Abstract

This lab introduces many of the development and administrative tools provided by IBM® WebSphere® Business Integration Server Express Version 4.4 on IBM System i5[™] systems and the i5/OS® Version 5 Release 3 operating system through a predefined, step-by-step example. This example is a typical development scenario that will let you gain hands-on experience with the tools. After completing the lab, you can continue to use the example materials to further your learning experience.

Introduction

This self-guided lab provides an introduction to the development and administrative tools provided in WebSphere Business Integration Server Express V4.4 on the i5/OS V5 R3 operating system. During this lab, you will specifically learn about the following:

- Creating a WebSphere InterChange Server Express (ICS Express) instance
- Using System Manager to import and modify a project
- Using Connector Configurator to configure a Java[™] Database Connectivity (JDBC[™]) connector
- Using Map Designer to define mapping between application-specific and generic business objects
- Using Process Designer to view a business process (collaboration)
- Deploying a solution to WebSphere InterChange Server Express
- Testing a simple data flow through the solution using the Visual Test Connector (VTC)

Prerequisites

To perform this lab, you must be familiar with the WebSphere Business Integration Server Express Plus product, its terminology, and capabilities. Complete the following two self-study courses prior to performing this lab. The first course introduces you to the product, terminology, and business process architecture and introduces the tool set. The second course shows how to install WebSphere Business Integration Server Express Plus and the prerequisite software, as well as how to verify that your WebSphere Business Integration business process environment is functioning properly. Provided on the **Resources** page is a link to these courses:

- WebSphere Business Integration on the IBM eServer™ iSeries™ platform
- Getting Started with IBM WebSphere Business Integration Server Express Plus on the IBM eServer i5 platform

Setup

You will need to perform the following setup steps prior to beginning the lab:

- 1. Download the lab zip file for this course to a folder on your PC.
- 2. Unzip the file. (Note: You will use the file called CommonLabFall05.jar later in the lab.)
- 3. Install WebSphere Business Integration Server Express Plus V4.4 on an i5/OS V5R3 system using the install information from the "Getting Started..." course listed above. Ensure that the following software prerequisites are installed:
 - WebSphere Business Integration Server Express is installed on an i5/OS V5R3 system.
 - WebSphere Business Integration Toolset Express is installed on your PC.
- 4. Restore the WBICOMMON.FILE to the WBICOMMON library that contains the SQL and i5/OS command line (CL) program that will be used to create the JDBC application database:
 - a. Create the **WBICOMMON** library: CRTLIB WBICOMMON
 - b. Create a **SAVF** file on the i5/OS system named WBICOMMON: CRTSAVF FILE(WBICOMMON/WBICOMMON)
 - c. FTP WBICOMMON.FILE in bin mode to the i5/OS system and overwrite the SAVF file created in step a.
 - d. Restore WBICOMMON SAVF using the Restore Library (RSTLIB) command. (The library is WBICOMMON.)

RSTLIB SAVLIB(WBICOMMON) DEV(*SAVF) SAVF(WBICOMMON/WBICOMMON)

- Map a drive to the i5/OS system and copy the CommonLabFall05.jar file from your PC to the following IFS directory on your i5/OS system:
 (OIBM/UserDate/WPISer/or44/bin
 - /QIBM/UserData/WBIServer44/bin
- 6. Create a user profile called **WBIUSER00** using the CRTUSRPRF command with the following authorities:

USRCLS of *SECOFR and SPCAUT of *JOBCTL, *SECADM, *ALLOBJ. CRTUSRPRF USRPRF(WBIUSER00) PASSWORD() USRCLS(*SECOFR) SPCAUT(*JOBCTL *SECADM *ALLOBJ)

Additionally, this lab will require several pieces of data that are used throughout the lab, including the following:

- Lab user profile name: WBIUSER00
- InterChange Server name: WBI00
- WebSphere MQ port number: 14100
- HTTP port number: 14200
- RBAC user ID: WBI00
- RBAC password: WBI00
- Application database name: APPDB00

Note: When entering values, enter them exactly as shown here. Do not change the case of the letters or omit characters.

Creating an InterChange Server Express instance on i5/OS

The i5/OS platform supports multiple WebSphere InterChange Server instances on the same machine. You can create these instances from the Qshell environment by running a script. You can also run multiple instances of the server at the same time. You can establish these instances in a scheme where you use some instances for testing and development, whereas others are production servers.

