of cultural diversity in relation to medicinal plants, an issue of obvious importance given the role of plants in traditional medicine. This book will be of relevance to a wide range of conservationists, from research students to policy makers.

The economics and ecology of biodiversity decline: the forces driving global change
TM Swanson (ed.). 1995. ISBN 0 521 48230 5 162 p. Cambridge University Press, The Edinburgh Building, Cambridge CB2 2RU, UK.
Contains papers originally presented at a symposium held at Cambridge in 1993. This publication looks at global change with regard to climate change and biodiversity decline.



Participatory plant breeding: proceedings of a workshop on participatory plant breeding, 26-29 July 1995, Wageningen, The Netherlands *P Eyzaguirre and Iwanaga M (eds). 1996. International Plant Genetic Resources Institute (IPGRI), Via delle Sette Chiese 142, 00145 Rome, Italy. 162 p. ISBN 92-9043-269-1.*
The workshop was convened to crystallise an approach that plant breeders, genetic resource conservationists and social scientists were demonstrating with increasing success. That approach is to place knowledge about genetic resources, as well as enhanced germplasm, directly at the disposal of farmers for them to use and develop according to their own needs and practices. Experiences indicated that in using this approach, biological and social scientists were learning a great deal about the useful diversity in target crops and farming systems. Farmers were also benefiting from access to greater diversity and from the partnerships they were forming with plant breeders. Three particular fields were discussed during this workshop: (1) how to institutionalise and legitimise this participatory approach, thereby creating a real partnership between breeders and farmers; (2) how to achieve actual participatory and decentralised breeding thereby conveying an actual crop management role to farmers; and (3) to learn more about the state of the art of participatory breeding in a global context. Suggestions were made during the workshop on ways to foster interest in implementing such approaches within the CGIAR and NARS. (WB)

Web sites

There are a large number of web sites dealing with aspects of biodiversity. We introduce a few of them here.

Rural Advancement Foundation International (RAFI)

http://www.rafi.org

RAFI is an international NGO with its headquarters in Winnipeg, Canada. RAFI is dedicated to the conservation and sustainable improvement of agricultural biodiversity and to the socially responsible development of technologies useful to rural societies. RAFI is concerned about the loss of genetic diversity - especially in agriculture - and about the impact of intellectual property on agriculture and world food security. RAFI is an important site to visit for those who are interested in policy aspects of biodiversity. RAFI produces a number of publications that are of interest to people around the world. **RAFI Communiqué**, RAFI's principal publication, provides original, in-depth research on biodiversity, new technologies, and intellectual property. It is published 4-6 times a year and is available on their web site. RAFI's **Occasional Papers** are irregular publications presenting independent RAFI research studies and information on RAFI work in progress. In addition, there is a list of other publications available. There is a section that gives visitors the opportunity to air their views about biodiversity and other concerns relating to policy. RAFI's recent activities include: the launching of a postcard campaign to fight the Basmati rice patent and the issuing of a very successful call for a "Seed Sovereignty" ban on Terminator patents. RAFI publishes a beautiful and very instructive map **Creators and Conservers of Diversity**, available at US$ 15 (folded) or US$ 35 (laminated). More information about this map can be found on the web site.

RAFI, PO Box 68016, RPO Osborne, Winnipeg MB R3L 2V9, Canada.
Tel.: (1) 204 453 5259, Fax: (1) 204 925 8034. Email: rafi@rafi.org.

International Institute for Environment and Development (IIED)

http://www.oneworld.org/iied/

IIED is an independent, non-profit making organisation that promotes sustainable patterns of world development through collaborative research, policy studies, consensus building and public information. With a focus on issues of equity and justice, and the rights and needs of poor people, the Institute works in an interdisciplinary way, addressing the connections between economic development, the environment and human needs. IIED's principal aim is to improve the management of natural resources so that communities and countries of the South can improve living standards without jeopardising their resource base. IIED believes there is a need for biodiversity to be "mainstreamed" into development policy and practice.

IIED works with partners around the world to address key constraints to the sustainable management of biodiversity resources, to explore the contribution of biodiversity to local livelihoods, and to encourage greater integration of biodiversity issues into mainstream policy-making. An example is IIED's Evaluating Eden initiative, which explores experience of community wildlife management. New research will explore mechanisms for local participation in the development of policies for access to biodiversity and benefit sharing. The biodiversity programme develops work on three thematic areas crucial to the successful implementation of the CBD:

- Integrating biodiversity into sectoral policy-making and practice
- Finance and incentives for sustainable biodiversity management
- Re-negotiating the roles, rights and responsibilities of stakeholders for sustainable biodiversity management

Other information on the Biodiversity Group to be found on the web site:

Genetic Resources Action International (GRAIN)

http://www.grain.org

GRAIN is an international NGO established in 1990, to help further a global movement of popular action against one of the most pervasive threats to world food and livelihood security: genetic erosion. The loss of biological diversity, particularly in the "gene rich" countries of the Third World, undermines sustainable agriculture as it destroys choices for the future and robs people of key resources. Genetic erosion is more than just the loss of genes. It is the loss of options for development.

GRAIN works to meet its aims through:

- Promoting popular control of agricultural biodiversity.
- Stopping the destruction of diversity by industrial agriculture.
- Support to agricultural biodiversity-based programmes.

GRAIN publishes a quarterly, ***Seedling***. Seedling aims to provide a platform for the exchange of news and analysis among people engaged in these issues. This publication is also accessible via the GRAIN site. ***Seedling*** is available free of charge to groups and individuals in the South, as well as to the NGO community at large, upon request. Institutions and others in industrialised countries are charged a subscription of US$35 per year, payable by cheque to GRAIN.

There are also other interesting publications on the GRAIN web site. **Global Trade and Biodiversity in Conflict** is a series of exposés produced jointly by the Gaia Foundation and GRAIN. The series examines critical points of conflict between the privatisation of biodiversity, which is being driven by corporate interests and the WTO and peoples' efforts to empower local communities in biological and cultural diversity management, particularly in developing countries. To our knowledge, 3 issues have been published so far: **TRIPs versus CBD** (No. 1, April 1998), **Ten reasons not to join UPOV** (No. 2, May 1998), **Intellectual Property Rights and biodiversity: the economic myths** (No. 3, October 1998).

GRAIN runs a list server on Intellectual Propert Rights (IPRs) accessible via the web site. Its purpose is to circulate information about recent developments in the field of intellectual property rights related to biodiversity & associated knowledge.

International Plant Genetic Resources Institute (IPGRI)

http://www.cgiar.org/ipgri/

The International Plant Genetic Resources Institute (IPGRI) is the world's largest organisation devoted solely to the study and promotion of agricultural biodiversity. IPGRI's mandate is to advance the conservation and use of plant genetic resources for the benefit of present and future generations. IPGRI's mission is to encourage, support and engage in activities to strengthen the conservation and use of plant genetic resources worldwide, with special emphasis on the needs of developing countries. IPGRI works in partnership with other organisations, undertakes research and training, and provides scientific and technical advice and information. IPGRI operates three major programmes:

- The Plant Genetic Resources Programme
- The International Network for the Improvement of Banana and Plantain (INIBAP)
- The CGIAR Genetic Resource Support Programme. This Programme comprises two main elements: support for the CGIAR in the area of genetic resources policy and the System-wide Genetic Resources Programme (SGRP).

The IPGRI site contains a large amount of downloadable information sources ranging from scientific publications to press releases and training materials. Geneflow, IPGRI's popular journal, is also available electronically on their site.

IPGRI, Via delle Sette Chiese 142, 00145 Rome, Italy. Tel: (39) 0651892, Fax: (39) 065750309, Email: ipgri@cgiar.org.

System-wide Genetic Resources Programme (SGRP)

http://www.sgrp.cgiar.org/

This programme was created in 1994 to focus the CGIAR's response to dynamic and rapidly evolving practical and policy challenges in the realm of biodiversity. The SGRP embraces all of the genetic resources activities of the Centres of the Consultative Group on International Agricultural Research (CGIAR). These include Centre programmes on livestock, forestry, aquatic and crop biodiversity. The SGRP provides the mechanism for the CGIAR to take an effective, united approach to the challenges posed by the Global Plan of Action for the Conservation and Sustainable Use of Plant Genetic Resources for Food and Agriculture, and other international strategies and plans governing the forestry, fisheries and animal sectors. Its goal is to strengthen the CGIAR's contribution to emerging global systems for genetic resources.

The CGIAR Centres hold more than half a million accessions of crop, forage and agroforestry species of importance for food and agriculture in trust for the world community. Information on the collections housed in 11 CGIAR genebanks is available through the

System-wide Information Network for Genetic Resources (SINGER). This network provides common access to information concerning the collections of genetic resources held by the CGIAR Centres. SINGER links the genetic resources databases of the CGIAR Centres and allows searches for information relating to the identity, origin, characteristics and distribution of the genetic resources in the individual Centre collections and access to further specific data on the collections. The categories of genetic resources data available in SINGER are described. The infrastructure of SINGER ensures that the central network database is kept current relative to the individual Centre databases.

The SGRP web site gives access to SINGER, gives a list of collaborative research activities and gives a list of (non-downloadable) publications.

Coordinator SGRP: Jane Toll (j.toll@cgiar.org), c/o International Plant Genetic Resources Institute (IPGRI), Via delle Sette Chiese, 142, 00145 Rome, Italy. Tel.: +39-06-518921, Fax: +39-06-5750309.

IRRI Genetic Resources Center (GRC)

http://www.cgiar.org/irri/GRC/home/home.html

The Genetic Resources Center (GRC) was established in 1989 to bring together two important components of IRRI's work – the long-term conservation of rice genetic resources and the international exchange and testing of elite germplasm. IRRI has conserved rice genetic resources since 1962. The IRRI genebank was opened in 1977, and became known as the International Rice Germplasm Center (IRGC) in 1983. A major renovation of the genebank facilities was carried out during 1993 and 1994, including expanded screenhouse facilities for the maintenance of the important wild species collection. In 1995, it was renamed the International Rice Genebank (IRG). The site holds descriptions of ongoing projects including Genotype x Environment Interactions. There is a long policy statement on Intellectual Property Rights (IPRs). There is a list of (non-downloadable) publications by the GCR. An interesting feature is that requests can be made for the germplasm of rice varieties.

Top 5

It is not easy making a Top 5. But after I had asked myself which books I would like to have on my own bookshelves it was not so difficult either. Top 5 books are those that do not age easily and ones that will be of value to me for a long time. Many of the publications I like to have at hand are books that do not directly relate to agrobiodiversity and cover fields that have become important to activities that support the use and maintenance of agrobiodiversity. I'm thinking of books like Participatory Learning and Action (J. Pretty, Guijt, I, Thompson J & Scoones, I, 1995), and Farming for the Future (C. Reijntjes, Haverkort B, & Waters-Bayer, A 1992).

This is not to say there are no publications available on agrobiodiversity, but most of the valuable ones have appeared in series or as journal articles. There are relatively few books with 'best practices', which is probably a reflection of the complexity of the role of biodiversity in sustainable agriculture. Here are a few exceptions.

Crops and man *(1992) JR Harlan, American Society of Agronomy, Madison, Wisconsin, USA. (Second ed.)*

I was already fascinated by seeds and evolution when I read parts of *Crops and Man* for the first time. Reading it really leaves one with the impression of the grandness and fascination of plant evolution and plant-man interaction. It describes plant evolution and how man has influenced it through gathering, cultivation and seed selection. The book is probably as valuable to read as Darwin's *Origin of Species* and is certainly much more enjoyable.

Agrobiodiversity: characterisation, utilisation and management *D Wood & Lenné JM (eds). (1999) CABI Publishing, Wallingford, 1999 ISBN 0 85199 337 0. USD 120.*

This book has a strong agroecological perspective and covers the entire field of agrobiodiversity. It collects together information that, until now, was scattered over many different articles in a wide range of journals. It is not a 'best practices' book, but it makes one understand interactions and functions connected with the use of agrobiodiversity. The book gives a good coverage of the different aspects of agrobiodiversity from an ecological perspective. It includes chapters on crop origin and traditional management; soil, pathogen and insect biodiversity but also on plant breeding, seed management systems, *in situ* conservation and the regulatory framework. The book is written in very readable language and is therefore accessible to non-specialists. The connection between the different chapters and cross-references are carefully edited and the references themselves allow the reader to go more deeply into the subject.

Seed savers' handbook *J Cherfas &. Fantan M&F Grover Books, Bristol, UK. ISBN 1 899233 1996, 01 6. 168 p.*

I like and use this publication a lot. In the first place because of the practical information it contains on how to reproduce seeds of vegetable varieties and herbs. I use this in my own garden. The book addresses cottage and hobby farmers in moderate climates, particularly in Britain. However, I think the book will also be very useful for grassroot organisations in developing countries. It presents simple and practical information in a clear way and it should be possible to use the information on seed production, selection, and harvesting in other conditions and with slightly different varieties. After all, many of the vegetables and herbs grown in Britain including beetroot, carrot, cabbages, tomato, mustards, peppers, potatoes are grown elsewhere in the world as well. With some understanding of the basics of seed production (also included in this book), of the similarities among crop relatives, and of differences between cross-, self- and vegetatively- propagated crops, the book is applicable to almost all crops. The drawings and layout make the book friendly and very accessible. A short overview of the significance of maintaining traditional varieties in relation to the discussions on biodiversity issues in agriculture is included as well.

Technology options and the gene struggle *T Berg, Björnstad A, Fowler C and Skröppa T 1991. A report to the Norwegian Research Council for Science and Humanities (NAVF), Oslo. (Development and Environment No. 8). (NORAGRIC Occasional Papers Series C).*

I really appreciated reading this book. It is already a few years old, but the history of how farmers have always utilised genes and how the formal system tried to get hold of genetic diversity is as valid today as when the book first appeared. The section on technical breeding and genetic diversity issues is very informative and written in such a way that non-breeders can also understand what is going on.

Genes in the field: on-farm conservation of crop diversity *SB Brush (ed.) Lewis Publishers, IPGRI and IDRC. ISBN 1 56670 405 7. 2000 US$29.95.*

Although it has not yet been published, I have included this book on my list. It provides an account of groundbreaking research, experiences and perspectives on the dynamics of genetic diversity *in situ*. Examples are drawn from the Fertile Crescent and Ethiopia, the work of Louette with maize in Mexico and Zimbabwe. The book promises an interesting introduction by Brush on *in situ* conservation. The second chapter by AHD Brown is on population biology and social science. It will probably be a newer and more 'agriculturally' focused elaboration of *'Plant genetic conservation; the in situ approach'* by Maxted, Ford-Lloyd and Hawkes (1997, Chapman & Hall). I suspect this book will be a reference work for many years to come. It is not only interesting for researchers but for all those fascinated by the subject.

Conny Almekinders

Biodiversity Conventions

The technological advances in genetic manipulation have increased our capacity to use genetic resources enormously. At the same time, however, human society, and its law, has difficulty in keeping up with the pace of development and coming to grips with it. New actors have also appeared on the scene. Until some ten years ago, the conservation and development of genetic resources was mainly the domain of public sector institutions and national seed enterprises. Recently, however, multinational companies have increased their involvement in research and the development of genetic resources dramatically. This was done in anticipation of the huge profits to be gained from manipulating genetic resources and has lead to conflicts of interest over the rights to these resources and the responsibilities these rights entail. The legal implications of the ownership and use of genetic resources are extremely complex in an increasingly globalised market. In this context, basic questions of ethics and equity arise. A large number of treaties and declarations in the past five years reflect the changed policy environment in which the management and control of genetic resources takes place. In an attempt to clarify these complex issues we have set out to describe a few of these conventions (Bragdon & Downes, 1998):

Convention on Biological Diversity

Signed in 1992, in the wake of the United Nations Conference on Environment and Development held in Rio de Janeiro. Currently, some 170 countries plus the European Union adhere to this convention. Objectives of the CBD are the conservation and sustainable use of biodiversity and benefit-sharing arising from its use. These objectives are to be achieved through a range of general, flexible obligations that emphasise the national sovereignty of each country over its own genetic resources. Although a framework of general principles has been set up to structure the international exchange of genetic resources, the implementation of objectives is difficult. Individual governments have their own priorities and there is no implementing agency.

International Undertaking on Plant Genetic Resources (IU)

A non-binding intergovernmental agreement to promote conservation, exchange and utilisation of plant genetic resources based on free access. Farmers' rights and *ex situ* germplasm collections are not addressed by the CBD, but they are by the IU. In 1998 about 110 countries were IU signatories. The body overseeing the IU is the FAO Commission on Genetic Resources for Food and Agriculture. The Commission is currently engaged in negotiations to revise the IU and bring it into harmony with the CBD. In 1994, the Consultative Group on International Agricultural Research (CGIAR) and FAO concluded an agreement under which the FAO would host, in trust, 'designated materials' in the 16 International Agricultural Research Centres that are part of the CGIAR. In this way, some 600,000 seed samples, possibly as much as 40% of the world's unique germplasm in storage would be conserved. The IARCs have pledged not to take out any form of intellectual property rights on this huge reservoir of genetic resources and they oblige those who use this material to do the same.

Agreement on Trade Related Aspects of Intellectual Property Rights (TRIPS)

This agreement, signed in 1994 under auspices of the World Trade Organisation (WTO), requires all parties to meet certain minimum standards for protecting Intellectual Property Rights (IPRs). Trade liberalisation is the underlying objective of the WTO, and TRIPS deals with effective legal mechanisms for enforcing patenting, a precondition considered necessary for free trade. TRIPS and other WTO agreements are binding on the 131 countries that are members of the WTO. Parties are required to protect plant varieties either by patents or by an 'effective *sui generis* system or by any combination of these mechanisms. A simplified explanation of *sui generis* legislation would be 'a form of intellectual property right designed to account for the unique nature of a new kind of innovation'. Plant Breeders' Rights as applied in many countries can be considered an example of such *sui generis* legislation for plant genetic resources. Implementing TRIPS has proved to be difficult. Promotion of IPRs, in the broad sense of the word, is the main concern of the World Intellectual Property Organisation (WIPO), a specialised agency of the UN. As WIPO had little to do with indigenous knowledge and genetic resources until recently, it has not been involved in the TRIPS Agreement.

International Union for the Protection of New Varieties of Plants (UPOV)

An intergovernmental organisation based in Geneva, Switzerland, with some 30 members mostly from the developed world. UPOV encourages the adoption of *sui generis* laws for protecting new plant varieties by creating its own distinct system outside the realm of patent law. UPOV aims to maximise plant breeding efforts and, as such, provides a model for securing protection for Plant Breeders' Rights for plant varieties. The 1991 revision of the UPOV Convention for the Protection of New Varieties of Plants gives members the option of allowing farmers to save seed for their own use, This is an important amendment.

National legislation

In response to the requirements of the treaties and agreements mentioned above, national legislative systems are emerging that define ownership of and access to genetic resources on a national level. Ideally, such legislation should also become proactive and in this way capable of, exerting an influence on the international debate. Bringing together questions of protection, use, ownership and benefit is a difficult process.

Indigenous & local communities including farmers and farm communities

A number of agreements address the rights of farmers and farmers' communities. In all previous agreements, negotiations have taken place either at governmental or institutional level, leaving indigenous communities to struggle to get their concerns introduced into negotiations. Examples of agreements that address the issue of farmers rights are: 'In Safe Hands: The Leipzig Commitment to Agricultural Biodiversity', an agreement of NGOs and People's Organisations, and the Vignola Declaration, in which IFOAM and IUCN played a major role, and which defined the role of organic agriculture in biodiversity and nature conservation.

In Safe Hands - Commitment to Agricultural Diversity

Representatives from 124 NGOs and peoples' organisations from nearly 40 northern and southern countries met in Leipzig, Germany, to discuss the future of agricultural diversity and how it could be conserved, used and developed in an sustainable way by farmers and indigenous communities. The conference preceded the 4th International Technical Conference of FAO on Plant Genetic Resources (4th ITC/PGR) held in 1996. The result of this NGO conference was the *Commitment to Agricultural Diversity*. The declaration summarises the views and demands of many NGOs and People's Organisations. A declaration 'In Safe Hands - Communities Safeguard Biodiversity for Food Security' was adopted by the conference.

In this way the conference committed itself to creating alternatives to intellectual property systems capable of safeguarding the rights of farming and indigenous communities. Long-term security of critical gene banks and their accessions would be ensured under the legal framework of the CBD to be implemented by the FAO. Removing agriculture, food security, and policies affecting life forms from the WTO is seen as a vital step in this process. The conference was strongly in favour of removing agriculture from the Uruguay Round agreement and to eliminating TRIPS.

The complete text of the Declaration can be obtained from: Forum Umwelt und Entwicklung, Am Michaelshof 8-10, D-53177 Bonn, Germany, forum.ue@t-online.de, fax +49 228 35 97 04.

Vignola Declaration and Action Plan

An Action Plan to join the organic and nature conservation movements was announced early in 1999 in Vignola, Italy. The Plan was the result of a three-day meeting convened by the World Conservation Union (IUCN), the International Federation for Organic Agriculture Movements (IFOAM), and AIAB, an Italian organic agriculture organisation that includes most of Italy's organic groups amongst its members. Seventy participants from 24 countries attended the meeting. The declaration embraces the objectives of the Convention on Biological Diversity (CBD) and concludes that organic agriculture is essential for biodiversity and nature conservation. In its Action Plan it recognises the link in expertise and experience between nature conservation and organic agriculture and provides guidelines for accelerating the growth of organic agriculture. These should be implemented at all levels of the private and public sector.

The full text of the Action plan can be obtained from: IFOAM (International Federation of Organic Agriculture Movements) Ökozentrum Imsbach, D – 66636 Tholey-Theley, Germany, Phone: +49 6853 5190; Fax: +49-6853-30110, E-Mail:IFOAM@T-Online.de http://www.ecoweb.dk/ifoam

Sustaining biodiversity in wetland paddy

In conventional wetland paddy cultivation all natural vegetation is removed during the establishment of the crop. This in turn eliminates all natural animals living within the ecosystem. In the humid tropics where wetland paddy is widely grown and the natural ecosystem can be very rich, this complete elimination of biodiversity could have serious repercussions. To reduce the loss of biodiversity, bunds can be left with vegetation. Our experience is that this is a profitable and ecologically sound approach.

G.K.Upawansa

Biodiversity eliminated

Paddy is normally grown in marshy land or converted to marshy condition by irrigation not because paddy needs inundated conditions but because it can tolerate such conditions. This ability has been used to control weeds by keeping paddy fields inundated. In Sri Lanka, a paddy field consists of several small units known as *liyaddas*. A *liyadda* is encircled by bunds and is perfectly leveled to retain water at a uniform depth. Bunds take 15-30% of the land area, depending on their slope.

Bunds are cleaned during preparatory tillage. The sods are thrown into the *liyaddas*, incorporated into the muddy soil and the colonies of ants that inhabit them are drowned: this reduces the ant population. After cleaning, the bunds are repaired, planed and plastered. The *liyaddas* are puddled and kept submerged for 3 to 4 days before sowing or transplanting takes place.

Between cleaning the bunds and three weeks after sowing or transplantation there are hardly any plants other than paddy in the *liyaddas*. During this period all animals, insects, worms and reptiles either leave the area or die of starvation. Hardly any birds are seen, as there is no food for them. Only insects and microbes that live on paddy plants thrive well. Though there is food for some predators and parasites, there are no plants to host them. In this condition pest attack and disease is unavoidable. The use of agrochemicals to combat pests and diseases degrades soil life. When high doses of chemical fertilisers are used, plants become even more vulnerable to pests and disease.

Weedy bund management

The '*new kekulam*' method of paddy cultivation, described in the ILEIA Newsletter Vol.13-3 provides an alternative to this disastrous conventional method of paddy cultivation. In this method weeds are kept on the bunds. Repairs are made with sods from the base of the bund. Vegetation gradually becomes more natural and after a few seasons the bunds become solid contours unlike those that receive regular seasonal cleaning and plastering. Bunds become so strong that they are able to resist damage by wild animals and floods.

Farmers experience many benefits from weedy bund management:

- Much of the natural vegetation is retained at least on the land covered by bunds.
- Together with the natural vegetation all forms of animals, insects and worms reappear. In this way the natural ecological balance is brought back. This is important for pest control in paddy cultivation. In Sri Lanka we have six dominant insect paddy pests. To keep their population down there are 27 predator insects. Both types of insects live in equilibrium on the bunds. In this way damage to the paddy crop and hence pest control can be kept to the minimum.
- Ants collect weed seeds from the fields during the harvest period when paddy fields are dry and store these seeds on the bunds. This reduces the amount of potential germinable weed seed in the next cultivation seasons. In the *kekulam* method weed control on the *liyadda* is further enhanced by mulching. Mulch of rice straw and loppings from the *Gliricidia* for example, are applied directly after sowing. Irrigation is applied once to soak the mulch. Thereafter, during the vegetative period, the soil is kept moist to ensure its aerobic condition and to enhance soil life. In this way the growth and yield of paddy is enhanced and weeds are controlled effectively without the use of herbicides and with minimal labour input. In addition there is a 50% saving on irrigation water.
- Also predators like birds, owls, reptiles and mongeese are attracted so that damage from crabs, rats and also to some extent from insect pests is reduced.
- Labour requirements are reduced by about eighteen to twenty man days per season and this brings down the cost of production.

The practice of weedy bund management is very simple, it saves labour and money and regenerates biodiversity.

Effect of mulching on rice root systems

More rice with good soil fertility management

photo: Ana Primavesi

Many people believe that lowland rice produces best when it receives water and minerals as if hydroponic techniques were being applied. But rice does not grow in water. It grows in soil and NPK fertiliser adds only 3 of 45 minerals needed for full development. Green Revolution technology has caused soil degradation and this is becoming increasingly visible. Sooner or later this will lead to stagnation or a decrease in yield. Degraded soils produce low quality food and this has a direct effect on human health. Far from rescuing populations from famine, the Green Revolution is becoming a threat to food security.

Ana M. Primavesi

However, soil productivity can be recovered. In southern Brazil we developed an alternative concept of irrigated rice production based on soil aeration, crop rotation, the restoration of organic matter and micro nutrients.

Soil reduction and growth

In submerged condition the amount of minerals available is reduced and oxygen ions are replaced by hydrogen ions. Some of these reduced minerals - SH2; NH3; CH4 and MnH2 - are extremely toxic to plants. A high pH in wet soil indicates that a very strong reduction in mineral compounds has taken place. In all low yielding soils, agronomists found dry soil was low in pH. In submerged conditions, however, it was high. In reduced conditions rice is poorly nourished and yield decreases.

Impoverishment of the soil can be halted if soil is drained just after the rice plants begin to emerge. Rice roots follow soil moisture and in doing so they penetrate below the reduced top layer. When plants begin to wilt, the field is irrigated and resubmerged for a short time. In this way rice grows in the oxidized rather than in the reduced soil layer. In sandy soils this is impossible because the reduction layer may extend to a depth of 70 to 80cm and roots rarely go so deep. The longer land is kept under monoculture the stronger the reduction effects will be.

Controlling soil reduction

Soil reduction can be controlled if soils are drained completely after rice has been harvested. In addition irrigated rice should be rotated with crops such as barley wheat soya beans and vegetables that do not need ponded irrigation. Organic fertilisers such as Sesbania, compost, farm yard manure and mulch should be applied to the 'dryland' crop. It not only fertilises the crop but it also saves water. Rice soils, it is believed, do not need liming because pH increases in submerged condition. However, lime does not only neutralise pH, it also nourishes the plant. Liming can raise rice yield considerably.

The reduction process in the soil layer can be brought under control if the soil layer is broken by roots and small soil organisms such as earthworms and insects. Soil must become porous again to allow minerals to oxidise and only the rice ears should be harvested because most of the straw should be incorporated into the top 8 cm of soil. In that way the straw will be able to contribute to oxidation, fertilisation and the improvement of soil structure. If ploughed in to a depth of 15 to 20 cm, straw will fix the nitrogen present in the soil and repress crop growth for a period of 3 months or more.

Nutrient deficiencies

If only NPK fertiliser is applied the soil will become depleted of the other nutrients rice extracts from the soil. Three to five years of NPK fertiliser is enough to exhaust the soil. Vegetables and fruits loose their biological value, taste and smell, and require at least 15 additives when canned to make them palatable. Cereals produced in these conditions are poor in proteins, fatty acids and higher sugars.

Soil nutrients have to be balanced. High doses of ammonia fertiliser lowers potash, calcium and magnesium absorption while high doses of nitrate fertiliser lowers the absorption of phosphorus and sulphur. This seriously disturbs the metabolism and productivity of the plant and reduces its resistance to parasites. Nutrient balances are best maintained with organic fertilisers. Very pronounced nutrient deficiencies, however, must be corrected chemically.

Rice frequently lacks copper, manganese and zinc. This is indicated by rice blast (*Piricularia oryzae*). Leaf analysis of blast-sick plants shows deficiencies in both manganese and copper. Spraying seeds with a solution of 1.0% of copper sulphate and 0.5% of manganese sulphate makes them able to absorb these nutrients. When 2.5 to 3 kg/ha of copper sulphate and 5 kg/ha of manganese sulphate are applied with the irrigation water no blast appears. When husks emerge without grain, copper is lacking. If varieties are used that are not well adapted to the soil some micro nutrients are nearly always required.

Herbicides

The two most problematic weeds in irrigated rice production are *Echinochloa* and red or bitter rice. Bitter rice can be more or less controlled by using pre-germinated seeds and seeding in slightly submerged soil. Crop rotation also helps. *Echinochloa* species can be combated with herbicides but this is not strictly necessary as *Echinochloa* plants are adapted to reduced soils. When reduction is strong, *Echinochloa* are more difficult to control. When this is the case, soil drainage and green manuring provide the best control.

When drainage, organic amendments, crop rotation and micronutrients are applied, yields can increase from 4,000 kg/ha to more than 11,000 kg/ha and the percentage of entire grains after husking can increase from 48% to 62%. Good soil fertility management is the basis for high yields and quality. ■

Revolution in rice intensification in Madagascar

Justin Rabenandrasana

A very productive System of Rice Intensification (SRI) is being developed in Madagascar. Over the past four years, some hundreds of farmers around Ranomafana have increased their irrigated rice yields from 2 tons/ha to up to 8 tons/ha and more. Instead of relying on the 'Green Revolution' recipe, which they could scarcely afford, they have followed innovative soil, plant, water and nutrient management practices. They continued to use their own seeds and compost and even though these intensified management practices costs them 40-65% more labour, they had a very high return.

The system was developed in 1983 by the late Fr. Henri de Laulaníe, who observed a strong increase in tillers and yield after an accidental early transplanting of rice. He went on to combine early transplanting with other practices that provided an optimal rice plant environment. In 1990, Fr. de Laulaníe helped to establish Association Tefy Saina (ATS), a NGO to promote and improve SRI in Madagascar.

photo: Association Tefy Saina

Close-up of well-developed rice plant

Basic principle: strong plants

With SRI, practices are followed that make a positive contribution to increasing production and, by combining them, production is increased still further. The success of SRI is based on the synergetic development of both the tillers and roots. With a more vigorous root growth, plants can become fuller and taller, and get better access to the nutrients and water they need to produce tillers and seeds. With more growth above ground to carry out photosynthesis, more energy is available for root growth and the stronger the plants, the more resistant they are to attacks by pests and diseases. In Madagascar, where soils are deficient in nutrients, a dense and extended root system gives plants many advantages.

Capture full potential for tillering

One of the "tricks" in SRI is that it capitalises on an in-built pattern of development in rice that had been identified many years ago by the Japanese researcher T. Katayama. He studied the patterns of growth and development in rice, wheat and barley and found that these plants put out tillers in a regular sequential pattern. In rice, each tiller produces another tiller two phyllochrons later (a phyllochron is an interval of plant growth, usually about 5 days but it can be longer or shorter depending on temperature and soil conditions). When soil and other conditions are favourable, the rice plant can go through as many as 12 phyllochrons (or more) before it moves from the vegetative growth phase to the reproductive phase (marked by panicle formation and flowering). The number of tillers can increase exponentially with as many as 84 or more forming on a single plant. The full potential for tillering can be captured by:

Early transplanting

Transplanting after the fourth phyllochron begins (after 12-18 days) sets back the growth momentum of rice plants so that their full potential for producing tillers, roots and grains is not achieved. If the 10th through the 12th phyllochrons of growth does not materialise because of late transplanting, 75% of a rice plants' potential tillering is lost. If transplantation is done poorly and the first two tillers get damaged, one cannot expect more than 16 tillers to grow. Transplantation should be carried out carefully and early, about 8 to 12 days after sowing when the seedlings have only two leaves. It should be done very soon after removing the seedlings from the seedbed and within 15 to 30 minutes after the tiny plants have been gently uprooted. The tiny roots should be placed horizontally in the soil so that the tip of the root can easily resume its downward growth. In this way the leaves of the seedlings will not become yellow and the plant will start to grow again within a few hours. The plants have time to adjust to their new environment before the first tiller starts to grow.

Planting one by one

If two, three or more plants are transplanted together in a clump, competition among their roots limits tillering to 5 per plant at the most. The close planting common in traditional rice cultivation could be considered anti-tillering rice cultivation. To enhance the development of roots and tillers and minimise competition between plants, seedlings are planted one by one in SRI.

Wide spacing

Farmers often believe they can boost their yields by planting rice more densely with 50 or more than a 100 plants per square meter. However, wider spacing encourages more rooting, more tillering, and more grain filling. In SRI, spacing follows a square pattern of between 25x25cm and 50x50cm. In this way a considerable amount of seed can be saved. In SRI, 5 to 8kg of seed is sufficient for one hectare of transplanted rice, whereas in Madagascar it is quite normal to use

100 to 200kg/ha. Rice plants grown under SRI management have between 50 and 80 tillers and routinely produce 150 to 200 grains or more per fertile tiller.

Capturing full root growth potential

For centuries rice farmers have kept their paddy fields inundated when their rice is growing. In this way they suppress weeds and reduce the amount of labour needed. This lead farmers and scientists to believe that rice plants benefit from being continuously flooded. However, rice is not an aquatic plant, and although it can survive with its roots submerged it does not really thrive. During its reproductive phase, when plants go through flowering, panicle initiation, grain filling and maturation, maintaining 1 to 2 cm. of water on rice fields has a beneficial effect. But during the preceding growth phase, rice plants grow better in unsaturated soil. The reasons are simple. When there is no standing water and there is air in the soil, the roots can acquire oxygen much more easily through the *aerenchyma* (air pockets) in the root cells. Lack of oxygen in the root zone leads to soil acidification that causes the destruction of *aerenchyma* and hampers nutrient up take, assimilation and plant growth. The nitrogen cycle in the soil is disturbed as well, and all kinds of toxicity will develop. Scientists from IRRI have identified the problems caused by anaerobic decomposition in continuously irrigated rice systems as one of the main causes of yield decline (Pingali et al, 1997). The full potential for root growth can be captured by:

Alternative wetting and drying of the field modifies the growing environment of rice: improves soil structure, gets more oxygen into the root zone, and enhances active soil life. As the soil dries air replaces water and when it rains or irrigation is applied this air is pushed downwards. Periodic water stress and the availability of oxygen facilitate root growth, and the volume of soil penetrated by the roots increases. In rice production, an effective drainage system to evacuate excessive rainfall and irrigation water from the field is as important as the irrigation system itself.

Minimum irrigation

At the beginning of tillering, there is still not much vegetative growth and the plant only requires a small amount of water. When the root system has been developed, 3 or 4 days of superficial dryness should not cause alarm even if some cracks develop in the field. During growth irrigation will only be needed if rainfall is inadequate and then should be applied in moderate amounts and at favourable times - preferably at night. In this way, irrigation requirements can be reduced by up to 50%.

Early and frequent weeding

Whatever the crop, early weeding is always important for a good return. In rice paddies, where traditional methods are used, hand weeding is usually done one and a half months after transplanting. This is far too late for two important reasons. Not only are weeds replacing half the expected harvest by this time, but farmers also loose the opportunity to bring oxygen into their soil. Aeration of soil by weeding may be even more important in rice cultivation than the removal of weeds. With SRI, simple mechanical push-weeders are used and these churn up the soil. In Ambatovaky, the community near Ranomafana where SRI has been adopted most enthusiastically, 75 farmers experimented with weeding during the 1997-98 season. The two farmers who did not do any weeding got almost 6 tons/ha; the 35 who did the recommended minimum of 1 or 2 weedings averaged between 7 and 7.5 tons/ha; while the 24 who did three weedings averaged 9 tons and the 15 who did four weedings averaged over 11 tons. This showed how early and frequent weeding is very important in enhancing the development of the root system and the entire rice plant. The extra labour needed for additional weeding more than pays for itself at harvest time.

Application of compost

SRI was first developed in the 1980s using chemical fertiliser. But after the price of fertiliser skyrocketed in the early 1990s, Fr. de Laulaníe began experimenting with compost. He used cattle manure where this was available, but mostly he used any sort of decomposed biomass, including rice straw. Cuttings from leguminous plants and shrubs proved particularly beneficial. He found that using organic sources of nutrients could help achieve levels of production that could not be obtained using conventional practices. In the north of Madagascar, a private company conducted trials to determine the best levels of chemical fertiliser for rice. It reported achieving average yields of 6.2 tons with modern methods and seeds. At the same time 27 farmers using SRI in the same area averaged 10.2 tons/ha.

It is still uncertain how and why these high yields are possible on such poor soils. Around Ranomafana, pH values are between 4.2 and 4.6 with extremely low levels of exchangeable bases [Ca, Mg and K] and phosphorus levels that average between 3-4 ppm, which is considered very deficient. Possibly this can be attributed to the large volume of soil penetrated by roots and the high activity of soil-life brought about by aerobic soil conditions and organic fertilisers.

Approach not package

In the past 10 years, SRI has been used with similar success in many places in Madagascar and under different production conditions (elevation, temperature, soil types). Currently, SRI is being promoted by several development programmes. The University of Antananarivo's *Ecole Superieure des Sciences Agronomiques* (ESSA) has supported field studies to evaluate and analyse the method. The Cornell International Institute for Food, Agriculture and Development (CIIFAD) has been working with ATS since 1994. Outside Madagascar interest in SRI is growing and SRI as a methodology is still being evaluated. ATS insists that it be treated as an approach, a strategy, even a philosophy, rather than a "package". It is the combination of practices that is important, more than any specific single method. These practices need to be tested and, if need be, adapted when introduced to new environments.

Even if such high increases in yields cannot be obtainable everywhere because of constraints such as water control, substantial gains in rice production should be possible by applying SRI insights and practices. By mobilising the experimental capacity of thousands of farmers to adapt the technology to different conditions, SRI could become one of the most beneficial innovations in agricultural practice this century.

MASIPAG - Farmer-Scientist partnership

MASIPAG is a farmer-led network of farmer organizations and local communities, representing more than 30,000 farmers in the Philippines who all believe in the sustainable use and management of biodiversity through people's control of genetic resources, including the associated knowledge.

Emmanuel Yap

In 1980, the glaring fact of rural poverty prompted NGOs (principally ACES Foundation) and a group of progressive scientists to initiate consultations among farmers in different parts of the Philippines. They discussed the impact of high yielding varietieson small farmers as well as other issues related to the rice industry. Starting at village level, these discussions were extended and coordinated throughout Luzon, Visayas and Mindanao and culminated in the BIGAS Conference in 1985.

In 1986, a farmer-NGO-scientist partnership was formed. A group of professors and researchers at the University of the Philippines, Los Baños, took the lead in establishing a "technical pool": the farmer-scientist partnership. In 1987, the Farmer-Scientist Partnership for Agricultural Development was formally registered and ready to embark on the MASIPAG programme - *Magsasaka at Siyentipiko Para sa Ikauunlad ng Agham Pang-Agrikultura*.

Quality and empowerment

MASIPAG tries to improve the quality of life and to empower resource-poor farmers by enabling them to regain control over strategic economic factors particularly seeds and the production process.
It also creates a legitimate space where farmers can meaningfully participate in policy formulation and decision making.

MASIPAG seeks an ecological balance on-farm by using local and renewable resources and promotes people's control over biodiversity to secure the sustainable use and management of genetic resources. MASIPAG also transfers the fundamental skills of breeding and farmers' research to farmers so they can share in the efforts of researchers' as they work to improve crops. It also creates a sense of patriotism among farmers by encouraging them to adopt cultivar diversity, in effect establishing a nationwide on-farm gene bank. In this way, farmers take an active role in conserving a national patrimony: the seeds.

Through its trial farm strategy, MASIPAG makes a diversity of crop cultivars available to farmers. From these they can select those best suited to local conditions and in doing so extend the range and selection of appropriate rice varieties available locally.

MASIPAG broadens the perspective and reinforces the knowledge and skill farmers need in order to develop their own farming system in the interests of better nutrition and more income. It also assists network members to formulate and advocate policy alternatives that will create an environment that will help promote MASIPAG.

Programme components

CIMME

Collection, Identification, Multiplication, Maintenance and Evaluation of lowland and upland rice cultivars and maize as well as the collection of vegetables, livestock, poultry, fruit/wood trees and rootcrops is an ongoing activity as MASIPAG works towards diversification. Collection is nation-wide in order to halt the rapid disappearance of biodiversity. After testing, the species and varieties collected are maintained in farmers' seed banks . This gives network members greater access to a wide range of choice both for production and breeding and helps stimulate the most appropriate cultural management practices.

Breeding programme

Crossing and selection of farmer-selected cultivars of rice and maize encourage and sustain farmers participation in the work of breeding, management, evaluation and selection of varieties. It also enables them to produce seeds according to their resources, priorities or needs breaking farmers dependence on seed companies.

Agroecosystems conversion

The approach that guides the sustained process of conversion from monocropping to diversified and integrated farming, and from chemical to organic farming both in lowland and upland rice systems.

Other activities focus on monitoring, evaluation, farmers training, institutional development and linkages, and the documentation and publication of farmer developed and adapted technologies.

Achievements

MASIPAG has made significant headway in research into and the development of rice seeds and sustainable production systems.

- A collection of 1196 traditional and improved rice cultivars 60 % of them grown in the MASIPAG network areas.
- 146 new rice crosses made between 1987 and 1997.
- There are 75 MASIPAG Trial Farms in 35 provinces throughout the Philippines. Varietal trials have been conducted at these sites for several years. MASIPAG also maintains three national back-up research farms in Nueva Ecija (lowland rice), Negros Occidental (upland rice and vegetables) and Cagayan de Oro (maize).
- Over a thousand farmers/NGO/GO representatives have been trained in the MASIPAG approach.
- Documentation of 50 indigenous knowledge systems (farmer-developed/ adapted technologies).
- At least 5000 farmers within the network are in various stages of converting their farms.
- Over a hundred orientation and technical training-workshops have been conducted involving more than 5000 farmers. Echo training and workshops have also been conducted by farmer-trainers themselves.

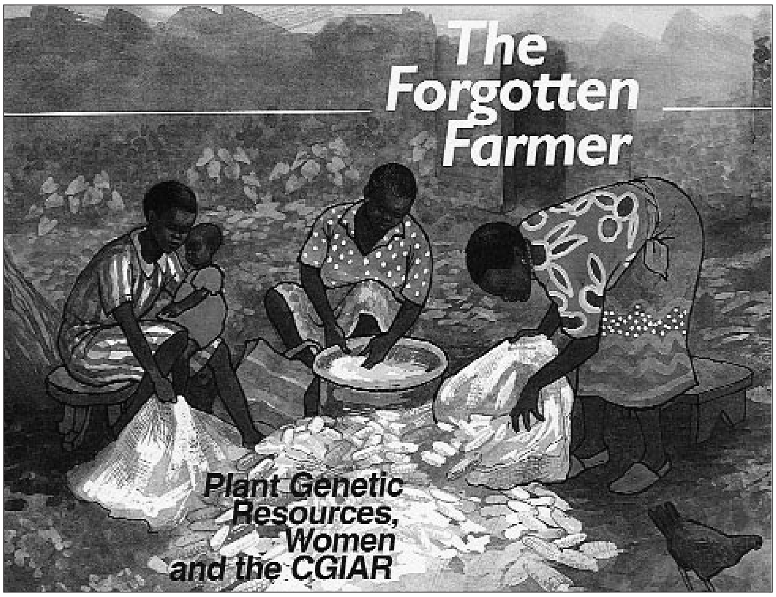
CGIAR: Towards gender sensitive research



"We have no idea what is being lost in genetic resources due to 'gender blindness'. Plant collectors miss a lot if they only talk to men"

Dr Susan Potts, CGIAR social scientist Ecuador

The mission statement of the Participatory Research and Gender Analysis (PRGA) Programme is to assess and develop *'methodologies and organisational innovations for gender-sensitive participatory research in plant breeding, crop and natural resource management"*.

The programme pursues a new kind of partnership between farmers and scientists. It aims to move farmer involvement "upstream" in the formal research process by involving farmers earlier in technology design and development. A related objective is to move scientists towards greater involvement in supporting, strengthening and complementing farmers' own research processes with specialised scientific input. This requires the attitudes and practices of agricultural researchers to change and that they become more supportive of farmer participation and gender analysis as a normal feature of research. This will benefit farmers as well as formal research. The benefits include quicker solutions to real problems, more efficient use of research resources, and better farmer-scientist relations.

Women play a vital role in the conservation and sustainable use of biological diversity and they need to participate at all levels of policy making and implementation for biological diversity conservation

Preamble, Convention on Biological Diversity

Poor women farmers are the main programme beneficiaries. Rural women form a growing proportion of the very poor, a trend known as the 'feminisation of poverty'. Household food security is deeply affected by women's access to income-generating technologies. Therefore, this new programme twins gender analysis with the development of participatory research methods. Gender analysis goes to the heart of participatory research by addressing a key issue: who exactly should participate? In helping to answer that question, gender analysis can contribute to making agricultural research more efficient.

The programme assesses the current practices of including different types of users at different stages of Participatory Plant Breeding (PPB) and Natural Resource Management (NRM) and is organised in a PPB, a NRM and a Gender Analysis work group. Each work group involves practitioners from international agricultural research centres, national agricultural research institutes, NGOs and government research organisations. They also include indigenous farmer research systems interested in implementing studies consistent with the PRGA work plan. Working group members interact through email conferencing, they meet face to face in periodic research workshops, or site visits, and members contribute to the programme's bi-annual international seminars.

PRGA uses competitive small grants to stimulate innovation in methodology development, institutional design and capacity building. Plant Breeding Small Grants support new studies which address knowledge gaps in participatory plant breeding. The NRM Small Grants support activities that seek to involve rural women in research and development for natural resource management including the appointment of three regional support persons to work with the action research, training and workshop components of these workshops.

PRGA programme partners in the international agricultural research centres, NGOs, national research institutes, universities and government research organisations have the capacity to contribute to the development of methodology. CIAT hosts the programme and CIMMYT, ICARDA and IRRI are cosponsors. The programme's planning group consists of eight elected members and one elected member from each of the three working groups; four representatives elected from each of the four stakeholder groups and one member from the Convening Centre.

For more information on PRGA: http://www.prgaprogram.org/prga or <prga@cgiar.org>.

Carchi, Ecuador's northern-most province is distinct in its culture, terrain and agricultural practices and was never under Inca influence. The countryside has relatively little Quichua, or indigenous, influence. Unlike the other sierran provinces which are dominated by high snow-capped volcanoes, Carchi has

Larry M. Frolich, Stephen Sherwood, Arlo Hemphill, and Esmeralda Guevara

well-defined western and eastern cordilleras bordering a rich agricultural central valley. Both cordilleras are topped by an extensive alpine plain, or *'paramo'*, with grasslands. On the western side this region forms one of the country's largest national

"Eco-Papas": through potato conservation towards agroecology

natural areas, "the El Angel Ecological Reserve." On the eastern side, the inter-Andean slope boasts an extensive 40,000 hectare stretch of forest that is perhaps the best example of relatively pristine inter-Andean vegetation encountered in the northern Andes. The forest lies on steep slopes between cultivated agricultural land and the alpine *paramo*.

Small pre-Colombian populations probably used the *paramo* for trade routes and undertook limited small-scale agriculture in the flat inter-Andean valley floor. Even today, the population of Carchi is small for a sierran province and pressure to cut forest for fuelwood is relatively limited. Colonial population centres formed with large haciendas in the valley floor around the cities of San Gabriel and Tulcan. But colonisation of the valley sides, in rural towns where small-scale farms predominate, only started in the last century.

Initially, rural colonisers -mostly hacienda workers- cleared small patches of land and planted a mix of potatoes and other Andean tubers in a trade and subsistence economy, the classic *"huasipungo"* system. Transport and communication infrastructure was primitive or non-existent and industrialised agricultural techniques were unknown. As highways improved and secondary roads were built, chemical fertiliser and pesticide businesses were among the first to capitalise on the accessibility of a new market.

Loss of productivity and biodiversity

Hard statistics do not exist, but according to older farmers in the region, chemical fertilisers initially increased potato production yields dramatically, often reaching an impressive 40-60 tons/ha. With time yields dropped, apparently due to loss of resistance to insect pests and fungal diseases. This triggered the large-scale application of chemical pesticides. Today, average yields are only 21.3 tons/ha (Crissman et al 1998) despite the continued, heavy, application of chemical fertilisers and pesticides. The use of pesticides has caused severe cases of poisoning among the farm population. The effects of residuals in food products among consumers are relatively unknown but probably important (Cole et al 1995)

The chemically intensive planting system now predominant in the entire province has led to soil fertility loss. Valley floor land, once among the richest in soil quality and some of the first land to be used for the intensive monocropping of potatoes for cash, is now almost exclusively dedicated to pasture and milk cow grazing. The shallow lower valley slopes, with a 20-30 year history of chemically intensive potato production, require ever-longer fallow period between potato plantings. Even so, yields continue to decline. Highest yields and shortest fallow time are now found in steep newly cleared forestlands high on the valley slope. Thus, although pressure to cut forest for fuelwood is relatively low, farmers continue to move up the valley slope to clear land for better potato production (Frolich et al 1998; Frolich & Guevara, in press).

Carchi is the only sierran province that does not have water shortages, probably due to the presence of the large tract of inter-Andean cloud forest. In addition, the forest is an important source of organic matter. However, if forest clearing and soil damage by use of chemicals continue, the system could easily degrade to the rocky-sandy land seen further south where forest land is completely absent. It would seem then, that in the long run, chemically intensive, potato monocropping is unsustainable.

Trying to overcome the loss of productivity, Ecuadorian national agricultural services have introduced a series of genetically improved potato varieties. These now account for over 90% of total production and usually show an initial increase in production and resistance to pests and diseases, especially late blight. However, over time production declines and resistance is lost. New varieties are generally crossed with genetic stock from the old varieties, thus limiting actual diversity. Farmers still cultivate two or three landraces or *"chaucha"* varieties. These are generally planted in small quantities for home consumption or sale on the local market. Although memories remain of tens or hundreds of varieties that were cultivated only one generation ago, these landraces are no longer found in the area.

The Eco-Papas project

The "Eco-Papas" project has a broad approach: reintroducing biological and ecological farming techniques that decrease the importance of chemical inputs and moving towards a more stable and sustainable agroecosystem. Unfortunately, this is not a simple relearning or reintroducing forgotten planting systems. The reality is that the introduction of semi-industrialised agriculture has completely changed the landscape and its elements requiring a reinvention and adaptation to existing conditions.

There are three lines of action within the Eco-Papas project: soil maintenance and improvement; integrated pest and disease management and re-introduction of crop biodiversity.

The Eco-Papas project's guiding principle is the notion that healthy, living soils will provide a stable base from which other adjustments and improvements to the production system can be made and managed. Perhaps the most significant soil damage in Carchi is a virtual dying-off of soil micro- and macro-organisms after repeated potato plantings. The cause of soil "death" is uncertain but more than likely it is related to a nutrient imbalance brought on by the use, and often over-use, of cheap, chemical fertilisers and, possibly, by pesticide fumigations.

Integrated farming techniques

The Eco-Papas project is investigating this loss of soil biodiversity with test plots distinguishing between the effects of fertiliser and pesticide application. In addition, the project promotes integrated farming techniques, such as the use of green manures especially in badly damaged or "dead" soils; inter-cropping and crop rotation, especially with legumes; incorporation of organic matter and animal fertilisers; and limited tillage and cover crops. With a healthy, biologically managed soil base, it may be possible to break the extreme dependence on external, imported chemical inputs. Fertiliser and pesticide use will continue to play some role, but the ideal is a well-managed farm with strong biological fundamentals and minimum use of chemical inputs.

Together with INIAP, Eco-Papas has conducted experiments on the reduction of chemical inputs. Initial results on a one-hectare test plot indicate average yields of about 10 tons/ha, but at less than half the normal production costs, using resistant varieties, integrated pest management techniques, and good soil management. The experimental site had been fallow for six years before potatoes were planted. The use of animal manure and compost maintained soil micro-organisms and only required minimal applications of chemical fertiliser. After harvesting, the usual diversity of soil microflora and -fauna was apparent.

photo: Larry Frolich

As with the integrated approach to soil management, the Eco-Papas project promotes the use of a range of preventive, biological technologies for treating pest and disease problems (Barrera et al 1998). Trapping techniques are used to reduce adult populations of noxious insects. In addition, the potential for endopathogenic control is being studied. Finally, intercropping and planting hedgerows with naturally anti-insecticidal species have shown positive results. Late blight is a particularly pernicious problem apparently best tackled by looking for resistant varieties.

Re-introducing biodiversity

Perhaps the most important component of the Eco-Papas project has been on-farm conservation and the re-introduction of potato biodiversity. Landraces and genetically improved local varieties may hold the key for natural pest resistance. A strong economic base, predictable over a long term, with many different products to offer is a precondition. An important corollary to the production of a more ecologically produced, healthy potato is the opening up of local market demand for such a potato. Consciousness raising, via farmer field training, schools and public awareness campaigns, is important for the adoption of a healthier potato growing system. A small local agricultural fair organised in 1999, for example, stimulated interest in growing traditional and low-chemical-input potatoes for local on local markets.

In order to re-introduce genetic diversity to the overall potato cultivation system the first step is to develop on-farm, living seed banks of genetically improved potato varieties as well as traditional landraces. This genetic diversity bank needs to be widespread, repeated, adapted to local conditions and managed by local farmers, with help from extensionists. At this moment, some 40 varieties are being cultivated and conserved on two local farms. Ongoing analysis of pest resistance in the landraces that are maintained in the "in vivo" collection is being carried out by farmers in order to assess which varieties can be used in local breeding and genetic improvement programmes.

From an initial collection of 70 cultivars and landraces collected in Ecuador and Colombia, 40 varieties have been found that produce good viable seed and a d esirable tubercle. Of these, 30 are landraces and 10 are genetically improved. Mixed production plots for these varieties employ integrated pest management and other techniques, such as selective thinning of possibly diseased plants, in order to produce high quality seed. Using the harvest from current plots, it should be possible to produce half a ton of seed for each variety within one year. So far, seed production has been entirely managed with local farmers who dedicate small plots to the production of seed in exchange for half the harvest.

Widespread interest

Perhaps the most positive early result of the Eco-Papas project has been the widespread interest and involvement of local farmers. Farmers from the local agricultural cooperative are involved in managing the test plot and in organic seed production. Together with INIAP, these initiatives are now spread to other towns and communities. Several farmers have planted their own gardens with traditional varieties, without the intervention of the project. The next step for the project is to establish local management of the potato variety bank with farmer field courses in the use of new varieties under low-chemical-input regimes.

Recent initiatives

Biodiversity has been dealt with from many different angles in recent projects. Three programmes - **the Community Biodiversity Development and Conservation** (CBDC), **the Centre for Biodiversity Utilisation and Development** (CBUD) programme, and **Biodiversity Research for Development** (BRD) programme in Mindanao, Philippines reflects this diversity of approaches and objectives.

1. Community Biodiversity Development and Conservation Programme

The CBDC programme involves some 15 countries and is implemented through a series of projects that focus on farmers' livelihood and Plant Genetic Resources (PGR). Apart from the project's immediate benefit to farmers it is also an experiment in cooperation between partners working in different sectors: research and development; North and South; formal and informal; and global and local.

The programme has been designed to produce research tools that can be used to study, validate and strengthen farmers' PGR systems. In addition, the programme aims to develop a framework to enable formal and informal institutions to cooperate more effectively in providing support to community PGR systems. One of the programmes basic principals was that local communities must retain control and complete freedom to decide on the use of their genetic resources and the knowledge associated with them. Projects have been carried out in the Philippines, Malaysia, Vietnam, Thailand, Sierra Leone, Kenya, Burkina Faso, Zimbabwe, Chile, Peru, Colombia and Brazil. An international policy and technical programme coordinated policy and technical support to the projects.

Most projects began with an assessment of the community PGR system, an inventory of present diversity and an estimation of the extent of genetic erosion. Using this information, activities were designed to support community systems. Through community variety trials, traditional varieties were re-introduced into local communities in project areas. At the same time, modern cultivars from research institutions were introduced. There was considerable interaction with other projects: the methodological elements of Participatory Variety Selection (PVS) and Participatory Plant Breeding (PPB) were integrated in Farmer Field School modules and some projects took up the concept of seed fairs.

Four types of associations seem to be emerging among partner organisations involved in the CBDC programme:

- Cooperation between NGOs and formal research institutions. The combination of informal and formal organisations ensures that the perspective of those who regard PGR as a power relations issue is broadly carried. At the same time, collaboration between scientific institutions ensures that organisations concerned with sociopolitical and development issues can be supported by research data and results. Such cooperation makes it possible to exert influence on formal research agendas and ensures that community perspectives and priorities are included.
- Cooperation between Northern and Southern organisations, both NGOs and public (government) research institutions. Partners in the programme represent a wide range of perspectives and this institutional diversity stimulates debate within the programme.
- Cooperation between NGOs working at local grassroots level and those working at national and international policy levels. Local organisation's skills and traditions are based on concrete partnerships with local communities. They confront issues that are specific and practical. In this way the activities of NGOs at the grassroots level are monitored and validated. Organisations that work at policy level are inevitably dis-

tanced from the reality of farmer communities. Local community concerns and interests need to be raised at policy level and the CBDC programme tries to combine all these levels into a single programme.
- Combining various disciplines. Social issues and participatory approaches that focus on power relations and address issues such as access to and control over PGR, are combined with natural science research on gene flow and the conservation of genetic combinations in crops.

The CBDC programme can be seen as an experiment in validating and strengthening farmers' PGR management. Its first aim is to address the concerns of local farmers and support farmers in their management of PGR by, for example, creating a farmer's field manual on PPB and models for Material Transfer Agreements for farmer germplasm exchange. These activities contribute directly to re-strengthening farmers' PGR management and broadening the genetic base of crops. If other farming communities adopt these programme approaches it will augment the programme's impact in other areas. Programme outputs are also expected to have an impact on policy formulation and institutional reforms. CBDC's second aim is to ensure that scientific publications and policy recommendations reach the scientific community and policy makers. The objectives of the CBDC programme are complex and organisations that decide to embark on this experiment open themselves to criticism. However, the collaborative learning process of the partners in the programme is unique and provides an excellent basis for further collaboration.

At present the programme partners are preparing a second phase. Building on the lessons of the first phase of the programme six so-called T(thematic) lines were planned: PVS/PPB, seed supply systems, Non-Domesticated and Semi-Domesticated Biodiversity (NDSDB), gender, mainstreaming, and policy. This thematic approach is meant to facilitate the global integration of country projects and topics and will reflect the future focus of the programme.

2. Centre for Biodiversity Utilisation and Development

The Centre for Biodiversity Utilisation and Development (CBUD) in southern Ghana was established in 1999 in an effort to preserve and develop forest resources in the south of the country through as series of projects with a clear market focus. The CBUD acts as an impartial intermediary between a range of very diverse stakeholders.

In the forest belt of West and Central Africa the forest features in all aspects of life. It plays a role in history, religion, medicine, art and language. In many communities, small forest areas have been protected as sacred groves and are sites of *in situ* conservation. In the South of Ghana, the predominant farming system is changing from shifting to permanent cultivation. This shift has serious implications for the practice of hunting and gathering wild forest products and rural people's knowledge of these resources. As areas under shifting cultivation shrink, resources become depleted and the threat of genetic erosion increases. To counter this process, a type of resource management has been proposed that increases the productivity of '-wild resources' and prevents overexploitation. This management can include some cultivation and 'domestication', as well as the development of products that add extra value to resources.

CBUD recognises that programmes to conserve biological diversity often ignore the potential for utilising and developing the products of biological resources. Farmers, foresters, rural and urban households, crop and animal scientists, marketing and processing specialists, development workers and conservationists, extension staff, and policy makers are amongst the many stakeholders involved in the process of utilising and developing forest biological resources. The CBUD functions as a stakeholder platform where actors meet and share their interests. CBUD aims to link conservation and development through a series of projects to develop different products. The project-wise organisation enables CBUD to build changing coalitions of partners.

The CBUD approach includes the following steps:
- identifying potential products and their related markets;
- identifying stakeholders;
- establishing a platform for product development and discussion;
- defining common objectives;
- defining the role of different stakeholders;
- designing appropriate property right systems for the products and resources;
- developing for production, processing and marketing chains;
- monitoring of harvesting and use of natural populations

The CBUD aims to act as facilitator and provides funds for financially viable options. Financial resources for such projects are drawn from the CBUD Trust funds. CBUD is currently being financed by the Netherlands, but is expected to generate its own funds.

3. Biodiversity Research for Development Programme

The Biodiversity Research for Development Programme (BRD), Mindanao, Philippines aims to develop a framework in which biodiversity at eco-system level in highly complex and threatened environments can be better understood. The programme, still in its initial stage, intends to undertake and promote collaborative, participatory and interdisciplinary research that will enable the sustainable use of biological resources, and effective decision-making on biodiversity conservation, to improve livelihood and cultural opportunities.

BRD involves Philippine and Dutch researchers and is committed to collaborative, participatory and interdisciplinary research that will support the sustainable use of biological resources, effective decision-making on biodiversity conservation, and improve livelihood and cultural opportunities. It is hoped that the results of the research programme will be used to influence policy on the sustainable use of biodiversity resources and in educational and development programmes.
The programme is the product of a series of studies, workshops and other activities between stakeholders and researchers.
A National Biodiversity Research Agenda has been developed by a multi-stakeholder group of researchers, government and non-government organisations and this provides the programme with direction and general content.

BRD began by identifying a more specific research site in the Mount Malindang area of Mindanao and by defining research priorities and the role of various project partners. Workshops to define the programme further were followed by a period of research, training and planning.

Three teams were assigned to upland, lowland and coastal ecosystems to conduct further problem analysis. A stakeholder analysis team that included members of the eco-system teams was also formed. All teams used Participatory Rural Appraisal (PRA) methods to get a good description of the research site and post-PRA workshops and a final workshop were held to define the programme's goals and strategies. The research programme will be implemented and tested in the coming years in the Mount Malindang area and will provide a framework, strategies and methods for similar programmes in other valuable but threatened concentrations of biodiversity elsewhere in the Philippines.

Participatory plant breeding for on-farm conservation

Landraces are varieties developed by farmers over many generations of selection without the intervention of formal plant breeding. Numerous landraces provide food security to many people in developing countries and also act as a primary source of breeding material for modern varieties. The use of landraces contributes to stable food production and income,

B.R Sthapit and D. Jarvis

especially in marginal environments where the impact of modern varieties is limited. Therefore, the Convention on Biological Diversity (CBD) has recognised the continued maintenance of traditional varieties *in situ* as an essential component of sustainable agricultural development.

In 1995, the International Plant Genetic Resources Institute (IPGRI) together with partners in nine countries, began to explore the potential of on-farm conservation in a global project. *In situ* (on-farm) conservation is the maintenance of species populations in their natural habitats either as uncultivated plant communities or in farmers' fields as a part of existing agro-ecosystems (Jarvis et al 1997). The project intends to develop insights into how on-farm conservation can best be carried out. This includes an analysis of the ways in which sustainable partnerships between the formal and informal sectors can be developed.

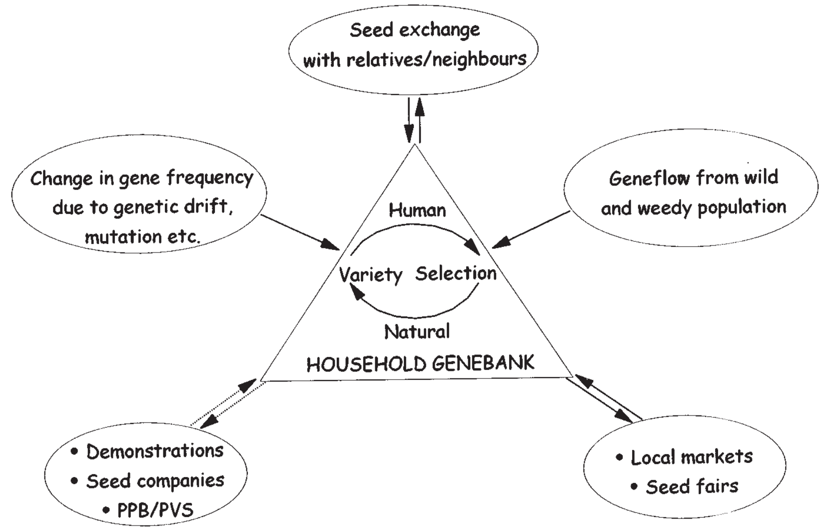

Figure 1 Informal seed supply systems in informal farming systems

Understanding

On-farm conservation is a process (Figure 1) which generates diversity. It encompasses four distinct steps:

- gene flow from wild to cultivated crops or seed flow through exchange of seeds;
- human selection of varieties;
- natural selection of varieties adapted to local conditions;
- seed storage methods for post-harvest assessment, and seed selection for next season's planting.

Traditional seed supply systems are important sources of diversity. Most farmers obtain the seeds of new varieties from informal seed sources generally within their own community. There are examples of widely diffused new varieties that were never officially released. This indicates the importance of farmer-to-farmer seed exchange mechanisms. Migrants, marriage outside the community, and outside job opportunities play an important role in seed exchange, especially over long distances between areas isolated by geographical or cultural barriers. Seed exchange, the introduction of new diversity from informal systems and seed fairs enhance the gene flow in villages and meet farmers' immediate needs (Figure 1).

Gene flow through seed exchange between the formal/informal sectors and through local seed merchants results in a dynamic seed supply system. The number of landraces, farmers' varieties and exotic varieties grown in a given locality, their genetic differences, and the area they occupy over time are important factors for sustainable agriculture. Yield stability is an important objective for farmers and an indicator of sustainable agricultural development. Yield stability is associated with genetic diversity, which acts as a buffer against biotic stresses. Participatory plant breeding (PPB) creates new diversity and provides an opportunity for transferring new breeding skills and knowledge thus strengthening on-farm conservation (Box 1).

Table 1. Role of farmer and breeder during PPB process

Fundamental steps	Nature of participation	Farmer	Breeder
Goal setting	Consultative	• Opinions and views considered	• Identify farmers using Farmer Network Analysis
Generating new diversity			• Key role
Selection	Collaborative	• Site selection for abiotic stress • Rejection of bulk population • Selection within and between population • Post-harvest selection • Trade off multi-traits vs. yield	• Screening incoming germ plasm • Screening for biotic stresses • Selection - early generations • Training - heritability
Variety release and distribution	Collaborative or collegiate	• Informal seed supply system	• Monitoring of spread • Prepare proposal for release

Threats

Farmers will continue maintaining landraces as long as they see benefits, but they may choose to replace them with modern varieties for the following reasons:

- poor yields of local landraces;
- lack of market for local varieties;
- disease and pest susceptibility;
- poor economic returns;

- unwanted traits such as taste;
- access to seeds of modern varieties, input and credit facilities and technical support.

We need to know why farmers grow landraces and where as well as how they maintain and use them. Figure 1 shows that farmers look for new seeds when the varieties they have do not perform well. For a farmer to maintain and use landraces, crop genetic resources must:

- be competitive with other options available to the farmer; and
- provide security and possible increase the farmer's income.

Participatory Plant Breeding (PPB)

When landraces and modern varieties are crossed and when there is a maximum selection by farmers in the target conditions at an early stage of the selection, then the breeding strategy closely resembles *in situ* genetic conservation of landraces (Witcombe et al 1996). A PPB approach using landraces as the source of genetic material for crop improvement symbolises a balance between the two goals of maintaining genetic diversity *in situ* and improving varieties according to the needs of farmers.

Table 1 illustrates four fundamental steps and roles of farmers and breeders in the PPB process. This process has been documented as an output of farmer-researcher interaction in Nepal and is being tested in the project area. The level of participation may vary with the expertise, skills and capacity of participating members. PPB needs to be used when Participatory Variety Selection (PVS) has failed to identify any suitable cultivar or if a new problem is identified in a cultivar. PVS and PPB cycles are inter-linked but still have their own distinct processes

Strengthening on-farm conservation

Does PPB create and conserve genetic diversity *in situ*? Does PPB enhance benefits to farmers? What is the incentive for farmers to collaborate with PPB and on-farm conservation activities? Will adding value to a particular landrace through PPB result in the spread of that variety at the expense of other varieties in the system? Six countries in the IPGRI's global project will address some of these technical questions.

Currently, on-farm conservation is under the domain of the farming community. Strengthening the capacity of farmers and local organisations will enhance on-farm conservation of crop genetic resources, thereby improving farmers' livelihoods. On-farm conservation can be strengthened through activities in the farming community, such as diversity fairs, community seed banks and PPB at grassroots (Figure 2). However, it requires more collaboration between the formal sector of plant genetic resources institutions and the informal sectors including community-based organisations (CBOs). Farmers' ability and knowledge of breeding have been generally undervalued if not ignored by plant breeders. Farmers, like plant breeders, have their own selection criteria to evaluate new cultivars.

Community participation in PPB in villages has empowered farmers. Farmers participating in PPB benefit from early access to new materials, gain recognition from the community and learn new selection techniques. In Nepal, farmers involved in PPB have successfully sold seeds of the new varieties at a higher price than the local landraces (Sthapit et al., 1996). The products of PPB remain under the control of the informal seed system. While a direct recompense to farmers is not intended in the framework of the project, it is important that the global and national investment in farmers' welfare is seen as indirect compensation in recognition of their role in on-farm crop conservation. This kind of indirect compensation may reach more farmers and thus be more equitable than a system of payment to a few farmers. PPB may, therefore, enhance community participation in managing local genetic resources making full use of farmers' knowledge and skills in crop improvement. ■

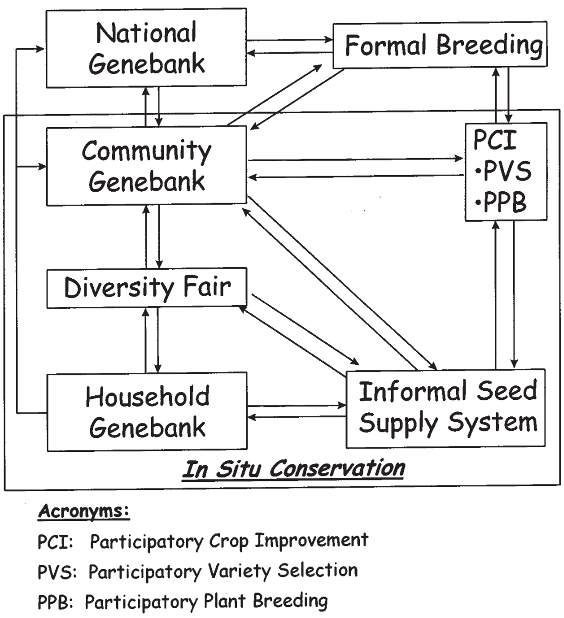

Figure 2 Participatory Plant Breeding and its linkages with *in situ* and *ex situ* conservation

Box 1.
Participatory crop improvement: definitions
(Joshi & Witcombe 1996; Sthapit et al 1996; Witcombe et al 1996).

Participatory Variety Selection (PVS)
PVS is the selection of fixed lines (released, advanced lines or landraces) by farmers in their target environments using their own selection criteria

A successful PVS involves the following four steps:

- identification of farmers' needs in a cultivar;
- search for suitable materials;
- experimentation on its acceptability in farmers' field; and
- wider dissemination of farmer-preferred cultivars.

Participatory Plant Breeding (PPB)
PPB is a breeding process in which farmers and plant breeders jointly select cultivars from segregating materials under target environment.

A successful PPB has the following features:

- understanding reasons for growing diverse varieties;
- identification of expert farmers with skills in managing diversity and seed selection;
- setting up breeding goals (and roles of participants) jointly to meet farmers' needs;
- use of landraces as parent materials;
- decentralised selection of segregating lines by farmers;
- use of farmers' observation and opinions;
- farmer participation at all stages of selection and evaluation;
- transfer of skills and knowledge between breeder and farmer;
- evaluation and monitoring of varietal spread by scientists;
- use of informal seed supply systems for wider dissemination.

Early attempts at stimulating seed flows in Cuba

Humberto Rios Labrada and Julia Wright

Since the disintegration of the USSR in 1989, the Cuban agricultural sector has had to cope with a drastic reduction in input and trade support, shifting gradually towards more self-sufficient and rational forms of production. Many remarkable technical and social transformations have occurred as a response to this challenge. In the 1980s, Cuba had carried out 87% of its external trade at preferential prices, imported 95% of its fertiliser and herbicide requirements, and owned one tractor for every 125 ha of farmed land. After the collapse of the socialist block, foreign purchase capacity was reduced from US$ 8,100M in 1989 to US$ 1,700M in 1993. This greatly affected the country's ability to buy agricultural inputs. Fortunately, since the early 1970s Cuban research institutes had been aware of the concept of low inputs and input substitutions and soon development and diffusion of alternative fertiliser and pest control measures was put into place.

However, the plant breeding sector has been slower to adapt. The solution is not as simple as technology substitution within the existing top-down infrastructure. The industrialised system had encouraged a vulnerable crop genetic framework with a low level of biodiversity. The homogeneous environment previously maintained with a high use of inputs was now no longer able to support the same crop varieties. The national seed supply system urgently needed to expand, but lacked the financial resources to do so. Between 1989 and now, its seed production capacity for maize and bean had fallen 50%.

The seed and breeding sector continues to operate almost wholly within the centralised state planning system, which does not respond comfortably to rural reality. Today, breeding strategies do take indirect yield attributes and regional variability into account but prioritising the breeding of seed for real conditions of low external input has yet to emerge at the institutional level. There is a need to supplement current dependency on the formal seed supply system with a more informal approach.

Lack of appropriate seed has meant that the informal seed system, operated directly by and for farmers, continues to exist although weakened by the dependencies created prior to 1989. The maintenance of wide variability and adaptation is traditionally carried out in small plots where farmers conserve *in vivo* those plants considered useful to the household. Through the informal system, the production of seeds of the basic staples of the Cuban diet has continued in many parts of the country. These genetic resources have provided a basis for plant breeders selecting commercial genotypes. However, relatively little attention has been paid to this informal seed management system in Cuba, and much genetic variability has already been eroded.

Some plant breeders exposed to contemporary concepts and developments have begun searching for alternative approaches. In eastern Cuba, a plant breeding project emphasising participatory approaches has been established. An independent initiative by a maverick plant breeder in the province of Havana started to take forward similar concepts and to develop the project on which this article is based.

This breeder observed striking differences in crop yields between provinces. These were related to differences in management techniques, support and local agroenvironmental conditions. The hypothesis was that high and stable yields necessitate high genetic diversity within a crop. Seed flows help to encourage this diversity, particularly flows from regions of high genetic resource variability to those of low availability. The isolated nature of many of these high genetic resource regions has protected them from the extension programmes of the formal seed sector but has also hindered informal seed flow networks between distant communities.

PPB at INCA

The aim of the project is to diversify and improve the varietal structure of maize and common bean crops for low input conditions. Prior to the start of the Participatory Plant Breeding (PPB) project, the Plant Breeding Department of the National Institute of Agricultural Sciences (INCA) organised a seed workshop and fair, in collaboration with the (then) Cuban Association of Organic Agriculture (ACAO). The two-day workshop was held in April 1999 at the INCA research institute. Focusing on maize, the researchers hoped to identify the varietal needs of a pre-identified group of small producers, introduce them to a diversity of varieties, encourage the selection of those varieties that were appropriate to their local conditions, and distribute seed for farmer experimentation and multiplication. The role of the seed fair was to facilitate the flow of seed from research institute to farmer,

photo: Julia Wright

rather than between farmers themselves. All the farmers invited came from Havana Province, and the core group from three agricultural cooperatives participating in an ongoing programme developing agroecological 'lighthouse' farms. 'Lighthouse' farmers were relatively accustomed to research interaction and intervention.

Havana Province is characterised by a relatively homogeneous environment. For the last few decades production systems have been dependent on high levels of input and are still dependent on the formal seed supply sector. There is little genetic diversity at present. Alternative seed material would have to come from the neighbouring but more remote province of Pinar del Rio. This province is characterised by a low level of external inputs systems and they have a high level of plant genetic resources and independence from the formal sector. Farmers maintain lines brought into the region over 15 years ago, but many reported regularly 'refreshing' their seeds by introducing desired characteristics from other sources. Many were farming so close to each other that natural cross-pollination occurred easily. Exchange of maize seed between farmers was common practice, particularly between the drier highland farms where there were two crops a year and the wetter lowland farms.

Preparation and methods

Some months before the workshop, two breeders undertook maize seed collection missions to a farming community in the province of Pinar del Rio. A selection was made for hardiness under low-input conditions and 66 landraces were collected including some from the focus communities in Havana Province. In addition, 4 commercial varieties were selected from research institutes. These were planted in December on an experimental plot at the research institute. Each of the 70 lines was sown in 3 rows, and wide border strips were sown with a mixture of different lines. Because of lack of finances, the experimental plot received only one irrigation and no fertiliser or pest control inputs.

Eighteen farmers, formal-sector maize breeders, soil specialists, social scientists from other research institutes, and representatives from the National Small-Farmer Association and the ACAO attended the workshop. Participants were split into 4 teams to identify and rank general problems associated with seed management and use. Farmers brainstormed over a list of problems and ranked the 6 most critical factors. After this, they were asked to name the 5 crops most affected by these problems.

On the second day of the workshop, the farmers were taken to inspect the maize experimental plot and to examine cobs of all the maize lines from this plot in order for each farmer to select 5 preferred lines. Seeds from these lines would later be given to the farmers for experimentation. Short questionnaires were used to gather information on the farmer's evaluation of each line chosen and the results were discussed.

Selection criteria

The main problems associated with seed management and use were identified as seed quality, seed availability, and the incidence of pests and diseases. Availability of training and extension, exchange of seeds, and input availability were considered less of a problem. In the field, the farmers rapidly selected from the large number of lines on offer. They showed an immediate preference for the mixed varietal border stands as these showed a better response to low input conditions than the mono-varietal rows. The importance of each of their selection criteria is shown in Table 1.

In the selection, 80% of the farmers identified different preference criteria for each of the five lines they had selected. Most popular was a landrace from Pinar del Rio province. Landraces from Pinar del Rio province showed a better performance than those from Havana province.

Table 1. Selection criteria for maize varieties, accepted as important by farmer participants.

Criteria	% of farmer acceptation
Plant yield	87.5
Plant height	87.5
Positioning of leaves	62.5
Number of leaves	60.0
Leaf colour	45.5
Leaf size	41.3
Stalk width	76.3
Number of cobs	57.5
Ear colour	32.5
Ear size	40.0
Susceptibility to lodging	31.3
Cob weight	50.0
Cob height	40.0
Cob fullness	40.0
Husk colour	28.7
Cob diameter	37.5
Cob husk cover	55.0
Cob size	42.5
Cob shape	55.0
Insect damage	35.0
Cob length	45.0

Insights

The observed better result from mixed variety rather than single-varietal planting, led researchers to conclude that they would have to work out contradictions using varietal maintenance through strict isolation as advocated by the formal system. It became clear that farmers not only looked at yield but also valued aspects such as plant height, stalk size, number of cobs, and number and position of leaves. This is an indication of the potential for more alternative breeding strategies. Selection criteria chosen for maize varieties indicated that farmers, in general, did not practice seed saving. In fact, during the discussion period, several of the farmers asked how to save seed. Different choices may be made if the farmers begin saving seed.

Further, farmers used different individual selection criteria for the choice of each variety. Researchers interpreted this as highlighting the fact that even in relatively more homogeneous areas such as Havana Province, the PPB approach favours an increase in diversity.

Positive reaction

The general reception given to this new participatory approach was positive, given that farmers are accustomed to a more top-down management style. Farmers had rapidly and easily selected between the 70 lines on show, and a very large range of new seed lines had been extended to them.

The plant breeders involved felt that this workshop indicated the need for new concept in seed management so yields and cob quality under low input conditions could be improved. Stimulating the flow of genetic resource variability had shown the potential available for increasing yield performance on trial plots and farmer acceptance. Further, they concluded that PPB, which was usually associated with more marginal environments, could also be an important tool in more homogeneous conditions. In Cuba, governmental institutions appear open to an informal seed system, but classical plant breeders may need more convincing arguments. ■

Decentralised Participatory Plant Breeding

Salvatore Ceccarelli and Stefania Grando

A fundamental problem in plant breeding is the relationship between selection environment and target environment. Direct selection in the target environment is always the most efficient. Selection efficiency is likely to decrease as the difference between the selection environment and the target environment increases.

Therefore, it is not surprising that plant breeding has been much more successful in environments with a great similarity to those where most selection usually takes place: the research stations where breeding material is customarily grown in near-optimum conditions. Plant breeders have considerable success in favourable environments, but they often address the problems of poor farmers living in unfavourable environments by simply extending the same methodologies and philosophies to favourable, high-potential environments. In doing so, they do not consider limitations associated with the presence of large interactions between Genotype and Environment (GE). Plant breeders regard these GE interactions to be among the main factors limiting response to selection and, in general, the efficiency of breeding programmes. When the selection environment is very different from the target environment, GE interactions usually become more important.

Plant breeders distinguish between two types of interactions: the first type changes the ranking of genotypes in the same location over time causing large *temporal* variability. The second type consistently changes the ranking of genotypes between different target environments causing large *spatial* (or geographical) variability. Farmers are mostly interested in avoiding or reducing temporal variability, while the majority of plant breeders (and the seed companies) are mostly interested in avoiding geographical variability.

In the case of temporal variability, the objective should be to avoid GE interactions by stabilising crop yields. One way in which this can be achieved is by breeding heterogeneous populations (genetically similar to the old landraces) rather than uniform cultivars, such as pure lines or hybrids, or by growing different varieties at the same location.

Decentralised selection

In the case of geographical variability, the objective should be to exploit GE interactions by breeding for specific adaptation within target environments. This can be achieved by selecting directly in the target environments: *decentralised selection*. In such cases, the breeding programme has a number of selection sites, with each site representing a different type of target environment. Decentralised selection becomes selection for specific adaptation when it is based on the performance within each target environment rather than on the average performance across all sites and all years.

This strategy has two important consequences. First, crops and cultivars are adapted to the biophysical and socioeconomic environment. Second, the importance of landraces in plant breeding is reassessed: these old cultivars usually do not perform well under the high-input conditions of the research stations, but are very difficult to beat in low-input, marginal conditions (Ceccarelli 1994).

Although decentralised selection is a powerful methodology to fit crops to the physical environment, crop breeding based on decentralised selection can still miss its objectives if it does not consider farmers' preferences and knowledge of the crops and the environment. Unless it becomes participatory, such crop breeding may fail to fit crops to the specific needs and uses of farming communities.

In the initial stages of breeding, breeders create a large genetic variability. Subsequently, farmers' perceptions of their own needs and their knowledge of the crop must be brought in. In this way it is possible to fully exploit potential gains from breeding for specific adaptation through decentralised selection. Farmers' participation in the very early stages of selection offers a solution to the problem of fitting the crop to a multitude of both target environments and users' preferences (Ceccarelli et al. 1996; Kornegay et al. 1996).

The acceptance of decentralised selection as a breeding strategy almost inevitably leads to the acceptance of farmers' participation as a tactical necessity. There are sound reasons for farmer participation to increase the efficiency and the effectiveness of a breeding programme, even though farmer participation is often advocated mainly on the basis of equity.

Barley variety selection project

The objective of this PPB project conducted in Syria is to test an alternative way of producing improved varieties of crops, such as barley, for marginal environments. The project operates in 9 villages chosen to represent variations in annual rainfall (from 200-250 mm), soil types, management practices, farm sizes, types of livestock ownership, and the formal education level of the farmers.

The area shows a range of agroecological conditions varying from high to low-potential cereal production environment. Barley is the main winter cereal. It is the principal feed crop for sheep in Syria. It is planted in autumn, usually after the first rain (mid-October to mid-December) and harvested in May-June. It covers over 2 million hectares with little use of modern or improved varieties. At the wettest end of the spectrum and on fertile soils, farmers can obtain up to 5 tons/ha of grain in a good season by using fertiliser. In very dry conditions where soils are generally poor and input levels low, grain yields only reach 1.5 tons/ha. Syria's national average barley grain yields are stagnant at a low of 0.65 tons/ha.

Landraces are predominant in Syria (99% of the area). They are exclusively two-row types, and known as either *Arabi Abiad* (white-seeded), common in slightly better environments (250 to 350 mm of rain) or *Arabi Aswad* (black-seeded), common in harsher environments (< 250 mm). Considerable phenotypic and genotypic heterogeneity exists both among landraces collected in different farmers' fields (even if designated by the same name) and among individual plants within the same farmer's field. Farmers in dry areas consider the grain and straw quality of the black-seeded landrace is best.

Methodology

In 1997, 208 barley lines were planted in the field of one farmer in each village. The lines were a random sample of those representing the early stages of the breeding process (normally planted only at the research station). The lines represented different types of germplasm such as two-row and six-row, modern and landraces, uniform lines and segregating (heterogeneous) populations, and black and white seed colour. The lines were also planted at 2 research stations, representing a favourable and an unfavourable environment, respectively.

The host farmers carried out the selection together with a breeder from the Syrian Directorate of Agriculture and Scientific Research. Each farmer and the breeder also selected at the 2 research stations. In 5 of the 9 villages, group selection sessions took place in which about 9 farmers scored each plot and indicated reasons for selecting or discarding them. In this way the project compared the following four strategies of selection:

- By farmers in their own fields (decentralised participatory selection),
- By farmers on the research station (centralised participatory selection),
- By the breeder in farmers fields (decentralised non-participatory selection),
- By the breeder in the research station (centralised non-participatory selection).

In the second year (1998), each of the 9 participating farmers planted the lines selected under the 4 strategies, and a second cycle of selection was conducted following the 1997 procedures. This is being repeated in 1999.

Results

The most important findings are the following (Ceccarelli et al., in press):

- In the first year farmers selected, in their own fields, about one-tenth of the number of entries selected by the breeder. On-station, the farmers selected, on average, about half the number of lines selected by the breeder. Farmers' selection was based only on the performance of the lines in their respective fields: they did not use their on-station observations. Breeder's selection was based on the performance of the lines in all 11 environments. Eventually, 2 groups of entries were selected, one for high-rainfall and one for low-rainfall areas.
- Landraces were selected more often in the dry sites and the modern cultivars more often in the wet sites.
- There was more diversity among farmers' selections in their own fields than among farmers' selections on research stations.
- Kernel size, grain yield, and total biomass were the most frequently selected characteristics by breeder and farmers.
- In their own fields, most farmers were slightly more efficient than the breeder in identifying the highest yielding entries.
- There were significant changes in selection preferences (both by farmers and breeders) under two different rotations, indicating an important (yet unplanned) advantage of decentralised breeding, namely the possibility of adapting the breeding material to changes occurring in the farming systems and agronomic practices of the target environments.

Impact

Farmers acquired the ability to conduct the trials without supervision, and were able to formulate suggestions about potential parents for crosses. They were able to explain the project to other farmers. Farmers began to realise that there could be many different types of barley. We showed farmers how crosses were made, and the different types of barley generated by a single cross. In one of the villages, a farmer's wife suddenly started sitting in the same room with us 'foreigners' and began participating in the discussion. Such a change obviously makes it much easier to find out the preferences of women which would otherwise be 'filtered' through the men. These reactions may seem small, but they indicate that this approach can have a major impact on variety adoption, skill building, increased female participation, and the capacity of farmers to redirect plant breeding and shape agricultural research to their needs.

Upscaling

National scientists visiting ICARDA were interested in developing similar activities in their own countries. As a result, there are now participatory barley breeding projects in Tunisia, Morocco, Yemen, Ethiopia and Eritrea and are being developed in Jordan and Egypt.

Conclusion

Plant breeding programmes can be organised so farmers become major actors in selection, testing and multiplication of new cultivars. PPB recognises that it is the farmers who ultimately decide whether or not to adopt a new variety and it reduces the chances of developing cultivars that are unacceptable to farmers. PPB may be the only possible type of breeding for crops grown in remote regions, for crops requiring a high level of diversity within the same farm, or for those considered as minor crops and therefore neglected in formal breeding.

There are a number of considerations, however. First, an important obstacle to PPB seems to be the reluctance of breeders to share with others the paternity of new varieties. Second, a critical step in participatory research seems to be the first contact with farmers during which scientists should be able to establish a relationship in which both partners have equal status. Third, PPB improves over time as scientists and farmers come to understand each other's skills, interests, motivations, problems, and limitations. Increased awareness of what plant breeding can do for them, will inevitably lead to more demands by farmers to formal breeding programmes. ■

Biodiversity for income generation

Andreas Gerrits

The Kigezi Highlands in south-west Uganda have good dairy production potential because of reliable rainfall and a moderate climate favourable to both humans and livestock. The Agroforestry Research Networks for Africa (AFRENA) - Uganda is an agroforestry research project in which the Forestry Research Institute (FORI) collaborates with the International Centre for Research in Agroforestry (ICRAF) in supporting smallholder dairy production. The project carries out research and development into producing quality fodder from trees and shrubs. *Calliandra calothyrsus*, an exotic, protein-rich fodder tree, is already widely used by smallholder dairy farmers. However, research on indigenous fodder trees and shrubs is trying to identify suitable alternatives to *C. calothyrsus* and to contribute to the conservation and enhancement of biodiversity. The project also carries out trials with indigenous tree species integrated into cropland to determine the potential for pole and timber production and to assess tree – crop competition.

A growing number of farmers in the Kigezi Highlands produce milk on a small-scale basis. Several NGOs distribute genetically improved heifers which are kept in zero grazing or supplementary feeding units. These are vital alternatives to free grazing in an area of land shortage and highly scattered fields. Currently, more than 300 owners of improved cows in Kabale District use zero grazing. Most farmers use Calliandra leaves as a supplementary source of fodder.

In Uganda, the dairy sector and smallholder dairy development in particular, can be a major catalyst in agriculture-led economic development if it can generate significant and regular income for producers, create employment through the production, processing and marketing of dairy products, and improve the diets of rural and urban consumers.

The Kigezi Highlands

The Kigezi Highlands are a rolling, mountainous region in the foothills of the Virunga Mountains. Altitude varies between 1800-2800 m. Hill slopes are very steep and can exceed 50° (Aluma et al, 1995). Soils were once deep and fertile, but have become degraded by unsustainable farming practices. The region enjoys a moderate tropical climate with an average annual rainfall of 1000-1500mm. The rainfall pattern is bimodal with a long rainy season from March to June and a short rainy season from October to December. Mean maximum and mean minimum temperatures are 23 and 10°C, respectively. Fog is common in the mornings.

Socio-cultural factors

Population density is estimated to be 230 per km^2 (Mugisha, 1997). Between 1980 and 1991, the average annual population increase was 2.17% indicating that the population will double in the next 35 years if this trend remains constant and there is no migration. The population pyramid is typical of developing countries with 60% of the population under the age of 20. The average household consists of 5-6 people.

Agricultural system

Small-scale cultivation to meet household consumption and a little trading characterises livelihoods in most rural households in the area. Land holdings are very small because of high population density and many households live off less than 1 ha. In addition, land is highly fragmented making it difficult to expand and manage agricultural activities. The bimodal rainfall pattern allows two cropping seasons. The main crops are sorghum, sweet potatoes, Irish potatoes, beans, and maize. Plantains are dominant in the lower and drier eastern parts of the Kigezi Highlands.

Indigenous knowledge

Most improved cows kept by smallholder farmers have a rather low milk production due to the poor composition of the fodder. Cultivated grasses, banana stems and leaves as well as vines from sweet potatoes are a common source of fodder but although they provide roughage, their nutritive value is low.

Local and exotic fodder trees could play an important role in a cow's diet. Feeding protein-rich tree leaves to dairy cows can be profitable in two ways: it substitutes expensive dairy meal and increases the production and fat content of milk.

Local trees and shrubs are well adapted to the soils and climate of the Kigezi Highlands. They are generally easy to propagate, grow fast and some show a rapid rate of re-growth after being browsed or pruned. In addition, their leaves are available during the dry season when grass fodder is scarce. Some trees and shrubs are reported useful in soil conservation and soil improvement, they provide firewood and medicines and have a wide range of other uses.

A survey carried out by AFRENA showed that the 82 farms studied sheltered 46 indigenous tree and shrubs species (Gerrits, 1999). Nine of these were actually exotic but introduced into the area so long ago that people consider them to be indigenous trees and have given them local names.

Between 0 and 9 tree species were found per farm, the average being 3-4 local tree species. One fifth of the farmers reported they had no local tree species on their land. The most frequently planted species were *Sesbania sesban*, *Ficus natalensis*, and *Acacia mearnsii.* Many species, like *Indigofera arrecta* or *Vernonia amygdalina*, grow naturally on fallow land.

Twenty of the trees or shrubs are used either as fodder or as veterinary medicine. Trees used as fodder are mainly grown close to the homestead, thus reducing the amount of labour needed to cut and carry the fodder to the cows. Trees or shrubs that form good hedges are especially suitable since they also provide protection, act as boundary markers and make useful browsable fodder banks for cows and goats.

Farmers select species according to whether they need to increase milk production or improve animal health. *Sesbania sesban* or *Vernonia amygdalina*, both indigenous species, contain the high amounts of protein essential for animal growth and increased milk production. The contribution of indigenous fodder trees and shrubs to a cow's diet is less than 10% but the crude protein they provide is crucial.

Most farmers plant local shrubs and trees and feed fodder to their animals on a regular basis. Although many use these fodder sources somewhat irregularly, they maintain that they are important especially during the dry season when less grass is available. Some farmers stated they had not tried to feed local tree species to their cows but concentrated on growing tree species suitable for timber and fuel. Farmers wanted better extension services so they could learn more about practices that help maintain milk production.

Sources of medicine

Farmers use many local trees and shrubs as traditional and cheap medicine for both humans and animals. For example, farmers treat cows with the leaves of *Sesbania sesban, Vernonia amygdalina* and *Dodonaea angustifolia* to cure intestinal diseases like worms and diarrhoea.

photo: Andreas Gerrits

Zero grazing cattle keeping system

Enhancing biodiversity

We observed a relatively low level of indigenous knowledge among farmers as far as fodder was concerned. There are several reasons for this. Few patches of natural forest remain in the area because much of the forest was cleared for cultivation decades ago. *Eucalyptus grandis* now dominates the landscape and has replaced the local tree species used for timber, poles and fuel. Farmers are interested in new, exotic tree and shrub species, some of which grow much faster than local species. Fodder from *Calliandra*, for example, is ready for harvesting in the second year (KARI-KEFRI-ICRAF, 1998). Some farmers also indicated that they had adopted Christianity and no longer believe in the traditional and spiritual uses of trees.

The disappearance of local tree species and fading indigenous knowledge are closely related and form a vicious circle. The AFRENA Project began to investigate the full potential of local tree species and to reintroduce them into the farming system. The survey showed, for example, that *Sesbania sesban, Vernonia amygdalina* and *Indigofera arrecta* are promising fodder trees. However, more in-depth nutritive analysis and feeding trials are needed to determine the response of cows to local fodder. Furthermore, little has been established on the medicinal use of local trees and shrubs for humans and animals. At a later stage, dissemination activities should include high quality local tree species for well-balanced fodder.

Preliminary results indicate that while most indigenous trees grow more slowly, their high-value products make it worth growing them on farms. In future, increasing emphasis will be put on conserving and enhancing biodiversity both in research and dissemination activities. The goal is an optimal combination of suitable indigenous and exotic tree species on the farm. The challenge for the future is to create awareness and disseminate knowledge on the natural heritage of the Kigezi Highlands. ■

Farmers from Candelaria Cochabamba selecting Yaraq oca for the marked

Andean tubers:
from conservation to sustainable use

Franz Terrazas, Rolando Oros, Gonzalo Alfaro, Blasco Vera, Raul Delgado and Graham Thiele

Andean tubers have been called the "lost crop of the Incas" and Candelaria in Bolivia is well known for its tuber production (Cardenas 1989). Farmers grow landraces of four different potato species (*Solanum andigena, S. x ajanhuiri, S. stenotomum* and *S. phureja*), oca (*Oxalis tuberosa*), ulluco (*Ullucus tuberosus*) and mashua (*Tropaeolum tuberosum*). At the local market in Colomi they make an extraordinary and beautiful display of diversity.

Andean tubers form part of different ecological tiers that extend from the 3200m irrigated valley floor to 3900m. Rotations and associations with other crops (faba beans and tarwi) help reduce pests. However, much diversity has been lost with increasing market integration. Farmers in Candelaria and elsewhere in Bolivia, concentrate production on the few varieties of potatoes widely accepted by the market. Monocropping tendencies and poor use of modern agricultural inputs have affected agroecosystem viability and increased pest damage.

The Foundation for the Promotion and Investigation of Andean Products (PROINPA) is custodian of the Bolivian Andean tuber germplasm collection. Its focus has shifted from *in situ* conservation and resolving specific production constraints to promoting the sustainable use of Andean tubers in the context of a complex local social, economic and political environment.

Initial approach

Work with Andean tubers began in 1993. Visits to agricultural fairs, markets and field reconnaissance identified 21 important Andean tubers zones. It was decided, after follow up visits, to concentrate *in situ* conservation work in Candelaria, one of the most important diversity microcentres.

An inventory of Andean tubers in Candelaria lead to the phenotypical classification of 22 landraces of *Solanum andigena*, 5 of *S. stenotomum*, 2 of S. x *ajanhuiri*, 2 of *S. phureja*, 27 of *oca* (*Oxalis tuberosa*), 7 of *ulluco* (*Ullucus tuberosus*) and 9 of *mashua* (*Tropaeolum tuberosum*). Local knowledge on production and use was systematised.

Farmers classify oca varieties according to soil aptitudes, pest susceptibility, production and storage qualities, culinary properties and market suitability. It is important in local diets between May and December and is eaten in many different ways. Most commonly the tubers are left in the sun for several days to reduce the oxalic acid content and become sweet. They are then boiled in their skins, baked or used in stews or for thickening soups. Specific dishes have evolved to exploit differences in flavour, texture colour and cooking time. Lluch'u oca is spread on the ground on cold nights, left to freeze, trodden to remove water and sun dried to make *chuño* which can be stored for months or years. *Chuño* is ground into oca flour for bread, *buñuelos* (a kind of doughnut) and starch for thickening soups. The Puka Kamusa variety has medicinal uses. Other Andean potato varieties are equally versatile. Ulluco is used in soups and stews, "Salsa Lisa" for salads, and mashua is good for fattening pigs and occasionally as medicine.

For two years a study was made of the way 12 families used and managed Andean tubers. On average they kept 8 landraces of oca, 2 of ulluco and 1 of mashua. Each family held between 5 and 11 landraces of oca. Between them they had 22 landraces. Some landraces were widely distributed.

Landraces managed by families varied over time. During 2 seasons, 4 families lost or eliminated one or more landraces and 5 families introduced a new one. Farmers have their own strategies for managing and replacing germplasm. They plant the same variety in different tiers to reduce the risk of loss and replace seed when it has become tired with seed obtained from another farmer, preferably outside their community. Seed is bought, bartered or paid for through labour. This dynamic, mosaic system that crosscuts local communities largely ensures germplasm is maintained. However, some varieties such as the ulluco "Llausa lisa" used for *chuño*, have been lost recently.

In situ conservation

PROINPA's principal support to *in situ* conservation has been the organisation of annual biodiversity fairs. The first was held in Colomi in 1994 in cooperation with the local government. Each participant or group was allocated a small stand where they laid out all the varieties they used. Prizes were given to participants with the largest number of varieties and to those who were most knowledgeable. One family brought 32 varieties of potato, 12 of oca, 2 of ulluco and 6 of mashua. Farmers were encouraged to exchange varieties. A follow-up of six families who had exchanged varieties showed they had planted 2 or 3 new varieties. The fairs helped PROINPA to discover new landraces and to meet the farmers managing them.

Technical limitations

Until recently, agricultural research in Bolivia has ignored Andean tubers. To complement *in situ* conservation, the specific problems confronting farmers were identified, prioritised and investigated. Ulluco is attacked by *roya* (*Aecidium ulluci*), a disease farmers call *"tojtu"*, a term also used to describe potato blight. By 1997, the specific pathogen causing *roya* had been identified and an efficient, but chemical, control strategy developed.

Farmers say that weevil in oca is a relatively new problem. Farmers also reported that some varieties resist weevil. The biology of the insect (*Systena sp.*) was studied and 200 entries in the national germplasm bank were evaluated during researcher-managed field trials. Forty varieties were found to be resistant to *Systena sp.* and two entries were able to act as nematode trap crops.

New approach

Farmers have managed germplasm for thousands of years under complex and changing conditions. The term "conservation" fails to capture the dynamics of adoption and selection, however. Technological interventions that target highly specific problems outside the context of the local agroecosystem do not allow the full utilisation of available biodiversity. PROINPA has tried to develop an alternative approach promoting new and sustainable uses of biodiversity in Candelaria.

PROINPA has joined the San Simon University's (Cochabamba) programme of Food Technology and Natural Products (PAPN) and the Institute for Socio-economic Studies (IESE) in forming the Integrated Candelaria Project (PIC). PAPN had already developed and evaluated a range of food products derived from Andean tubers and IESE had carried out studies on the market, price and demand for them. Within the PIC, realistic, interdisciplinary proposals for the sustainable use of biodiversity are being developed.

Linking farmers and PROINPA

Farmers replace seed when it has become tired. Potatoes, oca and ulluco tuber seed gradually becomes infected with viruses that lower yields. PROINPA has used meristem thermotherapy to produce virus-free seed in 24 potato landraces, and 2 landraces of oca and ulluco from the germplasm collection. Eight farmer families from Candelaria visited PROINPA's experimental station and selected 12 varieties. They were given 20 tubers of each variety and are now multiplying these for their own use. Plans to further improve farmer access to the materials held in the germplasm collection are being made.

PROINPA on-farm research has moved from developing interventions to target specific problems to studying the interactions of rotations, fertility and pests. Nutrient flows in the soil and the movement of pests between sites are being examined and 4 farmers are taking part in a study of the way Andean tubers are managed within the whole farm rather than the single field.

Markets

Accessing better quality germplasm and resolving production problems using an agroecosystem approach must be combined with identifying new markets for oca, ulluco and mashua. As PIC project members analysed market bottlenecks, farmers explained the detrimental effect of gluts on prices. Because ulluco does not store well, it has to be marketed immediately after harvest when prices are low. Farmers wanted to be able to take advantage of off-season prices. PAPN, together with farmers, concluded that improved storage and dehydrated flakes might solve the problem. PAPN developed and tested the technology for flakes and a pilot product, sold in the University store, was well received by consumers. Market studies revealed a potential demand of 437 tonnes per year, easily absorbing current production in Candelaria.

PROINPA has helped farmers select and grade high quality ulluco and oca and IESE has sold well-presented, 100kg bags with ease at local supermarket where consumers were prepared to pay several times the local market price of the loose ungraded product. IESE has also developed new recipes that do not require sun exposure and these are supplied with the packaged product.

Mashua has very high yields of up to 90 tonnes/h. Being a rustic crop adapted to the Andes it requires few inputs. Farmers feed cooked mashua to their pigs and it could replace maize in commercial balanced animal feed. The Bolivian Private University (UPB) has estimated the potential demand for mashua as balanced feed is about 150,000 tonnes per year. PROINPA has undertaken to study yields and select appropriate varieties. UPB is testing gas-drying methods of feed production and preliminary results from commercial pig producers suggest mashua is an efficient substitute. PAPN is now investigating artisan solar dryers for farm use.

Scaling up

The PIC Project is basically a research initiative. To reach more farmers and have greater impact on biodiversity it must work with other institutions including local government institutions responsible for rural development. PIC project members have helped Colomi municipality to organise an agricultural workshop where NGOs, local institutions, private sector food processors and farmer groups can analyse the problems associated with the major crops and explored solutions. Potatoes were voted the most important crop, oca and ulluco were joint third. Four institutions involved in the workshop are working with Andean tubers. As these also work with other crops and livestock, good coordination should make it possible to implement an agroecosystem approach. PROINPA hopes the workshop will evolve into a local forum for agricultural development capable of promoting the sustainable use of biodiversity.

Community Seedbank in Hahaile, Ethiopia

In situ conservation: the Ethiopian experience

Abebe Demissie

Plant species of economic importance are not randomly distributed throughout the world. N. I. Vavilov was among the first scientists to conceptualise this phenomenon and identified eight such centres of diversity. Because it has a wide range of ecogeographic, edaphic and climatic conditions, Ethiopia has considerable plant genetic diversity. It is a major world centre of genetic diversity for many regionally and globally important domesticated plant species including wheat, barley, sorghum, teff, chickpeas, coffee, as well as other less-appreciated but potentially useful crops.

The permanent interaction of cultivated crops with their wild relatives under diverse ecosystems, coupled with farmers' practices and socioeconomic factors, have contributed to making Ethiopia one of the richest areas of genetically diverse farmers' varieties in the world. Even crops that were originally domesticated elsewhere exhibit immense variation in various adaptive traits.

Farmers' varieties important

The critical importance of plant genetic resources as a component of natural resources management has been recognised for some time. Plant genetic resources form the basis for food security and sustainable agricultural development. A growing global population needs crop plants with improved tolerance to several stress factors and able to meet the growing need for food, fibre, and clothing. This means that plant breeders must have continuous and dependable access to plant genetic reservoirs. Farmers' varieties, their immediate relatives and related wild species are particularly important sources of new genes for breeding programmes.

Farmers' varieties are uniquely adapted, genetically diverse cultivars. They are repositories of traits that have evolved in local environments over long periods of time as a result of farmers' cultivation and selection. As sources of adapted genes, farmers' varieties have been the raw material from which modern and often higher yielding crop varieties have been developed. The conservation of local landraces is, therefore, of critical importance both for scientific crop improvement and subsistence agriculture.

Ex situ conservation

Two conservation strategies are generally distinguished: *in situ* and *ex situ* (see Box 1, p29). At the global level, genetic erosion has been addressed by efforts to conserve plant genetic resources in off-farm or *ex situ* gene banks, both as seeds and as living plants. To date, nearly all such efforts have focused on conserving crop genetic resources in formal gene banks that are part of an international institutional network. *Ex situ* conservation has limits. Gene banks are limited in what they can store. They have collected only a fraction of the existing genetic diversity and the size of the sample varies and depends on the crop. For instance, relatively large collections exist of the major food crops. Large holdings of rice, wheat, barley, maize, potato and other crops are kept in CGIAR international research centres. In contrast, minor food crops have hardly been collected for *ex situ* conservation even though the genetic diversity in these crops is more threatened with replacement by the principal crops. The disassociation of the material kept in genebanks from their users' communities limits access to the materials by the primary users and original custodian of the material, the farmers. It also terminates the enhancement of the material through the process of natural evolution.

In situ conservation

The primary objective of *in situ* conservation is to conserve the biodiversity of traditional crop varieties on the farm with the help of farmers' knowledge and traditional practices. *In situ* or on-farm conservation of agrobiodiversity is conservation in a dynamic agroecosystem, ideally one which is self-supporting and favouring evolutionary processes. Thus, it allows ongoing host-parasite co-evolution, which is likely to provide material resistant to diseases and pests. This contrasts with the efforts to conserve crop diversity in static off-farm gene banks. However, *in situ* maintained diversity is more difficult to access for breeders who like to use specific materials for their breeding programmes.

Community-based conservation

The objective of the Ethiopian on-farm initiative is to establish a programme linking *ex situ* and *in situ* conservation. *In situ* and *ex situ* conservation are seen as complementary in a way that maximises the retention and continued evolution of the genetic qualities of farmers' varieties. It also aims to avoid the loss of variation during rejuvenation and maintenance in formal gene banks. This means that farmers' *in situ* conservation must be part of the existing cropping system since this is the only way to maintain the complex interaction of genetically diverse traditional cultivated varieties with their associated pests, predators and pathogens. In this setup, both natural and human selection operate in the traditional way.

As part of the *in situ* conservation effort in Ethiopia, Community Seed Banks (CSBs) are being established as pilot projects in 6 different agroecological zones. Like the formal gene banks, conservation of locally adapted traditional varieties in community-managed seed banks will ensure the sustained provision of useful variability to the community and to various breeding programmes complementing the formal network of international gene banks.

The CSBs serve as a springboard for increased extension contact and local participation in the conservation of farmers' varieties. They can be used to organise local support for conservation, train farmers in conservation activities, build low cost and low maintenance storage facilities, and link farmers, extension agents and gene bank staff. In forming CSBs, the first step was to contact local leaders and farmers in selected districts and communities, and organise a local association, the Crop Conservation Association (CCA). The CCA is the principal contact point between the Community Seed Bank, extension agents and the gene bank. The CCA, the district extension agents, and the gene bank join in building the actual Community Seed Bank facility with funds made available by the project.

The next step in establishing a community based conservation programme was to select a local farmer conservator. This was done using criteria developed by the community and gene bank and took place during a meeting/workshop involving the CCA, community leaders, extension agents and local farmers. The farmer conservator belongs to the group of farmers who plant, select and store seeds from local materials. The farmer conservator is the primary local contact and is responsible for managing the CSB. In collaboration with extension agents the farmer conservator and other farmers are trained by gene bank staff in selecting, documenting and storing genetic resources in the CSB.

Community storage is already practised in Ethiopia to ensure seed in times of stress and the CSB builds on this age-old tradition. Farmers store part of their seed in the CSB and this seed is available for retrieval at any time. A small, but representative seed sample is taken for storage at the Community Gene Bank and a duplicate sample is kept in the national gene bank at the Institute for Biodiversity Conservation and Research.

Operational strategy

Initially, subsidies were provided on the basis of the yield differentials of advanced and farmers' varieties. In the long run, continuing *in situ* conservation cannot rely on direct production subsidies to farmers. In order to work towards a sustainable compensation scheme after project funding is over, a reward system needs to be put in place.

The production and utilisation of farmers' varieties is important for Ethiopian farming communities. In this context it would be important to identify where agricultural production and pricing policies are likely to have a negative effect on the continuing use of traditional varieties/landraces. At the end of the day, farmers themselves must feel there are advantages to continuing with traditional crops if they are to sustain their participation in the conservation of farmers' varieties.

Support

Another broad strategy that supports a farmer-based conservation programme is the generation of non-market and market incentives for growing farmers' varieties. Critical here is identifying the specific factors that enhance or limit the continued utilisation of farmers' varieties by farming communities. A key component is to identify special consumer products that make use of farmers' varieties on the local, national and international market. There is much potential, for example, in urban markets in industrially developed countries for organically produced products. Increasing interest in organic products may provide opportunities for the production of farmers' varieties with special high nutrient or culinary quality even though yields may be low.

Major non-market incentives to the farmers involved with the Community Gene Bank will be the increased training and enhanced extension packages received by the farmer conservator and associated farmers. Extension agents and the farmer conservator will not only be available to select and store local seed, but will also work with farmers in improving crop production. A flexible strategy to accommodate both improved crop production techniques and the conservation of local crop varieties is anticipated. Both the extension agents and the farmer conservator will be able to advise farmers on the advantages of different crop varieties and where these might do well. They will be able to help farmers increase production by improved crop management techniques such as soil erosion measures and pest control. They can also be of help in enhancing the material by incorporating desirable genes. Educational material that explains the importance of Ethiopian crop resources should also be developed.

The sustainability of a farm-based conservation of farmers' varieties may ultimately depend on the availability of local and external markets. The local market is unlikely to be large enough to absorb production and it is not sensitive to this type of product at present. The project will seek to identify products that are based on farmers varieties and which can be marketed as value-added products to support their cultivation. Other market niches for farmers' varieties probably exist and warrant special initiatives.

In spite of the low yields obtained, it is obvious from the experience gained so far that local farming communities want to continue cultivating farmers' varieties. This is because of their stable yield and the quality of traditional varieties. The communities clearly appreciated the project. However, it is unrealistic to expect it to be fully sustainable after just four years. This type of project will need international assistance for a long time if it is to make a lasting impact. Meanwhile, the international community should develop an awareness of the value of farmers' varieties for future food security and be ready to promote *in situ* conservation programmes.

This contribution is based on the project "Dynamic farmer-based approach to the conservation of Ethiopia's plant genetic resources" supported by the Global Environment Facility.

Campaign to Save Traditional Seeds

Oswald Quintal

In India irrigated agriculture and the use of high yielding varieties is strongly supported. This has led to an overproduction of rice and wheat. The Public Distribution System has been selling this subsidised surplus to the poor. As a result, millet had gradually been replaced as a staple food by wheat and rice. Rainfed agriculture in Tamil Nadu has become strongly marginalised and traditional varieties of small and minor millets and pulses have nearly disappeared. The Tamil Nadu LEISA Network* organised a campaign to 'Save Traditional Seeds' and, in the process, they have documented the traditional varieties that still exist. They have also identified those farmers interested in cultivating, upgrading and multiplying traditional varieties

On the road

A campaign "trail" committee was formed to tour the area. It consisted of members of farmer' associations and consumer forums. A core team was made responsible for addressing public meetings in colleges, universities and on the street. This team was also responsible for collecting information about the traditional varieties cultivated in the region and for forming village committees to cultivate and upgrade traditional seeds. A cultural team was responsible for street theatre performances that demonstrated the impact of modern agriculture, the threat to biodiversity and the importance of preserving, cultivating and upgrading traditional varieties.

The campaign was opened by the Vice-Chancellor of Anna University, Madras (Chennai) on 10 December 1997 and reached Kannikumari on 10 January 1998 after covering about 1200 km. Every day, during this 30 day period at least one meeting was held at a college or university and 3 to 4 street performances were given. Meetings often attracted between 2000 and 2500 people a day.

Without the solid support of the farmers, who provided food for 150 people 3 times a day; the NGOs, colleges and universities that provided accommodation, and contributions of grain and cash from the general public, the campaign would not have been possible.

All the daily and weekly magazines in Tamil Nadu and the State television service followed the campaign's progress. Subscriptions to the LEISA Network magazine doubled and some 180 farmers became involved in newly founded community seed conservation committees. The seed committees, in collaboration with the LEISA Network and universities and colleges will use the traditional varieties and the information collected in testing and multiplication experiments. Much information was also collected on traditional agriculture and the loss of biodiversity. This included, for example, inscriptions from a temple wall that indicated that rice yields of 7–9 tons were obtained in traditional rainfed agriculture, thus exploding the myth that the productivity of traditional varieties is low. ■

Oswald Quintal,
Tamil Nadu LEISA Network, 22, High Ways Colony, Subramaniyapuram, Trichy-620 020, Tamal Nadu, India

* The LEISA Network, founded in 1990, is dedicated to the development of sustainable small-scale rainfed agriculture. Its members are resource-poor farmers and small NGOs living and working in Tamil Nadu and Pondicherry in southern India where rainfed agriculture and livestock keeping predominate.

