At that point, the identifier will be checked for authorization using the configuration of that receiving queue manager – which can be LDAP or OS-based.

Output parameters to MQI calls

Wherever a user ID is provided to a program in an MQI structure, it is the 12-character short name version associated with the connection.

For example, the **MQAXC.UserId** value for API Exits is the short name returned from the LDAP mapping.

Other administrative MQSC and PCF commands

Commands that show user information in object status such as DISPLAY CONN USERID return the 12-character short name associated with the context. The full DN is not shown.

Commands that allow assertion of identities, such as the CHLAUTH mapping rules or MCAUSER values for channels, can take values up to the maximum length defined for those attributes (currently 64 characters).

There is no change to the syntax. When authorization is required for that identity, it is internally mapped to a DN using the same rules as for the **setmqaut**, **dmpmqaut**, and **dspmqaut** commands.

This means that the MCAUSER value on a channel definition might not display as the same string as DISPLAY CHSTATUS but they do refer to the same identity.

For example:

```
DEFINE CHL(SV1) CHLTYPE(SVRCONN) MCAUSER('cn=JohnDoe')
DEFINE CHL(SV2) CHLTYPE(SVRCONN) MCAUSER('jodoe')
DEFINE CHL(SV3) CHLTYPE(SVRCONN) MCAUSER('JohnDoe1@yourcompany.com')
```

Then DISPLAY CHSTATUS(*) ALL shows the SHORTUSR value, *MCAUSER(jodoe)* for all connections.

Switching between OS and LDAP authorization models

V 8.0.0.2 V 8.0.0.2

How you switch between the different authorization methods on different platforms.

The CONNAUTH attribute of the queue manager points at an AUTHINFO object. When the object is of type IDPWLDAP, an LDAP repository is used for authentication.

You can now apply an authorization method to that same object, which allows you to continue with OS-based authorization, or to work with LDAP authorization

UNIX platforms and IBM i

The queue manager can be switched at any time between OS and LDAP models. You can change the configuration and make that configuration active by using the REFRESH SECURITY TYPE (CONNAUTH) command.

For example, if this object has already been configured with the connection information for authentication:

```
ALTER AUTHINFO(MYLDAP) AUTHTYPE(IDPWLDAP) +
        AUTHORMD(SEARCHGRP) +
        BASEDNG('ou=groups,o=ibm,c=uk') +
        ⌂other attributes>
ALTER QMGR CONNAUTH(MYLDAP)
REFRESH SECURITY
```

Processing rules

When switching from OS to LDAP authorization, any existing OS authority rules that have been set, become inactive and invisible.

Commands such as **dmpmqaut** do not display those OS rules. Similarly, when switching back from LDAP to OS, any defined LDAP authorizations become inactive and invisible, restoring the original OS rules.

If you want to back up the definitions of a queue manager for any reason, using the **dmpmqcfg** command, then that backup will contain only the rules that are defined for the authorization method in effect at the time of the back up.

LDAP administration

V 8.0.0.2 V 8.0.0.2

An overview of how each platform administers LDAP.

When using LDAP authorization, membership of the `mqm` group (or equivalent) in the operating system is not that important. Being a member of that group only controls whether certain command-line commands can be processed.

In particular, you must be in that group to issue the strmqm and endmqm commands.

Once the queue manager is running, there are now limits on the fully-privileged account. Apart from the user ID of the person who issues the **`strmqm`** command, other users belonging to the OS `mqm` (or equivalent) group do not get special privileges.

Authorizations of other users are based on which LDAP groups they belong to. An unqualified use of the `mqm` group name in commands such as **`setmqaut`** is not allowed to map to any LDAP group.

UNIX platforms

Once the queue manager is running, the only automatically fully-privileged account is the real user who started the queue manager.

The `mqm` ID still exists and is used as the owner of OS resources, such as files, because `mqm` is the effective ID under which the queue manager is running. However, the `mqm` user will not automatically be able to do administrative tasks controlled by the OAM.

IBM i

On IBM i, the automatically-privileged accounts are the one that starts the queue manager and the QMQM ID.

You need both IDs, because the user ID that starts the queue manager is required only to start the system. Once running, the queue manager processes have QMQM authority only.

Sample script

As it is useful to have a group able to do full administration on a queue manager, a sample script is shipped on UNIX platforms as:

```
<install dir>/samp/bin/amqauthg.sh
```

This sample takes two parameters:
- A queue manager name
- An LDAP group name

The sample processes setmqaut commands, granting full authority for all objects. This is the same script that is generated by theMQ Explorer OAM Wizard for administrative roles. For example, the code starts:

```
setmqaut -t q -m <qmgr> -n "**" +alladm +allmqi -g
      <groupname>
```

Confidentiality of messages

To maintain confidentiality, encrypt your messages. There are various methods of encrypting messages in IBM MQ depending on your needs.

Your choice of CipherSpec determines what level of confidentiality you have.

If you need application-level, end-to-end data protection for your point to point messaging infrastructure, you can use IBM MQ Advanced Message Security to encrypt the messages, or write your own API exit or API-crossing exit.

If you need to encrypt messages only while they are being transported through a channel, because you have adequate security on your queue managers, you can use SSL or TLS, or you can write your own security exit, message exit, or send and receive exit programs.

For more information about IBM MQ Advanced Message Security, see “IBM MQ Advanced Message Security” on page 475. The use of SSL and TLS with IBM MQ is described at “SSL and TLS security protocols in IBM MQ” on page 397. The use of exit programs in message encryption is described at “Implementing confidentiality in user exit programs” on page 806.

Connecting a client to a queue manager securely

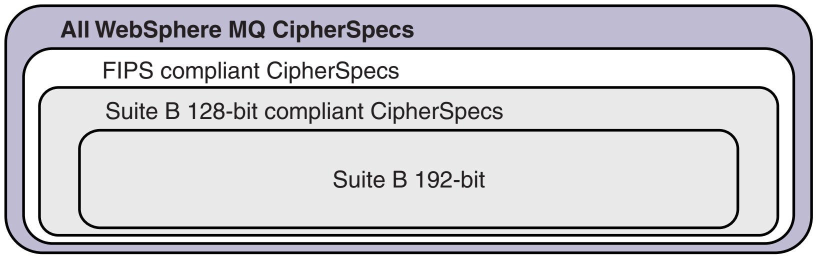
Enabling CipherSpecs

Enable a CipherSpec by using the **SSLCIPH** parameter in either the **DEFINE CHANNEL** MQSC command or the **ALTER CHANNEL** MQSC command.

Some of the CipherSpecs that you can use with IBM MQ are FIPS compliant. Some of the FIPS compliant CipherSpecs are also Suite B compliant although others, such as `TLS_RSA_WITH_3DES_EDE_CBC_SHA` (deprecated), are not.

All Suite B compliant CipherSpecs are also FIPS compliant. All Suite B compliant CipherSpecs fall into two groups: 128 bit (for example, `ECDHE_ECDSA_AES_128_GCM_SHA256`) and 192 bit (for example, `ECDHE_ECDSA_AES_256_GCM_SHA384`),

The following diagram illustrates the relationship between these subsets:



All WebSphere MQ CipherSpecs
FIPS compliant CipherSpecs
Suite B 128-bit compliant CipherSpecs
Suite B 192-bit

V 8.0.0.3 From IBM MQ Version 8.0.0, Fix Pack 3 the number of supported CipherSpecs has been reduced. See “CipherSpec values supported in IBM MQ” on page 413 for more information on the list of supported CipherSpecs and how you can enable deprecated CipherSpecs.

See “Deprecated CipherSpecs” on page 800 for a list of CipherSpecs that you must re-enable to use with IBM MQ.

Cipher specifications that you can use with the IBM MQ queue manager automatically are listed in the following table. When you request a personal certificate, you specify a key size for the public and private key pair. The key size that is used during the SSL handshake is the size stored in the certificate unless it is determined by the CipherSpec, as noted in the table.

Platform support[1]	**CipherSpec name**	**Protocol used**	**Data integrity**	**Encryption algorithm**	**Encryption bits**	**FIPS**[2]	**Suite B**
Linux Windows UNIX z/OS	`TLS_RSA_WITH_AES_128_CBC_SHA`	TLS 1.0	SHA-1	AES	128	Yes	No
Linux Windows UNIX z/OS	`TLS_RSA_WITH_AES_256_CBC_SHA`[3]	TLS 1.0	SHA-1	AES	256	Yes	No
All	`ECDHE_ECDSA_AES_128_CBC_SHA256`	TLS 1.2	SHA-256	AES	128	Yes	No
All	`ECDHE_ECDSA_AES_256_CBC_SHA384` 3 on page 799	TLS 1.2	SHA-384	AES	256	Yes	No
distributed	`ECDHE_ECDSA_AES_128_GCM_SHA256` [4]	TLS 1.2	AEAD AES-128 GCM	AES	128	Yes	128 bit
distributed	`ECDHE_ECDSA_AES_256_GCM_SHA384` [3] [4]	TLS 1.2	AEAD AES-128 GCM	AES	256	Yes	192 bit
All	`ECDHE_RSA_AES_128_CBC_SHA256`	TLS 1.2	SHA-256	AES	128	Yes	No

distributed	TLS_RSA_WITH_AES_128_GCM_SHA256 [4]	TLS 1.2	AEAD AES-128 GCM	AES	128	Yes	No
distributed	TLS_RSA_WITH_AES_256_GCM_SHA3843 [4]	TLS 1.2	AEAD AES-128 GCM	AES	256	Yes	No

Notes:

1. If no specific platform is noted, the CipherSpec is available on all platforms.
2. Specifies whether the CipherSpec is FIPS-certified on a FIPS-certified platform. See Federal Information Processing Standards (FIPS) for an explanation of FIPS.
3. This CipherSpec cannot be used to secure a connection from the MQ Explorer to a queue manager unless the appropriate unrestricted policy files are applied to the JRE used by the Explorer.
4. Following a recommendation by NIST, GCM CipherSpecs now have a restriction which means that after 2⌂22 TLS records are sent, using the same session key, the connection will be terminated with message AMQ9288.

   To prevent this error from happening: avoid using GCM Ciphers, enable secret key reset, or start your IBM MQ queue manager with the environment variable GSK_ENFORCE_GCM_RESTRICTION=GSK_FALSE set.
   Important: The GCM restriction is active, regardless of the FIPS mode being used.
5. The CipherSpecs listed as supported on IBM i apply to Versions 7.2 and 7.3 of IBM i.

Linux Windows UNIX	ECDHE_RSA_3DES_EDE_CBC_SHA256[9]	TLS 1.2	SHA-1	3DES	168	Yes	No	8.0.0.6

Platform support[1]	CipherSpec name	Protocol used	Data integrity	Encryption algorithm	Encryption bits	FIPS[2]	Suite B	Update when deprecated

Notes:

1. If no specific platform is noted, the CipherSpec is available on all platforms.
2. Specifies whether the CipherSpec is FIPS-certified on a FIPS-certified platform. See Federal Information Processing Standards (FIPS) for an explanation of FIPS.
3. The maximum handshake key size is 512 bits. If either of the certificates exchanged during the SSL handshake has a key size greater than 512 bits, a temporary 512-bit key is generated for use during the handshake.
4. The handshake key size is 1024 bits.
5. This CipherSpec was FIPS 140-2 certified before 19 May 2007.
6. This CipherSpec was FIPS 140-2 certified before 19 May 2007. The name `FIPS_WITH_DES_CBC_SHA` is historical and reflects the fact that this CipherSpec was previously (but is no longer) FIPS-compliant. This CipherSpec is deprecated and its use is not recommended.
7. The name `FIPS_WITH_3DES_EDE_CBC_SHA` is historical and reflects the fact that this CipherSpec was previously (but is no longer) FIPS-compliant. The use of this CipherSpec is deprecated.
8. These CipherSpecs are no longer supported by IBM MQ classes for Java or IBM MQ classes for JMS. For more information, see SSL/TLS CipherSpecs and CipherSuites in IBM MQ classes for Java or SSL/TLS CipherSpecs and CipherSuites in IBM MQ classes for JMS.
9. This CipherSpec can be used to transfer up to 32 GB of data before the connection is terminated with error AMQ9288. To avoid this error, either avoid using triple DES, or enable secret key reset when using this CipherSpec.

DEFINE CHANNEL

ALTER CHANNEL

Obtaining information about CipherSpecs using IBM MQ Explorer

You can use IBM MQ Explorer to display descriptions of CipherSpecs.

Use the following procedure to obtain information about the CipherSpecs in "Enabling CipherSpecs" on page 797:

1. Open **IBM MQ Explorer** and expand the **Queue Managers** folder.
2. Ensure that you have started your queue manager.
3. Select the queue manager you want to work with and click **Channels**.
4. Right-click the channel you want to work with and select **Properties**.
5. Select the **SSL** property page.
6. Select from the list the CipherSpec you want to work with. A description is displayed in the window below the list.

Alternatives for specifying CipherSpecs

For those platforms where the operating system provides the SSL support, your system might support new CipherSpecs. You can specify a new CipherSpec with the SSLCIPH parameter, but the value you supply depends on your platform.

Note: This section does not apply to UNIX, Linux or Windows systems, because the CipherSpecs are provided with the IBM MQ product, so new CipherSpecs do not become available after shipment.

For those platforms where the operating system provides the SSL support, your system might support new CipherSpecs that are not included in "Enabling CipherSpecs" on page 797. You can specify a new CipherSpec with the SSLCIPH parameter, but the value you supply depends on your platform. In all cases the specification *must* correspond to an SSL CipherSpec that is both valid and supported by the version of SSL your system is running.

IBM i

A two-character string representing a hexadecimal value.

For more information about the permitted values, refer to the appropriate product documentation (search on *cipher_spec*):

- For V5R3, the iSeries product documentation
- For V5R4, the IBM i product documentation

You can use either the CHGMQMCHL or the CRTMQMCHL command to specify the value, for example:

```
CRTMQMCHL CHLNAME(' channel name ') SSLCIPH(' hexadecimal value ')
```

You can also use the ALTER QMGR MQSC command to set the `SSLCIPH` parameter.

z/OS

A four-character string representing a hexadecimal value. The hexadecimal codes correspond to the values defined in the SSL protocol.

For more information, refer to the Cipher suite definitions in the z/OS Cryptographic Services System SSL Programming, where there is a list of all the supported SSL V3.0, TLS V1.0 and TLS V1.2 cipher specifications in the form of 4-digit hexadecimal codes.

Considerations for IBM MQ clusters

With IBM MQ clusters it is safest to use the CipherSpec names in "Enabling CipherSpecs" on page 797. If you use an alternative specification, be aware that the specification might not be valid on other platforms. For more information, refer to "SSL and clusters" on page 817.

Specifying a CipherSpec for an IBM MQ MQI client

You have three options for specifying a CipherSpec for an IBM MQ MQI client.

These options are as follows:

- Using a channel definition table
- Using the SSL configuration options structure, MQSCO, on an MQCONNX call
- Using the Active Directory (on Windows systems with Active Directory support)

Specifying a CipherSuite with IBM MQ classes for Java and IBM MQ classes for JMS

IBM MQ classes for Java and IBM MQ classes for JMS specify CipherSuites differently from other platforms.

For information about specifying a CipherSuite with IBM MQ classes for Java, see Secure Sockets Layer (SSL) support for Java

For information about specifying a CipherSuite with IBM MQ classes for JMS, see Using Secure Sockets Layer (SSL) with IBM MQ classes for JMS

Specifying a CipherSpec for IBM MQ.NET

For IBM MQ.NET you can specify the CipherSpec either by using the MQEnvironment class or by using the MQC.SSL_CIPHER_SPEC_PROPERTY in the hash table of connection properties.

For information about specifying a CipherSpec for the .NET unmanaged client, see Enabling SSL for the unmanaged .NET client

For information about specifying a CipherSpec for the .NET managed client, see CipherSpec support for the managed .NET client

Resetting SSL and TLS secret keys

IBM MQ supports the resetting of secret keys on queue managers and clients.

Secret keys are reset when a specified number of encrypted bytes of data have flowed across the channel, or after the channel has been idle for a period.

The key reset value is always set by the initiating side of the IBM MQ channel.

Queue manager

For a queue manager, use the command **ALTER QMGR** with the parameter **SSLRKEYC** to set the values used during key renegotiation.

IBM i On IBM i, use **CHGMQM** with the **SSLRSTCNT** parameter.

MQI client

By default, MQI clients do not renegotiate the secret key. You can make an MQI client renegotiate the key in any of three ways. In the following list, the methods are shown in order of priority. If you specify multiple values, the highest priority value is used.

1. By using the KeyResetCount field in the MQSCO structure on an MQCONNX call
2. By using the environment variable MQSSLRESET
3. By setting the SSLKeyResetCount attribute in the MQI client configuration file

These variables can be set to an integer in the range 0 through 999 999 999, representing the number of unencrypted bytes sent and received within an SSL or TLS conversation before the SSL or TLS secret key is renegotiated. Specifying a value of 0 indicates that SSL or TLS secret keys are never renegotiated. If you specify an SSL or TLS secret key reset count in the range 1 byte through 32 KB, SSL or TLS channels will use a secret key reset count of 32 KB. This is to avoid excessive key resets which would occur for small SSL or TLS secret key reset values.

If a value greater than zero is specified and channel heartbeats are enabled for the channel, the secret key is also renegotiated before message data is sent or received following a channel heartbeat.

The count of bytes until the next secret key renegotiation is reset after each successful renegotiation.

For full details of the MQSCO structure, see KeyResetCount (MQLONG). For full details of MQSSLRESET, see MQSSLRESET. For more information about the use of SSL or TLS in the client configuration file, see SSL stanza of the client configuration file.

Java

For IBM MQ classes for Java, an application can reset the secret key in either of the following ways:
- By setting the sslResetCount field in the MQEnvironment class.
- By setting the environment property MQC.SSL_RESET_COUNT_PROPERTY in a Hashtable object. The application then assigns the hashtable to the `properties` field in the MQEnvironment class, or passes the hashtable to an MQQueueManager object on its constructor.

If the application uses more than one of these ways, the usual precedence rules apply. See Class com.ibm.mq.MQEnvironment for the precedence rules.

The value of the sslResetCount field or environment property MQC.SSL_RESET_COUNT_PROPERTY represents the total number of bytes sent and received by the IBM MQ classes for Java client code before the secret key is renegotiated. The number of bytes sent is the number before encryption, and the number of bytes received is the number after decryption. The number of bytes also includes control information sent and received by the IBM MQ classes for Java client.

If the reset count is zero, which is the default value, the secret key is never renegotiated. The reset count is ignored if no CipherSuite is specified.

JMS

For IBM MQ classes for JMS, the SSLRESETCOUNT property represents the total number of bytes sent and received by a connection before the secret key that is used for encryption is renegotiated. The number of bytes sent is the number before encryption, and the number of bytes received is the number after decryption. The number of bytes also includes control information sent and received by IBM MQ classes for JMS. For example, to configure a ConnectionFactory object that can be used to create a connection over an SSL or TLS enabled MQI channel with a secret key that is renegotiated after 4 MB of data have flowed, issue the following command to JMSAdmin:

```
ALTER CF(my.cf) SSLRESETCOUNT(4194304)
```

If the value of SSLRESETCOUNT is zero, which is the default value, the secret key is never renegotiated. The SSLRESETCOUNT property is ignored if SSLCIPHERSUITE is not set.

.NET

For .NET unmanaged clients, the integer property SSLKeyResetCount indicates the number of unencrypted bytes sent and received within an SSL or TLS conversation before the secret key is renegotiated.

For information about the use of object properties in IBM MQ classes for .NET, see Getting and setting attribute values.

For .NET managed clients, the SSLStream class does not support secret key reset/renegotiation. However, to be consistent with other IBM MQ clients, the IBM MQ managed .NET client allows applications to set SSLKeyResetCount. For more information, see Secret key reset or renegotiation.

XMS .NET

For XMS .NET unmanaged clients, see Secure connections to an IBM WebSphere MQ queue manager.

Implementing confidentiality in user exit programs

Implementing confidentiality in security exits

Security exits can play a role in the confidentiality service by generating and distributing the symmetric key for encrypting and decrypting the data that flows on the channel. A common technique for doing this uses PKI technology.

One security exit generates a random data value, encrypts it with the public key of the queue manager or user that the partner security exit is representing, and sends the encrypted data to its partner in a security message. The partner security exit decrypts the random data value with the private key of the queue manager or user it is representing. Each security exit can now use the random data value to derive the symmetric key independently of the other by using an algorithm known to both of them. Alternatively, they can use the random data value as the key.

If the first security exit has not authenticated its partner by this time, the next security message sent by the partner can contain an expected value encrypted with the symmetric key. The first security exit can now authenticate its partner by checking that the partner security exit was able to encrypt the expected value correctly.

The security exits can also use this opportunity to agree the algorithm for encrypting and decrypting the data that flows on the channel, if more than one algorithm is available for use.

Implementing confidentiality in message exits

A message exit at the sending end of a channel can encrypt the application data in a message and another message exit at the receiving end of the channel can decrypt the data. For performance reasons, a symmetric key algorithm is normally used for this purpose. For more information about how the symmetric key can be generated and distributed, see "Implementing confidentiality in user exit programs."

Headers in a message, such as the transmission queue header, MQXQH, which includes the embedded message descriptor, must not be encrypted by a message exit. This is because data conversion of the message headers takes place either after a message exit is called at the sending end or before a message exit is called at the receiving end. If the headers are encrypted, data conversion fails and the channel stops.

Implementing confidentiality in send and receive exits

Send and receive exits can be used to encrypt and decrypt the data that flows on a channel. They are more appropriate than message exits for providing this service for the following reasons:

- On a message channel, message headers can be encrypted as well as the application data in the messages.

- Send and receive exits can be used on MQI channels as well as message channels. Parameters on MQI calls might contain sensitive application data that needs to be protected while it flows on an MQI channel. You can therefore use the same send and receive exits on both kinds of channels.

Implementing confidentiality in the API exit and API-crossing exit

The application data in a message can be encrypted by an API or API-crossing exit when the message is put by the sending application and decrypted by a second exit when the message is retrieved by the receiving application. For performance reasons, a symmetric key algorithm is typically used for this purpose. However, at the application level, where many users might be sending messages to each other, the problem is how to ensure that only the intended receiver of a message is able to decrypt the message. One solution is to use a different symmetric key for each pair of users that send messages to each other. But this solution might be difficult and time consuming to administer, particularly if the users belong to different organizations. A standard way of solving this problem is known as *digital enveloping* and uses PKI technology.

When an application puts a message on a queue, an API or API-crossing exit generates a random symmetric key and uses the key to encrypt the application data in the message. The exit encrypts the symmetric key with the public key of the intended receiver. It then replaces the application data in the message with the encrypted application data and the encrypted symmetric key. In this way, only the intended receiver can decrypt the symmetric key and therefore the application data. If an encrypted message has more than one possible intended receiver, the exit can encrypt a copy of the symmetric key for each intended receiver.

If different algorithms for encrypting and decrypting the application data are available for use, the exit can include the name of the algorithm it has used.

Data integrity of messages

To maintain data integrity, you can use various types of user exit program to provide message digests or digital signatures for your messages.

Data integrity

Implementing data integrity in messages
When you use SSL or TLS, your choice of CipherSpec determines the level of data integrity in the enterprise. If you use the IBM MQ Advanced Message Service (AMS) you can specify the integrity for a unique message.

Implementing data integrity in message exits

A message can be digitally signed by a message exit at the sending end of a channel. The digital signature can then be checked by a message exit at the receiving end of a channel to detect whether the message has been deliberately modified.

Some protection can be provided by using a message digest instead of a digital signature. A message digest might be effective against casual or indiscriminate tampering, but it does not prevent the more informed individual from changing or replacing the message, and generating a completely new digest for it. This is particularly true if the algorithm that is used to generate the message digest is a well known one.

Implementing data integrity in send and receive exits
On a message channel, message exits are more appropriate for providing this service because a message exit has access to a whole message. On an MQI channel, parameters on MQI calls might contain application data that needs to be protected and only send and receive exits can provide this protection.

Implementing data integrity in the API exit or API-crossing exit

A message can be digitally signed by an API or API-crossing exit when the message is put by the sending application. The digital signature can then be checked by a second exit when the message is retrieved by the receiving application to detect whether the message has been deliberately modified.

Some protection can be provided by using a message digest instead of a digital signature. A message digest might be effective against casual or indiscriminate tampering, but it does not prevent the more informed individual from changing or replacing the message, and generating a completely new digest for it. This is particularly true if the algorithm that is used to generate the message digest is a well known one,

Further information

See the section on “Enabling CipherSpecs” on page 797 for more information on ensuring data integrity.

Connecting a client to a queue manager securely

Auditing

You can check for security intrusions, or attempted intrusions, by using event messages. You can also check the security of your system by using the MQ Explorer.

To detect attempts to perform unauthorized actions such as connecting to a queue manager or put a message on a queue, inspect the event messages produced by your queue managers, particularly authority event messages. For more information about queue manager event messages, see Queue manager events, and for more information about event monitoring in general, see Event monitoring.

Keeping clusters secure

Authorize or prevent queue managers joining clusters or putting messages on cluster queues. Force a queue manager to leave a cluster. Take account of some additional considerations when configuring SSL for clusters.

Stopping unauthorized queue managers sending messages

Prevent unauthorized queue managers sending messages to your queue manager using a channel security exit.

Before you begin

Clustering has no effect on the way security exits work. You can restrict access to a queue manager in the same way as you would in a distributed queuing environment.

About this task

Prevent selected queue managers from sending messages to your queue manager:

Procedure

1. Define a channel security exit program on the `CLUSRCVR` channel definition.
2. Write a program that authenticates queue managers trying to send messages on your cluster-receiver channel and denies them access if they are not authorized.

What to do next

Channel security exit programs are called at MCA initiation and termination.

Stopping unauthorized queue managers putting messages on your queues

Use the channel put authority attribute on the cluster-receiver channel to stop unauthorized queue managers putting messages on your queues. Authorize a remote queue manager by checking the user ID in the message using RACF on z/OS, or the OAM on other platforms.

About this task

Use the security facilities of a platform and the access control mechanism in IBM MQ to control access to queues.

Procedure

1. To prevent certain queue managers from putting messages on a queue, use the security facilities available on your platform.

   For example:

   - RACF or other external security managers on IBM MQ for z/OS
   - The object authority manager (OAM) on other platforms.
2. Use the put authority, `PUTAUT`, attribute on the `CLUSRCVR` channel definition.

   The `PUTAUT` attribute allows you to specify what user identifiers are to be used to establish authority to put a message to a queue.

The options on the `PUTAUT` attribute are:

`DEF`
: Use the default user ID. On z/OS, the check might involve using both the user ID received from the network and that derived from `MCAUSER`.

`CTX`
: Use the user ID in the context information associated with the message. On z/OS the check might involve using either the user ID received from the network, or that derived from `MCAUSER`, or both. Use this option if the link is trusted and authenticated.

`ONLYMCA` (z/OS only)
: As for DEF, but any user ID received from the network is not used. Use this option if the link is not trusted. You want to allow only a specific set of actions on it, which are defined for the `MCAUSER`.

`ALTMCA` (z/OS only)
: As for `CTX`, but any user ID received from the network is not used.

Authorizing putting messages on remote cluster queues

On z/OS set up authorization to put to a cluster queue using RACF. On other platforms, authorize access to connect to the queue managers, and to put to the queues on those queue managers.

About this task

The default behavior is to perform access control against the `SYSTEM.CLUSTER.TRANSMIT.QUEUE`. Note that this behavior applies, even if you are using multiple transmission queues.

The specific behavior described in this topic applies only when you have configured the **`ClusterQueueAccessControl`** attribute in the `qm.ini` file to be *RQMName*, as described in the Security stanza topic, and restarted the queue manager.

Procedure

- For z/OS, issue the following commands:

```
RDEFINE MQQUEUE QMgrName.QUEUE. QueueName UACC(NONE)
PERMIT QMgrName.QUEUE. QueueName CLASS(MQADMIN) ID(GroupName) ACCESS(UPDATE)
```

- For UNIX, Linux and Windows systems, issue the following commands:

```
setmqaut -m QMgrName -t qmgr -g GroupName +connect
setmqaut -m QMgrName -t queue -n QueueName -g GroupName -all +put
```

- For IBM i, issue the following commands:

```
GRTMQMAUT OBJ(' QMgrName ') OBJTYPE(*MQM) USER(GroupName) AUT(*CONNECT)
GRTMQMAUT OBJ(' QueueName ') OBJTYPE(*Q) USER(GroupName) AUT(*PUT) MQMNAME(' QMgrName ')
```

The user can put messages only to the specified cluster queue, and no other cluster queues.

The variable names have the following meanings:

QMgrName
: The name of the queue manager. On z/OS, this value can also be the name of a queue-sharing group.

GroupName
: The name of the group to be granted access.

QueueName
: Name of the queue or generic profile for which to change authorizations.

What to do next

If you specify a reply-to queue when you put a message on a cluster queue, the consuming application must have authority to send the reply. Set this authority by following the instructions in "Granting authority to put messages to a remote cluster queue" on page 773.

Security stanza in qm.ini

Preventing queue managers joining a cluster

If a rogue queue manager joins a cluster it is difficult to prevent it receiving messages you do not want it to receive.

Procedure

If you want to ensure that only certain authorized queue managers join a cluster you have a choice of three techniques:

- Using channel authentication records you can block the cluster channel connection based on: the remote IP address, the remote queue manager name, or the SSL/TLS Distinguished Name provided by the remote system.
- Write an exit program to prevent unauthorized queue managers from writing to `SYSTEM.CLUSTER.COMMAND.QUEUE`. Do not restrict access to `SYSTEM.CLUSTER.COMMAND.QUEUE` such that no queue manager can write to it, or you would prevent any queue manager from joining the cluster.
- A security exit program on the `CLUSRCVR` channel definition.

Security exits on cluster channels

Extra considerations when using security exits on cluster channels.

About this task

When a cluster-sender channel is first started, it uses attributes defined manually by a system administrator. When the channel is stopped and restarted, it picks up the attributes from the corresponding cluster-receiver channel definition. The original cluster-sender channel definition is overwritten with the new attributes, including the `SecurityExit` attribute.

Procedure

1. You must define a security exit on both the cluster-sender end and the cluster-receiver end of a channel.

   The initial connection must be made with a security-exit handshake, even though the security exit name is sent over from the cluster-receiver definition.
2. Validate the `PartnerName` in the `MQCXP` structure in the security exit.

   The exit must allow the channel to start only if the partner queue manager is authorized
3. Design the security exit on the cluster-receiver definition to be receiver initiated.
4. If you design it as sender initiated, an unauthorized queue manager without a security exit can join the cluster because no security checks are performed.

   Not until the channel is stopped and restarted can the `SCYEXIT` name be sent over from the cluster-receiver definition and full security checks made.
5. To view the cluster-sender channel definition that is currently in use, use the command:

   ```
   DISPLAY CLUSQMGR( queue manager ) ALL
   ```

   The command displays the attributes that have been sent across from the cluster-receiver definition.
6. To view the original definition, use the command:

```
DISPLAY CHANNEL( channel name ) ALL
```

7. You might need to define a channel auto-definition exit, `CHADEXIT`, on the cluster-sender queue manager, if the queue managers are on different platforms.

   Use the channel auto-definition exit to set the `SecurityExit` attribute to an appropriate format for the target platform.
8. Deploy and configure the security-exit.

   z/OS **z/OS**

   The security-exit load module must be in the data set specified in the `CSQXLIB DD` statement of the channel-initiator address-space procedure.

   Windows UNIX Linux **Windows, UNIX and Linux systems**

   - The security-exit dynamic link library must be in the path specified in the `SCYEXIT` attribute of the channel definition.
   - The channel auto-definition exit dynamic link library must be in the path specified in the `CHADEXIT` attribute of the queue manager definition.

Forcing unwanted queue managers to leave a cluster

Force an unwanted queue manager to leave a cluster by issuing the `RESET CLUSTER` command at a full repository queue manager.

About this task

You can force an unwanted queue manager to leave a cluster. If for example, a queue manager is deleted but its cluster-receiver channels are still defined to the cluster. You might want to tidy up.

Only full repository queue managers are authorized to eject a queue manager from a cluster.

Note: Although using the RESET CLUSTER command forcibly removes a queue manager from a cluster, the use of RESET CLUSTER by itself does not prevent the queue manager rejoining the cluster later. To ensure that the queue manager does not rejoin the cluster, follow the steps detailed in "Preventing queue managers joining a cluster" on page 815.

Follow this procedure to eject the queue manager `OSLO` from the cluster `NORWAY`:

Procedure

1. On a full repository queue manager, issue the command:
   ```
   RESET CLUSTER(NORWAY) QMNAME(OSLO) ACTION(FORCEREMOVE)
   ```
2. Alternative use the `QMID` instead of `QMNAME` in the command:
   ```
   RESET CLUSTER(NORWAY) QMID(qmid) ACTION(FORCEREMOVE)
   ```

Results

The queue manager that is force removed does not change; its local cluster definitions show it to be in the cluster. The definitions at all other queue managers do not show it in the cluster.

Preventing queue managers receiving messages

You can prevent a cluster queue manager from receiving messages it is unauthorized to receive by using exit programs.

About this task

It is difficult to stop a queue manager that is a member of a cluster from defining a queue. There is a danger that a rogue queue manager joins a cluster, and defines its own instance of one of the queues in the cluster. It can now receive messages that it is not authorized to receive. To prevent a queue manager receiving messages, use one of the following options given in the procedure.

Procedure

- A channel exit program on each cluster-sender channel. The exit program uses the connection name to determine the suitability of the destination queue manager to be sent the messages.
- A cluster workload exit program, which uses the destination records to determine the suitability of the destination queue and queue manager to be sent the messages.

SSL and clusters

When configuring SSL for clusters, be aware a CLUSRCVR channel definition is propagated to other queue managers as an auto-defined CLUSSDR channel. If a CLUSRCVR channel uses SSL, you must configure SSL on all queue managers that communicate using the channel.

For more information about SSL and TLS, see "SSL and TLS security protocols in IBM MQ" on page 397. The advice there is generally applicable to cluster channels, but you might want to give some special consideration to the following:

In an IBM MQ cluster a particular `CLUSRCVR` channel definition is frequently propagated to many other queue managers where it is transformed into an auto-defined `CLUSSDR`. Subsequently the auto-defined `CLUSSDR` is used to start a channel to the `CLUSRCVR`. If the `CLUSRCVR` is configured for SSL connectivity the following considerations apply:

- All queue managers that want to communicate with this `CLUSRCVR` must have access to SSL support. This SSL provision must support the CipherSpec for the channel.
- The different queue managers to which the auto-defined cluster-sender channels have been propagated will each have a different distinguished name associated. If distinguished name peer checking is to be used on the `CLUSRCVR` it must be set up so all of the distinguished names that can be received are successfully matched.

  For example, let us assume that all of the queue managers that will host cluster-sender channels which will connect to a particular `CLUSRCVR`, have certificates associated. Let us also assume that the distinguished names in all of these certificates define the country as UK, organization as IBM, the organization unit as IBM MQ Development, and all have common names in the form `DEVT.QMnnn`, where `nnn` is numeric.

  In this case an `SSLPEER` value of `C=UK, O=IBM, OU=IBM MQ Development, CN=DEVT.QM*` on the `CLUSRCVR` will allow all the required cluster-sender channels to connect successfully, but will prevent unwanted cluster-sender channels from connecting.
- If custom CipherSpec strings are used, be aware that the custom string formats are not allowed on all platforms. An example of this is that the `CipherSpec` string `RC4_SHA_US` has a value of `05` on IBM i but is not a valid specification on UNIX, Linux or Windows systems. So if custom `SSLCIPH` parameters are used on a `CLUSRCVR`, all resulting auto-defined cluster-sender channels should reside on platforms on which the underlying SSL support implements this `CipherSpec` and on which it can be specified with the custom value. If you cannot select a value for the `SSLCIPH` parameter that will be understood

throughout your cluster you will need a channel auto definition exit to change it into something the platforms being used will understand. Use the textual `CipherSpec` strings where possible (for example `RC4_MD5_US`).

An `SSLCRLNL` parameter applies to an individual queue manager and is not propagated to other queue managers within a cluster.

Upgrading clustered queue managers and channels to SSL

Upgrade the cluster channels one at a time, changing all the `CLUSRCVR` channels before the `CLUSSDR` channels.

Before you begin

Consider the following considerations, as these might affect your choice of CipherSpec for a cluster:

- Some CipherSpecs are not available on all platforms. Take care to choose a CipherSpec that is supported by all of the queue managers in the cluster.
- Some CipherSpecs might be new in the current IBM MQ release and not supported in older releases. A cluster containing queue managers running at different MQ releases is only be able to use the CipherSpecs supported by each release.

  To use a new CipherSpec within a cluster, you must first migrate all of the cluster queue managers to the current release.
- Some CipherSpecs require a specific type of digital certificate to be used, notably those that use Elliptic Curve Cryptography.

Upgrade all queue managers in the cluster to IBM MQ V6 or higher, if they are not already at these levels. Distribute the certificates and keys so that SSL works from each of them.

About this task

Change the `CLUSRCVR` channels before the `CLUSSDR` channels.

Procedure

1. Switch the `CLUSRCVR` channels to SSL in any order you like, changing one `CLUSRCVR` at a time, and allow the changes to flow through the cluster before changing the next.

   Important: Make sure that you do not change the reverse path until the changes for the current channel have been distributed throughout the cluster.
2. Optional: Switch all manual `CLUSSDR` channels to SSL. This does not have any effect on the operation of the cluster, unless you use the `REFRESH CLUSTER` command with the `REPOS(YES)` option.

   Note: For large clusters, use of the **`REFRESH CLUSTER`** command can be disruptive to the cluster while it is in progress, and again at 27 day intervals thereafter when the cluster objects automatically send status updates to all interested queue managers. See Refreshing in a large cluster can affect performance and availability of the cluster.
3. Use the DISPLAY CLUSQMGR command to ensure that the new security configuration has been propagated throughout the cluster.
4. Restart the channels to use SSL or TLS and run REFRESH SECURITY (SSL).

Clustering: Using REFRESH CLUSTER best practices

Disabling TLS on clustered queue managers and channels

To turn off SSL or TLS, set the `SSLCIPH` parameter to `' '`. Disable TLS on the cluster channels individually, changing all the cluster receiver channels before the cluster sender channels.

About this task

Change one cluster receiver channel at a time, and allow the changes to flow through the cluster before changing the next.

Important: Ensure that you do not change the reverse path until the changes for the current channel have been distributed throughout the cluster.

Procedure

1. Set the value of the `SSLCIPH` parameter to `' '`, an empty string in a single quotation mark IBM i , or `*NONE` on IBM i . You can turn off TLS on the cluster receiver channels in any order you like.

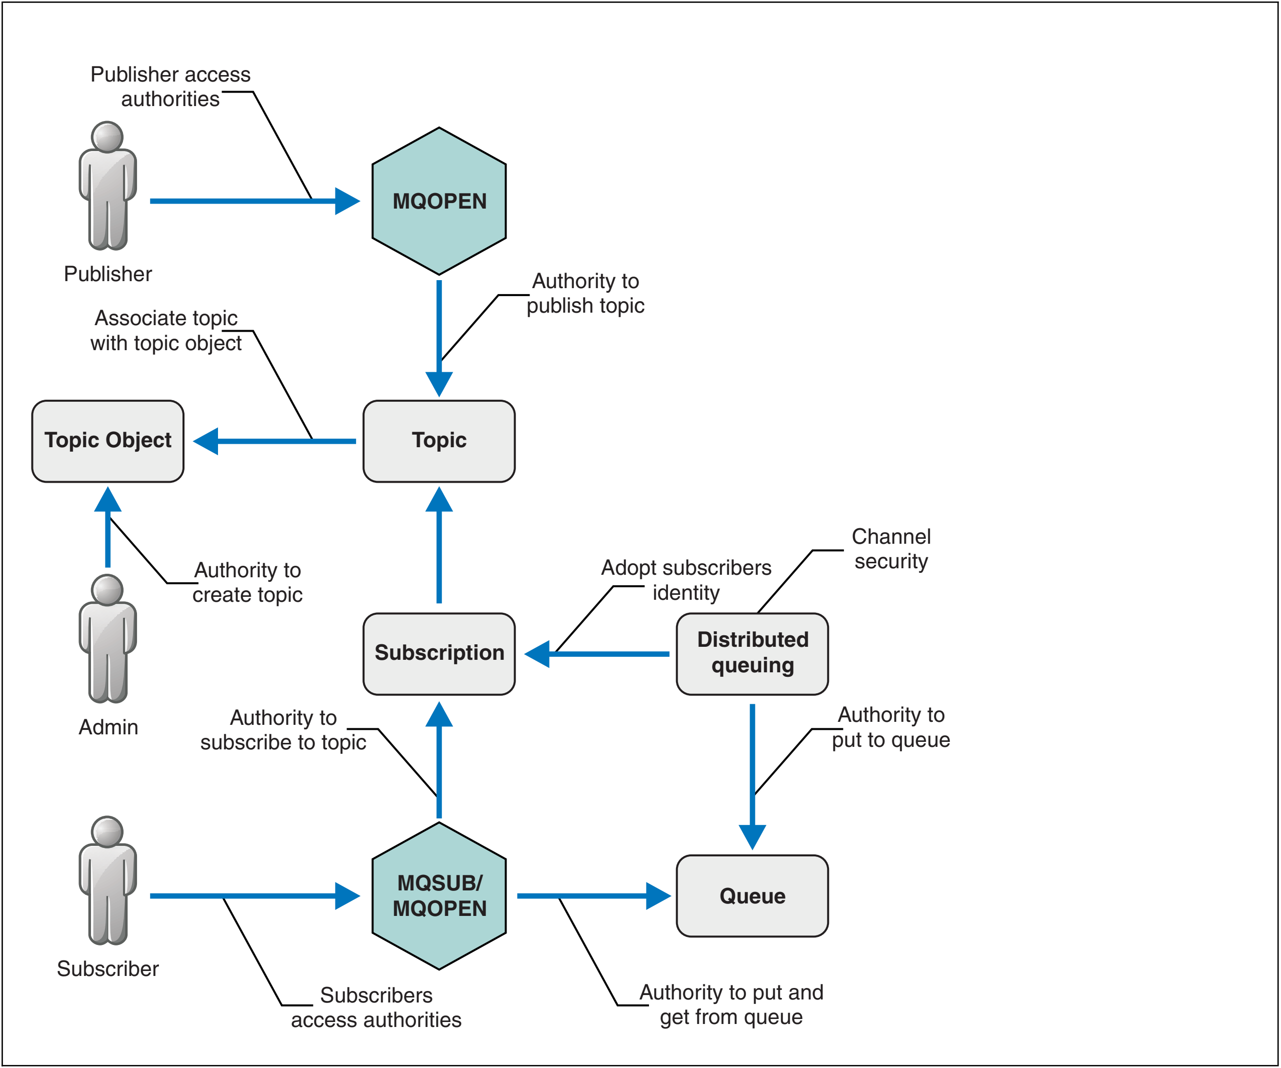
   Note that the changes flow in the opposite direction over channels on which you leave TLS active.
2. Check that the new value is reflected in all the other queue managers by using the command **`DISPLAY CLUSQMGR(*)`** `ALL`.
3. Turn off TLS on all manual cluster sender channels. This does not have any effect on the operation of the cluster, unless you use the **`REFRESH CLUSTER`** command with the `REPOS(YES)` option.

   For large clusters, use of the **`REFRESH CLUSTER`** command can be disruptive to the cluster while it is in progress, and again at regular intervals thereafter, when the cluster objects automatically send status updates to all interested queue managers. See Refreshing in a large cluster can affect performance and availability of the cluster for more information.
4. Stop and restart the cluster sender channels.

Publish/subscribe security

The components and interactions that are involved in publish/subscribe are described as an introduction to the more detailed explanations and examples that follow.

There are a number of components involved in publishing and subscribing to a topic. Some of the security relationships between them are illustrated in Figure 75 and described in the following example.



Publisher access authorities
Publisher
MQOPEN
Authority to publish topic
Associate topic with topic object
Topic Object
Topic
Authority to create topic
Admin
Channel security
Adopt subscribers identity
Subscription
Distributed queuing
Authority to subscribe to topic
Authority to put to queue
Subscriber
MQSUB/ MQOPEN
Queue
Subscribers access authorities
Authority to put and get from queue

Figure 75. Publish/subscribe security relationships between various components

Topics
: Topics are identified by topic strings, and are typically organized into trees, see Topic trees. You need to associate a topic with a topic object to control access to the topic. “Topic security model” on page 823 explains how you secure topics using topic objects.

Administrative topic objects
: You can control who has access to a topic, and for what purpose, by using the command **`setmqaut`** with a list of administrative topic objects. See the examples, “Grant access to a user to

subscribe to a topic" on page 828 and "Grant access to a user to publish to a topic" on page 835.

z/OS For controlling access to topic objects on z/OS, see Profiles for topic security.

Subscriptions

Subscribe to one or more topics by creating a subscription supplying a topic string, which can include wildcards, to match against the topic strings of publications. For further details, see:

Subscribe using a topic object
"Subscribing using the topic object name" on page 824

Subscribe using a topic
"Subscribing using a topic string where the topic node does not exist" on page 825

Subscribe using a topic with wildcards
"Subscribing using a topic string that contains wildcard characters" on page 826

A subscription contains information about the identity of the subscriber and the identity of the destination queue on to which the publications are to be placed. It also contains information about how the publication is to be placed on the destination queue.

As well as defining which subscribers have the authority to subscribe to certain topics, you can restrict subscriptions to being used by an individual subscriber. You can also control what information about the subscriber is used by the queue manager when publications are placed on to the destination queue. See "Subscription security" on page 840.

Queues

The destination queue is an important queue to secure. It is local to the subscriber, and publications that matched the subscription are placed onto it. You need to consider access to the destination queue from two perspectives:

1. Putting a publication on to the destination queue.
2. Getting the publication off the destination queue.

The queue manager puts a publication onto the destination queue using an identity provided by the subscriber. The subscriber, or a program that has been delegated the task of getting publications, takes messages off the queue. See "Authority to destination queues" on page 826.

There are no topic object aliases, but you can use an alias queue as the alias for a topic object. If you do so, as well as checking authority to use the topic for publish or subscribe, the queue manager checks authority to use the queue.

"Publish/subscribe security between queue managers" on page 842

Your permission to publish or subscribe to a topic is checked on the local queue manager using local identities and authorizations. Authorization does not depend on whether the topic is defined or not, nor where it is defined. Consequently, you need to perform topic authorization on every queue manager in a cluster when clustered topics are used.

Note: The security model for topics differs from the security model for queues. You can achieve the same result for queues by defining a queue alias locally for every clustered queue.

Queue managers exchange subscriptions in a cluster. In most IBM MQ cluster configurations, channels are configured with *PUTAUT* = *DEF* to place messages onto target queues using the authority of the channel process. You can modify the channel configuration to use *PUTAUT* = *CTX* to require the subscribing user to have authority to propagate a subscription onto another queue manager in a cluster.

"Publish/subscribe security between queue managers" on page 842 describes how to change your channel definitions to control who is allowed to propagate subscriptions onto other servers in the cluster.

Authorization

You can apply authorization to topic objects, just like queues and other objects. There are three authorization operations, `pub`, `sub`, and `resume` that you can apply only to topics. The details are described in Specifying authorities for different object types.

Function calls

In publish and subscribe programs, like in queued programs, authorization checks are made when objects are opened, created, changed, or deleted. Checks are not made when MQPUT or MQGET MQI calls are made to put and get publications.

To publish a topic, perform an MQOPEN on the topic, which performs the authorization checks. Publish messages to the topic handle using the MQPUT command, which performs no authorization checks.

To subscribe to a topic, typically you perform an MQSUB command to create or resume the subscription, and also to open the destination queue to receive publications. Alternatively, perform a separate MQOPEN to open the destination queue, and then perform the MQSUB to create or resume the subscription.

Whichever calls you use, the queue manager checks that you can subscribe to the topic and get the resulting publications from the destination queue. If the destination queue is unmanaged, authorization checks are also made that the queue manager is able to place publications on the destination queue. It uses the identity it adopted from a matching subscription. It is assumed that the queue manager is always able to place publications onto managed destination queues.

Roles

Users are involved in four roles in running publish/subscribe applications:

1. Publisher
2. Subscriber
3. Topic administrator
4. IBM MQ Administrator - member of group `mqm`

Define groups with appropriate authorizations corresponding to the publish, subscribe, and topic administration roles. You can then assign principals to these groups authorizing them to perform specific publish and subscribe tasks.

In addition, you need to extend the administrative operations authorizations to the administrator of the queues and channels responsible for moving publications and subscriptions.

Topic security model

Only defined topic objects can have associated security attributes. For a description of topic objects, see Administrative topic objects. The security attributes specify whether a specified user ID, or security group, is permitted to perform a subscribe or a publish operation on each topic object.

The security attributes are associated with the appropriate administration node in the topic tree. When an authority check is made for a particular user ID during a subscribe or publish operation, the authority granted is based on the security attributes of the associated topic tree node.

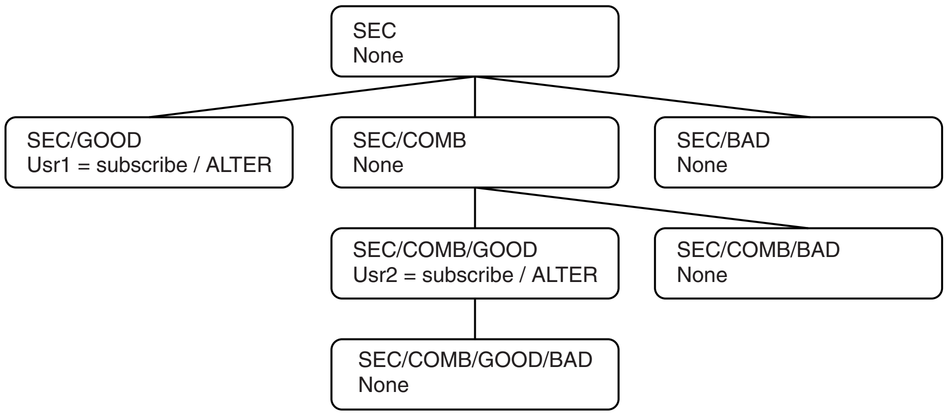
The security attributes are an access control list, indicating what authority a particular operating system user ID or security group has to the topic object.

Consider the following example where the topic objects have been defined with the security attributes, or authorities shown:

Table 84. Example topic object authorities

Topic name	Topic string	Authorities - not z/OS	z/OS authorities
SECROOT	SEC	None	None
SECGOOD	SEC/GOOD	usr1+subscribe	ALTER HLQ.SUBSCRIBE.SECGOOD
SECBAD	SEC/BAD	None	None HLQ.SUBSCRIBE.SECBAD
SECCOMB	SEC/COMB	None	None HLQ.SUBSCRIBE.SECCOMB
SECCOMBB	SEC/COMB/GOOD/BAD	None	None HLQ.SUBSCRIBE.SECCOMBB
SECCOMBG	SEC/COMB/GOOD	usr2+subscribe	ALTER HLQ.SUBSCRIBE.SECCOMBG
SECCOMBN	SEC/COMB/BAD	None	None HLQ.SUBSCRIBE.SECCOMBN

The topic tree with the associated security attributes at each node can be represented as follows:



The examples listed give the following authorizations:
- At the root node of the tree /SEC, no user has authority at that node.
- usr1 has been granted subscribe authority to the object /SEC/GOOD
- usr2 has been granted subscribe authority to the object /SEC/COMB/GOOD

Subscribing using the topic object name

When subscribing to a topic object by specifying the MQCHAR48 name, the corresponding node in the topic tree is located. If the security attributes associated with the node indicate that the user has authority to subscribe, then access is granted.

If the user is not granted access, the parent node in the tree determines if the user has authority to subscribe at the parent node level. If so, then access is granted. If not, then the parent of that node is considered. The recursion continues until a node is located that grants subscribe authority to the user. The recursion stops when the root node is considered without authority having been granted. In the latter case, access is denied.

In short, if any node in the path grants authority to subscribe to that user or application, the subscriber is allowed to subscribe at that node, or anywhere below that node in the topic tree.

The root node in the example is `SEC`.

The user is granted subscribe authority if the access control list indicates that the user ID itself has authority, or that an operating system security group of which the user ID is a member has authority.

So, for example:
- If `usr1` tries to subscribe, using a topic string of `SEC/GOOD`, the subscription would be allowed as the user ID has access to the node associated with that topic. However, if `usr1` tried to subscribe using topic string `SEC/COMB/GOOD` the subscription would not be allowed as the user ID does not have access to the node associated with it.
- If `usr2` tries to subscribe, using a topic string of `SEC/COMB/GOOD` the subscription would be allowed to as the user ID has access to the node associated with the topic. However, if `usr2` tried to subscribe to `SEC/GOOD` the subscription would not be allowed as the user ID does not have access to the node associated with it.
- If `usr2` tries to subscribe using a topic string of `SEC/COMB/GOOD/BAD` the subscription would be allowed to because the user ID has access to the parent node `SEC/COMB/GOOD`.
- If `usr1` or `usr2` tries to subscribe using a topic string of `/SEC/COMB/BAD`, neither would be allowed as they do not have access to the topic node associated with it, or the parent nodes of that topic.

A subscribe operation specifying the name of a topic object that does not exist results in an MQRC_UNKNOWN_OBJECT_NAME error.

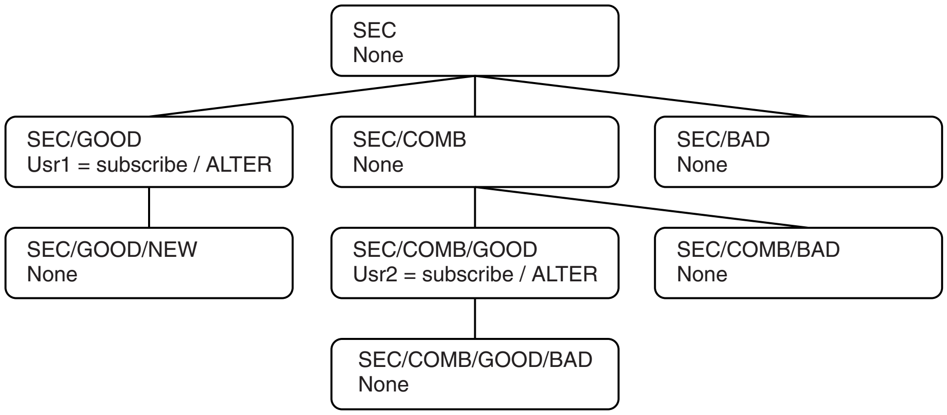
Subscribing using a topic string where the topic node exists

The behavior is the same as when specifying the topic by the MQCHAR48 object name.

Subscribing using a topic string where the topic node does not exist

Consider the case of an application subscribing, specifying a topic string representing a topic node that does not currently exist in the topic tree. The authority check is performed as outlined in the previous section. The check starts with the parent node of that which is represented by the topic string. If the authority is granted, a new node representing the topic string is created in the topic tree.

For example, `usr1` tries to subscribe to a topic `SEC/GOOD/NEW`. Authority is granted as `usr1` has access to the parent node `SEC/GOOD`. A new topic node is created in the tree as the following diagram shows. The new topic node is not a topic object it does not have any security attributes associated with it directly; the attributes are inherited from its parent.



Subscribing using a topic string that contains wildcard characters

Consider the case of subscribing using a topic string that contains a wildcard character. The authority check is made against the node in the topic tree that matches the fully qualified part of the topic string.

So, if an application subscribes to `SEC/COMB/GOOD/*`, an authority check is carried out as outlined in the previous two sections on the node `SEC/COMB/GOOD` in the topic tree.

Similarly, if an application needs to subscribe to `SEC/COMB/*/GOOD`, an authority check is carried out on the node `SEC/COMB`.

Authority to destination queues

When subscribing to a topic, one of the parameters is the handle `hobj` of a queue that has been opened for output to receive the publications.

If `hobj` is not specified, but is blank, a managed queue is created if the following conditions apply:

- The `MQSO_MANAGED` option has been specified.
- The subscription does not exist.
- Create is specified.

If `hobj` is blank, and you are altering or resuming an existing subscription, the previously provided destination queue could be either managed or unmanaged.

The application or user making the MQSUB request must have the authority to put messages to the destination queue it has provided; in effect authority to have published messages put on that queue. The authority check follows the existing rules for queue security checking.

The security checking includes alternate user ID and context security checks where required. To be able to set any of the Identity context fields you must specify the `MQSO_SET_IDENTITY_CONTEXT` option as well as the `MQSO_CREATE` or `MQSO_ALTER` option. You cannot set any of the Identity context fields on an `MQSO_RESUME` request.

If the destination is a managed queue, no security checks are performed against the managed destination. If you are allowed to subscribe to a topic it is assumed that you can use managed destinations.

Publishing using the topic name or topic string where the topic node exists

The security model for publishing is the same as that for subscribing, with the exception of wildcards. Publications do not contain wildcards; so there is no case of a topic string containing wildcards to consider.

The authorities to publish and subscribe are distinct. A user or group can have the authority to do one without necessarily being able to do the other.

When publishing to a topic object by specifying either the MQCHAR48 name or the topic string, the corresponding node in the topic tree is located. If the security attributes associated with the topic node indicates that the user has authority to publish, then access is granted.

If access is not granted, the parent node in the tree determines if the user has authority to publish at that level. If so, then access is granted. If not, the recursion continues until a node is located which grants publish authority to the user. The recursion stops when the root node is considered without authority having been granted. In the latter case, access is denied.

In short, if any node in the path grants authority to publish to that user or application, the publisher is allowed to publish at that node or anywhere below that node in the topic tree.

Publishing using the topic name or topic string where the topic node does not exist

As with the subscribe operation, when an application publishes, specifying a topic string representing a topic node that does not currently exist in the topic tree, the authority check is performed starting with the parent of the node represented by the topic string. If the authority is granted, a new node representing the topic string is created in the topic tree.

Publishing using an alias queue that resolves to a topic object

If you publish using an alias queue that resolves to a topic object then security checking occurs on both the alias queue and the underlying topic to which it resolves.

The security check on the alias queue verifies that the user has authority to put messages on that alias queue and the security check on the topic verifies that the user can publish to that topic. When an alias queue resolves to another queue, checks are *not* made on the underlying queue. Authority checking is performed differently for topics and queues.

Closing a subscription

There is additional security checking if you close a subscription using the `MQCO_REMOVE_SUB` option if you did not create the subscription under this handle.

A security check is performed to ensure that you have the correct authority to do this as the action results in the removal of the subscription. If the security attributes associated with the topic node indicate that the user has authority, then access is granted. If not, then the parent node in the tree is considered to determine if the user has authority to close the subscription. The recursion continues until either authority is granted or the root node is reached.

Defining, altering, and deleting a subscription

No subscribe security checks are performed when a subscription is created administratively, rather than using an MQSUB API request. The administrator has already been given this authority through the command.

Security checks are performed to ensure that publications can be put on the destination queue associated with the subscription. The checks are performed in the same way as for an MQSUB request.

The user ID that is used for these security checks depends upon the command being issued. If the **SUBUSER** parameter is specified it affects the way the check is performed, as shown in Table 85:

Table 85. User IDs used for security checks for commands

Command	SUBUSER specified and blank	SUBUSER specified and completed	SUBUSER not specified
`DEFINE LIKE`	Use the administrator ID	Use the user ID specified in **SUBUSER**	Use the user ID from the LIKE subscription
`DEFINE with no LIKE`	Use the administrator ID	Use the user ID specified in **SUBUSER**	Use the user ID from the SYSTEM.DEFAULT.SUB subscription - if blank, use the administrator ID
`ALTER`	Use the administrator ID	Use the user ID specified in **SUBUSER**	Use the user ID from the existing subscription

The only security check performed when deleting subscriptions using the DELETE SUB command is the command security check.

Example publish/subscribe security setup

This section describes a scenario that has access control setup on topics in a way that allows the security control to be applied as required.

Grant access to a user to subscribe to a topic

This topic is the first one in a list of tasks that tells you how to grant access to topics by more than one user.

About this task

This task assumes that no administrative topic objects exist, nor have any profiles been defined for subscription or publication. The applications are creating new subscriptions, rather than resuming existing ones, and are doing so using the topic string only.

An application can make a subscription by providing a topic object, or a topic string, or a combination of both. Whichever way the application selects, the effect is to make a subscription at a certain point in the topic tree. If this point in the topic tree is represented by an administrative topic object, a security profile is checked based on the name of that topic object.

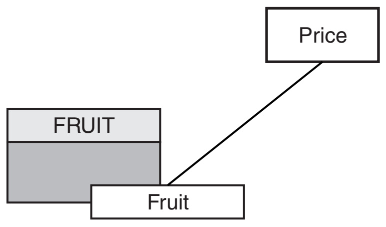


Figure 76. Topic object access example

Table 86. Example topic object access

Topic	Subscribe access required	Topic object
Price	No user	None
Price/Fruit	USER1	FRUIT

Define a new topic object as follows:

Procedure

1. Issue the MQSC command `DEF TOPIC(FRUIT) TOPICSTR('Price/Fruit')`.
2. Grant access as follows:
   - z/OS **z/OS** :

     Grant access to `USER1` to subscribe to topic `"Price/Fruit"` by granting the user access to the `hlq.SUBSCRIBE.FRUIT` profile. Do this, using the following RACF commands:
     ```
     RDEFINE MXTOPIC hlq.SUBSCRIBE.FRUIT UACC(NONE)
     PERMIT hlq.SUBSCRIBE.FRUIT CLASS(MXTOPIC) ID(USER1) ACCESS(ALTER)
     ```
   - Other platforms:

     Grant access to `USER1` to subscribe to topic `"Price/Fruit"` by granting the user access to the `FRUIT` object. Do this, using the authorization command for the platform:

     Windows UNIX Linux **Windows, UNIX and Linux systems**
     ```
     setmqaut -t topic -n FRUIT -p USER1 +sub
     ```

     IBM i **IBM i**
     ```
     GRTMQAUT OBJ(FRUIT) OBJTYPE(*TOPIC) USER(USER1) AUT(*SUB)
     ```

Results

When `USER1` attempts to subscribe to topic `"Price/Fruit"` the result is success.

When `USER2` attempts to subscribe to topic `"Price/Fruit"` the result is failure with an `MQRC_NOT_AUTHORIZED` message, together with:

- z/OS On z/OS, the following messages seen on the console that show the full security path through the topic tree that has been attempted:
  ```
  ICH408I USER(USER2   ) ...
    hlq.SUBSCRIBE.FRUIT ...

  ICH408I USER(USER2   ) ...
    hlq.SUBSCRIBE.SYSTEM.BASE.TOPIC ...
  ```
- Windows UNIX Linux On other platforms, the following authorization event:
  ```
  MQRC_NOT_AUTHORIZED
  ReasonQualifier   MQRQ_SUB_NOT_AUTHORIZED
  UserIdentifier     USER2
  AdminTopicNames   FRUIT, SYSTEM.BASE.TOPIC
  TopicString     "Price/Fruit"
  ```
- IBM i On IBMi, the following authorization event:
  ```
  MQRC_NOT_AUTHORIZED
  ReasonQualifier   MQRQ_SUB_NOT_AUTHORIZED
  UserIdentifier     USER2
  AdminTopicNames   FRUIT, SYSTEM.BASE.TOPIC
  TopicString     "Price/Fruit"
  ```

Note that this is an illustration of what you see; not all the fields.

Grant access to a user to subscribe to a topic deeper within the tree

This topic is the second in a list of tasks that tells you how to grant access to topics by more than one user.

Before you begin

This topic uses the setup described in “Grant access to a user to subscribe to a topic” on page 828.

About this task

If the point in the topic tree where the application makes the subscription is not represented by an administrative topic object, move up the tree until the closest parent administrative topic object is located. The security profile is checked, based on the name of that topic object.

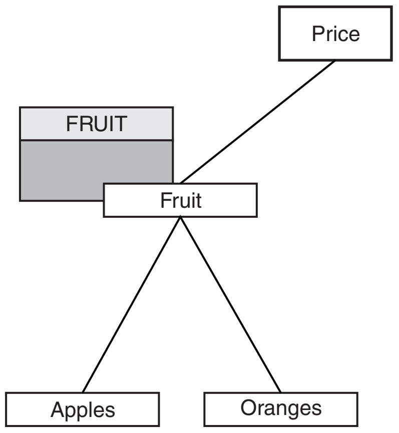

Figure 77. Example of granting access to a topic within a topic tree

Table 87. Access requirements for example topics and topic objects

Topic	Subscribe access required	Topic object
Price	No user	None
Price/Fruit	USER1	FRUIT
Price/Fruit/Apples	USER1	
Price/Fruit/Oranges	USER1	

In the previous task `USER1` was granted access to subscribe to topic `"Price/Fruit"` by granting it access to the `hlq.SUBSCRIBE.FRUIT` profile on z/OS and subscribe access to the `FRUIT` profile on other platforms. This single profile also grants `USER1` access to subscribe to `"Price/Fruit/Apples"`, `"Price/Fruit/Oranges"` and `"Price/Fruit/#"`.

When `USER1` attempts to subscribe to topic `"Price/Fruit/Apples"` the result is success.

When `USER2` attempts to subscribe to topic `"Price/Fruit/Apples"` the result is failure with an `MQRC_NOT_AUTHORIZED` message, together with:

- On z/OS, the following messages seen on the console that show the full security path through the topic tree that has been attempted:

```
ICH408I USER(USER2   ) ...
  hlq.SUBSCRIBE.FRUIT ...

ICH408I USER(USER2   ) ...
  hlq.SUBSCRIBE.SYSTEM.BASE.TOPIC ...
```

- On other platforms, the following authorization event:

```
MQRC_NOT_AUTHORIZED
ReasonQualifier   MQRQ_SUB_NOT_AUTHORIZED
UserIdentifier     USER2
AdminTopicNames   FRUIT, SYSTEM.BASE.TOPIC
TopicString     "Price/Fruit/Apples"
```

Note the following:

- The messages you receive on z/OS are identical to those received in the previous task as the same topic objects and profiles are controlling the access.
- The event message you receive on other platforms is similar to the one received in the previous task, but the actual topic string is different.

Grant another user access to subscribe to only the topic deeper within the tree

This topic is the third in a list of tasks that tells you how to grant access to subscribe to topics by more than one user.

Before you begin

This topic uses the setup described in “Grant access to a user to subscribe to a topic deeper within the tree” on page 830.

About this task

In the previous task USER2 was refused access to topic "Price/Fruit/Apples". This topic tells you how to grant access to that topic, but not to any other topics.

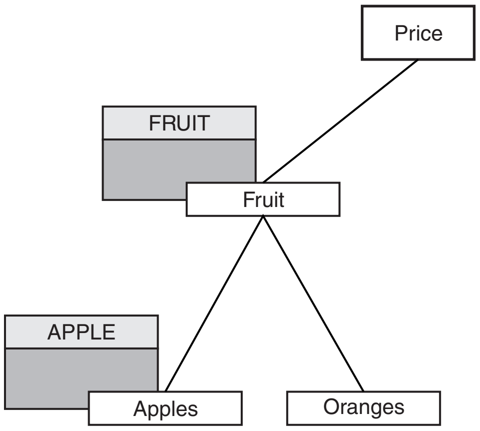

Figure 78. Granting access to specific topics within a topic tree

Table 88. Access requirements for example topics and topic objects

Topic	Subscribe access required	Topic object
Price	No user	None

Table 88. Access requirements for example topics and topic objects (continued)

Topic	Subscribe access required	Topic object
Price/Fruit	USER1	FRUIT
Price/Fruit/Apples	USER1 and USER2	APPLE
Price/Fruit/Oranges	USER1	

Define a new topic object as follows:

Procedure

1. Issue the MQSC command `DEF TOPIC(APPLE) TOPICSTR('Price/Fruit/Apples')`.
2. Grant access as follows:
   - z/OS **z/OS** :

     In the previous task `USER1` was granted access to subscribe to topic `"Price/Fruit/Apples"` by granting the user access to the `hlq.SUBSCRIBE.FRUIT` profile.

     This single profile also granted `USER1` access to subscribe to `"Price/Fruit/Oranges"` `"Price/Fruit/#"` and this access remains even with the addition of the new topic object and the profiles associated with it.

     Grant access to `USER2` to subscribe to topic `"Price/Fruit/Apples"` by granting the user access to the `hlq.SUBSCRIBE.APPLE` profile. Do this, using the following RACF commands:

     ```
     RDEFINE MXTOPIC hlq.SUBSCRIBE.APPLE UACC(NONE)
     PERMIT hlq.SUBSCRIBE.FRUIT APPLE(MXTOPIC) ID(USER2) ACCESS(ALTER)
     ```
   - Other platforms:

     In the previous task `USER1` was granted access to subscribe to topic `"Price/Fruit/Apples"` by granting the user subscribe access to the `FRUIT` profile.

     This single profile also granted `USER1` access to subscribe to `"Price/Fruit/Oranges"` and `"Price/Fruit/#"`, and this access remains even with the addition of the new topic object and the profiles associated with it.

     Grant access to `USER2` to subscribe to topic `"Price/Fruit/Apples"` by granting the user subscribe access to the `APPLE` profile. Do this, using the authorization command for the platform:

     Windows UNIX Linux **Windows, UNIX and Linux systems**

     ```
     setmqaut -t topic -n APPLE -p USER2 +sub
     ```

     IBM i **IBM i**

     ```
     GRTMQAUT OBJ(APPLE) OBJTYPE(*TOPIC) USER(USER2) AUT(*SUB)
     ```

Results

On z/OS, when `USER1` attempts to subscribe to topic `"Price/Fruit/Apples"` the first security check on the `hlq.SUBSCRIBE.APPLE` profile fails, but on moving up the tree the `hlq.SUBSCRIBE.FRUIT` profile allows USER1 to subscribe, so the subscription succeeds and no return code is sent to the MQSUB call. However, a RACF `ICH` message is generated for the first check:

```
ICH408I USER(USER1   ) ...
  hlq.SUBSCRIBE.APPLE ...
```

When `USER2` attempts to subscribe to topic `"Price/Fruit/Apples"` the result is success because the security check passes on the first profile.

When `USER2` attempts to subscribe to topic `"Price/Fruit/Oranges"` the result is failure with an `MQRC_NOT_AUTHORIZED` message, together with:

- z/OS On z/OS, the following messages seen on the console that show the full security path through the topic tree that has been attempted:

  ```
  ICH408I USER(USER2   ) ...
    hlq.SUBSCRIBE.FRUIT ...

  ICH408I USER(USER2   ) ...
    hlq.SUBSCRIBE.SYSTEM.BASE.TOPIC ...
  ```

- Windows UNIX Linux On Windows, UNIX and Linux platforms, the following authorization event:

  ```
  MQRC_NOT_AUTHORIZED
  ReasonQualifier   MQRQ_SUB_NOT_AUTHORIZED
  UserIdentifier     USER2
  AdminTopicNames   FRUIT, SYSTEM.BASE.TOPIC
  TopicString     "Price/Fruit/Oranges"
  ```

- IBM i On IBMi, the following authorization event:

  ```
  MQRC_NOT_AUTHORIZED
  ReasonQualifier   MQRQ_SUB_NOT_AUTHORIZED
  UserIdentifier     USER2
  AdminTopicNames   FRUIT, SYSTEM.BASE.TOPIC
  TopicString     "Price/Fruit/Oranges"
  ```

The disadvantage of this setup is that, on z/OS, you receive additional `ICH` messages on the console. You can avoid this if you secure the topic tree in a different manner.

Change access control to avoid additional messages

This topic is the fourth in a list of tasks that tells you how to grant access to subscribe to topics by more than one user and to avoid additional RACF ICH408I messages on z/OS.

Before you begin

This topic enhances the setup described in "Grant another user access to subscribe to only the topic deeper within the tree" on page 831 so that you avoid additional error messages.

About this task

This topic tells you how to grant access to topics deeper in the tree, and how to remove access to the topic lower down the tree when no user requires it.

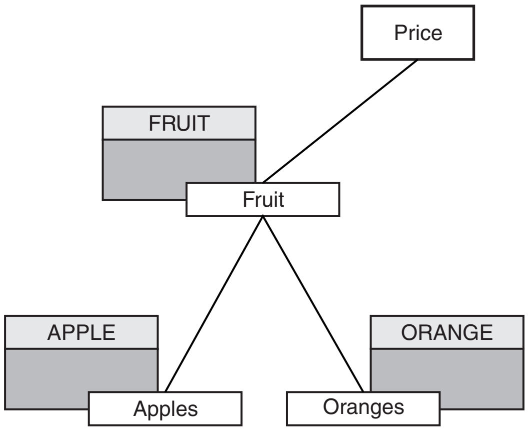

Figure 79. Example of granting access control to avoid additional messages.

Define a new topic object as follows:

Procedure

1. Issue the MQSC command `DEF TOPIC(ORANGE) TOPICSTR('Price/Fruit/Oranges')`.
2. Grant access as follows:
   - z/OS **z/OS** :

     Define a new profile and add access to that profile, and the existing profiles. Do this, using the following RACF commands:

     ```
     RDEFINE MXTOPIC hlq.SUBSCRIBE.ORANGE UACC(NONE)
     PERMIT hlq.SUBSCRIBE.ORANGE CLASS(MXTOPIC) ID(USER1) ACCESS(ALTER)
     PERMIT hlq.SUBSCRIBE.APPLE CLASS(MXTOPIC) ID(USER1) ACCESS(ALTER)
     ```
   - Other platforms:

     Setup the equivalent access by using the authorization commands for the platform:

     Windows UNIX Linux **Windows, UNIX and Linux systems**

     ```
     setmqaut -t topic -n ORANGE -p USER1 +sub
     setmqaut -t topic -n APPLE -p USER1 +sub
     ```

     IBM i **IBM i**

     ```
     GRTMQAUT OBJ(ORANGE) OBJTYPE(*TOPIC) USER(USER1) AUT(*SUB)
     GRTMQAUT OBJ(APPLE) OBJTYPE(*TOPIC) USER(USER1) AUT(*SUB)
     ```

Results

On z/OS, when `USER1` attempts to subscribe to topic `"Price/Fruit/Apples"` the first security check on the `hlq.SUBSCRIBE.APPLE` profile succeeds.

Similarly, when `USER2` attempts to subscribe to topic `"Price/Fruit/Apples"` the result is success because the security check passes on the first profile.

When `USER2` attempts to subscribe to topic `"Price/Fruit/Oranges"` the result is failure with an `MQRC_NOT_AUTHORIZED` message, together with:

- z/OS On z/OS, the following messages seen on the console that show the full security path through the topic tree that has been attempted:

  ```
  ICH408I USER(USER2   ) ...
    hlq.SUBSCRIBE.ORANGE ...

  ICH408I USER(USER2   ) ...
  ```

```
  hlq.SUBSCRIBE.FRUIT ...

ICH408I USER(USER2   ) ...
  hlq.SUBSCRIBE.SYSTEM.BASE.TOPIC ...
```

- Windows UNIX Linux On other platforms, the following authorization event:

```
MQRC_NOT_AUTHORIZED
ReasonQualifier   MQRQ_SUB_NOT_AUTHORIZED
UserIdentifier     USER2
AdminTopicNames   ORANGE, FRUIT, SYSTEM.BASE.TOPIC
TopicString     "Price/Fruit/Oranges"
```

- IBM i On IBMi, the following authorization event:

```
MQRC_NOT_AUTHORIZED
ReasonQualifier   MQRQ_SUB_NOT_AUTHORIZED
UserIdentifier     USER2
AdminTopicNames   ORANGE, FRUIT, SYSTEM.BASE.TOPIC
TopicString     "Price/Fruit/Oranges"
```

Grant access to a user to publish to a topic

This topic is the first one in a list of tasks that tells you how to grant access to publish topics by more than one user.

About this task

This task assumes that no administrative topic objects exist on the right hand side of the topic tree, nor have any profiles been defined for publication. The assumption used is that publishers are using the topic string only.

An application can publish to a topic by providing a topic object, or a topic string, or a combination of both. Whichever way the application selects, the effect is to publish at a certain point in the topic tree. If this point in the topic tree is represented by an administrative topic object, a security profile is checked based on the name of that topic object. For example:

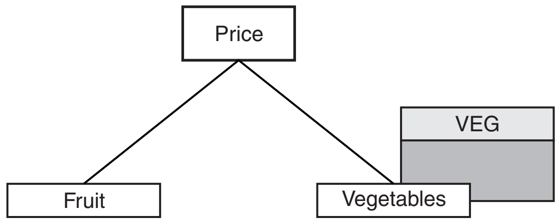

Figure 80. Granting publish access to a topic

Table 89. Example publish access requirements

Topic	Publish access required	Topic object
Price	No user	None
Price/Vegetables	USER1	VEG

Define a new topic object as follows:

Procedure

1. Issue the MQSC command `DEF TOPIC(VEG) TOPICSTR('Price/Vegetables')`.
2. Grant access as follows:

- z/OS **z/OS** :

  Grant access to USER1 to publish to topic "Price/Vegetables" by granting the user access to the hlq.PUBLISH.VEG profile. Do this, using the following RACF commands:

  ```
  RDEFINE MXTOPIC hlq.PUBLISH.VEG UACC(NONE)
  PERMIT hlq.PUBLISH.VEG CLASS(MXTOPIC) ID(USER1) ACCESS(UPDATE)
  ```
- Other platforms:

  Grant access to USER1 to publish to topic "Price/Vegetables" by granting the user access to the VEG profile. Do this, using the authorization command for the platform:

  Windows UNIX Linux **Windows, UNIX and Linux systems**

  ```
  setmqaut -t topic -n VEG -p USER1 +pub
  ```

  IBM i **IBM i**

  ```
  GRTMQAUT OBJ(VEG) OBJTYPE(*TOPIC) USER(USER1) AUT(*PUB)
  ```

Results

When USER1 attempts to publish to topic "Price/Vegetables" the result is success; that is, the MQOPEN call succeeds.

When USER2 attempts to publish to topic "Price/Vegetables" the MQOPEN call fails with an MQRC_NOT_AUTHORIZED message, together with:

- z/OS On z/OS, the following messages seen on the console that show the full security path through the topic tree that has been attempted:

  ```
  ICH408I USER(USER2   ) ...
    hlq.PUBLISH.VEG ...

  ICH408I USER(USER2   ) ...
    hlq.PUBLISH.SYSTEM.BASE.TOPIC ...
  ```
- Windows UNIX Linux On other platforms, the following authorization event:

  ```
  MQRC_NOT_AUTHORIZED
  ReasonQualifier   MQRQ_OPEN_NOT_AUTHORIZED
  UserIdentifier     USER2
  AdminTopicNames   VEG, SYSTEM.BASE.TOPIC
  TopicString     "Price/Vegetables"
  ```
- IBM i On IBMi, the following authorization event:

  ```
  MQRC_NOT_AUTHORIZED
  ReasonQualifier   MQRQ_OPEN_NOT_AUTHORIZED
  UserIdentifier     USER2
  AdminTopicNames   VEG, SYSTEM.BASE.TOPIC
  TopicString     "Price/Vegetables"
  ```

Note that this is an illustration of what you see; not all the fields.

Grant access to a user to publish to a topic deeper within the tree

This topic is the second in a list of tasks that tells you how to grant access to publish to topics by more than one user.

Before you begin

This topic uses the setup described in “Grant access to a user to publish to a topic” on page 835.

About this task

If the point in the topic tree where the application publishes is not represented by an administrative topic object, move up the tree until the closest parent administrative topic object is located. The security profile is checked, based on the name of that topic object.

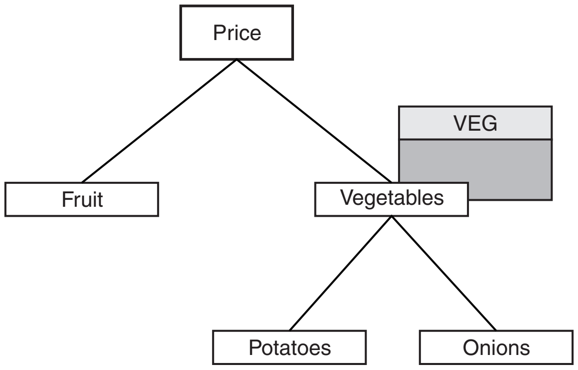

Figure 81. Granting publish access to a topic within a topic tree

Table 90. Example publish access requirements

Topic	Subscribe access required	Topic object
Price	No user	None
Price/Vegetables	USER1	VEG
Price/Vegetables/Potatoes	USER1	
Price/Vegetables/Onions	USER1	

In the previous task `USER1` was granted access to publish topic `"Price/Vegetables/Potatoes"` by granting it access to the `hlq.PUBLISH.VEG` profile on z/OS or publish access to the `VEG` profile on other platforms. This single profile also grants `USER1` access to publish at `"Price/Vegetables/Onions"`.

When `USER1` attempts to publish at topic `"Price/Vegetables/Potatoes"` the result is success; that is the MQOPEN call succeeds.

When `USER2` attempts to subscribe to topic `"Price/Vegetables/Potatoes"` the result is failure; that is, the MQOPEN call fails with an `MQRC_NOT_AUTHORIZED` message, together with:

- On z/OS, the following messages seen on the console that show the full security path through the topic tree that has been attempted:

```
ICH408I USER(USER2   ) ...
  hlq.PUBLISH.VEG ...

ICH408I USER(USER2   ) ...
  hlq.PUBLISH.SYSTEM.BASE.TOPIC ...
```

- On other platforms, the following authorization event:

```
MQRC_NOT_AUTHORIZED
ReasonQualifier   MQRQ_OPEN_NOT_AUTHORIZED
UserIdentifier     USER2
AdminTopicNames   VEG, SYSTEM.BASE.TOPIC
TopicString     "Price/Vegetables/Potatoes"
```

Note the following:

- The messages you receive on z/OS are identical to those received in the previous task as the same topic objects and profiles are controlling the access.
- The event message you receive on other platforms is similar to the one received in the previous task, but the actual topic string is different.

Grant access for publish and subscribe

This topic is the last in a list of tasks that tells you how to grant access to publish and subscribe to topics by more than one user.

Before you begin

This topic uses the setup described in "Grant access to a user to publish to a topic deeper within the tree" on page 837.

About this task

In a previous task `USER1` was given access to subscribe to the topic `"Price/Fruit"`. This topic tells you how to grant access to that user to publish to that topic.

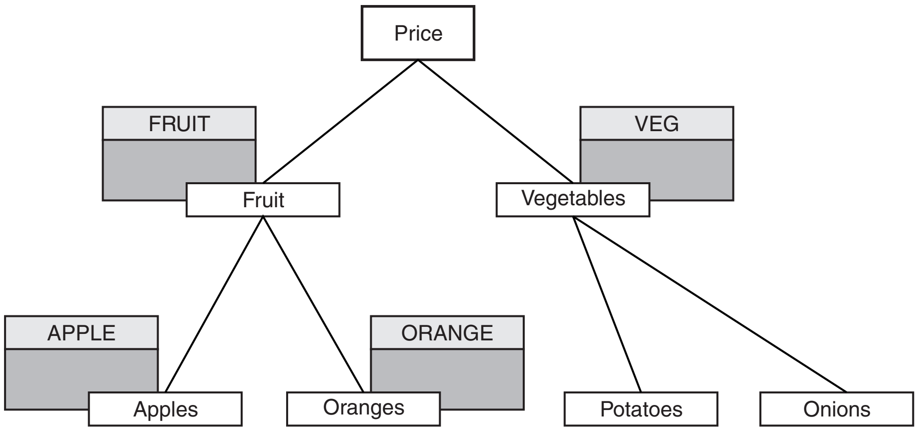

Figure 82. Granting access for publishing and subscribing

Table 91. Example publishing and subscribing access requirements

Topic	Subscribe access required	Publish access required	Topic object
Price	No user	No user	None
Price/Fruit	USER1	USER1	FRUIT
Price/Fruit/Apples	USER1 and USER2		APPLE
Price/Fruit/Oranges	USER1		ORANGE

Procedure

Grant access as follows:

- z/OS **z/OS** :

  In an earlier task USER1 was granted access to subscribe to topic "Price/Fruit" by granting the user access to the hlq.SUBSCRIBE.FRUIT profile.

  In order to publish to the "Price/Fruit" topic, grant access to USER1 to the hlq.PUBLISH.FRUIT profile. Do this, using the following RACF commands:

  ```
  RDEFINE MXTOPIC hlq.PUBLISH.FRUIT UACC(NONE)
  PERMIT hlq.PUBLISH.FRUIT CLASS(MXTOPIC) ID(USER1) ACCESS(ALTER)
  ```

- Other platforms:

  Grant access to USER1 to publish to topic "Price/Fruit" by granting the user publish access to the FRUIT profile. Do this, using the authorization command for the platform:

  Windows UNIX Linux **Windows, UNIX and Linux systems**

  ```
  setmqaut -t topic -n FRUIT -p USER1 +pub
  ```

  IBM i **IBM i**

  ```
  GRTMQAUT OBJ(FRUIT) OBJTYPE(*TOPIC) USER(USER1) AUT(*PUB)
  ```

Results

On z/OS, when USER1 attempts to publish to topic "Price/Fruit" the security check on the MQOPEN call passes.

When USER2 attempts to publish at topic "Price/Fruit" the result is failure with an MQRC_NOT_AUTHORIZED message, together with:

- z/OS On z/OS, the following messages seen on the console that show the full security path through the topic tree that has been attempted:

  ```
  ICH408I USER(USER2   ) ...
    hlq.PUBLISH.FRUIT ...

  ICH408I USER(USER2   ) ...
    hlq.PUBLISH.SYSTEM.BASE.TOPIC ...
  ```

- Windows UNIX Linux On Windows, UNIX, and Linux platforms, the following authorization event:

  ```
  MQRC_NOT_AUTHORIZED
  ReasonQualifier   MQRQ_OPEN_NOT_AUTHORIZED
  UserIdentifier     USER2
  AdminTopicNames   FRUIT, SYSTEM.BASE.TOPIC
  TopicString     "Price/Fruit"
  ```

- IBM i On IBMi, the following authorization event:

  ```
  MQRC_NOT_AUTHORIZED
  ReasonQualifier   MQRQ_OPEN_NOT_AUTHORIZED
  UserIdentifier     USER2
  AdminTopicNames   FRUIT, SYSTEM.BASE.TOPIC
  TopicString     "Price/Fruit"
  ```

Following the complete set of these tasks, gives USER1 and USER2 the following access authorities for publish and subscribe to the topics listed:

Table 92. Complete list of access authorities resulting from security examples

Topic	Subscribe access required	Publish access required	Topic object
Price	No user	No user	None
Price/Fruit	USER1	USER1	FRUIT
Price/Fruit/Apples	USER1 and USER2		APPLE
Price/Fruit/Oranges	USER1		ORANGE
Price/Vegetables		USER1	VEG
Price/Vegetables/Potatoes			
Price/Vegetables/Onions			

Where you have different requirements for security access at different levels within the topic tree, careful planning ensures that you do not receive extraneous security warnings on the z/OS console log. Setting up security at the correct level within the tree avoids misleading security messages.

Subscription security

MQSO_ALTERNATE_USER_AUTHORITY

The AlternateUserId field contains a user identifier to use to validate this MQSUB call. The call can succeed only if this AlternateUserId is authorized to subscribe to the topic with the specified access options, regardless of whether the user identifier under which the application is running is authorized to do so.

MQSO_SET_IDENTITY_CONTEXT

The subscription is to use the accounting token and application identity data supplied in the PubAccountingToken and PubApplIdentityData fields.

If this option is specified, the same authorization check is carried out as if the destination queue was accessed using an MQOPEN call with MQOO_SET_IDENTITY_CONTEXT, except in the case where the MQSO_MANAGED option is also used in which case there is no authorization check on the destination queue.

If this option is not specified, the publications sent to this subscriber have default context information associated with them as follows:

Table 93. Default publication context information

Field in MQMD	Value used
UserIdentifier	The user ID associated with the subscription (see SUBUSER field on DISPLAY SBSTATUS) at the time the publication is made.
AccountingToken	Determined from the environment if possible; set to MQACT_NONE otherwise.
ApplIdentityData	Set to blanks.

This option is only valid with MQSO_CREATE and MQSO_ALTER. If used with MQSO_RESUME, the PubAccountingToken and PubApplIdentityData fields are ignored, so this option has no effect.

If a subscription is altered without using this option where previously the subscription had supplied identity context information, default context information is generated for the altered subscription.

If a subscription allowing different user IDs to use it with option MQSO_ANY_USERID, is resumed by a different user ID, default identity context is generated for the new user ID now owning the subscription and any subsequent publications are delivered containing the new identity context.

AlternateSecurityId

This is a security identifier that is passed with the AlternateUserId to the authorization service to allow appropriate authorization checks to be performed. AlternateSecurityId is used only if MQSO_ALTERNATE_USER_AUTHORITY is specified, and the AlternateUserId field is not entirely blank up to the first null character or the end of the field.

MQSO_ANY_USERID subscription option

When MQSO_ANY_USERID is specified, the identity of the subscriber is not restricted to a single user ID. This allows any user to alter or resume the subscription when they have suitable authority. Only a single user may have the subscription at any one time. An attempt to resume use of a subscription currently in use by another application will cause the call to fail with MQRC_SUBSCRIPTION_IN_USE.

To add this option to an existing subscription the MQSUB call (using MQSO_ALTER) must come from the same user ID as the original subscription.

If an MQSUB call refers to an existing subscription with MQSO_ANY_USERID set, and the user ID differs from the original subscription, the call succeeds only if the new user ID has authority to subscribe to the topic. After successful completion, future publications to this subscriber are put to the subscriber's queue with the new user ID set in the publication.

MQSO_FIXED_USERID

When MQSO_FIXED_USERID is specified, the subscription can only be altered or resumed by a single owning user ID. This user ID is the last user ID to alter the subscription that set this option, thereby removing the MQSO_ANY_USERID option, or if no alters have taken place, it is the user ID that created the subscription.

If an MQSUB verb refers to an existing subscription with MQSO_ANY_USERID set and alters the subscription (using MQSO_ALTER) to use option MQSO_FIXED_USERID, the user ID of the subscription is now fixed at this new user ID. The call succeeds only if the new user ID has authority to subscribe to the topic.

If a user ID other than the one recorded as owning a subscription trys to resume or alter an MQSO_FIXED_USERID subscription, the call will fail with MQRC_IDENTITY_MISMATCH. The owning user ID of a subscription can be viewed using the DISPLAY SBSTATUS command.

If neither MQSO_ANY_USERID or MQSO_FIXED_USERID is specified, the default is MQSO_FIXED_USERID.

Publish/subscribe security between queue managers

Publish/subscribe internal messages, such as proxy subscriptions and publications, are put to publish/subscribe system queues using normal channel security rules. The information and diagrams in this topic highlight the various processes and user IDs involved in the delivery of these messages.

Local access control

Access to topics for publication and subscriptions is governed by local security definitions and rules that are described in Publish/subscribe security. On z/OS, no local topic object is required to establish access control. No local topic is required for access control on other platforms either. Administrators can choose to apply access control to clustered topic objects, irrespective of whether they exist in the cluster yet.

System administrators are responsible for access control on their local system. They must trust the administrators of other members of the hierarchy or cluster collectives to be responsible for their access control policy. Because access control is defined for each separate machine it is likely to be burdensome if fine level control is needed. It might not be necessary to impose any access control, or access control might be defined on high-level objects in the topic tree. Fine level access control can be defined for each subdivision of the topic namespace.

Making a proxy subscription

Trust for an organization to connect its queue manager to your queue manager is confirmed by normal channel authentication means. If that trusted organization is also allowed to do distributed publish/subscribe, an authority check is done. The check is made when the channel puts a message to a distributed publish/subscribe queue. For example, if a message is put to the `SYSTEM.INTER.QMGR.CONTROL` queue. The user ID for the queue authority check depends on the `PUTAUT` values of the receiving channel. For example, the user ID of the channel, `MCAUSER`, the message context, depending on the value and platform. For more information about channel security, see Channel security.

Proxy subscriptions are made with the user ID of the distributed publish/subscribe agent on the remote queue manager. For example, `QM2` in Figure 83. The user is then easily granted access to local topic object profiles, because that user ID is defined in the system and there are therefore no domain conflicts.

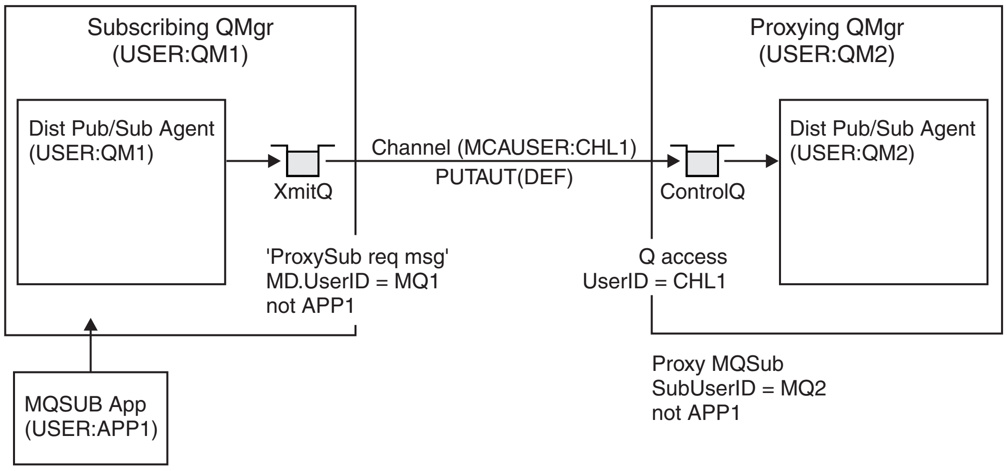

Figure 83. Proxy subscription security, making a subscription

Sending back remote publications

When a publication is created on the publishing queue manager, a copy of the publication is created for any proxy subscription. The context of the copied publication contains the context of the user ID which made the subscription; QM2 in Figure 84. The proxy subscription is created with a destination queue that is a remote queue, so the publication message is resolved onto a transmission queue.

Trust for an organization to connect its queue manager, QM2, to another queue manager, QM1, is confirmed by normal channel authentication means. If that trusted organization is then allowed to do distributed publish/subscribe, an authority check is done when the channel puts the publication message to the distributed publish/subscribe publication queue SYSTEM.INTER.QMGR.PUBS. The user ID for the queue authority check depends on the PUTAUT value of the receiving channel (for example, the user ID of the channel, MCAUSER, message context, and others, depending on value and platform). For more information about channel security, see Channel security.

When the publication message reaches the subscribing queue manager, another MQPUT to the topic is done under the authority of that queue manager and the context with the message is replaced by the context of each of the local subscribers as they are each given the message.

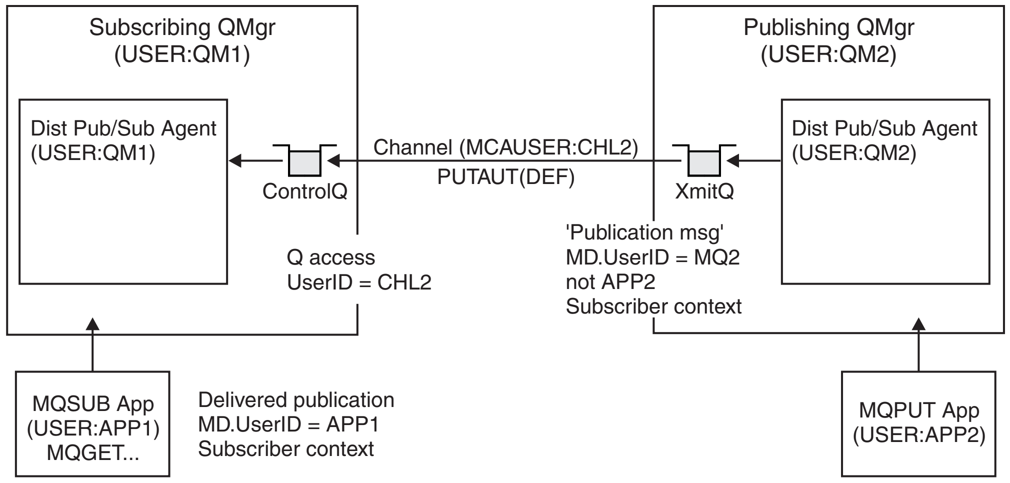

Figure 84. Proxy subscription security, forwarding publications

On a system where little has been considered regarding security, the distributed publish/subscribe processes are likely to be running under a user ID in the mqm group, the MCAUSER parameter on a channel is blank (the default), and messages are delivered to the various system queues as required. The unsecured system makes it easy to set up a proof of concept to demonstrate distributed publish/subscribe.

On a system where security is more seriously considered, these internal messages are subject to the same security controls as any message going over the channel.

If the channel is set up with a non-blank MCAUSER and a PUTAUT value specifying that MCAUSER must be checked, then the MCAUSER in question must be granted access to SYSTEM.INTER.QMGR.* queues. If there are multiple different remote queue managers, with channels running under different MCAUSER IDs, all those user IDs need to be granted access to the SYSTEM.INTER.QMGR.* queues. Channels running under different MCAUSER IDs might occur, for example, when multiple hierarchical connections are configured on a single queue manager.