The script that creates a new WebSphere InterChange Server instance is in the following location: /QIBM/ProdData/WBIServer44/bin/create_instance.sh

The script has the following usage:

create_instance.sh [-r<repository name>] [-q<queue manager name> [-exists]] [-d<db system> -n<db user> -w<db password>] [-u<rbac user> -p<rbac password>] <instance name> <mq listener port> <http port>

Here is a description of the arguments for this script:

- **instance name**: the name of the new instance (10 characters or less)
- mq listener port: the port number for the MQ listener
- http port: the port number for the HTTP server
- **repository name**: the name of the ICS repository (10 characters or less)
- queue manager name: the name of the queue manager (The -exists value specifies that the queue manager already exists.)
- **db system**: the name of the system where the existing database collection resides
- **db user**: a user name to access the database
- **db password**: the password for the database user name
- rbac user: a user to create for role-based access control (RBAC)
- **rbac password**: the password for the RBAC user to be created

The only required arguments for the **create_instance.sh** script are the instance name, MQ listener port, and HTTP port. All other arguments are optional. In cases where **rbac user** and **rbac password** are not provided (via the **-u** and **-p** options respectively), the ICS Express instance is created without RBAC security enabled. The remaining arguments are for more advanced configuration parameters; this lab will not discuss them.

For example, to create a new InterChange Server named **WBI00** (where the queue manager listener port is on port 14100 and the HTTP port is on port 14100), you can run the following command from QSH. (**Note**: RBAC security is not enabled for the following example.)

/QIBM/ProdData/WBIServer44/bin/create_instance.sh WBI00 14100 14100

Creating a new instance will build an InterChange Server IFS directory in UserData that will contain all the necessary files to support an ICS instance. The instance IFS directory structure will contain all the adapters and object discovery agents (ODA) that are installed on the machine. The create_instance script will also build a WebSphere MQ Queue Manager named **ICSNAME.QUEUE.MANAGER** and an SQL collection named **ICSNAME**, which will be used as the InterChange Server repository. You can use the advanced arguments for the create_instance.sh script to override the default queue manager and repository, but this function will not be covered here.

A log file will document the instance creation process in the following IFS location: /QIBM/UserData/WBIServer44/Logs/<icsname>.create

The newly created InterChange Server instance directory will be located in: /QIBM/UserData/WBIServer44/<icsname>

Creating a new InterChange Server

The following steps will guide you in setting up a new InterChange Server:

- 1. Start a 5250 session to the iSeries machine, through the icon on the desktop, and log on using the following information:
 - a. Your WBI lab user profile WBIUSER00
 - b. Your password
- 2. Start a new Qshell session on the iSeries system by entering the following command: QSH
- 3. From Qshell run the following create_instance.sh script:

/QIBM/ProdData/WBIServer44/bin/create_instance.sh -uWBI00 -pWBI00 WBI01 14100 14200

Notice that the following arguments are used:

- WBI01: your ICS name
- 14100: the port number assigned for your MQ listener port
- 14200: the HTTP port number

This can take a few minutes. Wait for the **Instance WBI00 created successfully** message to appear.

Note: RBAC has been enabled for this instance and will use WBI00 and WBI00 as the user name and password for RBAC (the ID and the password are the same for this example).

4. After the script has created your instance, use the following Qshell script to set the mode of the server to design mode:

/QIBM/ProdData/WBIServer44/bin/set_ics_server_mode.sh WBI00 design

You will use this mode while developing new solutions with the product. When you are ready to go into production, simply change the mode to production.

 Start your ICS instance using the following Qshell script: /QIBM/ProdData/WBIServer44/bin/submit_ics_server.sh WBI00

Using System Manager to import and modify a project

The System Manager tool is one of the main graphical user interface (GUI) tools for developing InterChange Server projects. Follow these steps:

 Access the System Manager tool by opening the following shortcut on your PC. Click Start > Programs > IBM WebSphere Business Integration Express > Toolset Express > Administrative > System Manager

System Manager - WebSphere Business Integration System Manager	_ 🗆 🗙

Creating the application database for the JDBC connector

The JDBC adapter monitors a specific application database collection. The adapter agent can poll for events. For example, it can receive events triggered in the collection. The adapter agent can also write events to the collection. (Business objects are normally stored in tables within the collection.) For this exercise, a test application database has been created for you to use. You will need to create your own copy before configuring the adapter.