Box 1 Complementarity and sustainability of *in situ* and *ex situ* conservation

Farmers have developed and shaped landraces through repeated seed selection and production. The *in situ* location for these genetic resources is the farm. For this reason, on-farm conservation is a synonym for *in situ* conservation of crop and livestock genetic resources. The on-farm or *in situ* maintenance of genetic diversity is a conservation strategy that is complementary to *ex situ* conservation in genebanks. The crucial importance of *in situ* conservation lies in the fact that the evolutionary process can continue, whereas the *ex situ* conservation represents a 'frozen and static' situation. Conservationists accept the fact that they cannot conserve all materials and genes *ex situ* because of limited resources and that materials are at risk from power cuts and delayed regeneration. However, *in situ* conservation is not fully adequate for the maintenance of material or genes (see Sthapit & Jarvis p40). First, because farmers may not wish to continue planting particular varieties or crops if better varieties become available. Second, the genetic make up of materials can change when farmers change production practices. This generates such discussions as whether farmers who maintain farmers' varieties/landraces should be encouraged (or allowed!) to use fertilisers or pesticides. From a 'pure' conservation perspective, this is not desirable. On the other hand, farmers cannot be forced or expected to grow particular farmers' varieties/landraces in the traditional way if they are not compensated for extra costs or yield losses.

photo: Conny Almekinders

The Ethiopian genebank of the Institute of Biodiversity Conservation and Research (IBCR) has adopted a compensation approach, at least in the short term. Some argue this is not a sustainable way of maintaining *in situ* conservation because compensation is only available for the length of the project. However, alternatives are not readily available. If the gene bank waits until policy makers have created a socioeconomic environment that favours the use of local genetic diversity by farmers, then many valuable genes will probably be lost as farmers turn to improved materials or abandon their farms in search of a more promising future.

The justification for the *in situ* and *ex situ* conservation of genetic resources is that resources will be used by farmers either directly or indirectly. Both approaches require policy support. A policy that provides for the creation of a regulatory seed framework and market can significantly contribute to the on-farm use of genetic diversity (see Demissie p30).
It is, however, essential that the value and complementarity of *in situ* conservation and the role that farmers play in conserving genetic diversity is recognised.

People's Biodiversity Register

Ghate Utkarsh

The People's Biodiversity Register was initiated in 1995 by the Foundation for the Revitalisation of Local Health Traditions (FRLHT), an NGO in Bangalore. Between 1996 and 1998 the Indian Institute of Sciences coordinated the activities of the People's Biodiversity Register at 52 sites in eight states. This was part of the Biodiversity Conservation Prioritisation Programme, a national initiative (Gadgil et al, 1998).

The People's Biodiversity Register aims to build an open and transparent information system on biodiversity resources from village level upwards. The register can be used to promote the sustainable management of natural resources and support claims of communities and individuals to knowledge about biodiversity resources and their use.

During the course of individual and group interviews and discussions at village assemblies, local biological resources and conservation priorities were explored and biodiversity user groups and knowledgeable individuals were identified. As many as 1000 villagers with extensive knowledge of biological resources became deeply involved in the programme. During these discussions biodiversity resources and practices for the sustainable use of local biological resources were identified. Peoples' perceptions and options for development and their personal and social choices were also discussed.

Over-harvesting and biopiracy

This work entails risks. The availability of easily accessible databases could encourage the over-harvesting of certain biodiversity resources by the communities themselves. Also information on biodiversity resources might be used by those who are not prepared to share the benefits equitably.

Information on biodiversity resources in the People's Biodiversity Registers has facilitated monitoring and provided measures for checking how this knowledge will be used . Establishing rewards for natural resources initiatives has created opportunities for local communities to participate in conservation programmes.

Information from local registers has been computerised at district level and made available to villagers throughout the country. The medicinal and seed industries are allowed access to this information for a reasonable fee. Some of the royalties accumulated in this way have been deposited in biodiversity funds for the support of local initiatives. These efforts will not be successful without publicity, training and education at the grassroots level through a local self-governance system.

Experiences gained

The registers were accepted by local councils as official documents and distributed publicly. This attracted considerable attention in the local media and helped raise awareness about these issues in neighbouring areas. It also worked as a signal to local politicians about the importance of local resource management and their responsibilities towards it.

In some villages people started looking for solutions to problems related to local natural resources. In Kigga village near Sringeri, for example, one trader used to collect moss in large quantities from nearby forests. The people asked him what he earned selling this moss on the urban market and, because he did not give a satisfactory reply, they refused to continue collecting. Mala village decided to ask the government to authorise the local council to charge fees to outsiders who wanted to collect forest products. People also looked for ways of reducing the pressure on the forests caused by the need for firewood. They began, for example, to look for alternative fuel resources for brick making and made efforts to protect sacred groves.

Response

The government of India has prepared a draft 'Biodiversity Act' (Anon 1998) to be discussed during the next parliamentary session. The draft act considers the role of local authorities, the documentation of local knowledge and resources, and the funding needed for conservation. Under the auspices of a local member of parliament some NGOs organised a public hearing on the contents of the draft bill.

As the government takes its time to decide about People's Biodiversity Registers, local NGOs have started promoting them vigorously. These experiences have been widely published both in English and in the local language and as a result many people from all over India have expressed an interest in undertaking similar exercises in their own areas. An informal network called *Srishtijigyaasa Pariwar*, the 'Family of People Desiring to Learning about Nature' has been set up. To facilitate this process, a methodology manual (Chhatre et al, 1998) and resource materials such as the Convention on Biological Diversity have been translated into several local languages.

Meanwhile other NGOs, including the International Union for Conservation of Nature and Natural Resources (IUCN), have expressed interest in undertaking similar initiatives in Nepal, Brazil and South Africa. People's Biodiversity Registers may become a global movement in the near future.

Learning about biodiversity in Peru

Market fairs where products are exchanged are common in the Andes. Competitions are also very much part of Andean culture and the organisation of “biodiversity fairs”, where farmers display their plant varieties and those with the “most biodiversity and knowledge” win prizes, have special appeal.

M. Scurrah, E. Fernandez-Baca, R. Canto, E. Nunez, E. Olivera, N. Zúñiga

One of the first biodiversity fairs took place in 1989 in Aymará. It was held as a competition among farmers and highlighted the diversity of potato varieties. Farmers responded positively to the fairs and they have become annual events. Every year more families enter the competitions and the number of varieties displayed increases.

Today, biodiversity fairs are held all over Peru and have expanded to include diversity in crops other than potato. Fairs encourage farmers to pay attention to the diversity of varieties they grow. On a more practical level, they provide a space where neighbours can exchange seed and plants and, at regional fairs, they bring farmers from more distant communities together ensuring that seed stocks are rebuilt and expanded. Farmers receive recognition from government and NGOs for their efforts in managing their biodiversity and the prizes also provide strong motivation.

Colpar

Grupo Yanapai works with rural communities in Quilcas district in the Mantaro Valley, Huancayo Province. Communities are scattered over two watersheds and three different agroecological zones: the low agroecological zone or valley floor (3000-3500 m.a.s.l.), the intermediate zone (3500-3950 m.a.s.l.) and the high zone (3950-4250 m.a.s.l.).

The Quilcas community is situated on the valley floor. It has some authority over the distribution of communal resources in the area although, over the years, the importance of communal resource management has diminished at lower heights where most of the land is now privately owned. Colpar with 74 families, 47 of whom are officially registered as community members, lies in the intermediate zone. Membership of the community brings obligations, such as the commitment to joint labour in the interests of the community, and rights to a plot of land and grazing areas in the high ecozone.

Families in Colpar practice small-scale agriculture combining it with animal husbandry. Cattle, sheep and llamas are herded in the high ecozones while other animals are kept near the family home. Cattle are a source of capital, manure and traction, pigs are sold when cash is needed, and guinea pigs, rabbits and fowl provide food for household use.

The families manage small privately or communally owned plots situated at different altitudes where they cultivate a variety of crops. The average amount of land owned by each family is 0.5-1 ha. On the steep slopes, soils are generally acidic and low in organic matter and hillsides suffer from varying degrees of soil erosion. Farmers think that since inorganic fertilisers were introduced soil health has declined (Ramos and Kauffman 1997). Subsistence agriculture dominates, surpluses are sold at the market and production depends almost entirely on manual labour.

Biodiversity Fair

Grupo Yanapai’s field team decided to organise a biodiversity fair in Colpar. It wanted to stimulate farmers to maintain crop diversity and variety in their fields, provide them with an opportunity to exchange seeds and knowledge and finally to obtain more information about crops and the diversity within them.

32 participants took part, 25 women and 7 men. Traditionally, women are responsible for selecting and maintaining seed and, therefore, the presence of men at the contest was a surprise. Particularly as the first three prizes awarded for showing the largest number of crops and variability within the crops went to men. This showed that there was close cooperation in each household and that men are also interested and knowledgeable about seed maintenance. The Yanapai team failed to find out how many of the 25 women were heads of households. However, a survey carried out among 20 women in 1995 showed that 45% were either widowed or heads of households (Axman 1996).

Crops and variability

A total of 828 samples from 17 different crops (5 tubers, 5 pulses, 5 grains, 1 fibre-oil and 1 vegetable) were presented at the fair, as well as apples, aromatic and medicinal plants (laurel and aloe) and garden produce (carrots, garlic and *"rocoto"* (*Capsicum pubescens*)). The variety name provided by the producer was taken as a diversity unit. Yanapai was unable to analyse whether more than one name had been given to a single genotype. There were a surprisingly large number of "unique" genotypes.

It is unclear whether the farmers or Yanapai consistently classified native potatoes and improved potatoes in two categories, although native potatoes occupy a different height niche and require different crop management and input levels. If treated as one category, potatoes were the most exhibited crop (92%) with the greatest cultivar diversity (61).

Maize
The most common crop was maize (*Zea mays*). It was present in most exhibits (82%) with 51 different variety names. It is undoubtedly an important crop in the village even though Colpar lies above the cut-off height for maize production. Maize is dominant because people from middle-height villages may have access to land on the valley floor and because ecotypes that are more tolerant to colder conditions have gradually been selected. One of the farmers said: "At first maize hardly gave any grains and was mainly cob but then after five years it began to produce more and the grain was good". Thus, maize seems to be ascending to higher altitudes. Two prize-winning entrants presented 16 different types of grain. Maize is rarely sold and when families find they do not have enough, they buy or exchange other crops for it.

Faba bean
The second most common cultivar at the fair was the faba bean (*Vicia faba*): 27 of the 32 participants had it. The greatest number of varieties displayed was 19 and the average was 6. Farmers sow faba bean by population, planting them together rather than separating them into varieties making possible the recombination of different types through cross-pollination. This management practice has given rise to Andean faba bean ecotypes. Since the faba bean stores well, it is consumed in the period October-December when there are no more potatoes left. Dry faba bean is sold in small quantities when money is needed. It is a nitrogen fixer and an important cleaning crop in the rotation cycle because it does not suffer from the same diseases as maize and potatoes.

Improved potato
The third most common crop was the "improved" potato, which originates from breeding programmes. These are mostly hybrids between *Solanum tuberosum, ssp. tuberosum* and *S. andigena*. 20 participants (63%) brought varieties of "improved" potato. On average each farmer grew 3 varieties. 60% of farmers had '*Yungay*', a late variety planted at the end of November and harvested in May. The *'Amaya'*, selected and maintained by farmers, is a variety unique to the area. *'Revolución'*, an early variety planted in October, is one of the first to be harvested. These improved varieties are grown for household consumption and sale.

Peas
Eighteen participants grew peas (*Pisum sativum*) with, on average, 2 varieties per person. Only 3 farmers had 4 varieties, including a purple mottle that "produces well but doesn't have a market". It is grown for consumption only on small plots in association with maize and faba bean.

Native potato
Native potato (Solanum tuberosum ssp. andigena, S. gonicalix, S. chaucha, S. curtilobum) came in fifth place. 17 people (53%) exhibited this type of potato. One participant brought in 28 different varieties. It is possible that other participants had more native potato varieties, but these potatoes are stored in the highlands and farmers may only have displayed the varieties they had on hand. Two women who had a large native potato collection travelled frequently to the highlands. They had the opportunity to pick up a more complete set of seed tubers from the highland store. This crop had the greatest diversity in the community with an average of 10 varieties per person.

Unlike maize, the native potato is grown in the highlands, which are still communally owned. Potatoes are not separated into varieties, but are planted as a mix designed as *"chagro"*. The community manages a seven-year rotation system and each family is allotted land in turn within the larger rotation field. Native potato seed is usually obtained through inheritance, by exchange and, as its Spanish name *"papa regalo"* suggest, as gifts. This potato is used for food, gifts, ceremonies and festivities.

Andean Tubers
Thirteen farmers (41%) had *ulluco* (*Ullucus tuberosus*) with an average of 3 varieties (one participant had 9). Eight farmers (25%) had *mashua* (*Tropaeolum tuberosum*) with an average of 3 and a maximum of 7 cultivars. Only one participant had *oca* (*Oxalis tuberosa*) and she brought 2 varieties. Farmers had stopped cultivating oca because weevil had become a serious problem and all the seed had been lost. *Ulluco*, mashua and oca are planted in rotation with improved potato, faba bean and cereals. With the exception of *ulluco*, which has a market, they seem to be losing variability and importance.

Pulses
All pulses grown have a high protein percentage and are important in soil fertility improvement because of their nitrogen fixing qualities. Even though the Mantaro valley is too cold for beans, 10 farmers brought them in. Those farmers who brought in maize also brought in a large number of bean varieties because they are grown in association. The maximum number of varieties displayed was 12 with an average of 5. Beans are mainly grown as food and are seldom sold.

Nine farmers brought tarwi (*Lupinus mutabilis*). It is grown for food and to protect small fields in the intermediate zone from livestock. The average number of different types was 3 although one participant had 7. It is the last crop in the rotation before the land is left to rest. Eight farmers brought vicia (*Vicia bilosa* and *V. sativa*) to the exhibition. Yanapai introduced this crop to alleviate the scarcity of forage and it seems to be doing well.

Other groups
Cereal crops showed the least genetic diversity. Wheat, barley, oats, *quinua* and *kiwicha* averaged one variety. 10 farmers presented wheat, 6 presented barley, 4 oats and 3 *quinua*. Land scarcity and climate restricts cereal growth. Seven people brought pumpkin and there were 3 varieties. Aromatic herbs and garden vegetables were not included in the list and only a few brought samples. It should be noted, however, that various families grow garlic, onions, carrots, and a combination of aromatic and medicinal herbs.

Conclusion
Colpar's first fair revealed that farmers grow a surprisingly large array of crops. There is a large diversity of phenotypes within each crop and great heterogeneity amongst them, suggesting contradictions between market and farmer strategy.
On the one hand, the market plays a reductionist role accepting only a limited number of crops and varieties. Farmers, however, aim to maximise crop diversity as well as diversity within crops in order to cope with the complex agroecology of their land, droughts, hail, frosts, diseases, and pests. The fair highlighted once again how farmer strategies are geared towards food security and ensuring the sustainability of their agriculture.

The Project 'Promotion of small-scale seed production by self-help groups' is a technical cooperation project between the Southern Africa Development Community (SADC) and Germany. The project seeks to develop an approach to achieving seed security at household level given that commercially-

Ortwin Neuendorf

oriented seed enterprises will do very little to supply quality seed from open-pollinated crops to farmers. To achieve its objectives, the project cooperates closely with NGOs, the extension service, farmer associations and other projects already working in the field with individual farmers and farmer groups. The project offers to supplement their activities with a seed component.

Seed fairs:
creating awareness of a rich heritage

After becoming acquainted with the target group, discussions usually shift to exploring the problems the group feels need to be addressed. It transpires that seed issues are an important element in the difficulties facing farming community. When farmers are asked to elaborate on the seed issue, a number of problems emerge: appropriate seed was unavailable or not available on time. What was available was often old and "tired" meaning the seed had been kept too long or had been recycled too many times and that it took too long to mature. In general, there was nothing new to be found especially where early maturing varieties were concerned and certified seed from the formal sector was too expensive.

Seed fair experience

To maintain farmers' interest in seed security concerns, the project finds it helpful to suggest that farming communities make an inventory of crops and varieties used at the local level. The whole community then displays its seed inventory at a 'seed fair'. The seed fairs have acquired their name because they combine the aesthetic values of sample displays with detailed explanations about the performance of a variety or a crop. This culminates in seed marketing and exchange between participants. The occasion is organised in such a way that it is entertaining as well as informative. A convenient time to hold a seed fair is at the end of the cropping season, just after the harvest when details of the crops' performance are still fresh in the farmer's mind. Understanding the farming systems in a particular area is also critical for the timing of such events. It is important that the farmers take heed of mixed crop stands and relay plantings which grow on residual moisture because the main objective is to capture as much diversity as possible.

Seed fairs in Zimbabwe have shown how important they can be in raising awareness about seed issues. Zimbabwe is characterised by a very strong and vibrant commercial farming sector that occupies about 30% of the arable land and a much less commercialised farming sector that is mostly situated on marginal crop land. The commercial sector produces and exports maize, wheat, soybeans, sugarcane, tobacco, cotton, fresh cut flowers, vegetables, fruits, tea, coffee, and beef. It relies on a well-developed formal seed supply system, which, through local production and imports, adequately meets the quality demands for seed and planting material.

However, the majority of Zimbabwe's farmers have to eke out a living in the subsistence farming sector. Here, overpopulation and decade-long poor land management has led to massive environmental degradation and erosion resulting in the loss of soil fertility. The combination of recurrent drought and economic structural adjustment measures has aggravated the problem and reduced state funding for this sector. A major problem has been to provide adequate, appropriate seed for the farming systems practised in these areas because economic liberalisation has increased seed prices to levels beyond the reach of many subsistence farming communities.

With these factors in mind, seed fairs seemed to provide a good opportunity for making farmers aware of and interested in the genetic resources they possess, to enhance diversity and to encourage special care in producing good seed.

Seed fairs began in the early 1990s and followed the most devastating drought to affect Southern Africa this century. There were fears that farmers had lost most, if not all, of their seed and planting material. Acting as an informal inventory, the seed fairs were quick to establish the resilience of traditional farming systems in the face of such major catastrophes. The seed fairs revealed that seeds, even of very old varieties, were still to be found in the farming communities.

Records for the past three years from two drought-stricken districts in Zimbabwe indicate that the number of seed fair exhibitors increased from 90 to 130 families and the number of visitors doubled. Most impressive, however, was the number of crops displayed. The list reads like a Southern African crop compendium. One such fair, for example, displayed 5 different grain crops with 110 different varieties, 6 leguminous crops with 75 varieties, 9 vegetable crops with 67 varieties, 3 industrial crops with 10 varieties and 2 root and tuber crops with 15 varieties. Varieties were distinguished according to the farmers' own standards. They gave names to the different phenotypes and these reflected their understanding of the performance of a crop or where it came from. As a result, there were varieties named after the president of the country because the seed was given as drought relief or with names like "wife does not run away" because the variety was short maturing and helped alleviate hunger. Similar numbers of varieties have since been found wherever a seed fair was held and they are rapidly becoming a popular event in low-input agricultural settings.

When questioned about the difference between seed fairs and the agricultural shows, participants remarked:
- Farmers pay to display their goods at agricultural shows, at seed fairs they can display their seeds for nothing.
- Produce are judged at shows in terms of quality. At seed fairs, the diversity of displayed varieties and their uniqueness is what is most important.
- At shows only registered varieties can be judged, while at seed fairs all crops and varieties are accepted, irrespective of their origin.
- It is easier to get seed from an exhibitor at a seed fair who lives in the vicinity, for payment or barter can be arranged any time before the planting season starts.

The main objectives of seed fairs are to:
- enable farmers in the area to share information regarding the performance of various varieties;
- give access to a wider range of crops and varieties so they can meet their food requirements;
- develop a competitive spirit in food production; and
- share skills and knowledge on how to produce the crop.

In the Zimbabwean context, the variety of crops displayed was impressive, especially given the two devastating droughts the country had experienced. Many farmers visiting the fair had thought that most of the exhibited crops and varieties had been lost. Some farmers remembered the role these crops had played in local food security in the past. Hence, seed was gladly exchanged or bought, so such crops could be grown again.

In a number of districts, seed fairs have become a regular annual feature. Generally they take the form of a one-day event. Organising these fairs are now entirely in the hands of the farming community. Farmers plan when to hold the fair and who to invite. They elect a committee to be responsible for running the fair. There are many things to deal with: money has to be collected for prizes; criteria set down for judging exhibits; knowledgeable persons have to be invited as judges and food and refreshments must be served.

Most of the farmers involved are women and they play a crucial role in setting up the fairs and exhibiting crops and varieties. Many of the crops displayed are the women's responsibility and they play an important role in securing household food security. It can be said that making sure seed is available at household level is mainly women's business.

However, farmers do not feel that they are the custodians of something geneticists want to preserve for future use. Their perception of biodiversity is pragmatic and more related to managing their immediate individual life-styles and economic needs. Two aspects seem particularly important to farmers: first, the search for crop diversity and, second, earliness to increase the farmers' ability to cope with adverse weather conditions.

Seed fairs have strong roots in the past. Zimbabwe has a concept of "zhunde ramambo" literally, 'the king's granary'. Communities were expected to donate seed to this granary. First, farmers had to display their wares for inspection by the king and the community. Then, seed was stored in a communal granary with much traditional ceremony. Because of these customs, each community has a different sociocultural approach to organising seed fairs because they assume a quasi-religious character.

Outlook

The present abundance of crops and varieties being displayed at seed fairs is, however, under threat. The advent of crop commercialisation brought with it the use of improved varieties. Their apparent qualities and uniformity made them seem very attractive and many farmers no longer saw any reason to maintain the old varieties. This trend is clearly illustrated by the fact that there are regularly 70 entries for sorghum and millet but only 4 entries for maize.

This situation is certainly influenced by some factors specific to Zimbabwe where open-pollinated maize varieties are not allowed on the official seed trade market. The environments where sorghum and millet do well are generally not well suited to maize. There is an indication that a more market-oriented crop production infringes on diversity. Still, we may yet witness a gradual change towards an increased use of traditional varieties as depressed commodity markets push farmers towards a farming system that is primarily geared to household food security. This may lead to farming systems that thrive on diversity of crops and varieties. New chances may also come as the demand from affluent societies for long forgotten indigenous vegetables, herbs, root, tubers, and grain increases.

Local views on genetic resources conservation

Raul Boncodin & Belita Vega

UPWARD studies of community-based conservation of root crops, especially sweetpotato, show there are gardeners, farmers, and traders who, by experience and skill, have developed a local reputation as "experts" in sweetpotato growing, processing and marketing. These local innovators serve as indigenous farmer leaders ensuring effective cultural farming practices and, as providers of new planting materials, they are important links in sweetpotato seed systems.

The significance of local involvement in genetic resources conservation is increasingly recognised. However, several basic questions still need to be explored. The UPWARD Genetic Resources and Biodiversity Contact Group brought researchers and local innovators together to share ideas on root crop genetic resource conservation during a Local Conservationists' Workshop held at ViSCA, Leyte, Philippines (1998). UPWARD's genetic resources projects - supported by IDRC (International Development Research Center) - were also scrutinised.

Genetic resources conservation

How do local people define genetic resources conservation? In agrobiodiversity conservation research it is a clearly defined concept with a definite purpose – stopping genetic erosion and increasing on-farm diversity. Local people, however, have very dynamic conservation perspectives. One workshop insight was that local people view genetic resources conservation in terms of the crop's importance to their lives – conservation cannot be dissociated from crop usage. Decisions to conserve a variety depend largely on its usefulness.

What crops are conserved?

Most participants were concerned about the need to conserve different root crop cultivars but recognised changing local socioeconomic and agroecological conditions limited possible initiatives. In the past, for example, commercial sweetpotato farmers from Leyte maintained several traditional sweetpotato cultivars to satisfy local demand. Recently, however, they were compelled to discard these cultivars in favour of the high starch content varieties needed by the newly opened sweetpotato starch factory. Although several farmers kept some of the discarded varieties for home use, a significant number of traditional sweetpotato cultivars were lost.

The Ivatans of Batanes also had a wide variety of sturdy root crop cultivars. Well adapted to the island's harsh environment, these traditional staple foods had been conserved for generations. In 1970, rice was introduced and rapidly took over. Root crops were relegated to supplementary foods useful during typhoon months when rice stocks were low. Because the Ivatans no longer found them useful, many root crop cultivars were lost as food preferences changed.

Such examples show that socioeconomic and agroecological change increases the vulnerability of local systems of conservation and should be considered in community-based conservation initiatives. Conservation cannot be limited to a formal institution's mandate crop. It must take account of the wide range of crops farmers need to survive.

How do people conserve?

Local farmers conserve preferred cultivars by continuously planting them on their farms, homegardens and plots. In Baloi, Lanao del Norte, farmers transferred some choice traditional sweetpotato cultivars to fertile upland areas when cassava became the dominant farm crop. When cassava farming became less attractive, farmers reintroduced sweetpotato. Upland plots provided the necessary planting material.

Storing planting materials using ancestral, indigenous storage techniques also contributes to the conservation of genetic resources. During prolonged drought, a gardener from Bukidnon, for example, preserves sweetpotato tubers by putting them in a basket covered with dry sweetpotato leaves and storing them, dry and cool, under her house.

photo: Raul Boncodin

Conservation through use was the strategy adopted by most workshop participants. The sustainability of conservation initiatives is enhanced when they lead to concrete uses and benefits. Homegardeners in Baguio City have ventured into sweetpotato-based snack food processing using different varieties of sweetpotato. This provides a livelihood for women gardeners and helps conserve traditional sweetpotato cultivars.

Who are local conservators?

Since conservation is a specialised activity, only a few individuals in a community can be considered local conservators. They are usually key members in the farming community, and have considerable knowledge of genetic resources conservation and a more conscious and systematic approach to crop conservation. Men tend to conserve on-farm while the women's domain is the homegarden. In Bukidnon, young pupils and schoolteachers are helping to conserve local traditional sweetpotato varieties by maintaining a school sweetpotato gene bank. This develops a culture of conservation among the children and provided the community with a source of good planting material. Sweetpotato traders also have a unique knowledge of conservation as workshop discussions made clear. Future initiatives should take this into account.

Two areas of community-based conservation for further UPWARD study were identified at the workshop:

- Developing a user-driven approach to participatory genetic resource conservation by creating market demand that encourages the use of a wide range of root crop varieties. This might be achieved by: a) linking genetic resources conservation to seed systems to ensure healthy sweetpotato planting material is available when needed; b) developing household-based snack food enterprises using home and school gardens as sources of raw materials.
- Investigating challenges in transition agroeconomies. This study should examine how economic, industrial, environmental, and social changes have affected local genetic resources conservation and the role root crops play in changing livelihood systems.

Creating common ground in collaborative crop improvement

Daniela Soleri, David A. Cleveland, Steven E. Smith

Improving farmers' crop populations may help meet farmers' needs and ensure the continued use and *in situ* conservation of local crop varieties. Collaborative or participatory plant breeding (CPB or PPB) is an approach with the potential to increase the productivity and relevance of crop improvement efforts, especially for low-resource farming households in difficult environments. Two elements are central in CPB. First, the adaptation of crop populations to local biophysical and sociocultural environments and second, interaction between farmers and professional plant breeders. Creating an effective basis for collaboration that integrates the insights and skills of farmers and breeders and ensures mutual respect is a major challenge for CPB. What methods can be used in CPB to help farmers and breeders talk and work together to produce crop varieties that better meets farmers' needs?

What can plant breeders offer?

Many small farmers in the Third World have derived little benefit from modern plant breeding. In part this was because conventional breeding approaches were ineffective, or because of the belief that improving the productivity of higher input systems was a better way of increasing food production and peoples' well-being than supporting low input systems. Modern scientific plant breeding has tended to emphasise the development of modern varieties (MVs) adapted to producing high yields in geographically widespread, but generally favourable environments. However, low adoption rates among small-scale, low-resource farmers indicate that MVs are not appropriate for these communities. Still, when some of the conclusions of modern plant breeding are understood in terms of the contributions of both the values and theory on which they are based, it is easier to see what plant breeders have to offer CPB . Theories, empirical knowledge, and techniques for analysis developed from years of experimentation and observation about plant development, the way genes function in this development, and the influence of growing environments, provide a systematic research framework. Recognising this fact, a small minority of plant breeders are applying plant breeding theory and techniques and CPB specifically to the needs of small-scale, low resource farmers.

What can farmers offer?

Until recently much CPB activity has emphasised the participation of farmers in such plant breeding tasks as selecting from breeder-developed material. Farmers' plant breeding experience and theory has not been brought into CPB because little is known about it, either in farmers' terms or in terms of the theory of scientific plant breeding. Farmers obviously have much to offer CPB. First, they are the ones who will use and judge varieties. Second, farmers' practices and theory frequently represent long-term experience with the plant genetic and environmental variation components of their farming system.

Table 1. Characteristics of the communities studied in the Central Valleys of Oaxaca, Mexico.

Characteristic	Santa Maria	San Antonio
Elevation (msal)	1490	1780
Average annual precipitation (mm)	685	468
Predominant soil characteristics	alluvial, sandy clay	piedmont, gravel
District average maize yield (t/ha)	0.76	0.45
Average maize sowing rate/ha	47,000	40,000
Population (1995) *	2800	2533
Predominant ethnic/linguistic group	Mestizo/Spanish	Zapotec/Zapotec

** 1998 estimates for both communities = 3000, M. Rees personal communication 1998.*

Research approach

In this article we use examples from ongoing research with maize farmers in the Central Valleys of Oaxaca, Mexico, to illustrate how the insights of farmers and plant breeders can be brought together to facilitate a better understanding of local maize seed selection practices. We also explore the implications for collaboration and hope to come to a clearer understanding of what the components of the biological model of selection used by plant breeders looks like from the farmers' perspective. Given the time and often money invested in seed, it seemed likely that farmers expect certain results from the selection process.

Materials and methods

We worked with a sample of eight farm families in a community in the Zimatlan Valley and with five families in the Mitla Valley (Table 1). We tried to make the sample representative of household types in each of these communities in terms of wealth and the gender of head of household. Interviews were conducted with those primarily responsible for agriculture: the wife and husband or mother and son. Younger workers were also interviewed but they usually deferred to the primary pair. In our analysis of these maize seed selection systems we wanted to describe and quantify selection and come to an understanding of the theory that guided farmer seed selection practices.

Quantifying farmers' practice

Through participant observation, informal discussion, and formal interviews with the 13 collaborating households, we identified three categories of selection criteria. First, seed quality and seedling vigour. Second, traits such as ear length, weight and diameter, kernel size and weight as well as the weight/volume of shelled kernels. Third, traits that define a variety type or subtype, which in our sample included such traits as grain type, grain form, and cob and husk colour. Although criteria in the third category varied from household to household and between the communities, the first two categories were universally applicable.

As selection exercises demonstrated, these criteria and particularly the first two categories, were reflected in farmers' selection practices. Using a random sample of 100 ears of the common local white maize variety from a field in their community, we asked households to select ten of the "best" ears for local planting seed. These were then evaluated for a series of traits including ear diameter, length and weight.

We then conducted a field experiment with white maize populations from three households in each community in order to quantify the response to farmers' selection in the maize populations. Since 1996, we have obtained three generations of farmer-selected samples and two generations of corresponding random samples from the same population from each household (Figure 1). All of these samples were sown with eight replications in a completely randomised block design in a field belonging to one of the collaborating households in the Zimatlan Valley. The experimental field was prepared and managed by the household according to local practices.

Farmers' theory

Participant observation, informal discussions and formal interviews all contributed to our understanding of the theory underlying farmers' selection practices. Using maize ears and photographs of maize tassels of different colours to illustrate the scenarios, farmers were asked what the phenotypes of the progeny of particular selections grown in different environments would look like. Questions about the expression of traits in normal and optimal environments provided a way of understanding farmers' theories regarding abstract concepts such as heritability in their maize varieties and environments. We found that the biological model provided a useful framework for understanding local selection practices. However, its utility in terms of supporting CPB appeared best when we tried to deliberately investigate its components from farmer's perspectives.

Common ground

We started to explore farmers' selection practices with the idea that selection is about changing crop populations. When we asked households what they were looking for when they made selections, we were invariably told "los mejores" - the best. When we asked questions about how they wanted to change their populations, the answers we got were often confusing. Looking at farmers' perspectives-exploring farmers' practices, the theory behind them, and their implications for maize populations was more productive. It revealed our own mistaken assumptions and allowed farmers to explain their own understandings, theories, practices and objectives in maize seed selection.

The following findings from the interviews, selection exercises, genetic perceptions scenarios, and field experiment in this study are of relevance for facilitating farmer and plant breeder interaction.

- Farmers' selection criteria as they defined them and their selection criteria as demonstrated by the selection exercises identified ears and, to a lesser extent, seed size traits as important once seed quality (freedom from pest and disease damage) had been assured.
- Selection for these criteria appeared directional and seemed to try to change the populations' mean value for these traits.
- Farmers' answers to genetic perception scenarios, however, showed that they saw traits such as ear length as having no heritability either in their own, variable fields or in hypothetical uniform ones (Figure 2). Most farmers regarded ear length to be product of the growing environment in which the maize population developed. This being the case they expected no response to selection for such traits and implied that they saw no genetic variation for that trait. This did not mean farmers were unable to recognise genetic variation or understand the potential of selection. They pointed out that a trait with a high heritability such as tassel colour, could be selected and change would appear in the progeny as a result of that selection (Figure 3). The presumption that farmers practise selection to change their maize populations, our original interpretation of farmer responses to interviews and selection exercises, was not supported by farmers' theories.
- There was virtually no response to selection in the field experiment. The absence of a response to selection for traits identified as primary selection criteria confirmed farmers' own opinion that their selection would not change their maize populations.

Relevance

Several of these findings are relevant to practice and may change the way in which farmers and breeders work together on CPB. Farmers are concerned with seed quality and seedling vigour at the moment. Farmers would probably be interested in research into improving the pest and disease resistance of maize ears especially during storage.

Second, understanding that farmers do not see the potential of selection to change some of the traits in their maize populations, and, therefore not the purpose of their seed selection, highlights a significant difference between their objectives and those typical of plant breeders. For this reason attempts to improve selection practices may not always seem worthwhile or even logical to farmers. A more affective approach may be to improve heritability for the traits farmers may want to change if they believed they could. This means making genetic variation visible and accessible to them and making it possible to respond to selection.

Finally, helping plant breeders and other researchers achieve a better understanding of farmers' practices and knowledge, including their theory, helps create a basis for mutual respect and collaboration. The genetic perception scenarios were not undertaken to test farmer knowledge, nor ▶

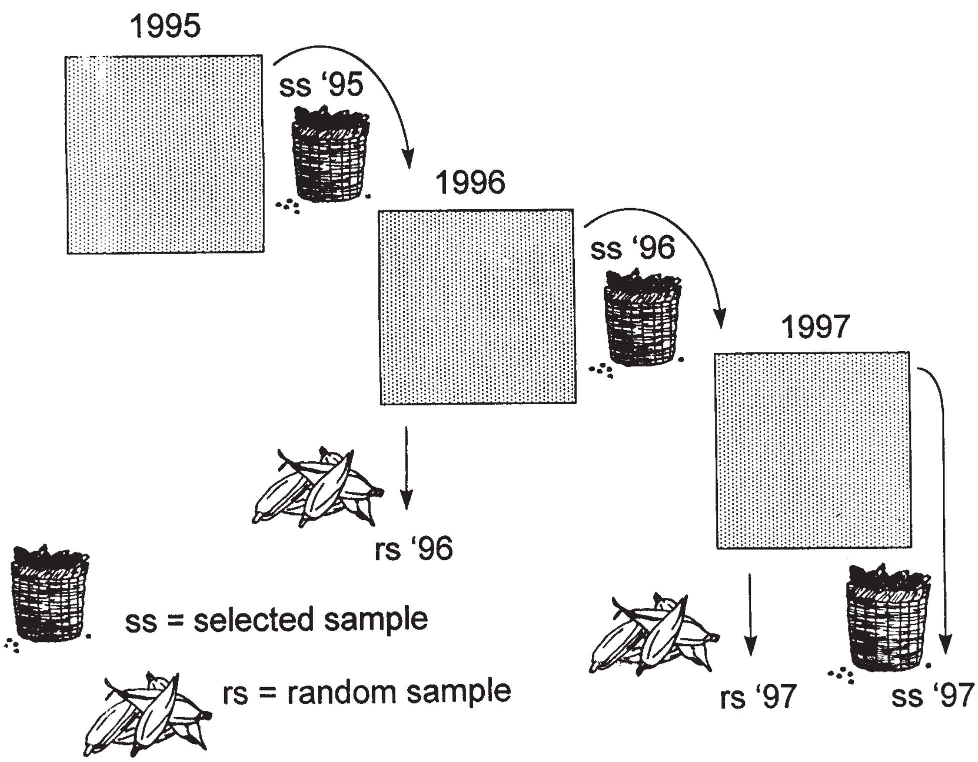

Figure 1 Response to selection: year and type of seed used for each population

was their knowledge compared to any "correct" or "scientific" standard. We recognise that many other factors contribute to farmers' knowledge about their crops including sociocultural, economic and individual variables. The approach described here tries to neutralise the realm of practice—in this case seed selection and crop improvement—to the extent that the dichotomy between "scientific" and "non-scientific" practice is abandoned—and the common elements contributing to farmer and plant breeder practice are recognised.

Seed selection and biodiversity maintenance by women farmers

The International Center for Wheat and Maize Improvement (CIMMYT) started a maize-breeding programme at the end of the 1970s in southwest China where 25 million poor farmers in remote upland areas depend on the crop for their staple food. An impact study of this ongoing programme was financially supported by CIMMYT and carried out by the author from 1994 to1998.

Yiching Song and Gigi Manicad

Food security in China will continue to occupy a top position on the international food security agenda in the coming century. Sustainable production of staples such as wheat, rice and maize depend on the systematic mixing of crop varieties of various origins and genetic makeup.

Researchers are becoming more aware of the role of farmers' seed systems and their knowledge of crop development and biodiversity conservation. China has followed a modern technology-oriented approach and has relied mainly on its public seed system to ensure national food security, notably in response to the great famines of the late 1950s. The most noteworthy development was the establishment of public agricultural research and extension systems for modern varieties. Some 30% of Chinese food production can be attributed to the development and promotion of improved planting materials, especially hybrid wheat, rice and maize (Lin 1998, Fan and Pardey 1997). China was the first country in the world to plant significant areas of genetically modified crops in the early 1990s (Song 1999).

The Chinese rural economy has experienced a rapid growth since the adoption of a broad programme of rural economic reforms in 1978, and China has been widely acclaimed for its achievements in food production and poverty alleviation. However, in a rapidly changing social context and natural environment, marginalised farmers, especially women, find it difficult to adapt to change. The farmers of the remote upland areas in south-western and north-western China make up a large proportion of the 60 million Chinese who live in poverty.

Feminisation of agriculture

The feminisation of agriculture is an important phenomenon in China. Women constitute more than 80% of the agricultural work force because of the volume of male out-migration (Song 1998). As a result, women are overburdened with agricultural activities that give little or no profit. There are fewer opportunities for women-headed households to adopt modern varieties owing to their limited access to resources and services (Jiggins 1986, Song 1998, 1999).

Furthermore, continuous agricultural exploitation since the early 1960s, guided by the state's single-minded aim of only targeting higher yields in its struggle to secure national food security, has tended to degrade natural resources and agroecology. This has negatively affected the resilience of the ecosystem and the sustainable livelihood of farmers and poor women in particular.

What has been happening in areas where natural resources are limited? How are improved plant materials meeting the needs of poor farmers and what is the role of formal and farmers' seed systems in crop development and biodiversity enhancement? The CIMMYT Collaborative Maize Breeding Programme in south-western China set out to collect information on areas with limited natural resources. The study assessed the impact of modern varieties and analysed the capabilities of public research and farmers' knowledge in dealing with food security, poverty alleviation, and agrobiodiversity conservation issues at different levels.

Impact of CIMMYT material

The impact study revealed that CIMMYT genetic material had had a significant effect both in hybrid development and in direct use. This had been achieved through the formal seed system and farmers' informal systems:

- Public breeding efforts have led to the adoption of CIMMYT-related hybrids but yield increments have been of limited benefit for resource-poor farmers in marginal rain-fed areas;
- CIMMYT's maize germplasm has had a considerable impact on household food security and poverty alleviation through the informal system which has assured the wide distribution of CIMMYT's improved populations.

Tuxpeño 1

Tuxpeño 1 (local name *Mexican 1*) is an improved population that was developed by CIMMYT from a landrace that originated from Tuxpau, Mexico. *Tuxpeño 1* was introduced in Southwest China in 1978, originally as a constituent for variety improvement and hybrid combination. However, *Tuxpeño 1* was rapidly disseminated through south-west China, mainly through farmers' seed exchange systems. Due to its broad adaptability, stability and good stress tolerance, especially lodging resistance, *Tuxpeño 1* became particularly popular with farmers in difficult farming systems in the remote mountainous areas. Here, it has contributed significantly to household food security and poverty alleviation in the last two decades. Meanwhile, due to the poor quality of government supplied hybrid seed, *Tuxpeño 1* has increasingly been adopted by farmers in relatively favourable areas. However, since maize is an out-breeding crop, *Tuxpeño 1* has, in the absence of an improvement effort from formal breeding, degenerated greatly by out-crossing, resulting in decrease of yield, increase in plant height and loss of stress resistance characteristics. Farmers have requested the government to assist them in improving the material but in vain. This has led to efforts by local women farmers to regenerate *Tuxpeño 1*.

Women farmers' initiatives

Geographical variation is a major feature of Chinese agriculture. Regional variability in farming systems and differentiation among farmers are increasing as a result of recent reforms. Different farming systems and other ways of using maize mean different needs for, and thus interests in, technology and genetic diversity. The big gap between the breeders' limited supply and the diversity of farmers' needs has led to indigenous knowledge systems being activated and developed as farmers work on the neglected, improved Open Pollen Varieties (OPVs) and landraces to suit them to their own needs. Socioeconomic factors, including the feminisation of agriculture has meant that local seed selection and landrace maintenance is mainly done by women.

Case studies were carried out in Wenteng and Zhichen villages in southwest China where conditions were representative but contrasted sharply. Wenteng is typical of the relatively better-off communities found in the valleys and flat areas, where farmers are educated and better integrated into the market economy. Pig raising is the main source of income for most villagers and farmers now use maize as pig feed. Zhichen is representative of the poorest and most remote of mountain communities. In this harsh and rugged environment access to market is very limited. Maize is the traditional, staple food crop and there is a large variety of landraces.

Different strategies followed

The following two cases show the initiatives made by women farmers in the two villages in transforming and 'creolising' exotic varieties and in maintaining landraces.

Case 1 Wenteng

Wenteng farmers used to cultivate hybrid maize. However, most of them have recently shifted to improved OPVs mainly as a result of the limited options offered by hybrid varieties, and the decreasing quality of government-supplied hybrid seed. Due to the lack of institutional support and the popularity of *Tuxpeño 1*, women in Wenteng village have been organising themselves to maintain and improve *Tuxpeño 1* since the 1980s. An innovative woman had initiated this activity by trying to maintain *Tuxpeño 1* after it had been adopted. The crop development methods used by the women include spatial separation through the use of plots at different locations, temporal isolation and seed selection. These methods are critical for population maintenance. The women explained that due to the popularity of *Tuxpeño 1* and the women's initiative in selection, it is easy to organise women farmers to grow it in adjoining fields isolated from other varieties. The women mainly select according to mass selection both in the field and after harvesting.

The three steps in seed selection are first to select the best plants in the middle of the field: phenotypes with big ears and other desired agronomic traits. Second, select the best ears (based on cob size, length and number of seed rows) and finally the best grains are chosen from the middle part of the cob according to kernel size, shape, quality, and colour. The women farmers claimed that these techniques have been passed on for generations and they use similar techniques for the maintenance and improvement of landraces. They also added that some of their selection knowledge and skills were gained by their parents or by themselves from the so-called 'bare-footed scientists' during the time of Mao.

As a result, the varietal quality, in terms of preferred agronomic traits and yield of *Tuxpeño 1* in Wenteng village has been maintained and improved in such a way that it is better adapted to local conditions. Most villagers now consider it to be a local rather than an exotic variety. It is not surprising that the improved *Tuxpeño 1* has spread rapidly to neighbouring areas through farmers' informal seed exchange systems. Today, Wenteng is a source for quality *Tuxpeño 1* seed over a large area.

Case 2 - Zhichen

Farmers in the harsh environmental conditions of Zhichen considered improved OPVs and some landraces appropriate technologies with the capacity to meet their needs. *Tuxpeño 1* was introduced into Zhichen at the end of the 1970s and became the dominant maize variety soon after. In contrast to Wenteng farmers, Zhichen villagers, mainly women, did not do much to improve *Tuxpeño 1* themselves. They maintained preferred landraces instead. Zhichen villagers feel that *Tuxpeño 1* has degenerated beyond their skills to improve it. While hoping that the government will improve *Tuxpeño 1* as a foreign variety, they also realise they will not receive any outside help to maintain their local varieties.

The farmers chose to maintain and improve three local varieties in accordance with their complex farming system and livelihood. *Duan 1*, an OPV improved by the county extension station in the 1960s, is maintained for its good drought resistance. Despite its low yield, farmers use this variety during the second cropping season in the autumn because no other variety will survive severe drought. The methods used by the women farmers to maintain the three local varieties include spatial isolation (growing them in isolated gardens or separate valleys) and post-harvest seed selection of the best cobs and kernels. Zhichen villagers say this knowledge has been passed down over the years. Compared with the women farmers in Wenteng, farmers in Zhichen maintain more diversity for risk management.

Fostering synergy

These farmer' adaptive strategies towards *Tuxpeño 1* show that their selection priorities and objectives reflect environmental conditions, market opportunities and institutional relations as well as socioeconomic positions and risk management. Wenteng has maintained and improved *Tuxpeño 1* while Zhichen has chosen to maintain local landraces. Given the fact that maize is their staple food crop, Zhichen farmers chose maize varieties that reflect their risk-aversion strategies. Despite the agronomic popularity of *Tuxpeño 1* other varieties were maintained and improved by Zhichen farmers for nutritional and cultural reasons and because they ensured a reliable supply in the most adverse environmental conditions. In Wenteng, on the other hand, *Tuxpeño 1* fitted the requirements for a commercial crop and a production surplus made farmers more ready to take risks. In addition, Wenteng women's greater skills in varietal improvement and seed selection reflect external influences and their better access to information and education. Zhichen women farmers, by contrast, live in isolation and are often illiterate.

Women expertise vital

These case studies also showed that the feminisation of agriculture was an important phenomenon in the remote upland areas and that women play a predominant role in subsistence agriculture and food security. Seed maintenance and selection are entirely managed by women who draw on their indigenous knowledge and informal systems. Women farmers play significant roles in crop development and agrobiodiversity maintenance. However, their access to resources and public services is much more limited than that of men farmers.

A gender analysis and the involvement of women expertise in technology design and development is vital in meeting the specific needs and interests of women. This can substantially contribute to reducing poverty, ensuring food security and enhancing biodiversity at farmer household level (Jiggins, 1986, Quisumbing, Brown et al. 1995, Song 1998)

Better collaboration needed

The experience of *Tuxpeño 1* and the two case studies related here show the considerable impact CIMMYT's genetic material has had on household food security and poverty alleviation. However, this potential was only fully exploited because of the mediation of farmer's informal systems. This shows the need for better institutional linkage and collaboration between the farmers' and formal systems in crop improvement. In this way local dynamics and the role of farmers can be fully exploited in ensuring sustainable food security and on-farm agrobiodiversity management. ■

Farmers' management of genetic variability in rice

Anthropological fieldwork undertaken among semi-subsistence rice cultivators in northern Sierra Leone found that a number of farmers practised a technique of intra-specific rice cropping whereby the seed of two carefully chosen varieties – usually a glaberrima and a sativa variety - is intentionally mixed. Farmers who mixed varieties in this

Catherine Longley and Malcolm Sellu-Jusu

way explained distinct gastronomic and agronomic advantages offered by this technique. Although the grain of the glaberrima type retains a slightly hard texture when it is cooked, it is pleasantly filling when eaten. This is because it has high gluten content and is less easily digested. High gluten content is regarded as a positive feature because it makes a person feel full for longer after eating it.

The sativa variety, on the other hand, is much 'lighter' in the stomach, making a person feel hungry again quite soon. The gastronomic advantages of the *sativa* variety lie in the texture and taste of the cooked grain, which is both softer and tastier than that of the glaberrima variety. Thus, the two rice types have complimentary gastronomic qualities in terms of texture, taste, and filling ability. The gastronomic disadvantages of each (hard texture, poor taste, and low filling quality) are reduced when eaten as a mixture.

In the case study area it is not uncommon to see farm plots sown to a mixture of *disi kono (O. glaberrima)* with *samban konko (O. sativa)*. The glaberrima variety is able to withstand drought, whereas the sativa variety is generally higher yielding. A number of farmers explained how they originally mixed the two seed types in carefully chosen ratios for optimum performance and preferred eating qualities. The ratios in which farmers mixed the glaberrima variety with the sativa variety were variable and ranged from roughly 30% to 150%. Seed for the following year is taken from the mixed stands and no particular method of panicle selection is used. Most farmers who intentionally mixed their seed in this way observed that the ratio of varieties in the mixture tends to change over the years, and some farmers add a certain quantity of one of the varieties so as to maintain the optimum ratio. There was considerable difference of opinion as to whether the *glaberrima* or the *sativa* variety became predominant over time. Although *O. sativa* tends to be higher yielding, *O. glaberrima* is considered to be the better upland competitor, particularly on drier soils. In drought years, *O. sativa* may produce a high proportion of empty grains and the more drought-resistant *O. glaberrima* becomes predominant.

Trials carried out over two seasons at the Rice Research Station, Rokupr, Sierra Leone used replacement series analysis. A replacement series experiment contains different proportions of two varieties in mixture in addition to pure stands (monoculture) of each variety. The yields of the varieties in mixture are compared with the yields of the varieties in pure stands to estimate their performance in competition. The purpose was to investigate how one variety influences the other when cultivated in mixtures involving *O. glaberrima* and *O. sativa* types collected from farmers' fields. The experiments were designed to study the effect of water availability on variety mixture; how changes in plant density affect varietal competition under different conditions; and the effects of competition on the agronomic features of the varieties grown in mixture. The results of these experiments are described in full by Jusu (1999). The trials largely confirmed the farmers' observations described below and showed that mixture yields were generally higher than the mean yield of the varieties grown in pure stands.

Varieties imitate one another

Farmers' observations reveal that the rice varieties, when planted together, behave differently than when grown in pure stands. This phenomenon is explained locally by both the competitive nature (known locally as *gbehteh*) and copycat behaviour or mimicry which farmers regard as common among crop species. Rather than a divergence in flowering times and the avoidance of competition, as might be expected, a small number of farmers very clearly report that the varieties appear to imitate one another in terms of flowering and ripening times, panicle size and tillering ability. Experimental results showed that both plant height and the number of tillers tended to converge when the varieties were grown in mixture. The variety that had fewer tillers in pure stand produced more tillers in mixture, and the variety with more tillers in pure stand produced fewer tillers in mixture. Similarly, the height of the shorter variety in pure stand increased in mixture and the taller variety decreased in height when grown in mixture.

When grown on low-fertility soils, the general pattern was that the flowering times of the varieties tended to coincide when in mixture so that they both came to maturity at the same time. This apparent synchronisation in the flowering times of rice planted in mixtures would appear to increase the likelihood of accidental cross-pollination.

Author Malcolm Sellu-Jusu and on-station rice experiment

Competitive interactions and neighbour effects are known to be major factors conditioning adaptive strategy and species diversity (Sano, Sano & Morishima 1984).

Risks decreased

Other agronomic advantages cited by farmers practising this technique of intra-specific cropping include an increased ability to withstand drought, increased resistance to bird attack, reduced lodging, and/or reduced panicle neck breakage. The *sativa* variety, *samban konko*, is known as a rice variety that has little resistance to drought; for this reason it is best planted early on low-lying, moisture-retentive soils. If the rains are late or insufficient, *samban konko* produces empty grains. The *glaberrima* variety, *disi kono*, on the other hand, is better able to withstand drought and can be cultivated on the dry, gravely soils at the top of the slope. A farm plot planted to a mixture of these two varieties will always yield something, even if the rains are insufficient; if the *samban konko* fails, the *disi kono* will succeed. In addition, a small number of farmers suggested that the roots of *disi kono* somehow help the *samban konko* to take up water, thus enabling it to better withstand drought. One farmer explained this by suggesting that *samban konko* sucks water from the roots of *disi kono*.

Most farmers who practised intra-specific cropping also reported that bird damage was reduced on plots planted to mixed varieties. Birds are believed to be attracted to rice as it begins to mature both by its scent and its visual appearance. The slight difference in flowering times and the duration from flowering to maturity on a plot containing *samban konko* and *disi kono* was believed by some farmers to confuse the birds and prevent damage. Other farmers described how the differences in the height and stature of the rice varieties made it difficult for the birds to see that the *disi kono* had flowered and was beginning to ripen. Farmers who did not practice intra-specific cropping tended to cite the same factors as evidence of increased bird attack. They claimed that the *disi kono* attracted birds as it ripened and that the birds not only damaged the *disi kono* but also the *samban konko*.

photo: Catherine Longley

Less yield losses

Farmers also differed in their observations of lodging on a plot planted to mixed varieties. *Disi kono* has a tendency to lodge when it is dry. This can be reduced to some extent on a mixed plot because rather than falling flat on the ground, the rice plants merely lean against the upright stalks of *samban konko*. On the other hand, *samban konko* has a large, heavy panicle and the panicle neck tends to break if the rice is not harvested on time. The damage caused by this breakage can be prevented in a mixed plot because the *disi kono* lodges and causes the *samban konko* to also fall and lie flat on the ground. Once flat on the ground, the panicle neck does not break. It was implied that this was an advantage to those lacking the labour necessary to ensure that harvesting is carried out on time, before the panicle neck breaks. This difference in observations on lodging is most probably related to the different ratios in which the varieties are mixed, and would seem to partly explain the variation in what is considered to be the optimum ratio, mentioned above.

An intermediate rice type?

In sum, it could be argued that intra-specific rice cropping is a risk avoidance strategy adopted by farmers who are short of labour for scaring birds and timely harvesting. Farmers who plant slightly later in the season also incur the risk that *samban konko* may not take sufficient water during its growing cycle. This risk is perhaps reduced when *samban konko* is sown in mixed stands, particularly if *disi kono* does indeed increase the former's ability to take up water. In any case, a farm planted to mixed varieties will always yield something, even if *samban konko* produces empty grains. Research from Nigeria has suggested that farmers practice intra-specific cropping 'because it is safer to obtain stable yields in conditions where the climate fluctuates year after year' (Sano, Sano & Morishima 1984: 253).

It has also been suggested that farmers who practise intra-specific cropping may do so for reasons relating to their choice of farm site (Longley & Richards 1993: 56). In the case study area, crop rotation is practised whereby rice is cultivated in the first year and groundnuts, an important cash crop, in the second year. The slightly gravely, rain-fed sites that are best suited for large-scale groundnut farming are not ideal for the high-yielding *sativa* rice such as *samban konko* which does best on low-lying, moisture-retentive soils. It is possible that some farmers, particularly those who are most dependent on the cash economy for their livelihoods, prefer to select farm sites that are most suitable for groundnut production. Such sites are best suited to lower-yielding *glaberrima* varieties. By planting a sativa variety (e.g. *samban konko*) on such sites, farmers run the risk of low rice yields if the rains are insufficient. However, this risk can be averted if *samban konko* is mixed with *disi kono*.

By intentionally mixing *O. sativa* and *O. glaberrima* rice types in this way, Susu farmers may be providing the conditions under which accidental fertilisation might occur across sterility barriers, giving rise to an intermediate rice type displaying characteristics of both *O. glaberrima* and *O. sativa*. Though cross-fertilisation is rare, such an intermediate type might be highly desirable, particularly if it displayed the sativa trait for high yield together with the *glaberrima's* stability in sub-optimal conditions. Rice breeders have, in the past, tried and failed to cross these species. Viable crosses have recently been made by Dr Monty Jones, a Sierra Leonean rice breeder currently on the staff of the West African Rice Development Association (WARDA) at Bouaké (Jones et al, 1997). Though it has yet to be verified, it is possible that farmers have unknowingly achieved what scientists have been trying to do for decades. ■

Informal bean seed systems

Frew Mekbib

Informal seed systems cover methods of local seed selection, production and diffusion. Such a system is described as traditional, informal and operates at community level through exchange mechanisms. Limited quantities are involved in each transaction. This corresponds with the traditional seed sector (Camargo et al 1989; Cromwell et al. 1992). According to Almekinders et al. (1994), it is non-specialised seed production, integrated into the production of grains, roots and tubers for consumption and marketing.

Informal seed systems are very important for crop production in Africa. The formal seed sector in Eastern and Southern Africa gives low priority to seed from self-pollinating crops such as common bean (*Phaesolus vulgaris L.*) (Sonia, 1994). For centuries virtually all Ethiopian seed supplies have been generated within an informal system. The country's formal seed system devotes much attention and money to lucrative hybrid producing crops.

Table 1. Farmers' criteria for good seed

Criteria	Percentage
Physical purity (no physical defect, not mixed, pure)	3.4
Seed characteristics (uniform size, red/white/mixed coloured, seed shape)	10.2
Growth characteristics (not climbing, early maturity, synchronised maturity, determinate growth habit, non shattering)	5.1
Performance (productivity, stress tolerance)	3.4
Seed health	1.1
Seed characteristics, performance	5.7
Physical purity, seed characteristics	11.9
Seed characteristics, seed health	8.0
Physical purity, seed characteristics, seed health	17.0
Seed characteristics, performance, seed health	6.3
Seed characteristics, growth characteristics, seed health	3.4
Combination of all five characteristics	37.7

Table 2. Reasons cited for loss of varieties

Reasons for loss	'74–'83	'84–now	Total %
Low productivity	2.3	7.4	9.7
Varietal growth characteristics	8.6	4.0	12.6
Pests and disease susceptibility	6.8	1.2	8.0
Lack of enough land and seed	0.6	4.0	4.6
Introduction of new variety	1.8	6.3	8.1
Marketability	9.3	6.3	15.6
Moisture stress	2.0	4.2	6.2
Problem in cooking	1.8	0.6	2.4

In Ethiopia, there is only one public seed enterprise and the capacity of Ethiopian Seed Enterprise (ESE) in terms of farmer demand is low. The ESE finds it difficult to provide seed cheaply and in time. Because the ESE concentrates on crops that pay well, important indigenous crops such as *tef*, *ensete* and *anchote* as well as horticultural seed are either not produced or do not receive enough attention. Meanwhile, new private foreign enterprises like Pioneer Hi-breed only concentrate on crops like maize (Agrawal and Worede, 1991).

Common bean is an established component of Ethiopian agriculture. It is grown both for export and food. Farmers in the region use beans as a cheap source of protein, a cash crop, an emergency crop in times of crop failures, a supplementary animal feed and as fuel. Beans are used in crop rotations, intercropping and alley cropping systems (Mekbib 1997). As the informal bean seed system had been largely ignored by breeders and seed technologists, systematic and quantitative data on farmers' seed systems was needed for an integrated approach to bean seed dissemination, management and protection.

The survey

In studying the informal bean seed system, a survey was carried out of 176 farmers in Eastern Ethiopia. Beans are produced in every economic class within the farming community. Farmers indicated the characteristics of good quality seed (see Table 1). Characteristics included physical purity, seed characteristics, growth characteristics, performance, and seed health. Nearly 40% of the farmers mentioned a combination of all five criteria for good quality seed. Interestingly, when looking at combinations of various characteristics physical purity, size, shape and colour were considered more important than growth characteristics and performance.

The economic situation of the farmer had a significant effect on the amount of land planted with different varieties. Many varieties have been lost either deliberately or accidentally. Accidental loss in the period 1974-1983 was 4%; by 1999 it had reached 8%. Deliberate loss remained constant at 20% over the period 1974-1999. Lack of marketability and growth characteristics were cited as major reasons for loss of varieties (see Table 2).

Farmers mentioned various initial seed sources: most were purchased or received as gifts and, to a lesser extent, through loans and exchange. When there was a good crop the farmer switched to own stock. Reasons for changing from one variety to another are given in Table 3. Seeds are not often bought, and poor farmers in particular rarely buy seed. Bean seeds are generally purchased every other year. In case of the Coloured Bean and White Pea Bean varieties, 6-8% of the farmers had never bought seed and had used their initial seed stock. Farmers control seed quality by sorting and selecting at different stages.

The informal bean seed system is cheap, accessible to all farmers, and relies on indigenous knowledge of seed production, quality control, processing and marketing. However, farmers know little about seed-borne diseases. Also, there is a lack of landraces in the region. These factors negatively affect the informal seed system. To improve performance, the formal seed system should play a complementary role by providing new varieties and farmers should be trained to recognising seed-borne diseases.

The survey has allowed a clearer characterisation of local seed systems: the varieties grown, their characteristics and the way seed networks function. These insights are opening up the way for an integration of the formal and informal seed systems by introducing new varieties into the local seed system, in situ conservation of varieties with good seed characteristics, and the development of local seed business.

■

Table 3: Reasons given for changing from one variety to another

Lack of seed	14.5%
To restore bean production	9.4%
When the whole harvest is used for home consumption or sold	26.3%
For maintenance of the original seed	20.8%
When the seed is destroyed by biotic or abiotic causes	26.6%
To increase yield	8.6%
To maintain quality and purity of the seed	4.3%

Multifunctional biodiversity in Latin American traditional agriculture

Miguel A. Altieri

Traditional agroecosystems, based on the cultivation of a diversity of crops and varieties have allowed traditional farmers to maximise harvest security using low levels of technology and with limited environmental impact. Many Latin American agroecosystems are small-scale, geographically discontinuous, and occupy a variety of ecological niches. Richly diverse, site-specific farming systems are well adapted to local conditions.

Plant diversity, generally in the form of polycultures and agroforestry patterns, characterises traditional farming systems. Planting several species and varieties of crops in a minimum risk strategy stabilises yields in the long term, ensures dietary diversity, and maximises returns. Traditional multiple cropping systems provide 20% of the world food supply (Francis 1986). In Latin American tropics, most crops are grown in polycultures and produce a higher combined yield than under monoculture conditions (Francis 1986). Yield variability in cereal/legume polycultures is also low.

Many traditional agroecosystems are located in centres of crop diversity and contain populations of variable and adapted landraces as well as wild relatives of crops. Traditional agroecosystems constitute in-situ repositories of genetic diversity (Altieri & Merrick 1987). Considerable documentation exists on systems where farmers, planting multiple varieties of each crop, provide both intraspecific and interspecific diversity and enhance harvest security.

Tropical agroecosystems consisting of agricultural and fallow fields, complex homegardens, and agroforestry plots often contain more than 100 plant species per field. Most diverse homegardens are in reality a collection of domesticated and semi-domesticated plants where perennials like fruit trees are conspicuous features. Homegardens are similar to a tropical forest, with diverse species and a layered configuration.

Agroecosystems and nature

Most studies of traditional agriculture focus on the productive units where crops are grown. This ignores the fact that many farmers utilise, maintain and preserve areas of natural ecosystems (forests, hillsides, lakes, grasslands, streams, swamps) which provide valuable food supplements, construction materials, medicines, organic fertilisers, fuels, and religious items. Crop production units and adjacent ecosystems form a continuum where plant gathering, fishing, and crop production take place.

Many peasant societies consider agriculture to be part of a larger system of land use. For the P'urhepecha Indians of Lake Patzcuaro, Mexico, for example, gathering is part of a complex subsistence pattern based on the multiple use of natural resources (Caballero and Mapes, 1985). They use more than 224 species of wild native and naturalised vascular plants for food, medicine and fuel. Similarly, the Jicaque Indians, (Central Honduras) use over 45 local plant species for their domestic needs. They use slash and burn techniques to grow maize and cultivated fields are widely spaced throughout the forest. While travelling between fields, the Jicaque collect edible wild plants (Lentz, 1986).

Links

When agricultural development takes place in a natural environment, it tends to result in a heterogeneous mosaic of varying types of habitat patches. The bulk of the land is intensely managed and frequently disturbed for agricultural production. However, borders and strips between fields, roadsides, and adjacent natural areas is intensely managed while wetlands, riparian corridors, and hillsides are left in a relatively natural state.

Coffee farmers in Latin America typically integrate many different fruit, fuel and fodder trees into their farms. These give shade and provide a habitat for birds and animals. In Mexico, shade coffee plantations support some 180 species of bird. Some of these are important in pest control and seed dispersal.

Where traditional farming predominates, the minimal use of industrial inputs has produced varied, highly heterogeneous landscapes - possibly more heterogeneous than would exist naturally. In such environments, patches of natural and semi-natural ecosystem included in the landscape can become an agroecosystem resource and help preserve the integrity of natural ecosystems. Many small-scale agroecosystems are designed and managed to be friendlier to native species.

Conclusions

Learning how to combine environmental and productive functions in managing agriculture will require the input of agroecologists, ethnoscientists, conservation biologists, and landscape ecologists. Unless ecologically sound management practices are adopted multifunctional agriculture will be impossible.

By adopting a multiple-use strategy, indigenous farmers manage a continuum of agricultural and natural systems and ensure multifunctional agriculture. Recent research into diversified cropping systems based on intercropping and agroforestry has revealed new evidence to show that these systems are more sustainable and more resource conserving (Vandermeer, 1995). Data also shows that plant biodiversity has a positive effect on the stabilisation of agroecosystem processes.

NGO-led agroecological field projects have demonstrated that traditional crop and animal combinations can often be adapted to increase productivity when the biological structure of the farm is improved and labour and local resources are used efficiently (Altieri, 1995). In fact, most agroecological technologies can improve traditional agricultural yields and enhance general agrobiodiversity.

Basing a rural development strategy on traditional farming, ethnobotanical knowledge and elements of modern agroecology assures continued use and maintenance of valuable agrobiodiversity. It also allows for the diversification of agricultural areas ensuring a variety of ecological services vital for food security, natural resource conservation, economic viability, climate amelioration, cultural preservation, and community empowerment. Many grassroots rural development programmes in Latin America now aim at maintaining and enhancing biodiversity in traditional agroecosystems. The challenge is to promote policies and institutional partnerships that allow an up-scaling of ecologically based agriculture so that its multifunctional impacts can be spread across the rural landscapes of Latin America. ■

Women guard the sacred seeds of biodiversity

Vanaja Ramprasad

GREEN Foundation, based in Bangalore, Southern India, strives to conserve the agricultural biodiversity that is based on local culture and knowledge. Activities to collect, multiply, characterise, conserve and distribute traditional crop varieties like millet, gram, lentils, fingermillet, rice and sorghum take place in 50 communities. GREEN's Biodiversity Conservation Centre is located in Thalli, a rural area in Karnataka and here subsistence agriculture is researched and documented. Activities include food processing, annual seed fairs, group training, documentation, developing publications such as seed catalogues and strengthening indigenous knowledge. This article deals with some aspects of the complex traditional seed system that is still existing in many regions where subsistence 'agriculture' is dominant.

Wild plants and food availability

An agricultural calender was drawn during a participatory survey amongst women farmers. This calendar was compared with seasonal food availability, the jobs done by men and women and the rituals performed. The calendar showed that during the main rains reserves of pulses and cereals were usually low and the entire farming community depended on the biodiversity of wild plants for supplies of fruits, vegetables, tubers, and shoots. For farmers, biodiversity manifests itself in cultivated foods as well as wild plants. Women in particular have a special knowledge of wild plants.

Food diversity is being threat as traditional genetic materials are replaced and natural resources that act as reservoirs of biodiversity are affected. This trend poses a particularly dangerous threat to people who depend on natural resources for survival for several months of the year.

Ceremonial seed germination test

Women play a major role

The survey clearly illustrated the important role women play in handling and conserving seeds. Seed selection by women is a continuous activity and starts the moment the crop comes into flower. Working in the fields, they observe the plants and decide which seeds to select. They identify plants of good quality on the basis of size, grain formation and their resistance to pests and insects. To cover the risk of drought, women select enough seed to see them through two seasons. They also decide on which method of preservation should be used.

Rituals are essential

Seeds are seen as the sacred carriers of life and are therefore surrounded with ritual. These ritual also have their functional aspects. Before seeds are taken into storage, for example, women ritually evoke the forces essential for a good crop during the coming growing season. This ritual is an important part of seed preservation. In it, water is symbolised by a winnowing pan, protection from pests by certain leaves and soil fertility by cow dung. Weeds are symbolised by grass. Some of the leaves used in the ceremony have insecticidal properties. Lakkli leaves *(Vitex negundo)*, for example, are used when paddy seeds are stored and neem leaves are used as an alternative when lakkli is unavailable.

In some cases paddy seeds are mixed with the seeds of field bean *(Dolichus lablab)* and mustard to help preservation and *Tur* is mixed with sand for the same reason. Sometimes seeds are stored above the kitchen where the smoke helps to keep the pests away.

Ceremonial germination test

Before sowing, a germination test or *Negilu Pooje* will be conducted. In areas where finger millet is grown this test takes place at *Ugadi* or the Hindu New Year. A traditional, sacred combination of nine seed varieties of cereals, pulses and oil seeds are put in a shell together with good manure. These are worshipped and inspected after seven days. If there are only a few shoots or these are too small, the seeds of that particular variety are considered unsuitable for the next agricultural season. The farmer will then exchange or borrow seeds to replace them. It is considered improper to buy seeds with money.

Sowing sacred seeds

Just before they are sown the women take the seeds to the house deity where they are worshipped. On their way to the field, the woman carrying the seeds will visit and make offerings to the seven village goddesses who are known as the 'Seven Sisters'. Women also worship the draft animals and farming implements used in sowing.

None of the above procedures are followed for the seeds of high-yielding varieties bought at the market. Local varieties are considered sacred whereas high-yielding varieties are treated as being impure. They are sent directly to the field where only the men are responsible for sowing them.

A general view of the Henwal Valley in Garhwal Himalaya, India: in situ conservation of genetic resources

Traditional agrobiodiversity re-introduced by farmers

Vir Singh

In 1989, large irrigated areas in the Henwal valley were planted in rotation with wheat and rice. Two varieties of each crop were used. A considerable amount of arable land in upper rainfed areas was also planted with soybean. Most farmers had made the switch to 'improved' cultivation practices. The valley, almost completely transformed, had been converted into a virtual experimental area for Government-sponsored agencies. They conducted experiments and demonstrations and farmers received 'tested' seeds of modern varieties with chemical inputs and 'improved' implements.

It was only a matter of time before this genetic uniformity revealed its weaknesses and destructive potential. In 1987-88, the valley was struck by an unprecedented drought followed by two years of pest infestation. The modern varieties, with their very narrow genetic base, were badly damaged and farmers experienced some of the worst days of their lives.

Indigenous varieties re-introduced

Farmers confronted the crisis of genetic vulnerability by collecting together the indigenous seeds that had almost disappeared from the valley. Initially, they collected seeds of 10 local rice varieties from remote rural areas and re-introduced them into their fields. These varieties performed remarkably but pest problems persisted even though the damage was less severe.

The following year, more farmers in the valley opted for indigenous varieties. Seeds produced during the first year were distributed to other valley farmers and another 35 indigenous rice varieties were collected and cultivated. By the end of the third year, a total of 110 local rice varieties had been re-introduced, dramatically increasing the genetic diversity in rice. By 1991, local rice varieties occupied nearly 90% of irrigated land in the valley.

The 'Save Seed Movement'

Farmers were satisfied with the results and relieved they could exercise some control over pests and unfavourable weather conditions. They launched the 'Beej Bachao Andolan' (Save Seed Movement) which spread throughout the Garhwal. The Beej Bachao Andolan searches, collects, re-introduces, tests, distributes, and popularises every indigenous variety of mountain crop available. So far, farmers have re-introduced 145 gentically distinct varieties of rice, 110 of kidney bean, 9 of rice bean, and 12 of amaranth.

Under the influence of modern agro-techniques, farmers in the valley had given up cultivating proso millet, pearl millet, and sorghum. These crops have now been re-established in their farming systems. The free exchange of seed within the community has also been revived and has proved to be a lifeline for traditional mountain agriculture.

Old and new varieties compared

The Beej Bachao Andolan keeps record of the performance of all local varieties and compares them with the so-called high-yielding varieties (HYVs) demonstrated by external development agencies. Results revealed that the average yield of local varieties of rice was significantly higher than that of HYVs. Thapachini, a widely cultivated local rice variety, produced as much as 5400 kg/ha. In comparable conditions, but with additional recommended amounts of chemical fertiliser, Saket-4, the best HYV, produced 4100 kg/ha. The GB Pant University for Agriculture and Tecghnology conducted the experiments with HYVs.

HYV varieties produced more husk than local varieties (grain husk ratio of 1.5:1) which is of little use to mountain farmers. Local varieties, however, produced more edible rice grains and had a grain-husk ratio of 2.6:1. Farmers in the mountains do not only grow crops for grain. Straw is an equally important by product and is used for feeding livestock. The straw-grain ratio is one of the factors that make local varieties popular among farming communities. Claims are also made for the rapid development potential of HYVs. However, experiments have showed that in this feature too, local varieties outclass HYVs.

It was because of the excessive external intervention that put emphasis only on HYVs of two major foodgrain crops that led people to believe into 'miracle' seed. Once the farmers experienced the ecological vulnerability and other problems associated with the 'miracle' seeds they started opting out of the Green Revolution type of agriculture and switch over to their biodiversity-based agriculture that has been tested by them over millennia.

Recognition of the role of farmers

For generations, biodiversity in mountain regions has been in the hands of traditional farmers. Traditional systems of management and traditional knowledge have been the way farming communities have developed and adapted their livelihood systems to specific local conditions. Recognising their unique role would help stimulate farmers' interest in conservation activities. Projects on sustainability-oriented biodiversity management could encourage them to set up their own conservation movements, experiments, demonstrations, and extension services, and would also help farmers to strengthen their creative networks. ■

Vir Singh, GB Pant University of Agriculture & Technology, Hill Campus, Ranichauri 249 199, Tehri Garhwal, India. Vir Singh is one of the founding members of Beej Bachao Andolan.

Seed shortages threaten organic farming

In 1997, following an initiative by several Dutch organic food merchants, the Louis Bolk Institute started work on the Sustainable Organic Plant Breeding project (SOPB). One of the results of that project was *Stichting Zaadgoed*. Set up to stimulate and increase the production of organic plant breeding material, it also concerns itself with policy and ownership issues. Through its Dutch, European (European Initiative for Organic Seed) and international network *Stichting Zaadgoed* stimulates the flow of information on seed breeding activities including the on-farm preservation of organic seed. It organises workshops, and conferences, coordinates research and maintains an international network of information on organic seeds. It ensures that information lists, seed databases and addresses are regularly updated, lobbies for organic plant breeding at the national and international level and seeks amendments to the existing legislation on intellectual property rights, registration criteria, patenting, and licencing to stimulate the transfer of seed and plant material.

Dilemas in organic agriculture

Stichting Zaadgoed encourages the development of an organic plant breeding programme. As the demand for organic products grows, stricter controls are being introduced to ensure integrety at each stage in the organic agricultural chain. In 2001, EU legislation will be enforced to guarantee the authenticity of organic products from seed breeding to food processing. This has highlighted a dilema. Organic agriculture cannot satisfy the demand for more and varied seed bred in an organic environment. At the same time traditional seed sources are drying up as conventional seed merchants move into the lucretative market of genetically modified plant breeding material, and gene-tech seed - unacceptable in organic farming - takes hold of the world's major food crops.

Unmonitored and modified

The Netherlands Association of Organic Traders maintain that, unless action is taken, it will become increasingly difficult to find non-genetically modified seed. The danger of the unmonitored, widespread use of transgenic seeds was emphasised in a recent case brought against the US Environmental Protection Agency (EPA) by IFOAM and Greenpeace. The plaintives alleged that the EPA had failed to carry out environmental impact studies on seed modified with the *Bacillus Thuringiensis* (Bt) toxin although US farmers plant 1.2 million hectares of Bt cotton, maize and potatoes annually. They argued that, in undermining biodiversity and narrowing the genetic basis of the world's major food crops, an unmonitored, market driven, transgenetic seed industry was a threat to public health and food security as well as to organic agriculture.

Investors choose gene-tech

Modern plant breeding and gene technology answer the needs of conventional agriculture and require heavy, long-term investments. Plants must be high yielding, uniform and capable of growing in the highly conditioned, large-field environment of chemical pesticides and fertiliser. Small seed companies cannot compete with the multinational conglomerates that dominate this market and recent seed company mergers have resulted in the disappearance of many of them. As the types and varieties of seeds available decline, concern about the sustainability and ethics of modern seed breeding practices grow. In this context the present Dutch organic plant breeding programme is taking shape.

Sustainable organic plant breeding

In the Netherlands organic food merchants intervened directly in the problem of organic seed breeding. Their initiatives took place in the favourable policy climate of the government's commitment to protecting the consumers right to GT-free food. Their approach to the Louis Bolk Institute - an independent research organisation with considerable experience in organic and biodynamic agriculture - lead to setting up SOPB and *Stichting Zaadgoed*.

Diversity

The Louis Bolk Institute supports the definition of GMO as "organisms in which the genetic material has been altered in a way that does not occur naturally by mating or natural recombination". It views the genetic modification of DNA as a one dimensional and drastic intervention in a plant's genetic make up that destroys its connection with the natural environment.

By contrast organic farmers look for natural reproductive ability, an ability to adapt independently to the environment, and genetic diversity with respect for natural species authenticity and species characteristics in their seeds. They prefer to work with a mixture of varieties to ensure sufficient diversity and economically feasible yields without exhausting the natural resources of the farm and its surroundings. Thus they require fairly heterogeneous varieties that are not only capable of adapting to different regional soils and climates but which are also resiliant to pests and diseases.

Setting up organic plant breeding

Any organic plant breeding programme will be heavily dependent on farmers' knowledge, initiative and participation. Encouraged by the Louis Bolk Institute, variety groups, regional extension groups and national crop groups have been set up to encourage communication between breeders and farmers. In such groups farmers as well other sector representatives, consumers organisations, research institutes, traders and conventional and organic seed companies can share experiences and participate in trial and variety assessments. Questions, needs and bottlenecks can be explored with other members of the chain and it becomes easier to tackle issues such as breeders rights and registration with the National Varieties List. Such participatory approaches, however, are still new to many in the North and there is much that can be learned from experiences of participatory plant breeding available in the South.

SOPB and *Stichting Zaadgoed* want to encourage many different types of breeding programmes including organic programmes set up by conventional breeders, programmes managed by specialist organic breeding companies and programmes in which organic farmers carry out selection *in situ* and in consultation with professional (organic) breeders. They maintain that genetic diversity can be preserved and developed if there is adequate diversity in breeding companies and programmes and if monitoring systems are set up to ensure seed and plant material are propagated in accordance with organic principals.

KRRS farmers protest outside Cargill, Amsterdam, May 1999

Green Caravan Challenges Gene Giants

Photo: Bangladesh People's Solidarity Centre

"Seeds are the basis of every farmers existence. To have free use of their own seeds of different varieties gives farmers a basic economic independence and ensures that their crops can adapt to changing environmental circumstances" Prof Mahanta Nanjundaswamy, Karnakata State Farmers Association (KRRS), India.

The green shawls and banners of KRRS farmers contrasted sharply with Cargill's austere harbourside building when members of the Intercontinental caravan launched their protest against the growing power of the agrarian multinational last Spring in Amsterdam. Several hundred farmers from all over India used their savings, community funds and farmers' union money to make the journey to the West.

To Professor Nanjundaswamy, president of KRRS, the Intercontinental Caravan (ICC) was an attempt to bring Western decision makers and public closer to the realities facing small farmers in the South. They brought "to the North the views of the South on systems of exploitation imposed by Western governments, the WTO, and multinational corporations" because their livelihoods were at stake.

Travelling in buses equipped with telephones and email they brought across their political and ethical message with emotional force as they lobbied Cargill and Pioneer Hi Breed in the Netherlands, Monsanto's Technical Centre, in Belgium, OECD in Paris, WTO in Geneva and the EU in Brussels. The climax was a mass protest at the G8 conference in Germany.

Seed satyagraha

For many Indian farmers Monsanto epitomised the stranglehold multinational conglomorates have over agricultural resources in the South. The way genetically modified products and seeds were being introduced into India raised issues of permission, information, monitoring and control. These had largely been ignored until Operation Cremate Monsanto was launched by the KRRS and 28 trial fields of GM cotton were burnt. The Ministry of Agriculture has now banned further Monsanto trials. For Kumud Chowahary who left her family and farm in Gujarat to join the caravan the problem is simple and personal: *"Kill Monsanto before it kills families like mine".* Others like Lal Shankar Upadhyaya, Vice President of Gujarat Khedut Samaj sketch a wider context, the *"fight of indigenous agriculture and market systems against Northern dominated gene technology and free market."*

Gene giants

The Farmers Caravan protest coincided with a spate of mergers in the gene industry that further concentrated technologies and patent rights in the hands of a few gene giants. Monsanto's portfolio illustrates the type of dominance protested by the Indian farmers. Ownership of Delta and PineLand with patents for terminator technology; ownership of Roundup (25% of US soyabeans produced from Roundup ready seed); control of 45% of the US corn seed market; grain trading and food processing capacity through takeover of Cargill and, through Unilever shares in the hybrid wheat market. In 1998, when Dupont bought Pioneer Hi-bred the Wall Street Journal observed that the US seed industry had been effectively divided between Dupont and Monsanto. As the gene giants grow, critics point out, public sector seed breeders disappear and farmers have fewer choices.

GM issues

Indian farmers, aware of the consequences of these changes, want a public debate on how to monitor GM crops. Problems include cross-pollination, antibiotic resistance, and resistance to broad-spectrum herbicides and pesticides. The potential dangers of GM maize, soya and potato with high residues of amikacine and, glyphosate in animal food must still be investigated and the monopoly of agricultural resources allow companies to further control farmers choices through patents, contracts and crop and pesticide packages.

Bt Cotton

Bt cotton was major issue for Indian ICC participants. Bt cotton produces a poison that kills pests but, as farmers in Southern India found, pests can develop such resistance that even 50 times the recommended amount of pesticide is ineffective. Crop failure, inability to repay loans and suicides were reported. In the US similar resistance was reported. 50% of GM cotton was damaged by boll weevil and there was no increase in production. Further, no steps were taken to prevent cross- pollination.

Act now

The need for legislation, monitoring and information on GMO is being stressed by an increasing number of organisations and scientists. This year, for example, both Nature and the Lancet have presented research findings critical of GMOs; farmers in America are preparing legal action against Monsanto for not warning them sufficiently of the possible risks of GM seed and in Brazil farmers have rejected GM soya. At the same time food producers and supermarkets across Europe are announcing they will not use or stock foods containing GM material. This Spring, with their Intercontinental Caravan, the farmers from India and Bangladesh brought these concerns to the main centres of European policymaking and industry. In meetings, interviews and direct action they made it clear that it was time for an urgent reappraisal of the effects of GMOs on the safety and security of the world's food supply and the ecology and culture of its farming communities. ■

Biodiversity in agriculture: policy issues

Biotechnology - a bundle of techniques used to exploit life forms and processes - is as old as the first loaf of leaven bread or the transformation of milk to yoghurt. What is dramatic about modern biotechnology is the technical sophistication that allows the selective manipulation of genetic material and the transfer of genes, not only between varieties but also between all plant, animal and microbial species. Proponents argue that biotechnology will solve mankind's food, energy, medical and environmental problems. However, concern centres on the fact that transnational food, pharmaceutical and chemical corporations (TNCs) now control biotechnology research.

GRAIN

Former agrochemical giants have converting themselves into "life-science" companies, eager to broker between humanity and nature. Since 1996, the sector has spent some US$ 34.3 billion to ensure control of the seed market which is currently worth US$ 30 billion (Assinsel's World Seed Statistics). TNCs develop uniform products that give high returns but produce monocultures, homogeneous farming practices, severely decreased biodiversity, and far-reaching environmental damage. In biotechnology, the rush towards private sector collaboration has lead to the reorientation of public R&D programmes to meet the needs of agroindustry while ignoring the diverse interests of wider society.

One of the hottest items in agricultural biotechnology research, for example, is the development of herbicide resistant crops. Between 1996 and 1998, the number of herbicide resistant, genetically engineered crops rose from 23%-71%. In the same period, however, the proportion of genetically engineered crops with insect resistance traits decreased from 37% to 28% and the number transgenic crops with other agronomic traits (virus or insect resistance) fell from 40 to 1%. The biotech industry claims that herbicide resistance makes it possible to reduce the adverse effects of broad-spectrum herbicides (which kill anything green). One obvious effect has been the stimulation of stagnating farm chemical sales and the encouragement of further dependency. Through patents and the development of plants with sterile seeds, the biotechnology industry tries to prevent farmers and competitors from reproducing genetically modified seeds.

Patents for maize

Recent changes in maize illustrate these trends. One of the world's main biotechnology reviews, Derwent Biotechnology Abstracts, reported in 1998 that 333 patents for transgenic maize plants had either been applied for or granted. An examination of patents indicates that R&D efforts are focusing on (Table 1):

- Miscellaneous genetic engineering methodologies including the use of promoters, the control of gene expression, or technologies with multiple practical applications.
- Agronomic characteristics particularly pest (mainly insect) resistance with nearly two-fifths of the patents covering the use of the crystal protein of *Bacillus thuringiensis*. Herbicide tolerance, disease resistance and environmental stress - mainly drought and salinity – are traits much favoured by patent applicants.
- Altering the plant's reproduction. Pioneer has led efforts to obtain male-sterile maize plants that would reduce the cost of producing maize hybrids. Considerable effort has been invested in altering flowering. Apomixis, or reproduction through asexual seeds, has the potential to get small farmers to switch to high-external input dependent hybrids by allowing them to re-plant their seeds with no loss of hybrid vigour. The inclusion of this reproductive mode in maize has been patented by three public institutions: USDA, CIMMYT and ORSTOM.
- Product quality or content of transgenic maize. Maize starch is transformed into food and industrial products including the high fructose syrup used by beverage companies for sweetening and ethylene for petrol. Modifying starch content is, thus, one important research focus. Pioneer Hi Bred, DuPont and Monsanto lead seed company efforts to turn maize into a better source of protein for cattle and research is also being carried out into the lignin, vitamin and phitases content of maize. Maize is becoming a "pharmactory" as patents are taken on maize plants that produce vaccine and human proteins.

Patents are concentrated in a small number of corporate hands (e.g. Du Pont/Pioneer 17% (55 patents), Novartis 11% and Monsanto 8%). By March 1999, after an unprecedented wave of corporate mergers and acquisitions, 47% of the 333 patents on maize now belong to the 6 agrochemical

Table 1: 362 claims made in 333 patents applied or granted on transgenic maize.

giants that control agricultural genetic engineering. A group of smaller companies and public institutions – including universities – also have important claims on maize. In total, the top 19 patentees control 66% of all patents applied for or granted on transgenic maize.

Terminator seeds

Novel biological means have also been used to gain corporate control over the first link in the food chain - the seed. New biotechnologies, controlled by corporations, allow the engineering of crops that kill their own seed in the second generation making it impossible for farmers to save and replant. The Rural Advancement Foundation International (RAFI) has dubbed this genetic sterilisation invention "Terminator Technology" and has analysed its serious social, economic and environmental implications (RAFI 1998). Companies are now working on controlling several important genetic traits with a number of external chemical catalysts. The six, transnational agroindustrial firms that control almost 100% of the biotech transgenic seed market will dominate these new technologies. Their ability to insert and externally manipulate vital DNA sequences within crops - and possibly insects and livestock - threatens the sovereignty of nations over their agriculture and biological resources.

Intellectual property rights

Can genetic engineering feed the world or should it be banned? As this heated debate gathers momentum another issue is waiting to explode. Should biodiversity - key resource of the billion-dollar biotech industry and basis for the survival of many in the Third World - be patentable? At the moment industrialised countries allow scientists to claim legal rights to genes and indigenous knowledge plucked from the biodiversity-rich tropics. The rationale for this "biopiracy" is that what comes from the rainforests of Ecuador or farms in Sri Lanka is "natural" and unpolished, while that produced in a lab is "a product of science" and should be patented as an invention.

The battle for and against patenting life - plants, animals, and now human genes – is a fierce one. Arguments against life patents centre on ethical and religious concerns, ownership, cost, and definitions of innovation. The Uruguay round of the General Agreement on Tariffs and Trade (GATT) negotiations was a particularly tough struggle. It resulted in agreements on intellectual property (TRIPS) and the establishment of the World Trade Organisation (WTO) to implement them. TRIPS (Trade-Related Intellectual Property System) requires countries to provide private ownership rights on plant varieties or face hostile action from trading partners. The forthcoming TRIPS review will be the next challenge in the life patents battle.

Delegations from developing countries assert their right to protect their people's biodiversity and indigenous knowledge and argue that TRIPS should allow countries to exclude these from intellectual property law. The conflict between the Convention on Biological Diversity (CBD) and TRIPS has escalated fast particularly in Southern countries. The CBD insists that intellectual property rights (IPRs) should not run counter to the Convention's objectives, namely the conservation and sustainable use of biodiversity.

Problems with TRIPS

TRIPS is problematic. First, studies show that IPRs encourage genetic erosion in agriculture in several ways. They stifle the flow of information and germ plasma; promote uniformity in breeding and exclude farmers from the commercial seed market. TRIPS could be undermining the CBD.

Second, the CBD is rooted in the principle that benefit from using genetic resources should be shared. However, TRIPS promotes the privatisation of genetic resources, not benefit-sharing.

Third, CBD supports the rights of local communities, while TRIPS supports the rights of formal scientists and TNCs. In recent months, countries in Africa, the Caribbean, Europe and the Pacific have made clear they want CBD to take legal precedence over TRIPS. This means changing the TRIPS. Agreement to comply with CBD, not the other way round, as Northern delegations would like.

If the amendments demanded by the United States government are carried, patenting plants and animals will have to be legalised in all WTO member states. All members would then have to implement both TRIPS and the 1978 UPOV Act (Union de Protection d'Obtention Végétale), which gives breeders exclusive ownership over the commercial use of varieties for the purpose of production and sale.

Patenting life is unacceptable to many in both the North and South. They cannot compromise on this principle. Many NGOs wish that governments were less obsessed with IPRs and more prepared to encourage socially responsible research through fiscal schemes and incentives for community-controlled public research. These would not preclude the sharing of knowledge and would be far more democratic and supportive of sustainable development than IPRs.

The "Biodiversity out of TRIPS" position complements the campaigns of those farmers' organisations that argue that agriculture should be taken out of the WTO. Biodiversity and agriculture go hand in hand. As Weeraphon Sopa of Thailand's Forum of the Poor stated at the recent Asia-Pacific Economic Cooperation summit, "Industrial agriculture and patenting of seeds take away the people's freedom to produce their own food." Trade liberalisation agreements on agriculture, investment and IPRs have to be resisted at both regional and sub-regional level: APEC, FTAA (Free Trade Agreement of the Americas), in South Asia, in Central America within MercoSur, and at the global level (WTO, OECD, the World Bank and the UN).

Achievements

The increased awareness of the importance of biodiversity and the role of local communities in its conservation and use is an important achievement. National sovereignty over biodiversity and community rights now needs to be reinforced. TRIPS is a cunning trap: it invites countries to devise *sui generis* legislation in a seemingly open manner but it is clear that any *sui generis* law tabled as TRIPS compliance has to be an intellectual property system. There have been considerable achievements in developing community rights: the OAU's Model Law for Africa; the Philippines' Community Intellectual Rights bill; the Indigenous Peoples' Rights and Traditional Medicine Acts; Thailand's three community biodiversity rights bills, and the new call for a Mesoamerican and Caribbean Convention for the Protection of Community Intellectual Rights. While not yet perfect, these show that alternatives are emerging and they should not be curtailed by calls for industrial-style plant breeders' rights.

Conclusion

Biodiversity conservation and improvement is an integral part of daily life for those practising LEISA. By definition, LEISA is only sustainable if it incorporates the widest variety of soil, plant and animal life, and works to strengthen indigenous knowledge and management systems based on local biodiversity. This diversity allows local farming systems to recycle nutrients, reduce pest and disease problems, control weeds, and handle climatic stress while producing nutrient-rich foods and meeting other livelihood needs. Diversity - both biological and cultural - is basic to these farming systems. Any national policy environment that seeks to sustain this diversity will need to exclude patent-type legislation on plants and animals, broaden democratic control over biotechnological research and introduce anti-trust legislation to limit the power of corporations seeking to control the food system.

The challenge of collaboration in the management of crop genetic diversity

Crop genetic diversity is only one part of total agrobiodiversity. It refers to the diversity of crops and the diversity of varieties within crops (see Box). Crop improvement has always played a central role in agricultural development. It is now widely recognised that crop and seed improvement in recent years has resulted in both success and failure (Tripp 1996).

Conny Almekinders and Walter de Boef

photo: Conny Almekinders

Improved varieties of the major food crops have been particularly successful in more favourable and uniform agricultural areas, such as the irrigated rice systems of South-east Asia. In these areas, farmers replaced their diverse local varieties with a few genetically improved varieties. These required an increased application of chemical inputs. The combination of reduced crop genetic diversity and the application of fertilisers and chemical crop protection has made these systems vulnerable and in many cases unsustainable.

In more marginal and heterogeneous areas, farmers still manage important portfolios of crops and varieties. In some areas farmers adopted improved varieties in one or more crops to partially replace local varieties - sometimes even increasing the number of varieties grown. In other areas, particularly the most marginal and heterogeneous ones, improved varieties have not brought much gain.

Farmers in these environments have benefited little from agricultural development. In many countries, national agricultural system of research and development are seriously hampered by shrinking funds and this has made it more difficult to address the diverse needs of farmers in resource-poor areas.

At the same time global political and legislative frameworks obstruct the free availability and use of genetic diversity (GRAIN p9). The forces behind developments in biotechnology, patenting, and the commercialisation of genetic resources are not driven by a concern for the development of local farming communities and the influence of multinational companies seriously threaten the way farmers use their genetic resources.

Pioneering farmers, researchers and development workers are looking for alternative ways to improve crops and seeds. By restoring diversity farmers become less vulnerable to pests and diseases, inputs can be reduced and household needs can be met more easily. Diversity also increases farmers' resilience to unexpected environmental and economic change.

This issue of the ILEIA Newsletter presents a range of such initiatives. One of the lessons to be drawn from them is the similarity in their focus: they all address the diverse needs of farmers in varied and location-specific conditions. Another lesson that emerges from these experiences is the need for collaboration between farmers and professionals.

Two systems

Below, we describe the use and management of plant genetic resources (PGRs) from an institutional perspective (Fig.1). This model proceeds from the farmers' role. We also consider an 'institutional system' of PGR management. The two-system model is a simplification of reality that varies from place to place and from crop to crop. It also varies between rich and poor farmers in a community and over time. We use a model to identify the opportunities and possibilities where the institutional system can support farmers because reality is so complex.

Farmers' system

Farmers have always been - and still are - the principal managers of agrobiodiversity. Farmers select crops (usually a diversity of species) and varieties (genetic variation within species) to plant, store and select seeds for replanting. (Figure 1).

Agrobiodiversity defined

Agrobiodiversity can be defined as that part of biodiversity on which man directly depends for food, fuel and fibre, including plants, animals, trees and other organisms that are of direct importance to agricultural production. There is 'planned' or 'intentional' biodiversity in the form of crops and varieties. And there is 'associated', 'incidental' or 'unplanned' biodiversity which includes pollinators, pests , parasites, predators, competitors and soil organisms. Following the definition of biodiversity (UNCED Convention on Biological Diversity, 1992), agrobiodiversity also encompasses (agro)ecosystem diversity represented by hedgerows, ditches, field margins, hillsides and humid depressions. These ecosystems within a farm are often essential for many of the organisms that interact with the crop or livestock.

Farmers producing their own seeds are involved in crop development (selection of the varieties and seeds) and the maintenance of genetic diversity. Simultaneously, they manage plant genetic resources in an integrated way and for a variety of purposes (Almekinders & Louwaars 1999). Farmers' selection, in combination with natural processes such as genetic mutations, crossings between varieties and wild relatives, and the influence of the natural environment, form a system of continuous crop evolution. The system has resulted in domesticated and cultivated varieties of a range of crop species (Harlan 1995; Wood 1999). Studies show that farmers' systems are complex and poorly understood (Longley and Jusu, p16; Soleri et al p18).

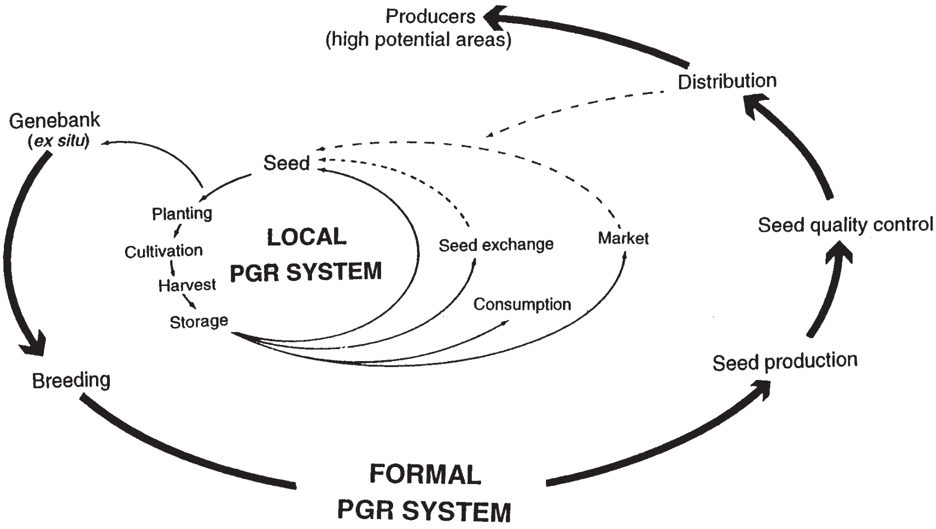

Figure 1 Farmers' and institutional system of management of plant genetic resources
(adapted from De Boef et al, 1997 and Almekinders & Louwaars, 1999)

The institutional system

The institutions involved in crop conservation (gene banks), improvement (breeding programmes) and seed supply form a PGR system that functions parallel to the farmers' system (Fig 1). The institutional system developed after 'genes' were discovered and knowledge about the possibility of manipulating plant characteristics through crossings increased (Kloppenburg 1988). Breeding became a specialised activity, taking place in research stations and carried out by breeder-researchers. Gene banks were set up as institutions to maintain collections of genetic material for ready supply to breeders. Seed programmes were designed to disseminate breeders' varieties to farmers in the form of quality seed. A chain-like organised institutional system developed with clear mandates and less integration than the farmers' system. This system successfully supported agricultural development in Europe and North America and was used as a 'blueprint' for agricultural development in the South. In this '-blueprint' the role of farmers in crop development, seed production and conservation has been totally ignored.

There are only two intentional points of contact between these parallel but separate systems. One is the collection-missions of gene banks to areas where farmers still grow many traditional varieties and where wild relatives occur. The second is during the distribution of improved seed from the institutional system to the farmers system. As mentioned earlier, the institutional plant breeding system has not been very effective where agroecological environments are more variable and the needs and preferences of farmers more diverse. As Ceccarelli (p36) explains, this is because farmers needs are not well understood, there are too few genetically uniform products for on-farm testing, and selections are made on station where conditions are quite different from the farms in the target environment.

Conventionally, seed programmes are required to supply seeds of improved varieties, ie the products of breeding programmes. In many situations these improved varieties are unattractive to farmers because of the mismatch between breeding and farmers' needs. In other situations they are only acceptable when accompanied by subsidised inputs. Conventional seed programmes are also handicapped by the, often good, quality of farmers' seed. Most farmers have no reason to buy new seeds unless they loose their seed, want to try a new variety or grow hybrid varieties of maize or vegetables. Seed programmes have overestimated farmers' interest in buying seed particularly in the case of self-pollinating and vegetatively propagated crops. Accessibility and the remoteness of agricultural production areas add to the problems of distributing seed from the institutional sector. Given these constraints it is not surprising that seed programmes - often copies of 'western blueprints'- were, in general, not successful.

Conservation or development?

The value of conserving the genetic diversity still cultivated in traditional systems is undisputed (Box 1 p29). It is becoming increasingly clear that farmers in both high and low potential areas will always need genetic diversity to buffer them against environmental hazards, changing market conditions and as insurance for the future. The challenge is to combine development with the maintenance of genetic diversity. The Green Revolution introduced improved varieties, which replaced a wide range of local materials, often reducing the number of varieties planted. For most breeders this is an accepted 'trade-off'. Selection of the best variety leads to the elimination of several others that perform less well. The selection of the best genotype in a variety (or elimination of the undesirable ones) reduces genetic diversity in a landrace. Because of this trade-off, many consider that the maintenance of genetic diversity cannot be combined with crop improvement.

Complementarity

Closer evaluation of the farmer's system and the institutional system makes clear that both have their own strengths and weaknesses. Actually, the two systems are quite complementary. The institutional system has had many opportunities to support the farmers' system (Almekinders & Louwaars 1999). History shows, however, that support will not be effective if offered as a standard package, unadapted to location specific conditions and preferences. The contributions in this Newsletter show the potential of decentralised approaches that build farmer and NGO participation. In the following sections we examine support in three conventional areas of intervention: seed supply, crop development and the conservation of genetic diversity.

Support to farmers' management

Better linkage between farmers' and institutional systems offer opportunities for combining the strengths of both systems. Through such linkages the needs of farmers' can be better addressed. There are several examples in this issue that show how such linkages increase the availability of suitable crop genetic diversity and farmers access to it. Such activities also increase the effectiveness of the institutional system by making it possible to address farmers needs more effectively. Key objectives of the Community Biodiversity Development and Conservation programme (CBDC) include exploring opportunities for linking the farmers' and the institutional system (p42).

Seed production and exchange

Use of seed produced on-farm or obtained from relatives, friends or other informal channels is by far the most important seed source for agriculture in developing countries, and is also important in many industrialised countries as well. 80% of all seed in developing countries are estimated to be produced on-farm. This percentage varies strongly from crop to crop tending to be high in crops such as barley that is self-pollinating and whose seed stores relatively well and much lower in crops such as beans or Bambara groundnut where diseases and local storage problems create difficulties. In maize, a cross-pollinating crop, the availability of on-farm seed depends very much on access to and adoption of improved open pollinated and hybrid varieties (Almekinders et al 1994).

Support to on-farm seed production can, for example, try to improved storage practices or seed health (eliminating diseased plants, selecting seed from healthy plants, promoting cultivation practices to suppress diseases). Another important area of support relates to variety maintenance, ie seed production and selection practices that maintain variety characteristics and genetic potential through positive and negative mass selection (Almekinders & Louwaars 1999). Such support activities are particularly useful for landraces. Seeds from these varieties are usually not available from institutional sources and quite often a mass selection can improve the yield of landraces.

Another important element of the local system is seed exchange between farmers (Mekbib p15) Seed exchange and spontaneous crossings between varieties and wild and cultivated relatives are the most important mechanisms ‘feeding’ the local gene pool with new materials and characteristics thus keeping it dynamic and diverse. Seed fairs, for example, are traditionally important events that facilitate seed exchange between farmers and communities and ensure access to a diversity of seed (Scurrah et al p27; Neuendorf p24; Abebe Demissie p30).

Crop improvement

The development of landraces from wild species by farmers’ selection illustrates that local crop development is an effective system of crop improvement. The weakness of the farmers’ system is also apparent. It is a dynamic system, with important genetic variation within and between landraces, but it is also a system with restricted opportunities for acquiring new exotic materials or genes. Introduction of resistance genes that are not available in the local gene pool almost inevitably requires support from the institutional sector. But, as Ceccareli (p36) notes, the introduction of varieties bred by breeders in a centralised breeding system does not necessarily give satisfactory or optimal results. Participatory plant breeding (PPB) approaches are a promising alternative in which farmers’ knowledge and capacity are combined with breeders expertise and access to materials. In this Newsletter Sthapit and Jarvis (p40) outline the relationship between *in situ* conservation and participatory breeding.

Conserving crop genetic diversity

The experiences presented in this Newsletters show that opportunities for supporting the agricultural development of small-scale farming do exist and does not have to involve the eradication of the diversity farmers already have and which they apparently need.

Farming households need genetic diversity for many reasons. With increased market integration, farmers tend to specialise, use less crop diversity and become out of touch with their cultural traditions. Since many of these are closely related to the rich use of biodiversity, maintaining local knowledge and culture can support the sustainable management of genetic and other resources.

The challenge now is to move from the innovative, but relatively isolated project activities of professionals and farmers to a situation in which these approaches are scaled-up and become normal practice in formal and informal, national and international institutions. This is not an easy challenge and requires the flexibility and willingness of professionals in government and non-government organisations to cooperate with farmers and other institutional actors. Contributions in this issue aim to share experiences that may serve as a basis for further experimentation and the implementation of activities that support the use of genetic diversity in farmers’ fields.

Seeds for agrobiodiversity

Several controversial issues have emerged in the current public debate on the management of genetic resources in agriculture. These include genetic modification, patenting and the loss of agrobiodiversity. This Newsletter focuses primarily on biodiversity in crop production but not without looking at the other two issues as well. As an introduction to the subject, Conny Almekinders (guest editor for this issue) and Walter de Boef (p5) discuss the institutional setting of plant genetic resource management and the new developments taking place.

In market agriculture there is an enormous loss of biodiversity both on-farm and in the wider environment. In more favourable conditions, traditional agriculture, highly diverse in functions, crops and varieties (Altieri p14), has evolved into agrarian systems dependent on a few commercial crops and uniform varieties with a narrow genetic base. This development started with the introduction of the Green Revolution but continues today as the market economy encourages farmers to adopt the most economically profitable crops and varieties. New developments such as genetic modification threaten to limit the choice between varieties still further (GRAIN p8).

Organic market farmers in the Netherlands are now complaining that conventional seeds are increasingly difficult to get as seed merchants move into the lucrative market of gen-tech seeds (Minderhoud p11). The need for varieties that are not genetically modified and are less uniform has lead the organic movement to initiate its own breeding programme.

Small farmers affected

Small, market-orientated farmers in regions where conditions are less favourable are most affected by these developments. They are unable to compete with farmers in more favourable conditions who can afford the use of expensive improved seeds and they lack improved varieties adapted to their diverse agroecological conditions. Soil degradation often exacerbates the situation making farmers particularly vulnerable to calamities such as drought (Singh p12).

As subsistence agriculture is less affected by the market economy, the loss of agrobiodiversity is much slower in agroecologically complex and isolated regions. Here, much traditional biodiversity and indigenous knowledge can still be found as indigenous culture and biodiversity are strongly interdependent (COMPAS Newsletter Vol.1-2 and Ramprasad p13). However, where indigenous cultures are disintegrating, biodiversity and the indigenous knowledge concerning its use and management are disappearing as well.

International action

In this context small farmers in many countries have organised themselves to conserve what is left of their rich traditional agrobiodiversity and are campaigning against genetic modification, patenting and the dominance of international corporations. They see these developments as a threat to their survival base, a risk to food safety and in conflict with their spiritual values. They are not alone in their opposition. There is growing international disquiet over the implications of genetic modification, resulting in political actions (Minderhoud p10).

In-situ conservation

In this issue you will find examples of initiatives to conserve and develop agrobiodiversity, especially in regions with less favourable agricultural conditions. Several articles deal with such initiatives and related indigenous knowledge (Boncodin p23), seed fairs (Neuendorf p24 and Scurrah p26), a biodiversity register (Utkarsh p28) and community seed banks (Demissie p30). Still, as Boncondin and Vega (p30) rightly argue, farmers will only conserve genetic resources if they attach value to them. Adding economic value to (agro)biodiversity, as in the cases presented by Terrazas et al (p32) and Gerrits (p34) will contribute to its sustainable use.

Crop development

However, conservation of agrobiodiversity is not enough. Seeds degrade and conditions and opportunities for agriculture change. This means that genetic resources have to be adapted and constantly improved. Seed selection and breeding for crop improvement are traditional practices but farmers do not always have enough skill and knowledge to keep up with changing needs. The scientific insights and breeding techniques of the formal sector could help farmers improve their efforts.

However, the formal sector is mainly interested in commercial agriculture. The varieties developed by the formal sector are often unsuitable for the diverse agroecological conditions and needs of small farmers. To improve genetic resource management in less favourable conditions, much can be gained by strengthening collaboration between the informal and formal sector (Almekinders et al p5).

Farmers and scientists collaborate

Scientists try to understand how traditional farmers manage their genetic resources (see Mekbib p15; Longley p16; Soleri p18 and Song p20). Participatory development approaches build on these indigenous skills. The experiences gained with participatory seed selection and participatory breeding (Ceccarelli p36; Wright p38; Sthapit p40; CBDC p48 & Yap p47) demonstrate this potential.

Towards integrated systems

Seed conservation and crop improvement are important in maintaining and broadening farmers' choice as far as crops and varieties are concerned but to really increase and make functional use of biodiversity farmers have to reconstruct and develop (traditional) integrated agriculture. As Altieri (p14) indicates, integrated agriculture (agroecology/LEISA) is the best option for subsistence farmers who intermittently produce for market and who wish to increase biodiversity and the resilience, productivity and sustainability of their farming system.

This can also be an effective approach in commercial agriculture. But, farmers who become fully involved in commercial farming not only loose their seeds but also their knowledge about integrated farming. As scientists have little experience with integrated agriculture, collaboration between the informal and the formal sector becomes crucial to its regeneration and development as the case of the 'Eco-Papas' project in Ecuador shows (Frolich et al p44).

However, where labour costs are too high, integrated agriculture may not be a viable option. Where this is the case, what approach should be followed to increase biodiversity in commercial agriculture? The articles do not provide many indications on how to resolve this fundamental problem nor on how much and what type of biodiversity is really needed in particular situations. Apparently the last word on agrobiodiversity has not yet been said!

EL BOLETIN DE ILEIA
The Spanish version of the ILEIA Newsletter can be ordered from ETC Andes – Perù, ap. Postal 18-0745 , Lima 18, Peru

LEISA INDIA INLAY
An Indian supplement to the ILEIA Newsletter was published for the first time in March 1999. It is scheduled to appear with the ILEIA Newsletter 4 times a year. The LEISA India Inlay can be ordered from AME, PO Box 7836, Bangladore 560 078, India.
E-mail: amebang@giasbg01.vsnl.net.in

EDITORIAL
This issue has been compiled by:
Conny Almekinders (guest editor),
Wietse Bruinsma (responsible editor),
Marilyn Minderhoud-Jones,
Ingrid Huibers-Govaert, Coen Reijntjes.

ADMINISTRATION
Marika v.d. Brom, Lila Felipie, Manuela Verweel

SUBSCRIPTIONS
Nicole Kunz
E-mail: subscriptions@ileia.nl
The ILEIA Newsletter is published 4 times a year.
Subscription fee 2000-2001:
Organisations and individuals in developing countries US$10 or Euro10;
Others US$25.00 or Euro25.00

The editors have taken every care to ensure that the contents of this Newsletter are as accurate as possible. The authors have ultimate responsibility, however, for the content of individual articles.

The editors encourage readers to photocopy and circulate Newsletter articles.

ISSN: 0920-8771

Dear Readers

Again a double issue of the ILEIA Newsletter, this time full of interesting articles and information on 'seeds for agrobiodiversity'. The Newsletters looks at how farmers, often in collaboration with development workers and researchers take special measures or participate in research programmes to try and stop the loss of agrobiodiversity; select and breed new crop varieties and improve seed management. There is information too on the heated genetic modification debate and on patenting and intellectual property rights. Those wishing to go further into these should turn to the Top 5, Sources, WebWorld and Networking pages.

There is much more to write about agrobiodiversity, particularly the genetic diversity of farm animals and 'natural' biodiversity in and around the farm and in the soil. New information is being generated daily. ILEIA wants to keep track of these developments and has decided to open an agrobiodiversity dossier on the ILEIA Website www.oneworld.org/ileia . You can read more about ILEIA's Web plans on our back page.

ILEIA has new funding, and the future of the Newsletter is assured for at least 3 years. Next year we will be back in our regular quarterly schedule. You can read what is in store for ILEIA readers and correspondents on the back page.

The ILEIA editors wish you, your family and friends a very sustainable and happy THIRD MILLENIUM!

The editorial team

The challenge of collaboration in the management of crop genetic diversity

Conny Almekinders and Walter de Boef

The authors give an overview of crop genetic diversity as a crucial element in total agrobiodiversity. Farmers need a certain degree of genetic diversity for their survival and resilience, especially in marginal areas where modern, improved varieties have not brought any profitability. Finding the right mix between (re)creating and conserving biodiversity and introducing improved varieties is the big challenge. Formal, or institutional, seed systems and farmers' seed systems operate parallel to each other. Much can be gained by closer cooperation. Examples of innovative approaches, still rare, need to be upscaled.

ILEIA is the Centre for Research and Information on Low-External-Input and Sustainable Agriculture. It seeks to exchange information on LEISA by publishing a quarterly newsletter, bibliographies, and books. ILEIADOC, the data base of ILEIA's documentation centre, is available on diskette and on ILEIA's Homepage on Internet: http://www.oneworld.org/ileia. Also the ILEIA Newsletter is now available on ILEIA's homepage.ILEIA's Collaborative Research Programme (mid-1995 to mid-1999) focused on assessing the viability of LEISA technology systems. This assessment built on participatory technology development, scientific studies and capacity building. Research took place in four areas of contrasting potential in agro ecological and socio economic terms: the dryland savannahs of northern Ghana, the high mountain valleys of Peru, the humid lowlands of the Philippines and on the semi-arid Deccan plateau.

LEISA is about Low-External-Input and Sustainable Agriculture. It is about the technical and social options open to farmers who seek to improve productivity and income in an ecologically sound way. LEISA is about the optimal use of local resources and natural processes and, if necessary, the safe and efficient use of external inputs. It is about the empowerment of male and female farmers and the communities who seek to build their future on the bases of their own knowledge, skills, values, culture and institutions. LEISA is also about participatory methodologies to strengthen the capacity of farmers and other actors, to improve agriculture and adapt it to changing needs and conditions. LEISA seeks to influence policy formulation to create a conducive environment for its further development. LEISA is a concept, an approach and a political message.

Biodiversity in agriculture: some policy issues

Genetic Resources Action International (GRAIN)

Biodiversity and farmers' intimate knowledge of it has made possible the evolution of agriculture. Today, as world agriculture industrialises, the irreversible destruction of biological and cultural resources raises critical policy issues. This article explores current trends in technology, trade and agricultural research and identifies the problems of local farming communities who, as custodians of genetic resources, are working to develop sustainable alternatives.