If the channel is set up with a PUTAUT value specifying that the context of the message is used, then access to the SYSTEM.INTER.QMGR.* queues are checked based on the user ID inside the internal message. Because all these messages are put with the user ID of the distributed publish/subscribe agent from the queue manager that is sending the internal message, or publication message (see Figure 84 on page 843), it is not too large a set of user IDs to grant access to the various system queues (one per remote queue manager), if you want to set up your distributed publish/subscribe security in this way. It still has all the same issues that channel context security always has; that of the different user ID domains and the fact that the user ID in the message might not be defined on the receiving system. However, it is a perfectly acceptable way to run if required.

z/OS System queue security provides a list of queues and the access that is required to securely set up your distributed publish/subscribe environment. If any internal messages or publications fail to be put due to security violations, the channel writes a message to the log in the normal manner and the messages can be sent to the dead-letter queue according to normal channel error processing.

All inter-queue manager messaging for the purposes of distributed publish/subscribe runs using normal channel security.

For information about restricting publications and proxy subscriptions at the topic level, see Publish/subscribe security.

Using default user IDs with a queue manager hierarchy

If you have a hierarchy of queue managers running on different platforms and are using default user IDs, note that these default user IDs differ between platforms and might not be known on the target platform. As a result, a queue manager running on one platform rejects messages received from queue managers on other platforms with the reason code `MQRC_NOT_AUTHORIZED`.

To avoid messages being rejected, at a minimum, the following authorities need to be added to the default user IDs used on other platforms:

- *PUT *GET authority on the SYSTEM.BROKER. queues
- *PUB *SUB authority on the SYSTEM.BROKER. topics
- *ADMCRT *ADMDLT *ADMCHG authority on the SYSTEM.BROKER.CONTROL.QUEUE queue.

The default user IDs are as follows:

Platform	**Default user ID**
Windows	`MUSR_MQADMIN` **Note:** `MUSR_MQADMIN` is the default user ID for the first installation only. For subsequent installations, the Prepare IBM MQ Wizard creates a user account named for `MUSR_MQADMINx`, where x is the next available number representing a user ID that does not exist.
UNIX and Linux systems	`mqm`
IBM i	`QMQM`
z/OS	The channel initiator address space user ID

Create and grant access to the 'qmqm' user ID if hierarchically attached to a queue manager on IBM i for Queue Managers on Windows, UNIX, Linux, and z/OS platforms.

Create and grant access to the 'mqm' user ID if hierarchically attached to a queue manager on Windows, UNIX, or Linux for Queue Managers on IBM i and z/OS platforms.

Create and grant user access to the z/OS channel initiator address space user ID if hierarchically attached to a queue manager on z/OS for Queue Managers on Windows, UNIX, Linux, and IBM i platforms.

User IDs can be case sensitive. The originating queue manager (if IBM i, Windows, UNIX, or Linux systems) forces the user ID to be all uppercase. The receiving queue manager (if Windows, UNIX or Linux systems) forces the user ID to be all lowercase. Therefore, all user IDs created on UNIX and Linux systems must be created in their lowercase form. If a message exit has been installed, forcing the user ID into uppercase or lowercase does not take place. Care must be taken to understand how the message exit processes the user ID.

To avoid potential problems with conversion of user IDs:
- On UNIX, Linux and Windows systems, ensure the user IDs are specified in lowercase.
- On IBM i and z/OS, ensure the user IDs are specified in uppercase.

Protection of database authentication details

V 8.0.0.4

If your are using user name and password authentication to connect to the database manager, you can store them in the MQ XA credentials store to avoid storing the password in plain text in the `qm.ini` file.

Update XAOpenString for the resource manager

To use the credentials store you must modify XAOpenString in the `qm.ini` file. The string is used to connect to the database manager. You specify replaceable fields to identify where the user name and password are substituted within the XAOpenString string.

- The `+USER+` field is replaced with the user name value stored in the XACredentials store.
- The `+PASSWORD+` field is replaced with the password value stored in the XACredentials store.

The following examples show how to modify an XAOpenString to use the credentials file to connect to the database.

Connecting to a Db2 database

```
XAResourceManager:
  Name=mydb2
  SwitchFile=db2swit
  XAOpenString=db=mydbname,uid=+USER+,pwd=+PASSWORD+,toc=t
  ThreadOfControl=THREAD
```

Connecting to an Oracle database

```
XAResourceManager:
  Name=myoracle
  SwitchFile=oraswit
  XAOpenString=Oracle_XA+Acc=P/+USER+/+PASSWORD++SesTm=35
            +LogDir=/tmp+threads=true
  ThreadOfControl=THREAD
```

Work with the credentials for the database to the MQ XA credentials store

After you update the `qm.ini` file with the replaceable credential strings, you must add the user name and password to the MQ credentials store by using the **`setmqxacred`** command. You can also use **`setmqxacred`** to modify existing credentials, delete credentials, or list credentials. The following examples give some typical use cases:

Adding credentials

The following command securely saves the user name and password for the queue manager `QM1` for the resource `mqdb2`.

```
setmqxacred -m QM1 -x mydb2 -u user1 -p Password2
```

Updating credentials

To update the user name and password used to connect to a database, re-issue the **`setmqxacred`** command with the new user-name and password:

```
setmqxacred -m QM1 -x mydb2 -u user3 -p Password4
```

You must restart the queue manager for the changes to take effect.

Deleting credentials

The following command deletes the credentials:

```
setmqxacred -m QM1 -x mydb2 -d
```

Listing credentials

The following command lists credentials:

```
setmqxacred -m QM1 -l
```

Related information:

`setmqxacred`

IBM MQ Advanced Message Security

IBM MQ Advanced Message Security (IBM MQ AMS) is a separately licensed component of IBM MQ that provides a high level of protection for sensitive data flowing through the IBM MQ network, while not impacting the end applications.

IBM MQ AMS overview

IBM MQ applications can use IBM MQ Advanced Message Security to send sensitive data, such as high-value financial transactions and personal information, with different levels of protection by using a public key cryptography model.

Behavior that has changed since Version 7.0.1

IBM MQ Advanced Message Security became a component in IBM MQ from Version 7.5. Some aspects of IBM MQ AMS functionality have changed, that might affect applications, administrative scripts, or management procedures.

Review the following list of changes carefully before upgrading queue managers to Version 7.5 or later. Decide whether you must plan to make changes to existing applications, scripts, and procedures before starting to migrate systems:

- IBM MQ AMS installation is a part of the IBM MQ installation process.
- IBM MQ AMS security capability are enabled with its installation and controlled with security policies. You do not need to enable interceptors to allow IBM MQ AMS start intercepting data.
- IBM MQ AMS in IBM MQ does not require the use of the **cfgmqs** command as in the stand-alone version of IBM WebSphere MQ Advanced Message Security.

Features and functions of IBM MQ Advanced Message Security

IBM MQ Advanced Message Security expands IBM MQ security services to provide data signing and encryption at the message level. The expanded services guarantee that message data has not been modified between when it is originally placed on a queue and when it is retrieved. In addition, IBM MQ AMS verifies that a sender of message data is authorized to place signed messages on a target queue.

IBM MQ AMS provides the following functions:

- Secures sensitive or high-value transactions processed by IBM MQ.
- Detects and removes rogue or unauthorized messages before they are processed by a receiving application.
- Verifies that messages were not modified while in transit from queue to queue.
- Protects the data not only as it flows across the network but also when it is put on a queue.
- Secures existing proprietary and customer-written applications for IBM MQ.

Error handling

IBM MQ Advanced Message Security defines an error handling queue to manage messages that contain errors or messages that cannot be unprotected.

Defective messages are dealt with as exceptional cases. If a received message does not meet the security requirements for the queue it is on, for example, if the message is signed when it should be encrypted, or decryption or signature verification fails, the message is sent to the error handling queue. A message might be sent to the error handling queue for the following reasons:

- Quality of protection mismatch - a quality of protection (QOP) mismatch exists between the received message and the QOP definition in the security policy.
- Decryption error - the message cannot be decrypted.
- PDMQ header error - the IBM MQ AMS message header cannot be accessed.
- Size mismatch - length of a message after decryption is different than expected.
- Encryption algorithm strength mismatch - the message encryption algorithm is weaker than required.
- Unknown error - unexpected error occurred.

IBM MQ Advanced Message Security uses the SYSTEM.PROTECTION.ERROR.QUEUE as its error handling queue. All messages put by IBM MQ AMS to the SYSTEM.PROTECTION.ERROR.QUEUE are preceded by an MQDLH header.

Your IBM MQ administrator can also define the SYSTEM.PROTECTION.ERROR.QUEUE as an alias queue pointing to another queue.

Key concepts

Learn about the key concepts in IBM MQ Advanced Message Security to understand how the tool works and how to manage it effectively.

Public key infrastructure

Public key infrastructure (PKI) is a system of facilities, policies, and services that support the use of public key cryptography to obtain secure communication.

There is no single standard that defines the components of a public key infrastructure, but a PKI typically involves usage of public key certificates and comprises certificate authorities (CA) and other registration authorities (RA) that provide the following services:

- Issuing digital certificates
- Validating digital certificates
- Revoking digital certificates
- Distributing certificates

Identity of users and applications are represented by the **distinguished name (DN)** field in a certificate associated with signed or encrypted messages. IBM MQ Advanced Message Security uses this identity to represent a user or an application. To authenticate this identity, the user or application must have access to the keystore where the certificate and associated private key are stored. Each certificate is represented by a label in the keystore.

Related concepts:

"Using keystores and certificates" on page 874
To provide transparent cryptographic protection to IBM MQ applications, IBM MQ Advanced Message Security uses the keystore file, where public key certificates and a private key are stored. On z/OS, a SAF key ring is used instead of a keystore file.

Digital certificates

IBM MQ Advanced Message Security associates users and applications with X.509 standard digital certificates. X.509 certificates are typically signed by a trusted certificate authority (CA) and involve private and public keys which are used for encryption and decryption.

Digital certificates provide protection against impersonation by binding a public key to its owner, whether that owner is an individual, a queue manager, or some other entity. Digital certificates are also known as public key certificates, because they give you assurance about the ownership of a public key when you use an asymmetric key scheme. This scheme requires that a public key and a private key be generated for an application. Data encrypted with the public key can only be decrypted using the corresponding private key while data encrypted with the private key can only be decrypted using the corresponding public key. The private key is stored in a key database file that is password-protected. Only its owner has the access to the private key used to decrypt messages that are encrypted using the corresponding public key.

If public keys are sent directly by their owner to another entity, there is a risk that the message could be intercepted and the public key substituted by another. This is known as a "man-in-the-middle" attack. The solution is to exchange public keys through a trusted third party, giving the user a strong assurance that the public key belongs to the entity with which you are communicating. Instead of sending your public key directly, you ask a trusted third party to incorporate it into a digital certificate. The trusted third-party who issues digital certificates is called a certificate authority (CA).

For more information about digital certificates, see What is in a digital certificate.

A digital certificate contains the public key for an entity and states that the public key belongs to that entity:

- when a certificate is for an individual entity, it is called a *personal certificate* or *user certificate*.
- when a certificate is for a certificate authority, the certificate is called a *CA certificate* or *signer certificate*.

Note: IBM MQ Advanced Message Security supports self-signed certificates in both Java and native applications

Related information:

Cryptography
Cryptography is the process of converting between readable text, called *plaintext*, and an unreadable form, called *ciphertext*.

Object authority manager

On platforms other than z/OS, the Object Authority Manager (OAM) is the authorization service component supplied with the IBM MQ products.

The access to IBM MQ Advanced Message Security entities is controlled through IBM MQ user groups and the OAM. Administrators can use the command-line interface to grant or revoke authorizations as required. Different groups of users can have different kinds of access authority to the same objects. For example, one group could perform both PUT and GET operations for a specific queue while another group might be allowed only to browse the queue. Similarly, some groups might have GET and PUT authority to a queue, but are not allowed to alter or delete the queue.

Through the OAM, you can control:

- Access to IBM MQ Advanced Message Security objects through MQI. When an application program attempts to access objects, the OAM checks if the user profile making the request has the authorization for the operation requested. This means that queues, and the messages on queues, can be protected from unauthorized access.
- Permission to use PCF and MQSC commands.

Related information:

Object authority manager

Supported technology

IBM MQ Advanced Message Security depends on several technology components to provide a security infrastructure.

IBM MQ Advanced Message Security supports the following IBM MQ application programming interfaces (APIs):

- Message queue interface (MQI)
- IBM MQ Java Message Service (JMS) 1.0.2 and 1.1.
- IBM MQ Base Classes for Java
- IBM MQ classes for .Net in an unmanaged mode

Note: IBM MQ Advanced Message Security supports X.509 compliant certificate authorities.

Known limitations

Learn about limitations of IBM MQ Advanced Message Security.

- The following IBM MQ options are not supported:
  - Publish/subscribe.
  - Channel data conversion.
  - Distribution lists.
  - Application message segmentation
  - The use of non-threaded applications using API exit on HP-UX platforms.
  - IBM MQ classes for .NET in a managed mode (client or bindings connections).
  - Message Service client for .NET (XMS) applications.
  - Message Service client for C/C++ (XMS supportPac IA94) applications.
  - IBM MQ queues processed by the IMS bridge.

  Note: IBM MQ AMS is supported on CICS Bridge queues. You should use the same user ID to MQPUT (encrypt) and MQGET (decrypt) on CICS Bridge queues.
- All Java applications are dependant on IBM Java Runtime. IBM MQ AMS does not support any JRE provided by other vendors.
- Users should avoid putting two or more certificates with the same Distinguished Names in a single keystore file because the IBM MQ AMS interceptor's functioning with such certificates is undefined.
- IBM MQ AMS is not supported in JMS if the **`WMQ_PROVIDER_VERSION`** property is set to 6.

User scenarios

Familiarize yourself with possible scenarios to understand what business goals you can achieve with IBM MQ Advanced Message Security.

Quick Start Guide for IBM MQ AMS on Windows platforms

Use this guide to quickly configure IBM MQ Advanced Message Security to provide message security on Windows platforms. By the time you complete it, you will have created a key database to verify user identities, and defined signing/encryption policies for your queue manager.

Before you begin

You should have at least the following features installed on your system:
- Server
- Development Toolkit (for the Sample programs)
- Advanced Message Security

Refer to IBM MQ features for Windows systems for details.

1. Creating a queue manager and a queue:
About this task

All the following examples use a queue named `TEST.Q` for passing messages between applications. IBM MQ Advanced Message Security uses interceptors to sign and encrypt messages at the point they enter the IBM MQ infrastructure through the standard IBM MQ interface. The basic setup is done in IBM MQ and is configured in the following steps.

You can use IBM MQ Explorer to create the queue manager QM_VERIFY_AMS and its local queue called `TEST.Q` by using all the default wizard settings, or you can use the commands found in `C:\Program Files\IBM\WebSphere MQ\bin`. Remember that you must be a member of the `mqm` user group to run the following administrative commands.

Procedure

1. Create a queue manager
   ```
   crtmqm QM_VERIFY_AMS
   ```
2. Start the queue manager
   ```
   strmqm QM_VERIFY_AMS
   ```
3. Create a queue called `TEST.Q` by entering the following command into **runmqsc** for queue manager `QM_VERIFY_AMS`
   ```
   DEFINE QLOCAL(TEST.Q)
   ```

Results

If the procedure is completed, command entered into **runmqsc** will display details about `TEST.Q`:

```
DISPLAY Q(TEST.Q)
```

2. Creating and authorizing users:
About this task

There are two users that appear in this example: `alice`, the sender, and `bob`, the receiver. To use the application queue, these users need to be granted authority to use it. Also to successfully use the protection policies that we will define these users must be granted access to some system queues. For more information about the **setmqaut** command refer to **setmqaut** .

Procedure

1. Create the two users and ensure that HOMEPATH and HOMEDRIVE are set for both these users.
2. Authorize the users to connect to the queue manager and to work with the queue

   ```
   setmqaut -m QM_VERIFY_AMS -t qmgr -p alice -p bob +connect +inq
   setmqaut -m QM_VERIFY_AMS -n TEST.Q -t queue -p alice +put
   setmqaut -m QM_VERIFY_AMS -n TEST.Q -t queue -p bob +get
   ```

3. You must also allow the two users to browse the system policy queue and put messages on the error queue.

   ```
   setmqaut -m QM_VERIFY_AMS -t queue -n SYSTEM.PROTECTION.POLICY.QUEUE -p alice -p bob +browse
   setmqaut -m QM_VERIFY_AMS -t queue -n SYSTEM.PROTECTION.ERROR.QUEUE -p alice -p bob +put
   ```

Results

Users are now created and the required authorities granted to them.

What to do next

To verify if the steps were carried out correctly, use the amqsput and amqsget samples as described in section “7. Testing the setup” on page 856.

3. Creating key database and certificates:
About this task

Interceptor requires the public key of the sending users to encrypt the message. Thus, the key database of user identities mapped to public and private keys must be created. In the real system, where users and applications are dispersed over several computers, each user would have its own private keystore. Similarly, in this guide, we create key databases for alice and bob and share the user certificates between them.

Note: In this guide, we use sample applications written in C connecting using local bindings. If you plan to use Java applications using client bindings, you must create a JKS keystore and certificates using the **keytool** command, which is part of the JRE (see “Quick Start Guide for IBM MQ AMS with Java clients” on page 863 for more details). For all other languages, and for Java applications using local bindings, the steps in this guide are correct.

Procedure

1. Use the IBM Key Management GUI (strmqikm.exe) to create a new key database for the user alice.

   ```
   Type:       CMS
   Filename:   alicekey.kdb
   Location:   C:/Documents and Settings/alice/AMS
   ```

   Note:
   - It is advisable to use a strong password to secure the database.
   - Make sure that **Stash password to a file** check box is selected.
2. Change the key database content view to **Personal Certificates**.
3. Select **New Self Signed** ; self signed certificates are used in this scenario.
4. Create a certificate identifying the user alice for use in encryption, using these fields:

   ```
   Key label: Alice_Cert
   Common Name: alice
   Organisation: IBM
   Country: GB
   ```

   Note:

- For the purpose of this guide, we are using self-signed certificate which can be created without using a Certificate Authority. For production systems, it is advisable not to use self-signed certificates but instead rely on certificates signed by a Certificate Authority.
- The **`Key label`** parameter specifies the name for the certificate, which interceptors will look up to receive necessary information.
- The **`Common Name`** and optional parameters specifies the details of the **Distinguished Name** (DN), which must be unique for each user.

5. Repeat step 1-4 for the user `bob`

Results

The two users `alice` and `bob` each now have a self-signed certificate.

4. Creating keystore.conf:
About this task

You must point IBM MQ Advanced Message Security interceptors to the directory where the key databases and certificates are located.This is done via the `keystore.conf` file, which hold that information in the plain text form. Each user must have a separate `keystore.conf` file in the `.mqs` folder. This step must be done for both, `alice` and `bob`.

The content of `keystore.conf` should be of the form:

```
cms.keystore = <dir>/keystore_file
cms.certificate = certificate_label
```

Example

For this scenario, the contents of the `keystore.conf` will be as follows:

```
cms.keystore = C:/Documents and Settings/alice/AMS/alicekey
cms.certificate = Alice_Cert
```

Note:
- The path to the keystore file must be provided with no file extension.
- The certificate label can include spaces, thus "Alice_Cert" and "Alice_Cert " (with a space on the end) for example, are recognized as labels of two different certificates. However, to avoid confusion, it is better not to use spaces in label's name.
- There are the following keystore formats: `CMS` (Cryptographic Message Syntax), `JKS` (Java Keystore) and `JCEKS` (Java Cryptographic Extension Keystore). For more information, refer to "Structure of the configuration file" on page 875.
- *`%HOMEDRIVE%\%HOMEPATH%`*`\.mqs\keystore.conf` (eg. C:\Documents and Settings\alice\.mqs\keystore.conf) is the default location where IBM MQ Advanced Message Security searches for the `keystore.conf` file. For information about how to use a non-default location for the `keystore.conf`, see "Using keystores and certificates" on page 874.
- To create `.mqs` directory, you must use the command prompt.

5. Sharing Certificates:
About this task

Share the certificates between the two key databases so that each user can successfully identify the other. This is done by extracting each user's public certificate to a file, which is then added to the other user's key database.

Note: Take care to use the *extract* option, and not the *export* option. *Extract* gets the user's public key, whereas *export* gets both the public and private key. Using *export* by mistake would completely compromise your application, by passing on its private key.

Procedure

1. Extract the certificate identifying `alice` to an external file:
   ```
   runmqakm -cert -extract -db "C:/Documents and Settings/alice/AMS/alicekey.kdb" -pw passw0rd -label Alice_Cert -target al
   ```
2. Add the certificate to `bob's` keystore:
   ```
   runmqakm -cert -add -db "C:/Documents and Settings/bob/AMS/bobkey.kdb" -pw passw0rd -label Alice_Cert -file alice_public
   ```
3. Repeat steps for `bob`:
   ```
   runmqakm -cert -extract -db "C:/Documents and Settings/bob/AMS/bobkey.kdb" -pw passw0rd -label Bob_Cert -target bob_publ
   ```
   ```
   runmqakm -cert -add -db "C:/Documents and Settings/alice/AMS/alicekey.kdb" -pw passw0rd -label Bob_Cert -file bob_public
   ```

Results

The two users `alice` and `bob` are now able to successfully identify each other having created and shared self-signed certificates.

What to do next

Verify that a certificate is in the keystore either by browsing it using the GUI or running the following commands which print out its details:

```
runmqakm -cert -details -db "C:/Documents and Settings/bob/AMS/bobkey.kdb" -pw passw0rd -label Alice_Cert
runmqakm -cert -details -db "C:/Documents and Settings/alice/AMS/alicekey.kdb" -pw passw0rd -label Bob_Cert
```

6. Defining queue policy:
About this task

With the queue manager created and interceptors prepared to intercept messages and access encryption keys, we can start defining protection policies on `QM_VERIFY_AMS` using the `setmqspl` command. Refer to setmqspl for more information on this command. Each policy name must be the same as the queue name it is to be applied to.

Example

This is an example of a policy defined for the `TEST.Q` queue. In the example, messages are signed with the `SHA1` algorithm and encrypted with the `AES256` algorithm. `alice` is the only valid sender and `bob` is the only receiver of the messages on this queue:

```
setmqspl -m QM_VERIFY_AMS -p TEST.Q -s SHA1 -a "CN=alice,O=IBM,C=GB" -e AES256 -r "CN=bob,O=IBM,C=GB"
```

Note: The DNs match exactly those specified in the receptive user's certificate from the key database.

What to do next

To verify the policy you have defined, issue the following command:

```
dspmqspl -m QM_VERIFY_AMS
```

To print the policy details as a set of `setmqspl` commands, the `-export` flag. This allows storing already defined policies:

```
dspmqspl -m QM_VERIFY_AMS -export >restore_my_policies.bat
```

7. Testing the setup:

About this task

By running different programs under different users you can verify if the application has been properly configured.

Procedure

1. Switch user to run as user `alice`

   Right-click `cmd.exe` and select **Run as...**. When prompted, log in as the user `alice`.
2. As the user `alice` put a message using a sample application:
   ```
   amqsput TEST.Q QM_VERIFY_AMS
   ```
3. Type the text of the message, then press Enter.
4. Switch user to run as user `bob`

   Open another window by right-clicking `cmd.exe` and selecting **Run as...**. When prompted, log in as the user `bob`.
5. As the user `bob` get a message using a sample application:
   ```
   amqsget TEST.Q QM_VERIFY_AMS
   ```

Results

If the application has been configured properly for both users, the user `alice` 's message is displayed when `bob` runs the getting application.

8. Testing encryption:
About this task

To verify that the encryption is occurring as expected, create an alias queue which references the original queue `TEST.Q`. This alias queue will have no security policy and so no user will have the information to decrypt the message and therefore the encrypted data will be shown.

Procedure

1. Using the **runmqsc** command against queue manager QM_VERIFY_AMS, create an alias queue.
   ```
   DEFINE QALIAS(TEST.ALIAS) TARGET(TEST.Q)
   ```
2. Grant `bob` access to browse from the alias queue
   ```
   setmqaut -m QM_VERIFY_AMS -n TEST.ALIAS -t queue -p bob +browse
   ```
3. As the user `alice`, put another message using a sample application just as before:
   ```
   amqsput TEST.Q QM_VERIFY_AMS
   ```
4. As the user `bob`, browse the message using a sample application via the alias queue this time:
   ```
   amqsbcg TEST.ALIAS QM_VERIFY_AMS
   ```
5. As the user `bob`, get the message using a sample application from the local queue:
   ```
   amqsget TEST.Q QM_VERIFY_AMS
   ```

Results

The output from the `amqsbcg` application shows the encrypted data that is on the queue proving that the message has been encrypted.

Quick Start Guide for IBM MQ AMS on UNIX platforms

Use this guide to quickly configure IBM MQ Advanced Message Security to provide message security on UNIX platforms. By the time you complete it, you will have created a key database to verify user identities, and defined signing/encryption policies for your queue manager.

Before you begin

You should have at least the following components installed on your system:
- Runtime
- Server
- Sample programs
- IBM Global Security Kit
- MQ Advanced Message Security

Refer to the following topics for the component names on each specific platform:
- IBM MQ components for Linux systems
- IBM MQ components for HP-UX systems
- IBM MQ components for AIX systems
- IBM MQ components for Solaris systems

1. Creating a queue manager and a queue:
About this task

All the following examples use a queue named `TEST.Q` for passing messages between applications. IBM MQ Advanced Message Security uses interceptors to sign and encrypt messages at the point they enter the IBM MQ infrastructure through the standard IBM MQ interface. The basic setup is done in IBM MQ and is configured in the following steps.

You can use IBM MQ Explorer to create the queue manager QM_VERIFY_AMS and its local queue called `TEST.Q` by using all the default wizard settings, or you can use the commands found in `<MQ_INSTALL_PATH>/bin`. Remember that you must be a member of the `mqm` user group to run the following administrative commands.

Procedure

1. Create a queue manager
   ```
   crtmqm QM_VERIFY_AMS
   ```
2. Start the queue manager
   ```
   strmqm QM_VERIFY_AMS
   ```
3. Create a queue called `TEST.Q` by entering the following command into **runmqsc** for queue manager `QM_VERIFY_AMS`
   ```
   DEFINE QLOCAL(TEST.Q)
   ```

Results

If the procedure completed successfully, the following command entered into **runmqsc** will display details about `TEST.Q`:

```
DISPLAY Q(TEST.Q)
```

2. Creating and authorizing users:
About this task

There are two users that appear in this example: `alice`, the sender, and `bob`, the receiver. To use the application queue, these users need to be granted authority to use it. Also to successfully use the protection policies that we will define these users must be granted access to some system queues. For more information about the **setmqaut** command refer to **setmqaut** .

Procedure

1. Create the two users
   ```
   useradd alice
   useradd bob
   ```
2. Authorize the users to connect to the queue manager and to work with the queue
   ```
   setmqaut -m QM_VERIFY_AMS -t qmgr -p alice -p bob +connect +inq
   setmqaut -m QM_VERIFY_AMS -n TEST.Q -t queue -p alice +put
   setmqaut -m QM_VERIFY_AMS -n TEST.Q -t queue -p bob +get
   ```
3. You must also allow the two users to browse the system policy queue and put messages on the error queue.
   ```
   setmqaut -m QM_VERIFY_AMS -t queue -n SYSTEM.PROTECTION.POLICY.QUEUE -p alice -p bob +browse
   setmqaut -m QM_VERIFY_AMS -t queue -n SYSTEM.PROTECTION.ERROR.QUEUE -p alice -p bob +put
   ```

Results

User groups are now created and the required authorities granted to them. This way users who are assigned to those groups will also have permission to connect to the queue manager and to put and get from the queue.

What to do next

To verify if the steps were carried out correctly, use the `amqsput` and `amqsget` samples as described in section "8. Testing encryption" on page 862.

3. Creating key database and certificates:
About this task

To encrypt the message, the interceptor requires the private key of the sending user and the public key(s) of the recipient(s). Thus, the key database of user identities mapped to public and private keys must be created. In the real system, where users and applications are dispersed over several computers, each user would have its own private keystore. Similarly, in this guide, we create key databases for `alice` and `bob` and share the user certificates between them.

Note: In this guide, we use sample applications written in C connecting using local bindings. If you plan to use Java applications using client bindings, you must create a JKS keystore and certificates using the **`keytool`** command, which is part of the JRE (see "Quick Start Guide for IBM MQ AMS with Java clients" on page 863 for more details). For all other languages, and for Java applications using local bindings, the steps in this guide are correct.

Procedure

1. Create a new key database for the user `alice`
   ```
   mkdir /home/alice/.mqs -p
   runmqakm -keydb -create -db /home/alice/.mqs/alicekey.kdb -pw passw0rd -stash
   ```
   Note:
   - It is advisable to use a strong password to secure the database.
   - The `stash` parameter stores the password into the `key.sth` file, which interceptors can use to open the database.
2. Ensure the key database is readable
   ```
   chmod +r /home/alice/.mqs/alicekey.kdb
   ```
3. Create a certificate identifying the user `alice` for use in encryption
   ```
   runmqakm -cert -create -db /home/alice/.mqs/alicekey.kdb -pw passw0rd
   -label Alice_Cert -dn "cn=alice,O=IBM,c=GB" -default_cert yes
   ```

Note:

- For the purpose of this guide, we are using self-signed certificate which can be created without using a Certificate Authority. For production systems, it is advisable not to use self-signed certificates but instead rely on certificates signed by a Certificate Authority.
- The `label` parameter specifies the name for the certificate, which interceptors will look up to receive necessary information.
- The `DN` parameter specifies the details of the **Distinguished Name** (DN), which must be unique for each user.

4. Now we have created the key database, we should set the ownership of it, and ensure it is unreadable by all other users.

   ```
   chown alice /home/alice/.mqs/alicekey.kdb /home/alice/.mqs/alicekey.sth
   chmod 600 /home/alice/.mqs/alicekey.kdb /home/alice/.mqs/alicekey.sth
   ```
5. Repeat step 1-4 for the user `bob`

Results

The two users `alice` and `bob` each now have a self-signed certificate.

4. Creating keystore.conf:
About this task

You must point IBM MQ Advanced Message Security interceptors to the directory where the key databases and certificates are located. This is done via the `keystore.conf` file, which hold that information in the plain text form. Each user must have a separate `keystore.conf` file. This step should be done for both `alice` and `bob`.

The content of `keystore.conf` must be of the form:

```
cms.keystore = <dir>/keystore_file
cms.certificate = certificate_label
```

Example

For this scenario, the contents of the `keystore.conf` will be as follows:

```
cms.keystore = /home/alice/.mqs/alicekey
cms.certificate = Alice_Cert
```

Note:

- The path to the keystore file must be provided with no file extension.
- There are the following keystore formats: `CMS` (Cryptographic Message Syntax), `JKS` (Java Keystore) and `JCEKS` (Java Cryptographic Extension Keystore). For more information, refer to “Structure of the configuration file” on page 875.
- `HOME/.mqs/keystore.conf` is the default location where IBM MQ Advanced Message Security searches for the `keystore.conf` file. For information about how to use a non-default location for the `keystore.conf`, see “Using keystores and certificates” on page 874.

5. Sharing Certificates:
About this task

Share the certificates between the two key databases so that each user can successfully identify the other. This is done by extracting each user's public certificate to a file, which is then added to the other user's key database.

Note: Take care to use the *extract* option, and not the *export* option. *Extract* gets the user's public key, whereas *export* gets both the public and private key. Using *export* by mistake would completely compromise your application, by passing on its private key.

Procedure

1. Extract the certificate identifying `alice` to an external file:
   ```
   runmqakm -cert -extract -db /home/alice/.mqs/alicekey.kdb -pw passw0rd -label Alice_Cert -target alice_public.arm
   ```
2. Add the certificate to `bob's` keystore:
   ```
   runmqakm -cert -add -db /home/bob/.mqs/bobkey.kdb -pw passw0rd -label Alice_Cert -file alice_public.arm
   ```
3. Repeat the step for `bob`:
   ```
   runmqakm -cert -extract -db /home/bob/.mqs/bobkey.kdb -pw passw0rd -label Bob_Cert -target bob_public.arm
   ```
4. Add the certificate for `bob` to `alice's` keystore:
   ```
   runmqakm -cert -add -db /home/alice/.mqs/alicekey.kdb -pw passw0rd -label Bob_Cert -file bob_public.arm
   ```

Results

The two users `alice` and `bob` are now able to successfully identify each other having created and shared self-signed certificates.

What to do next

Verify that a certificate is in the keystore by running the following commands which print out its details:

```
runmqakm -cert -details -db /home/bob/.mqs/bobkey.kdb -pw passw0rd -label Alice_Cert
runmqakm -cert -details -db /home/alice/.mqs/alicekey.kdb -pw passw0rd -label Bob_Cert
```

6. Defining queue policy:
About this task

With the queue manager created and interceptors prepared to intercept messages and access encryption keys, we can start defining protection policies on `QM_VERIFY_AMS` using the `setmqspl` command. Refer to setmqspl for more information on this command. Each policy name must be the same as the queue name it is to be applied to.

Example

This is an example of a policy defined for the `TEST.Q` queue. In this example, messages are signed by the user `alice` using the `SHA1` algorithm, and encrypted using the 256-bit `AES` algorithm. `alice` is the only valid sender and `bob` is the only receiver of the messages on this queue:

```
setmqspl -m QM_VERIFY_AMS -p TEST.Q -s SHA1 -a "CN=alice,O=IBM,C=GB" -e AES256 -r "CN=bob,O=IBM,C=GB"
```

Note: The DNs match exactly those specified in the receptive user's certificate from the key database.

What to do next

To verify the policy you have defined, issue the following command:

```
dspmqspl -m QM_VERIFY_AMS
```

To print the policy details as a set of `setmqspl` commands, the `-export` flag. This allows storing already defined policies:

```
dspmqspl -m QM_VERIFY_AMS -export >restore_my_policies.bat
```

7. Testing the setup:

About this task

By running different programs under different users you can verify if the application has been properly configured.

Procedure

1. Change to the directory containing the samples. If MQ is installed in a non-default location, this may be in a different place.
   ```
   cd /opt/mqm/samp/bin
   ```
2. Switch user to run as user `alice`
   ```
   su alice
   ```
3. As the user `alice`, put a message using a sample application:
   ```
   ./amqsput TEST.Q QM_VERIFY_AMS
   ```
4. Type the text of the message, then press Enter.
5. Stop running as user `alice`
   ```
   exit
   ```
6. Switch user to run as user `bob`
   ```
   su bob
   ```
7. As the user `bob`, get a message using a sample application:
   ```
   ./amqsget TEST.Q QM_VERIFY_AMS
   ```

Results

If the application has been configured properly for both users, the user `alice` 's message is displayed when `bob` runs the getting application.

8. Testing encryption:
About this task

To verify that the encryption is occurring as expected, create an alias queue which references the original queue `TEST.Q`. This alias queue will have no security policy and so no user will have the information to decrypt the message and therefore the encrypted data will be shown.

Procedure

1. Using the **`runmqsc`** command against queue manager QM_VERIFY_AMS, create an alias queue.
   ```
   DEFINE QALIAS(TEST.ALIAS) TARGET(TEST.Q)
   ```
2. Grant `bob` access to browse from the alias queue
   ```
   setmqaut -m QM_VERIFY_AMS -n TEST.ALIAS -t queue -p bob +browse
   ```
3. As the user `alice`, put another message using a sample application just as before:
   ```
   ./amqsput TEST.Q QM_VERIFY_AMS
   ```
4. As the user `bob`, browse the message using a sample application via the alias queue this time:
   ```
   ./amqsbcg TEST.ALIAS QM_VERIFY_AMS
   ```
5. As the user `bob`, get the message using a sample application from the local queue:
   ```
   ./amqsget TEST.Q QM_VERIFY_AMS
   ```

Results

The output from the `amqsbcg` application will show the encrypted data that is on the queue proving that the message has been encrypted.

Quick Start Guide for IBM MQ AMS with Java clients

Use this guide to quickly configure IBM MQ Advanced Message Security to provide message security for Java applications connecting using client bindings. By the time you complete it, you will have created a keystore to verify user identities, and defined signing/encryption policies for your queue manager.

Before you begin

Ensure you have the appropriate components installed as described in the **Quick Start Guide** (Windows or UNIX).

1. Creating a queue manager and a queue:
About this task

All the following examples use a queue named `TEST.Q` for passing messages between applications. IBM MQ Advanced Message Security uses interceptors to sign and encrypt messages at the point they enter the IBM MQ infrastructure through the standard IBM MQ interface. The basic setup is done in IBM MQ and is configured in the following steps.

Procedure

1. Create a queue manager
   ```
   crtmqm QM_VERIFY_AMS
   ```
2. Start the queue manager
   ```
   strmqm QM_VERIFY_AMS
   ```
3. Create and start a listener by entering the following commands into **runmqsc** for queue manager `QM_VERIFY_AMS`
   ```
   DEFINE LISTENER(AMS.LSTR) TRPTYPE(TCP) PORT(1414) CONTROL(QMGR)
   START LISTENER(AMS.LSTR)
   ```
4. Create a channel for our applications to connect in through by entering the following command into **runmqsc** for queue manager `QM_VERIFY_AMS`
   ```
   DEFINE CHANNEL(AMS.SVRCONN) CHLTYPE(SVRCONN)
   ```
5. Create a queue called `TEST.Q` by entering the following command into **runmqsc** for queue manager `QM_VERIFY_AMS`
   ```
   DEFINE QLOCAL(TEST.Q)
   ```

Results

If the procedure completed successfully, the following command entered into **runmqsc** displays details about `TEST.Q`:

```
DISPLAY Q(TEST.Q)
```

2. Creating and authorizing users:
About this task

There are two users that appear in this scenario: `alice`, the sender, and `bob`, the receiver. To use the application queue, these users need to be granted authority to use it. Also to successfully use the protection policies defined in this scenario, these users must be granted access to some system queues. For more information about the **setmqaut** command refer to **setmqaut** .

Procedure

1. Create the two users as described in the **Quick Start Guide** (Windows or UNIX) for your platform.
2. Authorize the users to connect to the queue manager and to work with the queue
   ```
   setmqaut -m QM_VERIFY_AMS -t qmgr -p alice -p bob +connect +inq
   setmqaut -m QM_VERIFY_AMS -n TEST.Q -t queue -p alice +put
   setmqaut -m QM_VERIFY_AMS -n TEST.Q -t queue -p bob +get +inq
   ```

3. You must also allow the two users to browse the system policy queue and put messages on the error queue.

   ```
   setmqaut -m QM_VERIFY_AMS -t queue -n SYSTEM.PROTECTION.POLICY.QUEUE -p alice -p bob +browse
   setmqaut -m QM_VERIFY_AMS -t queue -n SYSTEM.PROTECTION.ERROR.QUEUE -p alice -p bob +put
   ```

Results

Users are now created and the required authorities granted to them.

What to do next

To verify if the steps were carried out correctly, use the `JmsProducer` and `JmsConsumer` samples as described in section "7. Testing the setup" on page 866.

3. Creating key database and certificates:
About this task

To encrypt the message to interceptor requires the public key of the sending users. Thus, the key database of user identities mapped to public and private keys must be created. In the real system, where users and applications are dispersed over several computer, each user would have its own private keystore. Similarly, in this guide, we create key databases for `alice` and `bob` and share the user certificates between them.

Note: In this guide, we use sample applications written in Java connecting using client bindings. If you plan to use Java applications using local bindings or C applications, you must create a CMS keystore and certificates using the **`runmqakm`** command. This is shown in the **Quick Start Guide** (Windows or UNIX).

Procedure

1. Create a directory in which to create your keystore, for example `/home/alice/.mqs`. You might wish to create it in the same directory as used by the **Quick Start Guide** (Windows or UNIX) for your platform.

   Note: This directory is referred to as *keystore-dir* in the following steps
2. Create a new keystore and certificate identifying the user `alice` for use in encryption

   Note: The **`keytool`** command is part of the JRE.

   ```
   keytool -genkey -alias Alice_Java_Cert -keyalg RSA -keystore keystore-dir/keystore.jks -storepass passw0rd
   -dname "CN=alice, O=IBM, C=GB" -keypass passw0rd
   ```

   Note:
   - If your *keystore-dir* contains spaces, you must put quotes round the full name of your keystore
   - It is advisable to use a strong password to secure the keystore.
   - For the purpose of this guide, we are using self-signed certificate which can be created without using a Certificate Authority. For production systems, it is advisable not to use self-signed certificates but instead rely on certificates signed by a Certificate Authority.
   - The `alias` parameter specifies the name for the certificate, which interceptors will look up to receive necessary information.
   - The `dname` parameter specifies the details of the **Distinguished Name** (DN), which must be unique for each user.
3. On UNIX, ensure the keystore is readable

   ```
   chmod +r keystore-dir/keystore.jks
   ```
4. Repeat step1-4 for the user `bob`

Results

The two users `alice` and `bob` each now have a self-signed certificate.

4. Creating keystore.conf:
About this task

You must point IBM MQ Advanced Message Security interceptors to the directory where the key databases and certificates are located. This is done via the `keystore.conf` file, which hold that information in the plain text form. Each user must have a separate `keystore.conf` file. This step should be done for both `alice` and `bob`.

Example

For this scenario, the contents of the `keystore.conf` for `alice` are as follows:

```
JKS.keystore = keystore-dir/keystore
JKS.certificate = Alice_Java_Cert
JKS.encrypted = no
JKS.keystore_pass = passw0rd
JKS.key_pass = passw0rd
JKS.provider = IBMJCE
```

For this scenario, the contents of the `keystore.conf` for `bob` are as follows:

```
JKS.keystore = keystore-dir/keystore
JKS.certificate = Bob_Java_Cert
JKS.encrypted = no
JKS.keystore_pass = passw0rd
JKS.key_pass = passw0rd
JKS.provider = IBMJCE
```

Note:
- The path to the keystore file must be provided with no file extension.
- If you already have a `keystore.conf` file because you have followed the instructions in the Quick Start Guide (Windows or UNIX), you can edit the existing file to add these lines.

5. Sharing certificates:
About this task

Share the certificates between the two keystores so that each user can successfully identify the other. This is done by extracting each user's certificate and importing it into the other user's keystore.

Note: The terms *extract* and *export* are used differently by different certificate tools. For example the IBM GSKit Keyman (ikeyman) tool makes a distinction that you *extract* certificates (public keys) and you *export* private keys. This distinction is extremely important for tools that offer both options, since using *export* by mistake would completely compromise your application by passing on its private key. Because the distinction is so important, the IBM MQ documentation strives to use these terms consistently. However, the Java keytool provides a command line option called *exportcert* that extracts only the public key. For these reasons, the following procedure refers to *extracting* certificates by using the *exportcert* option.

Procedure

1. Extract the certificate identifying `alice`.

   ```
   keytool -exportcert -keystore alice-keystore-dir/keystore.jks -storepass passw0rd
   -alias Alice_Java_Cert -file alice-keystore-dir/Alice_Java_Cert.cer
   ```

2. Import the certificate identifying `alice` into the keystore that `bob` will use. When prompted indicate that you will trust this certificate.

```
keytool -importcert -file alice-keystore-dir/Alice_Java_Cert.cer -alias Alice_Java_Cert
-keystore bob-keystore-dir/keystore.jks -storepass passw0rd
```

3. Repeat the steps for `bob`

Results

The two users `alice` and `bob` are now able to successfully identify each other having created and shared self-signed certificates.

What to do next

Verify that a certificate is in the keystore by running the following commands which print out its details:

```
keytool -list -keystore bob-keystore-dir/keystore.jks -storepass passw0rd -alias Alice_Java_Cert
keytool -list -keystore alice-keystore-dir/keystore.jks -storepass passw0rd -alias Bob_Java_Cert
```

6. Defining queue policy:
About this task

With the queue manager created and interceptors prepared to intercept messages and access encryption keys, we can start defining protection policies on `QM_VERIFY_AMS` using the `setmqspl` command. Refer to setmqspl for more information on this command. Each policy name must be the same as the queue name it is to be applied to.

Example

This is an example of a policy defined on the `TEST.Q` queue, signed by the user `alice` using the `SHA1` algorithm, and encrypted using the 256-bit `AES` algorithm for the user `bob`:

```
setmqspl -m QM_VERIFY_AMS -p TEST.Q -s SHA1 -a "CN=alice,O=IBM,C=GB" -e AES256 -r "CN=bob,O=IBM,C=GB"
```

Note: The DNs match exactly those specified in the receptive user's certificate from the key database.

What to do next

To verify the policy you have defined, issue the following command:

```
dspmqspl -m QM_VERIFY_AMS
```

To print the policy details as a set of `setmqspl` commands, the `-export` flag. This allows storing already defined policies:

```
dspmqspl -m QM_VERIFY_AMS -export >restore_my_policies.bat
```

7. Testing the setup:
Before you begin

Ensure the version of Java you are using has the unrestricted JCE policy files installed.

Go to Unrestricted SDK JCE policy files to download the correct policy files if needed.

Note: The version of Java supplied in the IBM MQ installation already has these policy files. It can be found in *MQ_INSTALLATION_PATH*/java/bin.

About this task

By running different programs under different users you can verify if the application has been properly configured. Refer to the **Quick Start Guide** (Windows or UNIX) for your platform, for details about running programs under different users.

Procedure

1. To run these JMS sample applications, use the CLASSPATH setting for your platform as shown in Environment variables used by IBM MQ classes for JMS to ensure the samples directory is included.
2. As the user `alice`, put a message using a sample application, connecting as a client:
   ```
   java JMSProducer -m QM_VERIFY_AMS -d TEST.Q -h localhost -p 1414 -l AMS.SVRCONN
   ```
3. As the user `bob`, get a message using a sample application, connecting as a client:
   ```
   java JMSConsumer -m QM_VERIFY_AMS -d TEST.Q -h localhost -p 1414 -l AMS.SVRCONN
   ```

Results

If the application has been configured properly for both users, the user `alice` 's message is displayed when `bob` runs the getting application.

Protecting remote queues

To fully protect remote queue connections, the same policy must be set on the remote queue and local queue to which messages are transmitted.

When a message is put into a remote queue, IBM MQ Advanced Message Security intercepts the operation and processes the message according to a policy set for the remote queue. For example, for an encryption policy, the message is encrypted before it is passed to the IBM MQ to handle it. After IBM MQ Advanced Message Security has processed the message put into a remote queue, IBM MQ puts it into associated transmission queue and forwards it to the target queue manager and target queue.

When a GET operation is performed on the local queue, IBM MQ Advanced Message Security tries to decode the message according to the policy set on the local queue. For the operation to succeed, the policy used to decrypt the message must be identical to the one used to encrypt it. Any discrepancy will cause the message to be rejected.

If for any reason both policies cannot be set at the same time, a staged roll-out support is provided. The policy can be set on a local queue with toleration flag on, which indicates that a policy associated with a queue can be ignored when an attempt to retrieve a message from the queue involves a message that does not have the security policy set. In this case, GET will try to decrypt the message, but will allow non-encrypted messages to be delivered. This way policies on remote queues can be set after the local queues has been protected (and tested).

Remember: Remove the toleration flag once the IBM MQ Advanced Message Security roll-out has been completed.

Routing protected messages using IBM Integration Bus

IBM MQ Advanced Message Security can protect messages in an infrastructure where IBM Integration Bus, or WebSphere Message Broker Version 8.0.0.1 (or later) is installed. You should understand the nature of both products before applying security in the IBM Integration Bus environment.

About this task

IBM MQ Advanced Message Security provides end-to-end security of the message payload. This means that only the parties specified as the valid senders and recipients of a message are capable of producing or receiving it. This implies that in order to secure messages flowing through IBM Integration Bus, you can either allow IBM Integration Bus to process messages without knowing their content (Scenario 1) or make it an authorized user able to receive and send messages (Scenario 2).

Scenario 1 - Integration Bus cannot see message content:
Before you begin

You should have your IBM Integration Bus connected to an existing queue manager. Replace `QMgrName` with this existing queue manager name in the commands that follow.

About this task

In this scenario, Alice puts a protected message into an input queue `QIN`. Based on the message property `routeTo`, the message is routed either to *bob's* (`QBOB`),[2] (`QCECIL`), or the default (`QDEF`) queue. The routing is possible because IBM MQ Advanced Message Security protects only the message payload and not its headers and properties which remain unprotected and can be read by IBM Integration Bus. IBM MQ Advanced Message Security is used only by *alice*, *bob* and *cecil*. It is not necessary to install or configure it for the IBM Integration Bus.

IBM Integration Bus receives the protected message from the unprotected alias queue in order to avoid any attempt to decrypt the message. If it were to use the protected queue directly, the message would be put onto the DEAD LETTER queue as impossible to decrypt. The message is routed by IBM Integration Bus and arrives on the target queue unchanged. Therefore it is still signed by the original author (both *bob* and *cecil* only accept messages sent by *alice*) and protected as before (only *bob* and *cecil* can read it). IBM Integration Bus puts the routed message to an unprotected alias. The recipients retrieve the message from a protected output queue where IBM MQ AMS will transparently decrypt the message.

Procedure

1. Configure *alice*, *bob* and *cecil* to use IBM MQ Advanced Message Security as described in the **Quick Start Guide** (Windows or UNIX). Ensure the following steps are completed:
   - Creating and authorizing users
   - Creating Key Database and Certificates
   - Creating keystore.conf
2. Provide *alice's* certificate to *bob* and *cecil*, so *alice* can be identified by them when checking digital signatures on messages.

   Do this by extracting the certificate identifying *alice* to an external file, then adding the extracted certificate to *bob's* and *cecil's* keystores. It is important that you use the method described in **Task 5. Sharing Certificates** in the **Quick Start Guide** (Windows or UNIX).
3. Provide *bob* and *cecil's* certificates to *alice*, so *alice* can send messages encrypted for *bob* and *cecil*.

   Do this using the method specified in the previous step.
4. On your queue manager, define local queues called `QIN`, `QBOB`, `QCECIL` and `QDEF`.
   ```
   DEFINE QLOCAL(QIN)
   ```

2. cecil's

5. Setup the security policy for the QIN queue to an eligible configuration. Use the identical setup for the QBOB, QCECIL and QDEF queues.

   ```
   setmqspl -m QMgrName -p QIN -s SHA1 -a "CN=alice,O=IBM,C=GB"
   -e AES256 -r "CN=bob,O=IBM,C=GB" -r "CN=cecil,O=IBM,C=GB"
   ```

   This scenario assumes the security policy where *alice* is the only authorized sender and *bob* and *cecil* are the recipients.
6. Define alias queues AIN, ABOB and ACECIL referencing local queues QIN, QBOB and QCECIL respectively.

   ```
   DEFINE QALIAS(AIN) TARGET(QIN)
   ```
7. Verify that the security configuration for the aliases specified in the previous step is not present; otherwise set its policy to NONE.

   ```
   dspmqspl -m QMgrName -p AIN
   ```
8. In IBM Integration Bus create a message flow to route the messages arriving on the AIN alias queue to the BOB, CECIL, or DEF node depending on the routeTo property of the message. To do so:
   a. Create an MQInput node called IN and assign the AIN alias as its queue name.
   b. Create MQOutput nodes called BOB, CECIL and DEF, and assign alias queues ABOB, ACECIL and ADEF as their respective queue names.
   c. Create a route node and call it TEST.
   d. Connect the IN node to the input terminal of the TEST node.
   e. Create bob, and cecil output terminals for the TEST node.
   f. Connect the bob output terminal to the BOB node.
   g. Connect the cecil output terminal to the CECIL node.
   h. Connect the DEF node to the default output terminal.
   i. Apply the following rules:

      ```
      $Root/MQRFH2/usr/routeTo/text()="bob"
      $Root/MQRFH2/usr/routeTo/text()="cecil"
      ```
9. Deploy the message flow to the IBM Integration Bus runtime component.
10. Running as the user Alice put a message that also contains a message property called routeTo with a value of either bob or cecil. Running the sample application **amqsstm** will allow you to do this.

    ```
    Sample AMQSSTMA start
    target queue is TEST.Q
    Enter property name
    routeTo
    Enter property value
    bob
    Enter property name

    Enter message text
    My Message to Bob
    Sample AMQSSTMA end
    ```
11. Running as user *bob* retrieve the message from the queue QBOB using the sample application **amqsget**.

Results

When *alice* puts a message on the QIN queue, the message is protected. It is retrieved in protected form by the IBM Integration Bus from the AIN alias queue. IBM Integration Bus decides where to route the message reading the routeTo property which is, as all properties, not encrypted. IBM Integration Bus places the message on the appropriate unprotected alias avoiding its further protection. When received by *bob* or *cecil* from the queue, the message is decrypted and the digital signature is verified.

Scenario 2 - Integration Bus can see message content:

About this task

In this scenario, a group of individuals are allowed to send messages to IBM Integration Bus. Another group are authorized to receive messages which are created by IBM Integration Bus. The transmission between the parties and IBM Integration Bus cannot be eavesdropped.

Remember that IBM Integration Bus reads protection policies and certificates only when a queue is opened, so you must reload the execution group after making any updates to protection policies for the changes to take effect.

```
mqsireload execution-group-name
```

If IBM Integration Bus is considered an authorized party allowed to read or sign the message payload, you must configure IBM MQ Advanced Message Security for the user starting the IBM Integration Bus service. Be aware it is not necessarily the same user who puts/gets the messages onto queues nor the user creating and deploying the IBM Integration Bus applications.

Procedure

1. Configure *alice*, *bob*, *cecil* and *dave* and the IBM Integration Bus service user, to use IBM MQ Advanced Message Security as described in the **Quick Start Guide** (Windows or UNIX). Ensure the following steps are completed:
   - Creating and authorizing users
   - Creating Key Database and Certificates
   - Creating keystore.conf
2. Provide *alice*, *bob*, *cecil* and *dave's* certificates to the IBM Integration Bus service user.

   Do this by extracting each of the certificates identifying *alice*, *bob*, *cecil* and *dave* to external files, then adding the extracted certificates to the IBM Integration Bus keystore. It is important that you use the method described in **Task 5. Sharing Certificates** in the **Quick Start Guide** (Windows or UNIX).
3. Provide the IBM Integration Bus service user's certificate to *alice*, *bob*, *cecil* and *dave*.

   Do this using the method specified in the previous step.

   Note: *Alice* and *bob* need the IBM Integration Bus service user's certificate to encrypt the messages correctly. The IBM Integration Bus service user needs *alice's* and *bob's* certificates to verify authors of the messages. The IBM Integration Bus service user needs *cecil's* and *dave's* certificates to encrypt the messages for them. *cecil* and *dave* need the IBM Integration Bus service user's certificate to verify if the message comes from IBM Integration Bus.
4. Define a local queue named `IN` and define the security policy with *alice* and *bob* specified as authors, and the service user for the IBM Integration Bus specified as recipient:
   ```
   setmqspl -m QMgrName -p IN -s MD5 -a "CN=alice,O=IBM,C=GB" -a "CN=bob,O=IBM,C=GB"
   -e AES256 -r "CN=broker,O=IBM,C=GB"
   ```
5. Define a local queue named `OUT`, and define the security policy with the service user for the IBM Integration Bus specified as author, and *cecil* and *dave* specified as recipients:
   ```
   setmqspl -m QMgrName -p OUT -s MD5 -a "CN=broker,O=IBM,C=GB" -e AES256
   -r "CN=cecil,O=IBM,C=GB" -r "CN=dave,O=IBM,C=GB"
   ```
6. In IBM Integration Bus create a message flow with an `MQInput` and `MQOutput` node. Configure the `MQInput` node to use the `IN` queue and the `MQOutput` node to use the `OUT` queue.
7. Deploy the message flow to the IBM Integration Bus runtime component.
8. Running as user *alice* or *bob* put a message on the queue `IN` using the sample application **`amqsput`**.
9. Running as user *cecil* or *dave* retrieve the message from the queue `OUT` using the sample application **`amqsget`**.

Results

Messages sent by *alice* or *bob* to the input queue `IN` are encrypted allowing only IBM Integration Bus to read it. IBM Integration Bus only accepts messages from *alice* and *bob* and rejects any others. The accepted messages are appropriately processed, then signed and encrypted with *cecil's* and *dave's* keys before being put onto the output queue `OUT`. Only *cecil* and *dave* are capable of reading it, messages not signed by IBM Integration Bus are rejected.

Using IBM MQ AMS with IBM MQ Managed File Transfer

This scenario explains how to configure IBM MQ Advanced Message Security to provide message privacy for data being sent through an IBM MQ Managed File Transfer.

Before you begin

Ensure that you have IBM MQ Advanced Message Security component installed on the IBM MQ installation hosting the queues used by IBM MQ Managed File Transfer that you wish to protect.

If your IBM MQ Managed File Transfer agents are connecting in bindings mode, ensure you also have the GSKit component installed on their local installation.

About this task

When transfer of data between two IBM MQ Managed File Transfer agents is interrupted, possibly confidential data might remain unprotected on the underlying IBM MQ queues used to manage the transfer. This scenario explains how to configure and use IBM MQ Advanced Message Security to protect such data on the IBM MQ Managed File Transfer queues.

In this scenario we consider a simple topology comprising one machine with two IBM MQ Managed File Transfer queues. Agents, `AGENT1` and `AGENT2` sharing a single queue manager, `hubQM`, as is described in the scenario Scenario overview. Both agents are connecting in the same way, either in bindings mode or client mode.

1. Creating certificates:
Before you begin

This scenario uses a simple model where a user `ftagent` in a group `FTAGENTS` is used to run the IBM MQ Managed File Transfer agent processes. If you are using your own user and group names, change the commands accordingly.

About this task

IBM MQ Advanced Message Security uses public key cryptography to sign and/or encrypt messages on protected queues.

Note:
- If your IBM MQ Managed File Transfer agents are running in bindings mode, the commands that you use to create a CMS (Cryptographic Message Syntax) keystore are detailed in the **Quick Start Guide** (Windows or UNIX) for your platform.
- If your IBM MQ Managed File Transfer agents are running in client mode, the commands you will need to create a JKS (Java Keystore) are detailed in the "Quick Start Guide for IBM MQ AMS with Java clients" on page 863.

Procedure
1. Create a self-signed certificate to identify the user `ftagent` as detailed in the appropriate Quick Start Guide. Use a Distinguished Name (DN) as follows:

```
CN=ftagent, OU=MFT, O=IBM, L=Hursley, ST=Hampshire, C=GB
```

2. Create a `keystore.conf` file to identify the location of the keystore and the certificate within it as detailed in the appropriate Quick Start Guide.

2. Configuring message protection:
About this task

You should define a security policy for the data queue used by `AGENT2`, using the **`setmqspl`** command. In this scenario the same user is used to start both agents, and therefore the signer and receiver DN are the same and match the certificate we generated.

Procedure

1. Shut down the IBM MQ Managed File Transfer agents in preparation for protection using the **`fteStopAgent`** command.
2. Create a security policy to protect the `SYSTEM.FTE.DATA.AGENT2` queue.
   ```
   setmqspl -m hubQM -p SYSTEM.FTE.DATA.AGENT2 -s SHA1 -a "CN=ftagent, OU=MFT, O=IBM, L=Hursley, ST=Hampshire, C=GB"
   -e AES128 -r "CN=ftagent, OU=MFT, O=IBM, L=Hursley, ST=Hampshire, C=GB"
   ```
3. Ensure the user running the IBM MQ Managed File Transfer agent process has access to browse the system policy queue and put messages on the error queue.
   ```
   setmqaut -m hubQM -t queue -n SYSTEM.PROTECTION.POLICY.QUEUE -p ftagent +browse
   setmqaut -m hubQM -t queue -n SYSTEM.PROTECTION.ERROR.QUEUE -p ftagent +put
   ```
4. Restart your IBM MQ Managed File Transfer agents using the **`fteStartAgent`** command.
5. Confirm that your agents restarted successfully by using the **`fteListAgents`** command and verifying that the agents are in `READY` status.

Results

You are now able to submit transfers from `AGENT1` to `AGENT2`, and the file contents will be transmitted securely between the two agents.

Installing IBM MQ Advanced Message Security

Install IBM MQ Advanced Message Security component on various platforms.

About this task

For complete installation procedures, see Installing IBM MQ Advanced Message Security .

Related tasks:
Uninstalling IBM MQ Advanced Message Security

Auditing on z/OS

IBM MQ Advanced Message Security for z/OS provides a means for optional auditing of MQI operations on policy-protected queues. When enabled, IBM System Management Facility (SMF) audit records are generated for the success and failure of these operations on policy-protected queues. Operations audited include MQPUT, MQPUT1, and MQGET.

Auditing is disabled by default, however, you can activate auditing by configuring _AMS_SMF_TYPE and _AMS_SMF_AUDIT in the configured Language Environment® _CEE_ENVFILE file for the AMS address space. For more information, see Task 24: Create procedures for Advanced Message Security. The _AMS_SMF_TYPE variable is used to designate the SMF record type and is a number between 128 and 255. A SMF record type of 180 is usual, however is not mandatory. Auditing is disabled by specifying a value of 0. The _AMS_SMF_AUDIT variable configures whether audit records are created for MQI operations that are successful, MQI operations that fail, or both. The auditing options can also be dynamically changed while AMS is active using operator commands. For more information, see Operating IBM MQ Advanced Message Security.

The SMF record is defined using subtypes, with subtype 1 being a general auditing event. The SMF record contains all data relevant to the request being processed.

The SMF record is mapped by the CSQ0KSMF macro (note the zero in the macro name), which is provided in the target library SCSQMACS. If you are writing data-reduction programs for SMF data, you can include this mapping macro to aid in the development and customization of SMF post-processing routines.

In the SMF records produced by IBM MQ Advanced Message Security for z/OS, the data is organized into sections. The record consists of:

- a standard SMF header
- a header extension defined by IBM MQ Advanced Message Security for z/OS
- a product section
- a data section

The product section of the SMF record is always present in the records produced by IBM MQ Advanced Message Security for z/OS. The data section varies based on subtype. Currently, one subtype is defined and therefore a single data section is used.

SMF is described in the z/OS System Management Facilities manual (SA22-7630). Valid record types are described in the SMFPRMxx member of your system PARMLIB data set. See SMF documentation for more information.

IBM MQ Advanced Message Security audit report generator (CSQ0USMF)

IBM MQ Advanced Message Security (AMS) for z/OS provides an audit report generator tool called CSQ0USMF which is provided in the installation SCSQAUTH library. Sample JCL to run the CSQ0USMF utility called CSQ40RSM is provided in the installation library SCSQPROC.

As an example, the following JCL dumps SMF type 180 records from an SMF data set, and transfers them to a target data set.

```
//IFAUDUMP EXEC PGM=IFASMFDP
//INDD1 DD DSN=SYSn.MANn.syst,DISP=SHR
//OUTDD1 DD DSN=your.target.dataset,DISP=SHR
//SYSPRINT DD SYSOUT=*
//SYSIN DD *
INDD(INDD1,OPTIONS(DUMP))
OUTDD(OUTDD1,TYPE(180))
/*
```

You must verify the actual SMF data set names used by your installation. The target data set for the dumped records must have a record format of VBS, and a record length of 32760.

The target data set can then be used as input to the CSQ0USMF utility to produce an AMS audit report. For example:

```
//STEP1 EXEC PGM=CSQ0USMF,
// PARM=('/ -SMFTYPE 180 -M qmgr')
//STEPLIB DD DSN=thlqual.SCSQANLE,DISP=SHR
//    DD DSN=thlqual.SCSQAUTH,DISP=SHR
//SMFIN DD DSN=your.target.dataset,DISP=SHR
//
```

The CSQ0USMF program accepts two optional parameters, which are listed in the following table:

Table 94. CSQ0USMF optional parameters

Parameter	Value	Description
SMFTYPE	nnn	The SMF record type applicable to the audit report. The CSQ0USMF program uses only SMF records that match the SMFTYPE value when generating the report. If you do not specify SMFTYPE, a default value of 180 is used.
M	qmgr	The WMQ queue manager name applicable to the audit report. If you do not specify the -M parameter, the audit report will include all audit records for all queue managers represented in the SMFIN data set.

Using keystores and certificates

To provide transparent cryptographic protection to IBM MQ applications, IBM MQ Advanced Message Security uses the keystore file, where public key certificates and a private key are stored. On z/OS, a SAF key ring is used instead of a keystore file.

In IBM MQ Advanced Message Security, users and applications are represented by public key infrastructure (PKI) identities. This type of identity is used to sign and encrypt messages. The PKI identity is represented by the subject's **distinguished name (DN)** field in a certificate that is associated with signed and encrypted messages. For a user or application to encrypt their messages they require access to the keystore file where certificates and associated private and public keys are stored.

On Windows and UNIX the location of the keystore is provided in the keystore configuration file, which is `keystore.conf` by default. Each IBM MQ Advanced Message Security user must have the keystore configuration file that points to a keystore file. IBM MQ Advanced Message Security accepts the following format of keystore files: `.kdb`, `.jceks`, `.jks`.

The default location of the `keystore.conf` file is:
- On UNIX platforms and IBM i: `$HOME/.mqs/`
- On Windows platforms: `%HOMEDRIVE%%HOMEPATH%\.mqs\keystore.conf`

If you are using a specified keystore filename and location, you should use the following commands
- For Java: `java -D MQS_KEYSTORE_CONF = <path>/<filename> <app_name>`
- For C Client and Server:
  - On UNIX platforms: `export MQS_KEYSTORE_CONF= <path> /<filename>`
  - On Windows platforms: `set MQS_KEYSTORE_CONF= <path> \<filename>`

Related concepts:

"Sender distinguished names" on page 898
The sender distinguished names (DNs) identify users who are authorized to place messages on a queue.

"Recipient distinguished names" on page 899
The recipient distinguished names (DN) identify users who are authorized to retrieve messages from a queue.

Structure of the configuration file

The configuration file points IBM MQ Advanced Message Security to the location of the appropriate keystore.

Each of the five configuration file types has a prefix:

CMS Certificate Management System, configuration entries are prefixed with: `cms.`

PKCS#11
Public Key Cryptography Standard #11, configuration entries are prefixed with: `pkcs11.`

PEM Privacy Enhanced Mail format, configuration entries are prefixed with: `pem.`

JKS Java KeyStore, configuration entries are prefixed with: `jks.`

JCEKS
Java Cryptographic Encryption KeyStore, configuration entries are prefixed with: `jceks.`

Example structures for keystores:

CMS

```
cms.keystore = /<dir>/<keystore_file>
cms.certificate = certificate_label
```

PKCS#11

```
pkcs11.library = <dir>\cryptoki.dll
pkcs11.certificate = <certificatelabel>
pkcs11.token = <tokenlabel>
pkcs11.token_pin = <tokenpin>
pkcs11.secondary_keystore = <dir>\signers
```

PEM

```
pem.private = /<dir>/< keystore_file_private_key >
pem.public = /<dir>/< keystore_file_public_keys >
pem.password = <password>
```

Java JKS

```
jks.keystore = <dir>/Keystore
jks.certificate = <certificate_label >
jks.encrypted = no
jks.keystore_pass = <password>
jks.key_pass = <password>
jks.provider = IBMJCE
```

Java JCEKS

```
jceks.keystore = <dir>/Keystore
jceks.certificate = <certificate_label>
jceks.encrypted = no
jceks.keystore_pass = <password>
jceks.key_pass = <password>
jceks.provider = IBMJCE
```

Table 95. Summary of parameters needed for each configuration file type

Parameters	Configuration file type			
	Java (JKS and JCEKS)	**PEM**	**PKCS#11**	**CMS**
`keystore`	✓			
`private`		✓		
`public`		✓		
`password`		✓		
`library`			✓	
`certificate`	✓		✓	✓
`token`			✓	
`token_pin`			✓	
`secondary_keystore`			✓	
`encrypted`	✓			
`keystore_pass`	✓			
`provider`	✓			

Configuration file parameters are defined as follows:

`keystore`
CMS and Java configuration only. Path to the keystore file.

Important:
- The path to the keystore file must not include the file extension.

`private`
PEM configuration only. File name of a file that contains private key and certificate in PEM format.

`public`
PEM configuration only. File name of a file that contains trusted public certificates in PEM format.

`password`
PEM configuration only. Password that is used to decrypt an encrypted private key.

`library`
PKCS#11 only. Path name of the PKCS#11 library.

`certificate`
CMS, PKCS#11 and Java configuration only. Certificate label.

`token`
PKCS#11 only. Token label.

token_pin
PKCS#11 only. PIN to unlock the token.

secondary_keystore
PKCS#11 only. Path name of the CMS keystore, provided without the `.kdb` extension, that contains anchor certificates (root certificates) required by certificates stored on the PKCS #11 token. The secondary keystore can also contain certificates that are intermediate in the trust chain, as well as recipient certificates that are defined in the privacy security policy. This CMS keystore must be accompanied by a stash file which must be located in the same directory as the secondary keystore.

encrypted
Java configuration only. Status of the password.

keystore_pass
Java configuration only. Password for the keystore file.

Note:
- For the CMS keystore, IBM MQ AMS relies on the stash files (`.sth`), whereas JKS and JCEKS might require a password for both the certificate and the user's private key.
-

  Important: Storing passwords in plain text form is a security risk.

key_pass
Java configuration only. Password for the user's private key.

Important: Storing passwords in plain text form is a security risk.

provider
Java configuration only. The Java security provider that implements cryptographic algorithms required by the keystore certificate.

Note: Currently, IBMJCE is the only provider that is supported by IBM MQ Advanced Message Security.

Important: Information that is stored in the keystore is crucial for the secure flow of data that is sent by using IBM MQ. Security administrators must pay particular attention when they are assigning file permissions to these files.

For more information about managing the keystore by using GSKit commands, see GSKCapiCmd program users guide.

Example of the `keystore.conf` file:

```
cms.keystore = c:\Documents and Settings\Alice\AliceKeystore
cms.certificate = AliceCert

jceks.keystore = c:/Documents and Settings/Alice/AliceKeystore
jceks.certificate = AliceCert
jceks.encrypted = no
jceks.keystore_pass = <passw0rd >
jceks.key_pass = <passw0rd >
jceks.provider = IBMJCE
```

Related tasks:

"Protecting passwords in Java" on page 889
Storing keystore and private key passwords as plain text poses a security risk so IBM MQ Advanced Message Security provides a tool that can scramble those passwords using a user's key, which is available in the keystore file.

Message Channel Agent (MCA) interception

MCA interception enables a queue manager running under IBM MQ to selectively enable policies to be applied for server connection channels.

MCA interception allows clients that remain outside IBM MQ Advanced Message Security to still be connected to a queue manager and their messages to be encrypted and decrypted.

MCA interception is intended to provide IBM MQ AMS capability when IBM MQ AMS cannot be enabled at the client. Note that using MCA interception and an IBM MQ AMS-enabled client leads to double-protection of messages which might be problematic for receiving applications. For more information, see "Environment variables used to disable IBM MQ AMS at the client" on page 880.

Keystore configuration file

By default, the keystore configuration file for MCA interception is `keystore.conf` and is located in the `.mqs` directory in the HOME directory path of the user who started the queue manager or the listener. The keystore can also be configured by using the MQS_KEYSTORE_CONF environment variable. For more information about configuring the IBM MQ AMS keystore, see "Using keystores and certificates" on page 874.

To enable MCA interception, you must provide the name of a channel that you want to use in the keystore configuration file. In the specific case of MCA Interception, only a cms keystore type can be used.

For an example on setting up MCA interception, see "IBM MQ Advanced Message Security MCA interception example" on page 879.

Attention: You must complete client authentication and encryption on the selected channels, for example, by using SSL and SSLPEER or CHLAUTH TYPE(SSLPEERMAP), to ensure that only authorized clients can connect and use this capability.

IBM i

If your enterprise uses IBM i, and you selected a commercial Certificate Authority (CA) to sign your certificate, the Digital Certificate Manager creates a certificate request in PEM (Privacy-Enhanced Mail) format. You must forward the request to your chosen CA.

To do this, you must use the following command to select the correct certificate for the channel specified in `channelname`:

```
pem.certificate.channel.<channelname>
```

IBM MQ Advanced Message Security MCA interception example

An example task on how you setup an IBM MQ AMS MCA interception.

Before you begin

Attention: You must complete client authentication and encryption on the selected channels, for example, by using SSL and SSLPEER or CHLAUTH TYPE(SSLPEERMAP), to ensure that only authorized clients can connect and use this capability.

IBM i If your enterprise uses IBM i, and you selected a commercial Certificate Authority (CA) to sign your certificate, the Digital Certificate Manager creates a certificate request in PEM (Privacy-Enhanced Mail) format. You must forward the request to your chosen CA.

About this task

This task takes you through the process of setting up your system to use MCA interception, then verifying the setup.

Note: Prior to IBM WebSphere MQ Version 7.5, IBM MQ AMS was an add-on product that needed to be separately installed and interceptors configured to protect applications. From Version 7.5 onwards, the interceptors are automatically included and dynamically enabled in the MQ client and server runtime environments. In this MCA interception example, the interceptors are provided at the server end of the channel, and an older client runtime is used (in Step 12) to put an unprotected messages across the channel so that it can be seen to be protected by the MCA interceptors. If this example had used a Version 7.5 or later client, it would cause the message to be protected twice, because the MQ client runtime interceptor and the MCA interceptor would both protect the message as it comes into MQ.

Attention: Replace `userID` in the code with your user ID.

Procedure

1. Create the key database and certificates by using the following commands to create a shell script. Also, change the **`INSTLOC`** and **`KEYSTORELOC`** or run the required commands. Note that you might not need to create the certificate for `bob`.

```
INSTLOC=/opt/mq80
KEYSTORELOC=/home/testusr/ssl/ams1
mkdir -p $KEYSTORELOC
chmod -R 777 $KEYSTORELOC
chown -R mqm:mqm $KEYSTORELOC
export PATH=$PATH:$INSTLOC/gskit8/bin
echo "PATH = $PATH"
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:$INSTLOC/gskit8/lib64

gsk8capicmd_64 -keydb -create -db $KEYSTORELOC/alicekey.kdb -pw passw0rd -stash
gsk8capicmd_64 -keydb -create -db $KEYSTORELOC/bobkey.kdb -pw passw0rd -stash
gsk8capicmd_64 -cert -create -db $KEYSTORELOC/alicekey.kdb -pw passw0rd
-label alice_cert -dn "cn=alice,O=IBM,c=IN" -default_cert yes
gsk8capicmd_64 -cert -create -db $KEYSTORELOC/bobkey.kdb -pw passw0rd
-label bob_cert  -dn "cn=bob,O=IBM,c=IN"  -default_cert yes
```

2. Share the certificates between the two key databases so that each user can successfully identify the other.

   It is important that you use the method described in **Task 5. Sharing Certificates** in the **Quick Start Guide** (Windows or UNIX).

3. Create `keystore.conf` with the following configuration: `Keystore.conf location: /home/userID/ssl/ams1/`

```
cms.keystore = /home/userID/ssl/ams1/alicekey
cms.certificate.channel.SYSTEM.DEF.SVRCONN = alice_cert
```

4. Create and start queue manager `AMSQMGR1`
5. Define a listener with *port* 14567 and *control* `QMGR`

6. Disable channel authority or set the rules for channel authority. See SET CHLAUTH for more information.
7. Stop the queue manager.
8. Set the keystore:

```
export MQS_KEYSTORE_CONF=/home/userID/ssl/ams1/keystore.conf
```

9. Start the queue manager on the same shell.
10. Set the security policy and verify:

```
setmqspl -m AMSQMGR1 -s SHA256 -e AES256 -p TESTQ -a "CN=alice,O=IBM,C=IN"
-r "CN=alice,O=IBM,C=IN"
dspmqspl -m AMSQMGR1
```

    See setmqspl and dspmqspl for more information.
11. Set the channel configuration:

```
export MQSERVER='SYSTEM.DEF.SVRCONN/TCP/127.0.0.1(14567)'
```

12. Run **amqsputc** from an MQ client that does not automatically enable an MCA interceptor; for example an IBM WebSphere MQ Version 7.1 or earlier client. Put the following two messages:

```
/opt/mqm/samp/bin/amqsputc TESTQ TESTQMGR
```

13. Remove the security policy and verify the result:

```
setmqspl -m AMSQMGR1 -p TESTQ -remove
dspmqspl -m AMSQMGR1
```

14. Browse the queue from your IBM MQ Version 8.0 installation:

```
/opt/mq80/samp/bin/amqsbcg TESTQ AMSQMGR1
```

    The browse output shows the messages in encrypted format.
15. Set the security policy and verify the result:

```
setmqspl -m AMSQMGR1 -s SHA256 -e AES256 -p TESTQ -a "CN=alice,O=IBM,C=IN"
-r "CN=alice,O=IBM,C=IN"
dspmqspl -m AMSQMGR1
```

16. Run **amqsgetc** from your IBM MQ Version 8.0 installation:

```
/opt/mqm/samp/bin/amqsgetc TESTQ TESTQMGR
```

Related tasks:

"Quick Start Guide for IBM MQ AMS with Java clients" on page 863
Use this guide to quickly configure IBM MQ Advanced Message Security to provide message security for Java applications connecting using client bindings. By the time you complete it, you will have created a keystore to verify user identities, and defined signing/encryption policies for your queue manager.

Related reference:

"Known limitations" on page 852
Learn about limitations of IBM MQ Advanced Message Security.

Environment variables used to disable IBM MQ AMS at the client

Disable IBM MQ Advanced Message Security (AMS) at the client to prevent interception errors at the queue manager on the server that the client is connecting to. You can disable IBM MQ AMS by setting an environment variable or by setting a security property stanza in the `mqclient.ini` file.

You are using IBM WebSphere MQ Version 7.5 client, or later, and you are attempting to connect to a queue manager on a server from an earlier version of the product, for example, IBM WebSphere MQ Version 7.1. IBM WebSphere MQ Advanced Message Security is automatically enabled in a IBM WebSphere MQ client from Version 7.5, and so, by default the client tries to check the security policies for objects at the queue manager. However, servers on earlier versions of the product do not have IBM WebSphere MQ Advanced Message Security enabled and this causes 2085 (MQRC_UNKNOWN_OBJECT_NAME) error to be reported.

AMQ_DISABLE_CLIENT_AMS environment variable

You need to set this variable in the following cases:
- If you are using Java Runtime Environment (JRE) other than the IBM Java Runtime Environment (JRE)
- If you are using IBM WebSphere MQ Version 7.5, or later, IBM MQ classes for Java or JMS client.

To set the AMQ_DISABLE_CLIENT_AMS environment variable, you must be running IBM WebSphere MQ Version 7.5.0, Fix Pack 4 or later.

Create and set the environment variable AMQ_DISABLE_CLIENT_AMS to TRUE in the environment where the IBM WebSphere MQ Version 7.5, or later, client is running, to disable IBM WebSphere MQ Advanced Message Security at the client side.

For more information on problems with opening IBM MQ AMS protected queues, see "Problems opening protected queues when using JMS" on page 917.

MQS_DISABLE_ALL_INTERCEPT environment variable

You need to set this variable if:
- You are using IBM MQ Version 8.0 with native clients.
- You need to disable IBM MQ AMS at the client.

Create and set the environment variable MQS_DISABLE_ALL_INTERCEPT to TRUE in the environment where the client is running, to disable IBM MQ AMS at the client side.

DisableClientAMS property in the `mqclient.ini` file

For clients from IBM MQ Version 8.0, you can also disable or enable IBM MQ AMS at the client, in the `mqclient.ini` file, by using the property name `DisableClientAMS`, under the **`Security`** stanza.
- To disable IBM MQ AMS:
  ```
  Security:
  DisableClientAMS=Yes
  ```
- To enable IBM MQ AMS:
  ```
  Security:
  DisableClientAMS=No
  ```

Key usage extensions

Key usage extensions place additional restrictions on the way a certificate can be used.

In IBM MQ Advanced Message Security, the key usage must be set as following: for certificates in X.509 V3 or later standard that are used for the quality of protection integrity, if the key usage extensions are set, they must include at least one of the two:
- **`nonRepudiation`**
- **`digitalSignature`**

For the quality of protection privacy, if the key usage extensions are set, they must also include the **`keyEncipherment`** extension.

Related concepts:

"Quality of protection" on page 901
IBM MQ Advanced Message Security data-protection policies imply a quality of protection (QOP).

Certificate validation methods in IBM MQ AMS

You can use IBM MQ Advanced Message Security to detect and reject revoked certificates so that messages on your queues are not protected using certificates that do not fulfill security standards.

IBM MQ AMS allows you to verify a certificate validity by using either Online Certificate Status Protocol (OCSP) or certificate revocation list (CRL).

IBM MQ AMS can be configured for either OCSP or CRL checking or both. If both methods are enabled, then, for performance reasons, IBM MQ AMS uses OCSP for revocation status first. If the revocation status of a certificate is undetermined after the OCSP checking, IBM MQ AMS uses the CRL checking.

Note that both OCSP and CRL checking are enabled by default.

Related concepts:

"Online Certificate Status Protocol (OCSP)"
Online Certificate Status Protocol (OCSP) determines whether a certificate has been revoked and, therefore, helps to determine whether the certificate can be trusted. OCSP is enabled by default.

"Certificate revocation lists (CRLs)" on page 884
CRLs holds a list of certificates that have been marked by Certificate Authority (CA) as no longer trusted for a variety of reasons, for example, the private key has been lost or compromised.

Online Certificate Status Protocol (OCSP)

Online Certificate Status Protocol (OCSP) determines whether a certificate has been revoked and, therefore, helps to determine whether the certificate can be trusted. OCSP is enabled by default.

OCSP is not supported on IBM i sytems.

Enabling OCSP checking for native interceptors of IBM MQ AMS:

Online Certificate Status Protocol (OCSP) checking in IBM MQ Advanced Message Security is enabled by default, based on information in the certificates being used.

Procedure

Add the following options to the keystore configuration file:

Note: All the OCSP stanza are optional and can be specified independently.

Option	**Description**
`ocsp.enable=off`	Enable the OCSP checking if the certificate being checked has an Authority Info Access (AIA) Extension with an PKIX_AD_OCSP access method containing a URI of where the OCSP Responder is located. Possible values: `on` or `off`.
`ocsp.url=<` *`responder_URL`* `>`	The URL address of OCSP responder. If this option is omitted then non-AIA OCSP checking is disabled.
`ocsp.http.proxy.host=<` *`OCSP_proxy`* `>`	The URL address of the OCSP proxy server. If this option is omitted then a proxy is not used for non-AIA online certificate checks.

Option	Description
`ocsp.http.proxy.port=< port_number >`	The OCSP proxy server's port number. If this option is omitted then the default port of 8080 is used.
`ocsp.nonce.generation=on/off`	Generate nonce when querying OCSP. The default value is `off`.
`ocsp.nonce.check=on/off`	Check nonce after receiving a response from OCSP. The default value is `off`.
`ocsp.nonce.size=8`	Nonce size in bytes.
`ocsp.http.get=on/off`	Specify HTTP GET as your request method. If this option is set to `off`, HTTP POST is used. The default value is `off`.
`ocsp.max_response_size=20480`	Maximum size of response from the OCSP responder provided in bytes.
`ocsp.cache_size=100`	Enable internal OCSP response caching and set the limit for the number of cache entries.
`ocsp.timeout=30`	Waiting time for a server response, in seconds, after which IBM MQ Advanced Message Security times-out.
`ocsp.unknown=ACCEPT`	Defines the behavior when an OCSP server cannot be reached within a timeout period. Possible values: • `ACCEPT` Allows the certificate • `WARN` Allows the certificate and logs a warning • `REJECT` Prevents the certificate from being used and logs an error

Enabling OCSP checking in Java:

To enable OCSP checking for Java in IBM MQ Advanced Message Security, modify the `java.security` file or the keystore configuration file.

About this task

There are two ways of enabling OCSP checking in IBM MQ Advanced Message Security:

Using java.security:

Check whether your certificate contains an Authority Information Access (AIA) certificate extension.

Procedure

1. If AIA is not set up or you want to override your certificate, edit the `$JAVA_HOME/lib/security/java.security` file with the following properties:

   ```
   ocsp.responderURL=http://url.to.responder:port
   ocsp.responderCertSubjectName=CN=Example CA,O=IBM,C=US
   ```

   and enable OCSP checking by editing the `$JAVA_HOME/lib/security/java.security` file with the following line:

   ```
   ocsp.enable=true
   ```
2. If AIA is set up, enable OCSP checking by editing the `$JAVA_HOME/lib/security/java.security` file with the following line:

   ```
   ocsp.enable=true
   ```

What to do next

If you are using Java Security Manager, too complete the configuration, add the following Java permission to `lib/security/java.policy`

```
permission java.security.SecurityPermission "getProperty.ocsp.enable";
```

Using keystore.conf:
Procedure

Add the following attribute to the configuration file:

```
ocsp.enable=true
```

Important: Setting this attribute in the configuration file overrides java.security settings.

What to do next

To complete the configuration, add the following Java permissions to `lib/security/java.policy`:

```
permission java.security.SecurityPermission "getProperty.ocsp.enable";
permission java.security.SecurityPermission "setProperty.ocsp.enable";
```

Certificate revocation lists (CRLs)

CRLs holds a list of certificates that have been marked by Certificate Authority (CA) as no longer trusted for a variety of reasons, for example, the private key has been lost or compromised.

To validate certificates, IBM MQ Advanced Message Security constructs a certificate chain that consists of the signer's certificate and the certificate authority's (CA's) certificate chain up to a trust anchor. A trust anchor is a trusted keystore file that contains a trusted certificate or a trusted root certificate that is used to assert the trust of a certificate. IBM MQ AMS verifies the certificate path using a PKIX validation algorithm. When the chain is created and verified, IBM MQ AMS completes the certificate validation which includes validating the issue and expiry date of each certificate in the chain against the current date, checking if the key usage extension is present in the End Entity certificate. If the extension is appended to the certificate, IBM MQ AMS verifies whether **digitalSignature** or **nonRepudiation** are also set. If they are not, the `MQRC_SECURITY_ERROR` is reported and logged. Next, IBM MQ AMS downloads CRLs from files or from LDAP depending on what values were specified in the configuration file. Only CRLs that are encoded in DER format are supported by IBM MQ AMS. If no CRL related configuration is found in the keystore configuration file, IBM MQ AMS performs no CRL validity check. For each CA certificate, IBM MQ AMS queries LDAP for CRLs using Distinguished Names of a CA to find its CRL. The following attributes are included in the LDAP query:

```
certificateRevocationList,
certificateRevocationList;binary,
authorityRevocationList,
authorityRevocationList;binary
deltaRevocationList
deltaRevocationList;binary,
```

Note: `deltaRevocationList` is supported only when it is specified as distribution points.

Enabling certificate validation and certificate revocation list support in native interceptors:

You must modify the keystore configuration file so that IBM MQ Advanced Message Security can download CLRs from the Lightweight Directory Access Protocol (LDAP) server.

About this task

IBM i Enabling certificate validation and certificate revocation list support in native interceptors is not supported for IBM MQ Advanced Message Security on IBM i.

Procedure

Add the following options to the configuration file:

Note: All the CRL stanza are optional and can be specified independently.

Option	Description
`crl.ldap.host=<` *host_name* `>`	LDAP server host name.
`crl.ldap.port=<` *port_number* `>`	LDAP server port number. You can specify up to 11 servers. Multiple LDAP hosts are used to ensure transparent failover in case of LDAP connection failure. It is expected that all LDAP servers are replicas and contain the same data. When the IBM MQ AMS Java interceptor successfully connects to an LDAP server, it does not attempt to download CRLs from the remaining servers provided.
`crl.cdp=off`	Use this option to check or use CRLDistributionPoints extensions in certificates.
`crl.ldap.version=3`	LDAP protocol version number. Possible values: 2 or 3.
`crl.ldap.user=cn=<` *username* `>`	Log in to the LDAP server. If this value is not specified, CRL attributes in LDAP must be world-readable
`crl.ldap.pass=<` *password* `>`	Password for the LDAP server.
`crl.ldap.cache_lifetime=0`	LDAP cache lifetime in seconds. Possible values: 0-86400.
`crl.ldap.cache_size=50`	LDAP cache size. This option can be specified only if the `crl.ldap.cache_lifetime` value is larger than `0`.
`crl.http.proxy.host=some.host.com`	Http proxy server port for CDP CRL retrieval.
`crl.http.proxy.port=8080`	Http proxy server port number.
`crl.http.max_response_size=204800`	The maximum size of CRL, in bytes, that can be retrieved from an HTTP server that is accepted by GSKit.
`crl.http.timeout=30`	Waiting time for a server response, in seconds, after which IBM MQ AMS times outs.
`crl.http.cache_size=0`	HTTP cache size, in bytes.
`crl.unknown=ACCEPT`	Defines the behavior when a CRL server cannot be reached within a timeout period. Possible values: • `ACCEPT` Allows the certificate • `WARN` Allows the certificate and logs a warning • `REJECT` Prevents the certificate from being used and logs an error

Enabling certificate revocation list support in Java:

To enable CRL support in IBM MQ Advanced Message Security, you must modify the keystore configuration file to allow IBM MQ AMS to download CRLs from the Lightweight Directory Access Protocol (LDAP) server and configure the java.security file.

Procedure

1. Add the following options to the configuration file:

Header	Description
`crl.ldap.host=<` *`host_name`* `>`	LDAP host name.
`crl.ldap.port=<` *`port_number`* `>`	LDAP server port number. You can specify up to 11 servers. Multiple LDAP hosts are used to ensure transparent failover in case of LDAP connection failure. It is expected that all LDAP servers are replicas and contain the same data. When the IBM MQ AMS Java interceptor successfully connects to an LDAP server, it does not attempt to download CRLs from the remaining servers provided. Java does not use `crl.ldap.user` and crl.ldaworldp.pass values. It does not use a user and password when connecting to an LDAP server. As a consequence, CRL attributes in LDAP must be world-readable.
`crl.cdp=on/off`	Use this option to check or use CRLDistributionPoints extensions in certificates.

2. Modify the `JRE/lib/security/java.security` file with the following properties:

Property Name	Description
`com.ibm.security.enableCRLDP`	This property takes the following values: `true`, `false`. If it is set to `true`, when doing certificate revocation check, CRLs are located using the URL from CRL distribution points extension of the certificate. If it is set to `false` or not set, checking CRL by using the CRL distribution points extension is disabled.
`ibm.security.certpath.ldap.cache.lifetime`	This property can be used to set the lifetime of entries in the memory cache of LDAP CertStore to a value in seconds. A value of 0 disables the cache; -1 means unlimited lifetime. If not set, the default lifetime is 30 seconds.
`com.ibm.security.enableAIAEXT`	This property takes the following values: `true`, `false`. If it is set to `true`, any Authority Information Access extensions that are found within the certificates of the certificate path being built are examined to determine whether they contain LDAP URIs. For each LDAP URI found, an LDAPCertStore object is created and added to the collection of CertStores that is used to locate other certificates that are required to build the certificate path. If it is set to `false` or not set, additional LDAPCertStore objects are not created.

Enabling certificate revocation lists (CRLs) on z/OS:

IBM MQ Advanced Message Security supports Certificate Revocation List (CRL) checking of the digital certificates used to protect data messages

About this task

When enabled, IBM MQ Advanced Message Security will validate recipient certificates when messages are put to a privacy protected queue, and validate sender certificates when messages are retrieved from a protected queue (integrity or privacy). Validation in this case includes verification that relevant certificates are not registered in a relevant CRL.

IBM MQ Advanced Message Security uses IBM System SSL services to validate sender and recipient certificates. Detailed documentation regarding System SSL certificate validation can be found in the z/OS Cryptographic Services System Secure Sockets Layer Programming manual (SC24-5901).

To enabled CRL checking, you specify the location of a CRL configuration file via the CRLFILE DD in the started task JCL for the AMS address space. A sample CRL configuration file that can be customized is provided in *thlqual*.SCSQPROC(CSQ40CRL). Settings permitted in this file are as follows:

Table 96. IBM MQ Advanced Message Security CRL configuration variables

Variable	Valid values	Description
crl.ldap.host[.n]	*hostname -or- hostname:port*	The ipaddr/hostname of your LDAP server that hosts CRLs of your issuer certificates. If you do not specify a port number for your LDAP server, the port number specified by crl.ldap.port is used.
crl.ldap.port	*port*	The TCP/IP port number of your LDAP server.
crl.ldap.user	*ldap_user*	The LDAP user name to use when connecting to the LDAP server.
crl.ldap.pass	*ldap_password*	The LDAP password associated with the crl.ldap.user.

You can specify multiple LDAP server host names and ports as follows:

```
crl.ldap.host.1 = hostname -or hostname:port
crl.ldap.host.2 = hostname -or hostname:port
crl.ldap.host.3 = hostname -or hostname:port
```

You can specify up to 10 hostnames. If you do not specify a port number for your LDAP servers, the port number specified by crl.ldap.port is used. Each LDAP server must use the same crl.ldap.user/password combination for access.

When the CRLFILE DD is specified the configuration is loaded during initialization of the IBM MQ Advanced Message Security address space and CRL checking is enabled. If the CRLFILE DD is not specified, or the CRL configuration file is unavailable, or invalid, CRL checking is disabled.

IBM MQ AMS performs a CRL check using IBM System SSL certificate validation services as follows:

Table 97. IBM MQ Advanced Message Security CRL checks

Operation	Quality of protection	Certificate(s) checked
PUT	Privacy	Recipient(s)
GET	Integrity/Privacy	Sender

If a message operation fails a CRL check IBM MQ Advanced Message Security performs the following actions:

Table 98. IBM MQ Advanced Message Security CRL check failure behavior

Operation	CRL check failure
PUT	The message is not put to the target queue. A completion code of MQCC_FAILED and a reason code of MQRC_SECURITY_ERROR is returned to the application.
GET	The message is removed from the target queue and moved to the system protection error queue. A completion code of MQCC_FAILED and a reason code of MQRC_SECURITY_ERROR is returned to the application.

IBM MQ AMS for z/OS uses IBM System SSL services to validate certificates, which includes CRL and trust checking. IBM System SSL provides environment variable GSK_CRL_SECURITY_LEVEL to moderate the operation of CRL checking. For example:

```
GSK_CRL_SECURITY_LEVEL=MEDIUM
```

This variable is documented in the z/OS Cryptographic Services System Secure Sockets Layer Programming manual. Valid assignments include:

- LOW - Certificate validation will not fail if the LDAP server cannot be contacted.
- MEDIUM- Certificate validation requires the LDAP server to be contactable, but does not require a CRL to be defined.
- HIGH - Certificate validation requires the LDAP server to be contactable and a CRL to be defined.

The IBM System SSL default is MEDIUM. You can set this variable in the configuration file specified via the ENVARS DD in the started task JCL for the AMS address space. A sample environment variable configuration file is provided in *thlqual*.SCSQPROC(CSQ40ENV).

Note: It is the responsibility of administrators to ensure relevant LDAP services are available and to maintain CRL entries for relevant Certificate Authorities.

Protecting passwords in Java

Storing keystore and private key passwords as plain text poses a security risk so IBM MQ Advanced Message Security provides a tool that can scramble those passwords using a user's key, which is available in the keystore file.

Before you begin

The `keystore.conf` file owner must ensure that only the file owner is entitled to read the file. The passwords protection described in this chapter is only an additional measure of protection.

Procedure

1. Edit the `keystore.conf` files to include path to the keystore and users label.

   ```
   jceks.keystore = c:/Documents and Setting/Alice/AliceKeystore
   jceks.certificate = AliceCert
   jceks.provider = IBMJCE
   ```

2. To run the tool, issue:

   ```
   java -cp com.ibm.mq.jmqi.jar com.ibm.mq.ese.config.KeyStoreConfigProtector keystore_password private_key_password
   ```

   An output with encrypted passwords is generated and can be copied to the `keystore.conf` file.

   To copy the output to the `keystore.conf` file automatically, run:

   ```
   java -cp com.ibm.mq.jmqi.jar com.ibm.mq.ese.config.KeyStoreConfigProtector keystore_password private_key_password >>
   ```

   Note:

   For a list of default locations of `keystore.conf` on various platforms, see “Using keystores and certificates” on page 874.

Example

Here is an example of such output:

```
#Fri Jul 30 15:20:29 CEST 2010
jceks.key_pass=MMXh997n5ZOr8uRlJmc5qity9MN2CggGBMKCDxdbn1AyPklvdgTsOLG6X3C1YT7oDzwaqZFlOR4t\r\nmZsc7JGAx8nqqxLnAucdGn0NW
jceks.keystore_pass=OIdeayBnSCfLG4cFuxEVrk6SYyAsdSPpDqgPf16s9s1M04cqZjNbhgjoA2EXonudHZHH+4s2drvQ\r\nCUvQgu9GuaBMJK2F2OjtI
jceks.encrypted=yes
```

Using certificates on z/OS

About this task

IBM MQ Advanced Message Security implements two levels of protection: integrity and privacy. With the integrity level, messages are signed using the private key of the originator (the application doing the MQPUT). Integrity provides detection of message modification, but the message text itself is not encrypted.

With the privacy level, the message is not only signed, but it is also encrypted. The message is encrypted using a symmetric key and an algorithm specified in the relevant IBM MQ Advanced Message Security policy. The symmetric key itself is encrypted with the public key of each recipient (the application doing the MQGET). Public keys are associated with certificates stored in key rings.