- 1. Create a new collection from SQL (the application database), by entering the following commands from an i5/OS command prompt:
 - a. Start an SQL session: STRSQL
 - b. In the SQL session, enter: CREATE COLLECTION APPDB00
 - c. After the message is displayed that the collection was created, hit **F3** to exit the SQL session and hit **1** at the exit/save prompt.

The JDBC adapter ships with a command line (CL) program on the i5/OS platform that will create the necessary event and archive tables as well as the stored procedures for the JDBC adapter to poll.

- Create the event and archive tables for the JDBC adapter, as well as a stored procedure, by issuing the following from an iSeries prompt (where APPDB00 is the application database created in the previous step, and WBIUSER00 is the profile name on the i5/OS system): CALL QWBISVR44/QWBIJDBCSQ PARM('APPDB00' 'WBIUSER00')
- 3. Run a CL program (created for this lab) that will create three tables in your application database, as well as a database trigger.

This step will be necessary if you already have a database, because it creates the necessary database tables for the JDBC connector to function:

- One table will store a business object that will be sent as an event in the lab.
- One table will be used by the collaboration in this scenario.
- One table will store application-specific events.

Later in the lab, you will run another CL program that will perform an SQL **insert** in the application event table. A trigger will detect this insert and will copy the new row into the JDBC adapter's event table.

4. Enter the following from an i5/OS prompt (where APPDB00 is the application database created in the previous step, and WBIUSER00 is the profile name on the i5/OS system): CALL WBICOMMON/APPDBCRT PARM('APPDB00' 'WBIUSER00')

Using Connector Configurator and editing connectors

The following steps will help you learn how to use the Connector Configurator to configure the JDBC connectors:

- 1. From the System Manager screen, expand the ICL00 integration component library.
- 2. Expand the Connectors folder (Figure 9).

Figure 9: Expanding the Connectors folder

3. Double-click the **JDBC** connector to open the connector definition in Connector Configurator Express.

4. In the **Standard** properties for the connector, ensure that the **MessageFileName** property is set to **JDBCConnector.txt** (Figure 10).

Because this is a JDBC Connector, you want to use the existing message file to ensure that you get proper logging messages for the adapter. Also, notice that the **AgentTraceLevel** is set to **5**. This is the highest level of tracing. When you are ready to go into production, set the trace level to **0**, which is the lowest level of tracing.

Figure 11: Setting the connector-specific properties

- 7. Click the **Trace/Log Files** tab (Figure 12).
- 8. Ensure that both the **Logging To Console (STDOUT)** and **Tracing to console (STDOUT)** options are unchecked, and that the **Logging To File** and **Tracing to File** options are checked.

Note: If you leave the STDOUT boxes checked, the adapter will create a spool file when it runs. The correct place to log and trace on the i5/OS platform is to an integrated file system [IFS] file.

- 9. Enter a path and file name for logging and tracing for your JDBC adapter:
 - a. For the logging: /QIBM/UserData/WBIServer44/WBI00/log/myjdbc.log
 - b. For the tracing: /QIBM/UserData/WBIServer44/WBI00/log/myjdbc.trace

Figure 16: Opening the SourceAppConnector

Creating a new database connection pool

The database connection pool will be used from the logic within the collaboration to access a table in the application database. This table will contain the primary key and time stamp for each event that goes through the collaboration.

1. Right-click the **Database connection pools** folder in your integration component library (Figure 17) and select **Create New Database Connection**.

Figure 17: Selecting database connection pools

- 2. In the **Create new database connection** wizard, enter the following (Figure 18):
 - a. Database driver: DB2 iSeries (Type 2)
 - b. DBConnection Name: APPDBCon
 - c. Host name: localhost
 - d. Login: WBIUSER00 (your profile name on the i5/OS system)
 - e. Schema: APPDB00 (your application database)
 - f. Password: your i5/OS system password
 - g. Ensure the Unlimited option is checked for Maximum connections
 - h. Connected servers: WB100 (the name of your instance)
 - i. Max connect retries: 10
 - j. Connection retry interval: 60

Using the Business Object Designer Express

As the data passes through the adapter and ICS, it will be stored in a business object. You will recall from the WebSphere Business Integration presentation that there are two types of business objects:

- The application-specific business object represents how the application sees the data. In this example, this is the database.
- The generic business object is the generic representation of the data that the InterChange Server business process uses.

