# **z/OS® V1R9 Communications Server**

## ***zIIP assisted IPsec***

@business on demand.

© 2008 IBM Corporation  
Updated February 13, 2008

This presentation discusses the zIIP Assisted IPsec function in the z/OS V1R9 Communications Server.

## Background information

- IBM System z9<sup>®</sup> Integrated Information Processor (zIIP)
  - ▶ Specialty engine designed to free up general computing capacity and lower software costs for select workloads
- Communication Server's IPSec function becomes IBM's second exploiter of zIIP (first was DB2<sup>®</sup> V8)

The z9 Integrated Information Processor (zIIP) was announced in 1Q2006. At that time, IBM DB2 V8 was the only zIIP exploiter.

## Problem: IPSec - Heavy processor use

- Even with System z's specialized Crypto hardware, IPSec's data encryption/decryption and authentication processing can incur very heavy processor consumption on z/OS
- Users may have performance concerns about enabling IPSec on z/OS, due to potentially significant increase in processor consumption in handling IPSec protocol traffic

IPSec processor consumption for certain types of network traffic can be very intensive. For example, securing bulk data workloads (like FTP or TSM) with IPSec can be especially processor intensive, since IPSec processing cost is relative to the amount of data being moved. The extra cycles consumed by IPSec can be problematic if you are already running your z/OS LPARs at high utilization.

## Solution: Direct IPsec protocol traffic to zIIP

- A new 'ZIIP IPSECURITY' option has been added to the GLOBALCONFIG statement, enabling SRB-mode IPsec AH and ESP protocol traffic to be processed on zIIP.
  - ▶ **GLOBALCONFIG ZIIP IPSECURITY**
    - ✓ Directs all inbound IPsec AH|ESP protocol traffic to available zIIPs
      - IPv4 and IPv6 IPsec traffic supported on zIIP
    - ✓ Outbound IPsec AH|ESP protocol traffic will also be processed on zIIP in some cases
    - ✓ Useful for performance projection purposes even in a configuration with no zIIPs
    - ✓ Default is zIIP processors are NOT used for IPsec traffic (default is GLOBALCONFIG ZIIP NOIPSECURITY)
  - ▶ Will provide processor-busy relief on standard CPs for users already running IPsec on z/OS
  - ▶ Could result in lower software charges (since IBM imposes no software charges for zIIP capacity)
  - ▶ Should make z/OS IPsec deployment more attractive for users concerned about IPsec processor consumption

The zIIP IPSECURITY feature helps position IBM System z9 as a cost-effective server in environments requiring end-to-end security for IP network traffic. By directing IPsec's Authentication Header (AH) and Encapsulating Security Payload (ESP) protocol traffic to zIIP, your standard CPs will run less busy, and this can result in reduced software charges (since IBM imposes no software charges for zIIP capacity). If you have decided against IPsec deployment on z/OS (due to processor consumption issues), you may find the zIIP IPSECURITY feature now makes such deployment feasible.

Configuring GLOBALCONFIG ZIIP IPSECURITY causes *inbound* ESP and AH Protocol traffic to be processed in Enclave SRBs, and targeted to available zIIPs. *Outbound* ESP and AH protocol traffic may also be processed on available zIIPs when either the application invoking the send() function is already running on a zIIP, or when the data to be transmitted is in response to normal TCP flow control (for example, data transmitted in response to a received TCP acknowledgement or window update).

If you have no zIIPs, you can also use GLOBALCONFIG ZIIP IPSECURITY in conjunction with the MVS PROJECTCPU function, to obtain RMF projection data on the percentage of workload that is eligible to be run on zIIP.

The default setting is to leave IPsec processing on standard CPs, so if you do want to direct your IPsec processing to zIIP, you need to code GLOBALCONFIG ZIIP IPSECURITY.

## Diagnosis: Display zIIP configuration or usage

- Netstat STATS/onetstat -S shows inbound/outbound packets processed on a zIIP.
- Netstat Config/onetstat -f shows the setting of the GlobalConfig setting for zIIP IPSECURITY.
- MVS D M=CPU command shows zIIP online/offline status.
- IPCS Commands:
  - ▶ TCPIPCS IPSEC - shows whether zIIPs are handling IPSEC traffic
  - ▶ TCPIPCS PROFILE - shows whether GLOBALCONFIG zIIP IPSECURITY is set.