When a message that is protected with privacy is dequeued by a recipient application doing an MQGET, the message must be decrypted. Because it was encrypted using the recipient's public key, it must be decrypted using the recipient's private key found in a key ring.

Use of SAF key rings

IBM MQ Advanced Message Security makes use of existing SAF key ring services to define and manage the certificates needed for signing and encryption. Security products that are functionally equivalent to RACF may be used instead of RACF if they provide the same level of support.

Efficient use of key rings can reduce the administration needed to manage the certificates.

After a certificate is generated (or imported), it must be connected to a key ring to become accessible. The same certificate can be connected to more than one key ring.

IBM MQ Advanced Message Security uses two sets of key rings. One set consists of key rings owned by the individual user IDs that originate or receive messages. Each key ring contains the private key associated with the certificate of the owning user ID. The private key of each certificate is used to sign messages for integrity-protected or privacy-protected queues. It is also used to decrypt messages from privacy-protected queues when receiving messages.

The other set is actually a single key ring associated with the AMS address space. For integrity or privacy protection, it contains the chain of signing CA certificates necessary to validate the signature and message-signing certificate of the message originator.

When privacy protection is used, this key ring also contains the certificates of the message recipients. The public keys in these certificates are used to encrypt the symmetric key that was used to encrypt the message data when the message was put to the protected queue. When these messages are retrieved, the private key of relevant recipients is used to decrypt the symmetric key which is then used to decrypt the message data.

IBM MQ Advanced Message Security uses a key ring name of **drq.ams.keyring** when searching for certificates and private keys. This is the case for both the user and the AMS address space key rings.

For an illustration and further explanation of certificates and key ring, and their role in data protection, refer to Summary of the certificate-related operations.

The private key used for signing and decryption can have any label but must be connected as the default certificate.

Digital certificates and key rings are managed in RACF primarily by using the RACDCERT command.

For more information about certificates, labels, and the RACDCERT command, see *z/OS: Security Server RACF Command Language Reference* and *z/OS: Security Server RACF Security Administrator's Guide*.

Authorizing access to the RACDCERT command

Authorization to use the RACDCERT command is a post-installation task that should have been completed by your z/OS system programmer. This task involves granting relevant permissions to the IBM MQ Advanced Message Security security administrator.

As a summary, these commands are needed to allow access to the RACF RACDCERT command:

```
RDEFINE FACILITY IRR.DIGTCERT.* UACC(NONE)
PERMIT IRR.DIGTCERT.* CLASS(FACILITY) ID( admin ) ACCESS(CONTROL)
SETROPTS RACLIST(FACILITY) REFRESH
```

In this example, *admin* specifies the user ID of your security administrator, or any user you want to use the RACDCERT command.

Creating the certificates and key rings

This section documents the steps required to create the certificates and key rings necessary for z/OS users of IBM MQ Advanced Message Security, using a RACF Certificate Authority (CA).

A scenario of a sending application and a receiving application is used to explain the required steps.

In the examples that follow, user1 is the originator of a message and user2 is the recipient. The user ID of the IBM MQ Advanced Message Security address space is WMQAMSD.

All of the commands in the examples shown here are issued from ISPF option 6 by the administrative user ID `admin`.

Defining a local Certificate Authority certificate: If you are using RACF as your CA, you must create a certificate authority certificate, if you have not already done so. The command shown here creates a certificate authority (or signer) certificate. This example creates a certificate called AMSCA to be used when creating subsequent certificates that reflect the identity of IBM MQ Advanced Message Security users and applications.

This command may be modified, specifically `SUBJECTSDN`, to reflect the naming structure and conventions used at your installation:

```
RACDCERT CERTAUTH GENCERT SUBJECTSDN(CN('AMSCA') O('ibm') C('us'))
KEYUSAGE(CERTSIGN) WITHLABEL('AMSCA')
```

Note: Certificates signed with this local certificate authority certificate show an issuer of CN=AMSCA,O=ibm,C=us when listed with the RACDCERT LIST command.

Creating a digital certificate with a private key: A digital certificate with a private key must be generated for each IBM MQ Advanced Message Security user. In the example shown here, RACDCERT commands are used to generate certificates for user1 and user2, which are signed with the local CA certificate identified by the label AMSCA.

```
RACDCERT ID(user1) GENCERT SUBJECTSDN(CN('user1') O('ibm') C('us'))
WITHLABEL('user1') SIGNWITH(CERTAUTH LABEL('AMSCA'))
KEYUSAGE(HANDSHAKE DATAENCRYPT DOCSIGN)

RACDCERT ID(user2) GENCERT SUBJECTSDN(CN('user2') O('ibm') C('us'))
WITHLABEL('user2') SIGNWITH(CERTAUTH LABEL('AMSCA'))
KEYUSAGE(HANDSHAKE DATAENCRYPT DOCSIGN)

RACDCERT ID(user1) ALTER (LABEL('user1')) TRUST
RACDCERT ID(user2) ALTER (LABEL('user2')) TRUST
```

The RACDCERT ALTER command is required to add the TRUST attribute to the certificate. When a certificate is first created using this procedure, it has a different valid date range than the signing certificate. As a result, RACF marks it as NOTRUST, which means that the certificate is not to be used. Use the RACDCERT ALTER command to set the TRUST attribute.

The KEYUSAGE attributes HANDSHAKE, DATAENCRYPT and DOCSIGN must be specified for certificates used by IBM MQ Advanced Message Security.

Table 99. RACDCERT KEYUSAGE values and indicators

KEYUSAGE Value	**Indicators Set**
HANDSHAKE	digitalSignature and keyEncipherment
DATAENCRYPT	dataEncipherment
DOCSIGN	nonRepudiation
CERTSIGN	keyCertSign and cRLSign

Creating the RACF key rings: The commands shown here create a key ring for RACF-defined user IDs user1, user2, and the IBM MQ Advanced Message Security address space task user WMQAMSD. The key ring name is fixed by IBM MQ Advanced Message Security and must be coded as shown, without quotes. The name is case-sensitive.

```
RACDCERT ID(user1) ADDRING(drq.ams.keyring)
RACDCERT ID(user2) ADDRING(drq.ams.keyring)
RACDCERT ID(WMQAMSD) ADDRING(drq.ams.keyring)
```

Connecting the certificates to the key rings: Connect the user and CA certificates to the key rings:

```
RACDCERT ID(WMQAMSD) CONNECT(CERTAUTH LABEL('AMSCA')
RING(drq.ams.keyring))
RACDCERT ID(user1) CONNECT(ID(user1) LABEL('user1')
RING(drq.ams.keyring) DEFAULT USAGE(PERSONAL))
RACDCERT ID(user2) CONNECT(ID(user2) LABEL('user2')
RING(drq.ams.keyring) DEFAULT USAGE(PERSONAL))
RACDCERT ID(WMQAMSD) CONNECT(ID(user2) LABEL('user2')
RING(drq.ams.keyring) USAGE(SITE))
```

The certificate containing the private key used for decryption must be connected to the user's key ring as the default certificate.

The RACDCERT USAGE(SITE) attribute prevents the private key from being accessible in the key ring, while the RACDCERT USAGE(PERSONAL) attribute allows the private key to be used, if it exists. User2's certificate must be connected to the AMS address space key ring because its public key is needed to encrypt messages as they are put to the queue. USAGE(SITE) limits exposure of user2's private key.

The CERTAUTH certificate with label AMSCA must be connected to the IBM MQ Advanced Message Security address space key ring because it was used to sign the certificate of user1, who is the message originator. It is used to validate user1's signing certificate.

Key ring verification: The key ring should appear as shown here, after all commands have been entered:

```
RACDCERT ID(user1) LISTRING(drq.ams.keyring)
Digital ring information for user USER1:
Ring:
>drq.ams.keyring<:

Certificate Label Name           Cert Owner   USAGE    DEFAULT
-------------------------------- ------------ -------- -------
user1                            ID(USER1)    PERSONAL YES

RACDCERT ID(user2) LISTRING(drq.ams.keyring)
Digital ring information for user USER2:
Ring:
>drq.ams.keyring<:

Certificate Label Name           Cert Owner   USAGE    DEFAULT
-------------------------------- ------------ -------- -------
user2                            ID(USER2)    PERSONAL YES

RACDCERT ID(WMQAMSD) LISTRING(drq.ams.keyring)
Digital ring information for user WMQAMSD:
Ring:
>drq.ams.keyring<:

Certificate Label Name           Cert Owner   USAGE    DEFAULT
-------------------------------- ------------ -------- -------
AMSCA                            CERTAUTH     CERTAUTH NO
user2                            ID(USER2)    SITE     NO
User1                            ID(USER1)    SITE     NO
```

Listing the individual certificates also shows the ring association.

```
RACDCERT ID(user2) LIST(label('user2'))
Digital certificate information for user USER2:

***
Label: user2
Certificate ID: 2QfH8Pny9/LzpKKFmfFA
Status: TRUST
Start Date: 2010/05/03 22:59:53
End Date:  2011/05/04 22:59:52
Serial Number:
>15<:
Issuer's Name:
>OU=AMSCA.O=ibm.C=us<:
Subject's Name:
>CN=user2.O=ibm.C=us<:
Key Usage: HANDSHAKE, DATAENCRYPT, DOCSIGN
Private Key Type: Non-ICSF
Private Key Size: 1024
Ring Associations:
Ring Owner: USER2
Ring:
>drq.ams.keyring<:
Ring Owner: WMQAMSD
Ring:
>drq.ams.keyring<:
```

To improve performance, the contents of the drq.ams.keyring associated with the AMS address space is cached for the life of the address space. Changes to that key ring do not become effective automatically. The administrator can refresh the cache by either:
- Stopping and restarting the queue manager.
- Using the z/OS MODIFY command:

  ```
  F qmgr AMSM,REFRESH KEYRING
  ```

Operating IBM MQ Advanced Message Security

Summary of the certificate-related operations

Figure 85 illustrates the relationships between sending and receiving applications and relevant certificates. The scenario illustrated involves remote queuing between two z/OS queue managers using a data-protection policy of privacy. In Figure 85, "AMS" indicates " IBM MQ Advanced Message Security".

Local Queue

Figure 85. Application and certificate relationships

In this diagram, an application running as 'user1' puts a message to a remote queue managed by queue manager CSQ1, intended to be retrieved by an application running as 'user2' from a local queue managed by queue manager CSQ2. The diagram assumes an IBM MQ Advanced Message Security policy of privacy, which means the message is both signed and encrypted.

IBM MQ Advanced Message Security intercepts the message when a put occurs and uses user2's certificate (stored in the AMS address space user's key ring) to encrypt a symmetric key used to encrypt the message data.

Note that user2's certificate is connected to the AMS address space user key ring with option USAGE(SITE). This means the AMS address space user can access the certificate and public key, but not the private key.

On the receiving end, IBM MQ Advanced Message Security intercepts the get issued by user2, and uses user2's certificate to decrypt the symmetric key so that it can decrypt the message data. It then validates user1's signature using the CA certificate chain of user1's certificate stored in the AMS address space user's key ring.

Given this scenario, but with a data-protection policy of integrity, certificates for user2 would not be required.

To use IBM MQ Advanced Message Security to enqueue messages on IBM MQ-protected queues having a message protection policy of privacy or integrity, IBM MQ Advanced Message Security must have access to these data items:

- The X.509 V2 or V3 certificate and private key for the user enqueuing the message.
- The chain of certificates used to sign the digital certificates of all message signers.
- If the data protection policy is privacy, the X.509 V2 or V3 certificate of the intended recipients. The intended recipients are listed in the IBM MQ Advanced Message Security policy associated with the queue.

For processes and applications that run on z/OS, IBM MQ Advanced Message Security must have certificates in two places:

- In a SAF-managed key ring associated with the RACF identity of the sending application (the application that enqueues the protected message) or receiving application (if using privacy).

  The certificate that IBM MQ Advanced Message Security locates is the default certificate, and must include the private key. IBM MQ Advanced Message Security assumes the z/OS user identity of the sending application. That is, it acts as a surrogate, so it can access the user's private key.
- In a SAF-managed key ring associated with the AMS address space user.

  When sending messages protected with privacy, this key ring contains the public key certificates of the message recipients. When receiving messages, it contains the chain of Certificate Authority certificates needed to validate the message sender's signature.

The earlier examples shown have used RACF as the local CA. However, you may use another PKI provider (Certificate Authority) at your installation. If you intend to use another PKI product, remember that the private key and the certificate must be imported into a key ring associated with the z/OS RACF user IDs that originate IBM MQ messages protected by IBM MQ Advanced Message Security.

You can use the RACF RACDCERT command as the mechanism to generate certificate requests, which can be exported and sent to the PKI provider of your choice to be issued.

Here is a summary of the certificate-related steps:

1. Request the creation of a CA certificate, one in which RACF is the local CA. Omit this step if you are using another PKI provider.
2. Generate user certificates signed by the CA.
3. Create the key rings for the users and the IBM MQ Advanced Message Security AMS address space ID.
4. Connect the user certificate to the user key ring with the default attribute.
5. Connect the recipients certificates to the IBM MQ Advanced Message Security AMS address space user key ring using the usage(site) attribute (This step is necessary only for user certificates that will ultimately be the recipients of privacy-protected messages).
6. Connect the CA certificate chains for message senders to the IBM MQ Advanced Message Security AMS address space user key ring. (This step is necessary only for AMS tasks that will be verifying sender signatures.)

Configuring a non-z/OS resident PKI

IBM MQ Advanced Message Security for z/OS, uses X.509 V3 digital certificates in the protection-processing of messages placed on or received from IBM MQ queues. IBM MQ Advanced Message Security itself does not create or manage the life cycle of these certificates; that function is provided by a public key infrastructure (PKI). The examples in this publication that illustrate the use of certificates use z/OS Security Server RACF to fill certificate requests.

Whether or not a z/OS or non-z/OS resident PKI is used, IBM MQ AMS for z/OS uses only key rings that are managed by RACF or its equivalent. These key rings are based on Security Authorization Facility (SAF) and are the repository used by IBM MQ AMS for z/OS to retrieve certificates for originators and recipients of messages placed on or received from IBM MQ queues.

For messages that are originated from z/OS, which are protected by either integrity or encryption policy, the certificate and private key of the originating user ID must be stored in an SAF-managed key ring that is associated with the z/OS user ID of the message originator.

RACF includes the capability for importing certificates and private keys into RACF-managed key rings. See the z/OS Security Server RACF publications for the details and examples of how to load certificates to RACF managed key rings.

If your installation is using one of the supported PKI products, refer to the publications that accompany the product for information on how to deploy it.

Security policies

IBM MQ Advanced Message Security uses security policies to specify the cryptographic encryption and signature algorithms for encrypting and authenticating messages that flow through the queues.

Security policies overview

IBM MQ Advanced Message Security security policies are conceptual objects that describe the way a message is cryptographically encrypted and signed.

For details of the security policy attributes, see the following subtopics:

Related concepts:

"Quality of protection" on page 901
IBM MQ Advanced Message Security data-protection policies imply a quality of protection (QOP).

"Security policy attributes" on page 900
You can use IBM MQ Advanced Message Security to select a particular algorithm or method to protect the data.

Policy name

The policy name is a unique name that identifies a specific IBM MQ Advanced Message Security policy and the queue to which it applies.

The policy name must be the same as the queue name to which it applies. There is a one-to-one mapping between an IBM MQ Advanced Message Security (IBM MQ AMS) policy and a queue.

By creating a policy with the same name as a queue, you activate the policy for that queue. Queues without matching policy names are not protected by IBM MQ AMS.

The scope of the policy is relevant to the local queue manager and its queues. Remote queue managers must have their own locally-defined policies for the queues they manage.

Signature algorithm

The signature algorithm indicates the algorithm that should be used when signing data messages.

Valid values include:

- `MD5`
- `SHA-1`
- `SHA-2` family:
  - SHA256
  - SHA384 (minimum key length acceptable - 768 bits)
  - SHA512 (minimum key length acceptable - 768 bits)

A policy that does not specify a signature algorithm, or specifies an algorithm of `NONE`, implies that messages placed on the queue associated with the policy are not signed.

Note: The quality of protection used for the message put and get functions must match. If there is a policy quality of protection mismatch between the queue and the message in the queue, the message is not accepted and is sent to the error handling queue. This rule applies for both local and remote queues.

Encryption algorithm

The encryption algorithm indicates the algorithm that should be used when encrypting data messages placed on the queue associated with the policy.

Valid values include:

- `RC2`
- `DES`
- `3DES`
- `AES128`
- `AES256`

A policy that does not specify an encryption algorithm or specifies an algorithm of `NONE` implies that messages placed on the queue associated with the policy are not encrypted.

Note that a policy that specifies an encryption algorithm other than `NONE` must also specify at least one Recipient DN and a signature algorithm because IBM MQ Advanced Message Security encrypted messages are also signed.

Important: The quality of protection used for the message put and get functions must match. If there is a policy quality of protection mismatch between the queue and the message in the queue, the message is not accepted and is sent to the error handling queue. This rule applies for both local and remote queues.

Toleration

The toleration attribute indicates whether IBM MQ Advanced Message Security can accept messages with no security policy specified.

When retrieving a message from a queue with a policy to encrypt messages, if the message is not encrypted, it is returned to the calling application. Valid values include:

0	No (**default**).
1	Yes.

A policy that does not specify a toleration value or specifies 0, implies that messages placed on the queue associated with the policy must match the policy rules.

Toleration is optional and exists to facilitate configuration roll-out, where policies were applied to queues but those queues already contain messages that do not have a security policy specified.

Sender distinguished names

The sender distinguished names (DNs) identify users who are authorized to place messages on a queue.

IBM MQ Advanced Message Security (IBM MQ AMS) does not check whether a message has been placed on a data-protected queue by a valid user until the message is retrieved. At this time, if the policy stipulates one or more valid senders, and the user that placed the message on the queue is not in the list of valid senders, IBM MQ AMS returns an error to the getting application, and place the message on its error queue.

A policy can have 0 or more sender DNs specified. If no sender DNs are specified for the policy, any user can put data-protected messages to the queue providing the user's certificate is trusted.

Sender distinguished names have the following form:

```
CN=Common Name,O=Organization,C=Country
```

Important:

- All DNs must be in uppercase and in the same order as listed in the table.

Component name	Value
CN	The common name for the object of this DN, such as a full name or the intended purpose of a device.
OU	The unit within the organization with which the object of the DN is affiliated, such as a corporate division or a product name.
O	The organization with which the object of the DN is affiliated, such as a corporation.
L	The locality (city or municipality) where the object of the DN is located.
ST	The state or province name where the object of the DN is located.
C	The country where the object of the distinguished name (DN) is located.

- If one or more sender DNs are specified for the policy, only those users can put messages to the queue associated with the policy.
- Sender DNs, when specified, must match exactly the DN contained in the digital certificate associated with user putting the message.
- IBM MQ AMS supports DNs with values only from Latin-1 character set. To create DNs with characters of the set, you must first create a certificate with a DN that is created in UTF-8 coding using

UNIX platforms with UTF-8 coding turned on or with the iKeyman utility. Then you must create a policy from a UNIX platform with UTF-8 coding turned on or use the IBM MQ AMS plug-in to IBM MQ.

- The method used by IBM MQ AMS, to convert the name of the sender from x.509 format to DN format, always uses ST= for the State or Province value.
- The following special characters need escape characters:

```
    , (comma)
    + (plus)
    " (double quote)
    \ (backslash)
    < (less than)
    > (greater than)
    ; (semicolon)
```

- If the Distinguished Name contains embedded blanks, you should enclose the DN in double quotation marks.

Recipient distinguished names

The recipient distinguished names (DN) identify users who are authorized to retrieve messages from a queue.

A policy can have zero or more recipient DNs specified. Recipient distinguished names have the following form:

```
CN=Common Name,O=Organization,C=Country
```

Important:

- All DNs must be in uppercase and in the same order as listed in the table.

Component name	Value
CN	The common name for the object of this DN, such as a full name or the intended purpose of a device.
OU	The unit within the organization with which the object of the DN is affiliated, such as a corporate division or a product name.
O	The organization with which the object of the DN is affiliated, such as a corporation.
L	The locality (city or municipality) where the object of the DN is located.
ST	The state or province name where the object of the DN is located.
C	The country where the object of the distinguished name (DN) is located.

- If no recipient DNs are specified for the policy, any user can get messages from the queue associated with the policy.
- If one or more recipient DNs are specified for the policy, only those users can get messages from the queue associated with the policy.
- Recipient DNs, when specified, must match exactly the DN contained in the digital certificate associated with user getting the message.
- IBM MQ Advanced Message Security supports DNs with values only from Latin-1 character set. To create DNs with characters of the set, you must first create a certificate with a DN that is created in UTF-8 coding using UNIX platforms with UTF-8 coding turned on or with the iKeyman utility. Then you must create a policy from a UNIX platform with UTF-8 coding turned on or use the IBM MQ Advanced Message Security plug-in to IBM MQ.

Security policy attributes

You can use IBM MQ Advanced Message Security to select a particular algorithm or method to protect the data.

A security policy is a conceptual object that describes the way a message is cryptographically encrypted and signed. The following table presents the security policy attributes in IBM MQ Advanced Message Security:

Attributes	Description
Policy name	Unique name of the policy for a queue manager.
Signature algorithm	Cryptographic algorithm that is used to sign messages before sending.
Encryption algorithm	Cryptographic algorithm that is used to encrypt messages before sending.
Recipient list	List of certificate distinguished names (DNs) of potential receivers of a message.
Signature DN checklist	List of signature DNs to be validated during message retrieval.

In IBM MQ Advanced Message Security, messages are encrypted with a symmetric key, and the symmetric key is encrypted with the public keys of the recipients. Public keys are encrypted with the RSA algorithm, with keys of an effective length up to 2048 bits. The actual asymmetric key encryption depends on the certificate key length.

The supported symmetric-key algorithms are as follows:

- `RC2`
- `DES`
- `3DES`
- `AES128`
- `AES256`

IBM MQ Advanced Message Security also supports the following cryptographic hash functions:

- `MD5`
- `SHA-1`
- `SHA-2` family:
  - SHA256
  - SHA384 (minimum key length acceptable - 768 bits)
  - SHA512 (minimum key length acceptable - 768 bits)

Note: The quality of protection used for the message put and get functions must match. If there is a policy quality of protection mismatch between the queue and the message in the queue, the message is not accepted and is sent to the error handling queue. This rule applies for both local and remote queues.

Quality of protection

IBM MQ Advanced Message Security data-protection policies imply a quality of protection (QOP).

The three quality of protection levels in IBM MQ Advanced Message Security depend on cryptographic algorithms that are used to sign and encrypt the message:

- Privacy - messages placed on the queue must be signed and encrypted.
- Integrity - messages placed on the queue must be signed by the sender.
- None - no data protection is applicable.

A policy that stipulates that messages must be signed when placed on a queue has a QOP of INTEGRITY. A QOP of INTEGRITY means that a policy stipulates a signature algorithm, but does not stipulate an encryption algorithm. Integrity-protected messages are also referred to as "SIGNED".

A policy that stipulates that messages must be signed and encrypted when placed on a queue has a QOP of PRIVACY. A QOP of PRIVACY means that when a policy stipulates a signature algorithm and an encryption algorithm. Privacy-protected messages are also referred to as "SEALED".

A policy that does not stipulate a signature algorithm or an encryption algorithm has a QOP of NONE. IBM MQ Advanced Message Security provides no data-protection for queues that have a policy with a QOP of NONE.

Managing security policies

A security policy is a conceptual object that describes the way a message is cryptographically encrypted and signed.

All administrative tasks related to security policies are run from the following location:

- On UNIX platforms: `<MQInstallRoot>/bin`
- On Windows platforms administrative tasks can be run from any location as the `PATH` environment variable is updated at the installation.

  On UNIX platforms, and Windows, you use the DELETE POLICY, DISPLAY POLICY, and SET POLICY (or equivalent PCF) commands to manage your security policies.
- On IBM i, the DSPMQMSPL, SETMQMSPL, and WRKMQMSPL commands are installed into the QSYS system library for the primary language of the system when IBM MQ is installed.

  Additional national language versions get installed into QSYS29xx libraries according to the language feature load.

  For example, a machine with US English as the primary language and Korean as the secondary language has the US English commands installed into QSYS and the Korean secondary language load in QSYS2962 as 2962 is the language load for Korean.
- On z/OS, the administrative commands are run using the message security policy utility (CSQ0UTIL). When policies are created, modified or deleted on z/OS, the changes are not recognized by IBM MQ Advanced Message Security until the queue manager is stopped and restarted, or the z/OS MODIFY command is used to refresh the IBM MQ Advanced Message Security policy configuration. For example:

  ```
  F qmgr AMSM,REFRESH POLICY
  ```

The message security policy utility (CSQ0UTIL)

Operating IBM MQ Advanced Message Security

Creating security policies

Security policies define the way in which a message is protected when the message is put, or how a message must have been protected when a message is received.

Before you begin

There are some entry conditions which must be met when creating security policies:

- The queue manager must be running.
- The name of a security policy must follow Rules for naming IBM MQ objects.
- You must have the necessary authority to connect to the queue manager and create a security policy. On z/OS, grant the authorities documented in The message security policy utility (CSQ0UTIL). On other platforms other than z/OS, you must grant the necessary +connect, +inq and +chg authorities using the setmqaut command. For more information about configuring security see "Setting up security" on page 511.
- On z/OS, ensure the required system objects have been defined according to the definitions in CSQ4INSM.

Example

Here is an example of creating a policy on queue manager `QMGR`. The policy specifies that messages be signed using the `SHA1` algorithm and encrypted using the `AES256` algorithm for certificates with DN: CN=joe,O=IBM,C=US and DN: CN=jane,O=IBM,C=US. This policy is attached to `MY.QUEUE`:

```
setmqspl -m QMGR -p MY.QUEUE -s SHA1 -e AES256 -r CN=joe,O=IBM,C=US -r CN=jane,O=IBM,C=US
```

Here is an example of creating policy on the queue manager `QMGR`. The policy specifies that messages be encrypted using the `DES` algorithm for certificates with DNs: CN=john,O=IBM,C=US and CN=jeff,O=IBM,C=US and signed with the `MD5` algorithm for certificate with DN: CN=phil,O=IBM,C=US

```
setmqspl -m QMGR -p MY.OTHER.QUEUE -s MD5 -e DES -r CN=john,O=IBM,C=US -r CN=jeff,O=IBM,C=US -a CN=phil,O=IBM,C=US
```

Note:

- The quality of protection being used for the message put and get must match. If the policy quality of protection that is defined for the message is weaker than that defined for a queue, the message is sent to the error handling queue. This policy is valid for both local and remote queues.

Complete list of setmqspl command attributes

Changing security policies

You can use IBM MQ Advanced Message Security to alter details of security policies that you have already defined.

Before you begin

- The queue manager on which you want to operate must be running.
- You must have the necessary authority to connect to the queue manager and create a security policy. On z/OS, grant the authorities documented in The message security policy utility (CSQ0UTIL). On other platforms other than z/OS, you must grant the necessary +connect, +inq and +chg authorities using the setmqaut command. For more information about configuring security see "Setting up security" on page 511.

About this task

To change security policies, apply the `setmqspl` command to an already existing policy providing new attributes.

Example

Here is an example of creating a policy named `MYQUEUE` on a queue manager named `QMGR` specifying that messages will be encrypted using the `RC2` algorithm for certificates with DN:CN=bob,O=IBM,C=US and signed with the `SHA1` algorithm for certificates with DN:CN=jeff,O=IBM,C=US.

```
setmqspl -m QMGR -p MYQUEUE -e RC2 -s SHA1 -a CN=jeff,O=IBM,C=US -r CN=alice,O=IBM,C=US
```

To alter this policy, issue the `setmqspl` command with all attributes from the example changing only the values you want to modify. In this example, previously created policy is attached to a new queue and its encryption algorithm is changed to `AES256`:

```
setmqspl -m QMGR -p MYQUEUE -e AES256 -s SHA1 -a CN=jeff,O=IBM,C=US -r CN=alice,O=IBM,C=US
```

Related reference:

Complete list of setmqspl command attributes

Displaying and dumping security policies

Use the `dspmqspl` command to display a list of all security policies or details of a named policy depending on the command-line parameters you supply.

Before you begin

- To display security policies details, the queue manager must exist, and be running.
- You must have the necessary authority to connect to the queue manager and create a security policy. On z/OS, grant the authorities documented in The message security policy utility (CSQ0UTIL). On other platforms other than z/OS, you must grant the necessary +connect, +inq and +chg authorities using the setmqaut command. For more information about configuring security see "Setting up security" on page 511.

About this task

Here is the list of `dspmqspl` command flags:

Table 100. `dspmqspl` command flags.

Command flag	**Explanation**
`-m`	Queue manager name (**mandatory**).
`-p`	Policy name.
`-export`	Adding this flag generates output which can easily be applied to a different queue manager.

Example

In this example we will create two security policies for `venus.queue.manager`:

```
setmqspl -m venus.queue.manager -p AMS_POL_04_ONE -s MD5 -a "CN=signer1,O=IBM,C=US" -e NONE
setmqspl -m venus.queue.manager -p AMS_POL_06_THREE -s MD5 -a "CN=another signer,O=IBM,C=US" -e NONE
```

This example shows a command that displays details of all policies defined for `venus.queue.manager` and the output it produces:

```
dspmqspl -m  venus.queue.manager

Policy Details:
Policy name: AMS_POL_04_ONE
Quality of protection: INTEGRITY
Signature algorithm: MD5
Encryption algorithm: NONE
Signer DNs:
  CN=signer1,O=IBM,C=US
Recipient DNs: -
Toleration: 0
- - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - 
Policy Details:
Policy name: AMS_POL_06_THREE
Quality of protection: INTEGRITY
Signature algorithm: MD5
Encryption algorithm: NONE
Signer DNs:
  CN=another signer,O=IBM,C=US
Recipient DNs: -
Toleration: 0
```

This example shows a command that displays details of a selected security policy defined for `venus.queue.manager` and the output it produces:

```
dspmqspl -m venus.queue.manager -p AMS_POL_06_THREE

Policy Details:
Policy name: AMS_POL_06_THREE
Quality of protection: INTEGRITY
Signature algorithm: MD5
Encryption algorithm: NONE
Signer DNs:
  CN=another signer,O=IBM,C=US
Recipient DNs: -
Toleration: 0
```

In the next example, first, we create a security policy and then, we export the policy using the `-export` flag:

```
setmqspl -m venus.queue.manager -p AMS_POL_04_ONE -s MD5 -a "CN=signer1,O=IBM,C=US" -e NONE

dspmqspl -m venus.queue.manager -export
```

On z/OS, the exported policy information is written by CSQ0UTIL to the EXPORT DD. On platforms other than z/OS, redirect the output to a file, for example:

```
dspmqspl -m venus.queue.manager -export > policies.[bat|sh]
```

To import a security policy:

- On Windows platforms, run `policies.bat`
- On UNIX platforms:
  1. Log on as a user that belongs to the `mqm` IBM MQ administration group.
  2. Issue `. policies.sh`.
- On z/OS use the CSQ0UTIL utility, specifying to SYSIN the data set containing the exported policy information.

Removing security policies

To remove security policies in IBM MQ Advanced Message Security, you must use the `setmqspl` command.

Before you begin

There are some entry conditions which must be met when managing security policies:

- The queue manager must be running.
- You must have the necessary authority to connect to the queue manager and create a security policy. On z/OS, grant the authorities documented in The message security policy utility (CSQ0UTIL). On other platforms other than z/OS, you must grant the necessary +connect, +inq and +chg authorities using the setmqaut command. For more information about configuring security see “Setting up security” on page 511.

About this task

Use the `setmqspl` command with the `-remove` option.

Example

Here is an example of removing a policy:

```
setmqspl -m QMGR -remove -p MY.OTHER.QUEUE
```

Related reference:

Complete list of setmqspl command attributes

System queue protection

System queues enable communication between IBM MQ and its ancillary applications. Whenever a queue manager is created, a system queue is also created to store IBM MQ internal messages and data. You can protect system queues with IBM MQ Advanced Message Security so that only authorized users can access or decrypt them.

System queue protection follows the same pattern as the protection of regular queues. See “Creating security policies” on page 902.

To use system queue protection on Windows platforms, copy the `keystore.conf` file to the following directory:

```
c:\Documents and Settings\Default User\.mqs\keystore.conf
```

On platforms other than z/OS, to provide protection for `SYSTEM.ADMIN.COMMAND.QUEUE`, the command server must have access to the `keystore` and the `keystore.conf`, which contain keys and a configuration so that the command server can access keys and certificates. All changes made to the security policy of `SYSTEM.ADMIN.COMMAND.QUEUE` require the restart of the command server.

All messages that are sent and received from the command queue are signed or signed and encrypted depending on policy settings. If an administrator defines authorized signers, command messages that do not pass the signer Distinguished Name (DN) check are not executed by the command server and are not routed to the IBM MQ Advanced Message Security error handling queue. Messages that are sent as replies to IBM MQ Explorer temporary dynamic queues are not protected by IBM MQ AMS.

Security policies do not have an effect on the following SYSTEM queues:
- SYSTEM.ADMIN.ACCOUNTING.QUEUE
- SYSTEM.ADMIN.ACTIVITY.QUEUE
- SYSTEM.ADMIN.CHANNEL.EVENT
- SYSTEM.ADMIN.COMMAND.EVENT
- z/OS SYSTEM.ADMIN.COMMAND.QUEUE
- SYSTEM.ADMIN.CONFIG.EVENT
- SYSTEM.ADMIN.LOGGER.EVENT
- SYSTEM.ADMIN.PERFM.EVENT
- SYSTEM.ADMIN.PUBSUB.EVENT
- SYSTEM.ADMIN.QMGR.EVENT
- SYSTEM.ADMIN.STATISTICS.QUEUE
- SYSTEM.ADMIN.TRACE.ROUTE.QUEUE
- SYSTEM.AUTH.DATA.QUEUE
- SYSTEM.BROKER.ADMIN.STREAM
- z/OS SYSTEM.BROKER.CLIENTS.DATA
- SYSTEM.BROKER.CONTROL.QUEUE
- SYSTEM.BROKER.DEFAULT.STREAM
- SYSTEM.BROKER.INTER.BROKER.COMMUNICATIONS
- z/OS SYSTEM.BROKER.SUBSCRIPTIONS.DATA
- SYSTEM.CHANNEL.INITQ
- SYSTEM.CHANNEL.SYNCQ
- z/OS SYSTEM.CHLAUTH.DATA.QUEUE
- SYSTEM.CICS.INITIATION.QUEUE
- SYSTEM.CLUSTER.COMMAND.QUEUE
- SYSTEM.CLUSTER.HISTORY.QUEUE
- SYSTEM.CLUSTER.REPOSITORY.QUEUE
- SYSTEM.CLUSTER.TRANSMIT.QUEUE
- z/OS SYSTEM.COMMAND.INPUT
- z/OS SYSTEM.DDELAY.LOCAL.QUEUE
- SYSTEM.DEAD.LETTER.QUEUE
- SYSTEM.DURABLE.SUBSCRIBER.QUEUE
- SYSTEM.HIERARCHY.STATE
- SYSTEM.INTER.QMGR.CONTROL

Granting OAM permissions

File permissions authorize all users to execute `setmqspl` and `dspmqspl` commands. However, IBM MQ Advanced Message Security relies on the Object Authority Manager (OAM) and every attempt to execute these commands by a user who does not belong to the mqm group, which is the IBM MQ administration group, or does not have permissions to read security policy settings that are granted, results in an error.

Procedure

To grant necessary permissions to a user, run:

```
setmqaut -m SOME.QUEUE.MANAGER -t qmgr -p SOME.USER +connect +inq
setmqaut -m SOME.QUEUE.MANAGER -t queue -n SYSTEM.PROTECTION.POLICY.QUEUE -p SOME.USER +browse +put
setmqaut -m SOME.QUEUE.MANAGER -t queue -n SYSTEM.PROTECTION.ERROR.QUEUE -p SOME.USER +put
```

Note: You only need to set these OAM authorities if you intend to connect clients, to the queue manager, using IBM MQ Advanced Message Security Version 7.0.1.

Granting security permissions

When using command resource security you must set up permissions to allow IBM MQ Advanced Message Security to function. This topic uses RACF commands in the examples. If your enterprise uses a different external security manager (ESM) you must use the equivalent commands for that ESM.

There are three aspects to granting security permissions:
- "The AMSM address space" on page 908
- "CSQ0UTIL" on page 908
- "Using queues that have an IBM MQ Advanced Message Security policy defined." on page 908

Notes: The example commands use the following variables.
1. *QMgrName* - the name of the queue manager. On z/OS, this value can also be the name of a queue-sharing group.
2. *username* - this can be a group name.
3. The examples show the MQQUEUE class. this can also be MXQUEUE, GMQQUEUE or GMXQUEUE. See "Profiles for queue security" on page 581 for further information.

Furthermore, if the profile already exists, you do not require the RDEFINE command.

The AMSM address space

You need to issue some IBM MQ security to the user name that the IBM MQ Advanced Message Security address space runs under.

- For batch connection to the queue manager, issue

```
RDEFINE MQCONN QMgrName.BATCH UACC(NONE)
            PERMIT QMgrName.BATCH CLASS(MQCONN) ID(username) ACCESS(READ)
```

- For access to the SYSTEM.PROTECTION.POLICY.QUEUE, issue:

```
RDEFINE MQQUEUE QMgrName.SYSTEM.PROTECTION.POLICY.QUEUE UACC(NONE)
            PERMIT QMgrName.SYSTEM.PROTECTION.POLICY.QUEUE CLASS(MQQUEUE)
ID(username) ACCESS(READ)
```

CSQ0UTIL

The utility that allows users to run the **setmqspl** and **dspmqspl** commands requires the following permissions, where the user name is the job user ID:

- For batch connection to the queue manager, issue:

```
  RDEFINE MQCONN QMgrName.BATCH UACC(NONE)
             PERMIT QMgrName.BATCH CLASS(MQCONN) ID(username) ACCESS(READ)
```

- For access to the SYSTEM.PROTECTION.POLICY.QUEUE, required for the **setmqpol** command, issue:

```
  RDEFINE MQQUEUE QMgrName.SYSTEM.PROTECTION.POLICY.QUEUE UACC(NONE)
              PERMIT QMgrName.SYSTEM.PROTECTION.POLICY.QUEUE CLASS(MQQUEUE)
ID(username) ACCESS(ALTER)
```

- For access to the SYSTEM.PROTECTION.POLICY.QUEUE, required for the **dspmqpol** command, issue:

```
  RDEFINE MQQUEUE QMgrName.SYSTEM.PROTECTION.POLICY.QUEUE UACC(NONE)
                PERMIT QMgrName.SYSTEM.PROTECTION.POLICY.QUEUE CLASS(MQQUEUE)
ID(username) ACCESS(READ)
```

Using queues that have an IBM MQ Advanced Message Security policy defined.

When an application does any work with queues that have a policy defined on them, that application requires additional permissions to allow IBM MQ Advanced Message Security to protect messages.

The application requires:

- Read access to the SYSTEM.PROTECTION.POLICY.QUEUE. Do this by issuing:

```
RDEFINE MQQUEUE QMgrName.SYSTEM.PROTECTION.POLICY.QUEUE UACC(NONE)
          PERMIT QMgrName.SYSTEM.PROTECTION.POLICY.QUEUE CLASS(MQQUEUE)
ID(username) ACCESS(READ)
```

- Put access to the SYSTEM.PROTECTION.ERROR.QUEUE. Do this by issuing:

```
RDEFINE MQQUEUE QMgrName.SYSTEM.PROTECTION.ERROR.QUEUE UACC(NONE)
            PERMIT QMgrName.SYSTEM.PROTECTION.ERROR.QUEUE CLASS(MQQUEUE)
ID(username) ACCESS(READ)
```

IBM i: Setting up certificates and the keystore configuration file

Your first task when setting up IBM MQ Advanced Message Security protection is to create a certificate, and associate that with your environment. The association is configured through a file held in the integrated filesystem (IFS).

Procedure

1. To create a self-signed certificate using the OpenSSL tooling shipped with IBM i, issue the following command from QShell:

   ```
   /QOpenSys/usr/bin/openssl req -x509 -newkey rsa:2048 -keyout
   $HOME/private.pem -out $HOME/mycert.pem -nodes -days 365
   ```

   The command prompts for various distinguished name attributes for a new self-signed certificate, including:
   - Common Name (CN=)
   - Organization (O=)
   - Country (C=)

   This creates an unencrypted private key and a matching certificate, both in PEM (Privacy Enhanced Mail) format.

   For simplicity, just enter values for common name, organization, and country. These attributes and values are important when creating a policy.
2. IBM MQ AMS requires that both the certificate and private key are held in the same file. Issue the following command to achieve this:

   ```
   cat $HOME/mycert.pem >> $HOME/private.pem
   ```

   The `private.pem` file in `$HOME` now contains a matching private key and certificate, while the `mycert.pem` file contains all of the public certificates for which you can encrypt messages and validate signatures.

   The two files need to be associated with your environment by creating a keystore configuration file (`keystore.conf`) in your default location.

   By default, IBM MQ AMS looks for the keystore configuration in a `.mqs` subdirectory of your home directory.
3. In QShell create the `keystore.conf` file;

   ```
   mkdir -p $HOME/.mqs
   echo "pem.private = $HOME/private.pem" > $HOME/.mqs/keystore.conf
   echo "pem.public = $HOME/mycert.pem" >> $HOME/.mqs/keystore.conf
   echo "pem.password = unused" >> $HOME/.mqs/keystore.conf
   ```

Creating a policy

Before creating a policy, you need to create a queue to hold protected messages.

Procedure

1. At a command line prompt enter;

   ```
   CRTMQMQ QNAME(PROTECTED) QTYPE(*LCL) MQMNAME (<mqmname>)
   ```

   where `mqmname` is the name of your queue manager.

   Use the DSPMQM command to check that the queue manager is capable of using security policies. Ensure that **`Security Policy Capability`** shows **YES*.

   The simplest policy you can define is an integrity policy, which is achieved by creating a policy with a digital signature algorithm but no encryption algorithm.

   Messages are signed but not encrypted. If messages are to be encrypted, you must specify an encryption algorithm, and one or more intended message recipients.

   A certificate in the public keystore for an intended message recipient is identified through a distinguished name.

2. Display the distinguished names of the certificates in the public keystore, `mycert.pem` in `$HOME`, by using the following command in QShell:

   ```
   /QOpenSys/usr/bin/openssl x509 -in $HOME/mycert.pem -noout -subject -nameopt RFC2253
   ```

   You need to enter the distinguished name as an intended recipient, and the policy name must match the queue name to be protected.
3. At a CL command prompt enter, for example:

   ```
   SETMQMSPL POLICY(PROTECTED) MQMNAME (<mqmname>)SIGNALG(*SHA256) ENCALG(*AES256) RECIP('CN=.., O=.., C=..')
   ```

   where `mqmname` is the name of your queue manager.

   Once the policy is created, any messages that are put, browsed, or destructively removed through that queue name are subject to the IBM MQ AMS policy.

Display Message Queue Manager (DSPMQM)

Set MQM Security Policy (SETMQMSPL)

Testing the policy

Use the sample applications provided with the product to test your security policies.

About this task

You can use the sample applications provided with IBM MQ , such as AMQSPUT4, AMQSGET4, AMQSGBR4, and tools such as WRKMQMMSG to put, browse, and get messages using the PROTECTED queue name.

Provided everything has been configured correctly, there should be no difference in application behavior to that of an unprotected queue for this user.

A user not setup for IBM MQ Advanced Message Security , or a user that does not have the required private key to decrypt the message will, however, not be able to view the message. The user receives a completion code of RCFAIL, equivalent to MQCC_FAILED (2) and reason code of RC2063 (MQRC_SECURITY_ERROR).

To see that AMS protection is in effect, put some test messages to the PROTECTED queue, for example using AMQSPUT0. You can then create an alias queue to browse the raw protected data while at rest.

Procedure

To grant necessary permissions to a user, run:

```
CRTMQMQ QNAME(ALIAS) QTYPE(*ALS) TGTQNAME(PROTECTED) MQMNAME(<yourqm>)
```

Browsing using the ALIAS queue name, for example using AMQSBCG4 or WRKMQMMSG, should reveal larger `scrambled` messages where a browse of the PROTECTED queue shows cleartext messages. The scrambled messages are visible, but the original cleartext is not decipherable using the ALIAS queue, as there is no policy for AMS to enforce matching this name. Hence, the raw protected data is returned.

Work with MQ Messages (WRKMQMMSG)

Command and configuration events

With IBM MQ Advanced Message Security, you can generate command and configuration event messages, which can be logged and serve as a record of policy changes for auditing.

Command and configuration events generated by IBM MQ are messages of the PCF format sent to dedicated queues on the queue manager where the event occurs.

Configuration events messages are sent to the SYSTEM.ADMIN.CONFIG.EVENT queue.

Command events messages are sent to the SYSTEM.ADMIN.COMMAND.EVENT queue.

Events are generated regardless of tools you are using to manage IBM MQ Advanced Message Security security policies.

In IBM MQ Advanced Message Security, there are four types of events generated by different actions on security policies:

- "Creating security policies" on page 902, which generate two IBM MQ event messages:
  - A configuration event
  - A command event
- "Changing security policies" on page 903, which generates three IBM MQ event messages:
  - A configuration event that contains old security policy values
  - A configuration event that contains new security policy values
  - A command event
- "Displaying and dumping security policies" on page 903, which generates one IBM MQ event message:
  - A command event
- "Removing security policies" on page 905, which generates two IBM MQ event messages:
  - A configuration event
  - A command event

Enabling and disabling event logging

You control command and configuration events by using the queue manager attributes CONFIGEV and CMDEV. To enable these events, set the appropriate queue manager attribute to `ENABLED`. To disable these events, set the appropriate queue manager attribute to `DISABLED`.

Procedure

Configuration events

To enable configuration events, set CONFIGEV to `ENABLED`. To disable configuration events, set CONFIGEV to `DISABLED`. For example, you can enable configuration events by using the following MQSC command:

```
ALTER QMGR CONFIGEV (ENABLED)
```

Command events

To enable command events, set CMDEV to `ENABLED`. To enable command events for commands except DISPLAY MQSC commands and Inquire PCF commands, set the CMDEV to NODISPLAY. To disable command events, set CMDEV to `DISABLED`. For example, you can enable command events by using the following MQSC command:

```
ALTER QMGR CMDEV (ENABLED)
```

Controlling configuration, command, and logger events in Websphere MQ

Command event message format

Command event message consists of MQCFH structure and PCF parameters following it.

Here are selected MQCFH values:

```
Type = MQCFT_EVENT;
Command = MQCMD_COMMAND_EVENT;
MsgSeqNumber = 1;
Control = MQCFC_LAST;
ParameterCount = 2;
CompCode = MQCC_WARNING;
Reason = MQRC_COMMAND_PCF;
```

Note: ParameterCount value is two because there are always two paramteters of MQCFGR type (group). Each group consists of appropriate parameters. The event data consists of two groups, CommandContext and CommandData.

CommandContext contains:

EventUserID

Description:	The user ID that issued the command or call that generated the event. (This is the same user ID that is used to check the authority to issue the command or call; for commands received from a queue, this is also the user identifier (UserIdentifier) from the MD of the command message).
Identifier:	MQCACF_EVENT_USER_ID.
Data type:	MQCFST.
Maximum length:	MQ_USER_ID_LENGTH.
Returned:	Always.

EventOrigin

Description:	The origin of the action causing the event.
Identifier:	MQIACF_EVENT_ORIGIN.
Data type:	MQCFIN.
Values:	**MQEVO_CONSOLE** Console command - command line. **MQEVO_MSG** Command message from IBM MQ Explorer plugin.
Returned:	Always.

EventQMgr

Description:	The queue manager where the command or call was entered. (The queue manager where the command is executed and that generates the event is in the MD of the event message).
Identifier:	MQCACF_EVENT_Q_MGR.
Data type:	MQCFST.
Maximum length:	MQ_Q_MGR_NAME_LENGTH.
Returned:	Always.

EventAccountingToken

Description:	For commands received as a message (MQEVO_MSG), the accounting token (AccountingToken) from the MD of the command message.
Identifier:	MQBACF_EVENT_ACCOUNTING_TOKEN.
Data type:	MQCFBS.
Maximum length:	MQ_ACCOUNTING_TOKEN_LENGTH.
Returned:	Only if EventOrigin is MQEVO_MSG.

EventIdentityData

Description:	For commands received as a message (MQEVO_MSG), application identity data (ApplIdentityData) from the MD of the command message.
Identifier:	MQCACF_EVENT_APPL_IDENTITY.
Data type:	MQCFST.
Maximum length:	MQ_APPL_IDENTITY_DATA_LENGTH.
Returned:	Only if EventOrigin is MQEVO_MSG.

EventApplType

Description:	For commands received as a message (MQEVO_MSG), the type of application (PutApplType) from the MD of the command message.
Identifier:	MQIACF_EVENT_APPL_TYPE.
Data type:	MQCFIN.
Returned:	Only if EventOrigin is MQEVO_MSG.

EventApplName

Description:	For commands received as a message (MQEVO_MSG), the name of the application (PutApplName) from the MD of the command message.
Identifier:	MQCACF_EVENT_APPL_NAME.
Data type:	MQCFST.
Maximum length:	MQ_APPL_NAME_LENGTH.
Returned:	Only if EventOrigin is MQEVO_MSG.

EventApplOrigin

Description:	For commands received as a message (MQEVO_MSG), the application origin data (ApplOriginData) from the MD of the command message.
Identifier:	MQCACF_EVENT_APPL_ORIGIN.
Data type:	MQCFST.
Maximum length:	MQ_APPL_ORIGIN_DATA_LENGTH.
Returned:	Only if EventOrigin is MQEVO_MSG.

Command

Description:	The command code.
Identifier:	MQIACF_COMMAND.
Data type:	MQCFIN.
Values:	**MQCMD_INQUIRE_PROT_POLICY numeric value 205** **MQCMD_CREATE_PROT_POLICY numeric value 206** **MQCMD_DELETE_PROT_POLICY numeric value 207** **MQCMD_CHANGE_PROT_POLICY numeric value 208** These are defined in IBM MQ 8.0 `cmqcfc.h`
Returned:	Always.

CommandData contains PCF elements that comprised the PCF command.

Configuration event message format

Configuration events are PCF messages of standard IBM MQ Advanced Message Security format.

Possible values for the MQMD message descriptor can be found in Event message MQMD (message descriptor).

Here are selected MQMD values:

```
Format = MQFMT_EVENT
Peristence = MQPER_PERSISTENCE_AS_Q_DEF
PutApplType = MQAT_QMGR           //for both CLI and command server
```

Message buffer consist of MQCFH structure and the parameter structure that follows it. Possible MQCFH values can be found in Event message MQCFH (PCF header).

Here are selected MQCFH values:

```
Type = MQCFT_EVENT
Command = MQCMD_CONFIG_EVENT
MsgSeqNumber = 1 or 2          // 2 will be in case of Change Object event
Control = MQCFC_LAST or MQCFC_NOT_LAST     //MQCFC_NOT_LAST will be in case of 1 Change Object event
ParameterCount = reflects number of PCF parameters following MQCFH
CompCode = MQCC_WARNING
Reason = one of {MQRC_CONFIG_CREATE_OBJECT, MQRC_CONFIG_CHANGE_OBJECT, MQRC_CONFIG_DELETE_OBJECT}
```

The parameters following MQCFH are:

EventUserID

Description:	The user ID that issued the command or call that generated the event. (This is the same user ID that is used to check the authority to issue the command or call; for commands received from a queue, this is also the user identifier (UserIdentifier) from the MD of the command message).
Identifier:	**MQCACF_EVENT_USER_ID**
Data type:	MQCFST.
Maximum length:	MQ_USER_ID_LENGTH.
Returned:	Always.

SecurityId

Description:	Value of MQMD.AccountingToken in case of command server message or Windows SID for local command.
Identifier:	**MQBACF_EVENT_SECURITY_ID**
Data type:	MQCBS.
Maximum length:	MQ_SECURITY_ID_LENGTH.
Returned:	Always.

EventOrigin

Description:	The origin of the action causing the event.
Identifier:	**MQIACF_EVENT_ORIGIN**
Data type:	MQCFIN.
Values:	**MQEVO_CONSOLE** Console command - command line. **MQEVO_MSG** Command message from the IBM MQ Explorer plugin.
Returned:	Always.

EventQMgr

Description:	The queue manager where the command or call was entered. (The queue manager where the command is executed and that generates the event is in the MD of the event message).
Identifier:	**MQCACF_EVENT_Q_MGR**
Data type:	MQCFST
Maximum length:	MQ_Q_MGR_NAME_LENGTH
Returned:	Always.

ObjectType

Description:	Object type.
Identifier:	**MQIACF_OBJECT_TYPE**
Data type:	MQCFIN
Value:	**MQOT_PROT_POLICY** IBM MQ Advanced Message Security protection policy. **1019** - a numeric value defined in IBM MQ 8.0 or in the `cmqc.h` file.
Returned:	Always.

PolicyName

Description:	The IBM MQ Advanced Message Security policy name.
Identifier:	**MQCA_POLICY_NAME**.
Data type:	MQCFST.
Value:	**2112** - a numeric value defined in IBM MQ 8.0 or in the `cmqc.h` file.
Maximum length:	MQ_OBJECT_NAME_LENGTH.
Returned:	Always.

PolicyVersion

Description:	The IBM MQ Advanced Message Security policy version.
Identifier:	**MQIA_POLICY_VERSION**
Data type:	MQCFIN
Value	**238** - a numeric value defined in IBM MQ 8.0 or in the `cmqc.h` file.
Returned:	Always

TolerateFlag

Description:	The IBM MQ Advanced Message Security policy toleration flag.
Identifier:	**MQIA_TOLERATE_UNPROTECTED**
Data type:	MQCFIN
Value	**235** - a numeric value defined in IBM MQ 8.0 or in the `cmqc.h` file.
Returned:	Always.

SignatureAlgorithm

Description:	The IBM MQ Advanced Message Security policy signature algorithm.
Identifier:	**MQIA_SIGNATURE_ALGORITHM**
Data type:	MQCFIN
Value:	**236** - a numeric value defined in IBM MQ 8.0 or in the `cmqc.h` file.
Returned:	Whenever there is a signature algorithm defined in the IBM MQ Advanced Message Security policy

EncryptionAlgorithm

Description:	The IBM MQ Advanced Message Security policy encryption algorithm.
Identifier:	**MQIA_ENCRYPTION_ALGORITHM**
Data type:	MQCFIN
Value:	**237** - a numeric value defined in IBM MQ 8.0 or in the `cmqc.h` file.
Returned:	Whenever there is an encryption algorithm defined in the IBM MQ policy

SignerDNs

Description:	Subject DistinguishedName of allowed signers.
Identifier:	**MQCA_SIGNER_DN**
Data type:	MQCFSL
Value:	**2113** - a numeric value defined in IBM MQ 8.0 or in the `cmqc.h` file.
Maximum length:	Longest signer DN in the policy, but no longer then MQ_DISTINGUISHED_NAME_LENGTH
Returned:	Whenever defined in IBM MQ policy.

RecipientDNs

Description:	Subject DistinguishedName of allowed signers.
Identifier:	**MQCA_RECIPIENT_DN**
Data type:	MQCFSL
Value:	**2114** - a numeric value defined in IBM MQ 8.0 or in the `cmqc.h` file.
Maximum length:	Longest recipient DN in the policy, but no longer then MQ_DISTINGUISHED_NAME_LENGTH.
Returned:	Whenever defined in IBM MQ policy.

Problems and solutions

Information is provided to help you identify and resolve problems relating to IBM MQ Advanced Message Security.

For problems relating to IBM MQ Advanced Message Security check the queue manager error log first.

com.ibm.security.pkcsutil.PKCSException: Error encrypting contents

Error `com.ibm.security.pkcsutil.PKCSException: Error encrypting contents` suggests that IBM MQ Advanced Message Security has problems with accessing cryptographic algorithms.

If the following error is returned by IBM MQ Advanced Message Security:

```
DRQJP0103E  The IBM MQ Advanced Message Security Java interceptor failed to protect message.
com.ibm.security.pkcsutil.PKCSException: Error encrypting contents (java.security.InvalidKeyException: Illegal key size
```

verify if the JCE security policy in `JAVA_HOME/lib/security/local_policy.jar/*.policy` grants access to the signature algorithms used in MQ AMS policy.

If the signature algorithm you want to use is not specified in your current security policy, download the correct Java policy file, for your version of the product, from the following location :Fixes in the IBM Developer Kits.

OSGi support

To use OSGi bundle with IBM MQ Advanced Message Security additional parameters are required.

Run the following parameter during the OSGi bundle startup:

```
-Dorg.osgi.framework.system.packages.extra=com.ibm.security.pkcs7
```

When using encrypted password in your keystore.conf, the following statement must be added when OSGi bundle is running:

```
-Dorg.osgi.framework.system.packages.extra=com.ibm.security.pkcs7,com.ibm.misc
```

Restriction: IBM MQ AMS supports communication using only MQ Base Java Classes for queues protected from within the OSGi bundle.

Problems opening protected queues when using JMS

Various problems can arise when you open protected queues when using IBM MQ Advanced Message Security.

You are running JMS and you receive error 2085 (MQRC_UNKNOWN_OBJECT_NAME) together with error JMSMQ2008.

You have verified that you have set up your IBM MQ AMS as described in "Quick Start Guide for IBM MQ AMS with Java clients" on page 863.

A possible cause is that you are using a non-IBM Java Runtime Environment. This is a known limitation described in "Known limitations" on page 852.

You have not set the AMQ_DISABLE_CLIENT_AMS environment variable.

Resolving the problem

There are four options for working around this problem:

1. Start your JMS application under a supported IBM Java Runtime Environment (JRE).

2. Move your application to the same machine where your queue manager is running and have it connect using a bindings mode connection.

   A bindings mode connection uses platform native libraries to perform the IBM MQ API calls. Accordingly, the native AMS interceptor is used to perform the AMS operations and there is no reliance on the capabilities of the JRE.
3. Use an MCA interceptor, because this allows signing and encryption of messages as soon as they arrive at the queue manager, without the need for the client to perform any AMS processing.

   Given that the protection is applied at the queue manager, an alternate mechanism must be used to protect the messages in transit from the client to the queue manager. Most commonly this is achieved by configuring SSL/TLS encryption on the server connection channel used by the application.
4. Set the AMQ_DISABLE_CLIENT_AMS environment variable if you do not want to use IBM MQ AMS.

See "Message Channel Agent (MCA) interception" on page 878 for further information.

Note: A security policy must be in place for each queue that the MCA Interceptor will deliver messages onto. In other words, the target queue needs to have an AMS security policy in place with the distinguished name (DN) of the signer and recipient matching that of the certificate assigned to the MCA Interceptor. That is, the DN of the certificate designated by `cms.certificate.channel.SYSTEM.DEF.SVRCONN` property in the `keystore.conf` used by the queue manager.

Example configurations on z/OS

This section provides example configurations of policies and certificates for IBM MQ Advanced Message Security queuing scenarios on z/OS.

The examples cover the IBM MQ Advanced Message Security policies required, and the digital certificates that must exist relative to users and key rings. The examples assume that the users involved in the scenarios have been set up by following the instructions provided in Task 27: Grant users resource permissions for IBM MQ Advanced Message Security.

Local queuing of integrity-protected messages on z/OS

This example details the IBM MQ Advanced Message Security policies and certificates needed to send and retrieve integrity-protected messages to and from a queue, local to the putting and getting applications.

The example queue manager and queue are:

```
BNK6        - Queue manager
FIN.XFER.Q7 - Local queue
```

These users are used:

```
WMQBNK6  - IBM MQ AMS task user
TELLER5  - Sending user
FINADM2  - Recipient user
```

Create the user certificates

In this example, only one user certificate is needed. This is the sending user's certificate which is needed to sign integrity-protected messages. The sending user is 'TELLER5'.

The Certificate Authority (CA) certificate is also required. The CA certificate is the certificate of the authority that issued the user's certificate. This can be a chain of certificates. If so, all certificates in the chain are required in the key ring of the IBM MQ Advanced Message Security task user, in this case user WMQBNK6.

A CA certificate can be created using the RACF RACDCERT command. This certificate is used to issue user certificates. For example:

```
RACDCERT CERTAUTH GENCERT SUBJECTSDN(CN('BCOCA') O('BCO') C('US'))
KEYUSAGE(CERTSIGN) WITHLABEL('BCOCA')
```

This RACDCERT command creates a CA certificate which can then be used to issue a user certificate for user 'TELLER5'. For example:

```
RACDCERT ID(TELLER5) GENCERT SUBJECTSDN(CN('Teller5') O('BCO') C('US'))
WITHLABEL('Teller5') SIGNWITH(CERTAUTH LABEL('BCOCA'))
KEYUSAGE(HANDSHAKE DATAENCRYPT DOCSIGN)
```

Your installation will have procedures for choosing or creating a CA certificate, as well as procedures for issuing certificates and distributing them to relevant systems.

When exporting and importing these certificates, IBM MQ Advanced Message Security requires:
- The CA certificate (chain).
- The user certificate and its private key.

If you are using RACF, the RACDCERT EXPORT command can be used to export certificates to a data set, and the RACDCERT ADD command can be used to import certificates from the data set. For more information about these and other RACDCERT commands, refer to *z/OS: Security Server RACF Command Language Reference*.

The certificates in this case, are required on the z/OS system running queue manager BNK6.

When the certificates have been imported on the z/OS system running BNK6, the user certificate requires the TRUST attribute. The RACDCERT ALTER command can be used to add the TRUST attribute to the certificate. For example:

```
RACDCERT ID(TELLER5) ALTER (LABEL('Teller5')) TRUST
```

In this example, no certificate is required for the recipient user.

Connect certificates to relevant key rings

When the required certificates have been created or imported, and set as trusted, they must be connected to the appropriate user key rings on the z/OS system running BNK6. To create the key rings use the RACDCERT ADDRING commands:

```
RACDCERT ID(WMQBNK6) ADDRING(drq.ams.keyring)
RACDCERT ID(TELLER5) ADDRING(drq.ams.keyring)
```

This creates a key ring for the IBM MQ Advanced Message Security task user, WMQBNK6, and a key ring for the sending user, 'TELLER5'. Note that the key ring name drq.ams.keyring is mandatory, and the name is case-sensitive.

When the key rings have been created, the relevant certificates can be connected:

```
RACDCERT ID(WMQBNK6) CONNECT(CERTAUTH LABEL('BCOCA')
RING(drq.ams.keyring))

RACDCERT ID(TELLER5) CONNECT(ID(TELLER5) LABEL('Teller5')
RING(drq.ams.keyring) DEFAULT USAGE(PERSONAL))
```

The sending user certificate must be connected as DEFAULT. If the sending user has more than one certificate in its drq.ams.keyring, the default certificate is used for signing purposes.

The creation and modification of certificates is not recognized by IBM MQ Advanced Message Security until the queue manager is stopped and restarted, or the z/OS **MODIFY** command is used to refresh the IBM MQ Advanced Message Security certificate configuration. For example:

```
F BNK6AMSM,REFRESH KEYRING
```

Create the IBM MQ Advanced Message Security policy

In this example, integrity-protected messages are put to queue FIN.XFER.Q7 by an application running as user 'TELLER5', and retrieved from the same queue by an application running as user 'FINADM2', so only one IBM MQ Advanced Message Security policy is required.

IBM MQ Advanced Message Security policies are created using the CSQ0UTIL utility that is documented at The message security policy utility (CSQ0UTIL).

Use the CSQ0UTIL utility to run the following command:

```
setmqspl -m BNK6 -p FIN.XFER.Q7 -s MD5 -a CN=Teller5,O=BCO,C=US
```

In this policy, the queue manager is identified as BNK6. The policy name and associated queue is FIN.XFER.Q7. The algorithm that is used to generate the sender's signature is MD5, and the distinguished name (DN) of the sending user is 'CN=Teller5,O=BCO,C=US'.

After defining the policy, either restart the BNK6 queue manager, or use the z/OS **MODIFY** command to refresh the IBM MQ Advanced Message Security policy configuration. For example:

```
F BNK6AMSM,REFRESH POLICY
```

Local queuing of privacy-protected messages on z/OS

This example details the IBM MQ Advanced Message Security policies and certificates needed to send and retrieve privacy-protected messages to and from a queue, local to the putting and getting applications. Privacy-protected messages are both signed and encrypted.

The example queue manager and local queue are as follows:

```
BNK6        - Queue manager
FIN.XFER.Q8 - Local queue
```

These users are used:

```
WMQBNK6  - IBM MQ AMS task user
TELLER5  - Sending user
FINADM2  - Recipient user
```

The steps to configure this scenario are:

Create the user certificates

In this example, two user certificates are required. These are the sending user's certificate which is needed to sign messages, and the recipient user's certificate which is needed to encrypt and decrypt the message data. The sending user is 'TELLER5' and the recipient user is 'FINADM2'.

The Certificate Authority (CA) certificate is also required. The CA certificate is the certificate of the authority that issued the user's certificate. This can be a chain of certificates. If so, all certificates in the chain are required in the key ring of the IBM MQ Advanced Message Security task user, in this case user WMQBNK6.

A CA certificate can be created using the RACF RACDCERT command. This certificate is used to issue user certificates. For example:

```
RACDCERT CERTAUTH GENCERT SUBJECTSDN(CN('BCOCA') O('BCO') C('US'))
KEYUSAGE(CERTSIGN) WITHLABEL('BCOCA')
```

This RACDCERT command creates a CA certificate which can then be used to issue user certificates for users 'TELLER5' and 'FINADM2'. For example:

```
RACDCERT ID(TELLER5) GENCERT SUBJECTSDN(CN('Teller5') O('BCO') C('US'))
WITHLABEL('Teller5') SIGNWITH(CERTAUTH LABEL('BCOCA'))
KEYUSAGE(HANDSHAKE DATAENCRYPT DOCSIGN)

RACDCERT ID(FINADM2) GENCERT SUBJECTSDN(CN('FinAdm2') O('BCO') C('US'))
WITHLABEL('FinAdm2') SIGNWITH(CERTAUTH LABEL('BCOCA'))
KEYUSAGE(HANDSHAKE DATAENCRYPT DOCSIGN)
```

Your installation will have procedures for choosing or creating a CA certificate, as well as procedures for issuing certificates and distributing them to relevant systems.

When exporting and importing these certificates, IBM MQ Advanced Message Security requires:
- The CA certificate (chain).
- The sending user certificate and its private key.
- The recipient user certificate and its private key.

If you are using RACF, the RACDCERT EXPORT command can be used to export certificates to a data set, and the RACDCERT ADD command can be used to import certificates from the data set. For more information about these and other RACDCERT commands, refer to *z/OS: Security Server RACF Command Language Reference*.

The certificates in this case are required on the z/OS system running queue manager BNK6.

When the certificates have been imported on the z/OS system running BNK6, the user certificates require the TRUST attribute. The RACDCERT ALTER command can be used to add the TRUST attribute to the certificate. For example:

```
RACDCERT ID(TELLER5) ALTER (LABEL('Teller5')) TRUST
RACDCERT ID(FINADM2) ALTER (LABEL('FinAdm2')) TRUST
```

Connect certificates to relevant key rings

When the required certificates have been created or imported, and set as trusted, they must be connected to the appropriate user key rings on the z/OS system running BNK6. To create the key rings use the RACDCERT ADDRING command:

```
RACDCERT ID(WMQBNK6) ADDRING(drq.ams.keyring)
RACDCERT ID(TELLER5) ADDRING(drq.ams.keyring)
RACDCERT ID(FINADM2) ADDRING(drq.ams.keyring)
```

This creates a key ring for the IBM MQ Advanced Message Security task user and key rings for the sending and recipient users. Note that the key ring name drq.ams.keyring is mandatory, and the name is case-sensitive.

When the key rings have been created, the relevant certificates can be connected.

```
RACDCERT ID(WMQBNK6) CONNECT(CERTAUTH LABEL('BCOCA')
RING(drq.ams.keyring))

RACDCERT ID(WMQBNK6) CONNECT(ID(FINADM2) LABEL('FinAdm2')
RING(drq.ams.keyring) USAGE(SITE))

RACDCERT ID(TELLER5) CONNECT(ID(TELLER5) LABEL('Teller5')
RING(drq.ams.keyring) DEFAULT USAGE(PERSONAL))

RACDCERT ID(FINADM2) CONNECT(ID(FINADM2) LABEL('FinAdm2')
RING(drq.ams.keyring) DEFAULT USAGE(PERSONAL))
```

The sending and recipient user certificates must be connected as DEFAULT. If either user has more than one certificate in its drq.ams.keyring, the default certificate is used for signing and decryption purposes.

The recipient user's certificate must also be connected to the IBM MQ Advanced Message Security task user's key ring with USAGE(SITE). This is because the Advanced Message Security task needs the recipient's public key when encrypting the message data. The USAGE(SITE) prevents the private key from being accessible in the key ring.

The creation and modification of certificates is not recognized by IBM MQ Advanced Message Security until the queue manager is stopped and restarted, or the z/OS **MODIFY** command is used to refresh the IBM MQ Advanced Message Security certificate configuration. For example:

```
F BNK6AMSM,REFRESH KEYRING
```

Create the IBM MQ Advanced Message Security policy

In this example, privacy-protected messages are put to queue FIN.XFER.Q8 by an application running as user 'TELLER5', and retrieved from the same queue by an application running as user 'FINADM2', so only one IBM MQ Advanced Message Security policy is required.

IBM MQ Advanced Message Security policies are created using the CSQ0UTIL utility that is documented at The message security policy utility (CSQ0UTIL).

Use the CSQ0UTIL utility to run the following command:

```
setmqspl -m BNK6 -p FIN.XFER.Q8 -s SHA1 -e 3DES -a CN=Teller5,O=BCO,C=US -r CN=FinAdm2,O=BCO,C=US
```

In this policy, the queue manager is identified as BNK6. The policy name and associated queue is FIN.XFER.Q8. The algorithm that is used to generate the sender's signature is SHA1, and the distinguished name (DN) of the sending user is 'CN=Teller5,O=BCO,C=US', and the recipient user is 'CN=FinAdm2,O=BCO,C=US'. The algorithm that is used to encrypt the message data is 3DES.

After defining the policy, either restart the BNK6 queue manager, or use the z/OS **MODIFY** command to refresh the IBM MQ Advanced Message Security policy configuration. For example:

```
F BNK6AMSM,REFRESH POLICY
```

Remote queuing of integrity-protected messages on z/OS

This example details the IBM MQ Advanced Message Security policies and certificates needed to send and retrieve integrity-protected messages to and from queues managed by two different queue managers. The two queue managers can be running on the same z/OS system, or on different z/OS systems, or one queue manager can be on a distributed system running IBM MQ Advanced Message Security.

The example queue managers and queues are:

```
BNK6        - Sending queue manager
BNK7        - Recipient queue manager
FIN.XFER.Q7 - Remote queue on BNK6
FIN.RCPT.Q7 - Local queue on BNK7
```

Note: For this example, BNK6 and BNK7 are queue managers running on different z/OS systems.

These users are used:

```
WMQBNK6  - IBM MQ AMS task user on BNK6
WMQBNK7  - IBM MQ AMS task user on BNK7
TELLER5  - Sending user on BNK6
FINADM2  - Recipient user on BNK7
```

The steps to configure this scenario are as follows:

Create the user certificates

In this example, only one user certificate is needed. This is the sending user's certificate which is needed to sign integrity-protected message. The sending user is 'TELLER5'.

The Certificate Authority (CA) certificate is also required. The CA certificate is the certificate of the authority that issued the user's certificate. This can be a chain of certificates. If so, all certificates in the chain are required in the key ring of the IBM MQ Advanced Message Security task user, in this case user WMQBNK7.

A CA certificate can be created using the RACF RACDCERT command. This certificate is used to issue user certificates. For example:

```
RACDCERT CERTAUTH GENCERT SUBJECTSDN(CN('BCOCA') O('BCO') C('US'))
KEYUSAGE(CERTSIGN) WITHLABEL('BCOCA')
```

This RACDCERT command creates a CA certificate which can then be used to issue user certificate for user 'TELLER5'. For example:

```
RACDCERT ID(TELLER5) GENCERT SUBJECTSDN(CN('Teller5') O('BCO') C('US'))
WITHLABEL('Teller5') SIGNWITH(CERTAUTH LABEL('BCOCA'))
KEYUSAGE(HANDSHAKE DATAENCRYPT DOCSIGN)
```

Your installation will have procedures for choosing or creating a CA certificate, as well as procedures for issuing certificates and distributing them to relevant systems.

When exporting and importing these certificates, IBM MQ Advanced Message Security require:
- The CA certificate (chain).
- The sending user certificate and its private key.

If you are using RACF, the RACDCERT EXPORT command can be used to export certificates to a data set, and the RACDCERT ADD command can be used to import certificates from the data set. For more information about these and other RACDCERT commands, refer to *z/OS: Security Server RACF Command Language Reference*.

The certificates in this case, are required on the z/OS system running queue manager BNK6 and BNK7.

In this example, the sending certificate must be imported on the z/OS system running BNK6, and the CA certificate must be imported on the z/OS system running BNK7. When the certificates have been imported, the user certificate requires the TRUST attribute. The RACDCERT ALTER command can be used to add the TRUST attribute to the certificate. For example, on BNK6:

```
RACDCERT ID(TELLER5) ALTER (LABEL('Teller5')) TRUST
```

Connect certificates to relevant key rings

When the required certificates have been created or imported, and set as trusted, they must be connected to the appropriate user key rings on the z/OS system running BNK6 and BNK7.

To create the key rings use the RACDCERT ADDRING command, on BNK6:

```
RACDCERT ID(TELLER5) ADDRING(drq.ams.keyring)
```

This creates a key ring for the sending user on BNK6. Note that the key ring name drq.ams.keyring is mandatory, and the name is case-sensitive.

On BNK7:

```
RACDCERT ID(WMQBNK7) ADDRING(drq.ams.keyring)
```

This creates a key ring for the IBM MQ Advanced Message Security task user on BNK7. No user key ring is required for 'TELLER5' on BNK7.

When the key rings have been created, the relevant certificates can be connected.

On BNK6:

```
RACDCERT ID(TELLER5) CONNECT(ID(TELLER5) LABEL('Teller5')
RING(drq.ams.keyring) DEFAULT USAGE(PERSONAL))
```

On BNK7:

```
RACDCERT ID(WMQBNK7) CONNECT(CERTAUTH LABEL('BCOCA')
RING(drq.ams.keyring))
```

The sending user certificate must be connected as DEFAULT. If the sending user has more than one certificate in its drq.ams.keyring, the default certificate is used for signing purposes.

The creation and modification of certificates is not recognized by IBM MQ Advanced Message Security until the queue manager is stopped and restarted, or the z/OS **MODIFY** command is used to refresh the IBM MQ Advanced Message Security certificate configuration. For example:

On BNK6:

```
F BNK6AMSM,REFRESH,KEYRING
```

On BNK7:

```
F BNK7AMSM,REFRESH,KEYRING
```

Create the IBM MQ Advanced Message Security policies

In this example, integrity-protected messages are put to remote queue FIN.XFER.Q7 on BNK6 by an application running as user 'TELLER5', and retrieved from local queue FIN.RCPT.Q7 on BNK7 by an application running as user 'FINADM2', so two IBM MQ Advanced Message Security policies are required.

IBM MQ Advanced Message Security policies are created using the CSQ0UTIL utility that is documented at The message security policy utility (CSQ0UTIL).

Use the CSQ0UTIL utility to run the following command to define an integrity policy for the remote queue on BNK6:

```
setmqspl -m BNK6 -p FIN.XFER.Q7 -s MD5 -a CN=Teller5,O=BCO,C=US
```

In this policy, the queue manager is identified as BNK6. The policy name and associated queue is FIN.XFER.Q7. The algorithm that is used to generate the sender's signature is MD5, and the distinguished name (DN) of the sending user is 'CN=Teller5,O=BCO,C=US'.

Also, use the CSQ0UTIL utility to run the following command to define an integrity policy for the local queue on BNK7:

```
setmqspl -m BNK7 -p FIN.RCPT.Q7 -s MD5 -a CN=Teller5,O=BCO,C=US
```

In this policy, the queue manager is identified as BNK7. The policy name and associated queue is FIN.RCPT.Q7. The algorithm expected for the sender's signature is MD5, and the distinguished name (DN) of the sending user is expected to be 'CN=Teller5,O=BCO,C=US'.

After defining the two policies, either restart the BNK6 and BNK7 queue managers, or use the z/OS **MODIFY** command to refresh the IBM MQ Advanced Message Security policy configurations. For example:

On BNK6:

```
F BNK6AMSM,REFRESH,POLICY
```

On BNK7:

```
F BNK7AMSM,REFRESH,POLICY
```

Remote queuing of privacy-protected messages on z/OS

This example details the IBM MQ Advanced Message Security policies and certificates needed to send and retrieve privacy-protected messages to and from queues managed by two different queue managers. The two queue managers can be running on the same z/OS system, or on different z/OS systems, or one queue manager can be on a distributed system running IBM MQ Advanced Message Security.

The example queue managers and queues are:

```
BNK6        - Sending queue manager
BNK7        - Recipient queue manager
FIN.XFER.Q7 - Remote queue on BNK6
FIN.RCPT.Q7 - Local queue on BNK7
```

Note: For this example, BNK6 and BNK7 are queue managers running on different z/OS systems of the same name.

These users are used:

```
WMQBNK6  - IBM MQ AMS task user on BNK6
WMQBNK7  - IBM MQ AMS task user on BNK7
TELLER5  - Sending user on BNK6
FINADM2  - Recipient user on BNK7
```

The steps to configure this scenario are as follows:

Create the user certificates

In this example, two user certificates are required. These are the sending user's certificate which is needed to sign messages, and the recipient user's certificate which is needed to encrypt and decrypt the message data. The sending user is 'TELLER5' and the recipient user is 'FINADM2'.

The Certificate Authority (CA) certificate is also required. The CA certificate is the certificate of the authority that issued the user's certificate. This can be a chain of certificates. If so, all certificates in the chain are required in the key ring of the IBM MQ Advanced Message Security task user, in this case user WMQBNK7.

A CA certificate can be created using the RACF RACDCERT command. This certificate is used to issue user certificates. For example:

```
RACDCERT CERTAUTH GENCERT SUBJECTSDN(CN('BCOCA') O('BCO') C('US'))
KEYUSAGE(CERTSIGN) WITHLABEL('BCOCA')
```

This RACDCERT command creates a CA certificate which can then be used to issue user certificates for users 'TELLER5' and 'FINADM2'. For example:

```
RACDCERT ID(TELLER5) GENCERT SUBJECTSDN(CN('Teller5') O('BCO') C('US'))
WITHLABEL('Teller5') SIGNWITH(CERTAUTH LABEL('BCOCA'))
KEYUSAGE(HANDSHAKE DATAENCRYPT DOCSIGN)

RACDCERT ID(FINADM2) GENCERT SUBJECTSDN(CN('FinAdm2') O('BCO') C('US'))
WITHLABEL('FinAdm2') SIGNWITH(CERTAUTH LABEL('BCOCA'))
KEYUSAGE(HANDSHAKE DATAENCRYPT DOCSIGN)
```

Your installation will have procedures for choosing or creating a CA certificate, as well as procedures for issuing certificates and distributing them to relevant systems.

When exporting and importing these certificates, IBM MQ Advanced Message Security requires:
- The CA certificate (chain).
- The sending user certificate and its private key.
- The recipient user certificate and its private key.

If you are using RACF, the RACDCERT EXPORT command can be used to export certificates to a data set, and the RACDCERT ADD command can be used to import certificates from the data set. For more information about these and other RACDCERT commands, refer to *z/OS: Security Server RACF Command Language Reference*.

The certificates in this case, are required on the z/OS system running queue manager BNK6 and BNK7.

In this example, the sending and recipient certificates must be imported on the z/OS system running BNK6, and the CA and recipient certificates must be imported on the z/OS system running BNK7. When the certificates have been imported, the user certificates require the TRUST attribute. The RACDCERT ALTER command can be used to add the TRUST attribute to the certificate. For example:

On BNK6:

```
RACDCERT ID(TELLER5) ALTER (LABEL('Teller5')) TRUST
RACDCERT ID(FINADM2) ALTER (LABEL('FinAdm2')) TRUST
```

On BNK7:

```
RACDCERT ID(FINADM2) ALTER (LABEL('FinAdm2')) TRUST
```

Connect certificates to relevant key rings

When the required certificates have been created or imported, and set as trusted, they must be connected to the appropriate user key rings on the z/OS systems running BNK6 and BNK7.

To create the key rings use the RACDCERT ADDRING command:

On BNK6:

```
RACDCERT ID(WMQBNK6) ADDRING(drq.ams.keyring)
RACDCERT ID(TELLER5) ADDRING(drq.ams.keyring)
```

This creates a key ring for the IBM MQ Advanced Message Security task user and a key ring for the sending user on BNK6. Note that the key ring name drq.ams.keyring is mandatory, and the name is case-sensitive.

On BNK7:

```
RACDCERT ID(WMQBNK7) ADDRING(drq.ams.keyring)
RACDCERT ID(FINADM2) ADDRING(drq.ams.keyring)
```

This creates a key ring for the IBM MQ Advanced Message Security task user and a key ring for the recipient user on BNK7.

When the key rings have been created, the relevant certificates can be connected.

On BNK6:

```
RACDCERT ID(WMQBNK6) CONNECT(ID(FINADM2) LABEL('FinAdm2')
RING(drq.ams.keyring) USAGE(SITE))

RACDCERT ID(TELLER5) CONNECT(ID(TELLER5) LABEL('Teller5')
RING(drq.ams.keyring) DEFAULT USAGE(PERSONAL))
```

On BNK7:

```
RACDCERT ID(WMQBNK7) CONNECT(CERTAUTH LABEL('BCOCA')
RING(drq.ams.keyring))

RACDCERT ID(FINADM2) CONNECT(ID(FINADM2) LABEL('FinAdm2')
RING(drq.ams.keyring) DEFAULT USAGE(PERSONAL))
```

The sending and recipient user certificates must be connected as DEFAULT. If either user has more than one certificate in its drq.ams.keyring, the default certificate is used for signing and encryption/decryption purposes.

On BNK6, the recipient user's certificate must also be connected to the IBM MQ Advanced Message Security task user's key ring with USAGE(SITE). This is because the Advanced Message Security task needs the recipient's public key when encrypting the message data. The USAGE(SITE) prevents the private key from being accessible in the key ring.

The creation and modification of certificates is not recognized by IBM MQ Advanced Message Security until the queue manager is stopped and restarted, or the z/OS **MODIFY** command is used to refresh the IBM MQ Advanced Message Security certificate configuration. For example:

On BNK6:

```
F BNK6AMSM,REFRESH,KEYRING
```

On BNK7:

```
F BNK7AMSM,REFRESH,KEYRING
```

Create the IBM MQ Advanced Message Security policies

In this example, privacy-protected messages are put to remote queue FIN.XFER.Q7 on BNK6 by an application running as user 'TELLER5', and retrieved from local queue FIN.RCPT.Q7 on BNK7 by an application running as user 'FINADM2', so two IBM MQ Advanced Message Security policies are required.

IBM MQ Advanced Message Security policies are created using the CSQ0UTIL utility that is documented at The message security policy utility (CSQ0UTIL).

Use the CSQ0UTIL utility to run the following command to define a privacy policy for the remote queue on BNK6:

```
setmqspl -m BNK6 -p FIN.XFER.Q7 -s SHA1 -e 3DES -a CN=Teller5,O=BCO,C=US -r CN=FinAdm2,O=BCO,C=US
```

In this policy, the queue manager is identified as BNK6. The policy name and associated queue is FIN.XFER.Q7. The algorithm that is used to generate the sender's signature is SHA1, the distinguished name (DN) of the sending user is 'CN=Teller5,O=BCO,C=US', and the recipient user is 'CN=FinAdm2,O=BCO,C=US'. The algorithm that is used to encrypt the message data is 3DES.

Also, use the CSQ0UTIL utility to run the following command to define a privacy policy for the local queue on BNK7:

```
setmqspl -m BNK7 -p FIN.RCPT.Q7 -s SHA1 -e 3DES -a CN=Teller5,O=BCO,C=US -r CN=FinAdm2,O=BCO,C=US
```

In this policy, the queue manager is identified as BNK7. The policy name and associated queue is FIN.RCPT.Q7. The algorithm expected for the sender's signature is SHA1, the distinguished name (DN) of the sending user is expected to be 'CN=Teller5,O=BCO,C=US', and the recipient user is 'CN=FinAdm2,O=BCO,C=US'. The algorithm that is used to decrypt the message data is 3DES.

After defining the two policies, either restart the BNK6 and BNK7 queue managers, or use the z/OS **MODIFY** command to refresh the IBM MQ Advanced Message Security policy configuration. For example:

On BNK6:

```
F BNK6AMSM,REFRESH,POLICY
```

On BNK7:

```
F BNK7AMSM,REFRESH,POLICY
```

Monitoring and performance

Use the monitoring information and guidance in this section, and the specific tuning tips, to help improve the performance of your queue manager network.

Depending on the size and complexity of your queue manager network, you can obtain a range of information from monitoring the network. You can use that information, along with the information provided in specific tuning tips, to help you tune your network performance.

Monitoring your IBM MQ network

A number of monitoring techniques are available in IBM MQ to obtain statistics and other specific information about how your queue manager network is running. Use the monitoring information and guidance in this section to help improve the performance of your queue manager network.

The following list provides examples of reasons for monitoring your queue manager network:

- Detect problems in your queue manager network.
- Assist in determining the causes of problems in your queue manager network.
- Improve the efficiency of your queue manager network.
- Familiarize yourself with the running of your queue manager network.
- Confirm that your queue manager network is running correctly.
- Generate messages when certain events occur.
- Record message activity.
- Determine the last known location of a message.
- Check various statistics of a queue manager network in real time.
- Generate an audit trail.
- Account for application resource usage.
- Capacity planning.

Event monitoring

Event monitoring is the process of detecting occurrences of *instrumentation events* in a queue manager network. An instrumentation event is a logical combination of events that is detected by a queue manager or channel instance. Such an event causes the queue manager or channel instance to put a special message, called an *event message*, on an event queue.

IBM MQ instrumentation events provide information about errors, warnings, and other significant occurrences in a queue manager. Use these events to monitor the operation of the queue managers in your queue manager network to achieve the following goals:

- Detect problems in your queue manager network.
- Assist in determining the causes of problems in your queue manager network.
- Generate an audit trail.
- React to queue manager state changes

Event message format

Instrumentation events

An instrumentation event is a logical combination of conditions that a queue manager or channel instance detects and puts a special message, called an *event message*, on an event queue.

IBM MQ instrumentation events provide information about errors, warnings, and other significant occurrences in a queue manager. You can use these events to monitor the operation of queue managers (with other methods such as Tivoli NetView for z/OS).

Figure 86 on page 931 illustrates the concept of instrumentation events.

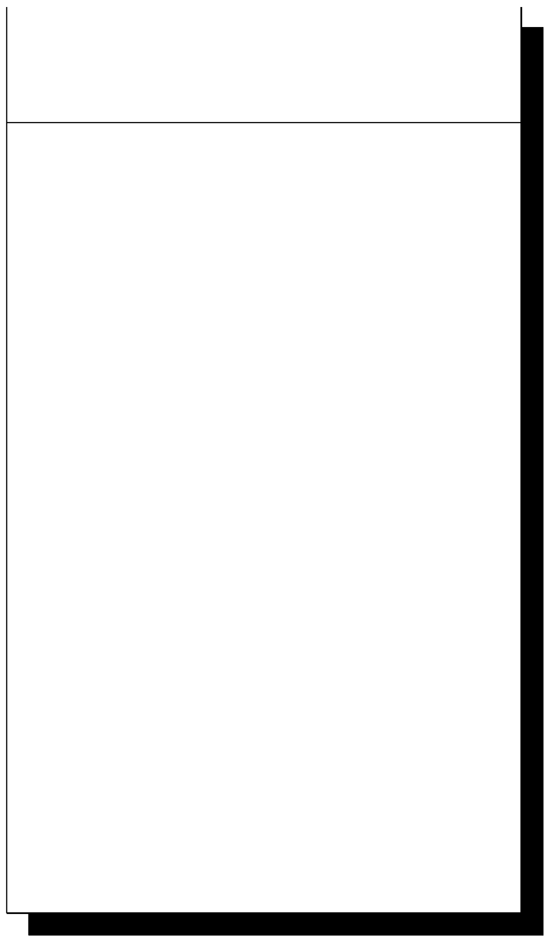

Figure 86. Understanding instrumentation events

Event monitoring applications

Applications that use events to monitor queue managers must include the following provisions:

1. Set up channels between the queue managers in your network.
2. Implement the required data conversions. The normal rules of data conversion apply. For example, if you are monitoring events on a UNIX system queue manager from a z/OS queue manager, ensure that you convert EBCDIC to ASCII.

Event notification through event queues

When an event occurs, the queue manager puts an event message on the appropriate event queue, if defined. The event message contains information about the event that you can retrieve by writing a suitable MQI application program that performs the following steps:

- Get the message from the queue.
- Process the message to extract the event data.

The related information describes the format of event messages.

Conditions that cause events

The following list gives examples of conditions that can cause instrumentation events:

- A threshold limit for the number of messages on a queue is reached.
- A channel instance is started or stopped.
- A queue manager becomes active, or is requested to stop.
- An application tries to open a queue specifying a user ID that is not authorized on IBM MQ for IBM i, Windows, UNIX and Linux systems.
- Objects are created, deleted, changed, or refreshed.
- An MQSC or PCF command runs successfully.
- A queue manager starts writing to a new log extent.
- Putting a message on the dead-letter queue, if the event conditions are met.

Related concepts:

"Performance events" on page 944
Performance events relate to conditions that can affect the performance of applications that use a specified queue. The scope of performance events is the queue. **MQPUT** calls and **MQGET** calls on one queue do not affect the generation of performance events on another queue.

"Sample program to monitor instrumentation events" on page 977
V 8.0.0.4 **amqsevt** formats the instrumentation events that a queue manager can create, and is supplied with IBM MQ. The program reads messages from event queues, and formats them into readable strings.

Event types:

Use this page to view the types of instrumentation event that a queue manager or channel instance can report

IBM MQ instrumentation events have the following types:

- Queue manager events
- Channel and bridge events
- Performance events
- Configuration events
- Command events
- Logger events
- Local events

For each queue manager, each category of event has its own event queue. All events in that category result in an event message being put onto the same queue.

This event queue:	Contains messages from:
SYSTEM.ADMIN.QMGR.EVENT	Queue manager events
SYSTEM.ADMIN.CHANNEL.EVENT	Channel events
SYSTEM.ADMIN.PERFM.EVENT	Performance events
SYSTEM.ADMIN.CONFIG.EVENT	Configuration events
SYSTEM.ADMIN.COMMAND.EVENT	Command events
SYSTEM.ADMIN.LOGGER.EVENT	Logger events
SYSTEM.ADMIN.PUBSUB.EVENT	Gets events related to Publish/Subscribe. Only used with Multicast. For more information see, Multicast application monitoring.

By incorporating instrumentation events into your own system management application, you can monitor the activities across many queue managers, across many different nodes, and for multiple IBM MQ applications. In particular, you can monitor all the nodes in your system from a single node (for those nodes that support IBM MQ events) as shown inFigure 87.

Instrumentation events can be reported through a user-written reporting mechanism to an administration application that can present the events to an operator.

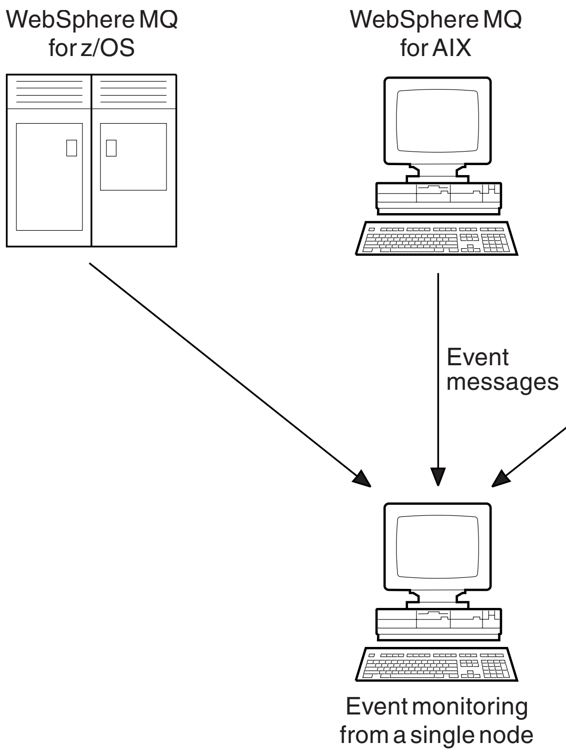

Figure 87. Monitoring queue managers across different platforms, on a single node

Instrumentation events also enable applications acting as agents for other administration networks, for example Tivoli NetView for z/OS, to monitor reports and create the appropriate alerts.

Queue manager events:

Queue manager events are related to the use of resources within queue managers. For example, a queue manager event is generated if an application tries to put a message on a queue that does not exist.

The following examples are conditions that can cause a queue manager event:

- An application issues an MQI call that fails. The reason code from the call is the same as the reason code in the event message.

  A similar condition can occur during the internal operation of a queue manager; for example, when generating a report message. The reason code in an event message might match an MQI reason code, even though it is not associated with any application. Do not assume that, because an event message reason code looks like an MQI reason code, the event was necessarily caused by an unsuccessful MQI call from an application.
- A command is issued to a queue manager and processing this command causes an event. For example:
  - A queue manager is stopped or started.
  - A command is issued where the associated user ID is not authorized for that command.

IBM MQ puts messages for queue manager events on the SYSTEM.ADMIN.QMGR.EVENT queue, and supports the following queue manager event types:

Authority (on Windows, and UNIX systems only)

Authority events report an authorization, such as an application trying to open a queue for which it does not have the required authority, or a command being issued from a user ID that does not have the required authority. The authority event message can contain the following event data:

- Not Authorized (type 1)
- Not Authorized (type 2)
- Not Authorized (type 3)
- Not Authorized (type 4)
- Not Authorized (type 5)
- Not Authorized (type 6)

All authority events are valid on Windows, and UNIX systems only.

Inhibit

Inhibit events indicate that an MQPUT or MQGET operation has been attempted against a queue where the queue is inhibited for puts or gets, or against a topic where the topic is inhibited for publishes. The inhibit event message can contain the following event data:

- Get Inhibited
- Put Inhibited

Local

Local events indicate that an application (or the queue manager) has not been able to access a local queue or other local object. For example, an application might try to access an object that has not been defined. The local event message can contain the following event data:

- Alias Base Queue Type Error
- Unknown Alias Base Queue
- Unknown Object Name

Remote

Remote events indicate that an application or the queue manager cannot access a remote queue on another queue manager. For example, the transmission queue to be used might not be correctly defined. The remote event message can contain the following event data:

- Default Transmission Queue Type Error
- Default Transmission Queue Usage Error
- Queue Type Error
- Remote Queue Name Error
- Transmission Queue Type Error
- Transmission Queue Usage Error
- Unknown Default Transmission Queue
- Unknown Remote Queue Manager
- Unknown Transmission Queue

Start and stop

Start and stop events indicate that a queue manager has been started or has been requested to stop or quiesce.

z/OS supports only start events.

Stop events are not recorded unless the default message-persistence of the SYSTEM.ADMIN.QMGR.EVENT queue is defined as persistent. The start and stop event message can contain the following event data:

- Queue Manager Active

- Queue Manager Not Active

For each event type in this list, you can set a queue manager attribute to enable or disable the event type.

Channel and bridge events:

Channels report these events as a result of conditions detected during their operation. For example, when a channel instance is stopped.

Channel events are generated in the following circumstances:
- When a command starts or stops a channel.
- When a channel instance starts or stops.
- When a channel receives a conversion error warning when getting a message.
- When an attempt is made to create a channel automatically; the event is generated whether the attempt succeeds or fails.

Note: Client connections do not cause Channel Started or Channel Stopped events.

When a command is used to start a channel, an event is generated. Another event is generated when the channel instance starts. However, starting a channel by a listener, the **runmqchl** command, or a queue manager trigger message does not generate an event. In these cases, an event is generated only when the channel instance starts.

A successful start or stop channel command generates at least two events. These events are generated for both queue managers connected by the channel (providing they support events).

If a channel event is put on an event queue, an error condition causes the queue manager to create an event.

The event messages for channel and bridge events are put on the SYSTEM.ADMIN.CHANNEL.EVENT queue.

The channel event messages can contain the following event data:
- Channel Activated
- Channel Auto-definition Error
- Channel Auto-definition OK
- Channel Conversion Error
- Channel Not Activated
- Channel Started
- Channel Stopped
- Channel Stopped By User
- Channel Blocked

z/OS

IMS bridge events (z/OS only)

These events are reported when an IMS bridge starts or stops.

The IMS bridge event messages can contain the following event data:
- Bridge Started
- Bridge Stopped

SSL events

The only Secure Sockets Layer (SSL or TLS) event is the Channel SSL Error event. This event is reported when a channel using SSL or TLS fails to establish an SSL connection.