You will not be adding or changing anything in Business Object Designer Express. However, it is beneficial to look at the information because it can help you add or customize.

- 1. In System Manager, expand the **Business Objects** folder in your integration component library.
- 2. Double-click the **PersonASBO** folder (Figure 21) to open it in Business Object Designer.

System Manager - WebSphere Business Integration Sys	tem Manager	JN

/ICL00/BusinessObjects/PersonASBO.xsd		

Figure 21: Opening a business objects folder

3. Click the General tab from Business Object Designer and notice the Business Object Level Application-specific information, which is TN=Person (Figure 22). This information tells the JDBC adapter that the PersonASBO is stored in a table named *Person*. This table must exist in the database that the JDBC adapter agent is monitoring. This was specified in the DataBaseURL property of the JDBCConnector. The actual database name is APPDB00 as specified in the jdbc:db2:localhost/APPDB00 command.

Figure 23: Understanding the PersonASBO business object Attributes

5. Exit Business Object Designer.

6. Double-click the **PersonGBO** business object (Figure 24) it from the System Manager screen to open it.

Notice this business object looks almost identical to PersonASBO except that it has no application-specific information, and it also contains a child business object of type AuditBO.

Also notice that PersonGBO only has one attribute for the name (which is *Name*). You will see in the maps that you can join and split attributes to make this implementation easy. This AuditBO stores information that is used in the collaboration to create an entry in a table in the APPDB00. (APPB00 records the time stamp of the event and the Key ID from the business object. As you will see, these values are set in the map.)

	10	10							255			
Ready												

Figure 24: Opening the PersonGBO business object

7. When finished, exit Business Object Designer.

Using Map Designer

The following steps define mapping between application-specific and generic business objects:

- 1. From the System Manager screen, expand the **Maps** folder in your integration component library.
- 2. Double-click the **Person_ASBOToGBO** map to open it in Map Designer (Figure 25). The mapping in this case is very simple; the PersonASBO can be directly moved from the PersonASBO to the PersonGBO. The one exception is that the PersonGBO only has one attribute for the name; thus the mapping uses a **Join** transformation to create the string **FirstName,LastName** in the PersonGBO.
- 3. Notice that the CustomerID of the PersonASBO (which is the key) is mapped into the **BOID** (business object ID) field of the PersonGBO's AuditBO. This is necessary because the AuditBO contains the key of the events business object. For this simple example, the remaining values of the AuditBO are filled with a **SetValue** transformation.

Figure 25: Using Map Designer

Note: You can test maps from Map Designer by clicking the **Test** tab and then clicking the **Run** icon. However, you will not do that in this lab.

- 4. From the Map Designer screen, right-click the **Join** rule for the **Name** attribute of the PersonGBO and select **Open** to see the **Join** transformation.
- 5. In Figure 26, there is simply a comma that is put between the first and last name. The comma is also stored in the attribute.
- 6. Click **Cancel** when you finish viewing the transformation.

Join	×
Attribute	Delimiter
ObjPersonASBO.FirstName	1
ObjPersonASBO.LastName	
Move Up Move Down	
Example	
ObjPersonASBO.FirstName,ObjPersonASB	0.LastName
View Code	<u>O</u> K Cancel

Figure 26: Viewing the Join transformation screen

7. Open the Person_GBOToASBO map in Map Designer by double-clicking it from the System Manager screen.

The only interesting thing about this map is that it must use the split transformation (Figure 27) to separate the first name from the last name in the PersonGBO. Nothing is needed in the ASBO that is related to the AuditBO; therefore, no mappings are necessary.

Using Process Designer

The steps in this section will show you how to use the Process Designer to view a business process (collaboration):

- 1. In the System Manager screen, expand the **Collaboration Templates** folder in your integration component library. Then, double-click the **AuditTemplate** collaboration template to open it in the process designer.
- 2. Double-click the **Definitions** leaf on the left side of the process designer (Figure 30).
- 3. Select the **Declarations** tab to show the variable definitions that are global to this template.
- 4. Notice that there is a variable to store the current triggering business object and a database connection object for database operations. There is also a variable to hold the AuditBO, which is a child business object of the PersonGBO.