Various Netstat options are available for viewing zIIP IPSEC behavior and configuration. If in doubt about zIIP online|offline status, use the

MVS D M=CPU command. If viewing a dump and you are interested in zIIP IPSEC configuration, you can use the TCPIPCS IPSEC or TCPIPCS PROFILE commands.

## D M=CPU command example

**D M=CPU shows the zIIP online/offline status.**

```

D M=CPU
IEE174I 01.35.25 DISPLAY M 277
PROCESSOR STATUS
ID CPU SERIAL
00 + 029B8E2094
01 + 029B8E2094
02 +I 029B8E2094

CPC ND = 002094.838.IBM.02.000000029B8E
CPC SI = 2094.730.IBM.02.0000000000029B8E
CPC ID = 00
CPC NAME = RP569
LP NAME = RALNS42 LP ID = 2
CSS ID = 0
MIF ID = 2

+ ONLINE - OFFLINE . DOES NOT EXIST W WLM-MANAGED
N NOT AVAILABLE

I INTEGRATED INFORMATION PROCESSOR (zIIP)
CPC ND CENTRAL PROCESSING COMPLEX NODE DESCRIPTOR
CPC SI SYSTEM INFORMATION FROM STSI INSTRUCTION
CPC ID CENTRAL PROCESSING COMPLEX IDENTIFIER
CPC NAME CENTRAL PROCESSING COMPLEX NAME
LP NAME LOGICAL PARTITION NAME
LP ID LOGICAL PARTITION IDENTIFIER

```

Once you have a zIIP configured to your LPAR, you can use the MVS D M=CPU command to display zIIP Status. In this example, there are two standard CPs and one zIIP online. The zIIP is identified by the “I” character next to the Online|Offline status indicator.

## Performance: Planning for zIIP

- Projecting zIIP effectiveness
  - ▶ How much existing (or future) workload is eligible to move to zIIPs?
  - ▶ How many zIIPs are needed to handle existing (or future) IPsec workload?
  - ▶ With zIIPs, how much processor busy relief to expect on standard CPs?
- There are two general methods for projecting zIIP effectiveness:
  - ▶ If you are already running IPsec, projection is straightforward – use PROJECTCPU function in z/OS Workload Manager.
    - ✓ Code PROJECTCPU=YES in PARMLIB member IEAOPTxx
    - ✓ Code GLOBALCONFIG ZIIP IPSECURITY in TCP/IP Profile dataset
    - ✓ Run your IPsec workload; collect RMF™ Workload Activity Report for representative intervals
  - ▶ If you are not yet running IPsec, some traffic modeling may be necessary – IBM's Washington System Center will guide you through this.

If you are running IPsec, zIIP may significantly reduce the processor utilization of your standard CPs. In planning for zIIP, you need to determine (a) how much of your workload is eligible to move to zIIP, (b) how many zIIPs are required to fully handle that load, then (c) once you do have zIIPs, how much processor busy relief you can expect on your standard CPs.

If you are already running your representative IPsec workload, performing zIIP Projection analysis is pretty simple. Function exists within z/OS that will allow users already running IPsec (but not currently using zIIPs) to accurately project the amount of their existing workload that is eligible to move to the zIIPs. This function builds upon the PROJECTCPU service present in z/OS. PROJECTCPU gives a very precise accounting of workload that is zIIP-eligible. Using PROJECTCPU for zIIP capacity planning purposes is therefore very accurate and simple, since no extra analysis of network traffic is required.

If you are not yet running IPsec, some complex traffic modeling may be necessary to derive accurate estimates of zIIP effectiveness in your future IPsec configuration. System z sales personnel will engage the Washington System Center to perform this modeling, when necessary.

## PROJECTCPU example: RMF workload activity report – Bulk data with no zIIP configured

This configuration has no zIIPs online, and it shows using the PROJECTCPU function to gather projection data.