The SSL event messages can contain the following event data:
- Channel SSL Error
- Channel SSL Warning

Performance events:

Performance events are notifications that a resource has reached a threshold condition. For example, a queue depth limit has been reached.

Performance events relate to conditions that can affect the performance of applications that use a specified queue. They are not generated for the event queues themselves.

The event type is returned in the command identifier field in the message data.

If a queue manager tries to put a queue manager event or performance event message on an event queue and an error that would typically create an event is detected, another event is not created and no action is taken.

MQGET and MQPUT calls within a unit of work can generate performance events regardless of whether the unit of work is committed or backed out.

The event messages for performance events are put on the SYSTEM.ADMIN.PERFM.EVENT queue.

There are two types of performance event:

Queue depth events
Queue depth events relate to the number of messages on a queue; that is, how full or empty the queue is. These events are supported for shared queues. The queue depth event messages can contain the following event data:
- Queue Depth High
- Queue Depth Low
- Queue Full

Queue service interval events
Queue service interval events relate to whether messages are processed within a user-specified time interval. These events are not supported for shared queues.

z/OS IBM MQ for z/OS supports queue depth events for QSGDISP (SHARED) queues, but not service interval events. Queue manager and channel events remain unaffected by shared queues. The queue service event messages can contain the following event data:
- Queue Service Interval High
- Queue Service Interval OK

Configuration events:

Configuration events are generated when a configuration event is requested explicitly, or automatically when an object is created, modified, or deleted.

A configuration event message contains information about the attributes of an object. For example, a configuration event message is generated if a namelist object is created, and contains information about the attributes of the namelist object.

The event messages for configuration events are put on the SYSTEM.ADMIN.CONFIG.EVENT queue.

There are four types of configuration event:

Create object events
Create object events are generated when an object is created. The event message contains the following event data: Create object.

Change object events
Change object events are generated when an object is changed. The event message contains the following event data: Change object.

Delete object events
Delete object events are generated when an object is deleted. The event message contains the following event data: Delete object.

Refresh object events
Refresh object events are generated by an explicit request to refresh. The event message contains the following event data: Refresh object.

Command events:

Command events are reported when an MQSC or PCF command runs successfully.

A command event message contains information about the origin, context, and content of a command. For example, a command event message is generated with such information if the MQSC command, ALTER QLOCAL, runs successfully.

The event messages for command events are put on the SYSTEM.ADMIN.COMMAND.EVENT queue.

Command events contain the following event data: Command.

Logger events:

Logger events are reported when a queue manager that uses linear logging starts writing log records to a new log extent IBM i or, on IBM i, to a new journal receiver. z/OS Logger events are not available with IBM MQ for z/OS.

A logger event message contains information specifying the log extents required by the queue manager to restart the queue manager, or for media recovery.

The event messages for logger events are put on the SYSTEM.ADMIN.LOGGER.EVENT queue.

The logger event message contains the following event data: Logger.

Event message data summary:

Use this summary to obtain information about the event data that each type of event message can contain.

Event type	**See these topics**
Authority events	Not Authorized (type 1)

Start and stop events	Queue Manager Active
	Queue Manager Not Active

Controlling events:

You enable and disable events by specifying the appropriate values for queue manager, queue attributes, or both, depending on the type of event.

You must enable each instrumentation event that you want to be generated. For example, the conditions causing a Queue Full event are:
- Queue Full events are enabled for a specified queue, and
- An application issues an MQPUT request to put a message on that queue, but the request fails because the queue is full.

Enable and disable events by using any of the following techniques:
- IBM MQ script commands (MQSC).
- The corresponding IBM MQ PCF commands.
- z/OS The operations and control panels for queue managers on z/OS.
- The IBM MQ Explorer.

Note: You can set attributes related to events for both queues and queue managers only by command. The MQI call MQSET does not support attributes related to events.

Related concepts:

"Instrumentation events" on page 930
An instrumentation event is a logical combination of conditions that a queue manager or channel instance detects and puts a special message, called an *event message*, on an event queue.

Related reference:

"Event types" on page 932
Use this page to view the types of instrumentation event that a queue manager or channel instance can report

Introducing the operations and control panels

Controlling queue manager events:

You control queue manager events by using queue manager attributes. To enable queue manager events, set the appropriate queue manager attribute to `ENABLED`. To disable queue manager events, set the appropriate queue manager attribute to `DISABLED`.

To enable or disable queue manager events, use the MQSC command ALTER QMGR, specifying the appropriate queue manager attribute. Table 101 summarizes how to enable queue manager events. To disable a queue manager event, set the appropriate parameter to `DISABLED`.

Table 101. Enabling queue manager events using MQSC commands

Event	**ALTER QMGR parameter**
Authority	AUTHOREV (ENABLED)
Inhibit	INHIBTEV (ENABLED)
Local	LOCALEV (ENABLED)
Remote	REMOTEEV (ENABLED)
Start and Stop	STRSTPEV (ENABLED)

Controlling channel and bridge events:

You control channel events by using queue manager attributes. To enable channel events, set the appropriate queue manager attribute to `ENABLED`. To disable channel events, set the appropriate queue manager attribute to `DISABLED`.

To enable or disable channels events use the MQSC command ALTER QMGR, specifying the appropriate queue manager attribute. Table 102 on page 941 summarizes how you enable channel and bridge events. To disable a queue manager event, set the appropriate parameter to `DISABLED`.

Restriction: z/OS Channel auto-definition events are not available on IBM MQ for z/OS.

Table 102. Enabling channel and bridge events using MQSC commands

Event	ALTER QMGR parameter
Channel	CHLEV (ENABLED)
Related to channel errors only	CHLEV (EXCEPTION)
IMS bridge	BRIDGEEV (ENABLED)
SSL	SSLEV (ENABLED)
Channel auto-definition	CHADEV(ENABLED)

With CHLEV set to exception, the following return codes, and corresponding reason qualifiers are generated:
- MQRC_CHANNEL_ACTIVATED
- MQRC_CHANNEL_CONV_ERROR
- MQRC_CHANNEL_NOT_ACTIVATED
- MQRC_CHANNEL_STOPPED
  - with the following ReasonQualifiers:
    - MQRQ_CHANNEL_STOPPED_ERROR
    - MQRQ_CHANNEL_STOPPED_RETRY
    - MQRQ_CHANNEL_STOPPED_DISABLED
- MQRC_CHANNEL_STOPPED_BY_USER
- MQRC_CHANNEL_BLOCKED
  - with the following ReasonQualifiers:
    - MQRQ_CHANNEL_BLOCKED_NOACCESS
    - MQRQ_CHANNEL_BLOCKED_USERID
    - MQRQ_CHANNEL_BLOCKED_ADDRESS

Controlling performance events:

You control performance events using the PERFMEV queue manager attribute. To enable performance events, set PERFMEV to `ENABLED`. To disable performance events, set the PERFMEV queue manager attribute to `DISABLED`.

To set the PERFMEV queue manager attribute to `ENABLED`, use the following MQSC command:

```
ALTER QMGR PERFMEV (ENABLED)
```

To enable specific performance events, set the appropriate queue attribute. Also, specify the conditions that cause the event.

Queue depth events

By default, all queue depth events are disabled. To configure a queue for any of the queue depth events:
1. Enable performance events on the queue manager.
2. Enable the event on the required queue.
3. Set the limits, if required, to the appropriate levels, expressed as a percentage of the maximum queue depth.

Queue service interval events

To configure a queue for queue service interval events you must:
1. Enable performance events on the queue manager.
2. Set the control attribute for a Queue Service Interval High or OK event on the queue as required.

3. Specify the service interval time by setting the QSVCINT attribute for the queue to the appropriate length of time.

Note: When enabled, a queue service interval event can be generated at any appropriate time, not necessarily waiting until an MQI call for the queue is issued. However, if an MQI call is used on a queue to put or remove a message, any applicable performance event is generated at that time. The event is *not* generated when the elapsed time becomes equal to the service interval time.

Controlling configuration, command, and logger events:

You control configuration, command, and logger events by using the queue manager attributes CONFIGEV, CMDEV, and LOGGEREV. To enable these events, set the appropriate queue manager attribute to ENABLED. To disable these events, set the appropriate queue manager attribute to DISABLED.

Configuration events
To enable configuration events, set CONFIGEV to ENABLED. To disable configuration events, set CONFIGEV to DISABLED. For example, you can enable configuration events by using the following MQSC command:

```
ALTER QMGR CONFIGEV (ENABLED)
```

Command events
To enable command events, set CMDEV to ENABLED. To enable command events for commands except DISPLAY MQSC commands and Inquire PCF commands, set the CMDEV to NODISPLAY. To disable command events, set CMDEV to DISABLED. For example, you can enable command events by using the following MQSC command:

```
ALTER QMGR CMDEV (ENABLED)
```

Logger events
To enable logger events, set LOGGEREV to ENABLED. To disable logger events, set LOGGEREV to DISABLED. For example, you can enable logger events by using the following MQSC command:

```
ALTER QMGR LOGGEREV(ENABLED)
```

Event queues:

When an event occurs, the queue manager puts an event message on the defined event queue. The event message contains information about the event.

You can define event queues, either as:
- Local queues
- Alias queues
- Local definitions of remote queues, or as
- Remote cluster queues

If you define all your event queues as local definitions of the same remote queue on one queue manager, you can centralize your monitoring activities.

You must not define event queues as transmission queues, because event messages have formats that are incompatible with the message format that is required for transmission queues.

Shared event queues are local queues defined with the QSGDISP(SHARED) value.

For more information about defining shared queues on z/OS, see Application programming with shared queues.

When an event queue is unavailable

If an event occurs when the event queue is not available, the event message is lost. For example, if you do not define an event queue for a category of event, all event messages for that category are lost. The event messages are not, for example, saved on the dead-letter (undelivered-message) queue.

However, you can define the event queue as a remote queue. Then, if there is a problem on the remote system putting messages to the resolved queue, the event message arrives on the dead-letter queue of the remote system.

An event queue might be unavailable for many different reasons including:
- The queue has not been defined.
- The queue has been deleted.
- The queue is full.
- The queue has been put-inhibited.

The absence of an event queue does not prevent the event from occurring. For example, after a performance event, the queue manager changes the queue attributes and resets the queue statistics. This change happens whether the event message is put on the performance event queue or not. The same is true in the case of configuration and command events.

Using triggered event queues

You can set up the event queues with triggers so that when an event is generated, the event message being put onto the event queue starts a user-written monitoring application. This application can process the event messages and take appropriate action. For example, certain events might require an operator to be informed, other events might start an application that performs some administration tasks automatically.

Event queues can have trigger actions associated with them and can create trigger messages. However, if these trigger messages in turn cause conditions that would normally generate an event, no event is generated. not generating an event in this instance ensures that looping does not occur.

Related concepts:

"Controlling events" on page 939
You enable and disable events by specifying the appropriate values for queue manager, queue attributes, or both, depending on the type of event.

"Format of event messages"
Event messages contain information about an event and its cause. Like other IBM MQ messages, an event message has two parts: a message descriptor and the message data.

Related information:

Application programming with shared queues

QSGDisp (MQLONG)

Conditions for a trigger event

Format of event messages:

Event messages contain information about an event and its cause. Like other IBM MQ messages, an event message has two parts: a message descriptor and the message data.
- The message descriptor is based on the MQMD structure.
- The message data consists of an *event header* and the *event data*. The event header contains the reason code that identifies the event type. Putting the event message, and any subsequent action, does not affect the reason code returned by the MQI call that caused the event. The event data provides further information about the event.

Typically, you process event messages with a system management application tailored to meet the requirements of the enterprise at which it runs.

When the queue managers in a queue sharing group detect the conditions for generating an event message, several queue managers can generate an event message for the shared queue, resulting in several event messages. To ensure that a system can correlate multiple event messages from different queue managers, these event messages have a unique correlation identifier *(CorrelId)* set in the message descriptor (MQMD).

Performance events

Performance events relate to conditions that can affect the performance of applications that use a specified queue. The scope of performance events is the queue. **MQPUT** calls and **MQGET** calls on one queue do not affect the generation of performance events on another queue.

Performance event messages can be generated at any appropriate time, not necessarily waiting until an MQI call for the queue is issued. However, if you use an MQI call on a queue to put or remove a message, any appropriate performance events are generated at that time.

Every performance event message that is generated is placed on the queue, SYSTEM.ADMIN.PERFM.EVENT.

The event data contains a reason code that identifies the cause of the event, a set of performance event statistics, and other data. The types of event data that can be returned in performance event messages are described in the following list:

- Queue Depth High
- Queue Depth Low
- Queue Full
- Queue Service Interval High
- Queue Service Interval OK

Examples that illustrate the use of performance events assume that you set queue attributes by using the appropriate IBM MQ commands (MQSC). On z/OS, you can also set queue attributes using the operations and controls panels for queue managers.

Related reference:

"Event types" on page 932
Use this page to view the types of instrumentation event that a queue manager or channel instance can report

Performance event statistics:

The performance event data in the event message contains statistics about the event. Use the statistics to analyze the behavior of a specified queue.

The event data in the event message contains information about the event for system management programs. For all performance events, the event data contains the names of the queue manager and the queue associated with the event. The event data also contains statistics related to the event. Table 103 summarizes the event statistics that you can use to analyze the behavior of a queue. All the statistics refer to what has happened since the last time the statistics were reset.

Table 103. Performance event statistics

Parameter	Description
TimeSinceReset	The elapsed time since the statistics were last reset.
HighQDepth	The maximum number of messages on the queue since the statistics were last reset.
MsgEnqCount	The number of messages enqueued (the number of MQPUT calls to the queue), since the statistics were last reset.
MsgDeqCount	The number of messages dequeued (the number of MQGET calls to the queue), since the statistics were last reset.

Performance event statistics are reset when any of the following changes occur:
- A performance event occurs (statistics are reset on all active queue managers).
- A queue manager stops and restarts.
- The PCF command, Reset Queue Statistics, is issued from an application program.
- z/OS On z/OS only, the RESET QSTATS command is issued at the console.

Related concepts:

"Performance events" on page 944
Performance events relate to conditions that can affect the performance of applications that use a specified queue. The scope of performance events is the queue. **MQPUT** calls and **MQGET** calls on one queue do not affect the generation of performance events on another queue.

"The service timer" on page 947
Queue service interval events use an internal timer, called the *service timer*, which is controlled by the queue manager. The service timer is used only if a queue service interval event is enabled.

"Rules for queue service interval events" on page 948
Formal rules control when the service timer is set and queue service interval events are generated.

To configure a queue for queue service interval events you set the appropriate queue manager and queue attributes.

Related information:

Queue Depth High

Reset Queue Statistics

RESET QSTATS

Queue service interval events:

Queue service interval events indicate whether an operation was performed on a queue within a user-defined time interval called the *service interval*. Depending on your installation, you can use queue service interval events to monitor whether messages are being taken off queues quickly enough.

Queue service interval events are *not* supported on shared queues.

The following types of queue service interval events can occur, where the term *get operation* refers to an **`MQGET`** call or an activity that removes a messages from a queue, such as using the **`CLEAR QLOCAL`** command:

Queue Service Interval OK

Indicates that after one of the following operations:

- An MQPUT call
- A get operation that leaves a non-empty queue

a get operation was performed within a user-defined time period, known as the *service interval*.

Only a get operation can cause the Queue Service Interval OK event message. Queue Service Interval OK events are sometimes described as OK events.

Queue Service Interval High

Indicates that after one of the following operations:

- An MQPUT call
- A get operation that leaves a non-empty queue

a get operation was **not** performed within a user-defined service interval.

Either a get operation or an MQPUT call can cause the Queue Service Interval High event message. Queue Service Interval High events are sometimes described as High events.

To enable both Queue Service Interval OK and Queue Service Interval High events, set the `QServiceIntervalEvent` control attribute to High. Queue Service Interval OK events are automatically enabled when a Queue Service Interval High event is generated. You do not need to enable Queue Service Interval OK events independently.

OK and High events are mutually exclusive, so if one is enabled the other is disabled. However, both events can be simultaneously disabled.

Figure 88 shows a graph of queue depth against time. At time P1, an application issues an MQPUT, to put a message on the queue. At time G1, another application issues an MQGET to remove the message from the queue.

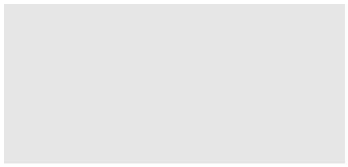

Figure 88. Understanding queue service interval events

The possible outcomes of queue service interval events are as follows:

- If the elapsed time between the put and the get is less than or equal to the service interval:
  - A *Queue Service Interval OK* event is generated at time G1, if queue service interval events are enabled
- If the elapsed time between the put and get is greater than the service interval:
  - A *Queue Service Interval High* event is generated at time G1, if queue service interval events are enabled.

The algorithm for starting the service timer and generating events is described in "Rules for queue service interval events" on page 948.

QServiceIntervalEvent (10-digit signed integer)

ServiceIntervalEvent property

The service timer:

Queue service interval events use an internal timer, called the *service timer*, which is controlled by the queue manager. The service timer is used only if a queue service interval event is enabled.

What precisely does the service timer measure?
The service timer measures the elapsed time between an MQPUT call to an empty queue or a get operation, and the next put or get, provided the queue depth is nonzero between these two operations.

When is the service timer active?
The service timer is always active (running), if the queue has messages on it (depth is nonzero) and a queue service interval event is enabled. If the queue becomes empty (queue depth zero), the timer is put into an OFF state, to be restarted on the next put.

When is the service timer reset?
The service timer is always reset after a get operation . It is also reset by an MQPUT call to an empty queue. However, it is not necessarily reset on a queue service interval event.

How is the service timer used?
Following a get operation or an MQPUT call, the queue manager compares the elapsed time as measured by the service timer, with the user-defined service interval. The result of this comparison is that:

- An OK event is generated if there is a get operation and the elapsed time is less than or equal to the service interval, AND this event is enabled.
- A high event is generated if the elapsed time is greater than the service interval, AND this event is enabled.

Can applications read the service timer?
No, the service timer is an internal timer that is not available to applications.

What about the *TimeSinceReset* parameter?
The *TimeSinceReset* parameter is returned as part of the event statistics in the event data. It specifies the time between successive queue service interval events, unless the event statistics are reset.

Rules for queue service interval events:

Formal rules control when the service timer is set and queue service interval events are generated.

Rules for the service timer

The service timer is reset to zero and restarted as follows:
- After an MQPUT call to an empty queue.
- After an MQGET call, if the queue is not empty after the MQGET call.

The resetting of the timer does not depend on whether an event has been generated.

At queue manager startup the service timer is set to startup time if the queue depth is greater than zero.

If the queue is empty following a get operation, the timer is put into an OFF state.

Queue Service Interval High events

The Queue Service Interval event must be enabled (set to `HIGH`).

Queue Service Interval High events are automatically enabled when a Queue Service Interval OK event is generated.

If the service time is greater than the service interval, an event is generated on, or before, the next MQPUT or get operation.

Queue Service Interval OK events

Queue Service Interval OK events are automatically enabled when a Queue Service Interval High event is generated.

If the service time (elapsed time) is less than or equal to the service interval, an event is generated on, or before, the next get operation.
Related tasks:
"Enabling queue service interval events"
To configure a queue for queue service interval events you set the appropriate queue manager and queue attributes.

Enabling queue service interval events:

To configure a queue for queue service interval events you set the appropriate queue manager and queue attributes.

About this task

The high and OK events are mutually exclusive; that is, when one is enabled, the other is automatically disabled:
- When a high event is generated on a queue, the queue manager automatically disables high events and enables OK events for that queue.
- When an OK event is generated on a queue, the queue manager automatically disables OK events and enables high events for that queue.

Table 104. Enabling queue service interval events using MQSC

Queue service interval event	Queue attributes
Queue Service Interval High Queue Service Interval OK No queue service interval events	QSVCIEV (HIGH) QSVCIEV (OK) QSVCIEV (NONE)
Service interval	QSVCINT (*tt*) where *tt* is the service interval time in milliseconds.

Perform the following steps to enable queue service interval events:

Procedure

1. Set the queue manager attribute PERFMEV to ENABLED. Performance events are enabled on the queue manager.
2. Set the control attribute, QSVCIEV, for a Queue Service Interval High or OK event on the queue, as required.
3. Set the QSVCINT attribute for the queue to specify the appropriate service interval time.

Example

To enable Queue Service Interval High events with a service interval time of 10 seconds (10 000 milliseconds) use the following MQSC commands:

```
ALTER QMGR PERFMEV(ENABLED)

ALTER QLOCAL('MYQUEUE') QSVCINT(10000) QSVCIEV(HIGH)
```

.

Queue service interval events examples:

Use the examples in this section to understand the information that you can obtain from queue service interval events.

The three subtopic examples provide progressively more complex illustrations of the use of queue service interval events.

The figures accompanying the examples in each subtopic have the same structure:

- Figure 1 is a graph of queue depth against time, showing individual MQGET calls and MQPUT calls.
- The Commentary section shows a comparison of the time constraints. There are three time periods that you must consider:
  - The user-defined service interval.
  - The time measured by the service timer.
  - The time since event statistics were last reset (TimeSinceReset in the event data).
- The Event statistics summary section shows which events are enabled at any instant and what events are generated.

The examples illustrate the following aspects of queue service interval events:

- How the queue depth varies over time.
- How the elapsed time as measured by the service timer compares with the service interval.
- Which event is enabled.
- Which events are generated.

Remember: Example 1 shows a simple case where the messages are intermittent and each message is removed from the queue before the next one arrives. From the event data, you know that the maximum number of messages on the queue was one. You can, therefore, work out how long each message was on the queue.

However, in the general case, where there is more than one message on the queue and the sequence of MQGET calls and MQPUT calls is not predictable, you cannot use queue service interval events to calculate how long an individual message remains on a queue. The TimeSinceReset parameter, which is returned in the event data, can include a proportion of time when there are no messages on the queue. Therefore any results you derive from these statistics are implicitly averaged to include these times.

Related concepts:

"Queue service interval events" on page 946

Queue service interval events indicate whether an operation was performed on a queue within a user-defined time interval called the *service interval*. Depending on your installation, you can use queue service interval events to monitor whether messages are being taken off queues quickly enough.

"The service timer" on page 947

Queue service interval events use an internal timer, called the *service timer*, which is controlled by the queue manager. The service timer is used only if a queue service interval event is enabled.

Queue service interval events: example 1:

A basic sequence of MQGET calls and MQPUT calls, where the queue depth is always one or zero.

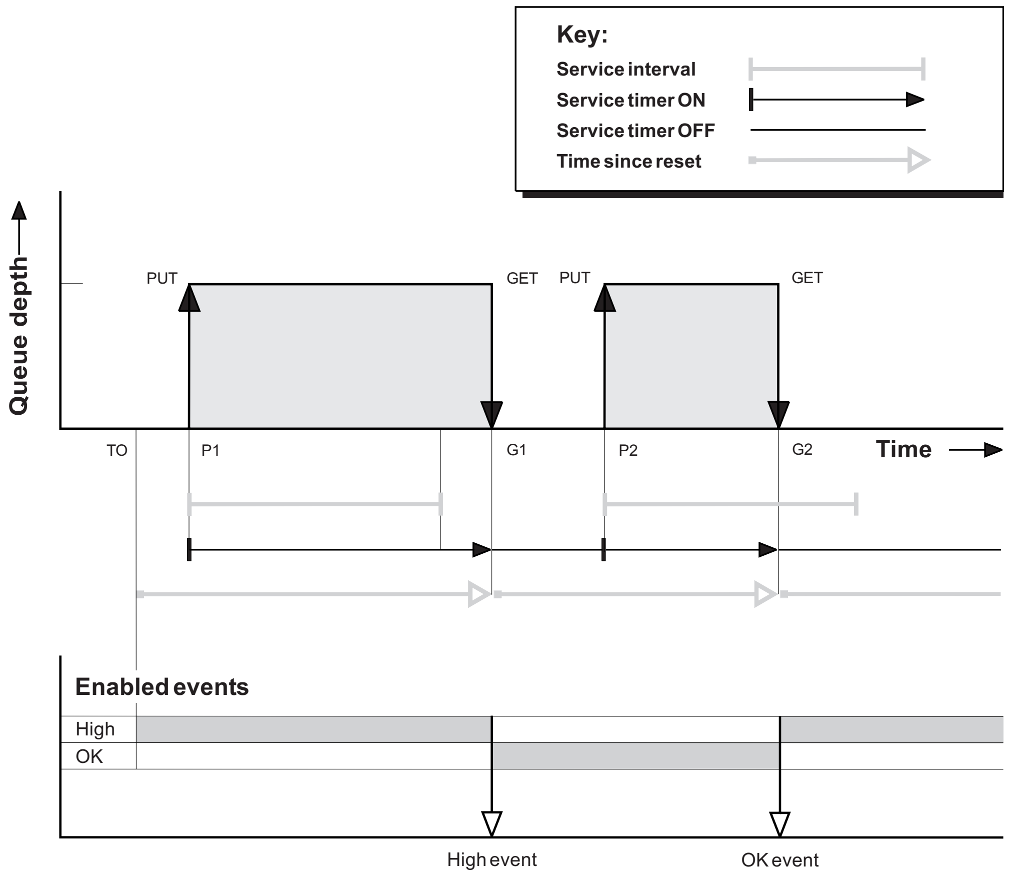

Figure 89. Queue service interval events - example 1

Commentary

1. At P1, an application puts a message onto an empty queue. This starts the service timer.

   Note that T0 might be queue manager startup time.
2. At G1, another application gets the message from the queue. Because the elapsed time between P1 and G1 is greater than the service interval, a Queue Service Interval High event is generated on the MQGET call at G1. When the high event is generated, the queue manager resets the event control attribute so that:
   a. The OK event is automatically enabled.
   b. The high event is disabled.

   Because the queue is now empty, the service timer is switched to an OFF state.
3. At P2, a second message is put onto the queue. This restarts the service timer.
4. At G2, the message is removed from the queue. However, because the elapsed time between P2 and G2 is less than the service interval, a Queue Service Interval OK event is generated on the MQGET call at G2. When the OK event is generated, the queue manager resets the control attribute so that:
   a. The high event is automatically enabled.
   b. The OK event is disabled.

   Because the queue is empty, the service timer is again switched to an OFF state.

Event statistics summary

Table 105 summarizes the event statistics for this example.

Table 105. Event statistics summary for example 1

	Event 1	**Event 2**
Time of event	T(G1)	T(G2)
Type of event	High	OK
TimeSinceReset	T(G1) - T(0)	T(G2) - T(G1)
HighQDepth	1	1
MsgEnqCount	1	1
MsgDeqCount	1	1

The middle part of Figure 89 on page 950 shows the elapsed time as measured by the service timer compared to the service interval for that queue. To see whether a queue service interval event might occur, compare the length of the horizontal line representing the service timer (with arrow) to that of the line representing the service interval. If the service timer line is longer, and the Queue Service Interval High event is enabled, a Queue Service Interval High event occurs on the next get. If the timer line is shorter, and the Queue Service Interval OK event is enabled, a Queue Service Interval OK event occurs on the next get.

Queue service interval events: example 2:

A sequence of MQPUT calls and MQGET calls, where the queue depth is not always one or zero.

This example also shows instances of the timer being reset without events being generated, for example, at time P2.

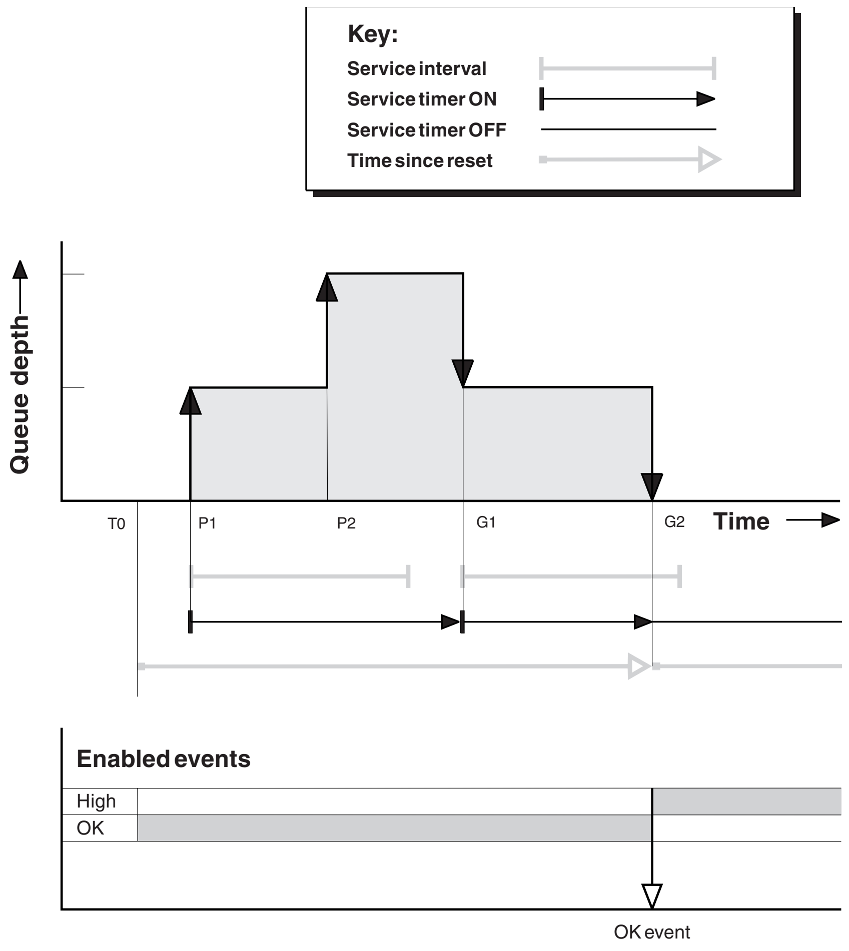

Figure 90. Queue service interval events - example 2

Commentary

In this example, OK events are enabled initially and queue statistics were reset at time T0.

1. At P1, the first put starts the service timer.
2. At P2, the second put does not generate an event because a put cannot cause an OK event.
3. At G1, the service interval has now been exceeded and therefore an OK event is not generated. However, the MQGET call causes the service timer to be reset.
4. At G2, the second get occurs within the service interval and this time an OK event is generated. The queue manager resets the event control attribute so that:
   a. The high event is automatically enabled.
   b. The OK event is disabled.

   Because the queue is now empty, the service timer is switched to an OFF state.

Event statistics summary

Table 106 summarizes the event statistics for this example.

Table 106. Event statistics summary for example 2

	Event 2
Time of event	T(G2)
Type of event	OK
TimeSinceReset	T(G2) - T(0)
HighQDepth	2
MsgEnqCount	2
MsgDeqCount	2

Queue service interval events: example 3:

A sequence of MQGET calls and MQPUT calls that is more sporadic than the previous examples.

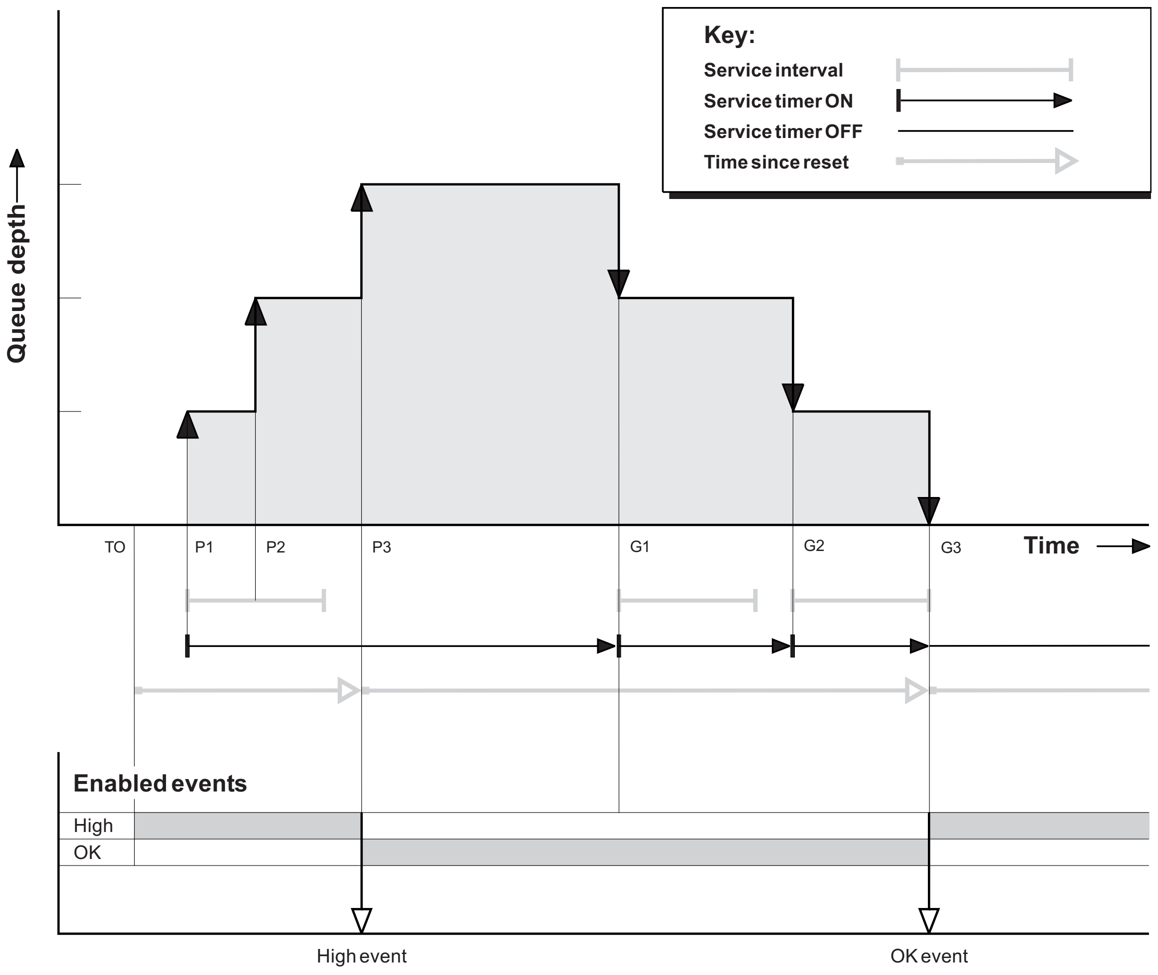

Figure 91. Queue service interval events - example 3

Commentary

1. At time T(0), the queue statistics are reset and Queue Service Interval High events are enabled.
2. At P1, the first put starts the service timer.
3. At P2, the second put increases the queue depth to two. A high event is not generated here because the service interval time has not been exceeded.
4. At P3, the third put causes a high event to be generated. (The timer has exceeded the service interval.) The timer is not reset because the queue depth was not zero before the put. However, OK events are enabled.
5. At G1, the MQGET call does not generate an event because the service interval has been exceeded and OK events are enabled. The MQGET call does, however, reset the service timer.
6. At G2, the MQGET call does not generate an event because the service interval has been exceeded and OK events are enabled. Again, the MQGET call resets the service timer.
7. At G3, the third get empties the queue and the service timer is *equal* to the service interval. Therefore an OK event is generated. The service timer is reset and high events are enabled. The MQGET call empties the queue, and this puts the timer in the OFF state.

Event statistics summary

Table 107 summarizes the event statistics for this example.

Table 107. Event statistics summary for example 3

	Event 1	**Event 2**
Time of event	T(P3)	T(G3)
Type of event	High	OK
TimeSinceReset	T(P3) - T(0)	T(G3) - T(P3)
HighQDepth	3	3
MsgEnqCount	3	0
MsgDeqCount	0	3

Queue depth events:

Queue depth events are related to the queue depth, that is, the number of messages on the queue.

In IBM MQ applications, queues must not become full. If they do, applications can no longer put messages on the queue that they specify. Although the message is not lost if this occurs, a full queue can cause considerable inconvenience. The number of messages can build up on a queue if the messages are being put onto the queue faster than the applications that process them can take them off.

The solution to this problem depends on the particular circumstances, but might involve:

- Diverting some messages to another queue.
- Starting new applications to take more messages off the queue.
- Stopping nonessential message traffic.
- Increasing the queue depth to overcome a transient maximum.

Advance warning that problems might be on their way makes it easier to take preventive action. For this purpose, IBM MQ provides the following queue depth events:

Queue Depth High events
: Indicate that the queue depth has increased to a predefined threshold called the Queue Depth High limit.

Queue Depth Low events
Indicate that the queue depth has decreased to a predefined threshold called the Queue Depth Low limit.

Queue Full events
Indicate that the queue has reached its maximum depth, that is, the queue is full.

A Queue Full Event is generated when an application attempts to put a message on a queue that has reached its maximum depth. Queue Depth High events give advance warning that a queue is filling up. This means that having received this event, the system administrator needs to take some preventive action. You can configure the queue manager such that, if the preventive action is successful and the queue depth drops to a safer level, the queue manager generates a Queue Depth Low event.

The first queue depth event example illustrates the effect of presumed action preventing the queue becoming full.

Queue Depth Low

Enabling queue depth events:

To configure a queue for any of the queue depth events you set the appropriate queue manager and queue attributes.

About this task

By default, all queue depth events are disabled. When enabled, queue depth events are generated as follows:

- A Queue Depth High event is generated when a message is put on the queue, causing the queue depth to be greater than or equal to the value determined by the Queue Depth High limit.
  - A Queue Depth High event is automatically enabled by a Queue Depth Low event on the same queue.
  - A Queue Depth High event automatically enables both a Queue Depth Low and a Queue Full event on the same queue.
- A Queue Depth Low event is generated when a message is removed from a queue by a get operation causing the queue depth to be less than or equal to the value determined by the Queue Depth Low limit.
  - A Queue Depth Low event is automatically enabled by a Queue Depth High event or a Queue Full event on the same queue.
  - A Queue Depth Low event automatically enables both a Queue Depth High and a Queue Full event on the same queue.
- A Queue Full event is generated when an application is unable to put a message onto a queue because the queue is full.
  - A Queue Full event is automatically enabled by a Queue Depth High or a Queue Depth Low event on the same queue.
  - A Queue Full event automatically enables a Queue Depth Low event on the same queue.

Perform the following steps to configure a queue for any of the queue depth events:

Procedure

1. Enable performance events on the queue manager, using the queue manager attribute PERFMEV.
2. Set one of the following attributes to enable the event on the required queue:
   - *QDepthHighEvent* (QDPHIEV in MQSC)
   - *QDepthLowEvent* (QDPLOEV in MQSC)
   - *QDepthMaxEvent* (QDPMAXEV in MQSC)
3. Optional: To set the limits, assign the following attributes, as a percentage of the maximum queue depth:
   - *QDepthHighLimit* (QDEPTHHI in MQSC)
   - *QDepthLowLimit* (QDEPTHLO in MQSC)

   Restriction: QDEPTHHI must not be less than QDEPTHLO.

   If QDEPTHHI equals QDEPTHLO an event message is generated every time the queue depth passes the value in either direction, because the high threshold is enabled when the queue depth is below the value and the low threshold is enabled when the depth is above the value.

Results

Note:

A Queue Depth Low event is not generated when expired messages are removed from a queue by a get operation causing the queue depth to be less than, or equal to, the value determined by the Queue Depth Low limit.

IBM MQ generates the low event message only during a successful get operation. Therefore, when the expired messages are removed from the queue, no queue depth low event message is generated.

Additionally, after the removal of these expired messages from the queue, queue depth high event and queue depth low event are not reset.

Example

To enable Queue Depth High events on the queue MYQUEUE with a limit set at 80%, use the following MQSC commands:

```
ALTER QMGR PERFMEV(ENABLED)
ALTER QLOCAL('MYQUEUE') QDEPTHHI(80) QDPHIEV(ENABLED)
```

To enable Queue Depth Low events on the queue MYQUEUE with a limit set at 20%, use the following MQSC commands:

```
ALTER QMGR PERFMEV(ENABLED)
ALTER QLOCAL('MYQUEUE') QDEPTHLO(20) QDPLOEV(ENABLED)
```

To enable Queue Full events on the queue MYQUEUE, use the following MQSC commands:

```
ALTER QMGR PERFMEV(ENABLED)
ALTER QLOCAL('MYQUEUE') QDPMAXEV(ENABLED)
```

Shared queues and queue depth events (IBM MQ for z/OS):

Event monitoring is more straightforward for an application that uses shared queues if all the queue managers in the queue-sharing group have the same setting for the PERFMEV attribute.

When a queue depth event occurs on a shared queue, and the queue manager attribute PERFMEV is set to ENABLED, the queue managers in the queue-sharing group produce an event message. If PERFMEV is set to DISABLED on some of the queue managers, event messages are not produced by those queue managers, making event monitoring from an application more difficult. For more straightforward monitoring, give each queue manager the same setting for the PERFMEV attribute.

This event message that each queue manager generates represents its individual usage of the shared queue. If a queue manager performs no activity on the shared queue, various values in the event message are null or zero. You can use null event messages as follows:
- Ensure that each active queue manager in a queue-sharing group generates one event message
- Highlight cases of no activity on a shared queue for the queue manager that produced the event message

Coordinating queue manager

When a queue manager issues a queue depth event, it updates the shared queue object definition to toggle the active performance event attributes. For example, depending on the definition of the queue attributes, a Queue Depth High event enables a Queue Depth Low and a Queue Full event. After updating the shared queue object successfully, the queue manager that detected the performance event initially becomes the *coordinating queue manager*.

If enabled for performance events, the coordinating queue manager performs the following actions:
1. Issues an event message that captures all shared queue performance data it has gathered since the last time an event message was created, or since the queue statistics were last reset. The message descriptor (MQMD) of this message contains a unique correlation identifier (*CorrelId*) created by the coordinating queue manager.
2. Broadcasts to all other *active* queue managers in the same queue-sharing group to request the production of an event message for the shared queue. The broadcast contains the correlation identifier created by the coordinating queue manager for the set of event messages.

Having received a request from the coordinating queue manager, if there is an active queue manager in the queue-sharing group that is enabled for performance events , that active queue manager issues an event message for the shared queue. The event message that is issued contains information about all the operations performed by the receiving (active) queue manager since the last time an event message was created, or since the statistics were last reset. The message descriptor (MQMD) of this event message contains the unique correlation identifier (*CorrelId*) specified by the coordinating queue manager.

When performance events occur on a shared queue, *n* event messages are produced, where *n* is a number from 1 to the number of active queue managers in the queue-sharing group. Each event message contains data that relates to the shared queue activity for the queue manager that generated the event message.

You can view event message data for a shared queue using the following views:

Queue-sharing view
Collects all data from event messages with the same correlation identifier.

Queue manager view

Each event message shows how much it has been used by its originating queue manager.

Differences between shared and nonshared queues

Enabling queue depth events on shared queues differs from enabling them on nonshared queues. A key difference is that events are switched on for shared queues even if PERFMEV is DISABLED on the queue manager. This is not the case for nonshared queues.

Consider the following example, which illustrates this difference:

- QM1 is a queue manager with `PerformanceEvent` (PERFMEV in MQSC) set to DISABLED.
- SQ1 is a shared queue with QSGDISP set to (SHARED) QLOCAL in MQSC.
- LQ1 is a nonshared queue with QSGDISP set to (QMGR) QLOCAL in MQSC.

Both queues have the following attributes set on their definitions:

- QDPHIEV (ENABLED)
- QDPLOEV (DISABLED)
- QDPMAXEV (DISABLED)

If messages are placed on both queues so that the depth meets or exceeds the QDEPTHHI threshold, the QDPHIEV value on SQ1 switches to DISABLED. Also, QDPLOEV and QDPMAXEV are switched to ENABLED. SQ1's attributes are automatically switched for each performance event at the time the event criteria are met.

In contrast the attributes for LQ1 remain unchanged until PERFMEV on the queue manager is ENABLED. This means that if the queue manager's PERFMEV attribute is ENABLED, DISABLED and then re-ENABLED for example, the performance event settings on shared queues might not be consistent with those of nonshared queues, even though they might have initially been the same.

Queue depth events examples:

Use these examples to understand the information that you can obtain from queue depth events

The first example provides a basic illustration of queue depth events. The second example is more extensive, but the principles are the same as for the first example. Both examples use the same queue definition, as follows:

The queue, MYQUEUE1, has a maximum depth of 1000 messages. The high queue depth limit is 80% and the low queue depth limit is 20%. Initially, Queue Depth High events are enabled, while the other queue depth events are disabled.

The IBM MQ commands (MQSC) to configure this queue are:

```
ALTER QMGR PERFMEV(ENABLED)

DEFINE QLOCAL('MYQUEUE1') MAXDEPTH(1000) QDPMAXEV(DISABLED) QDEPTHHI(80)
QDPHIEV(ENABLED) QDEPTHLO(20) QDPLOEV(DISABLED)
```

Related concepts:

The MQSC commands

Queue depth events: example 1:

A basic sequence of queue depth events.

Figure 92 shows the variation of queue depth over time.

Figure 92. Queue depth events (1)

Commentary

1. At T(1), the queue depth is increasing (more MQPUT calls than MQGET calls) and crosses the Queue Depth Low limit. No event is generated at this time.
2. The queue depth continues to increase until T(2), when the depth high limit (80%) is reached and a Queue Depth High event is generated.

   This enables both Queue Full and Queue Depth Low events.
3. The (presumed) preventive actions instigated by the event prevent the queue from becoming full. By time T(3), the Queue Depth High limit has been reached again, this time from above. No event is generated at this time.

4. The queue depth continues to fall until T(4), when it reaches the depth low limit (20%) and a Queue Depth Low event is generated.

   This enables both Queue Full and Queue Depth High events.

Event statistics summary

Table 108 summarizes the queue event statistics and Table 109 summarizes which events are enabled.

Table 108. Event statistics summary for queue depth events (example 1)

	Event 2	**Event 4**
Time of event	T(2)	T(4)
Type of event	Queue Depth High	Queue Depth Low
TimeSinceReset	T(2) - T(0)	T(4) - T(2)
HighQDepth (Maximum queue depth since reset)	800	900
MsgEnqCount	1157	1220
MsgDeqCount	357	1820

Table 109. Summary showing which events are enabled

Time period	**Queue Depth High event**	**Queue Depth Low event**	**Queue Full event**
Before T(1)	ENABLED	-	-
T(1) to T(2)	ENABLED	-	-
T(2) to T(3)	-	ENABLED	ENABLED
T(3) to T(4)	-	ENABLED	ENABLED
After T(4)	ENABLED	-	ENABLED

Queue depth events: example 2:

A more extensive sequence of queue depth events.

Figure 93 on page 961 shows the variation of queue depth over time.

Figure 93. Queue depth events (2)

Commentary

1. No Queue Depth Low event is generated at the following times:
   - T(1) (Queue depth increasing, and not enabled)
   - T(2) (Not enabled)
   - T(3) (Queue depth increasing, and not enabled)
2. At T(4) a Queue Depth High event occurs. This enables both Queue Full and Queue Depth Low events.
3. At T(9) a Queue Full event occurs **after** the first message that cannot be put on the queue because the queue is full.
4. At T(12) a Queue Depth Low event occurs.

Event statistics summary

Table 110 on page 962 summarizes the queue event statistics and Table 111 on page 962 summarizes which events are enabled at different times for this example.

Table 110. Event statistics summary for queue depth events (example 2)

	Event 4	Event 6	Event 8	Event 9	Event 12
Time of event	T(4)	T(6)	T(8)	T(9)	T(12)
Type of event	Queue Depth High	Queue Depth Low	Queue Depth High	Queue Full	Queue Depth Low
TimeSinceReset	T(4) - T(0)	T(6) - T(4)	T(8) - T(6)	T(9) - T(8)	T(12) - T(9)
HighQDepth	800	855	800	1000	1000
MsgEnqCount	1645	311	1377	324	221
MsgDeqCount	845	911	777	124	1021

Table 111. Summary showing which events are enabled

Time period	Queue Depth High event	Queue Depth Low event	Queue Full event
T(0) to T(4)	ENABLED	-	-
T(4) to T(6)	-	ENABLED	ENABLED
T(6) to T(8)	ENABLED	-	ENABLED
T(8) to T(9)	-	ENABLED	ENABLED
T(9) to T(12)	-	ENABLED	-
After T(12)	ENABLED	-	ENABLED

Note: Events are out of syncpoint. Therefore you could have an empty queue, then fill it up causing an event, then roll back all of the messages under the control of a syncpoint manager. However, event enabling has been automatically set, so that the next time the queue fills up, no event is generated.

Configuration events

Configuration events are notifications that are generated when an object is created, changed, or deleted, and can also be generated by explicit requests.

Configuration events notify you about changes to the attributes of an object. There are four types of configuration events:

- Create object events
- Change object events
- Delete object events
- Refresh object events

The event data contains the following information:

Origin information
: comprises the queue manager from where the change was made, the ID of the user that made the change, and how the change came about, for example by a console command.

Context information
: a replica of the context information in the message data from the command message.

: Context information is included in the event data only when the command was entered as a message on the SYSTEM.COMMAND.INPUT queue.

Object identity
: comprises the name, type and disposition of the object.

Object attributes
: comprises the values of all the attributes in the object.

In the case of change object events, two messages are generated, one with the information before the change, the other with the information after.

Every configuration event message that is generated is placed on the queue SYSTEM.ADMIN.CONFIG.EVENT.

Related concepts:

"Configuration events" on page 937
Configuration events are generated when a configuration event is requested explicitly, or automatically when an object is created, modified, or deleted.

Refresh object

Configuration event generation:

Use this page to view the commands that cause configuration events to be generated and to understand the circumstances in which configuration events are not generated

A configuration event message is put to the configuration event queue when the CONFIGEV queue manager attribute is ENABLED and

- any of the following commands, or their PCF equivalent, are issued:
  - DELETE AUTHINFO
  - DELETE CFSTRUCT
  - DELETE CHANNEL
  - DELETE NAMELIST
  - DELETE PROCESS
  - DELETE QMODEL/QALIAS/QREMOTE
  - DELETE STGCLASS
  - DELETE TOPIC
  - REFRESH QMGR
- any of the following commands, or their PCF equivalent, are issued even if there is no change to the object:
  - DEFINE/ALTER AUTHINFO
  - DEFINE/ALTER CFSTRUCT
  - DEFINE/ALTER CHANNEL
  - DEFINE/ALTER NAMELIST
  - DEFINE/ALTER PROCESS
  - DEFINE/ALTER QMODEL/QALIAS/QREMOTE
  - DEFINE/ALTER STGCLASS
  - DEFINE/ALTER TOPIC
  - DEFINE MAXSMSGS
  - SET CHLAUTH

- ALTER QMGR, unless the CONFIGEV attribute is DISABLED and is not changed to ENABLED

- any of the following commands, or their PCF equivalent, are issued for a local queue that is not temporary dynamic, even if there is no change to the queue.
  - DELETE QLOCAL
  - DEFINE/ALTER QLOCAL
- an MQSET call is issued, other than for a temporary dynamic queue, even if there is no change to the object.

When configuration events are not generated

Configuration events messages are not generated in the following circumstances:

- When a command or an MQSET call fails
- When a queue manager encounters an error trying to put a configuration event on the event queue, in which case the command or MQSET call completes, but no event message is generated
- For a temporary dynamic queue
- When internal changes are made to the TRIGGER queue attribute
- For the configuration event queue SYSTEM.ADMIN.CONFIG.EVENT, except by the REFRESH QMGR command
- For REFRESH/RESET CLUSTER and RESUME/SUSPEND QMGR commands that cause clustering changes
- When Creating or deleting a queue manager

MQSET - Set object attributes

Configuration event usage:

Use this page to view how you can use configuration events to obtain information about your system, and to understand the factors, such as CMDSCOPE, that can affect your use of configuration events.

You can use configuration events for the following purposes:

1. To produce and maintain a central configuration repository, from which reports can be produced and information about the structure of the system can be generated.
2. To generate an audit trail. For example, if an object is changed unexpectedly, information regarding who made the alteration and when it was done can be stored.

   This can be particularly useful when command events are also enabled. If an MQSC or PCF command causes a configuration event and a command event to be generated, both event messages will share the same correlation identifier in their message descriptor.

For an MQSET call or any of the following commands:

- DEFINE object
- ALTER object
- DELETE object

if the queue manager attribute CONFIGEV is enabled, but the configuration event message cannot be put on the configuration event queue, for example the event queue has not been defined, the command or MQSET call is executed regardless.

Effects of CMDSCOPE

For commands where CMDSCOPE is used, the configuration event message or messages will be generated on the queue manager or queue managers where the command is executed, not where the command is entered. However, all the origin and context information in the event data will relate to the original command as entered, even where the command using CMDSCOPE is one that has been generated by the source queue manager.

Where a queue sharing group includes queue managers that are not at the current version, events will be generated for any command that is executed by means of CMDSCOPE on a queue manager that is at the current version, but not on those that are at a previous version. This happens even if the queue manager where the command is entered is at the previous version, although in such a case no context information is included in the event data.

MQSET - Set object attributes

MQSET - Set object attributes

Refresh Object configuration event:

The Refresh Object configuration event is different from the other configuration events, because it occurs only when explicitly requested.

The create, change, and delete events are generated by an MQSET call or by a command to change an object but the refresh object event occurs only when explicitly requested by the MQSC command, REFRESH QMGR, or its PCF equivalent.

The REFRESH QMGR command is different from all the other commands that generate configuration events. All the other commands apply to a particular object and generate a single configuration event for that object. The REFRESH QMGR command can produce many configuration event messages potentially representing every object definition stored by a queue manager. One event message is generated for each object that is selected.

The REFRESH QMGR command uses a combination of three selection criteria to filter the number of objects involved:

- Object Name
- Object Type
- Refresh Interval

If you specify none of the selection criteria on the REFRESH QMGR command, the default values are used for each selection criteria and a refresh configuration event message is generated for every object definition stored by the queue manager. This might cause unacceptable processing times and event message generation. Consider specifying some selection criteria.

The REFRESH QMGR command that generates the refresh events can be used in the following situations:

- When configuration data is wanted about all or some of the objects in a system regardless of whether the objects have been recently manipulated, for example, when configuration events are first enabled.

  Consider using several commands, each with a different selection of objects, but such that all are included.
- If there has been an error in the SYSTEM.ADMIN.CONFIG.EVENT queue. In this circumstance, no configuration event messages are generated for Create, Change, or Delete events. When the error on the queue has been corrected, the Refresh Queue Manager command can be used to request the generation of event messages, which were lost while there was an error in the queue. In this situation consider setting the refresh interval to the time for which the queue was unavailable.

REFRESH QMGR

Refresh Queue Manager

Command events

Command events are notifications that an MQSC, or PCF command has run successfully.

The event data contains the following information:

Origin information
comprises the queue manager from where the command was issued, the ID of the user that issued the command, and how the command was issued, for example by a console command.

Context information
a replica of the context information in the message data from the command message. If a command is not entered using a message, context information is omitted.

Context information is included in the event data only when the command was entered as a message on the SYSTEM.COMMAND.INPUT queue.

Command information
the type of command that was issued.

Command data
- for PCF commands, a replica of the command data
- for MQSC commands, the command text

The command data format does not necessarily match the format of the original command. For example, on distributed platforms the command data format is always in PCF format, even if the original request was an MQSC command.

Every command event message that is generated is placed on the command event queue, SYSTEM.ADMIN.COMMAND.EVENT.

Command

Command event generation:

Use this page to view the situations that cause command events to be generated and to understand the circumstances in which command events are not generated

A command event message is generated in the following situations:
- When the CMDEV queue manager attribute is specified as ENABLED and an MQSC or PCF command runs successfully.
- When the CMDEV queue manager attribute is specified as NODISPLAY and any command runs successfully, with the exception of DISPLAY commands (MQSC), and Inquire commands (PCF).
- When you run the MQSC command, ALTER QMGR, or the PCF command, Change Queue Manager, and the CMDEV queue manager attribute meets either of the following conditions:
  - CMDEV is not specified as DISABLED after the change
  - CMDEV was not specified as DISABLED before the change

If a command runs against the command event queue, SYSTEM.ADMIN.COMMAND.EVENT, a command event is generated if the queue still exists and it is not put-inhibited.

When command events are not generated

A command event message is not generated in the following circumstances:
- When a command fails
- When a queue manager encounters an error trying to put a command event on the event queue, in which case the command runs regardless, but no event message is generated
- For the MQSC command REFRESH QMGR TYPE (EARLY)
- For the MQSC command START QMGR MQSC
- For the MQSC command SUSPEND QMGR, if the parameter LOG is specified
- For the MQSC command RESUME QMGR, if the parameter LOG is specified

RESUME QMGR

SUSPEND QMGR, RESUME QMGR and clusters

Command event usage:

Use this page to view how you can use command events to generate an audit trail of the commands that have run

For example, if an object is changed unexpectedly, information regarding who made the alteration and when it was done can be stored. This can be particularly useful when configuration events are also enabled. If an MQSC or PCF command causes a command event and a configuration event to be generated, both event messages will share the same correlation identifier in their message descriptor.

If a command event message is generated, but cannot be put on the command event queue, for example if the command event queue has not been defined, the command for which the command event was generated still runs regardless.

Effects of CMDSCOPE

For commands where CMDSCOPE is used, the command event message or messages will be generated on the queue manager or queue managers where the command runs, not where the command is entered. However, all the origin and context information in the event data will relate to the original command as entered, even where the command using CMDSCOPE is one that has been generated by the source queue manager.

Related concepts:

Logger events

Logger events are notifications that a queue manager has started writing to a new log extent IBM i or, on IBM i, a journal receiver. z/OS Logger event messages are not available with IBM MQ for z/OS.

The event data contains the following information:

- The name of the current log extent.
- The name of the earliest log extent needed for restart recovery.
- The name of the earliest log extent needed for media recovery.
- The directory in which the log extents are located.

Every logger event message that is generated is placed on the logger event queue, SYSTEM.ADMIN.LOGGER.EVENT.

Logger event generation:

Use this page to view the situations that cause logger events to be generated and to understand the circumstances in which logger events are not generated

A logger event message is generated in the following situations:

- When the LOGGEREV queue manager attribute is specified as ENABLED and the queue manager starts writing to a new log extent or, on IBM i, a journal receiver.
- When the LOGGEREV queue manager attribute is specified as ENABLED and the queue manager starts.
- When the LOGGEREV queue manager attribute is changed from DISABLED to ENABLED.

Tip: You can use the RESET QMGR MQSC command to request a queue manager to start writing to a new log extent.

When logger events are not generated

A logger event message is not generated in the following circumstances:

- When a queue manager is configured to use circular logging.

  In this case, the LOGGEREV queue manager attribute is set as DISABLED and cannot be altered.
- When a queue manager encounters an error trying to put a logger event on the event queue, in which case the action that caused the event completes, but no event message is generated.

Logger event usage:

Use this page to view how you can use logger events to determine the log extents that are no longer required for queue manager restart, or media recovery.

You can archive superfluous log extents to a medium such as tape for disaster recovery before removing them from the active log directory. Regular removal of superfluous log extents keeps disk space usage to a minimum.

If the LOGGEREV queue manager attribute is enabled, but a logger event message cannot be put on the logger event queue, for example because the event queue has not been defined, the action that caused the event continues regardless.

Authority configuration events

V 8.0.0.4

Authority configuration events are output when a change is made from any of the security control operations through the command line, MQSC, PCF, or corresponding iSeries commands.

The event data contains the following information:

Origin information
comprises the queue manager from where the change was made, the ID of the user that made the change, and how the change came about, for example by a console command.

Context information
a replica of the context information in the message data from the command message.

Context information is included in the event data when the command was entered as a message on the SYSTEM.ADMIN.COMMAND.QUEUE queue.

Authority Record identity
comprises the profile name, and object type of the authority record.

Object attributes
comprises the values of all the attributes in the authority record.

In the case of change authority record events, two messages are generated, one with the information before the change, the other with the information after the change.

Every event message that is generated is placed on the SYSTEM.ADMIN.CONFIG.EVENT queue.

"Event types" on page 932
Use this page to view the types of instrumentation event that a queue manager or channel instance can report

Authority configuration event generation: V 8.0.0.4

Use this page to view the situations that cause authority configuration events to be generated, and to understand the circumstances in which authority configuration events are not generated.

Authority configuration events notify you about changes to the attributes of an authority record. There are three types of authority configuration event:
- Change Authority Record
- Delete Authority Record
- Refresh Authority Record

An authority event message is put to the configuration event queue, when the **`CONFIGEV`** queue manager attribute is set to *ENABLED* and any of the following commands, or their MQSC equivalent, are issued, even if there is no actual change to the authority record:
- Delete Authority Record PCF command
- Set Authority Record PCF command
- setmqaut control command
- RVKMQMAUT CL command
- GRTMQMAUT CL command

When authority configuration events are not generated

The authority configuration event messages are not generated in the following circumstances:
- When a command fails
- When a queue manager encounters an error trying to put a message on the event queue, in which case the command completes, but no event message is generated
- When creating or deleting a queue manager
- When an object is deleted regardless of the **`AUTHREC`** option on the delete command. The corresponding command event shows that operation, which does not apply to the authority record for individual users.

Related concepts:

"Command events" on page 966
Command events are notifications that an MQSC, or PCF command has run successfully.

Sample program to monitor instrumentation events

V 8.0.0.4 **`amqsevt`** formats the instrumentation events that a queue manager can create, and is supplied with IBM MQ. The program reads messages from event queues, and formats them into readable strings.

V 8.0.0.4

As a sample program, both source and binary are provided. The sample is provided on all the distributed platforms, including IBM i.

The single binary file `amqsevt` (or `amqsevt.exe`) is shipped in the samples fileset and is installed in the samples bin (`tools\c\samples\bin` or `bin64`) directory.

The source files `amqsevta.c` is also shipped in the samples fileset, and is installed in the samples directory, that is, `tools\c\samples` on Windows.

Note that the program can read from multiple event queues, and subscribe to multiple topics, by using MQCB to retrieve the messages.

When running as a client, the sample can connect to any queue manager including z/OS.

Attention: You can use the program without specifying any parameters, in which case the program attempts to connect to the default queue manager and read messages from the standard set of event queues (SYSTEM.ADMIN.*.EVENT).

In this situation, the program waits forever for messages, until you press the Enter key to end the program.

However, you are more likely to use the program with the various options described.

V 8.0.0.4

Syntax

```
►►─amqsevt─┬───────────────┬─┬──────────────────────────────────────────────────────────────┬──►
           └─ -m─QMgrName─┘ │                            (1)                               │
                             └─ -r─Reconnection Options───────┬─d─Reconnect Disabled───────┘
                                                              ├─r─Reconnect───────────────┤
                                                              └─m─Reconnect Queue manager─┘

►─┬───────────────────────┬─┬────────────────────────┬──────────────────────────────────────────►
  └─ -b─Browse Messages─┘ └─ -c─Connect as Client─┘

►─┬────────────────────────────────────────┬─┬───────────────┬─┬────────────────┬──────────────►
  └─ -d─Print Definitions without formatting─┘ └─ -u─User ID─┘ └─ -w─Wait Time─┘
```

```
                     (2)                 (2)
►─┬──────────────┬──┬──────────────┬──────────────────────────────────────────────►◄
  └─ -t──Topic───┘  └─ -q──Queue───┘
```

Notes:

1 Available only when being used as a client

2 Queues and topics can have multiple entries

V 8.0.0.4

Optional parameters

-m *QueueManagerName*
Specify a specific queue manager for reading events.

-r *Reconnection Options*
Auto reconnection options when used as a client. The possible values are:

d Reconnect the client disabled

r Reconnect the client

m Reconnect the queue manager

-b Browse records only, rather than destructively reading the messages

-c Selects connection as a client.

-d Selects the printing mode used in the second example. The MQI constants are printed exactly as they appear in the header files.

-u *User ID*
Specify a specific user and causes a prompt to appear requesting a password

-w *Wait*
Causes the program to exit if no event messages have arrived within the number of seconds specified.

Note that, if you do not specify a time, the program only ends normally when you press the Enter key.

-t *Topic* **and**
-q *Queue*
Both the **–q** and **–t** options can be given multiple times on the command line.

Therefore, it is possible to read from some standard queues and also from topics (if events are being sent to them) from a single run of the program.

If no queues or topics are named on the command line, the default event queues are opened.

Note: The program detects if it has connected to a z/OS queue manager as a client, and changes the default set of event queues appropriately, as z/OS does not have the SYSTEM.ADMIN.LOGGER.EVENT queue.

When topics are used, the program uses a non-durable subscription with a managed queue so that everything gets cleaned out when it exits.

V 8.0.0.4

Sample output

The following two examples show the output from the program.

The first example uses the default formatting option where the program takes the MQI definition of a field and formats the output to make the output more readable.

```
**** Message (320 Bytes) on Queue SYSTEM.ADMIN.QMGR.EVENT ****
Event Type                       : Queue Mgr Event
Reason                           : Unknown Alias Base Queue
Event created                    : 2015/06/17 13:47:07.02 GMT
  Queue Mgr Name                 : V8003_A
  Queue Name                     : EVT.NO.BASE.QUEUE
  Base Object Name               : EVT.NOT.DEFINED
  Appl Type                      : Unix
  Appl Name                      : amqsput
  Base Type                      : Queue
```

The second example shows the alternative formatting, using the -d option, that does not try to translate MQI constants. This might be preferable for some scripting tools that look for specific MQI values.

```
**** Message (320 Bytes) on Queue SYSTEM.ADMIN.QMGR.EVENT ****
Event Type                       : MQCMD_Q_MGR_EVENT
Reason                           : MQRC_UNKNOWN_ALIAS_BASE_Q
Event created                    : 2015/06/17 13:52:48.18 GMT
  MQCA_Q_MGR_NAME                : V8003_A
  MQCA_Q_NAME                    : EVT.NO.BASE.QUEUE
  MQCA_BASE_OBJECT_NAME          : EVT.NOT.DEFINED
  MQIA_APPL_TYPE                 : MQAT_UNIX
  MQCACF_APPL_NAME               : amqsput
  MQIA_BASE_TYPE                 : MQOT_Q
```

V 8.0.0.4

Example usage

The following example shows you how to use more than one queue:

```
amqsevt -m QM1 -q SYSTEM.ADMIN.QMGR.EVENT -q SYSTEM.ADMIN.PERM.EVENT -w 1
```

Related concepts:

"Event monitoring" on page 929
Event monitoring is the process of detecting occurrences of *instrumentation events* in a queue manager network. An instrumentation event is a logical combination of events that is detected by a queue manager or channel instance. Such an event causes the queue manager or channel instance to put a special message, called an *event message*, on an event queue.

"Instrumentation events" on page 930
An instrumentation event is a logical combination of conditions that a queue manager or channel instance detects and puts a special message, called an *event message*, on an event queue.

Message monitoring

Message monitoring is the process of identifying the route a message has taken through a queue manager network. By identifying the types of activities, and the sequence of activities performed on behalf of a message, the message route can be determined.

As a message passes through a queue manager network, various processes perform activities on behalf of the message. Use one of the following techniques to determine a message route:
- The IBM MQ display route application (dspmqrte)
- Activity recording
- Trace-route messaging

These techniques all generate special messages that contain information about the activities performed on the message as it passed through a queue manager network. Use the information returned in these special messages to achieve the following objectives:
- Record message activity.
- Determine the last known location of a message.
- Detect routing problems in your queue manager network.
- Assist in determining the causes of routing problems in your queue manager network.
- Confirm that your queue manager network is running correctly.
- Familiarize yourself with the running of your queue manager network.
- Trace published messages.

Related information:

Types of message

Activities and operations

Activities are discrete actions that an application performs on behalf of a message. Activities consist of operations, which are single pieces of work that an application performs.

The following actions are examples of activities:
- A message channel agent (MCA) sends a message from a transmission queue down a channel
- An MCA receives a message from a channel and puts it on its target queue
- An application getting a message from a queue, and putting a reply message in response.
- The IBM MQ publish/subscribe engine processes a message.

Activities consist of one or more *operations*. Operations are single pieces of work that an application performs. For example, the activity of an MCA sending a message from a transmission queue down a channel consists of the following operations:
1. Getting a message from a transmission queue (a *Get* operation).
2. Sending the message down a channel (a *Send* operation).

In a publish/subscribe network, the activity of the IBM MQ publish/subscribe engine processing a message can consist of the following multiple operations:
1. Putting a message to a topic string (a *Put* operation).
2. Zero or more operations for each of the subscribers that are considered for receipt of the message (a *Publish* operation, a *Discarded Publish* operation or an *Excluded Publish* operation).

Information from activities

You can identify the sequence of activities performed on a message by recording information as the message is routed through a queue manager network. You can determine the route of a message through the queue manager network from the sequence of activities performed on the message, and can obtain the following information:

The last known location of a message
: If a message does not reach its intended destination, you can determine the last known location of the message from a complete or partial message route.

Configuration issues with a queue manager network

When studying the route of a message through a queue manager network, you might see that the message has not gone where expected. There are many reasons why this can occur, for example, if a channel is inactive, the message might take an alternative route.

For a publish/subscribe application, you can also determine the route of a message being published to a topic and any messages that flow in a queue manager network as a result of being published to subscribers. In such situations, a system administrator can determine whether there are any problems in the queue manager network, and if appropriate, correct them.

Message routes

Depending on your reason for determining a message route, you can use the following general approaches:

Using activity information recorded for a trace-route message

Trace-route messages record activity information for a specific purpose. You can use them to determine configuration issues with a queue manager network, or to determine the last known location of a message. If a trace-route message is generated to determine the last known location of a message that did not reach its intended destination, it can mimic the original message. This gives the trace-route message the greatest chance of following the route taken by the original message.

The IBM MQ display route application can generate trace-route messages.

Using activity information recorded for the original message

You can enable any message for activity recording and have activity information recorded on its behalf. If a message does not reach its intended destination, you can use the recorded activity information to determine the last known location of the message. By using activity information from the original message, the most accurate possible message route can be determined, leading to the last known location. To use this approach, the original message must be enabled for activity recording.

Warning: Avoid enabling all messages in a queue manager network for activity recording. Messages enabled for activity recording can have many activity reports generated on their behalf. If every message in a queue manager network is enabled for activity recording, the queue manager network traffic can increase to an unacceptable level.

Writing your own message channel agents

Message route techniques

Activity recording and trace-route messaging are techniques that allow you to record activity information for a message as it is routed through a queue manager network.

Activity recording

If a message has the appropriate report option specified, it requests that applications generate *activity reports* as it is routed through a queue manager network. When an application performs an activity on behalf of a message, an activity report can be generated, and delivered to an appropriate location. An activity report contains information about the activity that was performed on the message.

The activity information collected using activity reports must be arranged in order before a message route can be determined.

Trace-route messaging

Trace-route messaging is a technique that involves sending a *trace-route message* into a queue manager network. When an application performs an activity on behalf of the trace-route message, activity information can be accumulated in the message data of the trace-route message, or activity reports can be generated. If activity information is accumulated in the message data of the trace-route message, when it reaches its target queue a trace-route reply message containing all the information from the trace-route message can be generated and delivered to an appropriate location.

Because a trace-route message is dedicated to recording the sequence of activities performed on its behalf, there are more processing options available compared with normal messages that request activity reports.

Comparison of activity recording and trace-route messaging

Both activity recording and trace-route messaging can provide activity information to determine the route a message has taken through a queue manager network. Both methods have their own advantages.

Benefit	**Activity recording**	**Trace-route messaging**
Can determine the last known location of a message	Yes	Yes
Can determine configuration issues with a queue manager network	Yes	Yes
Can be requested by any message (is not restricted to use with trace-route messages)	Yes	No
Message data is left unmodified	Yes	No
Message processed normally	Yes	No
Activity information can be accumulated in the message data	No	Yes
Optional message delivery to target queue	No	Yes
If a message is caught in an infinite loop, it can be detected and dealt with	No	Yes
Activity information can be put in order reliably	No	Yes
Application provided to display the activity information	No	Yes

Message route completeness

In some cases it is not possible to identify the full sequence of activities performed on behalf of a message, so only a partial message route can be determined. The completeness of a message route is directly influenced by the queue manager network that the messages are routed through. The completeness of a message route depends on the level of the queue managers in the queue manager network, as follows:

Queue managers at IBM WebSphere MQ Version 6.0 and subsequent releases

MCAs and user-written applications connected to queue managers at IBM WebSphere MQ Version 6.0 or subsequent releases can record information related to the activities performed on behalf of a message. The recording of activity information is controlled by the queue manager attributes ACTIVREC and ROUTEREC. If a queue manager network consists of queue managers at IBM WebSphere MQ Version 6.0 or subsequent releases only, complete message routes can be determined.

IBM MQ queue managers before Version 6.0
Applications connected to IBM MQ queue managers before Version 6.0 **do not** record the activities that they have performed on behalf of a message. If a queue manager network contains any IBM MQ queue manager prior to Version 6.0, only a partial message route can be determined.

How activity information is stored

IBM MQ stores activity information in activity reports, trace-route messages, or trace-route reply messages. In each case the information is stored in a structure called the *Activity* PCF group. A trace-route message or trace-route reply message can contain many Activity PCF groups, depending on the number of activities performed on the message. Activity reports contain one Activity PCF group because a separate activity report is generated for every recorded activity.

With trace-route messaging, additional information can be recorded. This additional information is stored in a structure called the *TraceRoute* PCF group. The TraceRoute PCF group contains a number of PCF structures that are used to store additional activity information, and to specify options that determine how the trace-route message is handled as it is routed through a queue manager network.

Activity recording

Activity recording is a technique for determining the routes that messages take through a queue manager network. To determine the route that a message has taken, the activities performed on behalf of the message are recorded.

When using activity recording, each activity performed on behalf of a message can be recorded in an activity report. An activity report is a type of report message. Each activity report contains information about the application that performed the activity on behalf of the message, when the activity took place, and information about the operations that were performed as part of the activity. Activity reports are typically delivered to a reply-to queue where they are collected together. By studying the activity reports related to a message, you can determine the route that the message took through the queue manager network.

Activity report usage

When messages are routed through a queue manager network, activity reports can be generated. You can use activity report information in the following ways:

Determine the last known location of a message

If a message that is enabled for activity recording does not reach its intended destination, activity reports generated for the message as it was routed through a queue manager network can be studied to determine the last known location of the message.

Determine configuration issues with a queue manager network

A number of messages enabled for activity recording can be sent into a queue manager network. By studying the activity reports related to each message it can become apparent that they have not taken the expected route. There are many reasons why this can occur, for example, a channel could have stopped, forcing the message to take an alternative route. In these situations, a system administrator can determine whether there are any problems in the queue manager network, and if there are, correct them.

Note: You can use activity recording in conjunction with trace-route messages by using the IBM MQ display route application.

Activity report format

Activity reports are PCF messages generated by applications that have performed an activity on behalf of a message. Activity reports are standard IBM MQ report messages containing a message descriptor and message data, as follows:

The message descriptor

- An MQMD structure

Message data

- An embedded PCF header (MQEPH)
- Activity report message data

Activity report message data consists of the *Activity* PCF group, and if generated for a trace-route message, the *TraceRoute* PCF group.

Related information:

MQMD - Message descriptor

MQEPH - Embedded PCF header

Controlling activity recording:

Enable activity recording at the queue manager level. To enable an entire queue manager network, individually enable every queue manager in the network for activity recording. If you enable more queue managers, more activity reports are generated.

About this task

To generate activity reports for a message as it is routed through a queue manager: define the message to request activity reports; enable the queue manager for activity recording; and ensure that applications performing activities on the message are capable of generating activity reports.

If you do *not* want activity reports to be generated for a message as it is routed through a queue manager, *disable* the queue manager for activity recording.

Procedure

1. Request activity reports for a message
   a. In the message descriptor of the message, specify MQRO_ACTIVITY in the *Report* field.
   b. In the message descriptor of the message, specify the name of a reply-to queue in the *ReplyToQ* field.

Warning: Avoid enabling all messages in a queue manager network for activity recording. Messages enabled for activity recording can have many activity reports generated on their behalf. If every message in a queue manager network is enabled for activity recording, the queue manager network traffic can increase to an unacceptable level.

2. Enable or disable the queue manager for activity recording. Use the MQSC command `ALTER QMGR`, specifying the parameter `ACTIVREC`, to change the value of the queue manager attribute. The value can be:

   MSG The queue manager is enabled for activity recording. Any activity reports generated are delivered to the reply-to queue specified in the message descriptor of the message. This is the default value.

   QUEUE
   The queue manager is enabled for activity recording. Any activity reports generated are delivered to the local system queue SYSTEM.ADMIN.ACTIVITY.QUEUE. The system queue can also be used to forward activity reports to a common queue.

   DISABLED
   The queue manager is disabled for activity recording. No activity reports are generated while in the scope of this queue manager.

   For example, to enable a queue manager for activity recording and specify that any activity reports generated are delivered to the local system queue SYSTEM.ADMIN.ACTIVITY.QUEUE, use the following MQSC command:

   ```
   ALTER QMGR ACTIVREC(QUEUE)
   ```

   Remember: When you modify the *ACTIVREC* queue manager attribute, a running MCA does not detect the change until the channel is restarted.

3. Ensure that your application uses the same algorithm as MCAs use to determine whether to generate an activity report for a message:
   a. Verify that the message has requested activity reports to be generated
   b. Verify that the queue manager where the message currently resides is enabled for activity recording
   c. Put the activity report on the queue determined by the *ACTIVREC* queue manager attribute

Setting up a common queue for activity reports:

To determine the locations of the activity reports related to a specific message when the reports are delivered to the local system queue, it is more efficient to use a common queue on a single node

Before you begin

Set the `ACTIVREC` parameter to enable the queue manager for activity recording and to specify that any activity reports generated are delivered to the local system queue SYSTEM.ADMIN.ACTIVITY.QUEUE.

About this task

If a number of queue managers in a queue manager network are set to deliver activity reports to the local system queue, it can be time consuming to determine the locations of the activity reports related to a specific message. Alternatively, use a single node, which is a queue manager that hosts a common queue. All the queue managers in a queue manager network can deliver activity reports to this common queue. The benefit of using a common queue is that queue managers do not have to deliver activity reports to the reply-to queue specified in a message and, when determining the locations of the activity reports related to a message, you query one queue only.

To set up a common queue, perform the following steps:

Procedure

1. Select or define a queue manager as the single node
2. On the single node, select or define a queue for use as the common queue
3. On all queue managers where activity reports are to be delivered to the common queue, redefine the local system queue SYSTEM.ADMIN.ACTIVITY.QUEUE as a remote queue definition:
   a. Specify the name of the single node as the remote queue manager name
   b. Specify the name of the common queue as the remote queue name

Determining message route information:

To determine a message route, obtain the information from the activity reports collected. Determine whether enough activity reports are on the reply-to queue to enable you to determine the required information and arrange the activity reports in order.

About this task

The order that activity reports are put on the reply-to queue does not necessarily correlate to the order in which the activities were performed. You must order activity reports manually, unless they are generated for a trace-route message, in which case you can use the IBM MQ display route application to order the activity reports.

Determine whether enough activity reports are on the reply-to queue for you to obtain the necessary information:

Procedure

1. Identify all related activity reports on the reply-to queue by comparing identifiers of the activity reports and the original message. Ensure you set the report option of the original message such that the activity reports can be correlated with the original message.
2. Order the identified activity reports from the reply-to queue. You can use the following parameters from the activity report:

   OperationType

   > The types of operations performed might enable you to determine the activity report that was generated directly before, or after, the current activity report.
   >
   > For example, an activity report details that an MCA sent a message from a transmission queue down a channel. The last operation detailed in the activity report has an *OperationType* of **send** and details that the message was sent using the channel, CH1, to the destination queue manager, QM1. This means that the next activity performed on the message will have occurred on queue manager, QM1, and that it will have begun with a **receive** operation from channel, CH1. By using this information you can identify the next activity report, providing it exists and has been acquired.

   OperationDate **and** *OperationTime*

   > You can determine the general order of the activities from the dates and times of the operations in each activity report.
   >
   > **Warning:** Unless every queue manager in the queue manager network has their system clocks synchronized, ordering by date and time does not guarantee that the activity reports are in the correct sequence. You must establish the order manually.

   The order of the activity reports represents the route, or partial route, that the message took through the queue manager network.
3. Obtain the information you need from the activity information in the ordered activity reports. If you have insufficient information about the message, you might be able to acquire further activity reports.

Retrieving further activity reports:

To determine a message route, sufficient information must be available from the activity reports collected. If you retrieve the activity reports related to a message from the reply-to queue that the message specified, but you not have the necessary information, look for further activity reports.

About this task

To determine the locations of any further activity reports, perform the following steps:

Procedure

1. For any queue managers in the queue manager network that deliver activity reports to a common queue, retrieve activity reports from the common queue that have a *CorrelId* that matches the *MsgId* of the original message.
2. For any queue managers in the queue manager network that do not deliver activity reports to a common queue, retrieve activity reports as follows:
   a. Examine the existing activity reports to identify queue managers through which the message was routed.
   b. For these queue managers, identify the queue managers that are enabled for activity recording.
   c. For these queue managers, identify any that did not return activity reports to the specified reply-to queue.
   d. For each of the queue managers that you identify, check the system queue SYSTEM.ADMIN.ACTIVITY.QUEUE and retrieve any activity reports that have a *CorrelId* that matches the *MsgId* of the original message.
   e. If you find no activity reports on the system queue, check the queue manager dead letter queue, if one exists. An activity report can only be delivered to a dead letter queue if the report option, MQRO_DEAD_LETTER_Q, is set.
3. Arrange all the acquired activity reports in order. The order of the activity reports then represents the route, or partial route, that the message took.
4. Obtain the information you need from the activity information in the ordered activity reports. In some circumstances, recorded activity information cannot reach the specified reply-to queue, a common queue, or a system queue.

Circumstances where activity information is not acquired:

To determine the complete sequence of activities performed on behalf of a message, information related to every activity must be acquired. If the information relating to any activity has not been recorded, or has not been acquired, you can determine only a partial sequence of activities.

Activity information is not recorded in the following circumstances:
- The message is processed by an IBM MQ queue manager earlier than Version 6.0.
- The message is processed by a queue manager that is not enabled for activity recording.
- The application that expected to process the message is not running.

Recorded activity information is unable to reach the specified reply-to queue in the following circumstances:
- There is no channel defined to route activity reports to the reply-to queue.
- The channel to route activity reports to the reply-to queue is not running.
- The remote queue definition to route activity reports back to the queue manager where the reply-to queue resides (the queue manager alias), is not defined.
- The user that generated the original message does not have open, or put, authority to the queue manager alias.

- The user that generated the original message does not have open, or put, authority to the reply-to queue.
- The reply-to queue is put inhibited.

Recorded activity information is unable to reach the system queue, or a common queue, in the following circumstances:
- If a common queue is to be used and there is no channel defined to route activity reports to the common queue.
- If a common queue is to be used and the channel to route activity reports to the common queue is not running.
- If a common queue is to be used and the system queue is incorrectly defined.
- The user that generated the original message does not have open, or put, authority to the system queue.
- The system queue is put inhibited.
- If a common queue is to be used and the user that generated the original message does not have open, or put, authority to the common queue.
- If a common queue is to be used and the common queue is put inhibited.

In these circumstances, providing the activity report does not have the report option MQRO_DISCARD_MSG specified, the activity report can be retrieved from a dead letter queue if one was defined on the queue manager where the activity report was rejected. An activity report will only have this report option specified if the original message, from which the activity report was generated, had both MQRO_PASS_DISCARD_AND_EXPIRY and MQRO_DISCARD_MSG specified in the Report field of the message descriptor.

Trace-route messaging

Trace-route messaging is a technique that uses *trace-route messages* to record activity information for a message. Trace-route messaging involves sending a trace-route message into a queue manager network.

As the trace-route message is routed through the queue manager network, activity information is recorded. This activity information includes information about the applications that performed the activities, when they were performed, and the operations that were performed as part of the activities. You can use the information recorded using trace-route messaging for the following purposes:

To determine the last known location of a message

If a message does not reach its intended destination, you can use the activity information recorded for a trace-route message to determine the last known location of the message. A trace-route message is sent into a queue manager network with the same target destination as the original message, intending that it follows the same route. Activity information can be accumulated in the message data of the trace-route message, or recorded using activity reports. To increase the probability that the trace-route message follows the same route as the original message, you can modify the trace-route message to mimic the original message.

To determine configuration issues with a queue manager network

Trace-route messages are sent into a queue manager network and activity information is recorded. By studying the activity information recorded for a trace-route message, it can become apparent that the trace-route message did not follow the expected route. There are many reasons why this can occur, for example, a channel might be inactive, forcing the message to take an alternative route. In these situations, a system administrator can determine whether there are any problems in the queue manager network, and if there are, correct them.

You can use the IBM MQ display route application to configure, generate, and put trace-route messages into a queue manager network.

Warning: If you put a trace-route message to a distribution list, the results are undefined.

Related concepts:

"Trace-route message reference" on page 1048
Use this page to obtain an overview of the trace-route message format. The trace-route message data includes parameters that describe the activities that the trace-route message has caused

How activity information is recorded:

With trace-route messaging, you can record activity information in the message data of the trace-route message, or use activity reports. Alternatively, you can use both techniques.

Accumulating activity information in the message data of the trace-route message

As a trace-route message is routed through a queue manager network, information about the activities performed on behalf of the trace-route message can be accumulated in the message data of the trace-route message. The activity information is stored in *Activity* PCF groups. For every activity performed on behalf of the trace-route message, an *Activity* PCF group is written to the end of the PCF block in the message data of the trace-route message.

Additional activity information is recorded in trace-route messaging, in a PCF group called the *TraceRoute* PCF group. The additional activity information is stored in this PCF group, and can be used to help determine the sequence of recorded activities. This technique is controlled by the *Accumulate* parameter in the *TraceRoute* PCF group.

Recording activity information using activity reports

As a trace-route message is routed through a queue manager network, an activity report can be generated for every activity that was performed on behalf of the trace-route message. The activity information is stored in the *Activity* PCF group. For every activity performed on behalf of a trace-route message, an activity report is generated containing an *Activity* PCF group. Activity recording for trace-route messages works in the same way as for any other message.

Activity reports generated for trace-route messages contain additional activity information compared to the those generated for any other message. The additional information is returned in a *TraceRoute* PCF group. The information contained in the *TraceRoute* PCF group is accurate only from the time the activity report was generated. You can use the additional information to help determine the sequence of activities performed on behalf of the trace-route message.

Acquiring recorded activity information:

When a trace-route message has reached its intended destination, or is discarded, the method that you use to acquire the activity information depends on how that information was recorded.

Before you begin

If you are unfamiliar with activity information, refer to "How activity information is recorded."

About this task

Use the following methods to acquire the activity information after the trace-route message has reached its intended destination, or is discarded:

Procedure

- Retrieve the trace-route message. The *Deliver* parameter, in the *TraceRoute* PCF group, controls whether a trace-route message is placed on the target queue on arrival, or whether it is discarded. If the trace-route message is delivered to the target queue, you can retrieve the trace-route message from this queue. Then, you can use the IBM MQ display route application to display the activity information.

To request that activity information is accumulated in the message data of a trace-route message, set the *Accumulate* parameter in the *TraceRoute* PCF group to `MQROUTE_ACCUMULATE_IN_MSG`.

- Use a trace-route reply message. When a trace-route message reaches its intended destination, or the trace-route message cannot be routed any further in a queue manager network, a trace-route reply message can be generated. A trace-route reply message contains a duplicate of all the activity information from the trace-route message, and is either delivered to a specified reply-to queue, or the system queue SYSTEM.ADMIN.TRACE.ROUTE.QUEUE. You can use the IBM MQ display route application to display the activity information.

  To request a trace-route reply message, set the *Accumulate* parameter in the *TraceRoute* PCF group to `MQROUTE_ACCUMULATE_AND_REPLY`.
- Use activity reports. If activity reports are generated for a trace-route message, you must locate the activity reports before you can acquire the activity information. Then, to determine the sequence of activities, you must order the activity reports.

Controlling trace-route messaging:

Enable trace-route messaging at the queue manager level, so that applications in the scope of that queue manager can write activity information to a trace-route message. To enable an entire queue manager network, individually enable every queue manager in the network for trace-route messaging. If you enable more queue managers, more activity reports are generated.

Before you begin

If you are using activity reports to record activity information for a trace-route message, refer to "Controlling activity recording" on page 984.

About this task

To record activity information for a trace-route message as it is routed through a queue manager, perform the following steps:

Procedure

- Define how activity information is to be recorded for the trace-route message. Refer to "Generating and configuring a trace-route message" on page 993
- If you want to accumulate activity information in the trace-route message, ensure that the queue manager is enabled for trace-route messaging
- If you want to accumulate activity information in the trace-route message, ensure that applications performing activities on the trace-route message are capable of writing activity information to the message data of the trace-route message

Related concepts:

"Generating and configuring a trace-route message" on page 993
A trace-route message comprises specific message descriptor and message data parts. To generate a trace-route message, either create the message manually or use the IBM MQ display route application.

Related tasks:

"Controlling activity recording" on page 984
Enable activity recording at the queue manager level. To enable an entire queue manager network, individually enable every queue manager in the network for activity recording. If you enable more queue managers, more activity reports are generated.

Enabling queue managers for trace-route messaging:

To control whether queue managers are enabled or disabled for trace-route messaging use the queue manager attribute ROUTEREC.

Use the MQSC command `ALTER QMGR`, specifying the parameter `ROUTEREC` to change the value of the queue manager attribute. The value can be any of the following values:

MSG The queue manager is enabled for trace-route messaging. Applications within the scope of the queue manager can write activity information to the trace-route message.

If the *Accumulate* parameter in the *TraceRoute* PCF group is set as `MQROUTE_ACCUMULATE_AND_REPLY`, and the next activity to be performed on the trace-route message:

- is a discard
- is a put to a local queue (target queue or dead-letter queue)
- will cause the total number of activities performed on the trace-route message to exceed the value of parameter the *MaxActivities*, in the *TraceRoute* PCF group .

a trace-route reply message is generated, and delivered to the reply-to queue specified in the message descriptor of the trace-route message.

QUEUE

The queue manager is enabled for trace-route messaging. Applications within the scope of the queue manager can write activity information to the trace-route message.

If the *Accumulate* parameter in the *TraceRoute* PCF group is set as `MQROUTE_ACCUMULATE_AND_REPLY`, and the next activity to be performed on the trace-route message:

- is a discard
- is a put to a local queue (target queue or dead-letter queue)
- will cause the total number of activities performed on the trace-route message to exceed the value of parameter the *MaxActivities*, in the *TraceRoute* PCF group .

a trace-route reply message is generated, and delivered to the local system queue SYSTEM.ADMIN.TRACE.ROUTE.QUEUE.

DISABLED

The queue manager is disabled for trace-route messaging. Activity information is not accumulated in the the trace-route message, however the *TraceRoute* PCF group can be updated while in the scope of this queue manager.

For example, to disable a queue manager for trace-route messaging, use the following MQSC command:

```
ALTER QMGR ROUTEREC(DISABLED)
```

Remember: When you modify the *ROUTEREC* queue manager attribute, a running MCA does not detect the change until the channel is restarted.

Enabling applications for trace-route messaging:

To enable trace-route messaging for a user application, base your algorithm on the algorithm used by message channel agents (MCAs)

Before you begin

If you are not familiar with the format of a trace-route message, see "Trace-route message reference" on page 1048.

About this task

Message channel agents (MCAs) are enabled for trace-route messaging. To enable a user application for trace-route messaging, use the following steps from the algorithm that MCAs use:

Procedure

1. Determine whether the message being processed is a trace-route message. If the message does not conform to the format of a trace-route message, the message is not processed as a trace-route message.
2. Determine whether activity information is to be recorded. If the detail level of the performed activity is not less than the level of detail specified by the *Detail* parameter, activity information is recorded under specific circumstances. This information is only recorded if the trace-route message requests accumulation, and the queue manager is enabled for trace-route messaging, or if the trace-route message requests an activity report and the queue manager is enabled for activity recording.
   - If activity information is to be recorded, increment the *RecordedActivities* parameter.
   - If activity information is not to be recorded, increment the *UnrecordedActivities* parameter.
3. Determine whether the total number of activities performed on the trace-route message exceeds the value of the *MaxActivities* parameter.

   The total number of activities is the sum of *RecordedActivities*, *UnrecordedActivities*, and *DiscontinuityCount*.

   If the total number of activities exceeds *MaxActivities*, reject the message with feedback MQFB_MAX_ACTIVITIES.
4. If value of *Accumulate* is set as MQROUTE_ACCUMULATE_IN_MSG or MQROUTE_ACCUMULATE_AND_REPLY, and the queue manager is enabled for trace-route messaging, write an Activity PCF group to the end of the PCF block in the message data of a trace-route message.
5. Deliver the trace-route message to a local queue.
   - If the parameter, *Deliver*, is specified as MQROUTE_DELIVER_NO, reject the trace-route message with feedback MQFB_NOT_DELIVERED.
   - If the parameter, *Deliver*, is specified as MQROUTE_DELIVER_YES, deliver the trace-route message to the local queue.
6. Generate a trace-route reply message if all the following conditions are true:
   - The trace-route message was delivered to a local queue or rejected
   - The value of the parameter, *Accumulate*, is MQROUTE_ACCUMULATE_AND_REPLY
   - The queue manager is enabled for trace-route messaging

   The trace-route reply message is put on the queue determined by the ROUTEREC queue manager attribute.
7. If the trace-route message requested an activity report and the queue manager is enabled for activity recording, generate an activity report. The activity report is put on the queue determined by the ACTIVREC queue manager attribute.

Generating and configuring a trace-route message:

A trace-route message comprises specific message descriptor and message data parts. To generate a trace-route message, either create the message manually or use the IBM MQ display route application.

A trace-route message consists of the following parts:

Message descriptor
An MQMD structure, with the *Format* field set to MQFMT_ADMIN or MQFMT_EMBEDDED_PCF.

Message data
One of the following combinations:

- A PCF header (MQCFH) and trace-route message data, if *Format* is set to MQFMT_ADMIN
- An embedded PCF header (MQEPH), trace-route message data, and additional user-specified message data, if *Format* is set to MQFMT_EMBEDDED_PCF

The trace-route message data consists of the *TraceRoute* PCF group and one or more *Activity* PCF groups.

Manual generation

When generating a trace-route message manually, an *Activity* PCF group is not required. *Activity* PCF groups are written to the message data of the trace-route message when an MCA or user-written application performs an activity on its behalf.

The IBM MQ display route application

Use the IBM MQ display route application, **dspmqrte** , to configure, generate and put a trace-route message into a queue manager network. Set the *Format* parameter in the message descriptor to MQFMT_ADMIN. You cannot add user data to the trace-route message generated by the IBM MQ display route application.

Restriction: **dspmqrte** cannot be issued on queue managers before IBM WebSphere MQ Version 6.0 or on IBM MQ for z/OS queue managers. If you want the first queue manager the trace-route message is routed through to be a queue manager of this type, connect to the queue manager as a IBM WebSphere MQ Version 6.0 or later client using the optional parameter `-c`.

Mimicking the original message:

When using a trace-route message to determine the route another message has taken through a queue manager network, the more closely a trace-route message mimics the original message, the greater the chance that the trace-route message will follow the same route as the original message.

The following message characteristics can affect where a message is forwarded to within a queue manager network:

Priority
The priority can be specified in the message descriptor of the message.

Persistence
The persistence can be specified in the message descriptor of the message.

Expiration
The expiration can be specified in the message descriptor of the message.

Report options
Report options can be specified in the message descriptor of the message.

Message size

To mimic the size of a message, additional data can be written to the message data of the message. For this purpose, additional message data can be meaningless.

Tip: The IBM MQ display route application cannot specify message size.

Message data

Some queue manager networks use content based routing to determine where messages are forwarded. In these cases the message data of the trace-route message needs to be written to mimic the message data of the original message.

Tip: The IBM MQ display route application cannot specify message data.

The TraceRoute PCF group:

Attributes in the *TraceRoute* PCF group control the behavior of a trace-route message. The *TraceRoute* PCF group is in the message data of every trace-route message.

The following table lists the parameters in the *TraceRoute* group that an MCA recognizes. Further parameters can be added if user-written applications are written to recognize them, as described in "Additional activity information" on page 999.

Table 112. TraceRoute PCF group

Parameter	Type
TraceRoute	MQCFGR
Detail	MQCFIN
RecordedActivities	MQCFIN
UnrecordedActivities	MQCFIN
DiscontinuityCount	MQCFIN
MaxActivities	MQCFIN
Accumulate	MQCFIN
Forward	MQCFIN
Deliver	MQCFIN

Descriptions of each parameter in the *TraceRoute* PCF group follows:

Detail Specifies the detail level of activity information that is to be recorded. The value can be any of the following values:

MQROUTE_DETAIL_LOW

Only activities performed by user application are recorded.

MQROUTE_DETAIL_MEDIUM

Activities specified in MQROUTE_DETAIL_LOW should be recorded. Additionally, activities performed by MCAs are recorded.

MQROUTE_DETAIL_HIGH

Activities specified in MQROUTE_DETAIL_LOW, and MQROUTE_DETAIL_MEDIUM should be recorded. MCAs do not record any further activity information at this level of detail. This option is only available to user applications that are to record further activity information. For example, if a user application determines the route a message takes by considering certain message characteristics, the information about the routing logic could be included with this level of detail.