8

Farmers' management of genetic variability in rice

Catherine Longley and Malcolm Sellu-Jusu

Small-scale farmers manage genetic variability through a variety of different agricultural techniques. This article describes one such technique, that of maintaining varietal mixtures of a self-pollinated crop – in this case, rice. Sierra Leonean smallholders maintain 2 varieties in the same field not only as a risk avoidance strategy – the 2 varieties together perform better than alone - but also for nutritional purposes. Farmers adapt the composition of the seed mixture from year to year according to their own preferences and experiences.

Making up the balance

During the last 30 years, farming systems analysis and research has brought researchers closer to the realities confronting farmers and today farmers' knowledge is being explored more seriously. Yet despite Farmer Participatory Research and Participatory Technology Development many development and research efforts fail. This is a signal that development and research agendas have to change. New research partnerships must be forged with many different stakeholders. Providing insights into how these partnership can be developed has been one of the main components of participatory assessment and stakeholder concerted action in the ILEIA's Collaborative Research Programme. Looking back on the ILEIA Collaborative Research Programme there are two significant outputs: the experiences with research partnerships in Stakeholder Concerted Action and the results of Participatory Assessment.

Stakeholder Concerted Action for LEISA

Farmers and their research priorities determined ILEIA's research programme but as issues become more complex and scale increases, a wider range of stakeholders must be involved if development efforts are to be sustained (Rölings & Jiggins 1998). The ILEIA research programme was therefore farmer guided and collaborative. It brought stakeholders together in stakeholder or working groups to deal with concrete activities. Each stakeholder was able to define his or her own interest so that together win-win situations could be created. Working groups of farmers and staff from NGOs, government extension services, agricultural research stations and universities were set up to plan, coordinate and monitor PTD and participatory assessment (PA). Working together, they tried to answer research questions that had been developed collectively. The PTD/PA process provided stakeholder groups with a focus and, through SCA, their experiences were disseminated widely.

SCA can be seen as building on some of the steps involved in PTD (see p 8) in the interests of scaling-up and sustaining this process. The analysis of SCA experiences gained during the ILEIA research programme is interesting in this perspective because there are few such documented experience. In the articles by Abon (p 29), Alebikya (p 40), Canales (p 60), and the AME team (p 74) our research partners have discussed their experiences with SCA and PTD. Below some of the different conditions and dynamics of the stakeholder groups and their development will be brought together and the lessons of these SCA experiences will be examined.

Philippines: Scientists learning from farmers

In the Philippines, KADAMA and KALIKASAN farmer organisations were in the forefront of setting the research agenda and programme decision-making. They had strong political motives for participating in a LEISA working group of university staff and NGO members. First, these farmers' groups wanted to prove - through systematic research - that options other than those offered by Green Revolution technologies would maintain yields. They also wanted to convince policy makers to support such options.

KALIKASAN AND KADAMA had already considerable experience in conducting experiments and they had a strategic interest in verifying and demonstrating the effectiveness of their LEISA or organic agriculture. In this they needed the support of the university staff. The farmers had already made their problem analysis and priority choices before the ILEIA research programme began and with a clear agenda they had an important impact on the PTD process.

It took time, effort and some facilitation from ILEIA during a number of working group sessions to negotiate a balance between farmer' interests and insights, and the demands of formal, scientific research. It was decided that CLSU would provide additional scientific support (context studies relating to sustainability issues and the search for alternatives; documenting the research process and backstopping farmers' groups). The university ensured that the experiments, systematically conducted by about 140 farmers, generated interesting statistical material. Professor Marilou Abon, who coordinated the contribution of the CLSU/LEISA task force, described her staffs' experience of the LEISA Working Group as follows:

"If we try to compare (this) experience with that of the past it is now quite different. In the past it was more the scientist or the academe who imposed ideas or techniques on the farmer. In the ILEIA structure or framework the farmers worked with academics and scientists and each had a role as important as the other" (ILEIA video 'Building Bridges for LEISA' 1998).

Initially, scientists played a limited role in the working group partly because KALIKASAN and KADAMA farmers were afraid of loosing control of their agenda and autonomy. Later more CLSU staff took part in the CLSU/LEISA task force. Any future upscaling of the programme may find it useful to include other partners such as staff from PhilRice and the Ministry of Agriculture in future activities. Although the LEISA working group had its share of tempestuous moments, at the end of the research period there was a general feeling that much had been achieved and that a climate of mutual respect had been developed. Together with CLSU and PRRM, the two farmer organisations have developed project proposals for continuing PTD experimentation.

Peru: Building on farmers' knowledge

Two working groups were established in Peru: GIAREC in Huancayo in the Central Andes and GINCAE in Cajamarca in the Northern Andes. Those who participated in the working groups did so informally. There were no signed agreements and the role of coordinator rotated between the member organisations. Though both groups were interested in coordinating activities, each developed in its own way (see Canales p 60).

In Huancayo, GIAREC coordinated a research programme involving three NGOs and three research institutions. Sharing experiences, developing a clear vision of the future and stimulating an exchange of farming knowledge encouraged synergism. At the community level, the NGO and research institutes had their own, distinctive role. Each NGO had contact with a particular research institute. As a result, each worked with a group of farmers to develop its own process of technological innovation. Regular working group meetings were held during which the process and results from each area were shared with and documented by all six members.

Each member gained a comparative advantage from this arrangement. A platform was created where new ideas could be discussed. The research institutions provided studies, training, technical advice and information. Farmers gave insights into their specific farming systems and NGOs organised, monitored, gave technical guidance and liased between farmers and researchers. Local knowledge played a crucial role in identifying possible experiments and in many cases experiment design was based on or derived from established farming practices. As Norma Canales (p 60) remarked:

"It is obvious that the interaction of peasant and academic knowledge and experiences re-values local initiatives for development and generates trust and self-esteem in both men and women farmer innovators".

In this way it became possible to shift the development and research agendas of NGOs and agricultural research institutes and create new and interesting avenues for development. Different knowledge systems were integrated, sustainability aspects were prioritised and local innovative capacity was enhanced. GIAREC now has plans for the future and is committed to continuing collaborative activities.

GINCAE in Cajamarca had a more difficult time. It was unable to hold out against the individual agendas of its member organisations and align with ILEIA's research programme despite a shared interest in LEISA and the effort of CEDEPAS to keep the working group together. GINCAE comprised four NGOs, a university and a research institute. The internal dynamics of the group made role differentiation, the exchange of information and involvement in each other's activities difficult. All six partners became involved in PTD activities in their respective areas but few showed any interest in receiving scientific support from the research institute. This and the distance between the working areas of Centro Ideas and the other NGO resulted in an isolation that hindered complementarity. In addition it is possible that the presence of large amounts of donor funding in Cajamarca meant that ILEIA's limited funds were insufficient to attract the investment of staff and time in collaborative activities.

Nevertheless, a very interesting PTD process responsive to farmers' needs and involving some 90 farmers got off the ground in San Marcos. Centro Ideas in San Marcos and CEDEPAS in Magdalena have now expressed a keen interest in further developing and institutionalising PTD in their programmes.

Ghana: 'Plugging in' to farmer priorities

The start of the ILEIA research programme in Northern Ghana coincided with and gave momentum to the earlier initiatives of ACDEP in developing closer ties with government extension and research. In 1995, this led to a new, but informal institutional arrangement - the Northern Ghana LEISA Working Group - that brought together various organisations concerned with agricultural development in the interests of joint research, extension, advocacy and learning with farmers as equal partners..

An important motive for all participants was a shared critique of the failures of former, mainly HEIA- oriented attempts to improve agriculture in the region. There was keen interest among all professional disciplines to explore the potential of LEISA. Some of ACDEP's agricultural stations had already experienced PTD. The willingness to use it in the Northern Ghana LEISA Working Group programme was based on a determination to make research activities relevant to the development of farmer livelihoods. Both the orientation (LEISA) and the approach (PTD) contributed to strengthening relations within the working group. The major question was how to access farmers' knowledge, problems and priorities in the search for new ways to tackle the problem of soil fertility. As they looked for answers, mutual respect developed between farmers, NGOs and scientists. A sense of collective responsibility was generated and the confidence of both scientists and farmers in farmer-led research increased.

By 1998, after three years of activity, the working group had changed its character. Individual members who had initially become involved because of their personal interest in PTD and LEISA were now supported by their institutions. This combination of individual working group members participating on the basis of institutional interest but without any formal institutional membership has proved very successful. It created space for experimentation without jeopardising institutional relationships. The NGLWG research committee was responsible for daily management issues such as the planning, implementation and coordination of research programme activities.

The working group provided information and training, and monitored and planned activities. It began documentation and developed extension material. Farmers gradually became more involved in planning activities and in the process of sharing experiences. In a relatively short time the working group had succeeded in raising the interest of other stakeholders as well as district directors of agriculture, universities and research institutes outside the Northern Ghana region. This created a much wider platform where issues of agricultural development and the task of advocating LEISA and PTD could be discussed. In this way momentum was increased at the regional policy level. While farmers see the NGLWG as an organisation that collaborates in experimenting with LEISA technologies: policy makers know it best for its advocacy work.

Encouraged by the positive results of NGLWG, several institutions have indicated that LEISA and PTD will become part of their approach. The University of Development Studies has incorporated LEISA and PTD into its teaching curriculum and the Savanna Agricultural Research Institute and ARI include PTD and LEISA in their research proposals. District Agricultural Extension services also intend to use the approach and a World Bank programme for natural resource management in the Northern Ghana will be using the PTD approach and intends to draw on the experience of the NGLWG.

A factor that contributed to the internal coherence of the working group was ACDEP. As an NGO it had more freedom to promote and experiment with new institutional arrangements, such as the NGLWG, than government extension services or research institutions. ACDEP was readily accepted as working group coordinator. It had the skills needed to ensure that everybody was kept informed and interested. Great care was taken to maintain each stakeholder's sense of ownership as the working group was built up.

NGLWG, as a partner in the ILEIA Research Programme, seems to have contributed to shifting research and development agendas in the direction of LEISA and PTD. By accessing farmers' interests it created new hopes and avenues for agricultural development. NGLWG has decided to continue as a platform under the legal framework of ACDEP. In its new programme it will go on with action-research, platform building, scaling-up and advocacy.

India: Platforms for innovation

In less than five years, the Groundnut Working Group (GWG) on the Deccan Plateau in Southern India has become a platform for a multitude of research and NGO organisations. Meeting together in its annual workshop, the GWG provides a forum for debate and the exchange of ideas and technical support. It is not a consolidated stakeholder group in the sense that all members work together on specific subjects or in specific areas. However, there are subgroups in the GWG that do have special fields of interests.

NGOs do most of the PTD work with AME support. AME also brings in scientists and plays a key role in steering, coordinating and facilitating this stakeholder process. It regards activating a wide range of stakeholders to be of strategic importance. In this way the GWG has reached a very large number of farmers (see p 74). The GWG experience illustrates stages in the PTD/SCA scaling-up process

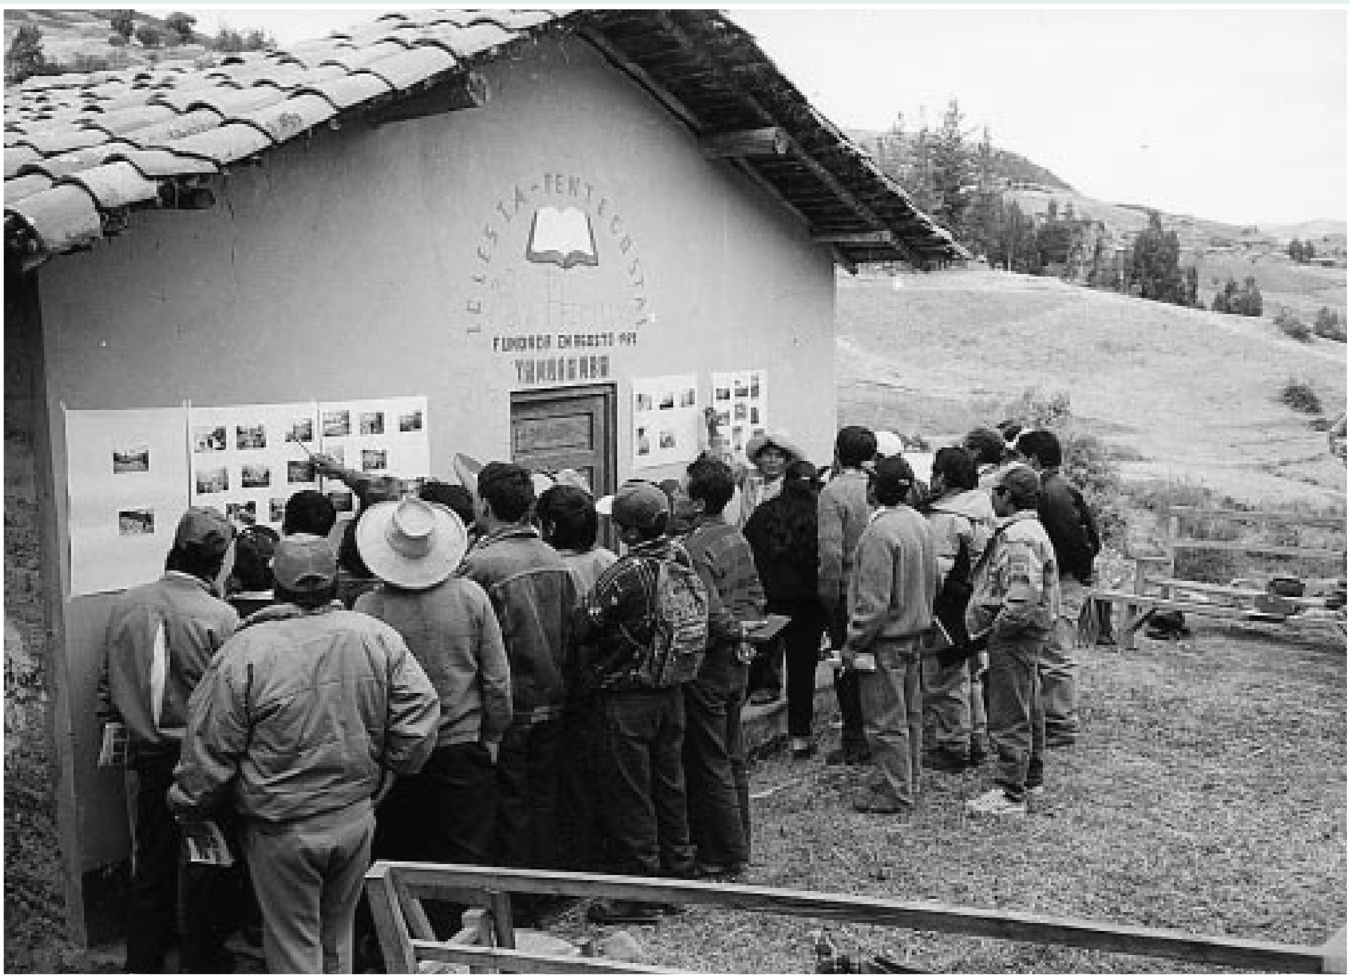

photo: Bert Lof

Farmers discussing experiences gained in farmer to farmer exchange.

Critical steps in scaling up PTD/SCA

- Starting small, local and specific by carrying out one crop /single factor field experiments which, over a two year period, provided a fairly good insight into the factors that affected groundnut production.
- Organising farmers interested in experimenting through NGOs serving also as an interface between farmers and government (and research). Increasing technical and PTD skills of NGOs and overcoming mistrust between NGOs and government and research was also important.
- Building expansion on positive results. Going to other communities in the same area. Having determined problems through PRAs and found similarities 'looking for things to try' is less necessary. More emphasis can then be put on demonstration and further development of found options.
- Recognising the need of scientific expertise and gradually expanding the platform. Learning from each other and establishing important links between NGOs and researchers. In this way the GWG, a platform for SCA came into being.
- Beginning with a single NGO or a homogenous group of NGOs, the steady build-up of relationships with other institutional actors is facilitated including community councils, government departments, input suppliers and credit institutions. This cumulated in the establishment of stakeholder platforms as a strategy for up-scaling participatory and integrated landuse development.
- Demonstrating the benefits of working together contributed to improving synergy between actors in the agricultural (groundnut) knowledge system and stimulated up-scaling.
- Good documentation is essential. On the basis of earlier experiences a provisional groundnut production manual was published in 1997. This laid the basis for further expansion to other areas.
- Not everything scales up automatically. Technologies, once validated by farmers, spread fast. Yet the experimentation process itself which provided the initial insights into these technologies does not scale up so easily. It requires continuous nurturing, able guidance and intensive monitoring.

Lessons learned in SCA

Bringing stakeholders together is not easy. Differences in social background and culture, the distrust farmers and NGO often exhibit towards researchers and competition between NGOs and government/research organisations are some of the factors that contribute to this situation. There are important preconditions for SCA and some of these are discussed below.

It is essential that stakeholders have a ***genuine interest*** in learning from each other and that they share activities, responsibilities and the work of achieving a common goal. Stakeholders may cooperate for opportunistic reasons and this is not a problem in itself. However, when financial benefits are the main reason for joining a stakeholder group, the group will be neither viable or sustainable. Having and building respect for the capacities, knowledge, limitations and institutional concerns of others is a must and a challenge. Such cooperation has added value and removing prejudices strengthens mutual respect.

Common goals are important but not sufficient. There must be concerted action from which all stakeholders benefit professionally. In the ILEIA situation it was the combination of the PTD process and additional studies which kept everybody involved. Stakeholder groups must be realistic about the time and resources available to different members if disappointments are to be avoided.

Leadership in stakeholder groups is a sensitive issue. An organisation or person with considerable credibility, accepted by all stakeholders (such as ACDEP in Ghana) and able to assume a coordinating or leadership role may not always be available. Sooner or later researchers have the tendency to take the lead and this can cause resentment among farmers who want to secure control over technology development. Finding a pragmatic solution - ensuring that the position of chairperson is rotated regularly (Peru) or establishing an external facilitator (the Philippines) - that is acceptable to everyone and that is evaluated regularly then becomes crucial.

Proper management of ***individual and institutional capacities and sensitivities*** is extremely important. Careful attention has to be given to ownership in goals, processes and activities. These matters should be dealt with by an accountable member of the stakeholder group. Considerable investments in awareness building, orientation and training in LEISA and PTD are necessary both at the beginning of the process and also at later stages. Although it is important that stakeholder groups build on the knowledge, skills and experiences of their members, it may sometimes be necessary for an experienced external institution or individual to give guidance and advice on the processes of SCA, PTD and the development of LEISA.

There must be a commitment to ***transparency*** in programme conception, internal decision making and financial aspects and the requirements of financial administration and reporting should not be underestimated. If not handled in an accountable, timely and transparent way there will be serious frustrations.

It has been shown that the ***documentation*** of the process and results together with the organisation of workshops involving a wider audience is an important way of achieving outside recognition and ensuring up-scaling and advocacy. It also gives weight to the stakeholder group itself.

Although every situation has its own dynamics stakeholder groups should not be ***institutionalised*** in a formal way. The 'in practice' recognition of an informal group of interested individuals perhaps with an institutional affiliation may be both flexible and workable (see Ghana p 40). However, more formal working relations may be required later. (see India p 74).

A Stakeholder Group may start with a relatively small number of members in order to ensure that the process is clear and manageable. However, there is the risk that a small group will continue to be inward-looking. In order for full technology development to occur new members from other groups and categories of farmers, scientists and institutions bringing other specialisations and insights must be involved. Such stakeholders may come from the banking world, for example, or from commercial or policy sectors. They will be crucial in broadening the scope of technology development and in ***up-scaling the process***.

Impact of SCA

The four case studies referred to here demonstrate that SCA contributed to the creation of a learning environment for all the stakeholders involved. It was instrumental in ensuring the effective, complementary use of knowledge both from farmers and scientists and lead to both groups acquiring new insights. Subsequent reassessments of the role played by farmers and the contribution indigenous knowledge can make to the development of technology lead to the break-down of the roles adopted by researchers, NGO staff and farmers. This and the building of skills have encouraged the collaboration of a wide range of stakeholders in participatory research and development. SCA has also been important in strengthening farmers' innovation capacities and empowering farmers and farmer organisations such that they become equal partners in agricultural research and grow in self-consciousness and enthusiasm. Finally SCA proved effective in coordinating the definition, monitoring and evaluation of participatory research and development programmes. In some cases it was able to influence land use policies and the scaling-up of research and development programmes. As such SCA seems to be an important pre-condition and methodological tool for developing sustainable agriculture and LEISA.

Farmers and scientists discussing groundnut production.

Stakeholder Assessment of LEISA alternatives

The studies on history and trends show that in each research zone agricultural development has been influenced by the pressures of market-oriented agriculture and modern technologies. Agriculture in each zone showed specific signs of an increasing lack of ecological, economic and social sustainability. Farmers are being forced to search for alternative ways to meet their food and cash needs.

Ecological degradation

Since the 1970s, rice farmers in the Philippines have adopted intensive Green Revolution practices. However, farmers have found that as the cost of these input continued to rise and the soil was becoming increasingly degraded, yields stagnated and financial benefits declined. Indiscriminate use of pesticides and herbicides has lead to a reduction in the numbers of living organisms and human health suffered. Water sources necessary for irrigation became less secure as water tables fell because of over-pumping and increased runoff in the up-lands.

In the Peruvian Andes the effectiveness of modern inputs has also declined. Presently, these are only being used in irrigated agriculture where market opportunities are good. Their use results in problems similar to those in the Philippines. Rain-fed agriculture faces severe soil erosion, overgrazing, loss of agrodiversity and, as a result, pest and disease incidence is high.

In Ghana, attempts to introduce modern agriculture have failed. In rain-fed agriculture soil fertility and water holding capacity have decreased due to nutrient mining. At the same time vegetation and the amount of organic matter in the soil have been seriously effected by burning and mechanised tillage has caused soil compaction. This has reduced food and cash security. Moreover, population growth has lead to an increase in the cultivation of marginal lands and the disappearance of fallow periods has lead to further deforestation, soil erosion and nutrient depletion.

In India, the cost of modern inputs is steadily increasing. On the Deccan Plateau, soil erosion, a scarcity of organic manures, an imbalance in the way chemical fertilisers are being used and groundnut monoculture have lead to an increased susceptibility to water stress, micronutrient deficiency and a vulnerability to pests and diseases.

Economic marginalisation

Economic transformation and the liberalisation of the market economy are important reasons for the marginalisation of many small farmers. In the Philippines farmers are being forced to look for other economic alternatives and these are often outside agriculture. In India during the last 20 years, small farmers have become strongly dependent on groundnuts for their cash income. As no other profitable crop is available, farmers continue with groundnut production despite the ecological degradation that is threatening their income. Often their only alternative is to leave farming and seek work elsewhere. Many farmers in northern Ghana have reverted to or remain in subsistence production. The difficult economic situation in the country means there are limited opportunities for labour migration and this is forcing farmers to look for ecologically sound strategies to intensify agriculture using whatever resources are available locally. The problems faced by Peruvian farmers are very similar. Food insecurity makes it necessary to look outside farming for an income and many farmers migrate to the coast or the Amazon to work as labourers.

Social disintegration

Many social problems found in the research sites are related to the ecological degradation of the natural resource base and the economic marginalisation of farmers' livelihoods. Social disintegration aggravated by migration (India, Peru, Ghana), land conversion (Philippines, India), indebtedness (Philippines, India), health hazards (Philippines, Peru) and the loss of indigenous knowledge (Peru, Ghana) threaten the future of many rural communities.

LEISA technologies needed

It is clear that the conventional HEIA technologies create many ecological problems and are no longer a profitable option for many farmers. In northern Ghana and the Andean highlands rain-fed agriculture is, of necessity, dependent on locally available resources. External inputs, whether organic or chemical, are necessary in market-oriented agriculture. Situation specific LEISA practices that make optimal use of local resources and ecological processes and, where feasible, complement these to secure ecological, economic and social sustainability are therefore more viable than conventional HEIA and LEIA practices. They are also an absolute necessity for sustainable agriculture.

Most farmers and development workers in the ILEIA research programme are convinced of the need for LEISA in both subsistence and market-oriented agriculture and have shown a keen interest in identifying the LEISA practices most appropriate to their situation.

LEISA technologies that fit

In identifying which LEISA technologies fit best within a particular farming context, local LEISA practices were documented and PTD experimentation initiated. PTD experiments were intended to result in technology innovation that respond to farmers' felt needs. More detailed information on the PTD experiments and results can be found in (Abon p 29; Millar p 43; Karbo et al. p 49; Aalongdong et al. p 47; Reyes p 67; Alvarez p 62; Canales and Canto p 65; AME p 74). Here only some highlights are mentioned:

In the Philippines the use of chicken manure, (improved) traditional rice varieties, natural pest management and diversification (ducks, vegetables, fruit trees) in rice farming proved to be popular alternatives for lowland rice producers. On land with a history of chemical farming about 126 PTD farmers demonstrated that chicken manure could be as productive as chemical fertiliser. On land with a history of organic farming, chicken manure gave even better results. The farmers also showed that improved traditional rice varieties could be as productive as high yielding varieties. Costs and benefits of these levels of chicken manure and chemical fertilisers were identical. However, farmers concluded that organic farming is less expensive: after a number of seasons less chicken manure is needed, there are fewer problems with pests and diseases and natural pest management is much cheaper than chemical pest management. Major constraints still seem to be the limited availability of chicken manure and other sources of organic fertilisers, lack of good quality, improved traditional seeds, a very underdeveloped alternative rice marketing system and few sources of credit for (alternative) rice production. However, experiences with integrated rice farming and the ecological system of rice intensification developed in Madagascar (see ILEIA Newsletter Vol. 15, No. 3/4) suggests there is still considerable potential for improving rice farming.

In Northern Ghana ILEIA Research studies revealed that an increasing number of farmers are adopting non-burning. In both research sites whole communities have decided to stop burning and to protect their fields. One of the major revelations of the research programme for farmers, however, was a visit to Burkina Faso where farmers had adopted many different techniques for water and soil conservation and soil fertility improvement including composting. These techniques could be also viable in northern Ghana where climatic conditions are not yet as dry as in Burkina Faso. Composting and the incorporation of left over biomass into the soil have been particularly successful. In two seasons 88 farmers in Langbensi and 55 in Sandema have taken over these practices. Many farmers are now in the process of further adapting and refining the technology to their specific conditions.

Experimentation with cover crops (*Mucuna, Calopogonium* and *Stylosanthes*) for improved fallow has raised farmers' interest and experimentation is still going on. There are also some isolated but successful experiences with agroforestry and organic farming.

In Peru there was overwhelming evidence that farmers were looking for alternative pest management strategies. In the course of ILEIA research new practices for potato storage and combating pests emerged. *Shipita* is being used to combat distomiasis (*alicuya*), a parasitic disease that has serious economic consequences for sheep breeders. Within a short space of time this practice was adopted both

Droughts, floods, lack of irrigation water and over-irrigation influence rice production to great extend.

within the community and further afield. In pasture management, farmers have started to grow fodder crops and conserve them for the dry season. Small-scale irrigation systems are being tested. These are low-cost and flexible enough to serve different users. Farmers have also taken up composting crop residues and combining these with cow dung to improve soil fertility. However, not all the new practices have been fully accepted by the communities and so experiments are continuing.

Quantitative underpinning

In all research sites, an attempt has been made to quantify the viability of LEISA practices in specific contexts. This has been particularly successful in the Philippines and India where statistically analysed data was developed. Results were seriously affected, however, by adverse weather conditions. In the Philippines, reliable quantitative data is only available for the first season because of drought and typhoons in the second and third seasons. In India quantitative data are available from 1994 onwards. Less quantitative data are available for Peru and Ghana where conditions in the experimental fields were less homogeneous making quantification unreliable.

As the data obtained from the PTD experiments only covers two or three seasons it is only possible to draw preliminary conclusions about the viability of LEISA practices under specific conditions. However, farmers used criteria and indicators that were important to them and their positive appraisal of LEISA technologies indicate that LEISA technologies better satisfy farmers' needs than current practices. However, the large-scale adoption of these practices by farmers is the best proof of viability and PTD experimentation in Ghana, Peru as well as India has lead to a rapid expansion of new technologies.

From LEISA practise to LEISA systems

The research programme also identified a number of viable transition strategies for a further development towards LEISA systems. In Peru there was shipita; in Ghana compost and other soil fertility management techniques; in the Philippines chicken manure and in India farmyard manure.

In Peru, the positive results of the shipita trials gave way to new experiments in managing the crop and to studies of the disease vector in order to improve natural pasture management. The success of composting in Ghana led to new practices of animal housing near the compost pit so dung could be collected more easily and to investments in donkey carts to transport the compost. Experiments were also carried out with fodder legumes for biomass production. These examples indicate that farmers and researchers have received fresh impetus to look for solutions with a new orientation.

The research partners see many of the results of the PTD experiments as valuable contributions that can help convince farmers, researchers and policy makers of the need for and potential of LEISA. The experiments and studies also helped convince research partners of the value of indigenous knowledge (see Kauffman p 9 ; Alvarez p 62 and Appiah p 44).

PA as methodology

In the ILEIA research programme, participatory assessment - farmers assessment complemented by scientific validation and studies - functioned as an approach that guided and monitored the development of sustainable agriculture at regional level. Participatory assessment is, in the first place, an integrated part of the PTD process in which farmers formulate their own objectives, values, criteria and indicators for the development of (sustainable) agriculture. The evolution of their farming or livelihood system and the impact of their experiments are analysed on the basis of these criteria. In a participatory cyclic process of experimentation, analysis and growing insights, these values, criteria and indicators gradually become more sustainability focused. Scientist can play an important role in participatory assessment by contributing their insights, information, skills and time.

The ILEIA research programme was only able to scratch the surface as far as the potential of this approach was concerned. Further development is needed at several levels including working effectively with criteria, values and indicators for monitoring and evaluating the development of sustainable agriculture. An important issue in PA is how to keep the balance between farmer and scientific assessment. In India a farmers' chance remark left the AME team wondering.

"Are we doing experiments for ourselves or for the researchers? We are convinced about technologies long before we can convince them".

Shifting R&D agendas and scaling-up

At the end of the Research Programme, the research partners and the ILEIA team concluded that the process and results had contributed to a deeper understanding of the need for and the potential of LEISA. The programme had demonstrated the usefulness of LEISA and SCA/PTD approaches for the development of sustainable agriculture.

"Through LEISA and the PTD process farmers gain a lot of self-confidence and self respect. They become more motivated to work by themselves, to identify their own problems and solutions and to transfer this into practical terms. I think this is a sustainable base for development" (Moses Appiah Abaare, Project manager Sandema Agricultural Station).

It also contributed to shifts in research, development and policy agendas something that is urgently needed if there is to be a scaled-up development in sustainable agriculture. In the Philippines, for example ILEIA research has demonstrated how farmer experience can be effectively combined with scientific approaches at a time when researchers are trying to understand why HEIA approaches have such significant weaknesses. Results of the ILEIA research programme and experiences of other organisations were discussed in a countrywide workshops attended by farmers, NGOs and scientists, in May 1999. The proceedings of this workshop will be published in a special IIRR/ILEIA publication towards the end of 1999.

In India the Groundnut Working Group has successfully raised the interest of formal research in farmer-identified problems in the neglected rain-fed areas and has helped lessen farmer and NGO distrust of formal research. Development agendas of NGOs, research institutes and universities are now becoming more sensitive to farmer priorities.

In Peru, new pathways were opened up by using local farmers' knowledge. Research institutes and universities are now doing more serious research on these local solutions, while NGOs are shifting their development programmes to incorporate farmer priorities.

In Ghana it has become evident that conventional extension and research focusing on HEIA solutions has very little to offer to farmers in the region. The dynamics of the NGLWG with their emphasis on LEISA and SCA/PTD has raised new hopes among farmers and development practitioners and stimulated interest among regional policy makers. The NGLWG is receiving recognition as a platform for debate, exchange and advocacy in Northern Ghana and the special publication devoted to the results of the Ghana research programme will undoubtedly contribute to this process.

ILEIA is aware that much more has to be done to understand and develop LEISA. Documenting and assessing strong LEISA cases that involve many more farmers are essential. In the next few years ILEIA intends - with the help of regional networks - to go on documenting and analysing LEISA experiences. The dynamics created in the Working Groups are definitely worth continuing. Some initiatives have already being made and others are in need of funding. The ILEIA team hopes that follow-up initiatives that build on PTD, SCA and LEISA will find active and financial support from regional stakeholders as well as national and international funders.

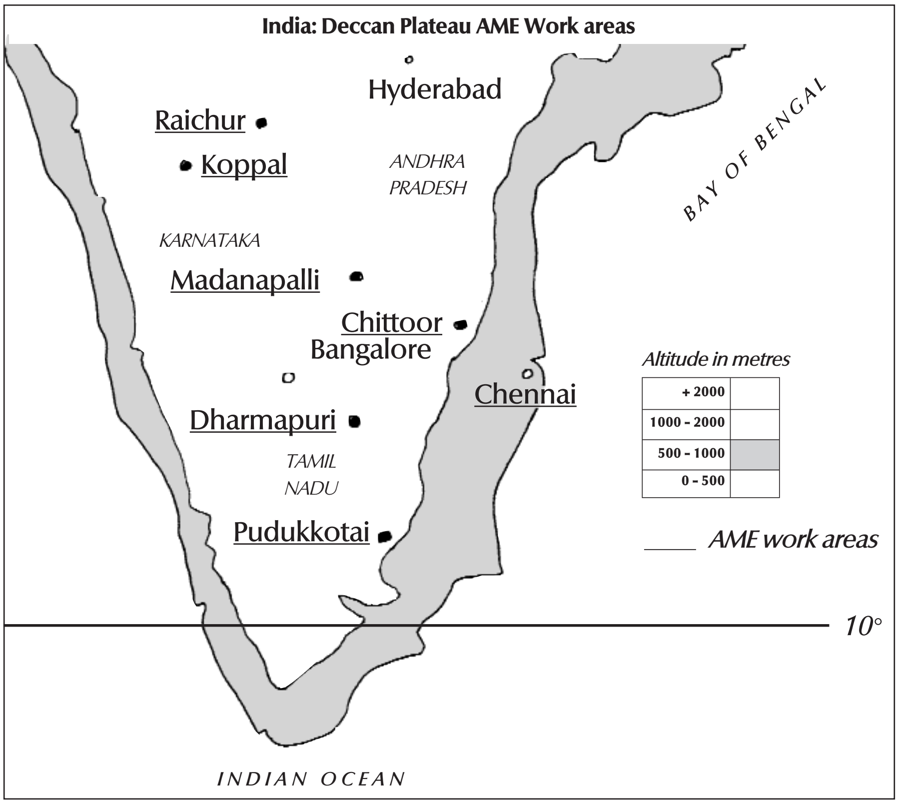
■

A platform for groundnut improvement

To broaden the basis for assessment in the ILEIA Research Programme, ILEIA collaborated with AME. AME facilitates a research platform of farmers, NGOs and research organisations that focuses on the improvement of groundnut production on the semi-arid Deccan Plateau in India. Additional studies have been funded to get more insight into the systems of groundnut production and their dynamic context through the ILEIA research programme. The groundnut platform is one of the platforms facilitated by AME, others focus on the production and marketing of rice, cotton and vegetables. Like ILEIA, AME is a programme implemented by the ETC Foundation

KVS Prasad, Chitrah Suresh & Mans Lanting

This section deals with the groundnut production programme. The first article provides information about agriculture on the Deccan Plateau and the history and sustainability of its groundnut production. The second article will focus on AME's strategy for technology development, the process of stakeholder concerted action and PTD experimentation.



The Deccan Plateau, a vast area of roughly 1000 by 300 km lies at about 600 m above sea level. It is a chronic drought prone and resource poor region, lying in the rain shadow of the Western Ghats, in the states of Andhra Pradesh, Karnataka, Maharashtra and Tamil Nadu. Annual rainfall ranges from 500 to 900 mm and can be very variable with substantial dry spells. Natural soil fertility is generally low. Total population in the region is about 100 million or about 20 million families some 10 million of which are farming families. Another 4 million are agricultural labourers. Eighty percent of the region is under rainfed farming and the rest is under irrigation.

Sustainability at stake

Farms on the Deccan plateau are generally small (one to ten acres) and the majority of farmers have less than three acres. In this vast area many types of farming systems are found. However, on most rainfed farms pearl millet, finger millet, sorghum, sesame, horse gram, foxtail millet, cow-pea, pigeon-pea and groundnuts are grown. Formerly these were cultivated in mixtures but today they are increasingly being grown as pure crops. Rice, bananas, cotton, and sunflowers are cultivated in irrigated areas. Farmers use a small amount of farm yard manure (about 1200 kg/acre) once in four years on rainfed land and the same quantity each year on irrigated land. This is supplemented with Di-Ammon Phosphate and urea. The use made of phosphorus fertilisers is about half what it should be. Micronutrients are generally not applied. About 50% of the farms have access to animal traction. Others rely on hiring bullocks for ploughing or, increasingly, on tractors. Pesticides are mainly used in irrigated agriculture. Trees and animals play an important role in the farming systems of the plateau.

> *Box 1* **Public Distribution System (PDS)**
> PDS provides rations of food at highly subsidised prices. Rice for example is sold in Andhra Pradesh for Rs 3.5/kg through PDS compared with Rs 10/ kg on the open market (1998). A poor family of about 5 persons has the right to purchase 25kg rice each month under this system.

Groundnut is a major cash crop in the three southern states and are grown on about 4 million hectares. This represents 50% of India's total groundnut area and is about 12% of the cultivated area of the Deccan plateau. Groundnuts are usually grown by marginal farmers with limited or no access to irrigation. Groundnut cultivation is favoured because the crop is fairly drought resistant, can be readily marketed and loans are easy to get. Besides it is a cost effective proposition to grow this cash crop and use the earnings to buy subsidised food grain from the Public Distribution System (PDS) (see Box 1).

New farming technologies have helped the richer pockets but this is offset by declining productivity in vast marginal areas. Over-exploitation of the natural resource base is an all-pervasive phenomenon that keeps the majority of farmers trapped in poverty. Traditional systems and resource management institutions have weakened and no alternative options are readily available.

Many marginal farmers and young people have been forced to stop or are unwilling to continue with agriculture as their main occupation. The rapidly growing industrial and service sector in the region has facilitated this economic transition. Male migration is increasing fast and has lead to the degeneration of family, gender and community relations. Many of these developments can be traced back to inappropriate resource use patterns and the inability of research and development organisations and the commercial sector to support farmers in the development of more profitable and sustainable agricultural practices.

A short history of groundnut

The groundnut entered India in the mid-sixteenth century either from China or the Pacific islands. Until 1900 'guarani', a variety which matured in 195 days and required 2-3 irrigations after the monsoon, was cultivated on less than 230,000 ha. During the next decade two varieties that could grow in rainfed conditions - Big Japan and Spanish - were introduced. Thus, spreading, semi-spreading and bunch varieties with higher oil content and maturing in 105-145 days, gained entry and reigned. Later, in the sixties and seventies, the short-duration, bunch varieties (95-105 days) were introduced. These could be grown in drought prone belts with shallow unproductive soils. Literature reveals that the average yield of groundnut (pods) declined from 1200kg/ha in 1920 to about 800 kg/ha in the fifties and remained stable until the late sixties. From the seventies onwards yields gradually rose to about 900kg/ha (see Box 2) .

Declining productivity in the fifties resulted from:

- the proportional increase in acreage of short duration varieties leading to reduction in the period of photosynthesis. The inherent production potential is lower than that of long duration varieties;
- the steady inclusion of low fertility soils for growing short duration groundnut varieties (between 1954 and 1973 the area expanded by 24% while yield increased by a mere 10%).

Until 1970, groundnut was only grown as a Kharif (rainy season) crop. After 1970, however, the area under irrigated (Rabi) groundnut expanded to about 1.5 million ha and this gave an interim increase in average productivity. Today, about 19% of groundnut land is irrigated. Support prices for groundnut also rose from Rs.350/100kg in 1984-85 to Rs.900/100kg in 1995-96 . Groundnuts commanded better prices than other oilseeds and food crops. Improvement in relative profitability during this period could have triggered off expansion into irrigated groundnut cultivation.

Groundnut farming in trouble

Thus far the groundnut story appears promising: increases in average productivity and total production, larger areas and remunerative prices. But in reality the development trends are quite negative.

Soil degradation induces pests

There are slow but definite changes that are progressively endangering sustainability in the rainfed groundnut cultivating areas.

By the sixties farmers moved *en masse* into groundnut cultivation in marginal areas, characterised by shallow (less than 60 cm deep), red, loamy sand soils on sloping (>5%) land. In 50 years an estimated 15-30 cm of topsoil has been lost to erosion.

The fragmentation of farms, the over-exploitation of common lands and the disappearance of cattle and bullocks have led to an acute scarcity of organic manures. This, coupled with an excessive application of nitrogenous fertilizers has depleted the organic matter in these soils. According to scientists, there are extreme cases where soil organic carbon content is below 0.3%, a third of what it used to be. Because groundnuts have been cropped continuously they have assumed a central place and account for anything from 25% to 80% of the crops grown in the farming systems of our operational areas.

The combined effects of these three factors - erosion, rapid mineralisation of organic matter and continuous groundnut cropping are:

- Loss of waterholding capacity and aggravated susceptibility to water stress, especially during dry spells;
- Increased micro-nutrient deficiencies (Zn, B);
- Extreme susceptibility to fungal diseases;
- Increased presence of inoculum of diseases; and
- Increased pest populations.

Box 2 **Irrigated versus rainfed groundnut productivity**

At present average groundnut production stands at 900 kg/ha pods with a shelling percentage of about 70%. There are important differences between production conditions. Under fairly good rainfed conditions on fairly good soils one can expect a pod yield of about 1200 kg/ha. Under adverse rainfed conditions pod yields can be as low as 300 kg/ha with a shelling percentage of 55%.. Under irrigated conditions yields up to 3000 kg of pods/ha would be possible.

Fungal diseases such as leaf-spot (early and late), root collar rot and stem rot are on the increase. Pests like red-hairy caterpillar, whitegrub, leaf-miner and tobacco army worm are creating increasing problems. As a result groundnut yields continue to decline in the marginal areas while production becomes more risky. At present, even in a year with average rainfall, many a farmer just about breaks even with a yield of 600kg/ha. The monsoon fails once in three years and yields fall to a mere 175ka/ha barely enough to replace the seed sown. Over the years the crop has become a loss making proposition for the resource-poor farmer. Ironically, even though many groundnut farmers are heavily in debt they continue with groundnuts because this is the only crop on which money lenders are ready to advance their expensive loans (at interests of up to 120% a year).

Severe competition

Roughly 80% of the groundnuts produced in India are for oil extraction, 15% for seed and only 2% are table grade and exported. Since 1994 the economy has opened up gradually and imports and international competition now play a larger role than ever before. The expensive Indian ground-

photo: Bert Lof

If the government would opt for deregulating groundnut prices, this would lead to losses for most farmers.

nut oil has now to compete with cheaper edible oils such as palm oil on the world market. Malaysia palm oil, for example, is cheaper because:

- palm oil production per unit of land and time is much higher than for groundnut oil, whilst processing costs per unit of oil are comparatively low;
- oil milling in India is far from efficient; most mills run at sub-optimal capacity and are beset by a plethora of administrative problems including over-staffing and weak accounting procedures.

The net effect is that oil millers have difficulty making a profit and staying in the market. Since the government maintains price support for groundnut - something crucial for many poor farmers - millers will have to increase production effeciency - an unlikely proposition at the present time. Some of them may have to close shop unless the government comes to their aid.

Alternatively, if the government opts for deregulating groundnut prices, lower farm-gate prices and decreased profits would lead to declining acreages (particularly marginal land) and losses for most farmers. The livelihood of poor farmers relying on groundnut income to buy food would be seriously undermined. With a loss of food security, migration to urban areas will become inevitable for poor farming families.

Given the gloomy ecological and economic situation as far as groundnuts are concerned and the high population pressure it is clear that something has to be done to improve sustainability of rainfed groundnut production and agriculture in general on the Deccan Plateau.

Getting our act together

Institutional responses to land degradation are gradually increasing and public investment, effort, and the numbers of institutional actors are all growing. The nature of the response is also changing and has moved from the primarily reactive efforts of single institutions focusing on technical interventions, to a more coordinated, pro-active, and people-centered approach. This is most significant in the field of watershed management. It may be noted, however, that dryland agriculture continues to be a relatively neglected area, and efforts to tackle its increasing problems continue to be disjointed.

In Southern India NGOs constitute an important interface between farmers and the government in such matters as agricultural research and watershed management, for example. However, despite significant achievements there is still a long way to go because their geographical spread and expertise in participatory development of sustainable land use is often limited. Further, though there have been instances of government-NGO linkages, the degree of synergy between these and other institutions in sustainable land use is inadequate. AME fills an important niche between these different types of organizations.

AME and its working strategy

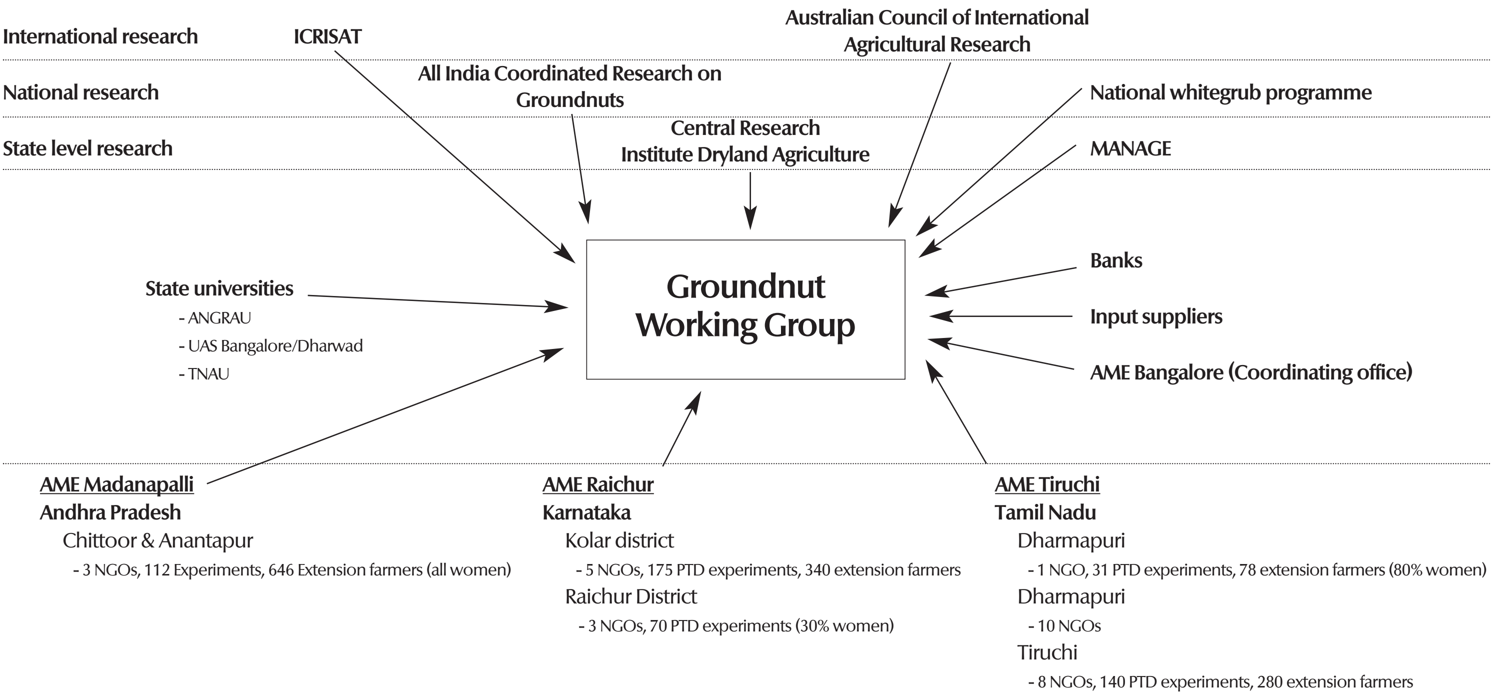
Since 1985 AME has been active in Southern India as an organisation focusing on training and professional support in the development of ecological agriculture. In 1990 PTD and SCA components were added to its programme. Its aim is to assist NGOs through capacity building in participatory technology development and contribute to the establishment of stakeholder platforms for research and negotiation in the interests of sustainable land use. AME believes that, to get a fair share of what the land has to offer or to be more effective in their own development role, all stakeholders in land use should participate in the effort to increase sustainability.

AME's approach is to focus initially on the ecologically sound production of a specific crop. Gradually the approach is broadened to address a variety of issues in the development of sustainable integrated farming systems and watersheds. Beginning with a single NGO or a homogenous group of NGOs, it facilitates the steady build-up of relationships with other institutional actors such as panchayats (community councils), government departments, research institutions, input suppliers and credit institutions. This cumulates in the establishment of stakeholder platforms as a strategy for up-scaling participatory and integrated land use development.

PTD in groundnut: getting started

While initiating a PTD process for groundnuts with small and marginal dryland farmers in south India, we discovered that local knowledge was not necessarily the answer to their problems. Traditionally long duration varieties were cultivated within the context of mixed cropping systems. It is possible that pest and disease problems were not so significant and therefore farmers did not have much knowledge about control measures. Perhaps because they

GROUNDNUT PTD AND EXTENSION PROGRAMME, AME INDIA



Box 3 **Our strategy was to restore soil fertility**

Farmers experimented with cheaper sources of nitrogen (rhizobium bacteria) and phosphorus (mussooriephos plus phosphobacteria) and applied gypsum at the flowering stage. We found yields had increased when compared to control plots where chemical fertilisers (DAP or other compound fertilisers) had been applied. Yields were similar or lower when compared to plots where substantial quantities of farmyard manure had been used. This focused our attention on farmyard manure. We found that when some 5 to 7.5 metric tons were applied per acre the monetary returns were twice as much as the costs involved. Our main problem was to generate the required quantities of farmyard manure as the average farmer has only two head of cattle producing about 4 metric tons of manure annually, not enough for one acre but the yield increases of groundnuts grown with this amount of farmyard manure is such that the area under groundnuts can be reduced without income being affected.

The area freed can be used for green manure production. One of the partners has started green manure production plots to evaluate the feasibility of this approach.

have only recently had to deal with new varieties and because many marginal farming communities are not traditional farmers, their knowledge of groundnut cultivation is limited. Also, the younger generation has lost interest in learning about traditional practices. The PTD process initiated by AME, therefore, had to rely more heavily on formal research.

AME's first experience with a groundnut PTD process took place in 1994 with an NGO and sixty farmers in the Dharmapuri district of Tamil Nadu. Here two groups of farmers decided to implement experiments. A fairly good insight into important factors influencing groundnut production was obtained over a two-year period. By 1996 this work expanded to Chittoor district in Andhra Pradesh where groundnut cultivation faced many problems. Working with 20 individual Dalit farmers in one village proved to be a slow process because their familiarity with farming was less than 25 years old. The Dalit were erstwhile untouchable, landless, agricultural labourers.

Consolidating and expanding PTD

A first sustainability analysis could be made on the bases of the Dharmapuri and Chittoor experiences and a strategy was developed to restore soil fertility and physical characteristics at low cost (see Box 3). With these experiences, a provisional groundnut production manual was published in early 1997 and provided a basis for working in other areas.

Having identified problems through PRAs and found similarities, it was not a question of looking for things to try, but rather a matter of getting started in a demonstration mode. But due to differences in climate and soils, new problems emerged and proper PTD experimentation on these issues started in 1998 and 1999.

Platform building for SCA

In the new areas we encountered the problem of whitegrub and leaf miner. AME had little information about these pests and we approached the researchers. This lead to a workshop in late 1997 which we organised with the National Institute for Extension Management (MANAGE). Representatives from the All India Coordinated Project on Groundnut and Whitegrub, state agricultural universities, ICRISAT and a broad group of NGOs also attended. We learned a lot from each other and established important links with the researchers. In this way the Groundnut Working Group (GWG), a platform for SCA was born. The idea was elaborated to create a platform that would bring together researchers, input suppliers, policy makers, NGO's and farmers on a regular annual bases to create more synergy through the exchange of experiences and information. This whould lead to more 'need'- driven research, an improvement in the knowledge of all parties involved, a better supply of new, environmentally-friendly inputs and improve farmers access to the banking system.

In 1998, NGOs presented findings from the 1997 PTD experiments to researchers and representatives of national programmes at a second GWG workshop organised at MANAGE. Banks and input suppliers were involved in the hope that they would become interested and willing to provide credit and ecofriendly inputs to the experimenting farmers. The workshop focused on whitegrub and leaf miner control and tried to promote collaborative efforts. The result was the birth of the whitegrub programme (see Box 4).

Scaling-up PTD and SCA

The first experiences with PTD experimentation in Dharmapuri in 1994 involved 60 farmers. Now the technology selected by PTD farmers is used on about 5000 acres by an estimated 2000 farmers. AME has also linked with two more NGOs, one in Chittoor (20 PTD farmers in 1997 now about 60 PTD farmers and 150 users) and one in neighbouring Anantapur district (20 PTD farmers in 1997, now about 30 PTD farmers and 700 users) working with the women farmer members of a self-help group and a young male farmers' group.

Now AME partners 14 NGOs and 500 farmers in five districts in Andhra Pradesh, Karnataka and Tamil Nadu in PTD processes. Further, other NGOs and an estimated 1500 farmers have been influenced in their way of cultivating groundnuts as they too use the results of our work.

AME has designed various ways of up-scaling:

- NGO staff train their colleagues in proven technologies which are then disseminated through normal extension.
- Farmers who attended the training take it upon themselves to assist other farmers trying out the proven technologies. Some aspects of PTD experimentation might be incorporated but it is mostly extension;
- New groups of farmers are identified by NGOs and new PTD processes are initiated;
- Farmers who participated in the PTD processes give interviews for radio programmes on agriculture;
- Small, user-friendly manuals with good illustrations are produced in local languages;
- Neighbouring farmers start using part of the technology which they have assessed to be valid.

Box 4 **The whitegrub programme**

One outcome of the GWG workshops was the decision of the Australian Council for International Agricultural Research (ACIAR), the Indian Council for Agricultural Research (ICAR) national whitegrub programme, ICRISAT, the Chittoor and Anantapur NGOs and AME to embark on a joint research initiative on ecofriendly whitegrub management. The objective was to isolate a congregation pheromone for whitegrub adults which would attract them to one spot making it easy to kill them before they could lay eggs. This would significantly reduce the pesticide load and would be much more economical than the present method of control. Such a congregation pheromone has been identified for the species in north India and after two years of control the level of pest infestation was reduced for five years.

At present a systemic insecticide is applied as a seed coating to control whitegrub. This insecticide also controls jassids, white flies and leaf miner to a certain degree but is expensive for farmers.

After the first year there were discussions at the level of the national whitegrub programme. The all India coordinator was not sure how important the pest was in south India. It was suggested that a survey be carried out there. In the third GWG workshop (1999) it was suggested that the NGOs take part in this effort. About 25 NGOs reacted positively and embarked on a systematic collection of whitegrub. Many insects were caught and sent to University of Agricultural Sciences, Bangalore and ICRISAT for identification. A collaborative survey of larval density is being carried out in endemic areas. Recently an area was discovered where damage was observed to be 100%. This observation is in sharp contrast to the prevailing government view that whitegrub is not a major pest in south India.

A major expansion of the PTD programme is presently taking place (see Box 5) since the experienced farmers have assumed the important role of training other farmers. The larger part of the programme comprises extension training in proven techniques of groundnut production, selected by PTD farmers in the area concerned.

New issues are coming up

In the third workshop (early 1999) organised at CRIDA (Central Research Institute for Dry-land Agriculture), problems related to groundnut diseases were explored. Farmers had incurred serious losses due to fungal diseases, mainly collar and stem rot, in the preceding growing season.

Leafspot and stemrot control

During the workshop it became clear that leafspot and stemrot control are interrelated. To prevent stemrot it is necessary to control leafspot. The most common way of controling leafspot is by spraying with chemical fungicides (Dithane M45, Bavistin, etc.) at regular interval starting at about 60 days after seeding and repeating applications at intervals of about 15 days. This means that about 3 sprays are required. This is too labourious and expensive for small-scale dry land farmers .

The early warning system developed by ICRISAT makes a more accurate timing of sprays possible. It can also indicate that conditions are unfavourable for the disease and spraying is unnecessary. This reduces labour and cost. Even so farmers found it still too expensive so we set about looking for alternatives.

In the literature we found that magnesium deficiencies could enhance susceptibility to leaf spot. Thus we tried magnesium fertilisers and saw a moderate decrease of disease incidence in the field. A partner NGO informed us that a concoction of leaf extracts of *Lantana camera* and eucalyptus has fungicidal properties, so we tried this as well. Farmers complained that spraying is difficult and expensive even with botanicals. We discussed the farmers' evaluation in the workshop.

Scientists and NGO agronomists assured us that resistant groundnut cultivars exist and perform well both on station and at farm level. They agreed to supply the NGOs with a basic quantity of seed of five cultivars. Quite a number of plots have been planted, NGO staff and farmers monitor disease incidence and ICRISAT staff visit the plots and train NGO staff and farmers in disease recognition and scoring. Scientists from national agricultural research institutes also presented research results that showed that a high dose of gypsum at planting time (200kg/acre) significantly reduced the incidence of stem rot. Other scientists expressed interest in the scientific validation of botanical extracts and homeopathic medicine in leaf spot control. The whitegrub programme has also decided to test the effectiveness of homeopathic medicine in controlling whitegrub as well.

Partcipatory documentation

We had found that many farmers and NGO staff were confusing the reasons why groundnut plants were dying. The whitegrub team took the initiative to develop a field determination booklet called *'Why are my groundnuts dying?'* This booklet provides a pictorial guideline for determining the cause of death. The draft was discussed in the workshop and comments have significantly altered the layout, choice of photographs and the text. A joint press conference with CRIDA provided newspaper, radio and television coverage which resulted mainly in political interest in our collaborative efforts.

What does the future hold?

Over the past five years we observed that the PTD process which AME initiated in a small way has gradually generated enormous enthusiasm, and spread rapidly to neighbouring areas. Today many organisations are involved. It is satisfying to witness that certain processes have become self-propelling, no longer requiring any effort from our side and that AME could gradually phase out its involvement.

We have also observed that not everything scales up by itself. Technologies once validated by farmers, spread fast. Yet, the experimentation process itself, which in the first place resulted in learning about technologies does not scale up so easily. It requires continuous nurturing, able guidance and intensive monitoring.

Knowing that the number of farmers who have become actively involved are a mere fraction of the total farming population and that much more remains to be done, we conclude that scaling up the capacity to guide experimentation remains a major challenge. It will perhaps require another half decade before this ability becomes self-perpetuating. ■

Box 5 **Involving women in PTD**

After two years of PTD experiments, a federation of self-help groups of women members in the Anantapur area decided to adopt gypsum, rock phosphate and biofertiliser application as proven technologies. They are now disseminating the technology throughout their federation of 120 women's self-help groups that have a total of 2000 members. About 700 of them started to use the tested technology in 1999. The self-help group involved in PTD experiments was able to inform the federation by inviting the leaders to PTD evaluation sessions. Women's groups in particular performed well in our PTD experiments. Men often mixed up their experimental and control plots whilst most of the women maintain the plots separately and collected data meticulously.

INDIA

RESEARCH PARTNERS

- More than 2000 farmers
- More than 20 NGOs
- State, national and international research
- State Universities
- Banks
- Input suppliers
- MANAGE
- AME

In southern India, on the semi-arid Deccan Plateau, AME is facilitating a research platform of farmers, NGOs and research organisations on groundnut production. Millions of small farmers with marginal land have become dependent on groundnut monoculture to obtain cash. However, due to soil degradation, pests and diseases and macro-economic issues groundnut increasingly gets an un-sustainable option to them. AME strengthens farmers and NGOs capability to analyse their situation, experiment with alternative practices and interact with scientists, bankers and input-suppliers. Many farmers recognized the viability of several of the soil fertility and pest and disease management practices experimented with. This has resulted in a fast growing coalition of stakeholders who discuss and coordinate their concerted actions in the 'Groundnut Working Group'.

Farmer explaining PTD results.

Results and impact of the PTD process

After two years of learning, experimenting and sharing results, the stakeholders in the PTD process examined the extent to which they had achieved the goals they had set themselves in 1997. The farmers, NGO staff and researchers who participated in the research programme assessed its impact and results in the following way.

Farmer' capacities strengthened

The majority of farmers showed a keen interest in experimenting, monitoring progress and assessing results. They organised themselves in groups to share and discuss the results and many now wish to go on conducting new experiments. A major attraction for both individuals and groups is having the opportunity to compare different options and learning moments. It strengthened the confidence of farmers in their own ability to find solutions. Traditional knowledge and management capacities were accepted as strategies for reaching production improvements and natural resource management.

Both farmers and technical staff have learned from these first experiments. They have come to a better understanding of such concepts as treatments, controls, variables and factors and farmers are now able to use them effectively. At the same time researchers have learned to adapt their scientific designs to farmers' realities and evaluation criteria. It is clear that farmers still have a lot to learn when it comes to recording and monitoring data. At the same time attention must be given to what are the most suitable statistical methods for analysing the results of farmer-managed experiments.

Experiments helped to develop LEISA

Farmer assessment of various experiments proved a positive move towards improving agricultural livelihoods. This was achieved either by reducing costs through the use of cheaper local inputs (eg herbal treatments for potato disease and shipita for the treatment of liver fluke) reducing dependence on external inputs or by introducing new elements into the production system (see p 67 pasture management). Follow-up experiments have started to identify solutions to related problems such as making silage from fodder legumes and trials to adapt shipita to different locations and altitudes.

During PTD activities it became clear that women possessed important knowledge and capacities when it came to designing and implementing experiments. Women were the carriers of most of the knowledge relating to local herbs and to their usefulness as botanical pesticides. They understood the specific characteristics of different varieties of plant material and were well aware of the treatments locally available for livestock disease. Better use should be made of this specific knowledge.

Farmers, scientists and NGOs

The experiments can be considered as a convergence between formal science and farmer knowledge. At all stages of the PTD process farmers worked closely with NGO staff and researchers from the various agricultural research organisations involved. The joint analysis of the causes and effects of the major problems laid the ground for a common understanding. The presentation of researcher-identified options, such as newly introduced fodder legumes, demonstrated the farmers the important role scientists can play in providing alternative solutions. Scientists can also provide the analytical tools to confirm experimental findings such as the laboratory tests carried out to determine the incidence of liver fluke in treated and non-treated animals.

PTD has facilitated a shift in how NGO partners approach farmer priorities. Instead of focusing on their own agendas, NGOs saw how PTD farmer-workshops brought farmer priorities to light that had not been identified in NGO programmes. It was clear from the beginning that focusing experiments on LEISA alternatives reflected farmers' needs and requirements.

PTD: long-term relationships

PTD experiments showed that there was still considerable scope when it came to finding alternatives to the conventional solutions presented by government agricultural research and extension. Most of the partners involved wished to develop their PTD capacities further and integrate PTD into their operation plans. The Peru experience shows the importance of training staff in government institutions to encourage a wider application of PTD at this level. It was recognised that PTD is a process that requires more time than a few cropping seasons. Creating networks among different types of institutions involves long-term relationships. ■

Farmers exchanging PTD experiences.

Sharing the PTD approach

Markus Staub Eisenlohr

The objective of PTD is to ensure that small-scale farmers genuinely participate in establishing their technological requirements and develop their capacity to carry out experiments in the field. This method of participation enables peasant families to achieve a more sustainable rural development. After gaining experience in PTD among self-sufficient farmers using few external agricultural inputs, CEDEPAS (Centre for Ecumenical Promotion and Social Action) a Cajamarca NGO, decided to apply the methodology with farmers using high levels of external inputs to grow potatoes. The experiences of two groups of small-scale farmers, who exchanged information about the research methods applied for PTD, indicate that experimenting farmers can be useful promoters of such an approach.

Learning and teaching

In 1997, CEDEPAS began applying PTD methodology in the Magdalena district, a self-sufficient area. The replica of PTD training provided by ILEIA coincided with the migration of peasants to the so-called Yunga (areas below 2300m) to work as labourers in the rice fields at the beginning of the dry season. The first PTD cycle began with only five families because of the experimental nature of the work and the heavy workload of the promoters. These families completed an entire PTD cycle in one year.

Farmers in Magdalena started to discuss the problems of their environment by identifying the natural resources available to them. Four main problems emerged: limited soil fertility, 'Rancha' in potatoes (*Phytophtera infestans*), the lack of pasture land for cattle and endo-parasites in cattle.

In order to further explore the problem of limited soil fertility, staff and farmers constructed a so-called 'problem tree' to describe cause and effect. Areas of possible intervention were pinpointed with a view to finding solutions. In their search for solutions that were within their own resources, farmers decided to plan and implement a field experiment involving the use of cattle dung in potato plantations. This would be applied in different forms: the traditional dry dung core sample, damp dung (kept in a manure heap), and damp dung mixed with straw (kept in a manure heap). The purpose of this experiment was to prove whether an adequate application of manure would increase soil fertility. Apart from other indicators observed during the farming season, yield was the main indicator against which the success of the experiment was measured. The best results were obtained with damp dung, equivalent to a 20% increase in the harvest when compared with the yield achieved using dry dung.

The fact that there were only a few participants enabled staff to closely monitor the entire process and maintain an intensive flow of communication with the farmers. In this way, both promoters and farmers satisfied their interests and learnt from the experiences and discussions. The PTD instrument was thus studied in depth and its characteristics and peculiarities were identified. The interest aroused by the experiment guaranteed the farmers' attention. Through their observations and considerations, with the help of promoters, they absorbed the whole process and adopted the results.

From farmer-to-farmer

Three farmers from Magdalena who were involved in the experiments were invited to accompany two CEDEPAS promoters. The latter were supposed to introduce the PTD methodology to farmers involved in a project promoting market-oriented potato production in another part of the northern highlands. The purpose of this two-day workshop was to introduce the methodology to other promoters and to start the PTD process with peasant families in the area.

The promoters took along panels with photographic sequences of the first PTD cycle to liven up the workshop. However, during the trip they came up with the idea that the experimenting farmers themselves should demonstrate their experience of the methodology to the workshop participants. Guided by the photos, the farmers from Magdalena did an excellent job. The experience gained throughout the process had turned them into PTD experts. As a result of the enthusiasm and conviction with which they showed how they had experimented with different forms of dung, the promoters attending the workshop were convinced of the viability of the PTD methodology. Farmers realised that the technical results of this experiment were better than with chicken manure, a product that was becoming increasingly expensive to buy. It became clear that the workshop participants were more influenced by the experiences of the experimenting farmers from Magdalena than by the explanations provided by the promoters. This was the more convincing as the experimenting farmers had gone through all the steps of the PTD cycle maintaining a constant dialogue with promoters.

The promotion of this experience convinced many families of the usefulness of the PTD methodology and these are now going through a similar process of implementation and learning. Experimenting farmers are well aware of the positive impact of their experiences on other families.

Farming is not only an economic activity in rural communities, it is also a lifestyle. Over the years, small-scale farmers have established and adapted production systems to sustain their families. They developed techniques by managing the natural resources available and by adjusting them to constantly chang-

Custodio Bojórquez Reyes

ing weather conditions. Andean farmers also organised themselves and planned, controlled and regulated land use collectively. This process gave rise to such practices as fallowing, crop rotation and crop associations, creating biological diversity,

Peasant expertise and formal science

utilising by-products and agricultural residues, livestock breeding complementarity, the use of plants for animal health and the management of microclimates.

The small-scale livestock breeders in the peasant communities of Miravalle, Quilcas and San Juan de Jarpa - joint participants in the ILEIA project - identified the lack of pastures during the dry season as one of the main problems they faced in their production systems and in maintaining their lifestyle. The Veterinary Institute of Tropical and Highland Research (IVITA), a member of GIAREC and mandated to provide advice to producers on matters concerning animal health and animal feed, assisted the farmers in finding solutions through a participatory process of innovation.

Lack of forage during dry seasons

In the Mantaro valley, livestock are bred at altitudes that range from 3200m in the flat valleys to 3800m on the steep slopes of intermediate areas and at 4200m on the high plains and plateaux. Farmers have adapted to these varying geographical conditions and established livestock production systems that are compatible with the various forms of land tenancy such as large-scale enterprises (SAIS), community associations and family farming units.

The tendency of peasant communities to breed more animals than the pastures can bear often result in overgrazing. To make matters worse, to meet the demands of a growing population, food crops are taking over pastures. Comparing the National Agricultural Censuses of 1972 and 1994 reveals that the area of pasture has decreased by 33% in the last 22 years and that farmland has increased by 52.5%. This means that there is less forage available for an increased number of livestock.

Sharing experiences

The application of PTD within the framework of GIAREC to tackle the problem of pastures helped establish a creative interaction between small-scale farmers in peasant communities and the NGOs and agricultural research centres promoting the process. In the process, the cause and effect of the major livestock feeding problems were identified and analysed. The next step was a session that exposed farmers to the techniques developed by IVITA. This made it possible to identify together possible solutions and to plan experiments. Consideration was given to the resources available to the producers. In this way local capacity to carry out experiments on the bases of peasant know-how and expertise and formal science were improved.

Advantage of harvest residues, producing and preserving pastures and forage material and improving the management of native pastures were among the alternative ways of overcoming fodder shortage discussed.

The technologies developed by IVITA and passed on to farmers included the use as feed of cereal straw (barley, wheat and oats) whose protein content had been increased by adding small quantities of green grass or by urea treatment. Cereal straw in the Central Highlands is seldom used for animal feed, mainly because ruminants cannot digest it because of its low protein content. A second option was the production of cultivated pastures and forage material by combining grasses with leguminous fodder. The production and management of oats is limited to the rainy season due to a lack of irrigation facilities in peasant communities. Cultivated pastures, on the other hand, are mainly adopted by intensive dairy-farming systems in intermediate valleys, under a rotational grazing system. The most common association consists of English ryegrass, Italian ryegrass, tangled grass, white clover and red clover.

Incorporation of improved leguminous plants in native meadows is another option and has been used with much success in the Southern Highlands. These crops should be employed in rotational grazing systems with short grazing periods thus preventing a heavy burden on the soil. Under this system between three and nine times more dry material is produced in native meadows.

The technique of sowing cereals alongside annual leguminous crops is based on the fact that in the Central Highlands it is common to find wild plants such as the annual leguminous Medicago species flourishing in fallow land and along the edges of the roads and irrigation canals. This is a high quality fodder similar to alfalfa. Cereals are combined with leguminous plants to produce a haystack that can be used as fodder once the cereals have been harvested. One of the problems with this technique, however, is the limited availability of seeds of these wild species.

The last option presented to farmers was the conservation of forage material. Storing the hay of upgraded feed oats is a simple process and is already used by a growing number of farmers. In order to produce the hay, the oats is cut when the grain is milky. It is allowed to dry outdoors for two or three weeks before being stored in haystacks or barns. Silos are another way of preserving green grass or improving the digestive properties of harvest residues such as dry fodder (starchy corn stubble) on a small scale. There are various types of silos built with local resources, in which fodder or treated harvest residues are stored ▶

and then covered with black plastic to keep them air-tight in order to prevent the fodder from decomposing.

Farmers' expertise

In most of the peasant communities in which rain-fed farming develops, the conservation of fodder is a strategic alternative to ensure a supply of animal feed. Farmers' animal feed practices centre around the use of harvest residues, the cultivation of fodder crops, the management of native meadows and limited irrigation or use of flooded fields. Dry fodder from harvest residues is a resource that small-scale farmers use exclusively for cattle feed during periods of low water. In order to improve this animal feed, farmers mix the dry fodder with alfalfa, ryegrass or green barley, or dampen it with salt water or urine to make it more palatable and improve its quality. Peasant farmers who have access to water usually sow grass: the most widespread species is Italian grass for cutting.

In many parts of the region, farmers have experience with native meadow improvement. This includes the regulation of the number of animals of each species that a farmer is allowed to put out to pasture in community-owned fields. At the same time communities have continued their ancient rotational grazing traditions, selecting their fields depending on the time of year and the ecological area. During the rainy season, all the farmers move their herds to the higher regions where plenty of pastures and watering places are available. When the dry season starts the animals go down to the lower area where the soil retains its humidy longer. This system gives the meadows time to recover. Farmers also divide grazing areas into sectors and rotate the fields, thus allowing the pastures to remain unchanged.

Some peasant communities have irrigated small areas and these enable them to have enough pasture land for their herds, particularly during periods of drought. Such areas include the so-called *'bofedales'* or flooded fields that provide large expanses of good quality natural pastures. Other communities have designed temporary irrigation facilities for native pastures in order to dampen dry meadows and revive the plants that have dried up due to lack of rain.

Farmers' and scientists' combined expertise

As a result of discussions between researchers, NGO extension workers and farmers after various options had been presented by IVITA, experimental groups decided to try producing fodder. They set out to evaluate the performance and adjustment of different species and associations within their own farming environment. In the three research sites, each group made an effort to clearly define the objective of the experiment:

- Miravalle: to compare how five varieties of grass adapt to three companion crop systems.
- Quilcas: to evaluate the performance of various varieties of grass cultivated at different altitudes.
- San Juan de Jarpa: to compare how different forage crop mixes perform, seeking to improve their year-round production and availability.

A total of 42 farmers participated in this experiment: 13 women and 29 men. Each experimenting farmer drew a sketch of their available land and indicated the layout of the trial.

The evaluation of the experiments was based on criteria formulated by farmers and technicians separately. While researchers put more emphasis on quantifiable production factors, farmers in general focus more on the factors determining the incorporation of different species into their production system. At group meetings, experimenting farmers exchanged their points of view on different aspects of the experiments (germination, growth, resistance to drought) and this led to comparisons being made between the different species of grass tested. This helped farmers form their own opinions about the most promising species. More important still, it encouraged them to continue experimenting and complementing their new skills in the conservation of fodder. Box 1 shows some of the results of the experiments in each zone.

The PTD approach proved to be an appropriate methodology for encouraging farmers to carry out collective action to identify and select the best solutions to the problems they themselves had identified. The exchange of experiences and know-how between farmers increased their self-confidence and encouraged them to organise themselves, discuss their problems and to propose a schedule of local experiments. Discussions between researchers, technicians and farmers enhanced peasant skills and improved the chance of obtaining specialised assistance from research institutions.

The positive results of the experiments created good prospects for new ones, thus triggering a collective local experimentation process. In the three sites, farmers have decided to start experimenting with silage techniques for fodder crops. They feel that growing fodder crops during the rainy season can have a beneficial effect and lead to an improvement in the fodder situation during the dry season when these crops are silaged.

Finally, the participatory and collaborative process that developed within the framework of GIAREC revealed that the interaction between peasant and scientific knowledge encourages rural populations to exchange technological and socio political views in a conscientious and sustainable way.

■

Box 1 **Results of experiments**

MIRAVALLE

- Red clover proved to be more resistant to the lack of water, whereas Italian Rye grass was the most productive (10.08 kg/m^2).
- Red clover and Italian Rye grass yielded the most green fodder (9.91 kg/m^2).
- The white clover and English rye grass association required more water.
- Alfalfa was not planted in all farms, its growth was slower and it was the most susceptible to the shortage of water.

QUILCAS

- Red clover and Italian rye grass was the combination that adjusted better to local conditions, although red clover only yielded 3.9 kg/m^2.
- Red clover and Italian rye grass were cut every 45 days.
- Alfalfa was the crop most ridden with weeds and proved well established after the second silage.
- The regrowth capacity during the rainy season was evident in all experiments.

SAN JUAN DE JARPA

- Red clover + Italian Rye grass proved to be the most well adjusted and productive combination.
- Red clover + Italian Rye grass proved to be resistant to diseases and tolerant to drought.
- Red clover + Dactylo was the slowest growing combination.
- Alfalfa grew slowly and was affected by aphid and stained leaves.
- The germination of the seeds used ranged from 50% to 90%.
- Soil acidity was a limiting factor which affected the yield. The higher the altitude, the greater the acidity of the soil.

Moth control with local plants

The high incidence of pests and diseases in potato crops has induced many farmers to apply different sanitation practices to reduce damage to tubers. In 1997, when GIAREC integrated PTD as a methodology to reinforce farmers' experimentation and innovation capabilities, the small farmers of Quilcas

Norma Canales & Raúl Canto

Peasant Community expressed their interest. This community has a long-standing working relationship with Yanapai, an NGO member of GIAREC. The farmers identified the rate of pests and diseases in potato crops as one of their main concerns. Among these pests was the 'Andes weevil' (*Prennotrypes suturicallus*), the 'potato moth' (*Symmetrischema tangolias Gyen*), and the soil worm known as utushcuro (*Copitarsia turbata*). Of the

Strengthening farmers' research

photo: GIAREC

Harvesting LEISA potatoes.

three, the one that required urgent control was the 'potato moth', particularly during seed storage.

Starting the search for innovations

After identifying and setting priorities for this particular problem, the PTD process enabled the farmers -together with the Yanapai facilitators- to visualise causes and effects, and to recognise why the problem occurred and with what results (Table 1).

After the identification of the causes and effects of moth infestation, the farmers decided which causes to experiment on, what could be learned, and what was beyond their control and could not be changed:

- Things that could be tried (trials): use of plants for moth control in potato storage
- Things to be learned (training): seed selection, biological cycle of moths
- Things that could not be changed: climate

In this way ideas emerged that could be tried in the experimentation phase. Promising solutions arose from farmers' knowledge of agricultural practices. Old ways of controlling moths using local plants such as 'muña' (*Minthostachys spp.*), eucalyptus (*Eucalyptus globulus*), and 'chilca' (*Baccharis sp.*) were recovered. The moment the farmers became aware that traditional solutions using local resources were possible, they became very enthusiastic. Old practices that had almost been forgotten by community members were revived and their usefulness discussed. During these discussions it became apparent that farmers were very disillusioned with the chemical alternatives, mainly because they were too expensive and the concern about their toxicity.

Designing the experiment

The need to develop reliable experimental designs that could be handled and evaluated by the farmers themselves gave rise to the following questions which had to be answered by the farmers involved in the experimental process:

- What has to be solved?
- What is to be experimented with?
- Why is it useful to compare?

This methodology allowed the participants to define the experimental objective: 'To compare three forms of potato seed storage to establish the best way to reduce moth damage'. The treatments were defined with the help of the following questions.

- What is to be tried?
- When will this trial be carried out?
- How is the trial going to be carried out?
- What are the amounts to be tried?

Based on the suggestions of the older, more experienced farmers, the treatments compared were as follows:

- *Eucalyptus*, *'muña'* and *'chilca' ashes*
People in the region used aromatic plants such as eucalyptus, muña and chilca to control potato moths in the storage site. Many people used the fresh branches of these plants while others used dried leaves. For this trial the farmers decided to spread a combination of ashes from these plants over the seeds.
- *Petroleum traps* An alternative way of controlling moths was the petroleum trap. The farmers suggested placing these traps in every corner of the storage site. White, one-litre trays containing 0.25 litre of petroleum were used.
- *Control* (farmers' practice of storage)
The common way of storing seeds was to place tubers over a straw bed without spreading any product on top.

Experimenting

In order to validate the experiment, it was necessary to set up certain basic rules. Constant factors had to be established, procedures that all the farmers would follow in each of their experiments. It was decided that constant factors were the time of harvest, amount of ▶

treated seed, variety and size of seed, the storage site, material in the storage site, amount of ashes, storage period, and the process of monitoring and evaluation.

The farmers designed the experiment using a participatory process. The way in which the trial was to be implemented (size, materials, place) was described. For statistical purposes each farmer represented a duplication of the trial. This allowed experimentation to be simplified but meant that the conditions of the trial had to be the same for all farmer experimenters.

The design consisted of three small storage sites of the 'pen' type (0.70 m x 0.70 m x 0.25 m) made from eucalyptus, a local resource, with 1.50 m between treatments. The storage sites were placed around the dwellings. Each storage site represented a different treatment. Treatments were allotted randomly.

When the scheme was finished, an activity plan and schedule were prepared. Each activity was detailed and programmed in time. Inputs used were described, those who had suggested them, and the names of those in charge of the experiment. Training and evaluations were also included in this schedule. In this way farmers were able to follow each step of the experiment chronologically and were able to start organising the trials to carry on with planning and implementing the experimentation process.

Finally, to systematise the results, simple easy to handle tools such as a peasant's log were introduced. These logs were used by the experimenters once every 20 days to note activities undertaken. In a parallel process technicians used the trial log to record quantitative data and the scientific evaluation of the trial.

Evaluating the experiment

It was decided that both farmers and technician would formulate evaluation criteria in order to seek complementarity and correspondence between the various opinions and avoid any one criteria being dominated by another. Table 1 shows the criteria defined.

According to the farmer experimenters, the results of the evaluation showed that the difference between the three treatments was not very great. However, farmers felt the ashes treatment was better because the moth damage was only observed in the 'guides'. Not many tubers had been attacked. Although the petroleum traps were effective in attracting adult moths, butterflies and flies, and served as a protection in all trials, they were not functional because animals and children could brush against them causing the contents to spill over the stored potatoes and cause loss through tuber pollution. The 'control' also had a low incidence of moth damage; the tubers were well preserved.

Statistical analysis

According to the field technician from the Yanapai Group who was facilitating in Quilcas, a statistical analysis was too complex because it implied the adaptation of a statistical design to small-size peasants' experimentation. The design used was one of random blocks with each farmer being considered a block. The statistical result shows that there was no significant difference in the weight of tubers damaged by moths in the three treatments, but there was a significant difference between the blocks (farmers), which showed a differentiation between the farmers in the control. Although the high variability between treatments and blocks could have been reduced with a larger number of duplications, this was complicated in the peasants' experimentation because of limitation in time, space and resources.

It should be noted that, for experimenting farmers, results from the storage sites alone were not enough. They also had to try the seeds in the field. In the following agricultural season, the seeds were sown and the statistical results showed that there was no significant difference in the yields from treatments. Nevertheless, a significant difference was found between farmers.

The scientific evaluation of the trials was an opportunity for NGO technicians and scientists from the agricultural research centres to discuss which statistical designs were best for farmers' trials. Ways of reducing variability in statistical analysis, and ensuring that these analyses were intelligible to all experimenting farmers, were also discussed. The need to establish statistical designs specifically suited to the farmers' trials was stressed because this was considered a critical factor for the scientific validation of farmers' experiments.

Strengthening farmers' capacity

It is important to observe that the analysis of cause and effect enabled farmers in the Quilcas Peasant Community to clarify such issues as differentiating the damage inflicted by pests and processes such as the moths' life cycle that had not been discussed earlier. This enabled them to differentiate the type of pest in the storage site from that produced in the fields. It helped them to develop a mental model of the experimentation process and to understand why a sequence must be followed. This knowledge allowed them to describe their experience and to share processes and results with other experimenting groups within GIAREC.

Despite these positive aspects which indicated a strengthened capacity of local peasant research, the follow-up process and the way trials were recorded was weak. The farmers were not used to noting down data, and that made it difficult to systematise quantitative information. Sheets from the trial were not always correctly registered because many women were illiterate. This shows the need to create or design more adequate tools for these types of social reality that might motivate a more permanent follow-up and strengthen the capacity of peasant experimentation and innovation from a gender perspective.

Table 1: Problem tree showing causes and effects of potato moth

EFFECTS:	CAUSES
1. Damage to tubers' eyes hampered budding	1. Not all tubers are harvested
2. Sour/acid taste in potatoes for consumption; not even suitable for animals	2. Use of contaminated manure or plant residues
3. Damage in all growing stages of the plant	3. Lack of knowledge on pests' biological cycle
4. Affects storage and field crops	4. Indiscriminate use of agrochemicals
5. Moths become resistant to agrochemicals	5. Lack of cleanliness in storing sites
	6. Bad selection of harvested potatoes

Table 2: Farmers' and technicians' evaluation criteria

Criteria of farmers evaluation	Criteria of technician's evaluation
Tubers with moths	Number of tubers damaged by pest and disease in the store site
Colour and size of 'guides'	Mechanical damage
The emergence of the tubers in the field	Weight loss per storage site
Quantity of tubers damaged by pests	Type of budding, emerging, height of plants
Quantity of input used	Yield (number and weight)
Yield	Tuber loss
	Pests and diseases

The use of local plants to control parasites

Ida Mendoza Alvarez and Vicente Nalvarte

The sheep-raising family farms of the Andes rely on natural pastures growing at altitudes that exceed 4000m. The extent of grazing land available varies, depending on the access peasant communities have to these areas and the climate. Pastures that flourish during the rainy season are depleted in the dry season. The lack of fodder and difficulties in managing flocks at these altitudes affect animal health and, consequently, the economy of peasant families. Such is the case in the communities of the San Juan de Jarpa and Yanacancha districts in the upper reaches of the Cunas river in Peru's central highlands. Here livestock breeding is the main activity among small-scale farmers. Family-owned flocks consist of sheep, alpacas and some bovine cattle. Although pastures are plentiful during the rainy season, over-grazing destroys them.

In the middle and lower parts of this river basin, peasant families grow potatoes, barley, broad beans and native varieties of tubers and edible roots to feed themselves and to sell any surplus. They also plant exotic fodder to complement their animal feed balance, mainly oats. The farmers have links with urban markets like Huancayo and Chupaca where they take their produce each week.

Diagnosis of farming constraints

Peasant communities in San Juan de Jarpa conducted community diagnosis and a diagnosis of their farms, with a great deal of knowledge and skill, particularly in identifying their main problems. They pointed out the following constraints:

- 'Andean weevil' (*Coleoptera Curlionidae Premnotrypes*) infestation of potato crops, which damaged between 45 and 50% of the production during 1997-98 season.
- Fodder shortage during the early months of the rainy season (November to February) when pastures have still not recovered from the dry season,
- Parasitism affecting sheep and cattle during the rainy season caused by *hepatic fasciola* or *distomatosis*, locally known as *'alicuya'*. Hence the low productivity of the livestock and the consequent negative impact on the family's economy.
- The low prices of meat in urban markets. These low prices fail to compensate production costs, particularly when the animals are sold at a time when pastures are scarce.

The family livestock-breeding system

Sheep breeding systems are based on the availability and extent of the natural pastures owned by each community. These include:

- *Permanent grassland:* Animals graze in a natural pasture assigned to each peasant family. This is capable of sustaining between 50 and 450 sheep and is run by a family member or a hired shepherd. The process is currently improving as management schedules have been established, sanitary conditions are more stable and fields are rotated. This is a mixed breeding, multi-family system (for examples sheep, beef cattle and alpacas) practised in large communities in which each community member is entitled to an average of 15 to 25ha of natural pastures.
- *Rotational grazing:* Sheep graze alongside beef cattle and rotate between two areas, depending on the season. In the higher parts (community pastureland), they graze during the rainy season (September and May), taking advantage of the re-growth of forage and water sources. During the dry season (June-August), they graze in the lower parts, taking advantage of stubble fields, damp meadows and small areas of permanent grassland. This is a multi-family system with flocks of between 20 and 150 sheep, practised in medium-sized communities with an average of 5 to 10ha natural grassland per community member.
- *Grazing on the borders of farm plots:* Under this system, sheep graze outside the farms, alongside roads and in small natural pastures under the control of a shepherd. Flocks range from 5 to 20 sheep per family and family members take turns in taking them out to graze. This system is practised among small communities and families with only a few animals.

Rate of occurrence of distomatosis

In the higher parts of the Cunas river basin, distomatosis is one of the parasitic diseases which has the greatest economic impact on sheep breeders because it results in a high mortality rate, low meat production and a poorer quality of wool.

The following are the main causes of the increasing frequency of this parasitic disease:

- Grazing in infested pastures, whether natural or cultivated. This problem is aggravated by the lack of grassland rotation.
- A lack of preventive treatment of the sheep because farmers cannot afford veterinary products.

A PTD experience in sheep-raising family farms in the Peruvian Andes

- Lack of awareness of the biological cycle and rate of occurrence of this parasite.
- Lack of preventive practices to control the vector (*Lymnea ssp.* snail) which thrives in moist or humid soil during hot periods.

The sanitary aspect is precisely one of the factors that restricts livestock-breeding, particularly if the intention is to improve animal productivity.

Traditional treatment: shipita

According to research studies carried out in the region, producers have traditional ways of controlling distomatosis or *'alicuya'*. These include adding copper sulphate and salt to the animal feed as well as a dose of wild artichoke leaf extract or a combination of bell pepper, red nettle and sharp lemon. Amazing results are obtained from a dose of a preparation made from a native shrub known as *'shipita'* (*Columnella abovata*).

The *shipita* is a perennial shrub that grows all over the southern part of Huancayo province. It has long thin stems which are flexible enough to be used for weaving baskets. It has plenty of small leaves of a dark green colour and has yellow flowers. It can reach a height between 1.5 and 2m and can be multiplied through seeds, by layering and through cuttings.

According to some local community members, treating alicuya with *'jaya shipita'* involves soaking dry leaves from the shrub overnight and, after straining the liquid, mixing it with oil. Half a bottle of this medication is fed to each adult sheep.

Table 1. Design of the experiment and treatment per family

Treatment A :
5 adult sheep that will be given the dosage and remain under observation for 14 days.

Treatment B:
5 adult sheep that will not be given the dosage (control)

Recipe used for the shipita preparation:
- Boil 250g of shipita stems and flowers in five litres of water for one hour at a high temperature.
- Remove the stems and flowers and grind them.
- Place the mixture back in the liquid and continue boiling for another hour until only about one litre remains.
- Let the mixture marinate in a covered container for 10 to 12 days
- Strain and use the extract

Dosage applied:
1cc of extract for every 3kg live weight.

One researcher (Cordova, 1981) recommended the use of one kilo of leaves of this plant per gallon of water (nearly 5 litres), soaked and strained as explained by community members, then mixing three parts of the extract with two parts of oil. The project's veterinarians changed this recipe to adapt the dosage to the limited number of sheep in family flocks and obtained a dosage of 1cc of extract per kilo of live weight.

As this plant is used frequently, communities obtain their supply from cattle merchants, basket vendors or from families who exchange products from the lower part of the valley for produce from the upper reaches.

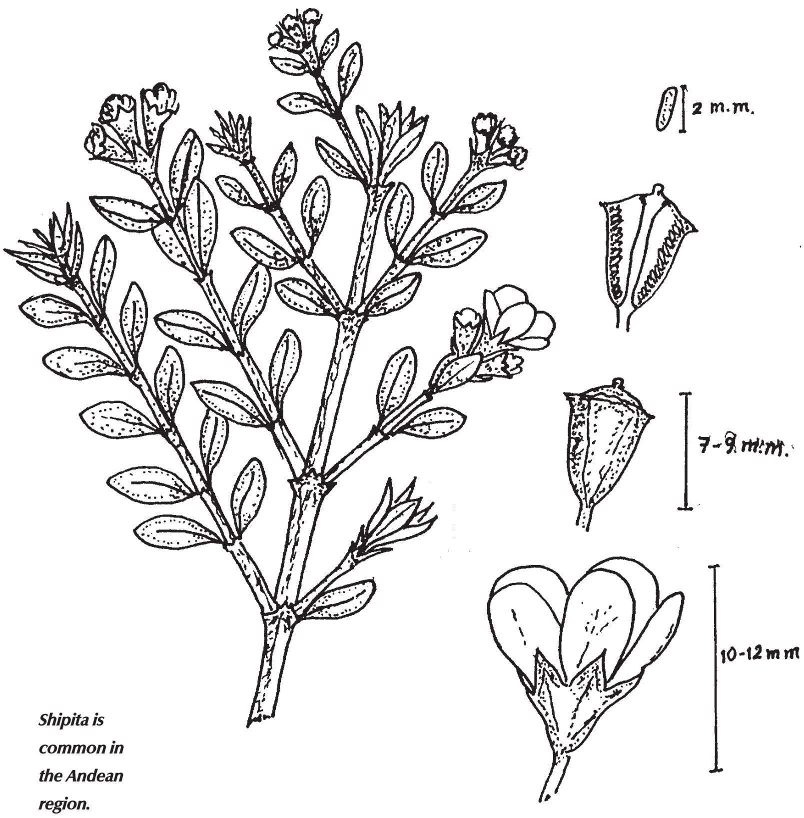
Designing the experiment with shipita

With a view to improving production and reducing the costs of family sheep-raising farms, the NGO staff involved in the ILEIA research programme decided to experiment with the use of shipita in controlling alicuya. To this end, arrangements were made with the Development Committee of the Peasant Communities of Alto Cunas, after the PTD approach had been presented. The Committee decided that the work would take place in six communities with an average of 4 to 6 research farmers - including women - per community. The research farmers were selected at a general assembly in each community, thus ensuring their participation and the replica of the results in each community. The participants formed working groups that were responsible to a coordinator.

The experiment was designed for 10 adult animals from each family flock. Half were treated with shipita and the rest of the animals formed the control group. The experiment was repeated 16 times in six peasant communities (see Table 1).

As experimentation is part of the peasant production system, they had no difficulty starting this 'learning by doing' approach as part of their efforts to improve their production through simple, small-scale comparisons. The close participation of farmers and their families in the implementation of the experiments was important for the assessment of the results.

The identification of evaluation indica-



Shipita is common in the Andean region.

tors for the experiment, such as the weight of the animal, reaction, quality of the wool, feed, quality of the meat and certain symptoms of the disease, were useful for improving accuracy of observation, registration and monitoring activities. The exchanges and evaluation meetings of community working groups also provided an opportunity for discussion. University staff were involved in laboratory testing animal faeces to establish the infection rate.

Results

Results of monitoring and evaluation carried out by experimenting farmers:

- *Weight:* Each animal was weighed at the beginning of the treatment and 30 days later. A 15 to 30% weight increase was recorded in the treated animals.
- *Animal reaction:* After receiving the dosage, many animals felt the impact of the remedy and were motionless. However, two hours later they were back to normal; they started eating and became more active as the days went by.
- *Wool:* some of the sheep had been losing wool. Now they started to recover it and its quality improved.
- *Feed:* After receiving the dosage, the animals acquired a greater appetite as the days went by and started to feed constantly.
- *Quality of the meat:* When the animals were slaughtered a month after the treatment, it was found that the quality of the meat had improved, the carcass weighed more, their livers were better. There was also no evidence of alicuya.

Furthermore, the laboratory tests on the faeces of treated animals proved that the dosage of shipita extract was 87.5% effective in controlling alicuya in adult sheep. Only 12.5% of the animals still had a Grade 2 (low degree) infestation. This shows the effectiveness of shipita in controlling alicuya.

Dissemination of results

Based on the results of the experiment, the NGO staff implemented the following:

- Reproduction and reforestation of shipita: 200 seedlings of that species were brought to the peasant community and planted in hedges and family plots so that shipita would be available to them in the future.
- Sheep handling and sanitation schedules were drawn up based on the results of the experiment and the livestock management system.
- A campaign against alicuya, using shipita was launched: 3248 sheep were treated in 25 farming units run by 60 community families.
- An overall parasite control proposal (MIPAR) based on the control of alicuya in family sheep-raising systems was designed. This included the study by university staff of the transfer of the disease vector. The results were discussed with the farmers.

Conclusions

The experiment confirmed the effectiveness of the natural product *shipita* in controlling *alicuya* as a low cost alternative for family sheep-breeders in Jarpa. The campaign that began with groups of experimental farmers and their families proved that the large-scale use of this method is possible. At the same time, producers were encouraged to continue with their research and experiments - in accordance with their needs - in order to improve their production.

In simpler terms, this process proved that with PTD, actions based on a participatory analysis can begin with a degree of understanding and motivation that reinforces a sense of commitment and guarantees results. At the same time, technologies can be created whilst the promotion is taking place providing they are based on farmers' primary needs.

The integration of local know-how and academic knowledge, cooperation between technicians and peasants and the incorporation of new professionals was another lesson obtained from the PTD exercise. In addition, it strengthened the relationship between research and NGO staff and the population. Finally, it was confirmed that PTD is a process that enhances local skills and resources without restricting external backstopping. ■

Constructing joint action networks

Norma Canales Rivera

In the late 1980s, persisting and increasing poverty, together with environmental erosion, made it clear that a revision and reformulation of approaches and development criteria was necessary. Small-scale agricultural development had focused on technological problems without considering ecological, social, cultural, political and economic issues. The necessity of overcoming the crisis in smallholder agriculture lead to the emergence of the concept of sustainable development and the adoption of environmental, economic and social objectives. This new development approach seeks the active involvement of small farmers in formulating proposals that define what they want from technological, economic and social change. Joint strategies are also being developed among small producers, NGOs, agricultural researchers and local governments to reach proposed development objectives and to promote community empowerment. Individual institutional capacity to integrate the many aspects of sustainable agriculture is limited and only a partnership initiative can have a significant impact on food security, environmental preservation and income generation. The experience of GIAREC (Collaborative Group of Agroecological Research) is one attempt to join forces.

Collaboration for sustainability

In 1995, a group of NGOs (Grupo Yanapai, IDEA-Peru, REDES) and agrarian research centres (CEA-UNCP, INIA, IVITA-UNMSM) - all active in the Mantaro Valley, Central Peru in the vicinity of the town of Huancayo - decided to create an inter-institutional group to promote sustainable agriculture in their area. This working group was called GIAREC. Its objectives were to promote a more rational management of natural resources and to develop LEISA in the peasant communities of the Central Andes.

In 1996, GIAREC - with support from ILEIA - started a process of discussing and analysing various agricultural concepts and approaches with the object of achieving a consensus on criteria relevant to sustainable agriculture. This was to be formulated in a common language readily understood by everyone. It was also necessary to give training in participatory methodologies in order to enhance the participation of farmers in analysing local problems. This process of collective learning enabled farmers, researchers and NGO staff to better understand the rural and environmental reality and how the social organisations involved worked. It also allowed men and women farmers to participate as actors interested in the process and ensured they received credit for the value of their knowledge. Strategic decisions were taken and a plan of action defined that promoted technological change and incorporated ecological principles. In developing this process of conceptual and methodological consensus, GIAREC envisaged becoming a platform with a long-term mission and vision which guaranteed democratic participation to its members.

Mid-1997, the reoriented ILEIA Research Programme proposed strengthening farmers' ability to experiment as an important condition for small farmers' agriculture sustainability. This generated a participatory process to evaluate suitable technologies. The PTD process opened a space in which technicians, promoters and farmers could exchange and share experiences by establishing an interactive communication network among the groups of experimenters, agrarian research stations and NGOs. Both men and women participated in all groups.

Members joint actions

During the 1980s, inter-institutional collaboration between research and agricultural institutions and rural development organisations was difficult for social and political reasons (eg terrorist violence). Trust and solidarity among institutions was affected. However, the need to reactivate small farming production encouraged an approach that would strengthen linkages between peasants' communities, NGOs and agrarian research stations.

The problems of smallholder agriculture were evaluated collectively through discussion and analisis, and ideas and alternatives that offered solutions were sought. Training in participatory methodologies reinforced the analytical capacity of researchers, technicians and small farmers, enabling them to propose strategies to integrate traditional and scientific knowledge while taking into consideration both sustainability and local innovative capacity. The implementation and evaluation of PTD created an opportunity for sharing farming knowledge from three regions (Chupaca, Huancayo and Concepción). It also highlighted various established farming practices as options that could be used to solve the problems described by each group of experimenting farmers.

Each area developed its own process of technological innovation according to its social, cultural and organisational characteristics. In Chupaca (San Juan de Jarpa and Iscos Peasant Communities) the PTD process stimulated agreements between experimenting groups, local institutions (municipality, development committees, community enterprises) and development organisations (NGOs, sector programmes). Together they agreed upon joint actions to solve pests in crops and animals. It also meant the involvement of young university students - acting as facilitators - and the experimenting groups. In Huancayo (Quilcas Peasant Community) the groups of farmer experimenters - both men and women - established close linkages with INIA and IVITA research organisations for consultation and technical training. In Concepción (Miravalle and San Antonio) the groups of experimenters were mainly young people and they established a relationship with the agrarian research stations (IVITA) and the regional university (CEA-UNCP). Through the latter they were able to contact professionals at the graduate school to make an in-depth analysis of veterinary problems and to process the data they collected. This supports the argument that innovative processes are autonomous and cannot be repeated in other spaces or environments.

The experience of joint actions developed by GIAREC with small farmers, researchers and agrarian technicians has shown that through the participation of various actors and the sharing of experiences and knowledge, local experimenting and natural resource management capacity can reinforce local capacity. It is obvious that the interaction of peasant and academic knowledge and experiences re-values local initiatives for development and generates trust and self-esteem in both men and women farmer innovators.

It is also important to highlight the fact that the full participation of state agencies, such as agrarian research stations and universities, and their integration into working groups such as GIAREC emerged very gradually. The participation of key researchers who have decision-making power and who contribute to advocating LEISA concepts within their institutions is instrumental for this collaboration.

However, despite such progress, there is still a need to increase coordination and integration in order to identify key topics for medium- and long-term research and agricultural development common to the agroecosystems of the Central Andean valleys. This will enable the potential capabilities and experiences of every GIAREC associate to be realised. Not only in issues and processes beyond the immediate interest and generating capabilities of the small farmers, but also in formulating proposals for regional policies that will ease the way towards more egalitarian, democratic and sustainable development.

Achievements

The GIAREC working group had many achievements during its first three years. The capabilities and skills of GIAREC members were identified and put to work in the interests of promoting LEISA as an alternative approach to the development of peasant communities' in central Peru. A consensus on the definition of common objectives was also reached. This eased the merging of ILEIA Collaborative Research objectives with those of the associate institutions. GIAREC associate staff members have been trained in LEISA principles and in gender-sensitive participatory approaches. The various participants have learned to interact in an integral and interdisciplinary manner. The LEISA approach to sustainable farming also implies a personal and institutional commitment to generating opportunities that reinforce farmers' capacities despite the restriction of limited resources. This goes beyond formulating collective proposals and obtaining financial resources.

The agrarian research stations (CEA-UNCP, INIA, IVITA) are now recognised as sources of information on technological alternatives that can be adapted to the conditions and local resources of smallholder farmers. This acknowledgement has contributed enormously to the creation of mutual understanding and complementarity between peasant and scientific knowledge. Communication and information are understood to be key factors strengthening interaction inside the GIAREC group and between the group and outsiders. GIAREC is now more flexible in its approach to criticism and recommendations. There is a platform where new ideas can be discussed and where there are willing hands ready to take part in experimentation.

Each space or place has its own dynamics for developmental innovation depending on the problems prioritised, the sociocultural setting and the organisational background of the farmers and technicians involved. This is reflected in the local capacity to coordinate and integrate actions with solidarity, trust and transparency. Local development initiatives are valued and serve to strengthen the self-esteem of both men and women and reinforce experimentation and local management capacity.

Future outlook

The member organisations that have joined this joint-action network to promote sustainable agriculture are quite clear about the future. GIAREC intends to continue developing joint and participatory programmes to improve natural resource management in the Central Andean valleys. They want to increase the living standards of the rural inhabitants. GIAREC's vision is to become an institutionalised platform for development, carrying out sustainable agriculture programmes and contributing to the formulation of research and the promotion of policies, taking equity of gender, social justice and democratic participation into consideration.

In order to achieve this, GIAREC should allow their members to benefit from the comparative advantages of each associate, creating synergism between experimenting farmers, community organisations, agrarian research stations, universities and rural development organisations. Linkages with other institutions should be used to analyse, document and disseminate the experiences of this collective work. This implies a major effort to integrate institutions and independent professionals committed to participatory and sustainable development.

Pesticides in Peru's Highlands

photos: Bert Lof

Farmers in San Marcos using local herbs in preparation of biological pesticide.

Since the late 1960s, pesticides used to control plagues in potato plantations in the Peruvian highlands have unsettled the balance of Andean ecosystems and given rise to numerous cases of poisoning among farmers.

Luis Gomero Osorio & Alfonso Lizárraga Travaglini

Initially, agro-chemicals brought a 'technological revolution' to the farming sector and as a result many farmers changed their techniques because they were encouraged by production and yield results. There were other farmers, however, who continued to use their ancient technologies.

A large variety of pesticides have been introduced into commercial potato production in the Peruvian Andes. It has been estimated that potatoes absorb 20% of the total amount of pesticides used in Peru.

In the highlands, pesticides are mainly used to control the Andean weevils (*Premnotrypes spp.*), potato moths (*Phthorimaea operculella* and *Symmetrischema tangolias*), fleaworts (*Epitrix* spp.) 'rancha' (*Phytophthora infestans*) and various species of nematodes that infest the potato plantations.

When categorising farmers in terms of insecticide use and ties with the market, one can distinguish three types of potato farmers: those who have never used pesticides, those who use them occasionally and those who use them constantly. The most frequently used preparations are fungicides to control 'rancha' and insecticides to control Andean weevils.

The introduction of agro-chemicals

Various strategies were used to introduce agrochemicals into the Peruvian highland markets and potato cultivation in particular. The main strategy was to establish a close relationship with government research centres, producer organisations and centres of higher education. Initially, during the era of large estates, contacts were established through the estate owners. Pesticides were such a breakthrough and were so fast and effective in controlling plagues that farmers soon started using them.

The marketing of agrochemicals has changed considerably over the last 20 years with sales campaigns becoming increasingly more aggressive. In Peru there are approximately 20 companies that import or prepare agrochemicals and most of them reach the potato farmers in the highlands, particularly those in the valleys between the Andes.

Cost has always retricted the use of pesticides especially among low-income farmers. Consequently, more economic products have been created for sale at the weekly markets held in the remoter towns. Low-cost pesticides, such as those made with organic phosphorus compounds, are usually the most hazardous to farmers.

Ecological impact

The greatest environmental problems in the ecosystems of potato farms are caused by the increased use of pesticides. These tend to make pests more resistant and, in a vicious circle, cause new plagues to emerge. Under such circumstances, the economic and environmental impacts are deplorable. Pollution is caused by the pesticides left on the ground and these are spread by the wind to neighbouring areas, contaminating watercourses (ditches, rivers and ponds), causing health hazards and threatening wild animals, pets, pollinating insects and other essential wildlife.

The initial effect in controlling significant plagues was satisfactory. However, pests soon became resistant to the use of pesticides and other substances had to be added. Hence the change from organochlorine insecticides to organophosphates and carbamates. Chitin inhibitors, biological insecticides and botanical pesticides such as pyrethrum were still too expensive to be used in the farming system.

The fact that potato pests and diseases have become resistant to pesticides is a serious threat to farmers. This resistance has developed mainly because farmers have been pressured into selecting pesticides with a specific effect. About 150 species of phyto-pathogenic fungi have become resistant to various fungicides under field conditions. The resistance of *Phytophtora infestans* to metalaxil was reported in 1980.

Another indicator of the level of resistance to pesticides acquired by plagues is the increasing dosage and frequency with which pesticides must be applied. In 1986, 25 kg/ha of commercial aldicarb plus 4.5 litres of insecticide was recommended in Huasahuasi. Ten years later, the technical recommendation was to use 36 kg/ha of commercial aldicarb and 5 litres of insecticides, although farmers tend to use much more than that.

Although the yield obtained with the use of agrochemicals generate more income, the environmental costs tend to be disregarded in profitability analyses. These include the loss of soil quality, the disappearance of essential and pollinating insects, reduced biodiversity as well as water contamination and an increased incidence of poisoning.

Economic impact

Given the state of information at present it is difficult to evaluate the economic impact of pesticides used in agriculture. All the information available on productivity refers to specific experiences. Global tendencies that would allow us to judge their impact on Peru have not been analysed.

The use of pesticides falls into two phases. The first between 1981 and 1987 when a significant amount of pesticides were used. The second began in 1988 when pesticide use levels started to drop sharply (see Graph 1).

The sharp decline in the use of pesticides after 1987 did not affect total agricultural output. Only slight changes were recorded both in terms of cultivated area and the yield. This proves that pesticides did not play an essential role in maintaining production levels and that they had a limited impact on the domestic economy. However, they did have a positive impact in certain regions and on specific crops.

The Table shows that the cost of pesticides varies between 13 and 27% of total potato production costs. After an exceptionally high expenditure on pesticides of US$1053/ha in 1988, costs have more or less stabalized slightly under US $ 400/ha. In general, the gross margin indicates that when less was spent on pesticides the profit margin was greater.

Table 1: Potato production costs in the Peruvian Highlands and expenditure on pesticides 1987-1997

Year	Total costs US$	Expenditure pesticides US$	% of pesticide expenditure	Estimated return kg/ha	Farmgate price/kg (US$)
1987	3 367	456	13.5	14 000	0.20
1988	5 767	1 053	18.2	12 000	0.39
1989	1 390	383	27.5	16 000	0.29
1993	2 630	395	15.0	20 000	0.16
1994	2 809	612	21.7	18 000	0.18
1997	2 536	386	15.2	20 000	0.15

Source: ONA, 1987-1997; Elaboración: RAAA,1998

Social impact

Farmers realise that the constant application of pesticides affects the quality of tubers, changes their texture and sometimes makes them taste bitter. Many farmers prefer not to eat potatoes treated with pesticide. For their own consumption, they grow crops in higher areas and only use fungicides to control 'rancha' (*Phythophtora infestans*).

Farmers are not always fully aware of the negative effect of pesticides and appear to have resigned themselves to believing that it is the only alternative. Farmers in Chaglla confirmed that 75% of the water sources and areas surrounding their farms were contaminated. Another indicator for establishing the social costs of the indiscriminate use of pesticides is the number of people poisoned each year in the countryside. The health sector does not pay enough attention to this problem, mainly because it is unaware of the danger and there is no policy of conducting epidemiological monitoring programmes in farming areas.

Poisoning is not the only problem. Farmers who use these inputs have become dependent on the technologies derived from other cultures and have forgotten alternative technologies and traditional ways of handling plagues.

Responses and alternatives

In order to respond to the environmental crisis generated by the use of agrochemicals and pesticides in particular, many institutions have started replacing chemical inputs with biological ones while maintaining the conventional farming structure based on single crop farming. Replacing chemical inputs with natural ones is a most significant change. Under this strategy, most of the natural inputs are produced outside the farming system. In other words, the system's dependency continues and a recycling of resources and energy in agricultural ecosystems has yet to be achieved. Furthermore, very few farmers, if any, are involved in the production of new inputs.

The experience gained in the Integrated Pest Management programmes promoted by public and private development projects have proved that it is possible to do without extremely toxic inputs when controlling plagues and diseases. Nevertheless, dependence upon external inputs remains and affects the productive stability of the agricultural ecosystems. Efforts are being undertaken to test the cultivation of specific natural pesticides to overcome this problem (see p 65).

Other local experiences show that farmers are trying to develop sustainable farming using limited amounts of external inputs. They intend to recycle local resources in order to generate inputs and techniques aimed at managing phytosanitary problems in potato farms. The combination of various ecological techniques, participatory training processes and the recovery and adjustment of peasant experiences is helping to reduce some of the damage caused by plagues.

Changing national policies

Through its Agriculture, Environment and Amazon Committees, the Peruvian Congress is responding to concerns about the negative impact of pesticides in the Peruvian farming sector. For example, the *Law Promoting Overall Management for Ecological Plague Control* establishes the political and legal framework necessary to start-up the process of reducing pesticides use and lays the foundation for sustainable farming practices. In addition, it has created a number of opportunities for State and private development projects to gain access to State funds and international technical cooperation and to implement actions based on the overall management of plagues.

In this respect, the RAAA (Action Network on Alternatives to the use of Agro chemicals) has made a considerable effort to generate positive attitudes towards initiatives designed to encourage new laws restricting or banning the most toxic pesticides and enforcing standards. Initiatives among civilians have lead to discussions with the agrochemical industry and government authorities on the viability of agricultural production models. Results obtained from civilian activities in recent years have been successful in generating initial changes in favour of sustainable farming practices.

Peru Programme

In South America the high valleys of Northern and Central Peru were chosen to represent the Andes ecoregion. This is one of the worldís most diverse but fragile environments. Running through seven countries it is home to some 135 million people. The mountain system itself has been severely damaged by soil erosion, deforestation, overgrazing, mining waste contamination, and poor water management. As a result more than 60% of rural families in Andean countries live in poverty.

In highland Peru farmers may plant up to 50 different crops and work in several fields each in a different agroecological zone at altitudes ranging from 2500 to 4500 m.a.s.l. Farmers risk aversion strategies ensure that at least some plants and crops will survive despite the pests and diseases virulent under any particular set of conditions.

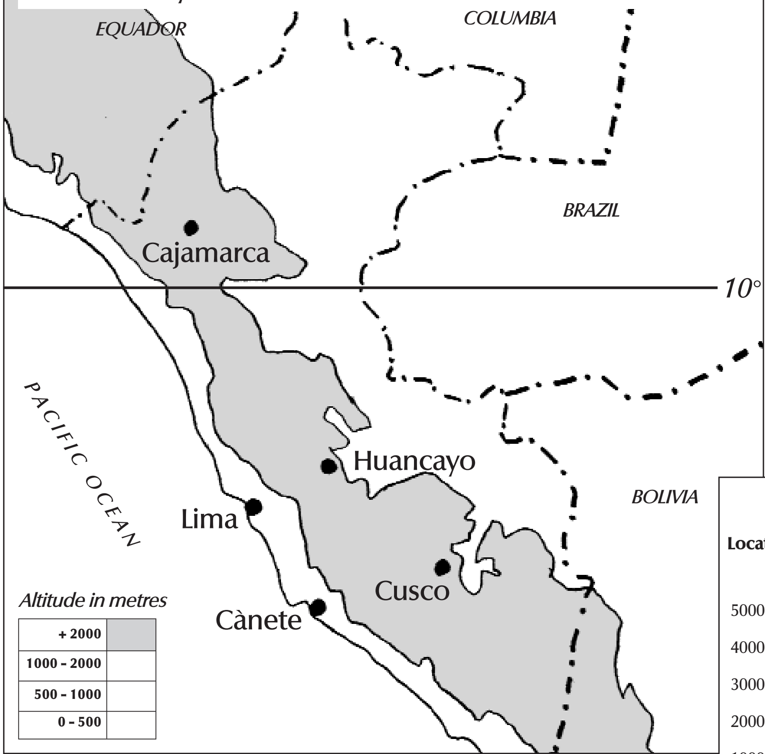
and livestock production. Most farming families live at subsistence level, with only a small part of their production being marketed. Self-sufficient farmers mostly grow rain-fed crops (tubers, corn, cereals and vegetables). Potato is the main crop and there are a large number of indigenous varieties. However, this diversity is slowly decreasing as 'improved' varieties replace indigenous ones. Commercialisation encourages the introduction of high-yielding varieties and the use of agrochemicals to protect them from pests. This process has lead not only to the loss of genetic diversity but crops have become less resistant to certain pesticides. In addition farmers have also been confronted with health problems and relatively high costs (see Gomero Osorio & Lizárraga Travaglini p 58). Abandoning ancient technical and social methods of controlling the way resources are used has also contributed to

central highlands and '*caserios'* or settlements in the northern highlands. The land is usually tilled by individual families. Community land and collective working practices are saved for public works or for work exchange purposes.

Government policies affecting agricultural research and development have, in general, favoured areas and crops that respond well to high external inputs. Together with the accelerated process of 'modernisation' that began with the initiation of land reform in the 1970s, these policies have led to massive migrations to the coastal towns and to the Amazon region.

