

This presentation will focus on Simulation Support in WebSphere Business Modeler V6.0.2.

The goals for this presentation are to provide an overview of the simulation capabilities and describe enhancements to simulation support in WebSphere Business Modeler V6.0.2

This section will provide an overview of simulation capabilities and available options.

WebSphere Business Modeler V6.0 provides some of the best simulation capabilities in the industry by taking a business process, resources that the process uses, costs, availability, and profit and executing them in a simulation format. With these capabilities you can do various types of analysis on information representative of your actual environment. You can also check if a process produces expected results based on the specified parameters.

There are three types of analysis available: Static, Dynamic and Simulation Profile.

The dynamic analyses are very tightly coupled to the simulations, that is to say the simulation is run to produce the data used by the dynamic analysis reports.

Each type of analysis is very important at different stages within the development process and at different points in the development life cycle.

Static analysis can be performed after a process has been defined and values such as cost, duration, and availability assigned. Static analysis allows you to see the breakdown of a task to roles or to other types of qualifiers that are defined on a particular element. With this analysis, you can have reports generated for the different information such as a list of role availability or total resource costs. These reports can be defined using Crystal Reports, which is new support for WebSphere Business Modeler V6.0 or you can also define your own report formats. Reports and results can be printed using these templates or Crystal Report formats.

The simulations and the input used for them are the basis of the dynamic analysis, therefore it is very important to understand what all the inputs are. The simulation profile specification analysis displays the simulation settings for each of the activities in a simulation profile as a report.

Once the simulation has been run and the data generated based on the simulation profile, additional information can be obtained by running the dynamic analysis reports and better insight into business process potential performance can also be obtained.

Simulation analysis results in a tabular format of results and only through dynamic analysis can you utilize these results and dive deeper into the performance of a business process and get more information from the results.

You can obtain information about how different factors affect different parts of business process, look at things such as multiple instances, shortest path, longest path, critical path and costs associated with them.

The simulation engine in WebSphere Business Modeler V6.0 is the same basic simulation engine used in WebSphere Business Integration Modeler V5.1 and has the same simulation features.

The weighted average analysis feature provides a static and long term view of the process, whereas the process simulation captures the shorter-term view.

WebSphere Business Modeler has the ability to model different scenarios and compare results and replay a simulation of a process with some changes to the model.

It provides the capability to specify different resources, resource allocations, processing time, costs and revenue and allows you to define multiple resources.

Simulation output provides detailed information regarding resource utilization levels, cost and cycle time calculations and supports multiple possible input distributions, which are based on a calendar date for varying data.

This section will provide an overview of simulation enhancements in WebSphere Business Modeler V6.0.

Simulation and analysis

With each release of WebSphere Business Modeler new features are added and some existing ones are refined.

Listed here are new and improved features in the area of Simulation and Dynamic Analysis. This this the bird's eye view. Notice that the focus is on performance, ease of use and accuracy.

The remainder of the presentation will discuss each of these in detail.

	IB	M Software Group
١	Nait for	resource to complete
	Existing V6.0.1	The task completes before all the allocated resources have been applied to the task.
	New V6.0.2	All of the allocated resources can now be applied to the task before the task completes.
	Benefits	A more accurate and realistic simulation of a resource based schedule.
		0 10 10 10 10 10 10 10 10 10 10 10 10 10

Here you can see what was missing in version V6.0.1 and the benefits of the new feature.

In V6.0.1 there were cases where a certain resource or set of resources were assigned to a task and the task would complete before all the associated resources had a chance to complete their work.

This has been addressed in V6.0.2, resulting in a more accurate and realistic simulation of a resourced based schedule.

Before getting started lets define some basic definitions. Each of these play an important role in determining when the task is actually completed.

The working duration is the time the task spends doing the real work

The resource duration is a little trickier because there may be more that one resource assigned to do the task. Another way to state this definition, in a more general way, is to say, "The resource duration is the sum of all the resources assigned to do the task".

The elapsed duration is the over all time that it takes to compete the task. Lets take a closer look.

This is what it looks like with WebSphere Business Modeler V6.0.1.

This is the single resource scenario, that is to say there is only one resource assigned to the task.

You can see that the elapsed duration is the working duration with a little delay added to it and the resource duration is not considered.

Shown here is a scenario that uses multiple resources. It is basically the same except now the resource duration is the sum of the availability of the resources.

Looking at the resources more carefully, notice that ...

Resource A is available in 15 minute chunks.

Resource B is available in 40 minute chunks.

Resource A puts in a total 30 minutes.

Resource B puts in in about 50 to 60 minutes.

From the resource perspective...

Only 1 ¹/₂ hour is actually used on a task that really takes 2 hours of resource.

This is not the behavior one would expect.

Here is a case with a single resource showing how it will behave in WebSphere Business Modeler V6.0.2

Notice that the total elapsed time and working duration have been stretched out to eable the resource to utilize all the time it has been allocated.

Shown here is the multiple resource scenario as it behaves in WebSphere Business Modeler V6.0.2.

Resource A is available in 15 minute chunks, for a total of 1 hour.