RecordedActivities

Specifies the number of recorded activities performed on behalf of the trace-route message. An activity is considered to be recorded if information about it has been written to the trace-route message, or if an activity report has been generated. For every recorded activity, *RecordedActivities* increments by one.

UnrecordedActivities
Specifies the number of unrecorded activities performed on behalf of the trace-route message. An activity is considered to be unrecorded if an application that is enabled for trace-route messaging neither accumulates, nor writes the related activity information to an activity report.

An activity performed on behalf of a trace-route message is unrecorded in the following circumstances:

- The detail level of the performed activity is less than the level of detail specified by the parameter *Detail*.
- The trace-route message requests an activity report but not accumulation, and the queue manager is not enabled for activity recording.
- The trace-route message requests accumulation but not an activity report, and the queue manager is not enabled for trace-route messaging.
- The trace-route message requests both accumulation and an activity report, and the queue manager is not enabled for activity recording and trace route messaging.
- The trace-route message requests neither accumulation nor an activity report.

For every unrecorded activity the parameter, *UnrecordedActivities*, increments by one.

DiscontinuityCount
Specifies the number of times the trace-route message has been routed through a queue manager with applications that were not enabled for trace-route messaging. This value is incremented by the queue manager. If this value is greater than 0, only a partial message route can be determined.

MaxActivities
Specifies the maximum number of activities that can be performed on behalf of the trace-route message.

The total number of activities is the sum of *RecordedActivities*, *UnrecordedActivities*, and *DiscontinuityCount*. The total number of activities must not exceed the value of *MaxActivities*.

The value of *MaxActivities* can be:

A positive integer
The maximum number of activities.

If the maximum number of activities is exceeded, the trace-route message is rejected with feedback MQFB_MAX_ACTIVITIES. This can prevent the trace-route message from being forwarded indefinitely if caught in an infinite loop.

MQROUTE_UNLIMITED_ACTIVITIES
An unlimited number of activities can be performed on behalf of the trace-route message.

Accumulate
Specifies the method used to accumulate activity information. The value can be any of the following values:

MQROUTE_ACCUMULATE_IN_MSG
If the queue manager is enabled for trace-route messaging, activity information is accumulated in the message data of the trace-route message.

If this value is specified, the trace-route message data consists of the following:

- The *TraceRoute* PCF group.
- Zero or more *Activity* PCF groups.

MQROUTE_ACCUMULATE_AND_REPLY
If the queue manager is enabled for trace-route messaging, activity information is accumulated in the message data of the trace-route message, and a trace-route reply message is generated if any of the following occur:

- The trace-route message is discarded by an IBM MQ Version 6 (or later) queue manager.
- The trace-route message is put to a local queue (target queue or dead-letter queue) by an IBM MQ Version 6 (or later) queue manager.
- The number of activities performed on the trace-route message exceeds the value of *MaxActivities*.

If this value is specified, the trace-route message data consists of the following:
- The *TraceRoute* PCF group.
- Zero or more *Activity* PCF groups.

MQROUTE_ACCUMULATE_NONE
Activity information is not accumulated in the message data of the trace-route message.

If this value is specified, the trace-route message data consists of the following:
- The *TraceRoute* PCF group.

Forward
Specifies where a trace-route message can be forwarded to. The value can be:

MQROUTE_FORWARD_IF_SUPPORTED
The trace-route message is only forwarded to queue managers that will honor the value of the *Deliver* parameter from the *TraceRoute* group.

MQROUTE_FORWARD_ALL
The trace-route message is forwarded to any queue manager, regardless of whether the value of the *Deliver* parameter will be honored.

Queue managers use the following algorithm when determining whether to forward a trace-route message to a remote queue manager:
1. Determine whether the remote queue manager is capable of supporting trace-route messaging.
   - If the remote queue manager is capable of supporting trace-route messaging, the algorithm continues to step 4.
   - If the remote queue manager is not capable of supporting trace-route messaging, the algorithm continues to step 2
2. Determine whether the *Deliver* parameter from the *TraceRoute* group contains any unrecognized delivery options in the MQROUTE_DELIVER_REJ_UNSUP_MASK bit mask.
   - If any unrecognized delivery options are found, the trace-route message is rejected with feedback MQFB_UNSUPPORTED_DELIVERY.
   - If no unrecognized delivery options are found, the algorithm continues to step 3.
3. Determine the value of the parameter *Deliver* from the *TraceRoute* PCF group in the trace-route message.
   - If *Deliver* is specified as MQROUTE_DELIVER_YES, the trace-route message is forwarded to the remote queue manager.
   - If *Deliver* is specified as MQROUTE_DELIVER_NO, the algorithm continues to step 4.
4. Determine whether the *Forward* parameter from the *TraceRoute* group contains any unrecognized forwarding options in the MQROUTE_FORWARDING_REJ_UNSUP_MASK bit mask.
   - If any unrecognized forwarding options are found, the trace-route message is rejected with feedback MQFB_UNSUPPORTED_FORWARDING.
   - If no unrecognized forwarding options are found, the algorithm continues to step 5.
5. Determine the value of the parameter *Forward* from the *TraceRoute* PCF group in the trace-route message.

- If *Forward* is specified as MQROUTE_FORWARD_IF_SUPPORTED, the trace-route message is rejected with feedback MQFB_NOT_FORWARDED.
- If *Forward* is specified as MQROUTE_FORWARD_ALL, trace-route message can be forwarded to the remote queue manager.

Deliver
Specifies the action to be taken if the trace-route message reaches its intended destination. User-written applications must check this attribute before placing a trace-route message on its target queue. The value can be any of the following values:

MQROUTE_DELIVER_YES
On arrival, the trace-route message is put on the target queue. Any application performing a get operation on the target queue can retrieve the trace-route message.

MQROUTE_DELIVER_NO
On arrival, the trace-route message is not delivered to the target queue. The message is processed according to its report options.

Setting up a common queue for trace-route reply messages:

To determine the locations of the trace-route reply messages related to a specific message when the reports are delivered to the local system queue, it is more efficient to use a common queue on a single node

Before you begin

Set the `ROUTEREC` parameter to enable the queue manager for trace-route messaging and to specify that any trace-route reply messages generated are delivered to the local system queue SYSTEM.ADMIN.TRACE.ROUTE.QUEUE.

About this task

If a number of queue managers in a queue manager network are set to deliver trace-route reply messages to the local system queue, it can be time consuming to determine the locations of the trace-route reply messages related to a specific message. Alternatively, use a single node, which is a queue manager that hosts a common queue. All the queue managers in a queue manager network can deliver trace-route reply messages to this common queue. The benefit of using a common queue is that queue managers do not have to deliver trace-route reply messages to the reply-to queue specified in a message and, when determining the locations of the trace-route reply messages related to a message, you query one queue only.

To set up a common queue, perform the following steps:

Procedure

1. Select or define a queue manager as the single node
2. On the single node, select or define a queue for use as the common queue
3. On all queue managers that forward trace-route reply messages to the common queue, redefine the local system queue SYSTEM.ADMIN.TRACE.ROUTE.QUEUE as a remote queue definition
   a. Specify the name of the single node as the remote queue manager name
   b. Specify the name of the common queue as the remote queue name

Acquiring and using recorded information:

Use any of the following techniques to acquire recorded activity information for a trace-route message

Note that the circumstances in which activity information is not acquired apply also to trace-route reply messages.

Activity information is not recorded when a trace-route message is processed by a queue manager that is disabled for both activity recording and trace-route messaging.

Acquiring information from trace-route reply messages:

To acquire activity information you locate the trace-route reply message. Then you retrieve the message and analyze the activity information.

About this task

You can acquire activity information from a trace-route reply message only if you know the location of the trace-route reply message. Locate the message and process the activity information as follows:

Procedure

1. Check the reply-to queue that was specified in the message descriptor of the trace-route message. If the trace-route reply message is not on the reply-to queue, check the following locations:
   - The local system queue, SYSTEM.ADMIN.TRACE.ROUTE.QUEUE, on the target queue manager of the trace-route message
   - The common queue, if you have set up a common queue for trace-route reply messages
   - The local system queue, SYSTEM.ADMIN.TRACE.ROUTE.QUEUE, on any other queue manager in the queue manager network, which can occur if the trace-route message has been put to a dead-letter queue, or the maximum number of activities was exceeded
2. Retrieve the trace-route reply message
3. Use the IBM MQ display route application to display the recorded activity information
4. Study the activity information and obtain the information that you need

Acquiring information from trace-route messages:

To acquire activity information you locate the trace-route message, which must have the appropriate parameters in the *TraceRoute* PCF group. Then you retrieve the message and analyze the activity information.

About this task

You can acquire activity information from a trace-route message only if you know the location of the trace-route message and it has the parameter *Accumulate* in the *TraceRoute* PCF group specified as either `MQROUTE_ACCUMULATE_IN_MSG` or `MQROUTE_ACCUMULATE_AND_REPLY`.

For the trace-route message to be delivered to the target queue the *Deliver* parameter in the *TraceRoute* PCF group must be specified as `MQROUTE_DELIVER_YES`.

Procedure

1. Check the target queue. If the trace-route message is not on the target queue, you can try to locate the trace-route message using a trace-route message enabled for activity recording. With the generated activity reports try to determine the last known location of the trace-route message.
2. Retrieve the trace-route message
3. Use the IBM MQ display route application to display the recorded activity information

4. Study the activity information and obtain the information that you need

Acquiring information from activity reports:

To acquire activity information you locate the activity report, which must have the report option specified in the message descriptor. Then you retrieve the activity report and analyze the activity information.

About this task

You can acquire activity information from an activity report only if you know the location of the activity report and the report option MQRO_ACTIVITY was specified in the message descriptor of the trace-route message.

Procedure

1. Locate and order the activity reports generated for a trace-route message. When you have located the activity reports, you can order them manually or use the IBM MQ display route application to order and display the activity information automatically.
2. Study the activity information and obtain the information that you need

Additional activity information:

As a trace-route message is routed through a queue manager network, user applications can record additional information by including one or more additional PCF parameters when writing the *Activity* group to the message data of the trace-route message or activity report.

Additional activity information can help system administrators to identify the route taken by a trace-route message took, or why that route was taken.

If you use the IBM MQ display route application to display the recorded information for a trace-route message, any additional PCF parameters can only be displayed with a numeric identifier, unless the parameter identifier of each parameter is recognized by the IBM MQ display route application. To recognize a parameter identifier, additional information must be recorded using the following PCF parameters. Include these PCF parameters in an appropriate place in the *Activity* PCF group.

GroupName

Table 113. Group name

Description	**Grouped parameters specifying the additional information.**
Identifier	MQGACF_VALUE_NAMING.
Data type	MQCFGR

Examples of recording additional activity information

The following examples illustrate how a user application can record additional information when performing an activity on behalf of a trace-route message. In both examples, the IBM MQ display route application is used to generate a trace-route message, and display the activity information returned to it.

Example 1:

Additional activity information is recorded by a user application in a format where the parameter identifier *is not* recognized by the IBM MQ display route application.

1. The IBM MQ display route application is used to generate and put a trace-route message into a queue manager network. The necessary options are set to request the following:
   - Activity information is accumulated in the message data of the trace-route message.
   - On arrival at the target queue the trace-route message is discarded, and a trace-route reply message is generated and delivered to a specified reply-to queue.
   - On receipt of the trace-route reply message, the IBM MQ display route application displays the accumulated activity information.

   The trace-route message is put into the queue manager network.
2. As the trace-route message is routed through the queue manager network a user application, that is enabled for trace-route messaging, performs a low detail activity on behalf of the message. In addition to writing the standard activity information to the trace-route message, the user application writes the following PCF parameter to the end of the Activity group:

   ColorValue

   Identifier
   65536

   Data type
   MQCFST

   Value 'Red'

This additional PCF parameter gives further information about the activity that was performed, however it is written in a format where the parameter identifier *is not* recognized by the IBM MQ display route application.

3. The trace-route messages reaches the target queue and a trace-route reply message is returned to the IBM MQ display route application. The additional activity information is displayed as follows:

   ```
   65536: 'Red'
   ```

   The IBM MQ display route application does not recognize the parameter identifier of the PCF parameter and displays it as a numeric value. The context of the additional information is not clear.

   For an example of when the IBM MQ display route application does recognize the parameter identifier of the PCF parameter, see "Example 2."

Example 2:

Additional activity information is recorded by a user application in a format where the parameter identifier *is* recognized by the IBM MQ display route application.

1. The IBM MQ display route application is used to generate and put a trace-route message into a queue manager network in the same fashion as in "Example 1" on page 1000.
2. As the trace-route message is routed through the queue manager network a user application, that is enabled for trace-route messaging, performs a low detail activity on behalf of the message. In addition to writing the standard activity information to the trace-route message, the user application writes the following PCF parameters to the end of the Activity group:

   ColorInfo

Table 116. Color information

Description	**Grouped parameters specifying information about a color.**
Identifier:	MQGACF_VALUE_NAMING.
Data type:	MQCFGR.
Parameters in group:	*ColorName* *ColorValue*

   ColorName

Table 117. Color name

Description	**Contains the name to be displayed by the IBM MQ display route application which puts the value of** *ColorValue* **into context.**
Identifier:	MQCA_VALUE_NAME.
Data type:	MQCFST.
Included in PCF group:	*ColorInfo*.
Value:	'Color'

   ColorValue

Table 118. Color value

Description	Contains the value to be displayed by the IBM MQ display route application.
Identifier:	65536.
Data type:	MQCFST.
Included in PCF group:	*ColorInfo*.
Value:	'Red'

These additional PCF parameters gives further information about the activity that was performed. These PCF parameters are written in a format where the parameter identifier *is* recognized by the IBM MQ display route application.

3. The trace-route messages reaches the target queue and a trace-route reply message is returned to the IBM MQ display route application. The additional activity information is displayed as follows:

```
Color: 'Red'
```

The IBM MQ display route application recognizes that the parameter identifier of the PCF structure containing the value of the additional activity information has a corresponding name. The corresponding name is displayed instead of the numeric value.

IBM MQ display route application

Use the IBM MQ display route application (**dspmqrte**) to work with trace-route messages and activity information related to a trace-route message, using a command-line interface. z/OS The IBM MQ display route application is not available for IBM MQ for z/OS queue managers.

You can use the IBM MQ display route application for the following purposes:

- To configure, generate, and put a trace-route message into a queue manager network.

  By putting a trace-route message into a queue manager network, activity information can be collected and used to determine the route that the trace-route message took. You can specify the characteristics of the trace-route messages as follows:
  - The destination of the trace-route message.
  - How the trace-route message mimics another message.
  - How the trace-route message should be handled as it is routed through a queue manager network.
  - Whether activity recording or trace-route messaging are used to record activity information.
- To order and display activity information related to a trace-route message.

  If the IBM MQ display route application has put a trace-route message into a queue manager network, after the related activity information has been returned, the information can be ordered and displayed immediately. Alternatively, the IBM MQ display route application can be used to order, and display, activity information related to a trace-route message that was previously generated.

Related information:
dspmqrte

Parameters for trace-route messages:

Use this page to obtain an overview of the parameters provided by the IBM MQ display route application, **dspmqrte**, to determine the characteristics of a trace-route message, including how it is treated as it is routed through a queue manager network.

Related information:
dspmqrte

Queue manager connection:

Use this page to specify the queue manager that the IBM MQ display route application connects to

-c Specifies that the IBM MQ display route application connects as a client application.

If you do not specify this parameter, the IBM MQ display route application does not connect as a client application.

-m *QMgrName*
The name of the queue manager to which the IBM MQ display route application connects. The name can contain up to 48 characters.

If you do not specify this parameter, the default queue manager is used.

The target destination:

Use this page to specify the target destination of a trace-route message

-q *TargetQName*
If the IBM MQ display route application is being used to send a trace-route message into a queue manager network, *TargetQName* specifies the name of the target queue.

-ts *TargetTopicString*
Specifies the topic string.

-qm *TargetQMgr*
Qualifies the target destination; normal queue manager name resolution will then apply. The target destination is specified with *-q TargetQName* or *-ts TargetTopicString* .

If you do not specify this parameter, the queue manager to which the IBM MQ display route application is connected is used as the target queue manager.

-o Specifies that the target destination is not bound to a specific destination. Typically this parameter is used when the trace-route message is to be put across a cluster. The target destination is opened with option MQOO_BIND_NOT_FIXED.

If you do not specify this parameter, the target destination is bound to a specific destination.

The publication topic:

For publish/subscribe applications, use this page to specify the topic string of a trace-route message for the IBM MQ display route application to publish

-ts *TopicName*
: Specifies a topic string to which the IBM MQ display route application is to publish a trace-route message, and puts this application into topic mode. In this mode, the application traces all of the messages that result from the publish request.

You can also use the IBM MQ display route application to display the results from an activity report that was generated for publish messages.

Message mimicking:

Use this page to configure a trace-route message to mimic a message, for example when the original message did not reach its intended destination

One use of trace-route messaging is to help determine the last known location of a message that did not reach its intended destination. The IBM MQ display route application provides parameters that can help configure a trace-route message to mimic the original message. When mimicking a message, you can use the following parameters:

-l *Persistence*

Specifies the persistence of the generated trace-route message. Possible values for *Persistence* are:

yes The generated trace-route message is persistent. (MQPER_PERSISTENT).

no The generated trace-route message is **not** persistent. (MQPER_NOT_PERSISTENT).

q The generated trace-route message inherits its persistence value from the destination specified by *-q TargetQName* or *-ts TargetTopicString*. (MQPER_PERSISTENCE_AS_Q_DEF).

A trace-route reply message, or any report messages, returned will share the same persistence value as the original trace-route message.

If *Persistence* is specified as **yes**, you must specify the parameter *-rq ReplyToQ*. The reply-to queue must not resolve to a temporary dynamic queue.

If you do not specify this parameter, the generated trace-route message is **not** persistent.

-p *Priority*

Specifies the priority of the trace-route message. The value of *Priority* is either greater than or equal to 0, or MQPRI_PRIORITY_AS_Q_DEF. MQPRI_PRIORITY_AS_Q_DEF specifies that the priority value is taken from the destination specified by *-q TargetQName* or *-ts TargetTopicString*.

If you do not specify this parameter, the priority value is taken from the destination specified by *-q TargetQName* or *-ts TargetTopicString*.

-xs *Expiry*

Specifies the expiry time for the trace-route message, in seconds.

If you do not specify this parameter, the expiry time is specified as 60 seconds.

-ro none | *ReportOption*

none Specifies no report options are set.

ReportOption

Specifies report options for the trace-route message. Multiple report options can be specified using a comma as a separator. Possible values for *ReportOption* are:

activity

The report option MQRO_ACTIVITY is set.

coa The report option MQRO_COA_WITH_FULL_DATA is set.

cod The report option MQRO_COD_WITH_FULL_DATA is set.

exception
The report option MQRO_EXCEPTION_WITH_FULL_DATA is set.

expiration
The report option MQRO_EXPIRATION_WITH_FULL_DATA is set.

discard
The report option MQRO_DISCARD_MSG is set.

If neither `-ro ReportOption` nor `-ro none` are specified, then the MQRO_ACTIVITY and MQRO_DISCARD_MSG report options are specified.

The IBM MQ display route application does not allow you to add user data to the trace-route message. If you require user data to be added to the trace-route message you must generate the trace-route message manually.

Recorded activity information:

Use this page to specify the method used to return recorded activity information, which you can then use to determine the route that a trace-route message has taken

Recorded activity information can be returned as follows:
- In activity reports
- In a trace-route reply message
- In the trace-route message itself (having been put on the target queue)

When using **`dspmqrte`**, the method used to return recorded activity information is determined using the following parameters:

`-ro` *`activity`*
Specifies that activity information is returned using activity reports. By default activity recording is enabled.

`-ac -ar`
Specifies that activity information is accumulated in the trace-route message, and that a trace-route reply message is to be generated.

`-ac`
Specifies that activity information is to be accumulated within the trace-route message.

If you do not specify this parameter, activity information is **not** accumulated within the trace-route message.

`-ar`
Requests that a trace-route reply message containing all accumulated activity information is generated in the following circumstances:
- The trace-route message is discarded by an IBM MQ queue manager.
- The trace-route message is put to a local queue (target queue or dead-letter queue) by an IBM MQ queue manager.
- The number of activities performed on the trace-route message exceeds the value of specified in *-s Activities*.

`-ac -d yes`
Specifies that activity information is accumulated in the trace-route message, and that on arrival, the trace-route message will be put on the target queue.

-ac
: Specifies that activity information is to be accumulated within the trace-route message.

  If you do not specify this parameter, activity information is **not** accumulated within the trace-route message.

-d yes
: On arrival, the trace-route message is put to the target queue, even if the queue manager does not support trace-route messaging.

  If you do not specify this parameter, the trace-route message is **not** put to the target queue.

The trace-route message can then be retrieved from the target queue, and the recorded activity information acquired.

You can combine these methods as required.

Additionally, the detail level of the recorded activity information can be specified using the following parameter:

-t *Detail*
: Specifies the activities that are recorded. The possible values for *Detail* are:

low Activities performed by user-defined application are recorded only.

medium

Activities specified in **low** are recorded. Additionally, publish activities and activities performed by MCAs are recorded.

high

Activities specified in **low**, and **medium** are recorded. MCAs do not expose any further activity information at this level of detail. This option is available to user-defined applications that are to expose further activity information only. For example, if a user-defined application determines the route a message takes by considering certain message characteristics, the routing logic could be included with this level of detail.

If you do not specify this parameter, medium level activities are recorded.

By default the IBM MQ display route application uses a temporary dynamic queue to store the returned messages. When the IBM MQ display route application ends, the temporary dynamic queue is closed, and any messages are purged. If the returned messages are required beyond the current execution of the IBM MQ display route application ends, then a permanent queue must be specified using the following parameters:

-rq *ReplyToQ*
: Specifies the name of the reply-to queue that all responses to the trace-route message are sent to. If the trace-route message is persistent, or if the *-n* parameter is specified, a reply-to queue must be specified that is **not** a temporary dynamic queue.

  If you do not specify this parameter then a dynamic reply-to queue is created using the system default model queue, SYSTEM.DEFAULT.MODEL.QUEUE.

-rqm *ReplyToQMgr*
: Specifies the name of the queue manager where the reply-to queue resides. The name can contain up to 48 characters.

  If you do not specify this parameter, the queue manager to which the IBM MQ display route application is connected is used as the reply-to queue manager.

How the trace-route message is handled:

Use this page to control how a trace-route message is handled as it is routed through a queue manager network.

The following parameters can restrict where the trace-route message can be routed in the queue manager network:

-d *Deliver*
: Specifies whether the trace-route message is to be delivered to the target queue on arrival. Possible values for *Deliver* are:

yes	On arrival, the trace-route message is put to the target queue, even if the queue manager does not support trace-route messaging.
no	On arrival, the trace-route message is **not** put to the target queue.

If you do not specify this parameter, the trace-route message is **not** put to the target queue.

-f *Forward*
: Specifies the type of queue manager that the trace-route message can be forwarded to. For details of the algorithm that queue managers use to determine whether to forward a message to a remote queue manager, refer to "The TraceRoute PCF group" on page 994. The possible values for *Forward* are:

all The trace-route message is forwarded to any queue manager.

Warning: If forwarded to an IBM MQ queue manager earlier than Version 6.0, the trace-route message will not be recognized and can be delivered to a local queue despite the value of the *-d Deliver* parameter.

supported
: The trace-route message is only forwarded to a queue manager that will honor the *Deliver* parameter from the *TraceRoute* PCF group

If you do not specify this parameter, the trace-route message will only be forwarded to a queue manager that will honor the *Deliver* parameter.

The following parameters can prevent a trace-route message from remaining in a queue manager network indefinitely:

-s *Activities*
: Specifies the maximum number of recorded activities that can be performed on behalf of the trace-route message before it is discarded. This prevents the trace-route message from being forwarded indefinitely if caught in an infinite loop. The value of *Activities* is either greater than or equal to 1, or MQROUTE_UNLIMITED_ACTIVITIES. MQROUTE_UNLIMITED_ACTIVITIES specifies that an unlimited number of activities can be performed on behalf of the trace-route message.

If you do not specify this parameter, an unlimited number of activities can be performed on behalf of the trace-route message.

-xs *Expiry*
: Specifies the expiry time for the trace-route message, in seconds.

If you do not specify this parameter, the expiry time is specified as 60 seconds.

-xp *PassExpiry*
: Specifies whether the expiry time from the trace-route message is passed on to a trace-route reply message. Possible values for *PassExpiry* are:

yes The report option MQRO_PASS_DISCARD_AND_EXPIRY is specified in the message descriptor of the trace-route message.

If a trace-route reply message, or activity reports, are generated for the trace-route message, the MQRO_DISCARD report option (if specified), and the remaining expiry time are passed on.

This is the default value.

no The report option MQRO_PASS_DISCARD_AND_EXPIRY is not specified.

If a trace-route reply message is generated for the trace-route message, the discard option and expiry time from the trace-route message are **not** passed on.

If you do not specify this parameter, MQRO_PASS_DISCARD_AND_EXPIRY is not specified.

`-ro` *`discard`*
Specifies the MQRO_DISCARD_MSG report option. This can prevent the trace-route message remaining in the queue manager network indefinitely.

Display of activity information:

The IBM MQ display route application can display activity information for a trace-route message that it has just put into a queue manager network, or it can display activity information for a previously generated trace-route message. It can also display additional information recorded by user-written applications.

To specify whether activity information returned for a trace-route message is displayed, specify the following parameter:

`-n` Specifies that activity information returned for the trace-route message is not to be displayed.

If this parameter is accompanied by a request for a trace-route reply message, (*`-ar`*), or any of the report generating options from (*`-ro ReportOption`*), then a specific (non-model) reply-to queue must be specified using *`-rq ReplyToQ`* . By default, only activity report messages are requested.

After the trace-route message is put to the specified target queue, a 48 character hexadecimal string is displayed containing the message identifier of the trace-route message. The message identifier can be used by the IBM MQ display route application to display the activity information for the trace-route message at a later time, using the *-i CorrelId* parameter.

If you do not specify this parameter, activity information returned for the trace-route message is displayed in the form specified by the *-v* parameter.

When displaying activity information for a trace-route message that has just been put into a queue manager network, the following parameter can be specified:

`-w` *`WaitTime`*
Specifies the time, in seconds, that the IBM MQ display route application will wait for activity reports, or a trace-route reply message, to return to the specified reply-to queue.

If you do not specify this parameter, the wait time is specified as the expiry time of the trace-route message, plus 60 seconds.

When displaying previously accumulated activity information the following parameters must be set:

`-q` *`TargetQName`*
If the IBM MQ display route application is being used to view previously gathered activity information, *TargetQName* specifies the name of the queue where the activity information is stored.

`-i` *`CorrelId`*
This parameter is used when the IBM MQ display route application is used to display previously accumulated activity information only. There can be many activity reports and trace-route reply

messages on the queue specified by *-q TargetQName*. *CorrelId* is used to identify the activity reports, or a trace-route reply message, related to a trace-route message. Specify the message identifier of the original trace-route message in *CorrelId*.

The format of *CorrelId* is a 48 character hexadecimal string.

The following parameters can be used when displaying previously accumulated activity information, or when displaying current activity information for a trace-route message:

-b Specifies that the IBM MQ display route application will only browse activity reports or a trace-route reply message related to a message. This allows activity information to be displayed again at a later time.

If you do not specify this parameter, the IBM MQ display route application will destructively get activity reports or a trace-route reply message related to a message.

`-v summary | all | none | outline` *`DisplayOption`*

summary
The queues that the trace-route message was routed through are displayed.

all All available information is displayed.

none No information is displayed.

outline *DisplayOption*
Specifies display options for the trace-route message. Multiple display options can be specified using a comma as a separator.

If no values are supplied the following is displayed:

- The application name
- The type of each operation
- Any operation specific parameters

Possible values for *DisplayOption* are:

activity
All non-PCF group parameters in *Activity* PCF groups are displayed.

identifiers
Values with parameter identifiers MQBACF_MSG_ID or MQBACF_CORREL_ID are displayed. This overrides *msgdelta*.

message
All non-PCF group parameters in *Message* PCF groups are displayed. When this value is specified, you cannot specify *msgdelta*.

msgdelta
All non-PCF group parameters in *Message* PCF groups, that have changed since the last operation, are displayed. When this value is specified, you cannot specify *message*.

operation
All non-PCF group parameters in *Operation* PCF groups are displayed.

traceroute
All non-PCF group parameters in *TraceRoute* PCF groups are displayed.

If you do not specify this parameter, a summary of the message route is displayed.

Display of additional information

As a trace-route message is routed through a queue manager network, user-written applications can record additional information by writing one or more additional PCF parameters to the message data of the trace-route message or to the message data of an activity report. For the IBM MQ display route application to display additional information in a readable form it must be recorded in a specific format, as described in “Additional activity information” on page 999.

IBM MQ display route application examples:

The following examples show how you can use the IBM MQ display route application. In each example, two queue managers (QM1 and QM2) are inter-connected by two channels (QM2.TO.QM1 and QM1.TO.QM2).

Example 1 - Requesting activity reports:

Display activity information from a trace-route message delivered to the target queue

In this example the IBM MQ display route application connects to queue manager, QM1, and is used to generate and deliver a trace-route message to the target queue, TARGET.Q, on remote queue manager, QM2. The necessary report option is specified so that activity reports are requested as the trace-route reply message is routed. On arrival at the target queue the trace-route message is discarded. Activity information returned to the IBM MQ display route application using activity reports is put in order and displayed.

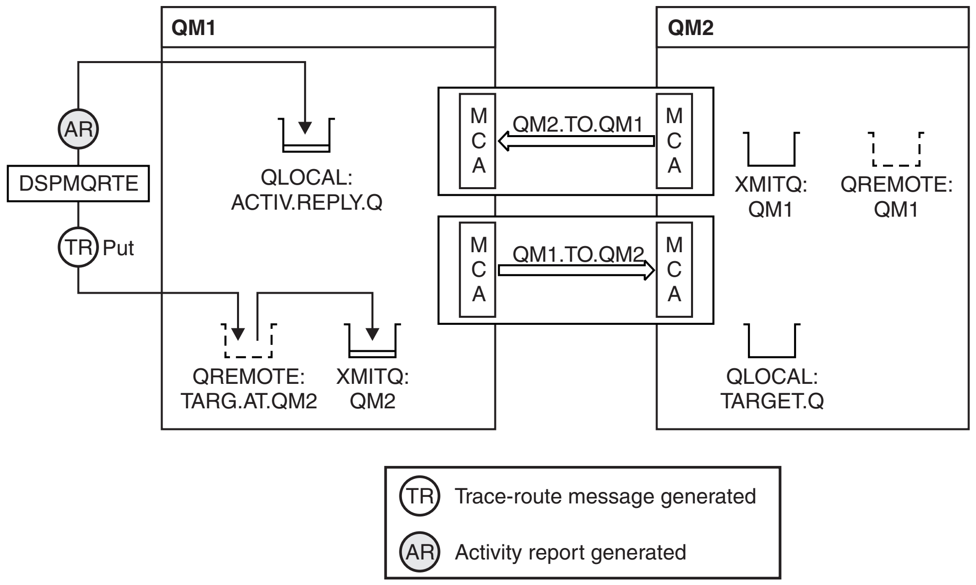

Figure 94. Requesting activity reports, Diagram 1

- The ACTIVREC attribute of each queue manager (QM1 and QM2) is set to MSG.
- The following command is issued:

  ```
  dspmqrte -m QM1 -q TARG.AT.QM2 -rq ACTIV.REPLY.Q
  ```

  QM1 is the name of the queue manager to which the IBM MQ display route application connects, TARG.AT.QM2 is the name of the target queue, and ACTIV.REPLY.Q is the name of the queue to which it is requested that all responses to the trace-route message are sent.

  Default values are assumed for all options that are not specified, but note in particular the -f option (the trace-route message is forwarded only to a queue manager that honors the Deliver parameter of the TraceRoute PCF group), the -d option (on arrival, the trace-route message is not put on the target queue), the -ro option (MQRO_ACTIVITY and MQRO_DISCARD_MSG report options are specified), and the -t option (medium detail level activity is recorded).
- DSPMQRTE generates the trace-route message and puts it on the remote queue TARG.AT.QM2.

- DSPMQRTE then looks at the value of the ACTIVREC attribute of queue manager QM1. The value is MSG, therefore DSPMQRTE generates an activity report and puts it on the reply queue ACTIV.REPLY.Q.

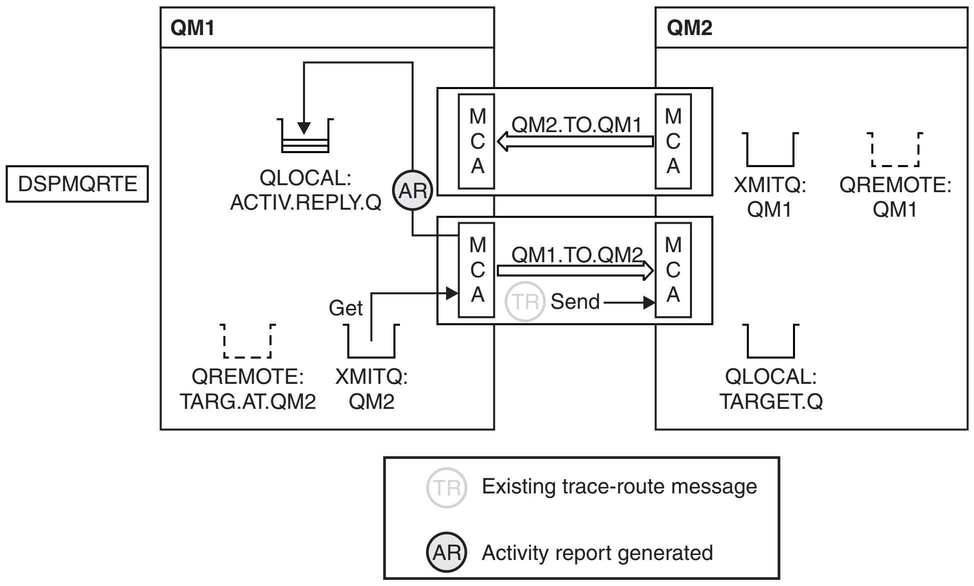

Figure 95. Requesting activity reports, Diagram 2

- The sending message channel agent (MCA) gets the trace-route message from the transmission queue. The message is a trace-route message, therefore the MCA begins to record the activity information.
- The ACTIVREC attribute of the queue manager (QM1) is MSG, and the MQRO_ACTIVITY option is specified in the Report field of the message descriptor, therefore the MCA will later generate an activity report. The RecordedActivities parameter value in the TraceRoute PCF group is incremented by 1.
- The MCA checks that the MaxActivities value in the TraceRoute PCF group has not been exceeded.
- Before the message is forwarded to QM2 the MCA follows the algorithm that is described in Forwarding (steps 1 on page 996, 4 on page 996, and 5 on page 996) and the MCA chooses to send the message.
- The MCA then generates an activity report and puts it on the reply queue (ACTIV.REPLY.Q).

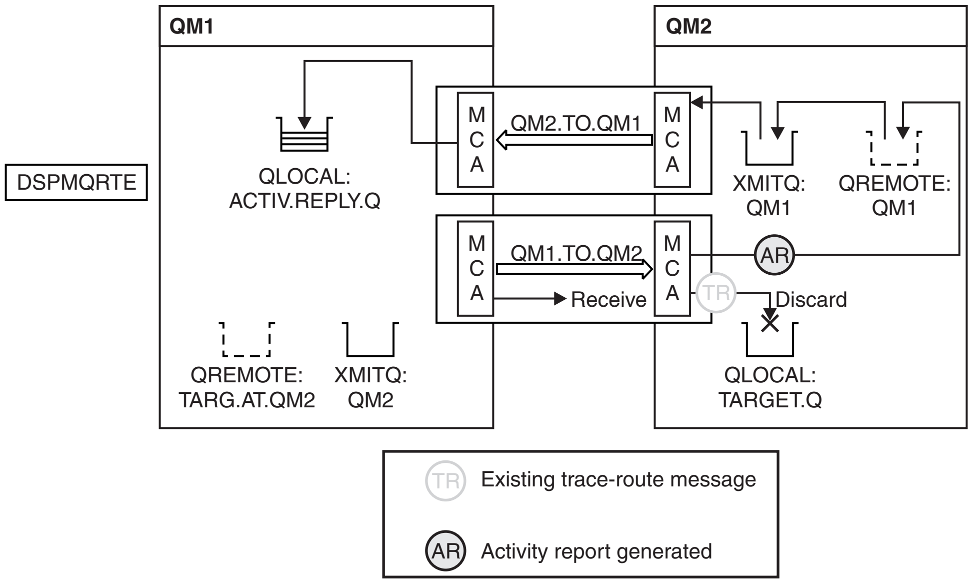

Figure 96. Requesting activity reports, Diagram 3

- The receiving MCA receives the trace-route message from the channel. The message is a trace-route message, therefore the MCA begins to record the information about the activity.
- If the queue manager that the trace-route message has come from is Version 5.3.1 or earlier, the MCA increments the DiscontinuityCount parameter of the TraceRoute PCF by 1. This is not the case here.
- The ACTIVREC attribute of the queue manager (QM2) is MSG, and the MQRO_ACTIVITY option is specified, therefore the MCA will generate an activity report. The RecordedActivities parameter value is incremented by 1.
- The target queue is a local queue, therefore the message is discarded with feedback MQFB_NOT_DELIVERED, in accordance with the Deliver parameter value in the TraceRoute PCF group.
- The MCA then generates the final activity report and puts it on the reply queue. This resolves to the transmission queue that is associated with queue manager QM1 and the activity report is returned to queue manager QM1 (ACTIV.REPLY.Q).

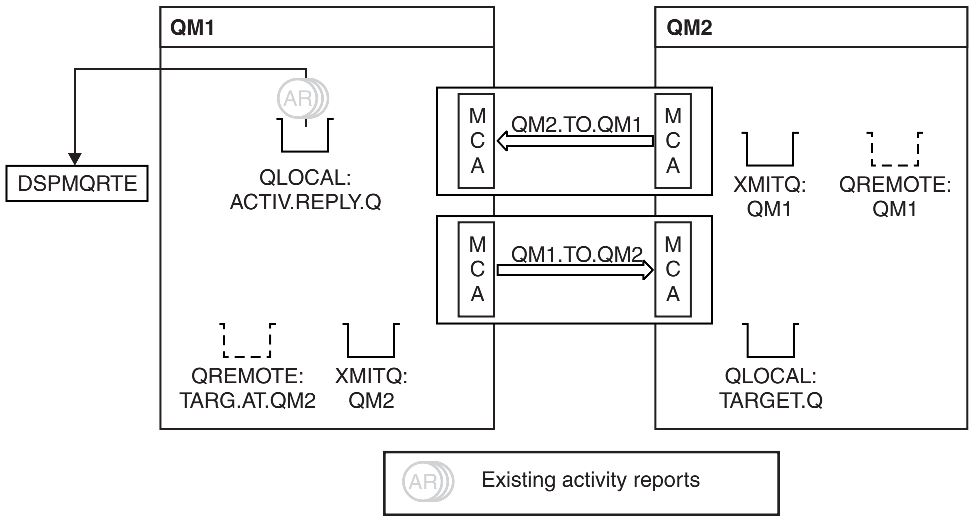

Figure 97. Requesting activity reports, Diagram 4

- Meanwhile, DSPMQRTE has been continually performing MQGETs on the reply queue (ACTIV.REPLY.Q), waiting for activity reports. It will wait for up to 120 seconds (60 seconds longer than the expiry time of the trace-route message) since -w was not specified when DSPMQRTE was started.
- DSPMQRTE gets the 3 activity reports off the reply queue.
- The activity reports are ordered using the RecordedActivities, UnrecordedActivities, and DiscontinuityCount parameters in the TraceRoute PCF group for each of the activities. The only value that is non-zero in this example is RecordedActivities, therefore this is the only parameter that is actually used.
- The program ends as soon as the discard operation is displayed. Even though the final operation was a discard, it is treated as though a put took place because the feedback is MQFB_NOT_DELIVERED.

  The output that is displayed follows:

```
AMQ8653: DSPMQRTE command started with options '-m QM1 -q TARG.AT.QM2
 -rq ACTIV.REPLY.Q'.
AMQ8659: DSPMQRTE command successfully put a message on queue 'QM2',
 queue manager 'QM1'.
AMQ8674: DSPMQRTE command is now waiting for information to display.
AMQ8666: Queue 'QM2' on queue manager 'QM1'.
AMQ8666: Queue 'TARGET.Q' on queue manager 'QM2'.
AMQ8652: DSPMQRTE command has finished.
```

Example 2 - Requesting a trace-route reply message:

Generate and deliver a trace-route message to the target queue

In this example the IBM MQ display route application connects to queue manager, QM1, and is used to generate and deliver a trace-route message to the target queue, TARGET.Q, on remote queue manager, QM2. The necessary option is specified so that activity information is accumulated in the trace-route message. On arrival at the target queue a trace-route reply message is requested, and the trace-route message is discarded.

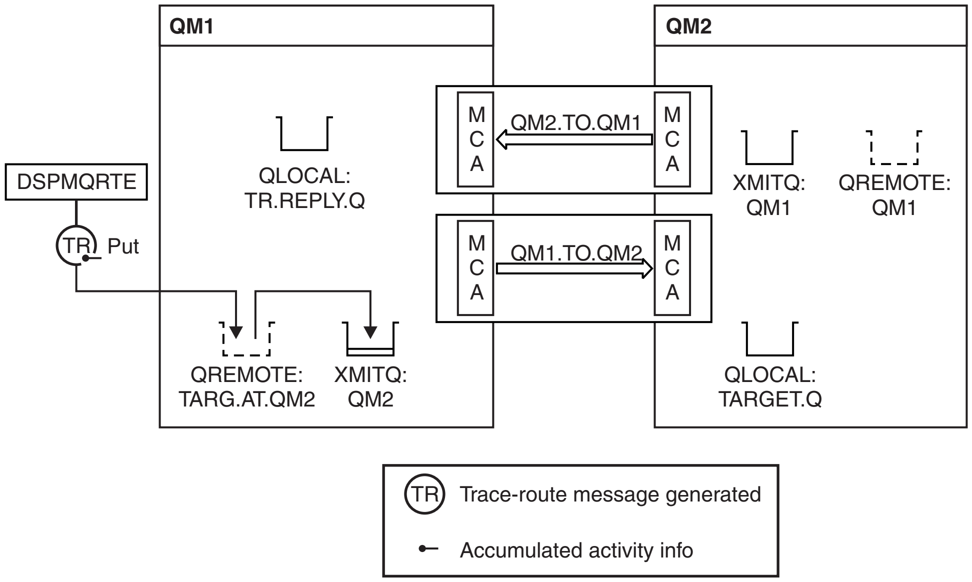

Figure 98. Requesting a trace-route reply message, Diagram 1

- The ROUTEREC attribute of each queue manager (QM1 and QM2) is set to MSG.
- The following command is issued:

  ```
  dspmqrte -m QM1 -q TARG.AT.QM2 -rq TR.REPLY.Q -ac -ar -ro discard
  ```

  QM1 is the name of the queue manager to which the IBM MQ display route application connects, TARG.AT.QM2 is the name of the target queue, and ACTIV.REPLY.Q is the name of the queue to which it is requested that all responses to the trace-route message are sent. The -ac option specifies that activity information is accumulated in the trace-route message, the -ar option specifies that all accumulated activity is sent to the reply-to queue that is specified by the -rq option (that is, TR.REPLY.Q). The -ro option specifies that report option MQRO_DISCARD_MSG is set which means that activity reports are not generated in this example.
- DSPMQRTE accumulates activity information in the trace-route message before the message is put on the target route. The queue manager attribute ROUTEREC must not be DISABLED for this to happen.

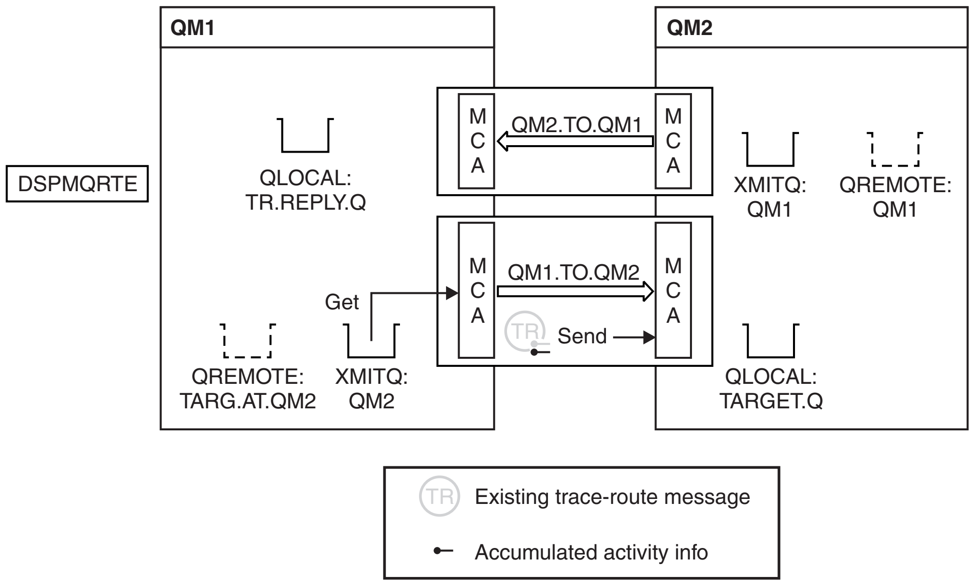

Figure 99. Requesting a trace-route reply message, Diagram 2

- The message is a trace-route message, therefore the sending MCA begins to record information about the activity.
- The queue manager attribute ROUTEREC on QM1 is not DISABLED, therefore the MCA accumulates the activity information within the message, before the message is forwarded to queue manager QM2.

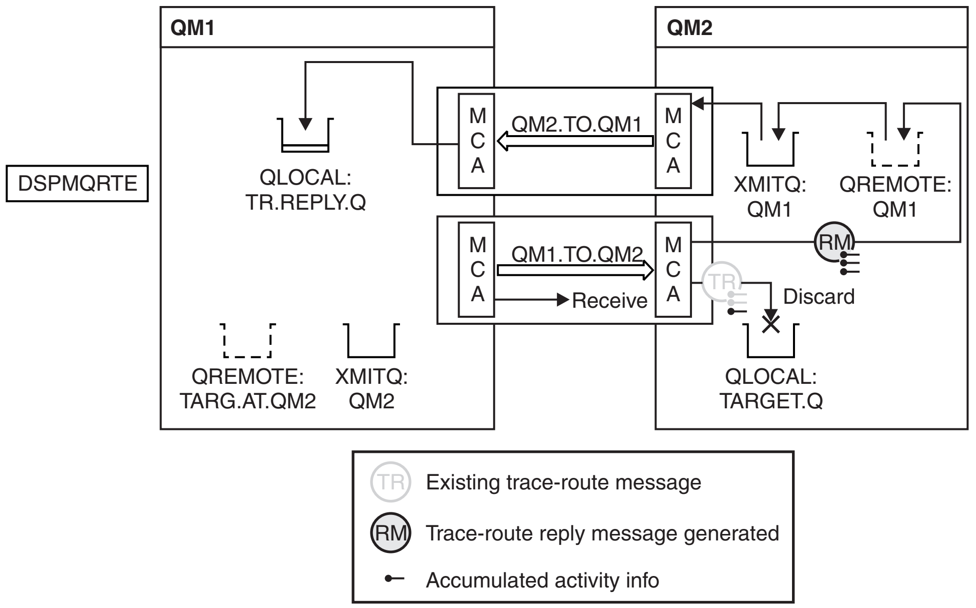

Figure 100. Requesting a trace-route reply message, Diagram 3

- The message is a trace-route message, therefore the receiving MCA begins to record information about the activity.

- The queue manager attribute ROUTEREC on QM2 is not DISABLED, therefore the MCA accumulates the information within the message.
- The target queue is a local queue, therefore the message is discarded with feedback MQFB_NOT_DELIVERED, in accordance with the Deliver parameter value in the TraceRoute PCF group.
- This is the last activity that will take place on the message, and because the queue manager attribute ROUTEREC on QM1 is not DISABLED, the MCA generates a trace-route reply message in accordance with the Accumulate value. The value of ROUTEREC is MSG, therefore the reply message is put on the reply queue. The reply message contains all the accumulated activity information from the trace-route message.

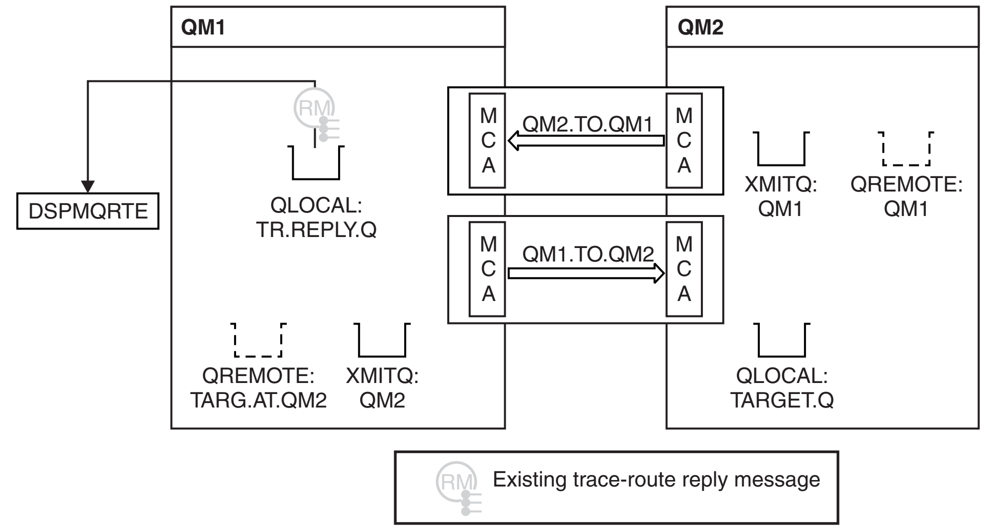

Figure 101. Requesting a trace-route reply message, Diagram 4

- Meanwhile DSPMQRTE is waiting for the trace-route reply message to return to the reply queue. When it returns, DSPMQRTE parses each activity that it contains and prints it out. The final operation is a discard operation. DSPMQRTE ends after it has been printed.

The output that is displayed follows:

```
AMQ8653: DSPMQRTE command started with options '-m QM1 -q TARG.AT.QM2 -rq
 TR.REPLY.Q'.
AMQ8659: DSPMQRTE command successfully put a message on queue 'QM2', queue
 manager 'QM1'.
AMQ8674: DSPMQRTE command is now waiting for information to display.
AMQ8666: Queue 'QM2' on queue manager 'QM1'.
AMQ8666: Queue 'TARGET.Q' on queue manager 'QM2'.
AMQ8652: DSPMQRTE command has finished.
```

Example 3 - Delivering activity reports to the system queue:

Detect when activity reports are delivered to queues other than the reply-to queue and use the IBM MQ display route application to read activity reports from the other queue.

This example is the same as "Example 1 - Requesting activity reports" on page 1010, except that QM2 now has the value of the ACTIVREC queue manage attribute set to QUEUE. Channel QM1.TO.QM2 must have been restarted for this to take effect.

This example demonstrates how to detect when activity reports are delivered to queues other than the reply-to queue. Once detected, the IBM MQ display route application is used to read activity reports from another queue.

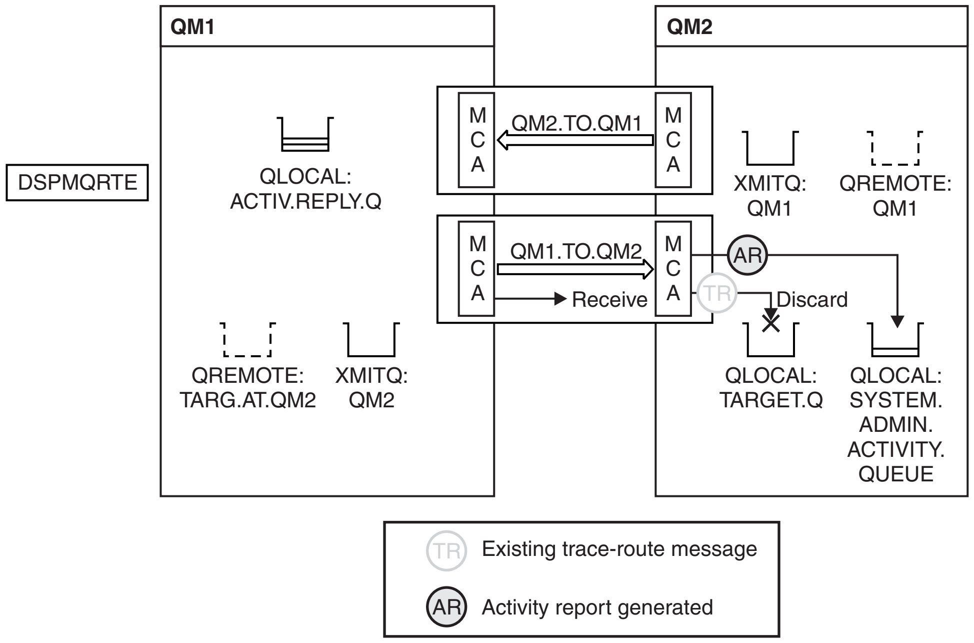

Figure 102. Delivering activity reports to the system queue, Diagram 1

- The message is a trace-route message, therefore the receiving MCA begins to record information about the activity.
- The value of the ACTIVREC queue manager attribute on QM2 is now QUEUE, therefore the MCA generates an activity report, but puts it on the system queue (SYSTEM.ADMIN.ACTIVITY.QUEUE) and not on the reply queue (ACTIV.REPLY.Q).

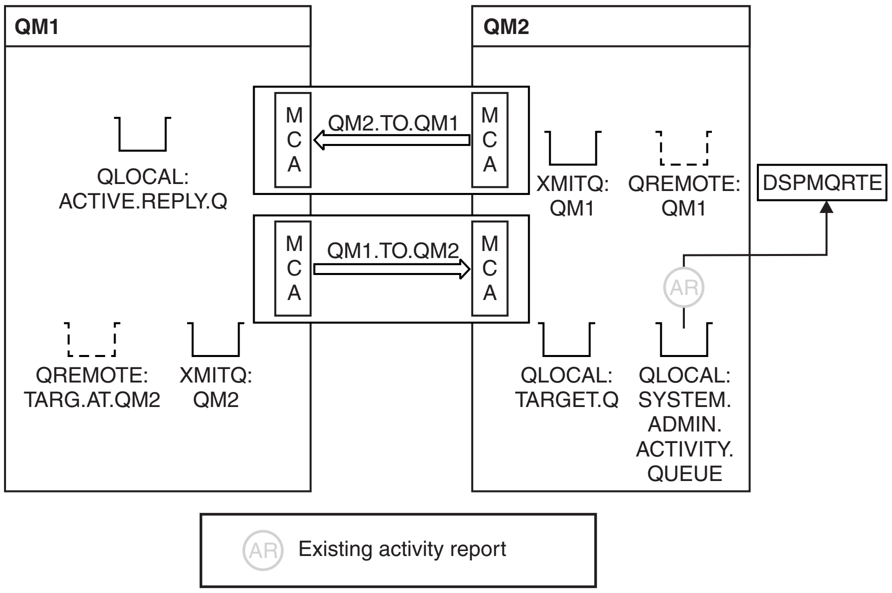

Figure 103. Delivering activity reports to the system queue, Diagram 2

- Meanwhile DSPMQRTE has been waiting for activity reports to arrive on ACTIV.REPLY.Q. Only two arrive. DSPMQRTE continues waiting for 120 seconds because it seems that the route is not yet complete.

The output that is displayed follows:

```
AMQ8653: DSPMQRTE command started with options '-m QM1 -q TARG.AT.QM2 -rq
         ACTIV.REPLY.Q -v outline identifiers'.
AMQ8659: DSPMQRTE command successfully put a message on queue 'QM2', queue
         manager 'QM1'.
AMQ8674: DSPMQRTE command is now waiting for information to display.

   MQMD:
    MsgId: X'414D51204C41524745512020202020A3C9154220001502'
    CorrelId: X'414D51204C41524745512020202020A3C9154220001503'
  QMgrName: 'QM1                                            '
  RemoteQMgrName: 'QM2                                            '
  ChannelName: 'QM1.TO.QM2          '
  ChannelType: Sender
  XmitQName: 'QM2                                            '
--------------------------------------------------------------------------------
AMQ8652: DSPMQRTE command has finished.
```

- The last operation that DSPMQRTE observed was a Send, therefore the channel is running. Now we must work out why we did not receive any more activity reports from queue manager QM2 (as identified in RemoteQMgrName).
- To check whether there is any activity information on the system queue, start DSPMQRTE on QM2 to try and collect more activity reports. Use the following command to start DSPMQRTE:

  ```
  dspmqrte -m QM2 -q SYSTEM.ADMIN.ACTIVITY.QUEUE
           -i 414D51204C41524745512020202020A3C9154220001502 -v outline
  ```

where 414D51204C41524745512020202020A3C9154220001502 is the MsgId of the trace-route message that was put.

- DSPMQRTE then performs a sequence of MQGETs again, waiting for responses on the system activity queue related to the trace-route message with the specified identifier.
- DSPMQRTE gets one more activity report, which it displays. DSPMQRTE determines that the preceding activity reports are missing, and displays a message saying this. We already know about this part of the route, however.

The output that is displayed follows:

```
AMQ8653: DSPMQRTE command started with options '-m QM2
         -q SYSTEM.ADMIN.ACTIVITY.QUEUE
         -i 414D51204C41524745512020202020A3C915420001502 -v outline'.
AMQ8674: DSPMQRTE command is now waiting for information to display.
--------------------------------------------------------------------------------

Activity:
 Activity information unavailable.

--------------------------------------------------------------------------------
Activity:
 ApplName: 'cann\output\bin\AMQRMPPA.EXE'

 Operation:
  OperationType: Receive
  QMgrName: 'QM2                                             '
  RemoteQMgrName: 'QM1                                           '
  ChannelName: 'QM1.TO.QM2          '
  ChannelType: Receiver

 Operation:
  OperationType: Discard
  QMgrName: 'QM2                                             '
  QName: 'TARGET.Q                                       '
  Feedback: NotDelivered

--------------------------------------------------------------------------------
AMQ8652: DSPMQRTE command has finished.
```

- This activity report indicates that the route information is now complete. No problem occurred.
- Just because route information is unavailable, or because DSPMQRTE cannot display all of the route, this does not mean that the message was not delivered. For example, the queue manager attributes of different queue managers might be different, or a reply queue might not be defined to get the response back.

Example 4 - Diagnosing a channel problem:

Diagnose a problem in which the trace-route message does not reach the target queue

In this example the IBM MQ display route application connects to queue manager, QM1, generates a trace-route message, then attempts to deliver it to the target queue, TARGET.Q, on remote queue manager, QM2. In this example the trace-route message does not reach the target queue. The available activity report is used to diagnose the problem.

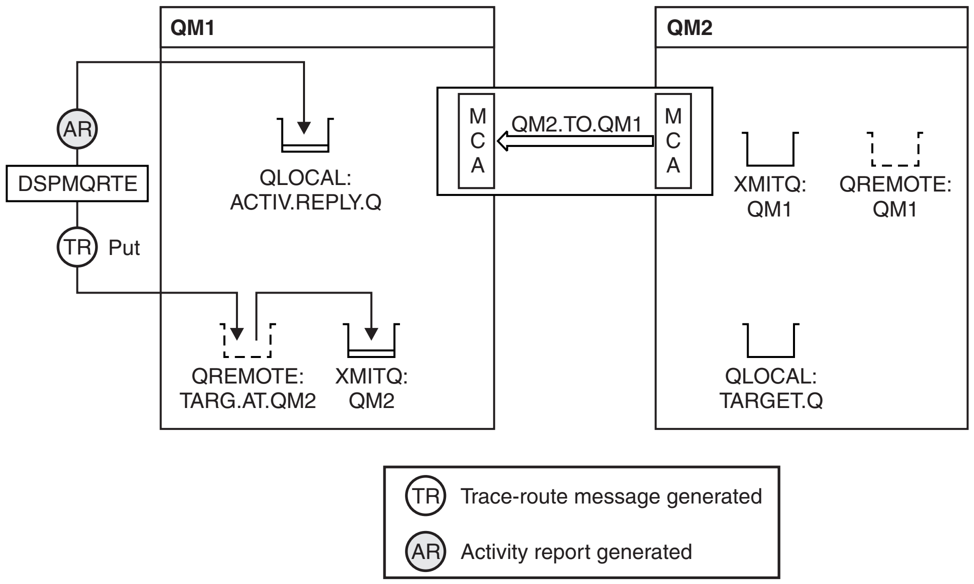

Figure 104. Diagnosing a channel problem

- In this example, the channel QM1.TO.QM2 is not running.
- DSPMQRTE puts a trace-route message (as in example 1) to the target queue and generates an activity report.
- There is no MCA to get the message from the transmission queue (QM2), therefore this is the only activity report that DSPMQRTE gets back from the reply queue. This time the fact that the route is not complete does indicate a problem. The administrator can use the transmission queue found in ResolvedQName to investigate why the transmission queue is not being serviced.

The output that is displayed follows:

```
AMQ8653: DSPMQRTE command started with options '-m QM1 -q TARG.AT.QM2
         -rq ACTIV.REPLY.Q -v outline'.
AMQ8659: DSPMQRTE command successfully put a message on queue 'QM2',
         queue manager 'QM1'.
AMQ8674: DSPMQRTE command is now waiting for information to display.
--------------------------------------------------------------------------------

--------------------------------------------------------------------------------
 AMQ8652: DSPMQRTE command has finished.
```

Activity report reference

Use this page to obtain an overview of the activity report message format. The activity report message data contains the parameters that describe the activity.

Activity report format:

Activity reports are standard IBM MQ report messages containing a message descriptor and message data. Activity reports are PCF messages generated by applications that have performed an activity on behalf of a message as it has been routed through a queue manager network.

Activity reports contain the following information:

A message descriptor
An MQMD structure

Message data
Consists of the following:
- An embedded PCF header (MQEPH).
- Activity report message data.

Activity report message data consists of the *Activity* PCF group and, if generated for a trace-route message, the *TraceRoute* PCF group.

Table 119 on page 1023 shows the structure of these reports, including parameters that are returned only under certain conditions.

Table 119. Activity report format

MQMD structure	Embedded PCF header MQEPH structure	Activity report message data
Structure identifier	Structure identifier	Activity
Structure version	Structure version	Activity application name
Report options	Structure length	Activity application type
Message type	Encoding	Activity description
Expiration time	Coded character set ID	Operation
Feedback	Message format	Operation type
Encoding	Flags	Operation date
Coded character set ID	PCF header (MQCFH)	Operation time
Message format	Structure type	Message
Priority	Structure length	Message length
Persistence	Structure version	MQMD [8]
Message identifier	Command identifier	EmbeddedMQMD
Correlation identifier	Message sequence number	Queue manager name
Backout count	Control options	Queue sharing group name
Reply-to queue	Completion code	Queue name [1] [2] [3] [7]
Reply-to queue manager	Reason code	Resolved queue name [1] [3] [7]
User identifier	Parameter count	Remote queue name [3] [7]
Accounting token		Remote queue manager name [2] [3] [4] [5] [7]
Application identity data		Subscription level [9]
Application type		Subscription identifier [9]
Application name		Feedback [2] [10]
Put date		Channel name [4] [5]
Put time		Channel type [4] [5]
Application origin data		Transmission queue name [5]
Group identifier		TraceRoute [6]
Message sequence number		Detail
Offset		Recorded activities
Message flags		Unrecorded activities
Original length		Discontinuity count
		Max activities
		Accumulate
		Deliver

Notes:

1. Returned for Get and Browse operations.
2. Returned for Discard operations.
3. Returned for Put, Put Reply, and Put Report operations.
4. Returned for Receive operations.
5. Returned for Send operations.
6. Returned for trace-route messages.
7. Not returned for Put operations to a topic, contained within Publish activities.
8. Not returned for Excluded Publish operations. For Publish and Discarded Publish operations, returned containing a subset of parameters.
9. Returned for Publish, Discarded Publish, and Excluded Publish operations.
10. Returned for Discarded Publish and Excluded Publish operations.

Activity report MQMD (message descriptor):

Use this page to view the values contained by the MQMD structure for an activity report

StrucId
Structure identifier:

Data type
MQCHAR4

Value MQMD_STRUC_ID.

Version
Structure version number

Data type
MQLONG

Values
Copied from the original message descriptor. Possible values are:

MQMD_VERSION_1
Version-1 message descriptor structure, supported in all environments.

MQMD_VERSION_2
Version-2 message descriptor structure, supported on AIX, HP-UX, z/OS, IBM i, Solaris, Linux, Windows, and all IBM MQ MQI clients connected to these systems.

Report Options for further report messages

Data type
MQLONG

Value If MQRO_PASS_DISCARD_AND_EXPIRY or MQRO_DISCARD_MSG were specified in the *Report* field of the original message descriptor:

MQRO_DISCARD
The report is discarded if it cannot be delivered to the destination queue.

Otherwise:

MQRO_NONE
No reports required.

MsgType
Indicates type of message

Data type
MQLONG

Value MQMT_REPORT

Expiry Report message lifetime

Data type
MQLONG

Value If the *Report* field in the original message descriptor is specified as MQRO_PASS_DISCARD_AND_EXPIRY, the remaining expiry time from the original message is used.

Otherwise:

MQEI_UNLIMITED
The report does not have an expiry time.

Feedback

Description:	Feedback or reason code.
Data type:	MQLONG.
Value:	**MQFB_ACTIVITY** Activity report.

Encoding

Description:	Numeric encoding of report message data.
Data type:	MQLONG.
Value:	MQENC_NATIVE.

CodedCharSetId

Description:	Character set identifier of report message data.
Data type:	MQLONG.
Value:	Set as appropriate.

Format

Description:	Format name of report message data
Data type:	MQCHAR8.
Value:	**MQFMT_EMBEDDED_PCF** Embedded PCF message.

Priority

Description:	Report message priority.
Data type:	MQLONG.
Value:	Copied from the original message descriptor.

Persistence

Description:	Report message persistence.
Data type:	MQLONG.
Value:	Copied from the original message descriptor.

MsgId

Description:	Message identifier.
Data type:	MQBYTE24.
Values:	If the *Report* field in the original message descriptor is specified as MQRO_PASS_MSG_ID, the message identifier from the original message is used. Otherwise, a unique value will be generated by the queue manager.

CorrelId

Description:	Correlation identifier.
Data type:	MQBYTE24.
Value:	If the *Report* field in the original message descriptor is specified as MQRO_PASS_CORREL_ID, the correlation identifier from the original message is used. Otherwise, the message identifier is copied from the original message.

BackoutCount

Description:	Backout counter.
Data type:	MQLONG.
Value:	0.

ReplyToQ

Description:	Name of reply queue.
Data type:	MQCHAR48.
Values:	Blank.

ReplyToQMgr

Description:	Name of reply queue manager.
Data type:	MQCHAR48.
Value:	The queue manager name that generated the report message.

UserIdentifier

Description:	The user identifier of the application that generated the report message.
Data type:	MQCHAR12.
Value:	Copied from the original message descriptor.

AccountingToken

Description:	Accounting token that allows an application to charge for work done as a result of the message.
Data type:	MQBYTE32.
Value:	Copied from the original message descriptor.

ApplIdentityData

Description:	Application data relating to identity.
Data type:	MQCHAR32.
Values:	Copied from the original message descriptor.

PutApplType

Description:	Type of application that put the report message.
Data type:	MQLONG.
Value:	**MQAT_QMGR** Queue manager generated message.

PutApplName

Description:	Name of application that put the report message.
Data type:	MQCHAR28.
Value:	Either the first 28 bytes of the queue manager name, or the name of the MCA that generated the report message.

PutDate

Description:	Date when message was put.
Data type:	MQCHAR8.
Value:	As generated by the queue manager.

PutTime

Description:	Time when message was put.
Data type:	MQCHAR8.
Value:	As generated by the queue manager.

ApplOriginData

Description:	Application data relating to origin.
Data type:	MQCHAR4.
Value:	Blank.

If *Version* is MQMD_VERSION_2, the following additional fields are present:

GroupId

Description:	Identifies to which message group or logical message the physical message belongs.
Data type:	MQBYTE24.
Value:	Copied from the original message descriptor.

MsgSeqNumber

Description:	Sequence number of logical message within group.
Data type:	MQLONG.
Value:	Copied from the original message descriptor.

Offset

Description:	Offset of data in physical message from start of logical message.
Data type:	MQLONG.
Value:	Copied from the original message descriptor.

MsgFlags

Description:	Message flags that specify attributes of the message or control its processing.
Data type:	MQLONG.
Value:	Copied from the original message descriptor.

OriginalLength

Description:	Length of original message.
Data type:	MQLONG.
Value:	Copied from the original message descriptor.

Activity report MQEPH (Embedded PCF header):

Use this page to view the values contained by the MQEPH structure for an activity report

The MQEPH structure contains a description of both the PCF information that accompanies the message data of an activity report, and the application message data that follows it.

For an activity report, the MQEPH structure contains the following values:

StrucId

Description:	Structure identifier.
Data type:	MQCHAR4.
Value:	MQEPH_STRUC_ID.

Version

Description:	Structure version number.
Data type:	MQLONG.
Values:	MQEPH_VERSION_1.

StrucLength

Description:	Structure length.
Data type:	MQLONG.
Value:	Total length of the structure including the PCF parameter structures that follow it.

Encoding

Description:	Numeric encoding of the message data that follows the last PCF parameter structure.
Data type:	MQLONG.
Value:	If any data from the original application message data is included in the report message, the value will be copied from the *Encoding* field of the original message descriptor. Otherwise, 0.

CodedCharSetId

Description:	Character set identifier of the message data that follows the last PCF parameter structure.
Data type:	MQLONG.
Value:	If any data from the original application message data is included in the report message, the value will be copied from the *CodedCharSetId* field of the original message descriptor. Otherwise, MQCCSI_UNDEFINED.

Format

Description:	Format name of message data that follows the last PCF parameter structure.
Data type:	MQCHAR8.
Value:	If any data from the original application message data is included in the report message, the value will be copied from the *Format* field of the original message descriptor. Otherwise, MQFMT_NONE.

Flags

Description:	Flags that specify attributes of the structure or control its processing.
Data type:	MQLONG.
Value:	**MQEPH_CCSID_EMBEDDED** Specifies that the character set of the parameters containing character data is specified individually within the *CodedCharSetId* field in each structure.

PCFHeader

Description:	Programmable Command Format Header
Data type:	MQCFH.
Value:	See "Activity report MQCFH (PCF header)" on page 1030.

Activity report MQCFH (PCF header):

Use this page to view the PCF values contained by the MQCFH structure for an activity report

For an activity report, the MQCFH structure contains the following values:

Type

Description:	Structure type that identifies the content of the report message.
Data type:	MQLONG.
Value:	**MQCFT_REPORT** Message is a report.

StrucLength

Description:	Structure length.
Data type:	MQLONG.
Value:	**MQCFH_STRUC_LENGTH** Length in bytes of MQCFH structure.

Version

Description:	Structure version number.
Data type:	MQLONG.
Values:	MQCFH_VERSION_3

Command

Description:	Command identifier. This identifies the category of the message.
Data type:	MQLONG.
Values:	**MQCMD_ACTIVITY_MSG** Message activity.

MsgSeqNumber

Description:	Message sequence number. This is the sequence number of the message within a group of related messages.
Data type:	MQLONG.
Values:	1.

Control

Description:	Control options.
Data type:	MQLONG.
Values:	MQCFC_LAST.

CompCode

Description:	Completion code.
Data type:	MQLONG.
Values:	MQCC_OK.

Reason

Description:	Reason code qualifying completion code.
Data type:	MQLONG.
Values:	MQRC_NONE.

ParameterCount

Description:	Count of parameter structures. This is the number of parameter structures that follow the MQCFH structure. A group structure (MQCFGR), and its included parameter structures, are counted as one structure only.
Data type:	MQLONG.
Values:	1 or greater.

Activity report message data:

Use this page to view the parameters contained by the *Activity* PCF group in an activity report message. Some parameters are returned only when specific operations have been performed.

Activity report message data consists of the *Activity* PCF group and, if generated for a trace-route message, the *TraceRoute* PCF group. The *Activity* PCF group is detailed in this topic.

Some parameters, which are described as Operation-specific activity report message data, are returned only when specific operations have been performed.

For an activity report, the activity report message data contains the following parameters:

Activity

Description:	Grouped parameters describing the activity.
Identifier:	MQGACF_ACTIVITY.
Data type:	MQCFGR.
Included in PCF group:	None.
Parameters in PCF group:	*ActivityApplName* *ActivityApplType* *ActivityDescription* *Operation* *TraceRoute*
Returned:	Always.

ActivityApplName

Description:	Name of application that performed the activity.
Identifier:	MQCACF_APPL_NAME.
Data type:	MQCFST.
Included in PCF group:	*Activity*.
Maximum length:	MQ_APPL_NAME_LENGTH.
Returned:	Always.

ActivityApplType

Description:	Type of application that performed the activity.
Identifier:	MQIA_APPL_TYPE.
Data type:	MQCFIN.
Included in PCF group:	*Activity*.
Returned:	Always.

ActivityDescription

Description:	Description of activity performed by the application.
Identifier:	MQCACF_ACTIVITY_DESCRIPTION.
Data type:	MQCFST.
Included in PCF group:	*Activity*.
Maximum length:	64
Returned:	Always.

Operation

Description:	Grouped parameters describing an operation of the activity.
Identifier:	MQGACF_OPERATION.
Data type:	MQCFGR.
Included in PCF group:	*Activity*.
Parameters in PCF group:	*OperationType* *OperationDate* *OperationTime* *Message* *QMgrName* *QSGName* **Note:** Additional parameters are returned in this group depending on the operation type. These additional parameters are described as Operation-specific activity report message data.
Returned:	One *Operation* PCF group per operation in the activity.

OperationType

Description:	Type of operation performed.
Identifier:	MQIACF_OPERATION_TYPE.
Data type:	MQCFIN.
Included in PCF group:	*Operation*.
Values:	MQOPER_*.
Returned:	Always.

OperationDate

Description:	Date when the operation was performed.
Identifier:	MQCACF_OPERATION_DATE.
Data type:	MQCFST.
Included in PCF group:	*Operation*.
Maximum length:	MQ_DATE_LENGTH.
Returned:	Always.

OperationTime

Description:	Time when the operation was performed.
Identifier:	MQCACF_OPERATION_TIME.
Data type:	MQCFST.
Included in PCF group:	*Operation*.
Maximum length:	MQ_TIME_LENGTH.
Returned:	Always.

Message

Description:	Grouped parameters describing the message that caused the activity.
Identifier:	MQGACF_MESSAGE.
Data type:	MQCFGR.
Included in PCF group:	*Operation*.
Parameters in group:	*MsgLength* *MQMD* *EmbeddedMQMD*
Returned:	Always, except for Excluded Publish operations.

MsgLength

Description:	Length of the message that caused the activity, before the activity occurred.
Identifier:	MQIACF_MSG_LENGTH.
Data type:	MQCFIN.
Included in PCF group:	*Message*.
Returned:	Always.

MQMD

Description:	Grouped parameters related to the message descriptor of the message that caused the activity.
Identifier:	MQGACF_MQMD.
Data type:	MQCFGR.
Included in PCF group:	*Message*.
Parameters in group:	*StrucId* *Version* *Report* *MsgType* *Expiry* *Feedback* *Encoding* *CodedCharSetId* *Format* *Priority* *Persistence* *MsgId* *CorrelId* *BackoutCount* *ReplyToQ* *ReplyToQMgr* *UserIdentifier* *AccountingToken* *ApplIdentityData* *PutApplType* *PutApplName* *PutDate* *PutTime* *ApplOriginData* *GroupId* *MsgSeqNumber* *Offset* *MsgFlags* *OriginalLength*
Returned:	Always, except for Excluded Publish operations.

EmbeddedMQMD

Description:	Grouped parameters describing the message descriptor embedded within a message on a transmission queue.
Identifier:	MQGACF_EMBEDDDED_MQMD.
Data type:	MQCFGR.
Included in PCF group:	*Message*.

Parameters in group:	*StrucId* *Version* *Report* *MsgType* *Expiry* *Feedback* *Encoding* *CodedCharSetId* *Format* *Priority* *Persistence* *MsgId* *CorrelId* *BackoutCount* *ReplyToQ* *ReplyToQMgr* *UserIdentifier* *AccountingToken* *ApplIdentityData* *PutApplType* *PutApplName* *PutDate* *PutTime* *ApplOriginData* *GroupId* *MsgSeqNumber* *Offset* *MsgFlags* *OriginalLength*
Returned:	For Get operations where the queue resolves to a transmission queue.

StrucId

Description:	Structure identifier
Identifier:	MQCACF_STRUC_ID.
Data type:	MQCFST.
Included in PCF group:	*MQMD* or *EmbeddedMQMD*.
Maximum length:	4.
Returned:	Always, except for Excluded Publish operations and in MQMD for Publish and Discarded Publish operations.

Version

Description:	Structure version number.
Identifier:	MQIACF_VERSION.
Data type:	MQCFIN.
Included in PCF group:	*MQMD* or *EmbeddedMQMD*.
Returned:	Always, except for Excluded Publish operations and in MQMD for Publish and Discarded Publish operations.

Report

Description:	Options for report messages.
Identifier:	MQIACF_REPORT.
Data type:	MQCFIN.
Included in PCF group:	*MQMD* or *EmbeddedMQMD*.
Returned:	Always, except for Excluded Publish operations and in MQMD for Publish and Discarded Publish operations.

MsgType

Description:	Indicates type of message.
Identifier:	MQIACF_MSG_TYPE.
Data type:	MQCFIN.
Included in PCF group:	*MQMD* or *EmbeddedMQMD*.
Returned:	Always, except for Excluded Publish operations and in MQMD for Publish and Discarded Publish operations.

Expiry

Description:	Message lifetime.
Identifier:	MQIACF_EXPIRY.
Data type:	MQCFIN.
Included in PCF group:	*MQMD* or *EmbeddedMQMD*.
Returned:	Always, except for Excluded Publish operations and in MQMD for Publish and Discarded Publish operations.

Feedback

Description:	Feedback or reason code.
Identifier:	MQIACF_FEEDBACK.
Data type:	MQCFIN.
Included in PCF group:	*MQMD* or *EmbeddedMQMD*.
Returned:	Always, except for Excluded Publish operations and in MQMD for Publish and Discarded Publish operations.

Encoding

Description:	Numeric encoding of message data.
Identifier:	MQIACF_ENCODING.
Data type:	MQCFIN.
Included in PCF group:	*MQMD* or *EmbeddedMQMD*.
Returned:	Always, except for Excluded Publish operations and in MQMD for Publish and Discarded Publish operations.

CodedCharSetId

Description:	Character set identifier of message data.
Identifier:	MQIA_CODED_CHAR_SET_ID.
Data type:	MQCFIN.
Included in PCF group:	*MQMD* or *EmbeddedMQMD*.
Returned:	Always, except for Excluded Publish operations and in MQMD for Publish and Discarded Publish operations.

Format

Description:	Format name of message data
Identifier:	MQCACH_FORMAT_NAME.
Data type:	MQCFST.
Included in PCF group:	*MQMD* or *EmbeddedMQMD*.
Maximum length:	MQ_FORMAT_LENGTH.
Returned:	Always, except for Excluded Publish operations.

Priority

Description:	Message priority.
Identifier:	MQIACF_PRIORITY.
Data type:	MQCFIN.
Included in PCF group:	*MQMD* or *EmbeddedMQMD*.
Returned:	Always, except for Excluded Publish operations.

Persistence

Description:	Message persistence.
Identifier:	MQIACF_PERSISTENCE.
Data type:	MQCFIN.
Included in PCF group:	*MQMD* or *EmbeddedMQMD*.
Returned:	Always, except for Excluded Publish operations.

MsgId

Description:	Message identifier.
Identifier:	MQBACF_MSG_ID.
Data type:	MQCFBS.
Included in PCF group:	*MQMD* or *EmbeddedMQMD*.
Maximum length:	MQ_MSG_ID_LENGTH.
Returned:	Always, except for Excluded Publish operations.

CorrelId

Description:	Correlation identifier.
Identifier:	MQBACF_CORREL_ID.
Data type:	MQCFBS.
Included in PCF group:	*MQMD* or *EmbeddedMQMD*.
Maximum length:	MQ_CORREL_ID_LENGTH.
Returned:	Always, except for Excluded Publish operations.

BackoutCount

Description:	Backout counter.
Identifier:	MQIACF_BACKOUT_COUNT.
Data type:	MQCFIN.
Included in PCF group:	*MQMD* or *EmbeddedMQMD*.
Returned:	Always, except for Excluded Publish operations and in MQMD for Publish and Discarded Publish operations.

ReplyToQ

Description:	Name of reply queue.
Identifier:	MQCACF_REPLY_TO_QUEUE.
Data type:	MQCFST.
Included in PCF group:	*MQMD* or *EmbeddedMQMD*.
Maximum length:	MQ_Q_NAME_LENGTH.
Returned:	Always, except for Excluded Publish Operations and in MQMD for Publish and Discarded Publish operations.

ReplyToQMgr

Description:	Name of reply queue manager.
Identifier:	MQCACF_REPLY_TO_Q_MGR.
Data type:	MQCFST.
Included in PCF group:	*MQMD* or *EmbeddedMQMD*.
Maximum length:	MQ_Q_MGR_NAME_LENGTH.
Returned:	Always, except for Excluded Publish Operations and in MQMD for Publish and Discarded Publish Operations.

UserIdentifier

Description:	The user identifier of the application that originated the message.
Identifier:	MQCACF_USER_IDENTIFIER.
Data type:	MQCFST.
Included in PCF group:	*MQMD* or *EmbeddedMQMD*.
Maximum length:	MQ_USER_ID_LENGTH.
Returned:	Always, except for Excluded Publish Operations.

AccountingToken

Description:	Accounting token that allows an application to charge for work done as a result of the message.
Identifier:	MQBACF_ACCOUNTING_TOKEN.
Data type:	MQCFBS.
Included in PCF group:	*MQMD* or *EmbeddedMQMD*.
Maximum length:	MQ_ACCOUNTING_TOKEN_LENGTH.
Returned:	Always, except for Excluded Publish Operations.

ApplIdentityData

Description:	Application data relating to identity.
Identifier:	MQCACF_APPL_IDENTITY_DATA.
Data type:	MQCFST.
Included in PCF group:	*MQMD* or *EmbeddedMQMD*.
Maximum length:	MQ_APPL_IDENTITY_DATA_LENGTH.
Returned:	Always, except for Excluded Publish Operations.

PutApplType

Description:	Type of application that put the message.
Identifier:	MQIA_APPL_TYPE.
Data type:	MQCFIN.
Included in PCF group:	*MQMD* or *EmbeddedMQMD*.
Returned:	Always, except for Excluded Publish Operations and in MQMD for Publish and Discarded Publish Operations.

PutApplName

Description:	Name of application that put the message.
Identifier:	MQCACF_APPL_NAME.
Data type:	MQCFST.
Included in PCF group:	*MQMD* or *EmbeddedMQMD*.
Maximum length:	MQ_APPL_NAME_LENGTH.
Returned:	Always, except for Excluded Publish Operations and in MQMD for Publish and Discarded Publish Operations.

PutDate

Description:	Date when message was put.
Identifier:	MQCACF_PUT_DATE.
Data type:	MQCFST.
Included in PCF group:	*MQMD* or *EmbeddedMQMD*.
Maximum length:	MQ_PUT_DATE_LENGTH.
Returned:	Always, except for Excluded Publish Operations and in MQMD for Publish and Discarded Publish Operations.

PutTime

Description:	Time when message was put.
Identifier:	MQCACF_PUT_TIME.
Data type:	MQCFST.
Included in PCF group:	*MQMD* or *EmbeddedMQMD*.
Maximum length:	MQ_PUT_TIME_LENGTH.
Returned:	Always, except for Excluded Publish Operations and in MQMD for Publish and Discarded Publish Operations.

ApplOriginData

Description:	Application data relating to origin.
Identifier:	MQCACF_APPL_ORIGIN_DATA.
Data type:	MQCFST.
Included in PCF group:	*MQMD* or *EmbeddedMQMD*.
Maximum length:	MQ_APPL_ORIGIN_DATA_LENGTH.
Returned:	Always, except for Excluded Publish Operations and in MQMD for Publish and Discarded Publish Operations.

GroupId

Description:	Identifies to which message group or logical message the physical message belongs.
Identifier:	MQBACF_GROUP_ID.
Data type:	MQCFBS.
Included in PCF group:	*MQMD* or *EmbeddedMQMD*.
Maximum length:	MQ_GROUP_ID_LENGTH.
Returned:	If the *Version* is specified as MQMD_VERSION_2. Not returned in Excluded Publish Operations and in MQMD for Publish and Discarded Publish Operations.

MsgSeqNumber

Description:	Sequence number of logical message within group.
Identifier:	MQIACH_MSG_SEQUENCE_NUMBER.
Data type:	MQCFIN.
Included in PCF group:	*MQMD* or *EmbeddedMQMD*.
Returned:	If *Version* is specified as MQMD_VERSION_2. Not returned in Excluded Publish Operations and in MQMD for Publish and Discarded Publish Operations.

Offset

Description:	Offset of data in physical message from start of logical message.
Identifier:	MQIACF_OFFSET.
Data type:	MQCFIN.
Included in PCF group:	*MQMD* or *EmbeddedMQMD*.
Returned:	If *Version* is specified as MQMD_VERSION_2. Not returned in Excluded Publish Operations and in MQMD for Publish and Discarded Publish Operations.

MsgFlags

Description:	Message flags that specify attributes of the message or control its processing.
Identifier:	MQIACF_MSG_FLAGS.
Data type:	MQCFIN.
Included in PCF group:	*MQMD* or *EmbeddedMQMD*.
Returned:	If *Version* is specified as MQMD_VERSION_2. Not returned in Excluded Publish Operations and in MQMD for Publish and Discarded Publish Operations.

OriginalLength

Description:	Length of original message.
Identifier:	MQIACF_ORIGINAL_LENGTH.
Data type:	MQCFIN.
Included in PCF group:	*MQMD* or *EmbeddedMQMD*.
Returned:	If *Version* is specified as MQMD_VERSION_2. Not returned in Excluded Publish Operations and in MQMD for Publish and Discarded Publish Operations.

QMgrName

Description:	Name of the queue manager where the activity was performed.
Identifier:	MQCA_Q_MGR_NAME.
Data type:	MQCFST.
Included in PCF group:	*Operation*.
Maximum length:	MQ_Q_MGR_NAME_LENGTH
Returned:	Always.

QSGName

Description:	Name of the queue-sharing group to which the queue manager where the activity was performed belongs.
Identifier:	MQCA_QSG_NAME.
Data type:	MQCFST.
Included in PCF group:	*Operation*.
Maximum length:	MQ_QSG_NAME_LENGTH
Returned:	If the activity was performed on an IBM MQ for z/OS queue manager.

TraceRoute

Description:	Grouped parameters specifying attributes of the trace-route message.
Identifier:	MQGACF_TRACE_ROUTE.
Data type:	MQCFGR.
Contained in PCF group:	*Activity*.
Parameters in group:	*Detail* *RecordedActivities* *UnrecordedActivities* *DiscontinuityCount* *MaxActivities* *Accumulate* *Forward* *Deliver*
Returned:	If the activity was performed on behalf of the trace-route message.

The values of the parameters in the *TraceRoute* PCF group are those from the trace-route message at the time the activity report was generated.

Operation-specific activity report message data:

Use this page to view the additional PCF parameters that might be returned in the PCF group *Operation* in an activity report, depending on the value of the *OperationType* parameter

The additional parameters vary depending on the following operation types:

Get/Browse (MQOPER_GET/MQOPER_BROWSE):

The additional activity report message data parameters that are returned in the PCF group *Operation* for the Get/Browse (MQOPER_GET/MQOPER_BROWSE) operation type (a message on a queue was got, or browsed).

QName

Description:	The name of the queue that was opened.
Identifier:	MQCA_Q_NAME.
Data type:	MQCFST.
Included in PCF group:	*Operation*.
Maximum length:	MQ_Q_NAME_LENGTH
Returned:	Always.

ResolvedQName

Description:	The name that the opened queue resolves to.
Identifier:	MQCACF_RESOLVED_Q_NAME.
Data type:	MQCFST.
Included in PCF group:	*Operation*.
Maximum length:	MQ_Q_NAME_LENGTH
Returned:	Always.

Discard (MQOPER_DISCARD):

The additional activity report message data parameters that are returned in the PCF group *Operation* for the Discard (MQOPER_DISCARD) operation type (a message was discarded).

Feedback

Description:	The reason for the message being discarded.
Identifier:	MQIACF_FEEDBACK.
Data type:	MQCFIN.
Included in PCF group:	*Operation*.
Returned:	Always.

QName

Description:	The name of the queue that was opened.
Identifier:	MQCA_Q_NAME.
Data type:	MQCFST.
Maximum length:	MQ_Q_NAME_LENGTH
Included in PCF group:	*Operation*.
Returned:	If the message was discarded because it was unsuccessfully put to a queue.

RemoteQMgrName

Description:	The name of the queue manager to which the message was destined.
Identifier:	MQCA_REMOTE_Q_MGR_NAME.
Data type:	MQCFST.
Maximum length:	MQ_Q_MGR_NAME_LENGTH
Included in PCF group:	*Operation*.
Returned:	If the value of *Feedback* is MQFB_NOT_FORWARDED.

Publish/Discarded Publish/Excluded Publish (MQOPER_PUBLISH/MQOPER_DISCARDED_PUBLISH/ MQOPER_EXCLUDED_PUBLISH):

The additional activity report message data parameters that are returned in the PCF group *Operation* for the Publish/Discarded Publish/Excluded Publish (MQOPER_PUBLISH/ MQOPER_DISCARDED_PUBLISH/MQOPER_EXCLUDED_PUBLISH) operation type (a publish/subscribe message was delivered, discarded, or excluded).

SubId

Description:	The subscription identifier.
Identifier:	MQBACF_SUB_ID.
Data type:	MQCFBS.
Included in PCF group:	*Operation*.
Returned:	Always.

SubLevel

Description:	The subscription level.
Identifier:	MQIACF_SUB_LEVEL.
Data type:	MQCFIN.
Included in PCF group:	*Operation*.
Returned:	Always.

Feedback

Description:	The reason for discarding the message.
Identifier:	MQIACF_FEEDBACK.
Data type:	MQCFIN.
Included in PCF group:	*Operation*.
Returned:	If the message was discarded because it was not delivered to a subscriber, or the message was not delivered because the subscriber was excluded.

The Publish operation MQOPER_PUBLISH provides information about a message delivered to a particular subscriber. This operation describes the elements of the onward message that might have changed from the message described in the associated Put operation. Similarly to a Put operation, it contains a message group MQGACF_MESSAGE and, inside that, an MQMD group MQGACF_MQMD. However, this MQMD group contains only the following fields, which can be overridden by a subscriber: *Format, Priority, Persistence, MsgId, CorrelId, UserIdentifier, AccountingToken, ApplIdentityData.*

The *SubId* and *SubLevel* of the subscriber are included in the operation information. You can use the *SubID* with the MQCMD_INQUIRE_SUBSCRIBER PCF command to retrieve all other attributes for a subscriber.

The Discarded Publish operation MQOPER_DISCARDED_PUBLISH is analogous to the Discard operation that is used when a message is not delivered in point-to-point messaging. A message is not delivered to a subscriber if the message was explicitly requested not to be delivered to a local destination and this subscriber specifies a local destination. A message is also considered not delivered if there is a problem getting the message to the destination queue, for example, because the queue is full.

The information in a Discarded Publish operation is the same as for a Publish operation, with the addition of a *Feedback* field that gives the reasons why the message was not delivered. This feedback field contains MQFB_* or MQRC_* values that are common with the MQOPER_DISCARD operation. The reason for discarding a publish, as opposed to excluding it, are the same as the reasons for discarding a put.

The Excluded Publish operation MQOPER_EXCLUDED_PUBLISH provides information about a subscriber that was considered for delivery of the message, because the topic on which the subscriber is subscribing matches that of the associated Put operation, but the message was not delivered to the subscriber because other selection criteria do not match with the message that is being put to the topic. As with a Discarded Publish operation, the *Feedback* field provides information about the reason why this subscription was excluded. However, unlike the Discarded Publish operation, no message-related information is provided because no message was generated for this subscriber.

Put/Put Reply/Put Report (MQOPER_PUT/MQOPER_PUT_REPLY/MQOPER_PUT_REPORT):

The additional activity report message data parameters that are returned in the PCF group *Operation* for the Put/Put Reply/Put Report (MQOPER_PUT/MQOPER_PUT_REPLY/MQOPER_PUT_REPORT) operation type (a message, reply message, or report message was put to a queue).

QName

Description:	The name of the queue that was opened.
Identifier:	MQCA_Q_NAME.
Data type:	MQCFST.
Included in PCF group:	*Operation*.
Maximum length:	MQ_Q_NAME_LENGTH
Returned:	Always, apart from one exception: not returned if the Put operation is to a topic, contained within a publish activity.

ResolvedQName

Description:	The name that the opened queue resolves to.
Identifier:	MQCACF_RESOLVED_Q_NAME.
Data type:	MQCFST.
Included in PCF group:	*Operation*.
Maximum length:	MQ_Q_NAME_LENGTH
Returned:	When the opened queue could be resolved. Not returned if the Put operation is to a topic, contained within a publish activity.

RemoteQName

Description:	The name of the opened queue, as it is known on the remote queue manager.
Identifier:	MQCA_REMOTE_Q_NAME.
Data type:	MQCFST.
Included in PCF group:	*Operation*.
Maximum length:	MQ_Q_NAME_LENGTH
Returned:	If the opened queue is a remote queue. Not returned if the Put operation is to a topic, contained within a publish activity.

RemoteQMgrName

Description:	The name of the remote queue manager on which the remote queue is defined.
Identifier:	MQCA_REMOTE_Q_MGR_NAME.
Data type:	MQCFST.
Included in PCF group:	*Operation*.
Maximum length:	MQ_Q_MGR_NAME_LENGTH
Returned:	If the opened queue is a remote queue. Not returned if the Put operation is to a topic, contained within a publish activity.

TopicString

Description:	The full topic string to which the message is being put.
Identifier:	MQCA_TOPIC_STRING.
Data type:	MQCFST.
Included in PCF group:	*Operation*.
Returned:	If the Put operation is to a topic, contained within a publish activity.

Feedback

Description:	The reason for the message being put on the dead-letter queue.
Identifier:	MQIACF_FEEDBACK.
Data type:	MQCFIN.
Included in PCF group:	*Operation*.
Returned:	If the message was put on the dead-letter queue.

Receive (MQOPER_RECEIVE):

The additional activity report message data parameters that are returned in the PCF group *Operation* for the Receive (MQOPER_RECEIVE) operation type (a message was received on a channel).

ChannelName

Description:	The name of the channel on which the message was received.
Identifier:	MQCACH_CHANNEL_NAME.
Data type:	MQCFST.
Included in PCF group:	*Operation*.
Maximum length:	MQ_CHANNEL_NAME_LENGTH
Returned:	Always.

ChannelType

Description:	The type of channel on which the message was received.
Identifier:	MQIACH_CHANNEL_TYPE.
Data type:	MQCFIN.
Included in PCF group:	*Operation*.
Returned:	Always.

RemoteQMgrName

Description:	The name of the queue manager from which the message was received.
Identifier:	MQCA_REMOTE_Q_MGR_NAME.
Data type:	MQCFST.
Included in PCF group:	*Operation*.
Maximum length:	MQ_Q_MGR_NAME_LENGTH
Returned:	Always.

Send (MQOPER_SEND):

The additional activity report message data parameters that are returned in the PCF group *Operation* for the Send (MQOPER_SEND) operation type (a message was sent on a channel).

ChannelName

Description:	The name of the channel where the message was sent.
Identifier:	MQCACH_CHANNEL_NAME.
Data type:	MQCFST.
Included in PCF group:	*Operation*.
Maximum length:	MQ_CHANNEL_NAME_LENGTH.
Returned:	Always.

ChannelType

Description:	The type of channel where the message was sent.
Identifier:	MQIACH_CHANNEL_TYPE.
Data type:	MQCFIN.
Included in PCF group:	*Operation*.
Returned:	Always.

XmitQName

Description:	The transmission queue from which the message was retrieved.
Identifier:	MQCACH_XMIT_Q_NAME.
Data type:	MQCFST.
Included in PCF group:	*Operation*.
Maximum length:	MQ_Q_NAME_LENGTH.
Returned:	Always.

RemoteQMgrName

Description:	The name of the remote queue manager to which the message was sent.
Identifier:	MQCA_REMOTE_Q_MGR_NAME.
Data type:	MQCFST.
Included in PCF group:	*Operation*.
Maximum length:	MQ_Q_MGR_NAME_LENGTH
Returned:	Always.