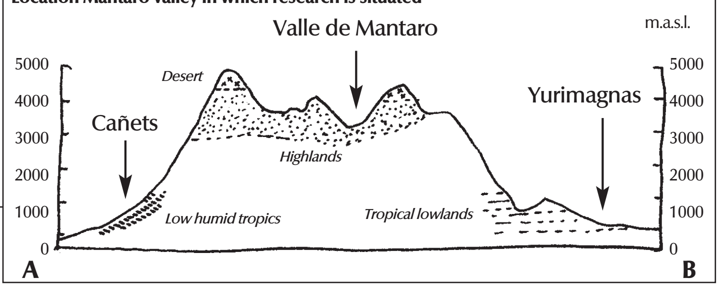
Since the 1980s, these policies have resulted in the abolition of government extension agencies. Apart from specialised agencies such as the '*Pronamachs*' (National Soil Conservation Programme), government involvement in agricultural development has mainly been confined to

Peru: Physical features and sites of LEISA Research activities



The high valleys of Northern and Central Peru were chosen to represent the Andean ecoregion. Altitudes in the research regions range from 2000 to 4500 meters above sea level. More than 80% of the region's available agricultural land is on steep hillsides and soils are very diverse. In Peru, an estimated 21 million hectares - 58% of the country's arable land is threatened by erosion. Weather varies throughout the region. The rainy season extends from November to April with an annual rainfall of between 200 and 1500mm. This gives rise to semi-dry to humid (micro-climates). Peru has a population of 22,350,000 mainly concentrated in the coastal plain.

Location Mantaro valley in which research is situated



Fields are often inter-cropped and crop rotations keep the soil fertile. In general, ecological and socioeconomic conditions are not particularly favourable to large-scale and high-external-input agriculture except in the lower valleys. These are the most productive areas as they are often endowed with irrigation facilities and have relatively better access to markets.

Farming systems often integrate crops soil erosion, over-grazing and firewood shortage. Having to face the various challenges that put the sustainability of their production systems at stake, farmers have been forced to find new ways out of their environmental and economic problems.

Small-scale farmers in Peru are organised in 'peasant communities' ('communidades') whose lands are divided into farming units known as '*parcialidades*' in the specialised research institutes and universities. NGOs have acquired quite a strong position through their search for alternative development models, especially when it comes to more agroecological approaches. In most cases agendas and priorities are determined by these organisations themselves and farmers only participate in the implementation of pre-determined programmes.

Stakeholders join for action

In 1995, ILEIA decided to work in two distinct zones in Peru: Cajamarca in the north and Huancayo in the centre. In both areas working groups of NGOs, universities and agricultural research institutes were set-up: GINCAE in Cajamarca and GIAREC in Huancayo. They started a collaborative programme to explore the potential of LEISA within the cultural, socioeconomic and ecological setting of their working areas. After the initial stage of setting-up stakeholder groups, men and women farmers, NGO staff and researchers made an inventory of agroecological conditions using AgroEcological Resource Mapping (AERM) and participatory soil surveys (see Kauffmann p 9). In the start up phase, technicians, researchers, and key producers were trained in the use of participatory tools and techniques in order to facilitate the process of reflection and analysis.

The dynamics of SCA in GIAREC is described by Norma Canales (p 60). Articles by Alvarez & Nalvarte (p 62) , Canales & Canto (p 65), and Bojórquez (p 67) also give insights into the collaboration between the different stakeholders and their development efforts in the working areas of the different NGOs.

Participatory Technology Development

It was only in 1997 that the two groups in Huancayo and Cajamarca took up PTD. More than 200 farmers (men and women) became actively engaged in a process of problem analysis, prioritisation, experimentation and the identification of possible solutions in trying to find new ways of dealing with their agricultural production problems. After two years, first results show that it is possible to identify adequate solutions that are within the reach of small subsistence farmers and have the potential to be ecologically sustainable. At the same time, the PTD process was important in bringing farmers, NGO staff and research institutes together in a shared action-research activity.

The PTD approach was introduced as a key element of the research programme. ILEIA's partners felt that PTD would contribute to specific goals (see Box 1). The internalisation of the PTD approach took place through an intensive, iterative process of learning by doing in which training and practice followed each other. An external facilitator guided the process of training and backstopping in PTD.

The PTD process was anchored in the following sequence of workshops:

- Training in AERM for farmers (men and women) and staff from the institutions involved in AERM;
- Training of institution staff in PTD concepts and techniques and in the facilitation of farmer' workshops to identify and prioritise problems and identify possible solutions that can be tried out in experiments;
- Training in facilitating farmer workshops to design, plan and monitor PTD experiments;
- Workshops at stakeholder group level to evaluate progress and results
- Joint workshops of stakeholder groups to plan the systematisation and documentation of the PTD process and to strengthen knowledge on PTD.

These workshops included practical sessions with farmers in one of the working areas ('farmer workshops') in order to provide hands-on practice to staff of participating institutions. It is important to note that all these workshops were followed-up by so-called *'replicas'*: farmer workshops repeated in other parts of the working areas. In this way, fast and effective scaling-up of PTD was realised and almost 250 farmers became involved in the PTD process.

The key training workshops focused on internalising PTD concepts, on its stepwise methodology and on communication techniques. The 'farmer workshops', on the other hand, followed a loose set of participatory procedures to identify problems and options (see Box 2). After the farmer-experimental design workshops, farmers started implementing and monitoring the experiments with support from institutional staff.

Box 1 **Expected results of the PTD approach**

- PTD will improve farmer innovation capacities through community endorsed group experimentation, which will permit processes that have a higher chance of generating viable and replicable agricultural technologies;
- PTD will improve existing agricultural production systems through the generation of systematic technological solutions that respond to the real problems of agricultural development and farmer economies;
- PTD will strengthen the LEISA approach permitting an opening towards development alternatives that are economically viable, socially acceptable and technically realistic - also from a gender perspective - and which will permit the development of efficient and equitable technologies;
- PTD will strengthen the convergence of formal science and farmer knowledge, permitting a mutual learning process;
- PTD will improve the capacity of institutions in participatory work by adding new elements;
- PTD will improve and contribute to the LEISA validation process in the ILEIA project's framework of concerted activities with GIAREC and GINCAE.

The articles by Alvarez & Nalvarte (p 62), Canales & Canto (p 65) and Bojórquez (p 67) describe three cases of implementing PTD work in Huancayo. The article by Staub (p 69) indicates the important role played by farmers in expanding the approach. In the final article in the Peru section (Results and impact of the PTD process p 70) , the learning points of two years of working with PTD in the two zones are summed up.

Box 2 **Looking for things to try: a PTD module for designing experiments with farmers**

Procedure:

1. Community meeting for commitment and endorsement of experiments
2. Drawing resource flows for farm enterprises *(Flow diagrams/AERM)*
3. Identifying problems and options for solving them (*Pair wise ranking)*
4. More detailed problem analysis (*Problem tree)*
5. Orienting the farmer experiments *(Ranking)*
6. Agreeing on the detailed design of the experiments (treatments; experiment lay-out; monitoring; etc.)
7. Conclusion: Project idea sheets

Major themes

Problem identification in the various research sites in Cajamarca and Huancayo resulted in a number of themes for backstopping research. Farmers considered potato pests and diseases, inadequate pasture management and livestock disease as the most important problems. In addition, one group focused on soil fertility and one group included an experiment with small scale irrigation. In support of the farmers' experiments, the working groups - together with ILEIA - also identified and commissioned a number of studies focusing on the problems brought forward. These studies made an effort to analyse the wider context and sustainability aspects of the constraints and to identify new options for farmer experimentation and cases of alternative development programmes. The studies were divided into three categories: context studies of the two zones (Huancayo and Cajamarca), technical studies covering the specific themes ('Pasture management', 'Ethnoveterinary control of *fasciola*' in cattle' and 'Pesticide use in Andean Potato Production Systems') and a study analysing the experiences with IPM in Cajamarca. In total six studies were commissioned. The study on pesticide use is presented in the article by Gomero Osorio & Lizárraga Travaglini (p 58). Some results of the study on 'pasture management' have been integrated into the article by Bojórquez (p 67).

In the highland valleys of the Peruvian Andes, NGOs and agricultural research institutes established two working groups, one in Huancayo (GIAREC) and another in Cajamarca (GINCAE). Farmers were invited to take part in participatory technology development. After analysing their situation farmers chose to focus their experiments on improving forage production, pest control in potato storage and parasite control in sheep. On the basis of their own criteria, farmers assessed the performance of different combinations of grasses and forage legumes and developed affordable ways of controlling potato moth in storage testing and comparing the viability of different ashes and a petroleum trap. Experiments with shipita, a traditional herbal medicine to control distomatosis, a serious parasitic sheep disease, were convincing and lead to a series of scaling-up activities to promote reforestation and the use of shipita. A study analysed experiences with the use of pesticides and Integrated Pest Management in potato production in the Andes.

A future for smallholder farming in the savanna

photo: Bert Lof

Both women and men are keen to continue experimenting.

During the PTD process, the smallholder farmers and scientists working together in northern Ghana agreed that the most serious current problem in agriculture is declining soil fertility. The farming communities involved in analysing their situation, identifying potentials and experimenting with options to improve soil fertility felt that the only realistic approach was to address this problem with primarily local means. Visits to other farmers operating under similar or even more difficult conditions, such as in Burkina Faso, stimulated the Ghanaian farmers to try out new ideas in new cycles of PTD.

Malex Alebikiya and Ann Waters-Bayer

The joint analysis and evaluation allowed the farmers to pinpoint more clearly for themselves and for the scientists involved the criteria they considered important in testing new ideas in crop production. In addition to yield, these criteria included germination rate, weed occurrence, labour requirements, other input requirements, drought tolerance, and seed quality after harvest. The trials showed that applying compost or farmyard manure led to good results, and adding phosphorus enhanced yields still further. The communities involved in the experimentation regarded the more efficient use of local biomass as the most promising option for improving soil fertility, as long as phosphorus fertiliser is not easily available. Analysis of experimental results led to new questions that the farmers were eager to explore and - after their experience in PTD - felt confident to explore. They identified the major problems related to use of compost - insufficient organic manure and higher weeding inputs - and are pursuing research to tackle these problems.

A similar gain in confidence could be seen in the women who experimented with different ways of storing cowpea, and found that wood ash and a local herb were the most effective. After this first experience in deliberate experimentation, they decided to test other botanicals to reduce pest damage in stored crops. The experiments by farmers in Garu to tackle the striga problem led other farmers to try using crop rotation to reduce the incidence of this weed.Thus, the more structured experimentation within PTD appears to stimulate informal experimentation on a wider scale.

Lessons learnt at SCA level

The difficulties in the first two years of the project and the progress made in the second two years indicate the importance of taking time to negotiate the purposes and mechanisms of collaboration. This is true at both the international level (between ILEIA and NGLWG) and locally (within NGLWG and in interaction with farmers). Transparency in terms of motivation and finances as well as good information flows facilitated the process of reaching agreement about what the stakeholders wanted to do together.

The mandate from above (the interest of ILEIA and its donors) to validate LEISA did not mix well with a participatory approach. As soon as ILEIA took participation seriously, the emphasis shifted to strengthening the capacity of farmers and local supporting organisations to conduct research for development.

The best way to learn how to do PTD and to build up a platform of stakeholders to sustain and promote the process is to get started in a concrete activity that demands collaboration (for example,. investigating ways to improve soil fertility), to review the process as one continues, and to learn from this action and reflection.

During the fieldwork conducted in the two-year project period, a process of supporting farmer-led experimentation to develop locally appropriate LEISA technologies was initiated and a wider interest in LEISA and PTD was stimulated within research and development institutions in northern Ghana. However, the period was not long enough to ensure that this approach was firmly institutionalised, although promising beginnings have been made.

Prospects for the future

Through their interaction with farmers and with each other, the NGLWG members have developed a vision of how sustainable farming practices can be developed in northern Ghana and, indeed, in the West African savanna. Their common mission is to promote LEISA as a more viable agricultural production strategy for achieving family food security and poverty reduction than the traditional low-external-input or the 'modern' high-external input systems.

The NGLWG clearly recognises the need for critical rethinking at the policy level of agricultural development issues and strategies, and feels that it is well-equipped to analyse and share information on such issues. It sees the need to internalise PTD and LEISA in agricultural institutions in northern Ghana. The composition of the NGLWG - which brings together people from a wide variety of institutions - should make this possible. Efforts at institutionalisation are already being made by the University for Development Studies, which is incorporating PTD and LEISA into its curriculum.

The two years of collaboration in supporting farmer-led action research have established a good base for continuation - a good base in terms of mutual respect and understanding among all partners and in terms of initial results that point the way to promising options that can be investigated further. The NGLWG is resolved to continue collaboration in this direction. ■

The mountains are disappearing

"These visits are an envy to the other communities. We are therefore very glad that you have come to open our eyes to see what we, on our own, can do for ourselves. We hope this will continue". These were the feelings expressed by a farmer from Tangbini near Langbensi during one of the PTD workshops.

Ben Bonzali

The following is a brief description of the research process in Bumboazio and Tangbini, two communities in Langbensi and how the experiences gained are being incorporated into the main-stream agriculture extension programme. The Agricultural Station in Langbensi has had two experiences with PTD. The earlier phase was between 1989 and 1994 and preceded the current collaborative research phase.

The PTD process

In the first phase farmers' participation was limited to problem identification at the field level. Their involvement in subsequent process planning, monitoring, assessment and feed back was taken over by the researcher. The ILEIA research programme made a bold attempt to involve farmers at every stage of the research process.

In the problem analysis farmers identified poor soils as the main cause of yield decline. Farmers identified the direct and indirect causes of yield decline as the consequence of their own activities and bad farming practices. They concluded that the options and the means to address these problems lay close at hand.

To make appropriate and relevant choices they prioritised these problems by matrix scoring and ranking. This was a most interesting and important learning exercise for both the field staff and farmers. Initially, the ranking was treated as an ordinary game but from the discussions that ensued when results were analysed it became clear that it was a useful tool for farmers' participation in decisions making.

The most difficult phase of the process was designing trials. Farmers discussed how they would carry out their experiments, what location they would use, what variables (assessment indicators) should be looked for, and how much time would be needed before they could come to any conclusion about adopting or rejecting a technology. The resulting trial, designed to address the problem of poor soil fertility, was fine-tuned by farmers in the light of their own practices and experiences. It became clear that farmers do experiment, although in a manner slightly different from conventional methods.

The experiences gained

Very early in the research process, we realised that NGO field staff needed to change their general orientation and perception about farmers. They would have to abandon their idea that farmers lacked knowledge, were primitive and resistant to change. Our previous interactions with farmers had invariably put them on the receiving end. A dependency syndrome had been created and many organisations pursuing participatory processes are now trying to reverse this.

At the beginning of the research process, it was essential that external partners familiarise and acquaint themselves with the people and their situation. This was an important step in winning the trust and confidence of the community and ensuring the cooperation on which the success of the research programme would eventually depend. The process involved a series of farmer workshops on topical issues concerning agricultural productivity and sustenance. Periodic assessments of the process, particularly the experiments and the farmer exchange visits, formed a significant part of the research. Group work was the basic strategy adopted to enhance the gathering of adequate, diverse, and rich information for analysis. The groups were usually segregated according to age and sex differences for the purpose of identifying the perceptions of each target group. A major research output was building up the capacity and confidence of farmers to enable them to take their own initiatives in solving problems rather than waiting for solutions from elsewhere.

The research process tried to develop technologies based on farmers' knowledge, capacities, and available local resources. Experimenting with composting was an idea put forward with enthusiasm by farmers. Before the PTD trials, only a few farmers used organic manure to improve soil fertility. When one approached their communities a common sight would be huge mountains of household refuse. Often the biggest ones would be close to the chiefs' compound. Once farmers' had remembered the value of using organic fertiliser to improve soil fertility and productivity, these mountains gradually began to be converted into nutrient-rich soil additives and they started to disappear. At an assessment meeting a farmer in Bumboazio stated:
"Our forefathers practiced it, and handed it down to us. However, you people came in with your chemical fertiliser to discourage us from continuing the practice. You were even giving the chemical fertiliser to us for free. Now its price is beyond our reach you have come back and you are saying use compost".

In contrast to this another farmer declared: *"They are telling us that our practices of old have better potential than the present use of fertiliser, because if you wish to succeed in life you have to work hard and endure suffering. That is our lot, and they are only helping us out".*

Conclusion

Through the PTD process we have realised that farmers do have a vast stock of knowledge, and have very good reasons for whatever they do. Most technological packages in the recent past could not be sustained probably because the potential of the farmers themselves was not recognised. This is the challenge we are confronting now the research programme is coming to an end. The Agricultural Station is trying to meet this challenge by adopting participatory approaches in all its extension programmes. Farmers' participation has been taken on board with the drawing up of community action plans and joint implementation and monitoring. On this basis a new three-year work programme was developed for the Stations' extension activities.

Many of our working communities are adopting LEISA technologies and are asking for a process similar to that followed in Bumboazio and Tangbini to be initiated in their communities.

It is clear that there is a potential for LEISA practices in the area, and it is our hope to continue and sustain the gains of the collaborative research programme so that more mountains will disappear.

Sustainable soil fertility management

Lessons from action research

The NGLWG and farmers from selected areas identified the issue of low soil fertility as a priority for their action research. Nutrients removed by cropping were traditionally replaced by bush fallowing and the use of farmyard manure and household refuse. However, these latter sources of nutrients are

Saa Dittoh

becoming increasingly scarce particularly because the number of livestock kept per household is decreasing. Inorganic fertilisers were used as long as they were subsidised, but now subsidies have been stopped. Now, fewer than 30% of smallholders in northern Ghana buy inorganic fertiliser for food crops and purchase small amounts for maize and rice. This has lead to declining soil fertility and unstable farming systems.

The indigenous methods of managing soil fertility probably worked reasonably well under the ecological and socioeconomic conditions that prevailed in the past. Now it is obvious that LEIA is not sustainable and prevailing economic conditions make HEIA impossible. During action research, smallholders in northern Ghana attempted to determine, in quantitative and qualitative terms, the role of organic manure in ensuring the continuity of crop production.

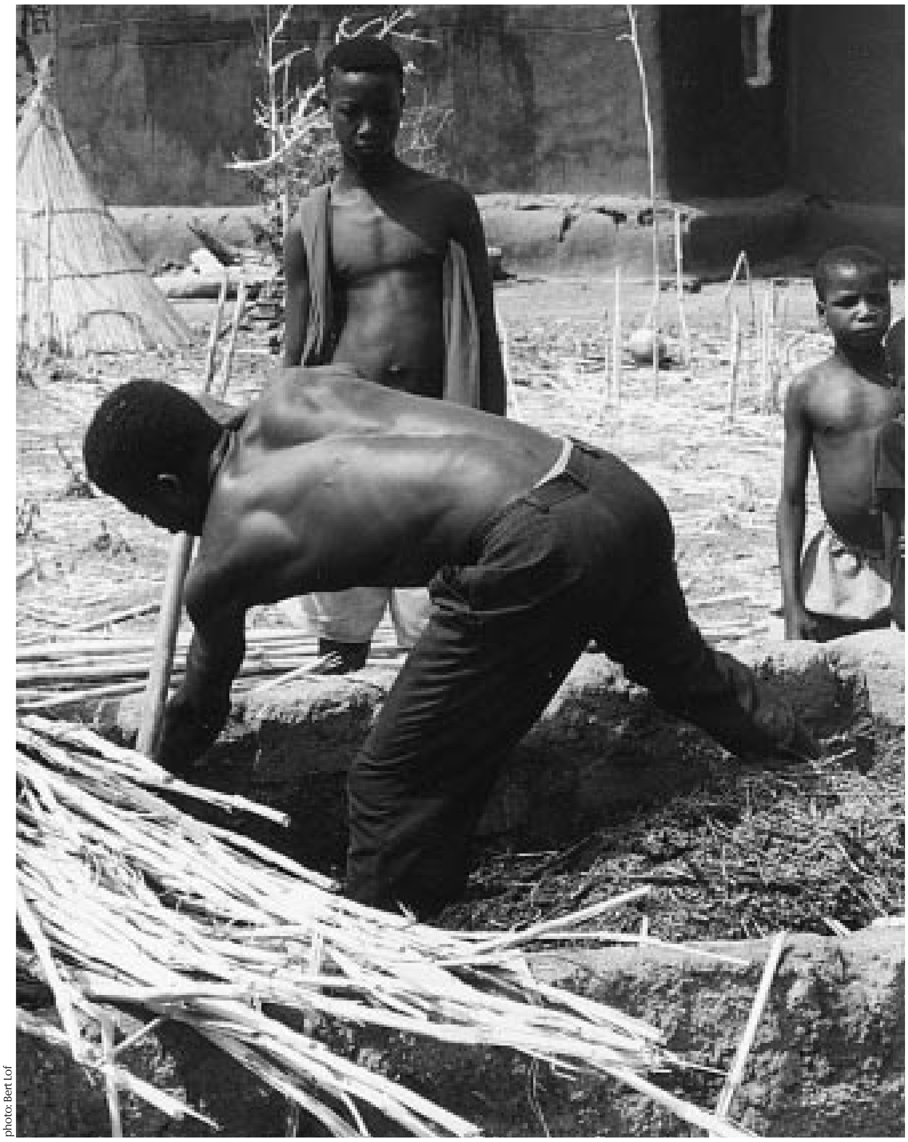

photo: Bert Lof

Recycling organic matter to restore soil productivity.

Sustainability in farmers' terms

Agricultural sustainability is a concept open to a wide range of interpretations. A simple grassroots definition given by Edward Agana from Zuedema, Builsa District in the Upper East Region is that their farming system can be considered sustainable when soils, crops, animals, trees, environment and people 'get better every year' and many other farmers in the area agree. This indigenous definition regards sustainability as something dynamic and suggests that there are degrees of sustainability.

But how should 'getting better' be determined and who should be the judge? The search for answers to these questions constituted a major part of the present research. There is a need to build up farmers' capacity to determine 'getting better' more systemmatically. The criteria developed by those with the highest stake in the process should be used in assessing sustainability. In the research process, farmers' criteria had to be brought to the fore, but it was also necessary to ensure that farmers became aware of other variables.

Managing soil fertility

Many farmers in northern Ghana have cultivated the same land for over 40 years without any significant use of chemical fertilisers. They have obviously been using some soil improvement techniques. They are well aware of the role of FYM, animal droppings and household refuse in crop production. Nevertheless, soil fertility is declining. In the two pilot areas of ILEIA-NGLWG collaboration in northern Ghana, farmers identified this as the most important research issue. "With a dead soil, one can forget about producing enough to feed the family", said a woman farmer at one of the workshops.

The collaborative research was designed to explore differences in the efficacy of the various types of organic manures known to the farmers. Our hypothesis was that LEIA could be transformed into LEISA if farmers would systematically improve their indigenous knowledge of soil fertility management. During this action research, we tried to assess LEISA practices for improving soil fertility. We explored the problems associated with using organic manure and how farmers were tackling or proposed to tackle these problems.

Two complementary methods were used: field plot experimentation (more akin to conventional on-farm trials) and farm monitoring (FARMS) in which the inputs and outputs of all the plots of experimenting farmers were analysed. We felt that, if the farmers could see more clearly what went into production, what came out and what remained in ▶

the soil to be used by crops the following season, they would become more aware of sustainability. Farmers, researchers and extension agents collaborated in monitoring the farmer-managed experiments, sharing ideas and solving problems encountered in the research. Women were fully involved in this community process of identifying problems, seeking solutions and experimenting with improved methods of making compost.

Potentials and constraints of manure

In two years of experimentation, many lessons were learnt. The use of organic manure leads to significant improvements in soil fertility and crop production over time. Farmers' assessments also clearly indicated the potential of organic manure in reducing crop production risks and lowering the incidence of notorious weeds such as striga.

The experimenting farmers realised that organic manures differ in quality, depending on how they are managed. Farmers explored better methods of managing manures and new methods of composting some of which they had seen during their trip to Burkina Faso (Box 2, p 46). This was a vital step towards more sustainable agriculture.

It became clear, however, that most farmers have a problem getting organic matter and that women farmers have virtually no access to FYM or household refuse for their own plots. Manure is probably the most valuable resource for sustainable farming in northern Ghana. However, because many households are without animals or the few they possess are tended by Fulani herders, manure is difficult to come by. The search for ways of better integrating crops and livestock needs to be intensified. The concept of crop-livestock integration is indigenous but was discouraged in the push towards 'modernise' in past decades. It should be possible to regain integration, perhaps in a modified way.

Another potential threat to moving towards more sustainable production is that organic manure is bulky and sometimes needs to be transported over long distances to the "bush farms". Farmers may need financial assistance to acquire donkeys and carts, not only to bring manure to the fields but also to bring farm products back to their homes.

Action research shows the way

In 1997, the first year of experimentation there was drought but in 1998 the rains were adequate. How can sustainability be inferred when conditions vary from year to year? Was the 1998 harvest better because farmers applied organic manure or because the rains were good? This could be difficult to answer with results from field plot experimentation. Taking the farm experimentation as a whole, analysis of the many different plot situations within and between farms indicated the positive effect of better fertility management. It is clear, however, that conclusive statements cannot be made after only two years of experimentation.

Despite this limitation, the action research has been a learning experience for farmers and other stakeholders. All were convinced of the potential of participatory research to help realise sustainable agriculture in northern Ghana. Those involved saw that problems relating to the availability of manure, its transportation to the fields, proper management to conserve nutrients, and the availability of water to make compost were hampering the move from LEIA to LEISA. Action research also led to a better understanding of the issues involved and to a more focussed approach to solving the key constraints to sustainability at farm level. ■

Saa Dittoh, Faculty of Agriculture, University for Development Studies, Tamale, Ghana, email: <saaditt@africaonline.com.gh>

Internalising PTD and LEISA in agricultural training

The ILEIA-NGLWG collaboration in Ghana involved the building of relationships between farmers, development workers, researchers and university teachers in agriculture and related disciplines. At the outset, these relations were loose and full of (often unspoken) contradictions in terms of beliefs, orientations and biases. It was in the process of concrete action, especially when the stakeholders repeatedly met in rural communities to discuss farmers' problems and to do research together, that points of consensus began to emerge. Mutual appreciation of the different professions and of the strengths and weaknesses of each began to grow. All stakeholders began to understand not only why farmers do what they do, but also why professors say what they say. It was the participatory nature of the methodology that led to the breaking down of psychological barriers. The process of PTD opened the way for better mutual understanding.

We came to the consensus that agriculture in northern Ghana is not likely to experience a 'Green Revolution'. However, if farmers are left to depend on their present LEIA methods, they are unlikely to survive long in agriculture. The only alternative is to work together with farmers in improving present practices and move gradually from LEIA to LEISA. During our collaboration, we recognised that participatory research can lead to a systematic movement in this direction.

The research was unconventional, and many were somewhat sceptical at the start. The Faculty of Agriculture of the UDS has the task of preparing future extension workers to work in rural communities and help farmers to solve their problems. However, most of the academic staff were originally trained in universities where there was little interest in participatory approaches and most government and donor-sponsored development efforts failed to emphasise them. In Ghana, it was left to the NGOs to promote the participatory approach.

Some of the Faculty of Agriculture agreed to become involved in the ILEIA-NGLWG research. Over the past two years, during interaction with farmers in PTD, many new things about agronomy, soil and water management, weed science, economics and sociology were learned. It was observed that farmers gained confidence in what faculty staff said, because they knew that their views and experiences were being taken into consideration.

We are now convinced of the merits of the PTD approach to LEISA. However, no matter how good it is, it is not likely to gain wide acceptance and be followed in mainstream research and extension activities in Ghana if most people being trained in agriculture do not know about it. The agricultural colleges and the faculties of agriculture have a key role to play in institutionalising LEISA and PTD in agricultural development. But first, these approaches have to be internalised by the staff of the training institutions. Professors of agriculture need to discard their biases against the knowledge and intellectual abilities of "illiterate" farmers. This can best be achieved by bringing them into direct interaction with farmers.

In the second year of ILEIA-NGLWG collaboration, it was decided that LEISA as a group of agricultural techniques and the PTD approach to LEISA should form an integral part of the curriculum of the Faculty of Agriculture. The theoretical aspects of LEISA and PTD are now taught on the campuses in Tamale-Nyankpala and Navrongo, and practically applied by university students and staff in NGO agricultural stations such at Langbensi, Garu, Sandema, Tumu, Funsi and Nandom, as well as in several other rural communities. As a result, graduates from UDS are likely to bring about radical changes in the methodology of agricultural extension in Ghana.

For rapid internalisation of LEISA and PTD, the agricultural extension workers with MOFA and donor-assisted projects will also need to be re-oriented toward more participatory approaches. For this reason, UDS is now preparing to offer short, in-service training courses in LEISA and PTD for extension workers.

Saa Dittoh and **Malex Alebikiya**

The role of livestock in sustaining soil fertility in northern Ghana

N. Karbo, J. Bruce & E.O. Otchere

In the northern Guinea savanna zone of Ghana, the predominant farming system is mixed crop-livestock production in smallholdings (Atengdem & Dery p 38). In the gently rolling landscape, cropping and animal grazing are concentrated mainly in the middle and lower slopes and valley bottoms. Growing population pressure has led to continuous cropping and decreasing periods of fallow. The major concern is the decline in the fertility of arable land. Here we look at the role of livestock in the integrated management of soil fertility. This is largely neglected in development efforts, although crop-livestock systems have existed for decades in the zone.

Some history

Before Independence, the colonial government established agricultural research and extension stations in different parts of northern Ghana. The Tamale station was set up 1909, but the majority began operations in the late 1930s. All these stations dealt mainly with crops. Bullock traction was also introduced in the late 1930s and cattle and sheep were introduced later to address the problem of low soil fertility in these areas, which were known as 'farmed out' lands. Soil conservation techniques promoted prior to Independence included contour farming, grass bunding and stone terracing, in addition to the fallow rotation and mixed cropping practised by farmers. Crop yields could be sustained.

In the two to three decades after Independence, government policy sought to achieve a 'Green Revolution' and initially crop yields per unit area increased considerably. Many farmers adopted and relied heavily on external inputs little knowing that conditions would change and sustainability would become a critical issue.

Recent experiences

In the 1980s the market price of external inputs soared as subsidies were removed. Many smallholders could no longer afford to buy them. From 1979 to 1986, the relative increase in input price was 106%. In concrete terms, a bag of maize that could be sold to buy about 7 bags of compound fertiliser between 1979 and 1982 was enough for only 3.5 bags in 1986 (Langyintuo & Karbo 1996). Even with the same rate of application, some soils in the zone do not give the high yields recorded when chemical fertilisers were first introduced. In most cases, application rates dropped. A survey in 1992 showed manuring to be the most popular technique to regenerate soil fertility, followed by chemical fertilisation and bush fallowing (Gyasi 1995). A survey of over 4000 fields in northern Ghana in 1993 revealed that only 16% received some mineral fertiliser (Albert 1995).

During the late 1980s and in the 1990s, most bilateral projects such as the IFAD-supported Smallholder Rehabilitation and Development Project (SRDP), the Land Conservation and Smallholder Rehabilitation Project (LACOSREP) and the Upper West Agricultural ▶

photo: Bertus Haverkort

Development Project (UWADEP) took an integrated development approach, one component of which was small ruminant husbandry.

All these projects, including the current National Livestock Services Project (NLSP), if sustained after project closing, could increase the contribution of livestock to the sustainable management of natural resources in the zone. Animals play an important role in the way farm households manage risk. Animal traction could improve the quality and timeliness of farming operations now done by hand and raise crop yields and incomes, the manure could improve soil fertility, and the livestock sales could generate cash to purchase other inputs.

In farmer-led experimentation in the ILEIA/NGLWG collaboration, various soil conditioners were tested. This confirmed that farmyard manure could increase crop yields, but that yields could be even higher if manure were combined with some chemical fertilisers. Nevertheless, farmers, researchers and development workers in the zone still saw constraints to the contribution of livestock to soil fertility management.

Constraints and coping strategies

During our interactions with farmers and development workers in the field, it became obvious that the use of manure to improve soil fertility varies from one location to the other. It is more important where human population pressure is high and land is scarce, such as in densely populated village settlements and peri-urban areas. The most common constraints and the ways in which farmers are trying to deal with them are summarised in Table 1. Although some farmers mentioned that manuring leads to more weeds, they felt it was easier to pull out the weeds from manured fields than from non-manured fields.

These coping strategies are backed by farmers' rich knowledge of manure quality, soil types and crops cultivated. In terms of nutrient 'strength' or power, the farmers ranked the manure types as follows: poultry → pig → sheep/goat → cattle. Manure from poultry and pigs releases nutrients faster than that from ruminants. Nutrient release to crops is slowest in the case of cattle manure, but its residual effect appears to be higher than in the case of the manure from other livestock species. Farmers said that a field fertilised with cow dung may need re-fertilisation after two or three years whereas when pig and poultry manure are used, yearly applications are necessary. This manure is preferred by farmers who grow vegetable crops because these have a relatively high level of growth energy and need instant releases of nutrients.

Similarly, farmers in Upper East Region explained that sheep and goat manure is most suitable for early millet and sorghum. It was interesting to learn from the farmers that the cow dung obtained in the dry season is of lower quality and is most suitable for trapping termites to feed to poultry. Thus, another link is made in the recycling of nutrients by animals for soil fertility management. Cattle that graze low-quality grass and cereal crop residues in the dry season produce low-quality dung, which is fed to termites, which are, in turn, fed to poultry, which produce not only meat and eggs but also leave concentrated droppings that improve soil fertility.

Poorer people, among whom are many women have few animals and they collect animal droppings to improve the condition of their soil. However, there are more and more competitive uses for cow dung for example, to plaster house walls and as a cooking fuel (both are women's tasks). Some cow dung is also applied in liquid form to crops where it acts as a repellent that protects the plants from being eaten by straying animals.

In most parts of the zone, Fulani herdsmen are hired by farmers to care for their cattle. This makes it possible for the farmers' children to attend school. In most cases, depending on the nature of the contract, the Fulani have the right to the manure. They either sell it or use it to fertilise plots leased out to them for maize cropping by their landlords. In our interviews, such land-cultivating Fulani stated that a maize yield of over 3.0 t/ha could be obtained from manured and continuously cropped plots.

Generally, dynamic kraaling is practised: the cattle are tethered overnight on the field to be fertilised and their location within the field is shifted at certain intervals. The number of nights on each spot varies with the season. Farmers indicated an average of three nights' kraaling in the wet season and ten nights in the dry. This method reduces the labour required to transport the manure. In parts of Upper East and Upper West Regions, widespread cattle theft does not make this an attractive system of manure management. In these areas, head loads of manure are transported to the fields, usually by women.

Table 1: Constraints to manure use and coping strategies in northern Ghana

1.0 Insufficient manure	1.1 Manure collection
	1.2 Composting
	1.3 Alternating plot application
	1.4 Crop-specific application
	1.5 Soil-specific application
2.0 Low quality of dry-season manure	2.1 Integrating poultry and termites in nutrient cycling with manure
	2.2 Grazing orbits involving crop residues and wet valleys
3.0 Insufficient labour to collect manure	3.1 Division of labour by gender
	3.2 Dynamic kraaling

Things to try in PTD activities

The use of manure in composting has already received much attention in the PTD sites of the ILEIA/NGLWG. The quantitative and qualitative aspects of manure raised earlier have been well addressed. Livestock will continue to play a significant role in integrated soil fertility management in the farming systems of northern Ghana. There is a great need to encourage farmer groups and individuals to also try out other technological options that could be adopted and further developed. These could include:

- Introduction of forage legumes (for example, *Stylosanthes* spp) and dual-purpose food legumes (for example, pigeon pea) into the cropping systems to enhance soil fertility and produce good fodder to generate high-quality manure.
- Minimum daytime (3-4 hours) and overnight confinement of small ruminants with some feed supplementation to increase the manure harvest.
- Development of fodder banks (protected areas of grass and sown legumes used for strategic grazing in the dry season) to address the seasonal shortage of feed.
- Strategic animal health-care management to reduce mortality and increase herd sizes
- Animal traction to address labour constraints.

Assessment of non-burning and organic-manuring practices

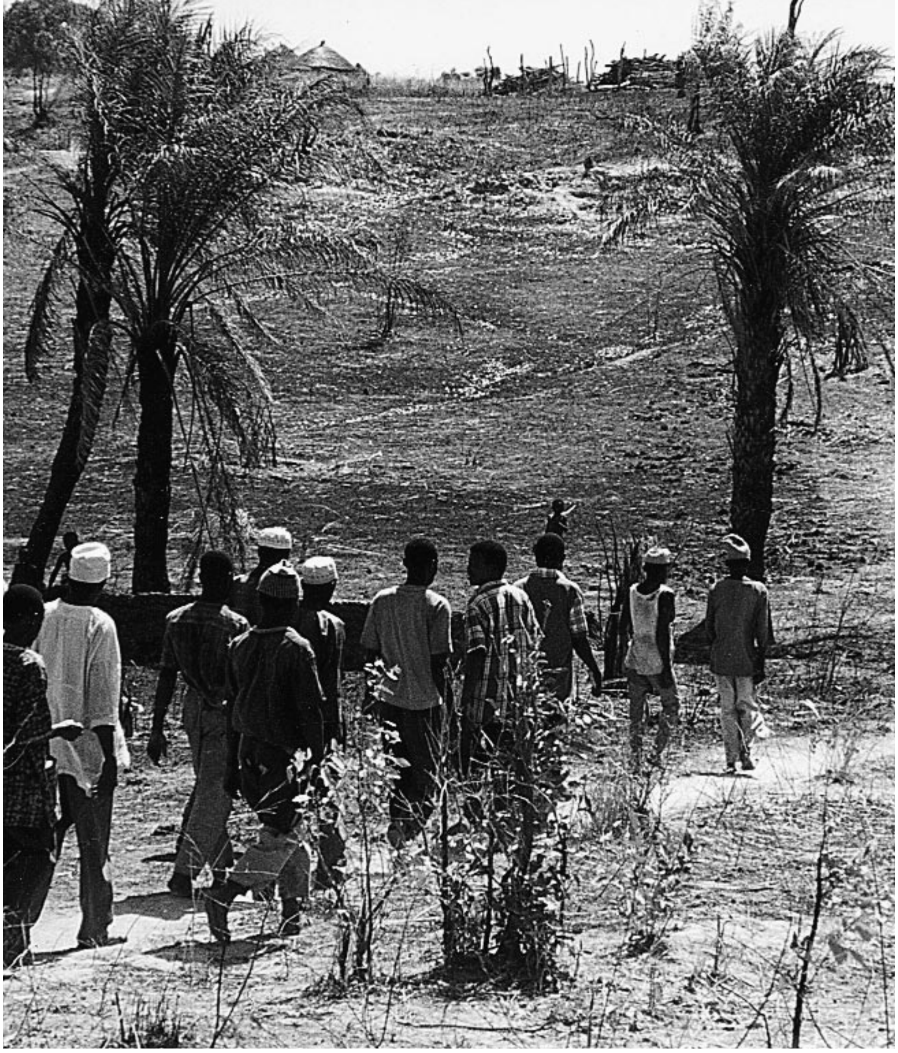

photo: Bert Lof

0.I. Aalangdong, J.M. Kombiok & A.Z. Salifu

Farmers, researchers and extension agents in northern Ghana regard low soil fertility as a major constraint to crop production. Increasing human population has led to the shortening of bush fallowing, a traditional method to replenish soil nutrients. Application of inorganic fertiliser to restore fertility has become non-profitable, as prices are beyond the reach of smallholders. They are therefore being encouraged to intensify their farming through intercropping, crop rotation, agroforestry, soil and water conservation, and organic manuring. Traditionally, widespread dry-season burning of vegetation was practised. Burning as a labour-saving tool to clear land and prevent weed infestation is now being brought into question, because more organic matter is needed in the soil. Many development agencies now advocate non-burning.

Assessment methods

Case studies of non-burning at Goziire (Upper West Region) and of non-burning and organic manuring at Zagsilaari (Northern Region) had suggested that these practices support sustainable agriculture by improving soil fertility and conserving soil and water (Kombiok, et al 1997). Existing experiences in sustainable agriculture can serve as examples for other communities in the same agro-ecological zone. However, other farmers are more likely to be convinced and to try these practices if they had more information on inputs and yields. A follow-up study was therefore designed to quantify the inputs and outputs of non-burning and organic-manuring practices, and to assess the benefits of these practices from the farmers' point of view.

The follow-up study was conducted in the 1998 cropping season (June-November) at the case-study sites chosen with extension agents from MOFA and some NG0s. At each site, four farmers - two who practise non-burning and/or organic manuring, and two who do not but were interested in the study - were selected.

In each farm, four 10x10m plots of various crops were demarcated randomly. Data were collected on labour inputs, plant height and population, and crop yields. During farmers' fora at the end of the cropping season, the communities assessed the advantages, disadvantages and problems associated with the practices. Participatory Rural Appraisal techniques were used to encourage them to discuss the issues and socioeconomic implications freely and to give their opinions.

Table 1: Grain yields (kg) from 10x10m areas on burnt and non-burnt plots at Zagsilaari

Farmer	Practice	Crop	Plot 1	Plot 2	Plot 3	Plot 4	Mean
David Agongo	Non-burning	Maize	27.0	23.0	26.0	24.0	25.0
Iddi Dorkurugu	Non-burning	Maize	11.0	10.0	8.0	11.0	10.0
Yakubu Mbangba	Burning	Maize	10.0	9.0	6.0	7.0	8.0
Alitu Dorkurugu	Burning	Maize	8.0	8.0	9.0	9.0	8.5
David Agongo	Non-burning	Sorghum	3.0	3.0	2.5	3.0	2.9
Yakubu Mbangba	Burning	Sorghum	2.0	1.0	1.5	1.5	1.5

Increased grain yields

At Goziire, sorghum was taller after three-year fallow than in the non-burnt plots. Millet in the non-burnt plots with farmyard manure was twice as tall as in the burnt plots with manure or without. Sorghum yields ranged from 1.1 to 1.4 t/ha and were higher after non-burnt fallow than after non-burnt continuous cropping, even with FYM. Yields of millet were lower (1.1-1.2 t/ha) than those of sorghum with the same treatment, and were as low as 0.48 t/ha even with FYM in the regularly burnt area.

At Zagsilaari, maize yields in the non-burnt plots were more than double those in the burnt plots. Sorghum ▶

yields in non-burnt plots were double those in the burnt plots (Table 1) and the sorghum heads were longer (45 vs. 34cm) and heavier (1650 vs. 1500 g).

The number of years an area is not burnt also affects crop yields. At Zagsilaari, plots not burnt for six years had higher yields than those not burnt for three years. This may be due to the longer accumulation of organic matter and the greater amount of soil nutrients for crop uptake.

More labour for weeding

Data on labour for land preparation, planting, weeding and applying manure/fertiliser were collected at Zagsilaari. All the farmers used bullock ploughs to prepare their land, but only David Agongo owns a pair of bullocks and a plough. The others hired bullock services, paying twenty thousand cedis per acre. Labour inputs for land preparation did not differ between practices, but more labour was needed to weed the non-burnt plots than those that had been burnt regularly (Table 2).

Farmers' fora

The farmers' fora were open to both men and women, but only about 20% of the participants were women. At both sites, the farmers agreed that non-burning and organic manuring bring tremendous benefits.

Table 2: Estimated labour inputs (person-days) in burnt and non-burnt plots cultivated to maize and sorghum in Zagsilaari

Farmer	Crop	Practice	Ploughing	Planting	Weeding	Applying manure/fertiliser
David Agongo	Maize	Non-burning	2	4	13	-
Dorkurugu	Maize	Non-burning	2.5	11	21	6
Yakubu Mbangba	Maize	Burning	3	6	11	-
Alitu Dorkurugu	Maize	Burning	2	3	8	8
David Agongo	Sorghum	Non-burning	2	3	14	-
Yakubu Mbangba	Sorghum	Burning	4	6.5	11	-

Advantages of non-burning at Goziire mentioned by the farmers were:

- regrowth of natural vegetation, especially grasses and trees for grazing and construction
- better establishment of wood lot plantations and improved yields of shea and *dawadawa (Parkia biglobosa)* trees
- good conservation of soil and water, thus reducing erosion, improving crop germination and increasing crop yields
- retention of livestock in village because forage is available during the dry season.

Benefits of non-burning and organic manuring mentioned by Zagsilaari farmers were:

- improvement of soil fertility
- reduction in soil erosion
- increased crop yields and self-sufficiency in food for families
- use of less land, allowing sedentary agriculture.

Disadvantages in non-burning were:

- fewer dead trees for woman to collect as firewood
- inaccessibility, with limited mobility and visibility; bushes become hideouts for thieves
- proliferation of pests such as rodents and insects which destroy crops.

Successful fire control

Conservation of natural vegetation and the protection of other plant material can provide the organic matter needed to enhance soil fertility. This can be achieved by reducing the frequency and extent of burning.

The success story of Goziire in this respect was a result of awareness creation that led the local people to mobilise themselves into a volunteer group to control fire. The community instituted locally endorsed by-laws. Culprits are sanctioned and must pay fines. The community also has the support of the Paramount Chief of Nandom to enforce the by-laws. The heightened awareness spread to surrounding villages, which have now also adopted non-burning.

More action needed

Farmers are seeking improved crop yields with low levels of external inputs. The study has shown that yields are higher where non-burning and organic manuring are practised. The sustainability of soil fertility depends on the availability of organic matter and this is possible only if crop residues and bush vegetation, the major sources of organic matter, are not burnt. We therefore recommend that:

- More education be given by environmental NG0s, government organisations, MOFA and District Assemblies to enhance awareness of the implications of bush burning.
- Traditional rulers, in consultation with their communities, institute bush fire bye-laws endorsed by the District Assemblies.
- Non-burning and organic-manuring practices be incorporated into school curricula.
- Fire-fighting volunteers be trained and supported by the Ghana National Fire Service and the District Assemblies.
- Communities be organised into groups to facilitate the training and adoption of non-burning and organic manuring.
- Workshops, seminars, video shows, and field visits be part of the educational programmes
- Farmers be encouraged to adopt technologies such as oversowing, cover cropping, improved fallow and agroforestry as complementary measures to increase organic matter.

Long-term monitoring of non-burning and organic-manuring practices would allow the quantification of their short- and long-term impact on agricultural production and environmental quality. Comparisons should be made on the basis of simple economic analyses.

Communities develop strategic burning

In recent years, the awareness-raising campaigns about non-burning have led to heated discussions in communities in northern Ghana. Burning of grass on fallow and bushland has several advantages: it removes heavy vegetation and reduces labour inputs to bring fallowed land back into cultivation, it reduces the incidence of weeds and pests in cropland, it prevents bush encroachment on grazing areas, it gets rid of low-quality over-mature grass and makes way for fresh regrowth of grass nutritious for livestock, it stimulates the germination of certain tree species, and it reduces the risk of devastating uncontrolled flash fires that can destroy crops and homes. On the other hand, farmers are aware that burning also destroys vegetative biomass that could be used to improve soil quality.

Through their observations and discussions, some communities are now developing a more differentiated view of fire: it is a question not of burning or non-burning but rather of when, where and how burning is practised. Burning at the right time of year, under strict control, can achieve the positive effects and reduce the negative impact of this practice. These communities have drawn up by-laws that stipulate when and where burning is allowed, and have strict social controls to ensure that burning outside these limits is punished. There is still room for action research by communities to determine the best ways to employ burning as a valuable tool when used strategically and with caution.

Farmers' paths of experimentation: the PTD process in northern Ghana

The Association of Church Development Projects ACDEP in northern Ghana was already working with the PTD approach in the late 1980s to develop LEISA technology with farmers. This received an impetus when an ACDEP member participated in the ILEIA workshop on PTD in 1989.

David Millar

However, the research collaboration with ILEIA that started in 1995 led to the formation of a more structured Northern Ghana LEISA Working Group involving other organisations like the government extension service, local research institutes and the University for Development Studies in Tamale. These people from different disciplines and with a wide range of experience needed to reach a common understanding of PTD.

Preparing for renewed PTD

Some training in PRA methods and an exercise in AERM were carried out during the first two years, but only in February 1997, after entering into collaboration with a new ILEIA team, did the NGLWG start to prepare in earnest to work together with farmers in LEISA assessment. We met to review the experiences gained in PTD in earlier years and to develop a common approach for the new research process planned at the pilot sites.

We recognised that PTD is meant to combine formal science and indigenous knowledge, but the initiative for collaboration comes from external stakeholders (researchers and extensionists), not from the farmers themselves. Entering collaboration means negotiating a balance of power such that outcomes are evaluated according to the interests of all stakeholders. We agreed to centre the new PTD process on building up the capacity of farmers, extension workers and researchers.

The NGLWG as a group was at the 'Getting started' stage of PTD. The farmers, however, were clearly well on their way in problem solving. We had to find out 'where the farmers were coming from' before we tried to introduce anything new. We were entering their ongoing process.

One woman and one man from each of the four communities selected in Langbensi and Sadema (two in each pilot site) joined the NGLWG members in a training workshop, during which the PTD approach was discussed and participatory tools were introduced and practised.

Situation analysis in farmer workshops

The farmers who took part in the training served as lead persons during subsequent two-day workshops held in March 1997 in the pilot areas. The starting point for analysing the current situation was either the AERM maps drawn by local men and women in 1996 or community walks made during the workshop. Four groups (older and younger men, older and younger women) drew problem trees to clarify the causes and effects of farming problems, listed constraints and ranked them by scoring with pebbles. All communities identified land (expressed in terms of availability and/or fertility) as the main factor limiting production. In addition, the women in Sandema identified pest control in grain storage as an important issue.

The villagers then drew a second tree, focusing on the causes and effects of problems associated with land. The causes of soil infertility included shortage of manure, tillage practices, continuously cropping the same land, limited crop rotation, sand collection, indiscriminate cutting of trees, burning of crop residues and bush fires.

Potential solutions

During the workshops, farmers proposed some ways of improving soil fertility based on their own experience and what they had heard earlier from extensionists. Their suggestions included:

- Incorporating crop residues into the soil
- Applying chemical fertilisers
- Legume-cereal rotations or mixtures
- Applying farmyard manure or household refuse
- Sowing cover crops
- Applying ash from burnt bush land
- Controlled burning
- Planting trees.

NGLWG's Research Coordinating Committee met to discuss the farmers' proposals as well as other possible ways of improving soil fertility drawn ▶

from literature and recent field studies. Researchers had shown that soils at the sites were deficient in phosphorous and recommended that the farmers could try to test the affect of including phosphorous in organic matter as one option.

During a second set of workshops held in April 1997, NGLWG members and farmers took a closer look at soil infertility and how farmers were trying to tackle it. They observed eroded places, infertile soils, fields manured by kraaled cattle, and some of the rotations used by farmers. In each community, potential solutions were discussed and ranked.

Drawing experimentation paths

NGLWG members were aware of their limited skills when it came to helping farmers design experiments. In previous attempts to follow a PTD approach, ACDEP staff had designed the experiments in their offices and presented them to farmers for approval. This time, the challenge was to enable the farmers to design the experiments themselves.

Starting from the basic assumption that farmers are already informal experimenters, we devoted the second day of the workshop to exploring local concepts of experimentation. First, farmers were asked to identify a local word for experimentation: they came up with *masim-nya*, which means ‘try and see’. We worked with the idea of a footpath (*sorle*): first, separate groups of men and women drew the path to their village, so that a stranger could find it. They marked important ‘signposts’ and difficult parts with symbols. Then we asked them to map the path of informal experimentation with a farming technology that someone in the group had recently tried in a similar way. The next step was to map the sorle they would take in an experiment to solve the problem of low soil fertility.

The groups presented their paths to each other and compared them. During the discussion, the facilitator probed for relevant features such as starting point, ending point and decisions that must be made along the way. This helped to bring the two designs into one, and to agree on what should be done at what point. Criteria and indicators for assessing the experiments (whether we are still on the path) were discussed, and critical times for collecting data to ascertain this were identified. Some aspects that farmers felt were important to observe are listed in Table 1.

The NGLWG reviewed the farmers’ criteria and the researchers’ and ILEIA’s criteria for assessing the validity of LEISA techniques. An attempt was made to balance quantitative and qualitative data and scientific acceptability without putting undue stress on farmers and extension staff for data collection, yet allowing all partners to compare and analyse the results. NGLWG drew up a proposal for research protocols that combined the interests of the various partners and brought them back to the pilot areas for discussion and revision. The treatments finally agreed on with farmers were as follows:

Table 1: Observations important to farmers for evaluating soil fertility amendments in cereal crops (women’s suggestions marked with ‘W’)

- Timing and amount of rainfall
- Tolerance to dry spells (W)
- Quantity and quality of seed
- Planting dates
- Germination (W)
- Rate of crop growth
- Rate of weed growth (W)
- Size of stalks and cobs
- Colour of leaves (W)
- Time of plant maturity
- Incidence of disease and pests
- Labour required to weed and harvest
- Yield in baskets
- Compactness of seeds on the cobs (W)
- Different uses that can be made of the crop
- Taste of the grains
- Ease of processing the grains
- Incidence of pests in storage.

In Sandema:
- Farmyard manure only
- Farmyard manure + phosphorus
- Phosphorus only
- Household refuse only
- Household refuse + phosphorus

In Langbensi:
- Farmyard manure only
- Farmyard manure + phosphorus
- Phosphorus only
- Control

In Sandema, the experimental plot with five treatments was set in the middle of the field: the rest of the field served as the control. In Langbensi, a control was included in the design.

Community-owned trials

The communities selected men and women to experiment on their behalf. In Sandema, 20 men volunteered to carry out the soil-fertility trials, while 15 women decided to experiment with bean storage (Box 1). In Langbensi, 20 men and 12 women agreed to do the soil-fertility trials.

At the beginning of the cropping season, one-day review workshops were held at each pilot site to ensure agreement on experiment design and on the roles and procedures that should be followed during implementation. The experimenting farmers and field staff were trained in data collection. The farmers provided the major inputs for the trials: land (about 100 m^2), labour and seed. The NGLWG provided the phosphorus fertiliser (25kg/experimenting farmer).

The farmers observed the agronomic parameters during the growing season and informed extension staff when they start-

Box 1 Women experiment with cowpea storage

During community meetings in Sandema to identify farming problems, the women said the biggest threat to family food security was pest damage in stored grains, especially cowpea, millet, sorghum, bambara beans and groundnuts. They drew up a list of locally available options to reduce damage. These included:
- periodic drying
- store in tight bottles and leave them in the sun
- store in pots with ash, sealed with cow dung
- store in cow dung
- store with local herbs (e.g. *kpaliok* and *titibinamagli*; scientific names unknown)
- store with neem powder or extract (solution)
- store with powder or extract of *dawadawa* (from the seed of *Parkia filioida*).

The women discussed the feasibility of these options and decided to compare ash, kpaliok, neem powder and neem solution. They agreed that the trial should be done with cowpea, the crop most damaged in storage. Fifteen women volunteered carry out the experiment. Each kept five small pots of cowpeas in the home: this gave a total of 75 pots (5 treatments x 15 replications, including a control).

After three months of storage and a cooking and tasting test, the women ranked the treatments according to the following previously agreed criteria:
- degree of pest infestation as measured by the number of holes
- colour of the cowpeas
- palatability.

They came to the conclusion that ash gave the best results, *kpaliok* was second best, and neem powder and solution were not very effective. They found that ash from sheanut, neem and *Parkia filioida* wood was particularly effective. This was the first time the women had systematically compared different ways of solving grain-storage problems. They were keen to continue and try out other indigenous botanicals and comparing them to ash and *kpaliok*.

Moses Appiah

ed major farm operations (for example, weeding, harvesting) that required data collection. The church development projects organised exchange visits between the experimenting farmers and the rest of the community. The owners of the research were the communities, not just the individuals experimenting on their behalf. Monitoring also involved cross-visits between the pilot areas, after which the participating farmers reported back to their communities.

Because the experimentation was supposed to provide information for validating LEISA, data for this purpose also had to be monitored. Two types of scientific analysis were planned. The laboratory analysis of soils, organic fertilisers, yields, and total nutrient input and uptake and a total farm input and output analysis in terms of labour, costs, materials and input-output flows between plots within the farm, to be done using a computer model called FARMS. Extension staff took samples for these analyses and made twice-weekly field visits to collect data.

Farmers eager to compare results

It had been planned that the observations, measurements and analyses made by the farmers and scientists would be brought together in end-of-season assessment workshops but farmers already began comparing notes during the regular monitoring sessions. They regarded the experiments as a kind of competition and insisted that the NGLWG visit each experimental plot to see what had been achieved. Some 'non-experimenting' farmers voluntarily joined the monitoring sessions. The farmers were eager to move ahead in discussing their experiments, and not wait for the scientific analysis of results.

The NGLWG organised a two-day assessment workshop in each area. Farmers indicated that the soils treated with farmyard manure (FYM) could hold more water. When rains were poor, crops in these plots were more vigorous than in the other plots. In both pilot areas, farmers judged that FYM plus phosphorus gave the best grain yields: over twice as much as in the control plots. The second best ranking was given to treatment with FYM alone. Quantitative assessment by scientists confirmed the farmers' conclusions. However, because phosphorus must be bought and is difficult to obtain locally, the farmers found that organic manure was the best option for their situation.

Nevertheless, farmers indicated the following constraints in producing and using farmyard manure.

- limited quantity of FYM available
- poor quality of FYM
- large amount of labour needed to produce and apply FYM
- high incidence of weeds in plots treated with FYM
- difficult access to the equipment needed for producing and using FYM.

The villagers expressed satisfaction with the outcome of the assessment workshops and wanted to continue the research. It was agreed that, in the next cropping season, farmers from neighbouring communities would be invited to join the trial-monitoring visits. As farmers and extension staff complained about the time spent collecting data, especially for the FARMS model, this was scaled down.

Continuing and extending PTD

Sustaining the PTD process and scaling it up were concerns of the NGLWG from the start of collaboration. Reports on the research were sent to the documentation centres and libraries of institutions concerned with agricultural development in northern Ghana. At each quarterly meeting of ACDEP, the Country Programme Coordinator briefed members about the farmers' research. This eventually led to plans to scale up the approach to other ACDEP member stations.

The climax of the PTD cycle was a one-week regional workshop, involving key people from the collaborating organisations, representatives of experimenting farmers selected by their communities, and both regional and national policymakers. In addition to being a forum to further analyse and share research results, the regional workshop provided an occasion for the advocacy of LEISA and PTD, and served as a platform for re-planning the general directions of research. Afterwards, the NGLWG helped the participating farmers prepare community workshops to brief their fellow farmers. This led into planning the next PTD cycle.

Feeding into the next PTD cycle

The community workshops in early 1998 combined the PTD phases 'Looking for things to try' and 'Designing the experiment' and were focused on the problems encountered with FYM. During the farmers' monitoring visits and assessment meetings, the communities had already asked for the number of experimenting farmers to be increased. The community workshops therefore started with reviewing the mandates, commitments, roles and responsibilities of all partners in the PTD process.

Discussion about new experiments focused on two main problem areas: insufficient organic matter and weed control. The farmers came up with several options that could be tried out (Table 2).

Based on results of scientific studies that had been commissioned by the NGLWG during the previous year, it was agreed that cover cropping with *Mucuna, Callapogonium* and *Stylosanthes* spp would be included in the 1998 trials. Some farmers also wanted to include the pit compost they had started to prepare after the Burkina Faso trip (Box 2). Weed growth was included as a principal indicator to be monitored in 1998 and a weed scientist was brought in for this purpose.

In 1998, all the experiments were repeated at the pilot sites by all the original experimenting farmers. Some farmers used the compost prepared after the Burkina Faso trip as a substitute for FYM or household refuse, while others used it in addition to these. In Langbensi, seven additional farmers started experiments with cover crops.

Table 2: Farmers' suggestions to improve the use of FYM

Problem	Suggested research directions
1. Insufficient organic matter	a. Compost making
	b. Improving animal health and husbandry
	c. Supplementary feeding and housing
	d. Expanding small ruminant production
2. Weed control	a. Revamping the communal labour system
	b. Using leguminous cover crops
	c. Developing appropriate weeding tools
	d. Animal traction

Farmers working with other ACDEP member projects chose to address issues of particular relevance to their situations such as comparing bush-farm composting with pit composting near the home, with particular attention to water requirements and inputs for transporting organic matter and compost.

The experiments are continuing with more experience, commitment and intensity. New farmers who have joined the PTD process are being encouraged and supported as part of the ACDEP agricultural projects extension programme. In addition, the NGLWG has commissioned a study on animal health and husbandry with the intention of feeding the outcome into the farmers' research.

▶

Box 2 Ghanaian farmers' excursion to Burkina Faso

An eye-opener for the experimenting farmers in northern Ghana was a visit to farmers in Burkina Faso to see how they coped with low soil fertility. The people who joined the excursion were chosen by their communities and mandated to report back. Before departure, the Country Programme Coordinator told the farmers what they would see and facilitated discussion of possible follow-up activities. The excursion team consisted of the Coordinator, four extensionists (a man and woman from each pilot site), 16 farmers (two men and two women from each of the four pilot communities), the Langbensi station manager and an interpreter.

In October 1997 they travelled to north-east Burkina Faso where vegetation is so sparse that sometimes only pure sandy soils and hard pans with scattered thorn bushes can be found. They spent a week visiting farmers who practise an eight-week pit composting of crop residues, household wastes, animal dung and chaff; the application of compost in zai (holes hacked into the soil); and the demi-lune (half-moon) method of conserving soil and water. The Ghanaians saw how the Burkinabé farmers integrate livestock and crop husbandry although they have even fewer animals than the visiting farmers and thus improve the quantity and quality of compost. They witnessed the important role of animal traction (donkeys) in the farming system. They learned that good compost does not contain weed seeds, as had been alleged by some farmers in Ghana.

The Ghanaian farmers discussed with their Burkinabé counterparts through the interpreter. The other members of the excursion team were largely silent observers. The farmers expressed amazement at what the Burkinabé had managed to achieve under even more difficult conditions than those found in northern Ghana:

> *We are very much blessed and yet are complaining of poor soils. A large proportion of our soils we have even discarded as 'dead' but, to our surprise, such soils are being used here to produce something even better than we are doing on our best soils. The Burkina experience shows that we are just jokers.*
>
> *We are not doing enough back in Ghana to improve our soils and to get more out of our sweat and toil. Yet we are in a better position [ecologically] to do better. We have to wake up. We have to tell our people what we have seen and start doing the same.*

After the trip, the NGLWG organised a one-day workshop in each pilot area. The farmers who had travelled to Burkina explained what they had seen and learnt. They were enthusiastic about the organic manuring practices of the Burkinabé, and some had already started collecting materials to construct compost pits for themselves. Their reports generated much discussion and a strong desire in other community members to have a similar experience.

The excursion to Burkina Faso exposed the farmers to new conditions and ideas, and challenged and motivated them to continue experimenting with ways of improving soil fertility with fresh zeal and commitment. Some of the experimenting farmers in Sandema and

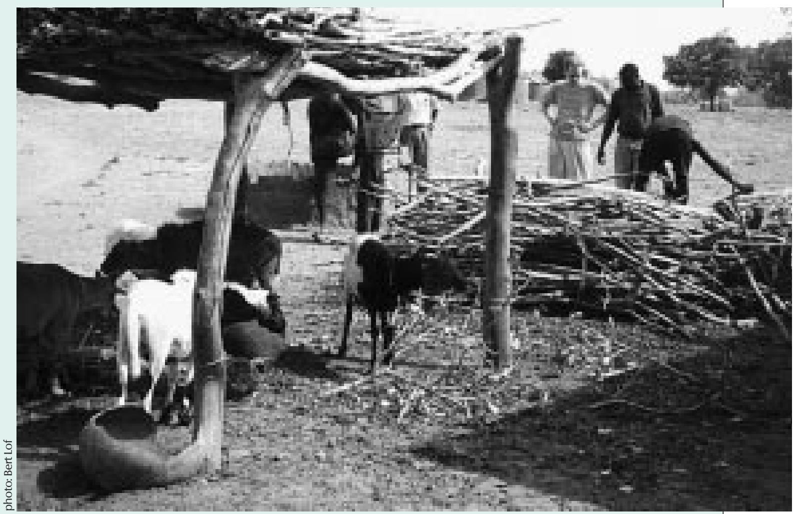

photo: Bert Lof

Seen in Burkino, then tried at home in Ghana: Tying goats near the compost pit.

Langbensi decided to add compost application as a treatment in the second year of their PTD trials. From the 10 x 10m plots in which yields were measured compost could result in a grain yield three times higher than from the control plot and also considerably higher than other treatments. Other farmers in the community who had not travelled to Burkina started to try out and adapt composting techniques on their own.

A number of initiatives arose after the farmers' assessment of the compost trial. With the greater appreciation of the value of compost, some farmers started to experiment with tying goats near to the compost pits. One farmer went as far as investing in a donkey cart, so that he could bring the compost to his remoter fields as well. Two farmers, on their own initiative, started a trial to compare the use of chemical fertiliser and the use of compost.

Experimenting with composting near homestead.

A platform developing sustainable agriculture

When ILEIA chose northern Ghana as a site for research for LEISA, it was not only because it fulfilled the agroecological criteria of being a dry land ecosystem. It was also because it was the home of a network, the Association of Church Development Projects, which was collaborating with

Malex Alebikiya

local research and training institutions in a participatory approach to developing LEISA. The ILEIA research project was to be based on the concerted action of stakeholders in agricultural development: governmental and non-governmental organisations involved in research, extension and teaching, and men and women farmers. In northern Ghana, the foundations for Stakeholder Concerted Action had already been laid.

ACDEP worked with governmental institutions in field-level planning of agricultural research and development, trained extension staff and ran joint workshops, and hosted university students doing field assignments. It had created a coordinating unit, the Agricultural Information Service, to facilitate this collaboration. In 1995, the ILEIA research gave ACDEP the impulse and opportunity to strengthen existing linkages and bring the various institutions together to form the Northern Ghana LEISA Working Group as a platform for sustainable agriculture. This article describes the experiences of this platform in its research and development activities, and as an advocate of LEISA in the policy sphere.

The NGLWG platform

The stakeholders that came together in 1995 to form the NGLWG came from development, research, and teaching. In the beginning, farmers were involved primarily as partners and beneficiaries in the experimentation and evaluation in the field rather than at the institutional level in project management and advocacy. Only gradually did the farmers from the pilot sites become more involved in the latter as they gained confidence in their abilities and influence.

The NGLWG wanted to collaborate with ILEIA in the research on LEISA in order to:

- feed into the on-going experimentation by farmers in their efforts to sustain production,
- collect field data to convince policy-makers about the potential of LEISA as an effective strategy for agricultural development, and
- encourage farmers to experiment and improve their skills in experimentation.

All the parties involved had witnessed the failure of past attempts to 'modernise' agriculture. The removal of government subsidies on 'modern' inputs had made them too costly for smallholders. In the meantime, the traditional farming systems based on local resources, including indigenous knowledge, had endured, albeit with diminishing yields. The vast majority of farmers continued to derive their livelihood from low-external-input agriculture.

Organising ourselves for joint action

The NGLWG organised a workshop to review the results of the initial field exercises designed to document socioeconomic conditions and local experiences with LEISA. Further training workshops in Participatory Rural Appraisal (PRA), PTD and Rapid Appraisal of Agricultural Knowledge Systems (RAAKS) gave people from the stakeholder institutions a chance to gain a better understanding not only of the existing situation but also of each other's roles, and to agree on joint action. We worked out our own management structure to ensure transparency, effec-

All stakeholders meet during the ILEIA-Northern Ghana LEISA Working Group workshop.

photo: Bert Lof

tiveness and participatory decision-making while implementing the collaborative research.

Three main activities in SCA

Participatory research. The PTD process (Millar p 43) harnessed the different strengths and expertise of the partners:

- indigenous knowledge and other resources of farmers, male and female, old and young;
- experience in participatory approaches of the NGOs and their rapport with farm communities;
- scientific knowledge and research experience of the research institutes and the university;
- the administrative support of MOFA at district level.

The farmers' knowledge of local conditions and practices and their experience in informal experimentation was combined with the scientists' knowledge in order to design experiments that the farmers could carry out themselves with their own resources. The experiments were jointly monitored and assessed by farmers, NGO staff and scientists, using agreed indicators. Farmers made their own changes in subsequent experiments on the basis of their new experiences. SARI did the soil and yield analyses, and fed the results back to the farmers.

Studies. Field studies were made by scientists as part of the PTD process of seeking options to test, and in order to understand the context, extent, causes and effects of the key problem identified by farmers: low soil fertility. The studies were better integrated into the PTD process after the NGLWG rather than ILEIA took over the tasks of identifying the studies to be implemented, commissioning them and discussing the results.

Advocacy workshops. The NGLWG organised research workshops that were attended by policy-makers from research, MOFA, the university and the NGOs involved in the collaboration, as well as by some regional and national politicians. At three such meetings held between 1997 and 1999, results and experiences from the field were presented. The experimenting farmers were the main resource persons. The workshops served to advocate the role of PTD and LEISA in sustainable development.

Experiences and learning points

Coming to terms with ILEIA. The research collaboration followed a rocky path to begin with. This was due to a lack of clarity in ILEIA and NGLWG about the project goal and strategies, the differing expectations of the collaboration, and conflicting views about roles. This problem was compounded by time pressure to complete the project and the expectations of those funding ILEIA and ACDEP activities.

ILEIA and ACDEP had worked together previously in information exchange. ACDEP saw the research project as an opportunity for more concrete collaboration on LEISA and PTD. The NGLWG developed a programme in this direction at its initial planning workshop before any personal contact with the newly recruited ILEIA research team was established.

That team saw things differently: it sought to understand the conditions and potentials for LEISA within the broad framework of natural resource management, supported by contextual and policy studies. It saw the NGLWG as an organisational structure that would help ILEIA reach the project targets. NGLWG, however, saw itself as a potential platform for advancing LEISA at farmer and policy level. It expected that, by the end of the project, the group's capacity and skills to continue this function would be strengthened. As part of the capacity-building process, it expected a guided devolution of project implementation from ILEIA to the group.

The ILEIA research team did not appear comfortable with this role for the group, possibly because, being new to ILEIA, the team had no previous contact with ACDEP. It saw only the specific outputs that had to be produced by the end of four years. For the NGLWG, any collaboration with external agencies had to benefit farmers directly, and it was not clear how the farmers would benefit from the approach proposed by the ILEIA research team.

The conflict eventually led to a call for an external review of the project. This review led to a new strategy that incorporated the expectations of the NGLWG. It was only then - almost two years after the official start of the project - that agreement could be reached between ILEIA and the NGLWG on programme, outputs, budget and implementation, and PTD work could begin in the field.

From 1997 onwards, ILEIA shared all project documents with the NGLWG and devolved all issues related to project implementation to it. This transparency and trust challenged the group to prove itself. The managers of the institutions involved gave their moral support to NGLWG by visiting the participating farmers and by taking part in the research workshops. ACDEP provided office space and secretarial service (partly financed by the project) as well as senior staff, with many years' experience in project management, to support the group. This played an important role in building the platform.

Reconciling internal differences. Despite the fact that the NGLWG was built on an existing foundation for collaboration, it was - in many respects - a new network. It had to go through a process of negotiating individual, institutional and group interests, building a collective vision, gaining the commitment of all members, and developing its own dynamics, norms, working principles and procedures.

One issue was the status of the group. Was it to be an independent network, or a working group under ACDEP? When the project started officially, the members accepted the lead role of ACDEP and the location of the network within the ACDEP secretariat. They saw the research project as a collaboration between ILEIA and ACDEP, which they were invited to join as resource institutions. However, in the course of project implementation, the group gradually recognised its potential as an institution in its own right and one that could support the fieldwork of NGOs and MOFA and influence policy on a more permanent basis.

Another issue was whether the group was based on individual or institutional membership. ILEIA and ACDEP had invited the institutions that were the most important actors in agricultural development in northern Ghana to form the NGLWG. The institutions were motivated to participate, partly because of government policy favouring closer interaction between government institutions and NGOs and partly because of the benefits they had come to recognise during their previous collaboration with ACDEP. The task at hand and the geographical area being covered fell within their mandate. To form the group, ACDEP deliberately ▶

contacted key allies within these institutions with relevant experience and interests. There was no formal institutional membership. Participation in the group was based on individual and institutional interest. This combination allowed the group to operate as an 'officially' recognised informal platform that functioned on a collegial basis. This accounted for the commitment of group members and the success of the group's activities.

Towards the end of the research project, all members of the NGLWG convened specifically to discuss these issues. We agreed that the future of the group would be best secured under a NGO, and decided to seek this under the legal framework of ACDEP. Furthermore, we sought to interest an increasing number of individuals from our respective institutions to join the platform as a strategy for institutionalising LEISA and PTD within the key agencies for research and development in northern Ghana.

All members of the group and some policy-makers expressed the need to concretise and expand the experiences and benefits of PTD with farmers. The NGLWG appears to be the most suitable platform for facilitating this scaling-up process and for generating information to support policy change at district and national level. The group has therefore drawn up a long-term programme to continue promoting PTD and LEISA in the field and in policy-making.

Achievements of the SCA

Gaining mutual respect. SCA provided an opportunity for experiential learning and appreciation of the knowledge not only of the farmers, who have been the prime teachers in the process, but also of the other professionals. The scientists began to respect the experience of the NGOs who, in turn, began to see that scientists and university teachers can bring useful insights to support farmer-led research. Each profession contributed to the process from a different perspective, thus generating a feeling of collective responsibility and enriching the process and outputs.

Internalising the approach. After only two years of collaboration, the Faculty of Agriculture of UDS became sufficiently interested in LEISA and PTD to include these subjects in its curriculum (see p 52) and a workshop on LEISA and PTD was organised for all lecturers. Several District Directors of Agriculture in MOFA requested a training programme for their staff, and the first such training has already taken place in Builsa District.

Building confidence. Concerted action is bridging the gap between farmers and scientists. The participating farmers realised that scientists use at least some of the same criteria as they do in evaluating technologies. The instruments for measurement may differ, but are mutually reinforcing. PRA methods showed that ranking and scoring with pebbles and discussing the meanings of these scores can bring out important aspects of a technology that go beyond measuring kilogrammes per hectare. During the discussions, scientists found that farmers could understand and expand on scientific interpretations of the results. This experience increased both the scientists' and the farmers' confidence in farmer-led research.

Training in action. Concerted action was an immersion course for the NGO staff in PTD. As the staff had received some training in PTD and had already tried to apply the approach before the research project began, they had a head start over government extensionists. However, during the fieldwork for the project, they realised that they still had a lot to learn about PTD. After two years of supporting farmer-led research, they were unanimous about the great learning effect of the experience.

Influencing policy. The NGLWG is best known to farmers for its collaboration in experimenting with LEISA technologies, but is best known to policy-makers for its advocacy work. The research workshops involving all stakeholders, including farmers, were vehicles for promoting LEISA as a more sustainable land-use system for northern Ghana than high-external-input agriculture. In their concerted action, the stakeholders have been showing how LEISA can be achieved.

Facilitating factors

While a structure for SCA may present a suitable framework for action research at farm level, it will become more than just a 'sum of numbers' only if the members can agree on a collective vision and can recognise that, by combining forces, they are more likely to achieve their individual goals. They must learn to respect the expertise of the different professions involved and the value that each brings into the concerted action. The training in PRA, PTD and RAAKS and the collaboration in field studies of LEISA and in supporting farmer-led experimentation helped the members of the NGLWG to achieve this.

The prior experience of collaboration between the individuals and institutions that joined the platform was doubtless a factor that favoured its development. The working relationship of mutual trust that had already been established between farmers and the NGOs greatly facilitated community entry and collaboration with farmers as equal partners in the research project. The government's encouragement of its institutions to seek closer links with NGOs also played a facilitating role.

The move that ILEIA, as external agency, eventually made towards transparency and devolution of management responsibilities was a key factor in forming the platform. Internally, the efforts of the NGLWG to carry all members along through open information flow and participatory decision-making procedures contributed to lively and sometimes heated discussions that forged our collaboration and resolve to continue.

Evolution instead of revolution

Northern Ghana represents a dryland savanna ecosystems. Traditional low-external-input agriculture is widely practised in a risk-prone environment where the 'Green Revolution' has failed. This article outlines the sociocultural setting of farming in northern Ghana, traces past attempts at 'modernisation', and describes the context in which smallholders, NGLWG and ILEIA conducted joint research.

P B Atengdem and A B Dery

Sociocultural setting

The characteristic social, economic and domestic unit is the patrilineal joint family. The head of family, usually the oldest patrilineal male descendant, controls family labour and farm produce, and rations it for daily consumption. However, emigration has led to the emergence of female-headed households, especially in the densely-populated Upper East Region. Household members are the main source of labour for the family farm, where staple crops are grown. However, adults also have their own plots where they can generate cash income for their personal needs.

The exploitation of nature (including agriculture) is governed by numerous taboos and social sanctions, enforced by traditional religious institutions. Land is communally owned and a land custodian, the *Tindana*, exercises spiritual power and allocates use rights according to custom. He performs the Earth rituals at the beginning and end of the farming season, or when the Earth must be pacified because taboos have been violated. In recent times, however, social sanctions are being eroded as a result of population pressure, 'Western' education and the coming of other religions, particularly Christianity. Some farmers attribute the low rainfall and declining yields to a breakdown of rituals associated with the use of land, rivers and trees.

Non-revolution in agriculture

In the first half of this century, the colonial government regarded the Northern Territories as a labour reserve for the army, police, mines and cocoa farms in the south. Little investment was made in the north although there was an attempt to produce cotton, groundnuts and sheanuts for export. Recurrent food shortages forced the government to set up agricultural research and extension stations in the late 1930s and early 1940s.

After Independence was gained in 1960, the Ghanaian government established large state farms, introduced tractors and drafted the able-bodied youth as labour. No support was given to smallholder farming.

The 1970s saw a shift from socialist to capitalist agriculture. Large-scale, mechanised rice and maize production on private farms was promoted. Through multilateral and bilateral projects, huge amounts of fertiliser, herbicides, insecticides and heavy equipment such as tractors, combine harvesters and land-clearing equipment were imported. Northern Ghana consumed more than 50% of the country's total fertiliser imports. The programme was backed by credit, subsidies and guaranteed prices. The urban elite, civil servants and entrepreneurs flocked to the north to take advantage of the 'Green Revolution'. Large expanses were cleared of all trees and planted with rice and maize.

From 1974 onward the Savanna Agricultural Research Institute (SARI) bred high-yielding rice and maize varieties (HYVs). The government's extension package was oriented to external inputs: monocropping of HYVs with chemical fertiliser application. The major task of extension staff was to distribute fertiliser and train farmers in its application. In the 1970s, several development programmes helped extend a similar package, including credit for seed and fertiliser, to smallholders.

In 1981, the Government began a Structural Adjustment Programme. Subsidies on agricultural inputs were removed. Procurement and distribution of inputs was privatised. Fertiliser prices rose sharply, and imports fell from 60,460 mt in 1980 to 12,000 mt by 1993. SARI's research agenda was redirected to 'identifying cropping systems that will ensure high and stable productivity under permanent cultivation without creating undue demand for external inputs' (Diehl 1993).

Agricultural extension in northern Ghana has been dominated by the Transfer-of-Technology approach, promoted through 'Contact Farmers' and 'Training and Visit'. Research and extension fall under different ministries: the former under the Ministry of Science and Technology, the latter under MOFA. To improve communication between the two services, Research-Extension Linkage Committees were set up. Even though the communication was still one-way, efforts were made to cooperate in designing and implementing the activities of the different Farming Systems

Farming in northern Ghana

Research (FSR) teams set up by SARI in the 1980s.

NGO reorientation to LEISA

Numerous NGOs are active in agricultural development in northern Ghana. The longest and most widespread effort is that of the church-sponsored agricultural stations. From their establishment in the 1960s and early 1970s, they collaborated with national and international researchers to conduct fertiliser and variety improvement trials. They operated demonstration farms and provided credit so that farmers could adopt ‘scientific’ farming methods including hiring tractor services and buying fertilisers, HYVs and improved animal breeds. To modernise smallholder agriculture, they worked with contact farmers, relying on the ‘trickle-down’ effect: results, however, were disappointing.

The stations began to change strategy and sought a path towards low-external-input and sustainable agriculture. They promoted animal traction instead of tractors, the use of compost and farmyard manure instead of chemical fertiliser, and they encouraged farmers to stop burning crop residues in order to maintain soil productivity. A campaign was launched against bush fires.

Smallholder farming prevails

Despite the attempts first to introduce socialist agriculture and then to revolutionise farming into modern businesses, more than 90% of rural people in northern Ghana continue to practise small-scale rainfed farming oriented primarily to subsistence. The smallholders adopted certain cash crops (mainly groundnuts, cotton and cowpea) to meet their needs for purchased goods. They adjusted their farming systems and practices as conditions changed, above all, as population density increased.

Now, relatively fixed cultivation is practised in the more densely populated Upper East and Upper West Regions, while semi-permanent and shifting cultivation is practised in the Northern Region and parts of the Upper West, where land availability is not yet a constraint. The average holding consists of a ‘compound farm’ around the home and several ‘bush farms’ a few kilometres away.

Depending on the region, the main staples are millet, sorghum, maize and/or yam. In addition bambara beans, cassava and rice are also grown for home consumption or sale. Intercropping is common, but rice is grown mainly by women as a monocrop in seasonally flooded lowlands. Traditional crop varieties, well adapted to the harsh climate and uncertain rainfall, are generally chosen. In the case of maize and, to some extent, sorghum, ‘improved’ varieties are grown. These have potentially higher yields and respond better to fertiliser but are less resistant to drought and the dry spell that falls in the middle of the wet season.

Tillage is done mainly with hoe and slasher (slash-and-burn). Tractors are hired for land preparation only and are more common in the Northern Region and parts of Upper West, largely because cotton companies are located there.

Livestock rearing is an integral part of the farming system. Most households keep some animals, mainly poultry, pigs, sheep and goats. Richer households also have cattle, but often hire Fulani pastoralists to herd them. Northern Ghana has a relatively high concentration of livestock: 75% of the countries cattle and 50% of its small ruminants are found here. Livestock range freely during the day. Smallholders use animals to supplement family diet and to generate occasional cash income. Livestock also play an important part in cultural and religious life. The use of animals for traction is more prominent in the Upper East and parts of Upper West but, even here, fewer than a third of farmers own draft animals.

Current development efforts

The MOFA extension service now emphasises soil conservation measures such as contour farming, ridging across the slope, more efficient fertiliser application, and good land preparation. Researchers at SARI are looking into other agronomic possibilities to improve the land, including cereal-legume rotation and intercropping, agroforestry, cover cropping, alley cropping, and improved fallow. Additional techniques promoted more recently by NGOs and, to a lesser extent, by MOFA include composting, non-burning of crop residues, integrated pest management, increased crop-livestock integration and animal traction. In the last decade, some NGOs - particularly the ACDEP stations - introduced the idea of developing technologies directly with farmers. It was in this context that farmers, researchers, the extension service, the local university and ACDEP started a concerted effort in action research to develop low-external-input and sustainable agriculture.

Sandema pilot site in Northern Ghana.

Northern Ghana Programme

Malex Alebikiya and Ann Waters-Bayer

The original aim of the research collaboration initiated by ILEIA was to validate LEISA as a viable option for agriculture. The dry land savanna site selected for this research was northern Ghana. A network of NGOs known as the Association of Church Development Projects (ACDEP), based in Tamale, the main city in northern Ghana, joined forces with individuals from research, extension and teaching organisations to form the Northern Ghana LEISA Working Group (NGLWG). This was the organisational structure for the Stakeholder Concerted Action (SCA) in LEISA research.

The research sites

Two pilot sites for the research were selected: Sandema in the Upper East Region and Langbensi in the Northern Region. Debates within the group and between the group and ILEIA about how far these sites represented the dry land savanna of northern Ghana led to the identification of four "syndicate sites": Garu, the driest and most densely populated site, where livestock play a significant role in agriculture and soil fertility management and dry-season cultivation of onions under irrigation is becoming a major activity; Tumu, with rich and deep loamy soils, low population density, a farming system based on yam and sorghum, and shifting cultivation to maintain soil fertility; Nandom, a transition area between Sandema and Garu, where animal traction is becoming widespread for tillage; and Tamale, a site with a high degree of urbanisation (Atengdem & Dery p 38).

Stakeholder concerted action

Collaboration began when ILEIA and ACDEP invited various organisations concerned with agricultural research and development in northern Ghana to a preparatory workshop in June 1995.

ILEIA had a mandate to work with local institutions in validating LEISA in scientific terms. This was an interest shared by scientists and academics from SARI, ARI and UDS, who saw the research project as an opportunity for field research and publication. In addition, the UDS staff saw it as an opportunity to strengthen links with NGOs in order to fulfil the mandate of pursuing a grassroots problem-solving approach to development. The MOFA staff were motivated primarily by the possibility of reaching more farmers with the additional resources that the project would provide. The church-based organisations within ACDEP were mainly interested in helping farmers solve their practical problems. The formation of the NGLWG, the long process of reaching an agreement about the purposes and mechanisms of collaboration with ILEIA, and the dynamics of the SCA are described in more detail in the article by Alebikiya (p 40)

The exposure of staff at UDS to the experience of supporting farmers' experimentation with LEISA techniques helped to break down barriers in communication between academics, extension agents and farmers. As Dittoh and Alebikiya (p 52) describe, this led to efforts within the university to incorporate PTD and LEISA into the curriculum in both lectures and practical training.

Participatory Technology Development

The approach chosen to assist farmers to move toward LEISA was PTD. The church-based agricultural stations within ACDEP already had some experience with this approach. Because the other members of the NGLWG were not so familiar with PTD, a series of workshops for information sharing and training was organised by the NGLWG. In northern Ghana, the six phases of PTD were as follows:

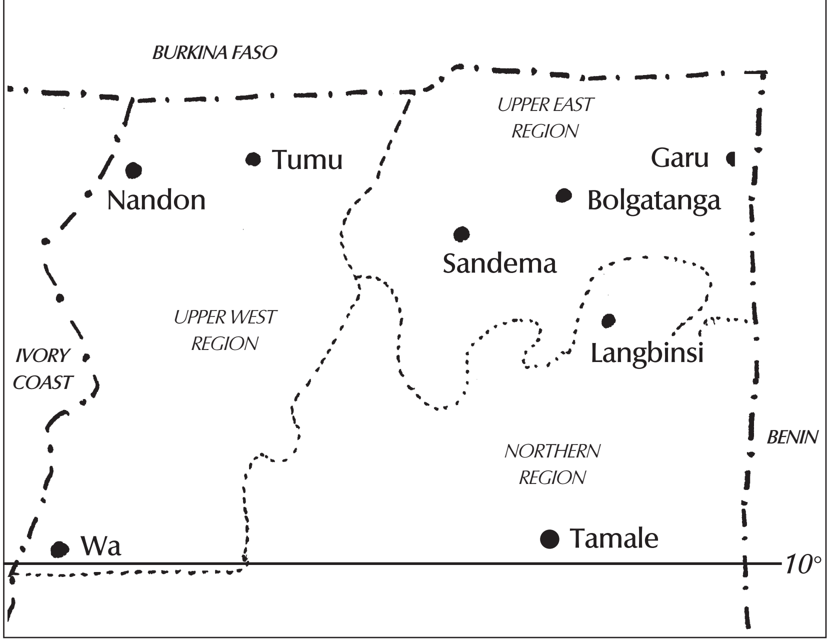
❶ ***Getting started:*** PTD courses for NGLWG members, and the first workshops with farmers to agree on collaboration;

❷ ***Looking for things to try:*** Second set of farmers' workshops, during which the farmers prioritised their problems, agreed to focus on soil fertility improvement, and decided who in the communities should carry out experiments on their behalf;

❸ ***Designing the experiment:*** A series of meetings and discussions between NGLWG members and farmers, during which the path of farmers' informal experimentation was traced and agreement was reached on designs for collaborative experiments: these involved comparing the effect of farmyard manure and household refuse, with and without the addition of phosphorus, on soil fertility.

❹ ***Trying out:*** Laying out the experimental plots for soil-fertility management trials in the fields of 52 men and women farmers, implementation of the trials by the farmers, and joint data collection by farmers and NGLWG members.

Northern Ghana: LEISA Research sites



Northern Ghana lies between 8°N and 11°N latitude at an altitude of 200-300m. Mean annual temperatures are 25-30°C and rainfall is highly variable (800-1300mm/year) with a wet season from May to September.The Sadama research site has coarse sandy loam, moderately acidic soils with low organic matter content. Available N is 10-30 kg/ha and P less than 10 kg/ha. There is considerable sheet erosion. Soils at the Langbensi site are strongly acidic and more suitable for cultivation. Organic matter content, N and P are higher here than in Sadema. Woodland savanna characterises much of Northern Ghana. The administrative regions of Upper East, Upper West and Northern Region account for 41% of the nation's territory and 20% of its population. Population densities vary from 125 persons/km² (Upper East Region) to 25 persons/km² (Northern Region). There is 3% population growth despite the continual out-migration of landless, unemployed youth. More than 90% of the population are farmers. Shifting cultivation dominates the less populated areas (5ha/household) and permanent agriculture the more densely populated regions (0.8ha/household). Millet (food) and groundnuts (cash) are the major crops in Sadema. In Langbensi, maize (food) and cotton and cowpeas (cash) are the most important.

❺ ***Sharing the results:*** Farmer assessment workshops after the end of the cropping season, when farmers and NGLWG members jointly analysed the results of the experiments and made them known to colleague farmers and scientists.
❻ ***Sustaining the process:*** Built into all above phases, in the form of workshops in which farmers were key resource persons and farmer exchange visits (for example, to Burkina Faso) to gain ideas which could be used in further experimentation and to influence policy

Also within the PTD process, a group of 15 women experimented with different ways of storing cowpea (see p 44) and men and women farmers in Garu, one of the syndicate sites, explored ways to eradicate the parasitic weed striga. Similar PTD experiments, mainly on techniques of soil fertility management, but with varying degrees of formal structure, were carried out at the other syndicate sites.

A more detailed description of the PTD process and the major results is given in the article by Millar (p 43). The intensive interaction of NGLWG members in the concrete activities of planning, implementing, monitoring, evaluating and documenting the PTD process made a great contribution to strengthening relations within this platform for concerted action in Northern Ghana. The PTD activities and results provided examples and information that could be used to convince policy makers about the effectiveness of bringing local and scientific knowledge together to improve smallholder farming.

Scientific studies

Various studies, initially commissioned by ILEIA, were undertaken to gain a better understanding of the physical and socio-economic environment. Most of the early studies were done by experts outside of the NGLWG. Later, the NGLWG took over the responsibility of commissioning studies to support the process of farmer-led research.

An exploratory study provided insights into the historical changes in agricultural practices and policies in northern Ghana; principal findings are summarised in the article by Atengdem and Dery (p 38). Agroecological resource mapping (AERM) provided information about the available resources and their interrelationships. A soil classification study (Kauffman p 9) and context studies were made of land forms in the pilot sites. Technical studies provided information on the soils in the pilot areas and on the role of livestock in improving soil fertility. This latter study identified options to explore in farmers' experimentation (Karbo et al. p 49). Case studies were made of ecological farming and non-burning practices (Aalangdong et al. p 47).

In order to carry out a more quantitative assessment of sustainability, data were continuously collected of all inputs into and all outputs out of the various plots of selected farmers by using the FARMS-software (ILEIA Newsletter 13.3). This was then used to determine nutrient and financial balances for the plots and for the farm as a whole. Unfortunately, because the computer software for FARMS could not be made operational during the project period, analyses are not yet available. However, the participating farmers found it enlightening to become more conscious of the inputs and outputs in their farm system.

The following articles describe the agroecological conditions in Northern Ghana and the history of agricultural research and development (Atengdem & Dery p 38); a consideration of the threats to sustainability in the dry land savanna that stakeholders are trying to address through their concerted action in collaborative research and policy influencing (Saa Dittoh p 51) and finally the major lessons learnt over the past four years and the prospects for continuing joint action for sustainable agriculture (Alebikiya & Waters-Bayer p 54).

GHANA

RESEARCH PARTNERS

- Langbensi and Sandema farmers
- Savanna Agricultural Research Institute
- Animal Research Institute
- University of Development Studies
- Ministry of Food and Agriculture
- The ACDEP NGO Network

In northern Ghana development workers and researchers created the Northern Ghana LEISA Working Group to enhance stakeholder concerted action and participatory technology development. The aim was to improve the productivity and sustainability of traditional smallholder agriculture. Activities focused on farmers' in Langbensi and Sandema and other secondary research sites. In these communities men experimented with farmyard manure, rock phosphate and compost for two seasons. Women focused on cowpea storage compared the effectiveness of ashes derived from three different local trees and a local herb. Studies were concerned with farmers' experiences with non-burning and the role of livestock in the savanna crop-livestock system. A study tour to Burkina Faso opened farmers's eyes to what could be done to improve farming in regions with real drought problems. This made many farmers eager to start experimenting with the production and use of compost. Advocacy workshops contributed to LEISA and PTD gaining wider acceptance as viable approaches in Northern Ghana by the University of Development Studies and the Savanna Agricultural Research Institute amongst others.

A new tone is set

photo: Marilou Abon

Looking for ways to continue collaboration.

It is strongly believed that the stakeholders in the ILEIA-Philippines Research Programme came together for a noble purpose: to prove the viability of LEISA as an alternative option for farming in this part of the world. This was a common goal shared by everyone involved in the programme and it was made concrete by the support of ILEIA Netherlands.

Marilou G. Abon

The farmers' organisations expected financial support from ILEIA and technical and moral support from the NGO and the academe. The academe expected acceptance by the farmers: acceptance of their thoughts, hearts and persons. Both groups were willing to make compromises. The farmers had a stock of learning obtained from a lifetime of farming. The academe had received theirs from books and simulated experiments. Each made a paradigm shift and decided to complement the other's learning in order to come up with concrete and scientifically accepted proofs that would substantiate their belief in sustainable agriculture as a viable option. ILEIA was expected to provide a forum through which this information could be shared with policy makers.

Negotiating working relations

The LEISA Working Groups were not spared conflict. In the initial encounter between academe and the farmers, the latter candidly stated that they felt academics were inexperienced as far as everyday farming activities were concerned. The people from the university felt they were not accepted by the farmers as partners in the programme and were, in fact, seen as competitors when it came to apportioning the budget. Farmers' resistance became more obvious when the academe recommended some scientific indicators and methodology in the experimental design. This resistance was spurred by the farmers' belief that they should be the ones to identify what was scientific and that the people from the academe should follow what they, the farmers, wanted to do in their experiments.

It was difficult to sustain the enthusiasm felt at the beginning of the PTD experiments when farmers, NGO staff and academe had invested a considerable amount of their free time. Not everyone could afford to invest so much time for a long period in activities with little paid compensation. Weekly visits to the farmers' fields by the academe and NGO staff had to be scaled down and were partially replaced by an 'on-call' system. Better payment, funded by ILEIA, made it possible to involve a broader group of specialists from the CLSU. Initially, farmers were disappointed with this development. Later it was understood that this system was more realistic and gave them more freedom to invite the specialists they needed.

The Working Groups went through a long period of adjustment before establishing stable working relationships. CLSU, KADAMA, KALIKASAN and PRRM were not always in agreement on a number of issues during the course of the programme. Issues such as approach, indicators, methodology, treatment of PTD and LEISA were continually being raised and other difficult questions included who should call the shots and who should take the leading role in projects. These differences were settled by continuous dialogue, meetings, and consultations among all involved in the programme and by constant work on 'team building' activities.

Lessons learned

Despite these differences and conflicts, the farmers' organisations and the CLSU-ILEIA task force worked hand-in-hand to accomplish their respective tasks, roles and functions for the sake of sustainable agriculture and in the end the stakeholders all claimed to have learned important lessons.

As a process, PTD - as practised within the ILEIA research programme - was seen to answer the farmers' wish to be involved in the process of articulating their needs and aspirations and having a real share in social and political power. The projects undertaken strengthen the experimental and technology management capacities of local farmers and communities. Farmers played a key role in the process and they participated in and facilitated project activities from problem identification to decision making on experimental designs and parameters. With continuous support this positive step can become a genuinely 'sustainable' progression.

Setting up a research framework based on farmers' perspectives puts farmers in a lead position. In all these activities they need technical backstopping from academe and financial support from organisations such as ILEIA. Stakeholder Concerted Action, through common activities such as planning, monitoring, evaluation, capacity building, networking, library support and documentation of results and lessons, is a support mechanisms that allows the programme to achieve its goal and meet its objectives.

Initial encounters of stakeholders and the mix of negative and positive reactions were seen as part of a natural process that can be found in any development initiative. It is a familiar stage. Mental baggage is unloaded and new ideas gradually accommodated. A new tone is set - one that facilitates better working relationships. It is a stage when new things are learnt and these can serve as the foundation for a new beginning.

We, as academics, have learned many things in the course of this research programme.

- Recognising the capability of farmers ensures their capacities will be developed in technology management.
- A complementary working relationship among stakeholders could serve as a model in any farmer-led development programme.
- The more farmers are exposed to scientific activities, the more they can develop their innovative skills and knowledge.
- Given all the necessary skills to conduct experiments and generate technology, the farmers could easily duplicate what scientists are doing in the interests of sustainable agriculture.
- Training to develop knowledge, skills and the attitude of farmers towards undertaking experimental activities is a prerequisite for programme implementation.
- Internalising farmer-led research is a continuous process that cannot be achieved in a short period of time.

What has been learned here will provide a basis for future activities in similar programmes.

PTD should be routine

Crop cutting on a sample plot.

A concluding Farmers' Forum on PTD was held in December 1998 to assess the results and processes of the PTD experiments and to formulate recommendations for the improvement of the PTD process. Fifty-eight farmers from the 10 farmer experimentation groups participated in the forum.

Carlos S. Basilio

According to farmers, several significant results had been observed after three cropping experimentation seasons of organic fertiliser application. Use of organic fertiliser and ITRV do not necessarily mean lower yields. This strengthened farmers belief that organic farming is cheaper and more profitable particularly because the need for organic fertiliser decreases after some seasons and chemical pesticides are no longer required. However, in the transition from chemical to organic agriculture time is needed to build up yield levels.

Farmers observed that plants produced by organic fertiliser were sturdier and had a healthy green colour. They were better able to withstand typhoons that devastated the rice planted in the area. This sturdiness is as important as high yield to farmers in typhoon-sensitive areas.

The farmers observed that farm organisms like paddy fish, frogs and snails have returned to their farms. Farm soils have regained their natural colour, form and capacity to nurture life. Field flora such as the *burat aso* (*Sphenoclea zeylanica* L.) which had disappeared because of the extensive use of agro-chemicals can now be seen again in farms in the KADAMA and KALIKASAN area.

Soil fertility highest priority

Each farmer group was asked to assess the results of their PTD experiments using their own criteria, indicators and parameters. The parameters were clustered into composite indicators such as crop growth, yield, grain quality, income and the effect on soil, environment and health. Each indicator was scored from 1 to 10 based on the group's perception of its importance or its effect on the experiment. The most important indicator was scored ten.

Farmers gave high priority to improving soil fertility (Table 1). Six groups ranked it first in their priority setting possibly because farmers felt their soil was being gradually degraded through continuous and intensive use. Soil fertility was seen as the best way to secure, improve and stabilise high yield and income in the long-term and farmers are ready to invest in it. Farmers also wanted a return of edible flora and fauna from their fields and saw this as an indirect, positive effect of using fertilisers capable of regenerating soil quality.

The second priority was income and yield. Cost reduction is important because many farmers are dependent on costly loans and indebtedness is widespread. High yield and income are essential, but farmers' are also concerned how farming affects human health and the environment.

Farmers feel empowered

Almost all farmers found PTD a good approach because they were fully involved throughout the research process. Farmers felt empowered by the programme as academe acknowledged farmers' indigenous knowledge, experiences and skills and their leading role in technology development. KALIKASAN-NE and KADAMA farmers became well known for their efforts to develop sustainable agriculture and they felt equal partners in the research programme.

While the farmers' organisations have been strengthened in respect of technology development, the research programme absorbed a lot of their management capacity for long periods of time. This meant that the regular activities of the farmers' federations were reduced to a minimum and many farmers became dissatisfied.

Recommendations to improve PTD

During the course of the experiments farmers made a number of innovations and adjustments to ensure that experiments were adjusted to farm and farmer realities without any loss of scientific rigor. Farmers recommended that:

- There should be agreement among the members of farmer groups on the use of common cultural management practices for the experimental plots. Any deviations from agreed practices should be recorded, reported and discussed within the group.
- Seedlings for all experimental plots should be raised on a common seedbed.
- Transplanting seedlings should be carried out on a specific day and, during transplanting, the group members should work on a mutual self-help basis.
- No replication of treatments is needed within the farm. Each farm serves as a replicate of the group's experiments.

Table 1. Summary of farmers' preference scores and ranks of the different composite indicators of PTD experiments.

Indicators	Total score	Average score	Rank frequency 1	2	3	4	5
Effect on crop growth	85	9.44	0	1	4	2	2
Effect on grain quality	89	9.89	0	1	5	3	0
Effect on yield	142	15.77	1	5	3	0	0
Effect on income	172	19.11	4	2	1	2	0
Effect on soil	195	21.67	6	2	1	0	0
Effect on environment	112	12.44	0	4	4	1	0
Effect on health	118	13.11	0	6	2	1	0

- Limit the number of sample plants and crop cuts to three.
- Increase the size of the plots from 333.33 m^2 to 500 m^2.
- Try to establish dikes between plots that are high and wide enough to prevent the mixing of treatments. Plant vegetables on the dikes to compensate for the loss of land to rice plants.
- Request the presence of the monitoring team at every critical activity especially during community orientation, site selection and evaluation, laying-out experimental plots, designing treatments, and harvesting crop cuts.
- Enforce strict use of criteria for farmer cooperators and put appropriate incentives and disciplinary mechanisms in place.
- Encourage and facilitate cross-farm and cross-site visits.
- Conduct regular, end of cropping season assessment and planning workshops.
- Conduct village level feedback of statistical and economic analysis.

Performance of roles

Farmer cooperators, area-coordinators, process documenters and monitoring team members were evaluated. Farmers observed that their experiments were hindered by their other obligations; shortage of irrigation water; scarcity of chicken manure at critical times; and climatic factors like El Niño and typhoons. Farmers acknowledge, however, that the traditional 'bayanihan' system of group collaboration and the orientation and training they had received were very helpful. In the beginning it was difficult for all farmers to be involved in data collection. After receiving better orientation from the area coordinators their involvement improved. Not all area coordinators could collect data and write reports satisfactorily.

Process documentation was sometimes difficult. Schedules were not followed, farmer cooperators had no time for meetings, data was submitted late and documentors lacked proper training. It was suggested that more attention should be given to proper selection and training of farmer cooperators, area coordinators and process documentors.

Monitoring was complicated by the fact that the team members, area coordinators and farmer cooperators had different working schedules and limited experience as well as by the climate during rainy season. The academe often had commitments at the university. Contradictory comments from members of the technical support group made farmers uncertain. It was stressed that monitoring should be carried out regularly even if area coordinators and cooperators were not present.

Participatory research was new to everyone involved so the learning process was very important. More exposure to carrying out experiments and studies is needed. This type of experimentation should become part of the everyday farming routine.

Table 2. Matrix ranking and scoring of recommended subjects for future PTD experiments

Research topics/activities	Total score	Rank
Plant breeding	9	2
Seed conservation	3	5
Varietal adaptability	11	1
Training in integrated cropping	2	6
Organic fertiliser production	4	4
Botanical pesticide production	4	4
Continue fertiliser experiments	7	3
Experiment with methods of rice planting	3	5
Experiment with Golden Snail control	1	7
Experiment with organic vegetable farming	2	6
Experiment with SALT farming	1	7

Recommendations for future studies

The participants were asked what sort of experiments and studies they wanted in future programmes. Most of the participants were interested in experiments on varietal adaptability of seed and plant breeding. Others wanted to continue with fertiliser experiments or study insect resistance, organic fertilisers, and seed conservation and collection (Table 2).

Presenting PTD to the community.

Participatory Technology Development

To introduce the PTD process, the Kadama and Kalikasan working groups conducted community orientations in their respective vilages. Social orientations were conducted by farmer leaders. This orientation familiarised the farmer members with PTD and its objectives. Farmers who attended the community orientations were also given historical perspective on how agriculture in the Philipinnes had evolved.

The process

KALIKASAN and KADAMA farmers who were interested in conducting PTD experiments were identified and selected according to criteria established by the group. These included a willingness to try organic farming and use 1000 m² of their farmland for experimental purposes; access to irrigation and a readiness to follow the research methodologies, activities and tasks required by the PTD process carefully.

Marilou G. Abon

Problem identification

The PTD process started with Participatory Appraisal Tools such as transect mapping, seasonal calendars and problem tree analysis in targeted KADAMA and KALIKASAN pilot sites. In cooperation with CLSU, PRRM and ILEIA, KADAMA and KALIKASAN members were encouraged to use resource flow diagrams and land-use maps developed from their own classification categories. This resulted in Agro-Ecological Resource Management (AERM) maps and descriptions of the prevailing farming systems in the Barangays Rajal Centro, Sta. Rosa and Triala, Guimba. A problem analysis was made, priorities set and the ‘options’ that could possibly resolve these problems was surveyed.

Training and planning

But first the research programme partners received PTD training. Concepts and principles were discussed and implementation plans prepared. Problems and issues affecting the management and implementation of the ILEIA-Philippine research agenda were identified.

Workshops were organised to operationalise the objectives, hypotheses and experimental designs. Methods of data collection, analysis, and the process of overall assessment to be used were established. Farmer cooperators determined the objectives and design of the experiments and decided which rice varieties to use, the type and amount of fertiliser to be applied, and the choice of planting method.

Standardised practices

The Bureau of Soil and Water Management (BSWM) carried out a soil analysis to determine the amount of fertiliser needed. Seedling establishment, land preparation and other cultural management practices followed the farmers’ usual practice. Fields were ploughed and harrowed using hand tractors, harrows and carabao-drawn ploughs. Three days later they were harrowed again. When the land was clod free and had been well pulverised, rice seeds were put to soak in water for 24 to 36 hours. They were given another 12 hours in moist condition to germinate. Seeds were then sown broadcast on seedbeds. Transplantation using the straight planting method occurred 25 to 30 days later. A distance of 15x15cm was left between hills.

Chicken manure was applied before the last harrowing. Chemical fertiliser, however, was applied some 10 to 15 days after transplantation. Botanical pesticides and other traditional and innovative practices were the only pest management practices used (see Box 1).

Variable treatments

Research objectives were identified and formulated by each group. The KADAMA experiments were designed to find the best type of fertiliser (pure organic, pure chemical or mixed organic-chemical) for improved traditional rice varieties (ITRV). KALIKASAN experimenters wanted to determine how traditional and high yielding rice varieties (HYV), planted on two different types of soil, responded to pure organic, pure chemical and a mixture of organic and chemical fertilisers.

Banitan and Tayabo farmers' groups used different levels of organic fertiliser on ITRV and HYV. The PMK and UGNAYAN farmers used different levels of organic fertiliser to cultivate ITRs. These last experiments were only conducted during the wet cropping season of 1998.

Experimental design varied with the type of experiment chosen. Most farmers' groups laid out their experiment in 3 blocks (one block, one treatment) without replication. Scientists asked some groups to use replication (3 replications per treatment). Each type of experiment was repeated on at least six farms. Some 69, 21 and 69 cooperators from KADAMA and 57, 48 and 43 from KALIKASAN undertook experiments during the first, second and third experimental seasons.

Monitoring and data collection

Farmer cooperators were responsible for implementing the experiments. Area coordinators visited the farms regularly to help the farmer cooperators with implementation, monitoring and data collection. Area coordinators ensured that the research process was carefully followed and they provided orientation and guidance where necessary. A monitoring team composed of farmer, CLSU, and PRRM working group members ensured the process and experiments stayed on track and were responsible for facilitating meetings and workshops and writing programme reports. They noted those factors affecting experiments and discussed problems with area coordinators and farmer cooperators. KADAMA and KALIKASAN provided the CLSU-ILEIA Task Force with the schedules of farm visits. KALIKASAN research sites were monitored once every two weeks and KADAMA research sites were monitored during the first week of the month. Indicators for monitoring and evaluation of the experiments were selected (Box 1).

Informal meetings were held during or after monitoring to assess the results of field visits and suggestions and recommendations were made to farmers and area coordinators on what needed to be done. Institutional, working group and programme level meetings were also held to update each partner on the status of the experiments and, if problems had been reported the steps taken.

Members of the CLSU team were consulted when special problems arose and specialist knowledge was required. When pest or disease outbreaks occurred, for example, samples of the affected plants were brought to the CLSU laboratory and farmers were later given the results and advice.

Box 1 **Farmer collaborators indicators for monitoring PTD experiments**

- Growth: plant height, number of tillers, panicle length (30, 50 and 70 days after transplanting)
- Yield: fresh and dry (per m^2 and total field)
- Amount of external and internal inputs
- Amount of chemicals used
- Amount of organic fertiliser used
- Number of beneficial and harmful insects
- Available soil nutrients
- Organic matter content
- Soil pH
- Ease of land preparation
- Weed occurrence
- Extent of moss/algae growth
- Soil colour
- Resistance to natural calamities, typhoons, floods, droughts
- Types, amount and taste of food
- Income
- Frequency of income generation
- Reduction in expenses/need for capital
- Amount of production loans or savings
- Amount of free time
- Health
- Number of natural organisms, plants and animals returning to farmlands
- Depth of water table
- Number of farmers using organic fertiliser

Data processing

Data on plant height, number of tillers and panicle length were collected 30, 50, and 70 days after transplantation. The fresh and dry yield weights per sample m^2 and per plot were noted immediately after harvesting and two days after sun drying. Farmers, guided by the monitoring team, used 10kg weighing scales to record yield data. Scientists used a structured interview schedule to gather additional data. All information was then filed in a database using the Statistical Package for Social Sciences (SPSS) file. The CLSU-ILEIA Task Force analysed all statistical and economic data collected. Results were explained to the farmers in the assessment workshops.

Soil sampling for scientific analysis.

Laying out experimental fields.

Assessment workshops

After each cropping season, assessment workshops to discuss PTD results were held at village and working group level. Results were further evaluated in country research workshops. At the village level, primary evaluation of the quantitative and qualitative data derived from experiments took place during group discussions when farmers discussed the strengths and weaknesses of their own experiments. Farmers' interest in continuing the project was also assessed and the assessment workshops served as stepping-stones to further PTD experiments. In December 1998, at the end of the project and after three rounds of experimentation, there was a final farmer assessment of the PTD results and processes (see Basilio p 32).

Process documentation

Process documentors were responsible for monitoring the PTD process. Photos, videos and voice tapes were used to analyse the research processes and results and to assess the applicability of the research in general. The process documentation team consisted of members of the farmers' groups and staff from the University.

Transplanting.

The results of the PTD experiments

Data collected by the farmers were forwarded to CLSU partners for statistical and economic analyses. The IRRISTAT programme was used for statistical analysis and an analysis of variance (ANOVA) for experiments laid out in Completely Randomised Design (CRD). Treatment means were compared by the Least Significant Difference (LSD) test. For unreplicated treatments, the data per federation was pooled and analysed through ANOVA with farms serving as replicates. Treatment means were compared using the LSD test. Farmers were compared using the Duncan's Multiple Range Test (DMRT). Statistical significance was set at the 5% level.

Full statistical and economic analysis of experiment results from KADAMA and KALIKASAN farms for the three cropping seasons can be found in the research reports (Abon 1999; Mendoza 1999) and the Philippine's Country Report (Abon et al, 1999).

The statistical analysis lead to the following conclusions:

- Within the KADAMA research sites homogeneous results through time were obtained when the effects of the same treatments (pure organic, mixed and pure chemical fertilisers) were assessed for three consecutive seasons. The growth and yield parameters had insignificant differences across treatments. The organic, mixed and chemical fertilisers used in the experiments were statistically comparable in growth and yield when applied to improved traditional rice varieties (ITRV) Ag5 and Ag8.
- Two factor experiments for rice varieties Ag5 (ITRV) and RC28 (HYV) and fertiliser types (pure organic and pure chemical) were conducted in KALIKASAN. With the exception of experiments in Mangandingay during the wet season of 1997, insignificant results were established for the effect of these factors on rice growth and yield parameters implying that the three types of fertiliser used in the experiments were equally suitable for ITRV and HYV.
- Sites in the Mangandingay experiments had a history of organic farming. Pure organic fertiliser was most suitable for ITRVs (Ag5 and Ag8) in clayey and sandy loam soil, for HYVs C18 (planted in sandy loam soil) and C28 (planted in the clay soil). Pure chemical and pure organic fertiliser only gave statistically identical results in the case of Ag5 planted in clay soil.
- In farms exposed to organic farming before PTD experiments started in Triala and Guimba, pure organic treatment out-yielded pure chemical and mixed treatments for both ITRV and HYV varieties. These farms may have already reached a point where soil conditions had more or less stabilised to favour the use of organic fertiliser.
- Experiments in the 1998 wet cropping season compared quantities of pure organic fertiliser (chicken manure in 30, 60 and 90 bags of 50 kg) on land with an organic history. Yield and growth parameters showed no significant difference. This could mean that the minimum level of 30 bags/ha of pure organic fertiliser is enough to secure relatively high yields with ITRVs and HYVs. Padua (1979) reports similar results with the IR-42 rice cultivar confirming the experience of KALIKASAN organic farmers who found that after 5 to 7 seasons of applying organic fertiliser high yields can be maintained with as little as 10 bags/ha of chicken manure. However, there is the risk that soil nutrient depletion may occur because 30 bags/ha chicken manure would be insufficient to fulfill the nutrient requirements of a 5 ton rice yield even if considerable biological nitrogen fixation were to take place.

Given time, the ITRVs treated with pure organic fertiliser or mixed organic and chemical fertiliser could out-yield those treated with pure chemical fertilisers. Mhayamaguru (1998), who observed rice experiments conducted at Phil Rice where experimental fields were exposed to organic fertiliser for three years, supports this contention. He established that plants treated with mixed urea (U) and

photos: Kalkasan

Monitoring growth.

chicken manure (CM) (25:75 and 50:50 U:CM ratio) gave the best grain yield (8.5 and 9.1 t/ha). Pure urea yielded 8.8 t/ha. Raja & Garcia and Garcia et al. had similar results in comparable experiments with lowland rice. Such findings suggest the potential benefits of organic fertiliser and animal manure when applied continuously for several cropping seasons (Obien, et al., 1995).

Multiple Regression

To draw conclusions from PTD research rooted in a holistic perspective, multivariate techniques such as multiple regression and factor analysis are required. Data were measured at site level and, because of the amount of data, the Statistical Package for Social Sciences (SPSS 7.0 for Windows) was used.

The final step in the stepwise procedure for multiple regression revealed that significant predictors of rice yield were gender; farmer-cooperators' education level; extractable potassium and phosphorus; the number of tillers; supplementary and farm irrigation; total rice area; incidence of disease and pests, and the use of mixed fertiliser.

Gender and educational attainment were the two personal characteristics extracted as predictors of rice yield. Male farmers had better yield productivity. This could be explained by the fact that male farmers had more exposure to and direct involvement in farm activities than women. Farmers with a higher level of education produced better yields, had more scientific and practical knowledge and had better access to agricultural information. This, in turn, facilitated a better farming system and better yield.