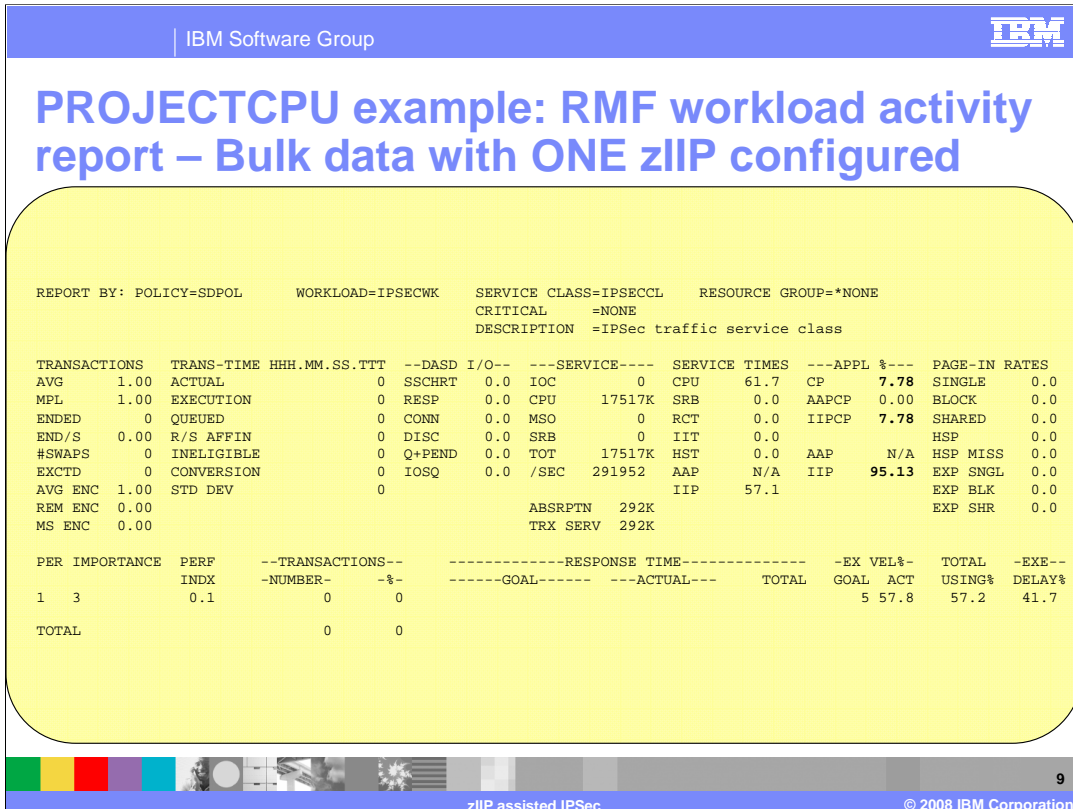

Note the Workload Activity Report for the IPSECCL service class, since IPsec traffic that can be processed on available zIIP processors will run in this WLM Service class. Interpretation of this workload activity report is as follows:

**IIP N/A** - since zIIP is not configured.

**IIPCP 105.17** - this is the percentage of processor time used by zIIP-eligible work (in the IPSECCL Service Class) running on standard CPs. This statistic is normalized to the capacity of a single standard CP, so the interpretation is: *This workload would fully saturate a single zIIP, with at least 5% spilling over to CPs.* Two zIIPs would be required to handle all of the zIIP eligible workload from the IPSECCL Service Class.

**CP 105.17** - The two CPs are each averaging  $105.17/2 = \sim 52.59\%$  busy handling this IP workload. Not shown here, the processor activity report indicates that each of the two standard CPs are averaging 56.88% busy (normalizing to the capacity of a single standard CP this becomes 113.76%). Therefore the percentage of processor time that was not zIIP eligible in this benchmark is  $113.76 - 105.17 = 8.59\%$ . If two zIIPs were added to this configuration,  $113.76/105.17 =$  approximately 92% of the processor consumption for this IP workload would move to zIIP, off of the standard CPs. This workload is especially well-suited to zIIP, due to the high degree of enclave SRB execution within CommServer for inbound bulk-data workload.