Trace-route message reference

Use this page to obtain an overview of the trace-route message format. The trace-route message data includes parameters that describe the activities that the trace-route message has caused

Trace-route message format:

Trace-route messages are standard IBM MQ messages containing a message descriptor and message data. The message data contains information about the activities performed on a trace-route message as it has been routed through a queue manager network.

Trace-route messages contain the following information:

A message descriptor
An MQMD structure, with the *Format* field set to MQFMT_ADMIN or MQFMT_EMBEDDED_PCF.

Message data
Consists of either:

- A PCF header (MQCFH) and trace-route message data, if *Format* is set to MQFMT_ADMIN, or
- An embedded PCF header (MQEPH), trace-route message data, and additional user-specified message data, if *Format* is set to MQFMT_EMBEDDED_PCF.

When using the IBM MQ display route application to generate a trace-route message, *Format* is set to MQFMT_ADMIN.

The content of the trace-route message data is determined by the *Accumulate* parameter from the *TraceRoute* PCF group, as follows:

- If *Accumulate* is set to MQROUTE_ACCUMULATE_NONE, the trace-route message data contains the *TraceRoute* PCF group.
- If *Accumulate* is set to either MQROUTE_ACCUMULATE_IN_MSG or MQROUTE_ACCUMULATE_AND_REPLY, the trace-route message data contains the *TraceRoute* PCF group and zero or more *Activity* PCF groups.

Table 120 on page 1049 shows the structure of a trace-route message.

Table 120. Trace-route message format

MQMD structure	Embedded PCF header MQEPH structure	Trace-route message data
Structure identifier	Structure identifier	TraceRoute
Structure version	Structure version	Detail
Report options	Structure length	Recorded activities
Message type	Encoding	Unrecorded activities
Expiration time	Coded character set ID	Discontinuity count
Feedback	Message format	Max activities
Encoding	Flags	Accumulate
Coded character set ID	PCF header (MQCFH)	Deliver
Message format	Structure type	
Priority	Structure length	
Persistence	Structure version	
Message identifier	Command identifier	
Correlation identifier	Message sequence number	
Backout count	Control options	
Reply-to queue	Completion code	
Reply-to queue manager	Reason code	
User identifier	Parameter count	
Accounting token		
Application identity data		
Application type		
Application name		
Put date		
Put time		
Application origin data		
Group identifier		
Message sequence number		
Offset		
Message flags		
Original length		

Trace-route message MQMD (message descriptor):

Use this page to view the values contained by the MQMD structure for a trace-route message

StrucId

Description:	Structure identifier.
Data type:	MQCHAR4.
Value:	MQMD_STRUC_ID.

Version

Description:	Structure version number.
Data type:	MQLONG.
Values:	**MQMD_VERSION_1.**

Report

Description:	Options for report messages.
Data type:	MQLONG.
Value:	Set according to requirements. Common report options follow:

MQRO_DISCARD_MSG
The message is discarded on arrival to a local queue.

MQRO_PASS_DISCARD_AND_EXPIRY
Every response (activity reports or trace-route reply message) will have the report option MQRO_DISCARD_MSG set, and the remaining expiry passed on. This ensures that responses do not remain in the queue manager network indefinitely.

MsgType

Description:	Type of message.
Data type:	MQLONG.
Value:	If the *Accumulate* parameter in the TraceRoute group is specified as MQROUTE_ACCUMULATE_AND_REPLY, then message type is MQMT_REQUEST

Otherwise:

MQMT_DATAGRAM.

Expiry

Description:	Message lifetime.
Data type:	MQLONG.
Value:	Set according to requirements. This parameter can be used to ensure trace-route messages are not left in a queue manager network indefinitely.

Feedback

Description:	Feedback or reason code.
Data type:	MQLONG.
Value:	**MQFB_NONE.**

Encoding

Description:	Numeric encoding of message data.
Data type:	MQLONG.
Value:	Set as appropriate.

CodedCharSetId

Description:	Character set identifier of message data.
Data type:	MQLONG.
Value:	Set as appropriate.

Format

Description:	Format name of message data
Data type:	MQCHAR8.
Value:	**MQFMT_ADMIN** Admin message. No user data follows the *TraceRoute* PCF group. **MQFMT_EMBEDDED_PCF** Embedded PCF message. User data follows the *TraceRoute* PCF group.

Priority

Description:	Message priority.
Data type:	MQLONG.
Value:	Set according to requirements.

Persistence

Description:	Message persistence.
Data type:	MQLONG.
Value:	Set according to requirements.

MsgId

Description:	Message identifier.
Data type:	MQBYTE24.
Value:	Set according to requirements.

CorrelId

Description:	Correlation identifier.
Data type:	MQBYTE24.
Value:	Set according to requirements.

BackoutCount

Description:	Backout counter.
Data type:	MQLONG.
Value:	0.

ReplyToQ

Description:	Name of reply queue.
Data type:	MQCHAR48.
Values:	Set according to requirements. If *MsgType* is set to MQMT_REQUEST or if *Report* has any report generating options set, then this parameter must be non-blank.

ReplyToQMgr

Description:	Name of reply queue manager.
Data type:	MQCHAR48.
Value:	Set according to requirements.

UserIdentifier

Description:	The user identifier of the application that originated the message.
Data type:	MQCHAR12.
Value:	Set as normal.

AccountingToken

Description:	Accounting token that allows an application to charge for work done as a result of the message.
Data type:	MQBYTE32.
Value:	Set as normal.

ApplIdentityData

Description:	Application data relating to identity.
Data type:	MQCHAR32.
Values:	Set as normal.

PutApplType

Description:	Type of application that put the message.
Data type:	MQLONG.
Value:	Set as normal.

PutApplName

Description:	Name of application that put the message.
Data type:	MQCHAR28.
Value:	Set as normal.

PutDate

Description:	Date when message was put.
Data type:	MQCHAR8.
Value:	Set as normal.

PutTime

Description:	Time when message was put.
Data type:	MQCHAR8.
Value:	Set as normal.

ApplOriginData

Description:	Application data relating to origin.
Data type:	MQCHAR4.
Value:	Set as normal..

Trace-route message MQEPH (Embedded PCF header):

Use this page to view the values contained by the MQEPH structure for a trace-route message

The MQEPH structure contains a description of both the PCF information that accompanies the message data of a trace-route message, and the application message data that follows it. An MQEPH structure is used only if additional user message data follows the TraceRoute PCF group.

For a trace-route message, the MQEPH structure contains the following values:

StrucId

Description:	Structure identifier.
Data type:	MQCHAR4.
Value:	MQEPH_STRUC_ID.

Version

Description:	Structure version number.
Data type:	MQLONG.
Values:	MQEPH_VERSION_1.

StrucLength

Description:	Structure length.
Data type:	MQLONG.
Value:	Total length of the structure including the PCF parameter structures that follow it.

Encoding

Description:	Numeric encoding of the message data that follows the last PCF parameter structure.
Data type:	MQLONG.
Value:	The encoding of the message data.

CodedCharSetId

Description:	Character set identifier of the message data that follows the last PCF parameter structure.
Data type:	MQLONG.
Value:	The character set of the message data.

Format

Description:	Format name of the message data that follows the last PCF parameter structure.
Data type:	MQCHAR8.
Value:	The format name of the message data.

Flags

Description:	Flags that specify attributes of the structure or control its processing.
Data type:	MQLONG.
Value:	**MQEPH_NONE** No flags specified. **MQEPH_CCSID_EMBEDDED** Specifies that the character set of the parameters containing character data is specified individually within the *CodedCharSetId* field in each structure.

PCFHeader

Description:	Programmable Command Format Header
Data type:	MQCFH.
Value:	See "Trace-route message MQCFH (PCF header)."

Trace-route message MQCFH (PCF header):

Use this page to view the PCF values contained by the MQCFH structure for a trace-route message

For a trace-route message, the MQCFH structure contains the following values:

Type

Description:	Structure type that identifies the content of the message.
Data type:	MQLONG.
Value:	**MQCFT_TRACE_ROUTE** Message is a trace-route message.

StrucLength

Description:	Structure length.
Data type:	MQLONG.
Value:	**MQCFH_STRUC_LENGTH** Length in bytes of MQCFH structure.

Version

Description:	Structure version number.
Data type:	MQLONG.
Values:	MQCFH_VERSION_3

Command

Description:	Command identifier. This identifies the category of the message.
Data type:	MQLONG.
Values:	**MQCMD_TRACE_ROUTE** Trace-route message.

MsgSeqNumber

Description:	Message sequence number. This is the sequence number of the message within a group of related messages.
Data type:	MQLONG.
Values:	1.

Control

Description:	Control options.
Data type:	MQLONG.
Values:	MQCFC_LAST.

CompCode

Description:	Completion code.
Data type:	MQLONG.
Values:	MQCC_OK.

Reason

Description:	Reason code qualifying completion code.
Data type:	MQLONG.
Values:	MQRC_NONE.

ParameterCount

Description:	Count of parameter structures. This is the number of parameter structures that follow the MQCFH structure. A group structure (MQCFGR), and its included parameter structures, are counted as one structure only.
Data type:	MQLONG.
Values:	1 or greater.

Trace-route message data:

Use this page to view the parameters that make up the *TraceRoute* PCF group part of trace-route message data

The content of trace-route message data depends on the *Accumulate* parameter from the *TraceRoute* PCF group. Trace-route message data consists of the *TraceRoute* PCF group, and zero or more *Activity* PCF groups. The *TraceRoute* PCF group is detailed in this topic. Refer to the related information for details of the *Activity* PCF group.

Trace-route message data contains the following parameters:

TraceRoute

Description:	Grouped parameters specifying attributes of the trace-route message. For a trace-route message, some of these parameters can be altered to control how it is processed.
Identifier:	MQGACF_TRACE_ROUTE.
Data type:	MQCFGR.
Contained in PCF group:	None.
Parameters in group:	*Detail* *RecordedActivities* *UnrecordedActivities* *DiscontinuityCount* *MaxActivities* *Accumulate* *Forward* *Deliver*

Detail

Description:	The detail level that will be recorded for the activity.
Identifier:	MQIACF_ROUTE_DETAIL.
Data type:	MQCFIN.
Contained in PCF group:	*TraceRoute*.
Values:	**MQROUTE_DETAIL_LOW** Activities performed by user-written application are recorded. **MQROUTE_DETAIL_MEDIUM** Activities specified in MQROUTE_DETAIL_LOW are recorded. Additionally, activities performed by MCAs are recorded. **MQROUTE_DETAIL_HIGH** Activities specified in MQROUTE_DETAIL_LOW, and MQROUTE_DETAIL_MEDIUM are recorded. MCAs do not record any further activity information at this level of detail. This option is only available to user-written applications that are to record further activity information.

RecordedActivities

Description:	The number of activities that the trace-route message has caused, where information was recorded.
Identifier:	MQIACF_RECORDED_ACTIVITIES.
Data type:	MQCFIN.
Contained in PCF group:	*TraceRoute*.

UnrecordedActivities

Description:	The number of activities that the trace-route message has caused, where information was not recorded.
Identifier:	MQIACF_UNRECORDED_ACTIVITIES.
Data type:	MQCFIN.
Contained in PCF group:	*TraceRoute*.

DiscontinuityCount

Description:	The number of times a trace-route message has been received from a queue manager that does not support trace-route messaging.
Identifier:	MQIACF_DISCONTINUITY_COUNT.
Data type:	MQCFIN.
Contained in PCF group:	*TraceRoute*.

MaxActivities

Description:	The maximum number of activities the trace-route message can be involved in before it stops being processed.
Identifier:	MQIACF_MAX_ACTIVITIES.
Data type:	MQCFIN.
Contained in PCF group:	*TraceRoute*.
Value:	**A positive integer** The maximum number of activities. **MQROUTE_UNLIMITED_ACTIVITIES** An unlimited number of activities.

Accumulate

Description:	Specifies whether activity information is accumulated within the trace-route message, and whether a reply message containing the accumulated activity information is generated before the trace-route message is discarded or is put on a non-transmission queue.
Identifier:	MQIACF_ROUTE_ACCUMULATION.
Data type:	MQCFIN.
Contained in PCF group:	*TraceRoute*.

Value:

MQROUTE_ACCUMULATE_NONE
Activity information is not accumulated in the message data of the trace-route message.

MQROUTE_ACCUMULATE_IN_MSG
Activity information is accumulated in the message data of the trace-route message.

MQROUTE_ACCUMULATE_AND_REPLY
Activity information is accumulated in the message data of the trace-route message, and a trace-route reply message will be generated.

Forward

Description:	Specifies queue managers that the trace-route message can be forwarded to. When determining whether to forward a message to a remote queue manager, queue managers use the algorithm that is described in Forwarding.
Identifier:	MQIACF_ROUTE_FORWARDING.
Data type:	MQCFIN.
Contained in PCF group:	*TraceRoute*.

Value:

MQROUTE_FORWARD_IF_SUPPORTED
The trace-route message is only forwarded to queue managers that will honor the value of the *Deliver* parameter from the *TraceRoute* group.

MQROUTE_FORWARD_ALL
The trace-route message is forwarded to any queue manager, regardless of whether the value of the *Deliver* parameter will be honored.

Deliver

Description:	Specifies the action to be taken if the trace-route message arrives at the destination queue successfully.
Identifier:	MQIACF_ROUTE_DELIVERY.
Data type:	MQCFIN.
Contained in PCF group:	*TraceRoute*.

Value:

MQROUTE_DELIVER_YES
On arrival, the trace-route message is put on the target queue. Any application performing a destructive get on the target queue can receive the trace-route message.

MQROUTE_DELIVER_NO
On arrival, the trace-route message is discarded.

Trace-route reply message reference

Use this page to obtain an overview of the trace-route reply message format. The trace-route reply message data is a duplicate of the trace-route message data from the trace-route message for which it was generated

Trace-route reply message format:

Trace-route reply messages are standard IBM MQ messages containing a message descriptor and message data. The message data contains information about the activities performed on a trace-route message as it has been routed through a queue manager network.

Trace-route reply messages contain the following information:

A message descriptor
An MQMD structure

Message data
A PCF header (MQCFH) and trace-route reply message data

Trace-route reply message data consists of one or more *Activity* PCF groups.

When a trace-route message reaches its target queue, a trace-route reply message can be generated that contains a copy of the activity information from the trace-route message. The trace-route reply message will be delivered to a reply-to queue or to a system queue.

Table 121 on page 1060 shows the structure of a trace-route reply message, including parameters that are only returned under certain conditions.

Table 121. Trace-route reply message format

MQMD structure	**PCF header MQCFH structure**	**Trace-route reply message data**
Structure identifier	PCF header (MQCFH)	Activity
Structure version	Structure type	Activity application name
Report options	Structure length	Activity application type
Message type	Structure version	Activity description
Expiration time	Command identifier	Operation
Feedback	Message sequence number	Operation type
Encoding	Control options	Operation date
Coded character set ID	Completion code	Operation time

Trace-route reply message MQMD (message descriptor):

Use this page to view the values contained by the MQMD structure for a trace-route reply message

For a trace-route reply message, the MQMD structure contains the parameters described in Activity report message descriptor. Some of the parameter values in a trace-route reply message descriptor are different from those in an activity report message descriptor, as follows:

MsgType

Description:	Type of message.
Data type:	MQLONG.
Value:	**MQMT_REPLY**

Feedback

Description:	Feedback or reason code.
Data type:	MQLONG.
Value:	**MQFB_NONE**

Encoding

Description:	Numeric encoding of message data.
Data type:	MQLONG.
Value:	Copied from trace-route message descriptor.

CodedCharSetId

Description:	Character set identifier of message data.
Data type:	MQLONG.
Value:	Copied from trace-route message descriptor.

Format

Description:	Format name of message data
Data type:	MQCHAR8.
Value:	**MQFMT_ADMIN** Admin message.

Trace-route reply message MQCFH (PCF header):

Use this page to view the PCF values contained by the MQCFH structure for a trace-route reply message

The PCF header (MQCFH) for a trace-route reply message is the same as for a trace-route message.

Trace-route reply message data:

The trace-route reply message data is a duplicate of the trace-route message data from the trace-route message for which it was generated

The trace-route reply message data contains one or more *Activity* groups. The parameters are described in "Activity report message data" on page 1031.

Accounting and statistics messages

Queue managers generate accounting and statistics messages to record information about the MQI operations performed by IBM MQ applications, or to record information about the activities occurring in an IBM MQ system.

Accounting messages
Accounting messages are used to record information about the MQI operations performed by IBM MQ applications, see "Accounting messages" on page 1063.

Statistics messages
Statistics messages are used to record information about the activities occurring in an IBM MQ system, see "Statistics messages" on page 1066.

z/OS Accounting messages and statistics messages as described here are not available on IBM MQ for z/OS, but equivalent functionality is available through the System Management Facility (SMF).

Accounting and statistics messages are delivered to one of two system queues. User applications can retrieve the messages from these system queues and use the recorded information for various purposes:

- Account for application resource use.
- Record application activity.
- Capacity planning.
- Detect problems in your queue manager network.
- Assist in determining the causes of problems in your queue manager network.
- Improve the efficiency of your queue manager network.
- Familiarize yourself with the running of your queue manager network.
- Confirm that your queue manager network is running correctly.

Related concepts:

z/OS "Using System Management Facility" on page 1224
You can use SMF to collect statistics and accounting information. To use SMF, certain parameters must be set in z/OS and in IBM MQ.

Accounting messages

Accounting messages record information about the MQI operations performed by IBM MQ applications. An accounting message is a PCF message that contains a number of PCF structures.

When an application disconnects from a queue manager, an accounting message is generated and delivered to the system accounting queue (SYSTEM.ADMIN.ACCOUNTING.QUEUE). For long running IBM MQ applications, intermediate accounting messages are generated as follows:

- When the time since the connection was established exceeds the configured interval.
- When the time since the last intermediate accounting message exceeds the configured interval.

Accounting messages are in the following categories:

MQI accounting messages
MQI accounting messages contain information relating to the number of MQI calls made using a connection to a queue manager.

Queue accounting messages
Queue accounting messages contain information relating to the number of MQI calls made using connections to a queue manager, grouped by queue.

Each queue accounting message can contain up to 100 records, with every record relating to an activity performed by the application with respect to a specific queue.

Accounting messages are recorded only for local queues. If an application makes an MQI call against an alias queue, the accounting data is recorded against the base queue, and, for a remote queue, the accounting data is recorded against the transmission queue.

Related reference:

"MQI accounting message data" on page 1080
Use this page to view the structure of an MQI accounting message

"Queue accounting message data" on page 1091
Use this page to view the structure of a queue accounting message

Accounting message format:

Accounting messages comprise a set of PCF fields that consist of a message descriptor and message data.

Message descriptor

- An accounting message MQMD (message descriptor)

Accounting message data

- An accounting message MQCFH (PCF header)
- Accounting message data that is always returned
- Accounting message data that is returned if available

The accounting message MQCFH (PCF header) contains information about the application, and the interval for which the accounting data was recorded.

Accounting message data comprises PCF parameters that store the accounting information. The content of accounting messages depends on the message category as follows:

MQI accounting message
MQI accounting message data consists of a number of PCF parameters, but no PCF groups.

Queue accounting message

Queue accounting message data consists of a number of PCF parameters, and in the range 1 through 100 *QAccountingData* PCF groups.

There is one *QAccountingData* PCF group for every queue that had accounting data collected. If an application accesses more than 100 queues, multiple accounting messages are generated. Each message has the *SeqNumber* in the MQCFH (PCF header) updated accordingly, and the last message in the sequence has the *Control* parameter in the MQCFH specified as `MQCFC_LAST`.

Accounting information collection:

Use queue and queue manager attributes to control the collection of accounting information. You can also use MQCONNX options to control collection at the connection level.

MQI accounting information:

Use the queue manager attribute ACCTMQI to control the collection of MQI accounting information

To change the value of this attribute, use the MQSC command, `ALTER QMGR`, and specify the parameter `ACCTMQI`. Accounting messages are generated only for connections that begin after accounting is enabled. The `ACCTMQI` parameter can have the following values:

ON MQI accounting information is collected for every connection to the queue manager.

OFF MQI accounting information is not collected. This is the default value.

For example, to enable MQI accounting information collection use the following MQSC command:

```
ALTER QMGR ACCTMQI(ON)
```

Queue accounting information:

Use the queue attribute ACCTQ and the queue manager attribute ACCTQ to control the collection of queue accounting information.

To change the value of the queue attribute, use the MQSC command, `ALTER QLOCAL` and specify the parameter `ACCTQ`. Accounting messages are generated only for connections that begin after accounting is enabled. The queue attribute ACCTQ can have the following values:

ON Queue accounting information for this queue is collected for every connection to the queue manager that opens the queue.

OFF Queue accounting information for this queue is not collected.

QMGR
The collection of queue accounting information for this queue is controlled according to the value of the queue manager attribute ACCTQ. This is the default value.

To change the value of the queue manager attribute, use the MQSC command, `ALTER QMGR` and specify the parameter `ACCTQ`. The queue manager attribute ACCTQ can have the following values:

ON Queue accounting information is collected for queues that have the queue attribute ACCTQ set as QMGR.

OFF Queue accounting information is not collected for queues that have the queue attribute ACCTQ set as QMGR. This is the default value.

NONE
The collection of queue accounting information is disabled for all queues, regardless of the queue attribute ACCTQ.

If the queue manager attribute, ACCTQ, is set to NONE, the collection of queue accounting information is disabled for all queues, regardless of the queue attribute ACCTQ.

For example, to enable accounting information collection for the queue, `Q1`, use the following MQSC command:

```
ALTER QLOCAL(Q1) ACCTQ(ON)
```

To enable accounting information collection for all queues that specify the queue attribute ACCTQ as QMGR, use the following MQSC command:

```
ALTER QMGR ACCTQ(ON)
```

MQCONNX options:

Use the **`ConnectOpts`** parameter on the MQCONNX call to modify the collection of both MQI and queue accounting information at the connection level by overriding the effective values of the queue manager attributes ACCTMQI and ACCTQ

The **`ConnectOpts`** parameter can have the following values:

MQCNO_ACCOUNTING_MQI_ENABLED
If the value of the queue manager attribute ACCTMQI is specified as OFF, MQI accounting is enabled for this connection. This is equivalent of the queue manager attribute ACCTMQI being specified as ON.

If the value of the queue manager attribute ACCTMQI is not specified as OFF, this attribute has no effect.

MQCNO_ACCOUNTING_MQI_DISABLED
If the value of the queue manager attribute ACCTMQI is specified as ON, MQI accounting is disabled for this connection. This is equivalent of the queue manager attribute ACCTMQI being specified as OFF.

If the value of the queue manager attribute ACCTMQI is not specified as ON, this attribute has no effect.

MQCNO_ACCOUNTING_Q_ENABLED
If the value of the queue manager attribute ACCTQ is specified as OFF, queue accounting is enabled for this connection. All queues with ACCTQ specified as QMGR, are enabled for queue accounting. This is equivalent of the queue manager attribute ACCTQ being specified as ON.

If the value of the queue manager attribute ACCTQ is not specified as OFF, this attribute has no effect.

MQCNO_ACCOUNTING_Q_DISABLED
If the value of the queue manager attribute ACCTQ is specified as ON, queue accounting is disabled for this connection. This is equivalent of the queue manager attribute ACCTQ being specified as OFF.

If the value of the queue manager attribute ACCTQ is not specified as ON, this attribute has no effect.

These overrides are by disabled by default. To enable them, set the queue manager attribute ACCTCONO to ENABLED. To enable accounting overrides for individual connections use the following MQSC command:

```
ALTER QMGR ACCTCONO(ENABLED)
```

Accounting message generation:

Accounting messages are generated when an application disconnects from the queue manager. Intermediate accounting messages are also written for long running IBM MQ applications.

Accounting messages are generated in either of the following ways when an application disconnects:
- The application issues an MQDISC call
- The queue manager recognises that the application has terminated

Intermediate accounting messages are written for long running IBM MQ applications when the interval since the connection was established or since the last intermediate accounting message that was written exceeds the configured interval. The queue manager attribute, ACCTINT, specifies the time, in seconds, after which intermediate accounting messages can be automatically written. Accounting messages are generated only when the application interacts with the queue manager, so applications that remain connected to the queue manager for long periods without executing MQI requests do not generate accounting messages until the execution of the first MQI request following the completion of the accounting interval.

The default accounting interval is 1800 seconds (30 minutes). For example, to change the accounting interval to 900 seconds (15 minutes) use the following MQSC command:

```
ALTER QMGR ACCTINT(900)
```

Statistics messages

Statistics messages record information about the activities occurring in an IBM MQ system. An statistics messages is a PCF message that contains a number of PCF structures.

Statistics messages are delivered to the system queue (SYSTEM.ADMIN.STATISTICS.QUEUE) at configured intervals, whenever there is some activity.

Statistics messages are in the following categories:

MQI statistics messages
: MQI statistics messages contain information relating to the number of MQI calls made during a configured interval. For example, the information can include the number of MQI calls issued by a queue manager.

Queue statistics messages
: Queue statistics messages contain information relating to the activity of a queue during a configured interval. The information includes the number of messages put on, and retrieved from, the queue, and the total number of bytes processed by a queue.

  Each queue statistics message can contain up to 100 records, with each record relating to the activity per queue for which statistics were collected.

  Statistics messages are recorded only for local queues. If an application makes an MQI call against an alias queue, the statistics data is recorded against the base queue, and, for a remote queue, the statistics data is recorded against the transmission queue.

Channel statistics messages
: Channel statistics messages contain information relating to the activity of a channel during a configured interval. For example the information might be the number of messages transferred by the channel, or the number of bytes transferred by the channel.

  Each channel statistics message contains up to 100 records, with each record relating to the activity per channel for which statistics were collected.

Related reference:
"MQI statistics information" on page 1068
Use the queue manager attribute STATMQI to control the collection of MQI statistics information
"Queue statistics information" on page 1068
Use the queue attribute STATQ and the queue manager attribute STATQ to control the collection of queue statistics information
"Channel statistics information" on page 1069
Use the channel attribute STATCHL to control the collection of channel statistics information. You can also set queue manager attributes to control information collection.

Statistics messages format:

Statistics messages comprise a set of PCF fields that consist of a message descriptor and message data.

Message descriptor

- A statistics message MQMD (message descriptor)

Accounting message data

- A statistics message MQCFH (PCF header)
- Statistics message data that is always returned
- Statistics message data that is returned if available

The statistics message MQCFH (PCF header) contains information about the interval for which the statistics data was recorded.

Statistics message data comprises PCF parameters that store the statistics information. The content of statistics messages depends on the message category as follows:

MQI statistics message
MQI statistics message data consists of a number of PCF parameters, but no PCF groups.

Queue statistics message
Queue statistics message data consists of a number of PCF parameters, and in the range 1 through 100 *QStatisticsData* PCF groups.

There is one *QStatisticsData* PCF group for every queue was active in the interval. If more than 100 queues were active in the interval, multiple statistics messages are generated. Each message has the *SeqNumber* in the MQCFH (PCF header) updated accordingly, and the last message in the sequence has the *Control* parameter in the MQCFH specified as `MQCFC_LAST`.

Channel statistics message
Channel statistics message data consists of a number of PCF parameters, and in the range 1 through 100 *ChlStatisticsData* PCF groups.

There is one *ChlStatisticsData* PCF group for every channel that was active in the interval. If more than 100 channels were active in the interval, multiple statistics messages are generated. Each message has the *SeqNumber* in the MQCFH (PCF header) updated accordingly, and the last message in the sequence has the *Control* parameter in the MQCFH specified as `MQCFC_LAST`.

Statistics information collection:

Use queue, queue manager, and channel attributes to control the collection of statistics information

MQI statistics information:

Use the queue manager attribute STATMQI to control the collection of MQI statistics information

To change the value of this attribute, use the MQSC command, `ALTER QMGR` and specify the parameter `STATMQI`. Statistics messages are generated only for queues that are opened after statistics collection has been enabled. The `STATMQI` parameter can have the following values:

ON MQI statistics information is collected for every connection to the queue manager.

OFF MQI statistics information is not collected. This is the default value.

For example, to enable MQI statistics information collection use the following MQSC command:

```
ALTER QMGR STATMQI(ON)
```

Queue statistics information:

Use the queue attribute STATQ and the queue manager attribute STATQ to control the collection of queue statistics information

You can enable or disable queue statistics information collection for individual queues or for multiple queues. To control individual queues, set the queue attribute STATQ. You enable or disable queue statistics information collection at the queue manager level by using the queue manager attribute STATQ. For all queues that have the queue attribute STATQ specified with the value QMGR, queue statistics information collection is controlled at the queue manager level.

Queue statistics are incremented only for operations using IBM MQ MQI Object Handles that were opened after statistics collection has been enabled.

Queue Statistics messages are generated only for queues for which statistics data has been collected in the previous time period.

The same queue can have several put operations and get operations through several Object Handles. Some Object Handles might have been opened before statistics collection was enabled, but others were opened afterwards. Therefore, it is possible for the queue statistics to record the activity of some put operations and get operations, and not all.

To ensure that the Queue Statistics are recording the activity of all applications, you must close and reopen new Object Handles on the queue, or queues, that you are monitoring. The best way to achieve this, is to end and restart all applications after enabling statistics collection.

To change the value of the queue attribute STATQ, use the MQSC command, `ALTER QLOCAL` and specify the parameter `STATQ`. The queue attribute STATQ can have the following values:

ON Queue statistics information is collected for every connection to the queue manager that opens the queue.

OFF Queue statistics information for this queue is not collected.

QMGR
The collection of queue statistics information for this queue is controlled according to the value of the queue manager attribute, STATQ. This is the default value.

To change the value of the queue manager attribute STATQ, use the MQSC command, `ALTER QMGR` and specify the parameter `STATQ`. The queue manager attribute STATQ can have the following values:

ON
Queue statistics information is collected for queues that have the queue attribute STATQ set as QMGR

OFF
Queue statistics information is not collected for queues that have the queue attribute STATQ set as QMGR. This is the default value.

NONE
The collection of queue statistics information is disabled for all queues, regardless of the queue attribute STATQ.

If the queue manager attribute STATQ is set to NONE, the collection of queue statistics information is disabled for all queues, regardless of the queue attribute STATQ.

For example, to enable statistics information collection for the queue, `Q1`, use the following MQSC command:

```
ALTER QLOCAL(Q1) STATQ(ON)
```

To enable statistics information collection for all queues that specify the queue attribute STATQ as QMGR, use the following MQSC command:

```
ALTER QMGR STATQ(ON)
```

Channel statistics information: distributed IBM i

Use the channel attribute STATCHL to control the collection of channel statistics information. You can also set queue manager attributes to control information collection.

You can enable or disable channel statistics information collection for individual channels, or for multiple channels. To control individual channels, you must set the channel attribute STATCHL to enable or disable channel statistic information collection. To control many channels together, you enable or disable channel accounting information collection at the queue manager level by using the queue manager attribute STATCHL. For all channels that have the channel attribute STATCHL specified with the value QMGR, channel accounting information collection is controlled at the queue manager level.

Automatically defined cluster-sender channels are not IBM MQ objects, so do not have attributes in the same way as channel objects. To control automatically defined cluster-sender channels, use the queue manager attribute STATACLS. This attribute determines whether automatically defined cluster-sender channels within a queue manager are enabled or disabled for channel statistics information collection.

You can set channel statistics information collection to one of the three monitoring levels: low, medium or high. You can set the monitoring level at either object level or at the queue manager level. The choice of which level to use is dependent on your system. Collecting statistics information data might require some instructions that are relatively expensive computationally, so to reduce the impact of channel statistics information collection, the medium and low monitoring options measure a sample of the data at regular intervals rather than collecting data all the time. Table 122 on page 1070 summarizes the levels available with channel statistics information collection:

Table 122. Detail level of channel statistics information collection

Level	Description	Usage
Low	Measure a small sample of the data, at regular intervals.	For objects that process a high volume of messages.
Medium	Measure a sample of the data, at regular intervals.	For most objects.
High	Measure all data, at regular intervals.	For objects that process only a few messages per second, on which the most current information is important.

To change the value of the channel attribute STATCHL, use the MQSC command, `ALTER CHANNEL` and specify the parameter `STATCHL`.

To change the value of the queue manager attribute STATCHL, use the MQSC command, `ALTER QMGR` and specify the parameter `STATCHL`.

To change the value of the queue manager attribute STATACLS, use the MQSC command, `ALTER QMGR` and specify the parameter `STATACLS`.

The channel attribute, STATCHL, can have the following values:

LOW Channel statistics information is collected with a low level of detail.

MEDIUM
Channel statistics information is collected with a medium level of detail.

HIGH Channel statistics information is collected with a high level of detail.

OFF Channel statistics information is not collected for this channel.

QMGR
The channel attribute is set as QMGR. The collection of statistics information for this channel is controlled by the value of the queue manager attribute, STATCHL.

This is the default value.

On z/OS, this parameter simply turns on statistics data collection, regardless of the value you select. Specifying LOW, MEDIUM, or HIGH makes no difference to your results.

The queue manager attribute, STATCHL, can have the following values:

LOW Channel statistics information is collected with a low level of detail, for all channels that have the channel attribute STATCHL set as QMGR.

MEDIUM
Channel statistics information is collected with a medium level of detail, for all channels that have the channel attribute STATCHL set as QMGR.

HIGH Channel statistics information is collected with a high level of detail, for all channels that have the channel attribute STATCHL set as QMGR.

OFF Channel statistics information is not collected for all channels that have the channel attribute STATCHL set as QMGR.

This is the default value.

NONE
The collection of channel statistics information is disabled for all channel, regardless of the channel attribute STATCHL.

On z/OS, this parameter simply turns on statistics data collection, regardless of the value you select. Specifying LOW, MEDIUM, or HIGH makes no difference to your results.

The queue manager attribute, STATACLS, can have the following values:

LOW Statistics information is collected with a low level of detail for automatically defined cluster-sender channels.

MEDIUM
Statistics information is collected with a medium level of detail for automatically defined cluster-sender channels.

HIGH Statistics information is collected with a high level of detail for automatically defined cluster-sender channels.

OFF Statistics information is not collected for automatically defined cluster-sender channels.

QMGR
The collection of statistics information for automatically defined cluster-sender channels is controlled by the value of the queue manager attribute, STATCHL.

This is the default value.

On z/OS, this parameter simply turns on statistics data collection, regardless of the value you select. Specifying LOW, MEDIUM, or HIGH makes no difference to your results.

For example, to enable statistics information collection, with a medium level of detail, for the sender channel `QM1.TO.QM2`, use the following MQSC command:

```
ALTER CHANNEL(QM1.TO.QM2) CHLTYPE(SDR) STATCHL(MEDIUM)
```

To enable statistics information collection, at a medium level of detail, for all channels that specify the channel attribute STATCHL as QMGR, use the following MQSC command:

```
ALTER QMGR STATCHL(MEDIUM)
```

To enable statistics information collection, at a medium level of detail, for all automatically defined cluster-sender channels, use the following MQSC command:

```
ALTER QMGR STATACLS(MEDIUM)
```

Statistics message generation:

Statistics messages are generated at configured intervals, and when a queue manager shuts down in a controlled fashion.

The configured interval is controlled by the STATINT queue manager attribute, which specifies the interval, in seconds, between the generation of statistics messages. The default statistics interval is 1800 seconds (30 minutes). To change the statistics interval, use the MQSC command `ALTER QMGR` and specify the `STATINT` parameter. For example, to change the statistics interval to 900 seconds (15 minutes) use the following MQSC command:

```
ALTER QMGR STATINT(900)
```

To write the currently collected statistics data to the statistics queue before the statistics collection interval is due to expire, use the MQSC command `RESET QMGR TYPE(STATISTICS)`. Issuing this command causes the collected statistics data to be written to the statistics queue and a new statistics data collection interval to begin.

Displaying accounting and statistics information

To use the information recorded in accounting and statistics messages, run an application such as the **amqsmon** sample program to transform the recorded information into a suitable format

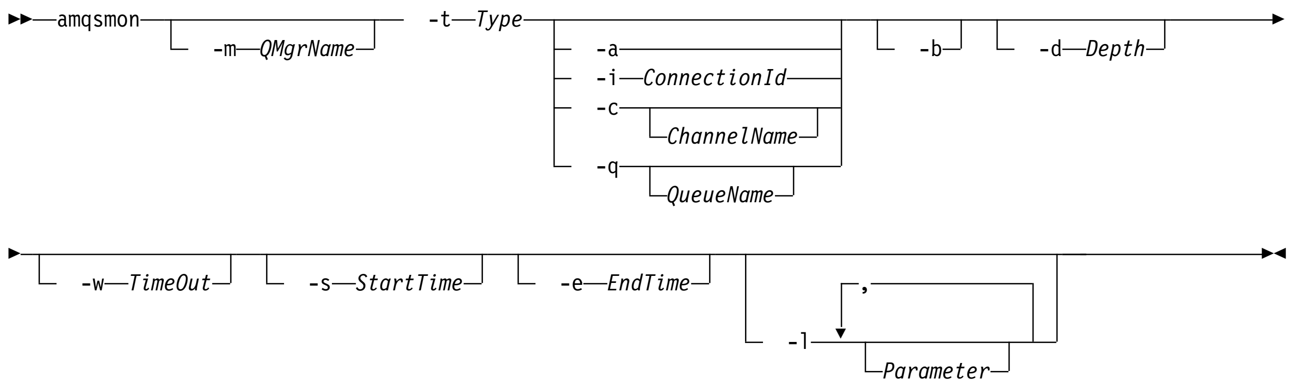
Accounting and statistics messages are written to the system accounting and statistics queues. **amqsmon** is a sample program supplied with IBM MQ that processes messages from the accounting and statistics queues and displays the information to the screen in a readable form.

Because **amqsmon** is a sample program, you can use the supplied source code as template for writing your own application to process accounting or statistics messages, or modify the **amqsmon** source code to meet your own particular requirements.

amqsmon (Display formatted monitoring information):

Use the **amqsmon** sample program to display in a readable format the information contained within accounting and statistics messages. The **amqsmon** program reads accounting messages from the accounting queue, SYSTEM.ADMIN.ACCOUNTING.QUEUE. and reads statistics messages from the statistics queue, SYSTEM.ADMIN.STATISTICS.QUEUE.

Syntax



Required parameters

`-t` *Type*
: The type of messages to process. Specify *Type* as one of the following:

accounting
: Accounting records are processed. Messages are read from the system queue, SYSTEM.ADMIN.ACCOUNTING.QUEUE.

statistics
: Statistics records are processed. Messages are read from the system queue, SYSTEM.ADMIN.STATISTICS.QUEUE.

Optional Parameters

-m *QMgrName*
: The name of the queue manager from which accounting or statistics messages are to be processed.

If you do not specify this parameter, the default queue manager is used.

-a Process messages containing MQI records only.

Only display MQI records. Messages not containing MQI records will always be left on the queue they were read from.

-q *`QueueName`*
QueueName is an optional parameter.

If *QueueName* is not supplied:	Displays queue accounting and queue statistics records only.
If *QueueName* is supplied:	Displays queue accounting and queue statistics records for the queue specified by *QueueName* only. If *`-b`* is not specified then the accounting and statistics messages from which the records came are discarded. Since accounting and statistics messages can also contain records from other queues, if *`-b`* is not specified then unseen records can be discarded.

-c *`ChannelName`*
ChannelName is an optional parameter.

If *ChannelName* is not supplied:	Displays channel statistics records only.
If *ChannelName* is supplied:	Displays channel statistics records for the channel specified by *ChannelName* only. If *`-b`* is not specified then the statistics messages from which the records came are discarded. Since statistics messages can also contain records from other channels, if *`-b`* is not specified then unseen records can be discarded.

This parameter is available when displaying statistics messages only, (*-t statistics*).

-i *`ConnectionId`*
Displays records related to the connection identifier specified by *ConnectionId* only.

This parameter is available when displaying accounting messages only, (*-t accounting*).

If *`-b`* is not specified then the statistics messages from which the records came are discarded. Since statistics messages can also contain records from other channels, if *`-b`* is not specified then unseen records can be discarded.

-b Browse messages.

Messages are retrieved non-destructively.

-d *`Depth`*
The maximum number of messages that can be processed.

If you do not specify this parameter, then an unlimited number of messages can be processed.

-w *`TimeOut`*
Time maximum number of seconds to wait for a message to become available.

If you do not specify this parameter, **amqsmon** will end once there are no more messages to process.

-s *`StartTime`*
Process messages put after the specified *StartTime* only.

StartTime is specified in the format `yyyy-mm-dd hh.mm.ss`. If a date is specified without a time, then the time will default to `00.00.00` on the date specified. Times are in GMT.

For the effect of not specifying this parameter, see Note 1.

-e *`EndTime`*
Process messages put before the specified *EndTime* only.

The *EndTime* is specified in the format `yyyy-mm-dd hh.mm.ss`. If a date is specified without a time, then the time will default to `23.59.59` on the date specified. Times are in GMT.

For the effect of not specifying this parameter, see Note 1.

-l *Parameter*

Only display the selected fields from the records processed. *Parameter* is a comma-separated list of integer values, with each integer value mapping to the numeric constant of a field, see amqsmon example 5.

If you do not specify this parameter, then all available fields are displayed.

Note:

1. If you do not specify *-s StartTime* or *-e EndTime*, the messages that can be processed are not restricted by put time.

amqsmon examples:

Use this page to view examples of running the amqsmon (Display formatted monitoring information) sample program

1. The following command displays all MQI statistics messages from queue manager `saturn.queue.manager`:

   ```
   amqsmon -m saturn.queue.manager -t statistics -a
   ```

   The output from this command follows:

   ```
   RecordType: MQIStatistics
   QueueManager: 'saturn.queue.manager'
   IntervalStartDate: '2005-04-30'
   IntervalStartTime: '15.09.02'
   IntervalEndDate: '2005-04-30'
   IntervalEndTime: '15.39.02'

2. The following command displays all queue statistics messages for queue `LOCALQ` on queue manager `saturn.queue.manager`:

   ```
   amqsmon -m saturn.queue.manager -t statistics -q LOCALQ
   ```

   The output from this command follows:

```
RecordType: QueueStatistics
QueueManager: 'saturn.queue.manager'
IntervalStartDate: '2005-04-30'
IntervalStartTime: '15.09.02'
IntervalEndDate: '2005-04-30'
IntervalEndTime: '15.39.02'
CommandLevel: 600
ObjectCount: 3
QueueStatistics:
  QueueName: 'LOCALQ'

Accounting and statistics message reference

Use this page to obtain an overview of the format of accounting and statistics messages and the information returned in these messages

Accounting and statistics message messages are standard IBM MQ messages containing a message descriptor and message data. The message data contains information about the MQI operations performed by IBM MQ applications, or information about the activities occurring in an IBM MQ system.

Message descriptor

- An MQMD structure

Message data

- A PCF header (MQCFH)
- Accounting or statistics message data that is always returned
- Accounting or statistics message data that is returned if available

Accounting and statistics message format:

Use this page as an example of the structure of an MQI accounting message

Table 123. MQI accounting message structure

MQMD structure	Accounting message header MQCFH structure	MQI accounting message data [1]
Structure identifier	Structure type	Queue manager
Structure version	Structure length	Interval start date
Report options	Structure version	Interval start time
Message type	Command identifier	Interval end date
Expiration time	Message sequence number	Interval end time
Feedback code	Control options	Command level
Encoding	Completion code	Connection identifier
Coded character set ID	Reason code	Sequence number
Message format	Parameter count	Application name
Message priority		Application process identifier
Persistence		Application thread identifier
Message identifier		User identifier
Correlation identifier		Connection date
Backout count		Connection time
Reply-to queue		Connection name
Reply-to queue manager		Channel name
User identifier		Disconnect date
Accounting token		Disconnect time
Application identity data		Disconnect type
Application type		Open count
Application name		Open fail count
Put date		Close count
Put time		Close fail count
Application origin data		Put count
Group identifier		Put fail count
Message sequence number		Put1 count
Offset		Put1 fail count
Message flags		Put bytes
Original length		Get count
		Get fail count
		Get bytes
		Browse count
		Browse fail count
		Browse bytes
		Commit count
		Commit fail count
		Backout count
		Inquire count
		Inquire fail count

Note:

1. The parameters shown are those returned for an MQI accounting message. The actual accounting or statistics message data depends on the message category.

Accounting and statistics message MQMD (message descriptor):

Use this page to understand the differences between the message descriptor of accounting and statistics messages and the message descriptor of event messages

The parameters and values in the message descriptor of accounting and statistics message are the same as in the message descriptor of event messages, with the following exception:

Format

Description:	Format name of message data.
Data type:	MQCHAR8.
Value:	**MQFMT_ADMIN** Admin message.

Some of the parameters contained in the message descriptor of accounting and statistics message contain fixed data supplied by the queue manager that generated the message.

The MQMD also specifies the name of the queue manager (truncated to 28 characters) that put the message, and the date and time when the message was put on the accounting, or statistics, queue.

Message data in accounting and statistics messages:

The message data in accounting and statistics messages is based on the programmable command format (PCF), which is used in PCF command inquiries and responses. The message data in accounting and statistics messages consists of a PCF header (MQCFH) and an accounting or statistics report.

Accounting and statistics message MQCFH (PCF header)

The message header of accounting and statistics messages is an MQCFH structure. The parameters and values in the message header of accounting and statistics message are the same as in the message header of event messages, with the following exceptions:

Command

Description:	Command identifier. This identifies the accounting or statistics message category.
Data type:	MQLONG.
Values:	**MQCMD_ACCOUNTING_MQI** MQI accounting message. **MQCMD_ACCOUNTING_Q** Queue accounting message. **MQCMD_STATISTICS_MQI** MQI statistics message. **MQCMD_STATISTICS_Q** Queue statistics message. **MQCMD_STATISTICS_CHANNEL** Channel statistics message.

Version

Description:	Structure version number.
Data type:	MQLONG.
Value:	**MQCFH_VERSION_3** Version-3 for accounting and statistics messages.

Accounting and statistics message data

The content of accounting and statistics message data is dependent on the category of the accounting or statistics message, as follows:

MQI accounting message
MQI accounting message data consists of a number of PCF parameters, but no PCF groups.

Queue accounting message
Queue accounting message data consists of a number of PCF parameters, and in the range 1 through 100 *QAccountingData* PCF groups.

MQI statistics message
MQI statistics message data consists of a number of PCF parameters, but no PCF groups.

Queue statistics message
Queue statistics message data consists of a number of PCF parameters, and in the range 1 through 100 *QStatisticsData* PCF groups.

Channel statistics message
Channel statistics message data consists of a number of PCF parameters, and in the range 1 through 100 *ChlStatisticsData* PCF groups.

MQI accounting message data:

Use this page to view the structure of an MQI accounting message

Message name:	MQI accounting message.
Platforms:	All, except IBM MQ for z/OS.
System queue:	SYSTEM.ADMIN.ACCOUNTING.QUEUE.

QueueManager

Description:	The name of the queue manager
Identifier:	MQCA_Q_MGR_NAME
Data type:	MQCFST
Maximum length:	MQ_Q_MGR_NAME_LENGTH
Returned:	Always

IntervalStartDate

Description:	The date of the start of the monitoring period
Identifier:	MQCAMO_START_DATE
Data type:	MQCFST
Maximum length:	MQ_DATE_LENGTH
Returned:	Always

IntervalStartTime

Description:	The time of the start of the monitoring period
Identifier:	MQCAMO_START_TIME
Data type:	MQCFST
Maximum length:	MQ_TIME_LENGTH
Returned:	Always

IntervalEndDate

Description:	The date of the end of the monitoring period
Identifier:	MQCAMO_END_DATE
Data type:	MQCFST
Maximum length:	MQ_DATE_LENGTH
Returned:	Always

IntervalEndTime

Description:	The time of the end of the monitoring period
Identifier:	MQCAMO_END_TIME
Data type:	MQCFST
Maximum length:	MQ_TIME_LENGTH
Returned:	Always

CommandLevel

Description:	The queue manager command level
Identifier:	MQIA_COMMAND_LEVEL
Data type:	MQCFIN
Returned:	Always

ConnectionId

Description:	The connection identifier for the IBM MQ connection
Identifier:	MQBACF_CONNECTION_ID
Data type:	MQCFBS
Maximum length:	MQ_CONNECTION_ID_LENGTH
Returned:	Always

SeqNumber

Description:	The sequence number. This value is incremented for each subsequent record for long running connections.
Identifier:	MQIACF_SEQUENCE_NUMBER
Data type:	MQCFIN
Returned:	Always

ApplicationName

Description:	The name of the application. The contents of this field are equivalent to the contents of the *PutApplName* field in the message descriptor.
Identifier:	MQCACF_APPL_NAME
Data type:	MQCFST
Maximum length:	MQ_APPL_NAME_LENGTH
Returned:	Always

ApplicationPid

Description:	The operating system process identifier of the application
Identifier:	MQIACF_PROCESS_ID
Data type:	MQCFIN
Returned:	Always

ApplicationTid

Description:	The IBM MQ thread identifier of the connection in the application
Identifier:	MQIACF_THREAD_ID
Data type:	MQCFIN
Returned:	Always

UserId

Description:	The user identifier context of the application
Identifier:	MQCACF_USER_IDENTIFIER
Data type:	MQCFST
Maximum length:	MQ_USER_ID_LENGTH
Returned:	Always

ConnDate

Description:	Date of MQCONN operation
Identifier:	MQCAMO_CONN_DATE
Data type:	MQCFST
Maximum length:	MQ_TIME_LENGTH
Returned:	When available

ConnTime

Description:	Time of MQCONN operation
Identifier:	MQCAMO_CONN_TIME
Data type:	MQCFST
Maximum length:	MQ_TIME_LENGTH
Returned:	When available

ConnName

Description:	Connection name for client connection
Identifier:	MQCACH_CONNECTION_NAME
Data type:	MQCFST
Maximum length:	MQ_CONN_NAME_LENGTH
Returned:	When available

ChannelName

Description:	Channel name for client connection
Identifier:	MQCACH_CHANNEL_NAME
Data type:	MQCFST
Maximum length:	MQ_CHANNEL_NAME_LENGTH
Returned:	When available

DiscDate

Description:	Date of MQDISC operation
Identifier:	MQCAMO_DISC_DATE
Data type:	MQCFST
Maximum length:	MQ_DATE_LENGTH
Returned:	When available

DiscTime

Description:	Time of MQDISC operation
Identifier:	MQCAMO_DISC_TIME
Data type:	MQCFST
Maximum length:	MQ_TIME_LENGTH
Returned:	When available

DiscType

Description:	Type of disconnect
Identifier:	MQIAMO_DISC_TYPE
Data type:	MQCFIN
Values:	The possible values are: **MQDISCONNECT_NORMAL** Requested by application; **MQDISCONNECT_IMPLICIT** Abnormal application termination; **MQDISCONNECT_Q_MGR** Connection broken by queue manager
Returned:	When available

OpenCount

Description:	The number of objects opened. This parameter is an integer list indexed by object type, see Reference note 1.
Identifier:	MQIAMO_OPENS
Data type:	MQCFIL
Returned:	When available

OpenFailCount

Description:	The number of unsuccessful attempts to open an object. This parameter is an integer list indexed by object type, see Reference note 1.
Identifier:	MQIAMO_OPENS_FAILED
Data type:	MQCFIL
Returned:	When available

CloseCount

Description:	The number of objects closed. This parameter is an integer list indexed by object type, see Reference note 1.
Identifier:	MQIAMO_CLOSES
Data type:	MQCFIL
Returned:	When available

CloseFailCount

Description:	The number of unsuccessful attempts to close an object. This parameter is an integer list indexed by object type, see Reference note 1.
Identifier:	MQIAMO_CLOSES_FAILED
Data type:	MQCFIL
Returned:	When available

PutCount

Description:	The number persistent and nonpersistent messages successfully put to a queue, with the exception of messages put using the MQPUT1 call. This parameter is an integer list indexed by persistence value, see Reference note 2.
Identifier:	MQIAMO_PUTS
Data type:	MQCFIL
Returned:	When available

PutFailCount

Description:	The number of unsuccessful attempts to put a message
Identifier:	MQIAMO_PUTS_FAILED
Data type:	MQCFIN
Returned:	When available

Put1Count

Description:	The number of persistent and nonpersistent messages successfully put to the queue using MQPUT1 calls. This parameter is an integer list indexed by persistence value, see Reference note 2.
Identifier:	MQIAMO_PUT1S
Data type:	MQCFIL
Included in PCF group:	*QAccountingData*
Returned:	When available

Put1FailCount

Description:	The number of unsuccessful attempts to put a message using MQPUT1 calls
Identifier:	MQIAMO_PUT1S_FAILED
Data type:	MQCFIN
Included in PCF group:	*QAccountingData*
Returned:	When available

PutBytes

Description:	The number bytes written using put calls for persistent and nonpersistent messages. This parameter is an integer list indexed by persistence value, see Reference note 2.
Identifier:	MQIAMO64_PUT_BYTES
Data type:	MQCFIL64
Returned:	When available

GetCount

Description:	The number of successful destructive MQGET calls for persistent and nonpersistent messages. This parameter is an integer list indexed by persistence value, see Reference note 2.
Identifier:	MQIAMO_GETS
Data type:	MQCFIL
Returned:	When available

GetFailCount

Description:	The number of failed destructive MQGET calls
Identifier:	MQIAMO_GETS_FAILED
Data type:	MQCFIN
Returned:	When available

GetBytes

Description:	Total number of bytes retrieved for persistent and nonpersistent messages. This parameter is an integer list indexed by persistence value, see Reference note 2.
Identifier:	MQIAMO64_GET_BYTES
Data type:	MQCFIL64
Returned:	When available

BrowseCount

Description:	The number of successful non-destructive MQGET calls for persistent and nonpersistent messages. This parameter is an integer list indexed by persistence value, see Reference note 2.
Identifier:	MQIAMO_BROWSES
Data type:	MQCFIL
Returned:	When available

BrowseFailCount

Description:	The number of unsuccessful non-destructive MQGET calls
Identifier:	MQIAMO_BROWSES_FAILED
Data type:	MQCFIN
Returned:	When available

BrowseBytes

Description:	Total number of bytes browsed for persistent and nonpersistent messages. This parameter is an integer list indexed by persistence value, see Reference note 2.
Identifier:	MQIAMO64_BROWSE_BYTES
Data type:	MQCFIL64
Returned:	When available

CommitCount

Description:	The number of successful transactions. This number includes those transactions committed implicitly by the connected application. Commit requests where there is no outstanding work are included in this count.
Identifier:	MQIAMO_COMMITS
Data type:	MQCFIN
Returned:	When available

CommitFailCount

Description:	The number of unsuccessful attempts to complete a transaction
Identifier:	MQIAMO_COMMITS_FAILED
Data type:	MQCFIN
Returned:	When available

BackCount

Description:	The number of backouts processed, including implicit backouts due to abnormal disconnection
Identifier:	MQIAMO_BACKOUTS
Data type:	MQCFIN
Returned:	When available

InqCount

Description:	The number of successful objects inquired upon. This parameter is an integer list indexed by object type, see Reference note 1.
Identifier:	MQIAMO_INQS
Data type:	MQCFIL
Returned:	When available

InqFailCount

Description:	The number of unsuccessful object inquire attempts. This parameter is an integer list indexed by object type, see Reference note 1.
Identifier:	MQIAMO_INQS_FAILED
Data type:	MQCFIL
Returned:	When available

SetCount

Description:	The number of successful MQSET calls. This parameter is an integer list indexed by object type, see Reference note 1.
Identifier:	MQIAMO_SETS
Data type:	MQCFIL
Returned:	When available

SetFailCount

Description:	The number of unsuccessful MQSET calls. This parameter is an integer list indexed by object type, see Reference note 1.
Identifier:	MQIAMO_SETS_FAILED
Data type:	MQCFIL
Returned:	When available

SubCountDur

Description:	The number of succesful subscribe requests which created, altered or resumed durable subscriptions. This is an array of values indexed by the type of operation 0 = The number of subscriptions created 1 = The number of subscriptions altered 2 = The number of subscriptions resumed
Identifier:	MQIAMO_SUBS_DUR
Data type:	MQCFIL
Returned:	When available.

SubCountNDur

Description:	The number of succesful subscribe requests which created, altered or resumed non-durable subscriptions. This is an array of values indexed by the type of operation 0 = The number of subscriptions created 1 = The number of subscriptions altered 2 = The number of subscriptions resumed
Identifier:	MQIAMO_SUBS_NDUR
Data type:	MQCFIL
Returned:	When available.

SubFailCount

Description:	The number of unsuccessful Subscribe requests.
Identifier:	MQIAMO_SUBS_FAILED
Data type:	MQCFIN
Returned:	When available.

UnsubCountDur

Description:	The number of succesful unsubscribe requests for durable subscriptions. This is an array of values indexed by the type of operation 0 - The subscription was closed but not removed 1 - The subscription was closed and removed
Identifier:	MQIAMO_UNSUBS_DUR
Data type:	MQCFIL
Returned:	When available.

UnsubCountNDur

Description:	The number of succesful unsubscribe requests for durable subscriptions. This is an array of values indexed by the type of operation 0 - The subscription was closed but not removed 1 - The subscription was closed and removed
Identifier:	MQIAMO_UNSUBS_NDUR
Data type:	MQCFIL
Returned:	When available.

UnsubFailCount

Description:	The number of unsuccessful unsubscribe requests.
Identifier:	MQIAMO_UNSUBS_FAILED
Data type:	MQCFIN
Returned:	When available.

SubRqCount

Description:	The number of successful MQSUBRQ requests.
Identifier:	MQIAMO_SUBRQS
Data type:	MQCFIN
Returned:	When available.

SubRqFailCount

Description:	The number of unsuccessful MQSUB requests.
Identifier:	MQIAMO_SUBRQS_FAILED
Data type:	MQCFIN
Returned:	When available.

CBCount

Description:	The number of successful MQCB requests. This is an array of values indexed by the type of operation 0 - A callback was created or altered 1 - A callback was removed 2 - A callback was resumed 3 - A callback was suspended
Identifier:	MQIAMO_CBS
Data type:	MQCFIN
Returned:	When available.

CBFailCount

Description:	The number of unsuccessful MQCB requests.
Identifier:	MQIAMO_CBS_FAILED
Data type:	MQCFIN
Returned:	When available.

CtlCount

Description:	The number of successful MQCTL requests. This is an array of values indexed by the type of operation 0 - The connection was started 1 - The connection was stopped 2 - The connection was resumed 3 - The connection was suspended
Identifier:	MQIAMO_CTLS
Data type:	MQCFIL
Returned:	When available.

CtlFailCount

Description:	The number of unsuccessful MQCTL requests.
Identifier:	MQIAMO_CTLS_FAILED
Data type:	MQCFIN
Returned:	When available.

StatCount

Description:	The number of successful MQSTAT requests.
Identifier:	MQIAMO_STATS.
Data type:	MQCFIN
Returned:	When available.

StatFailCount

Description:	The number of unsuccessful MQSTAT requests.
Identifier:	MQIAMO_STATS_FAILED
Data type:	MQCFIN
Returned:	When available.

PutTopicCount

Description:	The number persistent and nonpersistent messages successfully put to a topic, with the exception of messages put using the MQPUT1 call. This parameter is an integer list indexed by persistence value, see Reference note 2. Note: Messages put using a queue alias which resolve to a topic are included in this value.
Identifier:	MQIAMO_TOPIC_PUTS
Data type:	MQCFIL
Returned:	When available.

PutTopicFailCount

Description:	The number of unsuccessful attempts to put a message to a topic.
Identifier:	MQIAMO_TOPIC_PUTS_FAILED
Data type:	MQCFIN
Returned:	When available.

Put1TopicCount

Description:	The number of persistent and nonpersistent messages successfully put to a topic using MQPUT1 calls. This parameter is an integer list indexed by persistence value, see Reference note 2. Note: Messages put using a queue alias which resolve to a topic are included in this value.
Identifier:	MQIAMO_TOPIC_PUT1S
Data type:	MQCFIL
Returned:	When available.

Put1TopicFailCount

Description:	The number of unsuccessful attempts to put a message to a topic using MQPUT1 calls.
Identifier:	MQIAMO_TOPIC_PUT1S_FAILED
Data type:	MQCFIN
Returned:	When available.

PutTopicBytes

Description:	The number bytes written using put calls for persistent and nonpersistent messages which resolve to a publish operation. This is number of bytes put by the application and not the resultant number of bytes delivered to subscribers. This parameter is an integer list indexed by persistence value, see Reference note 2.
Identifier:	MQIAMO64_TOPIC_PUT_BYTES
Data type:	MQCFIL64
Returned:	When available.

Queue accounting message data:

Use this page to view the structure of a queue accounting message

Message name:	Queue accounting message.
Platforms:	All, except IBM MQ for z/OS.
System queue:	SYSTEM.ADMIN.ACCOUNTING.QUEUE.

QueueManager

Description:	The name of the queue manager
Identifier:	MQCA_Q_MGR_NAME
Data type:	MQCFST
Maximum length:	MQ_Q_MGR_NAME_LENGTH
Returned:	Always

IntervalStartDate

Description:	The date of the start of the monitoring period
Identifier:	MQCAMO_START_DATE
Data type:	MQCFST
Maximum length:	MQ_DATE_LENGTH
Returned:	Always

IntervalStartTime

Description:	The time of the start of the monitoring period
Identifier:	MQCAMO_START_TIME
Data type:	MQCFST
Maximum length:	MQ_TIME_LENGTH
Returned:	Always

IntervalEndDate

Description:	The date of the end of the monitoring period
Identifier:	MQCAMO_END_DATE
Data type:	MQCFST
Maximum length:	MQ_DATE_LENGTH
Returned:	Always

IntervalEndTime

Description:	The time of the end of the monitoring period
Identifier:	MQCAMO_END_TIME
Data type:	MQCFST
Maximum length:	MQ_TIME_LENGTH
Returned:	Always

CommandLevel

Description:	The queue manager command level
Identifier:	MQIA_COMMAND_LEVEL
Data type:	MQCFIN
Returned:	Always

ConnectionId

Description:	The connection identifier for the IBM MQ connection
Identifier:	MQBACF_CONNECTION_ID
Data type:	MQCFBS
Maximum length:	MQ_CONNECTION_ID_LENGTH
Returned:	Always

SeqNumber

Description:	The sequence number. This value is incremented for each subsequent record for long running connections.
Identifier:	MQIACF_SEQUENCE_NUMBER
Data type:	MQCFIN
Returned:	Always

ApplicationName

Description:	The name of the application. The contents of this field are equivalent to the contents of the PutApplName field in the message descriptor.
Identifier:	MQCACF_APPL_NAME
Data type:	MQCFST
Maximum length:	MQ_APPL_NAME_LENGTH
Returned:	Always

ApplicationPid

Description:	The operating system process identifier of the application
Identifier:	MQIACF_PROCESS_ID
Data type:	MQCFIN
Returned:	Always

ApplicationTid

Description:	The IBM MQ thread identifier of the connection in the application
Identifier:	MQIACF_THREAD_ID
Data type:	MQCFIN
Returned:	Always

UserId

Description:	The user identifier context of the application
Identifier:	MQCACF_USER_IDENTIFIER
Data type:	MQCFST
Maximum length:	MQ_USER_ID_LENGTH
Returned:	Always

ObjectCount

Description:	The number of queues accessed in the interval for which accounting data has been recorded. This value is set to the number of *QAccountingData* PCF groups contained in the message.
Identifier:	MQIAMO_OBJECT_COUNT
Data type:	MQCFIN
Returned:	Always

QAccountingData

Description:	Grouped parameters specifying accounting details for a queue
Identifier:	MQGACF_Q_ACCOUNTING_DATA
Data type:	MQCFGR

Parameters in group:	*QName* *CreateDate* *CreateTime* *QType* *QDefinitionType* *OpenCount* *OpenDate* *OpenTime* *CloseDate* *CloseTime* *PutCount* *PutFailCount* *Put1Count* *Put1FailCount* *PutBytes* *PutMinBytes* *PutMaxBytes* *GetCount* *GetFailCount* *GetBytes* *GetMinBytes* *GetMaxBytes* *BrowseCount* *BrowseFailCount* *BrowseBytes* *BrowseMinBytes* *BrowseMaxBytes* *TimeOnQMin* *TimeOnQAvg* *TimeOnQMax*
Returned:	Always

QName

Description:	The name of the queue
Identifier:	MQCA_Q_NAME
Data type:	MQCFST
Included in PCF group:	*QAccountingData*
Maximum length:	MQ_Q_NAME_LENGTH
Returned:	When available

CreateDate

Description:	The date the queue was created
Identifier:	MQCA_CREATION_DATE
Data type:	MQCFST
Included in PCF group:	*QAccountingData*
Maximum length:	MQ_DATE_LENGTH
Returned:	When available

CreateTime

Description:	The time the queue was created
Identifier:	MQCA_CREATION_TIME
Data type:	MQCFST
Included in PCF group:	*QAccountingData*
Maximum length:	MQ_TIME_LENGTH
Returned:	When available

QType

Description:	The type of the queue
Identifier:	MQIA_Q_TYPE
Data type:	MQCFIN
Included in PCF group:	*QAccountingData*
Value:	MQQT_LOCAL
Returned:	When available

QDefinitionType

Description:	The queue definition type
Identifier:	MQIA_DEFINITION_TYPE
Data type:	MQCFIN
Included in PCF group:	*QAccountingData*
Values:	Possible values are: **MQQDT_PREDEFINED** **MQQDT_PERMANENT_DYNAMIC** **MQQDT_TEMPORARY_DYNAMIC**
Returned:	When available

OpenCount

Description:	The number of times this queue was opened by the application in this interval
Identifier:	MQIAMO_OPENS
Data type:	MQCFIL
Included in PCF group:	*QAccountingData*
Returned:	When available

OpenDate

Description:	The date the queue was first opened in this recording interval. If the queue was already open at the start of this interval, this value reflects the date the queue was originally opened.
Identifier:	MQCAMO_OPEN_DATE
Data type:	MQCFST
Included in PCF group:	*QAccountingData*
Returned:	When available

OpenTime

Description:	The time the queue was first opened in this recording interval. If the queue was already open at the start of this interval, this value reflects the time the queue was originally opened.
Identifier:	MQCAMO_OPEN_TIME
Data type:	MQCFST
Included in PCF group:	*QAccountingData*
Returned:	When available

CloseDate

Description:	The date of the final close of the queue in this recording interval. If the queue is still open then the value is not returned.
Identifier:	MQCAMO_CLOSE_DATE
Data type:	MQCFST
Included in PCF group:	*QAccountingData*
Returned:	When available

CloseTime

Description:	The time of final close of the queue in this recording interval. If the queue is still open then the value is not returned.
Identifier:	MQCAMO_CLOSE_TIME
Data type:	MQCFST
Included in PCF group:	*QAccountingData*
Returned:	When available

PutCount

Description:	The number of persistent and nonpersistent messages successfully put to the queue, with the exception of MQPUT1 calls. This parameter is an integer list indexed by persistence value, see Reference note 2.
Identifier:	MQIAMO_PUTS
Data type:	MQCFIL
Included in PCF group:	*QAccountingData*
Returned:	When available

PutFailCount

Description:	The number of unsuccessful attempts to put a message, with the exception of MQPUT1 calls
Identifier:	MQIAMO_PUTS_FAILED
Data type:	MQCFIN
Included in PCF group:	*QAccountingData*
Returned:	When available

Put1Count

Description:	The number of persistent and nonpersistent messages successfully put to the queue using MQPUT1 calls. This parameter is an integer list indexed by persistence value, see Reference note 2.
Identifier:	MQIAMO_PUT1S
Data type:	MQCFIL
Included in PCF group:	*QAccountingData*
Returned:	When available

Put1FailCount

Description:	The number of unsuccessful attempts to put a message using MQPUT1 calls
Identifier:	MQIAMO_PUT1S_FAILED
Data type:	MQCFIN
Included in PCF group:	*QAccountingData*
Returned:	When available

PutBytes

Description:	The total number of bytes put for persistent and nonpersistent messages. This parameter is an integer list indexed by persistence value, see Reference note 2.
Identifier:	MQIAMO64_PUT_BYTES
Data type:	MQCFIL64
Included in PCF group:	*QAccountingData*
Returned:	When available

PutMinBytes

Description:	The smallest persistent and nonpersistent message size placed on the queue. This parameter is an integer list indexed by persistence value, see Reference note 2.
Identifier:	MQIAMO_PUT_MIN_BYTES
Data type:	MQCFIL
Included in PCF group:	*QAccountingData*
Returned:	When available

PutMaxBytes

Description:	The largest persistent and nonpersistent message size placed on the queue. This parameter is an integer list indexed by persistence value, see Reference note 2.
Identifier:	MQIAMO_PUT_MAX_BYTES
Data type:	MQCFIL
Included in PCF group:	*QAccountingData*
Returned:	When available

GeneratedMsgCount

Description:	The number of generated messages. Generated messages are • Trigger messages • Queue Depth Hi Events • Queue Depth Low Events
Identifier:	MQIAMO_GENERATED_MSGS
Data type:	MQCFIN
Included in PCF group:	*QAccountingData*
Returned:	When available

GetCount

Description:	The number of successful destructive MQGET calls for persistent and nonpersistent messages. This parameter is an integer list indexed by persistence value, see Reference note 2.
Identifier:	MQIAMO_GETS
Data type:	MQCFIL
Included in PCF group:	*QAccountingData*
Returned:	When available

GetFailCount

Description:	The number of failed destructive MQGET calls
Identifier:	MQIAMO_GETS_FAILED
Data type:	MQCFIN
Included in PCF group:	*QAccountingData*
Returned:	When available

GetBytes

Description:	The number of bytes read in destructive MQGET calls for persistent and nonpersistent messages. This parameter is an integer list indexed by persistence value, see Reference note 2.
Identifier:	MQIAMO64_GET_BYTES
Data type:	MQCFIL64
Included in PCF group:	*QAccountingData*
Returned:	When available

GetMinBytes

Description:	The size of the smallest persistent and nonpersistent message retrieved rom the queue. This parameter is an integer list indexed by persistence value, see Reference note 2.
Identifier:	MQIAMO_GET_MIN_BYTES
Data type:	MQCFIL
Included in PCF group:	*QAccountingData*
Returned:	When available

GetMaxBytes

Description:	The size of the largest persistent and nonpersistent message retrieved rom the queue. This parameter is an integer list indexed by persistence value, see Reference note 2.
Identifier:	MQIAMO_GET_MAX_BYTES
Data type:	MQCFIL
Included in PCF group:	*QAccountingData*
Returned:	When available

BrowseCount

Description:	The number of successful non-destructive MQGET calls for persistent and nonpersistent messages. This parameter is an integer list indexed by persistence value, see Reference note 2.
Identifier:	MQIAMO_BROWSES
Data type:	MQCFIL
Included in PCF group:	*QAccountingData*
Returned:	When available

BrowseFailCount

Description:	The number of unsuccessful non-destructive MQGET calls
Identifier:	MQIAMO_BROWSES_FAILED
Data type:	MQCFIN
Included in PCF group:	*QAccountingData*
Returned:	When available

BrowseBytes

Description:	The number of bytes read in non-destructive MQGET calls that returned persistent messages
Identifier:	MQIAMO64_BROWSE_BYTES
Data type:	MQCFIL64
Included in PCF group:	*QAccountingData*
Returned:	When available

BrowseMinBytes

Description:	The size of the smallest persistent and nonpersistent message browsed from the queue. This parameter is an integer list indexed by persistence value, see Reference note 2.
Identifier:	MQIAMO_BROWSE_MIN_BYTES
Data type:	MQCFIL
Included in PCF group:	*QAccountingData*
Returned:	When available

BrowseMaxBytes

Description:	The size of the largest persistent and nonpersistent message browsed from the queue. This parameter is an integer list indexed by persistence value, see Reference note 2.
Identifier:	MQIAMO_BROWSE_MAX_BYTES
Data type:	MQCFIL
Included in PCF group:	*QAccountingData*
Returned:	When available

CBCount

Description:	The number of successful MQCB requests. This is an array of values indexed by the type of operation 0 - A callback was created or altered 1 - A callback was removed 2 - A callback was resumed 3 - A callback was suspended
Identifier:	MQIAMO_CBS
Data type:	MQCFIN
Returned:	When available.

CBFailCount

Description:	The number of unsuccessful MQCB requests.
Identifier:	MQIAMO_CBS_FAILED
Data type:	MQCFIN
Returned:	When available.

TimeOnQMin

Description:	The shortest time a persistent and nonpersistent message remained on the queue before being destructively retrieved, in microseconds. For messages retrieved under syncpoint this value does not included the time before the get operation is committed. This parameter is an integer list indexed by persistence value, see Reference note 2.
Identifier:	MQIAMO64_Q_TIME_MIN
Data type:	MQCFIL64
Included in PCF group:	*QAccountingData*
Returned:	When available

TimeOnQAvg

Description:	The average time a persistent and nonpersistent message remained on the queue before being destructively retrieved, in microseconds. For messages retrieved under syncpoint this value does not included the time before the get operation is committed. This parameter is an integer list indexed by persistence value, see Reference note 2.
Identifier:	MQIAMO64_Q_TIME_AVG
Data type:	MQCFIL64
Included in PCF group:	*QAccountingData*
Returned:	When available

TimeOnQMax

Description:	The longest time a persistent and nonpersistent message remained on the queue before being destructively retrieved, in microseconds. For messages retrieved under syncpoint this value does not included the time before the get operation is committed. This parameter is an integer list indexed by persistence value, see Reference note 2.
Identifier:	MQIAMO64_Q_TIME_MAX
Data type:	MQCFIL64
Included in PCF group:	*QAccountingData*
Returned:	When available

MQI statistics message data:

Use this page to view the structure of an MQI statistics message

Message name:	MQI statistics message.
Platforms:	All, except IBM MQ for z/OS.
System queue:	SYSTEM.ADMIN.STATISTICS.QUEUE.

QueueManager

Description:	Name of the queue manager.
Identifier:	MQCA_Q_MGR_NAME.
Data type:	MQCFST.
Maximum length:	MQ_Q_MGR_NAME_LENGTH.
Returned:	Always.

IntervalStartDate

Description:	The date at the start of the monitoring period.
Identifier:	MQCAMO_START_DATE.
Data type:	MQCFST.
Maximum length:	MQ_DATE_LENGTH
Returned:	Always.

IntervalStartTime

Description:	The time at the start of the monitoring period.
Identifier:	MQCAMO_START_TIME.
Data type:	MQCFST.
Maximum length:	MQ_TIME_LENGTH
Returned:	Always.

IntervalEndDate

Description:	The date at the end of the monitoring period.
Identifier:	MQCAMO_END_DATE.
Data type:	MQCFST.
Maximum length:	MQ_DATE_LENGTH
Returned:	Always.

IntervalEndTime

Description:	The time at the end of the monitoring period.
Identifier:	MQCAMO_END_TIME.
Data type:	MQCFST.
Maximum length:	MQ_TIME_LENGTH
Returned:	Always.

CommandLevel

Description:	The queue manager command level.
Identifier:	MQIA_COMMAND_LEVEL.
Data type:	MQCFIN.
Returned:	Always.

ConnCount

Description:	The number of successful connections to the queue manager.
Identifier:	MQIAMO_CONNS.
Data type:	MQCFIN.
Returned:	When available.

ConnFailCount

Description:	The number of unsuccessful connection attempts.
Identifier:	MQIAMO_CONNS_FAILED.
Data type:	MQCFIN.
Returned:	When available.

ConnsMax

Description:	The maximum number of concurrent connections in the recording interval.
Identifier:	MQIAMO_CONNS_MAX.
Data type:	MQCFIN.
Returned:	When available.

DiscCount

Description:	The number of disconnects from the queue manager. This is an integer array, indexed by the following constants: • MQDISCONNECT_NORMAL • MQDISCONNECT_IMPLICIT • MQDISCONNECT_Q_MGR
Identifier:	MQIAMO_DISCS.
Data type:	MQCFIL.
Returned:	When available.

OpenCount

Description:	The number of objects successfully opened. This parameter is an integer list indexed by object type, see Reference note 1.
Identifier:	MQIAMO_OPENS.
Data type:	MQCFIL.
Returned:	When available.

OpenFailCount

Description:	The number of unsuccessful open object attempts. This parameter is an integer list indexed by object type, see Reference note 1.
Identifier:	MQIAMO_OPENS_FAILED.
Data type:	MQCFIL.
Returned:	When available.

CloseCount

Description:	The number of objects successfully closed. This parameter is an integer list indexed by object type, see Reference note 1.
Identifier:	MQIAMO_CLOSES.
Data type:	MQCFIL.
Returned:	When available.

CloseFailCount

Description:	The number of unsuccessful close object attempts. This parameter is an integer list indexed by object type, see Reference note 1.
Identifier:	MQIAMO_CLOSES_FAILED.
Data type:	MQCFIL.
Returned:	When available.

InqCount

Description:	The number of objects successfully inquired upon. This parameter is an integer list indexed by object type, see Reference note 1.
Identifier:	MQIAMO_INQS.
Data type:	MQCFIL.
Returned:	When available.

InqFailCount

Description:	The number of unsuccessful object inquire attempts. This parameter is an integer list indexed by object type, see Reference note 1.
Identifier:	MQIAMO_INQS_FAILED.
Data type:	MQCFIL.
Returned:	When available.

SetCount

Description:	The number of objects successfully updated (SET). This parameter is an integer list indexed by object type, see Reference note 1.
Identifier:	MQIAMO_SETS.
Data type:	MQCFIL.
Returned:	When available.

SetFailCount

Description:	The number of unsuccessful SET attempts. This parameter is an integer list indexed by object type, see Reference note 1.
Identifier:	MQIAMO_SETS_FAILED.
Data type:	MQCFIL.
Returned:	When available.

PutCount

Description:	The number of persistent and nonpersistent messages successfully put to a queue, with the exception of MQPUT1 requests. This parameter is an integer list indexed by persistence value, see Reference note 2.
Identifier:	MQIAMO_PUTS.
Data type:	MQCFIL.
Returned:	When available.

PutFailCount

Description:	The number of unsuccessful put message attempts.
Identifier:	MQIAMO_PUTS_FAILED.
Data type:	MQCFIN.
Returned:	When available.

Put1Count

Description:	The number of persistent and nonpersistent messages successfully put to a queue using MQPUT1 requests. This parameter is an integer list indexed by persistence value, see Reference note 2
Identifier:	MQIAMO_PUT1S.
Data type:	MQCFIL.
Returned:	When available.

Put1FailCount

Description:	The number of unsuccessful attempts to put a persistent and nonpersistent message to a queue using MQPUT1 requests. This parameter is an integer list indexed by persistence value, see Reference note 2
Identifier:	MQIAMO_PUT1S_FAILED.
Data type:	MQCFIL.
Returned:	When available.

PutBytes

Description:	The number bytes for persistent and nonpersistent messages written in using put requests. This parameter is an integer list indexed by persistence value, see Reference note 2
Identifier:	MQIAMO64_PUT_BYTES.
Data type:	MQCFIL64.
Returned:	When available.

GetCount

Description:	The number of successful destructive get requests for persistent and nonpersistent messages. This parameter is an integer list indexed by persistence value, see Reference note 2
Identifier:	MQIAMO_GETS.
Data type:	MQCFIL.
Returned:	When available.

GetFailCount

Description:	The number of unsuccessful destructive get requests.
Identifier:	MQIAMO_GETS_FAILED.
Data type:	MQCFIN.
Returned:	When available.

GetBytes

Description:	The number of bytes read in destructive gets requests for persistent and nonpersistent messages. This parameter is an integer list indexed by persistence value, see Reference note 2
Identifier:	MQIAMO64_GET_BYTES.
Data type:	MQCFIL64.
Returned:	When available.

BrowseCount

Description:	The number of successful non-destructive get requests for persistent and nonpersistent messages. This parameter is an integer list indexed by persistence value, see Reference note 2
Identifier:	MQIAMO_BROWSES.
Data type:	MQCFIL.
Returned:	When available.

BrowseFailCount

Description:	The number of unsuccessful non-destructive get requests.
Identifier:	MQIAMO_BROWSES_FAILED.
Data type:	MQCFIN.
Returned:	When available.

BrowseBytes

Description:	The number of bytes read in non-destructive get requests for persistent and nonpersistent messages. This parameter is an integer list indexed by persistence value, see Reference note 2
Identifier:	MQIAMO64_BROWSE_BYTES.
Data type:	MQCFIL64.
Returned:	When available.

CommitCount

Description:	The number of transactions successfully completed. This number includes transactions committed implicitly by the application disconnecting, and commit requests where there is no outstanding work.
Identifier:	MQIAMO_COMMITS.
Data type:	MQCFIN.
Returned:	When available.

CommitFailCount

Description:	The number of unsuccessful attempts to complete a transaction.
Identifier:	MQIAMO_COMMITS_FAILED.
Data type:	MQCFIN.
Returned:	When available.

BackCount

Description:	The number of backouts processed, including implicit backout upon abnormal disconnect.
Identifier:	MQIAMO_BACKOUTS.
Data type:	MQCFIN.
Returned:	When available.

ExpiredMsgCount

Description:	The number of persistent and nonpersistent messages that were discarded because they had expired, before they could be retrieved.
Identifier:	MQIAMO_MSGS_EXPIRED.
Data type:	MQCFIN.
Returned:	When available.

PurgeCount

Description:	The number of times the queue has been cleared.
Identifier:	MQIAMO_MSGS_PURGED.
Data type:	MQCFIN.
Returned:	When available.

SubCountDur

Description:	The number of successful Subscribe requests which created, altered or resumed durable subscriptions. This is an array of values indexed by the type of operation 0 = The number of subscriptions created 1 = The number of subscriptions altered 2 = The number of subscriptions resumed
Identifier:	MQIAMO_SUBS_DUR.
Data type:	MQCFIL
Returned:	When available.

SubCountNDur

Description:	The number of successful Subscribe requests which created, altered or resumed non-durable subscriptions. This is an array of values indexed by the type of operation 0 = The number of subscriptions created 1 = The number of subscriptions altered 2 = The number of subscriptions resumed
Identifier:	MQIAMO_SUBS_NDUR.
Data type:	MQCFIL.
Returned:	When available.

SubFailCount

Description:	The number of unsuccessful Subscribe requests.
Identifier:	MQIAMO_SUBS_FAILED.
Data type:	MQCFIN.
Returned:	When available.

UnsubCountDur

Description:	The number of succesful unsubscribe requests for durable subscriptions. This is an array of values indexed by the type of operation 0 - The subscription was closed but not removed 1 - The subscription was closed and removed
Identifier:	MQIAMO_UNSUBS_DUR.
Data type:	MQCFIL.
Returned:	When available.

UnsubCountNDur

Description:	The number of succesful unsubscribe requests for non-durable subscriptions. This is an array of values indexed by the type of operation 0 - The subscription was closed but not removed 1 - The subscription was closed and removed
Identifier:	MQIAMO_UNSUBS_NDUR.
Data type:	MQCFIL.
Returned:	When available.

UnsubFailCount

Description:	The number of failed unsubscribe requests.
Identifier:	MQIAMO_UNSUBS_FAILED.
Data type:	MQCFIN.
Returned:	When available.

SubRqCount

Description:	The number of successful MQSUBRQ requests.
Identifier:	MQIAMO_SUBRQS
Data type:	MQCFIN
Returned:	When available.

SubRqFailCount

Description:	The number of unsuccessful MQSUBRQ requests.
Identifier:	MQIAMO_SUBRQS_FAILED.
Data type:	MQCFIN.
Returned:	When available.

CBCount

Description:	The number of successful MQCB requests. This is an array of values indexed by the type of operation 0 - A callback was created or altered 1 - A callback was removed 2 - A callback was resumed 3 - A callback was suspended
Identifier:	MQIAMO_CBS.
Data type:	MQCFIL.
Returned:	When available.

CBFailCount

Description:	The number of unsuccessful MQCB requests.
Identifier:	MQIAMO_CBS_FAILED.
Data type:	MQCFIN.
Returned:	When available.

CtlCount

Description:	The number of successful MQCTL requests. This is an array of values indexed by the type of operation : 0 - The connection was started 1 - The connection was stopped 2 - The connection was resumed 3 - The connection was suspended
Identifier:	MQIAMO_CTLS.
Data type:	MQCFIL.
Returned:	When available.

CtlFailCount

Description:	The number of unsuccessful MQCTL requests.
Identifier:	MQIAMO_CTLS_FAILED.
Data type:	MQCFIN.
Returned:	When available.

StatCount

Description:	The number of successful MQSTAT requests.
Identifier:	MQIAMO_STATS.
Data type:	MQCFIN.
Returned:	When available.

StatFailCount

Description:	The number of unsuccessful MQSTAT requests.
Identifier:	MQIAMO_STATS_FAILED.
Data type:	MQCFIN.
Returned:	When available.

SubCountDurHighWater

Description:	The high-water mark on the number of durable subscriptions during the time interval. This is an array of values indexed by SUBTYPE 0 - The high-water mark for all durable subscriptions in the system 1 - The high-water mark for durable application subscriptions (MQSUBTYPE_API) 2 - The high-water mark for durable admin subscription (MQSUBTYPE_ADMIN) 3 - The high-water mark for durable proxy subscriptions (MQSUBTYPE_PROXY)
Identifier:	MQIAMO_SUB_DUR_HIGHWATER
Data type:	MQCFIL.
Returned:	When available.

SubCountDurLowWater

Description:	The low-water mark on the number of durable subscriptions during the time interval. This is an array of values indexed by SUBTYPE. 0 - The low-water mark for all durable subscriptions in the system 1 - The low-water mark for durable application subscriptions (MQSUBTYPE_API) 2 - The low-water mark for durable admin subscriptions (MQSUBTYPE_ADMIN) 3 - The low-water mark for durable proxy subscriptions (MQSUBTYPE_PROXY)
Identifier:	MQIAMO_SUB_DUR_LOWWATER
Data type:	MQCFIL.
Returned:	When available.

SubCountNDurHighWater

Description:	The high-water mark on the number of non-durable subscriptions during the time interval. This is an array of values indexed by SUBTYPE 0 - The high-water mark for all non-durable subscriptions in the system 1 - The high-water mark for non-durable application subscriptions (MQSUBTYPE_API) 2 - The high-water mark for non-durable admin subscription (MQSUBTYPE_ADMIN) 3 - The high-water mark for non-durable proxy subscriptions (MQSUBTYPE_PROXY)
Identifier:	MQIAMO_SUB_NDUR_HIGHWATER
Data type:	MQCFIL.
Returned:	When available.

SubCountNDurLowWater

Description:	The low-water mark on the number of non-durable subscriptions during the time interval. This is an array of values indexed by SUBTYPE. 0 - The low-water mark for all non-durable subscriptions in the system 1 - The low-water mark for non-durable application subscriptions (MQSUBTYPE_API) 2 - The low-water mark for non-durable admin subscriptions (MQSUBTYPE_ADMIN) 3 - The low-water mark for non-durable proxy subscriptions (MQSUBTYPE_PROXY)
Identifier:	MQIAMO_SUB_NDUR_LOWWATER
Data type:	MQCFIL.
Returned:	When available.

PutTopicCount

Description:	The number persistent and nonpersistent messages successfully put to a topic, with the exception of messages put using the MQPUT1 call. This parameter is an integer list indexed by persistence value, see Reference note 2. Note: Messages put using a queue alias which resolve to a topic are included in this value.
Identifier:	MQIAMO_TOPIC_PUTS.
Data type:	MQCFIL.
Returned:	When available.

PutTopicFailCount

Description:	The number of unsuccessful attempts to put a message to a topic.
Identifier:	MQIAMO_TOPIC_PUTS_FAILED.
Data type:	MQCFIN.
Returned:	When available.

Put1TopicCount

Description:	The number of persistent and nonpersistent messages successfully put to a topic using MQPUT1 calls. This parameter is an integer list indexed by persistence value, see Reference note 2. Note: Messages put using a queue alias which resolve to a topic are included in this value.
Identifier:	MQIAMO_TOPIC_PUT1S.
Data type:	MQCFIL.
Returned:	When available.

Put1TopicFailCount

Description:	The number of unsuccessful attempts to put a message to a topic using MQPUT1 calls.
Identifier:	MQIAMO_TOPIC_PUT1S_FAILED.
Data type:	MQCFIN.
Returned:	When available.

PutTopicBytes

Description:	The number bytes written using put calls for persistent and nonpersistent messages which resolve to a publish operation. This is number of bytes put by the application and not the resultant number of bytes delivered to subscribers, see PublishMsgBytes for this value. This parameter is an integer list indexed by persistence value, see Reference note 2.
Identifier:	MQIAMO64_TOPIC_PUT_BYTES.
Data type:	MQCFIL64.
Returned:	When available.

PublishMsgCount

Description:	The number of messages delivered to subscriptions in the time interval. This parameter is an integer list indexed by persistence value, see Reference note 2.
Identifier:	MQIAMO64_PUBLISH_MSG_COUNT
Data type:	MQCFIL.
Returned:	When available.

PublishMsgBytes

Description:	The number of bytes delivered to subscriptions in the time interval. This parameter is an integer list indexed by persistence value, see Reference note 2.
Identifier:	MQIAMO64_PUBLISH_MSG_BYTES
Data type:	MQCFIL64.
Returned:	When available.

Queue statistics message data:

Use this page to view the structure of a queue statistics message

Message name:	Queue statistics message.
Platforms:	All, except IBM MQ for z/OS.
System queue:	SYSTEM.ADMIN.STATISTICS.QUEUE.

QueueManager

Description:	Name of the queue manager
Identifier:	MQCA_Q_MGR_NAME
Data type:	MQCFST
Maximum length:	MQ_Q_MGR_NAME_LENGTH
Returned:	Always

IntervalStartDate

Description:	The date at the start of the monitoring period
Identifier:	MQCAMO_START_DATE
Data type:	MQCFST
Maximum length:	MQ_DATE_LENGTH
Returned:	Always

IntervalStartTime

Description:	The time at the start of the monitoring period
Identifier:	MQCAMO_START_TIME
Data type:	MQCFST
Maximum length:	MQ_TIME_LENGTH
Returned:	Always

IntervalEndDate

Description:	The date at the end of the monitoring period
Identifier:	MQCAMO_END_DATE
Data type:	MQCFST
Maximum length:	MQ_DATE_LENGTH
Returned:	Always

IntervalEndTime

Description:	The time at the end of the monitoring period
Identifier:	MQCAMO_END_TIME
Data type:	MQCFST
Maximum length:	MQ_TIME_LENGTH
Returned:	Always

CommandLevel

Description:	The queue manager command level
Identifier:	MQIA_COMMAND_LEVEL
Data type:	MQCFIN
Returned:	Always

ObjectCount

Description:	The number of queue objects accessed in the interval for which statistics data has been recorded. This value is set to the number of QStatisticsData PCF groups contained in the message.
Identifier:	MQIAMO_OBJECT_COUNT
Data type:	MQCFIN
Returned:	Always

QStatisticsData

Description:	Grouped parameters specifying statistics details for a queue
Identifier:	MQGACF_Q_STATISTICS_DATA
Data type:	MQCFGR

Parameters in group:	*QName* *CreateDate* *CreateTime* *QType* *QDefinitionType* *QMinDepth* *QMaxDepth* *AvgTimeOnQ* *PutCount* *PutFailCount* *Put1Count* *Put1FailCount* *PutBytes* *GetCount* *GetFailCount* *GetBytes* *BrowseCount* *BrowseFailCount* *BrowseBytes* *NonQueuedMsgCount* *ExpiredMsgCount* *PurgeCount*
Returned:	Always

QName

Description:	The name of the queue
Identifier:	MQCA_Q_NAME
Data type:	MQCFST
Maximum length:	MQ_Q_NAME_LENGTH
Returned:	Always

CreateDate

Description:	The date when the queue was created
Identifier:	MQCA_CREATION_DATE
Data type:	MQCFST
Maximum length:	MQ_DATE_LENGTH
Returned:	Always

CreateTime

Description:	The time when the queue was created
Identifier:	MQCA_CREATION_TIME
Data type:	MQCFST
Maximum length:	MQ_TIME_LENGTH
Returned:	Always

QType

Description:	The type of the queue
Identifier:	MQIA_Q_TYPE
Data type:	MQCFIN
Value:	MQOT_LOCAL
Returned:	Always

QDefinitionType

Description:	The queue definition type
Identifier:	MQIA_DEFINITION_TYPE
Data type:	MQCFIN
Values:	Possible values are • MQQDT_PREDEFINED • MQQDT_PERMANENT_DYNAMIC • MQQDT_TEMPORARY_DYNAMIC
Returned:	When available

QMinDepth

Description:	The minimum queue depth during the monitoring period
Identifier:	MQIAMO_Q_MIN_DEPTH
Data type:	MQCFIN
Included in PCF group:	*QStatisticsData*
Returned:	When available

QMaxDepth

Description:	The maximum queue depth during the monitoring period
Identifier:	MQIAMO_Q_MAX_DEPTH
Data type:	MQCFIN
Included in PCF group:	*QStatisticsData*
Returned:	When available

AvgTimeOnQ

Description:	The average latency, in microseconds, of messages destructively retrieved from the queue during the monitoring period. This parameter is an integer list indexed by persistence value, see Reference note 2.
Identifier:	MQIAMO64_AVG_Q_TIME
Data type:	MQCFIL64
Included in PCF group:	*QStatisticsData*
Returned:	When available

PutCount

Description:	The number of persistent and nonpersistent messages successfully put to the queue, with exception of MQPUT1 requests. This parameter is an integer list indexed by persistence value. See Reference note 2.
Identifier:	MQIAMO_PUTS
Data type:	MQCFIL
Included in PCF group:	*QStatisticsData*
Returned:	When available

PutFailCount

Description:	The number of unsuccessful attempts to put a message to the queue
Identifier:	MQIAMO_PUTS_FAILED
Data type:	MQCFIN
Included in PCF group:	*QStatisticsData*
Returned:	When available

Put1Count

Description:	The number of persistent and nonpersistent messages successfully put to the queue using MQPUT1 calls. This parameter is an integer list indexed by persistence value. See Reference note 2.
Identifier:	MQIAMO_PUT1S
Data type:	MQCFIL
Included in PCF group:	*QStatisticsData*
Returned:	When available

Put1FailCount

Description:	The number of unsuccessful attempts to put a message using MQPUT1 calls
Identifier:	MQIAMO_PUT1S_FAILED
Data type:	MQCFIN
Included in PCF group:	*QStatisticsData*
Returned:	When available

PutBytes

Description:	The number of bytes written in put requests to the queue
Identifier:	MQIAMO64_PUT_BYTES
Data type:	MQCFIL64
Included in PCF group:	*QStatisticsData*
Returned:	When available

GetCount

Description:	The number of successful destructive get requests for persistent and nonpersistent messages. This parameter is an integer list indexed by persistence value. See Reference note 2.
Identifier:	MQIAMO_GETS
Data type:	MQCFIL
Included in PCF group:	*QStatisticsData*
Returned:	When available

GeneratedMsgCount

Description:	The number of generated messages. Generated messages are: • Trigger messages • Queue Depth Low Events • Queue Depth Hi Events
Identifier:	MQIAMO_GENERATED_MSGS
Data type:	MQCFIN
Included in PCF group:	*QStatisticsData*
Returned:	When available

GetFailCount

Description:	The number of unsuccessful destructive get requests
Identifier:	MQIAMO_GETS_FAILED
Data type:	MQCFIN
Included in PCF group:	*QStatisticsData*
Returned:	When available

GetBytes

Description:	The number of bytes read in destructive put requests for persistent and nonpersistent messages. This parameter is an integer list indexed by persistence value. See Reference note 2.
Identifier:	MQIAMO64_GET_BYTES
Data type:	MQCFIL64
Included in PCF group:	*QStatisticsData*
Returned:	When available

BrowseCount

Description:	The number of successful non-destructive get requests for persistent and nonpersistent messages. This parameter is an integer list indexed by persistence value. See Reference note 2.
Identifier:	MQIAMO_BROWSES
Data type:	MQCFIL
Included in PCF group:	*QStatisticsData*
Returned:	When available

BrowseFailCount

Description:	The number of unsuccessful non-destructive get requests
Identifier:	MQIAMO_BROWSES_FAILED
Data type:	MQCFIN
Included in PCF group:	*QStatisticsData*
Returned:	When available

BrowseBytes

Description:	The number of bytes read in non-destructive get requests for persistent and nonpersistent messages. This parameter is an integer list indexed by persistence value. See Reference note 2.
Identifier:	MQIAMO64_BROWSE_BYTES
Data type:	MQCFIL64
Included in PCF group:	*QStatisticsData*
Returned:	When available

NonQueuedMsgCount

Description:	The number of messages that bypassed the queue and were transferred directly to a waiting application. Bypassing a queue can only occur in certain circumstances. This number represents how many times IBM MQ was able to bypass the queue, and not the number of times an application was waiting.
Identifier:	MQIAMO_MSGS_NOT_QUEUED
Data type:	MQCFIN
Included in PCF group:	*QStatisticsData*
Returned:	When available

ExpiredMsgCount

Description:	The number of persistent and nonpersistent messages that were discarded because they had expired before they could be retrieved.
Identifier:	MQIAMO_MSGS_EXPIRED
Data type:	MQCFIN
Included in PCF group:	*QStatisticsData*
Returned:	When available

PurgeCount

Description:	The number of messages purged.
Identifier:	MQIAMO_MSGS_PURGED
Data type:	MQCFIN
Included in PCF group:	*QStatisticsData*
Returned:	When available

CBCount

Description:	The number of successful MQCB requests. This is an array of values indexed by the type of operation 0 - A callback was created or altered 1 - A callback was removed 2 - A callback was resumed 3 - A callback was suspended
Identifier:	MQIAMO_CBS
Data type:	MQCFIN
Returned:	When available.