Extractable potassium and phosphorus were found to contribute positively to yield and were the prime limiting factors in PTD farms. Although nitrogen is the usual element needed for growth and better rice yield, regression did not establish it as a primary yield indicator. This could be due to the fact that all PTD experimental sites were relatively rich and sufficient in extractable nitrogen, as the soil acidification studies confirm (Hipolito p 24).

Factor analysis of the same data showed that the principal component group of factors for yield prediction were farm irrigation; extractable potassium, nitrogen and phosphorus; pH; number of tillers; number of years of organic management; and the farmer organisation. These accounted for 22.1% of total variation.

Correlations were also established between pest and disease incidence and the use of indigenous pesticides. Exposure to organic farming practices was interrelated with soil and water characteristics and suggested that the organic farms studied could be on the road to ecological sustainability.

Factor analysis supports the regression results to a large extent and provides a strong argument for paying more attention to these factors in the next PTD series.

Table 1. Average productivity indicators by treatment in all experimental areas in Nueva Ecija: wet cropping season, July-December, 1997.

Item	Organic	Treatment Inorganic	Mixed fertilizer
Land productivity (cav/ha)	117.82	127.17	135.20
Labour productivity (P/P)	3.54	3.62	3.78
Capital productivity (P/P)	1.85	2.04	2.02
Net income (P/ha)	21,715.31	25,303.00	26,630.11
Return to labour (P)	2.62	2.8	2.91
Return to capital/operating expenses (P)	0.85	1.04	1.02
Net profit margin	0.44	0.49	0.49

Table 2. Typical results for the experiments on fields with an organic history (from Guimba)

	Pure chicken manure 90 bags/ha	Pure chemical urea/16-20-0	Mixed fertilizer	
Total expenses	24,762.34	19,814.02	22,575.74	P/ha
Net profit	38,312.66	35,430.98	33,539.26	P/ha
Land productivity	145.00	127.00	129.00	Cavans /ha
Labour productivity	5.07	4.87	4.89	P/P
Capital productivity	2.55	2.79	2.49	P/P

Monitoring rice before harvest.

Sample plots are randomly selected for harvest.

Economic Analysis

The economic analysis showed that in the first wet cropping season on farms beginning to make the transition from conventional to organic farming a combination of chicken manure and urea/16-20-0 is the best fertiliser to apply to ITRVs (Table 1). This is particularly so in irrigated areas with silty loam soil but appears to be more labour and capital productive. Moreover, earnings per peso revenue generated as well as earnings per peso spent on the production operation were equivalent to results obtained using pure chemical fertilisers. El Niño and La Niña made it impossible to substantiate the results of the second wet cropping season and the subsequent dry cropping season.

Experiments in fields with an organic history showed that chicken manure was most profitable (Table 2). This is certainly the case if the amount of organic fertiliser can be reduced after several seasons.

A series of natural disasters hit the experimental areas during the three-cropping seasons so more experiments are needed before definite economic conclusions can be drawn.

Nevertheless, results established during PTD experiments indicate the importance of improving soil fertility by applying organic matter. There is reason to believe that applying organic manure (OM) to rice fields helps secure sustainable high yields. The KADAMA and KALIKASAN experiments appear to provide an example of how this can be achieved. Liam (1993) presented data from a long-term Japanese experiment showing that in the first ten years yields from plots supplied with organic matter (manure in this case) were clearly lower each year than yields from plots treated with chemical fertiliser. However, during subsequent years, yields in OM plots reached yield levels similar to plots where chemical fertilisers were used. After 30 years, the yield from OM plots surpassed yields from chemical fertiliser plots.

In the Philippine case it may not take so long for organically treated farms to outyield chemically treated farms. Despite their small scale PTD experiments have established consistent comparability trends.

Area coordinators collect data.

Soil acidification: myth or reality?

photo: Bert Lof

Keeping the soil fertile and in good condition.

KADAMA and KALIKASAN farmers complained about 'soil acidification'. They believe it to be one of the factors causing yield decline and why they needed to increase the use of chemical fertilisers to prevent further falls. A study on soil acidification was carried out for the ILEIA Research

Marilene C. Hipolito

Programme to look more closely at the problem (Hipolito et al, 1999).

Focus group discussion was organised amongst 82 farmer cooperators from KADAMA and KALIKASAN. Among the 82 respondents, 61% claimed that they had experienced problems with rice production. The others stated they had had no problems in the last five years. Among the difficulties experienced by farmers a lack of capital (61 respondents) and water shortage (52 respondents) ranked highest. Soil acidification (19 respondents) ranked third.

Changes in the properties of the soil leading to ploughing difficulties (1), poor water retention (2), hard soil (3), a susceptibility to pests (4) and diseases (6/7), many weeds (5) and colour changes (6/7) were identified by farmers as the main indicators of 'soil acidification'. However, some farmers admitted to having no clear concept of 'soil acidification' or any clear indicators. In most cases the term had come from 'technicians'. The farmers understood it to be the probable cause of the soil-related problems they encountered in rice production. Some of them believed that these problems were the result of intensive farming and the slow decomposition of farm residues. The slow growth of rice plants and a hardening of the soil were generally associated with 'soil acidification. However, farmers themselves were not sure whether real acidification was taking place because no soil analysis had ever been done.

Soil acidification

In the Philippines the relationship between soil acidity and plant growth has been the subject of considerable, although not extensive research. Acidification is a process in which the H+ concentration of a soil system increases resulting in a decrease in the observed pH. In the soil system, acidification is related to a complex set of processes that cannot be quantitatively described by a single parameter. One way of looking at soil acidity is through the cation exchange complex. This is the adsorption of positively charged cations on negative charges on the surface of clay minerals and soil organic matter (Reuss et al. 1986). A deficiency in adsorption capacity, CEC (Cation Exchange Capacity), may lead to the accumulation of positively charged ions like those of aluminium, hydrogen and Fe and to acidification.

Problem analysis

To establish the 'truth' about 'soil acidification', the results of the soil sample analysis carried out by the KADAMA and KALIKASAN farmers groups were examined. The analysis showed that the soils were low in organic matter content and medium to low in phosphorous, though hot sulphuric acid extractable potassium was high. Soil pH was either slightly acidic or neutral. The average pH of the soils studied ranged from 5.76 to 6.89 (Table 1), while OM ranged from 1.36% to 2.51 %. The potassium content of the soils at between 113 and 417 ppm was high. The phosphorous content, on the other hand, was between 4.81 to 16.94 ppm and could be considered deficient.

Symptoms observed by the farmers such as stunted growth, chlorosis (yellowing), necrotic spots, ageing, poor tillers, thin and erect leaves and dark green coloured leaves are indicative of nitrogen and phosphorous deficiency. No aluminium or manganese toxicities were observed. At the moment, soil acidification does not appear to be a major problem. However, if the low organic matter content of the soils persists, the buffering capacity of the soil may be lowered and toxicity, together with nutrient deficiency, may occur as a result of acidification.

Nevertheless, the indicators of 'soil acidification' mentioned by the farmers - including hard soil, low water retention, susceptibility to pests and diseases - seem to suggest problems related to 'soil degradation'. These problems are also

Table 1. Average chemical analysis of the surface soils of the KADAMA and KALIKASAN farmer cooperators in the PTD experiments (Bureau of Soils 1997)

Soil samples	pH	OM(%)	Hot K (ppm)	P (ppm)	
KADAMA					
Bunga	6.34	1.94	149	7.32	+
Rajal Centro	6.89	1.89	417	12.11	+/-
San Fernando	6.88	2.51	171	5.85	+
KALIKASAN					
Banitan	5.95	2.40	113	15.3	+/-
Mangandingay	7,6	1.96	130	4.81	++
Tayabo	5.88	1.36	166	16.94	+/-

Legend: ++ severely deficient + moderately deficient +/- slightly deficient mentioned by Pingali et al. (1997) who studied the causes of yield decline in rice production (Kabir p 14). The yield data provided by farmers covered a six-year period and although there was no evidence that yield declined, these problems will have to be taken seriously if the present level of rice production is to be sustained or even improved.

Low fertiliser efficiency

The focus group discussion also revealed that during the wet seasons in the period 1992-1997, the most commonly used fertilisers were ‘complete’ (14-14-14) (30-68 % of the farmers), urea (46-0-0) (55-67 %) and ammonium phosphate (16-20-0) (11-16 %). The percentage of respondents using organic fertilisers gradually increased from 3 % in 1992 to 30 % in 1997. The amount of fertiliser most commonly applied in irrigated rice production was found to be about 90-30-30 kg/ha (N-P-K) in the wet season and 100-40-30 kg/ha in the dry season. This is slightly lower than the recommended amounts of 90-40-40 kg/ha and 120-40-40 kg/ha. Many farmers, however, could hardly afford to buy this amount of fertiliser.

According to Sri Adinigsh (1988) organic matter acts as a biological buffer ensuring that a balanced supply of nutrients are available to the plant roots. Soils that are poor in organic matter lose this buffering capacity and their fertiliser efficiency will decrease. The observed deficiencies in N and P may be caused by low rate of fertiliser application and the low amount of organic matter present in the soil leading to a low efficiency of N and P fertilisers.

Benefits of increasing organic matter

Follet (1981) showed there are many benefits to be derived from organic matter. It serves as the principal storehouse for anions such as nitrates, sulphates, borates, molybdates, and chlorides that are essential for plant growth. It increases the CEC of soils by a factor five to ten times that of clay. It acts as a buffer against rapid changes caused by acidity, alkalinity, salinity, pesticides and toxic heavy metals. Organic matter also supplies food for beneficial soil organisms like earthworms, symbiotic nitrogen-fixing bacteria, and mycorrhizae (beneficial fungi).

An increased and better use of organic ‘waste’ and green manures (animal manure, crop residues, household refuse and leguminous plants collected within and outside the farm) as organic fertiliser would greatly enhance nutrient availability, the biological functioning of the soil and the efficiency of chemical fertilisers. The soil would be softened and water retention improved. It would also make plants more resistant to pests and disease and prevent ‘soil acidification’. In a follow up study (Peñaloza et al p 25) options for organic soil fertility management have been analysed in an effort to find alternatives to current soil fertility management practices.

More studies needed

Soil degradation in rice production is a complex problem and different processes play inter-related roles (Kabir p 14). The solution does not lie in simply increasing and improving the use of organic fertilisers. Monocultures, the indiscriminate use of agro-chemicals, mechanised soil management and continuous irrigation also contribute to soil degradation. Further studies and farmer experimentation should concentrate on finding combinations of practices that best fit farmers needs and the changing conditions under which they work.

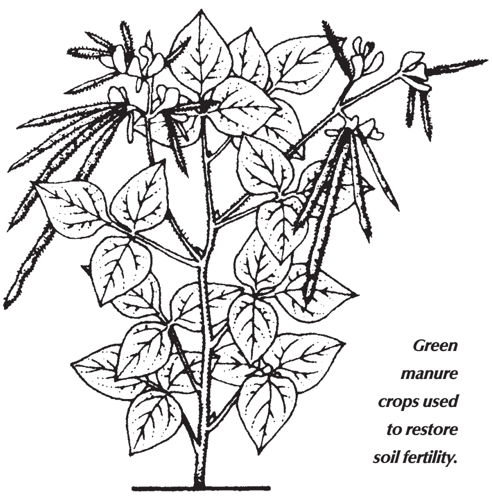
Rebuilding soil fertility

The authors’ task force studied options for appropriate, alternative, soil fertility management techniques. Secondary data were collected and analysed from CLSU, the Philippine Rice Research Institute (PhilRice), the Bureau of Post-Harvest Research and Extension (BPRE) in Muñoz, Nueva Ecija, the

David P. Peñaloza, Helene M. Mescallado and Marilene C. Hipolito



Green manure crops used to restore soil fertility.

University of the Philippines at Los Baños and the International Rice Research Institute (IRRI) in Laguna. Options identified included the use of green manure, farmyard manure (FYM), crop residue, municipal waste, and night soil. Combinations of organic and inorganic fertilisers were also considered.

Studies by Ladha, et al (1989) showed that Asian farmers prefer *Sesbania aculeata* as green manure. It grows vigorously, can withstand a wide range of adverse soil conditions including salinity, alkalinity and water logging and fixes nitrogen via root nodules. The plant can produce 15 to 22.5 t/ha biomass in six weeks giving nutrient yields of 82 kg nitrogen (N)/ha, 11-16 kg phosphates (P_2O_5)/ha and 23-34 kg potash (K_2O)/ha.

Researchers have also studied the green manure properties of Ipil-ipil (*Leucaena leucocephala* Lam.) leaves. Agustin (1978), found the best application level was 3,000 kg dried ipil-ipil leaves/ha. This produced 5775 kg rice/ha. Grain yield increased by about 15% (0.9 t/ha) as applied nitrogen increased from 60 kg/ha using ipil-ipil leaves to 120 kg/ha using either ipil-ipil leaves or ammonium sulfate (Lao-lao et al, 1978)]. Other green manure crops may be more suitable for specific local conditions (Misra and Hesse, 1983)

Long-term experimental evidence reviewed by Webster and Wilson (1966) suggests green manure crops can play an important role in fertility maintenance by acting as cover crops, raising the organic matter content of the soil, holding plant nutrients, and fixing nitrogen. Green manure crops can supply nutrients at the same level as inorganic fertilisers. Labour is the only significant cost, otherwise there are no transport costs and livestock husbandry is unnecessary.

However, several difficulties affect their acceptability. Considerable human, animal and fossil energy is needed to plough in green manure. Providing water to further the growth and decomposition of the crop in the soil can be expensive particularly where water is a constraint. Land under green manure crops should also have a higher opportunity cost than fallow land and land requirements, particularly where population is dense and agriculture intensive as in Nueva Ecija can be a problem. Managing green manure crops requires specific knowledge and skill. KADAMA and KALIKASAN farmers have tried some green manure crops without satisfactory results.

Azolla

Azolla spp., a small aquatic fern that lives in symbiosis with the nitrogen fixing blue-green alga, *Anabaena azollae*, has proved to be a valuable green manure for wetland irrigated rice. It has a high nitrogen fixing ability, grows rapidly and can be grown before and during the rice crop (Ventura, et al., 1992). Farmers using azolla have ▶

stated that rice yields are comparable to those achieved with inorganic fertilisers and production costs are less. A study in Japan showed that incorporating azolla produced a 1-2 t/ha increase in paddy yield.

Azolla can be used in animal feed, cooking, and as food. It provides shelter for fish, suppresses weeds and is an income-generating crop (Pelegrina et al, 1992). Azolla is easily propagated but requires abundant standing water, relative humidity of 85-90%, pH of 4.5-6.5, salinity of between 90-150 mg/L and adequate phosphorus for its nutritional needs. It is labour intensive, grows fast and can clog irrigation canals and rice fields and can compete with the rice crop. Azolla doubles its weight in 3-5 days. From a start of 1t/ha, it can reach a fresh weight of 15-20 t/ha in about 20 days (Khan, 1983). KALIKASAN and KADAMA farmers used azolla in the past but found that growing conditions were so favourable that it was difficult to control.

Farmyard manure

Carabao, cattle, pig and chicken manures are potential sources of nutrients for soil fertility management. An application of farmyard manure (FYM) at the rate of 3.1 t/ha produced rice yields similar to those achieved when chemical fertiliser is applied at a rate of 18.7, 6.5 and 6 kg/ha of N, P and K, respectively (Songmuang, et al, 1989). However, usually farmers only have relatively small amounts of FYM available. This means that it can only be used to improve soil fertility in small areas of the farm and has little impact on overall rice production. Where livestock production is concentrated in pig or chicken bio-industrial units larger amounts of farmyard manure may be available for sale.

Results obtained by Manaog (1965) showed chicken manure gave the highest yield/ha on Macapagai BPI 121, a lowland rice variety. It proved better than horse, cow and carabao manure and ammonium sulfate (21%N). Padua (1979) showed that when different levels of chicken manure (0, 3, 6 and 9 t/ha) were applied to IR-42 rice 9t/ha gave the best results:1650 kg/ha more grain than the control plots.

KALIKASAN farmers started using chicken manure in 1992. After five years they harvested rice yields (5-6.25 t) comparable to or higher than those produced using inorganic fertilisers. Applications could be reduced from 60 bags/ha (3000 kg/ha) to 10 bags/ha without an immediate drop in yield, a great saving as chicken manure costs P40 a bag.

Crop residues

When the grain and straw from a five-ton paddy crop are removed, about 150 kg N, 20 kg P, 150 kg K and 20 kg S is taken from the soil. Almost all the K and about one third of the N, P and S are in the straw. Although lower in nutrients than azolla and chicken manure, crop residues, readily available on the farm, are cheap sources of nutrients. Long-term experiments show that when straw is incorporated rather than burnt or removed, higher rice yields are recorded. These benefits were confirmed in a study of three soils with pH values 4.7, 6.6 and 7.4 and no fertiliser. When straw was incorporation at a rate equivalent to 5t/ha, increases in grain and straw averaged over a seven-year period, were 31% and 71% respectively. However, incorporating straw into poorly drained soils over a long period depresses yields. In order to avoid this, Tanaka (1974) suggested that 6t/ha was the maximum amount of straw that could be incorporated without adverse effects.

Incorporating rice straw into the paddy field is a problem for farmers. They may not have the right machinery and in-situ decomposition of crop residues in anaerobic conditions can be too slow for those planting two to three crops a year. There is also the risk of nitrogen deficiency and depressed yields. Ordinary composting of crop residues is also very slow. However, the IBS rapid composting method introduced in 1986 (Cuevas 1993) speeds up the process with a compost fungus activator, *Trichoderma harzianum*, and procedures that facilitate the rapid decay of agricultural wastes.

Farmers need to mix a source of nitrogen and either animal or green manure, or urea with the straw for quick decomposition and good quality compost. If compost and inorganic fertilisers are combined, rice yields increase 10-15% and incomes rise by 10-20%. These results are better than those achieved using 100% inorganic fertilisers (Cuevas 1993).

Municipal waste and night soil

Municipal and industrial organic waste either as compost or sludge is plentiful in urban areas and is an important source of nutrients. Lardinois and Van der Klundert (1993) found little municipal waste recycling in low-income countries. Technology introduced from Europe for the large-scale processing of waste often does not work and transporting and making compost are often too expensive to compete effectively with chemical fertilisers. Small-scale recycling can provide a feasible alternative. The nutrient content of municipal organic waste varies considerably depending on type, treatment and how heavily it is polluted with plastics, heavy metals and other chemicals. Urgent investment is needed in urban waste recycling to facilitate the better utilisation of this important nutrient resource and to improve the environment and health of the urban population

Night soil, composted human excreta and urine are rich sources of nutrients. Although less important today, night soil is still widely used by many farmers particularly in China. Researchers at CLSU have used night soil fertiliser to produce squash and sunflower. Patricio and Urban (1981) reported that the highest seed yield per plot of sunflowers was obtained when 30t/ha of night soil was added in four applications. The computed net income from this treatment was P3,958.00/ha, an earning of P0.74 on each peso invested. However, whether night soil is acceptable as an organic fertiliser will depend on the cost of labour, health risks and culturally determined attitudes.

Organic-inorganic combinations

Intensive cropping, high yielding varieties and market production increases the demand for soil nutrients. The supply of organic fertilisers and green manures cannot meet this demand because recycling organic waste is only possible to a limited extent and green manures often compete with crop production. Using organic fertilisers alone may not be profitable enough. The best technical and financial option is often to use both organic and inorganic fertilisers. Many studies deal with this issue and countless combinations are possible. Results depend on the materials used and the costs involved.

Individual farmers report interesting experiences in this respect. In 1985, Ricardo Libo-on applied 6 bags of 16-20-0 and 3 bags of urea/ha to his 12ha rice field and harvested an average 7t/ha/season. When he used a mixture of 5t each of azolla, rice hull and sludge from the bio-gas digester and 3 bags of urea plus 2l of foliar fertiliser/ha, he harvested nearly 15t/ha (Pelegrina et al 1992).

AGTALON Cooperative, Pangasinan, produces a commercial organic fertiliser Ag-Bio which cost P135 for 50kg. Yields ranging from 5-6t/ha and returns of P2.90 on investment were achieved with a mixture of 10 bags of Ag-Bio and 1 bag of (14-14-14) inorganic fertiliser. However, pure Ag-Bio organic fertiliser used at a rate of 12 bags/ha yields 4.5-5t/ha giving an estimated return of P3.10 on investment.

Conclusions

Each individual option seems to have its own strengths and weaknesses. The most suitable option will depend largely on local conditions, market opportunities and farmers' preference. In subsistence agriculture and where farmers produce for the organic market, different options for pure organic fertilisers will be needed. Where farmers produce for the conventional market the best way to keep the soil fertile is to combine nutrient sources of different types: organic matter, green manures and commercial inorganic fertilisers (Pandey 1991).

Alternative Rice Marketing: concerted efforts needed

Aurea G. Miclat-Teves

Farmer cooperators from KADAMA and KALIKASAN found that one of the major economic constraints to improving their economic position was the difficulty of marketing paddy. The National Food Authority can only afford to buy a fraction of the rice produced and it chooses to buy from accredited cooperatives and a few individuals. Farmers are completely dependent on local traders who pay relatively low prices. Getting more control of the rice market and obtaining premium prices for organic and pesticide-free (LEISA) rice and traditional rice varieties could greatly improve the farmers' economic situation.

In 1993, the farmers from KALIKASAN entered a joint business venture with PRRM for Alternative Rice Marketing (ARM). However, they encountered serious difficulties. An exploratory survey was carried out for the ILEIA Research Programme in order to get a better insight into the conditions that determine supply and demand for alternative rice and into current and alternative (LEISA) rice marketing systems (Teves & Liangco, 1999). The study was made in collaboration with five NGOs: AGTALON, PDI, GRASS-ROOTS, GRATIA PLENA and PRRM.

The emerging alternative rice market

NGOs and people's organisations (POs) in the Philippines began campaigning for sustainable agriculture in the mid-1970s as a response and an alternative to the technology introduced by the Green Revolution programme. At that time, the socio-economic programmes being adopted by NGOs were primarily concerned with increasing the production of rice and other crops. These programmes were very popular, particularly in depressed upland communities where TRVs were being grown. Later, without any clear-cut programmes or funding, alternative rice marketing became part of the overall NGO support scheme. At an early stage, efforts were made to involve farmers in the supply of rice stocks, post-harvest activities, milling and transport as well as in the trading and marketing of rice and other products. Although these projects were undertaken only in specific areas and with very few resources, the support extended to farmers helped them gain control of certain aspects of rice production and marketing. NGOs and POs participated in trade fairs and exhibitions. Pilot marketing of large volumes of rice started in the early 1990s and some efforts were made at Fair Trading abroad.

Marketing assistance usually consisted of providing transport and storage for paddy and facilitating the sale of rice either directly or through intermediaries. Most NGOs were relatively new to this kind of work and had limited time, personnel and financial resources at their disposal. The only NGO to have conducted a market feasibility study on organic rice trading was AGTALON. There is very little information available on experiences with alternative rice marketing.

Constraints to production

Members of those organisations involved in the Teves and Liango study produced about 2,412.00t of LEISA rice on 517 ha in 1998. Average yields on irrigated lowlands were about 4t/ha although farmers in Gratia Plena had average yields of 5.5 tons. Most of the LEISA rice produced is consumed by the farmers themselves or sold locally. Only 37% is bought by the NGOs for the alternative rice market. One of the reasons for this is lack of capital; another is that the rice is sometimes rejected as inferior quality. The most significant varieties grown for their favorable traits include Diket (glutinous), Aroma (scented), RC 18 (good eating quality), RC 14 & 18 (early maturing), Ag 5, 8 & 10 and M (MASIPAG) 12 & 40. Different varieties are often mixed and this also reduces the overall quality of the final product (cereal) and the purity of seed.

Processing, storage and milling

Climate conditions are not ideal for the post-harvest drying of paddy during the wet season. Harvested rice is mostly sun-dried on concrete highways or pavements. Sometimes paddy is sold wet at low prices to avoid further crop losses. Since drying facilities are very expensive to establish, this is a common and serious problem amongst farmers.

AGTALON is the only NGO with its own portable moisture-testing unit. NGO staff and farmer cooperators follow certain crude testing procedures when judging quality. AGTALON recently developed 'post-harvest quality standards' in order to upgrade the quality of the rice offered for sale. These included assessing the amount of foreign material present and establishing levels of purity and discoloration. Such factors, together with the scent of the paddy are used to determine its class and price.

It was observed that in NGO storage few measures were taken to prevent attacks by rodents and birds and the build up of moisture could not be controlled. Proper sanitation was also lacking. Good quality milling facilities were hard to find in the study sites and, when milled, NGO

Drying paddy in the wet season is a common problem. Sun drying is often done on the road but in Nueva Ecija this has been prohibited.

rice is seldom of high-grade quality. Lower grade milled rice does not command a good price on the market The prohibitive cost of getting access to large, multi-pass rice mills is another major obstacle. Such mills require a minimum of 3 tons of paddy to run. Starting an NGO milling facility would be very expensive.

Supply still limited

The general market and supply conditions for rice are distorted because of inefficient buying practices in the public sector, unfair practices by rice traders and price manipulation by the rice cartel resulting in low farm gate prices. The importation of good quality rice, i.e. of the aromatic and glutinous type also contributes to keeping prices low.

The premium of P1.00 for pesticide-free (purchase price 1998 P 9.35) and organic rice (purchase price P 9.75), is not sufficient incentive for farmers to go into organic rice production. The retail price of LEISA rice is P 24.00/kg. This is relatively low given that the retail price of commercial rice varies from P 21.36 to P 29.80. Lower costs and production loans of between P 7,000.00 and P10,000.00 provided by the NGOs are the main economic incentives inducing farmers to produce and market alternative rice.

There are several reasons for the small supply of alternative rice.

- Limited availability of organic fertilisers.
- High level of home consumption (20-70 %).
- Lack of government support in the promotion of organic products.
- Lack of loan incentives not tied to the use of chemical pesticides or the use of certified HYV seeds.
- Farmers sell in bulk to local traders to pay off debts.
- NGOs lack capital to buy in rice.
- Farmers sell to local traders in slack months, when higher prices are offered than the ARM system can afford.
- High unit costs for processing, marketing and distribution due to the very low volume produced and the distance to the Manila market.
- Lack of facilities and procedures to improve the quality of milled alternative rice.

Although there is a growing awareness of the need for alternative and sustainable rice production, many constraints still make it difficult for farmers to move in this direction.

Satisfying the increasing demand

There is a growing awareness and demand among consumers for healthy food and alternative rice. We calculated that the potential demand for alternative rice is far higher than present production can satisfy. Since the supply and retail system is still weakly developed, this potential demand cannot be met. Alternative rice is retailed through direct and walk-in sales and on the open market. Only AGTALON and OPTA have developed retail systems. OPTA, whose source of rice also includes GRATIA PLENA, has established market outlets for alternative rice in Makati, Alabang and other parts of Metro Manila.

Relations between farmers and NGOs are based on mutual trust. The NGOs accept what is offered to them. There is no proper labelling of rice. Consumers cannot see if there is a quality guarantee or if the rice has been produced organically and is pesticide free. A certification system has to be set up which can guarantee quality to consumers. In the Philippines there is an emerging movement that supports alternative rice production and marketing. Food Web and AVDF and their member organisations have started discussions about organic product certification.

At national government level and amongst research institutes there is a growing interest in sustainable and organic rice production. Apparently, it is time to invest in its improvement and in the further development of the marketing system.

The following strategies could be applied for the re-organisation and strengthening of the present ARM system.

- A stable supply system of preferred rice varieties should be established by ensuring a steady supply of good quality seeds and organic fertilisers.
- Facilities for production support should cover a block of rice producing municipalities per province;
- A coordinating organisation for marketing and distributing seed should be set up.
- An overall information and monitoring system should be put in place in the target areas.
- Technologies, skills, available equipment and systems for drying, milling and rice grading should be improved.
- A more in-depth analysis of the alternative marketing policy environment should be conducted to plan future courses of action and advocacy work.

The realities of the problems and potentials of alternative rice production and marketing in specific areas must be grasped if effective improvement plans for the different SA/LEISA and organic rice producing organisations are to be developed. The development of site-specific models for alternative rice marketing would be required to effectively gauge the capacity of each organisation to implement more aggressive and coordinated programmes, as well as define convergence points for NGOs, POs, consumer groups and other stakeholders in the alternative rice marketing movement.

Small retailers often reject traditional rice varieties.

photo: ILEIA process documentation

Our observations

Current alternative rice production, processing, marketing and distribution activities need to be improved through the re-organisation and further strengthening of the system. There is a need for better cooperation and specialisation among the agencies involved to make it more efficient and cost-effective. A lead agency could be chosen for each stage of the production and marketing chain, from supply inputs (organic fertilisers, quality seeds), quality control, storage and milling to actual marketing and distribution.

What farmers learned from other farmers

A. Corales, E. Valiente, M. Razon, L. de Guzman, R. Manabat, T. Amurao, R. Gabriel

photo: Ria Midat-Teves

A delegation of KADAMA and KALIKASAN farmers visited five NGO-supported farmer groups to exchange experiences on developments in LEISA rice production. These groups were the Bukidnon Centre for Sustainable Agriculture (BCSA); Technical Assistance Centre for the Development of Rural and Urban Poor (TACDRUP); the Community-based Native Seeds Research Centre (CONSERVE) in Mindanao; Infanta Integrated Community Development Assistance Incorporated (ICDAI) and Philippine Rural Reconstruction Movement-Camarines Sur Branch (PRRM-CamSur) in Luzon. BCSA is involved in the MASIPAG programme. Most of the farmers supported by TACDRUP and ICDAI follow a pesticide free or low-external-input approach while the others practice organic agriculture. The five groups visited included some 300 organic farmers with about 400ha of organic rice yielding an average 3-5t/ha.

Discussions made it clear that farmers are motivated for LEISA rice farming because of it offers environmental and health benefits. It also requires less capital and leads to cost reduction and improved incomes. Farmers also benefit from premium price, household food security and improved soils.

Most farmers involved in these NGO programmes are small farmers who can afford to produce organic rice because they own their land and derive an income from other livelihood activities. Many farmers grow rice mainly for home consumption and devote the largest portion of their land to other cash crops such as coconut, sweet potato, corn and citrus. The area under organic rice is relatively small and the family can easily provide the labour and organic materials required.

Experiences gained so far

Both indigenous traditional rice varieties (ITRV), traditional rice varieties (TRV) and high yielding varieties (HYVs) are used in organic and pesticide-free rice production. BCSA (MASIPAG) and CONSERVE advocate the use of TRVs and ITRVs in organic rice farming. They train farmers in seed selection and breeding to increase yield and lessen dependency.

Some farmers do not spray while others rely on botanical pesticides made from '*makabuhay*', '*sili*', '*madre cacao*', '*lagumbre*', and '*amarillo* claiming that traditional varieties are resistant to black bug, for example, a major rice pest in Mindanao. Other use chemical pesticides.

Many farmers experienced a serious drop in yield during the first 4 to 6 cropping seasons. This was discouraging. Farmers who initially applied a combination of chemical and organic fertilisers had fewer problems. Later yields improved as soils became more fertile. Now, yields come close to those achieved in conventional agriculture but costs are less and farmers are able to avoid debt. Initially only relatively low amounts of organic fertilisers were used. Some farmers only used rice straw as fertiliser. They found this was insufficient to maintain yield during the transition phase. After the soil has been regenerated and yield brought up to an acceptable level some farmers succeeded - at least for a time - in sustaining high yields with zero purchased external inputs.

Rice straw and chicken manure are the main organic fertilisers. In Mindanao, rotary tractors are used to incorporate rice straw into the soil. This hand tractor, called a 'turtle', can cut rice straw more easily than the usual hand tractor used in Luzon, making incorporation faster and easier. There are adequate amounts of water and rice straw is almost completely decomposed by the time transplanting takes place.

In most groups LEISA rice farming works because of the heavy support provided by the NGOs, the academe and the diocese. In the ICDAI programme, where a participatory and relatively broad approach is being followed, conversion to LEISA has been easier and faster even with minimal support.

Still a long way to go

It was observed that there were still many problems in LEISA rice production. Only chicken manure and commercial organic fertilisers are used and this makes farmers dependent on those producing these organic external inputs. A case in point is TACDRUP who import chicken manure pellets from the Netherlands. As chicken manure decompose easily and contains high amounts of nitrogen its application may lead to higher nitrogen losses than from the chemical nitrogen fertilisers used in conventional agriculture. The presence of heavy metals and toxins in poultry feed also makes it non-sustainable in the long term. Biodiversity is still very low on organic farms but a further evolution of organic rice production toward more integrated systems should stimulate biodiversity.

Farmers gave several reasons for the limited adoption of organic rice production. Yields were lower during the transition phase; organic farming is laborious and raw chicken manure has a foul smell; organic fertilisers are in short supply and farmers who do not own their land will not invest in organic farming. Some prefer conventional farming because they think chemical fertilisers and pesticides are more effective or they are put off by the unstable and low prices offered for TRVs. Farmers felt there was a general lack of support for LEISA farming and that organic farmers are sometimes ridiculed.

LEISA rice production in the Philippines still has a long way to go before any large-scale adoption can be envisaged or sustainable integrated systems have been developed. Nevertheless, the members of the KADAMA and KALIKASAN delegation concluded that the farmers visited, although they had only had two to five years' experience with LEISA rice production, were clearly on the right track. ■

KALIKASAN: aiming at integrated organic agriculture

Kalikasan has received national recognition for its organic rice production.

photo: Bert Lof

In 1992, after a PRRM facilitated training in Low External Input Rice Production (LEIRP = LEISA), seven farmers from Lupao, Munoz and Guimba in Nueva Ecija province started to experiment with organic farming and TRV/ITRV seeds from the MASIPAG programme. The results were satisfactory, the experiments were replicated and more farmers were trained. In 1993, 64 farmers founded KALIKASAN-NE. Their aim was to develop sustainable rice-based organic agriculture. Each cooperator devoted about one hectare of his or her land to organic rice production.

An Alternative Trading and Marketing (ATM) programme was started in a joint business venture with PRRM, a premium price was obtained for organic rice and a crop production loan scheme of P10,000.00 was extended to each farmer.

KALIKASAN's activities include the provision of technical assistance, the training of new members and making inputs such as chicken manure and rice seedlings available to farmers. This has resulted in a considerable reduction in production costs and an increase in the net income of farmer cooperators. Farmers have to pay an annual membership fee of P50.00 and a P1,2000.00 contribution to capital build up.

Toward integrated organic agriculture

In 1997, KALIKASAN-NE had 179 farmer cooperators cultivating some 142 ha of organic rice. During the early years yields dropped. However, after four years of organic rice production farmers succeeded in increasing yield to between 4.5 and 5 ton about the same amount as produced on conventional rice farms. The recommended application of chicken manure on clayey and sandy soils is 40 and 60 bags/ha (1 bag = 50 kg.) respectively in the first season. The application is reduced by 10 bags/ha each season until only 10 bags/ha are required in the fourth season on clayey soil and the sixth season on sandy soil. Some farmers have succeeded in sustaining high yields for a time without applying inputs.

Various ITRVs and TRVs (M-88, Benggawan, Wagwag, Sikades, Milagrosa, Ag-14, Ag-10, Ag-8, Ag-5, Brown Rice, Elonelon and Muguama) are being tested in demonstration farms. Farmers prefer Ag 5 and Ag 8 because of their strong vegetative growth, prolific tilling, grain filling capacity and medium height as well as their resistance to lodging, pests and diseases and palatability. Ag-5, Ag-8, Ag-10 and Benggawan proved resistant to 'tungro' virus in the 1994 rainy season when HYVs suffered serious attack.

Although there are generally fewer pest problems in organic rice, farmers do use biological pesticides. Some farmers successfully experiment with both traditional and new methods of pest management.

> *Box 1* **Pest management: the example of the Golden Snail**
>
> Mario Imperio from Triala, Guimba, experimented with the pest control techniques used by his ancestors. One technique involved placing pounded '*makabuhay*' vines in the waterways of rice field so that the bitter sap would be washed out by the water and carried to the Golden Snails' breeding ground. Another method was to lure snails to *'gabi'*, papaya and banana leaves that had been scattered in the rice field in the early morning. The leaves were collected before noon when the snails had moved onto them. The third experiment involved water management. Small canals filled with rice bran were built along the banks of the rice field. All three experiments were successful.

KALIKASAN-NE farmers are well known throughout the Philippines for their success in developing organic rice farming and marketing. Their partnership with the ILEIA Research Programme helped KALIKASAN to obtain quantitative proof of the economic viability of their organic practices. It also strengthened their skill in carrying out experiments designed to develop farming systems that were well adapted to their conditions, needs and objectives. This further consolidated their position in relation to conventional farmers, scientists and policy makers. Membership has increased rapidly and by 1998 there were 259 members in 18 communities.

Farmers recently started experimenting with organic vegetable production. They aim to gradually evolve their rice farming systems into diverse integrated farming systems. Farmers intend to experiment with soil fertility management, plant breeding, conservation of genetic resources, and diversification.

The continuing discussion on LEISA and Masipag organic rice production.

KADAMA: recreating lost biodiversity

KADAMA farmers' organisation was founded in 1991 as a confederation of five farmer organisations: DIWA, UGNAYAN, LIKHA, PMK and KADAMA. It has about 1500 members. Cooperation between farmers dates from 1981-1984 when the Agency for Community Education Services (ACES Foundation), a rural development NGO, facilitated participatory assessment of Green Revolution technologies on small farmers in four communities.

A consensus was created on the need to unite with other farmer groups in the interests of change and the development of alternative technologies. Similar assessments were organised in other communities and, in 1985, four 'BIGAS' follow-up conferences were organised, three at regional level and one national conference. Here farmers described their negative experiences with HYVs and related technologies and programmes and were able to recommend alternatives (Modina and Ridao, 1987).

In 1986 the 'MASIPAG' Centre (*Mga Magsasaka at Siyentipiko para sa Pagpapaunlad ng Pang-agrikulturang Agham* = Farmers and Scientists for Agricultural Science Development) was set up in Jaen, Nueva Ecija. Facilitated by ACES Foundation, it started to cooperate with farmers in eight communities where DIWA was active. This Centre was the first of thirteen envisioned for the various provinces and aimed at stimulating grassroot change. Its programme was intended to enhance direct cooperation between farmers, scientists and development workers. MASIPAG focused on collecting and evaluating traditional rice varieties (TRVs); breeding improved traditional varieties (ITRVs) appropriate to local soils and climates; alternative pest management using locally produced pest traps; biological pesticides; resistant varieties and diversified farming techniques; organic farming using organic fertilisers; and training farmers in rice breeding and documentation.

The farmers established community seed banks in farms managed by each federation and at the same time maintained at least five varieties on their own farms. Varieties were not only characterised and multiplied but were also subjected to variety adaptability trials. Interested farmers chose parent materials for breeding from the pool of locally adapted varieties and, after some training, they made their own crosses (Basilio, Razon and Estrella, forthcoming).

KADAMA's involvement in the MASIPAG programme and the support of ACES Foundation ended in 1994. MASIPAG now focuses on Mindanao and Negros where it has become very successful.

A new impulse

Twelve members started to test the MASIPAG package. It consisted of traditional and improved traditional varieties, chicken manure (at a rate of 90 sacks i.e. 4,500 kg/ha.) straight planting (40x40) facing an east-west direction and 2-3 seedlings per pocket. After a few seasons about 200 farmers were involved in testing.

The KADAMA federation aimed to enhance farmer cooperation, spread the use of MASIPAG technology and organise the marketing of MASIPAG rice. Marketing was unsuccessful, however. Farmers where forced to sell their rice to local traders who paid them lower prices for TRVs and ITRVs. This problem and because there was no crop assurance for farmers using the MASIPAG package, made many KADAMA members lose interest even though their production costs were lower and there had been no negative effects on the environment or community. Some of the more motivated farmers, however, continued to use organic fertilisers and ITRVs.

In 1996 the ILEIA Research Programme gave a new impulse to experimenting with alternative/ LEISA rice production. PTD experiments provided strong evidence that soil fertility management with chicken manure produced results equivalent to local practices based on chemical fertilisers at reduced cost (see Abon p 29). ITRVs also proved as productive as the commonly used HYVs.

KADAMA is giving high priority to recreating the biodiversity lost through rice production and has launched a new ITRV selection and breeding initiative. It plans to continue PTD experiments on soil fertility management and on such new approaches as the rice intensification system (SRI) developed in Madagascar (see ILEIA Newsletter Vol 15 No 3 & 4, Dec. 99).

Looking back for the future

There has been a marked change in rice farming in Nueva Ecija in recent decades. The ILEIA Research Programme made an exploratory study of development trends and their impact on the sustainability of agriculture in the province. With a better understanding of this process farmers may learn from their history and be better equipped to choose appropriate options for the future.

Danilo S. Vargas, Marilou G. Abon, Cynthia C. Divina and Lolita D. Bibal

Three important periods in the recent agricultural history in the Philippines' lowlands were studied. (Vargas et al, 1999). However, lack of time and difficulties in accessing information means further study is still needed to get a full insight into current trends and opportunities for developing sustainable rice farming.

Pre-Green Revolution

Prior to the Green revolution in 1972, the hacienda system was prominent in Nueva Ecija reflecting the influence of Spanish colonisation. The landlord had a direct interest in rice as a cash crop and the farmers were sharecroppers required to turn over 50 to 75% of their rice harvest to him. The development of transport, and the Cabanatuan-Manila rail link in particular, opened up a market for surplus rice. By the 1880s, Nueva Ecija had become a major rice exporter, shipping out 500,000 'cavans' (1 cavan = 50 kg) of paddy annually. By the mid-1930s surplus production had increased to 8 or 9 million cavans/year as natural forest and grasslands were brought under cultivation. Farmers produced vegetables such as maize, string beans, squash, *upo* (*Lagenara siceraria Mol.*) and *patola* (*Luffa cylindrica L.*) and raised carabaos, cows, ducks and chickens for subsistence. Natural animals and plants such as frogs, fishes, crabs, trees and herbs were important sources of food, fodder, medicine and construction material.

One rice crop was produced annually and the largest paddy yield was 2.5t/ha. Farms were rain fed with supplementary irrigation from small tanks and rivers. Traditional rice varieties were planted and took 5-6 months to mature. Soil fertility management was minimal and involved nutrient harvesting, fallow vegetation and manuring. Farmers recall that the soil was fertile, black and loose, and able to retain water for 2-4 weeks. Earthworms were abundant.

In those days, Filipino rice farmers were essentially organic farmers using

photo: Bert Lof

The traditional rice system was an integrated system and included trees, vegetables, small livestock, fish and poultry.

Development trends in the Philippines rice bowl

indigenous production methods well adapted to local conditions. Endemic plants such as *madre de cacao* (*Gliricidia sepium*) and cogon grass warded off pests and diseases and the farmers' belief in God was reflected in farming activities. Prayers or '*oracion*', for example, were offered to prevent insects infesting rice seedlings and strong cultural traditions such as '*bayanihan*' (labour sharing), harvest thanksgiving and respect for nature permeated farming. This system remained intact until 1972 when the government launched the 'Masagana 99' development programme.

Masagana 99

Radical changes took place in Philippine agriculture during President Marcos' rule (1965-1986). Structural changes in the agricultural system were effected through the implementation of major agrarian policies, programmes and legislation. Objectives included the implementation of land reform in tenanted rice and maize production areas; self-sufficiency in food production, especially as far as rice was concerned; the expansion of export crop production; and the promotion of import substitution. These changes were accompanied by Green Revolution technology and agribusiness development.

The Agrarian Reform changed the land tenure system from share to leasehold and introduced a government controlled fixed rent. In 1982 this was between 9-15 cavans of rice per farmer. Rice and maize land above a landlord's entitlement was redistributed and farmers became leaseholders and amortising landowners with holdings of between 1.2 and 3 irrigated or rain fed hectares. However not all farmers benefited from the redistribution.

The *Masagana 99* programme introduced in the early 1970s persuaded farmers to adopt the 'Green Revolution' technology package developed by the IRRI. It offered farmers collateral-free loans at relatively low interest (12%), a subsidised package of HYV seeds, and chemical fertilisers and pesticides. Land preparation was mechanised, and hand tractors, rotovators and threshers replaced carabaos. The construction of the Pantabangan Dam and the development of the National Irrigation Agency (NIA) gave many farmers access to cheap irrigation.

The Central Luzon Loop Survey, conducted by IRRI in 1980, reported that between 1966 and 1975 there had been a 95% increase in the adoption of modern varieties. This, together with chemical fertilisers, pesticides and improved irrigation made double cropping possible. Productivity increased from about 2 t/ha per cropping season in the early 1970s to 4 t/ha in 1985. By 1977, the Philippines was self-sufficient in rice and exported it as well. Between 1966 and 1979, the average Central Luzon farmer increased rice output by 80% and his or her annual rice equivalent income by 39%. However, if income from rice production is adjusted against increased input and consumer prices, the real average farmer income in 1979 was only 60% of their 1974 earnings. Thus, despite producing more, small farmers lost out in terms of their power to purchasing other goods.

A study by the Chamber of Agriculture and Natural Resources showed that between 1976 and 1981 wage rates increased 207%, fuel prices 260%, fertiliser and pesticide 126% and the consumer price index 74%. Prices for rice and corn, however, increased by a mere 44% in the same period.

At the same time, socioeconomic conditions improved at village level. Villagers had better access to health services and education, they were able to upgrade their houses and the transport and retail system began to function better, facilitating access to food and goods. In addition, agricultural extension services were intensified and it became easier to farmers to get up to date agricultural information and technology.

Deregulation

From 1982-1983 there was a dramatic decline in agricultural production and in rice in particular. This was precipitated by serious drought caused by *El Niño* and by the general economic situation. Many farmers found themselves heavily in debt and scarcely able to afford the *Masagana 99* technology package. The decline in production forced the Philippines to start importing rice again and prompted the government to advocate a new approach to agricultural development.

Deregulation, with the emphasis on free enterprise and greater private sector investments in agriculture, became the official policy. In 1985, lifting price controls on milled rice, liberalising fertiliser imports and removing fertiliser subsidies signalled the end of *Masagana 99*. The Aquino and Ramos' administrations followed similar deregulation policies and opened up the country to the world market with a shift to high-value export production and the importation of cheap rice. Since 1996, average rice imports have returned to 1960's levels. In Nueva Ecija the yield from irrigated rice has stagnated at about 5 or 6 tons in a good season. Some farmers claim yield has decreased. With a population growth of 2.3% (1994), this scenario will surely lead to a further decline in rice self-sufficiency.

The new rice production programme requires farmers to form organisations before they can get loans. Only 15% of the farmers targeted by the government's Grain Production Enhancement Programme (renamed *Gintong Ani* in 1996) have borrowed from the programme's accredited sources. The big landowners benefit most from the programme and can easily get loan privileges because they control production and have strong political and business connections. Most small farmers continued to depend on usurers for their loans and have to pay up to 30% interest per season for this service.

▶

Between 1988 and 1992, the price index for rice only increased 44.1% against increases in the general price index of 65.6%. Farmers' claim profits from rice production continues to fall because chemical fertilisers are becoming less effective and inputs and labour costs increase faster than the price of paddy at the farm gate. The cost and shortage of labour has forced a shift from transplanting rice to direct seeding during the dry season and has meant greater dependence on herbicides and further decreases in farmers real income. Many of them have taken up off-farm activities, others migrate to the urban areas or seek employment abroad. Farmers have increased their efforts to raise chickens, ducks and pigs, cultivate fruit trees such as the mango and grow vegetables like onion, garlic, pepper, and cucumber. These 'side-lines' are becoming increasingly important elements in farmers' cash incomes. However, such products are mainly grown on a contract basis, thus increasing farmers' dependence on agribusiness.

Because agriculture does not seem to have a promising future, farmers are strongly motivated to invest in the education of their children so that the new generation can build its future outside agriculture. In the early 1990s there was favorable economic development in the Philippines. Many new jobs outside agriculture were created allowing the process of economic transformation to proceed quickly. Unfortunately, the general economic crisis in the South-east Asia and a growing negative balance of trade (US$ 5,383 million in 1997) increased unemployment from 10.9% in 1996 to 13.3% in 1998 and cut off the supply of jobs outside agriculture.

Sustainability at Stake

Not only is the economic sustainability of rice farming in Nueva Ecija under constant pressure but farmers also face serious ecological problems (see Kabir p 14). Soil quality is deteriorating probably because of imbalances caused by chemical fertilisers, pesticides, herbicides and continuous irrigation. Problems identified by farmers include hard pans, soil acidification and increasingly ineffective nitrogen fertilisers (see Hipolito p 24). Scientists from PhilRice, BSWM and IRRI are concerned about P, K and Zn deficiencies and the low level of organic matter in the soil.

Many farmers not served by the National Irrigation Agency (NIA) installed shallow wells, as irrigation water is one of the most critical inputs in intensive rice production. However, the water table began to fall and farmers had less irrigation water particularly during periods with low recharge such as the 1998 drought. As more wells are drilled and upland watersheds are denuded, there is a growing threat that ground water in Central Luzon will soon be depleted.

Prior to the Green Revolution, the Nueva Ecija farmers used a wide range of traditional rice varieties including *Tjeremas, Intan, Binato, Raminad, Wagwag* and *Milagrosa*. These were late maturing and long stemmed varieties and were superior to modern varieties in eating quality. Today, traditional varieties are rarely planted in Nueva Ecija.

Farm organisms such as frogs, snails, crabs, mole crickets, shrimps, fish and other insect predators vital to maintaining a balanced ecosystem have nearly all disappeared. Many of these species were important and inexpensive sources of food. Health problems have also increased and farmers attribute these to the continuous and intensive use of chemical fertilisers, pesticides and herbicides.

Not all Nueva Ecija farmers were prepared to remain the passive victims of the problems accompanying development. By 1980, KADAMA and KALIKASAN farmers were already experimenting with alternatives to the Green Revolution package. Traditional rice varieties, biological pesticides and organic fertilisers were reintroduced and improved (see pp 19 & 20). Farmers started to rebuild cooperative ties with each other recognising that these had grown weak.

KADAMA and KALIKASAN are sensitive and responsive to the needs of their communities. Looking back at the past they assessed their experiences and made sustainable rice agriculture their choice for the future. In this they are pioneers. ■

Sustainability of intensive rice production threatened

Use of agro-chemicals, continuous irrigation and intensive mechanisation leads to soil degradation.

photo: Bert Lof

Humayun Kabir

The sustainability of intensive rice production is under threat and the problem is attracting increasing attention. An exploratory study was carried out for the ILEIA Research Programme to establish an overview of the ecological and economic impact of development trends in rice production (Kabir, 1999). The study was based on a literature survey and was subsequently reviewed by rice specialists from PhilRice, PCARRD and UPLB. This article summarises the main findings.

The intensification of rice production on the humid lowlands has meant that relatively extensive systems based on one annual rain-fed or irrigated rice crop and drought resistant crops or fallow vegetation have been turned into an intensive rice monoculture of two or three crops of rice. This has brought about several important changes in the production system.

- Year round production with a limited number of rice varieties.
- Rice paddies flooded most of the year without adequate drying period.
- Heavy dependence on inorganic fertilisers and pesticides;
- Greater uniformity in the varieties cultivated.

These production system changes have lead to long-term biophysical changes in the natural resource base. This threatens the ecological sustainability of rice farming (Pingali et al, 1997). At research station and farm level, these trends are reflected in declining factor productivity and falling profitability and input efficiencies. All have serious implications for economic sustainability.

Yield decline has been recorded in long-term, on-station experiments in several countries and at IRRI's in-house research station. However, yield decline at farm level has yet to be confirmed by scientific assessment. Rice production and yield growth rates are slowing down and, in the major rice growing countries, fall well short of population growth. The processes and trends discussed below threaten the ecological and economic sustainability of intensive lowland rice production.

Soil management

The chemical fertilisers used in rice production have a low and declining efficiency. Nutrients are lost through volatilisation, de-nitrification, percolation and run-off. Forty to seventy percent of the chemical nitrogen applied to the soil is lost to the environment leading to air pollution and pollution of ground and surface waters. At the same time, increased methane emissions contribute to climate change - the greenhouse effect.

Declines in the partial factor productivity of nitrogen fertiliser have frequently been observed. Recent work at IRRI suggests that continuously irrigated wetland soils have a reduced capacity to supply nitrogen. Flooded soil mineralises organic matter very slowly. Huge amounts of nutrients are lost through the removal and burning of rice straw. When rice straw, for example, is removed from a one hectare plot of HYV rice, 66kg N, 6kg P and 160kg K are lost as well. This loss, together with imbalances in the use of fertilisers, has increased the incidence of phosphorus, potassium and micro nutrient deficiencies in many rice soils.

Seasonal cycles of mechanised ploughing and puddling over a longer period result in the formation of hard pans and water logging in paddy soils. While favourable for rice production, these hard pans create problems for subsequent non-rice crops and this limits diversification within intensive rice systems.

Water management

Since 1979, the expansion of irrigated land has lagged behind population growth. This is mainly because of increasing irrigation costs, inadequate government investment, and policies that favour privatisation. Due to insufficient drainage and low water quality, 25% of irrigated rice suffers from some degree of salinity. Severe upland erosion causes siltation that in turn affects the storage capacity of reservoirs and reduces the amount of irrigation water available. Because of over-pumping and increased run-off there has been a steady and widespread decline in ground water reserves. At the same time, the rapid pace of industrialisation and urbanisation has resulted in growing competition for scarce land and water resources

The amount of irrigated land is shrinking rapidly due to population growth, urbanisation and industrialisation. In China, for example, where land is in short supply, nearly 4 million hectares of cropland - most of it in irrigated areas - has been lost. In addition, large tracts of irrigated land are no longer in production because existing irrigation infrastructures are poorly maintained.

Pest management

Continuous rice cultivation, uniformity in the varieties cultivated and the injudicious use of pesticides has lead to the build up of pests in irrigated rice systems and to further increases in pesticide application. Many pests become resistant to pesticides, fungicides and herbicides. Pesticide is used because it is believed that rice production is not possible without high levels of chemical pest control. A recent study by IRRI has shown that 80% of the pesticide applied by rice farmers were unnecessary. Pesticides cause ecological and health problems for humans and animals. They also contaminate surface water and this is one of the main reasons why the natural predators of pests and diseases as well as edible fish, frogs, snails, crabs and shrimps have disappeared from natural and farm environments.

Integrated Pest Management (IPM) has proved effective in reversing these trends. In countries where it has been encouraged there have been significant decreases in the amount of insecticide used. However, alarming amounts of herbicide are still being used to offset increasing labour costs and to facilitate direct sowing.

Crop improvement

Intensive rice monoculture is dominated by modern varieties with a very narrow genetic base. Traditional rice varieties are becoming increasingly rare and are only used by a few farmers. There has been little increase in the yield potential of modern varieties since the 1960s. Only hybrid rice varieties have a higher potential but these are more expensive and need well-controlled irrigated conditions. Poor and marginal farmers often cannot afford them. In regions with favourable production conditions the yield levels of many farmers come close to the assumed yield potentials of the modern varieties.

Researchers, using genetic engineering, are now trying to develop new, super rice with a yield potential of 13-15t/ha. Although it is still too early to assess the economic, social and ecological impact of the super rice, it is doubtful whether it will be able to improve the economic position of the small farmer. The full risks of genetically engineering a major food staple are also not yet fully understood.

Because doubts are being raised about the ability of plant breeders to increase the yield potential of rice. The necessary increase in food production must, therefore, come from an increase in average yield. This will be difficult in places where crop production has already been greatly intensified. When yield levels come close to 75% of their potential maximum, the incidence of disease will increase, the number of pests will intensify and it is difficult to keep soil in good condition. This means that it will be increasingly important to improve rice yield in less favourable conditions.

New insights into rice ecology indicate that the yield potential of available rice varieties is much higher than has been assumed (see article on the 'System of Rice Intensification in Madagascar. ILEIA Newsletter Vol 15. 3 & 4, December 1999). Considerable yield increases may be possible without the use of genetic engineering and may also be within the reach of poorer farmers working in marginal conditions.

Farmers are leaving the land

Higher wages in urban areas and rural poverty cause labour migration from the countryside to the towns. This creates a labour crisis on the land particularly during seasons when farm work is heaviest. When labour becomes scarce and more expensive, farmers are forced to use labour saving technologies including herbicides and mechanisation. In the long term this may lead to an increase in the size of rice farms.

The declining efficiency of chemical fertilisers, pesticides and irrigation water induced by the above mentioned ecological problems together with the increasing costs of labour and inputs relative to the price of paddy have contributed to making rice farming less profitable. Liberalisation and the globalisation of the rice market have put further pressure on rice prices. The general decline in the terms of trade between agricultural and industrial products and services has also helped to marginalise rice farming economically and farmers are being forced to look for other sources of income. Young people are being driven to seek employment outside agriculture and, in the long-term, this may mean that the number of farmers will decline.

Rice farming towards sustainability

Such developments will affect the future of rice farming and the choice of technologies and policies will heavily influence the sustainability of the rice economy. The available technology options developed by scientists and innovative, traditional and ecological farmers should be carefully analysed and their economic, social and ecological impacts described. Results can be used to support the decisions made by farmers, researchers and policy makers in their efforts to secure sustainable rice production.

New super rice has high yield potential but the risks for small farmers are yet unknown.

Humayun Kabir, International Institute of Rural Reconstruction, Silang Cavite, Philippines.
Email: iirr@phil.gn.apc.org

Humayun Kabir is a rice specialist at the International Institute of Rural Reconstruction in the Philippines. This article is a summary of Kabir H, **Sustainability issues in lowland rice production. Report for the ILEIA Research Programme.**

Philippines Programme

A working group made up of members of the KALIKASAN and KADAMA farmers' organisations together with a task-force from Central Luzon State University co-ordinated by the Centre for Central Luzon Studies (CCLS), and the Nueva Ecija branch of the Philippine Rural Reconstruction

Marilou Abon

Movement (PRRM-NE) was responsible for the LEISA research programme in the Philippines (Box 1). Staff from the Bureau of Soils and Water Management (BSWM), the International Soil Reference and Information Centre (ISRIC), the Philippine Rice Research Institute (PhilRice), the International Institute for Rural Reconstruction (IIRR) and the Philippine Development Institute (PDI) were involved in specific research activities.

The research programme set out to validate the capacity of LEISA technologies to sustain intensive lowland rice production in the specific development context and conditions of Nueva Ecija. The programme was guided by Stakeholder Concerted Action (SCA). SCA involved planning, monitoring, evaluation, capacity building, networking, process documentation and information sharing among partners. Farmer-led Participatory Technology Development was supported by farmer-led case studies and researcher-led context and technical studies. Process documentation and training were an essential part of the programme.

Sustainability at stake

One of the main reasons why farmers, NGO staff and academics became interested in the Research Programme was that they felt conventional lowland rice production was not economically and ecologically sustainable and they wanted to investigate the viability of the alternative technologies being practised by some farmers. Two context studies were carried out: an examination of intensive lowland rice production in general (Kabir, p 14) and a more specific investigation of lowland rice production in Nueva Ecija (Vargas et al, p 16). These studies provided a framework for the PTD experiments and the case and technical studies.

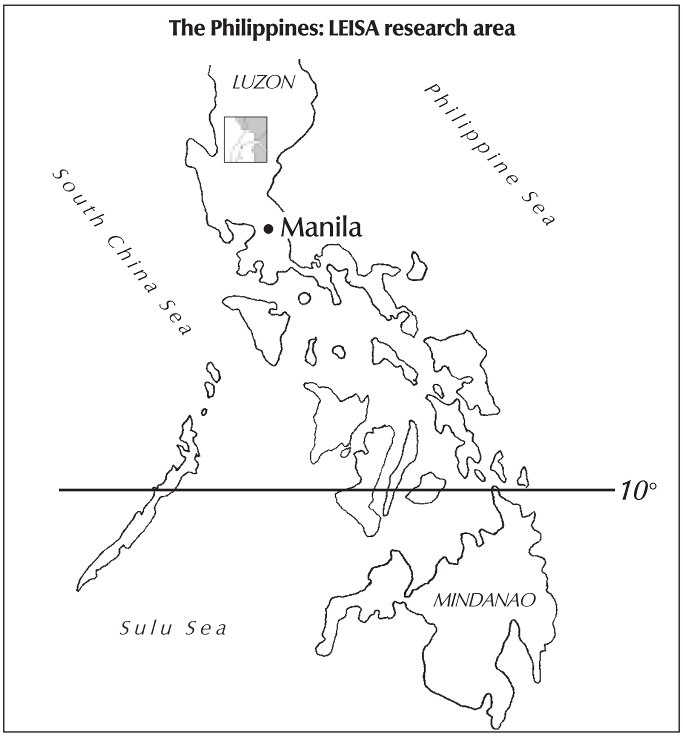
Participatory Technology Development

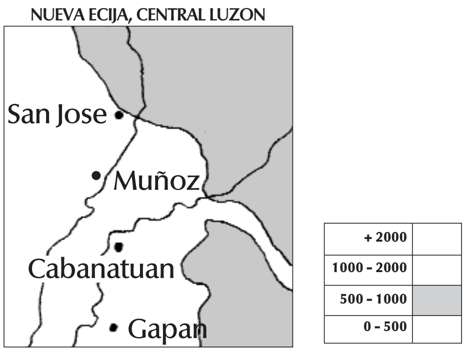
Farmers used Agro Ecological Mapping to analyse the evolution of their resource base. Research priorities were set drawing on the results of this problem analysis. Farmers considered soil fertility to be the bases of ecological and economic sustainability and soil fertility management became the focus of the research programme. To monitor the performance of their PTD experiments, farmers selected indicators appropriate to their production systems, objectives and social and ecological environment (Box 1, p 28).

BSWM and ISRIC made soil classifications at two representative sites and established information about the natural resource base. Scientific and indigenous soil and land use classifications were also compared (Kauffman, p 9).

Comparative PTD experiments on soil fertility management (pure chicken manure versus pure chemical fertiliser and a fifty-fifty mixture of both) and rice varieties (improved traditional varieties versus conventional high yielding varieties) were undertaken by some 120 farmers all of whom belonged to the KADAMA and KALIKASAN federations. Experiments extended over three cropping seasons: wet season 1997 and dry and wet seasons 1998. At the end of each cropping season assessment workshops were held and results were compared to farmer objectives. Where necessary, indicators and monitoring and assessment procedures were reviewed and modified. Scientists from CLSU subjected the results of these experiments to statistical and economic analysis. Farmers made a final assessment at the end of the third season (Basilio, p 32).

In 1997, during the first season of experiments, climate conditions were favourable. However, in the dry and wet seasons of 1998, drought (El Niño) and typhoons (La Niña) caused serious crop damage and only a few farmers could take part in dry season experiments because irrigation water was scarce. The 1998 results are, therefore, unreliable. Conclusions presented here are based mainly on the results of the 1997 wet season. The PTD process used in this research and the results of the PTD experiments are described by Abon (pp 27 & 29).





Nueva Ecija, one of the largest provinces in Central Luzon, provides 20% of the nation's rice and is known as the 'Rice Bowl'. It has an aggregated area of 528,430 ha. Half the province is alluvial plain. The Caraballo Mountains rise in the north and the Sierra Madre ranges, running north to south, dominate the east. About 230,000 ha or 95% of the province's agricultural land is under rice - 54% irrigated and 46% rain fed. The soil in Nueva Ecija is generally fertile and well drained with moisture-retentive clay and silt loams. Between 1951 and 1985 annual rainfall was 1874mm with 121 rainy days per year. The wet season extends from July to October and the rest of the year is dry. August has the most rainy days and February the least. Rain often coincides with typhoons which can cause heavy yield losses. El Niño and El Niña bring serious droughts and floods once a decade.

Case and technical studies

Case studies were carried out to support the PTD process and to help identify possible experiments. The development of organic farming amongst KALIKASAN-NE farmer cooperators (p 20) and the experience of KADAMA with LEISA rice production were studied and documented (p 19). A field trip was also made to five, NGO-supported, LEISA organic and integrated rice production programmes in Mindenao and Central Luzon and the viability of organic farming in these programmes was evaluated in farmer to farmer discussion (Corales et al. p 21).

Technical studies were based on the analysis of secondary data and focused discussion groups, a process directed by scientists. Experiences with marketing alternative and organic rice in Central Luzon (Teves & Liangco, p 22) were studied and an attempt was made to come to a better understanding of the soil fertility related problems identified by farmers as 'soil acidification' (Hipolito p 24). The soil fertility study was complemented by a literature survey that analysed options for LEISA soil fertility management (Peñaloza et al. p 25).

Sharing the results

Research programme results were discussed at a national workshop organised by the International Institute of Rural Reconstruction (IIRR) in the Philippines attended by representatives of farmer organisations, NGOs and national and international research institutions. Participants shared experiences of developing sustainable lowland rice production. A detailed account of the workshop will be published in a special IIRR ILEIA publication.

The LEISA research programme was reported several times on Philippine national television. Two videos have been made: a general video on the PTD process (in English) and a training video (in Tagalog). The Country Research Report together with reports of most of the studies (Box 2) and the videos can be ordered against costs from Dr. M.G. Abon, CCLS, CLSU, Muñoz, Nueva Ecija. ■

References are not included in the articles.
A full list of references can be obtained on request.

Box 1 **Organisations in the Philippine LEISA Working Group**

KALIKASAN-NE Peasant Federation for Sustainable Farming in Nueva Ecija has members who come from people's organisations and farmer groups as well as individual farmers from Carranglan, Lupao, San Jose City, Muñoz, Talavera, Sto. Domingo, and Guimba. The federation aims to develop organic, integrated, sustainable farming to improve the livelihood of its members.

KALIKASAN has grown from seven demonstration farms totalling 1.75 ha in 1992 to 274 farms and 171 ha in 1998. KALIKASAN receives support from the Philippine Rural Reconstruction Movement - Nueva Ecija Branch. For more information see p 20.

KADAMA Confederation of Nationalist Peasants is a confederation of five farmers' federations in Nueva Ecija. Member federations are DIWA, KADAMA, UGNAYAN, LIKHA, and PMK from the towns of Sta. Rosa; Jaen, Zaragosa and Cabiao; Carranglan; and Cabanatuan City. The confederation began more than five years ago. Some of its member federations have more than a decade experience in organic agriculture, community organisation, cooperative development and advocating policy. For more information see p 19.

Central Luzon State University (CLSU) was established as an agricultural school in 1907 and subsequently developed into a regional university. It is located in Muñoz, Nueva Ecija. The university's academic programme involves the training of the researchers, farm managers, extension agents, farm technicians, entrepreneurs, home economists, fishery graduates and teachers who make up the country's agro-technical manpower. The university carries out its research, extension and training mission by supporting sustainable agro-industrialisation and encouraging balanced socio economic growth. Technology, information generation, commercialisation; integrated capacity building; communication, advocacy, market-driven innovation and partnerships with key sectors of development are important elements in this process.

Philippine Rural Reconstruction Movement (PRRM) is a non-governmental organisation made up of committed professionals, industrialists, and other volunteers who work together to liberate the peasants and the rural poor from structures of oppression. Dr. James Yen, a Chinese scholar and founder of the International Mass Education Movement, set up PRRM in 1952. PRRM has a fourfold programme that focuses on livelihood development, education, health and self-government. In addition, it conducts policy studies and is concerned with rural planning in the interests of comprehensive rural development.

The services provided by PRRM through its Nueva Ecija branch include supporting local community development and cooperation, business development, environmental resource management, and basic social support systems. PRRM- NE supported KALIKASAN-NE and later it became one of PRRM-NE main partners in implementing sustainable agriculture development projects in the area.

THE PHILIPPINES

RESEARCH PARTNERS

- KADAMA farmers federation
- KALIKASAN farmers federation
- Central Luzon State University
- Philippine Rural Reconstruction Movement

In the humid lowlands of Central Luzon, The Philippines, the research programme focused on irrigated rice. Members of the farmers' federations KADAMA and KALIKASAN chose to experiment with soil fertility and improved traditional rice varieties. They compared the performance of chicken manure and chemical fertilisers, improved traditional and high yielding varieties and different amounts of chicken manure. Scientists from Central Luzon State University carried out the statistical and economic analysis. Beside making studies on the sustainability and history of rice production in Central Luzon, scientists looked at farmers' problems with soil degradation and the options for organic and integrated soil fertility management. The experiences of KADAMA and KALIKASAN and other groups of farmers in Central Luzon and Mindanao with alternative rice production and marketing were also documented and analysed. Provisionally, farmers reconfirmed their earlier conclusion that, for them, compared to current conventional practices, LEISA and organic practices were viable options. Identical yields could be obtained and costs were lower after several seasons. However, although a necessity given the ecological unsustainability of intensive rice production, much has still to be done to make LEISA rice production a viable option for all farmers in the region.

Towards Integrated Soil Management

Sjef Kauffman*

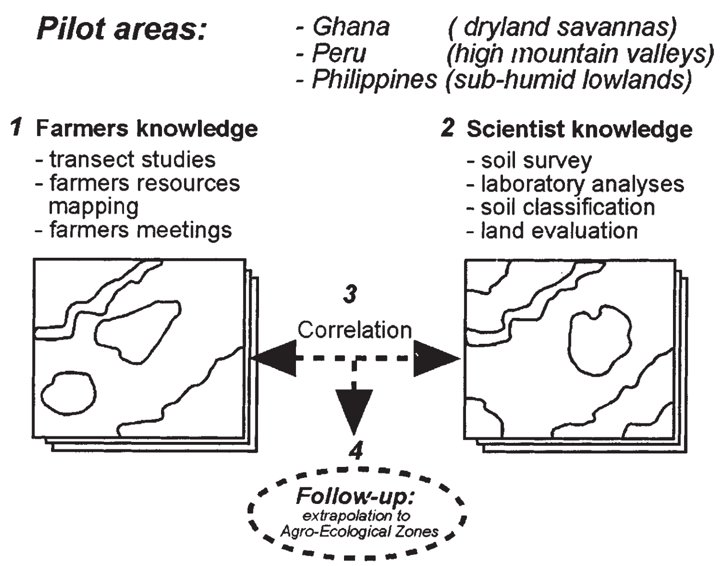
One of the first activities of the ILEIA collaborated research programme in the Philippines, Ghana, and Peru was the characterisation and evaluation of soils in six research sites by farmers and soil scientists. ISRIC sub-contracted three national soil institutions in Ghana, Philippines and Peru (see below), to work in close cooperation with farmers and NGOs in the pilot areas on this task. The comparison and integration of views held by farmers and scientists about the soils was a major part of the project. The objective was to contribute to a participatory process aimed at solving soil-related production constraints in farming. The soil study proceeded from the following questions:

- Is it possible to correlate farmers (indigenous) soil knowledge with formal soil science?
- How do farmers manage their various soils to produce crops?
- How are farmers dealing with soil-related production constraints/ limitations?
- Is there a LEISA solution for land threatened by the degradation caused by present-day land uses?

Methodology

A schematic presentation of main activities is given in Figure 1. In the six research sites the national soil scientists first executed a classical field soil survey complemented by an analytical characterisation of soil samples. The research sites were selected by ILEIA staff, farmers and soil scientists. The farmers' and scientists' soil knowledge was correlated through joint field observations. For this purpose different approaches were used. In Ghana and Peru, farmers and scientists followed closely the traverses and soil pits used in conventional soil mapping. In the Philippines joint walk-throughs were made to observe different land uses and different soils. Farmers indicated soil changes and named the soils according to local custom and language. Scientists asked farmers a series of standard questions. These questions focused on recognition of different soil types, indicators for soil characterisation, local soil names, present and potential land uses and soil management operations. Land suitability questions focused on the dominant soil-related constraints to agricultural production and the management of soil-related constraints to productivity, a question that included a consideration of the ecological threats of present land use. These farmer-scientist dialogues had a different character in the three countries. In Ghana, a series of standard questions were used (Asiamah and Spaargaren, 1997). In the Philippines the farmers were asked to make soil and land use observations by categorising their observations by using the basic human senses - sight, hearing, smell and sound (Conception and Batjes, 1997). In Peru, besides the use of standard soil characterisation questions, the dialogue had a rather free character, especially when production constraints were discussed (Kauffman and Valencia, 1998). In addition to the fieldwork, plenary sessions were held, in which the farmers and scientists discussed the results of the fieldwork. Farmers frequently mentioned non-soil related constraints to production, which were discussed and included in the reports.

Figure 1 – A schematic presentation of four major project activities



Results

The research sites in North Ghana are located in a nearly level to weak undulating plain with long slopes towards valley bottoms with slope gradients between 1 to 5 %. A large number of soil types is distinguished by both farmers and soil scientists (see Figure 2: Farmer and scientists soil maps).

In the Philippines the pilot areas are located in the broad alluvial plain of Central Luzon. Soils are pre dominantly poorly drained, dark grey coloured clays. In Peru the research sites are situated in the north and the centre of the Andean mountains. Both areas have a strongly dissected mountainous landform and are situated between 2700 and 4500 m above sea level. Variation in soil types is largely determined by geological parent material, slope and altitude zone.

More information on the environmental conditions of the pilot areas is given in the country sections in this Newsletter. For detailed information reference is made to the project reports (Asiamah and Spaargaren, 1997; Conception and Batjes, 1997; Kauffman and Valencia, 1998).

Knowledge compared

To a certain extent it is possible to correlate farmers soil knowledge with formal soil science. However, correlation of local soil names cannot always be made in a consistent way, because of the different criteria and rules used by farmers and scientists. Farmers have a pragmatic way of characterising and classifying soils based on their strong practical focus. For example, they will mainly consider topsoil properties when weighing up agricultural soil use. When looking at soil as a building material, generally only subsoil properties are taken into account. Soil science views soil properties over a standardised control soil depth for multi-purpose assessments. An additional difficulty is the variation in local soil names, which can be very large depending on the variation in idioms and languages in a region. Nonetheless, it is recommended that the potential use of indigenous soil names should be maximally explored for strengthened communication between the stakeholders at local level.

Agreement about problems

From the results in the research sites, it follows that farmers and scientists were ►

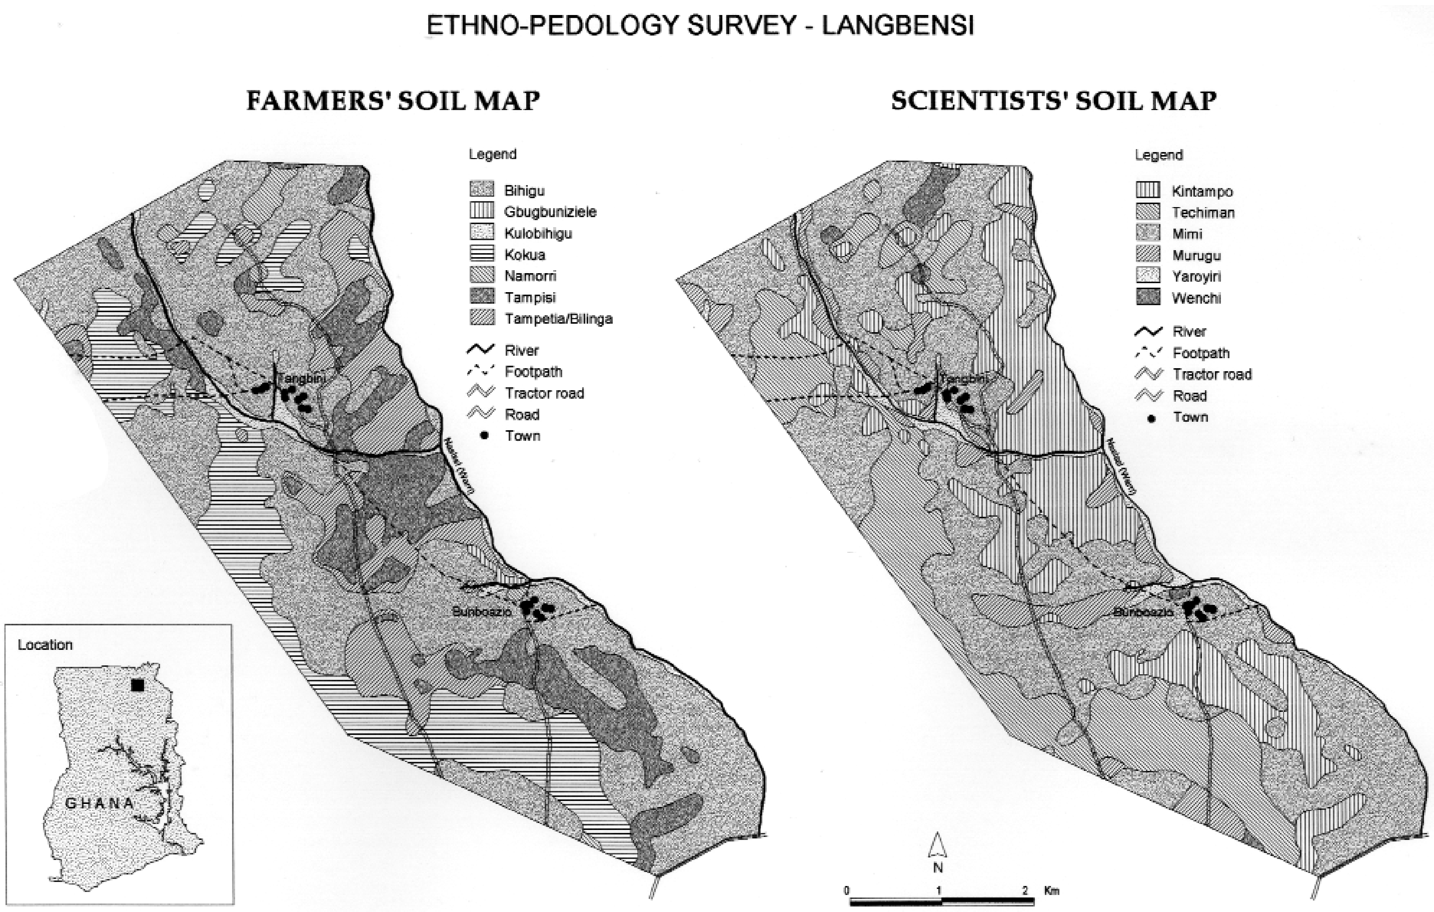


Figure 2 – Farmer and scientists soil maps

able to discuss soil-related production constraints, the local soil management techniques and potential solutions for how to overcome these constraints. The three main soil-related production constraints, indicated by both farmers and scientists in the research sites are related to water availability, plant nutrients (soil fertility), and soil degradation. The participatory process of farmers and scientists on how to solve these three constraints in a joint effort should result in the development of an Integrated Soil Management (ISM) approach.

Towards Integrated Soil Management

ISM will help to realise the agronomic potential of existing soil types, and prevent the reduction of this potential by further soil degradation. ISM will require the simultaneous application of water and soil conservation measures and organic and inorganic soil fertility measures (the latter including amendments such as local by-products and rock phosphate). ISM will contribute strongly to efficient water-use in rain-fed agriculture in the semi-arid and seasonally dry (sub-)tropics, a major challenge given anticipated population growth and accompanying food needs, especially in sub-Sahara Africa. A cornerstone of the ISM approach is the recognition of the importance of soil organic matter to preserve soil fertility and soil physical properties. Therefore one of the goals is to look for those land uses and soil management practices, which will maintain or increase soil organic matter content. Such considerations are also important in the context of enhancing terrestrial C-sinks with a view to mitigating atmospheric CO^2 levels as emphasised in the Kyoto protocol on climate change. The synergism of the various elements of such an ISM approach is especially important (Breman, 1997; Kauffman 1996). However, an ISM approach involves considerable investment. For soil and water conservation and organic fertility measures, these consist mainly of labour time; for inorganic soil amendments, mainly of money. ISM should have a sound economic basis, because the full benefits of these investments will only appear after several years. This is partly caused by learning effects: farmers may need considerable time to become acquainted with the new technologies involved in ISM, and to adapt them to local circumstances. Moreover, there are considerable time lags in the bio-physical process of soil improvement itself (Koning et al. 1997).

A recommended follow-up activity for these studies is the extrapolation of results from the research sites to the respective major ecological zones (see Figure 1 Stage 4). Such an activity will provide a tool for transferring results to policy levels responsible for policy measures for the proposed ISM approach.

ILEIA Collaborative Research Programme

From 1984, ILEIA has been concerned with collecting, analysing and exchanging experiences on the participatory development of Low-External-Input and Sustainable Agriculture (LEISA). LEISA is sustainable agriculture based on ecological principles. It makes optimal use of combinations of locally available internal and external inputs and indigenous and scientific knowledge adapted to local conditions and needs. LEISA sets out to provide alternatives to unsustainable 'conventional', 'modern' or 'High-External-Input' Agriculture (HEIA) and to unsustainable 'traditional' or 'Low-External-Input' Agriculture practices (LEIA) (see also box 1).

Box 1 **What is LEISA?**

LEISA is an approach to sustainable agriculture that builds on:

- Agroecology: a scientific knowledge base from which ecological concepts and principals can be applied to the design and management of sustainable agroecosystems;
- Indigenous knowledge: knowledge farmers have of their locality generated from their own and their ancestors' experiences. It includes knowledge originating from outside the region that has been internalised. Indigenous knowledge is holistic and encompasses all aspects of rural life;
- Scientific knowledge: knowledge base developed by scientists;
- Participatory learning, planning and action: participation of development supporters in local development processes to strengthen farmers' and own capacity to adapt to changing needs and conditions and towards sustainability;
- Economic viability, ecological soundness, social justice and cultural integrity: sustainable development is important but should not be pursued at the expense of the cultural and social values of those segments of the population who have little influence over economic and political decision making.

ILEIA sees LEISA as dealing with the technical and social options open to farmers wanting to improve their productivity and income in an ecologically sustainable way. LEISA builds on the optimal use of local resources and natural processes and, if necessary, acceptable, and feasible, on the safe and efficient use of modest amounts of modern external inputs. LEISA systems, which are highly situation specific, build on indigenous and scientific agroecological knowledge. In its social and political dimensions LEISA is concerned with empowering men and women to use their knowledge, skills, values, cultures and institutions to build up their farming future.

LEISA involves participatory methodologies to strengthen the capacity of farmers and other actors to adapt to changing needs and conditions and make agriculture sustainable. Creating an environment conducive to sustainable agricultural development means making LEISA effective at the policy-making level. As a concept and knowledge base LEISA provides direction, practical options and methodologies for development and achieving sustainable agriculture. LEISA is not, however, a blueprint for this, it is a development approach with a strong political message.
(see **LEISA in perspective; 15 years ILEIA.** *ILEIA Newsletter* Vol. 14 2&3, 1998.)

In the cases reported in ILEIA's Newsletter and other publications the reasons for the successes and failures of LEISA experiences were often unclear because many factors involved in their development remained unexplored. In order to come to a better understanding of the necessity and opportunities for developing LEISA, those evaluating Phase III of the ILEIA programme recommended adding a research component to the project's core activities.

In 1994, the Dutch Ministry for Development Cooperation (DGIS) asked ILEIA to initiate and facilitate a research programme mandated to make:

> *A participatory assessment of the viability of LEISA technologies in different environmental and socio-economic settings and substantiate this as far as possible by quantitative data. This participatory assessment should include an attempt to understand the processes that lead to changes in farmers' livelihood and land-use strategies.*

Objectives

This mandate involved implementing three regional research programmes in contrasting economic and ecological conditions. It was intended to provide farmers, researchers, policy makers and funding agencies with convincing insights into the necessity and viability of developing LEISA. It would also show what specific LEISA practices were appropriate for given conditions. Viability in this context meant that when specific LEISA practices were compared to conventional farmer practices they would be both more effective in satisfying farmers' needs and in meeting the economic, ecological and social criteria for sustainability. However, adopting LEISA practices had to be feasible for local farmers.

The second objective was to demonstrate the effectiveness of participatory approaches to technology development by strengthening and supporting farmer experimentation. In this way the knowledge of farmers and scientists would be combined in the interests of developing sustainable agriculture.

The collection of scientifically valid data was imperative. Policy makers had to be convinced of the importance of supporting the development of LEISA and conventional research agendas had to be moved in the direction of the real needs and priorities of farmers, LEISA and sustainability issues.

The research questions

There were two main research questions. First, when compared with other forms of agriculture is LEISA a viable option in the research sites and in situations with comparable farming conditions? Second, how can development/transition processes towards LEISA be supported in the research sites and comparable farming conditions?

Five specific questions followed. To what extent is the type of LEISA envisaged for a particular research site a more viable and sustainable development option than the agricultural practices generally used in the area? Can LEISA technologies satisfy farmers' objectives and to what extent are the preconditions for adopting LEISA technologies? How far are national objectives satisfied by LEISA technologies? And finally to what extent is the policy environment conducive to making a transition towards LEISA?

The vision behind the research approach

To implement this research mandate ILEIA developed an innovative research approach built on the following assumptions:

- Farmers and researchers (and other outsiders) see agriculture in different ways because they have different world visions, values, experiences, needs and objectives. They also use different languages, expressions and categories to describe agriculture.
- LEISA is a holistic approach to land use and can be examined either from the perspective of the interests of the individual farmer or those of society as a whole. Farmers and governments may have conflicting visions and interests.
- Research is too often determined by researchers' individual or institutional agenda's and takes little account of farmers' priorities and knowledge.
- Sustainability is an objective. Farmers' (and other stakeholders') innovative ability to adapt agriculture to often complex processes of change is an essential element in developing sustainable agriculture. The involvement of farmers, development workers and researchers (and at a later stage traders, bankers and policy makers) in processes of 'participatory' development can enhance the effectiveness of learning, farmer experimentation and scientific research in the development of sustainable agriculture.
- Knowledge of the dynamics of the farm-household system and its wider socioeconomic context is necessary in order to understand what conceptual, technical, institutional and policy changes are needed to make the transition towards LEISA feasible.
- As the context, needs and objectives of agriculture are constantly changing, assessment should cover a sufficiently long period of time and include the present and future situation. It should also focus on actual (unsustainable) and alternative (more sustainable) techniques.
- Such an assessment should be convincing both for farmers and researchers.
- Active and sustainable collaboration with local partners is only possible if the research fits the agenda's of farmers, development workers and researchers. It must also have a development perspective, satisfy a felt need for assessment and create a capacity to institutionalise the assessment and monitoring of sustainability at farmer' and other levels.

It was concluded that an assessment of the viability of LEISA should:

- Take farmers' priorities as a starting point and focus on concrete problems;
- Include the visions and categories of farmers and scientists;
- Include farmers' assessment (criteria and indicators) and scientific validation;
- Assess agriculture from a micro and macro perspective;
- Compare technologies and analyse contexts and trends;
- Include relatively large groups of farmers and build on quantitative data as much as possible;
- Run for a sufficiently long period;
- Be firmly rooted in PTD (see box 2) and SCA (see box 3) in working groups of farmers, development workers and scientists;
- Create local capacities in LEISA, PTD, SCA, participatory assessment, the monitoring of sustainability and emphasise a process of long-term concerted learning and action.

Finding research partners

In 1995, three contrasting regions in Ghana, Peru and the Philippines were selected for ILEIA research. Three criteria were used in the selection of partners: their region was representative of specific, contrasting agroecological and socioeconomic conditions; they had long-term working relations, and they had experience with the participatory development of LEISA. Research sites were located in the following zones:

- the sub-humid zone of northern Ghana;
- the high Andean valleys of Central and Northern Peru;
- the humid lowlands of Central Luzon in the Philippines;

In 1997, a fourth region - the dry zone of India's Deccan Plateau - was added when AME in south India (ILEIA's sister programme) became involved. In India, however, research followed its own internal dynamics.

In northern Ghana farmers are mainly subsistence oriented and entirely dependent on locally available resources. In the Andean valleys and on the Deccan Plateau agriculture is partly subsistence and partly market oriented. Production is dominated by one cash crop that uses external inputs. In the lowlands of Luzon irrigated rice is grown for market with high amounts of external inputs.

Box 2 Participatory Technology Development

PTD is essentially a process of purposeful and creative interaction between rural people and outside facilitators. Through this interaction, the partners try to increase their understanding of the main features and dynamics of local farming systems and define problems and opportunities. They also learn how to experiment with a selection of 'best-bet' options for improvement. These options are based on ideas and experiences derived from indigenous knowledge and formal science. This process of technology development does not only attempt to find solutions to current problems. It also tries to develop sustainable agricultural practices that conserve and enhance natural resources for future generations. Most important of all PTD aims to strengthen the capacity of farmers and rural communities and enable them to analyse ongoing processes and develop relevant, feasible and useful innovations.

There are six main steps in PTD:

❶ *Getting started*: building relationships for cooperation; preliminary situation analysis; awareness mobilisation.
❷ *Looking for things to try*: identifying priorities; identifying 'best-bet' options from indigenous knowledge and scientific sources; screening options.
❸ *Designing experiments*: reviewing existing experimental practice; planning and designing experiments; designing, monitoring and evaluating protocols.
❹ *Trying things out*: implementing experiments, monitoring and evaluation.
❺ *Sharing the results*: communicating basic ideas, principles, results, and the PTD process; training in skills, proven technologies, use of experimental methods and farmer to farmer extension.
❻ *Keeping up the process*: creating favourable conditions for continuing experimentation and agricultural development (Veldhuizen et al 1997; Reijntjes et al 1992).

This process of technology development is closely linked with social change and encourages local innovation, self-confidence, and self respect through self-organised planning, implementation and the evaluation of systematic experiments. The process also fosters a cultural awareness as planning and assessment obliges participants to take account of their own situation and the responsibilities and needs of others in the community.

photo: Bert Lof

Box 4 FARMS

FARMS is a computerised farm management data system based on the FoxPro database management software programme. The package was developed by Aavishkar Software Consultancies, Madras, in close collaboration with AME, Bangalore, India and allows quick data entry and cross-checks. It has the potential to rapidly analyse the various aspects of farm management including the results of financial performance, agricultural production, labour requirements and nutrient, energy and groundwater balances. It also provides sustainability indicators at plot, crop, crop group, enterprise and farm level.

Box 3 Stakeholder Concerted Action

SCA aims to strengthening local participatory development processes by creating stakeholder working groups or platforms. In agricultural development such stakeholder groups involve farmers and other land users, development workers, researchers, policy makers, banks and agribusiness. Stakeholders have a clear interest in working together to achieve a common goal while at the same time ensuring that each others interests are taken into account. Concerted actions provide SCA with a focus. These actions imply analysis, developing an action plan, conflict resolution, monitoring and evaluation, information exchange and lobbying. In the ILEIA research programme PTD gave an initial focus to SCA.

LEISA Working Groups consisting of representatives of farmer organisations, NGOs, agricultural research institutes, universities and/or government extension services were set up in each region. These stakeholder groups were the main research partners in the ILEIA Collaborative Research Programme. Other independently operating organisations and consultants were also involved in the programme from time to time.

In each region, one or two research sites were identified. These played a central role in the research. The working groups in each country are described in the country sections later in this Newsletter. ILEIA played an important role in conceptual guidance, backstopping, funding, inter-region coordination and final management. AME played the same role in India with some conceptual and funding support from ILEIA.

Setting the research framework

The research framework was designed as an action-oriented R&D programme by ILEIA staff working directly with research partners and external advisors. It grew out of a common interest in ‘assessing the viability of their experiences with developing LEISA’ in a participatory way and the need to strengthen regional capacities in PTD.

In a general research workshop held in the Netherlands in June 1997, an overall research framework was finalised, adopted and accepted by delegates from the different working groups, country programme officers and the external advisors.

The ILEIA Collaborative Research Programme was designed to accommodate three interactive lines of activity:

➊ **Stakeholder Concerted Action**: the formation of working groups of farmers, development workers and researchers; setting the research agenda; defining sustainability; selecting key indicators and measuring methods; planning; negotiation; sharing and monitoring programme activities; process documentation; library and information management; programme evaluation; training and networking.

➋ **Participatory Technology Development**: farmer analysis of land-use problems, setting objectives and priorities for research, identifying experiment options, selection of farmer indicators, experimentation, monitoring, evaluating results, dissemination, farmer-to farmer visits and scaling-up.

➌ **Assessment Research**: scientific monitoring and validation of farmer practices; experiments and farm-household systems (FARMS); exploratory studies on history, trends and the sustainability of agriculture in the region; case studies on successful LEISA practices in the region and technical studies on the specific technical problems facing farmers at micro and macro level.

PTD was supported and complemented in the research process by scientific validation. Scientific studies proceeded from the problems and priorities identified by farmers in the research sites and were implemented as much as possible in a participatory way. The working groups provided platforms for SCA to direct, coordinate and evaluate the programme (see also Box 5).

Table 1: Criteria for LEISA

Ecological criteria	Economic criteria	Social criteria
· Balanced use of nutrients and organic matter · Efficient use of water resources · Diversity of genetic resources · Efficient use of energy sources · Minimal negative environmental effects · Minimal use of external inputs	· Sustained farmer livelihood systems · Competitiveness · Efficient use of production factors · Low relative value of external inputs	· Widespread and equitable adoption potential especially among small farmers · Reduced dependency on external institutions · Enhanced food security at the family and national level · Respect and build on indigenous knowledge, beliefs and value systems · Contribute to employment generation

Source: ILEIA Research Workshop, June 1997

Setting the reference base

A reference base was needed to assess the development of agriculture in the context of sustainability and to assess the comparative viability of LEISA. Such a reference base can be created by criteria for defining sustainable agriculture. This process has to be repeated regularly as insights into sustainable agriculture and the skills needed to measure indicators evolve. The partners in the ILEIA Research Programme proposed and formulated such criteria. These proposals were discussed and combined into a common set of criteria for LEISA during the general research workshop and were subsequently finalised at regional-level meetings (see Table 1). Indicators and norms for each criterion had to be developed further in the ecological and socioeconomic environment specific to each local level.

In assessing the viability of LEISA at the household level, emphasis was placed on farmers' objectives and the preconditions that determine how motivated farmers are when it comes to adopting LEISA production systems. Important at the societal level were national objectives and the premise that sustainable agriculture must be "economically viable, socioculturally just and ecologically sound" (Brundtland 1987).

Answering research questions

The viability of LEISA systems depends on the comparative performance of the technologies involved and the technology development process. Conclusions should be derived from the results of assessment research, PTD and SCA. Figure 1 shows the strategic footsteps taken in order to validate LEISA. At the end of the research programme farmers, scientist and the stakeholders should try to reach a conclusion together.

Agricultural conditions change constantly and the viability of LEISA technologies change with them. Conclusions about the viability of specific LEISA technologies are therefore only valid for a specific time and for specific local conditions. To get answers to research questions that cover longer periods, a system of sustainability monitoring is required. Such a monitoring system should build on farmer experimentation and scientific monitoring and evaluation.

Expected outputs

- Initial analysis of sustainability of current agricultural practices.
- First analysis of viability of LEISA practices in the research areas.
- Collection of scientific information on specific problem issues.
- Strengthening capacity of all stakeholders to implement SCA.
- Strengthen capacity of stakeholder to carry out PTD experimentation.
- Further development of methodologies.

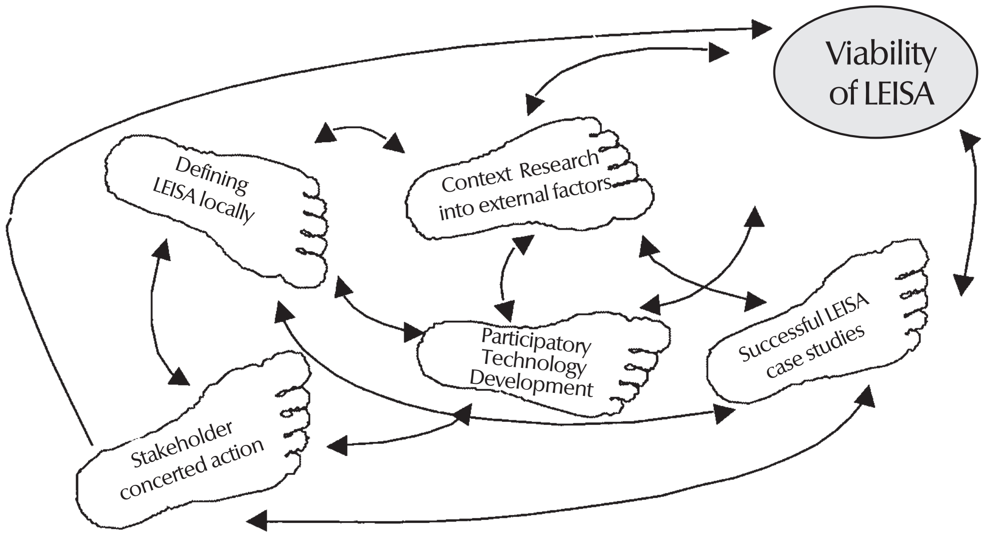

Figure 1. Strategic footsteps: iterative steps in the development – research process

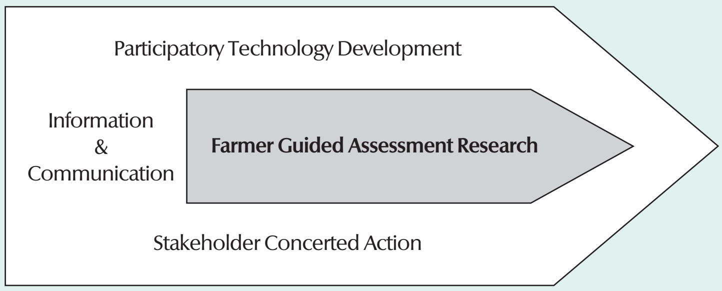
Box 5 **Big and small boats of LEISA development**

Research programme objectives had to be in line with the development agenda and processes of NGOs and other development organisations working with farmers on sustainable land use and poverty alle viation. In the research framework workshop this broader development process was conceptualised as the 'Big Boat' within which LEISA development would take place. In this process farmers' innovate and their land-use practices have an own dynamic with or without external support from interested stakeholders. ILEIA contributed to these processes by providing information, facilitating communication (library support, documentation, Newsletter and other publications) and by supporting PTD and SCA. Development objectives were therefore high on ILEIA's research agenda.

PROCESSES FOR THE DEVELOPMENT OF LEISA



In ILEIA's research programme, the Small Boat of assessment research - carried within the Big Boat' of the development process - had a pilot role. It drew inspiration from and guided and sharpened PTD and SCA activities. Assessment research involved context and case studies, farmer experiments and the scientific monitoring and analysis of farm production systems (FARMS). It focused on specific problems and practices identified and prioritised by farmers at field and macro level. PTD activities associated with farmer experimentation formed an integral part of Small Boat research activities. This was important because ILEIA considers farmer assessment essential to the outcome of the ILEIA research programme. Small Boat research gave direction to the overall PTD process. The PTD and SCA process within the larger development process provided the social mechanisms through which problems and priorities were tackled. Thus, PTD activities occurred both inside and outside the Small Boat.

Assessment was part of ILEIA's research mandate and therefore ILEIA focussed on the Small Boat. Collecting verifiable data was imperative because policy makers had to be convinced it was necessary to support the development of LEISA. Conventional research agendas also need to be better orientated to needs and priorities of farmers.

Although PTD and SCA were not the direct subjects of assessment they were supposed to generate interesting methodological results for the overall research programme. Moreover, they were important in obtaining valid research results from participatory, jointly-implemented research. Therefore, there was close interaction between the activities of the two 'boats'. Both were part and parcel of ILEIA's overall research effort and contributed to the development processes of the 'Big Boat' pursued by ILEIA's partners in the research

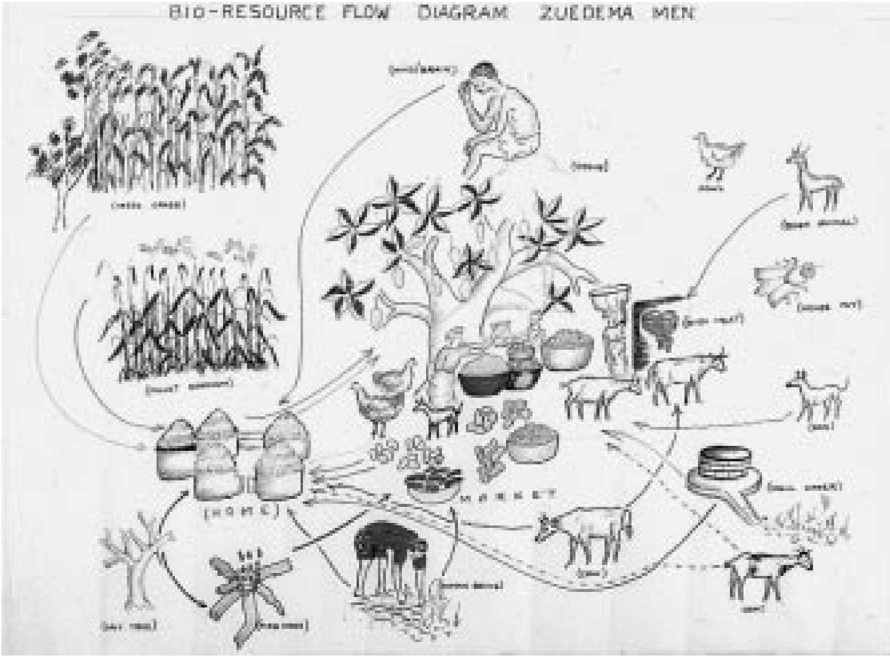


illustration: Ghana Research Archive

Implementation

The working groups were responsible for the day-to-day planning, coordination and monitoring of the programme. Biannual workshops with staff from ILEIA Netherlands were held to formulate general plans. Contracts with terms of reference and budgets were drawn up for each activity. ILEIA (NL) and country programme officers were responsible for budgets, administration, programme monitoring, reporting to the funding agency, quality control, trouble shooting and general support. ILEIA (NL) was closely involved in programme conceptualisation but not in direct implementation. Visits two or three times a year and long distance communication enabled ILEIA (NL) to meet general monitoring, management and support obligations.

The conditions, focus and dynamics of research in Ghana, the Philippines, India and Peru were very different and this was reflected in the process and the results obtained in each country. Serious conflicts within the initial ILEIA research team (1996) caused delays. The research programme outlined here started in early 1997 and it was summer before PTD experiments and studies began. The time available for experimentation was therefore short: two seasons in Ghana and Peru and three in the Philippines. In India the situation was different because AME had initiated the PTD process in 1994.

Given the limited amount of time available assessment research focused on the first three specific research questions. A start had been made with the FARMS programme but due to software problems this activity had to be stopped. Most of the planned context, technical and case studies were implemented before the end of 1998. Considerable attention was given to capacity building in SCA and PTD at the beginning of the research process. In this way conditions were created for a research effort that could be sustained beyond the planned withdrawal of ILEIA in 1999. Bad weather brought about by El Niño strongly influenced the results of PTD experiments during two seasons in the Philippines and one in Peru.

Newsletter reports results

This issue of the ILEIA Newsletter presents the research programmes in the four countries. In each country section articles are included on the overall country programme, sustainability problems, the main trends in agricultural development in the region, the case and technical studies carried out, the SCA and PTD process and the PTD results. An introductory article by Kauffman outlines the results of a study in Peru, Philippines and Ghana to compare farmers' and scientists' land use categories. Each country section carries articles on the overall country programme, sustainability problems, main trends in regional agricultural development, case and technical studies, SCA and the PTD process and its results. A concluding article written by the ILEIA team, attempts to synthesis the main results of the programme.

If you would like to know more about the ILEIA research programme and the wide diversity of information and insights gained you might like to consult our Web site for reports, country documents, and other source material. A series of local publications (see country sections for references) will become available during the year 2000.

Low-cost solutions are being used to increase yield and income in groundnut cultivation.

Groundnuts: from subsistence runner to bunchy cash crop

AME, operational in Southern India, is a partner of the ILEIA research programme. Its research focuses on farming systems where groundnuts constitute about 70% of the area farmed. Twenty to thirty years ago bunch type groundnuts were introduced in the area as a cash crop. Before that runner type groundnuts were grown in rotation with finger millet, in mixed crop systems with cowpea, pigeon pea and castor. Marginal farmers on poor quality soils still use this system but the runner type has been replaced with the bunch type.

Declining yields turn profits into losses Farmers claim that in the last ten years yields have declined and fungal diseases such as leaf-spot (early and late), root collar rot and stem rot are on the increase. Pests like red-hairy caterpillar, white grub, leaf-miner and tobacco army worm are creating increasing problems. Thus whilst yields are declining, the costs of production show the increasing costs of controlling these pests and diseases. Some farmers are forced to grow groundnuts, as money lenders are only willing to provide loans guaranteed by groundnuts. Consequently, farmers have to sell their produce through the same money lender. The compound interest can be as high as 120% a year. Crop failures are certain to occur once in three years, either due to inadequate or excessive rain, or unfavourable rainfall distribution.

Many groundnut farmers are heavily in debt. The culprits are soil degradation and mono-culture. We hypothesise that, on the basis of three cycles of PTD experiments, the problems are caused by the following factors. First, soils up-hill have been eroded and soil depth has declined, hence water holding capacity has come down and dry-spells lead to more severe drought stress.

Second, decline in organic matter content of the soil leads to relative shortage of micro-nutrients and to deterioration of soil physical characteristics: infiltration rate, aeration and water holding capacity of the soil decline. Third, relative micro-nutrient deficiencies (of Mg, Zn) caused by the removal of the residual foliage for cattle feeding, lead to susceptibility to fungal diseases. Four, inter-crops were useful in controlling pests and mono-cropping of groundnut increased pest incidence. Finally, the increase in the area under groundnuts and the decline in the practice of rotating groundnuts with cereals has led to higher levels of pest and disease incidence.

Our strategy was to restore soil fertility and physical characteristics at low cost. Together with 300 farmers and using the PTD approach we experimented to increase the yield. We found cheaper sources of nitrogen: rhizobium bacteria; phosphorus: mussooriephos plus phospho-bacteria. We applied gypsum at flowering stage. We found that the yields increased compared with the control plots in which fertilisers (DAP or other compound fertilisers) were applied but that yields were similar or lower when compared with plots in which substantial quantities of farmyard manure had been applied. This focused our attention on farmyard manure. We found that when some 5 to 7.5 metric tons were applied per acre the monetary returns were twice as high as the costs involved. Our main problem was to generate the required quantities of farmyard manure as the average farmer has two heads of cattle generating no more than 4 metric tons per year. This is insufficient for one acre. The yield increase of groundnuts grown with farmyard manure is such that the area under groundnuts can be reduced without income being affected. The area freed can be used for green leaf manure production. One of our partners has started green manure production plots to evaluate the feasibility of this approach.

Pests and diseases are controlled in eco-friendly ways. Leaf-spot is controlled by application of magnesium fertiliser, leaf extract of Lantana and Agave or commercial fungicide. The latter are applied on an early warning system that measures leaf wetness. Preliminary results suggest that applications of magnesium might be the most cost-effective solution. Together with the Indian Council of Agricultural Research (ICAR), ICRISAT and the Australian Council for International Agricultural Research (ACIAR) we are now developing ways to control white grub jassids, white flies and leaf miner with a systemic insecticide. More eco-friendly methods will also be tried. Congregation pheromone isolation for white grub adults to attract them to one spot and kill them before they can lay eggs is also being tried. Neem-cake applied to the soil is being tried to control white grub, jassids and possibly leaf-miner. Inter-cropping with trap crops like soybean and cowpea to manage leaf-miner population, sunflower for tobacco army worm, castor for red hairy caterpillar will be tested further. Village-based experiments with the control of red hairy caterpillar will be undertaken next year in endemic areas.

LETSystems to strengthen local economies

Camilo Ramada

The money system as we know it, is an accumulation system where wealth, resources and energy tend to flow towards the center of economic power. One of the main mechanisms behind this tendency is interest. Because of interest, money and capital goods are only used for those activities that hold the greatest promise of economic profit to those who own them. This makes the economic system a competitive one rather than one of co-operation. Its 'growth compulsion' forces everybody to exploit labour and plunder nature.

Another typical feature of our economic system is that the creation of money is in the hands of a few private institutions - banks. These banks are only controlled by governments to a limited extent. This means money can be manipulated and separates the creation and flow of money from real production. Financial trade (making money with money) is nowadays ten times the size of real trade in commodities. These three elements - interest, money in the hands of a few and money separated from production - are the main characteristics of an accumulative money system.

LETSystems

Local Exchange and Trading Systems (LETSystems) can prevent the benefits of local activities leaking away to external economic players. In a LETS-economy, people trade with each other on the basis of a self-created means of exchange. Somewhere, whether in a computer or on the back of a piece of paper, accounts are kept of the economic activities of LETS-members. Every LETS-member starts with an account on zero. When someone makes a transaction, he or she goes into debit and the receiver gets a credit. This means that money is no longer scarce: when you need it, you create it. It also means that money is only created when a transaction is completed. In other words the moment of valuation (production) and money-creation are on the same level. Because all the credits in a system are exactly as large as all the debits, the system always comes to zero. This is an economy of reciprocity.

Computerized LETSystems

LETS is relatively new in most European countries but the system has been in use elsewhere in the world for over ten years. Other similar systems for exchange of goods and services at local level are much older. The first computerized LETSsystem started in 1983 in the Comox Valley near Vancouver in Canada. The local economy had been based on timber, tourism and a military base but had gone into freefall when logging was restricted, the tourist industry declined because of the strength of the Canadian dollar and the military base closed. Many people lost their jobs and had their houses repossessed. Several local service sector businesses went bankrupt. A local resident decided to try to stimulate the local exchange of goods and services by enabling people to trade with each other without having to use national currency. He organized a central computerized bookkeeping system to keep a record of trade as in a LETSystem.

The first European LETSystem was set up in Great Britain in 1988 and the concept was quickly taken up elsewhere. Britain now has about three hundred systems in operation, partly due to the existence of the very active umbrella organisation LETSLINK UK. From Britain LETS spread to The Netherlands, and from there to Belgium, Germany, France and Denmark. In The Netherlands the LETS-movement now consists of about 85 systems with an average of about hundred members each. The biggest is the Noppes-system in Amsterdam with a thousand members. By trading in the LETSystem, the members combat their economic (and social) exclusion and frustration.

Local money systems

Another interesting example of LETS is the Red Global del Trueque in Argentina. What started as a simple LETSystem in the neighbourhood of Bernal, a suburb of Buenos Aires, acquired a totally unexpected dimension. The existing structure of neigbourhood and community based organisations proved fertile ground for the economic self-help a system such as LETS can provide. After receiving some media coverage, the idea spread so fast that it proved very difficult to keep accounts. When different communities wanted to trade with each other a new solution was found: the issuing of alternative money or 'Creditos'. These are notes equivalent to a dollar, but they have their own characteristics. They are distributed in an egalitarian manner. Each new member receives fifty Creditos, which he or she can spend freely. This created a very active economy where people proved able to provide a large array of goods and services for themselves and each other. The Trueque idea has now spread all over Argentina (and has grown to 100,000 members within three years). It can now be found in Uruguay, Brazil, Bolivia and other countries.

There are also some experiments in Africa, Senegal and Ivory Coast for example, and Asia. In Africa traditional saving systems have always been organized in ways that fortify the local community. Nowadays, various trading systems are being introduced, according to the LETSystem or variants of local money systems like the Trueque system.

Socially sound and environmentally friendly

The economic activities a LETSystem generates are labour rather than resource intensive. In many cases LETS-activities involves maintenance and repair work or work that makes it possible to reuse things. Frequently ecologically sustainable methods of agriculture are involved. LETSystems increase trade at the local level and therefore strengthen the local economy and know-how. This tends to reduce the need for the (inter)-national transport of goods. Hence, LETSystems alleviate poverty and reduce environmental damage.

Should such systems become successful on a large-scale, then we could speak of a global movement towards strengthening local economies. LETSystems may result in stable, inclusive and sustainable local economies, giving ample space for human values.

Reciprocity for life security

When we say that there are few ways Southern countries can counteract the negative effects of the market economy we often overlook the alternatives offered by economies of reciprocity. Today, these potentials are being rediscovered. From the sixteenth century farmers throughout the Andean region have actively participated in the commercialisation process but they have not forgotten the cultural legacy or principles of 'El Don'.

Freddy Delgado, Juan San Martin and Domingo Torrico

El Don refers to the moral reciprocity between people, nature and the spiritual world. For the farming communities of Bolivia and other Andean countries, these forms of exchange are based on traditional survival strategies. Traditional Andean life moves between three spheres: the material, the social and the spiritual. Economic logic is also reflected in these spheres: *commercial transactions* for the material life, the *trueque* for social life, and the *cambiacuy* for spiritual life.

The 'Seventh Friday Fair' and the 'inter-ecological journeys' discussed in this article are clear examples of Andean reciprocity. Traditionally, they provide Andean farmers with access to products from different ecological zones that secures and broadens their subsistence base. The case studies presented are based on research carried out over a nine years period by a group of researchers attached to the Agroecology programme of the Universidad Estatal de San Simón, Cochabamba, Bolivia.

The Seventh Friday Fair

Sipe-Sipe is a small town of approximately 2000 inhabitants and is the capital of the second municipal section of Quillacollo province. It lies 28 kilometers south-east of Cochabamba at an altitude of 2500 meters. It is a typical Latin American town with a Catholic church and roofed market clustered around a central 'plaza'. At half-past-five in the morning on the seventh Friday after Easter, several hundred farmers from over 35 villages travel some 15 km to take part in a vivid fair.

The fair is very important for farmers in the region because it contributes to food security through non-monetary and monetary exchange, re-creates and strengthens social relationships between relatives, friends and 'compadres' from different communities in the valleys and highlands, and is an occasion when religious feelings can be expressed. The timing of the fair is important because it coincides with the harvesting of the last tubers in the highlands and maize in the valleys. It is the festival of seeds and takes place at the same time as Taurus Pleiades and the sun come into alignment. Farmers from the highlands arrive at Sipe-Sipe on Thursday or very early on Friday morning with a variety of recently harvested agricultural products. Throughout the day and into the night exchanges take place guided by the concepts of *cambiacuy*, *trueque* and *purchase-sale* each complementing the other in objective, time and importance.

The *cambiacuy* is the most important form of exchange and begins early in the morning. It has a strong spiritual and emotional dimension strengthening relationships between individuals and signaling a new friendship. Exchange is based on affinity rather than interest in gain and this eliminates the mere quantitative aspect of exchange. Relationships are recreated through sharing family and community news which strengthens feelings of solidarity. The produce is handed over as a gift to satisfy and please the receiving family and in the confidence that a gift will be given in return.

Farmers come from the highlands and valleys and offer the products of their different agricultural ecosystems. Farmers from the highlands bring potatoes and other local tubers (*oca* and *papalisa*) while farmers from the valleys bring varieties of local maize. Local biodiversity is clearly reflected in these transactions.

The *trueque* (barter) is another form of exchange. It is less spiritual and emotional than *cambiacuy*. However, the *trueque* does not lose the sense of the spiritual altogether. The *trueque* can take place between farmers or between 'sales people' and the individuals concerned do not necessarily know each other. For instance, a clay plate produced by a farmer may be exchanged for the *oca* content of two similar plates, or for the full *oca* content of a plate of maize. Farmers can obtain ceramics, weavings, baskets and other agricultural products through *trueque* which they could not have accessed through *cambiacuy*.

Purchase-sale is the third form of exchange used by farmers. In it they adopt 'market logic' although there are still indigenous Andean characteristics involved such as 'liking each other' and 'bargaining'.