This configuration has one zIIP online, running the same workload as in the previous chart.

Interpretation of this workload activity report is as follows:

**IIP 95.13** - The zIIP is 95.13% busy handling this IP workload. The remaining 4.87% of single-zIIP capacity is uncaptured time (z/OS base functions such as interrupt handling, dispatching, etc).

**IIPCP 7.78** - In the earlier analysis (Workload Activity Report and processor activity report with NO zIIP), at least 5% of the zIIP-eligible workload spills over to standard CPs if a single zIIP is added to the configuration. In this case you are seeing 7.78% is spilling over. The portion greater than 5% is attributable to uncaptured time.

**CP 7.78** - In the earlier analysis (Workload Activity Report with NO zIIP), the IPSECCL Service Class accounted for 52.5% busy on each of the standard CPs. With the zIIP now configured, IPSECCL-related CP utilization (averaged on each CP) has dropped to  $7.78/2 = 3.89\%$  busy; a utilization reduction of over 48 percentage points on each of the standard CPs. The IPSECCL service class work remaining on the standard CPs here is work that "spilled over" from the single zIIP.

## Things to think about

- Whitepaper: *'Capacity Planning for zIIP Assisted IPsec'*
  - ▶ More in-depth discussion of this function
  - ▶ <http://www.ibm.com/support/docview.wss?rs=852&uid=swg27009459>
- Using GLOBALCONFIG ZIIP IPSECURITY for projection purposes before you have any zIIPs in your configuration:
  - ▶ Remove this option from your TCP/IP profile once you have finished collecting your projection data. (Running in this mode with no zIIPs online will result in slightly higher processor consumption.)
- RMF Analysis:
  - ▶ With the zIIP IPsec feature enabled, most IPsec processing moves to Enclave SRBs. This being the case, the RMF Monitor II Address Space Resource Data (ARD) report will not show processor consumption related to IPsec processing – use Workload Activity Report.

There is a whitepaper that covers zIIP IPsec projection modeling in depth, and presents some of the early zIIP IPsec performance data collected in IBM labs. It can be found on [ibm.com](http://ibm.com).

Specify GLOBALCONFIG ZIIP IPSECURITY only if (a) you already have zIIPs online to your LPAR or (b) you are running performance runs to obtain RMF data to project zIIP effectiveness.

## Things to think about (continued)

- Controlling “spillover” of work back to standard CPs
  - PARMLIB Member IEAOPTXX:  
IIPHONORPRIORITY statement
    - ▶ Controls whether zIIP eligible work is allowed to run on standard CPs
    - ▶ IIPHONORPRIORITY=YES is recommended and default value (zIIP eligible work is allowed to run on CPs if zIIP requests help)
    - ▶ IIPHONORPRIORITY=NO means z/OS will try to contain all zIIP-eligible workload on zIIPs; this can lead to throughput and response time degradation when zIIP is highly used

11

zIIP assisted IPsec

© 2008 IBM Corporation

Specifying IIPHONORPRIORITY=YES allows zIIP eligible workload to run on standard CPs, if zIIP work is not completed in a reasonable time period. This is the default and recommended value.

Specifying IIPHONORPRIORITY=NO disallows any zIIP eligible work from running on CPs (unless no zIIPs are online, or zIIP work is holding system locks or other resources impeding non zIIP work). When the NO value is set and zIIPs are present in the configuration, zIIP eligible work is contained on the zIIPs. During periods of very high zIIP utilization, throughput and response time may suffer. It may be reasonable to tradeoff throughput/response time in some environments, where minimizing utilization of the standard CPs is paramount

Performance is based on measurements and projections using standard IBM benchmarks in a controlled environment. All customer examples described are presented as illustrations of how those customers have used IBM products and the results they may have achieved. The actual throughput or performance that any user will experience will vary depending upon considerations such as the amount of multiprogramming in the user's job stream, the I/O configuration, the storage configuration, and the workload processed. Therefore, no assurance can be given that an individual user will achieve throughput or performance improvements equivalent to the ratios stated here.