Process Designer Express - AuditTempl	e : ICL00 - [Template Definitions]	
	▁▖▖

	Type Name Initial Value Modifier1 Modifier3 Comment 1 BusObj processing new BusO Image: State Sta	
	pdate	
	Apply Discard Close	
Ready .	Template De	

Figure 30: Viewing AuditTemplate definitions

5. Double-click the Audit_Create scenario (Figure 31) from the left side of the Process Designer screen to open the scenario for the create verb.

Note: All the scenarios are identical, except that they are triggered by different verbs.

Figure 31: Viewing the Audit_Create scenario

The logic in this template is quite simple and behaves as follows:

Attributes are extracted from the triggering business object that contains information necessary to the audit operation. (For example, the AuditBO contains the name of the database connection pool that is needed to obtain the database connection object.)

- If step 1 is successful, then the actual audit operation is performed, which simply writes the triggering business object's key attribute and the current time stamp into a database table.
- The triggering business object is sent to the destination port.
- 6. Double-click the Init Vars action node in the diagram to view the code (Figure 32).

This code first initializes processingBO as a copy of the triggering business object because it is not good programming practice to operate on the triggering business object. Next, the AuditBO is extracted and saved into the auditBO variable. Finally, the database connection pool name is extracted from the AuditBO, and the database connection object is obtained.

Action Properties: Action_2	
Label:	
Init Vars	* *
Description:	
	<u> </u>
	<u> </u>
le la	Edit Clear
Code fragment:	
<pre>// copy the triggering BO to processingBO variable processingBO.copy(triggeringBusObj); // extract the child audit BO auditBO = processingBO.getBusObj("Audit"); // get the DB pool name from the BO attribute String poolName = auditBO.getString("DBPoolName"); // obtain the db connection object try{ dbConnection = getDBConnection(poolName); success = true; }catch(CwDBConnectionFactoryException connex){ logError("Failed attempt to obtain db connection : " + connex.getMessage()); success = false; raiseException(connex.getType(), connex.getMessage()); }</pre>	
<u>Apply</u> <u>Discard</u>	

Figure 32: Viewing the code

7. Double-click the **Audit** action node from the diagram to view its code (Figure 33).

This code first extracts the business object key, the name of the audit table, and the column name to store the time stamp. The code then creates an SQL statement to insert the current time and the key attribute of the triggering business object. This SQL statement is then executed using the database connection object.

Action Properties: Action_9	
Label:	
Audit	
Description:	
	Edit Clear
Code fragment:	
String BOID = auditBO.getString("BOID"); String table = auditBO.getString("AuditTable");	
try{	
String timeCol = auditBO.getString("TimeColName");	
//String insertStm = "insert into TESTTBL (TestBOID, TestData) values ("" + key + "', "" + gvtD String insert = "insert into " + table + " (BOID, " + timeCol + ") values ("" + BOID + "', "' + r	Data + "')"; new Date().toString() + ")";
dbConnection.executeSQL(insert); while(dbConnection.hasMoreRows()){ dbConnection.nextRow(); } trace(1, "*** Audit Log Complete ***");	
<pre>}catch(CwDBSQLException connex){ logError("Failed attemped executeSQL: " + connex.getMessage()); success = false; raiseException(connex.getType(), connex.getMessage()); }</pre>	
ToBusObj.copy(processingBO);	
Apply Discard Close	

Figure 33: Viewing the Audit action node

Deploying the project

Before deploying, you first need to create a **User Project** and associate it with your integration component library.

- 1. From the System Manager screen, expand User Projects.
- 2. Right-click InterChange Server Projects and select New InterChange Server Project.
- 3. Enter **ICLProj00** (Figure 34) for the name of the project and select **ICL00** from the available integration component libraries.
- 4. Click **Finish** to create the project.

🛞 New User project	×
New User project	
New user project creation	*

Figure 35: Selecting the components to deploy

- 8. After the project deployment is complete, shut down the server gracefully by right-clicking your server instance from the **InterChange Server Component Management** view in the System Manager screen (located in the lower left portion of the System Manager window).
- 9. Select Shutdown > Gracefully.
- 10. To start the server, open Start > Programs > IBM WebSphere Business Integration Express > Toolset Express > Administrative > Console.
- 11. Enter the following information at the console's server login dialog (Figure 36), then click **OK**:
 - System: your i5/OS system name
 - User ID: WBIUSER00
 - Password: your user profile's password

Figure 37: Starting the InterChange Server instance

- 15. Depending on the content deployed to the InterChange Server instance and the system resources available, it might take a few minutes for the server to come up. Once the instance has started, the WBI00 instance will show up as **Running** from the console.
- 16. In the System Manager view, right-click your server instance, and select **Connect**. Ensure that both the user ID and password are set to WBI00 (as specified for the RBAC information when creating the instance), and click **OK**.