Resource B is available in 40 minute chunks, for a total of 1 hour.

The total resource time is 2 hours, which it the time it takes to do the task.

Again the elapsed time and the working duration have been extended to allow the all the assigned resources to use their allocated time slots.

Now that you know what this new feature is about, where do you configure it so that it will be used in your simulations.

Like many of the new features we'll be discussing, it's controlled in the preferences. In this case it is the General preferences under Simulation.

	3M Software Group
Static p	ath validation for implicit termination
Existing	Business Processes without explicit stop nodes would cause the simulator to run to the end date without completing the simulation
V6.0.1	Before running a simulation a manual inspection of all the business processes must be made in order to locate any business processes that don't have a stop node.
New V6.0.2	Using the new Simulation <u>Preference</u> setting a warning dialog is presented, with an option to check for <i>implicit terminations</i> , which presents a list of the places that need to be terminated.
Benefits	Time is saved in identifying the implicit terminations and time is saved by not running simulations that will never terminate.

For a simulation to run properly it needs to know when to stop. With V6.0.1 the business analyst has to go thorough all the processes and sub-processes to ensure that they are properly terminated. If one is missed then the simulation will run until all the machine resources are exhausted.

With V6.0.2, this check can now be done automatically just before running the simulation.

				© 2007 IBN	18 A Corporation

To set this option, go to the General Preferences again.

The "Show Check Paths Confirmation" dialog is circled in red. This is set to yes by default.

If this option is set to yes, then when a simulation is run you'll be prompted with the "Check That all Paths Stop" dialog.

IBM Software Group	IBM
Static path validation: Results	
Check That All Paths Stop Paths without stop nodes will not simulate correctly. Do you want to check for paths without stop nodes before creating simulation snapshot? Always show this dialogue Yes No	ting a Cancel
Or T	The results can be saved to a text file.
Check That All Paths Stop	following processes have paths without stop nodes and will not simulate correctly: Order Handling (Future 1)
	<u>or</u> <u>Cancel</u> 19

If you select yes you'll either get a confirmation that all the paths are terminated properly or you'll get a list of the processes that need to have the stop nodes added to them.

It will still be up to the business analyst to manually include the stop nodes where necessary. The benefit is that time won't be wasted on an incomplete simulation and the places where the stop nodes need to be added are listed so the time to make the changes will be dramatically reduced.

Saving the results to a text file will make it easier to make the corrections in a large model that has many places to correct.

There are certain cases where the static path validation cannot be made. In that case you may see this dialog.

The exception cases are described in the WebSphere Business Modeler Infocenter and help. They are listed on the next slide for your convenience.

To find this information in the on-line help look of the topic, "Static process case summary analysis".

Read this carefully and be familiar with it before running your simulations.

IB	M Software Group	IBM
Snapsho	ot generation	
Existing V6.0.1	When creating a simulation snapshot, all top lever processes, referenced or not, are copied to snapshot, resulting in a large footprint.	/el
New V6.0.2	When creating a simulation snapshot, only the referenced processes, directly or indirectly, will copied into the simulation snapshot.	be
Benefits	A much smaller footprint.	
	© © 2007 IE	22 M Corporation

With V6.0.1 when a simulation snapshot is created all of the top level processes, whether they were referenced or not, are copied to the snapshot. For very large models where there are many snapshots, this creates an atypically large memory footprint.

In V6.0.2 when a simulation snapshot is created, only the processes that are referenced, either directly or indirectly are copied.

It should be noted that there are no preferences or options related to this improvement.

	IB	M Software Group	M
١	Norking	J duration	
	Existing V6.0.1	There is no Working Duration reported in the Dynamic Analyses.	
	New V6.0.2	A new attribute for the Working Duration has been added to the Dynamic Analyses.	
	Benefits	A more accurate and meaningful report of the simulation.	
		© © 2007 IBM Corpo	23 ration

Moving on to the Dynamic Analysis,

The dynamic analysis reports now include the working duration in the output of certain Dynamic Analysis cases.

This provides the analyst with more meaningful reports as a result of the simulation.

These are the Dynamic Analysis cases that have the new working duration field added to them.

This is an example of "Process Instance Time" analysis with the new field added.

IB	M Software Group	
Aggrega	ating cost and duration	
Existing V6.0.1	The cost and durations are not aggregated to the upper levels of the analyses.	
New V6.0.2	The cost and durations are now aggregated to all levels that are appropriate for the analyses.	
Benefits	A more accurate analysis of the simulation which shows the total cost and durations for the sub-processes. This eliminates the need to manually aggregate the data. Saves time and reduces errors.	
	2 © 2007 IBM Corporati	!5 ion

The cost and duration attributes are key attributes for understanding a business process. With V6.0.2 these attributes are now aggregated to all levels that are appropriate to the analysis.

By aggregating this information automatically, the analyst no longer has to manually aggregate them, saving time and reducing errors.

Shown here is an example of a report where there is a call to a sub-process to do some blood work. In the course doing the blood work there are several tasks which have a cost associated with them, such as, "take the sample", "examine the blood" and "record the results".