Money from purchase-sale enables farmers to complement their diets with food items such as sugar, rice, cooking oil, radio batteries and candles difficult to get through exchange. Purchase-sale also makes it possible for them to pay for transport and *chicha* (local beer made from maize).

Flexible exchange

In both *cambiacuy* and *trueque* there is wide flexibility in the exchange parameter. For instance, in the exchange of maize for tubers, bags woven from sheep or llama wool (or even synthetic fibers) are used. These have a mark to indicate a level or amount. This mark is not based on either the metric system or Imperial system. In Quechua the mark is called *chimpu*. This mark is the parameter that allows bargaining to take place about the quantities of tubers or maize to be exchanged. Here factors such as individual needs, the productivity of the harvest and 'liking each other' play a role.

Before the exchange takes places both parties come to an agreement on the content needed to fill the chimpu. A bag might only contain potatoes which are then exchanged for a bag of good quality maize. Another bag might contain a mixture of potatoes, *oca* and *papalisa* to be exchanged for a similar bag of yellow or white maize.

About half the *oca* and *papalisa* harvest of highland farmers is exchanged in Sipe-Sipe. The rest is either consumed at home or sold at other markets and festivities. According to the farmers, the products received in Sipe-Sipe through *cambiacuy*, *trueque* and purchase-sale have a special spiritual or vital energy.

Thanksgiving

The Seventh Friday Fair provides an opportunity for meeting with distant relatives, friends and compadres, for making new friendships, and exchanging the latest news. At the end of the afternoon, when the exchange is over, the farmers begin a celebration to give thanks to Nature, to the 'Little God' (Diosito) of food, and to the Urkupiña Virgin by pouring a small amount of *chicha* on the soil. In song and dance they express their appreciation to *Pachamama* or Mother Earth. The celebration takes place in the only church in the village. Masses are held around noon followed by a procession around the plaza.

It is not known how the 'Seventh Friday Fair' originated. According to farmers themselves and older people of the villages, it may date back to the time before the Incas.

The fair in Sipe-Sipe provides farmers with an opportunity to recreate their 'economic' logic as part of a worldview in which spiritual, social and material aspects of life interact and where the security sought goes beyond ensuring physical and economic access to food.

Inter-ecological journeys

The farmers form Japo, a village on the highlands of Tapacarí, practice reciprocity with several communities in the valleys of Morochata in neighbouring Ayopaya province. Exchange in the form of *cambiacuy* or *trueque* can take place through inter-ecological journeys. These journeys are marked and accompanied by rituals and festivities during the months of July and August when the harvest is over.

The women farmers from the highlands produce a cheese called 'Valle Tika' intended for *cambiacuy* or *trueque*. The women prepare this dried cheese from sheep milk during the rainy season (January and February) and it is stored until July and August.

Fifteen years ago this journey was made on foot with a herd of llamas (beasts of burden used in the Andes) and took three to four days. Today, the women travel by truck and the journey to Japo takes about five hours. Once they arrive at a valley community, the large group separates into smaller groups. Visits are then made to different farming villages where their relatives, compadres or friends live. Each small family group will lodge for 4 to 10 days at the home of friends until their cheese supplies are gone. In some cases they will stay longer if they have arranged to carry out construction work for the valley farmers or to help with farm work. Sometimes there is a kind of 'agreement' between a puna community and valley community. For instance, it has been noticed that farmers bring clay and tools to make hand-crafted pots and plates which are exchanged for maize with the valley community.

Sharing the benefits

From the moment they arrive in the community, there is mutual flattery and friendly treatment and presents are exchanged. The highland farmers take *kañahua* (Andean grain similar to quinua), or *chuño* (dehydrated potato) to give to the valley farmers because these are highly valued products and not available at local fairs and markets. Valley farmers offer the visitors a large plate of cooked maize, called *mote* accompanied by egg and some spicy salad which is enough to support them for the day. This means they do not need to prepare food and so they can spend their time visiting homes to exchange cheese for maize. Normally, the highlanders bring with them between 40 and 150 cheeses, 2 to 5 *arrobas* (25 pounds) of *chuño*, sheep skins, and sometimes *charque* (dried meat) for sale or barter. In years when the maize harvest is good, the valley farmers feel committed to give more; in bad years they are able to give less. Two medium sized 'Valle Tika' cheeses or three small ones are exchanged for one *chimpu*, the exact amount depends on how good the seasons yield has been. Sometimes highland farmers will take *chuño* to sell or exchange for maize or exchange sheep skins for hens.

Farmers return to the highlands by truck and generally they carry a larger load than when they arrived. The maize they have obtained is distributed in small quantities to those relatives who for some reason were unable to travel. This helps them to secure a balanced diet for the coming year and ensures material, social and cultural reproduction.

Conclusion

According to macro-economic indicators, Tapacarí, Ayopaya and Quillacollo are poor provinces. The use of money is limited and complementary. However, as we have seen, reciprocity is the basic economic principle among Andean farmers. The market economy only complements the indigenous economic principles to improve quality of life.

Marketing produce through self help groups

R. Prakash and S. Motilal Nehru

Kerala, the southern most state of India has a wide variety of plantation and food crops. In order to develop the horticultural sector, the Kerala Horticulture Development Programme (KHDP) was set up in 1993. It is a co-operation between the European Union and the Government of Kerala. The programme aims at enhancing and sustaining the income of participating farmers through organic farming practices and appropriate marketing of vegetables, banana, pineapple and mango.

The essence of the programme is building up self help groups. Local communities will be strengthened through the self help groups, which will facilitate the development of group organisational and management skills. The programme adopts an integrated approach involving activities encompassing all phases of horticultural production, produce handling and marketing and it operates in selected geographic locations in the State of Kerala.

Self help groups

All programme activities are converged into voluntary neighbourhood self help groups of about 20 participating farmers. Each self help group selects Master Farmers who will be trained and will take up a lead role and will act as facilitators. This system aims at providing sustainability to the development process and ensures greater farmer participation. The farmers are selected and inducted to the programme-based self help group system on clearly set criteria.

The programmes have introduced a unique concept of promoting master farmers to take up functional leadership in production, marketing and credit related activities in each self help group. Farmers are provided with training in crop production technology, produce handling and enterprise management. Training programmes are organised based on need identification and using relevant training modules. The programmes have introduced a new methodology of appropriate technology through Participatory Technology Development. Farmer experimenters conduct on-farm experiments for developing better technologies and for adapting existing technologies which will combine latest scientific knowledge in the field with the practical wisdom of the farming community.

The programme promotes pest and disease surveillance in the project areas to provide timely warning and forecasting of possible out breaks of pest and diseases in the fields with the objective of reducing the indiscriminate and over-use of pesticides by farmers.

Credit linked production system

KHDP has introduced a unique credit system for lease land farmers who formerly had no access to credit. The credit support to the farmers is designed to provide money in time and in adequate amounts in a fast, easy and cost effective way. The credit delivery arrangement has been formalised through a memorandum of understanding with four selected public sector bans with details of specific responsibilities. The credit delivery process has been streamlined, with the master farmer in each self help group. acting as a key person and with close co-operation between extension staff and bank officers. Credit planning is at the self help group level. The scale of finance is based on realistic estimates on cost of production. A new credit culture is being evolved through the self help group structure where repayment rates are above 90%. A credit linked crop insurance scheme has been introduced by KHDP for all banana growing farmers. Their crops are automatically insured against damage or losses caused by pest and diseases. This scheme is farmer friendly.

Focus on marketing

The major problem facing farmers is the marketing of their produce. The programme is extending not only horticultural crop production but also the processing and marketing of their products through a well-planned and better-managed horticulture enterprise. The shift is from ‘what it is possible to produce: to producing what is marketable’. This change demands better understanding of the markets and the changing consumer needs. Through group marketing, farmers are able to fetch fair and reasonable price.

Procedure

Marketing infrastructures at site level have been set up. This includes establishing field centres for bulking the produce from 10 to 15 self help groups. The concept of field centres is to create farmers’ markets where commission agents and wholesalers come together to buy produce. Farmers receive the latest market information from the programme, which improves their marketing power. Field centres are developed through a bottom-up approach. The group marketing efforts of self help groups will be combined through a field centre when the volume of bulking justifies the establishing of such a centre. The field centre operations are managed by a committee of master farmers from the participating self-help groups.

The self help groups proved to be very effective and boosted the confidence of the farmers who are able to fetch a fair price for their produce.

Explore local potential to begin marketing

G.K. Upawansa

A country such as Sri Lanka, with several agroclimatic or ecological zones, is able to produce a rich assortment of agricultural products. It has a mountainous centre and seasonal monsoons that govern rainfall rhythm and soil characteristics. Each season starts with a little rain at the beginning in the form of the rainfall pattern of inter monsoonal rain and reaches a peak before it fades off into a small drought. The crops grown and cropping patterns are determined by the rainfall pattern and sometimes the windfall pattern of an ecological zone. In the mountainous areas exotic crops such as pears, apples, potatoes, beet, carrot, and cabbages, are grown. At lower elevations all tropical crops, and spices are cultivated.

Capitalising on demand

Such conditions allow a wide variety of crops to be grown at different times of the year. At times markets are flooded with particular commodities and prices are below the cost of production. There are no cold storage facilities or processing to even out gluts and shortages. Poor packaging causes heavy post harvest loss, transport costs remain constant and, of course, wholesalers keep their normal profit margin even when prices for the farmer are low. Marketing and transport has evolved to complement existing production and consumption patterns.

Studies carried out in Sri Lanka show that over 90% of vegetables and grains contain poisonous agro-chemical residues and are unsuitable for consumption. In fact, some traders pay extra to get products sprayed to improve their keeping quality. Many consumers, particularly in big cities, are concerned about this and there is a demand for organic and ecological products.

Capitalising on this demand, unscrupulous traders offer insect-damaged commodities as organic or ecological products as there is no certifying system. But even if a certifying system is in place, abuses cannot be ruled out. Further certifying is costly and difficult because of very small farm size and certified products would become too expensive for ordinary consumers. However, there are also organisations promoting organic and ecological farming and producing and selling for almost the same price as conventionally produced commodities. Eco conservation (ECO) is one such organisation.

Preconditions not yet fulfilled

There is a demand for ecological products in cities. However, producers in rural areas cannot get a reasonable price for ecologically grown commodities. This is mainly because of transport costs and the scattered nature of production. In order to run an eco-shop continuously in a city, the following three conditions have to be fulfilled.There must be a regular supply irrespective of climatic rhythm; there must be a variety of products and the quantity must be sufficient to meet demand.

Presently none of these conditions can be realised. But ecological farming is indispensable for several reasons, namely, to rehabilitate devastated farm land, reduce the cost of production, improve ecosystem and environment, sustain sufficiently high yields and to produce poison-free food items. Unless marketing is assured it is difficult to promote ecological farming. Hence organisations individually and collectively attempt to find solutions and ways of marketing.

Current experiences

Palm foundation, a Dutch NGO, implements an organic farming programme in rural villages. It collects produce once a week and brings them to the eco-shop in Nuwara-eliya, the hill city. If there is a surplus, they send this to Colombo. Transport is provided by Palm. Prices paid to producers are higher than for conventionally produced items. Gami Seva Sevana, another NGO with farmers in neighbouring villages, produces vegetables organically. It collects produce once a week and prepares parcels containing a mixture of seasonal vegetables. These parcels are deliver to their regular customers and some are sold in their shop. Transport is provided by Gami Seva Sevana but costs are recovered.

Local demand explored

ECO observed that even in vegetable growing area, the conventional producers avoid agro-chemicals on products for home consumption. Some tended to buy vegetables from eco-farmers. Therefore, ECO began a programme of educating consumers to help them identify eco products using their senses and to let them see for themselves that the colour, smell, and touch of fresh and cooked Eco products are different from conventionally produced vegetables and fruits. Eco producers also started selling their products at their own farms.

What eco-farmers in Kurunagala cannot dispose of at the farm gate they send once a week to the village fair. They nominate one or more willing farmers to collect excess produce and pay them for transporting it. At the village fair, fruits and vegetables are sold at the same price as other products and they sell quickly. Demand has increased over time and a reliable clientele has gradually been built up.

In all cases what is produced is sold and supply often falls short of demand. This is particularly important during gluts. As there is direct contact between producers and consumers no profit is taken by middle men and transporters. Producers get a reasonably high price and consumer get better quality.

In this way, after organic agriculture has been developed in different ecological zones on the basis of an assessment of local demand, it will become easier to fulfil the preconditions for marketing at national level. Lanka Organic Agriculture Movement (LOAM) are working towards introducing a certifying system to support this process.

Marketing organic vegetables
a balancing act

photo: Coen Reijntjes

Mans Lanting

and Dilip Chinnakonda

AME's foray into organic methods of vegetable cultivation was triggered off by discussions on recycling organic waste in the city of Bangalore in south India. We came in contact with ACTS Ministries, an NGO composting biodegradable refuse with farm land at their disposal. Consumers' Collective (CoCo), a micro level collective marketing organic produce, had already approached AME to see if it was possible to get a supply of organic vegetables for its member-consumers. The situation seemed almost 'ideal'. There were partners interested in and with the capacity to produce and purchase organic vegetables.

Statistics for farming in these areas show that 50% of all pesticides used went into 5% of the area under cotton cultivation and another 30% of pesticide usage was accounted for by vegetables grown on 10% of the area. Hence, it was an attractive proposition for AME to explore the possibility of organic vegetable cultivation and marketing.

AME's objectives
AME objectives were to systematically develop technical knowledge on organic vegetable cultivation through field experimentation, to demonstrate a 'model' of recycling organic waste from a particular zone in the city, and to develop viable producer and consumer linkages in one part of the city. Our effort started from the demand side. A consumer survey of members of CoCo conducted in 1996 provided the basis for a production plan. It indicated that consumers required small quantities of about 12 vegetables throughout the year. These were needed on a regular and rotational basis, which meant staggered production on very small plots.

ACTS was expected to assume the following roles: production, marketing and extension. Production was to take place on their farm. Marketing would be done with their own transport, and involved the same families who provided organic waste. Extension of the project to farmers in the neighbouring villages would be the task of their staff. AME had agreed to provide technical guidance.

Unexpected turns!
Management problems at ACTS Farm, complicated by our inexperience in projecting yields and envisaging crop losses, resulted in irregular supplies of vegetables and financial losses to ACTS. Eventually, ACTS backed out as losses mounted. Initially CoCo had agreed to take the produce but due to irregular production and lack of transport, a number of other problems emerged. AME had to provide transport; CoCo could not absorb the imbalanced (extra) supplies and AME had to market the excess produce and foot the bill for the leftovers. Finally, extension also caused problems as staff from ACTS were unavailable because they had other committments. This meant that AME had to guide the farmers.

While the pilot experiments were underway in ACTS Farm, the process of dialogue to motivate farmers from the nearby villages began. Though sceptical initially, the notion of small plots and staggered planting of a variety of vegetables for a continuous and steady yields of vegetables gained acceptance after a series of meetings and exposure visits. Group size increased to ten and supplies grew.

AME encouraged a link between a school and CoCo for bulk sales. But the vacation periods of the school tended to coincide with peak production periods and upset the supply-demand equilibrium. The inclusion of ICRA, another NGO marketing organic products, as a bulk purchaser and more individual customers created a better demand.

Supplies

Difficulties were also experienced in ensuring farmers kept up a regular supply of quality vegetables. Imbalances in production occurred due to the tendency of farmers to alter production schedules by replacing long duration crops with quick return short duration crops. Production was also affected by such factors as adverse weather conditions. Today, each plot is cultivated three times a year and each harvest yields an average of 1.75 kg/m^2 (of any vegetable). About 5.25 kg/m^2 of vegetables can be harvested annually. It has been estimated that one family in Bangalore requires approximately 5 kg of assorted vegetables every week. Annual demand per family is 260 kg. This means that 50 m^2 is needed to meet one families annual vegetable requirements.

The average price for any vegetable is Rs.10 per kg. This allows a margin of 10% for the retailer, of which about 5% is absorbed by weighing and other losses. The actual profit margin is therefore about 5% or Rs.0.50 per kg. Rentals and other overheads for a store could easily be about Rs.1500 per month. So, a retailer has to sell at least 3000 kg of vegetables per month (660 kg/week) to 130 customers to break even on fixed cost. Transport has not been taken into account. The weekly harvesting should be 660 kg giving 1.75 kg/m^2 and an area of approximately 350 m^2 under production. In real terms though, a retailer should be able to service at least 260 customers with 1200 kg of vegetables every week, to run an outlet profitably. If transport has to be optimised and then a minimum of 2500 kg is necessary for the smallest lorry load. For the sake of freshness, 5000 kg have to be supplied twice a week. So weekly, a 1000 customers will be required for the shop to be economically viable.

Planning production according to season is at the heart of maintaining a year round supply of vegetables this includes crop rotation schedules, irrigation requirement and labour availability. Practically, this entails the creation and management of blocks containing small plots, to accommodate both staggered planting and crop rotation. Initially, each farmer offered 0.25 acres, which was divided into four blocks with twelve plots in each. The current cultivation practices emphasise low external inputs, soil fertility management through the application of compost/FYM, efficient methods of irrigation, trap cropping, companion planting, crop diversity and appropriate land preparation i.e. raised beds and Trichoderma mixed with the soil, for effective pest and disease management.

photo: Coen Reijntjes

Harvesting of organic vegetables

See-sawing supply and demand can be explained by drops in vegetable supplies due to uncertainties of weather, pests, and seasonality, or because only a few farmers cultivate vegetables. Consumer interest may be affected and decline leaving very few clients, a problem if supplies then increase. When the area is small, the slightest change can trigger off problems of over- or under-production. The balancing act is a delicate one since vegetables are perishable. AME spent Rs.1,00,000/- (US$ 2500) for a year to support marketing. This was mainly absorbed by subsidising unsold produce.

Marketing issues

By May 1998, the production level had reached 1200 kg per week, requiring around 260 clients. It was at this juncture that marketing operations received another jolt with the closure of CoCo. We realised then that organisations such as CoCo and ICRA had virtually no risk bearing capacity. Besides, modest numbers of consumers put a limit to the quantity of vegetables these alternative outlets could absorb. This was the factor that had constrained CoCo from being able to generate enough money for its staff. So, even though AME had supported the shop manager's salary for a year, CoCo could not enhance its turnover during this period and it became unviable. ICRA, meanwhile, continues to attract consumers and AME is handling the major aspects of the marketing.

Consumers have expectations; they insist on high quality produce and variety. If the quality dips even marginally, they are unwilling to pay market prices. The 'bag system' was not very appealing, since clients want the content to change every week. In effect, our initial notion that high income earners would be inclined to buy '-healthy' vegetables at marked up prices went bust!

The quality demands of the consumers compelled AME to apply fairly stringent monitoring of quality and variety at farmer level. Any produce not meeting the required minimum standards were being sent back. We noticed that small-scale farmers backed out because they had difficulty in maintaining quality standards.The decline in the number of farmers from 10 to six hampered formation of a self help group, a credit management organisation of the farmers which is necessary if collective marketing is to becomes a reality.

From our experiences we have learned that small farmers cannot easily absorb novelties and uncertainties. We have to turn to medium farmers who have adequate financial resources, water and enough household labour to sustain intensive organic vegetable cultivation. The project now faces a dilemma! Those farmers still involved are keen to expand the acreage under vegetable cultivation since this makes management easier. But AME is hesitant, because creating an expanded market has its own dynamics - it means a phenomenal effort to identify and motivate about 400 additional clients. We hope to rope in commercial retailers with risk-taking capacity to take over marketing.

The project is poised for a 'quantum leap'. It implies that AME is likely to have less control over quality aspects and variety. But market realities mean some modifications are necessary. We now realise that it is necessary to go a step further and explore avenues for formal certification and we intend to initiate this with an accredited certifying agency and the conveners of CoCo and ICRA

Creating a green market

Experiences from Green Net–Thailand

Vitoon Panyakul

During the last few years the organic market in Thailand has been booming and the number of green shops has increased from zero in 1992 to around 40 shops in 1997. In the long-term the national market looks quite promising. There is an increased awareness of the health and environmental issues involved in organic food consumption. Due to the macro-economic recession, consumers have had to cut down on 'luxury products' which has affected some categories of organic food and environmental products. However, increasing number of people have become health conscious and are spending more on health food. Because of the economic slump many are tending to cook and eat more at home. This has increased the amount they spend on basic food items, such as rice, vegetables, fruits.

The organic market in Thailand is a new market and there are still only a few operators in the business. A much larger market is waiting to be tapped. At the moment there is little competition among the operators and most of them can co-operate at some level. Present competition centres on product availability, assortment, and product information. In the future this may shift towards product quality and services.

Most sales take place through green shops and green corners in conventional shops. In green shops there is a personal relationship between customers and sale staffs and this is an advantage particularly when it comes to promoting new products. In conventional stores there is little communication with consumers but this type of store is better located and more accessible. A smaller volume of sales passes through regular lunch-time stalls in office buildings and through membership/home-delivery systems. These services make it possible to keep in touch with consumers and their reactions can be passed on to producers thus helping improve product quality.

Outside the domestic market, the Thai-European Fair Trade partnership on jasmine rice has shifting its focus to organic rice. Around 10-20% of a total 150 tons of rice is now inspected by Swiss-based inspectors and certified according to EC regulation. Apart from jasmine rice, the European groups have also become interested in indigenous rice varieties, non-GMO-organic soya oil, and dried fruits.

Improvements are needed

It is clear that to unlock the potential market, we need to improve product quality and quantity. First, most products are only available seasonally: at certain period there is too much and at others not enough to satisfy demand. Continuity must be guaranteed so that marketing can be planned and some degree of reliability is necessary. Second, many products are of low quality and are rejected by the A class consumers who are the largest group purchasing organic product at the moment. Third, product quality is not consistent. In one delivery the product will be good but in the next it will be unacceptable. Fourth, product assortment is limited. There is considerable scope for new product development, especially for processed food items.

Labelling to avoid confusion

Some mainstream traders have launched 'hygienic products' (conventional products contaminated with agro-chemicals at a level which is considered safe) with the support of the Ministry of Agriculture. Many consumers are misled into believing that these products are genuine organic products only to realise later that this is not the case. This confusion may have negative implications for organic trade. The Alternative Agriculture Network together with consumer organisations and concerned groups have initiated a national certification programme known as Organic Agriculture Certification Thailand (ACT). Operating as an independent inspection and certification agency, ACT could provide organic labels for organic food produced according to ACT Basic Standard. More than 100 farmers have been certified by ACT since 1997. The organic ACT-certified products label will become available at the end of 1998. However, due to lack of international recognition, the ACT label cannot yet be offered to organic exports. ACT is, in the process of building up competency with the aim of applying for IFOAM accreditation in the near future.

Fresh products

Most organic producers focus on rice production. There are also a small number of vegetable and fruit growers. Field crops are also expanding quite fast. However, there are very few organic chicken farms and there is no organic livestock production.

Following the collapse of the bubble economy, it seems that there is a growing interest among some farmers and the urban middle class to return to the land. Both Green Net and ACT as well as other NGOs in the Alternative Agriculture Network have received many enquires regarding organic farming techniques and marketing prospects. Green Net, in co-operation with Technology for Rural Ecology and Enrichment (TREE), has organised some workshop. However, due to lack of technical capacity, only basic courses can be offered. The Thai organic movement would find it very useful if there was an international exchange of technical knowledge and training curricula as well as more published materials. These could form the basis for a more comprehensive training programme and provide practical information for those interested in knowing more about organic farming.

Processed products

Food processing is strategically important for the development of organic agriculture and alternative marketing. Organic food processing adds value to raw materials, prolongs their shelf life, leads to an increase in product assortment, provides additional income for women producers and builds

Organic Market Survey

In October 1997, Green Net conducted a consumer survey in Bangkok which showed that of the green consumers currently visiting organic shops. 84% were women and 66% of them were between 21 and 40 years of age. 60% were single and 53% had had tertiary education. Their occupations varied from civil servants, to private company employees and academics. 37% has a monthly income of between 10,000 and 20,000 baht while 34% has less than 10,000 baht. 29% has more than 20,000 baht to spend each month. The average middle-class income would be around 10,000-30,000 baht per month. 43% of the respondents had been consuming organic food for more than 3 years and 27% for 1-2 years. Most of the green consumers were quite conscious of health and environmental issues.

Enquires into green consumers' interest in organic products showed that 97% claimed to be most interested in information about the product itself, while 94% wanted to know about product hygienic and 82% felt it was important to know the address of producers or distributors.

With regard to prices, 58% of consumers felt that present price levels for organic food were too high while 55% found them appropriate. Those respondents who said they were not regular consumers of organic food said this was because only a very few varieties of organic vegetables were available, they often did not cook at home, prices were too high, or Green Net shops were not within easy reach.

up grassroots community enterprises. It can also lead to developing new ways of processing perishable fresh products thus increasing the profitability of marketing operation and can create opportunities for foreign-exchange earnings

At present, local producers only use simple processing technologies such as sun drying, heating, jamming and pickling. There seems to be a large market for processed products but quality must be improved. The Alternative Marketing Network, a network of NGOs working on fair-trade of organic products, decided to focus its development efforts on 13 selected assortments with good market prospects. These products are strawberry jam, dried logan, sesame oil, soya sauce, sesame snacks, palm sugar, shrimp paste, canned water chestnut, local herb tea, dried chilli, wild honey and rice.

Food-Processing by Communities

Many factors have to be considered in setting up a processing unit. These include the issue of the quantity of the raw materials. Quality must be suitable for processing and the price of the raw material must not be so high that it endangers the competitiveness of the end product. Community enterprise needs to be based on sound financial and business plans. Financial investment has always been a stumble block in community enterprise. Local producers often have little capital to invest in such projects. At the same time, very few financial organisations are willing to lend money to local initiatives without some physical quarantees. Given the recent financial crisis, it is highly unlikely that local communities would be able to obtain a loan from private commercial firms or government agencies. Communities, therefore, depend on ethical or green finance from both local and international sources. It may, therefore, be wise simply to contract processing out to local factories.

The technical problems of food-processing and packing can be a little complicated. However, there are several universities and research institutes willing to support a community-based food processing programme. Management is also a critical factor in the success or failure of a project. Major areas to be considered are processing, personnel, finance and marketing. Processing management refers to controlling processing and ensuring that it takes place in accordance with defined objectives and standards. This means technical knowledge and skills, something that local staff and producers often lack. Also personnel, financial and marketing management need to be strengthened as they are often not part of the common culture of local communities.

Consumer campaign

Despite growing consumer awareness, many consumers continue to insist on a 'consumerist' approach to food consumption. They often demand that organic fruits and vegetables should look nice, be as cheap as conventional products (if not cheaper), and even that they be available the whole year round. Such demands are not compatible with the natural way of organic farming which emphasises diversity and seasonality.

Organic products must be traded fairly so that farmers can earn a decent income from a financially viable operation. Consumer education and life-style change are therefore crucial to the success of organic agriculture. Recently, Green Net has launched a 'green consumer' campaign to encourage health-conscious consumers to act in a more socially responsible manner.

Conclusion

Unlike other markets, an organic market is not born naturally. It is not advisable to wait for conventional market forces to organise the organic market. From Thai experiences, an organic market requires conscious actions and comprehensive efforts to foster its development. Wholesale distributor, retail outlets, production extension, food-processing community enterprises, certification, and consumer education are among the principal pillars of the organic market. These must be developed simultaneously so that each reinforces the other and no element becomes a bottle-neck. National co-operation is certainly required to synergise efforts and avoid duplication and competition. This means that all those concerned whether consumer groups, NGOs, or farmer organisation must develop a strong political will.

Food for Thought presents new insights into the knowledge of rural people. In many societies, good harvests and good health can only be obtained if the laws of nature, community regulations and rules set by the spiritual beings are properly followed. This book hopes to stimulate development agencies to take indigenous knowledge seriously. Based on the experiences and insights of some 15 organizations in ten countries, it goes beyond the technical knowledge embodied in traditional farming, land use and health practices. The book deals with ancient worldviews or cosmovisions and the role of traditional leaders. It draws conclusions about the holistic nature, strengths and also limitations of this knowledge and describes how in various countries in Asia, Africa, Latin America and Europe some development agencies are supporting rural people in carrying out practical experiments based on local concepts. A framework for such on-farm experiments and ideas for a methodology for supporting endogenous development are presented.

Regional typical food production is a promising option for marginal rural areas. Experiences from Italy show that where production per hectare is low, prices per kilogram can be high. Value is added to these products primarily during processing and marketing. However, there are obstacles to introducing regional-typical food production and these problems are often organisational not technical.

Regional typical food production

the value-added scenario

Hielke S. van der Meulen

Umbria is known as the *The Green Heart* of Central Italy. Predominantly rural, with a low average population density, its farmers produce a large number of typical food products. These include *Lenticchie di Castelluccio* (lentils), *Casciotta di Norcia* (cheese), *Patate Rosse di Colfiorito* (potatoes), *Olio di Spoleto* (olive oil), *Sedano di Trevi* (celery), *Tartuffo Nero della Valnerina* and *Tartuffo Biancho di Umbertide* (black and white truffles), *Miele di Gubbio* (honey), *Farro di Monteleone di Spoleto* (spelt), *Sagrantino di Montefalco* and *Orvieto Classico* (wines). This article discusses the marketing of two of these products: lentils and spelt.

Castelluccio lentils

Castelluccio di Norcia is a small town high in the Apennine mountains. The surrounding plain (1300 meters) is surprisingly barren and is generally used as sheep pasture. Rye, fodder and lentils are cultivated on the low-lying peaty land where acid soils yield small quantities of tiny, but tasty lentils (*Lens culinaris*). The volcanic soil of Monte Vettore could produce three times the volume of lentils per hectare, but these do not cook well and have a 'muddy' taste. In recent years the *Piano Grande di Castelluccio*, has become a major summer tourist attraction. At the end of August the lentil crop is harvested and threshed. Old wooden combines stand scattered over the fields and people travel great distances to buy lentils directly from the farmers. They prefer to buy uncleaned lentils mixed with small stones and straw to avoid being cheated. Genuine Castelluccio lentils sold in shops carry a hall mark as a guarantee.

Castelluccio lentils cost about US$8 per kilo off-farm and US$10 in the food store, more than twice the price of ordinary lentils. Tourism has stimulated price and helped spread their reputation throughout Italy. Farmers of the Colfiorito Plain (800 meters) are trying to copy the Castelluccio's success but have run into problems. Their product is less palatable, tourism is less, and Colfiorito is traditionally well-known for red potatoes and chick peas (*Cicer arietinum*) not lentils. Images are hard to change!

Monteleone farro

Farro di Monteleone di Spoleto is similar to *Lenticchie di Castelluccio* in product type, scale of production and image. But processing techniques, packaging and marketing strategy have played an important role in its success. It is, however, not a village product. It is a region-typical product launched by one family.

Farro (*Triticum dicoccum*) is an ancient cereal and has been a staple food for 2000 years. It is still grown in mountain regions throughout the Mediterranean. It is highly resistant to pests, drought, cold and poor soils and is therefore an excellent crop for organic farming. Chemical fertilisers and rich soils have an adverse effect on productivity. This is particularly true for *Triticum Dicoccum Durum*, a variety cultivated on the high plain of Monteleone di Spoleto. After ploughing and sowing in October, no further weeding or care is needed until it is harvested in August. Only sheep manure is added to the crop and sheep breeders receive straw in exchange for mature sheep dung. Yields average 1500 kilogram per hectare. In Monteleone di Spoleto the classical rotation is one year farro, one year barley and three years lucerne/grass meadow. According to local farmers the most appropriate soil has 'iron in it'. It gets as hard as steel and red as rust when dry.

Farro is used as sheep fodder but in difficult times farmers eat it as well. Traditionally, broken grains were added to a vegetable soup or *minestra*. Its special quality is that it does not get too soft when cooked. Threshing farro is a laborious process because there is a double chaff and it is difficult to break the grain. Most of the women in Monteleone abandoned *farro da minestra* after the Second World War. However, Giuliana Cicchetti began to trade her farro to families in the village in order to pay her children's school fees. When work became too heavy, she asked her husband to invent something to help her. During the 1980s Renato Cicchetti built an eight-stage processing plant from various machine parts. Today this home-industry provides a living for three families.

The Cicchetti's have four grades for their products: whole grains, 'minestra', flour and popped farro. The products are all packed in air-tight packets weighing 500 gram. The pack carries information about the origin and special qualities of Monteleone farro and suggests recipes for soups and pastry. Ciccetti's two sons deal with marketing. They visit every shop in the area and present their products at food fairs. Cicchetti's *Farro d'Oro* (golden farro) is now sold in food stores and delicatessen shops throughout Central Italy. The Ciccetti family control each link in the production chain. They add the value and they keep it.

As demand for Monteleone farro grew, the Cicchetti's began to borrow land from families who had left the village for Rome and from retired farmers. Other farmers in the neighbourhood tried to profit from

Lentil straw is turned using traditional wooden machinery.

growing, processing and selling farro but they have not been able to reach the same standard of processing and marketing. If the farmers of Monteleone were able to agree on common production regulations and a definition of their farro products, instead of competing over price and product innovation, an entire economy and culture could be constructed. Such an economy would make it possible to preserve the liveability and landscape of this beautiful area.

Tradition: a unique selling point

Lenticchie di Castelluccio and *Farro di Monteleone di Spoleto* are successful because they draw upon relatively exclusive traditions. These relate to two aspects of local culture: agri-culture and eating culture. Monteleone farro is processed according to traditional techniques which are difficult to imitate and account for a large proportion of the added value. In the case of Castelluccio lentils, soil and micro-climate are important elements that provide extra value.

It can be argued that in Castelluccio even the soil is the result of tradition. Years of cultivation has turned the swampy valley bottom into arable land with unique properties.

Tradition has value on the market. Industries gladly abuse it and farmers often ignore it. This does not mean that new products cannot establish a name as regional specialities. Every tradition must start somewhere and tradition is practically the only selling point that cannot be reproduced. It is unique.

Marketing

However rich the tradition and unique and difficult to reproduce the product, the success of a regional typical food product ultimately depends on the marketing efforts of producers and traders. It is important to market a regional typical food in the context of the area of origin and retain the association with local and unique culture and landscape. The product should not come from one entrepreneur but from several farmers. This makes the product more authentic and credible to the consumer. The harvesting of Castelluccio lentils during the August tourist season is a perfect example of how a region can be successfully sold. Producers in an area with clear-cut boundaries, with characteristics that can be easily visualised and with a name of their own, have a strong marketing advantage.

Another important factor in promoting a product is the package. The commercial success of the Monteleone farro produced by the Cicchetti family is largely the result of the delicatessen image of the packaging and the clear written text that informs the consumer about its origin, characteristics and how it should be prepared. Farro is sealed in a solid vacuum pack. This reduces the risk of decay and makes food store owners more willing to experiment. The Cicchetti's wanted to sell their farro products at a relatively high price and give the retailers a fair margin. In Italy, the delicatessen approach to food marketing attracts better prices than approaches that centres on the rustic, organic or environment-friendly. Italian farmers are very capable of 'radiating' high-quality images and convincing buyers by demonstrations of passion and good taste. Another critical factor, at least in the initial phase of entering the market, is direct contact between producers, consumers and retailers. This enables producers to get the extra price they need to cover higher production costs. It also provides them with feed-back and helps them improve their product or presentation. Personal contacts with buyers must be seen as an investment in future sale.

A final important factor in the marketing of regional typical food products is certification. The first step is for local producers to agree on common regulations. The resulting label will usually be based on self-certification. The next step will be the application for the national Italian DOC-label or its European equivalent the PDO (Protected Designation of Origin). The growing use of hall-marks shows that regional typical food production is becoming a social construction that needs to be protected against the quick flows of information and investment capital in modern society. It is far from being a 'natural' product of geo-physical conditions and local tradition. Farmers and processors often feel pressed to adopt technological innovation. In general, the more courage producers show in restricting themselves, the greater the success of their regional typical product.

Low external input agriculture?

Though regional typical food production is low-external-input in nature, it is characterised not so much by the reduction of costs, inputs or energy but by the value added to each unit of product. This goes far beyond the adjustments involved in simple commodity production. Since it involves processing, packing and marketing, the benefits of regional typical food production filter from the farming community into the wider economy.

The creation of added value linked to a particular region tends to make the sale of food products more sustainable. Without sustainable sale, sustainable agriculture seems impossible as low prices and an insecure market easily leads to the exploitation of the soil.

Third World countries certainly have considerable potential when it comes to developing regional typical food production. Gradually some of the products have found their way through the same trading networks used for durable consumer goods. The major problems will arise from the 'social construction of quality'. This means the organisation of production and processing according to a set of more or less strict common rules and the limitation of production volume in order to maintain scarcity on the market.

The personal primary needs of poor peasants should be fulfilled. However, we should bear in mind that in Europe, many high-priced regional typical foodstuffs were part of a poor man's diet until very recently. Regionally typical food production strategy is, by definition, restricted to specific regions and specific groups of producers who can distinguish themselves from the 'rest'. It is not an alternative to political measures to tackle the structural problems of poor and 'backward' areas.

Sale of lentils to tourists.

Hielke S. van der Meulen, Department Rural Sociology, Wageningen Agricultural University, Hollandseweg 1, NL-6706 KN Wageningen, Phone. +31-(0)317-483032; E-mail: hielke.vandermeulen@alg.swg.wau.nl

Sustainable agriculture needs sustainable markets

'I like your talk about saving the environment... But what is in it for me? (a realistic Kenyan smallholder farmer)'

Jos van Oostrum

Many farmers in situations of radical change and uncertainty trying to conform to 'best practice for sustainability' are asking the same question. How to combine making a living with conserving their resource base. Kenyan smallholders got together with the Association for Better Land Husbandry (ABLH) in 1993 to develop a conservation for business' approach in which farmers' groups committed themselves to developing a business plan.

Since then remarkable progress has been made in promoting conservation farming practices. In 1992, few would have thought it possible that small farmers could increase their self-sufficiency in maize from 22% to 48% or that they could decrease the incidence of hunger in their communities by 33%. Sales of vegetables produced by farmers who have adopted the conservation for business approach have increased dramatically and their dependence on the market for their own vegetable supplies have declined equally significantly (Hamilton, 1997).

Working as a team, farmers and facilitators in four ABLH target areas in the districts of Busia, Kakamega, Kirinyaga and Vihiga managed to ensured a continuous supply of 24 fresh and 12 processed Conservation Supreme certified products to 14 different market outlets in Nairobi and Kisumu, over a period of 14 weeks.

Impact of conservation farming

ABLH and partner agencies aim to help rural people to overcome poverty by increasing their food production and generating income on the farm. The project follows a participatory approach. Farmers are helped to develop their skills, organise their activities and become credit worthy. They test the suitability of new practices and set-up farmer-to-farmer advisory and training services. A basic principal is that farmers can make economic progress without having to make large cash investments and practices requiring little or no cash inputs - a very important feature when dealing with poor farmers - have been introduced. Double digging of vegetable beds (a system of deep digging and incorporating compost into the soil) in home gardens, for example, has had a significant effect on small farmers' livelihoods. Combining water harvesting, recycling organic matter and introducing different types of vegetables has also proved successful and has been extended beyond the kitchen garden to the maize fields.

Linking farmers with markets

As conservation farming becomes more widely adopted, smallholder farmers have to sell their surplus farther away from home. Increasing demand from urban centres and international markets offer attractive opportunities but at present many farmers are exploited by traders and middlemen. In response, ABLH has set up the Smallholder Marketing and Certification Project (SMCP) which aims to promote fair trade, fair and stable prices and the opportunity for small farmers to trade directly with big buyers by marketing Conservation Supreme (CS) and organically certified products.

CS is similar to the Integrated Arable Farming (IAF) system that replaces chemical inputs of pesticides and minerals with mechanical and biological products and processes. It does not ban them entirely. IAF requires a considerable change in farming practices and the adoption of different environmentally friendly technologies. Farmers are advised to manage their farm as an ecosystem and they must observe, interpret and anticipate. The CS pilot project has been undertaken by SMCP and marked the start of a joint learning process, that formed the basis for certification procedures and standards to be developed on a larger scale. It also created consumer awareness.

Project aims

First, the project aimed to develop CS products in selected stores and extend the CS concept and standards for certifying and regulating crop production. Second, it aimed to show the potential of collective marketing of fresh and processed smallholder crops in accessing and maintaining stable and profitable market opportunities. Finally, it was concerned with developing low cost strategies for conservation-based food businesses capable of reducing poverty, improving rural people's livelihoods and boosting rural economies.

Conservation Supreme and organic standards offer quality assurance to the customer. Once an awareness about conservation products has been created, consumer demand can be establish and smallholder livelihoods and the environments in which products are produced can be improved. As farmers often find themselves in an uncertain and unfamiliar market situation, the aim of the CS project was involve them in marketing their products and increase their knowledge and confidence. The project guides farmers from producer organisation, to handling organisation to farmers' own marketing and distribution agencies. It facilitates group networking, bringing farmers together to share experiences and market collectively. Model food processing factories were set up and farmers were actively involved in production and training.

Maintaining a constant and sufficient supply of CS quality produce is a major challenge. The farmers involved in the first pilot project were rainfed. Farmers with access to irrigation water were later identified to ensure continuity of supply through the dry season. The integration of irrigation and rainfed farmers will require training, careful planning and a clear division of roles.

Transport is a determining factor in the profitability of any CS food business and transport costs must be reduced to the minimum. Smallholder groups should be spatial concentrated. In the project the groups decided to pay the farmer driver (vehicle was supplied by ABLH), and to contribute to networking costs (a 10% levy on fresh sales was agreed and paid by the farmers). This was re-invested in the project and farmers agreed to put aside 5% of revenue as group savings.

Product identity

CS produce acquired a distinct identity in the stores because farmers labeled and packaged them. The public reacted positively to the CS concept. However, price premiums could not be expected in the first trials and active lobbying will be necessary to explore opportunities in niche markets.

Farmers were able to trade directly with market outlets and avoid exploitation by brokers and middlemen at farm-gate level. They were exposed to real market situations, including timely deliveries, different modes of payment, and the negotiation of orders. They could also explore opportunities. The transfer of information between market outlets and the groups has been critical.

Group and business capacity building

The development of organisational and management capacity at farmer and facilitator level is as important as new technology in the conservation for business approach. Farmers in the project formalised their relations through networking by establishing Farmer Action Associations. Amongst other things they were training in production scheduling, grading, recording, and accounting and this greatly improved their knowledge, skills and self-confidence. Exchange visits were used to enhanced farmer to farmer learning and interaction, creating a 'develop ourselves attitude' as a first step towards empowerment.

The complexity of human interaction in practical approaches to rural development demands a balanced, step-by-step development of skills, capacity and confidence. Any scaling up of the CS programme next year must include a proper staff development programme and a significant increase in staff numbers.

The concept of added value

Value adding is a concept that has been adopted by development agencies world-wide. However, this strategy sometimes involves setting-up sophisticated production processes in places where electricity supply is unstable and facilities for repairs are non-existent. The effect on consumer confidence of factors that disrupt supply is often disastrous. In this article the concept of value adding is explained in the context of developing countries. Several examples are given of the pitfalls of value adding strategies and some case studies are discussed.

The lessons to be drawn from examples of failure have a wide application as the following case studies show.

Senegal: A group of Senegalese women used to do very well selling dry fruit on Dakar's local, informal market. They decided to venture into the local tourist and supermarkets trade and their co-operative acquired an expensive sizing and packaging machine. However, the drying was of poor quality and did not appeal to the targeted middle class and tourist consumer. Meanwhile, the product had become too expensive for the traditional customers.

Kenya: in Kenya, a German NGO invested heavily in fruit drying projects involving hundreds of producers. However, no marketing plans were made. The NGO was obliged to buy the products itself and found it could not sell them.

Philipinnes: three coir (coconut fibre) processor co-operatives in Samar, the Philippines were supplied with processing plants by a Netherlands donor. However, because the co-operative members considered themselves workers, any attempts to involve them in improving the plant failed. They had no sense of ownership or responsibility for the new materials and infrastructures.

The basic idea

Such experiences are not uncommon. Many producers' groups, entrepreneurs, and NGOs attempt to add value to the product but instead of the expected profits, they make losses. As a product moves from raw material to end product, its value can increase. It is legitimate that small producers should strive to maximise the return on their product by processing it further. Without market surveys, appropriate technology and skills, however, there is a very real danger of failure. Market oriented value adding is directly related to what the customer is willing to pay. Market oriented solutions involve making the product as attractive as possible to customers by adjusting the appearance, quality, quantity, and the emotional value of a product and providing the right service or promoting the product in such a way that it reaches the target group. First, the potential consumer has to be defined and then producers can focus on what the customer wants. Knowing the market is to understand the potential value of the product. Without knowing the potential value of the product, it is difficult to use the right value adding strategies. Such strategies include adding emotional value (for example, the attractions of organic products to the customer); packaging and giving more attention to the promotion.

There is an overlap between production oriented and market oriented value adding. Production oriented value adding involves offering good quality products and thus lowering production costs as much as possible. Once a definition has been made of what can be expected from a product, a list of value adding extras can be defined. The clearest and easiest method of determining whether value can be added to a product is to go through the production cycle (see Box). Before reaching the customer the production cycle goes through the following stages: crop selection, planting, weeding, fertilising, pest control, harvesting, transport, storage, post harvest activities, and processing. At each stage choices can be made that may lower production costs and give additional value. Some choices can be implemented by the producer others require knowledge, labour, machines and money from outside sources.

Standardisation and preventing loss

Standardisation of the production process increases efficiency and leads to cost reduction and therefore profit maximisation. The lack of standardised production procedures, proper production process lay-out, clearly defined tasks and operation procedures for workers often result in low product quality, accidents and disastrous losses. The losses, wastes and financial costs resulting from low and variable quality of products in developing countries are high. Proper harvesting and processing techniques, together with adequate storage facilities can, for example, protect small holders from the rodents, insects and humidity that can destroy up to 25% of their stored product. (J.W.Clay, 1996).

Efforts to add value to a product should be carried out with caution. Interventions that seem an obvious way of increasing profits can easily lead to the opposite result. Marketing, the various stages in the production cycle, and the best way to structure production must all be carefully analysed in the context of costs and benefits. This is particularly important when working with small-scale producers who are extremely vulnerable to the consequences of poorly developed ideas.

A feasibility study was conducted for the organic production of sunflower oil in the Bungoma district in Western Kenya at the request of the HOPE Community Development Programme. An analysis of HOPE's production cycle involved the following questions:

- Is using a different seed variety as profitable as it seems?
- How much more does it cost (work, money, time etc.) and what are the profits?
- Is it viable to offer cold pressed sunflower oil which has a better price on the market?
- How much extra would it cost and what are the extra returns?

This research resulted in a action plan for the next four years

The weakest go to the wall

Plans for an expensive and unreasonable control mechanism to monitor small farmers' co-operatives are in the pipe-line threatening the livelihoods of thousands.

Petra Heid

Organic produce is increasingly popular in Europe and a wide variety of products are available. All products are subject to inspection according to the guidelines of the current European regulation 2092/91. Under this system organic produce is deemed to comply with these standards if it can be proven that it has been subject to comparable guidelines and monitoring procedures. This makes it possible to monitor products originating in a wide variety of climatic conditions and agrarian structures. Monitoring small farmers (normally co-operatives) in Latin America, Africa and Asia, who are the main producers of organic coffee, for example, has proven to be an extremely arduous task. We are now trying to develop a practical and sophisticated monitoring procedure that is applicable to different farming structures and that meets stringent EU requirements for a 100% inspection rate and spot checks.

EU procedures

Over the years the various international certification organisations have each managed to develop such modified monitoring systems. These have been incorporated within the requirements of the IFOAM accreditation programme and have been accepted by the EU.

Several European member states are now questioning the reliability of these control mechanisms. France in particular is demanding a stricter spot check regime of small farmers' organisations. This would inevitably lead to higher inspection fees for these organisations. An even less acceptable consequence would be, however, that the improvement in quality envisaged by this measure might lead to exactly the opposite!

Ever increasing numbers of small farmers' co-operatives, especially in Latin America, have converted their production to conform with organic agriculture guidelines. A more sustainable approach to farming diminishing agricultural areas has brought farmers a more dependable and, in some cases, even richer harvests, which they can sell at higher prices on the international organic market. This has made a major contribution to improving the living standards of hitherto economically disadvantaged small farmers, and to strengthening their self-governing organisations.

Small farmers' groups wishing to sell their organic produce to European member states have to agree to be inspected at least once a year according to European regulation 2092/91. This involves experienced inspectors from monitoring organisations recognised by the EU making on-site inspections, interviewing the farmers and checking their records. On the basis of this information they decide whether the production, processing and marketing of the organically cultivated produce meets requirements. It is extremely difficult to inspect all the small farming units that make up a group. In large organisations, comprising hundreds or even thousands of small farmers from several villages scattered over an area of up to 10,000 square kilometres, it is absolutely impossible for an inspector to perform this task in a reasonable time and at reasonable expense.

Complementary control

Years ago, with the primary objective of solving this difficult problem, Naturland and other international certifiers guided by the IFOAM accreditation programme, IOAS, introduced a 'quality control system' (see Box) that would be a major component in the inspection procedures applied to small farmers' groups. The idea was to establish a framework for these organisations enabling them to establish and develop internal control mechanisms. Selected employees were trained in special courses and became qualified inspectors capable of assisting EU inspectors. This meant that the local inspectors were entrusted with the inspection of each small farmer's plot according to European regulation 2092/91, enabling EU recognised inspectors, on their annual visit, to concentrate on the processing and marketing of the organic produce and to determine whether the internal quality control system was operating satisfactorily.

A precondition for the establishment of such quality control systems is an enormous transfer of know-how from the certification organisation responsible to the small farmers' groups. This is the only way small farmers' groups can be educated step by step towards assuming some of the demanding tasks involved under EU requirements. This means, for example, developing standards within the small farmers' organisation which are equivalent in stringency to EU regulation but are worded in such a way that members can understand them. Furthermore reference is made to local conditions and to the organic cultivation of indigenous crops. A team of advisors must ensure that these internal standards are communicated to all small farmers wanting to join the organic programme. Locally trained inspectors will then check whether each of the organic units is complying with these standards. Local inspectors have an exact knowledge of their region, its inhabitants and farming methods practised, and can also take part more intensively in inspection procedures. They can work with more insight and more cheaply than an official from a EU recognised inspection organisation.

The internal quality control system is examined by the external European inspector on the basis of the data produced by the small farmers' organisation concerned. Its quality and veracity are tested in spot checks in the form of on-site inspections and interviews with randomly selected small farmers. If inspectors discover flaws in the internal inspection system, the spot checks and on-site inspections are increased. If, on the other hand, all is satisfactory, the number of spot checks may be reduced. This flexible method of proceeding motivates small farmer groups because, if internal quality control is done well, the work load of the external inspector can be reduced and money can be saved.

In introducing internal inspection systems, Naturland and other international-

Inspection of small farmers' groups is a severe challenge to any certifying organisation.

ly operating certifiers first invested much effort in convincing and guiding small farmers and in restructuring procedures. However, this effort was rewarded. Production co-operatives managed to establish economically viable quality control systems and data became available for statistical purposes and for correcting any weakness identified.

Threats

The plans now in the pipe-line will mean that most of this effort was a waste of energy. Brussels is debating a procedure whereby EU organic control of small farmers' groups will be put on a different footing. The percentage of small farmers who are to be subject to spot checks by the external inspector will be set,and no matter how good the internal inspection system is, at least 10% - 30% of all small farmers in an organisation will have to be inspected annually by an external inspector who will visit their farms. Presently, it is the external inspector who determines the percentage of inspections after consultation with the certifying organisations. In the case of large, well-organised small farmers' groups, this was significantly below the envisaged percentage (about 2% - 5%), whilst smaller organisations were subject to a considerably higher percentage (20% - 50%).

Fixing spot-check ratios will diminish the flexibility and adaptability of the system and may result in a rigid, over-expensive and unrealistic construction. Even if the level of spot-checks decided upon is only 10% it will still mean increased inspection charges, especially in the case of small farmers' groups with a large number of members (500 or more). Here a rapid deterioration in the quality control system can be expected, since the time available cannot be expanded at will to accommodate the disproportionate increase in the number of spot-checks required and a drastic inflation in the inspection charges cannot be avoided.

Let us take the example of a coffee co-operative in Mexico with 2,100 members that cultivates organic coffee over about 4,200 hectares. At an inspection rate requirement of 10%, this would mean the external inspector visiting 210 farms even though each of the 2,100 members had already been subject to internal inspection. An inspector who is expected to verify the documentation provided has to allow enough time to visit the farms and to conduct interviews with the farmers. The inspector can only visit four to eight producers at the most per day and there are also the more remote farms that can only be reached on foot.

This means that an inspector would need at least thirty days or more only to spot checks the small farmers and even if local specialists were asked to assist, this inspection procedure would cost the small farmers' associations a fortune (between US$ 5,000 and US$ 12,000). Organic production would no longer be economically viable.

What will happen if the amendment planned in Brussels is passed? 'Time is money' is the motto. In order to save time, interviews with farmers will be kept short, probing conversations and skilled questioning to reveal less obvious but important details, enabling the situation to be judged more realistically, will become a luxury and be scrapped. Only those plots that are easily accessible by foot and car will be checked regularly. These 'show-case farms' may well be managed in an exemplary way since they will be expecting external inspectors to visit them regularly. In order to cope with visiting the large number of farmers to be inspected in a few days, the temptation will be great to enrol cheap assistants. It is quite conceivable that recourse will be taken to inadequately prepared and poorly instructed assistants in order to be able to achieve the inspection target. In short, the 'practical' side of the external inspection may be so adversely affected that it makes no sense at all.

A percentage which may be too high for the larger small farmers' organisations may be too low for a very small organisation. In the case of small farmers' groups with just twenty members, for example, the inspector would, in theory, only have to check two farms. This is far too few to enable a judgement to be made as to how well internal inspection systems are working.

These examples make it clear that strict regimentation of the inspection procedure as in the current concept will do nothing to produce the intended results. Naturland, is making a case for the percentage of spot checks to be graded in a reasonable way, bearing in mind the number of members in a small farmers' group, with the aim of maintaining expenses and quality at an acceptable level and enabling the small farmers' groups to take an active part in the running of their organisation as partners in organic agriculture, whilst not denying the European Union or the consumer their perfect right to be supplied with organic produce of guaranteed quality.

■

Criteria for the quality control of small farmers' organisations

The performance of tours of inspection of small farmers' groups which can comprise several thousand members with widely scattered plots of less than two hectares on average in poorly accessible regions is a severe challenge to any certifying organisation. The aim is to follow a practical procedure which will meet the requirements for a 100% inspection under the EU regulation 2092/91 and keep inspection charges at a level acceptable to all the parties concerned. Naturland, as one such certifying organisation, has devised special criteria for quality assurance, in co-operation with the inspection organisation IMO (Institute for Market-Ecology) and in accordance with IFOAM's accreditation programme. These criteria are the basis for Naturland's certification of small farmers' groups.

Development of internal standards
Every organisation is obliged to develop internal standards for organic agriculture applicable to the crops cultivated and in compliance with EU regulation 2092/91 and to pass these on to all its members farming organically.

Proof of a well-managed advisory system
Proper advisory services are indispensable for the successful application and development of any method of organic agriculture. It can be realised either by an external advisory service or an internal advisor, whereby agricultural engineers experienced in organic agriculture form the core of a team of advisors who, in turn, instruct experienced farmers who have contact with every member of the organisation. In this way they ensure that every farmer is familiar with the internal standards determined by the organisation and applies them correctly.

Performance of qualified inspection
In order to comply fully with EU Regulation 2092/91, every small farmer must be inspected at least once a year. This inspection is performed by specially trained and qualified staff of the small farmers' organisation, who visit every plot and document the results in exhaustive survey files. Particular attention is paid to ensuring that the inspectors do not visit their own locality.

Documentation of all procedures and organisation structures
A contract has to be drawn up between each small farmer and the organisation to which he or she belongs. In this contract the small farmer pledges to maintain internal standards determined and specific penalties are agreed upon for every infringement. The organisation is obliged to provide comprehensive proof of the results of each inspection before the harvest begins and to maintain lists of the producers. Purchasing lists and all records documenting the flow of goods to the point of export are an equally important component of the organisation's internal quality assurance system.

Sustainable chocolate
a practical business example

Craig Sams

In 1991 we launched Green & Black's organic dark chocolate made with cacao grown in Togo, West Africa. The chocolate was a high quality product, the first 70% cocoa solids organic product to be sold in the UK. It was a success at the very top end of the chocolate market. In 1993, we needed an alternative source of cacao and started a new project in Belize that embodied organic and fair trade principles.

There had been a cacoa planting project in Belize since 1983 run first by the Overseas Development Agency (ODA) and from 1986 by USAID in co-operation with the food giant Hershey's. These schemes were funded by bank loans secured against the collateral of Indian Reservation land. Farmers were encourage to buy hybrid seeds and agri-chemicals, clear forests and plant trees close together. This left little room for shade trees and fertilisers and fungicides became essential. The economics of the programme were carefully worked out, but were based on a selling price of US$1.80 per lb. The programme finished in 1992.

In October 1993, I spoke to Justino Peck, the Chairman of the Toledo Cacao Growers Association (TCGA), the co-operative that represents the Maya Indian cacao growers of the Toledo District of southern Belize. They were facing serious problems. The selling price for cacao had fallen from US$1.80 to 55c and loans could not be repaid. The bank threatened repossession and plantations were becoming overgrown as cacao farmers migrated north to work as orange pickers and sugar cane cutters to earn enough to service their debts and feed their families.

Co-operating with TCGA

Together with TCGA, Green & Black's worked out a new deal for a new product - MAYA GOLD. The co-operative signed a five year rolling contract to be our exclusive supplier of organically grown cacao for use in Maya Gold chocolate at a starting price of $1.25 per pound. We assured them that if we used cacao from other organic sources in Maya Gold we would pay the TCGA US$200 per tonne of such cacao used. We also agreed to assist them to obtain organic and fair trade certification and provision was made for training. A US$20,000 cash advance was made so farmer members could be paid in cash for their cacao.
A 5 cent per lb forestry premium was offered to encouraged growers to thin out their trees and plant more shade trees. We also offered an additional 5 cent per lb to any grower who planted one mahogany, one cedar, one mamey fruit and one cohune nut tree per acre of cacao. This was to encourage long-term investment because after twenty years one mahogany tree could easily be worth more than a year's cacao harvest. It was also to protect wildlife and biodiversity, an essential but difficult to measure aspect of organic farming. Trees would attract migratory birds, insects, and mammals and help maintain the balance of life that ensures no single species gets out of control. A habitat would also be preserved for game, an important source of protein in the Maya diet. Two members of the TCGA set up tree nurseries to provide the baby mahogany and cedar to plant out on the cacao. The TCGA took responsibility for implementing these provisions and the Soil Association inspected and approved the area for organic production. Slowly the project got off the ground as farmers adjust their agricultural pattern and, after a good start, the TCGA has kept going.

What made it a success?

The quantity and value of the cacao increased. In 1993, the gross area income from cacao was US$10,000. In 1997 it was over US$100,000. Organic certification allowed the TCGA to tap into the fastest growing sector of the European and North American food industry. Next year the TCGA anticipate total income from Green & Black's of nearly US$200,000.

Securing the market in advance played an important role in this success. Before Green & Black approach TCGA, we discussed the Maya Gold concept with Sainsbury's, a leading UK supermarket chain. They agreed to stock the product for six months when it was ready. We also sought and gained Fairtrade Foundation certification and Maya Gold was the first product to bear their mark.

Maya Gold was launched at a press conference at the Oxfam stand at the BBC Good Food Show in London. The same day BBC Newsround sent a film crew to Belize and came back with footage of Maya villagers harvesting cacao which was shown on the afternoon and evening television news. Other press coverage was extensive and supermarkets were soon sending in orders. Sales have now levelled out but are still moving upwards.

Problems

Despite the commercial success, problems emerged at the interface between the Maya deal with Green & Black's, and the ODA's master plan for the region, which was based on selling logging concessions to Asian companies to gain foreign exchange and on extensive rice growing. The ODA representatives in the South were cautious about us, probably rightly so, as there are plenty of people who come to the Toledo District, make all kinds of promises, and then disappear without trace. The ODA team warned the Maya of the risks of taking the organic route, advising caution.

Our 5 cent per lb tree planting scheme also met with resistance. The ODA's forestry advisor notified the growers that any mature hardwood trees would belong to the Forestry Department and would not be the property of the grower. This was deeply discouraging to the growers and the new tree nurseries were closed down.

In addition, WHO's malaria control programme in the area had a policy of spraying houses and areas where malaria had been notified with DDT. This nearly led to contamination of some organic cacao. Because there was no telephone communication, villagers had no advanced notice of spraying. The authorities have now agreed to give two weeks' notice when they intend to spray so that villagers can get their cocoa sacks, as well as their children and animals out of the way before the sprayers arrive.

The future

Growers are switching back to the local variety of cacao. It tastes better and although yields are lower the quality is superb. As well as increasing cacao production, the TCGA wants to diversify and, with organic status, they find they have an advantage. This season the TCGA grew a trial crop of 5 tonnes of red kidney beans and 5 tonnes of black beans which Green & Black agreed to purchase at EU organic market prices. A considerable increase is planned for 1999 because quality is excellent and prices are good.

Ginger is also being planted around the edges of the cacao trees and produces a good crop. This increases earnings from the same area of land enabling farmers to look after two crops at the same time. The ginger does not compete for fertility with the cacao. Annatto has also been grown widely and is processed in the villages to produce a yellow colouring paste which can be used in organic margarine and butter.

Social gains

First, cacao production has strengthened the position of women. Unlike rice, post harvest processing is an important part of cacao production and women play a key role. Beans are fermented in boxes next to houses for five days. Once they are fermented, they are dried in the sun, turned, and protected from rain. Women control these operations and as a result they can benefit directly from the income generated by cacao.

Second, secondary education in Belize is free, but the nearest high school is in Punta Gorda, 20 miles from the villages in the Maya Mountains. With no daily bus service, students have to board with families in Punta Gorda, a significant cost. As a result of increased cacao income, more students go to high school and a bus service has been set up on a daily basis. There is even talk of building a high school in one of the central villages.

Third, the TCGA has become a unifying force in a community where there are two distinct cultural and language groups: the Kekchi Maya and their neighbours the Mopan Maya. Mistrust and suspicion between the communities had been exacerbated when aid workers, missionaries and government officials were suspected of favouring one group over the other. Within the TCGA there is one shared goal - to sell Green & Black's as much good quality cacao as possible.

Challenges ahead

The leaders of the TCGA are respected figures in their local communities, consulting to ensure that the Maya speak with one voice on matters where their community has hitherto been weak and divided. This is important as there are challenges ahead.

Traditional landholding patterns based on use have been weakened by Government policy and land the Maya considered to be their reservation land has passed to Malaysian and Chinese logging concessions. Loggers damage watercourses and take out all the valuable trees leaving only an impoverished landscape. This land could be reclaimed for organic cacao with the replanting of mahogany and other hardwoods but government policy discourages this. Government is also reluctant to recognise the historic right of the Maya to occupy and harvest their homeland.

To support their claims the Toledo Maya Cultural Council, in conjunction with the Indian Law Resource Centre and the National Geographic Society, recently produced a 150 page Maya Atlas that details Maya land use and occupation patterns in the Toledo District. The Council stakes a claim to land that has been used by the Maya for hundreds, indeed thousands of years.

Plans by the Interamerican Development Bank (IDB) have also threatened Mayan land security. The IDB has agreed to pave the Southern Highway, the road to the South, and this will open up the area to more economic activity. Originally IDB funding was conditional on the recognition of Maya rights, but these conditions have not been satisfied and, despite Maya protests, the construction of the highway is now open to tender. The Toledo Maya Cultural Council have taken their appeal to the Belize Supreme Court of Justice and it may well end up in the Privy Council in London if their legally legitimate claims are not satisfied.

Despite these problems we hope that Maya Gold will continue to serve as a model for larger projects and that our trading and marketing venture with the Maya of Belize will become typical of the way ethical trade can be conducted globally.

Organic agriculture *lessons from the field*

Studies have shown that organic agriculture is economically viable, that farmers can achieve more income as a result of premiums and that they need fewer inputs to maintain returns. Organic systems are based on the optimum use of local resources and technologies and can give farmers greater independence and more control over their means of production. However, more comprehensive monitoring is needed to analyse their sustainability and impact.

Many farmers enter organic production because they want to farm in a more holistic way. Other major stimuli for developing organic agriculture include environmental and social concerns, economic necessity, a lack of chemical inputs, and market demands. Small farmers are also encouraged to take up and stay in organic farming by the prospect of being able to produce more food at the subsistence level, having a larger surplus for local sale, or being able to cultivate a product of significant export value. Farmers are most responsive to organic agriculture when they have not been exposed to the 'chemical message' and their farming systems involve traditional or nil inputs. When production is relatively labour intensive and if farmers have the chance of developing the organic concept themselves they are also more inclined to convert to organic agriculture.

Farmers are less likely to take up organic farming in situations of high labour cost and labour scarcity and where there has been an over-exposure to the chemical message . Farmers with relatively mechanised farms and a commitment to high input, high output strategies are also less likely to convert. Insecure land tenure means small farmers will be reluctant to plant permanent crops.

Local and foreign NGOs, local and foreign buyers, government agencies and large private farmers are generally the main initiators of developments in organic agriculture. Development often occurs at one focal point and spreads outwards to link a widening range of organisations. In Egypt, the Dominican Republic and India, pioneering work by individuals has lead to the development of local organisations capable of representing the organic sector and to government recognition programme provides access to premium prices if certain practices are followed. It functions as an effective extension method with the capacity to support sustainability.

The challenge of going organic

Organic agriculture relies on natural predators and an understanding of local soil and environment. It is knowledge intensive and, from the beginning, requires more design and management. When farmers only known chemical solutions, implementing control of pests and diseases through measures such as rotation, composting and time of planting represents a major change. Organic agriculture requires time and well-trained extension workers. Active organic management is required for a least twelve months before organic status is conferred. Benefits will not be immediate and small farmers will require considerable support in the first years. High input farmers will require financial support such as capital grants or annual area payments to offset the financial problems associated with conversion. Studies show that, in Western Europe, farmer's enthusiasm for organic agriculture correlates closely with the size of the conversion grants available.

It is probably no accident that coffee, cacao and tea are so prominent among the organic products supplied by developing countries. Conversion often does not involve radical change. These crops are often planted with shade trees even in conventional systems and, as such, they support a diversity similar to that encouraged in organic systems. Organic cocoa, for example, in contrast to conventionally cultivated plantation crops such as citrus, supports biodiversity and because the ground is not disturbed or cleared during planting and the root structures of other trees remain intact, soil and water resources are also conserved. However, an annual cropping system on bare, semi-arid land where there is little diversity and where few farmers can afford livestock will require much more time before it becomes a viable organic system. These factors represent a significant challenge to the small farmers' motivation to converting to organic production.

Strategies to commercialise agroforestry products

The Northern Bolivian Amazon region has an abundant vegetation cover of humid tropical forests with a high diversity of timber and non-timber species. Rubber and Brazil nut have been important for the livelihoods of indigenous groups and peasants. Rubber has not been exploited for about twenty years but there is increasing exploitation of palm heart. Shifting cultivation is practiced and a hectare of forest is cut each year to grow food, a process that can be sustained for two years. To counter this and increase incomes, Instituto para el Hombre, Agricultura y Ecologia (IPHAE) has a project which uses agroforestry systems to improve land use sustainability and generate higher incomes for farmer families.

Rik Overmars, Nelson Mariaca and Armelinda Zonta

Development of agroforestry cannot be achieved by only producing for home consumption. Species with commercial potential such as fruit species, palms, timber producing species and leguminous cover crops are used and provide farmers with an income in the short-, medium- and long-term and therefore they cut less forest each year. Large-scale plantations are unfeasible because farm families lack labour and conditions are unsuitable for mechanisation. Marketing is, however, critical.

Rapid production

To get early returns and stimulate farmer interest, IPHAE uses a species with rapid production. Urucú or Anatto is a resistant variety that is productive 18 months after planting. When the project started in 1995, Urucu was selling for US $ 1.7 per kg. Subsequently, in 1997, the price dropped US $ 0.5 per kg in 1997 which did not justify harvesting the crop. This clearly demonstrated the importance of market research, small-scale plantations and diversification.

Urucú *(Bixa orellana)* or Annatto is a medium, tall shrub that produces seeds rapidly. The seeds are covered by Bixina, a substance that is a natural red/orange colourant that is widely used in the dairy industry, and in tomato pastes and ketchup. Principal producers are Peru, Ecuador and Brazil. It is exported to the United States, Japan and Europe.

Together with the municipal government and a private company, IPHAE is looking into the possibility of installing an anatto paste processing plant in the region. It should bring added value and better prices.

Market creation

Copoazu is a cacao-related species. It is not well known in Bolivia but shows great potential. For this reason IPHAE generated a local and regional demand by introducing imported pulp from Brazil. Today, IPHAE sells 10 tons of pulp annually. This can be supplied by the first group of farmers to plant copoazu in their agroforestry systems. We have to actively promote the consumption of Copoazu in other parts of Bolivia for new agroforestry systems.

Copoazu *(Theobroma grandiflorum)* is endemic in the Amazon and produces a fruit similar to cacao. The pulp is used as a basis for juices, marmalades, jellies, and nectar (see photo) and can be added to yogurt and ice-creams. 'Cupulate' is processed from the seeds and is similar to chocolate.

In order to reduce transportation costs for national and international markets, IPHAE is investigating conservation and processing of Copoazu pulp (pasteurisation and marmalades) and, with the help of fair trade organisations, is exploring European markets.

Substitution of raw material

The region has a palm-heart industry (13 processing plants) using natural *Asaí (Euterpe precatoria)* as raw material. Unlike the Brazilian Asaí, this species does not return after cutting and takes about 60 years to produce palmito. It is estimated that 60,000 palm-hearts are being cut daily in the region. This means that the natural resource base of palm-heart will be economically depleted within 5 years.

Pupuña, Pejibaye or Peach-Palm *(Bactris gasipaes)*: Once the mother stem has been cut, suckers sprout from its base and produce palm heart within one year and yield a regular and sustainable production provided soils are not depleted and are fertilised. When mature, the species also produces edible fruits rich in protein and vitamin A.

Peach-palm was introduced by IPHAE as an alternative to natural palm heart. IPHAE's agro-industry desk has been successfully in processing palm hearts from Peach-palm using the same technology as was used for Asaí. Taste tests, market acceptability and cost benefit analysis of the agroforestry systems have been made.

Increasing densities

Brazil nut is an important economic resource and farmers migrate to the barracas, large forest properties owned by a patron, to harvest them. Collectors have to walk long distances carrying heavy loads and incomes are low, living conditions provided are minimal and the patronage system keeps many indebted and dependent.

Brazil nut *(Bertholletia excelsa)* occurs naturally in the Amazon forest with a natural density of between 0 and 9 trees per hectare. Production can be increased by augmenting densities in poorly stocked forest areas and by management in fallow and agroforestry systems.

By planting Brazil nuts in their fallow, or stimulating the natural re-growth and regeneration of the tree, natural densities can be increased. In agroforestry systems, trees start producing at 12 years and, with grafting, much earlier. Many farmers sell Brazil nuts from their own land to the Farmers Cooperative (CAIC). This has a processing plant and exports under fair trade schemes to solidarity markets in Europe and the United States.

Agroforestry systems play a major role in raising farmers' incomes in the Amazon and help counter the deforestation caused by shifting cultivation. The combination of farmers' extension and the promotion, processing and commercialisation of agroforestry products helps overcome a major bottleneck experienced by many development projects: lack of markets.

Unlocking trade opportunities

Nick Robins and Sarah Roberts

In today's globalising world, export success is one of the major routes to economic progress for developing countries. But the conditions for success are changing as producers face rising environmental expectations in key export markets, resulting from tightening regulations, new corporate practices and changes in consumer values and lifestyles. These new expectations reflect the growing recognition that current patterns of consumption, particularly in the richer, industrialised world, are not environmentally sustainable. Profound changes in the ways in which goods and services are produced, traded and consumed will be required, both to reduce the burden on the global environment and to ensure that a growing population has resources to meet its needs.

For those who can adapt to these requirements and start moving to anticipate trends, there are new opportunities to be found in sustainable trade that can generate financial, environmental and social benefits. Already growing numbers of farmers in the South are receiving higher prices and more long-term security by selling their products into environmentally friendly or fair trade markets in the North. Consumer demand for organic products is gradually increasing in responding to concerns about the environmental and health implications of industrial agriculture.

New opportunities in a growing market

Latin American producers have been quick to tap into these markets. The organic sector in Mexico, for example, is now estimated to be worth US$ 500 million and Argentina is making serious efforts to develop its organic sector with sales rising from US$ 1.5 million to US$ 20 million in the last six years. This rapid development has been supported by efforts to overcome the bureaucracy surrounding EU recognition of imported organic goods. By requesting equivalency status for its certification system, Argentina became the first developing country to obtain a place in the EU provisional list, thereby gaining market advantages.

Partnerships are needed

Organic certification can be a slow, laborious and relatively costly process and a particular challenge to smaller producers. A common solution is to form co-operatives to share the load. In Uganda, for example, the Lango Co-operatives Union has made the transition to organic cotton production with the support of the Swedish International Development Agency (SIDA). SIDA provided technical assistance, organised crop finance, and ensured organic certification. It also supported the training of local certifiers thus reducing the cost of third-party inspection. The way prices were set was another innovative feature of this project. Before conducting business, all partners in the chain list their costs and claim a fixed margin based on open books. A fair trade organisation then looks for the best possible price on the market. Any excess funds are paid out to the producers, either as extra premiums or as development fund contributions. For the 5,500 farmers involved in organic cotton production in Lango, this has meant a 20% average increase on farm gate prices.

Links between members of the supply chain has meant that Lango solved one of the major problems facing Ugandan exporters: banks that refuse to pay crop finance. With the help of the Dutch government, the project received a loan, at commercial rates, and SIDA arranged that risks were covered by the Dutch HIVOS/Triodos Fund that provides funding for environmental and social projects in developing countries.

Another organic cotton partnership that has paid dividends is that between the Swiss cotton trading company Remei, and Maikaal Fibers, a spinning mill in Madhya Pradesh, India. Eighty-five villages produce cotton for Maikaal, which is certified by a Swiss company. The project guarantees to buy cotton and provides extension services, interest-free credit and a price premium of around 20% An estimated three-quarters of the cotton is sold through the Swiss Co-op, which launched a new range of clothes - Natura Line - in 1995 and aims to be entirely organic by the year 2000. It should be noted that the Co-op has kept the price of Natura-Line products at the same level as conventional brands, despite the premium price paid to cotton growers.

Action for Fair Trade

Fair trade organisations have been working with Southern producer organisations for decades to try and ensure that they receive a decent income for their work. Only recently, however, have fair trade products begun to reach mainstream Northern markets.

Coffee is probably the most successful fair trade product. It is also the most important traded commodity after oil and the main export for many Southern countries. Most comes from family-owned farms in developing countries. Fair trade organisations work with the producer organisations, promote the sale of fair trade coffee, monitor buyers and roasters and guarantee that labeled products meet fair trade criteria. The ethical trading organisations bear the costs of inspecting producers.

The fair trade market was boosted by the development of recognisable fair trade marks awarded for products that met clear criteria. However, it was the development of a clearly recognisable brand, Cafedirect, that brought fair trade coffee into mainstream retail outlets and within easy reach of consumers. Cafedirect was developed by a partnership of four fair trade organisations that bought coffee from 14 producer organisations in Africa and Latin America. Sales have increased dramatically over the last five years and Cafedirect controls 3% of the roast and ground market and 2% of the instant market in the United Kingdom despite being 10% more expensive than most conventional brands.

As well as higher income and greater security, fair trade can also lead to environmental benefits. Fair trade organisations often work with producers to improve the ecological sustainability of production.

Serious barriers

Small- and medium-sized exporters often face serious capacity constraints in responding to the challenges presented by sustainable trade. Conventional trade barriers in the industrialised world, such as restrictive trade policies in the agricultural and textile sectors, perverse subsidies and bureaucratic regulations are also serious barriers to Southern producers. Partnership along the product chain is essential in overcoming these problems. NGOs, government agencies and buyers in the North can all play an important role by providing technical or financial assistance, long-term security or in helping to develop producer organisations. Positive policy choices also help expand sustainable trade opportunities.

Governments in industrialised countries should ensure that policy making processes are transparent to exporting countries and that new regulations are phased in such a way that producers have time to make the necessary changes. Whilst Northern governments could play a much more proactive role in developing the market and improving access for sustainably produced goods, governments in developing countries can do much to promote sustainable trade by integrating environmental factors into their export promotion strategies.

Fair trade and trade development

Bert Beekman

'Fair trade' covers a wide range of ideas. The Fair Trade Commission in the UK monitors fair competition between market operators and companies. Those who follow its Code of Conduct and comply with local labour laws are, by definition, engaged in fair trade. In this article, however, fair trade is seen as a conscious decision to help small producers in the Third World become viable exporters of their own produce and to support their learning process. Fair Trade does not mean, however, that other forms of trade are unfair.

Fair trade, of course, is not limited to agricultural commodities and agricultural producers. All disadvantaged producers of any marketable product fall within the definition of the fair trade movement. In practice the fair trade labelling movement and organisations such as Equal Exchange in the USA and ATJ in Japan are mainly concerned with coffee, cocoa, tea, bananas, honey and sugar. The older alternative trading organisations work on a smaller scale and deal with thousands of food and non-food products. In this article we focus on small, co-operatively organised, agricultural commodity producers.

Small farmers disadvantaged

Major international agricultural commodities are frequently produced by small farmers who have no secure title to land. Their land holdings are small and they are unable to assert their civil and economic rights even when these are protected by law. Their access to market often depends on long and exploitative chains of intermediaries. Not only do they lack bargaining power, they have no access to information on world market prices. It is difficult for small farmers to acquire the technology and technical skills and the cost of financial services are frequently beyond their reach. As many farm in fragile, near subsistence economies, their choice of survival strategies are not necessarily rational from the economic and ecological point of view. Due to imperfections in the market, lack of transparency and politically inspired distortion, small farmers tend to receive lower prices for their produce.

Addressing the dilemma

There are many reasons why the problems of small farmers should be addressed. First, maintaining and boosting the economic viability of smallholdings puts a brake on migration to overcrowded cities incapable of offering employment alternatives. Second, creating an effective economic and institutional environment makes it possible for people to exploit the market potential of their area. Finally, supporting farmers initiatives by encouraging co-operatives and associations enables them, collectively, to gain fair access to the (world) market: trade is better than aid. In recent years, fair trade labelling has increased the effectiveness of such interventions.

Aims of fair trade labelling

Fair trade labelling aims to develop market niches where newcomers to the world market can learn the ins and outs of this type of trade in a relatively protected environment. In doing so, it tries to provide small farmers' organisations with fair access to the (world) market, under conditions appropriate to their needs. The movement also supports farmers' organisations in their attempt to secure working capital and long-term loans for investments, market information, communications, management support and technical assistance.

Promoters of Fair Trade

Over the years, alternative trading organisations have promoted fair trade through specialised chains of (Third) World shops. The movement began about 30 years ago in the Netherlands and the *Fair Trade Organisation* is still one of the most dynamic organisations in the field. Today, trading organisations are found in almost all industrialised countries and most of them share suppliers' databases.

In the eighties, the movement stagnated. World Shops could not cope with the demand for markets coming from Third World suppliers. Mainstream distribution networks had to be accessed and pressure built up to professionalise the network of World Shops. This lead to the development of fair trade certification and labelling. The model was first developed and tested in the Netherlands under the name Max Havelaar. Later it spread within and outside the European Union until today certification

Small-scale ecological coffee farmer in Jalapa, Guatemala.

and labelling is carried out in some 15 countries. Some use the name 'Max Havelaar', others have chosen names and labels that reflect their own national and cultural identity. However, all are members of Fair Trade Labelling International.

Coming up to standard

National fair trade labelling organisations own their label and defined the conditions under which producers, traders and industry acquire the right to use the fair trade label in their commercial promotion. Royalties have to be paid to the labelling organisation when labels are used and these are used to cover operating costs. Fair trade regulations vary from organisation to organisation. In principal, however, there are a number of fundamental conditions. Third World producers and exporters have to be democratically organised and exert effective democratic control over their management. Their products must be up to international standards in terms of quality and quantity and they must be accountable to the labelling organisations.

Buyers and importers using Fair Trade labels have to comply with certain conditions. These include giving their suppliers secure market access; enabling them to build effective and sustainable commercial relationship; paying them a premium over current market prices and guaranteeing a floor price that effectively covers both direct and indirect production. In addition they must ensure that their suppliers have access to credit facilities so they can finance their commercial operations.

For its part the labelling organisation must define and adapt the fair trade criteria, enforce and supervise the rules of the game, maintain a register of authorised producer organisations and buyers, and maintain an environment that allows the system to work effectively. It is also responsible for profiling and defending the public authority and credibility of the label and promoting labelled products. Most importantly, the labelling organisation remains accountable to the consumer public and must retain their confidence. Fair trade rules exist for many major Third World agricultural commodities including coffee, cocoa, tea, bananas honey and sugar. Regulations for orange juice and nuts are being drawn up.

Ten years fair trade

Fair trade certification has helped bring fair trade products into mainstream European distribution networks. Sales of coffee and bananas have increased tenfold. Today, small farmers are able to sell 14,000 tons of coffee with a trade value of some US$ 40 million in this way. In the Netherlands the market share of fair trade coffee has risen from 0.2% to 2% and in Switzerland to 5%. Mechanisms and alliances have been created to make substantial amounts of short- and medium-term ethical bank loans available. While the impact of fair trade labelling appears to be unquestioned, its global impact should not be overestimated. In a global perspective fair trade is no more that a tiny niche market.

Although its impact is growing, results have been reached under very special market conditions and at a time when world market prices were persistently below subsistence level. Under these circumstances, fair trade offered a valuable alternative to those who had their name on the Fair Trade Labelling Producers' Register and who had secured an outlet for their product. However, not all organisations used (were able to use) this opportunity to effectively develop the capacity to survive under 'normal' market conditions. In 1994, coffee prices on the world market started to return to 'normal' levels, i.e. above the floor price established by the fair trade labelling organisations. For many farmers' organisations, the price premium of US$ 0.05 per pound above the market price was insufficient, while the inflexibilities inherent in the fair trade model eroded a substantial part of the price premium. A growing number of farmers' organisations who had been operating within the fair trade market ran into serious trouble despite higher-than-market prices, while others managed to survive and went on to develop into strong and respected co-operative organisations, addressing the economic needs and rights of many thousands of small farmers and their families.

Photo: Bert Beekman

To operate on the world market, small farmers need to co-operate. Co-operative of small coffee farmers Marcala, Honduras.

Critical factors

It would seem that in some cases fair trade procedures have not been adapted to the operational needs of farmers' organisations, especially under present unstable market conditions. In addition, the fair trade labelling organisations have not paid sufficient attention to the development and organisation of the necessary management support services. Management is also a critical factor at farmer level. The minimum scale of operations needed to run an export business is far beyond the scope of small and often isolated farmers. Lacking the management skills needed to operate the business, they have to hire in managers over whom they may have little control. If there is no effective control and accountability is not enforced, the temptation to address private interests above co-operative interests can be irresistible and leads to serious problems. In this way a vicious circle develops and the co-operative is excluded from credit and loans because it has become uncreditworthy and its commercial liability has been further compromised by inadequate quality control.

Many co-operative organisations, however, have successfully exploited the opportunities of the fair trade market and built up and diversified their businesses to the benefit of their members. Critical success factors seem to be the availability of highly competent and reliable management, sustained management support, and market diversification into conventional, fair trade and organic markets.

Challenges

There are several major challenges facing the fair trade and organic market. A strategy must be developed to facilitate the merger of ecological and fair trade criteria incorporating social fairness and ecological responsibility as preconditions for sustainable production. Criteria must be adapted to the operational needs and limitations of Third World realities and international markets. At the same time the management and information gap must be closed and a solution found to the recurrent problem of credit. It is clear that the certifying organisations cannot solve these huge problems on their own. Strong global alliances with trade and industry, development organisations, ethical (and conventional) financial institutions, universities and consultants are needed in order to build a system that works and hence challenges 'business as usual'.

The organic market
opportunities and challenges

Photo: Bernward Geier

Bio-café stand at IFOAM café conference, Chiapas, Mexico.

Bernward Geier

The trade in organic products is growing rapidly and becoming a reality throughout the world. Growth rates in the sector show organic products, that a few years ago supplied niche markets, have now entered mainstream marketing channels. Already 30,000 organic farmers are certified in Italy. In Scandinavian countries like Sweden and Finland and in Switzerland some 8 % of farming is (certified) organic. Austria leads the world with 10 % organic farming and in some Austrian provinces such as Salzburg and Tirol, the proportion is almost 50%. Although some in the organic movement might question whether we are straying from the path of 'healthy natural' growth, it cannot be denied that we are heading for a boom.

Respected organic market analysts, such as Professor Ulrich Hamm in Germany, have forecast an annual growth rate of between 20 to 30%. In some countries this might be as high as 50 percent. The largest organic trader in the UK predicts that the organic market world wide will increase from US$ 11 billion to US$ 100 billion over the next ten years with the USA, Europe and Japan leading the way. In this context, Denmark's plans to make organic products account for 20% of the total domestic food market by the turn of the century seems far from being a green dream.

Farmers in North and South are asking how they can take advantage of this growth. The export opportunities offered by the so-called developed world have clearly been a major stimulus in getting organic farming established in many countries. It is unlikely that organic agriculture would have developed so successfully in the northern hemisphere if there had been no demand pressure. Supplying a market in which demand outstrips supply is a producer's dream. This has been the case with organic farming for a long time and figures show that this trend is set to continue. Yet, the sector has shown it is also vulnerable and that prices can collapse if there are sudden and exceptional increases in the supply of particular products. Therefore, marketing with a clearly targeted strategy is a must for organic products. The organic market is a special one, partly because premium prices are involved. It requires a special effort. Attention should be given to meeting the requirements of a guarantee system that will ensure organic quality and allow consumers to develop their preferences for organic products with a feeling of trust.

Setting up a guarantee system

The first pillars of this guarantee system are the organic standards, rules and (governmental) regulations that clearly define the practice of organic farming. From the beginning, the organic farming movement has been more than a set of ideas. It is firmly rooted in a normative description of farming in harmony with nature.

Standards, whether international, regional or linked to a specific philosophy, are not intended to be a handbook for farmers working in the field. Indeed they make rather 'dry' reading. What they do provide is a guide to organic production and the means to develop a truly ecologically sound farming system. They define our systems and technologies and give us a huge advantage as we face the urgent need to distinguish organic farming from 'half-way approaches' such as integrated pest-crop management. Standards are not simply a collection of prohibitions describing what is not allowed in organic farming. Standards reflect clearly the positive approach and definitions of organic farming by emphasising what ought to be done in order to farm organically and stressing the avoidance of synthetic chemical substitutes that have lead conventional agriculture to its present 'dead end'.

Implementing organic standards requires inspection. A body that is independent of standard setting and control should evaluate facts and findings and where farmers and products are shown to have complied with organic standards, it should be able to issue a certificate confirming a product 'certified organic'. A logo or seal that functions as a trademark is used to translate this into a statement of quality that the consumer can understand.

It is still a fact of organic life that a lot of product inspection and certification carried out in the southern hemisphere are done by institutions based in the North. However, efforts are being made in many parts of the world to develop regional and national organic product guarantee systems. Such systems not only reduce costs but also give organic producers in the 'developing' world more independence and self-control. IFOAM (see page 16) and many of its member organisations actively support this decentralisation strategy.

However, even if regional and national guarantee systems are established, there will still be a need for producers to work in close co-operation with certification programmes in the North if products are to be exported to these markets. I estimate that, world wide, there are about 300 organic trade marks on the market. Few consumers have an overview of this 'seal jungle'. There is an obvious need to establish international 'control' and supervision of organic certification. Therefore, IFOAM has established an accreditation system for certifying institutions where, on the bases of mutual recognition, it is possible, for example, to allow licensing agreements.

Co-operation with partners

Knowing the rules and working with them is not sufficient to bring an organic product successfully onto the export market. Partners are needed to take care of such matters as shipping, processing, and ensuring trade is well organised. Besides the usual information on transport logistics, custom regulations, tariffs and price mechanisms necessary in exporting any product, trading within the organic sector requires a particular type of knowledge. Most of this cannot readily be found in the literature on economics and marketing. Perhaps one of the most effective ways of developing an understanding of how the organic market works is to attend one of the several international organic fairs. The most international, prominent and by far the strictest of these 'organic' fairs is the Biofach which takes place in Germany every year (p 16).

A number of donor organisations including SIDA and GTZ and development agencies in the North have established promotion and training programmes to foster export opportunities for organic products. These projects have already helped to encourage producers in developing countries to enter the rapidly growing market for organic products.

Challenges and traps

The global market in organic products was foreshadowed by the export of grain and soya from the US to Europe in the 1960s. Over the last ten years organic products have been marketed in increasingly larger quantities outside the area in which they are grown. Whilst seasonal production and regional markets remain an important objective in organic farming, there is nevertheless plenty of export opportunities for such products from the South as coffee, tea, cacao, bananas, spices, herbs and other subtropical and tropical products.

'Ecological dumping' is becoming more common and is a practice strongly resisted by the organic movement. There is a very real difference between production in keeping with the holistic principals of the organic movement and the purely commercial production of 'natural', 'biological', or 'organic' products such as organic cash-crops in monoculture. It is not enough to exclude what is known as 'ecological dumping' from the organic sector. Given the holistic nature of our movement, we also care about social aspects. In joining forces with the Fair Trade movement we also hope to be able to seriously challenge the 'social dumping' that involves the exploitation of cheap labour and child labour.

The danger of bio-colonialism

'Bio-colonialism' is one of the major challenges facing the organic movement. Given the much greater economic wealth and 'buying power' of the North, many products of organic quality find their way into these premium markets and so become unavailable to local and regional populations. Much more effort and creativity is needed if organic food is to become accessible to more people throughout the world. The SEKEM initiative (p 5) is a good example of how this can be achieved. Community supported agriculture with direct links between producer and consumer, in Japan and Asia known as TEKEI (see ILEIA Newsletter Vol 10 No 1 1994), offer a way of getting out of the bio-colonialism trap. Today, there are organic shops in India and Malaysia, farmer markets in Brazil, and organic produce in supermarkets in Argentina. Box schemes and home delivery of organic products are also being set up in several southern countries.

Very often organic farming systems begin with the production of 'cash crops' and gradually, with the knowledge gained in producing for export, the whole farming unit is converted to organic systems. Thus, planting shadow trees in coffee plantations and using compost is often followed by introducing organic methods into the cultivation of staple foods such as corn and beans.

About prices and fairness

Fair trade is always associated with production in the developing world. However, we need fair and real cost covering prices for farmers all over the world. And here the organic market has something to offer all farmers. Organic production often requires more effort and may result in lower ('optimum rather than maximum') yields. Also, as millions of consumers all over the world have come to realise - 'nature has its price'. Therefore, growing numbers of consumers are prepared to pay premium prices because they know they are getting premium quality products in return. In calculating the price of organic products more factors are involved than in the pricing of conventional products. Demand, for example, plays a much bigger role. The complex of aspects involved makes it difficult for us to discuss price finding and setting mechanisms in the organic sector here. However, we can say that premium prices ranging from 20% to 30% seem to be normal and, when combined with often higher fair trade premiums, they make it possible for small farmers to continue to work their land, feed their families and enjoy real development.

Beginning a new lifestyle

As we have seen, the booming development taking place in organic farming and marketing offers many opportunities. But there are challenges as well and these have to be faced. However, if we do not give up our holistic principles, we will be able to go on contributing to the establishment of organic production systems. And this could lead to changes in life style and consumption patterns that will reach far beyond food and nutrition.

Agricultural trade, opportunity or trap?

Editorial

There has always been agricultural trade. Trade remains a necessity whether it is barter between neighbours or long-distance trade facilitated by money. Trade makes it possible for households to supplement their own production and satisfy their need for food and money whilst exploiting comparative advantages. In this century, there has been an enormous expansion in trade supported by cheap fossil energy, agro-chemicals, refrigeration and increasingly sophisticated forms of transport. At the same time, the buying power of urban populations in both the North and South have combined with trade liberalisation and globalisation to give a powerful stimulus to markets everywhere.

This trade expansion has brought benefits to many agricultural producers and consumers. However, it has also been responsible for an uncontrolled concentration of power and wealth in the hands of a few countries, companies and persons, most of whom can be found in the industrial West. Control over capital and knowledge-intensive technologies, unfair trade practices including the dumping of cheap subsidised food and the manipulation of small farmers whose market choices are already limited have seriously effected small farmers everywhere. At the same time the capacity of industrialised countries to protect their own agricultural markets and the worsening terms of trade between agricultural and industrial products have also contributed to the decline and poverty of many agricultural communities. As small, market-oriented farmers lose out to larger farmers and the non-farming professions, and trans-national companies gain control over international commercial flows and agricultural production, many leave their land to search for jobs elsewhere. (Coote 1996; Reijntjes et.al., 1998).

This not only leads to an increasing gap between rich and poor but also to the loss of food security, ecological degradation, pollution and the decline of indigenous knowledge and cultural diversity. Market-oriented agriculture and agricultural trade can lead to a serious depletion of soil fertility, soil erosion and a loss of biodiversity. Agriculture under such circumstances is not ecologically sustainable.

However, agricultural trade and market-oriented agriculture do not have to be a trap for the small farmer! Fair and green trade offers important economic and ecological opportunities for sustainable development (Panayotou 1993).

Fair Trade

Alternative approaches are being developed in reaction to the free trade model. Since the 1970s, the Fair Trade movement has been developing fast (Beekman, p 8). Import organisations buy direct from Southern producer partners, pay a fair price and establish long-term working relationship. Initially, health food and Fair Trade shops were important alternative trade outlets. Today, however, Fair Trade products can be found in most supermarkets. Trade organisations that respect the principals of Fair Trade and accept external monitoring by labelling organisations, are awarded a seal (label) of approval. The fundamental principal of Fair Trade is equal partnership between Southern producers, Northern importers, labelling organisations, Fair Trade shops and consumers (EFTA 1998).

Organic agriculture

The demand for organic products from the tropics and within the tropics is growing fast (Geier p6; Robins and Roberts p10; Panyakul p22). This not only provides hundreds of thousands of farmers in the tropics with an opportunity to get a premium for their products, it also makes it possible for them to cultivate in an ecologically sound way. The International Federation of Organic Agricultural Movements (IFOAM) has formulated basic standards to define organic production. At the moment national market, trading and certification systems for organic products are being developed in many tropical countries (Geier p6; Beekman p8). Certification, whether from the Fair Trade or the Organic Agriculture Movement, is necessary to create confidence and trust. Not only does certification protect consumers from fraud, it enhances ecologically sound production and fair trade Sams p12).

High value products

Also the production and marketing of high-value, non-conventional, indigenous and local agricultural products such as medicinal herbs and traditional agricultural and non-timber tree products with specific qualities may offer small farmers and indigenous people, particularly those working in marginal areas, ways of increasing their income in an ecologically sound way. Overmars (p11) reports on the new production processes and markets being created in Brazil for non-timber tree products and Van der Meulen (p20) describes the potential of niche markets for local, traditional products.

Critical factors

However, to unlock the opportunities of international trade in green, fair and high value products it is very important for producers to find reliable partners who can take care of certification, financing, shipping, processing, marketing and distribution (Geier p6; Robins and Roberts p10). To be successful, the scale of trade operations has to be sufficiently large. This makes co-operation between farmers a necessity. However, a larger scale also

Photo: GK Upawansa

Local marketing of eco-products in Sri Lanka.

means that management becomes more complex and often the necessary skills are missing (Panyakul p22). According to Beekman (p8) the availability of highly competent and reliable management and sustained management support are critical success factors.

Toward a new protectionism?

Unless alternative approaches to trade become mainstream, the inequity and environmental damage inherent in conventional trading practices will remain unchallenged. Lang and Hines (1993) argue the need for a more appropriate economic framework to redirect the world economy towards sustainability. This is not a feasible option in the short-term. A more immediate approach would be a new type of protectionism in which governments formulate trade regulations based on socially fair and ecologically sound standards capable of creating enabling conditions for green and Fair Trade and for LEISA and sustainable agriculture in general.

Priority to local economies

Even if such legislation were to be adopted, it would not be possible to eliminate completely the negative social and environmental effects of international trade. There will always be an important group of farmers who are unable to compete on the (inter)national market and whose farms fall in the margins of the globalising economy. International trade is wholly dependent on fossil energy, itself an important source of pollution and, in this sense, (inter)national trade is inherently unsustainable. To avoid the environmentally unsound transport of agricultural products over long-distances and a risky dependence on distant consumers, sustainable development should focus on the development and protection of the local economy. Particular attention should be paid to marginalised peoples and guaranteeing ecological and cultural appropriateness.

Strengthening the local economy fosters a community's sense of social and environmental accountability, self-reliance, food security, cultural and biological diversity and the commitment to conserving its natural resource base. Delgado et al (p28) show how indigenous people in the Andes protect the cultural, ecological and economic integrity of their communities by sustaining barter - which as a system is probably more widely spread than officially recognised - as an important element of their economic and cultural system.

Strengthening local economies

In many communities economic activities function at an unnecessarily low level as money and local natural resources leak away into the wider market economy. Local exchanges of goods and services can be greatly enhanced by the development of local money systems. Ramada (p30) describes how a local money system has successfully stimulated the local economy in Argentina. Many local groups and communities in the North and in the South are currently experimenting with these Local Exchange and Trade Systems (LETS) (Douthwaite, 1996).

Although income from (inter)national green and fair trade can play an important role in strengthening local economies (Beekman p8), Upawansa (p26) rightly points out that the priorities of poor countries such as Sri Lanka should be to ensure that enough healthy food is produced for the local market rather than to struggle to access national and international organic trade. Lanting et al (p24) and Prakash and Nehru (p27) describe examples of successful initiatives to organise organic production and trade at the local level. Finding the right balance between local and (inter)national green and Fair Trade is crucial in the development of sustainable agriculture.

SEKEM in Egypt: bio-dynamic production and a way of life

The SEKEM farm in Egypt is situated in the desert near the south tip of the Nile delta, not far from Cairo. It was established in 1977. The total farm area is 55 ha, of which about 30 ha are under cultivation. Additional farms which supply products on a contract basis to the main farm cover about 500 ha. And this area is steadily expanding. The products are certified in accordance with the Demeter standards for biodynamic agriculture. The main crops grown can be divided into three categories: fruit trees, herbs and spices, and vegetables. A wide range of vegetables are grown for the Egyptian home market as well as for off-season fresh vegetable consumption in Western Europe. Spices and herbs are designed for both domestic consumption and exports. The farm also includes animal production.

From the very beginning SEKEM aimed at supplying local people with high quality organic food. SEKEM has contributed to getting organic production onto its feet in Egypt. It has established several organic shops in Cairo and delivers its products to about 7,000 pharmacies and 2,000 shops. In a tea-drinking country like Egpyt it is significant that certified organic herb teas from SEKEM are amongst the most popular in the country. Because of the success of the SEKEM products on the West European market, exports have now risen to 40 percent of the total turnover instead of the 10-20 percent planned initially.

There is little doubt that the SEKEM initiative is a show case of holism within the organic movement. Well-rooted in anthroposophic and bio-dynamic philosophy, all SEKEM's projects and enterprises have developed very rapidly. Today, SEKEM has more than 120 people in full-time employment and co-operation with over a hundred bio-dynamic farms marketing their products through SEKEM provides another 250 employment places for Egyptian men and women. SEKEM has also played a pioneer role in developing organic cotton production.

What began as a farm on sandy desert soil on the outskirts of Cairo, has now become a centre of cultural and social development. The SEKEM kindergarten and school provides education for 350 children some of who are handicapped. A health clinic provides medical care and a mobile ambulance station reaches those who are unable to get to the clinic. Art and culture within the SEKEM community are expressions of SEKEM's approach to life and the design of its building and the conditions and environment reflect these principals.

ILEIA research

Highlights Ghana

Photo: Huub Ruijgrok, Small World

Women farmers began trials to control the incidence of pests in stored cowpeas.

The Northern Ghana LEISA Working Group (NGLWG), a network of NGOs, research institutes and university and government employees concerned with agricultural development have committed themselves to a research and advocacy programme that will investigate the feasibility, sustainability and conditions for the further expansion of low-external-input agriculture in Ghana.

In 1997, PTD research began in two areas, Langbinsi and Sandema. Two villages were chosen in each area and, in each village, with the assistance of Working Group members, the NGO took the lead in organising a problem analysis, identifying possible actions and in implementing experiments. The majority of those farmers who participated recognised the need to maintain soil fertility and were willing to look for new options. Women identified storage pests - especially in cowpeas - as an important food security constraint.

About 50 farmers were selected by the village to participate in the soil fertility management experiments. These were designed to improve soil nutrient content by incorporating organic manure from local sources including cattle manure, household refuse and crop residues. Treatment with a phosphorus fertiliser was also included in the trial design because research at the Savannah Agricultural Research Institute and soil analyses at the Soil Research Institute had concluded that soils at the sites were deficient in P. At the end of the season farmers found that organic manure had lead to yield increases but consensus was not reached on the benefits of adding phosphorus. Farmers agreed that organic manure had been of benefit during the drought conditions that had prevailed during the growing season (with or without P). Farmers observed that P was an external input and, although relatively cheap compared to other inorganic fertilisers, it had to be bought. It was also difficult to get locally. Men and women farmers considered organic manure the best option and new ideas emerged about using compost in further experimentation (see Box)

After the harvest, women farmers began trials to control the incidence of pests in stored cowpeas. The treatments applied were all based on locally available substances one of which was an extract from the neem tree. Results of these trials will be assessed in May.

Apart from the PTD process other ILEIA research activities focus on understanding the agroecological, socioeconomic, cultural and policy environment of northern Ghana. A recent study commissioned by the NGLWG examined the development and transitions of farming systems from an historical perspective and concluded that "villages were getting poorer" because the natural resource base was becoming exhausted, there was soil erosion, a decreasing diversity of trees and grasses, tree and shrub cover was disappearing and grazing land was getting scarcer. It argued one explanation for this was not population pressure and decreasing rainfall as often suggested but the annual practice of bush burning. Another reason put forward was concentrating cultivation on fields near the homestead. This had lead to shorter fallows and more intensive land use.

A study was also commissioned to investigate how farmers tackle this 'man-led' depletion of natural resources. Individual farmers and, in some cases, entire villages came to the same conclusion: bush burning. Now, by restricting burning, many farmers have increased their yields, have made themselves more resilient to drought and are benefiting from the re-establishment of trees and grasses. They are also trying to find ways of using organic manure and of preventing run-off by building stone bunds. Many villages report that increasing numbers of farmers are adopting these practices.

In Langbinsi and Sandema collective participatory action by farmers, NGOs and researchers has provided useful lessons in collaborative participatory research. The assessments made of PTD experiments and the studies carried out by farmers and researchers will set the agricultural agenda in the coming months.

Farmers' visit Burkina Faso

In October 1997, fourteen farmers from the pilot sites of Langbinsi and Sandema visited their Burkina counterparts in areas less endowed with natural resources. The farmers visited north–eastern Burkina where mulching, integrated crop and livestock farming and composting have been adopted by many farmers.

When they returned they reported the innovations they had seen to a village meeting. Villagers were particularly interested in the practice of making compost from crop residues mixed with household refuse, animal dung and chaff. Some villagers have already started making compost pits. The awareness that organic matter is the key to improved soil fertility maintenance made them anxious to try out compost making. As one woman farmer said "It used to be easy to collect dung from my neighbours, but now everyone wants to use it for their own compost pit."

Improved forages benefits Ethiopian farmers

Cattle, sheep and goats are vital for Ethiopian agriculture. They feed mainly on crop residues and harvested fields but this forage cannot satisfy their needs. They do not produce as much milk and meat as they could, and the oxen are sometimes so poorly fed that they have little strength. In order to improve animal performance, high-quality forage is needed. The Ministry of Agriculture's Fourth Livestock Development Project (FLDP, 1987-94) focused on forage improvement strategies suitable for smallholders. The strategies reported here come from Bihar Dar District, in West Gojjam Zone, which lies close to Lake Tana. Lying at an altitude of 1700 to 2300 metre. It has an annual rainfall of 800-1200 mm most of which falls between June and September. Average farm size is 1.5-2 ha. About 95 % of farm households keep about 3 head of cattle as well as some sheep and goats. In terms of better animal nutrition, higher livestock yields, enhanced soil fertility and erosion control, results of forage strategies are promising. Multiplication of forage legume seed has played a large role in this success.

Abraha Lemlem

Thousands of farmers in Bahir Dar District have established hedges of tall forage plants such as Sesbania sesban, *Leucaena leucocephela*, *Cajanus cajan* (pigeon pea) and *Pennisetum purpureum* (elephant grass) inside their farm compounds. These plants provide forage, shelter and fuelwood and are sown around the edges of the garden so they do not compete with garden crops.

A few farmers have also established mixed plots (50-100 m^2) of perennial herbaceous legumes in their backyards. Where space is very limited, they sometimes plant climbing legumes. Measurements made in farmers' backyards throughout Ethiopia showed a forage yield of 195 kg of dry matter (DM) per year from 50 m of hedge and 100 m^2 of herbaceous legumes (Alemaheyu et al 1987), with large variations between sites. In Bahir Dar, farmers' yields were 53-84 kg DM from a 50 m sesbania hedge and around 200 kg DM from a 50 m row of elephant grass, with one cut per year.

Change is gradual, but now 200 farmers in West Gojjam fatten their animals on improved legumes. They sell cull oxen at high prices using the cash, for example, to buy replacement stock. One farmer with dairy cattle fed on home-grown forage legumes gets up to 8 litres of milk per cow per day without supplementing the animals' diet with industrial by-products.

Undersowing

Forage legumes are sown under another established crop. The legume is usually sown after the final weeding of the main crop, but may be sown earlier if weeding is light or weeds are cut. The legumes are grown in crops such as maize, sorghum, barley, wheat or plantation crops such as coffee, and are grazed with the crop residues or cut-and-carried away with crop remains. In our district, the main food crop is maize, and the main undersown legume is vetch (*Vicia dasy carpal*). Under this programme, about 120 farmers now sow 60 ha.

Neither we nor the farmers have measured the effect of undersowing forage legumes on the yield of the main crop. According to researchers elsewhere in Ethiopia, yield is reduced by 5-15 %. At the Adet Agricultural Research Station, local *Trifolium* species were undersown in wheat. This gave slightly higher grain and straw yields than on the control plot, probably because of the increased soil fertility. In addition, these treatment plots also yielded legume forage.

Many farmers in the district say that undersowing helps to keep the soil *sibam* (fertile in Amharic) as well as boosting milk production. Ato Muluken Lakew, a farmer in Sebatamit Peasants Association, reported that his maize plants were yellow in previous years but had turned green because of undersowing. Some farmers make hay from the vetch.

Forage strips

These are narrow lines of forage established between arable crops and provide cut-and-carry feed, fuelwood, help reduce soil erosion and improve soil fertility. Forage is planted in bunds or on contour strips without bunds. Tree and shrub legumes are used for alley farming and shelter belts.

Some 170 smallholders have planted about 17 km of *sesbania* tree legumes around food crops. These trees are cut back during the cropping season to provide feed and reduce shade. Initial measurements showed annual yields of 75-100 kg DM per

100 m of forage strip (Alemayehu et al 1987). My own farm-level studies in Bahir Dar suggest that 200 m of sesbania shelter-belt around a 0.25 ha plot provides 200 kg DM with one cut per year.

Farmers prefer to plant forage as shelter-belts (*imballelie*). Formerly they grew eucalyptus and the oil crop noug (*Guizitea abysinnica*) around their food crops and to protect cash crops from livestock and wind. Shelter-belts provides forage, do not compete for land and, unlike other ways of planting strip forage, do not disturb normal cropping patterns.

Oversowing

A mixture of legume seed is broadcast on grazing areas without cultivation or fertiliser. This is a simple, low-cost strategy to increase natural pasture quality and productivity. Sowing roadsides from a moving vehicle is one way of covering a large area. In Bahir Dar, 200 farmers have oversown 25 ha and good results have been reported from degraded grazing lands. Farmers prefer *Desmodium intortum*, *Macroptilium atropurpureum* (Siratro), *Desmodium uncinatum*, *Stylosanthes scabra* (Seca), *Stylosanthes hamata* (Verano) and *Macrotyloma axillare* (Axillaris) for oversowing.

Farmers see little point in oversowing communal grazing land. They prefer to oversow the degraded natural pastures under their own control. Real benefits take two years to appear and some farmers do not have the patience to wait. They prefer oversowing herbaceous legumes rather than grasses, possibly because they see this improves soil fertility.

Seedling survival

Free-ranging livestock and drought are the biggest threats to seedlings. Fences and thorny branches are used as protection until plants are well established. By the end of the rainy season, they are strong enough to survive browsing and the long, dry season until they are harvested during the second rainy season.

Seedlings transplanted from the farmers' own backyard nurseries have a higher chance of survival than those obtained from MoA. The farmers can chose when they transplant their own seedlings and take greater care with preparing the site and watering.

Farmers' preferences and practices

Some farmers complained their animals did not like the new forages. However, MoA held farmer field-days and farmers experienced in the cut-and-carry feeding of stall-kept animals showed how this was done. As a result of these field days, many farmers began to get their animals used to eating these forages.

Farmers prefer the fast growing sesbania for hedging. It can survive in a wide range of soils and climates and provides a better shelter-belt in forage strips. It is particularly popular as a dual-purpose plant in coffee cultivation.

Another dual-purpose legume is pigeon pea. It is harvested as a family food and what remains after the harvest becomes animal forage. Elephant grass is also popular for hedges and, in fertile soils, it is ready for forage use at the same time as sesbania. However, it is more palatable and animals get used to it more quickly. Once elephant grass has been established, farmers can readily propagate it from cuttings.

Farmers prefer tree legumes to herbaceous legumes because trees provide more feed in times of drought. Farmers who produce seed for sale prefer stylo to vetch because it is more productive, disease resistant and fetches higher prices.

Some of the farmers are now experimenting with mixing cereal straws and green forages such as vetch, Desmodium and Rhodes grass (*Chloris gayana*), to get better forage use out of the straw.

Farmers' preferences among forage plants

Criteria	Preferred species in order of ranking
Early feed	Elephant grass, sesbania
Survival rate	Elephant grass, sesbania, leucaena
Fuelwood	Sesbania
Palatability (acceptability to animals)	Elephant grass, leucaena, sesbania, vetch
Ease to expand	Elephant grass, sesbania
Forage strips	Sesbania
Food + forage	Pigeon pea
Shade for coffee	Sesbania
Long lifetime	Leucaena, sesbania, elephant grass
Seed production	Stylo (Verano, Seca), vetch
Oversowing on severely degraded areas	Stylo species, Siratro, Desmodium
Resistance to grazing	Stylo species, Desmodium

Seed production

It is not feasible to meet the seed requirements of these various forage-improvement strategies by importing seed. The success of the forage programme depends on building up local capacity to supply seed. FLDP introduced a seed contract system to encourage farmers to produce high-quality forage seed at low cost and in large quantities. Growers are paid contract rates for clean seed.

In one year (1992/93) when the MoA provided herbicide (Triflan) free of charge, farmers produced stylo seed during the first rainy season. But now no herbicide is provided, they produce stylo seed in the second season. Some seed producers have started to sow stylo between rows of maize, so that they can harvest maize in the first rainy season and stylo in the second. The African bollworm, aphids and thrips were problems for farmers producing vetch. MoA offered them the opportunity to try insecticides (Malatione, Seven, Basodinek), initially free of charge. Farmers now pay for these inputs.

Toward local seed marketing

Farmer-to-farmer exchange of forage seed, seedlings and cuttings is developing. Farmers who have started to collect seed from their own forage trees or legume plots no longer ask the MoA for seed. There are signs of self-sustainable seed production. Development agents encourage this by telling farmers that MoA will only provide free seed once. We hope that this strategy will gradually lead to the creation of a local market for seed and planting material.

Women grasp the opportunities

Many women heads of household have also started to grow sesbania for shelter and fuelwood. The Ministry of Social Affairs recently started a programme in our area to provide women with local, female goats. The programme also encourages women to grow tree legumes to feed them. In Bahir Dar this approach is just beginning but it has been very successful in other parts of Ethiopia.

Both women and men are finding seed production provides an interesting income. In our district 22 women produce stylo (Verano) which gives them an income of between 300 to 1000 birr. Women appear to be especially skilled in collecting and multiplying forage seed, and their earnings contribute significantly to the total cash income of their households. We now have three women development agents in our forage programme: one in forage husbandry and two in seed production. It is recognised that forage production and seed multiplication offer particular opportunities for women. ■

Experimenting within farmers' worldviews

Photo: Bertus Haverkort

Rukman Wagachchi of the Network for Agri-cultural revival in Sri Lanka (on the left) is taking part in a 'kem' with the shaman (on the right).

In recent years, much work has been put into understanding the products of indigenous knowledge. Many traditional, indigenous soil and water conservation techniques, ethnoveterinary practices, natural pesticides and intercropping have been documented, assessed and improved. ILEIA is one of the organisations following these developments. However, in documentation and assessment as well as participatory technology development (PTD) there has been a Western bias. Indigenous knowledge is being approached with concepts derived from contemporary Western science. Our comprehension of the concepts of life (or cosmovision) and the internal logic of indigenous knowledge and our understanding of the processes of indigenous learning, experimentation and the roles of the indigenous institutions is very undeveloped.

Bertus Haverkort and Wim Hiemstra

COMPAS (Comparing and Supporting Indigenous Agricultural Systems) supports the process of endogenous development. Compas consists of 13 NGOs and 2 universities in 10 countries in Asia, Africa, Latin America and Europe. COMPAS wants to be able to function as an open platform with members and activities at the regional, national and global level.

COMPAS has observed the sophistication with which indigenous people explain their reality. Farming, for example, is more than the bio-physical elements of seeds, soil and water and the economics of the market. It is placed in the context of a larger worldview in which the natural, social and spiritual are inextricable. Thus, farming involves the application of rules that reflect notions of a sacred nature, a spiritual world and a natural environment. For many traditional farmers, a good harvest and good health depend on a farming practised in harmony with the laws of nature, the regulations of the community and prescriptions of the gods and other spiritual beings.

Indigenous reality

Rural people often feel their indigenous knowledge and traditional institutions are neither understood nor appreciated. Outsiders are ready to disdain the non-material elements of their culture. Indigenous communities have learnt not to express their worldviews too openly. Indigenous knowledge is gradually disappearing. In many cases indigenous institutions have gone underground and indigenous knowledge is maintained, transferred and modified without being noticed by outsiders.

A peoples' understanding and description of their spiritual world is rich, diverse and structured. It is experiential and may be based on the teachings of visionaries (spirit mediums or shamans); it can be expressed in classical texts such as the Veda's (India), or in linguistic and artistic symbols. The spiritual world is seen as containing a creating force, there may be a polarity between good and evil and it is peopled with gods, spirits and ancestors. These spiritual beings may express themselves in nature and through living creatures.