CBFailCount

Description:	The number of unsuccessful MQCB requests.
Identifier:	MQIAMO_CBS_FAILED
Data type:	MQCFIN
Returned:	When available.

Channel statistics message data:

Use this page to view the structure of a channel statistics message

Message name:	Channel statistics message.
Platforms:	All, except IBM MQ for z/OS.
System queue:	SYSTEM.ADMIN.STATISTICS.QUEUE.

QueueManager

Description:	The name of the queue manager.
Identifier:	MQCA_Q_MGR_NAME.
Data type:	MQCFST.
Maximum length:	MQ_Q_MGR_NAME_LENGTH.
Returned:	Always.

IntervalStartDate

Description:	The date at the start of the monitoring period.
Identifier:	MQCAMO_START_DATE.
Data type:	MQCFST.
Maximum length:	MQ_DATE_LENGTH.
Returned:	Always.

IntervalStartTime

Description:	The time at the start of the monitoring period.
Identifier:	MQCAMO_START_TIME.
Data type:	MQCFST.
Maximum length:	MQ_TIME_LENGTH.
Returned:	Always.

IntervalEndDate

Description:	The date at the end of the monitoring period
Identifier:	MQCAMO_END_DATE.
Data type:	MQCFST.
Maximum length:	MQ_DATE_LENGTH.
Returned:	Always.

IntervalEndTime

Description:	The time at the end of the monitoring period
Identifier:	MQCAMO_END_TIME.
Data type:	MQCFST.
Maximum length:	MQ_TIME_LENGTH
Returned:	Always.

CommandLevel

Description:	The queue manager command level.
Identifier:	MQIA_COMMAND_LEVEL.
Data type:	MQCFIN.
Returned:	Always.

ObjectCount

Description:	The number of Channel objects accessed in the interval for which statistics data has been recorded. This value is set to the number of ChlStatisticsData PCF groups contained in the message.
Identifier:	MQIAMO_OBJECT_COUNT
Data type:	MQCFIN.
Returned:	Always.

ChlStatisticsData

Description:	Grouped parameters specifying statistics details for a channel.
Identifier:	MQGACF_CHL_STATISTICS_DATA.
Data type:	MQCFGR.
Parameters in group:	*ChannelName* *ChannelType* *RemoteQmgr* *ConnectionName* *MsgCount* *TotalBytes* *NetTimeMin* *NetTimeAvg* *NetTimeMax* *ExitTimeMin* *ExitTimeAvg* *ExitTimeMax* *FullBatchCount* *IncmplBatchCount* *AverageBatchSize* *PutRetryCount*
Returned:	Always.

ChannelName

Description:	The name of the channel.
Identifier:	MQCACH_CHANNEL_NAME.
Data type:	MQCFST.
Maximum length:	MQ_CHANNEL_NAME_LENGTH.
Returned:	Always.

ChannelType

Description:	The channel type.
Identifier:	MQIACH_CHANNEL_TYPE.
Data type:	MQCFIN.
Values:	Possible values are: **MQCHT_SENDER** Sender channel. **MQCHT_SERVER** Server channel. **MQCHT_RECEIVER** Receiver channel. **MQCHT_REQUESTER** Requester channel. **MQCHT_CLUSRCVR** Cluster receiver channel. **MQCHT_CLUSSDR** Cluster sender channel.
Returned:	Always.

RemoteQmgr

Description:	The name of the remote queue manager.
Identifier:	MQCA_REMOTE_Q_MGR_NAME.
Data type:	MQCFST.
Maximum length:	MQ_Q_MGR_NAME_LENGTH
Returned:	When available.

ConnectionName

Description:	Connection name of remote queue manager.
Identifier:	MQCACH_CONNECTION_NAME.
Data type:	MQCFST
Maximum length:	MQ_CONN_NAME_LENGTH
Returned:	When available.

MsgCount

Description:	The number of persistent and nonpersistent messages sent or received.
Identifier:	MQIAMO_MSGS.
Data type:	MQCFIN
Returned:	When available.

TotalBytes

Description:	The number of bytes sent or received for persistent and nonpersistent messages.
Identifier:	MQIAMO64_BYTES.
Data type:	MQCFIN64.
Returned:	When available.

NetTimeMin

Description:	The shortest recorded channel round trip measured in the recording interval, in microseconds.
Identifier:	MQIAMO_NET_TIME_MIN.
Data type:	MQCFIN.
Returned:	When available.

NetTimeAvg

Description:	The average recorded channel round trip measured in the recording interval, in microseconds.
Identifier:	MQIAMO_NET_TIME_AVG.
Data type:	MQCFIN.
Returned:	When available.

NetTimeMax

Description:	The longest recorded channel round trip measured in the recording interval, in microseconds.
Identifier:	MQIAMO_NET_TIME_MAX.
Data type:	MQCFIN.
Returned:	When available.

ExitTimeMin

Description:	The shortest recorded time, in microseconds, spent executing a user exit in the recording interval,
Identifier:	MQIAMO_EXIT_TIME_MIN.
Data type:	MQCFIN.
Returned:	When available.

ExitTimeAvg

Description:	The average recorded time, in microseconds, spent executing a user exit in the recording interval. Measured in microseconds.
Identifier:	MQIAMO_EXIT_TIME_AVG.
Data type:	MQCFIN.
Returned:	When available.

ExitTimeMax

Description:	The longest recorded time, in microseconds, spent executing a user exit in the recording interval. Measured in microseconds.
Identifier:	MQIAMO_EXIT_TIME_MAX.
Data type:	MQCFIN.
Returned:	When available.

FullBatchCount

Description:	The number of batches processed by the channel that were sent because the value of the channel attributes BATCHSZ or BATCHLIM was reached.
Identifier:	MQIAMO_FULL_BATCHES.
Data type:	MQCFIN.
Returned:	When available.

IncmplBatchCount

Description:	The number of batches processed by the channel, that were sent without the value of the channel attribute BATCHSZ being reached.
Identifier:	MQIAMO_INCOMPLETE_BATCHES.
Data type:	MQCFIN.
Returned:	When available.

AverageBatchSize

Description:	The average batch size of batches processed by the channel.
Identifier:	MQIAMO_AVG_BATCH_SIZE.
Data type:	MQCFIN.
Returned:	When available.

PutRetryCount

Description:	The number of times in the time interval that a message failed to be put, and entered a retry loop.
Identifier:	MQIAMO_PUT_RETRIES.
Data type:	MQCFIN.
Returned:	When available.

Reference notes:

Use this page to view the notes to which descriptions of the structure of accounting and statistics messages refer

The following message data descriptions refer to these notes:
- "MQI accounting message data" on page 1080
- "Queue accounting message data" on page 1091
- "MQI statistics message data" on page 1101
- "Queue statistics message data" on page 1112
- "Channel statistics message data" on page 1119

1. This parameter relates to IBM MQ objects. This parameter is an array of values (MQCFIL or MQCFIL64) indexed by the following constants:

Table 124. Array indexed by object type

Object type	Value context
MQOT_Q (1)	Contains the value relating to queue objects.
MQOT_NAMELIST (2)	Contains the value relating to namelist objects.
MQOT_PROCESS (3)	Contains the value relating to process objects.
MQOT_Q_MGR (5)	Contains the value relating to queue manager objects.
MQOT_CHANNEL (6)	Contains the value relating to channel objects.
MQOT_AUTH_INFO (7)	Contains the value relating to authentication information objects.
MQOT_TOPIC (8)	Contains the value relating to topic objects.

   Note: An array of 13 MQCFIL or MQCFIL64 values are returned but only those listed are meaningful.

2. This parameter relates to IBM MQ messages. This parameter is an array of values (MQCFIL or MQCFIL64) indexed by the following constants:

Table 125. Array indexed by persistence value

Constant	Value
1	Contains the value for nonpersistent messages.
2	Contains the value for persistent messages.

Note: The index for each of these arrays starts at zero, so an index of 1 refers to the second row of the array. Elements of these arrays not listed in these tables contain no accounting or statistics information.

Application activity trace

Application activity trace produces detailed information about the behavior of applications connected to a queue manager. It traces the behavior of an application and provides a detailed view of the parameters used by an application as it interacts with IBM MQ resources. It also shows the sequence of MQI calls issued by an application.

Use Application activity trace when you require more information than is provided by Event monitoring, Message monitoring, Accounting and statistics messages, and Real-time monitoring.

Note that activity trace is not supported by IBM MQ for z/OS.

Collecting application activity trace information

An application activity trace message is a PCF message. You configure activity trace using a configuration file. To collect application activity trace information you set the ACTVTRC queue manager attribute. You can override this setting at connection level using MQCONNX options, or at application stanza level using the activity trace configuration file.

About this task

Activity trace messages are composed of an MQMD structure: a PCF (MQCFH) header structure, followed by a number of PCF parameters. A sequence of ApplicationTraceData PCF groups follows the PCF parameters. These PCF groups collect information about the MQI operations that an application performs while connected to a queue manager. You configure activity trace using a configuration file called `mqat.ini`.

To control whether or not application activity trace information is collected, you configure one or more of the following settings:

1. The ACTVTRC queue manager attribute.
2. The ACTVCONO settings (in the MQCNO structure passed in MQCONNX).
3. The matching stanza for the application in the activity trace configuration file `mqat.ini`.

The previous sequence is significant. The ACTVTRC attribute is overridden by the ACTVCONO settings, which are overridden by the settings in the `mqat.ini` file.

Trace entries are written after each operation has completed, unless otherwise stated. These entries are first written to the system queue SYSTEM.ADMIN.TRACE.ACTIVITY.QUEUE, then written to application activity trace messages when the application disconnects from the queue manager. For long running applications, intermediate messages are written if any of the following events occurs:

- The lifetime of the connection reaches a defined timeout value.
- The number of operations reaches a specified number.
- The amount of data collected in memory reaches the maximum message length allowed for the queue.

You set the timeout value using the `ActivityInterval` parameter. You set the number of operations using the `ActivityCount` parameter. Both parameters are specified in the activity trace configuration file `mqat.ini`.

Enabling application activity trace can affect performance. The overhead can be reduced by tuning the **ActivityCount** and the **ActivityInterval** settings. See "Tuning the performance impact of application activity trace" on page 1133.

The simplest way to view the contents of application activity trace messages is to use the "amqsact sample program" on page 1134.

Procedure

1. "Setting ACTVTRC to control collection of activity trace information."
2. "Setting MQCONNX options to control collection of activity trace information" on page 1127.
3. "Configuring activity trace behavior using `mqat.ini`" on page 1127.
4. "Tuning the performance impact of application activity trace" on page 1133.

Setting ACTVTRC to control collection of activity trace information:

Use the queue manager attribute ACTVTRC to control the collection of MQI application activity trace information

About this task

Application activity trace messages are generated only for connections that begin after application activity trace is enabled. The **ACTVTRC** parameter can have the following values:

ON API activity trace collection is switched on

OFF
API activity trace collection is switched off

Note: The **ACTVTRC** setting can be overridden by the queue manager **ACTVCONO** parameter. If you set the **ACTVCONO** parameter to `ENABLED`, then the **ACTVTRC** setting can be overridden for a given connection using the **Options** field in the MQCNO structure. See"Setting MQCONNX options to control collection of activity trace information" on page 1127.

Example

To change the value of the **ACTVTRC** parameter, you use the MQSC command `ALTER QMGR`. For example, to enable MQI application activity trace information collection use the following MQSC command:

```
ALTER QMGR ACTVTRC(ON)
```

What to do next

The simplest way to view the contents of application activity trace messages is to use the "amqsact sample program" on page 1134.

Enabling application activity trace can affect performance. The overhead can be reduced by tuning the **ActivityCount** and the **ActivityInterval** settings. See "Tuning the performance impact of application activity trace" on page 1133.

Setting MQCONNX options to control collection of activity trace information:

If the queue manager attribute **`ACTVCONO`** is set to `ENABLED`, you can use the **`ConnectOpts`** parameter on the MQCONNX call to enable or disable application activity reports on a per connection basis. These options override the activity trace behavior defined by the queue manager attribute **`ACTVTRC`**, and can be overridden by settings in the activity trace configuration file `mqat.ini`.

Procedure

1. Set the queue manager attribute **`ACTVCONO`** to `ENABLED`.

   Note: If an application attempts to modify the accounting behavior of an application using the **`ConnectOpts`** parameter, and the QMGR attribute **`ACTVCONO`** is set to `DISABLED`, then no error is returned to the application, and activity trace collection is defined by the queue manager attributes or the activity trace configuration file `mqat.ini`.
2. Set the **`ConnectOpts`** parameter on the MQCONNX call to `MQCNO_ ACTIVITY_ TRACE_ENABLED`.

   The **`ConnectOpts`** parameter on the MQCONNX call can have the following values:

   `MQCNO_ACTIVITY_ TRACE_DISABLED`
   Activity trace is switched off for the connection.

   `MQCNO_ ACTIVITY_ TRACE_ENABLED`
   Activity trace is switched on for the connection.

   Note: If an application selects both `MQCNO_ ACTIVITY_ TRACE_ENABLED` and `MQCNO_ACTIVITY_ TRACE_DISABLED` for MQCONNX, the call fails with a reason code of MQRC_OPTIONS_ERROR.
3. Check that these activity trace settings are not being overridden by settings in the activity trace configuration file `mqat.ini`.

   See"Configuring activity trace behavior using `mqat.ini`."

What to do next

The simplest way to view the contents of application activity trace messages is to use the "amqsact sample program" on page 1134.

Enabling application activity trace can affect performance. The overhead can be reduced by tuning the **`ActivityCount`** and the **`ActivityInterval`** settings. See "Tuning the performance impact of application activity trace" on page 1133.

Configuring activity trace behavior using `mqat.ini`:

Activity trace behavior is configured using a configuration file called `mqat.ini`. This file is used to define the level and frequency of reporting activity trace data. The file also provides a way to define rules to enable and disable activity trace based on the name of an application.

About this task

UNIX Linux On UNIX and Linux systems, `mqat.ini` is located in the queue manager data directory, which is the same location as the `qm.ini` file.

Windows On Windows systems, `mqat.ini` is located in the queue manager data directory `C:\Program Files\IBM\WebSphere MQ\qmgrs\queue_manager_name`. Users running applications to be traced need permission to read this file.

When the mqat.ini file is modified, newly created IBM MQ connections will be processed according to the modified version. Existing connections will continue to use the previous version unless the queue manager parameters are altered, for example following an ALTER QMGR command.

This file follows the same stanza key and parameter-value pair format as the mqs.ini and qm.ini files. It is located in the queue manager data directory, this is, the same location as the qm.ini file for the queue manager.

The file consists of a single stanza, **AllActivityTrace**, to configure the level and frequency of reporting activity trace data by default for all activity trace.

The file can also contain multiple **ApplicationTrace** stanzas. Each one of these, defines a rule for the trace behavior for one or more connections, based on matching the application name of the connections to the rule.

AllActivityTrace stanza

A single **AllActivityTrace** stanza defines settings for the activity trace that is applied to all IBM MQ connections, unless overridden.

Individual values in the **AllActivityTrace** stanza can be overridden by more specific information in an **ApplicationTrace stanza** stanza.

If more than one **AllActivityTrace** stanza is specified then the values in the last stanza is used. Parameters missing from the chosen **AllActivityTrace** take default values. Parameters and values from previous **AllActivityTrace** stanzas are ignored.

The following parameters can be specified under the **AllActivityTrace** stanza:

Table 126. Parameter/value pairs that can be used in the activity trace configuration file

Name	Values (default in bold type)	Description
ActivityInterval	0-99999999 (**1**)	Approximate time interval in seconds between trace messages. All activity performed by a connection in that interval will be written in a single message. If this value is 0, the trace message is written when the connection disconnects (or when the activity count is reached).
ActivityCount	0-99999999 (**100**)	Number of MQI or XA operations between trace messages. If this value is 0, the trace message is written when the connection disconnects (or when the activity interval has elapsed).
TraceLevel	LOW / **MEDIUM** / HIGH	Amount of parameter detail traced for each operation. The description of individual operations details which parameters are included for each trace level.
TraceMessageData	**0** - 104 857 600 (maximum 100 MB)	Amount of message data traced in bytes for MQGET, MQPUT, MQPUT1, and Callback operations
StopOnGetTraceMsg	**ON** / OFF	Using activity trace, to trace applications that are also processing activity trace messages, is not advisable due to possible looping occurring.

ApplicationTrace stanza

An ApplicationTrace stanza contains a rule which defines which IBM MQ connections will be traced or not trace based on the application name. Optionally, the default behaviour defined under the Allsettings which override the global trace level and frequency settings.

This stanza can include ApplName, ApplFunction and ApplClass parameters which are used according to the matching rules defined in Connection Matching Rules to determine whether the stanza applies to a particular connection or not.

The stanza must include the Trace parameter to determine if this rule turns activity trace on or off for matching connections.

An off rule can be used to explicitly disable trace for more specific application names and to override the ACTVTRC setting of the queue manager or activity trace connection options.

The following parameters can be specified under the **ApplicationTrace** stanza:

Table 127. Parameter/value pairs that can be used in the application trace configuration file

Name	**Values (default in bold type)**	**Description**
Trace	ON / OFF (Required parameter - no default value)	Activity trace switch. This switch can be used in the application-specific stanza to determine whether activity trace is active for the scope of the current application stanza. Note that this value overrides ACTVTRC and ACTVCONO settings for the queue manager.
ApplName	Character string (Required parameter - no default)	This value is used to determine which applications the ApplicationTrace stanza applies to. It is matched to the ApplName value from the API exit context structure (which is equivalent to the MQMD.PutApplName). The content of the ApplName value varies according to the application environment. For platforms other than z/OS, only the filename portion of the MQAXC.ApplName is matched to the value in the stanza. Characters to the left of the rightmost path separator are ignored when the comparison is made. z/OS For z/OS applications, the entire MQAXC.ApplName is matched to the value in the stanza. A single wildcard character (*) can be used at the end of the ApplName value to match any number of characters after that point. If the ApplName value is set to a single wildcard character (*) then the ApplName value matches all applications.

Table 127. Parameter/value pairs that can be used in the application trace configuration file (continued)

Name	**Values (default in bold type)**	**Description**
IBM i ApplFunction	Character string (default value *)	This value is used to qualify which application programs the **ApplicationTrace** stanza and **ApplName** value applies to. The stanza is optional, but is only valid for IBM i queue managers. A single wildcard character (*) can be used at the end of the **ApplName** value to match any number of characters. For example, an **ApplicationTrace** stanza specifying **ApplName** = * and **ApplFunction** = *AMQSPUT0* applies to all invocations of the AMQSPUT0 program from any job.
ApplClass	USER / MCA / **ALL**	The class of application. See the following table for an explanation of how the **AppType** values correspond to IBM MQ connections.

The following table shows how the *AppClass* values correspond to the **APICallerType** and **APIEnvironment** fields in the connection API exit context structure.

Table 128. Appclass values and how they correspond to the APICallerType and APIEnvironment fields

APPLCLASS	**API Caller Type:**	**API Environment:**	**Description**
USER	MQXACT_EXTERNAL	MQXE_OTHER	Only user applications are traced
MCA	(Any value)	MQXE_MCA MQXE_MCA_CLNTCONN MQXE_MCA_SVRCONN	Clients and channels (amqrmppa)
ALL	(Any value)	(Any value)	All connections are traced

Attention: You must use an **APPLCLASS** of *MCA* for client user applications, as a class of *USER* does not match these.

For example, to trace the **amqsputc** sample application, you could use the following code:

```
ApplicationTrace:
ApplClass=MCA                          # Application type
                                        #   Values:  (USER | MCA | INTERNAL | ALL)
                                        #   Default: USER
ApplName=amqsputc     # Application name (may be wildcarded)
                                        #   (matched to app name without path)
                                        #   Default: *
Trace=ON                                # Activity trace switch for application
                                        #   Values:  ( ON | OFF )
                                        #   Default: OFF
ActivityInterval=30                      # Time interval between trace messages
                                        #   Values: 0-99999999 (0=off)
                                        #   Default: 0
ActivityCount=1                         # Number of operations between trace msgs
                                        #   Values: 0-99999999  (0=off)
                                        #   Default: 0
TraceLevel=MEDIUM                       # Amount of data traced for each operation
                                        #   Values: LOW | MEDIUM | HIGH
                                        #   Default: MEDIUM
TraceMessageData=1000                   # Amount of message data traced
                                        #   Values: 0-100000000
                                        #   Default: 0
```

The default `mqat.ini` generated when a queue manager is created, contains a single rule to explicitly disable activity trace for the supplied activity trace sample, **amqsact**.

Connection Matching Rules

The queue manager applies the following rules to determine which stanzas settings to use for a connection.

1. A value specified in the **AllActivityTrace** stanza is used for the connection unless the value also occurs in an **ApplicationTrace** stanza and the stanza fulfills the matching criteria for the connection described in points 2, 3, and 4.
2. The **ApplClass** is matched against the type of the IBM MQ connection. If the **ApplClass** does not match the connection type then the stanza is ignored for this connection.
3. The *ApplName* value in the stanza is matched against the file name portion of the **ApplName** field from the API exit context structure (MQAXC) for the connection.

   The file name portion is derived from the characters to the right of the final path separator (/ or \) character. If the stanza **ApplName** includes a wildcard (*) then only the characters to the left of the wildcard are compared with the equivalent number of characters from the **ApplName** of the connection.

   For example, if a stanza value of "FRE*" is specified then only the first three characters are used in the comparison, so "path/FREEDOM" and "path\FREDDY" match, but "path/FRIEND" does not. If the *ApplName* value of the stanza does not match the connection **ApplName**, the stanza is ignored for this connection.
4. If more than one stanza matches the **ApplName** and **ApplClass** of the connection, then the stanza with the most specific **ApplName** is used.

   The most specific **ApplName** is defined as the one that uses the most characters to match the **ApplName** of the connection.

   For example, if the `ini` file contains a stanza with **ApplName** = *"FRE*"* and another stanza with **ApplName** = *"FREE*"* then the stanza with **ApplName** = *"FREE*"* is chosen as the best match for a connection with **ApplName** = *"path/FREEDOM"* because it matches four characters (whereas **ApplName** = *"FRE*"* matches only three).
5. If after applying the rules in points 2, 3, and 4, there is more than one stanza that matches the connections **ApplName** and **ApplClass** of the connection, the values from the last matching will be used and all other stanzas will be ignored.

Overriding default settings for each rule

Optionally, the global trace level and frequency settings under the **AllActivityTrace** stanza can be overridden for those connections matching an **ApplicationTrace** stanza.

The following parameters can be set under an **ApplicationTrace** stanza. If they are not set, the value is inherited from the **AllActivityTrace** stanza settings:

- **ActivityInterval**
- **ActivityCount**
- **TraceLevel**
- **TraceMessageData**
- **StopOnTraceMsg**

`mqat.ini` syntax

The syntax rules for the format of the `mqat.ini` file are:

- Text beginning with a hash or semicolon is considered to be a comment that extends to the end of the line.
- The first significant (non-comment) line must be a stanza key.
- A stanza key consists of the name of the stanza followed by a colon.

- A parameter-value pair consists of the name of a parameter followed by an equals sign and then the value.
- Only a single parameter-value pair can appear on a line. (A parameter-value must not wrap onto another line).
- Leading and trailing whitespace is ignored. There is no limit on the amount of white space between stanza names, parameter names and values, or parameter/value pairs. Line breaks are significant and not ignored
- The maximum length for any line is 2048 characters
- The stanza keys, parameter names, and constant parameter values are not case-sensitive, but the variable parameter values (*ApplName* and *DebugPath*) are case-sensitive.

Application Activity Trace File Example

The following example shows how the configuration data is specified in the Activity Trace ini file.

```
AllActivityTrace:
ActivityInterval=1
ActivityCount=100
TraceLevel=MEDIUM
TraceMessageData=0
StopOnGetTraceMsg=ON

ApplicationTrace:
ApplName=amqs*
Trace=ON
TraceLevel=HIGH
TraceMessageData=1000

ApplicationTrace:
ApplName=amqsact*
Trace=OFF
```

The above **AllActivityTrace** stanza defines how activity trace will perform by default when enabled, either through ApplicationTrace rules or through the queue manager ACTVTRC attribute or programmatically enabled by an application.

The first **ApplicationTrace** stanza defines a rule that will result in any MQI activity by an application whose name starts with "amqs" being traced. Trace generated for these applications will be of high detail and include up to 1000 bytes of message data. The activity interval and count parameters will be inherited

The second **ApplicationTrace** stanza defines a rule that turns trace off for applications with names starting "amqsact" (the activity trace sample). This rule will override the earlier 'on' rule for the amqsact application, resulting in no trace for that application.

An example is also shipped as a sample called `mqat.ini` in the C samples directory (the same directory as the amqsact.c file). This file can be copied to the queue manager data directory, for queue managers that have been migrated from an earlier release of IBM MQ.

What to do next

Enabling application activity trace can affect performance. The overhead can be reduced by tuning the **`ActivityCount`** and the **`ActivityInterval`** settings. See "Tuning the performance impact of application activity trace" on page 1133.

Tuning the performance impact of application activity trace:

Enabling application activity trace can incur a performance penalty. This can be reduced by only tracing the applications that you need, by increasing the number of applications draining the queue, and by tuning **`ActivityInterval`**, **`ActivityCount`** and **`TraceLevel`** in `mqat.ini`.

About this task

Enabling application activity trace selectively for an application or for all queue manager applications can result in additional messaging activity, and in the queue manager requiring additional storage space. In environments where messaging performance is critical, for example, in high workload applications or where a service level agreement (SLA) requires a minimum response time from the messaging provider, it might not be appropriate to collect application activity trace or it might be necessary to adjust the detail or frequency of trace activity messages that are produced. The preset values of **`ActivityInterval`**, **`ActivityCount`** and **`TraceLevel`** in the `mqat.ini` file give a default balance of detail and performance. However, you can tune these values to meet the precise functional and performance requirements of your system.

Procedure

- Only trace the applications that you need.

  Do this by creating an ApplicationTrace application-specific stanza in `mqat.ini`, or by changing the application to specify `MQCNO_ACTIVITY_TRACE_ENABLED` in the options field on the **`MQCNO`** structure on an MQCONNX call. See"Configuring activity trace behavior using `mqat.ini`" on page 1127and"Setting MQCONNX options to control collection of activity trace information" on page 1127.
- Before starting trace, check that at least one application is running and is ready to retrieve the activity trace message data from the SYSTEM.ADMIN.TRACE.ACTIVITY.QUEUE.
- Keep the queue depth as low as possible, by increasing the number of applications draining the queue.
- Set the **`TraceLevel`** value in the `mqat.ini` file to collect the minimum amount of data required.

  `TraceLevel=LOW` has the lowest impact to messaging performance. See"Configuring activity trace behavior using `mqat.ini`" on page 1127.
- Tune the **`ActivityCount`** and **`ActivityInterval`** values in `mqat.ini`, to adjust how often activity trace messages are generated.

  If you are tracing multiple applications, the activity trace messages might be being produced faster than they can be removed from the SYSTEM.ADMIN.TRACE.ACTIVITY.QUEUE. However, when you reduce how often activity trace messages are generated, you are also increasing the storage space required by the queue manager and the size of the messages when they are written to the queue.

What to do next

The simplest way to view the contents of application activity trace messages is to use the "amqsact sample program" on page 1134.

amqsact sample program

amqsact formats Application Activity Trace messages for you and is provided with IBM MQ.

The compiled program is located in the samples directory:

- On Linux and UNIX platforms `MQ_INSTALLATION_PATH/samp/bin`
- On Windows `MQ_INSTALLATION_PATH\tools\c\Samples\Bin`

Display mode

By default, **amqsact** in display mode processes messages on SYSTEM.ADMIN.TRACE.ACTIVITY.QUEUE. You can override this behavior by specifying a queue name or topic string.

You can also control the trace period displayed and specify whether the activity trace messages are removed or retained after display.

```
►►──amqsact── -m──QMgrName──┬──────────────┬─┬───────────────────┬─┬──────────────┬──────────────►
                            └─ -q──QName───┘ └─ -t──TopicString──┘ └─ -b──Browse──┘

►──┬──────────────────┬── -d──Depth── -w──Timeout── -s──StartTime── -e──EndTime──────────────────►◄
   └─ -v──Verbose─────┘
```

Required parameters

-m *QMgrName*
Name of the queue manager.

-d *Depth*
Number of records to display.

-w *Timeout*
Time to wait, in seconds. If no trace messages appear in the specified period, **amqsact** exits.

-s *StartTime*
Start time of record to process.

-e *EndTime*
End time of record to process.

Optional parameters

-q *QName*
Specify a specific queue to override the default queue name

-t *TopicString*
Subscribe to an event topic

-b Browse records only

-v Verbose output

Example output

Use **amqsact** on queue manager *TESTQM*, with verbose output, on an MQCONN API call:

```
amqsact -m TESTQM -v
```

The preceding command gives the following example output:

```
MonitoringType: MQI Activity Trace
Correl_id:
00000000: 414D 5143 5445 5354 514D 2020 2020 2020 'AMQCTESTQM      '
00000010: B5F6 4251 2000 E601                     '        '
```

```
QueueManager: 'TESTQM'
Host Name: 'ADMINIB-1VTJ6N1'
IntervalStartDate: '2014-03-15'
IntervalStartTime: '12:08:10'
IntervalEndDate: '2014-03-15'
IntervalEndTime: '12:08:10'
CommandLevel: 750
SeqNumber: 0
ApplicationName: 'IBM MQ_1\bin\amqsput.exe'
Application Type: MQAT_WINDOWS_7
ApplicationPid: 14076
UserId: 'Emma_Bushby'
API Caller Type: MQXACT_EXTERNAL
API Environment: MQXE_OTHER
Application Function: ''
Appl Function Type: MQFUN_TYPE_UNKNOWN

00000000: 414D 5143 5445 5354 514D 2020 2020 2020 'AMQCTESTQM      '
00000010: FFFFFFB5FFFFFFF6 4251 2000 FFFFFE601  '         '
QueueManager: 'TESTQM'
Completion Code: MQCC_OK
Reason Code: 0
```

V 8.0.0.2

Dynamic mode

Dynamic mode applies only when using IBM MQ Appliance.

You enable dynamic mode by specifying an application name, a channel name, or a connection identifier as an argument to **amqsact**. Note that you can use wildcard characters in the name.

In dynamic mode, activity trace data is enabled at the start of the sample by use of a nondurable subscription to a system topic. Collecting activity trace data stops when **amqsact** stops. You must specify a timeout for **amqsact** in dynamic mode. You can run multiple copies of **amqsact** concurrently, with each instance receiving a copy of any activity trace data.

```
►►─amqsact── -m─QMgrName── -w─Timeout─┬─────────────────────┬─┬─────────────────┬──────►
                                      └─ -a─Application name─┘ └─ -c─Channel name─┘

►─┬──────────────────┬─┬─────────────┬────────────────────────────────────────────────►◄
  └─ -i─Connection ID─┘ └─ -v─Verbose─┘
```

V 8.0.0.2

Required parameters

-m *QMgrName*
    Name of the queue manager.

-w *Timeout*
    Time to wait, in seconds. If no trace messages appear in the specified period, **amqsact** exits.

V 8.0.0.2

Optional parameters

-a *Application name*
: Specify an application name to collect messages for

-c *Channel name*
: Specify a channel to collect messages for

-i *Connection ID*
: Specify a connection to collect messages for.

-v Verbose output

V 8.0.0.2

Example output

The following command generates and displays activity trace messages for any connections made by applications that start with the text "amqs". After 30 seconds of inactivity, the **amqsact** program ends, and no new activity trace data is generated.

```
amqsactc -m QMGR1 -w 30 -a amqs*
```

The following command generates and displays activity trace messages for any activity on the QMGR1.TO.QMGR2 channel. After 10 seconds of inactivity, the **amqsact** program ends, and no new activity trace data is generated.

```
amqsactc -m QMGR1 -w 10 -c QMGR1.TO.QMGR2
```

The following command generates and displays verbose activity trace messages for any activity on the existing IBM MQ connection that has a CONN of "6B576B5420000701", and an EXTCONN of "414D5143514D47523120202020202020". After a minute of inactivity, the **amqsact** program ends, and no new activity trace data is generated.

```
amqsactc -m QMGR1 -w 60 -i 414D5143514D475231202020202020206B576B5420000701 -v
```

Application activity trace message reference

Use this page to obtain an overview of the format of application activity trace messages and the information returned in these messages

Application activity trace messages are standard IBM MQ messages containing a message descriptor and message data. The message data contains information about the MQI operations performed by IBM MQ applications, or information about the activities occurring in an IBM MQ system.

Message descriptor
- An MQMD structure

Message data
- A PCF header (MQCFH)
- Application activity trace message data that is always returned
- Application activity trace message data that is operation-specific

Application activity trace message MQMD (message descriptor):

Use this page to understand the differences between the message descriptor of application activity trace messages and the message descriptor of event messages

The parameters and values in the message descriptor of application activity trace message are the same as in the message descriptor of event messages, with the following exception:

Format

Description:	Format name of message data.
Value:	**MQFMT_ADMIN** Admin message.

CorrelId

Description:	Correlation identifier.
Value:	Initialized with the ConnectionId of the application

MQCFH (PCF Header):

Use this page to view the PCF values contained by the MQCFH structure for an activity trace message

For an activity trace message, the MQCFH structure contains the following values:

Type

Description:	Structure type that identifies the content of the message.
Data type:	MQLONG.
Value:	MQCFT_APP_ACTIVITY

StrucLength

Description:	Length in bytes of MQCFH structure.
Data type:	MQLONG.
Value:	MQCFH_STRUC_LENGTH

Version

Description:	Structure version number.
Data type:	MQLONG.
Values:	MQCFH_VERSION_3

Command

Description:	Command identifier. This field identifies the category of the message.
Data type:	MQLONG.
Values:	MQCMD_ACTIVITY_TRACE

MsgSeqNumber

Description:	Message sequence number. This field is the sequence number of the message within a group of related messages.
Data type:	MQLONG.
Values:	1

Control

Description:	Control options.
Data type:	MQLONG.
Values:	MQCFC_LAST.

CompCode

Description:	Completion code.
Data type:	MQLONG.
Values:	MQCC_OK.

Reason

Description:	Reason code qualifying completion code.
Data type:	MQLONG.
Values:	MQRC_NONE.

ParameterCount

Description:	Count of parameter structures. This field is the number of parameter structures that follow the MQCFH structure. A group structure (MQCFGR), and its included parameter structures, are counted as one structure only.
Data type:	MQLONG.
Values:	1 or greater

Application activity trace message data:

Immediately following the PCF header is a set of parameters describing the time interval for the activity trace. These parameters also indicate the sequence of messages in the event of messages being written. The order and number of fields following the header is not guaranteed, allowing additional information to be added in the future.

Message name:	Activity trace message.
System queue:	SYSTEM.ADMIN.TRACE.ACTIVITY.QUEUE.

QueueManager

Description:	The name of the queue manager
Identifier:	MQCA_Q_MGR_NAME
Data type:	MQCFST
Maximum length:	MQ_Q_MGR_NAME_LENGTH

QSGName

z/OS

Description:	The name of QSG that the Queue Manager is a member of (z/OS only)
Identifier:	MQCA_QSG_NAME
Data type:	MQCFST
Maximum length:	MQ_Q_MGR_NAME_LENGTH

HostName

Description:	The host name of the machine the Queue Manager is running on
Identifier:	MQCACF_HOST_NAME
Data type:	MQCFST

IntervalStartDate

Description:	The date of the start of the monitoring period
Identifier:	MQCAMO_START_DATE
Data type:	MQCFST
Maximum length:	MQ_DATE_LENGTH

IntervalStartTime

Description:	The time of the start of the monitoring period
Identifier:	MQCAMO_START_TIME
Data type:	MQCFST
Maximum length:	MQ_TIME_LENGTH

IntervalEndDate

Description:	The date of the end of the monitoring period
Identifier:	MQCAMO_END_DATE
Data type:	MQCFST
Maximum length:	MQ_DATE_LENGTH

IntervalEndTime

Description:	The time of the end of the monitoring period
Identifier:	MQCAMO_END_TIME
Data type:	MQCFST
Maximum length:	MQ_TIME_LENGTH

CommandLevel

Description:	The IBM MQ command level
Identifier:	MQIA_COMMAND_LEVEL
Data type:	MQCFIN

SeqNumber

Description:	The sequence number normally zero. This value is incremented for each subsequent record for long running connections.
Identifier:	MQIACF_SEQUENCE_NUMBER
Data type:	MQCFIN

ApplicationName

Description:	The name of the application. (program name)
Identifier:	MQCACF_APPL_NAME
Data type:	MQCFST
Maximum length:	MQ_APPL_NAME_LENGTH

ApplClass

Description:	Type of application that performed the activity. Possible values: MQAT_*
Identifier:	MQIA_APPL_TYPE
Data type:	MQCFIN

ApplicationPid

Description:	The operating system Process ID of the application.
Identifier:	MQIACF_PROCESS_ID
Data type:	MQCFIN

UserId

Description:	The user identifier context of the application
Identifier:	MQCACF_USER_IDENTIFIER
Data type:	MQCFST
Maximum length:	MQ_USER_ID_LENGTH

APICallerType

Description:	The type of the application. Possible values: MQXACT_EXTERNAL or MQXACT_INTERNAL
Identifier:	MQIACF_API_CALLER_TYPE
Data type:	MQCFIN

Environment

Description:	The runtime environment of the application. Possible values: MQXE_OTHER MQXE_MCA MQXE_MCA_SVRCONN MQXE_COMMAND_SERVER MQXE_MQSC
Identifier:	MQIACF_API_ENVIRONMENT
Data type:	MQCFIN

Detail

Description:	The detail level that is recorded for the connection. Possible values: 1=LOW 2=MEDIUM 3=HIGH
Identifier:	MQIACF_TRACE_DETAIL
Data type:	MQCFIN

TraceDataLength

Description:	The length of message data (in bytes) that is traced for this connection.
Identifier:	MQIACF_TRACE_DATA_LENGTH
Data type:	MQCFIN

Pointer Size

Description:	The length (in bytes) of pointers on the platform the application is running (to assist in interpretation of binary structures)
Identifier:	MQIACF_POINTER_SIZE
Data type:	MQCFIN

Platform

Description:	The platform on which the queue manager is running. Value is one of the MQPL_* values.
Identifier:	MQIA_PLATFORM
Data type:	MQCFIN

Variable parameters for application activity MQI operations:

The application activity data `MQCFGR` structure is followed by the set of PCF parameters which corresponds to the operation being performed . The parameters for each operation are defined in the following section.

The trace level indicates the level of trace granularity that is required for the parameters to be included in the trace. The possible trace level values are:

1. Low

   The parameter is included when "low", "medium" or "high" activity tracing is configured for an application. This setting means that a parameter is always included in the AppActivityData group for the operation. This set of parameters is sufficient to trace the MQI calls an application makes, and to see if they are successful.
2. Medium

   The parameter is only included in the AppActivityData group for the operation when "medium" or "high" activity tracing is configured for an application. This set of parameters adds information about the resources, for example, queue and topic names used by the application.
3. High

   The parameter is only included in the AppActivityData group for the operation when "high" activity tracing is configured for an application. This set of parameters includes memory dumps of the structures passed to the MQI and XA functions. For this reason, it contains more information about the parameters used in MQI and XA calls. The structure memory dumps are shallow copies of the structures. To avoid erroneous attempts to dereference pointers, the pointer values in the structures are set to `NULL`.

   Note: The version of the structure that is dumped is not necessarily identical to the version used by an application. The structure can be modified by an API crossing exit, by the activity trace code, or by the queue manager. A queue manager can modify a structure to a later version, but the queue manager never changes it to an earlier version of the structure. To do so, would risk losing data.

MQBACK:

Application has started the MQBACK MQI function

`CompCode`

Description:	The completion code indicating the result of the operation
PCF Parameter:	MQIACF_COMP_CODE
Trace level:	1
Type	MQCFIN

`Reason`

Description:	The reason code result of the operation
PCF Parameter:	MQIACF_REASON_CODE
Trace level:	1
Type	MQCFIN

V 8.0.0.2 *`QMgrOpDuration`*

Description:	Approximate API call duration, in microseconds, within the queue manager. The duration does not include the time spent outside of the queue manager. For example, the time taken as an IBM MQ client. **Note:** The accuracy of this timer varies according to the platform that your enterprise uses.
PCF Parameter:	MQIAMO64_QMGR_OP_DURATION
Trace level:	2
Type	MQCFIN64

MQBEGIN:

Application has started the MQBEGIN MQI function

CompCode

Description:	The completion code indicating the result of the operation
PCF Parameter:	MQIACF_COMP_CODE
Trace level:	1
Type	MQCFIN

Reason

Description:	The reason code result of the operation
PCF Parameter:	MQIACF_REASON_CODE
Trace level:	1
Type	MQCFIN

MQBO

Description:	The MQBEGIN options structure. This parameter is not included if a NULL pointer is used on the MQBEGIN call.
PCF Parameter:	MQBACF_MQBO_STRUCT
Trace level:	3
Type	MQCFBS
Length:	The length in bytes of the MQBO structure.

V 8.0.0.2 *QMgrOpDuration*

Description:	Approximate API call duration, in microseconds, within the queue manager. The duration does not include the time spent outside of the queue manager. For example, the time taken as an IBM MQ client. **Note:** The accuracy of this timer varies according to the platform that your enterprise uses.
PCF Parameter:	MQIAMO64_QMGR_OP_DURATION
Trace level:	2
Type	MQCFIN64

MQCALLBACK:

Application has started the MQCALLBACK function

ObjectHandle

Description:	The object handle
PCF Parameter:	MQIACF_HOBJ
Trace level:	1
Type	MQCFIN

CallType

Description:	Why function has been called. One of the MQCBCT_* values
PCF Parameter:	MQIACF_CALL_TYPE
Trace level:	1
Type	MQCFIN

MsgBuffer

Description:	Message data.
PCF Parameter:	MQBACF_MESSAGE_DATA
Trace level:	1
Type	MQCFBS
Length:	Length is governed by the TRACEDATA() parameter set in the APPTRACE configuration. If TRACEDATA=NONE then this parameter is omitted.

MsgLength

Description:	Length of the message. (Taken from the DataLength field in the MQCBC structure).
PCF Parameter:	MQIACF_MSG_LENGTH
Trace level:	1
Type	MQCFIN

HighResTime

Description:	Time of operation in microseconds since midnight, January 1st 1970 (UTC) **Note:** The accuracy of this timer varies according to platform support for high a resolution timer
PCF Parameter:	MQIAMO64_HIGHRES_TIME
Trace level:	2
Type	MQCFIN64

ReportOptions

Description:	Options for report messages
PCF Parameter:	MQIACF_REPORT
Trace level:	2
Type	MQCFIN

MsgType

Description:	Type of message
PCF Parameter:	MQIACF_MSG_TYPE
Trace level:	2
Type	MQCFIN

Expiry

Description:	Message lifetime
PCF Parameter:	MQIACF_EXPIRY
Trace level:	2
Type	MQCFIN

Format

Description:	Format name of message data
PCF Parameter:	MQCACH_FORMAT_NAME
Trace level:	2
Type	MQCFST
Length:	MQ_FORMAT_LENGTH

Priority

Description:	Message priority
PCF Parameter:	MQIACF_PRIORITY
Trace level:	2
Type	MQCFIN

Persistence

Description:	Message persistence
PCF Parameter:	MQIACF_PERSISTENCE
Trace level:	2
Type	MQCFIN

MsgId

Description:	Message identifier
PCF Parameter:	MQBACF_MSG_ID
Trace level:	2
Type	MQCFBS
Length:	MQ_MSG_ID_LENGTH

CorrelId

Description:	Correlation identifier
PCF Parameter:	MQBACF_CORREL_ID
Trace level:	2
Type	MQCFBS
Length:	MQ_CORREL_ID_LENGTH

ObjectName

Description:	The name of the opened object.
PCF Parameter:	MQCACF_OBJECT_NAME
Trace level:	2
Type	MQCFST
Length:	MQ_Q_NAME_LENGTH

ResolvedQName

Description:	The local name of the queue from which the message was retrieved.
PCF Parameter:	MQCACF_RESOLVED_Q_NAME
Trace level:	2
Type	MQCFST
Length:	MQ_Q_NAME_LENGTH

ReplyToQueue

Description:	MQ_Q_NAME_LENGTH
PCF Parameter:	MQCACF_REPLY_TO_Q
Trace level:	2
Type	MQCFST

ReplyToQMgr

Description:	MQ_Q_MGR_NAME_LENGTH
PCF Parameter:	MQCACF_REPLY_TO_Q_MGR
Trace level:	2
Type	MQCFST

CodedCharSetId

Description:	Character set identifier of message data
PCF Parameter:	MQIA_CODED_CHAR_SET_ID
Trace level:	2
Type	MQCFIN

Encoding

Description:	Numeric encoding of message data.
PCF Parameter:	MQIACF_ENCODING
Trace level:	2
Type	MQCFIN

PutDate

Description:	MQ_PUT_DATE_LENGTH
PCF Parameter:	MQCACF_PUT_DATE
Trace level:	2
Type	MQCFST

PutTime

Description:	MQ_PUT_TIME_LENGTH
PCF Parameter:	MQCACF_PUT_TIME
Trace level:	2
Type	MQCFST

ResolvedQName

Description:	The queue name referred to by the ObjectHandle, when ResolvedType is MQOT_Q.
PCF Parameter:	MQCACF_RESOLVED_LOCAL _Q_NAME
Trace level:	2
Type	MQCFST
Length:	MQ_Q_NAME_LENGTH.

ResObjectString

Description:	The object name referred to by the ObjectHandle, when ResolvedType is MQOT_TOPIC.
PCF Parameter:	MQCACF_RESOLVED_OBJECT_STRING
Trace level:	2
Type	MQCFST
Length:	Length varies.

ResolvedType

Description:	The type of the object referred to by the ObjectHandle. Possible values are MQOT_Q, MQOT_TOPIC, or MQOT_NONE.
PCF Parameter:	MQIACF_RESOLVED_TYPE
Trace level:	2
Type	MQCFIN

PolicyName

Description:	The policy name that was applied to this message. **Note:** AMS protected messages only
PCF Parameter:	MQCA_POLICY_NAME
Trace level:	2
Type	MQCFST
Length:	MQ_OBJECT_NAME_LENGTH

XmitqMsgId

Description:	The message ID of the message in the transmission queue header. **Note:** Only when Format is MQFMT_XMIT_Q_HEADER
PCF Parameter:	MQBACF_XQH_MSG_ID
Trace level:	2
Type	MQCFBS
Length:	MQ_MSG_ID_LENGTH

XmitqCorrelId

Description:	The correlation ID of the message in the transmission queue header. **Note:** Only when Format is MQFMT_XMIT_Q_HEADER
PCF Parameter:	MQBACF_XQH_CORREL_ID
Trace level:	2
Type	MQCFBS
Length:	MQ_CORREL_ID_LENGTH

XmitqPutTime

Description:	The put time of the message in the transmission queue header. **Note:** Only when Format is MQFMT_XMIT_Q_HEADER
PCF Parameter:	MQCACF_XQH_PUT_TIME
Trace level:	2
Type	MQCFST
Length:	MQ_PUT_TIME_LENGTH

XmitqPutDate

Description:	The put date of the message in the transmission queue header. **Note:** Only when Format is MQFMT_XMIT_Q_HEADER
PCF Parameter:	MQCACF_XQH_PUT_DATE
Trace level:	2
Type	MQCFST
Length:	MQ_PUT_DATE_LENGTH

XmitqRemoteQName

Description:	The remote queue destination of the message in the transmission queue header. **Note:** Only when Format is MQFMT_XMIT_Q_HEADER
PCF Parameter:	MQCACF_XQH_REMOTE_Q_Name
Trace level:	2
Type	MQCFST
Length:	MQ_Q_NAME_LENGTH

XmitqRemoteQMgr

Description:	The message ID of the message in the transmission queue header. **Note:** Only when Format is MQFMT_XMIT_Q_HEADER
PCF Parameter:	MQCACF_XQH_REMOTE_Q_MGR
Trace level:	2
Type	MQCFST
Length:	MQ_MSG_ID_LENGTH

MsgDescStructure

Description:	The MQMD structure. This parameter is omitted if a version 4 MQGMO was used to request that a Message Handle be returned instead of an MQMD
PCF Parameter:	MQBACF_MQMD_STRUCT
Trace level:	3
Type	MQCFBS
Length:	The length in bytes of the MQMD structure (actual size is dependent on structure version)

GetMsgOptsStructure

Description:	The MQGMO structure.
PCF Parameter:	MQBACF_MQGMO_STRUCT
Trace level:	3
Type	MQCFBS
Length:	The length in bytes of the MQGMO structure (actual size is dependent on structure version)

MQCBContextStructure

Description:	The MQCBC structure.
PCF Parameter:	MQBACF_MQCBC_STRUCT
Trace level:	3
Type	MQCFBS
Length:	The length in bytes of the MQCBC structure (actual size is dependent on structure version)

V 8.0.0.2 *QMgrOpDuration*

Description:	Approximate API call duration, in microseconds, within the queue manager. The duration does not include the time spent outside of the queue manager. For example, the time taken as an IBM MQ client. **Note:** The accuracy of this timer varies according to the platform that your enterprise uses.
PCF Parameter:	MQIAMO64_QMGR_OP_DURATION
Trace level:	2
Type	MQCFIN64

MQCB:

Application has started the manage callback MQI function

CallbackOperation

Description:	The manage callback function operation. Set to one of the MQOP_* values
PCF Parameter:	MQIACF_MQCB_OPERATION
Trace level:	1
Type	MQCFIN

CallbackType

Description:	The type of the callback function (CallbackType field from the MQCBD structure). Set to one of the MQCBT_* values
PCF Parameter:	MQIACF_MQCB_TYPE
Trace level:	1
Type	MQCFIN

CallbackOptions

Description:	The callback options. Set to one of the MQCBDO_* values
PCF Parameter:	MQIACF_MQCB_OPTIONS
Trace level:	1
Type	MQCFIN

CallbackFunction

Description:	The pointer to the callback function if started as a function call.
PCF Parameter:	MQBACF_MQCB_FUNCTION
Trace level:	1
Type	MQCFBS
Length:	Size of MQPTR

CallbackName

Description:	The name of the callback function if started as a dynamically linked program.
PCF Parameter:	MQCACF_MQCB_NAME
Trace level:	1
Type	MQCFST
Length:	Size of MQCHAR128

ObjectHandle

Description:	The object handle
PCF Parameter:	MQIACF_HOBJ
Trace level:	1
Type	MQCFIN

MaxMsgLength

Description:	Maximum message length. Set to an integer, or the special value MQCBD_FULL_MSG_LENGTH
PCF Parameter:	MQIACH_MAX_MSG_LENGTH
Trace level:	2
Type	MQCFIN

CompCode

Description:	The completion code indicating the result of the operation
PCF Parameter:	MQIACF_COMP_CODE
Trace level:	1
Type	MQCFIN

Reason

Description:	The reason code result of the operation
PCF Parameter:	MQIACF_REASON_CODE
Trace level:	1
Type	MQCFIN

ResolvedQName

Description:	The queue name referred to by the ObjectHandle, when ResolvedType is MQOT_Q.
PCF Parameter:	MQCACF_RESOLVED_LOCAL_Q_NAME
Trace level:	2
Type	MQCFST
Length:	MQ_Q_NAME_LENGTH.

ResObjectString

Description:	The object name referred to by the ObjectHandle, when ResolvedType is MQOT_TOPIC.
PCF Parameter:	MQCACF_RESOLVED_OBJECT_STRING
Trace level:	2
Type	MQCFST
Length:	Length varies.

ResolvedType

Description:	The type of the object referred to by the ObjectHandle. Possible values are MQOT_Q, MQOT_TOPIC, or MQOT_NONE.
PCF Parameter:	MQIACF_RESOLVED_TYPE
Trace level:	2
Type	MQCFIN

CallBack DescriptorStructure

Description:	The MQCBD structure. This parameter is omitted if a NULL MQCBC value is passed to the MQCB call.
PCF Parameter:	MQBACF_MQCBD_STRUCT
Trace level:	3
Type	MQCFBS
Length:	The length in bytes of the MQCBC structure

MsgDescStructure

Description:	The MQMD structure. The MsgDescStructure parameter is omitted if a NULL MQMD value is passed to the MQCB call.
PCF Parameter:	MQBACF_MQMD_STRUCT
Trace level:	3
Type	MQCFBS
Length:	The length in bytes of the MQMD structure (actual size depends on structure version)

GetMsgOptsStructure

Description:	The MQGMO structure. This parameter is omitted if a NULL MQGMO value is passed to the MQCB call.
PCF Parameter:	MQBACF_MQGMO_STRUCT
Trace level:	3
Type	MQCFBS
Length:	The length in bytes of the MQGMO structure (actual size depends on structure version)

V 8.0.0.2 *QMgrOpDuration*

Description:	Approximate API call duration, in microseconds, within the queue manager. The duration does not include the time spent outside of the queue manager. For example, the time taken as an IBM MQ client. **Note:** The accuracy of this timer varies according to the platform that your enterprise uses.
PCF Parameter:	MQIAMO64_QMGR_OP_DURATION
Trace level:	2
Type	MQCFIN64

MQCLOSE:

Application has started the MQCLOSE MQI function

ObjectHandle

Description:	The object handle
PCF Parameter:	MQIACF_HOBJ
Trace level:	1
Type	MQCFIN

CloseOptions

Description:	Close options
PCF Parameter:	MQIACF_CLOSE_OPTIONS
Trace level:	1
Type	MQCFIN

CompCode

Description:	The completion code indicating the result of the operation
PCF Parameter:	MQIACF_COMP_CODE
Trace level:	1
Type	MQCFIN

Reason

Description:	The reason code result of the operation
PCF Parameter:	MQIACF_REASON_CODE
Trace level:	1
Type	MQCFIN

ResolvedQName

Description:	The queue name referred to by the ObjectHandle, when ResolvedType is MQOT_Q.
PCF Parameter:	MQCACF_RESOLVED_LOCAL_Q_NAME
Trace level:	2
Type	MQCFST
Length:	MQ_Q_NAME_LENGTH.

ResObjectString

Description:	The object name referred to by the ObjectHandle, when ResolvedType is MQOT_TOPIC.
PCF Parameter:	MQCACF_RESOLVED_OBJECT_STRING
Trace level:	2
Type	MQCFST
Length:	Length varies.

ResolvedType

Description:	The type of the object referred to by the ObjectHandle. Possible values are MQOT_Q, MQOT_TOPIC, or MQOT_NONE.
PCF Parameter:	MQIACF_RESOLVED_TYPE
Trace level:	2
Type	MQCFIN

V 8.0.0.2 *QMgrOpDuration*

Description:	Approximate API call duration, in microseconds, within the queue manager. The duration does not include the time spent outside of the queue manager. For example, the time taken as an IBM MQ client. **Note:** The accuracy of this timer varies according to the platform that your enterprise uses.
PCF Parameter:	MQIAMO64_QMGR_OP_DURATION
Trace level:	2
Type	MQCFIN64

MQCMIT:

Application has started the MQCMIT MQI function

CompCode

Description:	The completion code indicating the result of the operation
PCF Parameter:	MQIACF_COMP_CODE
Trace level:	1
Type	MQCFIN

Reason

Description:	The reason code result of the operation
PCF Parameter:	MQIACF_REASON_CODE
Trace level:	1
Type	MQCFIN

V 8.0.0.2 *QMgrOpDuration*

Description:	Approximate API call duration, in microseconds, within the queue manager. The duration does not include the time spent outside of the queue manager. For example, the time taken as an IBM MQ client. **Note:** The accuracy of this timer varies according to the platform that your enterprise uses.
PCF Parameter:	MQIAMO64_QMGR_OP_DURATION
Trace level:	2
Type	MQCFIN64

MQCONN and MQCONNX:

Application has started the MQCONN or MQCONNX MQI function

ConnectionId

Description:	The Connection ID if available or MQCONNID_NONE if not
PCF Parameter:	MQBACF_CONNECTION_ID
Trace level:	1
Type:	MQCFBS
Maximum length:	MQ_CONNECTION_ID_LENGTH

QueueManagerName

Description:	The (unresolved) name of the queue manager used in the MQCONN(X) call
PCF Parameter:	MQCA_Q_MGR_NAME
Trace level:	1
Type:	MQCFST
Maximum length:	MQ_Q_MGR_NAME_LENGTH

CompCode

Description:	The completion code indicating the result of the operation
PCF Parameter:	MQIACF_COMP_CODE
Trace level:	1
Type:	MQCFIN

Reason

Description:	The reason code result of the operation
PCF Parameter:	MQIACF_REASON_CODE
Trace level:	1
Type:	MQCFIN

ConnectOptions

Description:	Connect Options Derived from MQCNO_* values **Note:** MQCONNX only
PCF Parameter:	MQIACF_CONNECT_OPTIONS
Trace level:	2
Type:	MQCFIN

ConnectionOptionsStructure

Description:	The MQCNO structure. **Note:** MQCONNX only)
PCF Parameter:	MQBACF_MQCNO_STRUCT
Trace level:	3
Type:	MQCFBS
Maximum length:	The length in bytes of the MQCNO structure (actual size depends on structure version)

ChannelDefinitionStructure

Description:	The MQCD structure. **Note:** Client connections only
PCF Parameter:	MQBACF_MQCD_STRUCT
Trace level:	3
Type:	MQCFBS
Maximum length:	The length in bytes of the MQCD structure (actual size depends on structure version)

V 8.0.0.2 *QMgrOpDuration*

Description:	Approximate API call duration, in microseconds, within the queue manager. The duration does not include the time spent outside of the queue manager. For example, the time taken as an IBM MQ client. **Note:** The accuracy of this timer varies according to the platform that your enterprise uses.
PCF Parameter:	MQIAMO64_QMGR_OP_DURATION
Trace level:	2
Type	MQCFIN64

MQCTL:

Application has started the MQCTL MQI function

CompCode

Description:	The completion code indicating the result of the operation
PCF Parameter:	MQIACF_COMP_CODE
Trace level:	1
Type:	MQCFIN

Reason

Description:	The reason code result of the operation
PCF Parameter:	MQIACF_REASON_CODE
Trace level:	1
Type:	MQCFIN

CtlOperation

Description:	One of MQOP_* values
PCF Parameter:	MQIACF_CTL_OPERATION
Trace level:	1
Type:	MQCFIN

V 8.0.0.2 *QMgrOpDuration*

Description:	Approximate API call duration, in microseconds, within the queue manager. The duration does not include the time spent outside of the queue manager. For example, the time taken as an IBM MQ client. **Note:** The accuracy of this timer varies according to the platform that your enterprise uses.
PCF Parameter:	MQIAMO64_QMGR_OP_DURATION
Trace level:	2
Type	MQCFIN64

MQDISC:

Application has started the MQDISC MQI function

CompCode

Description:	The completion code indicating the result of the operation
PCF Parameter:	MQIACF_COMP_CODE
Trace level:	1
Type:	MQCFIN

Reason

Description:	The reason code result of the operation
PCF Parameter:	MQIACF_REASON_CODE
Trace level:	1
Type:	MQCFIN

MQGET:

Application has started the MQGET MQI function

ObjectHandle

Description:	The object handle
PCF Parameter:	MQIACF_HOBJ
Trace level:	1
Type:	MQCFIN

GetOptions

Description:	The get options from MQGMO.Options
PCF Parameter:	MQIACF_GET_OPTIONS
Trace level:	1
Type:	MQCFIN

CompCode

Description:	The completion code indicating the result of the operation
PCF Parameter:	MQIACF_COMP_CODE
Trace level:	1
Type:	MQCFIN

Reason

Description:	The reason code result of the operation
PCF Parameter:	MQIACF_REASON_CODE
Trace level:	1
Type:	MQCFIN

MsgBuffer

Description:	Message data. If TRACEDATA=NONE then this parameter is omitted
PCF Parameter:	MQBACF_MESSAGE_DATA
Trace level:	1
Type:	MQCFBS
Maximum length:	Length is governed by the TRACEDATA() parameter set in the APPTRACE configuration. (Included in the trace message as MQIACF_TRACE_DATA_LENGTH).

MsgLength

Description:	Length of the message.
PCF Parameter:	MQIACF_MSG_LENGTH
Trace level:	1
Type:	MQCFIN

HighResTime

Description:	Time of operation in microseconds since midnight, January 1 1970 (UTC) **Note:** The accuracy of this timer varies according to platform support for high a resolution timer
PCF Parameter:	MQIAMO64_HIGHRES_TIME
Trace level:	2
Type:	MQCFIN64

BufferLength

Description:	Length of the buffer provided by the application
PCF Parameter:	MQIACF_BUFFER_LENGTH
Trace level:	2
Type:	MQCFIN

ObjectName

Description:	The name of the opened object
PCF Parameter:	MQCACF_OBJECT_NAME
Trace level:	2
Type:	MQCFST
Length:	MQ_Q_NAME_LENGTH

ResolvedQName

Description:	The local name of the queue from which the message was retrieved.
PCF Parameter:	MQCACF_RESOLVED_Q_NAME
Trace level:	2
Type:	MQCFST
Maximum length:	MQ_Q_NAME_LENGTH

ReportOptions

Description:	Message report options
PCF Parameter:	MQIACF_REPORT
Trace level:	2
Type:	MQCFIN

MsgType

Description:	Type of message
PCF Parameter:	MQIACF_MSG_TYPE
Trace level:	2
Type:	MQCFIN

Expiry

Description:	Message lifetime
PCF Parameter:	MQIACF_EXPIRY
Trace level:	2
Type:	MQCFIN

Format

Description:	Format name of message data
PCF Parameter:	MQCACH_FORMAT_NAME
Trace level:	2
Type:	MQCFST
Maximum length:	MQ_FORMAT_LENGTH

Priority

Description:	Message priority
PCF Parameter:	MQIACF_PRIORITY
Trace level:	2
Type:	MQCFIN

Persistence

Description:	Message persistence
PCF Parameter:	MQIACF_PERSISTENCE
Trace level:	2
Type:	MQCFIN

MsgId

Description:	Message identifier
PCF Parameter:	MQBACF_MSG_ID
Trace level:	2
Type:	MQCFBS
Maximum length:	MQ_MSG_ID_LENGTH

CorrelId

Description:	Correlation identifier
PCF Parameter:	MQBACF_CORREL_ID
Trace level:	2
Type:	MQCFBS
Maximum length:	MQ_CORREL_ID_LENGTH

ReplyToQueue

Description:	
PCF Parameter:	MQCACF_REPLY_TO_Q
Trace level:	2
Type:	MQCFST
Maximum length:	MQ_Q_NAME_LENGTH

ReplyToQMgr

Description:	
PCF Parameter:	MQCACF_REPLY_TO_Q_MGR
Trace level:	2
Type:	MQCFST
Maximum length:	MQ_Q_MGR_NAME_LENGTH

CodedCharSetId

Description:	Character set identifier of message data
PCF Parameter:	MQIA_CODED_CHAR_SET_ID
Trace level:	2
Type:	MQCFIN

Encoding

Description:	Numeric encoding of message data.
PCF Parameter:	MQIACF_ENCODING
Trace level:	2
Type:	MQCFIN

PutDate

Description:	
PCF Parameter:	MQCACF_PUT_DATE
Trace level:	2
Type:	MQCFST
Maximum length:	MQ_PUT_DATE_LENGTH

PutTime

Description:	
PCF Parameter:	MQCACF_PUT_TIME
Trace level:	2
Type:	MQCFST
Maximum length:	MQ_PUT_TIME_LENGTH

ResolvedQName

Description:	The queue name referred to by the ObjectHandle, when ResolvedType is MQOT_Q.
PCF Parameter:	MQCACF_RESOLVED_LOCAL_Q_NAME
Trace level:	2
Type	MQCFST
Length:	MQ_Q_NAME_LENGTH.

ResObjectString

Description:	The object name referred to by the ObjectHandle, when ResolvedType is MQOT_TOPIC.
PCF Parameter:	MQCACF_RESOLVED_OBJECT_STRING
Trace level:	2
Type	MQCFST
Length:	Length varies.

ResolvedType

Description:	The type of the object referred to by the ObjectHandle. Possible values are MQOT_Q, MQOT_TOPIC, or MQOT_NONE.
PCF Parameter:	MQIACF_RESOLVED_TYPE
Trace level:	2
Type	MQCFIN

PolicyName

Description:	The policy name that was applied to this message. **Note:** AMS protected messages only
PCF Parameter:	MQCA_POLICY_NAME
Trace level:	2
Type:	MQCFST
Length:	MQ_OBJECT_NAME_LENGTH

XmitqMsgId

Description:	The message ID of the message in the transmission queue header. **Note:** Only when Format is MQFMT_XMIT_Q_HEADER
PCF Parameter:	MQBACF_XQH_MSG_ID
Trace level:	2
Type:	MQCFBS
Length:	MQ_MSG_ID_LENGTH

XmitqCorrelId

Description:	The correlation ID of the message in the transmission queue header. **Note:** Only when Format is MQFMT_XMIT_Q_HEADER
PCF Parameter:	MQBACF_XQH_CORREL_ID
Trace level:	2
Type:	MQCFBS
Length:	MQ_CORREL_ID_LENGTH

XmitqPutTime

Description:	The put time of the message in the transmission queue header. **Note:** Only when Format is MQFMT_XMIT_Q_HEADER
PCF Parameter:	MQCACF_XQH_PUT_TIME
Trace level:	2
Type:	MQCFST
Length:	MQ_PUT_TIME_LENGTH

XmitqPutDate

Description:	The put date of the message in the transmission queue header. **Note:** Only when Format is MQFMT_XMIT_Q_HEADER
PCF Parameter:	MQCACF_XQH_PUT_DATE
Trace level:	2
Type:	MQCFST
Length:	MQ_PUT_DATE_LENGTH

XmitqRemoteQName

Description:	The remote queue destination of the message in the transmission queue header. **Note:** Only when Format is MQFMT_XMIT_Q_HEADER
PCF Parameter:	MQCACF_XQH_REMOTE_Q_NAME
Trace level:	2
Type:	MQCFST
Length:	MQ_Q_NAME_LENGTH

XmitqRemoteQMgr

Description:	The remote queue manager destination of the message in the transmission queue header. **Note:** Only when Format is MQFMT_XMIT_Q_HEADER
PCF Parameter:	MQCACF_XQH_REMOTE_Q_MGR
Trace level:	2
Type:	MQCFST
Length:	MQ_Q_NAME_LENGTH

MsgDescStructure

Description:	The MQMD structure.
PCF Parameter:	MQBACF_MQMD_STRUCT
Trace level:	3
Type:	MQCFBS
Maximum length:	The length in bytes of the MQMD structure (actual size depends on structure version)

GetMsgOptsStructure

Description:	The MQGMO structure.
PCF Parameter:	MQBACF_MQGMO_STRUCT
Trace level:	3
Type:	MQCFBS
Maximum length:	The length in bytes of the MQGMO structure (actual size depends on structure version)

V 8.0.0.2 *QMgrOpDuration*

Description:	Approximate API call duration, in microseconds, within the queue manager. The duration does not include the time spent outside of the queue manager. For example, the time taken as an IBM MQ client. **Note:** The accuracy of this timer varies according to the platform that your enterprise uses.
PCF Parameter:	MQIAMO64_QMGR_OP_DURATION
Trace level:	2
Type	MQCFIN64

MQINQ:

Application has started the MQINQ MQI function

ObjectHandle

Description:	The object handle
PCF Parameter:	MQIACF_HOBJ
Trace level:	1
Type:	MQCFIN

CompCode

Description:	The completion code indicating the result of the operation
PCF Parameter:	MQIACF_COMP_CODE
Trace level:	1
Type:	MQCFIN

Reason

Description:	The reason code result of the operation
PCF Parameter:	MQIACF_REASON_CODE
Trace level:	1
Type:	MQCFIN

SelectorCount

Description:	The count of selectors that are supplied in the Selectors array.
PCF Parameter:	MQIACF_SELECTOR_COUNT
Trace level:	2
Type:	MQCFIN

Selectors

Description:	The list of attributes (integer or character) whose values must be returned by MQINQ.
PCF Parameter:	MQIACF_SELECTORS
Trace level:	2
Type:	MQCFIL

ResolvedQName

Description:	The queue name referred to by the ObjectHandle, when ResolvedType is MQOT_Q.
PCF Parameter:	MQCACF_RESOLVED_Q_NAME
Trace level:	2
Type:	MQCFST
Maximum length:	MQ_Q_NAME_LENGTH

ResObjectString

Description:	The object name referred to by the ObjectHandle, when ResolvedType is MQOT_TOPIC.
PCF Parameter:	MQCACF_RESOLVED_OBJECT_STRING
Trace level:	2
Type:	MQCFST
Maximum length:	Length varies

ResolvedType

Description:	The type of the object referred to by the ObjectHandle. Possible values are MQOT_Q, MQOT_TOPIC, or MQOT_NONE.
PCF Parameter:	MQIACF_RESOLVED_TYPE
Trace level:	2
Type:	MQCFIN

IntAttrCount

Description:	The number of integer attributes returned by the inquire operation
PCF Parameter:	MQIACF_INTATTR_COUNT
Trace level:	3
Type:	MQCFIN

IntAttrs

Description:	The integer attribute values returned by the inquire operation. This parameter is only present if IntAttrCount is > 0 when MQINQ returns.
PCF Parameter:	MQIACF_INT_ATTRS
Trace level:	3
Type:	MQCFIL

CharAttrs

Description:	The character attributes returned by the inquire operation. The values are concatenated together. This parameter is only included if CharAttrLength is > 0 when MQINQ returns.
PCF Parameter:	MQCACF_CHAR_ATTRS
Trace level:	3
Type:	MQCFST

V 8.0.0.2 *QMgrOpDuration*

Description:	Approximate API call duration, in microseconds, within the queue manager. The duration does not include the time spent outside of the queue manager. For example, the time taken as an IBM MQ client. **Note:** The accuracy of this timer varies according to the platform that your enterprise uses.
PCF Parameter:	MQIAMO64_QMGR_OP_DURATION
Trace level:	2
Type	MQCFIN64

MQOPEN:

Application has started the MQOPEN MQI function

ObjectType

Description:	The object type passed in MQOT.ObjectType
PCF Parameter:	MQIACF_OBJECT_TYPE
Trace level:	1
Type:	MQCFIN

ObjectName

Description:	The name of the object passed to the MQI call before any queue name resolution is attempted.
PCF Parameter:	MQCACF_OBJECT_NAME
Trace level:	1
Type:	MQCFST
Maximum length:	MQ_Q_NAME_LENGTH

ObjectQMgrName

Description:	The name of the object queue manager passed to the MQI call before any queue name resolution is attempted.
PCF Parameter:	MQCACF_OBJECT_Q_MGR_NAME
Trace level:	1
Type:	MQCFST
Maximum length:	MQ_Q_MGR_NAME_LENGTH

ObjectHandle

Description:	The object handle
PCF Parameter:	MQIACF_HOBJ
Trace level:	1
Type:	MQCFIN

CompCode

Description:	The completion code indicating the result of the operation
PCF Parameter:	MQIACF_COMP_CODE
Trace level:	1
Type:	MQCFIN

Reason

Description:	The reason code result of the operation
PCF Parameter:	MQIACF_REASON_CODE
Trace level:	1
Type:	MQCFIN

OpenOptions

Description:	Options used to open the object
PCF Parameter:	MQIACF_OPEN_OPTIONS
Trace level:	1
Type:	MQCFIN

AlternateUserId

Description:	Only included if MQOO_ALTERNATE_USER_AUTHORITY is specified
PCF Parameter:	MQCACF_ALTERNATE_USERID
Trace level:	2
Type:	MQCFST
Maximum length:	MQ_USER_ID_LENGTH

RecsPresent

Description:	The number of object name records present. Only included if MQOD Version >= MQOD_VERSION_2
PCF Parameter:	MQIACF_RECS_PRESENT
Trace level:	1
Type:	MQCFIN

KnownDestCount

Description:	Number of local queues opened successfully Only included if MQOD Version >= MQOD_VERSION_2
PCF Parameter:	MQIACF_KNOWN_DEST_COUNT
Trace level:	1
Type:	MQCFIN

UnknownDestCount

Description:	Number of remote queues opened successfully Only included if MQOD Version >= MQOD_VERSION_2
PCF Parameter:	MQIACF_UNKNOWN_DEST_COUNT
Trace level:	1
Type:	MQCFIN

InvalidDestCount

Description:	Number of queues that failed to open Only included if MQOD Version >= MQOD_VERSION_2
PCF Parameter:	MQIACF_INVALID_DEST_COUNT
Trace level:	1
Type:	MQCFIN

DynamicQName

Description:	The dynamic queue name passed as input to the MQOPEN call.
PCF Parameter:	MQCACF_DYNAMIC_Q_NAME
Trace level:	2
Type:	MQCFST
Maximum length:	MQ_Q_NAME_LENGTH

ResolvedLocalQName [3] [4]

Description:	Contains the local queue name after name resolution has been carried out. (e.g. for remote queues this will be the name of the transmit queue)
PCF Parameter:	MQCACF_RESOLVED_LOCAL_Q_NAME
Trace level:	2
Type:	MQCFST
Range:	If MQOD.Version is less than MQOD_VERSION_3 this contains the value of the MQOD.ObjectName field after the MQOPEN call has completed. If MQOD.Version is equal or greater than MQOD_VERSION_3 this contains the value in the MQOD. ResolvedQName field.
Maximum length:	MQ_Q_NAME_LENGTH

ResolvedLocalQMgrName 3 4

Description:	The local queue manager name after name resolution has been performed.
PCF Parameter:	MQCACF_RESOLVED_LOCAL_Q_MGR
Trace level:	2
Type:	MQCFST
Range:	Only if MQOD.Version >= MQOD_VERSION_3
Maximum length:	MQ_Q_MGR_NAME_LENGTH

ResolvedQName 3 4

Description:	The queue name after name resolution has been carried out.
PCF Parameter:	MQCACF_RESOLVED_Q_NAME
Trace level:	2
Type:	MQCFST
Range:	If MQOD.Version is less than MQOD_VERSION_3 this contains the value of the MQOD.ObjectName field after the MQOPEN call has completed. If MQOD.Version is equal or greater than MQOD_VERSION_3 this contains the value in the MQOD. ResolvedQName field.
Maximum length:	MQ_Q_NAME_LENGTH

ResolvedQMgrName 3 4

Description:	Contains the queue manager name after name resolution has been carried out. If MQOD.Version is less than MQOD_VERSION_3 this contains the value of the MQOD. ObjectQMgrName field after the MQOPEN call has completed. If MQOD.Version is equal or greater than MQOD_VERSION_3 this contains the value in the MQOD. ResolvedQMgrName field.
PCF Parameter:	MQCACF_RESOLVED_Q_MGR
Trace level:	2
Type:	MQCFST
Maximum length:	MQ_Q_MGR_NAME_LENGTH

AlternateSecurityId

Description:	Alternative security identifier. Only present if MQOD.Version is equal or greater than MQOD_VERSION_3, MQOO_ALTERNATE_USER_AUTHORITY is specified, and MQOD.AlternateSecurityId is not equal to MQSID_NONE.
PCF Parameter:	MQBACF_ALTERNATE_SECURITYID
Trace level:	2
Type:	MQCFBS
Maximum length:	MQ_SECURITY_ID_LENGTH

ObjectString

Description:	Long object name. Only included if MQOD.Version is equal or greater than MQOD_VERSION_4 and the VSLength field of MQOD.ObjectString is MQVS_NULL_TERMINATED or greater than zero.
PCF Parameter:	MQCACF_OBJECT_STRING
Trace level:	2
Type:	MQCFST
Maximum length:	Length varies.

SelectionString

Description:	Selection string. Only included if MQOD.Version is equal or greater than MQOD_VERSION_4 and the VSLength field of MQOD. SelectionString is MQVS_NULL_TERMINATED or greater than zero.
PCF Parameter:	MQCACF_SELECTION_STRING
Trace level:	2
Type:	MQCFST
Maximum length:	Length varies.

ResObjectString

Description:	The long object name after the queue manager resolves the name provided in the ObjectName field. Only included for topics and queue aliases that reference a topic object if MQOD.Version is equal or greater than MQOD_VERSION_4 and VSLength is MQVS_NULL_TERMINATED or greater than zero.
PCF Parameter:	MQCACF_RESOLVED_OBJECT_STRING
Trace level:	2
Type:	MQCFST
Maximum length:	Length varies.

ResolvedType

Description:	The type of the resolved (base) object being opened. Only included if MQOD.Version is equal or greater than MQOD_VERSION_4. Possible values are MQOT_Q, MQOT_TOPIC, or MQOT_NONE.
PCF Parameter:	MQIACF_RESOLVED_TYPE
Trace level:	2
Type:	MQCFIN

V 8.0.0.2 *QMgrOpDuration*

Description:	Approximate API call duration, in microseconds, within the queue manager. The duration does not include the time spent outside of the queue manager. For example, the time taken as an IBM MQ client. **Note:** The accuracy of this timer varies according to the platform that your enterprise uses.
PCF Parameter:	MQIAMO64_QMGR_OP_DURATION
Trace level:	2
Type	MQCFIN64

Application Activity Distribution List PCF Group Header Structure:

If the MQOPEN function opens a distribution list, then the MQOPEN parameters includes one AppActivityDistList PCF group for each of the queues in the distribution list up to the number of structures numbered in RecsPresent. The Ap-pActivityDistList PCF group combines information from the MQOR, and MQRR structures to identify the queue name, and indicate the result of the open operation on the queue. An AppActivityDistList group always starts with the following MQCFGR structure:

Table 129. AppActivityDistList group MQCFGR structure

MQCFGR field	Value	Description
Type	MQCFT_GROUP	
StrucLength	Length in bytes of the MQCFGR structure	
Parameter	MQGACF_APP_DIST_LIST	Distribution list group parameter
ParameterCount	4	The number of parameter structures following the MQCFGR structure that are contained within this group.

ObjectName

Description:	The name of a queue in the distribution list MQ_Q_NAME_LENGTH. Only included if MQOR structures are provided.
PCF Parameter:	MQCACF_OBJECT_NAME
Trace level:	2
Type:	MQCFST
Length:	MQ_Q_NAME_LENGTH. Only included if MQOR structures are provided.

ObjectQMgrName

Description:	The name of the queue manager on which the queue named in ObjectName is defined.
PCF Parameter:	MQCACF_OBJECT_Q_MGR_NAME
Trace level:	2
Type:	MQCFST
Length:	MQ_Q_MGR_NAME_LENGTH. Only included if MQOR structures are provided.

CompCode

3. This parameter is only included if the object being opened resolves to a queue, and the queue is opened for MQOO_INPUT_*, MQOO_OUTPUT, or MQOO_BROWSE

4. The ResolvedLocalQName parameter is only included if it is different from the ResolvedQName parameter.

Description:	The completion code indicating the result of the open for this object. Only included if MQRR structures are provided and the reason code for the MQOPEN is MQRC_MULTIPLE_REASONS
PCF Parameter:	MQIACF_COMP_CODE
Trace level:	2
Type:	MQCFIN

Reason

Description:	The reason code indicating the result of the open for this object. Only included if MQRR structures are provided and the reason code for the MQOPEN is MQRC_MULTIPLE_REASONS
PCF Parameter:	MQIACF_REASON_CODE
Trace level:	2
Type:	MQCFIN

MQPUT:

Application has started the MQPUT MQI function.

ObjectHandle

Description:	The object handle
PCF Parameter:	MQIACF_HOBJ
Trace level:	1
Type:	MQCFIN

PutOptions

Description:	The put options from MQPMO.Options
PCF Parameter:	MQIACF_PUT_OPTIONS
Trace level:	1
Type:	MQCFIN

CompCode

Description:	The completion code indicating the result of the operation
PCF Parameter:	MQIACF_COMP_CODE
Trace level:	1
Type:	MQCFIN

Reason

Description:	The reason code result of the operation
PCF Parameter:	MQIACF_REASON_CODE
Trace level:	1
Type:	MQCFIN

MsgBuffer

Description:	Message data.
PCF Parameter:	MQBACF_MESSAGE_DATA
Trace level:	1
Type:	MQCFBS
Length:	Length is governed by the TRACEDATA() parameter set in the APPTRACE configuration. If TRACEDATA=NONE then this parameter is omitted.

MsgLength

Description:	Length of the message.
PCF Parameter:	MQIACF_MSG_LENGTH
Trace level:	1
Type:	MQCFIN

RecsPresent

Description:	The number of put message records or response records present. Only included if MQPMO Version >= MQPMO_VERSION_2
PCF Parameter:	MQIACF_RECS_PRESENT
Trace level:	1
Type:	MQCFIN

KnownDestCount

Description:	Number of messages sent successfully to local queues
PCF Parameter:	MQIACF_KNOWN_DEST_COUNT
Trace level:	1
Type:	MQCFIN

UnknownDestCount

Description:	Number of messages sent successfully to remote queues
PCF Parameter:	MQIACF_UNKNOWN_DEST_COUNT
Trace level:	1
Type:	MQCFIN

InvalidDestCount

Description:	Number of messages that could not be sent
PCF Parameter:	MQIACF_INVALID_DEST_COUNT
Trace level:	1
Type:	MQCFIN

HighResTime

Description:	Time of operation in microseconds since midnight, January 1st 1970 (UTC) **Note:** The accuracy of this timer varies according to platform support for high a resolution timer.
PCF Parameter:	MQIAMO64_HIGHRES_TIME
Trace level:	2
Type:	MQCFIN64

ObjectName

Description:	The name of the opened object.
PCF Parameter:	MQCACF_OBJECT_NAME
Trace level:	2
Type:	MQCFST
Length:	MQ_Q_NAME_LENGTH

ResolvedQName

Description:	The name of the queue after queue name resolution has been performed.
PCF Parameter:	MQCACF_RESOLVED_Q_NAME
Trace level:	2
Type:	MQCFST
Length:	MQ_Q_NAME_LENGTH

ResolvedQMgrName

Description:	The queue manager name after name resolution has been performed.
PCF Parameter:	MQCACF_RESOLVED_Q_MGR
Trace level:	2
Type:	MQCFST
Length:	MQ_Q_MGR_NAME_LENGTH

ResolvedLocalQName [5]

Description:	Contains the local queue name after name resolution has been carried out.
PCF Parameter:	MQCACF_RESOLVED_LOCAL_Q_NAME
Trace level:	2
Type:	MQCFST

ResolvedLocalQMgrName [5]

Description:	Contains the local queue manager name after name resolution has been carried out.
PCF Parameter:	MQCACF_RESOLVED_LOCAL_Q_MGR
Trace level:	2
Type:	MQCFST
Length:	MQ_Q_MGR_NAME_LENGTH

ReportOptions

Description:	Message report options
PCF Parameter:	MQIACF_REPORT
Trace level:	2
Type:	MQCFIN

MsgType

Description:	Type of message
PCF Parameter:	MQIACF_MSG_TYPE
Trace level:	2
Type:	MQCFIN

Expiry

Description:	Message lifetime
PCF Parameter:	MQIACF_EXPIRY
Trace level:	2
Type:	MQCFIN

Format

Description:	Format name of message data
PCF Parameter:	MQCACH_FORMAT_NAME
Trace level:	2
Type:	MQCFST
Length:	MQ_FORMAT_LENGTH

Priority

Description:	Message priority
PCF Parameter:	MQIACF_PRIORITY
Trace level:	2
Type:	MQCFIN

Persistence

Description:	Message persistence
PCF Parameter:	MQIACF_PERSISTENCE
Trace level:	2
Type:	MQCFIN

MsgId

Description:	Message identifier
PCF Parameter:	MQBACF_MSG_ID
Trace level:	2
Type:	MQCFBS
Length:	MQ_MSG_ID_LENGTH

CorrelId

Description:	Correlation identifier
PCF Parameter:	MQBACF_CORREL_ID
Trace level:	2
Type:	MQCFBS
Length:	MQ_CORREL_ID_LENGTH

ReplyToQueue

Description:	
PCF Parameter:	MQCACF_REPLY_TO_Q
Trace level:	2
Type:	MQCFST
Length:	MQ_Q_NAME_LENGTH

ReplyToQMgr

Description:	
PCF Parameter:	MQCACF_REPLY_TO_Q_MGR
Trace level:	2
Type:	MQCFST
Length:	MQ_Q_MGR_NAME_LENGTH

CodedCharSetId

Description:	Character set identifier of message data
PCF Parameter:	MQIA_CODED_CHAR_SET_ID
Trace level:	2
Type:	MQCFIN

Encoding

Description:	Numeric encoding of message data.
PCF Parameter:	MQIACF_ENCODING
Trace level:	2
Type:	MQCFIN

PutDate

Description:	
PCF Parameter:	MQCACF_PUT_DATE
Trace level:	2
Type:	MQCFST
Length:	MQ_PUT_DATE_LENGTH

PutTime

Description:	
PCF Parameter:	MQCACF_PUT_TIME
Trace level:	2
Type:	MQCFST
Length:	MQ_PUT_TIME_LENGTH

ResolvedQName

Description:	The queue name referred to by the ObjectHandle, when ResolvedType is MQOT_Q.
PCF Parameter:	MQCACF_RESOLVED_LOCAL_Q_NAME
Trace level:	2
Type:	MQCFST
Length:	MQ_Q_NAME_LENGTH.

ResObjectString

Description:	The object name referred to by the ObjectHandle, when ResolvedType is MQOT_TOPIC.
PCF Parameter:	MQCACF_RESOLVED_OBJECT_STRING
Trace level:	2
Type:	MQCFST
Length:	Length varies.

ResolvedType

Description:	The type of the object referred to by the ObjectHandle. Possible values are MQOT_Q, MQOT_TOPIC, or MQOT_NONE.
PCF Parameter:	MQIACF_RESOLVED_TYPE
Trace level:	2
Type:	MQCFIN

PolicyName

Description:	The policy name that was applied to this message. **Note:** AMS protected messages only
PCF Parameter:	MQCA_POLICY_NAME
Trace level:	2
Type:	MQCFST
Length:	MQ_OBJECT_NAME_LENGTH

XmitqMsgId

Description:	The message ID of the message in the transmission queue header. **Note:** Only when Format is MQFMT_XMIT_Q_HEADER
PCF Parameter:	MQBACF_XQH_MSG_ID
Trace level:	2
Type:	MQCFBS
Length:	MQ_MSG_ID_LENGTH

XmitqCorrelId

Description:	The correlation ID of the message in the transmission queue header. **Note:** Only when Format is MQFMT_XMIT_Q_HEADER
PCF Parameter:	MQBACF_XQH_CORREL_ID
Trace level:	2
Type:	MQCFBS
Length:	MQ_CORREL_ID_LENGTH

XmitqPutTime

Description:	The put time of the message in the transmission queue header. **Note:** Only when Format is MQFMT_XMIT_Q_HEADER
PCF Parameter:	MQCACF_XQH_PUT_TIME
Trace level:	2
Type:	MQCFST
Length:	MQ_PUT_TIME_LENGTH

XmitqPutDate

Description:	The put date of the message in the transmission queue header. **Note:** Only when Format is MQFMT_XMIT_Q_HEADER
PCF Parameter:	MQCACF_XQH_PUT_DATE
Trace level:	2
Type:	MQCFST
Length:	MQ_PUT_DATE_LENGTH

XmitqRemoteQName

Description:	The remote queue destination of the message in the transmission queue header. **Note:** Only when Format is MQFMT_XMIT_Q_HEADER
PCF Parameter:	MQCACF_XQH_REMOTE_Q_NAME
Trace level:	2
Type:	MQCFST
Length:	MQ_Q_NAME_LENGTH

XmitqRemoteQMgr

Description:	The remote queue manager destination of the message in the transmission queue header. **Note:** Only when Format is MQFMT_XMIT_Q_HEADER
PCF Parameter:	MQCACF_XQH_REMOTE_Q_MGR
Trace level:	2
Type:	MQCFST
Length:	MQ_Q_NAME_LENGTH

PutMsgOptsStructure

Description:	The MQPMO structure.
PCF Parameter:	MQBACF_MQPMO_STRUCT
Trace level:	3
Type:	MQCFBS
Length:	The length in bytes of the MQPMO structure (actual size depends on structure version)

V 8.0.0.2 *QMgrOpDuration*

Description:	Approximate API call duration, in microseconds, within the queue manager. The duration does not include the time spent outside of the queue manager. For example, the time taken as an IBM MQ client. **Note:** The accuracy of this timer varies according to the platform that your enterprise uses.
PCF Parameter:	MQIAMO64_QMGR_OP_DURATION
Trace level:	2
Type	MQCFIN64

MQPUT Application Activity Distribution List PCF Group Header Structure:

If the MQPUT function is putting to a distribution list, then the MQPUT parameters include one AppActivityDistList PCF group. For each of the queues in the distribution list, see "Application Activity Distribution List PCF Group Header Structure" on page 1170. The AppActivityDistList PCF group combines information from the MQPMR, and MQRR structures to identify the PUT parameters, and indicate the result of the PUT operation on each queue. For MQPUT operations the AppActivityDistList group contains some or all of the following parameters (the CompCode and Reason is present if the reason code is MQRC_MULTIPLE_REASONS and the other parameters are determined by the MQPMO.PutMsgRecFields field):

CompCode

Description:	The completion code indicating the result of the operation. Only included if MQRR structures are provided and the reason code for the MQPUT is MQRC_MULTIPLE_REASONS
PCF Parameter:	MQIACF_COMP_CODE
Trace level:	2
Type:	MQCFIN

Reason

Description:	The reason code indicating the result of the put for this object. Only included if MQRR structures are provided and the reason code for the MQPUT is MQRC_MULTIPLE_REASONS
PCF Parameter:	MQIACF_REASON_CODE
Trace level:	2
Type:	MQCFIN

MsgId

5. The ResolvedLocalQName parameter is only included if it is different from the ResolvedQName parameter.

Description:	Message identifier. Only included if MQPMR structures are provided.and PutMsgRecFields includes MQPMRF_MSG_ID
PCF Parameter:	MQBACF_MSG_ID
Trace level:	2
Type:	MQCFBS
Length:	MQ_MSG_ID_LENGTH

CorrelId

Description:	Correlation identifier. Only included if MQPMR structures are provided.and PutMsgRecFields includes MQPMRF_CORREL_ID
PCF Parameter:	MQBACF_CORREL_ID
Trace level:	2
Type:	MQCFBS
Length:	MQ_CORREL_ID_LENGTH

GroupId

Description:	Group identifier. Only included if MQPMR structures are provided.and PutMsgRecFields includes MQPMRF_GROUP_ID
PCF Parameter:	MQBACF_GROUP_ID
Trace level:	2
Type:	MQCFBS
Length:	MQ_GROUP_ID_LENGTH

Feedback

Description:	Feedback. Only included if MQPMR structures are provided.and PutMsgRecFields includes MQPMRF_FEEDBACK
PCF Parameter:	MQIACF_FEEDBACK
Trace level:	2
Type:	MQCFIN

AccountingToken

Description:	AccountingToken. Only included if MQPMR structures are provided.and PutMsgRecFields includes MQPMRF_ACCOUNTING_TOKEN
PCF Parameter:	MQBACF_ACCOUNTING_TOKEN
Trace level:	2
Type:	MQCFBS
Length:	MQ_ACCOUNTING_TOKEN_LENGTH.

MQPUT1:

Application has started the MQPUT1 MQI function

ObjectType

Description:	The object type passed in MQOT.ObjectType
PCF Parameter:	MQIACF_OBJECT_TYPE
Trace level:	1
Type:	MQCFIN

ObjectName

Description:	The name of the object passed to the MQI call before any queue name resolution is attempted.
PCF Parameter:	MQCACF_OBJECT_NAME
Trace level:	1
Type:	MQCFST
Length:	MQ_Q_NAME_LENGTH

ObjectQMgrName

Description:	The name of the object queue manager passed to the MQI call before any queue name resolution is attempted.
PCF Parameter:	MQCACF_OBJECT_Q_MGR_NAME
Trace level:	1
Type:	MQCFST
Length:	MQ_Q_MGR_NAME_LENGTH

CompCode

Description:	The completion code indicating the result of the operation
PCF Parameter:	MQIACF_COMP_CODE
Trace level:	1
Type:	MQCFIN

Reason

Description:	The reason code result of the operation
PCF Parameter:	MQIACF_REASON_CODE
Trace level:	1
Type:	MQCFIN

PutOptions

Description:	The put options from MQPMO.Options
PCF Parameter:	MQIACF_PUT_OPTIONS
Trace level:	1
Type:	MQCFIN

AlternateUserId

Description:	Only included if MQPMO_ALTERNATE_USER_AUTHORITY is specified.
PCF Parameter:	MQCACF_ALTERNATE_USERID
Trace level:	2
Type:	MQCFST
Length:	MQ_USER_ID_LENGTH

RecsPresent

Description:	The number of object name records present
PCF Parameter:	MQIACF_RECS_PRESENT
Trace level:	1
Type:	MQCFIN

KnownDestCount

Description:	Number of local queues opened successfully
PCF Parameter:	MQIACF_KNOWN_DEST_COUNT
Trace level:	1
Type:	MQCFIN

UnknownDestCount

Description:	Number of remote queues opened successfully
PCF Parameter:	MQIACF_UNKNOWN_DEST_COUNT
Trace level:	1
Type:	MQCFIN

InvalidDestCount

Description:	Number of queues that failed to open
PCF Parameter:	MQIACF_INVALID_DEST_COUNT
Trace level:	1
Type:	MQCFIN

MsgBuffer

Description:	Message data.
PCF Parameter:	MQBACF_MESSAGE_DATA
Trace level:	1
Type:	MQCFBS
Length:	Length is governed by the TRACEDATA() parameter set in the APPTRACE configuration. If TRACEDATA=NONE then this parameter is omitted.

MsgLength

Description:	Length of the message.
PCF Parameter:	MQIACF_MSG_LENGTH
Trace level:	1
Type:	MQCFIN

HighResTime

Description:	Time of operation in microseconds since midnight, January 1st 1970 (UTC) **Note:** The accuracy of this timer will vary according to platform support for high a resolution timer.
PCF Parameter:	MQIAMO64_HIGHRES_TIME
Trace level:	2
Type:	MQCFIN64

ResolvedQName

Description:	The name of the queue after queue name resolution has been performed.
PCF Parameter:	MQCACF_RESOLVED_Q_NAME
Trace level:	2
Type:	MQCFST
Length:	MQ_Q_NAME_LENGTH

ResolvedQMgrName

Description:	The queue manager name after name resolution has been performed.
PCF Parameter:	MQCACF_RESOLVED_Q_MGR
Trace level:	2
Type:	MQCFST
Length:	MQ_Q_MGR_NAME_LENGTH

ResolvedLocalQName [6]

Description:	Contains the local queue name after name resolution has been carried out
PCF Parameter:	MQCACF_RESOLVED_LOCAL_Q_NAME
Trace level:	2
Type:	MQCFST

ResolvedLocalQMgrName [6]

Description:	Contains the local queue manager name after name resolution has been carried out.
PCF Parameter:	MQCACF_RESOLVED_LOCAL_Q_MGR
Trace level:	2
Type:	MQCFST
Length:	MQ_Q_MGR_NAME_LENGTH

AlternateSecurityId

Description:	Alternate security identifier. Only present if MQOD.Version is equal or greater than MQOD_VERSION_3 and MQOD.AlternateSecurityId is not equal to MQSID_NONE.
PCF Parameter:	MQBACF_ALTERNATE_SECURITYID
Trace level:	2
Type:	MQCFBS
Length:	MQ_SECURITY_ID_LENGTH

ObjectString

Description:	Long object name. Only included if MQOD.Version is equal or greater than MQOD_VERSION_4 and the VSLength field of MQOD.ObjectString is MQVS_NULL_TERMINATED or greater than zero.
PCF Parameter:	MQCACF_OBJECT_STRING
Trace level:	2
Type:	MQCFST
Length:	Length varies.

ResObjectString

Description:	The long object name after the queue manager resolves the name provided in the ObjectName field. Only included for topics and queue aliases that reference a topic object if MQOD.Version is equal or greater than MQOD_VERSION_4 and VSLength is MQVS_NULL_TERMINATED or greater than zero.
PCF Parameter:	MQCACF_RESOLVED_OBJECT_STRING
Trace level:	2
Type:	MQCFST
Length:	Length varies.