- 17. After you have connected to your server instance, expand the **Collaboration Objects**, **Connectors**, and **Maps** folders in the **InterChange Server component management** view in the System Manager screen (Figure 38).
- 18. If any of the elements in the folders are stopped (which is indicated when their icon is red), rightclick the stopped element and select **Start**.

Figure 38: Viewing the InterChange Server component management options

Testing the solution using Visual Test Connector

Before testing the solution using the Visual Test Connector (VTC), you must first start the JDBC agent on the i5/OS machine.

1. From the console application used to start the server instance, select **JDBC** in the **Adapters** section under the **WBI00** instance you created, and click the **Start** icon (Figure 39).

Figure 47: Entering the New Instance name

- 14. You will now see the attributes of the business object in the **Business Object Editor** portion of the VTC window.
- 15. Enter some data for each of the business object attributes (the values are arbitrary) (Figure 48).
- 16. Ensure the **CustomerID** attribute is a valid integer. (In other words, use only numbers.)
- 17. After entering some data for the business object, select **Request > Send** from the VTC menu to send the business object to the server.

Figure 48: Entering business object attributes

- 18. To view the database tables, start an SQL session from the 5250 session by entering **STRSQL**. To view the contents on the audit table, enter: *SELECT * FROM APPDB00/AUDIT*
- 19. Here, you will see your CustomerID attribute for the **BOID** column (Figure 49) that was specified in the Virtual Test Connector a few steps ago. Also, you will find the time stamp for this event in the **TIME** column of the database table.

Session A - [27 x 132]	<u>- 🗆 ×</u>

Figure 49: Viewing the CustomerID attribute information for the BOID column

20. Similarly, you can verify that the attributes of the business object were saved into the **Person** table (Figure 50) by entering the following SQL statement: SELECT * FROM APPDB00/PERSON

🛡 <mark>]</mark> Session A - [27 x 132]

Figure 50: Verifying the Person table information

You have now successfully sent a business object from your Virtual Test Connector to the ICS where it executed the collaboration. You have also sent the business object to the JDBC connector where a record was written to the database.

To demonstrate the polling feature of the JDBC adapter, you will run a command line script that will execute some SQL to produce an **INSERT** statement. You will also insert some sample data into the Person_Event table. A database trigger is set up for the Person_Event table that extracts the newly inserted data and inserts it into the XWORLDS_EVENTS table. The JDBC agent is set up to inspect this event table, and properties related to this polling mechanism can be set in the adapter agent from the Connector Configurator window.

- 1. Execute the following CL statement from the iSeries command line: CALL WBICOMMON/APPDBINS PARM('APPDB00' 'WBIUSER00')
- 2. In the Virtual Test Connector window, you will see a PersonASBO with a Create verb (Figure 51).

OK Cancel			

Figure 52: Viewing the business object contents

- 4. When you finish inspecting the business object, click **OK**.
- 5. It is necessary to send a reply to complete the process, select **Request > Reply > Success**.

You have now successfully inserted a record in your application database. The JDBC connector picked it up and sent it through the collaboration to your Virtual Test Connector.

Conclusion

This concludes the lab exercise. Although the exercise was simple and you did not develop a collaboration business process, this introduction to the product and its tools will hopefully heighten your interest. It will also give you a basis for developing a real solution using this product.

Cleaning up your i5/OS system

To clean up your i5/OS system and your PC, follow these steps:

- 1. Exit the Virtual Test Connector window.
- 2. From the System Manager screen, select your JDBC adapter. Right-click it and select **Shutdown JDBC**. This will end your JDBC connection.
- 3. From the System Manager screen, select your InterChange Server, **WBI00**. Right-click it and select **shutdown gracefully**. This will end your InterChange Server.
- 4. Right-click your **User Project**, and select it to be deleted.
- 5. Right-click your integration component library and select it to be deleted.
- 6. Exit the System Manager screen.
- 7. Exit the console.