There is no reason to romanticise traditional cosmovisions. It cannot be concluded that indigenous cosmovisions and traditional practices have always been effective in preventing overexploitation of soils, overgrazing, deforestation, water pollution, erosion and environmental disaster. Nor have they always been able to maintain social stability and equity.

Joining endogenous development

For (non)governmental development organisations to be effective, there is a need to take part in endogenous development. This is development from within the local culture, based on changing local conditions, resources, cosmovisions, knowledge, objectives and values. This implies a good understanding of the evolution of local culture and the characteristics and dynamics of the local knowledge system and cosmovision. There should be respectful cooperation with local (traditional) leaders and communities and an appreciation of the potentials and limitations of the resources for agriculture, health and nature management available locally.

From in-depth case studies and intercultural dialogues, COMPAS partners concluded that a focus on rural people's cosmovisions can help re-connect the work of development agencies with rural people's indigenous knowledge. Farmers interpret (agricultural) development within their cosmovision. This cosmovison is the context within which they define their relationship with outside agencies and make decisions about the technologies to be used and production strategies to be followed.

Development organisations are being challenged to go beyond validating indigenous technical knowledge. Farmers' concepts of life - and the agricultural practices derived from them - are dimensions of reality they must relate to even though they may not fully understand them. Developing a climate of mutual trust requires learning, South-South exchange and an objective approach to Western knowledge.

Second Phase of COMPAS

The second phase of COMPAS (1997-2002) will take the documentation of indigenous cosmovisions a step further. Fifteen partners will seek to:

- strengthen the cultural identity of local populations by a joint assessment of cosmovisions, indigenous institutions and farmer to farmer exchange;
- develop approaches for strengthening endogenous development;
- conduct local experiments with farming methods that are based on local concepts and traditional institutions;
- network with other organisations at national and regional level and train field staff in approaches of endogenous development.

Exchanges will also take place at the international level through workshops, newsletters and visits. COMPAS seeks to find the best combination of knowledge and practices from (non) western sources appropriate for specific ecological, cultural and knowledge contexts. This means taking into account cultural and spiritual sources of knowledge still present or which can be reconstructed.

During a workshop in February 1998, the partners elaborated a framework for their approach. Considerable attention was given to the issue of local experiments carried out within farmers' worldviews. It was concluded that such experiments were important to test the effectiveness and relevance of local practices, to improve local experimental practices and skills and to develop a theory which could explain the effectiveness of indigenous technologies.

Cultural and spiritual dimensions

Most of the steps used in PTD were considered relevant in designing the framework. However, a further step was taken. The cultural and spiritual dimension was integrated into the experimental design and it was decided to seek the cooperation of spirit mediums, traditional religious leaders, local healers and elders.

Examples of parameters for experimentation include the use of time-frames that respect ritual and astrological calenders; show respect for sacred places and animals; incorporate sociocultural issues such as taboos, totems, class and caste and draw on spiritual elements indicated by spiritual leaders showing respect for ancestors, dreams and visions. These parameters involve both qualitative and quantitative data. In this process, the field worker must have an open attitude and be ready to learn from indigenous' epistemologies.

Work of partners

Partners in Sri Lanka described traditional worldviews where the power of sound (mantras), symbols (yantras), auspicious times (astrology) were presented by traditional leaders. These powers play an important role in agriculture and are 'managed' by traditional spiritual leaders who perform '*kems*' (rituals) at farm levels (see Box 2 *Agnihotra*). In India, unlike Africa and Latin America, classical knowledge has been preserved in a literary tradition. Veda's are centuries old texts, some written in Sanskrit, dealing with religion, health, agriculture and other matters (see Box 1). The *Ayurvedic* approach to health is practised in hospitals and universities but in agriculture, this stock of knowledge has systematically been neglected. Some COMPAS partners (FRLHT, KPP, CIKS, GREEN) are collecting and studying these classical texts and using them to design farm-level experiments. In Zimbabwe, a COMPAS partner (AZTREC) works together with the traditional spirit mediums and village chiefs to include their knowledge and spiritual practices in nature conservation. In Bolivia, AGRUCO has reconstructed the cosmovision of the Andean people and is working together with the ancestral institutions to improve farming activities.

Farmers very enthusiastic

Kalyani Palasinghe shared her experiences on organising a farmers exchange meeting on spiritual agricultural practices in Galle, Sri Lanka.

"With the help of farmer leaders, I identified key people: those who have a spiritual function, knowledgeable farmers and Ayurvedic doctors. Also those who were simply interested in the subject were invited. The objective of the meeting was to discuss with resource people, to present to farmers the spiritual practices used in their own tradition and how spiritual leaders go about their work. In Sri Lanka, shamans carry out rituals to influence good crop growth using the enhancing powers of sound (mantras) and symbols (yantras). These rituals have to be performed at times considered auspicious by astrologers. The shamans has undergone an extensive apprenticeship, is inaugurated and lives a pious life. Shamans were asked to talk about the mantras they use, show some of the yantras and demonstrate a particular ritual. Other shamans were asked to make drawings of the rituals they usually performed so they could be presented to the meeting. My role was to prepare and facilitate the meeting.

We used traditional symbols and ceremonies to introduce the meeting. An oil lamp was lit, mantras were intoned, and

VRIKSHAYURVEDA or the science of plant life, by Surapala, tenth century. *Translated into English by Nalini Sadhale. 1996. Asian Agri-History Foundation, 47 ICRISAT Colony-I, Brig. Sayeed Road, Secundarabad 500 009 India. Order code: AHB 001.*
The original Sanskrit text of Surapala's Vrikshayurveda contains 325 verses about the importance of trees and agriculture. The part on agriculture deals with topics such as propagation and planting, soil and 'nourishment', 'ailments' and treatments. Further, three scientists comment on the texts. They reveal the broad agricultural knowledge base that existed in India centuries ago.
KPP in Southern India, one of the COMPAS partners, will design farm level experiments to test ancient knowledge and adjust it to present day conditions.

a ritual was performed. First, however, we asked participants if they would like to share. It is very important to search for the right resource persons. We also made a kind of healthy curative oil, a small demonstration whose applicability was immediately clear.

The farmers were enthusiastic. They sensed that in this way their knowledge, their culture and their spirituality was respected. The meeting lasted longer than usual. Farmers continued their discussions long after it had ended. Most of the participants wrote down the mantras and, in some cases, they recognised them from their parents day.

During the meeting drawings of spiritual practices were shown. They provoked so much reaction that we only needed to ask: What do you see on this poster, and do you think it is useful, to start a lively discussion. At the end of the meeting we asked farmers whether they would be interested in experimenting with some of these traditional practices. We got more than twenty volunteers and I promised I would help them experiment. I now need to define the methods for field experiments. My colleagues at the Ministry of Agriculture are surprised at the level of participation and the self-respect shown by the leaders. Nobody said it was nonsense. The idea was apparently well received and the idea of testing these traditional practices appealed to farmers and professional scientists alike."

■

Further information

We feel that the COMPAS approach is challenging and relevant. There is a great need to learn together, to inform each other and to have an intercultural dialogue on the different sources of knowledge present in cultures all over the world. A report of the February workshop and the names of COMPAS partners are available from the ILEIA Newsletter on request. Readers who want to share their experiences of indigenous knowledge or are interested in the COMPAS newsletter should contact:

Mr Purushottama Roa, an organic farmer in Thirthahalli, Karnataka, is preparing Agnihorta a traditional anti–pollution ritual. He has been performing this ritual on his farm for the last six years.

Agnihotra, an ancient fire ritual

Agnihotra is one of the rituals of the ancient Hindu religion and is used today in traditional farming and health care where it is known as 'Homa therapy'. *Agnihotra* brings and keeps life in balance. In Sanskrit agni means fire and hotra the offering of sacrifices. Agnihotra has a scientific as well as a spiritual dimension.

Fire in the Hindu tradition is a symbol of purity and is believed to improve the mind. *Agnihotra* must be performed daily by an elderly member of the household and involves burning, mantras and timing.

The ritual is performed in time to the natural rhythm of sunrise and sunset. A cow dung cake is burned in a pyramid-shaped copper pot. Then at sunset and sunrise a few grains of rice covered with ghee (butter) are burned as an offering whilst mantras are intoned. At sunset the evening mantra "I offer to Agni, this belongs to Agni, this is not mine" *Prajapataye svaha, prajapataye idam na mama* (I offer to Almighty Father, this belongs to him, this is not mine) is chanted. In the morning, the mantras *"Suryaya svaha, suryaya idam, na mama"* (I offer to the Sun, this belongs to the Sun, this is not mine) is used.

Those attending the ritual sit near the fire-pot until the sacrifice is burnt. Sacrifices are offered at the critical moments of sunset and sunrise to the cosmic energy and the life force (sun) and to their earthly representative fire. *Agnihotra* expresses man's gratitude to divine energy. Intoning *idam na mama* (this is not mine) at sensitive moments reflects a total submission to mother nature and generates a feeling of detachment from the idea of wealth. The cumulative effects of the mantra's vibrations and the vapours released during burning have a multi-dimensional impact on human, animal and plant life. Inhaling these energised gases helps restore metabolic equilibrium. Scientists observe that ozone (O^3) is created during the burning ritual which makes *Agnihotra* an anti-pollution ritual.

Comparative experiments have been carried out to test the impact of *Agnihotra*. These experiments have been reported in Madan and Manohar (1990). Dr. B.G. Bhujbal of Pune's M.J.P. Agricultural University has conducted experiments in germinating grape seed and rooting grape cuttings treated with *Agnihotra*. He reported that seeds germinate in 21 days whilst the control sample took 6 months to germinate. Cuttings treated with *Agnihotra* developed better roots than the control sample. Dr Ramashraya Mishra experimented with the germination and development of wheat plants. He compared the growth of plants treated with hotra, those grown in the traditional way, and those in a control sample.

Dr A.G. Mondkar, a microbiologist from Bombay, observed the therapeutic effects of *Agnihotra* ash when he successfully cured scabies in rabbits by applying ash for three days. This method is much safer than the Benzyl benzoate or Salicylic acid usually used.

Farmers' reports are also positive. Mr Bharamagoudra, an organic farmer from Dharwad District in Karnataka, India, uses *Agnihotra* ash to protect seeds from seed-borne fungal and bacterial pathogens. He treats his wheat, sorghum and chilli seed with *Agnihotra* ash before sowing and reports better germination, minimal disease attack and better crop quality. Mr M.N. Varkar started practising *Agnihotra* on his organic farm 11 years ago. He cured psoriasis and now uses *Agnihotra* ash as manure and to revitalise the soil.

Farmers' innovations in land and water management

In the semi-arid highlands of Tigray in Northern Ethiopia, generations of farmers have developed land-husbandry systems that allowed them to live under harsh conditions. Their systems involve physical and biological techniques of soil and water conservation (SWC) and integrate aspects of agronomy, livestock husbandry and forestry. Farmers continue to innovate and refine their practices. Local innovation can be a source of inspiration for more widespread development.

Mekelle University College (MUC), the Bureau of Agriculture and Natural Resources (BoANR) and other governmental and nongovernmental organisations in Tigray are looking for indigenous land husbandry innovations and see this as an entry point into Participatory Technology Development (PTD), in the second phase of a Dutch-supported programme 'Indigenous Soil and Water Conservation' (ISWC). The aim is to promote existing processes of improvement by recognising local initiatives, by linking innovative farmers with each other and with formal research and extension, by validating and disseminating successful technologies, and by supporting farmers and rural communities in their own experiments. This article deals with some of these farmers' innovations and the above programme.

Fetien Abay, Mitiku Haile and Ann Waters-Bayer

Tigray is an area of extreme land forms, with flat plateaux and lowlands separated by steep slopes and escarpments. ISWC works in the semi-arid highlands at 2000-2500 metres. Average annual rainfall is usually between 450-900 mm. The rainy season is June to September. Smallholder farms are between 0.2 and 1.5 ha. The soils are shallow, stony and of low fertility. Barley, wheat, teff, finger millet, field peas, maize and sorghum are the main crops and the land is worked with oxen and the *maresha* plough.

Seeking local innovation

Our inventory of indigenous innovations in SWC was carried out in Tigray's western, central, eastern and southern zones. Extension agents, university teaching and research staff and university students completing their 5 month practical period were involved. They observed local differences in practices and asked local people about individuals and groups who had discovered new ideas and experimented with innovations without the support of formal extension services. Attempts were made to identify both male and female innovators.

Integrated management of hill and farm

One example of a very creative innovator is Ato Haile Gebrehiwot, a 50–year old farmer in Western Tigray. Over the past 13 years, he has developed an integrated farm system that combines various innovations: revegetation with diverse indigenous species, moisture conservation and soil-fertility management, apiculture and improved farm implements. His farm has an average annual rainfall of 860 mm. He and the nine members of his family farm 1.25 ha of land. His main crops are maize, teff and fruit and he keeps 5 head of cattle, 3 donkeys, 5 goats, numerous poultry and an increasing number of bees. In Western Tigray, where farm sizes are larger than elsewhere in the region, he is seen a moderately well–off farmer.

Slope revegetation to reduce floods

Like most other farmers in his area, Ato Haile's land is frequently flooded and covered with silt and stones from a steep, treeless hillside above his home. In 1984, without external assistance and using only family labour, he started to build stone terraces on the hillside to control run-off. He collected seeds and the vegetative parts of various local tree, shrub and grass species and established them on the slope. The hillside is now a forest dominated by indigenous species and some more recently introduced fruit trees. Altogether there are 43 tree and shrub species, 5 fruit and beverage species, and 6 grass species.

The physical structures and soil cover have solved the problem of flooding, and from the vegetation he gets firewood for home use and sale. Moreover, the organic matter has allowed much water to infiltrate and this ensures moisture over a longer period which benefits his farm and homestead garden. He has deliberately planted bee-forage species amongst the vegetation because he wanted to expand his production of honey and bees.

The sale of bees is very lucrative so he developed a system to increase swarming frequency. First, he keeps the bees in a narrow hive fixed on an elevated pole or beam. He then exposes them to alternating cold and warm conditions, and does not harvest the honey produced. The bee population increases and in their discomfort the bees form new colonies in the small gourd hives he provides. These bees are sold at the local market.

New animal-drawn implements

To make it easier to transport heavy stones for SWC, Ato Haile designed and manufactured the *menkorkor* (Fig. 1) which is drawn by two oxen. It is a kind of wheelbarrow with a wooden frame supported on a wheel made by fitting together two spent bombshells. This is an example of using resources available locally and left over from Ethiopia's long war. A wooden shaft connects the frame to the oxen yoke.

He decided to plough with one ox to solve the problem of an unbalanced team of oxen. He thought that a plough drawn by a single animal would be useful for neighbours who only have one ox. He himself has two oxen and now he can prepare land for sowing more quickly because his family can plough two plots at the same time. He made a single-ox yoke to pull the *maresha*.

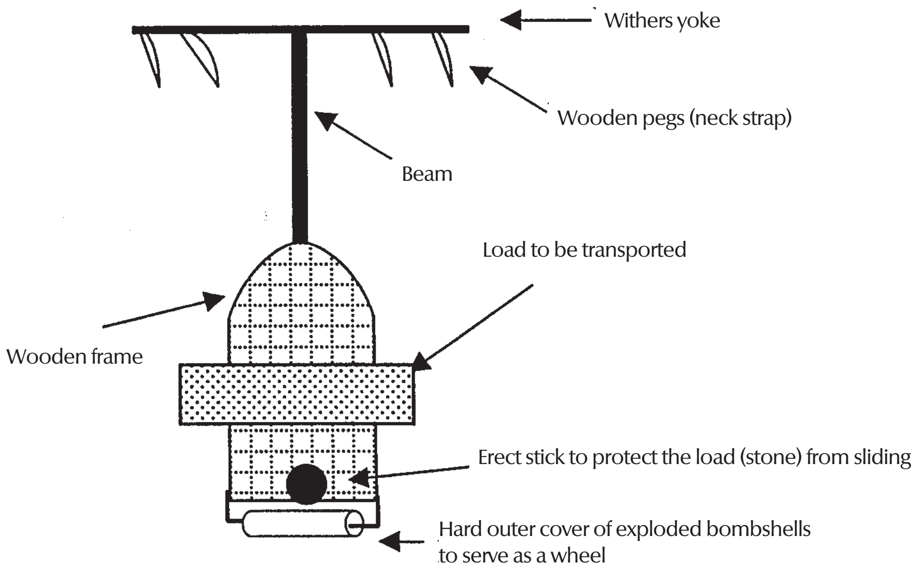

Figure 1. Menkorkor used to transport heavy loads

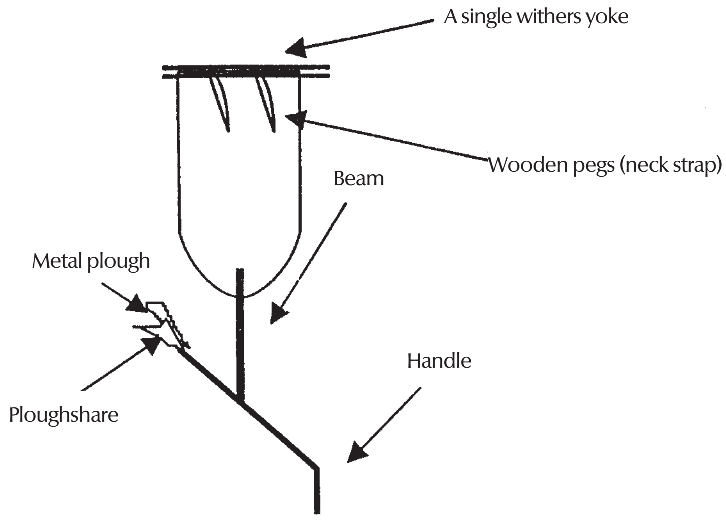

Figure 2. Single-ox plough

Generous dissemination

Ato Haile wants to promote his innovations. Hundreds of extension agents and farmers have come to learn from him about revegetation using indigenous species, bee-keeping and manufacturing improved implements. These visits have been organised by the BoANR and the Tigray Development Association. Ato Haile takes the lead in demonstrating and explaining his innovations. He lends his implements to other farmers, so that they can try them out for themselves. He also supplies the seeds of various tree species to interested farmers and gives them technical advice - free of charge - on raising and transplanting seedlings and establishing the trees.

He says that 13 years of experience proves his system is well-adapted to the environment and is effective. He has integrated SWC measures, crops, trees and livestock, including guinea fowl which he has domesticated from the wild. According to Ato Haile, his system will be sustainable if no deliberate man-made interventions disturb it.

Seeking new ideas

Ato Haile is keen to talk to scientists and other farmers about new ideas. For example, before he reforested the slope above his home, a gully had formed on his farm. Indeed, the gully formation ultimately motivated him to plant trees above it and on its edges. The gully is not getting worse, but now he would like to re-establish his field there, and would like to exchange ideas with other farmers who have successfully reclaimed gullies. He is also interested in trying out new plant species suitable for terrace stabilisation and animal feed, including tree fodder.

Innovative women

During the inventory, examples were found of women farmers who had observed and analysed the unintended effects of actions that were either a 'mistake' or originally meant for another purpose. They recognised the useful effects of these practices and developed them further.

W/ro Leteyesus Gobena is a 26-year-old woman who farms in Central Tigray, where annual rainfall is about 600 mm. Three years ago, after her husband died, she started ploughing on her own. In the Tigrian culture, where men traditionally plough, this is an innovation in itself. Leteyesus applied various traditional practices she had learned from her husband, such as sowing presoaked seed of maize and sorghum to accelerate germination, using the hoof action of small ruminants to work teff seed into the soil, and cultivating teff by ox plough between uncultivated strips (*terwah*).

During her first attempt at *terwah*, Leteyesus formed, unintentionally, some furrows on each side of the grass strips. She observed that the teff growing in the field with these furrows had a higher yield than the teff in her neighbour's adjacent, uniformly ploughed field. She recognised the utility of the furrows and prepared them intentionally during the next season's ploughing.

In order to gain even more benefits from *terwah*, she dug up sods of the grasses livestock preferred and moved them to the grass strips. She explained that the shade from the grass stops water from disappearing so quickly in the sun. In addition, she deliberately collects seed of grasses she finds useful for different purposes, including broom-making, to plant on the strips. In the second year, she cultivated where the enriched grass strips had been, and made grass strips lined with furrows where she had previously grown teff. She thus seems to have developed a system of simultaneous enriched fallow on her very small landholding (0.2 ha). In this high-population area of Tigray, the practice of fallowing has long been abandoned.

Infiltration pits

W/ro Azmera Atseba is a 38-year-old woman farming in an area of Eastern Tigray that receives about 450 mm rainfall per year. She sows teff, wheat, barley, sorghum and tomato in irrigable fields with a total area of 1 ha. In 1996 she followed instructions given by the Home Agent to dig a shallow pit in her backyard for garbage disposal. However, in the early wet season, the pit filled up with run-off water. Later in the season, there was not enough rain for the crops and most farmers in the area failed to harvest anything.

W/ro Azmera observed that the wheat she had sown near the pit in her backyard grew well, and she harvested more grain and straw from this area than from the other parts of her backyard farm, even more than in other years with better rain. She concluded that the plants grown near the pit benefited from the water stored there which had infiltrated the soil. The next year, she deliberately dug infiltration pits in her backyard and even in the fields outside. She harvested over 3 quintals from 0.25 ha. Before her innovation she would have expected no more than 1 quintal.

Difficulties in spreading innovations

It seems to be difficult for other farmers to accept women's innovations. Indeed, the very sight of a woman behind a plough raises the comments from some men that it will bring misfortune to the village. An additional problem is that many women farmers (household heads without husbands) are quite poor and cannot spare time from their work to discuss their ideas with others. Some farmers were impressed by the results of Leteyesus' infiltration furrows, and the local council asked her would she teach this to others. She replied that she must farm and think of new ways to get the most out of the little she has for her family's survival. She cannot leave her work without some kind of compensation.

More and more examples

This is only a small sample of the still growing number of innovations being discovered by researchers, students and fieldworkers in Tigray. Other innovations include:

- trapping silt and water in ephemeral water courses to create new land (see also Hagos & Asfaha 1997);
- reclaiming farmland from a river by constructing walls in the river bed and diverting the water flow
- distributing manure through water diverted into fields at points where silt traps were built into gullies
- changing the shape of unploughed strips designed to retain more water in a traditional community-managed irrigation system.

Men and women in Tigray experiment with using every conceivable resource available to them to improve their land-husbandry systems. They integrate physical and biological methods of water control, crop husbandry, soil-fertility management, livestock and manure management, plant introduction and selection, crop-residue management and agroforestry. Indeed, the innovations go beyond agriculture and include the use of wildlife. One farmer in Central Tigray, for example, uses manure of the wild *ghyhe* (hyrax) on his cropland. The *ghyhe* has the convenient habit of depositing its manure repeatedly on the same site; it is therefore easy to collect. Ato Abreha claims that it improves the fertility and moisture-holding capacity of the soil for up to 4 years and greatly increases his crop yield.

Promoting small-scale farmers' ideas

Data are still too few to be able to analyse differences in innovation behaviour, types of innovation attempted and spread of innovations according to gender, age and relative wealth. However, the initial data suggest that some women develop innovations that can be useful for both farm and household chores, and that communicating women's ideas more widely is a more difficult task than communicating those of men.

Extremely poor farmers, whether male or female, are finding new ways of making intensive use of local resources. Such innovations are of particular interest to very small-scale farmers. Other innovations discovered were developed by better-off farmers and need more resources than poorer farmers can invest. The richer farmers also have more time to teach others and can lend implements or donate planting materials. Ways must be found to compensate very poor farmers and help them share their ideas with others.

Generating enthusiasm

We publish information on farmer innovations in a Tigrigna language newsletter and distribute this to interested field staff, supervisors and farmers. T-shirts are distributed to workshop participants and as prizes for discovering farmer innovation: the picture on the T-shirt is of W/ro Leteyesus ploughing her fields.

We encourage researchers to make detailed investigations of the various innovations discovered by field workers, to assess their positive and negative impacts together with farmers and to work with farmers to improve their land-husbandry systems. In workshops in the field, the men and women farmers explain their innovations to governmental and nongovernmental researchers, field agents and programme managers. Joint on-farm experiments under the control of farmers, and in watersheds under the control of local resource users are being designed in the framework of PTD training workshops.

Farmers experiments will be complemented by studies and, where necessary, on-station research which will help explain or show how farmers' practices can be improved, and generate the information innovative farmers and communities need to continue development activities. As a result of these activities enthusiasm for local innovation and experimentation to improved land husbandry in Tigray is growing.

Vetiver, the super grass for water conservation

In the 1988 December issue of the ILEIA Newsletter John C. Greenfield reported on the use of Vetiver grass for moisture conservation in rainfed agriculture. This was at the beginning of a very successful worldwide effort to reintroduce the use of Vetiver grass (Vetiveria zizanioides) for soil and water conservation. Today it is an important grass used in stabilising engineered earthworks, land rehabilitation, and pollution mitigation. It is used in at least 60 countries and is promoted by governments, NGOs, and the private sector. In 1996, positive experiences with Vetiver grass resulted in the Vetiver Network being awarded the John Franz Sustainability Award for the best judged environmental technology. Nevertheless, there may be farmers, development workers or researchers who do not agree with this evaluation. ILEIA would like to invite them to write about their experiences with Vetiver grass.

Richard G. Grimshaw

There is overwhelming evidence that properly established Vetiver hedgerows will reduce soil loss to acceptable levels (< 3 tons/ha) and rainfall runoff by as much as 70% depending on slope and soil type. Soil moisture content is improved, and crop yields, particularly on shallow soils in dry years, have increased by as much as 30%. There is a clear correlation between Vetiver hedgerows and improved groundwater recharge. Where Vetiver leaves have been used as mulch on adjacent orchard crops (Jiangxi Province, China) there has been dramatic increases in soil organic matter (from 0.04% to 1.8% in two years, plus significant increases in N, P, K and other minor elements).

Evaluation results from El Salvador, Tanzania, and the Philippines show that about 80% of farmers who began using Vetiver technology continued to do so after three years. In Tanzania (HIMA/DANIDA project) 1600 farmers tried four different conservation systems (Vetiver, Napier and Guatemala grass hedgerows, and Fanya Juu terraces). 85% of farmers preferred Vetiver hedgerows because they were simple to make, are not labour intensive (in Madagascar farmers can plant 200 meters of Vetiver hedgerow in one day as against digging only 15 meters of Fanya Juu terrace), remain good for many years, and effectively reduce soil erosion. Farmers also see Vetiver hedgerows as improving runoff infiltration, and reducing runoff velocity. On well conserved farms production per unit area increased. Farmers indicated that Vetiver grows upright and causes very little disturbance to the adjacent crops; terraces are easily formed behind the hedgerows (30 - 40 cm in 2 or 3 seasons). Vetiver grows well under drought conditions, is rarely browsed by livestock, and can be used as thatch.

Few downsides

There are a few downsides to this technology. Because it is sterile, the grass can only be propagated vegetatively, this can be a problem initially, but after a few years a plentiful supply of new plant material can be obtained from dividing existing hedgerows. The question of its fodder value is also problematic. Farmers and researchers have provided evidence that if Vetiver is cut every three weeks most livestock find it palatable. If left to mature it is generally unpalatable.

Vetiver grass technology can be used by those small communities who want to take initiatives themselves without having to wait for a 'big plan'. Vetiner can be used without risk and without depending on 'officials' and formal institutional for support. The technology is simple and easy to disseminate and learn and cannot fail if applied correctly. User training is, therefore, essential.

Availability and multiplication

Vetiver grass is found in almost every tropical and subtropical country. If you want to find sources of Vetiver get in touch with the local Ministry of Agriculture research station, or the national herbarium. As it is used for medicinal purposes, the local medicine seller will perhaps know about it. You can also contact the Vetiver Network Once a source has been located the grass has to be multiplied in simple nurseries. One hectare from an average quality nursery will produce enough planting material annually to establish 100 - 150 km of Vetiver hedgerow.

The Vetiver Network

Since 1996, the Vetiver Network has helped establish and support five regional (Latin America, Southern Africa, West Africa, European and Mediterranean, and Pacific Rim) and four national networks (China, Thailand, Philippines, and Madagascar); and has supported some fifteen NGO's in Asia, Africa, and Latin America. The programme seems to be very successful and use of the technology is accelerating. ■

Transferred technology in a basket of options

In the Communal areas of Zimbabwe, the attitude towards soil and water conservation (SWC) is slowly changing. This article analyses experiences from a partnership programme for natural resources management, particularly SWC, in Zaka Communal Area. One important lesson learnt has been that technologies transferred from other parts of the world work surprisingly well. But adoption has only taken place after participatory awareness raising workshops, where farmers have identified their problems and have been encouraged to experiment with and adapt the technical options provided by the extension staff.

Søren Dreyer

Zaka District, in southeastern Zimbabwe, consists almost entirely of communal land. Subsistence farming is the main economic activity and the crops grown are maize, groundnuts, cotton, sorghum, millets, and sunflower. Soils are generally poor and sandy and population densities are more than 65 persons/km^2, which is very high for a mountainous, steeply sloping area with many rock outcrops.

Five years ago, the Danish NGO MS-Zimbabwe and Zaka Rural District Council went into partnership. With the objective of working with communal farmers to conserve natural resources. The idea was to introduce a range of options for SWC very different from the blanket contour ridging of the past. The programme has now been largely implemented by government extension agencies who felt strongly that a more participatory-oriented approach to extension was necessary.

Workshops for problem identification

Participatory workshops for both local communities and extension staff were organised to identify natural resource management problems. Villagers considered drought, soil erosion, deforestation, and reduced soil fertility as their main problems. Extension staff saw convincing farmers about the usefulness of contour ridges, avoiding cultivation on steep mountain slopes and providing solutions to the problems of reduced soil fertility as their main concerns.

Based on the results of these workshops, plans were made for a three-year programme. Options included Vetiver grass contour strips; Fanya Juu contours; infiltration/composting pits in existing contour drains; establishing woodlots with eucalyptus *ssp*. or indigenous species; planting orchards; the sustainable management of existing woodlands; intercropping and improved crop rotation.

Look and Learn Tours

The most efficient tool in introducing these technologies proved to be Look and Learn Tours. After the first demonstrations, we decided to let the transfer of technology take place not from technocrat to farmer, but from farmer to farmer.

Between 1993-95 quite a number of farmers participated in Look & Learn Tours to the nearby Makoholi Research Station where they were given some idea of the technologies available. These visits proved very valuable later when pilot activities were initiated in the district. Today, farmers visit pilot areas within the district in an environment similar to their own and where projects have been initiated by farmers like themselves. During the visits, farmers from the pilot areas explain in their own words what they have done, show how they have done it, and prove what they have achieved. After the tour, the visitors are usually very keen to start their own activities. Since most of the technologies are cheap and easy to use, they can get to work immediately. Supported by their local extension staff, they can, for example, start by establishing small forestry or Vetiver nurseries on their homesteads and at schools or by borrowing tools for digging mechanical conservation works.

Popular technologies

The programme is now in its fifth year and its success is clearly visible. One remarkable technology very popular with farmers is

Mr. P. Jacobs, at the far left, is converting his conventional standard contour bunds into vetiver contour hedges. Following his own ideas, he has planted the vetiver hedge just above the drainage channel (left), so that when the hedge is well established, he will destroy the drain and ridge which will release land for cultivation.

photo: Søren Dreyer

Vetiver grass (*Vetiveria zizanioides*), which the World Bank has been promoting for many years as conservation's 'miracle grass'. It is in great demand in Zaka. The grass is popular because of its low labour requirements and, when it is used properly, the speed at which results can be achieved. Women household heads are particularly appreciative of its low labour requirements, for labour in this area is a scarce resource.

Farmers have had surprisingly few problems in getting used to the concept of biological contouring (Vetiver grass strips). Mechanical contouring is still unpopular and considered to be very hard work. The Kenyan Fanya Juu system, another mechanical system, is also becoming more widespread because it demands less labour than conventional contouring.

A further success is infiltration pits, which are an improvement on existing contour ridges. Good compost can also be made in these pits during the rainy season. Thus, like many other SWC technologies, infiltration pits or *chibatamvura* have more than one function.

Many farmers have tried several of these options at the same time. For example, agroforestry plots protected by Fanya Juu contours with Vetiver strips to control rill erosion inside the plot or using Vetiver strips to control erosion in existing woodlands in order to provide a better environment for natural regrowth. Farmers themselves are deciding how to implement and combine these different technologies and in doing so take full responsible for the results.

Rain water harvesting costly

Rain water can be collected below a rock outcrop and stored in a tank to water vegetable gardens and fruit trees in the dry season. But not ever farmer can afford this expensive technology. The price of a simple rain water harvesting project with a 70-80 m^3 tank is approximately US$ 300. The programme has supported water harvesting amongst some farmers who have shown genuine interest in conserving their land. A few better-off farmers have started water harvesting projects without any programme support. It is hoped that villages or groups may later adopt water harvesting projects collectively.

Conclusion

A conventional and 'packaged-based' extension system does not seem to be able to mobilise farmers. In Zimbabwe with its long history of blanket recommendations and enforcement-oriented extension, the concept of participatory methods and the provision of options has much potential even if the technologies being transfered are not wholly indigenous.

A crazy family's model for land regeneration

When Gopalakrishnan and Vijayalakshmi bought their 16 acres farm, Sarang, in 1982, it was abandoned land, situated at about 800 m on the slopes of three hillocks. Agriculture was impossible: the land was denuded and eroded. The only source of water was drying up. Sarang is in the Attapaddy region in Kerala, India and is a man-made desert although it used to be full of dense rain forests. The government has invested millions of rupees in the construction of contour bunds for soil and water conservation here, but planted no trees.

The two teachers wanted to start an alternative school to prepare youngsters for farming. Subsistence farming would be an important part of the curriculum.

Photo: 'Shree' Padre

Sarang's forest regeneration after one and half decade. An oasis in the desert of Attappady. Mulching is an important method in natural farming.

They needed to regenerate their land. They reasoned "If deforestation caused water sources to dry up, wouldn't the reverse rectify the damage"? They sunk several percolation tanks and asked neighbours not to allow livestock to graze on their land. The question was how long would it take for the spring to be reborn?

'Mother nature' did her work! First grass like lantana became more abundant. Later grass gave way to small shrubs and trees. Gopala and Vijaya did not plant more than half a dozen trees on their farm and once there was no human or animal interference, forests started growing naturally. Birds and wind must have helped spread the trees. Six years later the spring was reborn! Several checkdams were built across the valley to hold back the spring water.

Today, thick deciduous forest covers much of Sarang. Dry leaves form a thick forest floor and prevent erosion and enhance percolation. Below this mulch, soft fertile soil is being rebuilt. Weeds like lantana and eupatorium, abundant in neighbouring farms, have vanished. When deciduous trees reached a certain height, evergreen trees like rosewood appeared.

Gopalakrishnan believes tilling, a method widely used, is unsuitable for these sloppy areas. Mulching is the technique they use. It retains moisture, controls soil erosion and facilitates growth of microorganisms. Green gram (a legume) is grown to enrich the soil. Today, Sarang has a good top soil which can reach depths of 30 cm. External inputa are zero.

Sarang contrasts sharply with the rest of Attappady. All the crops are rainfed. They grow millet, banana, elephant yam, pumpkin and sorghum. There is a variety of wild bitter gourd and tomato that is self seeding and grows with zero attention. Gopala and Vijaya are convinced that "Farmers have to adjust their taste-buds to what can be grown in the soil". Their farm is almost self-sufficient in food and vegetables, a rare achievement in Kerala where farmers aim to produce irrigated cash crops and end up growing deserts.

'Shree' Padre, P.O. Vaninagar, via: Perla, Kerala, India-671 552.

In Enugu State, southeast Nigeria, present day population densities of up to 400 persons per square kilometre and the limited availability of land for agriculture have encouraged intensified land-use practices such as dry season gardening. Parastatal controlled formal irrigation schemes, concentrating mainly on rice production, currently operate at only 20% of their capacity. Given the present economic crisis, government funding to rehabilitate these schemes is unlikely. Informal vegetable irrigation by smallholder farmers, however, is on the increase with many men cultivating these traditionally women's crops. This article focuses on the response of farmers to the problems of water and labour scarcity, and potential low-cost improvements that can be made to current water management practices.

Bridging gaps in water and labour supply

Anne Gobin, Paul Campling and Jan Feyen

In Enugu State, annual rainfall is between 800 and 2000 mm with a distinct dry season that lasts from November to March. Smallholder farming systems are predominantly rainfed with a focus on tuber-based crop mixtures and oil palm. Additional income is derived from small ruminants and poultry. Crop densities and the level of farm inputs decrease with distance from the homestead and are affected by land tenure status. Home gardens in the immediate vicinity of the house are individually owned and comprise multipurpose trees and shrubs, and a large range of annual crops and vegetables. The family/clan owned 'near fields' are located close to the settlements in an intensive fallow system associated with oil palm dominated forest. The 'distant fields' are located on communal farmland where tuber crops are produced in an extensive bush-fallow system.

Micro-scale irrigation is a minor but increasingly widespread activity in the region where 65 to 70 % of farmers have practised irrigation for 10 to 15 years. Farmers give preference to pepper, tomato, amaranthus, telfeiria and eggplant. Depending on the water source used, field sizes range from about 200 m^2 to 1000 m^2. Though practised on a micro-scale, the sale of irrigated vegetables, and particularly yellow hot pepper, provide an important additional source of income and can fetch high prices. The major production constraints for micro-scale irrigated farming are insufficient water supply for irrigation (91 % of farmers), labour and lack of money to pay for handwatering (72% of farmers). These expenses are often given as reasons for not starting irrigation.

Indigenous management practices for dry season agriculture try to tackle the problem of water scarcity and reduce the labour needed for watering. Depending on the location of the farmer's field in relation to a reliable dry season water resource, a distinction can be made between:

- Irrigated home gardens and nurseries located next to the homestead
- Irrigated fields located near perennial water sources such as springs and rivers

Home garden vegetable cultivation

Home garden irrigation involves the production of seedlings and the cultivation of small vegetable plots. Depending on the quantity of water available at the homestead, villagers will transplant some of the seedlings to a small homestead plot. Vegetable cash crops and/or seedlings are watered twice a day with rainwater stocks built up during the wet season and water purchased from tankers or carried home from often distant perennial sources. Household waste water is used to a limited degree but only in watering plots. The most popular system is to fill up an oil drum at the water source and water the plots either by sprinkling water by hand or pouring it over a broom.

A common strategy to reduce labour and water costs in pepper and tomato cultivation is to keep young plants in a fenced nursery covered with palm leaves for as long as possible. Seedlings are kept in well-manured baskets lined with plastic. Plants are regularly transplanted during the vegetative period until about 20 stands per basket are maintained. Planting to the home garden or family owned near-fields is delayed till just before the full flowering stage, which farmers hope will coincide with the start of the rainy season. Supplementary irrigation is still required since rainfall is often erratic during this period. Many farmers maintain both a nursery and a small plot to get two cropping periods and minimise the risk of failure.

Micro-scale irrigation

Fields near perennial water sources are increasingly being irrigated during the dry season. The most widespread crop is yellow hot pepper cultivated in a mono-cropping system. Some farmers plant a few stands of

Women manufacturing clay pipes and pitchers for micro-scale irrigation

telfeiria along the beds. Women are hired to carry water from the river, spring or stream and pour it into storage vessels located at regular intervals in the fields and water pepper stands in the morning and evening. A mixture of chicken manure and grass is carefully placed around each plant to provide manure and conserve moisture. Fear of snakes prevents farmers from mulching the entire field.

Two farming systems can be distinguished depending on the location of the irrigated plot. Plots are started in November on river or stream floodplains, and are harvested before flooding in June. After the first floods, rice is transplanted on the same plots. Since full irrigation is required throughout the dry season, plot sizes depend on a farmer's ability to pay for handwatering. In more upland areas, pepper is planted from early February; the period of full irrigation is shorter and use is made of the rainy season. Around June cassava is interplanted and allowed to overgrow the pepper stands.

Potential technological improvements

There are two approaches to improving the existing micro-scale irrigation systems: increasing water supply to the field and improving water application effectiveness and efficiency within the field.

Since the 1980s, government support for small-scale informal irrigation has concentrated on increasing water supply to the field by setting up loan schemes for farmers to purchase relatively low-cost, low-head petrol pumps for lifting surface water from rivers, streams and lakes or tapping the high-yielding shallow aquifers of the Anambra Plains. However, these schemes have faltered with the devaluation of the local currency and 'low-cost' is no longer an appropriate term. In addition, spare parts are difficult to get and there are no maintenance support programmes. Furthermore, low-head pumps are only suitable where water supplies are readily available and an infrastructure of ditches exists to convey the water within the plot or to the fields by gravity. This might be possible in floodplain areas (precluding upland areas), but would require levels of investment beyond the means of local farmers in an essentially peripheral farming activity. In addition, risk aversion is the predominant strategy adopted by farmers to minimise crop failure so fields are kept small and intensive when irrigation is needed. Thus a technology which is expensive, not village-maintained and needs large quantities of water is unlikely to be adopted by farmers. The practice of carrying water to storage vessels on individual fields, often at a substantial distance from the water source, is likely to continue. A different approach to improving irrigation practices is therefore needed.

Effective and efficient water use

Modern concepts of irrigation management have introduced the Soil-Plant-Atmosphere Continuum (SPAC) as a unified system where moisture availability is a function of a conjuction of these components. The advent of permanently installed irrigation systems has established that optimal moisture levels in the SPAC are best maintained by high-frequency, low-volume (i.e. small daily) water applications (Hillel 1990). The consequences for water-use effectiveness are illustrated by high yields of daily watered fields on coarse sandy soils hitherto classified as unsuitable for irrigation.

Micro-scale irrigation techniques, highly efficient in water use and labour-saving when compared to handwatering, can offer simple, low-cost solutions to problems of water and labour scarcity. Three methods that have shown promise in Africa are pitcher irrigation, subsurface pipe irrigation and low head drip irrigation. All three are classified as localised irrigation systems since only the soil at the base of the plant, i.e. the plant root zone, is wetted. Methods, technical adjustments, conclusions from our own experiments and discussions with farmers in the region are reported below.

Pitcher irrigation is an efficient and economic way of providing localised subsurface irrigation by using unglazed porous clay pots (Mandol, 1974; Dupriez and De Leener, 1989). The pots are buried neck-deep in the soil next to the plants or between plant rows and water is poured into the pitcher. When full, water oozes out at a rate controlled by the porosity of the pitcher wall, the waterhead in the pitcher and the water potential of the surrounding soil. Pitcher irrigation proved particularly useful for creepers such as telfeiria and melon since their roots are concentrated and can easily be traced. Technical adjustments were made by piercing holes near the neck of the pitchers thus allowing immediate soil-water replenishment at the time of irrigation and making the technique more useful for less drought tolerant crops.

Photo: Anne Gobin

Low-head drip irrigation.

Subsurface pipe irrigation is achieved by means of shallow-buried small-diameter clay tile drains or slotted PVC, bamboo or metal pipes (Batchelor et al 1994). The total length of pipe or clay tile is equal to about 10 m. At one end of the pipe, either an elbow piece or basin is formed to allow filling; the other end is blocked. If PVC, bamboo or metal pipes are used, slots are cut in the surface of the pipe to allow water to seep through. Clay tile drains of about 30 cm are abutted to each other and water exits via the joints as a result of the imperfect fit between the ends of the pipe sections. The pipes are buried so that they cross the root zone allowing for a terrain roughness within a range of 30 cm. Undulating fields must be levelled during land preparation to ensure optimal efficiency. Improper installation and high inside pipe roughness leads to unequal water distribution and might lead to plants being cut off from irrigation. Farmers complained about the skills required to install the pipes. Slotted continuous pipes proved easier to install and manufacture and are much smoother than clay tiles.

Low-head drip systems operate under pressures of 0.5 to 2 metres water head compared to 10 to 15 metres water head needed for standard drip irrigation (Miller 1990). Small reservoirs such as oil drums can be used as header water tanks which are mounted on block supports so that water pressures fall within the required range. Perforated flexible plastic piping conveys water to the plants. Low-head drip irrigation was found suitable notably for stands with a 100% ground cover, such as closely spaced amaranthus, since humidity is well retained under the canopy after a water application. ■

Three-layer cropping system around Tunisian oases

Improved irrigation efficiencies in Tunesian oases

The experience reported in this paper underlines the importance of actual field knowledge when agencies plan to improve water use efficiencies in an irrigation system. A strictly technical solution is inadequate. Knowledge of the field situation provides insights into the real functioning of the system, actual water distribution and the importance of socioeconomic factors.

Mohamed Mechergui and Gerrit Van Vuren

Kebili, in the Tunisian Sahara, has a mean maximum temperature of 40ºC and minimum 5ºC. Annual rainfall is below 100 mm and wind speed is sometimes high and charged with dust. Formerly, irrigated agriculture was only practised near the natural water springs and the cropping system consisted of three layer, namely date palms, fruit trees and a ground crop. Today, irrigation has increased considerably and now covers an area of around 7,660 hectares spread around 68 oases.

Two distinct groundwater layers are in use: the so-called terminal complex and the continental intercalair aquifer. The former, which is most used is over-exploited in the Kebili region because there are a large number of illegal wells. In 1986, 680 of these illegal wells were pumping 2,700 l/s, over 40% of the total 6,200 l/s being extracted. A sustainable flow rate should not have exceed 4,500 l/s. The second aquifer is less intensively used: the rate in Kebili being 980 l/s and 650 l/s in Tozeur. This is because extraction requires a high technological input where wells are installed. Apart from these two aquifers, water can also be drawn from the shallow water table. Theoretically, the capacity of this shallow water table should be 4.8 million m^3/year but only 1.6 million m^3 is used because some of this water is saline.

Piezometer readings clearly show the degradation of the water sources with a drop in piezometric head of about one meter per year in both aquifers. The degradation of shallow ground water through salinisation is the result of high ground water levels. Observations show, for example, that the water table in Faouar oasis was 47 meter below soil surface in 1956; today it is at surface level. The rapid degradation of the different water sources show that the present agricultural oasis system is far from sustainable. In this article we will describe suggestions for improvement, with special emphasis on the oasis of Rahmat, which is fairly representative of the majority of traditional oases in the region.

The oasis of Rahmat

When it was created in 1932, Rahmat supplied a total irrigated area of 32 ha from two artesian wells. These were sufficient to irrigate a crop system of date palm, fruit trees and alfalfa. The area was subdivided in 0.25 ha individually owned plots.

Over the years the oasis has been extended to 92 ha and is equipped with two pumped wells operating 20 hours a day. The total discharge is 86 l/s and this water is collected in a concrete distribution box from which it is divided into three equal parts and lead through pipes to three sectors. Here there are a number of outlets each serving a block of about 3 ha. Water is brought to the surface into open canals that further distribute it to the farms. In each sector, the water delivery rotates over the blocks to create an irrigation interval of 14 days, with an irrigation length of 8 hours per ha and a discharge of about 30 l/s. Within the sector the irrigation is organised so that water delivery starts from the outlet at the top of each canal. On these sandy soils, surface irrigation is the only technique used.

The Association of Collective Interest (AIC), a farmers organisation, plays an important role in all but daily management. It fixes the water price with district authorities, gives directives on how water distribution should be organised and settles conflicts between farmers.

The day-to-day distribution of water is handled by an operator, who is responsible for opening and closing the outlets. The only guidance herefore is the time required per hectare (which is 8 hours) and the sequence of opening, normally from head to tail. Farmers know when they will get water, so they open the canal bund in the basin nearest the canal in advance.

An office-based solution

In the present irrigation approach, the depletion of water resources is clearly a major problem. Part of the water is pumped from non-renewable fossil water, the rest comes from an over-extraction of renewable ground water. At the same time, heavy leakage from the earth canals causes high groundwater levels in the oasis and leads to land salinisation. As a solution to this problem, engineers suggested replacing the open canals with 200 mm PVC pipes. Each farmer would get a riser pipe from which water can be taken. It was believed that this would prevent farmers using more water than they needed, depletion of the groundwater reserve would be reduced and ground water levels would be lowered.

Actual water management

Field observations revealed that water management is actually organised very differently. It became clear that the operators role is more important than is formally recognised. In practise he decides on the irrigation time for each owner depending on his estimation of plot size, his relation to the farmer and his social position.

It was observed that the three sectors, although equal in size, did not receive the same discharge. In one sector actual discharge was 25% higher than in the other two sectors under the pretext that its irrigated area was larger.

Inconsistencies also occurred at the outlets. Farmers take water from different outlets giving different excuses for doing so. Although irrigation timings appear to be respected, water is sometimes transferred to another farmer.

Another problem in the management of water was observed inside the irrigated area of one outlet. Contrary to the specifications of the project, which defines a standard plot as being 0.25 ha, actual areas vary from one palm tree to 2 ha. Each farm managed the water in its own way in the absence of a specific recommended method. Some farmers do not do any levelling inside the parcel which leads to considerable water loss. Whilst the required dose was 50 mm, we observed actual irrigation gifts varying from 100 to 300 mm and more. This was partly because farmers have no method of control. In one case we observed that the profile was wetted beyond a depth of two meters although the palm tree's active root-zone does not go below 120 cm.

Another observation is that the irrigation system is just supply based, in the sense that the quantity of pumped water does not depend on the quantity needed in the system. In summer this fixed supply is in good equilibrium with crop water requirements. In the winter season, however, the supply is several times higher than demand and causes a steep increase in groundwater level.

Water losses in the unlined, very sandy canals is high. We measured canal losses of 30 to 60 % over a length of 400 to 1000 meters.

Both cropping system and type of farmer was not what we expected. Instead of the three layer cropping system, we observed that date palm was the main crop. Only occasionally was there a second layer crop of apricots, fig or olives. There was generally no third layer crop except in those places where alfalfa, an important crop for those farmers raising goats, was cultivated. Many plots were owned by absentee farmers who lived in Kebili or even Tunis and who hired labour to cultivate their plots. There was also share cropping. Many of these 0.25 ha plots were not, in fact, being cultivated by farmer families.

A different strategy

On the basis of this field research it became clear that the problems surrounding water management in these oases were more complex than assumed. Apart from the problem of diminishing water resources, we found an extensive type of agriculture being practised in which only palm tree cultivation is important. Water management at farm level is poor and water distribution to farms is unequal. In this situation, the construction of a buried pipeline system up to field level would be insufficient to solve the problems of irrigation inefficiencies at field level, especially during the winter season; discrepancies between the designed and actual irrigated area; and inequity in water distribution.

To improve water use efficiencies, it is important that farmers should first be willing to re-establish the three layer crop system on which the irrigation system was first established. It is suggested that improvements that require little external input, improve the knowledge base of farmers and, which are oriented towards improving organisation, be introduced. The construction of a buried pipeline system would only then be possible. The advantage of this system would be that payment per unit of land could be changed into payment per volume of water supplied, an approach that certainly helps to increase water use efficiency. It might facilitate a demand-based irrigation system, where farmers have to apply for water in advance and create options for changing from present surface irrigation towards low pressure sprinkler or even drip system techniques.

This case of the oases in Tunisia touches on a common problem in irrigation development. Although irrigation agencies are generally well informed about regional water resources, they tend to work with a generalised (idealised) picture of the field situation in mind. Detailed field observations would provide them with a much better insight into how farmers handle water, and contribute to the development of more appropriate solutions. Often such an approach will focus more closely on the farmers' organisational structure and knowledge base. Sometimes, a bottom-up and participative approach can reduce the level of investments required for construction work and safeguard the use and management of the scheme because farmers feel involved in the analysis of the problems.

Traditional water harvesting systems need to be improved

In the dry regions of south and centre Tunisia, with a long-term average rainfall of around 200 mm, water harvesting is the only way to secure crop production. The landscape consists of undulating hills and mountains denuded of natural vegetation. Soils are poor and extremely shallow and rocky. Most land is being used as marginal rangeland except for those places where runoff water and soil are being harvested which permits cultivation of olives and barley and sometimes even apples, apricots, chickpea, faba bean, lentiles or watermelons. Different traditional water harvesting systems can be found of which the *Jessour* systems is best known. This system consists of a series of stone and earth walls, called tabias, built across the stream beds of narrow valleys. The *tabias* collect and retain soil washed down hillsides by torrential rains, forming terraces in a stair-step fashion down the slope of the valley. This has worked for centuries, but recently the *jessours* have not been well maintained because of outmigration, shortage of labour and loss of skills and traditional knowledge. This is destroying the systems and is causing serious erosion.

The Institut des Regions Arides (IRA) in cooperation with the International Centre on Agricultural Research in Dryland Agriculture (ICARDA) are now trying to adapt these traditional systems to existing economic conditions. Farmers as well as scientist have made some innovations. For example farmers are using plastic bottles to irrigate young olive trees. The bottles (without bottom) are filled with pebbles and placed top down with the opening near the roots of the trees. In this way irrigation water is stored and gradually made available to the plants.

Scientists have designed new techniques to store and guide the precious water directly to the roots of the trees or crops to increase water efficiency. In a process of participatory technology development these techniques are now being adapted to the conditions in which the farmers work.

This programme is also part of the documentation of farmer innovations in soil and water conservation exercise referred to on page 21 of this issue.

Meeting of the Ramanath Sangha, a self-help group in Kamalapur

Self-help groups in watershed management

MYRADA's involvement with watershed management began in Gulbarga 10 years ago. The PIDOW-MYRADA project was a partnership between Government, the Swiss Development Cooperation and MYRADA. Its objective was to enable the farmers involved to emerge as a fourth partner and progressively control watershed resources. MYRADA's role was to ensure that the process of planning and implementation would help people acquire the skills, confidence and organisational expertise to control and manage the resources within their watershed. This should increase productivity and sustainably and make it possible for vulnerable groups to derive benefits from these investments. Initiatives taken in Gulbarga spread rapidly to other MYRADA watershed projects. Recently MYRADA's experiences have been evaluated. This article discusses what has been learned about the function and role of Self-help Credit Management Groups (SHGs) as basic social groupings responsible for watershed management.

Aloysius P. Fernandez

From MYRADA's experiences it became clear that the strategy accepted by many research and government institutions that each watershed should have one association - the Sangha - was not viable. The social configuration of the 'Sangha' does not necessarily coincide with the geographical unit of a watershed. Even in micro-watersheds several groups emerge when people are free to decide for themselves. Large associations accommodate different interest groups as well as socially distinct configurations like caste, family, occupation, lifestyle or origin. If they are to stay together, these large groups need the intervention of outsiders like NGOs. It was found that intervenors spent more time and energy keeping large groups together than in actually helping them acquire the skills necessary to manage resources. It became clear that the basic social grouping even within a micro-watershed must be a 'socially functional group' or a group that does not require outside intervention to stay together. Such groups will usually be small with less than 20 members, have common interests and be largely homogeneous in terms of cast, class and livelihood.

Self-Help Credit Management Groups

MYRADA, therefore, focused activities on small, homogeneous watershed management groups that had started as Self-help Credit Management Groups (SHGs). MYRADA used credit management as an entry point and training tool. Credit is an appropriate training tool because it is familiar and meets a felt need. Being able to successfully managing their common fund gives a group the confidence that they can achieve their objectives provided they are willing to observe certain rules and create a culture that motivates people to support each other. Self-help Credit Management Group members acquire considerable management experience while conducting the affairs of their organisation. They learn to set priorities, to take decisions and risks, to draw up rules of behaviour, to resolve conflicts and to apply sanctions effectively for non-compliance. They acquire the skills required to institutionalise and administrate cooperation. These skills are necessary in managing watershed resources. They cannot be easily acquired during a watershed programme since the process of watershed development is still heavily influenced by intervenors who insists on technical specifications and guidelines. This transfer of technology approach within a delivery system leaves little room for the development of local people's institutions.

Apex Societies

In several micro-watersheds throughout the Gulbarga project more than one homogeneous group emerged. There were also large farmers who did not join any of these groups but wanted to be represented when watershed activities were discussed. To cope with this situation Apex Societies or Watershed Management Committees were formed by representatives from the small homogeneous groups, large farmers, and representatives of farmers with land in the watershed who did not live in it. Apex Societies coordinated the implementation of the treatment plan and dealt with outside intervenors. They supervised the work done on farmers fields and later assessed it before sanctioning payments. In some cases the funds for treatment works were given to the Apex Societies, in others funds passed directly to individual farmers after the Apex Society confirmed that work had been satisfactorily completed. Apex Societies also played a key role in resolving disputes that arose during implementation.

Maintenance secured

The issue of maintaining treatment measures is crucial for sustainable watershed management. People suspected that there were many areas where outside contractors had been the major beneficiaries. This weakened their commitment to maintaining these measures. It was possible to solve this problem by establishing a transparent procedure which involved SHG members and the Apex Societies in assessing work, handling cash and maintaining records.

Initially the intervenors expected the Apex Societies to play a central role in maintaining treatment measures. In practice the small homogeneous SHGs have emerged as the most appropriate institutions to maintain the resources that benefit group members. It was, for example, the SHGs who entered into agreements with other farmers to regenerate and maintain fallow lands. In Gulbarga over 35 such agreements have been negotiated. This strategy has transformed previously neglected land into regenerated parks, increased biomass production and been effective in managing soil erosion and water run-off.

The common fund

Farmers need to have a stake in watershed investment. It is the SHG that has the financial resources - the common fund - from which an individual farmer can borrow to undertake improvement and maintenance work after the project ends. Commercial Banks do not advance credit for such measures. The Land Development Banks, where they exist and have resources, do have provision but conservation measures on dryland are not considered viable investments. Further, the official specifications for treatment measures in terms of size, structure and location usually conflict with farmers requirements and with what they can manage. This makes the approval of such credits difficult and raises transaction costs. One of the main reasons why farmers do not invest in maintenance work is that most credit involves high transaction costs. Farmers need credit because, to construct the treatment measures, they either have to give up alternative wage employment to do it themselves or they have to hire bullocks, carts and labour.

Photo: Aloysius P. Fernandez

AK Doddi watershed showing stone bunding and bund strengthening with vegetative measures

Some SHGs decided to convert all the grants given by the Government for agricultural inputs into loans returnable to the common fund. Farmers were motivated to contribute both in cash and kind. The contribution from each farmer varied depending on the value he placed on each measure. For example, farmers tend to contribute much more to activities from which they expect immediate returns like silt traps, while measures involving cement and concrete get lower priority and hence lower contributions.

Reasons for disinterest

There are of course other reasons why farmers have not come forward to take up conservation measures. The perception that the increased productivity will not be large enough to warrant investment is a major reason. There is evidence that farmers, even on drylands, are willing to borrow up to 20% of costs from SHGs to construct treatment measures if good soils and better moisture retention capacity assures them of a crop. After investing in such structures, however, there have been instances where farmers have not cooperated in efforts to prevent erosion from higher slopes because they anticipated a lower harvest of silt lower down. Their strategy was to concentrate soil rather than to conserve it.

There are other factors that dissuade investment. The pull of the city, the increasing demand for cash and the rising price of land which is viewed as a scarce resource even without treatment measures, the shift to irrigation and the problems of unstable markets which favour those with staying power.

Initiatives by SHGs

The role played by SHGs so far depend on the resource to be maintained. If it is a common resource like revenue, waste land, and private fallows which were protected and from which all members derived regular benefits, the SHGs have taken the initiative to organise, develop, manage and maintain it. The cost of efforts to acquire this common resource have been shared by the SHG and the intervenors. The SHG usually contacts the owner of the private fallow land and negotiates an agreement. The NGO played an important role in lobbying with the Government for the release of revenue lands. The activities involved in developing this resource have been funded by the intervenors with the SHG organising the work and contributing labour at generally lower rates. Management of this resource are taken on by the SHG where members are confident that they have access to and control of the produce and adequate protection from cattle. It must be noted, however, that the initiative to manage a common resource where titles and user rights are not clear is normally not taken up by the SHG. As far as the management of revenue lands is concerned it is only after some years, when they have gained confidence, that the SHGs take the initiative. Access to these lands has been open but in some cases traditional grazing rights have been exercised. The potential for conflict in these areas is high.

If the measure is a substantial one such as a weir being constructed with cement, the SHGs do not agree to maintain them. Their position is that they do not have the resources and skills required to maintain such structures. MYRADA staff, however, believe that if people place a cash value on water collection in weirs which is used by domestic animals for drinking and wallowing and for washing clothes, adequate revenue can be mobilised to pay for maintenance. In practice, however, as water for animals and domestic purposes are considered basic needs, it is difficult to levy a charge. Sub-soil water is seen as a common resource. It is, therefore, difficult to charge farmers whose wells have been recharged significantly due to water conservation measures.

A broader approach needed

MYRADA's interventions have motivated people to cooperate and to build institutions which they find relevant to their needs and which they can manage. As farmers become convinced that watershed management is paying there is a growing hope that these institutions will be sustainable. But it is not only productivity and institutions that need to be sustained, equity should also be ensured. This has proved more difficult to achieve, especially in areas where resources are scarce. The landless and marginal farmers tend to be marginalised in watershed programmes. During the implementation period they get work and income, but this has to be sustained. In some watersheds this has been achieved by giving the landless a stake in the increased biomass, by increasing their capacity to earn through training and by helping them to start small businesses and cottage industries. They also have become members of the credit groups and have access to credit. For this, however, watershed management programmes need to have a broader approach than they do at the moment.

Social differences in water resource management

Water security goes hand in hand with food security and is crucial for economic and social well-being. With consumption levels spiralling, water management strategies are necessary to meet national and communal needs. No clear consensus exists and debates on water management are polarised. Two views dominate; both approaches are technocentric and pay insufficient attention to social differences. What alternative approaches could be followed?

Lyla Mehta

At country and regional level, the 'Big is Beautiful' view dominates. Large dams are seen as a panacea for water-scarce areas. International dam-builders assert that the social and environmental costs of these schemes are marginal when compared to the benefits of hydropower and irrigation (Biswas and El-Habr, 1993). They advocate top-down, centrally-organised hydroelectric and irrigation systems based on extra-basin transfer of water. The controversial Narmada dam in western India is a good example of such a project.

Small watershed projects

At community and village level, the 'Small is Beautiful' view plays an important role in highlighting the socio-environmental problems of large dams, including the unequal benefits of canal irrigation (McCully, 1996). It highlights the advantages of small-scale projects based on the principles of water harvesting and watershed management, which are seen as more ecofriendly. However, there is a tendency to gloss over location-specific discrepancies arising from social difference.

Both technocentric

In some ways both views have flaws. Both tend to be technocentric and, until very recently, supply dominated. Both also maintain an aggregated view of the community involved. Whilst the advocates of large projects focus on superlatives and inflate the actual number of beneficiaries, the advocates of small projects espouse the principles of democracy, equity and participation, forgetting that existing power relations within a community are based on different axioms. There is often a rather naive assumption that just because a project is small, it is bound to be successful and egalitarian.

In reality, both macro and micro projects often fail on social grounds because they neglect the fact that any kind of water or ecological intervention will build on and feed into existing social and power relations. Social differences, including such variables as class, gender, caste, ethnicity, historical legacies, power, occupation and political rivalries, can hinder the smooth functioning of any water scheme.

Weaker groups disadvantaged

Clearly, a village is rarely the homogenous and happy place it is often made out to be. There are poor and rich; weak and powerful. In order to gain legitimacy the implementing agency nearly always operates through traditional power-brokers. These are often men and from the higher castes. Only occasionally do the concerns of women, key water users, and those from lower castes come to the fore. Economically weaker groups such as the landless and pastoralists are also largely excluded from benefits.

In many small-scale schemes, targets such as technicality and environmental regeneration seem more important than issues of equity and social justice. They opt for homogenous communities or to focus on just one articulate (powerful) group. Thus, despite often lofty intensions to secure participation and equality, such projects build on skewed power and social relations.

The twenty-first century will possibly see many micro-level watershed projects. Despite the surge of ideas on watershed development, there is a danger that the problems of social differences will be ignored.

Alternative approaches

How can this problem be avoided? Clearly, the social feasibility of a project is just as important as its technical feasibility and perhaps socioeconomic appraisals should precede technical ones. One should ensure that marginalised groups participate by according them more power in the context of intervention and by establishing solidarity with them at the very outset. This entails being aggressively partisan. Through aggressive partisanship, groups which would otherwise be excluded could be explicitly targeted (Mehta 1997). An alternative would be to opt for the more subtle but protracted process of negotiating between social actors within and outside communities. Through this negotiating process, points of conflict could be exposed and systematically worked through (Leach, Mearns and Scoones, 1997).

Resource management in rainfed drylands: an information kit.
1997. Bangalore : MYRADA; Silang : IIRR, 1997. 356 p. ISBN 0 942717 71 6. MYRADA, 2 Service Road, Domlur Layout, Bangalore 560071, India; International Institute of Rural Reconstruction (IIRR), Y.C. James Yen Center, Silang, Cavite 4118, Philippines.

The International Institute of Rural Reconstruction (IIRR) conducted in the past decade about 20 workshops on different topics, all resulting very attractive, practical information kits. This last one in this series was produced at a workshop jointly organised by IIRR and MYRADA, a South India based NGO. It describes successful agricultural strategies for drylands, areas with less than 800 mm per year rainfall. In India, the largest part of the country consists of rainfed dry areas, and hence it is not surprising that a lot of research and successful field action in dryland agriculture originates from there. This manual compiles these Indian experiences with farmer-tested, dryland technologies. They involve traditional approaches to natural resource management, gender issues, soil and water conservation, crop management, soil management techniques, alternative land use systems, post-harvest practices and agricultural implements and a concluding chapter on innovative approaches in participation, extension and institutional partnerships. Very accessible, practical information, richly illustrated with excellent drawings. (IHG)

Mass marriage provides SLM volunteers with an opportunity to explain the open well recharging method and its importance to people.

Saurashtra's water insurer

'Shree' Padre

The Saurashtra region of Gujarath, India, resembles an inverted saucer, surrounded on three sides by the sea. Saurashtra has about 4700 villages and a population of some one million people. In a normal year the monsoon brings between 300 and 500 mm of rain. If the monsoon smiles, there is plenty of water and good crops of groundnuts, cotton and millet: the money tinkles in. Every 2 to 3 years, however, there is a drought and between 1985 and 1987 there was one of unprecedented severity. Most of the open wells that normally contain between 350,000 to 400,000 litres of water and provide the main source of irrigation water in the district, dried up.

1988 brought hope. There were good rains and Ramjibhal Manjibhai, a farmer in the small town of Dhoraji had an idea. He diverted run-off water into his open well. Although his neighbours warned him this would silt up the well, he was adamant. The next summer, though some silt had got into his well, Ramjil had water while his neighbours had none.

Shamjibhal Antala also lives in Dhoraji and he watched these developments with interest. He was impressed by this way of increasing the water table and wanted to pass on the idea to others in Saurashtra.

After many discussions with friends he improved upon the method. A 6 x 6 foot filter tank was dug close to the well and filled with 2-3 layers of pebbles of different sizes. Just above the bottom of the tank, a cement pipe - 9 inches in diameter - was installed to guide the water into the well. Rainwater came into the filter tank through open channels and gushed into the well through a pipe. This installation cost the farmer between Rs.500 and Rs.1000.

If there were streams or rivers in the vicinity, cement pipelines were laid between them to the filter tank. All Saurashtra's rivers flood at least 4 times during the monsoon. When their water is diverted, it is enough to recharge nearby wells.

Spreading the message

Antala and his friends approached the farmers in the evenings. Many of them rejected the idea, others asked for subsidy. There were no takers for the recharging plan. Shamjibhai did not want to give up the idea. He and his friends set up the 'Saurashtra Lok Manch' (SLM) with water conservation as its main objective.

SLM did not wait for government programmes or finance. It plunged into action determined to convince people that there was a way of solving the water crises. First, the SLM approached the dharmic leaders - the Mahanths, Priests and Swamis. Heed the SLM's advice, they warned, otherwise disaster will strike.

Meanwhile, social reforms were underway. Mass marriages were becoming popular because people were fed up with the lavish marriage ceremonies that turned many parents into paupers. The SLM saw this as a way to spread its message. Volunteers displayed a model of the recharging method at mass marriage ceremonies and explain how it worked. Between 1994 and 1995, 42 mass marriages were held in Saurashtra and 2000 couples entered wedlock. Each ceremony was witnessed by some 25,000 people. Thus, thanks to mass marriage, the well recharge concept reached 800,000 people.

Demonstration was not the only strategy used by SLM. It also held hundreds of meetings at village level. Many articles were published in Gujarathi and, in 1994, the SLM organised a 'Jala Sanchayan Abhiyan' (Water Conservation Movement) that involved 750 villages in the Rajkot district.

Slowly but steadily the campaigns began to bear fruit. Between 1992 and 1993, 3,000 wells were recharged. The following year SLM raised its target to 10,000 wells. The successes of individual farmers got around quickly. Total number of recharged wells rose to 25,000 in 1995, far beyond SLM's expectation. Today there are more than 30,000 recharged wells.

Simple and cheap

The recharging method is particularly suitable for irrigation wells. In Saurashtra if water remains in the irrigation wells for the winter and summer, farmers can be sure of two more crops. Gundasara village has 277 wells, 210 have water thanks to the recharging method. According to estimates, farming is possible when wells are recharged on 30,000 ha.This has led to increasing income by Rs 150,000,000. The popularity of the method is that it is low cost and does not require external inputs or external knowledge.

SLM has identified 99 drought prone districts. Many wells can still can be recharged. Wherever Antala goes, he has one simple message: *"Forget about the government for the moment. Don't ask what it can do for you. Be independent. Water is your problem and here is a solution which you can keep entirely in your own hands*".

A proud farmer with his lined irrigation furrow

Challenges of organising catchment councils

This article discusses key issues in the operationalisation of (sub-)catchment water-user organisations. In the Nyanyadzi river catchment in Chimanimani district, Zimbabwe (see map) there are many indigenous, farmer-initiated irrigation furrows but few have legal water rights. Water scarcity in recent years has lead to a struggle between downstream irrigators in the government-run Nyanyadzi irrigation scheme and the various groups of upstream irrigators in the Shinja resettlement scheme and the Mutambara and Muusha communal areas (see Bolding et al 1996). The Zimbabwean Ministry of Water and Rural Resources has initiated a process of decentralisation. Responsibility for water management has been devolved to (sub-)catchment councils consisting of water users themselves. This system has considerable potential but legal and practical problems have created difficulties.

Alex Bolding and Lawrence Nyagwande

From its source in the eastern highlands of Chimanimani district, the Nyanyadzi flows west into the Odzi river. The Nyanyadzi runs through all of Zimbabwe's five agroecological zones. Its source is at 1200-1500 metres in a region of high annual rainfall (circa 1200 mm) and fertile soils. On its way west it flows through an area of large-scale commercial farming and subsequently through resettlement and communal areas. It enters the Odzi in the dry, low veld where, at an altitude of 550 meters, soils are marginal and annual rainfall less than 400 mm. Just before it enters the Odzi, a small-holder irrigation scheme taps away water by means of a permanent weir. The Nyanyadzi irrigation scheme as it is known, was established by the government in 1934 and has been government managed ever since. A thousand de facto plot holders occupy a 414 hectare site.

Most farming households in the 800km^2 Nyanyadzi catchment area depend on dryland agriculture. They harvest one rain-fed crop of per annum: maize in the better rainfall zones and millet/sorghum elsewhere. Two harvests in five fail. The catchment is dissected by more than one hundred small furrows that tap water from the river and its tributaries. Most of these furrows water between 0.1 and 25 hectares and have been constructed by the indigenous irrigators who manage them. Most of these furrows are simple in infrastructure. Temporary stone weirs divert water from the river and earthen furrows carry it to the fields. The main crops in summer are maize, cotton and paprika and in winter wheat, tomatoes and sugar beans.

From 1983, plot holders from the Nyanyadzi irrigation scheme together with the national extension and irrigation service (Agritex) have organised regular raids upstream along Nyanyadzi river to destroy '-informal' irrigation furrows and get water for their intake.

Water entitlements

Those using the water are not over concerned with legal entitlements as defined in the Water Act. Basically most Nyanyadzi catchment irrigators feel that water belongs to God or is a public good which should be shared with others. Few accept that the Government owns the water. Practically speaking entitlement is confined to those who own or use land along the river. However, formal irrigators like those in the Nyanyadzi project claim the water from the Nyanyadzi river belongs to their scheme. They have entitlements to all the water. Upstream furrow irrigators with water rights tend to put forward the same claim. However, they do not deny others 'a chance'. It is impossible to divert the river's entire flow.

Within the Ruwedza valley entitlements are related to type of land holding. Most downstream furrow irrigators will agree that the white and black commercial farmers upstream have a right to extract water since they own title deeds to the land. During the severe water scarcity of 1992-95, the headman at the downstream end of Ruwedza valley claimed that his furrow was the oldest in the area. Upstream furrow irrigators generally seem to claim entitlement on the basis of their top position. In most cases downstreamers are ignored in the matter of entitlements.

Some claim more rights than others

Some successful furrow irrigators claim they make better use of the water than the wasteful Nyanyadzi plot holders whose main canal loses some 70% of its water through its sandy, unlined canal embankment. Other furrow irrigators, those who have made heavy investments in canal infrastructure, feel their investment gives them the right to deny Nyanyadzi plot holders access to water because the latter have been provided with canals free of charge.

Springs are generally considered to be the private property of those working the surrounding land. There is consensus among communal and resettlement farmers that households with no direct access to land near the river should only be entitled to use water for domestic purposes. Usually unoccupied river banks are not included in this rule.

All these local perceptions of entitlements should be considered in setting up catchment users organisation, since government definitions of who owns water seems to mean little to those involved.

Boundaries

In the Nyanyadzi catchment water users differ in their awareness and understanding of hydraulic interdependence. The issue of hydrological boundaries strongly ties in with local conceptions of entitlements to water. Hydrological units, however, do not correspond with social units. In organising catchment users, what should be the criteria for sub-division: the number of inhabitants/water users; administrative units; available water flow; distinct features in the landscape or social communities? There has been little debate on the exact criteria involved in setting the boundaries for catchments and sub-catchments. It has been assumed that these boundaries can be determined in Harare on the bases of watershed maps, righted water users, and hydrological zones. In practice this is impossible.

Ground and surface water

Most surface water originates from sub-soil sources (springs, aquifers). This implies that any regulations with regard to river water abstraction must include ground water use.

In places like the Ruwedza valley the intricate interplay between ground and surface water is fully appreciated by local water users. Furrows are spread geographically to optimise the benefits from recharge of the river by sub-soil aquifers. Springs are carefully exploited and riverine vegetation is promoted especially in the upper reaches of the Ruwedza river. Thus sponges in the river bed are allowed to continue. When a spring surfaces relatively far from the river bed, land users near that site may use the water for their own benefit. This has implications for the membership of future Catchment Authorities and means that membership of catchment councils should not be confined to furrow irrigators alone.

Uses and users

Farmer-initiated furrows are used for a variety of purposes. Each user has a particular need. Gardening and the use of spring water, for example, is nearly always women's work whilst commercial crop production in furrow irrigation is done by men. Discussions on water distribution and allocation are usually initiated and led by men. However, a catchment council that involves only male dominated channels of communication and decision making will be ineffective.

Historical roots

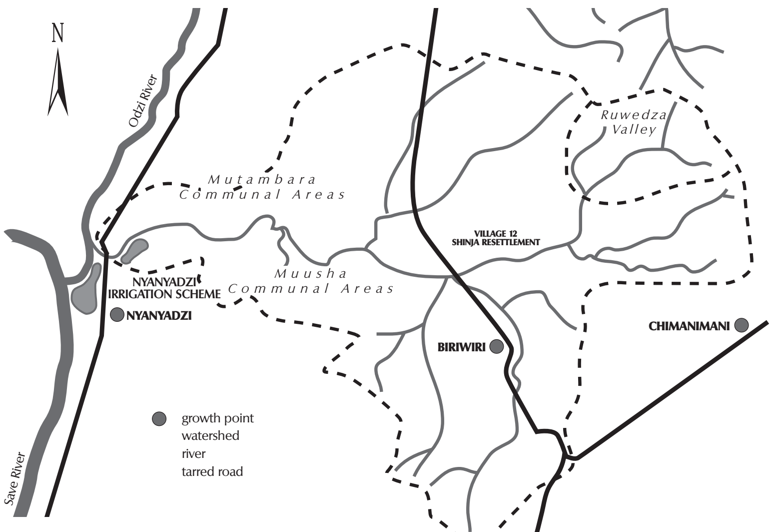
Some water users have worked out their own strategies for dealing with water scarcities because conflicts had to be settled or because of mutual dependence. In the Ruwedza valley, downstream furrow users share the available water during periods of water scarcities. The weekly rotation of turns used does not include upstream commercial and resettlement farmers. Downstream furrow users would never challenge the (white) commercial farmer's right to water, despite the fact that he has no water rights and they do, because he helps with road maintenance (to enable trucks to come and collect produce from the irrigation furrows) and supported the downstream water users in their struggle to retain some autonomy and not be incorporated in the resettlement scheme. These relationships are varied and complex. By highlighting one aspect of the interdependence and interfering with it, other aspects may be jeopardised.

During the upstream raids in 1987 and again in 1991 some furrow irrigators in Village Twelve struck a water sharing agreement with the Nyanyadzi plot holders through the mediation of the District Administrator. It was agreed that water from upstream would be released every other week by furrow irrigators in Village Twelve. These water sharing arrangements and the complex relationships between groups in a catchment demand careful appraisal in future water user organisations.

Representation and leadership

Zimbabwe has a large variety of social institutions, each with their own, sometimes overlapping, allegiances. Many proposals originating from policy makers' desks pay little more than lip service to the diversity of present day Zimbabwe. Village Twelve in the Shinja resettlement scheme is a good example of this diversity. Who should represent this village on the catchment council? The traditional leaders, recognised by the new comers ('illegal land squatters'), but despised by some official settlers? The members of the Village Development Committee who seem mainly to represent the official settlers? The Zimbabwe Farmers Union representative who runs a small, informal furrow, but has hardly any following in the village? Or should it be the one officially in charge, the government resettlement officer, who hardly ever visits the village?

It is clear that representation and leadership issues demand careful study. Each locality is different. Simplified or reified models of how people should be represented have little relevance here.



The Nyanyadzi Catchment, Zimbabwe

Not everybody gains

The main stumbling block in setting up a catchment council in Nyanyadzi has been that few were interested in joining such an organisation. During times of water scarcity downstream users are interested in striking a deal with upstream users . However, the problem will always be that top-enders are unlikely to gain much from such arrangements.

This has serious implications for the setting up of successful catchment authorities. Somehow top enders must be provided with incentives to take part. Subsidies for good land husbandry practices (perhaps extended to sustainable forms of stream bank cultivation) are one option but unlikely to be very effective. More substantial benefits in the shape of infrastructural improvements (dams) are likely to make a deeper impression. Penalties could also be imposed by recognised authorities. However, for these to be effective and well administered, the catchment council must first be allowed to mature. Hydrological units do not coincide with social units and the council is more likely to succeed in becoming accepted as a social entity if it is not immediately associated with punishment. Win-win options should first be exploited.

Win-win options

This is why in Nyanyadzi two experimental centres in water and soil conservation were established in the upper parts of the catchment. This *kuturaya* (try out in Shona) approach - takes up farmers' suggestions and tests them in the local trial centres. It promised almost immediate gains for local upstream farmers who would benefit from increased yields. Down stream users would also benefit in the longer term because sedimentation would be reduced and base flow would be increased. The basic challenge in setting up catchment authorities lies in the identification and exploitation of such win-win options.

Irrigation development in the Peruvian Andes

SNV Netherlands Development Organisation has over 15 years experience in providing technical assistance to partner organisations working to improve irrigation management in the northern and southern Peruvian Andes. Willem Kastelein co-ordinates these activities and, in this article, discusses some of the lessons and experiences gathered over the years.

Willem Kastelein

The Peruvian Andes are located between the arid desert of the Pacific Coast and the humid tropical rainforests of the Amazon. The highest peaks are almost 7000 m above sea level. Between the mountain ridges are highland plains or punas and steep valleys.

The main agricultural areas are concentrated in the valleys. These lie at between 2000 and 3500 m and tend to have a semi-arid climate with a relatively short rainy season and irregular, unreliable precipitation. In these conditions the use of irrigation is generally advantageous. The availability of irrigation reduces drought risk and can help extend the growing season, sometimes even making it possible to grow a second crop. Irrigation is widely practised and considered important for development. Irrigation was also important in Pre-Hispanic Andes cultures and was reflected in their religion and temples. Quite a number of these ancient irrigation systems, some of which are more than 2000 years old, are still functioning today.

Spanish colonisation resulted in the decimation of the indigenous population. In its social organisation, post-Hispanic rural society consists of indigenous comunidades - generally 30-200 families with common territorial property rights, mestizo (smallholders) and haciendas (large estates) owned by European immigrants. In the agrarian reform of the late 1960s haciendas were subdivided into smallholdings. The comunidades have also been reorganised into individual farms, though formal communal property rights remained intact and communal organisation has generally been maintained as far as common interests and the common use of resources are concerned.

Smallholders generally produce for their own consumption, selling only some of their crops to cover cash needs. Irrigation is used to produce potatoes, maize, beans, peas and several local cereals for the market. Pasture land is also irrigated, particularly to overcome the dry season in areas where dairy cattle are kept.

There are various ecological zones in the Sierra and most irrigation systems are small-scale with between 5 and 200 water users. Larger schemes with more than 1000 smallholder water users are not uncommon. Irrigation is practised both on the valley floors and on the (generally steep) slopes.

Intervention in irrigation by both governmental and non-governmental development organisations has aimed at improving existing irrigation and the construction of new systems. Generally speaking, these interventions have not produced the expected economic results and their sustainability is questionable.

Irrigation interventions

The introduction of improved irrigation may create new possibilities for production and development projects. But it must be understood that a change in irrigation alone is not enough in most cases. To be successful, change must respond to the needs and priorities of the interest groups concerned. In many situations, more inputs, including access to extension, additional labour, investments and a market infrastructure are needed. These inputs should be available at a reasonable price and give sufficiently high returns. In many cases these conditions are often not met and as a result irrigation interventions fail to secure improvements in production.

An analysis of six cases in the Cusco area has shown that more water had become available as a result of these improved irrigation systems. However, the amount of labour required to manage the systems was such that the productivity per unit of labour remained unchanged, even with higher production per unit of land. Meanwhile, soil erosion had increased significantly. As labour can be considered the most precious input in these LEISA systems, these results cannot be considered satisfactory.

Women and water

In recent decades the role of Andean women in decision making at household level has increased. Many men have fled because of political violence or because economic opportunities elsewhere are more attractive. However, formal irrigation organisations usually only include women who are household heads, this despite the important role played by women in agriculture and irrigation. Women are major water users and need water for livestock and domestic purposes. Therefore, it is important that they are included when decisions are made on water management and irrigation. Projects have failed in the Peruvian Andes because insufficient account has been taken of women in project planning and implementation. Experience has shown that women can be closely drawn into the process of decision making and the establishment of water rights if the importance and logic of their participation is explained and discussed. Experience has shown that this type of approach has led to more sustainable results.

Establishment of rights

In irrigation systems that function without external intervention, water rights and the right to use the irrigation system are generally related to an individual's involvement in the construction and improvement of irrigation infrastructure. This can either be a cash or a labour involvement. Rights are consolidated through participation in operation, maintenance and repair work. These rights will normally be inherited by children and, in most cases, they can be sold. Normally the irrigation organisation would have to give permission for such sale, however. New users may obtain rights by making a contribution which is considered equivalent to the efforts already invested by present water users.

Irrigation interventions by most development organisations tend to focus on the construction of physical infrastructure and do not take existing rights and the mechanism that establish new rights into account. Development organisations increasingly recognise the importance of adequate water-user organisation and seek to include this in their intervention strategies. Only a few however, seem to realise that the development of rights through participation in construction is an essential and fundamental starting point. This seriously limits the effectiveness of development interventions aimed at strengthening sustainable irrigation organisation.

Where existing rights are not taken sufficiently into account, water users will be reluctant to participate in projects. If the creation of new rights and obligations is not sufficiently clear, people will be less inclined to invest in new developments. If all investment costs (sometimes including labour) are paid from external sources, people do not feel that rights have been legitimately established for the beneficiaries. Consequently, water users are not likely to see such schemes as their own property and responsibility.

Appropriate technical design

Designing irrigation in the Andes is technically complex because of steep topography, irregular geology and the variety of soil types. The use in the Sierra of irrigation design criteria developed for conditions on the Peruvian Coast has had serious negative consequences. In some cases the construction of irrigation canals has destabilised the slope of the land causing landslides through overtopping of canal banks. This has lead to serious erosion damage both to canals and environment whilst construction of canals over unstable calcareous and gypsum rocks has resulted in collapses.

In some parts of the Andes farmers have developed sprinkler irrigation appropriate to their own conditions and needs. Around the village of Paucartambo, for example, water originates in small springs with discharges often well below 2 litres per second. This is difficult to handle efficiently in surface irrigation. Constructing appropriate storage reservoirs to enable more efficient surface irrigation would require considerable investments. As the relatively steep topography easily provides the required pressure, simple but effective irrigation is achieved using relatively low-cost polyethylene tubes (50 to 100 m long) connected to locally made or imported sprinklers. Although the application of sprinkler irrigation has considerable potential in the Andes, many development organisations are now promoting it without adequately assessing local conditions.

There are examples of cases where sprinkler irrigation, introduced to replace current surface irrigation systems, has given rise to disturbing effects and where serious conflicts have arisen because of its consequences for water distribution and the rights and obligations of water users. Further it has been observed that on heavy soils, water from sprinklers infiltrates very slowly causing it to flow into depressions. This results in low water use efficiencies. The advantages of sprinkler irrigation are often not realised in practice because plots are small and irregular which leads to high fringe losses.

In the Andes, as elsewhere in the world, transplanting technical options from one place to another can have adverse effects. Irrigation infrastructure must be designed to respond to the social and organisational requirements particular to each irrigation system and to the complex physical condition of specific locations. Irrigation alone cannot ensure sustainable development. ■

Challenging water scarcity

Photo: Coen Reijntjes

Water, lifeline in farming. Low cost and biophysically and socially adapted technologies are needed. A treadle pump used by smallholders near Gorakhpur, Uttar Pradesh, India.

Editorial

Whether it comes from rainfall or irrigation, water means life in agriculture. When there is a water shortage plants become stunted, yields drop, animals become weak and men and women have to struggle to find the water they need. Most farmers have to deal with the problem of uncertain and variable rainfall and the effect it has on agricultural production. Rainfall is a serious risk factor in farming and farmers are always vulnerable to yield losses caused by extreme climate fluctuations. Besides recurrent natural phenomena such as El Niño with its devastating droughts and floods there are also the droughts and floods that are man-made and are the result of local deforestation and erosion, global warming and modern agricultural practices. To feed a growing world population, agricultural production must be increased and secured. One of the ways this can be done is by improving water management in rainfed agriculture or by irrigation which is one of the main ways of increasing yield and reducing the risk associated with drought.

However, irrigation often gives rise to its own problems. Competition for water between agriculture and industry is becoming increasingly acute. Untapped water reserves are becoming more difficult to find and over-consumption of water leads to such problems as the disturbance of natural flow patterns in river systems, ground water depletion and salt water intrusion in coastal zones. Due to insufficient drainage, a considerable amount of irrigated land has been degraded by water logging and salinisation. In some places, pesticide pollution and industrial waste has made water unsafe.

The amount of rainfall infiltrating the soil is decreasing because deforestation, soil erosion, monocropping and urbanisation is hampering groundwater replenishment. Access to water is becoming a critical issue, conflicts over water rights between farmers, between traditional and modern water laws, and between countries increase. At the same time, much irrigation water is being used inefficiently. Many new and promising schemes have been unsuccessful because the technology chosen has proved inappropriate for local economic, social and biophysical conditions or inadequate attention was paid to the importance of water rights, social organisation and gender.

Although irrigation is an important technique in food production it can still be improved. It also has its limitations and should not be seen as the only way in which water can be secured for agricultural production. In fact, there is a wide diversity of strategies that can be employed to conserve scarce water resources. Where irrigation development has reached its limits or is not possible, other types of strategies become important. In this issue of the ILEIA Newsletter we have combined different approaches to water management: irrigation, water harvesting, watershed management and water conservation. Several articles, from Peru (p6), Zimbabwe (p8) and India (p11 and p12) focus on the social organisation of water management. Others, from India (p10), Tunisia (p14), Nigeria (p16), Ethiopia (p21) and Kenya (p29) examine low-cost technology adapted to local conditions.

Water management is complex

Water is not only managed by individual farmers but also by groups of farmers in irrigation schemes and watersheds. Entitlement to land and water, social cooperation and legislation are important aspects of water management. Initiatives to improve water management can be taken by individual farmers as well as by communities, governments or projects. At the community level and above, processes of participatory planning are essential.

There are many traditional water management techniques. Some irrigation and water harvesting systems are very old and at field level these traditional strategies and techniques are still being used to make optimal use of available rainfall. Watershed management, however, is a relatively new approach and has become increasingly necessary as population pressure, modern agriculture and deforestation continues to disturb the ecosystems of natural watersheds. As water becomes more and more scarce, there is a need for an integrated approach to water management that encompasses all water users, types of water use and sources of water. Water conservation is also becoming increasingly important in planning and development. Water management, however, can never be an aim in itself, it is an integral part of farm and land husbandry and its objective should always be to protect and improve the farmers' situation.

Social organisation

The design, implementation and management of irrigation and watershed schemes depends to a large extent on the way farmers and the other actors involved relate and work together, and organise access to resources. The rural population is far from homogeneous (Mehta p11). Differences in wealth, gender, caste, ethnical background and political preferences, for example, mean that people have different access to resources, have their own rights and obligations, adopt livelihood strategies appropriate to them, have their own patterns of cooperation and thus have different and sometimes conflicting interests and perceptions of the local situation. This can make collaboration in irrigation and watershed schemes difficult (Bolding p.8). Many irrigation and watershed projects have failed because their design was based on physical and economic criteria alone with little consideration being given to social factors and issues such as entitlements to land and water (Kastelein p6; Diemer & Huibers, 1996). However, getting all groups of users involved and organised is often far from easy (Bolding p8). Self-help credit management groups (Fernandez p12) and farmer experimentation (Bolding p8) can increase the level of interest in water management and strengthen social cooperation.

Technology

High-external-input techniques may be too expensive for smallholders or are inappropriate to local biophysical and social conditions (Somashekhara Reddy and Sharathchandra p5; Kastelein p6; Mechergui & Van Vuren p14; Gobin et al p16). Many farmers would benefit from low-cost techniques more suited to their conditions and needs and which also ensure an increase in water use efficiency and conservation. Examples of such techniques include locally made sprinklers (Kastelein p6), low-pressure drip irrigation (Gobin et al p16; Chapin p29), water harvesting techniques (Padre p10; Fetien et al p21; Muhia p29) and the use of Vetiver grass (Dreyer p18; Grimshaw p20). Mulching (Padre p21) and the use of organic fertilisers are basic soil management techniques that increase water infiltration, water-holding capacity and help prevent water losses. Multiple cropping systems, like mixed cropping and inter-cropping, can help farmers to get the most out of the water available to them during particular seasons and from different layers of the soil. They can also help protect the farmer against the risk of complete crop failure.

Farmer innovation

Farmers, men as well as women, have developed many low-cost water saving techniques but often these innovations remain unrecognised. A programme on Indigenous Soil and Water Conservation in Africa is cooperating with technical services, universities and NGO's in Zimbabwe, Tanzania, Cameroon, Ethiopia, Burkina Faso and Tunisia in making an inventory of farmer innovations in soil and water conservation. Fetien et al (p.21) report on several of these innovations. Also Padre (p.10) reports on an interesting farmer innovation in India. Better insight is needed into why some of these innovations are being adopted by farmers and others not. Fetien (p.21) and Padre (p.19) describe two initiatives undertaken by farmers in Ethiopia and India to reforest their land. These experiences clearly show the impact of man-made drought and the positive effects of water conservation and reforestation on the availability of water and the productivity of land.

Many of these low-cost measures are within the reach of farmers. Water scarcity, therefore, can be challenged!

Mud Katta, still appropriate

The coastal region of Karnataka, India receives an average annual rainfall of 3800 mm between April and October. Little water flows down the streams to the Western Ghats after October. There is hardly any rainfall between February and April and the demand for irrigation is heavy. The perennial crops in the uplands are areca nut, coconut and coffee and in the valleys and coastal zone, paddy and vegetables are grown. Holdings are very small, normally not more than 0.5 ha. There are no major dams and ground water yields from wells are low. Irrigation, therefore, depends on tapping and conserving lean stream flow.

Mud Katta, the solution

Farmers build temporary bunds in the streams to harvest and store irrigation water. This water is guided through canals into smaller ponds or *kere* dug out and located on individually owned fields. Irrigation water is lifted manually from the *kere*. The bund, constructed from wood and earth, allows enough seepage to fill downstream bunds. Heavy floods are prevented from entering the fields by bunds constructed in such a way that they are easily washed away by heavy, early rainy season flows. They are rebuilt after every rainy season.

A farmer-elected committee is responsible for constructing and managing the system. Older people, experienced in estimating stream flow, are responsible for timing bund construction. The farmers receiving water from the main pond contribute a fixed amount of poles, leafy material and labour and help construct the bund at an agreed time. The farmers also desilt the canals. There is no lack of trees; 40% of the upland is forested and farmers in the coastal zone grow trees on their land.

This irrigation system is known as *Mud Katta* and can be found in every stream in Dakshina and Uttara Kannada. In the taluk of Mangalore, for example, some 3550 ha are irrigated in this way.

Conserving water

Farmers lessen evaporation by growing aquatic weeds in the *kere*. These cover the whole pond and are harvested regularly. They provide bedding for the animals and afterwards good manure for the fields. Drinking water is also tapped from the *Mud Katta* and stored in separate wells. These are only used when there is not enough ground water.

All structures are kept well filled in the dry season. As the soil is sandy, this enhances the recharging of ground water, another function of *Mud Katta*. This is important because salt water intrusion is increasing along India's coast due to heavy deforestation and overpumping of ground water for urban and industrial needs.

Mud Katta fits local needs and conditions

The arrival of pump sets and bore wells has not affected *Mud Katta*. Smallholders find it uneconomic to maintain individual wells and install pump sets. *Mud Katta* is cheaper, it uses local materials and no large investment is needed. Attempts to replace *Mud Katta* by concrete structures has failed because they tend to collapse.

The construction and management of *Mud Katta* does not seem to be affected by the break-down of social cohesion among rural communities. The benefits and limitations of pumping water from wells has forced farmers to cooperate. *Mud Katta* is well adapted to local conditions and continues to satisfy the need for irrigation water. At the same time this traditional system plays an important role in checking the intrusion of salt water.

Two cases from the field

Caterpillars and ducks

Integrated rice-duck cultivation in Vietnam

M.A. Qaium

The Red Hairy Caterpillar, or *Amsacta albistriga* is a voracious polyphagous pest attacking many rainfed crops in low-rainfall areas of Andra Pradesh, Tamil Nadu, Karnataka, Madhya Pradesh, Maharashtra and Rajasthan in India. The caterpillars devour sprouting seedlings and cause damage rates that vary from 25-100 percent. Farmers try to avoid the pest by postponing resowing until late in the season but losses are still heavy. Deep ploughing to expose pupae to the sun, destruction of egg masses and digging trenches to prevent the migration of catepillars are also ineffective.

Pesticide applications are not an option for smallholder subsistence farmers because egg hatching occurs in many different batches and requires adequate and immediate control. Women, children and the elderly catch caterpillars but cannot keep up with the speed at which they emerge. Sanghi and Qaium developed a Natural Pest Management (NPM) strategy that draws on communal resources and promises to reduce the work load that catching caterpillars currently imposes on women.

This NPM approach is based on the observation that only collective action can ensure the effective implementation of non-pesticide control. Taking the behaviour patterns of the parent moth as their starting point, Sanghi and Qaium, supported by regular meetings with scientists and NGOs, set about motivating farmers and training them to recognise patterns in the moths life cycle and behaviour. Light traps, each of which proved effective for an area of 7 - 8 hectares were set up at night - the time when moths are most active. Rainfall predictions were monitored by farmers enabling them to anticipate when moths were likely to emerge and the eggs deposited by female moths around light sources were collected and destroyed. Migratory caterpillars were locked into traps baited with their favourite food, such as cowpea or cucumbers in intercropped fields or the leaves of *Calotropis* or *Jatropha* at field boundaries.

Whilst this strategy was successful and pesticides were avoided, it was labour intensive and made heavy demands on the capacity of farmers to cooperate together. It did, however, help free women from the week-long work of catching caterpillars because night monitoring was generally carried out by men. The results of this strategy have been such that the Andra Pradesh State Department of Agriculture, working in close cooperation with NGOs, has adopted it in a number of areas and it is being recommended as a control strategy by the Andra Pradesh Agricultural University.

Integrated rice-duck cultivation in Vietnam

Pham Cong Phin

Duck raising has a long history in Vietnam. Duck owners are constantly trying to reduce feeding cost and use paddy grains dropped around rice fields to feed their ducks during the harvest period. When the young rice plants are well established, ducklings are got ready. The birds must be big enough to feed themselves when they are allowed into the rice fields after the crop has been harvested.

An integrated rice-duck cultivation method developed in Japan offers another approach to integrating duck-rice production. Ten day-old ducklings are released into recently transplanted rice fields at a density of about 190 ducks per hectare. As they feed they help control insects, weeds, snails and even mice. In doing so, they considerably reduce the amount of human labour needed in cultivation. The ducks are taken out of the fields before the rice ears appear. They are then big enough eat.

In 1994, the rice-duck system was tested for the first time in Vietnam. Trials took place in the Sustainable Agriculture Promotion Centre, Haiphong and were guided by VAC VINA (Garden Association of Haiphong). Farmers' interest was immediately aroused and the method is now being used by several hundred families in the locality. More data is necessary, however, before it can be introduced into extension programmes.

This method of chemical-free rice cultivation has aroused much interest in Japan, where some 10,000 families have adopted the system, and in Korea, China and Taiwan. Recently, Tanzania also began experimented with this organic alternative.

ILEIA research

Highlights Peru

photo: Marielle Dubbeling

The Peruvian Andes are characterised by several different altitude zones and this has given rise to considerable agricultural diversity. Farmers in the region have had long experience in growing potatoes. They are the staple crop of the region and are cultivated on valley floors and hillsides during the rainy season (September-April) and, under irrigation, during the dry season (May-August).

However, despite their long history and their prominence in the local diet, the potato yields of small Andean farmers are generally low. This is largely due to pest and disease related losses. Intensified potato production, less reliance on local species and varieties, and the indiscriminate use of pesticides has resulted in a high incidence of pests and diseases.

Early in 1997, the ILEIA programme in Peru initiated a PTD process amongst farmer groups in Huancayo (Central Peru) and Cajamarca (Northern Peru). The majority of these groups identified potato pests as a major constraint in agricultural production. It was decided to carry out a series of experiments on controlling late blight (*Phytophthora infestans* - one of the main problems in potato cultivation all over the world), and in the control of the potato moth (*Phthorimaea operculella*), a pest which generally attacks the crop during storage. Farmers have allied with local NGOs and research institutes such as INIA (National Institute for Agricultural Research) to design and evaluate these experiments.

Two different trials on ways of controlling the potato moth, and thus reducing the damage it inflicts on stored potatoes, have already been finalised and evaluated. One trial, conducted by a farmer group in Cajamarca and supported by INIA, involved four different methods of storage:
a) storage in sand,
b) storage in barley straw,
c) storage in quinua chaff, and
d) plain storage, the traditional method of storage that served as a control.

The moth inflicted most damage in the control method, with the result that there was a considerable loss and a low percentage of sprouting. There was virtually no incidence of pest found in the other categories of storage. However, the number and quality of sprouts varied considerably. Straw treatments resulted in a large number of short sprouts with seemingly burned ends whilst potatoes stored in sand had a small number of long sprouts that were easily damaged during planting.

In Huancayo, a farmer group supported by *Grupo Yanapai* and INIA tested three different storage methods: a) plain storage, the traditional method serving as a control, b) use of herbal ashes, and c) use of petrol traps. Generally speaking, farmers considered treatment with ash to be the best. The problem with petrol traps was that petrol often spilled from the traps and damaged the potatoes.

New trial designs for 1998 have been formulated on the basis of these results. The exchange of results between the two different farmers' groups and the support of research institutes such as INIA (for example, in terms of training on the life cycle of the moth, plus monitoring and evaluation of results) has been an important stimulus.

However, the question of what strategy farmers will adopt towards controlling pests in the near future remains an open one. The government has eliminated the tax on pesticides making them more easily available to farmers. PTD as it is being implemented at present concentrates on one specific agricultural problem and technique. The challenge to ILEIA and its partners is to extend beyond this technique to sustainable development of the farming system as a whole. To this end, ILEIA is monitoring and analysing the economic and ecological performance of a limited number of ecological and conventional farming systems within Peru. This research will not only broaden our understanding of these farming systems and their management strategies, but will also provide information on the economic and ecological costs and benefits involved. Hopefully, this will give us more insight into the bottlenecks and opportunities for sustainable agricultural development - our ultimate objective!

The potato is of fundamental importance in the diet and economy of the farmer in the Bolivian Andes. Usually this crop is either grown in rain-fed conditions above 4000 meters or under irrigation in the valleys where the altitude varies from 2500m to 800m. The Andean potato weevil - various species of the genus Premnotrypes - is the main pest at higher altitudes. The adult female lays her eggs at the base of the potato plant. The hatching larvae move through the soil and feed on the tubers formed underground.
At harvesting time, the larvae leave the tubers and enter the soil forming pupae and later as adults they invade recently planted potato fields. The weevil produces one generation each year a process well synchronised with the potato crop.

Training Bolivian farmers in IPM

Rayne Calderón, Raúl Esprella and Luis Crespo

The larvae cause most damage making deep, irregular tunnels in the potato tubers. Farmers report that often over 50 percent of tubers are damaged in this way and that in some cases damage runs to between 78 and 100 percent have been found. Highly toxic insecticide, often used in a dangerous and inefficient manner, is the main way these pests are controled. Farmers have no knowledge of alternative control methods.

IPM of the Andean Potato Weevil

Building on earlier work by the International Potato Centre (CIP) in Peru (Cisneros and Gregory, 1994), the Bolivian Potato Research Programme (PROINPA) began working with IPM in Kollana, a community in the Altiplano or central highlands of Bolivia. Here, at an altitude of 3900m, the most prevalent potato pests were weevils and tuber moths. The PROINPA programme looked at existing control methods and compared them to IPM technologies so that farmers could see the advantages of the latter for themselves.

Training farmers

Farmers must understand the enemy if they are to fight it. Lack of knowledge makes control methods ineffective. The project began by providing farmers with information about the weevil. Its habits are such that many farmers are unaware of its life cycle (it walks not flys, but only walks and its habits are nocturnal) and do not know that the larva and the adult pest are different stages in the weevils development. Farmers need information on its behaviour, the length of each stage of its life cycle and the periods when the insect is most vulnerable to the various IPM strategies possible.

Training activities such as courses and field days were organised for a variety of groups including farmers, school children and extensionists from NGOs. Children were quick to learn: they were inquisitive, had a good memory and plenty of time to practice IPM components, such as manual collection. A variety of materials were used during these training sessions. PROINPA and CIP produced handouts, pamphlets, posters, slides, videos and flip charts according to local needs.

Implementing measures

Various control methods were discussed during the course of training and the farmers analysed them before deciding which were the most appropriate. IPM strategies included: **Harvesting potatoes on woollen bags** Directly after harvesting potatoes are heaped onto the bags normally used for transport. This allows the larvae that leave tubers to be caught so they cannot return to the soil and complete their cycle.
Stirring up soil in areas of concentrated infestation where potatoes were mounded in the field or where seed was selected. This left larvae and pupae exposed to light and predators. **Covering ditches with plastic in the vicinity of stores and fields.** The weevils, who are unable to fly, could not negotiate their way over the slippery plastic into the potato fields. **Ditches around the fields covered with straw** The ditch is filled with straw which creates a perfect environment for the weevils during the day making it possible to catch them easily.
Adults collected manually This is a night job because the weevils are nocturnal.
Elimination of volunteer plants
Volunteer plants may be a source of infestation. **Use of chickens** Chickens are important predators and find the weevil palatable at all stages of its development. **Directed application of insecticides and chemical barriers**. Such spot application involves the proper use of insecticides with a low toxicity. Insecticide is sprayed around the base of the plant where the adults weevils rest during the day. Chemical barriers can also be sprayed around the fields to keep weevils at bay.

Amongst the most promising components of IPM adopted by farmers in Kollana were the use of bags during harvesting; the timely and well-directed use of insecticides; covering ditches around the fields with plastic and using chickens as predators.

PROINPA and other institutions have organised weevil collection competitions to sensitise farmers to the weevil problem. Farmers who handed in the most adult weevils were given small prizes. So far eight “collection competitions” have been organised in various parts of Bolivia so far. Four have been held in La Paz and a total of 470,000 adult weevils have been collected, a figure that represents a potential population of 118,000,000 larvae. These collection competitions are most useful when run immediately prior to the time when the female weevil start to lay their eggs.

Institutional follow-up

The weevil project has stimulated interest amongst many NGOs in the central Altiplano. NGO staff have been trained in weevil control by PROINPA and this information is now being spread through several communities in other provinces.

Gender and Integrated Pest Management

In 1995, a PAN Asia and the Pacific study of women and pesticides, through interviews with more than 2,500 farmers and workers most of whom were women showed that most farmers and workers spray pesticides or come in direct contact with pesticides .

Sarojeni V. Rengam

Most are unaware of the adverse effects of pesticides and many of those who apply pesticides often cannot read labels or do not follow instructions. Users often do not use protective clothing because it is unsuitable for the climate, is unavailable or too expensive; farmers and agricultural workers in the region use highly toxic pesticides listed as World Health Organization's Class 1 pesticides, extremely hazardous pesticides. Most of those surveyed stated that they have been poisoned, citing acute effects like dizziness, muscular pain, sneezing, itching, skin burns, blisters, difficulty breathing, nausea, nail changing colour and sore eyes.

The development of IPM, which has centred on food crops like rice and vegetables will be able to benefit women farmers and workers - the main contributors to food production. But unless women are specifically identified and included in project planning, implementation, and encouraged to assume leadership roles they are likely to remain invisible. It is essential that IPM training, information and extension reaches these women. IPM programmes, training methodologies and technologies need to take women's time committments into consideration.

Sungai Buaya Case Study

In 1994 a series of meetings were held with farmers of Sungai Buaya, Seberang Perak, in the Malaysian peninsular. The farmers of Sungai Buaya were heavy users of agrochemicals and the degree of mechanisation in the region is considerable. After initial high yields, farmers needed ever increasing inputs of pesticides and fertilisers, with ensuing health hazards and environmental damage. The farmers approached the Education and Research Association for Consumers (ERA) who then contacted PAN AP for support to tackle the problems involved in pesticide use .

The village consisted of about 100 families, most of whom live below the official poverty line. The average size of a family was about 8 members. Average monthly income from rice was below US$ 100. Most of the farmers borrowed heavily at the beginning of the rice season.

After initial discussions with key people in the 'kampung' (village), we started an intensive one-day orientation programme on IPM, and shared achievements in other Asian countries. More than 150 farmers participated, expressing concerns about the health hazards of pesticides, increasing operating costs, and notable decreases in yields. Significantly the women farmers, although present, sat at a distance and did not participate. After the meeting, we had informal discussions with these women for their feedback on the IPM discussions. They had many questions about IPM and its success in other countries. They had not raised these questions earlier because they were 'shy', and "after all, the men were there to raise these questions" - we encouraged them to speak out. Regular meetings with the Steering Group (or Jawatan Kuasa Kelompok) in the kampung followed, but no women was involved.

We had to make sure that we continued to meet with women after the discussions had taken place. In developing the IPM curriculum for the first rice season, the Government Agriculture Training Centre helped to identify and bring together key IPM trainers and extension officers (from the Department of Agriculture (DOA) in the Northern Region of West Malaysia), and ERA and PAN AP. In discussing the participation of women and how to encourage it, all DOA personnel felt that it was a bad idea - since the families in Sungai Buaya were Muslims, it would be difficult to conduct the training of a mixed group. However, we agreed that after the first season we could try to reintroduce the topic.

The IPM training schedule, and the issue of women's participation, was put to the village steering group who discussed it with the village. They suggested changes in the training schedule, and the head of the village volunteered his field for training and as a 'demonstration plot'. But the unexpected suggestion was that women farmers were to be involved in the training.

These training sessions covered two full rice-growing seasons with 25 field-training sessions. 50 farmers were trained, with one-fifth of the participants being women. In the beginning, the women were silent and kept to themselves. But as the training involved weekly observations and identification of pests and predators in the rice fields, as well as experiments with fertiliser use, the women began to share their observations in the group.

Also, the women initiated follow-up discussions after the training sessions. While the men rarely got together afterwards, the women made time to get together to discuss the training, the difficulties they faced and generally shared their ideas and thoughts. They often sought clarification from the organisers of ERA or PAN AP, who were women, since they felt more comfortable with us. Their group discussions often included others not involved in the training - they were sharing their knowledge.

In addition, at the end of the first season, a training session on gender issues was organised with the village women (including the 10 women participants of the IPM training). ERA and Tenaganita, a local women's organisation, conducted the highly successful training which discussed the many problems and issues they faced as women and farmers.

In the second season, there was a marked difference in the women's responses during training sessions. A few became actively involved during the mixed group discussions. The sitting arrangements during discussions had also slowly changed. While at first the women sat at the back; they were now in a separate row but side by side with the men. Although 50 farmers formed the core of the training programme, others from the village were also dropping in at the training sessions. The IPM training had become more of a village activity and others benefited from the experience.

During the training evaluation, the trainers and the participants acknowledged that the women were collectively the best participants. In addition, the women have organised saving schemes, and income generating projects including making snacks for sale. The IPM participants are also rearing fish for consumption and sale, with the women being fully involved in this successful enterprise. . For about a year, the women have also been hired by the farmers in adjacent villages to check fields for pests and predators, and advise them about their pest problems. These women farmers have also taken on leadership roles in their village especially if matters relating to IPM issues. They have been invited to speak about their experiences, and their needs as rice farmers, in several seminars. In fact, they have been asked to represent their village in these activities.

New Directions

Given the inequalities within society and within the household, it is essential that women are part of planning and implementation, in order to reach the goal of sustainable pest management and food security. It is only when women have access to, and control of, resources that they can be equal participants in food production. Women must also have more access to information - only then will they be empowered to take decisions regarding sustainable farming practices and manage finances. This will also enhance their status in their families and communities.

Sarojeni V. Rengam, Executive Director, PAN Asia and the Pacific, PO Box 1170, 10850 Penang, Malaysia

Developing an African model for effective IPM training

There is growing concern in Africa about the dramatic rise in the use of pesticides by small-scale farmers. Cases of acute poisoning and problems with pesticide residues in local and export produce attract growing attention. Smallholders in the East African highlands grow cash crops such as coffee in a mixed cropping system that includes vegetables. Pesticides are increasingly being used on a calendar basis. The cost of agrochemicals is a heavy drain on the farmers' income, and sometimes pesticides destined for coffee are used for vegetables and other food crops. This puts human health at risk. Although alternative pest and disease control options exist, there is very little information on IPM and integrated crop management (ICM) available to this group of farmers. NGOs promoting organic farming often focus on kitchen gardens and subsistence crops.

Brigitte Nyambo, Martin Kimani and Stephanie Williamson

To address these issues, a small pilot project was started in Kenya in late 1995. Its aim was to develop and disseminate appropriate crop management options. The Farmer Field School (FFS) approach to implementing IPM has been used with great success in many Asian countries in rice and vegetable cropping systems. This approach combines training with field-based, location-specific research to give farmers the skills, knowledge and confidence to make ecologically sound and cost-effective decisions on crop health.

The Kenya pilot project set out to discover whether FFS training methods developed mainly in the paddy rice monoculture and small-scale, commercial vegetable production from the Asian farming context would work in Africa. The project team therefore adapted existing FFS curricula to develop a training programme tailored to the specific agro-ecological and socio-cultural needs of Kenyan smallholders who grow a variable mixture of annual and perennial crops for domestic consumption and for sale. In particular, the project team needed to develop learning exercises to help farmers explore integrated crop management options for long-established coffee gardens.

Running the project

Many IPM projects have failed to bring farmers, researchers and extensionists together, and poor linkages amongst these groups have been one of the major obstacles facing farmers when they try to implement IPM techniques. To avoid such pitfalls, this project aimed at developing inter-institutional collaboration between research, extension and an NGO, in order to build bridges between key players and better support farmers ready to experiment with IPM. The International Institute of Biological Control (IIBC) Kenya station, the Coffee Research Foundation, the Kenyan Agricultural Research Institute, the Extension Division of the Kenyan Ministry of Agriculture, Livestock Development and Marketing, and the Kenya Institute of Organic Farming (KIOF), an NGO, cooperated in running this project.

The project team ran a Participatory Rural Appraisal amongst farmers in the Kiambu area to identify immediate pest and disease problems in their coffee and vegetable production, and to discuss the wider implications of their farming systems. Many small-scale farmers in this area have virtually abandoned their coffee bushes, because of the low price of coffee and the rising cost of pesticides. Those growing tomatoes for the local market find that insecticide and pesticide form an increasingly large proportion of production expenses. Farmers tend to apply these pesticides as an insurance measure against pests and diseases, with little regard to need or timing, and as a result do not achieve higher yields or better quality produce.

The Farmer Field Schools project decided to focus on developing options that were cheap, sustainable and based on ecological principles. Farmers should be able to see the benefit of these options within one growing season.

Setting up Farmer Field Schools

The project team then put together a draft training and research curriculum for a Training of Trainers (TOT) course and for Farmer Field Schools, that combined discovery-learning exercises on pests, weeds, natural enemies and disease transmission with experimentation on organic methods, including liquid manures and botanical pest repellents. Eleven Ministry and KIOF extension staff were trained to become FFS facilitators and they set up FFS groups in four agro-ecological zones. About 65 farmers were involved in the project. The crops they grew included coffee, kale, cabbage and tomato.

Two of the groups had already been trained by KIOF and had no wish to use agrochemicals. However, they were having problems with vegetable diseases and were troubled by low coffee yields. The other groups were committed to treating their tomato crop with pesticides.

The FFS sessions were held for half a day once or twice a week in the fields of one of the farmers. The sessions were conducted over a period of six months. Each group carried out weekly observations on small plots in this field, in order to compare their usual cultivation practices with the pest control practices using IPM/ICM options developed by the project. They also conducted experiments on alternative crop management methods, including traditional non-chemical methods. The groups visited each other to discuss their experiments and findings.

Preliminary results

The Farmer Field Schools generated a great deal of enthusiasm amongst all the farmers who attended them. One of the contributing factors was that sessions were carried out in local languages. English, Kiswahili and the use of scientific names were kept to a minimum. There were no local names for some diseases or insects, so farmers invented their own on the basis of a careful observation of these organisms. For example, they observed that hoverfly larvae were common predators of aphids on vegetables and dubbed these new-found friends 'helicopter insects' because of the flight patterns of the adult insect. These activities helped give farmers a sense that they were in control of the learning process, and this gave them the confidence they needed to tackle experimentation.