It is good to know the cost of each task but it is also good to know the total cost.

The blue arrow on the slide points to the total of \$15.57, which is the aggregation of the three sub-tasks.

| IBM Software Group

Selectable columns

Existing V6.0.1	The dynamic analyses generate reports with all the possible columns. There are no options to tailor the reports by the end user.
New V6.0.2	By enabling the <i>column selection dialog</i> in the Dynamic and Profile Analysis preferences, the user can <u>hide the columns</u> that are not part of their area of interest.
Benefits	More concise analysis and profile reports, tailored to the goals of the end user. This feature saves time in reading and understanding the output from a simulation analysis.
	2 © 2007 IBM Corporati

When getting a report there are many attributes (columns) that are reported. It is good to have all the information but quite often the business analyst is only interested in a small sub-set. Finding the information of interest can often be very tedious.

With V6.0.2, for certain case summaries, the analyst has the option to apply a filter to the columns and thus narrow the focus to the area of interest.

Install/Update					

First note that this option only applies to the Process Cases Summary, Static Process Cases Summary and Process Instances Summary.

This option can be set as the global default from the Dynamic and Profile Analysis preferences and can be overridden for each individual report after the analysis has been run.

If the option is set in the Dynamic and Profile Analysis preferences, then the column selection dialog will be presented when the analyst chooses to run one of the reports that support this feature. Those reports are the Process Cases Summary, Static Process Cases Summary and Process Instances Summary.

After the analysis has been run, the business analyst can change the columns by selecting the report and using the context menu (right-mouse-click) and selecting the option to change the columns. The column selection dialog will be displayed.

	IB	M Software Group
E	Export	
	Existing V6.0.1	Dynamic analysis and profile reports can be exported in delimited text format, only.
	New V6.0.2	Two new options are available for exporting dynamic analysis and profile reports. XML Offset Delimited Text
	Benefits	The XML option provides the data in a standard format that can be easily consumed by many different applications. The Offset Delimited Text option provides a way to clearly and accurately export the data when there are column names that are overloaded due to nested processes.
		30 © 2007 IBM Corporation

With WebSphere Business Modeler V6.0.2 the export options for the dynamic analysis reports have been expanded to include XML and offset delimited text.

The XML format is desirable because there are many external tools that can consume XML data. This allows for the incorporation of the data into other reporting tools.

The offset delimited text option solves a problem that occurs with delimited text output when there are different columns that have the same name. An example of this will be shown in the next few slides.

The export options are available from the context menu (right-mouse-click) of the report.

Note that the export to Offset Delimited Text is only supported for the certain case reports as listed in this slide.

Also notice the menu option for selecting the columns is also enabled for this report.

Exporting ALL to XML will give you the familiar XML format as shown here.

The report shown here is a report of a process that has a sub-process in it.

As a result, there are some columns that have the same name, as shown. There are the columns which are from the atomic tasks, the tasks inside the sub-process, and then there are the columns that belong to the next level up, the columns for the containing sub-process.

If the columns weren't offset the way they are then the information from the 2 different levels would be collapsed into one column, providing an incorrect and misleading representation of the analysis.

This picture shows the actual report before it was exported. There is information for three items, T1, Sub1 and T2.

As shown by the second snippet, the Average Process Duration for the overall process is 3 hours.

This is because the value for Sub1 includes T2.

With the offset delimited text option, the columns with the same name are separated, that is they are offset, from the others with like name.

If the columns weren't separated then the total "average elapsed time duration" would be reported as 5 instead of 3 hours.

Before the introduction of the offset delimited text option, this would have been reported incorrectly as 5 hours when exporting to delimited text. Now with the offset delimited text option, the container is separated from the items it contains by offsetting the columns as shown.

	© 2007 IE	36 3M Corporation

For a very large and complex business model, the static analysis has the potential to run for a very long time and eventually consume all the available resources on the machine.

With V6.0.1 the static analysis and the dynamic analysis are linked together. Whenever a dynamic analysis is run the static cases are also run. In the case of a very large and complex model there may be a situation where the dynamic analysis information cannot be obtained.

This issue is addressed in V6.0.2 with a slight change in the behavior of an existing Dynamic and Profile Analysis preference. A new entry field for entering a limit to the number of static cases that will be generated.

The existing preference is called, "match process case names between Static and Dynamic analysis".

If this preference is unchecked then only the dynamic cases will be generated. It indicates that the analyst is not interested at all in the static cases.

If there is a need or interest in the static cases and the model is large and complex, then this preference should be enabled. The total number of static cases generated can be limited by the value specified in the entry field below, called, "maximum number of paths to analyze for selected process.

This discussion began with a brief overview of the simulation capabilities of WebSphere Business Modeler and illustrating its importance in the development of service oriented architectures.

The distinction between the static analysis and the dynamic analysis was made.

New and improved features were discussed.

The new features and improvements are in the areas of performance, usability and accuracy.

That is to say a smaller footprint for the snapshots, assistance in identifying un-terminated processes, setting limits on the number of static analysis cases generated, to mention a few.

For learning more about how to run a simulation see the demonstration associated with this topic.