Both the organic and non-organic farmers were able to learn useful new methods for improving the health and profitability of their crops. The interaction between the KIOF and the Ministry extension staff during the TOT gave rise to much discussion on integrated crop management, and highlighted the need for taking a critical look at all recommendations - whether these were for synthetic or organic compounds. The tomato growers in particular discovered the benefit of preparing compost and using liquid manures and plant tonics to produce more robust plants.

All the groups came to appreciate the value of predators and parasites in controlling pests, and developed an understanding of the consequences of pesticide application and other management practices on these natural enemies. For example, the organic coffee farmers were able to observe higher numbers of parasitised *Antestia* bugs (a pest that sucks and damages developing coffee berries) in well-pruned IPM plots. They could compare this to conditions in the plots where coffee bushes were currently left unpruned. All the groups learned the value of making management decisions based on a regular monitoring of crop ecology, input costs and labour effort.

The FFS process clearly demonstrated the need for farmers to experiment with options in order to find the best solutions for their particular situation and problem. Mulching vegetable crops is commonly recommended as a means of conserving moisture and reducing the diseases spread by rain splash. During their weekly observations, the groups discovered that many crickets and cutworms were found hiding under the straw mulch and that these were destroying young seedlings. Farmers concluded that it was better not to apply mulch until the transplants were well established.

The farmers chose to test a variety of local methods for controlling soil pests and diseases in nursery beds. These were methods which they had heard of, but never used. Many farmers simply sow in topsoil enriched with compost, and disease incidence among seedlings is high. In the FFS, comparison plots were set up to investigate the effects of different treatments. Three of the groups found that burning plant trash on the top soil before sowing was most effective when measured in terms of percentage germination, seedling vigour, and the reduction achieved in the incidence of rootknot nematodes.

Preparing a coffee agro-ecosystem analysis poster

After producing immediate, visible results in vegetable plots, the FFS persuaded participants that it would be worthwhile to invest more time and effort in their coffee bushes and to try out IPM and ICM options. In the groups where coffee bushes had been neglected, farmers were able to see a marked difference after a few weeks. Plant health and potential yield improved as a result of pruning, mulching and the application of organic matter. Where farmers were using pesticides, IPM experiments showed that good coffee husbandry and decisions taken on the basis of agro-ecosystem analysis could halve the number of fungicide applications needed, without causing any reduction in potential yield.

The season-long interaction in the FFS also allowed coffee researchers to discuss the question of coffee management. The informal setting made it possible to address some issues that were difficult to tackle through official channels, such as the extent to which current research was relevant to smallholder systems.

Of major concern to smallholders is the lack of guidance on which food crops can be intercropped without negatively affecting coffee yields. Preliminary research from the Coffee Research Foundation showed that maize, sweet potato and cassava compete heavily with coffee, but potato and legumes can be grown so long as they are not planted directly under the coffee canopy. The project team was able to discuss these findings in the FFS, and relate them practically to learning activities showing the position of coffee feeder roots and where mulch and manure should be applied for maximum benefit. The interaction generated informative responses to farmers' and extensionists' questions. The information provided was immediate, and more direct that the communications that emerge from the formal recommendations handed down from research to extension.

The FFS provided a forum in which farmers and researchers could study topics that were not on the formal research agenda, and they were able to complement each other's experimentation. For example, an interesting disease management method suggested by one farmer - and later tested by several groups - involved diluting skimmed milk in water and spraying this onto tomato plants to delay the onset of blight. By using milk, one group was able to halve the usual number of applications of the expensive *Ridomil* (metalaxyl) fungicide. Another group found that the protective effect was not sufficient to prevent blight in cool, wet weather. As a result, researchers are now studying the usefulness of milk solutions and other non-chemical pest and disease controls that showed promise in the FFS plots.

The next stage

This FFS project provided many interesting and encouraging results. It was a first attempt to develop an African model of IPM training in smallholder cash crops. Most farmers were extremely keen to continue FFS sessions and many were already sharing their new experiences with family members and neighbours. Other groups asked for FFS to be organised in their area. Both farmers and extension staff gained not only skills and knowledge, but also the confidence to take decisions and set up small experiments. Researchers involved in the project were generally positive about this new form of collaboration and felt they had learned a great deal about non-chemical crop management practices, and gained an insight into the way farmers view production problems. The FFS pilot project succeeded in stimulating farmers to set up experiments in their communities. In this they were supported by a set of guided learning activities that were flexible enough to accommodate the different ideas and particular interests of the groups concerned.

This approach has much to offer in cropping system situations where pesticide misuse is not a major issue, as the experience of organic farmers and those with badly neglected coffee bushes confirmed. This small pilot, even though it was short and had limited resources, nevertheless raised several questions. IIBC and collaborating organisations are planning a full impact assessment of the FFS pilot project, in order to assess the lessons that can be drawn from it for farmer participatory integrated pest and crop management research and training in perennial cash crop systems. The assessment will analyse the technical output and the results of FFS experiments, as well as the cost/benefit of IPM/ICM options and whether ecological principles learned in the annual crop context can be readily transferred to perennials. It will also focus on indicators in the process, such as the sustainability of FFS impact at farm and community level and the likelihood of continued collaboration between project partners. Decision-making in coffee cultivation was an area where important gender differences emerged in the FFS groups and this needs to be considered in future programmes. Other issues to be explored include the best way to build farmer participatory methods into the state extension system, and the relevance of the experiences of this FFS project to other smallholders operating in mixed cropping systems.

The Kenya FFS pilot project generated a great deal of enthusiasm among the farmers, extension staff and researchers involved, and created a demand for further FFS training. As one of the FFS participants said during the evaluation session, "We are researchers too and we are proud of our findings". ■

Courses transfer more than information. They provide examples of how information can be communicated in the learning situation. Participants on an international IPM refreshing course were introduced to Non-Formal Education (NFE) in the hope that they would use this method to train IPM extension workers in their own countries.

The philosophy of IPM learning

Huub A.I. Stoetzer

It is now accepted that IPM is a knowledge-intensive and location-specific process involving direct field observations, data gathering and decision making by farmers in their own fields. The inappropriateness of extension methods based on conventional methods of transferring technical knowledge in IPM programmes has been highlighted by the success of Farmer Field Schools (FFSs). In emphasising a participatory approach FFS uses discovery to achieve active learning. Field ecology emerges as a holistic system involving the whole cropping cycle and not simply specific production components and farmers experiment rather than watch demonstrations carried out by extension workers or researchers. After critical testing they select from a '-basket' of options rather than adopt fixed recommendations and in this way farmers enhance their decision-making skills.

Although the FFS approach is spreading rapidly and many NGOs work with participatory extension methods, traditional learning methods are still characteristic of extension systems particularly those within national extension services. Here, in a top-down approach, the extension worker acts as an intermediary between researchers and farmers in transferring the 'new' technology generated by researchers.

For staff involved in the IPM knowledge system, working in a participatory system represents an important shift in attitude and thinking. The question is how can staff involved in the traditional, top-down knowledge system be reassured that participatory approaches are not life threatening! The answer seems to be through training courses and workshops. However, experience has shown that despite innumerable workshops and articles, many misconceptions still exist about the participatory extension approach. To overcome these problems the IAC extension refresher adopted the Non-Formal Learning approach and, as we explain below, it was a success.

International IPM training

The International Agricultural Centre (IAC), Wageningen, the Netherlands has been running a three-month, international course on IPM in the early 1970s. Using a variety of training methodologies, the course deals with practical, technical and scientific aspects of IPM and includes an IPM Extension module. It addresses a target audience of higher and mid-level officers concerned with crop protection and working within governmental organisations and NGOs. Most course participants come from the South.

Over the years experience has shown how difficult it is to introduce in-depth participatory extension approaches effectively into the IAC-IPM extension course. Technical crop protection specialists and extension workers tend to be more familiar with the traditional transfer of technology type of extension system. Therefore, a short, regionally-based refresher course in extension was designed as a followed up to the international IPM training course held in the Netherlands.

Regional IPM extension courses

These regional two-week **Extension Development for IPM** courses held in cooperation with such organisations as the International Centre of Insect Physiology and Ecology (ICIPE), Kenya and BAIF, Development Research Foundation, Pune, India.

Training trainers

The course anticipates that when participants return to their home countries they will use their new experience to train others. The course is based on ideas developed and tested in IPM extension and training in recent years and makes an attempt to extrapolate the IPM experience to sustainable agriculture in general. IPM seems an appropriate methodological starting point when introducing sustainable practices and improving farmers' and extension workers' capacity to think in ecological terms because many of the ecological processes involved in IPM are easy for farmers and extensionists to observe.

Extension Development for IPM is based on the principles of NFE and adult education: learning through experience, experimentation, and self-discovery and building on existing knowledge and experience.

Field problem are translated into learning experiences and group dynamic exercises are an important part of this process. It is known that people tend to imitate the teaching methods used on them in the past. It is important, therefore, that course participants' experience NFE for themselves. All methods and activities used on the course are consistent with those to be used later in the participants work situation and the course itself is structured according to NFE principles.

Participants' experiences

Some participants on the refresher course showed an initial resistance to this learning-by-doing and learning-by-discovering method. They still expected lectures and more technical subjects and the fact that neither facilitator(s) nor participants were supposed to lecture was rather difficult for some course members. This problem was most evident in discussions with the farmers. Once in a while facilitators had to intervene by breaking into the lectures that developed when participants addressed farmers. In general, however, participants showed interest in discussing opportunities and constraints with farmers and in using the participatory rural appraisal techniques when visiting their fields. It was interesting to see that participants involved with organic farmers in Kenya tried to get as much technical information as possible about growing crops according to organic principles.

Although the course was held in English, communication with farmers was in the local language. The number of participants speaking the local language on each refresher course was usually a little less than 50 percent.

In discussion sessions with farmers, translation was required but this did not appear to be present a problem. If full use had been made of PRA techniques translation would have been less necessary as visualisation strongly assists the mutual understanding of the topics introduced. In analysing the many problems confronting farmers, it was found that facilitators were needed to guide both the selection of key issues and the choice of how these issues should be approached by the extension session. An initial proposal for the extension session put forward by the course participants themselves, for example, was a series of lectures on technical subjects. The facilitators had to probe for new ideas and alternatives and then encouraged the participants to formulate these into improved proposals.

Farmers were supposed to participate as much as possible in all activities, demonstrations, explanations, and group interactions. The techniques necessary to ensure this degree of farmer involvement were used during the course. Whilst some still found it difficult to use these methods, in their final evaluation participants showed that, in general, they were convinced of the effectiveness of the participatory extension approach and the learning methodologies it involved.

Experiences during the extension day

These extension sessions generated considerable interest although often there was some tension at the beginning. The farmers did not quite know what to expect from the group which contained several foreign faces. Course members, on the other hand, saw it as a ‘day of truth’, a kind of practical examination. In addition farmers were not used to the agro-ecosystem analysis. However, drawing attention to the differences between beneficials (the farmers’ friends) and pests (the farmers’ enemies) and the positive and negative factors that influenced crop health provided plenty of opportunity for the group to warm up. Discussions were particularly interesting when the groups presented their conclusions on the status of their crop and suggested ways in which problems could be prevented or controlled. During the extension day the field was the training material and the farmers’ own observations the groups’ source of knowledge. This was clearly a new learning experience for both farmers and course participants.

Visual aids were used as much as possible and farmers reacted positively to the exercises in group dynamic exercises. They were excited to discover that their fields did not only contain ‘farmers’ enemies’ but ‘farmers friends’ as well and that using pesticides might endanger these beneficial insects. Such issues led to long discussions. In their evaluation farmers made it clear that they had enjoyed the way the sessions were organised and appreciated the approach. They were positive (and sometimes very kind) in their evaluations of the course participants and made a number of striking remarks. I conclude this article by letting the farmers’ comments speak for themselves. “Today we are not told what we have to do in our crops”. ”For the first time in contacts with extension workers or researchers we feel that they (participants) treat us as equals”. ”These participants sit together with us on the ground at the same level”. ”We learned a lot of new things about growing our crops and trying to prevent or control the pests”.

”We did not know that we have friends (parasitoids and predators) in our crops, helping us to control the pests.” (This remark was also made by a group of organic farmers in Kenya!); ”When can we have a next field day. We want to go and try to implement new ideas”.

Using *Tithonia* concoctions for termite control in Busia District, Kenya

As part of the Kenya Woodfuel and Agroforestry Programme (KWAP) farmers in Western Kenya are taking part in an on-farm experiment in pest control. In keeping with the participatory approach, farmers identified the major insect pests in their area. A number of local, wild shrubs were selected and used to prepare insecticides. Tithonia turned out to be a very effective multi-purpose shrub.

Floice Adoyo, John Bwire Mukalama and Musa Enyola

Busia is a district in Western Kenya that lies close to the Ugandan border. Altitudes in the region vary from 1128 to 1500 metres above sea level. The district falls within the Lake Victoria Basin and receives a mean annual rainfall of between 600 and 2030 mm. Mean annual maximum temperatures range from 26° C to 37° C and mean annual minimum temperatures fall between 14° C and 22° C. Evapotranspiration rates range from 1800 mm to 2200 mm. Busia covers some 1776 km² and 137 km² of this is permanent water. Crop cultivation, animal husbandry and fishing are the main economic activities.

KWAP has been active in Busia since 1984. It uses Participatory Rural Appraisal techniques (PRA) to analyse the factors that constrain tree growing in the district. Farmers have identified the scarcity of firewood, a lack of building materials and fodder trees, the absence of fruit trees, shallow soils, and the heavy incidence of such pests as termites, moles, monkeys, weevils, stalk borers, ticks, liver-fluke and worms as major problems. Pests threaten food supply at the household level, and the main cereal crops of this drought-prone area - maize, sorghum and finger millet - are especially vulnerable. Termites are particularly destructive and attack planted trees as well as dried materials being used in building. Chemical pesticides are not used very much in Busia because they are too expensive for most smallholders and are not thought to be very effective.

Since 1986, KWAP has been actively developing an operational approach designed to help farmers in Western Kenya achieve more effective farming practices. Small-scale, on-farm experiments have been part of this initiative. Working together with research institutes and government extensionists, farmers have adapted and modified technologies in an attempt to find concrete solutions to their farming problems.

Busia's wonder shrubs

A number of remarkable shrubs can be found along the roadsides of Western Kenya. In Busia, the botanical pesticide potential of these shrubs had not yet been fully recognised by development workers. Local shrubs that may provide a solution to the widespread problem of termite infestation include *Tithonia diversifolia* which has proved useful in improving soil fertility (see ILEIA Newsletter 13.3). *Tithonia* decomposes fast, releases plant nutrients readily, and is particularly rich in phosphorus.

During on-farm bio-mass transfer trials, it was noted that plots treated with *Tithonia diversifolia* or with a mixture of Tithonia and *Melia azedarach* hardly suffered from termite attack, irrespective of the stage of crop development. This motivated many farmers to experiment with Tithonia and to combine it with other herbs and shrubs in an attempt to control termites on their farms. This article draws on the farm records kept by one of the farmers who took part in these trials.

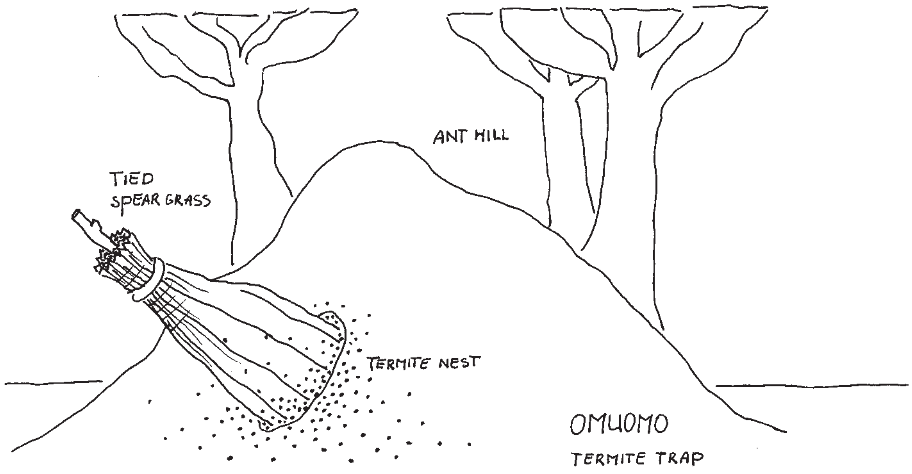

Figure 1: Trapping termites

Experiments in termite control

Mr Egesa took part in the experiments designed to test the effectiveness of various termite control substances. He lives on a 7-acre farm which he shares with his three brothers. Egesa has one wife and their marriage has been blessed with five children. Farm activities include dairy farming under zero grazing and Egesa has one animal and one heifer. He cultivates fodder crops, napier grass and calliandra trees, and observes soil and water conservation measures. The family's horticultural crops consist mainly of tomatoes and pigeon peas which are grown on two acres of land. Maize, beans and cassava are the main subsistence crops. To earn extra income, Egesa has taken up selling tree seed to his neighbours, and often travels from market to market in search of customers. He has been experimenting with various technologies in order to increased his production. In his farm records he notes how he experimented with a solution of Tithonia and Cassia spp. in an attempt to control termites and increase his production.

"I mixed the leaves of two kilograms of *Tithonia diversifolia* with two kilograms of *Cassia spectabilis* and *Cassia siamea*. I left it for three days before I stirred it. After 15 days, on 23 October 1994, it was ready for use. I applied the solution to my trees. It stopped the termites for two weeks. I filled a 100 gram tin with the mixture and used this to treat each tree. I forgot to mention that I used 16 litres of water to make the solution. I prepared another batch of the solution the same day using the same amount of leaves and water. This was ready for use on 17 December. I used the same 100 gram tin but this time added a half measure extra. I sprinkled this mixture on my trees and it kept the termites away for about 18 days. The mixture has a bad smell. You really have to be devoted to your work to use it! In the meantime I prepared another 'tea'. This time I sprinkled twice as much solution on my trees as I had done the very first time. I am still waiting for the results".

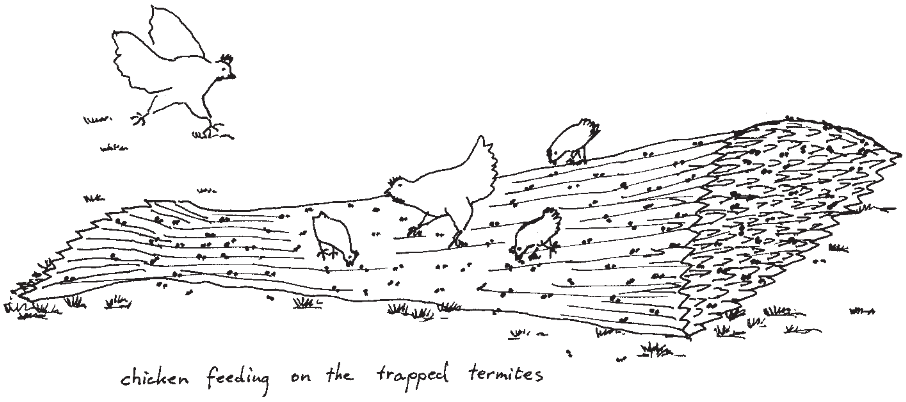

Figure 2: Excellent chicken food

Egesa also reports experimenting with a mixture of tithonia and cassia spp ash. Here he had less success. "On 10 January 1994 I picked 6.5 kilograms of *Tithonia diversifolia* and six kilograms of *Cassia spectabilis* and *Cassia siamea*. After I had dried them I was left with 8.5 kilograms of dry matter. I burned this and applied the ash to the trees using a 100 gram container as a measure. I applied 100 grams of ash to each tree. After five days I found the termites were already destroying my trees".

A third experiment was considerably more successful. On 24 November 1994 Egesa prepared a solution from these ashes rather than applying the ash directly. The solution controlled the termite attack for about a month. A week later he reported that he had made yet another solution, using 8.5 kilograms of dried leaves. This time, however, he made it stronger.

"I added 14 litres of water to the leaves in my third experiment so the solution would be stronger. On 12 December it was ready for use. Because it was stronger it controlled the termites for 40 days, and between 16 December and 24 January I had no problem with these pests. On 24 January I made another solution using the same amount of leaves and water. I wanted to repeat the experiment because last time it had worked well. The new solution was ready on 8 February 1995. I poured it around my trees and it helped control the termites for 45 days.

Next, Egesa prepared a treatment using 2 kilograms of *Tithonia diversifolia* leaves and a mixture of two kilograms of *Cassia spectabilis* and *Cassia siamea*. This time he used ten litres of water and was curious to find out how strong the result would be. When it was ready he poured it around his trees. It worked for 20 days. He assumed that this was because much of the solution was washed away by the rains.

Two farmers were involved in the *Tithonia diversifolia, Cassia siamea* and *Cassia spectabilis* experiments. Other farmers carried out similar experiments using a mixture of *Tithonia diversifolia* and *Agave sisalana*. There were also farmers who used pepper mixed with the sisal leaves and leaves of *Vernonia amygdalina* and tobacco. After boiling this mixture for about 30 minutes they sprayed it on fruit trees in particular. These solutions and the ash mixture were applied to crops as well as trees. Some farmers poured the solution directly into the termite nest in an attempt to kill these pests. As farmer Isako Ramondo explained, organic concoctions were quite effective in destroying termite mounds.

"I had eight ant hills on my farm and the underground termites destroyed my crops and trees. I pounded together 4 kilograms of fresh *Tithonia diversifolia* leaves and 4 kilograms of fresh *Melia azedarach* leaves. I immersed this mixture in 20 litres of water and left it to ferment for four days. I then poured the fermented mixture into the opening of each of the eight termite nests. The solution was very effective and controlled most types of underground termites. The good thing is that this mixture is cheap. I do not have to repeat the treatment until new termites move onto my farm. When they do they'll get the same treatment. However, this method only works on underground termites".

Trapping termites

The termite trap, or *Omuomo* as it is called in the Luhya language, is made from spear grass. A bundle of grass is tied at one end and left open at the other. A peg is pushed into the bundle and is anchored to a hole dug in the termite mound. The fresh grass attracts the termites and they come out to feed on it. Once the termites have completely infested the grass, the bundle is carefully pulled out (see Figure 1). The termites are then fed to poultry and to quails, which are a local delicacy (Figure 2). This technique helps reduce the termite population to some extent.

Farmers were involved in a variety of trials. In this way, results could be compared and it was possible to see which technique was the most effective. This created a sense of ownership, farmers felt the research process was theirs and it had a favourable effect on participation. After two years of research, all the on-farm trials were analysed. The farmers were closely involved in this process. When the data had been compiled, it was found that the solution made from Tithonia/Vernonia and sisal leaves had an advantage over the other solutions. In addition to controlling termites, it contributed to soil fertility. Crops and trees sprinkled with this solution were healthier and grew faster.

Farmers also concluded that the pepper/ sisal/Vernonia/tobacco solution could be used very effectively to remove scales from fruit trees. Scales could easily be brushed off after trees had been sprayed with this solution.

After the results had been analysed, farmer-managed field days were organised to explain the research findings to other farmers in the area. Now many farmers are using either the ash or one of the solutions to control termites and other pests. As Jenipher, a farmer from one of the project areas explained, "We use Tithonia solution on our fruit trees. It is very effective. The insecticide from the shops is too expensive for us. Tithonia has really helped us save our crops and trees". The Tithonia solution works well when poured into the termite nest, although it is sometimes difficult to identify nests because some of the termites are migratory and do not build nests.

Apart from its pesticidal qualities, *Tithonia diversifolia* is considered to be a medicinal shrub and people use it to deworm young children. It is used to prevent malaria and to cure fevers and stomach upsets. It is also given as fodder to goats, sheep and cattle in the dry season.

Farmers noted that there were some negative aspects to using Tithonia. It has a bitter taste, and after gathering and processing it farmers find it difficult to remove the stains it makes from their hands. Despite these problems farmers were enthusiastic about the shrub because it was so effective. It improves soil fertility, gives an increased yield, and saves farmers from having to spend money on chemical pesticides. It can also keep termite damage to acceptable levels. Using Tithonia has made it possible for farmers to increase theirfood production and tree planting activities, and the survival rate amongst newly planted tree seedlings has increased by sixty percent.

__Pyrethrins are a group of economically very important natural plant insecticides. These compounds are derived from the dried flowers of the pyrethrum daisy, Chrysanthemum cinerariaefolium (Fam. Compositae). Pyrethrum powder and extract, containing various pyrethrins, have been used as insecticides for more than a century. After the Second World War, the demonstration of the powerful insecticidal working of the pyrethrins came at a time when there was growing concern about the use of environmental unfriendly chemicals such as DDT.__

drawing: source: J.W.Purseglove: Tropical crops-Dicotyledons

Natural insecticide pyrethrum

Rik Thijssen

The natural pyrethrins have some of the qualities of an ideal pest-control agent. They are very effective against a broad range of insects and up to now there have been no reports of the development of resistant strains. Pyrethrins paralyse insects very rapidly on contact, a much valued characteristic. One of the major advantages of the pyrethrins is their low toxicity to all warm-blooded animals including human beings.

Pyrethrins processed from pyrethrum plants are not stable making the insecticide not so useful for crop protection. The pyrethrins are an effective pesticide only when exposed to light and when air is limited. This means they can be used effectively in domestic sprays but are not efficient or economic when used to control pests in agricultural crops and in forest areas. However, industrial imitations of pyrethrins called pyrethroids can be used for general crop spraying.

The plant

Pyrethrum plants grow wild on the Dalmatian coast of Yugoslavia. In 1929, Captain Gilbert Walker, who was the first planter to grow pyrethrum commercially in Kenya, imported some seed from Yugoslavia and planted it on his farm in the highlands near Nakuru town. With the outbreak of the Second World War, Kenya became the leading producer of pyrethrum, a position it still retains, and Nakuru remains the centre of production.

Pyrethrum is a perennial herb with white-yellow flowers that grows to a height of about 60cm. In Kenya it is grown by more than 100,000 small-scale farmers at altitudes between 1500m and 3000m. Pyrethrins are concentrated in the flowers to a level of 1 to 2 percent of dry weight. Pyrethrin content is larger at higher altitudes. The pyrethrum plant is propagated by seeds or vegetatively by splitting parent plants. The first flower picking takes place about 4 months after planting seedlings or splits, and thereafter at intervals of 2-3 weeks during flowering, a period which, in Kenya, extends over 9-10 months of the year. The flowers are picked by hand, usually by women and children, and a skilful picker can harvest up to 25kg of fresh flowers per day. The harvesting of flowers is labour intensive, and this has resulted in a decrease in cultivation in some parts of the world.

Production and market possibilities

A special assessment study by the Biotechnology Programme of the Dutch Ministry of Foreign Affairs (Jovetic, 1994) concludes that despite high global market demands for natural pyrethrins, it is very unlikely that production of pyrethrum materials ‘in vitro’ in greenhouses will be commercialised in the near future as productivity is low when compared to farm production. In addition, the market price of pyrethrins is not very high and the natural source is a relatively high-yielding and fast-growing plant, with not very strict climatic requirements.

The yield of fresh flowers and the content of pyrethrins depend on the variety used, and on factors such as soil, climate, picking interval, and drying methods. On average, 3 to 4kg of fresh flowers yield 1kg of dried flowers. About 250kg per hectare of dried flowers are produced during the first year, increasing to 1000-1200kg per hectare for the second and third year. The price of dried pyrethrum flowers depends, of course, on the quality, but with an average pyrethrins content of 1.5 percent farmers in Kenya get US$1 per kilo. After the third year yields decline.

In the early days pyrethrum was exported from Kenya as baled dried flowers and contained a minimum of 1.3 percent pyrethrins. Pyrethrum flowers are now processed by the Pyrethrum Board of Kenya and marketed as an extract containing 25-50 percent pyrethrins. Present production in Kenya is about 10,000 tons of dried flowers per annum, roughly 50 percent of the world production. The largest importers of pyrethrins are the USA and Europe.

New uses of pyrethrum

In the past, growing pyrethrum was seen as the way small-scale Kenyan farmers raised a little cash for their farm family. All the produce was sold to the processing industry and few farmers were really aware of the potentials of pyrethrum. Extension agents from the Pyrethrum Board gave pyrethrum growers advice on the technical aspects of production and the best drying techniques for the harvested flowers. In return farmers were able to generate a regular and reasonable amount of money.

Recent developments, however, have opened up new and interesting options for the use of pyrethrum in pest management on smallholdings. A combination of pyrethrum and non-toxic piperonyl butoxide results in a powder that is highly effective in preventing insect damage to stored grain, particularly wheat, maize, barley and oats. This powder, mixed with grain immediately after harvest, controls weevils, beetles, grain borers and meal worms for up to two years. Both large- and small-scale users can apply it easily and safely. A similar formula was designed by researchers from the Kenya Agricultural Research Institute (KARI) to protect stored tobacco from the cigarette beetle and the tobacco moth.

Other very interesting new developments are related to the initial problem of what to do with the 'waste materials' of the pyrethrin industry. Out of every 10 lorries delivering the dried pyrethrum flowers to the factory, 9 lorries can be filled with the powder that remains after pyrethrins have been extracted. It was found that this powder, the pyrethrum marc, was a healthy feed supplement for dairy cattle, sheep, goats, pigs and horses and is comparable to other common feeds such as hay, Napier grass and bran (Table 1). Pyrethrum marc is sold to farmers at Ksh300 (about US$5) per 50 kg bag.

It has been reported that livestock fed on pyrethrum marc have a reduced load of intestinal parasites and have ticks less often. Regular feeding with pyrethrum marc also results in an improved general appearance and has meant that farmers presenting livestock for display in agricultural shows now put their animals on a pyrethrum marc diet. The output of the factory in Nakuru sustains about 10,000 cows every year at the recommended feeding level of 3 kg per day per adult animal.

Farming Systems Kenya, an NGO, and farmers have been experimenting over the last six years with the use of pyrethrum marc to control maize stem-borers, one of the most important pests of Kenya's staple food. Female moths deposit their eggs on the leaves of the maize plant and the larvae eat out extensive tunnels in the stem. This sometimes results in complete crop failure. A small handful of pyrethrum marc with a slightly higher level of pyrethrins (about 0.3 percent), placed in the heart of the plants at the critical time when the stem-borers' eggs hatch, can almost completely control this hazard. With a grant from the UNDP Global Environment Facility (GEF), Farming Systems Kenya will now begin an awareness and training campaign to share these findings with more farmers and to develop better ways of fitting the on-farm production and use of Pyrethrum into existing farming systems.

The Kenya Institute of Organic Farming (KIOF), an NGO that has been promoting organic agriculture since 1986, describes the preparation and use of pyrethrum to control insects such as aphids, white fly, spidermite, mealy bug, on crops in its **Field Notes on Organic Farming** in the following way. Boil 500 g of fresh pyrethrum flowers in four litres of water to make a 'strong tea'. Let the infusion cool before straining or filtering. Dilute this mixture with an equal amount of water made soapy with a 30 gram bar of soap. Soap enhances the effect of pyrethrum by making it stick better to the plants. The mixture should then be applied to or sprayed on the affected crop.

Meanwhile, some farmers have been experimenting with pyrethrum on their own. Hellen Chirchir, a retired teacher with a farm in the termite- and tick-infested drier areas of Kericho district, is a good example. She was given about half a kilogramme of dried pyrethrum flowers by a friend in Molo, one of the major pyrethrum growing areas in Kenya, 40 km from Nakuru. She pounded the leaves into a powder and because she had read somewhere that mixing pyrethrum with sesame oil would increase its effectiveness against insects she mixed the pyrethrum powder with half a litre of sesame oil and 3 litres of used deep-frying oil. After making a small opening in two termite mounds on her farm she poured a little of this mixture into the mounds every day for about a week. Much to her surprise the termites disappeared completely after a week.

Later Mrs. Chirchir found that mixing a little pyrethrum powder with milking salve and smearing this mixture under the tail, the legs, and behind the ears of her dairy cows protected them from tick attack. Her only regret is that she cannot grow pyrethrum on her farm.

This article discusses the role of women in agriculture in Vietnam and focuses on the participation of women farmers in IPM Farmer Field Schools (FFS). The article is based on the findings of a study 'Women and IPM in Vietnam' carried out in 1994 by the Hanoi- based Centre for Family and Women Studies on behalf of the FAO.

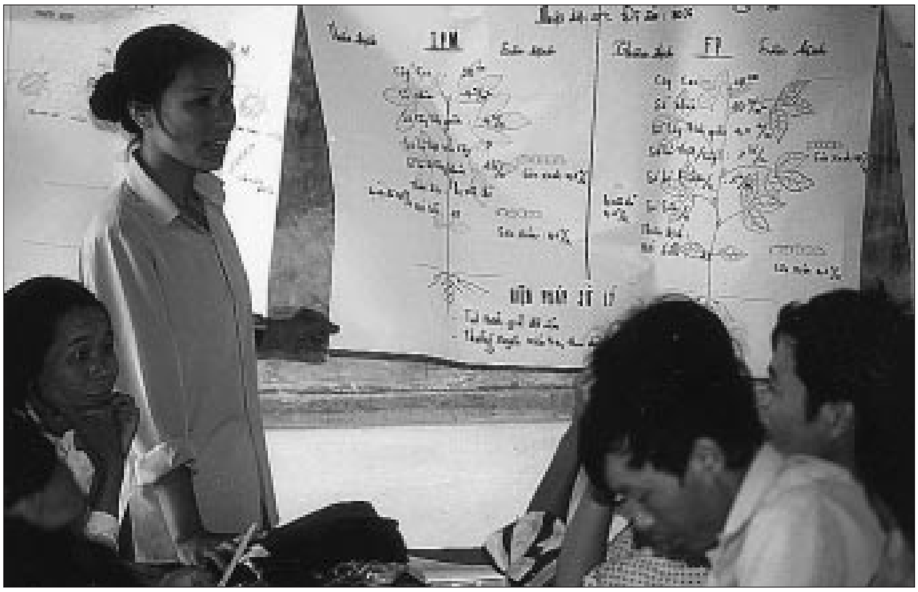

photo: National Programme IPM, Vietnam

Women farmers and IPM Farmer Field Schools in Vietnam*

Nguyen Nhat Tuyen

Since the early 1990s, the Vietnam government has participated in FAO's Inter-country Programme on Integrated Pest Management in rice in South and Southeast Asia. After the agrarian reforms of the late 1980s, the Vietnam government became increasingly interested in renewing the role of its plant protection and extension agencies, and in handing over more responsibility to farmers. It also wished to cut subsidies on such agricultural inputs as pesticides and fertilisers. Farmer Field Schools (FFS) - where farmers re-discover the agro-ecosystem of their fields - were introduced in Vietnam on a national scale in 1992.

Agriculture and gender

The major food crop in Vietnam is rice. Rice production is practised in almost all Vietnam. The deltas of the Red River in the north and the Mekong in the south account for more than 50 percent of all cultivated land. Eighty percent of Vietnam's 75 million population live in the rural areas and 70 percent make a livelihood from agriculture. While there are roughly the same number of men as women in the total labour force, the largest proportion of female labour (72 percent) is to be found in the agricultural sector. Although traditionally women are supposed to perform only 'light' agricultural work and men the 'heavier' jobs, in practice this is little more than a stereotype. Women actually perform almost all the work done in agriculture. Nearly twenty years of war has only served to exacerbate this situation.

In the post-war period, the collectivisation model was introduced into Vietnam, and men and women became members of cooperatives. During this period, women were pushed back into their traditional roles and the work done by women was valued much less than the jobs carried out by men. Various studies show that the payment for a day's ploughing (done by men) was twice as much as that paid for a day of transplanting, watering and weeding (done by women) (Hong Hai, 1988). By the end of the 1980s, the collective model had been succeeded by an individual household-based form of production, and families had been given title to their land for 25 years.

A survey carried out in southern Vietnam in 1993 (CFWS, 1994) showed that women do a larger proportion of the farm work than men. Also, many women work as day labourers and as such have to carry out tasks that include harmful activities like spraying pesticides. Another study by Cantho Agricultural University confirms that women form the largest part of the labour force and are involved in transplanting, weeding, harvesting and drying rice. In households where male members are absent, women also undertake most of the winnowing, watering and pesticide spraying. Finally, we should note that in the country as a whole there are 12 million households, 3 million of which are headed by women.

In general, studies of the division of labour between men and women in the rural areas show clearly that labour is not divided simply according to sex on the basis of health conditions or physiological characteristics. Rather, the division of labour between genders is social in nature and depends on long-standing habits, customs and superstitions.

Women's access to knowledge

Despite the fact that women take part directly in many stages of the agricultural production process, women are neglected in the field of agricultural training. This is largely due to the widespread bias that training supposedly deals with 'technical' knowledge and technology is supposed to be a male domain. Women learn about agriculture from their neighbours, husbands, parents, the radio or the newspapers and to a very small extent (3.5 percent) from extension staff. (Thai, 1994).

When IPM Farmer Field Schools were introduced into Vietnam, the bias favouring male farmer participation was still prevalent. It was present in the selection criteria used to determine who to admit into FFSs. Criteria included the completion of lower secondary school, farming experience, and the ability to communicate knowledge to others. Although useful in themselves - especially as far as ensuring the dissemination of knowledge was concerned - these criteria, if formally and rigidly applied, restrict women's access to FFSs.

In Vietnam there are not enough extension workers at grass roots level. Extension workers are usually male, and 100 percent of the senior positions are occupied by men. In countries where high input Green Revolution agriculture has become the dominant agricultural practice, the use of pesticides, including highly toxic products, is common. Extension and plant protection agencies have become the major vehicle promoting the use of these inputs, and generally there is very little discussion about their impact on health and the environment. Prior to the introduction of IPM Farmer Field Schools in Vietnam, pesticides were widely used and were stored in the farmers' houses - even in their kitchens. Women did not use any protective clothing when they sprayed their crops, and even lactating women handled and sprayed pesticides.

The introduction of IPM Farmer Field Schools a few years after the agrarian reform laws came into force was at just the right time. Men and women farmers were eager to know more about how to cultivate their crops in a sound and economic way. Women farmers, however, did not automatically benefit from the Field Schools and were under-represented from the start, as the following data shows. Up to the autumn of 1995 only 13 percent of the 37,000 farmers who attended FFS were women. Women were better represented in the training of trainers programme for IPM: by the autumn of 1995, some 1,250 trainers/facilitators had completed a Training of Trainers course and 422 of these were women. However, as 50 percent of all farmers are women, there is clearly still room for improvement.

What are the factors that prevent women from participating in IPM FFS? The greatest constraint experienced by women is time. Women have to divide their time between tasks in the home and in agriculture. A woman farmer: "In the evening, before going to the Field School, I have to prepare the feed for the pigs for the next day. Although my children can help me, I don't want them to work while I am out studying". Time is also more 'costly' for the poor, for widows, and for women with small children. Besides their farm activities and housework, these women often work to earn the extra income they need by doing off-farm activities such as trading or wage labour. If this time spent on earning additional income could be compensated, then the lowest income groups would be better represented in the Farmer Field Schools.

Family backing

Men usually take part in training activities because they decided to do so. Women often have to seek their husband's or family's approval first. In a discussion with women in Thang Binh, one woman said: "Whether or not a woman comes to this training depends on the attitude of her husband. I am lucky. My husband understands me and my desire for 'improvements' and when I go to the course my mother and sister help me with the household work. If they didn't I would not be able to go each time".

Local leadership

Village leadership, including village administration and cooperative management, plays an important - if not essential - role in organising IPM training courses. They are the ones who interpret and apply the selection criteria. If men dominate village leadership, as is often the case, this can easily lead to male bias in selection. Although there is a set quota for women's participation, the number of female trainees has always been smaller than required. The main reason for this is that there has not been enough detailed discussion with women. Insufficient information is given about what goes on in Farmer Field Schools, or about how important they are for women.

Trainers

Trainers have a major role to play in organising a training event such that it meet the requirements of both male and female farmers. When introducing a training course to local leaders, trainers often lack information or knowledge about the way gender operates in the division of labour in the locality concerned. Because of this, they do not have the negotiating capacity to ensure a fair representation of women in the FFS, and often trainers themselves are not convinced that such equality of representation is important. The degree to which women have participated in FFS up to now has depended on the perception and initiative of individual staff and trainers.

However, there is also a positive side to the story. The fact that there are a reasonable number of female trainers in Vietnam (of course there is always room for improvement) has influenced the way local leaders perceive women's capabilities. Also, women farmers tend to take female trainers as their example, and become more self-confident as a result. They find it easier to communicate and talk openly with trainers who are also women.

Training curriculum

The 1994 study by the Centre for Family and Women Studies revealed that, generally speaking, trainers lacked the practical skills to integrate gender awareness in the concrete activities of the training programme. The FFS takes up one growing season. Is it possible to cover the gender inequalities that women experience in the household, the community and their agricultural labour in one short growing season of 12-14 weeks? The answer is, of course, no. A quota for female representation in the FFS is not sufficient to address - let alone to redress - gender biases and the problems confronting women in their households and agricultural work.

Although women play an essential and important role in agriculture in Vietnam, they rarely have a chance to participate in any formal or informal agricultural learning programmes. The IPM Farmer Field Schools have certainly enabled some women to participate more fully, but in future FFSs should focus more strongly on redressing inequality by critically evaluating those selection criteria that have so far hindered the admittance of women. A closer look should also be taken at the stereotypes involved in the gender division of labour, and special attention should be paid to local traditions and customs that constrain women's equality in agriculture. A gender quota for field school training is not an adequate long-term solution. It is more important to raise gender awareness among social organisations, government agencies, extension and other agricultural departments, the local community and its institutions - and amongst women themselves. This should be done in a culturally sensitive way, building on women's own achievements in their own society and locality.

Since 1995, the national IPM programme has done much to address the issues raised in the Women in IPM study discussed here. The Women's Union has become more involved, especially at a local level. More effort has been put into encouraging local leaders to facilitate women's participation. In addition, there have been several initiatives to draw public attention to the problem of women and pesticide use. A national contest was organised and broadcast on TV, and a selection was made of those farmers' groups whose songs and poems most eloquently expressed the importance of preserving natural conditions in the rice fields.

General concern about the importance of women in agriculture at a national level (Ministry of Agriculture, Women's Union) and at international level (FAO) is still not fully reflected in the specific activities of the IPM programme. This is because of the way FFS are linked institutionally to plant protection agencies, and, to some degree, to the extension service. As a result, they tend to be more technical than holistic in their approach to agriculture.

With the introduction of FFS, the Vietnamese government has made an important step forward, and has enabled farmers, both men and women, to gain access to the most recent scientific insights into agro-ecosystem analyses and to more information on how to care for their health and their fields. At the same time, however, the FAO and the Ministry of Agriculture should try to develop a vision of more sustainable and healthy agriculture which will secure a lasting livelihood for future generations of farmers.

Food security and local production of biopesticides in Cuba

photo: P.Rosset

Artisanal biopesticide production

Until recently, Cuban agricultural production was based almost entirely on the conventional industrialised model characterised by a strong dependence on synthetic pesticides and fertilisers, fossil fuels and other Green Revolution inputs. With the collapse of the socialist trading bloc in 1989, however, the country's access to pesticides and other inputs it had relied on vanished almost overnight.

Peter Rosset and Monica Moore

The simultaneous loss of most of the country's imported agricultural and industrial inputs, direct food imports, international markets and sources of foreign exchange resulted in a profound and continuing crisis for the Cuban people and government, a crisis amplified by escalation of the US government's long-standing economic and political blockade of the island nation. Most critically, agricultural production and food access plummeted to record lows, resulting in acute food shortages in a country that for decades had guaranteed an ample, low-cost food supply as a right of citizenship.

In 1990, the Cuban President Fidel Castro declared the start of an indefinite 'Special Period in Peacetime' as the framework for the dramatic policy reforms necessary to meet the basic food requirements of the island's population. It was to be a period in which Cuba's agricultural and economic productivity would be rebuilt. As a direct result of the Special Period, Cuba has embarked on an unprecedented national transition from high-external input to low-input and organic agriculture, including the implementation of biological, control-based, integrated pest management (IPM) approaches throughout the country.

Drawing on experience and investments in human resources that predate the Special Period by many years, policy makers, producers and researchers began adapting and reconstructing Cuba's agricultural infrastructures to facilitate low external input production, including the breakup of state farms into smaller units under more direct management by producers; the creation of a national network of small laboratories producing an increasing variety of biological control agents, botanical pesticides and biofertilisers; legalisation and promotion of private sector farmers' markets; widespread development of urban agriculture; and a new emphasis on farmer-to-farmer and farmer-to-extensionist exchanges, on-farm research and agro-ecological training for producers and scientists alike.

Cuba's agricultural conversion not only challenges the common belief that feeding a nation's population depends on pesticides, but also highlights the strengths and limitations of two different versions of IPM: the 'input substitution' approach as opposed to using IPM as a component of an ecological agricultural system.

Local Production of Biological Agents

Coping with a more than 80 percent drop in the availability of pesticides and fertilisers was among the more desperate challenges at the start of the Special Period. Cuba's decades of experience with biological control proved crucial in meeting this challenge. Historically, much of this experience was with mass-reared parasitoids. Since 1968, the parasitic fly *Lixophaga diatraeae* had been used against the sugar cane borer in almost 100 percent of the areas planted with sugar cane. Parasitic wasps (*Trichogramma* spp.) have been widely used since the early 1980s against Lepidopteran pests in pasture management, and later in tobacco, tomato and cassava. Also in the early 1980s, the sweet potato weevil *Cylas formicarius* began to be controlled in sweet potato using predatory ants (*Pheidole megacephala*). Reservoir populations of these ants were established where they were naturally abundant, and colonies moved into sweet potato fields from these areas, achieving up to 99 percent control.

Despite such successes and the adoption of a national policy favouring IPM in 1982, pesticides remained the main form of pest control in Cuba until the onset of the Special Period. At that point, researchers working on biological control and other aspects of ecologically-based agricultural production systems were mobilised from within different universities, ministries and research institutions to respond to the crisis. In effect, this instantly mainstreamed the ideas of a number of younger scientists whose exposure to the environmental movement and ecological principles had led them to develop a critique of Cuba's dependent modernised agriculture, but whose ideas were marginalised within the infrastructure supporting that system.

Based on the work of such researchers and using existing technologies, the Ministry of Agriculture significantly accelerated and expanded existing plans to increase the production of natural enemies in order to replace the lost pesticide imports. By 1994 some 222 decentralised 'artisanal' laboratories were in operation and provided insects, nematodes and entomopathogens (bacteria, fungi and viruses that cause insect diseases) throughout Cuba's 15 provinces. These labs, which are called Centres for the Production of Entomophages and Entomopathogens (CREEs), facilitated the rapid adoption of IPM systems in crops previously managed under pesticide-based systems.

A typical CREE we visited in Pinar del Rio province employed 4 technicians with college degrees, 4 mid-level technicians, and 7 high school graduates. All were children of members of the cooperative where it was located. The cooperative received a ten-year loan from the bank to construct and equip the centre - a medium-sized house filled with sterile microbiology-type lab rooms and about a dozen autoclaves. According to the director, the CREE provided their products free of charge to the cooperative, at the same time selling them to neighbouring farmers, state farms and other co-ops. He said that sales were sufficient for them to break even, covering the cost of their salaries, loan payments, and the pest control needs of the entire cooperative.

While many CREEs are on cooperatives, others can be found in agricultural high schools, universities, and mixed agro-industrial enterprises. Some are smaller than the one described above, whilst others are much larger. Cuban technicians have even helped set up CREEs in other countries, among them Mexico and Nicaragua.

With the creation of the CREE network, applications of biological control-based IPM systems quickly expanded into new crops and crop/pest combinations. CREE personnel are in close contact with the producers they supply, and interact regularly with them to improve the efficacy of biological control in their regions. The production and use of entomopathogens has expanded particularly dramatically, and Cuba has developed unique capacities in this area. Many improved techniques of production, harvesting, formulation, application and quality control have been elaborated for numerous bacteria and fungi. *Bacillus thuringiensis* (B.t.), is a bacterial insecticide widely used to control a great variety of Lepidopteran pests in many crops and is used for mosquito control in public health programmes. In addition to the CREE's production of B.t., three 'semi-industrial' plants also produce a more uniform B.t. biopesticide, which is seen as a potentially important export product. Fungi-based biopesticides produced by the CREEs and in widespread use include: *Beauveria bassiana*, used extensively to control Coleopteran pests - including weevils that attack sweet potato and plantain; *Verticillium lecanii*, to control whitefly; (*Bemisia tabaci*), a vector of viral diseases in tobacco, tomato, beans and numerous other crops; *Metarhizium anisopliae*, for various insect pests; and *Trichoderma* spp., used as an antagonist of the soil-borne pathogens of tobacco seedlings (see Table 1). Other biopesticides now being developed for scaled-up production include *Nomuraea rileyi* and *Hirsutella thomsonii*.

Table 1. National production figures for biopesticides in Cuba (metric tons).

For insect control 1994	
Bacillus thuringiensis	1,312
Beauveria bassiana	781
Verticillium lecanii	196
Metarhizium anisopliae	142
For plant disease control	
Trichoderma spp.	2,842
For nematode control	
Paecilomyces lilacinus	173

Source: Díaz, 1995.

Given the importance of tobacco in the Cuban economy and culture, the success of biological control in this crop is extremely interesting. Tobacco production in most countries is heavily reliant on methyl bromide, a highly hazardous and ozone-depleting fumigant pesticide listed for worldwide phase-out under the Montreal Protocol. Based on the success of Trichoderma spp. as an alternative, Cuba now plans to prohibit all use of methyl bromide in 1998.

No panacea

We do not mean to suggest that biological pesticides have been a panacea for Cuba. First, it is hard to obtain accurate estimates of efficacy in Cuba. Second, many other factors have gone into stimulating increased food production, not the least of which are the higher prices paid to farmers, land distribution and new marketing mechanisms. Furthermore, artisanal production of biological control agents has not been without problems.

CREE staff readily admit they cannot ensure quality control standards or production goals in their artisanal laboratories, given unpredictable supply shortages and power cuts that are still common features of the Special Period. The resulting uneven quality and availability of biopesticides are significant obstacles to the efficacy of the pest management systems that depend on them. Producers' unfamiliarity with biological control is, more generally, another obstacle. Most extension personnel are new to biocontrol themselves, and training capacity is not yet sufficient to ensure that the biopesticides are always used to greatest effect. As chemical pesticides are either unavailable and/or unaffordable, however, producer experience with and enthusiasm for biological pest control continues to grow. According to the Director of an award-winning CREE in the Province of La Habana, the country's most important food-producing province, demand for biopesticides outstrips supply at most CREEs during peak seasons, suggesting that limited production capacity may also constrain IPM efficacy.

In a larger sense, pesticides - whether biological or chemical - cannot substitute for prevention. In that light it is interesting that there has been a virtual explosion of intercropping across Cuba's previously monocultural landscape, as farmers have raced ahead of agronomic research to use traditional methods where modern ones have disappeared. Many farmers argue that the intercrops reduce pest attack and produce more per unit area. A now ubiquitous cropping system is the maize/sweet potato intercrop, which is said to greatly reduce both sweet potato weevil and armyworm infestations, enabling high productivity without pesticides. In the absence of precise data, it is difficult to measure the relative contributions of new technologies like biopesticides versus traditional and suddenly back-in-style practices like intercropping.

The Cuban case is a crucial one in that it extends what have been local experiences to the level of national self-reliance and food security. That is important in the 1990s, an era in which concrete proof is more important that idealistic rhetoric.
It cannot be denied that locally produced biopesticides have played a key role in allowing Cuba to overcome a food crisis, although the actual efficacy of these products and their importance in relation to other changes in contemporary Cuba have proven hard to quantify.

Pemba is characterised by two rainy seasons. Cassava is the staple food, although rice, grown twice a year under irrigation, is preferred. In the 1980s, to reduce dependence on imported rice, the Ministry of Agriculture introduced irrigation schemes for resource-poor farmers. Local rice variety yields were low under rain-fed conditions, but showed tolerance to prevailing pests and diseases. Irrigated rice yields were not much better, however, because of low soil fertility, water management problems, and such pests and diseases as Hispa (Trichispa sericea), Rice Yellow Mottle Virus (RYMV) and stem borers.

IPM in irrigated rice for smallholders on Pemba, Zanzibar

Asha Omar Fakih, Shariff Maalim Hamad and Christine Wipfler

During the 1970s and the 1980s, clove prices were good and there was enough money for the Plant Protection Service (PPS) to offer farmers a variety of chemical pesticides and spraying services almost free of charge. Little consideration was given to environmental effects.

In the early 1990s, clove prices fell and a cheaper IPM approach was adopted. Research into harmful organisms and crop protection practices had provided insights into pest and disease management. Chemical pesticides not only presented a health hazard, they also killed off natural enemies, and pests had become resistant to them.

Farmers proved reluctant to adopt these extension messages. Changing from a conventional research and extension approach to IPM proved difficult. Technicians have to learn when and how to cooperate with farmers, and farmers have to rely more on themselves. Participation did increase during the course of the PPS-IPM programme, although mistakes were made because farmers had not participated enough in the early stages of programme development.

The history of the IPM programme

The IPM irrigated rice programme was developed in three stages. First, on-farm research into Hispa and Rice Yellow Mottle Virus. Second, the results of the trials were used to train farmers, and third, participative training and a research programme were designed.

Stage one: on-farm research

The problems with Hispa (*Trichispa sericea*) and RYMV came to the attention of the PPS in 1990. Farmers were not involved in initial on-farm research trials, where synthetic and botanical *Tephrosia vogelii*) pesticides were used against Hispa. Common rice varieties were screened, and RYMV tolerant varieties were recommended. The rice technology package presented to farmers suggested early planting to reduce Hispa and RYMV incidence; simultaneous planting by all the farmers in the valley to diminish the risk of Hispa infestation and minimise RYMV problems; keeping the bonds clean to reduce multiplication of Hispa on alternative host plants around the rice fields; controlling water levels in the fields as the Hispa beetle readily attacked tender plants too deeply immersed in water; the continual monitoring of fields to enable the farmers to detect and solve field problems as early as possible; and the use of *Tephrosia vogelii* to control Hispa.

Stage two: conventional training

In 1996, this new package seemed effective and a training curriculum was designed which aimed at overcoming farmers' reluctance to introduce new cultivation techniques. In March 1997, the first group of farmers was selected, and seven women and eight men met every two weeks. Training on crop husbandry was given in the farmers' own fields, and field tours were organised to the irrigated rice valleys.

The training programme involved very limited farmer participation and demonstrations were the main teaching tool. However, farmers were more interested in solving their soil fertility and irrigation management problems. Training programme evaluations also showed that farmers had not understood some of the topics and, therefore, rejected some of the recommendations.

Stage three: Farmer Field Schools

The training approach was changed. The Southeast Asian Farmer Field School approach was adopted and agro-ecosystem analysis (AESA) was introduced. Farmers were encouraged to make a detailed analysis of their crop, looking at the numbers of insects per plant, water, weeds, number of tillers and general crop health. They learned to formulate research proposals themselves and, on the basis of group analysis, came to decisions on crop, disease and pest management.

As a result of farmer initiatives, a new rice variety gained increasing popularity. In 1994, farmers received rice from Pakistan as food aid. The farmers who sowed some of this as seed found that one variety showed promise. They asked Ali Badru, a technician from the Irrigated Rice Department, to verify their findings. He compared the variety to recommended hybrids and local varieties. Highly productive, it yielded only a little less than the hybrids. It also required less fertiliser than hybrid varieties, and farmers could produce their own seeds. The variety proved tolerant to Rice Yellow Mottle Virus, had a good taste and was easy to harvest because of its height. The new variety took Ali Badru's name and is extremely popular today.

More participatory research focusing on alternatives to chemical fertilisers is planned. Trials will be conducted with green manure, and farmers will use the AESA method to assess their crops. ■

Chinese rice farmers

The new IPM experts

The farmer training approach discussed here is FFS. The field schools run in the Chinese case study examined here involved some 25 farmers who met each week. Training took place in the farmers' own rice fields. In this supportive learning environment, local ecology and practices were discussed and the farmers' perceptions of their farm agro-ecosystems were developed further. This process of observation is known as agro-ecosystem analysis. The outcome of the farmers' weekly agro-ecosystem analysis became the basis of such decision-making as whether or not to continue relying on spiders and parasitic wasps to control rice pests.

Margaret S. Mangan

The FAO-IPM programme is based on a new understanding of rice field ecology. Experience in many countries has shown that insecticides actually cause more pests, and there is now a better understanding of the importance of beneficial insects and spiders in the rice ecosystem. Research has shown that the use of insecticides early in the season destroys the detritivore and plankton feeding insect populations which are the first food source for generalist predators such as spiders. A lack of generalist predators leaves the crop more vulnerable to pest population increases later in the season.

Four Principles of IPM

There are four principles central to IPM. First, to encourage the growth of healthy crops and to stimulate farmers to use the best possible agricultural practices. Second, FFSs should emphasise the importance of conserving beneficials: pesticides should only be used as a last resort. Third, crops should be observed every week and farmers should be guided in this during training sessions designed to improve their skills. Finally, farmers should become experts, their training empowering them to make crop protection decisions responsive to the needs of their crops.

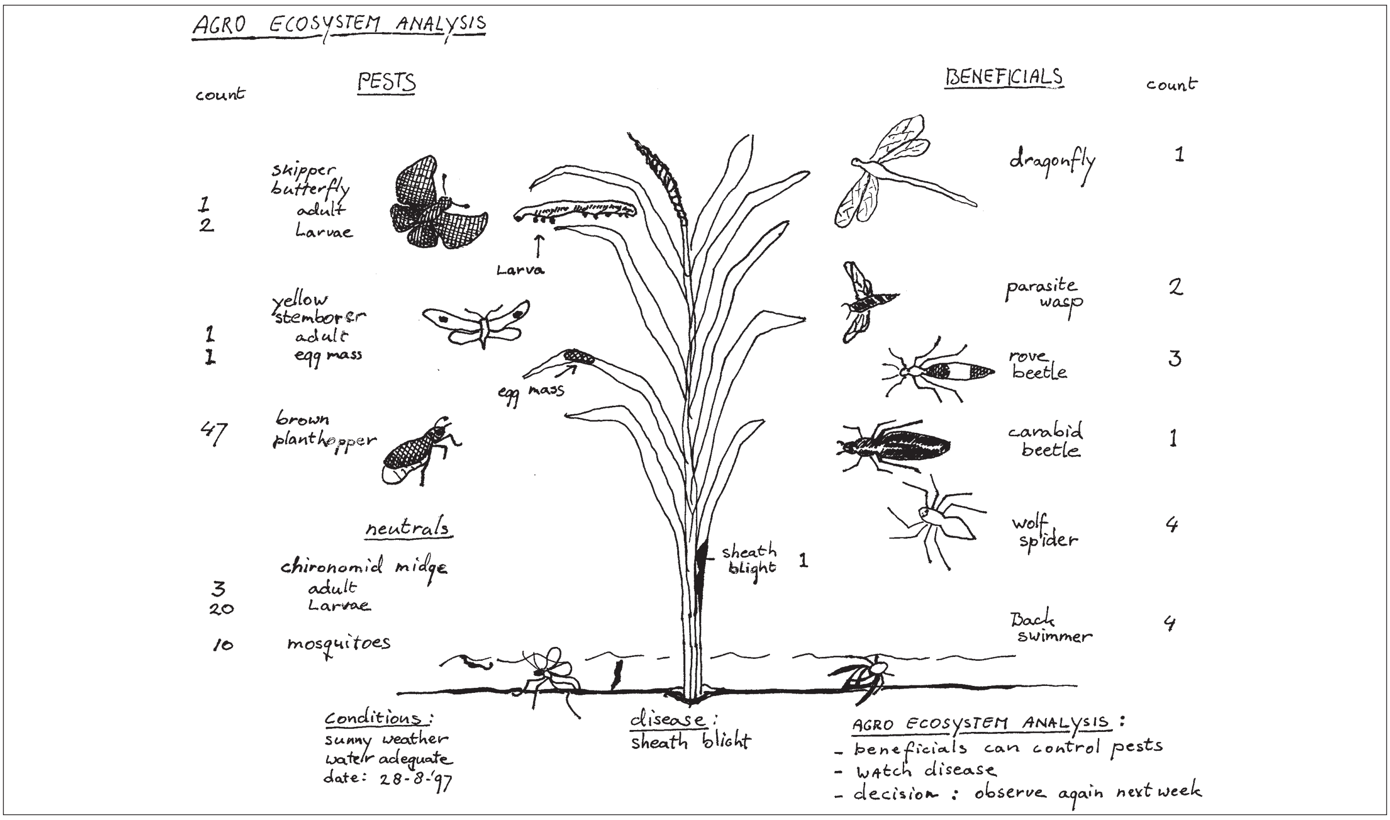
Farmers need to know which pests, diseases and animals are beneficial. In rice fields, beneficial species tend to outnumber pest species by about two or three to one. Farmers should also be able to identify neutrals - insects that are neither pests nor beneficials. Above all, they must be able to identify all these agro-ecosystem elements in their fields - not only on a classroom chart.

The agro-ecosystem of all crops changes in the course of the cropping season. In Sichuan, for example, very few stemborers are found early in the rice season, whereas thrips abound at this time. The proportion of these two pests changes as the rice grows. Parasitic wasps (beneficials killing leaf-eating caterpillars) are scarce early in the season, but become numerous in the second half. In the FFS, farmers acquire the skills needed to observe these changes as they occur from week to week.

This model was first used to train farmers in China in 1994. Twenty-five farmers who took part in the FFS in Wan Po Village, Sichuan, China, in 1995 were interviewed both before and after training and were observed during the weekly training sessions (Mangan, 1997).

Wan Po is situated in Meishan County, in the Red Basin of Sichuan, about two hours' drive south of Chengdu, the provincial capital. It has mild winters and very occasional snowfall. Summer temperatures rarely exceed 40°C. A single hybrid rice crop is grown in the summer, and canola or other crops are planted during the winter.

The Wan Po FFS farmers were organised into small groups of four or five people. Each group was named after some beneficial, for example, 'dragonfly', 'spider', 'parasitic wasp', or 'ladybird'. Every week, each group would complete an agro-ecosystem analysis of their FFS rice field. This consisted of examining approximately ten hills (clumps) of rice in a transect across the field. Observations included recording the types and numbers of insects, spiders and other animals, and collecting information



Drawing: Mangan/Steenhuis

on disease, weather, general plant health, and water level. This information was then transferred to paper. Each group made a drawing of a rice plant on a large sheet of paper using crayons or coloured pens. The farmers drew in all the pests on one side of the plant and all the predators on the other. Neutrals were grouped together in one corner, and weather and water conditions were clearly indicated. Using this method, farmers were easily able to track the ratio of various pests to selected beneficials from week to week (Mangan 1997).

Group presentations

After entering the observations made in the rice field on their drawings, each group presented its analysis to the other farmers in the FFS. Observations, conclusions and the decisions they had made during the week were discussed. Every week a different member of the group was encouraged to be the presenter. The other group members contributed by answering questions. Initial shyness and reluctance soon gave way to confidence and self-assurance as the training progressed.

FFSs covered other activities besides agro-ecosystem analysis, the 'insect zoo' being an example. A potted rice plant was placed in a simple cage built by the farmers, and a specific number of a particular kind of pest - such as 100 brown planthoppers - were introduced into the cage. The pest's predators - five wolf spiders, for example - were also released into the cage. Each group of farmers was able to vary the pest/predator ratio. At the end of the week, the group opened up its insect zoo, and pests and predators were counted. The results, which usually demonstrate how effective beneficials can be in destroying pests, were then discussed with the members of the FFS. One of the results of the insect zoo demonstration was that farmers often started to experiment on their own and brought these informal results back to the group (Mangan 1997). Other games were designed to strengthen group cooperation and to helped farmers identify pests and recognise their habits.

Because the farmers applied what they were learning from the very first activity undertaken in the FFS, learning was functional. Farmers developed a deeper understanding of how the different components of the rice ecosystem interact, and this enabled them to make more informed decisions about their own field management.

Results of interviews

Twenty-five farmers in Wan Po were interviewed before and after FFS training. Questions were asked about beneficials, pests, neutrals, pest-predator relationships, the ecosystem in general, and the effects of pesticides used in the field.

Before the FFS, only 11 farmers knew the names of those insects that were pests, while 15 farmers, 60 percent of the total sample, could not give a specific example of any beneficial in the field. In pre-FFS interviews, 4 farmers said 'All insects are pests'. Before FFS training, of the 25 farmers interviewed, only spiders (7 farmers), dragonflies (4 farmers) and ladybirds (1 farmer) were known to be beneficial. In addition, before the FFS farmers could name very few insects individually. The total number of insects/spiders farmers referred to by name ranged from one (both times stemborers) to a maximum of nine. The average number of insects mentioned was four.

After training, all 25 farmers mentioned spiders, 23 farmers mentioned dragonflies, and 6 farmers mentioned ladybirds. Seven more beneficial insects were also named. Most importantly, farmers could identify these in the field. There was a 233 percent increase in the total number of beneficials named by the farmers after training. There was a 22 percent increase in pest species named. The lower percentage was due to the fact that farmers were already familiar with pest species, but had not known very much about beneficial species.

Before FFS training, 4 of the 25 farmers had said they had seen some predatory spider/insect attack another insect. After training, 14 farmers had seen some predatory spider or insect attack another insect, and 12 farmers described in detail what they had seen. The FFS had successfully focused farmers' attention on understanding how beneficials actively controlled pests.

Before training, 15 of the 25 farmers said it was beneficial to spray pesticides on their rice. After training, only 5 farmers continued to claim pesticides were beneficial, and 19 of the farmers explained pesticides were not good because beneficial insects/spiders were also killed in the process.

Before training, only one farmer was able to give an answer that showed no misunderstandings about the way pesticides worked. After training, 8 farmers provided answers that indicated they understood how pesticides killed insects, and another 9 farmers gave a correct explanation although they added a few facts that were not correct. A fundamental change in the understanding of the function of pesticides had taken place.

Only 5 farmers could give examples of neutral insects - those that are neither pests nor beneficials - before the FFS. The mosquito was the insect most named. After the FFS, 23 farmers were able to give correct examples, and most often these were mosquito larvae and ants. However, even after training, farmers still did not understand very clearly how neutrals functioned as a major food source for beneficials during the first third of the rice season, before populations of plant-eating pests began to increase. This was a concept that was not obvious to farmers.

Before FFS training, farmers were asked what would happen if all the spiders were removed from their fields. Only 6 farmers said that pest populations would increase. After training, all farmers said pests would increase if spiders were removed from their rice fields. After FFS training, only 7 of the 25 farmers thought it would not be beneficial to have insects in the field, but none of these 7 farmers said they would kill the insects they found there, even if this were possible. They recognised that there were predator and neutral insects as well as pests in their fields, and that a balance between them was necessary to maintain a healthy ecosystem and protect the crop. After training, only one farmer was unable to name more beneficials. No farmer said that all insects were pests. The number of insects/spiders named by the farmers in their post-FFS interviews ranged from 5 to 14. On average, ten kinds of insects were named.

These answers show the influence of the FFS on developing a concept of the pest-predator relationships in the field, and on extending farmers' understanding of how generalist predators protect crops. During the course of the FFS, the farmers' concept of the rice ecosystem, and their understanding of the function of beneficial insects in that ecosystem deepened considerably.

In the FFS, understanding and skills are developed through direct participation in specially designed situations. The careful arrangement of FFS activities in this educational experience strongly contributed to the formation of more scientific concepts. The FFS was effective because learning activities took place in a rice field - a familiar and learner-friendly environment.

The use of small groups of farmer trainees to make observations, and the role played by the FFS in challenging their conclusions, proved effective in bringing about change in farmer practices. Interviews conducted one year after the FFS had been held showed that the basic objective - to secure a reduction in pesticide use - had been achieved.

The application of these new IPM methods taught through Farmer Field Schools is environmentally sound and sustainable. The Farmer Field School is an efficient model for empowering farmers to reduce the use of pesticides. Wider application of this training approach benefits farmers economically - they save money because they buy less pesticides - and benefits the planet's environment. Everyone wins.

Natural pest management in Zimbabwe

The Zimbabwean Eco-lab has an innovative way of tackling farmer participatory training in pest management. ZIP Research operates from the ECO-lab and is concerned with training the Farmer Field Workers (FFWs) selected by farmers' groups.

Sam L.J. Page

Since independence in 1980, communal farmers in Zimbabwe have been persuaded to use increasing amounts of fertiliser and pesticides on crops such as maize and cotton and on their horticultural produce. As a result, pests are becoming resistant and soils are growing more acidic and infertile. The use of toxic and expensive inputs has brought health and money problems to many farmers and their families.

In order to counter this trend, a small NGO known as ZIP Research has recently been set up to offer safe and sustainable alternatives to synthetic fertilisers and pesticides. ZIP Research operates from the Eco-lab, a purpose-built, fully equipped laboratory built from NORAD funds (Norwegian development aid). It is situated in the Fambidzanai Permaculture Centre, 20 kilometers west of Harare. One section of the Eco-lab is devoted to research into the indigenous natural enemies of common pests, while the other is dedicated to training Farmer Field Workers (FFW) in Natural Pest Management (NPM) and organic farming methods. NPM is concerned with developing farming systems that manage pests naturally, that is without synthetic pesticides. NPM strategies rely on farmers' knowledge and try to minimise the need for interventions.

Farmer Participatory Training in NPM

Training provided by ZIP Research has borrowed the 'learning through experimentation' approach of FAO Farmer Field Schools. However, ZIP Research training is less 'top-down', in that training is given mainly to farmers rather than extension workers. There are three reasons for this. First, farmers are highly motivated because they depend on farming for their survival. Second, farmers are mainly women whereas extension workers are generally men. Third, training farmers directly ensures that the knowledge stays within the community. If an extension worker received specialised training, he or she might be tempted to look for a more lucrative job elsewhere. ZIP Research trains in NPM and its approach is holistic and agro-ecosystem oriented. This means that the farmers who participate can eliminate all synthetic pesticides from their farming system and are then able to apply for organic certification in order to receive a premium for their produce.

Each training programme is 'tailor-made' for a particular group of participants and proceeds from the demands of their agro-ecological zones and cropping systems. Training is only offered to farmers who are actively seeking help to reduce their pesticide use. It forms part of a project which is designed to eliminate all pesticides from the farming system, promote environmental awareness, and lead to improved incomes through the sale of organic produce either on the local or overseas market. In some cases, local extension officers are also trained in NPM and organic farming methods, so they can help provide follow-up support to Farmer Field Workers (FFWs) and act as a buffer between farmers and over-zealous pesticide sales representatives.

Training at the Eco-lab

Farmers select FFWs from their own communities. The FFWs spend four weeks at the Eco-lab, where they learn relevant facts about soil science, insect life cycles, pest-predator relations, disease transmission and development, and the way natural and synthetic pesticides work, through a series of in-field and 'jam-jar' experiments.

These FFWs also learn about the value of indigenous seed, exchange ideas on traditional grain storage techniques, discuss ways of designing simple experiments, and learn the importance of maintaining diversity and soil fertility through mixed cropping, composting, green manuring and crop rotation. For the purposes of organic certification, the FFWs are introduced to mapping, record keeping and the regulations laid down by the International Federation of Organic Agriculture

Movements (IFOAM). Farmer exchange visits and market survey opportunities are also arranged, and games and songs are used to consolidate the learning process.

This training is carried out in a spirit of 'sharing ideas' and the FFWs learn techniques which enable them to become keen observers and innovators in both a scientific and creative way. The extended training period also allows time for friendships to develop between the FFWs. This ensures that the participants work as a team and skills are shared.

ZIP Research decides whether trainees will make suitable FFWs. This final assessment is not based on academic achievements, but on a candidate's motivation, outgoing nature, and his or her ability to empathise with other farmers in their community. Ideal FFWs are married, and therefore have access to their own land. The composition of the group reflects the age, gender and level of poverty of the farmers in their community.

FFW-led Farmer Field Schools

On returning to their communities, the FFWs share their new knowledge and ways of learning with the ten farmers who originally selected them. At the same time they continue to receive support from ZIP Research and from trained extension officers. The FFWs conduct regular Farmer Field Schools, ensure that individual farmers adhere to the agreed guidelines for organic production and certification, and write monthly reports.

During the Farmer Field Schools, the farmers' groups scout for pests and predators, discuss control strategies and carry out simple experiments on insect life cycles. They also examine the efficacy of local natural pesticides, grain storage treatments and the comparative susceptibility of crop varieties to pests. ZIP Research's role during these Farmer Field Schools is to support the FFWs in their job as facilitators and to offer advice when asked to do so.

Donor support

The FFWs receive a small salary. This is provided initially by DANIDA, the donor, although in the long term these salaries will be paid for by the organic premium, which should be at least 20 percent above normal farm-gate prices. Expenses associated with training and providing follow-up support for the first two or three years must also be met by donors. These costs, however, appear well justified because results so far have been impressive.

At the moment ZIP Research has two projects. The first is being funded by DANIDA, and involves a collective of 60 farmers and 6 FFWs in Chinamhora. This group has just started to supply Harare with its first fresh organic vegetables. The collective grows tomatoes, peas and carrots in rotation with brassicas such as cabbage and alliums such as onion, in order to control root-knot nematodes and satisfy local consumer demand for these vegetables. They have discovered two native plant extracts, Mucherekesi (*Swartzia madagascariensis*), an effective fungicide, and Chowa (*Datura stramonium*), a good insecticide.

photo: S. Page

Experimenting in organic production

The farmers have also composed a number of songs, and these help illiterate members of the group to retain facts about such organic farming practices as composting, intercropping and rotation. The songs also seem to strengthen a dying tradition, the practice of singing together while tilling the land.

One FFW working in the cotton growing area of Mtoko has discovered a small ant which is predacious on stem-borers and bollworms but which is only active when there is an intercrop of indigenous cowpea to provide shade and nectar. The FFW also discovered a 'zebra' caterpillar that, astonishingly, seems to relish aphids!

The second project, supported by the SIDA EPOPA programme, is based in the Zambezi Valley in northwest Zimbabwe. Here, resettled farmers have cleared land that was once home to thousands of elephants, and now grow cotton and other crops. Many farmers are concerned about the environmental degradation triggered by this land clearance and the consequences of heavy pesticide use. They have started to experiment and grow cotton without pesticides.

ZIP Research has recently trained 30 FFWs to ensure that 330 farmers will be able to produce organic cotton in the coming season. A minimum of 15 tons of lint is required before spinning can begin. So far the new FFWs have greeted their training with enthusiasm, and have been spurred on by the achievements of the organic farmers in Chinamhora (they are planning to hold a singing competition next year!) However, opposition from the many multinational chemical companies which operate in the valley is anticipated.

Farmer-Participatory Research

Research conducted at the Eco-lab is designed to support on-going projects. Research topics are often initiated and carried out by FFWs and their farmers' groups, and results are shared amongst project members. This coming season farmers will be reporting on the incidence of predatory ants on intercropped and monocropped fields, and will be finding out which varieties of tomato perform best during the rainy season. Organic cotton growers will be observing the impact of strip-cropping sweet sorghum as a trap crop for the American bollworm, and assessing the suitability of different live fencing materials for encouraging insect predators.

Meanwhile, scientists at ZIP Research will explore the efficacy of the 'zebra' caterpillar and various other indigenous natural enemies such as parasitoid wasps, insect viruses and entomopathogenic nematodes. They also intend to come up with standards that can be used to measure the effectiveness and selectivity of the many plant-based insecticidal sprays used in farmers' experiments. In this way scientists and farmers can share the excitement of applied research.

Crop protection in the 1990s

During the 1990s, there have been new awarenesses and developments in crop protection. There have been improvements in user, consumer and environmental protection at the product development level and in the approaches adopted. When we analyse the relevance of these improvements for small farmers in developing countries, however, it becomes clear that there is still a lack of progress in making the new crop protection practices available to them.

Gaby Stoll

Product development during the period under consideration is characterised by the intensive and aggressive development of products using biotechnology and genetic engineering. This can be seen from the following figures:

Table 1: Predicted US Market for biopesticides, 1992-2002 (in millions of US$)

	1992	1997	2002	AGR in %
Pyrethroids	410	487	560	3.2
Bacterial	68	137	275	15.0
Pheromones	42	56	75	6.0
Viral & fungal	26	44 69	10.3	
Others	13	16	23	5.9
TOTAL	559	740	1002	6.0

AGR = Annual growth rate

*Source: **Pesticide Outlook**, February 1994*

The US government is actively supporting this trend. Between 1991 and 1994, 50-70 % of all new pesticide registrations were issued for biotechnologically and genetically engineered products. In addition to developing products using these advanced technologies, another trend can be observed. The agrochemical industry is putting considerable effort into stimulating the market for conventional pesticides in Latin America and Asia, as these offer the greatest growth rates. Countries such as Brazil, China and India have become important producers of conventional pesticides in recent years, and in a number of developing countries these products are sold very cheaply at local markets. One consequence is that it is easier for farmers to buy these products so they are able to make more frequent applications, a practice that we know is harmful for users, consumers and the environment (Table 2). This table shows that resource-poor farmers have little access to the new developments being made in pesticide products. Resource-rich farmers, however, can afford the newer and safer pesticides. Poor smallholders are only able to afford the older generation of pesticides. These show widespread resistance and contain the most toxic substances. However, as we shall see in this article, small farmers can benefit from an integrated approach to crop protection.

Approach to development

During the 1990s, important integrated approaches to user, consumer and environment friendly crop protection have been developed. These include integrated cultivation systems for organic cotton involving elements of preventive crop protection; Farmer Field Schools; Farmer First Research; Participatory Technical Development(PTD); and Local Knowledge.

With experience and confidence in these approaches growing, it became obvious that it is possible to secure yields using far less pesticides than had previously been suggested. Cotton provides an excellent example of this. With the development of integrated cultivation systems for organic cotton that contain elements of preventive/natural crop protection, it can be demonstrated that a crop that consumed 25% of the world's insecticides could be grown successfully without any insecticide at all. Tadeo Caldas (1997) has reported on the major crop protection strategies in cotton (Table 3). Interestingly, neither the Consultative Group on International Agricultural Research (CGIAR) nor the agrochemical industry contributed in any way to the development of organic cotton cultivation systems. Instead, its success was due to the concerted effort of private companies, advisers and farmers.

The following comparison of crop protection strategies adopted in conventional and organic cotton shows that yields are lower in organic cotton. However, the reduced costs involved in crop protection measures and the price premium offer compensation (Table 4).

The cotton example shows that belief in the indispensability of pesticides arises from a scientific bias, and that this is maintained by particular interests. It also shows that the development of a viable alternative crop protection concept requires a holistic approach incorporating elements of the natural, social and economic sciences. Finally, we see that non-traditional researchers can further develop results from basic research, through such strategies as adaptive research and PTD for example, and achieve acceptance in the field. Similar conclusions can be drawn from studies of rice production.

Table 2: Access to pesticides, productivity, income and danger of pesticide poisoning for farmers with different resource endowment

Farmer Field Schools (FFS)

The concept of FFS was originally developed as an extension methodology for IPM in rice. This methodology is based on a structured learning process. The concept allows farmers to explore areas of research that are of particular interest and importance to them. This training concept is not only limited to IPM in the strict sense. In Asia, many NGOs and farmers' organisations have adapted and interpreted it to suit their own specific situations and interest. Some of these organisations apply the FFS concept not to IPM as such, but to agricultural system development in general. The flexibility of the concept and the experiential learning on which it is based have made it a widely used and valuable extension tool.

These approaches start with a participatory problem analysis and local knowledge. The experimental site is usually the farmer's field or a special experimental site identified by the farmers' group. The key to this approach is to teach farmers to experiment with their local knowledge or new/external information in order to make it effective and suitable to their specific situation. Farmers and extension workers gain methodological skills to develop their own solutions. This challenges conventional research paradigms and calls for a new relationship and respect between the various actors involved. Examples of this approach are the development of neem extracts in Thailand, the MASIPAG programme in the Philippines where farmers select and breed rice varieties according to their own criteria, and coffee farmer cooperatives that rear their own beneficial insects.

Smallholder options

Now we have to answer the question we posed earlier: what access do resource-poor farmers have to natural crop protection practices? Let me quote the participant from a workshop on natural crop protection held in Tanzania in December 1996 who said, "There exists a significant amount of knowledge on natural crop protection, but we believe it is not well organised and developed. It is still largely undervalued, not well experimented and there has been little diffusion. There is, therefore, a need for us to share the various experiences and methodologies used here and there and to develop this field further".

This participant acknowledges that access to information on natural crop protection practices in the widest sense has improved. But this does not mean that the information is getting to the right place. Information only becomes relevant when it is enlivened, that is when it has been transformed in such a way that it can be incorporated into people's daily life and work. However, this is the 'big gap'. The interplay between the various actors is still not optimal when one looks beyond the small islands of innovations. Research topics are still determined more by who and what receives financing, rather than by what is relevant to small farmers. This means that topics important to this group are largely under-represented.

Final reflections

During the last 10 years, and particularly while working with the people of Southeast Asia on the development of natural crop protection practices, I learned by observation and experience that they are guided more by the concept of *'but-as-well'* than by the Western concept of *'either-or'*. Underlying the 'but-as-well' is the concept of multiple approaches capable of responding to multiple realities, realities which might seem to contradict each other if we take the 'either-or' perspective. If we relate this insight to crop protection, we create room for multiple approaches where the one does not hinder the other.

■

A Perspective on IPM

In the past six weeks I visited the future of IPM in two places. One was about 3 hours east of Jakarta, in a rice growing village in Kalensari, District Indramayu, West Java, Indonesia. My hosts included Warsiyah, Madamin, Sobari, H. Yusuf, and about a dozen other farmers who have done research for the last two years on the agro-ecology of their village. My companions included a young Japanese staff member of his Ministry of Agriculture and two FAO field staff who both had visited Kalensari before. Our facilitator was Arief, also with FAO, who moved to Kalensari two years ago and studies agro-ecology with farmers there. While my learning came from participating in meetings, field visits, and interviews, the scientist farmers of Kalensari have recently completed a detailed monograph.

Peter Kenmore

Scientists have been characterised as having three essential tools: clear understanding of currently accepted explanations and concepts, fresh observations from nature, and a profound dissatisfaction with these two, because they do not match. The scientist farmers in Kalensari have all three. When extension agents told farmers to apply insecticides to control rice stemborer (*Scirpophaga spp.*) , and they did, they observed that damage to treated fields was nevertheless often high. When extension told them to plant on a rigid calendar schedule to avoid stemborers, and they did, they observed that stemborers sometimes caused heavy damage, and sometimes not. They were dissatisfied with the current explanations, and they conducted, and continue to conduct, a number of field studies to create better knowledge. Many of these studies examined in detail the behavioural and population consequences of the stemborers' life cycle which has evolved and adapted to the uncertainties of rainfall. The scientist farmers have discovered by asking straight questions in the field how to observe and analyse insect populations during the dry fallow season from August to November. They track quantitatively the survivorship, diapause, emergence and invasion flights of stemborers. This allows them to decide for themselves, based on precise 'readings' of their local agro-ecosystem, when to plant rice so as to minimise the immigration of pests.

They understood from the beginning that their results would bring them into conflict with a centrally managed extension system. They addressed this conflict with confidence and skill. They began the task of convincement with influential villagers, carrying the local extension worker along with them, then proceeded to the sub-district officials, neighbouring sub-districts, and ultimately the district head, in whom they found receptive. In their organisational meetings, and later in educational seminars for officials, they used the power of their science to make their case. At the same time they made clear that they would take full responsibility for the management of insect pests in their communities. This was an important announcement, because when accepted it relieved local officials from central crop protection targets and allowed them to learn about the local agro-ecosystem.

In consequence, the irrigation schedule for the district Indramayu - often Indonesia's highest rice producing district - has been adapted to the scientist farmers' recommendations. Educational seminars have been organised with farmers from all the other sub-districts. All sub-district agricultural officials and many local government staff have been or are in training courses given by farmers. In agro-economic terms, the communities are growing as much or more rice with fewer inputs. While El Nir scientists are confident they know what is happening with stemborer populations in their slightly moistened fallow fields, and they are ready with alternative management strategies.

The second, temporary, home of the future of IPM was 2 hours west of Boston, USA, where a group of Indonesian and Vietnamese IPM trainers and managers are spending six sabbatical months. These are seasoned field experts and organisers. They have each been responsible for a number of Farmers Field Schools and the community IPM linkages after the Farmers Field Schools. A very innovative grant has made it possible not only for them to improve their command of English, but more importantly to interact with community organisers, adult educators, and IPM farmers in a very exotic ecosystem. This allows them time to analyse together and at a distance their Asian IPM experiences, to forge their own linkages as an international IPM management team, and by comparing North Atlantic IPM with Asian IPM, to reflect in an academic setting on the rapidly changing roles of civil society and the state. They have already become participants and teachers at the local university. When they return to Asia they will work as a networked team among Asian countries as well as within each of their own countries.

Scope of IPM

Participatory IPM led by farmers is now practiced in over 50,000 communities found mostly in Indonesia, Vietnam, Philippines, Bangladesh, China, Sri Lanka, India, Cambodia, Lao PDR, Republic of Korea, Ghana, Kenya, Cote d'Ivoire, Burkina Faso, Mali, Egypt, Sudan, Honduras, Nicaragua, Senegal and Zimbabwe. This is over 2 percent of all rural villages in all developing countries. There are over 30,000 competent IPM trainers any of whom can facilitate a Farmers Field School through an entire crop season, and then the resulting farmers' IPM group through the remainder of their year-round production agro-ecosystem. The majority of those trainers are themselves small-scale farmers. Farmers practicing IPM have increased their seasonal profits by as much as 30 percent, increased yields per hectare from 1 percent to over 10 percent, all while reducing pesticide use by 30 percent to over 95 percent (and often eliminating insecticide use) and substantially lowering occupational health risks. Most of the communities practicing IPM grow rice, but IPM is also practiced by farmers of maize, soyabean and other field beans, cabbage, tomato, groundnut, coconut, cacao, coffee, peppers, sweet potato, cotton, mango, and cucumber. Government agencies and NGOs have both initiated IPM programmes, and found that they were transforming their own institutions as farmers demanded better technical information, better service, and a larger role in planning programmes.

History

The history of IPM in and by rice-farming communities falls into three periods. From 1967 to 1977 was the era of the high Green Revolution. Even before the official release of rice variety IR8 more than 50 percent of farmers had already begun using insecticides in the Philippines, up from about 3 percent ten years before. By 1985 more than 90 percent of farmers in Southeast Asia were using insecticides in irrigated rice. The vast majority of those insecticides were subsidised. Farmers were not paying a market price for insecticides, so they could not make an informed financial decision.

Yet nearly from the beginning of the Green Revolution increases in insect populations following insecticide applications were detected. In a survey of farmers' fields in West Java conducted in 1970-71. In 1971 staff members at the IRRI were routinely treating varietal screening trials with insecticides to build up populations of planthoppers. Insecticide-induced increases in populations of plant-sucking insects are among the first reliable symptoms of an intensification syndrome, exemplified by the Green Revolution model, that de-stabilises production.

The ecology of this syndrome had been sketched - but left incomplete due to political economic pressures - in Japan in the early 1960s by Y. Ito and K. Kiritani. In tropical countries it was only re-discovered in the later 1970s after insecticide-induced outbreaks became common. Destruction of predators and parasites of planthoppers by insecticides allowed these insects to multiply. Insecticide resistance did not play a major role in the politically strategic outbreaks of the 1970s and 1980s. The capacity of insects to multiply, and the ferociously local character of population dynamics - where ten square meters could maintain a population one thousand times larger than an adjacent ten square meters - meant that local managers of individual paddies - the rice farmers, could benefit from in depth knowledge of agro-ecology.

From 1977 to 1987 IPM moved from research towards extension. By 1988 Training and Visit extension systems in the Philippines, Indonesia, Sri Lanka, Bangladesh, India, Thailand and Malaysia were attempting to introduce IPM to rice farmers through their systems of 'impact points' or through strategic extension campaigns designed on the principles of social marketing. These centrally driven message delivery systems, no matter how sophisticated, could not respond to fine-grained local ecological variation. Recommendations were inflexibly early, late, or inappropriate. More dangerously, in the area of crop protection these recommendations often collapsed under commercial marketing pressure to chemical product pushing. The logical fears of extension agents that by failing to push (even optional) chemicals they would be culpable for any crop failure, whether pest-associated or not, led to a one dimensional view of their job. To satisfy superiors who communicated by setting targets for inputs distribution extension agents often became chemical dealers themselves.

New sources of local expertise had to be engaged. Those sources are the communities themselves. In most Asian extension systems the crop protection units are semi-autonomous. Their staff are supposed to have special qualifications, and they are required to go into farmers' fields in order to report upwards on threatening pest populations. While their surveillance work often served as a trigger to release more subsidised pesticides, their relative independence and assignments to the field created windows of opportunity for training and education. These field staff, most never having planted and grown a complete rice crop, were put through intensive field Training of Trainers courses for four months, six days per week in the field. As farmers became pest control experts, pest control staff gained credibility as farmers. They also learned and practiced adult non-formal education skills, and welded together in teams that could rely on each other when they were re-inserted into their home office bureaucracies.

From 1988 to the present IPM, while for the most part remaining within national structures of agricultural extension, has moved toward education rather than training, and through education towards community organization, community management, planning and community control of IPM. Full time IPM trainers facilitating and then following up Farmers Field Schools have been succeeded naturally by networks of farmer trainers who can call upon specialists for specific advice. These farmer IPM trainers now carry out the majority of training in Indonesia. In 1993 a Global IPM Field Exchange and Meeting was held in Southeast Asia. Participants from Africa, the Near East, Latin America, and Europe spent ten days in the field learning from Asian IPM farmers, then planning for their own countries. This has led to strong initiatives of participatory IPM in Africa, the Near East, and Latin America.

Impact of IPM

As IPM becomes a doorway for transformation and community empowerment we require new thinking about impact. While agro-economic criteria of impact are necessary they are not sufficient. The quality of scientific process and the social-political momentum of empowerment are equally necessary, and the three dimensions must be accounted for in studies of impact.

The narrowly agro-economic impact of IPM, after taking into consideration the costs of Farmers' Field Schools and Training of Trainers, is considerable. One study of over 1300 villages in Vietnam showed a 4 percent yield increase in rice and over 20 percent increase in profits. Farmers Field Schools organised by trainers in seasons after their own training was completed in Ghana, Cote d'Ivoire, and Burkina Faso have shown savings for rice farmers of over US$90 per hectare, with at least as high yields, and profits increasing by over 25 percent. In Philippines, when cabbages were contaminated by over-use of pesticides, IPM training resulted in farmers reducing from over 20 applications per season to three, including one treatment with an insect pathogen. In Indonesia there were three nationally threatening planthopper outbreaks on rice between 1977 and 1987. In the ten years since, under an IPM national declaration and removal of pesticide subsidies, there have been no national outbreaks. The savings to the government of Indonesia by eliminating the subsidies has exceeded US$1 billion. India eliminated a US$30 million annual subsidy by the central government for insecticides, and instead imposed a 10 percent excise tax on them. This has meant US$60 million annual new income to the government, which spends over US$10 million per year on IPM field training. In China, provincial governments, impressed by farmers' profits increasing by over 15 percent from practising IPM, now pay for more IPM training than the central government. When calculated from field-derived estimates of micro-benefits to farms, the financial rates of return of IPM investment have exceeded World Bank and Asian Development Bank critieria for project approval.

A crucial dimension of IPM impact is empowerment. The Kalensari experience illustrates how communities come to control the IPM research, planning and implementation process by engaging the world around themselves. This is the path forward. My final examples, from Africa, show how the path may be followed in other regions. In Kiambu district, Kenya, a group of women farmers held an IPM Farmers Field School and continue to meet every week, a year later, in the field often with their facilitators and technical advisers,who are also women. They work in coffee-tomato-maize systems. During my visit in July 1997 the Director of CropProtection of the Kenya Agricultural Research Institute delivered to this group of 25 women a diagnostic report on a tomato pathogen that the farmer scientists had recognised was neither a nutritional disorder nor insect damage. The report offered both chemical and cultural management options. The group discussed the report, and seemed likely to choose the cultural management option and not the chemical one. What was remarkable was that this group of farmers had accessed the leading national institution and received service, just as giant plantation operators do, in order to inform their decision making. This is the power of scientist farmers.

The final case is from Mali, where a group of farmers had completed Farmers' Field Schools and were reporting results to our August 1997 visitors group of outsiders and irrigation system officials. When these scientist farmers explained that insect pests were not observed to be a threat in that season, due to effective natural enemies, the most senior of the irrigation officials, with a plant protection background, protested. He accused the farmers of being complacent, that other pests they could not observe might be destroying their crop. In reply, the senior female farmer raised her voice from the end of the room, and accompanied by affirmations from both men and women farmers, engaged the official in discussion. She explained that because they had conducted simulation studies of rice crop damage and observed and measured how the crop had recovered, the scientist farmers were confident that other damage, even if unobserved, would not result in yield loss. She then went on to raise the issue of the "package" of inputs that each farmer was required to take and pay for out of the harvest. She recalled that the package included about US$80 worth of pesticides, which were not needed at all that season. Faced with scientific arguments and with the unanimity of the group of IPM scientist farmers that season, the irrigation official conceded that the package would be re-examined. When the content and process of IPM are linked to community power, even during the first seasons, transformation begins.

Indigenous and modern approaches to IPM in Latin America

Prevailing economic policies in Latin America encourage the production of export and/or commercial crops, primarily in large-scale monocultures. Pesticide expenditures in the Latin American region increased from US$1.0 billion in 1980 to US$2.7 billion in 1990. The major recipients of pesticides were large-scale production systems producing sugar cane, cotton, maize, soya beans, rice, citrus and tomatoes, especially in Brazil, Colombia, Argentina and Mexico. Predictably, the emphasis of the chemical-intensive agricultural export model has intensified ecologically-based crisis conditions and has led to serious environmental and health consequences (Belloti et al., 1990).

Miguel A. Altieri and Clara I. Nicholls

Despite the above trends, there are several documented cases of alternative pest management approaches scattered throughout the region that have resulted in sustainable crop production. These are both traditional crop protection practices (indigenous IPM systems) developed by indigenous farmers using traditional knowledge and local resources, and modern IPM systems developed by innovative researchers involved in the search for more sustainable methods of food production.

Despite many scientific advances, it is still arguable whether ecological principles have actually had an impact on the practice of modern IPM. In many cases, modern IPM has come to mean Intelligent Pesticide Management, which aims at scouting crops to monitor pest densities in order to take action (usually insecticide application) when they threaten economic viability (the economic threshold (ET)). As long as the simplified structure of monocultures is maintained, pest problems will continue because the process of ecological simplification has been set in motion. The IPM projects described below are, however, a step in the right direction as they em phasise the withdrawal of pesticides, allowing beneficial fauna to recover and a more desirable level of biodiversity to re-establish itself within agro-ecosystems.

Peru

In the mid-1950s, as cotton production reached a peak in the Canete Valley, organochlorinated insecticides were in intensive use. Several pests had already developed resistence to these pesticides, and heavier dosages and more frequent applications became necessary. Six new species of secondary pests made their appearance and cotton yields fell sharply.

A number of changes in pest control practices were introduced in response to this crisis including the banning of synthetic organic pesticide use, the reintroduction of beneficial insects, crop diversification schemes, planting of early maturing varieties and the destruction of cotton crop residue. Pest problems declined dramatically, and pest control costs were substantially reduced (Hansen, 1987).

Nicaragua

In Nicaragua, cotton also exhibited the classic pesticide 'treadmill' pattern observed earlier in Peru. After a successful production phase in which cotton yields peaked in 1964-1965, pesticide-induced ecological disruptions made themselves felt: insecticide-resistant pests, secondary pests and the elimination of natural enemies. Average yields fell by 15-30% because of insect damage, despite 28 insecticide applications per season. In 1971, a programme started by UN-FAO began to yield information on, amongst other things, economic thresholds, the seasons when natural enemies were most abundant, and cotton phenology. This helped researchers to identify the best time for planting cotton and the conditions that gave the best growth environment to the plant, allowing it to escape boll weevil and boll worm attack. Later, a 'trap cropping' system was developed. This consisted of planting small cotton plots at the beginning and end of the growing seasons to attract and concentrate weevils. Once trapped, they were then killed off by selective insecticides (Swezey et al., 1986).

Costa Rica

Another case of insecticide-induced ecological disruption comes from the Pacific coastal plains. In 1954, over 12,000 hectares of United Fruit Company banana plantations were treated with an aerial application of dieldrin granules against banana weevil and rust thrips. This killed off many natural enemies and led to the appearance of other pests which had previously been of minor significance. An outbreak of banana stalk borer, Castiomera humbolti was countered by more pesticide spraying. By 1958, in spite of increasing pesticide use, there was an unprecedented outbreak of pests, with even six major Lepidopteran pests including Ceramidia moth, owleye and the West Indian bag worm that had not previously been a problem. In 1973, the oil crisis prompted United Fruit entomologists to stop all insecticide sprays in the entire Golfito banana division. Insect pests fell to below a level where they were a threat to profitability within one to three generations (a period of several months) with little or no fruit loss. Within two years, virtually all of the former pest species had almost disappeared from the plantations. Indeed, pests like Ceramidia and the owleyes were rarely seen. There were occasional small outbreaks of larvae of the West Indian bag worm, but their numbers did

Table 1. Selected examples of multiple cropping systems that effectively prevent insect-pest outbreaks in Latin America (after Altieri, 1994).

Multiple cropping System	Pest(s) regulated	Factor(s) involved	Country
Cassava intercropped with cowpeas	Whiteflies *Aleurotrachelus socialis* and *Trialeurodes variabilis*	Changes in plant vigour and increased abundance of natural enemies	Colombia
Corn intercropped with beans	Leafhoppers (*Empoasca kraemeri*), leaf beetle (*Diabrotica balteata*) and fall armyworm (*Spodoptera frugiperda*)	Increase in beneficial insects and interference with colonisation	Colombia
Corn intercropped with beans	Corn leafhopper (*Dalbulus maidis*)	Interference with leafhopper movement	Nicaragua
Cucumbers intercropped with maize and broccoli	Flea beetles (*Acalymma vitata*)	?	Costa Rica
Corn-bean-squash	Caterpillar (*Diaphania hyalinata*)	Enhanced parasitisation	Mexico
Corn-beans	Stalk borer (*Diatraea lineolata*)	?	Nicaragua

not threaten the economic threshold. The same was true of the banana weevil. Stopping pesticide sprays allowed natural enemies to move in from the surrounding jungle, colonise the area, become more abundant and thus re-exert a natural control over many of the pest populations (Stephens, 1984).

Brazil

By 1970, total soya bean production had reached 2.278 x 106 tons, especially in the states of Parana and Rio Grande do Sul, covering an area of about 5.5 x 106 has. As soya bean acreage increased, so did the number of insect pests. In 1974, Brazil adopted an IPM programme that relied primarily on monitoring pest damage, establishing economic thresholds and the application of specific insecticides. This IPM programme was so successful that between 1974 and 1982 insecticide applications fell by 80-90%. In the 1980s, the programme was expanded to include the use of Nuclear Polyhedrosis Virus against the velvetbean caterpillar. This virus is host specific and it can be readily mass-produced by farmers themselves. They collect sick larvae that, when macerated and filtered, can be applied in a water solution (Campanhola et al., 1995).

Colombia

During the late 1970s and early 1980s, it would have been considered usual to make some 20 to 30 pesticide applications in a tomato growing area covering about 2,000 hectares. An IPM programme in the Cauca Valley implemented in 1985 succeeded in reducing the number of pesticide applications to two or three. This saved over US$ 650 per hectare. Use of a microbial insecticide derived from *Bacillus thuringiensis* combined with the release of natural enemies such as *Trichogramma* spp., and the encouragement of natural populations of the parasite *Apanteles* spp., were particularly effective in reducing the major pest *Scrobipalpula absoluta*, a leaf miner/fruit borer (Belloti et al., 1990).

Chile

In 1972, populations of two aphid species (*Sitobium avenae* and *Metopolophium dirhodum*) were detected in cereal fields. Despite the presence of resident natural enemies, these aphids reached outbreak proportions. As a result, over 120,000 hectares of wheat were sprayed aerially with insecticides. In 1975, the aphids and the Barley Yellow Dwarf Virus they transmit were responsible for the loss of about 20% of national wheat production. In 1976, the Chilean government's agricultural research centre, in conjunction with the FAO, initiated a pest management programme. As part of the strategy, several aphidophagous insects and parasitoids were introduced against the aphids. Five species of predators were brought in from South Africa, Canada and Israel, and nine species of parasitoids of the families Aphidiidae and Aphelinidae came from Europe, California, Israel and Iran. In 1975, more than 300,000 Coccinellidae were mass-reared and released, and from 1976 to 1981 more than 4x106 parasitoids were distributed throughout the cereal areas of the country. Aphid populations were maintained below the threshold where they could inflict economic damage by the action of biological control agents (Zuñiga, 1986).

Cuba

Since trade relations with the socialist bloc collapsed in 1990, pesticide imports to the island have dropped by more than 60 percent. Because of this, the Cuban government adopted an IPM policy which focused on biological control in its search for techniques that would enable biologically sophisticated management of agro-ecosystems (Rosset and Benjamin, 1994). Key components of their strategy are the Centers for the Production of Entomophagae and Entomopathogens (CREEs), where the centralised, 'artesanal' production of biocontrol agents takes place. By the end of 1992, 218 CREEs had been built throughout Cuba and were providing services to the State, cooperatives, and individual farmers.

CREEs produce a number of entomopathogens (*Bacillus thuringiensis, Beauveria bassiana, Metarhizium anisopliae*, and *Verticillium lecanii*), as well as one or more species of *Trichogramma* wasps. Their production depends on what crops are being grown in the area.

The array of both proven and promising IPM technologies developed by innovative researchers and indigenous farmers offers considerable potential for reducing agrochemical use and improving agricultural sustainability. The challenge now is how to incorporate local knowledge and skills as well as innovative IPM research into the research agenda of national and international organisations. The other challenge is how to mobilise these organisations to help scale up the initiatives described here and make wider eco-regional impact possible. At the political level it is clear that a true reduction and/or elimination of pesticide use in the agro-export sector will require major political reforms that deal with the reasons why farmers turn to chemicals. These include government pesticide subsidies, corporate control of agricultural enterprises, research serving the needs of the private sector, and internationally set, unrealistic, cosmetic standards.

Table 2. Selected examples of cropping systems in which the presence of weeds enhances the biological control of specific crop pests (after Altieri, 1994).

Cropping systems	Weed species	Pest(s) regulated	Factor(s) involved	Country
Beans	Goosegrass (*Eleusine indica*) and red sprangle-top (*Leptochloa filiformis*)	Leafhoppers (*Empoasca kraemeri*)	Chemical repellence or masking	Colombia
Brussels sprouts	Natural weed complex	Imported cabbage butterfly (*Pieris rapae*) and aphids (*Brevicoryne brassicae*)	Alteration of colonisation background and increase of predators	Chile
Corn	Natural weed complex	*Heliothis zea, Spodoptera frugiperda*	Enhancement of predators	Colombia
Corn	Natural weed complex	*Dalbulus maidis*	Interference with leafhopper movement	Nicaragua
Soybean	Broodleaf weeds and grasses	*Epilachna varivestis*	Enhancement of parasites	Mexico, Colombia
Soybean	*Cassia obtusifolia*	*Nezara viridula, Anticarsia gemmatalis*	Increased abundance of predators	Brazil
Soybean	*Crotalaria usaramoensis*	*Nezara viridula*	Enhancement of Tachinid parasite (*Trichopoda sp.*)	Brazil
Sweet potatoes	Morning glory *Ipomoea asarifolia*	Argus tortoise beetle (*Chelymorpha cassidea*)	Provision of alternate host for the parasite *Emersonella* sp.	Costa Rica
Vineyards	Natural weed complex	Grape mealy bug *Pseudococcus affinis*	Enhance natural enemies	Chile

Integrated Pest Management:

Smallholders fight back with IPM

This issue of the Newsletter is about substituting external inputs for labour, management skills and knowledge. It is about Integrated Pest Management (IPM) and men and women farmers participating in Farmer Field Schools, experiential learning and non-formal education.

from the editors

Although 35 years have passed since Rachel Carson published **Silent Spring** with its devastating account of the effects of the indiscriminate use of agro-chemicals, the one-sided push for increased output continues. Nature is controlled to this end and reliance on pesticide has not diminished. In northern countries, the environmental movement, followed hesitantly by government regulation, has had some impact on stabilising and perhaps curbing agro-chemicals, but in the South the use of pesticides has increased and chemical companies aggressively expand their markets.

Since the 1950s agriculture has been dominated by the vision of modernisation and the potential for using technology to mould nature to this end. This model has dominated the industrial agriculture of the North and the history of Green Revolution agriculture in the South.

Fortunately there have been initiatives within several agencies and governments to implement alternative approaches. FAO's Inter-Country IPM programme, which introduced the participative learning model of Farmer Field Schools, is one such example. First in Asia and later in Africa, many farmers were led to explore the wonderful and complex ecological relations present in their own fields and eco-regions. In this last Newsletter of 1997 we focus on IPM and try to give a picture of the changes that have taken place in recent years.

IPM

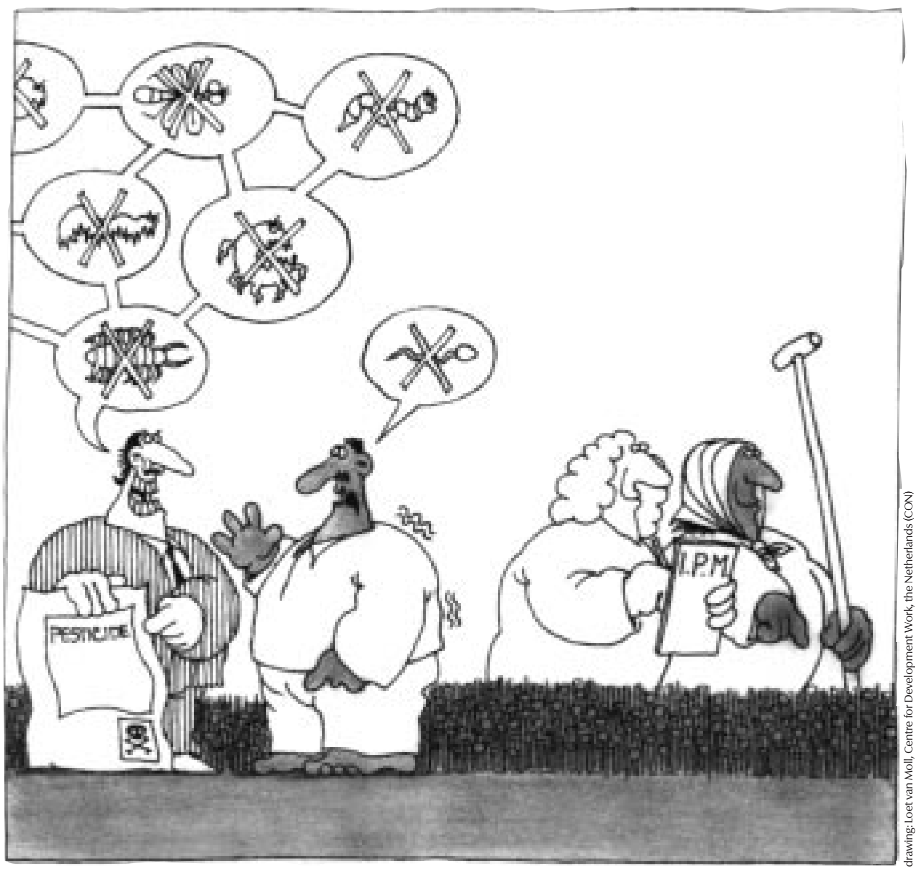
Integrated Pest Management developed in the 1970s as a response to the negative side effects of using pesticides. Pests were becoming resistant to chemical treatments, and the health of farmers, farm workers and consumers was in danger. These hazards were far greater in Third World countries, and today's evidence suggests that the situation has become even more volatile. The latest WHO figures suggest that at least 3 million, and perhaps as many as 25 million, agricultural workers are poisoned each year by pesticides, and some 20,000 deaths can be directly attributed to agro-chemical use. Studies from the Philippines have computed the alarming costs of pesticide to the national economy, showing these negative effects extend far beyond the individual (Pretty 1995).

In its early stages, IPM was a technical approach designed to reduce the number of pesticide applications. It subsequently developed into a methodology in which farmers were encouraged to develop IPM interventions themselves, in the process of coming to a better understanding of their agro-ecosystems. We can distinguish three stages in the development of IPM.

First, **the integration of control methods and target pests**. Technically, IPM consists of a combination of control methods including biological control, host plant resistance, cultural control, and selective chemical control. First generation IPM projects focused on reducing the use of insecticide by introducing the idea of pest population thresholds. Above this threshold, spraying against a particular pest - supervised control - was considered justified. Next, various control methods were combined to combat one or two key insect pests. Second generation technical IPM projects targeted more pests, and by including diseases and weeds, addressed the many crop protection problems experienced by farmers.

Second, **crop protection was integrated with farm and natural resources management**. When it was realised that many agricultural practices influenced pest development, and that crop intensification often leads to increased pest problems, control measures were designed that fitted into overall farm management. Indigenous knowledge and traditional cropping practices were studied, adapted and eventually served as the building blocks in IPM programmes. Natural Resource Management (NRM) became a deliberate objective because of the importance of bio-diversity in biological control and the social value of environmental protection. IPM projects practised Integrated Crop Management to solve the conflicting needs of agricultural production and the environment.

Third, **the integration of the natural and social sciences**. It became clear that fixed prescriptions do not work in tropical agriculture since site-specific agro-ecological and socio-economic conditions determine what is best in any one situation.



drawing: Loet van Moll, Centre for Development Work, the Netherlands (CON)

Farmers must be able to choose from a 'basket' of technologies. Existing extension systems, such as Training and Visit did not provide sufficient flexibility because they were based on the concept of a 'transfer of technology'. IPM projects started to develop around a more dynamic extension model - the Farmer Field School (FFS). This approach combined training with field-based, location-specific research to give farmers the skills, knowledge and confidence to make ecologically sound and cost-effective decisions on crop health. A number of examples of the ways in which FFS has developed in different countries are discussed in this Newsletter (see the articles by Kenmore, Page, Mangan, Nguyen, Nyambo, Fakih and Rengam).

Instead of promoting the transfer of ready-made techniques, FFSs emphasis building on farmers' ability to experiment and draw conclusions, on enhancing the farmer's ability to make good decisions, and on 'empowering them so that they can improve their socio-economic position (Van de Fliert 1993). This new model of IPM extension also generates research questions. The research agenda develops at the point when, in attempting to train farmers, critical gaps in knowledge are identified.

In order to create an environment that encourages farmers to adopt IPM, the problems of research and extension have been addressed and agricultural policies - particularly those that favour pesticide use - have been critically reviewed. The relevance of third generation IPM projects goes beyond crop protection to address Integrated Nutrient Management and Integrated Tillage Management. The involvement and organisation of farmers is essential in maintaining the momentum in this process.

Project design is vital and should be open-ended enough to allow the inclusion of pest problems. Adoyo (see pp 24-25), describes an agro-forestry and woodfuel project in which farmers identified pest control as a priority and began to experiment with botanicals in an attempt to control termites.

Subsistence farming

The existence of indigenous knowledge on pest management cannot be taken for granted. Bentley (1997) reports important misconceptions among Bolivian smallholders about pests and, hence, about ways to combat them. In some situations, this might lead to pesticide abuse. Knowledge and insight are essential if farmers are to invent their own, alternative techniques. Alternative pest and disease control options may exist, but poor communication can prevent this knowledge reaching farmers.

Pesticide is not used much on subsistence crops, and pests and diseases often form only a small part of a farmer's problem. In such situations, an Integrated Crop Management (ICM) approach may be very useful. An interesting example of this is given in the article by Page (pp 13-14). Other acute crop production problems include water availability and soil fertility, issues that call for the intervention of multidisciplinary teams. Such an integrated approach is much more difficult to operationalise and is less easily mobilised for subsistence crops than it is for cash crops.

Participatory approaches

Agricultural development projects that are based on farmers' participation draw on indigenous knowledge. Farmers search for solutions based on their own needs, because farmers understand their own responsibilities and possibilities the best. In Adoyo's article, farmers carry out experiments. As one Kenyan farmer put it at the end of an FFS training session, "We are researchers too and we are proud of our findings".

The participatory approach analyses problems and uses local knowledge. The experimental site is usually the farmer's field or a special experimental site selected by the farmers' group. Farmers are taught to experiment with their local knowledge and this is complemented by new or external information. In the process, farmers and extension workers gain methodological skills which help them develop their own solutions. Such a sequence challenges the conventional research paradigm, and calls for new relationships and respect between the actors.

Trends in product development

Despite the potential of IPM, the use of pesticides continues to grow (Altieri, pp 6-7). The agro-chemical industry is concentrating its efforts on promoting conventional pesticides in Latin America and Asia. In 1996, pesticide use increased by 6 percent in Latin America and countries such as Brazil, China and India have become important producers of conventional pesticides (see Stoll, pp 11-12). In a number of developing countries these can now be obtained very cheaply at the local market, lowering the economic threshold for pesticide use and allowing more frequent application.

In many cases, IPM has been the equivalent of Intelligent Pesticide Management. Crops are scouted to monitor pest densities so action (usually an insecticide application) can be taken when the economic threshold (ET) has been exceeded. As long as the simplified structure of monocultures is maintained, ecological simplification will lead to pest problems. We are convinced that this is not the case in the integrated agro-ecosystem approach.

Working for smallholders

The article by Sam Page (pp 13-14) gives an interesting example of how a small NGO organised itself to meet the needs of smallholders in Zimbabwe. The training given borrowed the 'learning through experimentation approach' from FAO 'Farmer Field Schools'. However, some variations were introduced, in the sense that training was given primarily to farmers directly selected by farmers groups. Those farmers participating in the project abandoned the use of synthetic pesticides and were able to apply for the organic certification that entitled them to a premium for their produce. On returning to their communities, 'Farmer Field Workers'(FFWs) supported by the project, shared their new knowledge and ways of learning with the ten farmers who had originally selected them. The FFWs conduct regular Farmer Field Schools, ensure that individual farmers adhere to the guidelines for organic production and certification, and write monthly reports.

Achievements in IPM amongst small farmers are still modest. Nevertheless, the array of both proven and promising IPM technologies developed by indigenous farmers and researchers described in this Newsletter show the potential that exists for reducing the amounts of agro-chemical used and for improving agricultural sustainability. Farmers cannot simply cut their use of external inputs and still hope to maintain output. External inputs must be substituted by labour, management skills and knowledge. Farmers must, therefore, invest in learning (Pretty 1995). The challenge is how to use local knowledge and skills to motivate national and international organisations to change their research agendas and help fill the gaps in IPM knowledge.

The other challenge is to mobilise organisations such as those described in this Newsletter for a wider eco-regional impact. Care must be taken to avoid the indiscriminate copying of approaches that have been successful in other regions. The Asian FFS, for example, is not necessarily the approach for every African situation. It may well be that the African FFS model will ultimately be very different from the one developed in Asia.

The road to sustainable pest control is not a romantic short cut through the domain of traditional farming. Overcoming the obstacles, detours and deadends will challenge creative farmers and scientists for many years to come (Bentley 1997).