ResolvedType

Description:	The type of the resolved (base) object being opened. Only included if MQOD.Version is equal or greater than MQOD_VERSION_4. Possible values are MQOT_Q, MQOT_TOPIC, or MQOT_NONE.
PCF Parameter:	MQIACF_RESOLVED_TYPE
Trace level:	2
Type:	MQCFIN

ReportOptions

Description:	Message report options
PCF Parameter:	MQIACF_REPORT
Trace level:	2
Type:	MQCFIN

MsgType

Description:	Type of message
PCF Parameter:	MQIACF_MSG_TYPE
Trace level:	2
Type:	MQCFIN

Expiry

Description:	Message lifetime
PCF Parameter:	MQIACF_EXPIRY
Trace level:	2
Type:	MQCFIN

Format

Description:	Format name of message data
PCF Parameter:	MQCACH_FORMAT_NAME
Trace level:	2
Type:	MQCFST
Length:	MQ_FORMAT_LENGTH

Priority

Description:	Message priority
PCF Parameter:	MQIACF_PRIORITY
Trace level:	2
Type:	MQCFIN

Persistence

Description:	Message persistence
PCF Parameter:	MQIACF_PERSISTENCE
Trace level:	2
Type:	MQCFIN

MsgId

Description:	Message identifier
PCF Parameter:	MQBACF_MSG_ID
Trace level:	2
Type:	MQCFBS
Length:	MQ_MSG_ID_LENGTH

CorrelId

PCF Parameter:	Correlation identifier
Description:	MQBACF_CORREL_ID
Trace level:	2
Type:	MQCFBS
Length:	MQ_CORREL_ID_LENGTH

ReplyToQueue

Description:	
PCF Parameter:	MQCACF_REPLY_TO_Q
Trace level:	2
Type:	MQCFST
Length:	MQ_Q_NAME_LENGTH

ReplyToQMgr

Description:	
PCF Parameter:	MQCACF_REPLY_TO_Q_MGR
Trace level:	2
Type:	MQCFST
Length:	MQCFST

CodedCharSetId

Description:	Character set identifier of message data
PCF Parameter:	MQIA_CODED_CHAR_SET_ID
Trace level:	2
Type:	MQCFIN

Encoding

Description:	Numeric encoding of message data.
PCF Parameter:	MQIACF_ENCODING
Trace level:	2
Type:	MQCFIN

PutDate

Description:	
PCF Parameter:	MQCACF_PUT_DATE
Trace level:	2
Type:	MQCFST
Length:	MQ_PUT_DATE_LENGTH

PutTime

Description:	
PCF Parameter:	MQCACF_PUT_TIME
Trace level:	2
Type:	MQCFST
Length:	MQ_PUT_TIME_LENGTH

PolicyName

Description:	The policy name that was applied to this message. **Note:** AMS protected messages only
PCF Parameter:	MQCA_POLICY_NAME
Trace level:	2
Type:	MQCFST
Length:	MQ_OBJECT_NAME_LENGTH

XmitqMsgId

Description:	The message ID of the message in the transmission queue header. **Note:** Only when Format is MQFMT_XMIT_Q_HEADER
PCF Parameter:	MQBACF_XQH_MSG_ID
Trace level:	2
Type:	MQCFBS
Length:	MQ_MSG_ID_LENGTH

XmitqCorrelId

Description:	The correlation ID of the message in the transmission queue header. **Note:** Only when Format is MQFMT_XMIT_Q_HEADER
PCF Parameter:	MQBACF_XQH_CORREL_ID
Trace level:	2
Type:	MQCFBS
Length:	MQ_CORREL_ID_LENGTH

XmitqPutTime

Description:	The put time of the message in the transmission queue header. **Note:** Only when Format is MQFMT_XMIT_Q_HEADER
PCF Parameter:	MQCACF_XQH_PUT_TIME
Trace level:	2
Type:	MQCFST
Length:	MQ_PUT_TIME_LENGTH

XmitqPutDate

Description:	The put date of the message in the transmission queue header. **Note:** Only when Format is MQFMT_XMIT_Q_HEADER
PCF Parameter:	MQCACF_XQH_PUT_DATE
Trace level:	2
Type:	MQCFST
Length:	MQ_PUT_DATE_LENGTH

XmitqRemoteQName

Description:	The remote queue destination of the message in the transmission queue header. **Note:** Only when Format is MQFMT_XMIT_Q_HEADER
PCF Parameter:	MQCACF_XQH_REMOTE_Q_NAME
Trace level:	2
Type:	MQCFST
Length:	MQ_Q_NAME_LENGTH

XmitqRemoteQMgr

Description:	The remote queue manager destination of the message in the transmission queue header. **Note:** Only when Format is MQFMT_XMIT_Q_HEADER
PCF Parameter:	MQCACF_XQH_REMOTE_Q_MGR
Trace level:	2
Type:	MQCFST
Length:	MQ_Q_NAME_LENGTH

PutMsgOptsStructure

Description:	The MQPMO structure.
PCF Parameter:	MQBACF_MQPMO_STRUCT
Trace level:	3
Type:	MQCFBS
Length:	The length in bytes of the MQPMO structure (actual size depends on structure version)

V 8.0.0.2 *QMgrOpDuration*

Description:	Approximate API call duration, in microseconds, within the queue manager. The duration does not include the time spent outside of the queue manager. For example, the time taken as an IBM MQ client. **Note:** The accuracy of this timer varies according to the platform that your enterprise uses.
PCF Parameter:	MQIAMO64_QMGR_OP_DURATION
Trace level:	2
Type	MQCFIN64

MQPUT1 AppActivityDistList PCF Group Header Structure:

If the MQPUT1 function is putting to a distribution list, then the variable parameters include one AppActivityDistList PCF group. For each of the queues in the distribution list, see “Application Activity Distribution List PCF Group Header Structure” on page 1170. The AppActivityDistList PCF group combines information from the MQOR, MQPMR, and MQRR structures to identify the objects, and the PUT parameters , and indicate the result of the PUT operation on each queue. For MQPUT1 operations the AppActivityDistList group contains some or all of the following parameters (the CompCode, Reason, ObjectName, and ObjectQMgrName is present if the reason code is MQRC_MULTIPLE_REASONS and the other parameters is determined by the MQPMO.PutMsgRecFields field):

CompCode

6. The ResolvedLocalQName parameter is only included if it is different from the ResolvedQName parameter.

Description:	The completion code indicating the result of the put for this object. Only included if MQRR structures are provided and the reason code for the MQPUT1 is MQRC_MULTIPLE_REASONS
PCF Parameter:	MQIACF_COMP_CODE
Trace level:	2
Type:	MQCFIN

Reason

Description:	The reason code indicating the result of the put for this object. Only included if MQRR structures are provided and the reason code for the MQPUT1 is MQRC_MULTIPLE_REASONS
PCF Parameter:	MQIACF_REASON_CODE
Trace level:	2
Type:	MQCFIN

ObjectName

Description:	The name of a queue in the distribution list. Only included if MQOR structures are provided.
PCF Parameter:	MQCACF_OBJECT_NAME
Trace level:	2
Type:	MQCFST
Length:	MQ_Q_NAME_LENGTH

MsgId

Description:	Message identifier. Only included if MQPMR structures are provided.and PutMsgRecFields includes MQPMRF_MSG_ID
PCF Parameter:	MQBACF_MSG_ID
Trace level:	2
Type:	MQCFBS
Length:	MQ_MSG_ID_LENGTH

CorrelId

Description:	Correlation identifier. Only included if MQPMR structures are provided.and PutMsgRecFields includes MQPMRF_CORREL_ID
PCF Parameter:	MQBACF_CORREL_ID
Trace level:	2
Type:	MQCFBS
Length:	MQ_CORREL_ID_LENGTH

GroupId

Description:	Group identifier. Only included if MQPMR structures are provided.and PutMsgRecFields includes MQPMRF_GROUP_ID
PCF Parameter:	MQBACF_GROUP_ID
Trace level:	2
Type:	MQCFBS
Length:	MQ_GROUP_ID_LENGTH

Feedback

Description:	Feedback. Only included if MQPMR structures are provided.and PutMsgRecFields includes MQPMRF_FEEDBACK
PCF Parameter:	MQIACF_FEEDBACK
Trace level:	2
Type:	MQCFIN

AccountingToken

Description:	AccountingToken. Only included if MQPMR structures are provided.and PutMsgRecFields includes MQPMRF_ACCOUNTING_TOKEN
PCF Parameter:	MQBACF_ACCOUNTING_TOKEN
Trace level:	2
Type:	MQCFBS
Length:	MQ_ACCOUNTING_TOKEN_LENGTH.

MQSET:

Application has started the MQSET MQI function

ObjectHandle

Description:	The object handle
PCF Parameter:	MQIACF_HOBJ
Trace level:	1
Type:	MQCFIN

CompCode

Description:	The completion code indicating the result of the operation
PCF Parameter:	MQIACF_COMP_CODE
Trace level:	1
Type:	MQCFIN

Reason

Description:	The reason code result of the operation
PCF Parameter:	MQIACF_REASON_CODE
Trace level:	1
Type:	MQCFIN

SelectorCount

Description:	The count of selectors that are supplied in the Selectors array.
PCF Parameter:	MQIACF_SELECTOR_COUNT
Trace level:	2
Type:	MQCFIN

Selectors

Description:	The list of attributes (integer or character) whose values are being updated by MQSET.
PCF Parameter:	MQIACF_SELECTORS
Trace level:	2
Type:	MQCFIL

ResolvedQName

Description:	The queue name referred to by the ObjectHandle, when ResolvedType is MQOT_Q.
PCF Parameter:	MQCACF_RESOLVED_LOCAL_Q_NAME
Trace level:	2
Type	MQCFST
Length:	MQ_Q_NAME_LENGTH.

ResObjectString

Description:	The object name referred to by the ObjectHandle, when ResolvedType is MQOT_TOPIC.
PCF Parameter:	MQCACF_RESOLVED_OBJECT_STRING
Trace level:	2
Type	MQCFST
Length:	Length varies.

ResolvedType

Description:	The type of the object referred to by the ObjectHandle. Possible values are MQOT_Q, MQOT_TOPIC, or MQOT_NONE.
PCF Parameter:	MQIACF_RESOLVED_TYPE
Trace level:	2
Type	MQCFIN

IntAttrCount

Description:	The number of integer attributes to be updated by the set operation.
PCF Parameter:	MQIACF_INTATTR_COUNT
Trace level:	3
Type:	MQCFIN

IntAttrs

Description:	The integer attribute values
PCF Parameter:	MQIACF_INT_ATTRS
Trace level:	3
Type:	MQCFIL
Range:	This parameter is only present if IntAttrCount is > 0

CharAttrs

Description:	The character attributes to be updated by the set operation. The values are concatenated together.
PCF Parameter:	MQCACF_CHAR_ATTRS
Trace level:	3
Type:	MQCFST
Range:	This parameter is only included if CharAttrLength is > 0

V 8.0.0.2 *QMgrOpDuration*

Description:	Approximate API call duration, in microseconds, within the queue manager. The duration does not include the time spent outside of the queue manager. For example, the time taken as an IBM MQ client. **Note:** The accuracy of this timer varies according to the platform that your enterprise uses.
PCF Parameter:	MQIAMO64_QMGR_OP_DURATION
Trace level:	2
Type	MQCFIN64

MQSUB:

Application has started the MQSUB MQI function

CompCode

Description:	The completion code indicating the result of the operation
PCF Parameter:	MQIACF_COMP_CODE
Trace level:	1
Type:	MQCFIN

Reason

Description:	The reason code result of the operation
PCF Parameter:	MQIACF_REASON_CODE
Trace level:	1
Type:	MQCFIN

SubHandle

Description:	The subscription handle
PCF Parameter:	MQIACF_HSUB
Trace level:	1
Type:	MQCFIN

ObjectHandle

Description:	The object handle
PCF Parameter:	MQIACF_HOBJ
Trace level:	1
Type:	MQCFIN

Options

Description:	Subscription options
PCF Parameter:	MQIACF_SUB_OPTIONS
Trace level:	1
Type:	MQCFIN

ObjectName

Description:	The name of the object.
PCF Parameter:	MQCACF_OBJECT_NAME
Trace level:	1
Type:	MQCFST
Length:	MQ_Q_NAME_LENGTH

ObjectString

Description:	Long object name.
PCF Parameter:	MQCACF_OBJECT_STRING
Trace level:	1
Type:	MQCFST
Range:	Only included if the VSLength field of MQSD.ObjectString is greater than zero or MQVS_NULL_TERMINATED.
Length:	Length varies.

AlternateUserId

Description:	
PCF Parameter:	MQCACF_ALTERNATE_USERID
Trace level:	2
Type:	MQCFST
Range:	Only included if MQSO_ALTERNATE_USER_AUTHORITY is specified.
Length:	MQ_USER_ID_LENGTH

AlternateSecurityId

Description:	Alternate security identifier.
PCF Parameter:	MQBACF_ALTERNATE_SECURITYID
Trace level:	2
Type:	MQCFBS
Range:	Only present if MQSO_ALTERNATE_USER_AUTHORITY is specified and MQSD.AlternateSecurityId is not equal to MQSID_NONE.
Length:	MQ_SECURITY_ID_LENGTH

SubName

Description:	Subscription Name
PCF Parameter:	MQCACF_SUB_NAME
Trace level:	2
Type:	MQCFST
Range:	Only included if the VSLength field of MQSD.SubName is greater than zero or MQVS_NULL_TERMINATED.
Length:	Length varies.

SubUserData

Description:	Subscription User Data
PCF Parameter:	MQCACF_SUB_USER_DATA
Trace level:	2
Type:	MQCFST
Range:	Only included if the VSLength field of MQSD.SubName is greater than zero or MQVS_NULL_TERMINATED.
Length:	Length varies.

SubCorrelId

Description:	Subscription Correlation identifier
PCF Parameter:	MQBACF_SUB_CORREL_ID
Trace level:	2
Type:	MQCFBS
Length:	MQ_CORREL_ID_LENGTH

SelectionString

Description:	Selection string.
PCF Parameter:	MQCACF_SELECTION_STRING
Trace level:	2
Type:	MQCFST
Range:	Only included if the VSLength field of MQSD. SelectionString is MQVS_NULL_TERMINATED or greater than zero.
Length:	Length varies.

ResolvedQName

Description:	The queue name referred to by the ObjectHandle, when ResolvedType is MQOT_Q.
PCF Parameter:	MQCACF_RESOLVED_LOCAL_Q_NAME
Trace level:	2
Type	MQCFST
Length:	MQ_Q_NAME_LENGTH.

ResObjectString

Description:	The object name referred to by the ObjectHandle, when ResolvedType is MQOT_TOPIC.
PCF Parameter:	MQCACF_RESOLVED_OBJECT_STRING
Trace level:	2
Type	MQCFST
Length:	Length varies.

ResolvedType

Description:	The type of the object referred to by the ObjectHandle. Possible values are MQOT_Q, MQOT_TOPIC, or MQOT_NONE.
PCF Parameter:	MQIACF_RESOLVED_TYPE
Trace level:	2
Type	MQCFIN

SubDescriptorStructure

Description:	The MQSD structure.
PCF Parameter:	MQBACF_MQSD_STRUCT
Trace level:	3
Type:	MQCFBS
Length:	The length in bytes of the MQSD structure.

V 8.0.0.2 *QMgrOpDuration*

Description:	Approximate API call duration, in microseconds, within the queue manager. The duration does not include the time spent outside of the queue manager. For example, the time taken as an IBM MQ client. **Note:** The accuracy of this timer varies according to the platform that your enterprise uses.
PCF Parameter:	MQIAMO64_QMGR_OP_DURATION
Trace level:	2
Type	MQCFIN64

MQSUBRQ:

Application has started the MQSUBRQ MQI function

CompCode

Description:	The completion code indicating the result of the operation
PCF Parameter:	MQIACF_COMP_CODE
Trace level:	1
Type:	MQCFIN

Reason

Description:	The reason code result of the operation
PCF Parameter:	MQIACF_REASON_CODE
Trace level:	1
Type:	MQCFIN

SubHandle

Description:	The subscription handle
PCF Parameter:	MQIACF_HSUB
Trace level:	1
Type:	MQCFIN

SubOptions

Description:	The sub options from MQSB.Options
PCF Parameter:	MQIACF_SUBRQ_OPTIONS
Trace level:	2
Type:	MQCFIN

Action

Description:	The subscription request action (MQSR_*)
PCF Parameter:	MQIACF_SUBRQ_ACTION
Trace level:	2
Type:	MQCFIN

NumPubs

Description:	The number of publications sent as a result of this call (from MQSB.NumPubs)
PCF Parameter:	MQIACF_NUM_PUBS
Trace level:	2
Type:	MQCFIN

V 8.0.0.2 *QMgrOpDuration*

Description:	Approximate API call duration, in microseconds, within the queue manager. The duration does not include the time spent outside of the queue manager. For example, the time taken as an IBM MQ client. **Note:** The accuracy of this timer varies according to the platform that your enterprise uses.
PCF Parameter:	MQIAMO64_QMGR_OP_DURATION
Trace level:	2
Type	MQCFIN64

MQSTAT:

Application has started the MQSTAT MQI function

CompCode

Description:	The completion code indicating the result of the operation
PCF Parameter:	MQIACF_COMP_CODE
Trace level:	1
Type:	MQCFIN

Reason

Description:	The reason code result of the operation
PCF Parameter:	MQIACF_REASON_CODE
Trace level:	1
Type:	MQCFIN

Type

Description:	Type of status information being requested
PCF Parameter:	MQIACF_STATUS_TYPE
Trace level:	2
Type:	MQCFIN

StatusStructure

Description:	The MQSTS structure.
PCF Parameter:	MQBACF_MQSTS_STRUCT
Trace level:	3
Type:	MQCFBS
Length:	The length in bytes of the MQSTS structure (actual size depends on structure version)

V 8.0.0.2 *QMgrOpDuration*

Description:	Approximate API call duration, in microseconds, within the queue manager. The duration does not include the time spent outside of the queue manager. For example, the time taken as an IBM MQ client. **Note:** The accuracy of this timer varies according to the platform that your enterprise uses.
PCF Parameter:	MQIAMO64_QMGR_OP_DURATION
Trace level:	2
Type	MQCFIN64

Variable Parameters for Application Activity XA Operations:

XA operations are API calls that applications can make to enable MQ to participate in a transaction. The parameters for each operation are defined in the following section.

The trace level indicates the level of trace granularity that is required for the parameters to be included in the trace. The possible trace level values are:

1. Low

   The parameter is included when “low”, “medium” or “high” activity tracing is configured for an application. This setting means that a parameter is always included in the AppActivityData group for the operation. This set of parameters is sufficient to trace the MQI calls an application makes, and to see if they are successful.
2. Medium

   The parameter is only included in the AppActivityData group for the operation when “medium” or “high” activity tracing is configured for an application. This set of parameters adds information about the resources, for example, queue and topic names used by the application.
3. High

   The parameter is only included in the AppActivityData group for the operation when “high” activity tracing is configured for an application. This set of parameters includes memory dumps of the structures passed to the MQI and XA functions. For this reason, it contains more information about the parameters used in MQI and XA calls. The structure memory dumps are shallow copies of the structures. To avoid erroneous attempts to dereference pointers, the pointer values in the structures are set to `NULL`.

   Note: The version of the structure that is dumped is not necessarily identical to the version used by an application. The structure can be modified by an API crossing exit, by the activity trace code, or by the queue manager. A queue manager can modify a structure to a later version, but the queue manager never changes it to an earlier version of the structure. To do so, would risk losing data.

AXREG:

Application has started the AXREG AX function

`XID`

Description:	The XID structure
PCF Parameter:	MQBACF_XA_XID
Trace level:	1
Type:	MQCFBS

Real-time monitoring

Real-time monitoring is a technique that allows you to determine the current state of queues and channels within a queue manager. The information returned is accurate at the moment the command was issued.

A number of commands are available that when issued return real-time information about queues and channels. Information can be returned for one or more queues or channels and can vary in quantity. Real-time monitoring can be used in the following tasks:

- Helping system administrators understand the steady state of their IBM MQ system. This helps with problem diagnosis if a problem occurs in the system.
- Determining the condition of your queue manager at any moment, even if no specific event or problem has been detected.
- Assisting with determining the cause of a problem in your system.

With real-time monitoring, information can be returned for either queues or channels. The amount of real-time information returned is controlled by queue manager, queue, and channel attributes.

- You monitor a queue by issuing commands to ensure that the queue is being serviced properly. Before you can use some of the queue attributes, you must enable them for real-time monitoring.
- You monitor a channel by issuing commands to ensure that the channel is running properly. Before you can use some of the channel attributes, you must enable them for real-time monitoring.

Real-time monitoring for queues and channels is in addition to, and separate from, performance and channel event monitoring.

Attributes that control real-time monitoring

Some queue and channel status attributes hold monitoring information, if real-time monitoring is enabled. If real-time monitoring is not enabled, no monitoring information is held in these monitoring attributes. Examples demonstrate how you can use these queue and channel status attributes.

You can enable or disable real-time monitoring for individual queues or channels, or for multiple queues or channels. To control individual queues or channels, set the queue attribute MONQ or the channel attribute MONCHL, to enable or disable real-time monitoring. To control many queues or channels together, enable or disable real-time monitoring at the queue manager level by using the queue manager attributes MONQ and MONCHL. For all queue and channel objects with a monitoring attribute that is specified with the default value, QMGR, real-time monitoring is controlled at the queue manager level.

Automatically defined cluster-sender channels are not IBM MQ objects, so do not have attributes in the same way as channel objects. To control automatically defined cluster-sender channels, use the queue manager attribute, MONACLS. This attribute determines whether automatically defined cluster-sender channels within a queue manager are enabled or disabled for channel monitoring.

For real-time monitoring of channels, you can set the MONCHL attribute to one of the three monitoring levels: low, medium, or high. You can set the monitoring level either at the object level or at the queue manager level. The choice of level is dependent on your system. Collecting monitoring data might require some instructions that are relatively expensive computationally, such as obtaining system time. To reduce the effect of real-time monitoring, the medium and low monitoring options measure a sample of the data at regular intervals rather than collecting data all the time. Table 130 summarizes the monitoring levels available for real-time monitoring of channels:

Table 130. Monitoring levels

Level	Description	Usage
Low	Measure a small sample of the data, at regular intervals.	For objects that process a high volume of messages.
Medium	Measure a sample of the data, at regular intervals.	For most objects.
High	Measure all data, at regular intervals.	For objects that process only a few messages per second, on which the most current information is important.

For real-time monitoring of queues, you can set the MONQ attribute to one of the three monitoring levels, low, medium or high. However, there is no distinction between these values. The values all enable data collection, but do not affect the size of the sample.

Examples

The following examples demonstrate how to set the necessary queue, channel, and queue manager attributes to control the level of monitoring. For all of the examples, when monitoring is enabled, queue and channel objects have a medium level of monitoring.

1. To enable both queue and channel monitoring for all queues and channels at the queue manager level, use the following commands:
   ```
   ALTER QMGR MONQ(MEDIUM) MONCHL(MEDIUM)
   ALTER QL(Q1) MONQ(QMGR)
   ALTER CHL(QM1.TO.QM2) CHLTYPE(SDR) MONCHL(QMGR)
   ```
2. To enable monitoring for all queues and channels, with the exception of local queue, `Q1`, and sender channel, `QM1.TO.QM2`, use the following commands:
   ```
   ALTER QMGR MONQ(MEDIUM) MONCHL(MEDIUM)
   ALTER QL(Q1) MONQ(OFF)
   ALTER CHL(QM1.TO.QM2) CHLTYPE(SDR) MONCHL(OFF)
   ```

3. To disable both queue and channel monitoring for all queues and channels, with the exception of local queue, `Q1`, and sender channel, `QM1.TO.QM2`, use the following commands:

```
ALTER QMGR MONQ(OFF) MONCHL(OFF)
ALTER QL(Q1) MONQ(MEDIUM)
ALTER CHL(QM1.TO.QM2) CHLTYPE(SDR) MONCHL(MEDIUM)
```

4. To disable both queue and channel monitoring for all queues and channels, regardless of individual object attributes, use the following command:

```
ALTER QMGR MONQ(NONE) MONCHL(NONE)
```

5. To control the monitoring capabilities of automatically defined cluster-sender channels use the following command:

```
ALTER QMGR MONACLS(MEDIUM)
```

6. To specify that automatically defined cluster-sender channels are to use the queue manager setting for channel monitoring, use the following command:

```
ALTER QMGR MONACLS(QMGR)
```

"Real-time monitoring" on page 1206
Real-time monitoring is a technique that allows you to determine the current state of queues and channels within a queue manager. The information returned is accurate at the moment the command was issued.

"Using IBM MQ online monitoring" on page 1223
You can collect monitoring data for queues and channels (including automatically defined cluster-server channels) by setting the MONQ, MONCHL, and MONACLS attributes.

Related tasks:

"Displaying queue and channel monitoring data"
To display real-time monitoring information for a queue or channel, use either the IBM MQ Explorer or the appropriate MQSC command. Some monitoring fields display a comma-separated pair of indicator values, which help you to monitor the operation of your queue manager. Examples demonstrate how you can display monitoring data.

Related information:

Working with queue managers

Monitoring (MONCHL)

Displaying queue and channel monitoring data

To display real-time monitoring information for a queue or channel, use either the IBM MQ Explorer or the appropriate MQSC command. Some monitoring fields display a comma-separated pair of indicator values, which help you to monitor the operation of your queue manager. Examples demonstrate how you can display monitoring data.

About this task

Monitoring fields that display a pair of values separated by a comma provide short term and long term indicators for the time measured since monitoring was enabled for the object, or from when the queue manager was started:

- The short term indicator is the first value in the pair and is calculated in a way such that more recent measurements are given a higher weighting and will have a greater effect on this value. This gives an indication of recent trend in measurements taken.
- The long term indicator in the second value in the pair and is calculated in a way such that more recent measurements are not given such a high weighting. This gives an indication of the longer term activity on performance of a resource.

These indicator values are most useful to detect changes in the operation of your queue manager. This requires knowledge of the times these indicators show when in normal use, in order to detect increases in these times. By collecting and checking these values regularly you can detect fluctuations in the operation of your queue manager. This can indicate a change in performance.

Obtain real-time monitoring information as follows:

Procedure

1. To display real-time monitoring information for a queue, use either the IBM MQ Explorer or the MQSC command `DISPLAY QSTATUS`, specifying the optional parameter `MONITOR`.
2. To display real-time monitoring information for a channel, use either the IBM MQ Explorer or the MQSC command `DISPLAY CHSTATUS`, specifying the optional parameter `MONITOR`.

Example

The queue, `Q1`, has the attribute MONQ set to the default value, QMGR, and the queue manager that owns the queue has the attribute MONQ set to MEDIUM. To display the monitoring fields collected for this queue, use the following command:

```
DISPLAY QSTATUS(Q1) MONITOR
```

The monitoring fields and monitoring level of queue, `Q1` are displayed as follows:

```
QSTATUS(Q1)
TYPE(QUEUE)
MONQ(MEDIUM)
QTIME(11892157,24052785)
MSGAGE(37)
LPUTDATE(2005-03-02)
LPUTTIME(09.52.13)
LGETDATE(2005-03-02)
LGETTIME(09.51.02)
```

The sender channel, `QM1.TO.QM2`, has the attribute MONCHL set to the default value, QMGR, and the queue manager that owns the queue has the attribute MONCHL set to MEDIUM. To display the monitoring fields collected for this sender channel, use the following command:

```
DISPLAY CHSTATUS(QM1.TO.QM2) MONITOR
```

The monitoring fields and monitoring level of sender channel, `QM1.TO.QM2` are displayed as follows:

```
CHSTATUS(QM1.TO.QM2)
XMITQ(Q1)
CONNAME(127.0.0.1)
CURRENT
CHLTYPE(SDR)
STATUS(RUNNING)
SUBSTATE(MQGET)
MONCHL(MEDIUM)
XQTIME(755394737,755199260)
NETTIME(13372,13372)
EXITTIME(0,0)
XBATCHSZ(50,50)
COMPTIME(0,0)
STOPREQ(NO)
RQMNAME(QM2)
```

DISPLAY QSTATUS

Monitoring queues

Use this page to view tasks that help you to resolve a problem with a queue and the application that services that queue. Various monitoring options are available to determine the problem

Frequently, the first sign of a problem with a queue that is being serviced is that the number of messages on the queue (CURDEPTH) increases. If you expect an increase at certain times of day or under certain workloads, an increasing number of messages might not indicate a problem. However, if you have no explanation for the increasing number of messages, you might want to investigate the cause.

You might have an application queue where there is a problem with the application, or a transmission queue where there is a problem with the channel. Additional monitoring options are available when the application that services the queue is a channel.

The following examples investigate problems with a particular queue, called Q1, and describe the fields that you look at in the output of various commands:

Determining whether your application has the queue open:

If you have a problem with a queue, check whether your application has the queue open

About this task

Perform the following steps to determine whether your application has the queue open:

Procedure

1. Ensure that the application that is running against the queue is the application that you expect. Issue the following command for the queue in question:
   ```
   DISPLAY QSTATUS(Q1) TYPE(HANDLE) ALL
   ```
   In the output, look at the APPLTAG field, and check that the name of your application is shown. If the name of your application is not shown, or if there is no output at all, start your application.
2. If the queue is a transmission queue, look in the output at the CHANNEL field. If the channel name is not shown in the CHANNEL field, determine whether the channel is running.
3. Ensure that the application that is running against the queue has the queue open for input. Issue the following command:
   ```
   DISPLAY QSTATUS(Q1) TYPE(QUEUE) ALL
   ```
   In the output, look at the IPPROCS field to see if any application has the queue open for input. If the value is 0 and this is a user application queue, make sure that the application opens the queue for input to get the messages off the queue.

Checking that messages on the queue are available:

If you have a large number of messages on the queue and your application is not processing any of those messages, check whether the messages on the queue are available to your application

About this task

Perform the following steps to investigate why your application is not processing messages from the queue:

Procedure

1. Ensure that your application is not asking for a specific message ID or correlation ID when it should be processing all the messages on the queue.
2. Although the current depth of the queue might show that there is an increasing number of messages on the queue, some messages on the queue might not be available to be got by an application, because they are not committed; the current depth includes the number of uncommitted MQPUTs of messages to the queue. Issue the following command:
   ```
   DISPLAY QSTATUS(Q1) TYPE(QUEUE) ALL
   ```
   In the output, look at the UNCOM field to see whether there are any uncommitted messages on the queue.
3. If your application is attempting to get any messages from the queue, check whether the putting application is committing the messages correctly. Issue the following command to find out the names of applications that are putting messages to this queue:
   ```
   DISPLAY QSTATUS(Q1) TYPE(HANDLE) OPENTYPE(OUTPUT)
   ```
4. Then issue the following command, inserting in <appltag> the APPLTAG value from the output of the previous command:
   ```
   DISPLAY CONN(*) WHERE(APPLTAG EQ <appltag>) UOWSTDA UOWSTTI
   ```
   This shows when the unit of work was started and will help you discover whether the application is creating a long running unit of work. If the putting application is a channel, you might want to investigate why a batch is taking a long time to complete.

Checking whether your application is getting messages off the queue:

If you have a problem with a queue and the application that services that queue, check whether your application is getting messages off the queue

About this task

To check whether your application is getting messages off the queue, perform the following checks:

Procedure

1. Ensure that the application that is running against the queue is actually processing messages from the queue. Issue the following command:
   ```
   DISPLAY QSTATUS(Q1) TYPE(QUEUE) ALL
   ```
   In the output, look at the LGETDATE and LGETTIME fields which show when the last get was done from the queue.
2. If the last get from this queue was longer ago than expected, ensure that the application is processing messages correctly. If the application is a channel, check whether messages are moving through that channel

Determining whether the application can process messages fast enough:

If messages are building up on the queue, but your other checks have not found any processing problems, check that the application can process messages fast enough. If the application is a channel, check that the channel can process messages fast enough.

About this task

To determine whether the application is processing messages fast enough, perform the following tests:

Procedure

1. Issue the following command periodically to gather performance data about the queue:
   ```
   DISPLAY QSTATUS(Q1) TYPE(QUEUE) ALL
   ```
   If the values in the QTIME indicators are high, or are increasing over the period, and you have already ruled out the possibility of long running Units of Work by checking that messages on the queue are available, the getting application might not be keeping up with the putting applications.
2. If your getting application cannot keep up with the putting applications, consider adding another getting application to process the queue. Whether you can add another getting application depends on the design of the application and whether the queue can be shared by more than one application. Features such as message grouping or getting by correlation ID might help to ensure that two applications can process a queue simultaneously.

Checking the queue when the current depth is not increasing:

Even if the current depth of your queue is not increasing, it might still be useful to monitor the queue to check whether your application is processing messages correctly.

About this task

To gather performance data about the queue: Issue the following command periodically:

Procedure

Issue the following command periodically:
```
DISPLAY QSTATUS(Q1) TYPE(QUEUE) MSGAGE QTIME
```

In the output, if the value in MSGAGE increases over the period of time, and your application is designed to process all messages, this might indicate that some messages are not being processed at all.

Monitoring channels

Use this page to view tasks that help you to resolve a problem with a transmission queue and the channel that services that queue. Various channel monitoring options are available to determine the problem.

Frequently, the first sign of a problem with a queue that is being serviced is that the number of messages on the queue (CURDEPTH) increases. If you expect an increase at certain times of day or under certain workloads, an increasing number of messages might not indicate a problem. However, if you have no explanation for the increasing number of messages, you might want to investigate the cause.

You might have a problem with the channel that services a transmission queue. Various channel monitoring options are available to help you to determine the problem.

The following examples investigate problems with a transmission queue called QM2 and a channel called QM1.TO.QM2. This channel is used to send messages from queue manager, QM1, to queue manager, QM2. The channel definition at queue manager QM1 is either a sender or server channel, and the channel definition at queue manager, QM2, is either a receiver or requester channel.

Determining whether the channel is running:

If you have a problem with a transmission queue, check whether the channel is running.

About this task

Perform the following steps to check the status of the channel that is servicing the transmission queue:

Procedure

1. Issue the following command to find out which channel you expect to process the transmission queue QM2:
   ```
   DIS CHANNEL(*) WHERE(XMITQ EQ QM2)
   ```
   In this example, the output of this command shows that the channel servicing the transmission queue is QM1.TO.QM2
2. Issue the following command to determine the status of the channel, QM1.TO.QM2:
   ```
   DIS CHSTATUS(QM1.TO.QM2) ALL
   ```
3. Inspect the STATUS field of the output from the **CHSTATUS** command:
   - If the value of the STATUS field is `RUNNING`, check that the channel is moving messages
   - If the output from the command shows no status, or the value of the STATUS field is `STOPPED`, `RETRY`, `BINDING`, or `REQUESTING`, perform the appropriate step, as follows:
4. Optional: If the value of the STATUS field shows no status, the channel is inactive, so perform the following steps:
   a. If the channel should have been started automatically by a trigger, check that the messages on the transmission queue are available. If there are messages available on the transmission queue, check that the trigger settings on the transmission queue are correct.
   b. Issue the following command to start the channel again manually:
   ```
   START CHANNEL(QM1.TO.QM2)
   ```
5. Optional: If the value of the STATUS field is `STOPPED`, perform the following steps:
   a. Check the error logs to determine why the channel stopped. If the channel stopped owing to an error, correct the problem. Ensure also that the channel has values specified for the retry attributes: *SHORTRTY* and *LONGRTY*. In the event of transient failures such as network errors, the channel will then attempt to restart automatically.
   b. Issue the following command to start the channel again manually:

```
START CHANNEL(QM1.TO.QM2)
```

z/OS On IBM MQ for z/OS, you can detect when a user stops a channel by using command event messages.

6. Optional: If the value of the STATUS field is `RETRY`, perform the following steps:
   a. Check the error logs to identify the error, then correct the problem.
   b. Issue the following command to start the channel again manually:
      ```
      START CHANNEL(QM1.TO.QM2)
      ```
      or wait for the channel to connect successfully on its next retry.
7. Optional: If the value of the STATUS field is `BINDING` or `REQUESTING`, the channel has not yet successfully connected to the partner. Perform the following steps:
   a. Issue the following command, at both ends of the channel, to determine the substate of the channel:
      ```
      DIS CHSTATUS(QM1.TO.QM2) ALL
      ```
      Note:
      1) In some cases there might be a substate at one end of the channel only.
      2) Many substates are transitory, so issue the command a few times to detect whether a channel is stuck in a particular substate.
   b. Check Table 131 to determine what action to take:

Table 131. Substates seen with status binding or requesting

Initiating MCA substate [1]	Responding MCA substate [2]	Notes
NAMESERVER		The initiating MCA is waiting for a name server request to complete. Ensure that the correct host name has been specified in the channel attribute, CONNAME, and that your name servers are set up correctly.
SCYEXIT	SCYEXIT	The MCAs are currently *in conversation* through a security exit. For more information, see “Determining whether the channel can process messages fast enough” on page 1217.
	CHADEXIT	The channel autodefinition exit is currently executing. For more information, see “Determining whether the channel can process messages fast enough” on page 1217.
RCVEXIT SENDEXIT MSGEXIT MREXIT	RCVEXIT SENDEXIT MSGEXIT MREXIT	Exits are called at channel startup for MQXR_INIT. Review the processing in this part of your exit if this takes a long time. For more information, see “Determining whether the channel can process messages fast enough” on page 1217.
SERIALIZE	SERIALIZE	This substate only applies to channels with a disposition of SHARED.
NETCONNECT		This substate is shown if there is a delay in connecting due to incorrect network configuration.
SSLHANDSHAKE	SSLHANDSHAKE	An SSL handshake consists of a number of sends and receives. If network times are slow, or connection to lookup CRLs are slow, this affects the time taken to do the handshake. z/OS On IBM MQ for z/OS this substate can also be indicative of not having enough SSLTASKS.

Notes:

1) The initiating MCA is the end of the channel which started the conversation. This can be senders, cluster-senders, fully-qualified servers and requesters. In a server-requester pair, it is the end from which you started the channel.
2) The responding MCA is the end of the channel which responded to the request to start the conversation. This can be receivers, cluster-receivers, requesters (when the server or sender is started), servers (when the requester is started) and senders (in a requester-sender call-back pair of channels).

Checking that the channel is moving messages:

If you have a problem with a transmission queue, check that the channel is moving messages

Before you begin

Issue the command `DIS CHSTATUS(QM1.TO.QM2) ALL`. If the value of the STATUS field is `RUNNING`, the channel has successfully connected to the partner system.

Check that there are no uncommitted messages on the transmission queue, as described in "Checking that messages on the queue are available" on page 1211.

About this task

If there are messages available for the channel to get and send, perform the following checks:

Procedure

1. In the output from the display channel status command, `DIS CHSTATUS(QM1.TO.QM2) ALL`, look at the following fields:

   MSGS
   Number of messages sent or received (or, for server-connection channels, the number of MQI calls handled) during this session (since the channel was started).

   BUFSSENT
   Number of transmission buffers sent. This includes transmissions to send control information only.

   BYTSSENT
   Number of bytes sent during this session (since the channel was started). This includes control information sent by the message channel agent.

   LSTMSGDA
   Date when the last message was sent or MQI call was handled, see LSTMSGTI.

   LSTMSGTI
   Time when the last message was sent or MQI call was handled. For a sender or server, this is the time the last message (the last part of it if it was split) was sent. For a requester or receiver, it is the time the last message was put to its target queue. For a server-connection channel, it is the time when the last MQI call completed.

   CURMSGS
   For a sending channel, this is the number of messages that have been sent in the current batch. For a receiving channel, it is the number of messages that have been received in the current batch. The value is reset to zero, for both sending and receiving channels, when the batch is committed.
2. Determine whether the channel has sent any messages since it started. If any have been sent, determine when the last message was sent.
3. If the channel has started a batch that has not yet completed, as indicated by a non-zero value in CURMSGS, the channel might be waiting for the other end of the channel to acknowledge the batch.

Look at the SUBSTATE field in the output and refer to Table 132:

Table 132. Sender and receiver MCA substates

Sender SUBSTATE	Receiver SUBSTATE	Notes
MQGET	RECEIVE	Normal states of a channel at rest.
SEND	RECEIVE	SEND is usually a transitory state. If SEND is seen it indicates that the communication protocol buffers have filled. This can indicate a network problem.
RECEIVE		If the sender is seen in RECEIVE substate for any length of time, it is waiting on a response, either to a batch completion or a heartbeat. You might want to check why a batch takes a long time to complete.

Note: You might also want to determine whether the channel can process messages fast enough, especially if the channel has a substate associated with exit processing.

Checking why a batch takes a long time to complete:

Reasons why a batch can take a long time to complete include a slow network or a channel is using message retry processing.

About this task

When a sender channel has sent a batch of messages it waits for confirmation of that batch from the receiver, unless the channel is pipelined. The factors described in this task can affect how long the sender channel waits.

Procedure

- Check whether the network is slow. The NETTIME value is the amount of time, displayed in microseconds, taken to send an end of batch request to the remote end of the channel and receive a response minus the time to process the end of batch request. This value can be large for either of the following reasons:
  - The network is slow. A slow network can affect the time it takes to complete a batch. The measurements that result in the indicators for the NETTIME field are measured at the end of a batch. However, the first batch affected by a slowdown in the network is not indicated with a change in the NETTIME value because it is measured at the end of the batch.
  - Requests are queued at the remote end, for example a channel can be retrying a put, or a put request may be slow due to page set I/O. Once any queued requests have completed, the duration of the end of batch request is measured. So if you get a large NETTIME value, check for unusual processing at the remote end.
- Check whether the channel is using message retry. If the receiver channel fails to put a message to a target queue, it might use message retry processing, rather than put the message to a dead-letter immediately. Retry processing can cause the batch to slow down. In between MQPUT attempts, the channel will have STATUS(PAUSED), indicating that it is waiting for the message retry interval to pass.

Determining whether the channel can process messages fast enough:

If there messages are building up on the transmission queue, but you have found no processing problems, determine whether the channel can process messages fast enough.

Before you begin

Issue the following command repeatedly over a period of time to gather performance data about the channel:

```
DIS CHSTATUS(QM1.TO.QM2) ALL
```

About this task

Confirm that there are no uncommitted messages on the transmission queue, as described in “Checking that messages on the queue are available” on page 1211, then check the XQTIME field in the output from the display channel status command. When the values of the XQTIME indicators are consistently high, or increase over the measurement period, the indication is that the channel is not keeping pace with the putting applications.

Perform the following tests:

Procedure

1. Check whether exits are processing. If exits are used on the channel that is delivering these messages, they might add to the time spent processing messages. To identify if this is the case, do the following checks:
   a. In the output of the command `DIS CHSTATUS(QM1.TO.QM2) ALL`, check the EXITTIME field. If the time spent in exits is higher than expected, review the processing in your exits for any unnecessary loops or extra processing, especially in message, send, and receive exits. Such processing affects all messages moved across the channel.
   b. In the output of the command `DIS CHSTATUS(QM1.TO.QM2) ALL`, check the SUBSTATE field. If the channel has of one of the following substates for a significant time, review the processing in your exits:
      - SCYEXIT
      - RCVEXIT
      - SENDEXIT
      - MSGEXIT
      - MREXIT
2. Check whether the network is slow. If messages are not moving fast enough across a channel, it might be because the network is slow. To identify if this is the case, do the following checks:
   a. In the output of the command `DIS CHSTATUS(QM1.TO.QM2) ALL`, check the NETTIME field. These indicators are measured when the sending channel asks its partner for a response. This happens at the end of each batch and, when a channel is idle during heartbeating.
   b. If this indicator shows that round trips are taking longer than expected, use other network monitoring tools to investigate the performance of your network.
3. Check whether the channel is using compression. If the channel is using compression, this adds to the time spent processing messages. If the channel is using only one compression algorithm, do the following checks:
   a. In the output of the command `DIS CHSTATUS(QM1.TO.QM2) ALL`, check the COMPTIME field. These indicators show the time spent during compression or decompression.
   b. If the chosen compression is not reducing the amount of data to send by the expected amount, change the compression algorithm.
4. If the channel is using multiple compression algorithms, do the following checks:

a. In the output of the command `DIS CHSTATUS(QM1.TO.QM2) ALL`, check the COMPTIME, COMPHDR, and COMPMSG fields.
b. Change the compression algorithms specified on the channel definition, or consider writing a message exit to override the channel's choice of compression algorithm for particular messages if the rate of compression, or choice of algorithm, is not providing the required compression or performance.

Solving problems with cluster channels:

If you have a build up of messages on the SYSTEM.CLUSTER.TRANSMIT.QUEUE queue, the first step in diagnosing the problem is discovering which channel, or channels, are having a problem delivering messages.

About this task

To discover which channel, or channels, using the SYSTEM.CLUSTER.TRANSMIT.QUEUE are having a problem delivering messages. Perform the following checks:

Procedure

1. Issue the following command:
   ```
   DIS CHSTATUS(*) WHERE(XQMSGSA GT 1)
   ```
   Note: If you have a busy cluster that has many messages moving, consider issuing this command with a higher number to eliminate the channels that have only a few messages available to deliver.
2. Look through the output for the channel, or channels, that have large values in the field XQMSGSA. Determine why the channel is not moving messages, or is not moving them fast enough. Use the tasks outlined in "Monitoring channels" on page 1213 to diagnose the problems with the channels found to be causing the build up.

The Windows performance monitor

In IBM WebSphere MQ Version 7.0 and earlier versions, it was possible to monitor the performance of local queues on Windows systems by using the Windows performance monitor. As of IBM WebSphere MQ Version 7.1, this method of performance monitoring is no longer available.

You can monitor queues on all supported platforms by using methods described in "Real-time monitoring" on page 1206.

Monitoring clusters

Within a cluster you can monitor application messages, control messages, and logs. There are special monitoring ocnsiderations when the cluster load balances between two or more instances of a queue.

Monitoring application messages in the cluster

Typically, all cluster messages that leave the queue manager pass through the `SYSTEM.CLUSTER.TRANSMIT.QUEUE`, irrespective of which cluster sender channel is being used to transmit the message. Each channel is draining messages targeted for that channel in parallel with all other cluster sender channels. A growing build-up of messages on this queue can indicate a problem with one or more channels and must be investigated:

- The depth of the queue must be monitored appropriately for the cluster design.
- The following command returns all channels that have more than one message that is waiting on the transmit queue:
  ```
  DIS CHSTATUS(*) WHERE(XQMSGSA GT 1)
  ```

With all cluster messages on a single queue, it is not always easy to see which channel has problems when it begins to fill up. Using this command is an easy way to see which channel is responsible.

You can configure a cluster queue manager to have multiple transmission queues. If you change the queue manager attribute DEFCLXQ to CHANNEL, every cluster-sender channel is associated with a different cluster transmit queue. Alternatively you can configure separate transmission queues manually. To display all the cluster transmit queues that are associated with cluster-sender channels, run the command:

```
DISPLAY CLUSQMGR (qmgrName) XMITQ
```

Define cluster transmission queues so that they follow the pattern of having the fixed stem of the queue name on the left. You can then query the depth of all the cluster transmission queues returned by the **DISPLAY CLUSMGR** command, by using a generic queue name:

```
DISPLAY QUEUE (qname *) CURDEPTH
```

Monitoring control messages in the cluster

The SYSTEM.CLUSTER.COMMAND.QUEUE queue is used for processing all cluster control messages for a queue manager, either generated by the local queue manager or sent to this queue manager from other queue managers in the cluster. When a queue manager is correctly maintaining its cluster state, this queue tends toward zero. There are situations where the depth of messages on this queue can temporarily grow however:

- Having lots of messages on the queue indicates churn in the cluster state.
- When making significant changes, allow the queue to settle in between those changes. For example, when moving repositories, allow the queue to reach zero before moving the second repository.

While a backlog of messages exists on this queue, updates to the cluster state or cluster-related commands are not processed. If messages are not being removed from this queue for a long time, further investigation is required, initially through inspection of the queue manager error logs z/OS (or CHINIT logs on z/OS) which might explain the process that is causing this situation.

The SYSTEM.CLUSTER.REPOSITORY.QUEUE holds the cluster repository cache information as a number of messages. It is usual for messages to always exist on this queue, and more for larger clusters. Therefore, the depth of messages on this queue is not an issue for concern.

Monitoring logs

Problems that occur in the cluster might not show external symptoms to applications for many days (and even months) after the problem originally occurs due to the caching of information and the distributed nature of clustering. However, the original problem is often reported in the IBM MQ error logs z/OS (and CHINIT logs on z/OS). For this reason, it is vital to actively monitor these logs for any messages written that relate to clustering. These messages must be read and understood, with any action taken where necessary.

For example: A break in communications with a queue manager in a cluster can result in knowledge of certain cluster resources that are being deleted due to the way that clusters regularly revalidate the cluster resources by republishing the information. A warning of such an event potentially occurring is reported by the message AMQ9465 z/OS or CSQX465I on z/OS systems. This message indicates that the problem needs to be investigated.

Special considerations for load balancing

When the cluster load balances between two or more instances of a queue, consuming applications must be processing messages on each of the instances. If one or more of those consuming applications terminates or stops processing messages, it is possible that clustering might continue to send messages to those instances of the queue. In this situation, those messages are not processed until the applications are functioning correctly again. For this reason the monitoring of the applications is an important part of the solution and action must be taken to reroute messages in that situation. An example of a mechanism to automate such monitoring can be found in this sample: The Cluster Queue Monitoring sample program (AMQSCLM).

Related concepts:

"Tuning distributed publish/subscribe networks" on page 1263
Use the tuning tips in this section to help improve the performance of your IBM MQ distributed publish/subscribe clusters and hierarchies.

"Balancing producers and consumers in publish/subscribe networks" on page 1267
An important concept in asynchronous messaging performance is *balance*. Unless message consumers are balanced with message producers, there is the danger that a backlog of unconsumed messages might build up and seriously affect the performance of multiple applications.

Monitoring performance and resource usage

Use this topic to understand the facilities available to monitor the performance, and resource usage of your IBM MQ for z/OS subsystems.

Configuring z/OS

Administering IBM MQ for z/OS

Introduction to monitoring

z/OS

Use this topic as an overview of the monitoring facilities available for IBM MQ for z/OS. For example, obtaining snapshots, using IBM MQ trace, online monitoring, and events.

This topic describes how to monitor the performance and resource usage of IBM MQ.
- It outlines some of the information that you can retrieve and briefly describes a general approach to investigating performance problems. z/OS (You can find information about dealing with performance problems in the Problem determination on z/OS .)
- It describes how you can collect statistics about the performance of IBM MQ by using SMF records.
- It describes how to gather accounting data to enable you to charge your customers for their use of your IBM MQ systems.
- It describes how to use IBM MQ events (alerts) to monitor your systems.

Here are some of the tools you might use to monitor IBM MQ; they are described in the sections that follow:
- Tools provided by IBM MQ:
  - Using DISPLAY commands
  - "Using CICS adapter statistics" on page 1222
  - "Using IBM MQ events" on page 1224
- z/OS service aids:
  - "Using System Management Facility" on page 1224
- Other IBM licensed programs:
  - Using the Resource Measurement Facility
  - Using Tivoli Decision Support for z/OS
  - Using the CICS monitoring facility

Information about interpreting the data gathered by the performance statistics trace is given in“Interpreting IBM MQ performance statistics” on page 1227.

Information about interpreting the data gathered by the accounting trace is given in“Interpreting IBM MQ accounting data” on page 1251.

Getting snapshots of IBM MQ using the DISPLAY commands:

IBM MQ provides the MQSC facility which can give a snapshot of the performance, and resource usage using the DISPLAY commands.

You can get an idea of the current state of IBM MQ by using the DISPLAY commands and, for the CICS adapter, the CICS adapter panels.

Using DISPLAY commands

You can use the IBM MQ MQSC DISPLAY or PCF Inquire commands to obtain information about the current state of IBM MQ. They provide information about the status of the command server, process definitions, queues, the queue manager, and its associated components. These commands are:

MQSC command	PCF command
DISPLAY ARCHIVE	Inquire Archive
DISPLAY AUTHINFO	Inquire Authentication Information Object
DISPLAY CFSTATUS	Inquire CF Structure Status
DISPLAY CFSTRUCT	Inquire CF Structure
DISPLAY CHANNEL	Inquire Channel
DISPLAY CHINIT	Inquire Channel Initiator
DISPLAY CHSTATUS	Inquire Channel Status
DISPLAY CMDSERV	
DISPLAY CLUSQMGR	Inquire Cluster Queue Manager
DISPLAY CONN	Inquire Connection
DISPLAY GROUP	Inquire Group
DISPLAY LOG	Inquire Log
DISPLAY PROCESS	Inquire Process
DISPLAY QMGR	Inquire Queue Manager
DISPLAY QSTATUS	Inquire Queue Status
DISPLAY QUEUE	Inquire Queue
DISPLAY SECURITY	Inquire Security
DISPLAY STGCLASS	Inquire Storage Class
DISPLAY SYSTEM	Inquire System
DISPLAY TRACE	
DISPLAY USAGE	Inquire Usage

For the detailed syntax of each command, see MQSC commands or PCF commands. All of the functions of these commands (except DISPLAY CMDSERV and DISPLAY TRACE) are also available through the operations and control panels.

These commands provide a snapshot of the system *only* at the moment the command was processed. If you want to examine trends in the system, you must start an IBM MQ trace and analyze the results over a period of time.

Using CICS adapter statistics:

If you are an authorized CICS user, you can use the CICS adapter control panels to display CICS adapter statistics dynamically.

These statistics provide a snapshot of information related to CICS thread usage and situations when all threads are busy. The display connection panel can be refreshed by pressing the Enter key. For more information, see "The CICS-IBM MQ Adapter" section in the CICS Transaction Server for z/OS Version 4.1 product documentation at: CICS Transaction Server for z/OS Version 4.1, The CICS-IBM MQ adapter.

Using IBM MQ trace:

You can record performance statistics and accounting data for IBM MQ by using the IBM MQ trace facility. Use this topic to understand how to control IBM MQ trace.

The data generated by IBM MQ is sent to:

- The System Management Facility (SMF), specifically as SMF record type 115, subtypes 1 and 2 for the performance statistics trace
- The SMF, specifically as SMF record type 116, subtypes zero, 1, and 2 for the accounting trace.

If you prefer, the data generated by the IBM MQ accounting trace can also be sent to the generalized trace facility (GTF).

Starting IBM MQ trace

You can start the IBM MQ trace facility at any time by issuing the IBM MQ START TRACE command.

Accounting data can be lost if the accounting trace is started or stopped while applications are running. To collect accounting data successfully, the following conditions must apply:

- The accounting trace must be active when an application starts, and it must still be active when the application finishes.
- If the accounting trace is stopped, any accounting data collection that was active stops.

You can also start collecting some trace information automatically if you specify YES on the SMFSTAT (SMF STATISTICS) and SMFACCT (SMF ACCOUNTING) parameters of the CSQ6SYSP macro.
z/OS These parameters are described in Using CSQ6SYSP.

You cannot use this method to start collecting class 3 accounting information (thread-level and queue-level accounting). You must use the START TRACE command to collect such information. However, you can include the command in your CSQINP2 input data set so that the trace is started automatically when you start your queue manager.

Before starting an IBM MQ trace, read "Using System Management Facility" on page 1224.

Controlling IBM MQ trace

To control the IBM MQ trace data collection at start-up, specify values for the parameters in the CSQ6SYSP macro when you customize IBM MQ. z/OS See Using CSQ6SYSP for details.

You can control IBM MQ tracing when the queue manager is running with these commands:

- START TRACE
- ALTER TRACE
- STOP TRACE

You can choose the destination to which trace data is sent. Possible destinations are:

SMF System Management Facility

GTF Generalized Trace Facility (accounting trace only)

SRV Serviceability routine for diagnostic use by IBM service personnel

For daily monitoring, information is sent to SMF (the default destination). SMF data sets typically contain information from other systems; this information is not available for reporting until the SMF data set is dumped.

You can also send accounting trace information to the GTF. This information has an event identifier of 5EE. z/OS The The MQI call and user parameter, and z/OS generalized trace facility (GTF) describes how to deal with IBM MQ trace information sent to the GTF.

For information about IBM MQ commands, see MQSC commands.

Effect of trace on IBM MQ performance

Using the IBM MQ trace facility can have a significant effect on IBM MQ and transaction performance. For example, if you start a global trace for class 1 or for all classes, it is likely to increase processor usage and transaction response times by approximately 50%. However, if you start a global trace for classes 2 - 4 alone, the increase in processor usage and transaction response times is likely to be less than 1% additional processor cost to the cost of IBM MQ calls. The same applies for a statistics or accounting trace.

Using IBM MQ online monitoring:

You can collect monitoring data for queues and channels (including automatically defined cluster-server channels) by setting the MONQ, MONCHL, and MONACLS attributes.

Table 133 summarizes the commands to set these attributes at different levels and to display the monitoring information.

Table 133. Setting and displaying attributes to control online monitoring

Attribute	Applicable at this level	Set using command	Display monitoring information using command
MONQ	Queue	DEFINE QLOCAL DEFINE QMODEL ALTER QLOCAL ALTER QMODEL	DISPLAY QSTATUS
	Queue manager	ALTER QMGR	
MONCHL	Channel	DEFINE CHANNEL ALTER CHANNEL	DISPLAY CHSTATUS
	Queue manager	ALTER QMGR	
MONACLS	Queue manager	ALTER QMGR	

For full details of these commands, see MQSC commands. For more information about online monitoring, see “Monitoring your IBM MQ network” on page 929.

Using IBM MQ events:

IBM MQ instrumentation events provide information about errors, warnings, and other significant occurrences in a queue manager. You can monitor the operation of all your queue managers by incorporating these events into your own system management application.

IBM MQ instrumentation events fall into the following categories:

Queue manager events
These events are related to the definitions of resources within queue managers. For example, an application attempts to put a message to a queue that does not exist.

Performance events
These events are notifications that a threshold condition has been reached by a resource. For example, a queue depth limit has been reached, or the queue was not serviced within a predefined time limit.

Channel events
These events are reported by channels as a result of conditions detected during their operation. For example, a channel instance is stopped.

Configuration events
These events are notifications that an object has been created, changed, or deleted.

When an event occurs, the queue manager puts an *event message* on the appropriate *event queue*, if defined. The event message contains information about the event that can be retrieved by a suitable IBM MQ application.

IBM MQ events can be enabled using the IBM MQ commands or the operations and control panels.

See "Event types" on page 932 for information about the IBM MQ events that generate messages, and for information about the format of these messages. See Event message reference for information about enabling the events.

Using System Management Facility: z/OS

You can use SMF to collect statistics and accounting information. To use SMF, certain parameters must be set in z/OS and in IBM MQ.

System management facility (SMF) is a z/OS service aid used to collect information from various z/OS subsystems. This information is dumped and reported periodically, for example, hourly. You can use SMF with the IBM MQ trace facility to collect data from IBM MQ. In this way you can monitor *trends*, for example, in system utilization and performance, and collect accounting information about each user ID using IBM MQ.

To record performance statistics (record type 115) to SMF specify the following in the SMFPRMxx member of SYS1.PARMLIB or with the SETSMF z/OS operator command.

```
SYS(TYPE(115))
```

To record accounting information (record type 116) to SMF specify the following in the SMFPRMxx member of SYS1.PARMLIB or with the SETSMF z/OS operator command.

```
SYS(TYPE(116))
```

You can turn on or off the recording of accounting information at the queue or queue manager level using the ACCTQ parameter of the DEFINE QLOCAL, DEFINE QMODEL, ALTER QLOCAL, ALTER QMODEL, or ALTER QMGR commands. See MQSC commands for details of these commands.

To use the z/OS command SETSMF, either PROMPT(ALL) or PROMPT(LIST) must be specified in the SMFPRM *xx* member. See the z/OS MVS Initialization and Tuning Reference and the z/OS MVS System Commands manuals for more information.

You can start collecting some trace information automatically if you specify YES on the SMFSTAT (SMF STATISTICS) and SMFACCT (SMF ACCOUNTING) parameters of the CSQ6SYSP macro; this is described in Using CSQ6SYSP.

Specifying YES on the SMFSTAT and SMFACCT parameters enables you to collect trace information as a queue manager starts.

You can also start collection of the data on a queue manager by specifying START TRACE(A) or START TRACE(S).

You can specify the interval at which IBM MQ collects statistics and accounting data in one of two ways:

- You can specify a value for STATIME in your system parameters z/OS (described in Using CSQ6SYSP).
- You can specify zero for STATIME and use the SMF global accounting interval (described in the z/OS MVS Initialization and Tuning Reference).

SMF must be running before you can send data to it. For more information about SMF, see the MVS System Management Facilities (SMF) manual.

For the statistics and accounting data to be reset, at least one MQI call must be issued during the accounting interval.

Allocating additional SMF buffers

When you start a trace, you must ensure that you allocate adequate SMF buffers. Specify SMF buffering on the VSAM BUFSP parameter of the access method services DEFINE CLUSTER statement. Specify CISZ(4096) and BUFSP(81920) on the DEFINE CLUSTER statement for each SMF VSAM data set.

If an SMF buffer shortage occurs, SMF rejects any trace records sent to it. IBM MQ sends a CSQW133I message to the z/OS console when this occurs. IBM MQ treats the error as temporary and remains active even though SMF data can be lost. When the shortage has been alleviated and trace recording has resumed, IBM MQ sends a CSQW123I message to the z/OS console.

Reporting data in SMF

You can use the SMF program IFASMFDP to dump SMF records to a sequential data set so that they can be processed.

There are several ways to report on this data, for example:

- Write an application program to read and report information from the SMF data set. You can then tailor the report to fit your exact needs.
- Use Performance Reporter to process the records. For more information, see “Using other products with IBM MQ” on page 1226.

Using other products with IBM MQ:

You can use other products to help you to improve the presentation of, or to augment statistics related to, performance and accounting. For example, Resource Measurement Facility, Tivoli Decision Support, and CICS monitoring.

Using the Resource Measurement Facility

Resource Measurement Facility (RMF) is an IBM licensed program (program number 5685-029) that provides system-wide information about processor utilization, I/O activity, storage, and paging. You can use RMF to monitor the utilization of physical resources across the whole system dynamically. For more information, see the *MVS Resource Measurement Facility User's Guide*.

Using Tivoli Decision Support for z/OS

You can use Tivoli Decision Support for z/OS to interpret RMF and SMF records.

Tivoli Decision Support for z/OS is an IBM licensed program (program number 5698-B06) that enables you to manage the performance of your system by collecting performance data in a Db2 database and presenting the data in various formats for use in systems management. Tivoli Decision Support for can generate graphic and tabular reports using systems management data it stores in its Db2 database. It includes an administration dialog, a reporting dialog, and a log collector, all of which interact with a standard Db2 database.

This is described in the *Tivoli Decision Support Administrator's Guide*.

Using the CICS monitoring facility

The CICS monitoring facility provides performance information about each CICS transaction running. It can be used to investigate the resources used and the time spent processing transactions. For background information, see the *CICS Performance Guide* and the *CICS Customization Guide*.

Investigating performance problems:

Performance problems can arise from various factors. For example, incorrect resource allocation, poor application design, and I/O restraints. Use this topic to investigate some of the possible causes of performance problems.

Performance can be adversely affected by:
- Buffer pools that are an incorrect size
- Lack of real storage
- I/O contention for page sets or logs
- Log buffer thresholds that are set incorrectly
- Incorrect setting of the number of log buffers
- Large messages
- Units of recovery that last a long time, incorporating many messages for each sync point
- Messages that remain on a queue for a long time
- RACF auditing
- Unnecessary security checks
- Inefficient program design

When you analyze performance data, always start by looking at the overall system before you decide that you have a specific IBM MQ problem. Remember that almost all symptoms of reduced performance are magnified when there is contention. For example, if there is contention for DASD, transaction response times can increase. Also, the more transactions there are in the system, the greater the processor usage and greater the demand for both virtual and real storage.

In such situations, the system shows heavy use of *all* its resources. However, the system is actually experiencing normal system stress, and this stress might be hiding the cause of a performance reduction. To find the cause of such a loss of performance, you must consider all items that might be affecting your active tasks.

Investigating the overall system

Within IBM MQ, the performance problem is either increased response time or an unexpected and unexplained heavy use of resources. First check factors such as total processor usage, DASD activity, and paging. An IBM tool for checking total processor usage is resource management facility (RMF). In general, you must look at the system in some detail to see why tasks are progressing slowly, or why a specific resource is being heavily used.

Start by looking at general task activity, then focus on particular activities, such as specific tasks or a specific time interval.

Another possibility is that the system has limited real storage; therefore, because of paging interrupts, the tasks progress more slowly than expected.

Investigating individual tasks

You can use the accounting trace to gather information about IBM MQ tasks. These trace records tell you a great deal about the activity that the task has performed, and about how much time the task spent suspended, waiting for latches. The trace record also includes information about how much Db2 and coupling facility activity were performed by the task.

Interpreting IBM MQ accounting data is described in “Interpreting IBM MQ accounting data” on page 1251.

Long running units of work can be identified by the presence of message CSQR026I in the job log. This message indicates that a task has existed for more than three queue manager checkpoints and its log records have been shunted. z/OS For a description of log record shunting, see The log files.

Interpreting IBM MQ performance statistics

Use this topic as an index to the different SMF records created by IBM MQ for z/OS.

IBM MQ performance statistics are written as SMF type 115 records. Statistics records are produced periodically at a time interval specified by the STATIME parameter of the CSQ6SYSP system parameter module, or at the SMF global accounting interval if you specify zero for STATIME. The information provided in the SMF records comes from the following components of IBM MQ:

Buffer manager	Manages the buffer pools in virtual storage and the writing of pages to page sets as the buffer pools become full. Also manages the reading of pages from page sets.
Coupling facility manager	Manages the interface with the coupling facility.
Data manager	Manages the links between messages and queues. It calls the buffer manager to process the pages with messages on them.
Db2 manager	Manages the interface with the Db2 database that is used as the shared repository.
Lock manager	Manages locks for IBM MQ for z/OS.

Log manager	Manages the writing of log records, which are essential for maintaining the integrity of the system if there is a back out request, or for recovery, if there is a system or media failure.
Message manager	Processes all IBM MQ API requests.
Storage manager	Manages storage for IBM MQ for z/OS, for example, storage pool allocation, expansion, and deallocation.
Topic manager	Manages the Topic and Subscription information for IBM MQ for z/OS.
Coupling facility SMDS manager	Manages the shared message data sets (SMDS) for large messages stored in the coupling facility.

IBM MQ statistics are written to SMF as SMF type 115 records. The following subtypes can be present:

1 System information, for example, related to the logs and storage.

2 Information about number of messages, buffer, and paging information. Queue-sharing group information related to the coupling facility and Db2.

3 More detailed information about storage usage in the MSTR address space.

215 Bufferpool information when the queue manager is running in `OPMODE=(NEWFUNC,800)` mode.

231 System information for the CHIN address space.

Note that:

- Subtype 1, 2, and 215 are created with statistics trace class(1)
- Subtype 3 with statistics trace classes 2 and 3
- Subtype 231 with statistics trace class(4)

The subtype is specified in the SM115STF field (shown in Table 134 on page 1229).

Layout of an SMF type 115 record:

You can use this section as a reference for the format of an SMF type 115 record.

The standard layout for SMF records involves three parts:

SMF header
Provides format, identification, and time and date information about the record itself.

Self-defining section
Defines the location and size of the individual data records within the SMF record.

Data records
The actual data from IBM MQ that you want to analyze.

For more information about SMF record formats, see the *MVS System Management Facilities (SMF)* manual.

Related reference:

"The SMF header"
Use this topic as a reference for the format of the SMF header.

"Self-defining sections" on page 1230
Use this topic as a reference for format of the self-defining sections of the SMF record.

Use this topic to understand some example SMF records.

The SMF header:

Use this topic as a reference for the format of the SMF header.

Table 134 shows the format of SMF record header (SM115).

Table 134. SMF record 115 header description

Offset: Dec	Offset: Hex	Type	Len	Name	Description	Example
0	0	Structure	28	SM115	SMF record header.	
0	0	Integer	2	SM115LEN	SMF record length.	14A0
2	2		2		Reserved.	
4	4	Integer	1	SM115FLG	System indicator.	5E
5	5	Integer	1	SM115RTY	Record type. The SMF record type, for IBM MQ statistics records this is always 115 (X'73').	73
6	6	Integer	4	SM115TME	Time when SMF moved record.	00355575
10	A	Integer	4	SM115DTE	Date when SMF moved record.	0100223F
14	E	Character	4	SM115SID	z/OS subsystem ID. Defines the z/OS subsystem on which the records were collected.	D4E5F4F1 (MV41)
18	12	Character	4	SM115SSI	IBM MQ subsystem ID.	D4D8F0F7 (MQ07)
22	16	Integer	2	SM115STF	Record subtype.	0002
24	18	Character	3	SM115REL	IBM MQ version.	F6F0F0 (600)
27	1B		1		Reserved	
28	1C	Character	0	SM115END	End of SMF header and start of self-defining section.	

Self-defining sections:

Use this topic as a reference for format of the self-defining sections of the SMF record.

A self-defining section of a type 115 SMF record tells you where to find a statistics record, how long it is, and how many times that type of record is repeated (with different values). The self-defining sections follow the header, at fixed offsets from the start of the SMF record. Each statistics record can be identified by an eye-catcher string.

The following types of self-defining section are available to users for type 115 records. Each self-defining section points to statistics data related to one of the IBM MQ components. Table 135 summarizes the sources of the statistics, the eye-catcher strings, and the offsets of the self-defining sections from the start of the SMF record header.

Table 135. Offsets to self-defining sections

Source of statistics	**Record subtype (SM115STF)**	**Offset of self-defining section**		**Eye-catcher of data**
		Dec	**Hex**	
Storage manager	1	100	X'64'	QSST
Log manager	1	116	X'74'	QJST
Message manager	2	36	X'24'	QMST
Data manager	2	44	X'2C'	QIST
Buffer manager - one for each buffer pool, see note below	2	52	X'34'	QPST
Lock manager	2	60	X'3C'	QLST
Db2 manager	2	68	X'44'	Q5ST
Coupling Facility manager	2	76	X'4C'	QEST
Topic manager	2	84	X'54'	QTST
SMDS usage	2	92	X'5C'	QESD
Buffer manager - one for each buffer pool, see note below	215	36	X'24'	QPST
Channel initiator	231			QWSX

Notes:

1. For the Buffer Manager entry in subtype 2 the self-defining section will always show zeros indicating that there are no buffer manager records.
2. Other self-defining sections refer to data for IBM use only.

Buffer manager statistics go into different subtypes depending on the settings for OPMODE in the system parameters. If `OPMODE(NEWFUNC,800)` is in effect, buffer manager statistics will go into subtype 215, and the self defining section for buffer manager statistics in subtype 2 will be all zeros. If `OPMODE(COMPAT,800)`, or equivalent, is in effect, buffer manager statistics will go into subtype 2 and subtype 215 statistics will not be generated.

Each self-defining section is two fullwords long and has this format:

```
ssssssssllllnnnn
```

where:

ssssssss	Fullword containing the offset from the start of the SMF record.
llll	Halfword giving the length of this data record.
nnnn	Halfword giving the number of data records in this SMF record.

For more information see, "Examples of SMF statistics records."

Note: Always use offsets in the self-defining sections to locate the statistics records.

Examples of SMF statistics records:

Use this topic to understand some example SMF records.

Figure 105 shows an example of part of the SMF record for subtype 1. Subtype 1 includes the storage manager and log manager statistics records. The SMF record header is shown underlined.

The self-defining section at offset X'64' refers to storage manager statistics and the self-defining section at offset X'74' refers to log manager statistics, both shown in **bold**.

The storage manager statistics record is located at offset X'0000011C' from the start of the header and is X'48' bytes long. There is one set of storage manager statistics, identified by the eye-catcher string QSST. The start of this statistics record is also shown in the example.

The log manager statistics record is located at offset X'00000164' from the start of the header and is X'78' bytes long. There is one set of log manager statistics, identified by the eye-catcher string QJST.

Figure 105. SMF record 115, subtype 1

Figure 106 on page 1232 shows an example of part of the SMF record for subtype 2. Subtype 2 includes the statistics records for the message, data, lock, coupling facility, topic, and Db2 managers. The SMF record header is shown underlined; the self-defining sections are shown alternately **bold** and *italic*.

- The self-defining section at offset X'24' refers to message manager statistics. The message manager statistics record is located at offset X'00000064' from the start of the header and is X'48' bytes long. There is one set of these statistics, identified by the eye-catcher string QMST.
- The self-defining section at offset X'2C' refers to data manager statistics. The data manager statistics record is located at offset X'000000AC' from the start of the header and is X'50' bytes long. There is one set of these statistics, identified by the eye-catcher string QIST.

- The self-defining section at offset X'34' refers to buffer manager statistics. As this SMF record was taken from a queue manager that has OPMODE(NEWFUNC,800) set in its system parameters, the buffer manager self-defining section is set to zeros to indicate that there are no buffer manager statistics. Instead, these statistics are in SMF 115 subtype 215 records.
- The self-defining section at offset X'3C' refers to lock manager statistics. The lock manager statistics record is located at offset X'000000FC' from the start of the header and is X'20' bytes long. There is one set of these statistics, identified by the eye-catcher string QLST.
- The self-defining section at offset X'44' refers to Db2 manager statistics. The Db2 manager statistics record is located at offset X'0000011C' from the start of the header and is X'2A0' bytes long. There is one set of these statistics, identified by the eye-catcher string Q5ST.
- The self-defining section at offset X'4C' refers to coupling facility manager statistics. The coupling facility manager statistics record is located at offset X'000003BC' from the start of the header and is X'1008' bytes long. There is one set of these statistics, identified by the eye-catcher string QEST.
- The self-defining section at offset X'54' refers to topic manager statistics. The topic manager statistics record is located at offset X'000013C4' from the start of the header and is X'64' bytes long. There is one set of these statistics, identified by the eye-catcher string QTST.
- The self-defining section at offset X'5C' is for SMDS statistics. This self defining section is set to zeros indicating that SMDS is not being used.

Figure 106. SMF record 115, subtype 2

Processing type 115 SMF records:

Use this topic as a reference for processing type 115 SMF records.

You must process any data you collect from SMF to extract useful information. When you process the data, verify that the records are from IBM MQ and that they are the records you are expecting.

Validate the values of the following fields:
- SM115RTY, the SMF record number, must be X'73' (115)
- SM115STF, the record subtype, must be 0001, 0002, 0215, or 0231

Reading from the active SMF data sets is not supported. You must use the SMF program IFASMFDP to dump SMF record to a sequential data set so that they can be processed. For more information see "Using System Management Facility" on page 1224.

There is a C sample program called CSQ4SMFD which prints the contents of SMF type 115 and 116 records. The program is provided as source in thlqual.SCSQC37S and in executable format in thlqual.SCSQLOAD. Sample JCL is provided in thlqual.SCSQPROC(CSQ4SMFJ).

Storage manager data records:

Use this topic as a reference for storage manager data records.

The format of the storage manager statistics record is described in assembler macro thlqual.SCSQMACS(CSQDQSST).

The data contains information about the number of fixed and variable storage pools that the queue manager has allocated, expanded, contracted, and deleted during the statistics interval, plus the number of GETMAIN, FREEMAIN, and STORAGE requests to z/OS, including a count of those requests that were unsuccessful. Additional information includes a count of the number of times the short-on-storage condition was detected and a count of the number of abends that occurred as a result of that condition.

Log manager data records:

Use this topic as a reference for format of log manager data records.

The format of the log manager statistics record is described in assembler macro thlqual.SCSQMACS(CSQDQJST).

In the statistics, these counts are important:
1. The total number of log write requests:

   $N_{logwrite}$ = QJSTWRW + QJSTWRNW + QJSTWRF
2. The total number of log read requests:

   $N_{logread}$ = QJSTRBUF + QJSTRACT + QJSTRARH

The problem symptoms that can be examined using log manager statistics are described in the following table.

Symptom 1
QJSTWTB is nonzero.

Reason
Tasks are being suspended while the in-storage buffer is being written to the active log.

There might be problems writing to the active log.

The OUTBUFF parameter within CSQ6LOGP is too small.

Action
Investigate the problems writing to the active log.

Increase the value of the OUTBUFF parameter within CSQ6LOGP.

Symptom 2
The ratio: $\mathtt{QJSTWTL}/\mathtt{N}_{\mathtt{logread}}$ is greater than 1%.

Reason
Log reads were initiated that had to read from an archive log, but IBM MQ could not allocate a data set because MAXRTU data sets were already allocated.

Action
Increase MAXRTU.

Symptom 3
The ratio: $\mathtt{QJSTRARH}/\mathtt{N}_{\mathtt{logread}}$ is larger than normal.

Reason
Most log read requests should come from the output buffer or the active log. To satisfy requests for back out, unit-of-recovery records are read from the in-storage buffer, the active log, and the archived logs.

A long-running unit of recovery, extending over a period of many minutes, might have log records spread across many different logs. This degrades performance because extra work has to be done to recover the log records.

Action
Change the application to reduce the length of a unit of recovery. Also, consider increasing the size of the active log to reduce the possibility of a single unit of recovery being spread out over more than one log.

Other pointers
The ratio $\mathtt{N}_{\mathtt{logread}}/\mathtt{N}_{\mathtt{logwrite}}$ gives an indication of how much work has to be backed out.

Symptom 4
QJSTLLCP is more than 10 an hour.

Reason
On a busy system, you would expect to see typically 10 checkpoints an hour. If the QJSTLLCP value is larger than this, it indicates a problem in the setup of the queue manager.

The most likely reason for this is that the LOGLOAD parameter in CSQ6SYSP is too small. The other event that causes a checkpoint is when an active log fills up and switches to the next active log data set. If your logs are too small, this can cause frequent checkpoints. The QJSTLLCP counter is not incremented for log switch induced checkpoints; you must look in the JES logs for the queue managers to determine if the rate log files are switched.

Action
Increase the LOGLOAD parameter, or increase the size of your log data sets as required.

Symptom 5

QJSTCmpFail > 0 or QJSTCmpComp not much less than QJSTCmpUncmp

Reason

The queue manager is unable to significantly compress log records.

QJSTCmpFail is the number of times the queue manager was unable to achieve any reduction in record length. You should compare the number to QJSTCmpReq (number of compression requests) to see if the number of failures is significant.

QJSTCmpComp is the total of compressed bytes written to the log and QJSTCmpUncmp is the total bytes before compression. Neither total contains bytes written for log records that were not eligible for compression. If the numbers are similar then compression has achieved little benefit.

Action

Turn off log compression. Issue the SET LOG COMPLOG(NONE) command. See the SET LOG command for details.

Note: In the first set of statistics produced after system startup, there might be significant log activity due to the resolution of in-flight units of recovery.

Message manager data records:

Use this topic as a reference for message manager data records.

The format of the message manager statistics record is described in assembler macro thlqual.SCSQMACS(CSQDQMST).

The data gives you counts of different IBM MQ API requests.

Data manager data records:

Use this topic as a reference for the format of the Data Manager data records.

The format of the data manager statistics record is described in assembler macro thlqual.SCSQMACS(CSQDQIST).

The data gives you counts of different object requests.

Buffer manager data records:

Use this topic as a reference for the format of buffer manager data records.

The format of the buffer manager statistics record is described in assembler macro thlqual.SCSQMACS(CSQDQPST).

Note: Buffer manager statistics records will only be created for buffer pools that are defined. If a buffer pool is defined but not used then no values will be set and its buffer manager statistics record will not contain any data.

For information about efficiently managing your buffer pools, see "Managing your buffer pools" on page 1237.

When interpreting the statistics, you are recommended to consider the following factors because the values of these fields can be used to improve the performance of your system:

1. If QPSTSOS, QPSTSTLA, or QPSTDMC is greater than zero, you should either increase the size of the buffer pool or reallocate the page sets to different buffer pools.

- QPSTSOS is the number of times that there were no buffers available for page get requests. If QPSTSOS ever becomes nonzero, it shows that IBM MQ is under severe stress. The buffer pool size should be increased. If increasing the buffer pool size does not make the value of QPSTSOS zero, there might be I/O contention on the DASD page sets.
- QPSTDMC is the number of updates that were performed synchronously because there was either more than 95% of the pages in the buffer pool waiting for write I/O, or there was less than 5% of the buffer pool available for read requests. If this number is not zero, the buffer pool might be too small and should be enlarged. If increasing the buffer pool size does not reduce QPSTDMC to zero, there might be I/O contention on the DASD page sets.
- QPSTIMW is a count of the number of times pages were written out synchronously. If QPSTDMC is zero, QPSTIMW is the number of times pages were found on the queue waiting for write I/O that had been there for at least two checkpoints.

2. For buffer pool zero and buffer pools that contain short-lived messages:
   - QPSTDWT should be zero, and the percentage QPSTCBSL/QPSTNBUF should be greater than 15%.

     QPSTDWT is the number of times the asynchronous write processor was started because there was either more than 85% of the pages in the buffer pool waiting for write I/O, or there was less than 15% of the buffer pool available for read requests. Increasing the buffer pool size should reduce this value. If it does not, the pattern of access is one of long delays between puts and gets.
   - QPSTTPW might be greater than zero due to checkpointing activity.
   - QPSTRIO should be zero unless messages are being read from a page set after the queue manager is restarted.

     The ratio of QPSTRIO to QPSTGETP shows the efficiency of page retrieval within the buffer pool. Increasing the buffer pool size should decrease this ratio and, therefore, increase the page retrieval efficiency. If this does not happen, it indicates that pages are not being frequently reaccessed. This implies a transaction pattern where there is a long delay between messages being put and then later retrieved.

     The ratio of QPSTGETN to QPSTGETP indicates the number of times an empty page, as opposed to a non-empty page, has been requested. This ratio is more an indication of transaction pattern, than a value that can be used to tune the system.
   - If QPSTSTL has a value greater than zero, this indicates that pages that have not been used before are now being used. This might be caused by an increased message rate, messages not being processed as fast as they were previously (leading to a buildup of messages), or larger messages being used.

     QPSTSTL is a count of the number of times a page access request did not find the page already in the buffer pool. Again, the lower the ratio of QPSTSTL to (QPSTGETP + QPSTGETN) is, the higher the page retrieval efficiency. Increasing the buffer pool size should decrease this ratio but, if it does not, it is an indication that there are long delays between puts and gets.
   - You are recommended to have sufficient buffers to handle your peak message rate.
3. For buffer pools with long-lived messages, where there are more messages than can fit into the buffer pool:
   - (QPSTRIO+QPSTWIO)/Statistics interval is the I/O rate to page sets. If this value is high, you should consider using multiple page sets on different volumes to allow I/O to be carried out in parallel.

     The higher the ratio of QPSTSTW to QPSTWIO, the better the efficiency of the asynchronous write processor. You can increase this ratio, and therefore the efficiency of the asynchronous write processor, by increasing the buffer pool size.
   - Over the period of time that the messages are processed (for example, if messages are written to a queue during the day and processed overnight) the number of read I/Os (QPSTRIO) should be approximately the total number of pages written (QPSTTPW). This shows that one page is read for every page written.

If QPSTRIO is much larger than QPSTTPW, this shows that pages are being read in multiple times. This might be a result of the application using **MQGET** by `MsgId` or `CorrelId` when the queue is not indexed, or browsing messages on the queue using get next.

The following actions might relieve this problem:

a. Increase the size of the buffer pool so that there are enough pages to hold the queue, in addition to any changed pages.
b. Use the INDXTYPE queue attribute, which allows a queue to be indexed by `MsgId` or `CorrelId` and eliminates the need for a sequential scan of the queue.
c. Change the design of the application to eliminate the use of **MQGET** with `MsgId` or `CorrelId`, or the get next with browse option.

   Note: Applications using long-lived messages typically process the first available message and do not use **MQGET** with `MsgId` or `CorrelId`, and they might browse only the first available message.
d. Move page sets to a different buffer pool to reduce contention between messages from different applications.

Managing your buffer pools:

To manage your buffer pools efficiently, you must consider the factors that affect the buffer pool I/O operations and also the statistics associated with the buffer pools.

The following factors affect buffer pool I/O operations.

- If a page containing the required data is not found in the buffer pool, it is read in synchronously to an available buffer from its DASD page set.
- Whenever a page is updated, it is put on an internal queue of pages to be (potentially) written out to DASD. This means that the buffer used by that page is unavailable for use by any other page until the buffer has been written to DASD.
- If the number of pages queued to be written to DASD exceeds 85% of the total number of buffers in the pool, an asynchronous write processor is started to put the buffers to DASD.

  Similarly, if the number of buffers available for page get requests become less than 15% of the total number of buffers in the pool, the asynchronous write processor is started to perform the write I/O operations.

  The write processor stops when the number of pages queued to be written to DASD has fallen to 75% of the total number of buffers in the pool.
- If the number of pages queued for writing to DASD exceeds 95% of the total number of buffers in the pool, all updates result in a synchronous write of the page to DASD.

  Similarly, if the number of buffers available for page get requests becomes less than 5% of the total number of buffers in the pool, all updates result in a synchronous write of the page to DASD.
- If the number of buffers available for page get requests ever reaches zero, a transaction that encounters this condition is suspended until the asynchronous write processor has finished.
- If a page is frequently updated, the page spends most of its time on the queue of pages waiting to be written to DASD. Because this queue is in least recently used order, it is possible that a frequently updated page placed on this least recently used queue is never written out to DASD. For this reason, at the time of update, if the page is found to have been waiting on the write operation to DASD queue for at least two checkpoints, it is synchronously written to DASD. Updating occurs at checkpoint time and is suspended until the asynchronous write processor has finished.

  The aim of this algorithm is to maximize the time pages spend in buffer pool memory while allowing the system to function if the system load puts the buffer pool usage under stress.

Lock manager data records:

Use this topic as a reference to the format of the lock manager data records.

The format of the lock manager statistics record is described in assembler macro thlqual.SCSQMACS(CSQDQLST).

The records contain data about the following information:
- The number of lock get requests and lock release requests.
- The number of times a lock get request determined that the requested lock was already held.

Db2 manager data records:

Use this topic as a reference to the format of the Db2 manager data records.

The format of the Db2 manager statistics record is described in the following table and in assembler macro thlqual.SCSQMACS(CSQDQ5ST) and C header file thlqual.SCSQC370(CSQDSMFC). The field names in C are all in lowercase, for example q5st, q5stid.

If the queue manager was not started as a member of a queue-sharing group, no data is recorded in this record.

Table 136. Db2 statistics record (Q5ST)

Offset: Dec	Offset: Hex	Type	Len	Name	Description
0	0	Structure	668	Q5ST	Db2 manager statistics
0	0	Bitstring	2	Q5STID	Control block identifier
2	2	Integer	2	Q5STLL	Control block length
4	4	Character	4	Q5STEYEC	Control block eye catcher
8	8	Character	660	Q5STZERO	QMST part cleared on occasion
8	8	Integer	4	NUMTASK	Number of server tasks
12	C	Integer	4	ACTTASK	Number of active server tasks
16	10	Integer	4	CONNCNT	Number of connect requests
20	14	Integer	4	DISCCNT	Number of disconnect requests
24	18	Integer	4	DHIGMAX	Max. request queue depth
28	1C	Integer	4	ABNDCNT	Number of Db2SRV task abends
32	20	Integer	4	REQUCNT	Number of requests requeued
36	24	Integer	4	DEADCNT	Number of deadlock timeouts
40	28	Integer	4	DELECNT	Number of delete requests
44	2C	Integer	4	LISTCNT	Number of list requests
48	30	Integer	4	READCNT	Number of read requests
52	34	Integer	4	UPDTCNT	Number of update requests
56	38	Integer	4	WRITCNT	Number of write requests
60	3C	Integer	4	SCSSEL	SCST (shared-channel-status) selects
64	40	Integer	4	SCSINS	SCST inserts
68	44	Integer	4	SCSUPD	SCST updates
72	48	Integer	4	SCSDEL	SCST deletes

Table 136. Db2 statistics record (Q5ST) (continued)

Offset: Dec	Offset: Hex	Type	Len	Name	Description

572	23C	64 bit integer	8	LMSUTCUW	Total elapsed time for all thread update BLOB requests
580	244	64 bit integer	8	LMSUTMXW	Maximum elapsed time for a thread update BLOB request
588	24C	64 bit integer	8	LMSUSCUW	Total elapsed time for all SQL update BLOB requests

Table 136. Db2 statistics record (Q5ST) (continued)

Offset: Dec	Offset: Hex	Type	Len	Name	Description
596	254	64 bit integer	8	LMSUSMXW	Maximum elapsed time for an SQL update BLOB request
604	25C	64 bit integer	8	LMSDTCUW	Total elapsed time for all thread delete BLOB requests
612	264	64 bit integer	8	LMSDTMXW	Maximum elapsed time for a thread delete BLOB request
620	26C	64 bit integer	8	LMSDSCUW	Total elapsed time for all SQL delete BLOB requests
628	274	64 bit integer	8	LMSDSMXW	Maximum elapsed time for an SQL delete BLOB request
636	27C	64 bit integer	8	LMSLTCUW	Total elapsed time for all thread list BLOB requests
644	284	64 bit integer	8	LMSLTMXW	Maximum elapsed time for a thread list BLOB request
652	28C	64 bit integer	8	LMSLSCUW	Total elapsed time for all SQL list BLOB requests
660	294	64 bit integer	8	LMSLSMXW	Maximum elapsed time for an SQL list BLOB request

The data contains counts for each request type that the Db2 resource manager supports. For these request types, maximum and cumulative elapse times are kept for the following:

- The time spent in the Db2 resource manager as a whole (called the thread time).
- The time that was spent performing the RRSAF and SQL parts of the request (a subset of the thread time called the SQL time).

Information is also provided for:

- The number of server tasks attached.
- The maximum overall request depth against any of the server tasks.
- The number of times any of the server task requests terminated abnormally.

If the abnormal termination count is not zero, a requeue count is provided indicating the number of queued requests that were requeued to other server tasks as a result of the abnormal termination.

If the average thread time is significantly greater that the average SQL time, this might indicate that thread requests are spending an excessive amount of time waiting for a server task to process the SQL part of the request. If this is the case, examine the DHIGMAX field and, if the value is greater than one, consider increasing the number of Db2 server tasks specified in the QSGDATA parameter of the CSQ6SYSP system parameter macro.

Coupling facility manager data records:

Use this topic as a reference to the format of the coupling facility manager data records.

The format of the coupling facility manager statistics record is described in the following table and in assembler macro thlqual. SCSQMACS(CSQDQEST) and C header file thlqual.SCSQC370(CSQDSMFC). The field names in C are all in lowercase, for example qest, qestid.

If the queue manager was not started as a member of a queue-sharing group, no data is recorded in this record.

Table 137. Coupling facility statistics record (QEST)

Offset: Dec	Offset: Hex	Type	Len	Name	Description
0	0	Structure	4104	QEST	CF manager statistics
0	0	Bitstring	2	QESTID	Control block identifier
2	2	Integer	2	QESTLL	Control block length
4	4	Character	4	QESTEYEC	Control block eye catcher
8	8	Character	4096	QESTZERO	QEST part cleared on occasion
8	8	Character	64	QESTSTUC (0:63)	Array (one entry per structure)
8	8	Character	12	QESTSTR	Structure name
20	14	Integer	4	QESTSTRN	Structure number
24	18	Integer	4	QESTCSEC	Number of IXLLSTE calls
28	1C	Integer	4	QESTCMEC	Number of IXLLSTM calls
32	20	Character	8	QESTSSTC	Time spent doing IXLLSTE calls
40	28	Character	8	QESTMSTC	Time spent doing IXLLSTM calls
48	30	Integer	4	QESTRSEC	Number of IXLLSTE redrives
52	34	Integer	4	QESTRMEC	Number of IXLLSTM redrives
56	38	Integer	4	QESTSFUL	Number of structure fulls
60	3C	Integer	4	QESTMNUS	Maximum number of entries in use
64	40	Integer	4	QESTMLUS	Maximum number of elements in use
68	44	Character	4	*	Reserved
4104	1008	Character	0	*	End of control block

The data contains information for each coupling facility list structure, including the CSQ_ADMIN structure, that the queue manager could connect to during the statistics interval. The information for each structure includes the following:

- The number of and cumulative elapsed times for IXLLSTE and IXLLSTM requests.
- The number of times a request had to be retried because of a timeout.
- The number of times a 'structure full' condition occurred.

Topic manager data records:

Use this topic as a reference to the format of the topic manager data records.

The format of the Topic manager statistics record is described in the following table and in assembler macro thlqual.SCSQMACS(CSQDQTST) and C header file thlqual.SCSQC370(CSQDSMFC). The field names in C are all in lowercase, for example qtst, qtstid.

Table 138. Topic manager statistics record (QTST)

Offset: Dec	Offset: Hex	Type	Len	Name	Description
0	0	Structure	96	QTST	Topic manager statistics
0	0	Bitstring	2	QTSTID	Control block identifier
2	2	Integer	2	QTSTLL	Control block length
4	4	Character	4	TESTEYEC	Control block eye catcher
8	8	Character	88	QTSTZERO	QTST part cleared on occasion
8	8	Integer	4	QTSTSTOT	Total subscription requests
12	0C	Integer	4	QTSTSDUR	Durable subscription requests
16	10	Integer	4	QTSTSHIG (1:3)	Subscription high water mark array (API, ADMIN, PROXY)
28	1C	Integer	4	QTSTSLOW (1:3)	Subscription low water mark array (API, ADMIN, PROXY)
40	28	Integer	4	QTSTSEXP	Subscriptions expired
44	2C	Integer	4	QTSTTMSG	Total messages put to Sub queue
48	30	Integer	4	QTSTSPHW	Single publish subscriber high water mark
52	34	Integer	4	QTSTPTOT (1:3)	Total Publication requests (API, ADMIN, PROXY)
64	40	Integer	4	QTSTPTHI	Total publish high water mark
68	44	Integer	4	QTSTPTLO	Total publish low water mark
72	48	Integer	4	QTSTPNOS	Count of publishes to no subscriber
76	4C	Integer	4	*	Reserved
80	50	Bitstring	8	QTSTETHW	Elapse time HW on publish
88	58	Bitstring	8	QTSTETTO	Elapse time total on publish

Coupling facility manager SMDS data records:

Use this topic as a reference to the format of the coupling facility manager shared message data set (SMDS) data records.

The format of the coupling facility manager shared message data set (SMDS) statistics record is described in assembler macro thlqual.SCSQMACS(CSQDQESD), C header file thlqual.SCSQC370(CSQDSMFC) and in IBM MQ SupportPac MP1B.

The statistics provide information about the utilization of the owned shared message data set, I/O activity for the group of shared message data sets, and SMDS buffer utilization.

If the queue manager was not started as a member of a queue-sharing group, no data is recorded in this record.

Layout of SMF records for the channel initiator:

The layouts of channel accounting data (SMF type 116, subtype 10) and channel initiator statistics data (SMF type 115 , subtype 231 records) are described in this topic.

Processing the SMF data for the CHINIT

The data written to SMF is in the standard triplet format.

Accounting data SMF type 116, subtype 10

There is the standard SMF header.

The triplets are mapped by qws5 in csqdsmfc.h and csqdqws5.macro, and have the following layout:

4 bytes offset to the QWHS
2 bytes length of the QWHS
2 bytes count of the number of instances of QWHS
4 bytes offset to the QCST
2 bytes length of the QCST
2 bytes count of the number of instances of QCST

The QWHS mapped is mapped by csqdqwhs.macro and csqdsmfc.h, and has the following key fields:

- qwhsnsda 1 byte, count of the number of self defining section.
- qwhssmfc 1 bit. If this is on there are multiple SMF records containing information for this interval. If this is off, this is the last or only record.
- Qwhstime 8 bytes in STCK format. The local time of the start of the interval.
- qwhsdurn 8 bytes in STCK format. The duration from the start of the interval to the end of the interval.
- Qwhsstck 8 bytes STCK format. The end of the interval in GMT.

The QCST is mapped by csqdsmfc.h and csqdqcst.macro.

Statistics data SMF type 115, subtype 231

There is the standard SMF header.

The triplets are mapped by qwsx in csqdsmfc.h and csqdqwsx.macro, and have the following layout:

4 bytes offset to the QWHS

2 bytes length of the QWHS
2 bytes count of the number of instances of QWHS

CHINIT Control Information, number of channels. and so on is mapped by csqdsmfc.h and csqdqcct.macro:
4 bytes offset to the QCCT
2 bytes length of the QCCT
2 bytes count of the number of instances of the QCCT

Dispatcher tasks are mapped by csqdsmfc.h and the QCT_DSP structure in the CSQDQCTA macro:
4 bytes offset to the QCT_DSP
2 bytes length of the QCT_DSP
2 bytes count of the number of instances of the QCT_DSP

Adapter tasks are mapped by csqdsmfc.h and the QCT_ADP structure in the CSQDQCTA macro:
4 bytes offset to the QCT_ADP
2 bytes length of the QCT_ADP
2 bytes count of the number of instances of QCT_ADP

SSL tasks are mapped by csqdsmfc.h and the QCT_SSL structure in the CSQDQCTA macro:
4 bytes offset to the QCT_SSL
2 bytes length of the QCT_SSL
2 bytes count of the number of instances of QCT_SSL

DNS task is mapped by csqdsmfc.h and the QCT_DNS structure in the CSQDQCTA macro:
4 bytes offset to the QCT_DNS
2 bytes length of the QCT_DNS
2 bytes count of the number of instances of QCT_DNS

Typically one record contains all the data. If there are a large number of dispatchers, adapters, or SSL tasks, the data is split over more than one record.

If this happens, the count of instances of the dispatchers can be zero, and information about a group of TCBs can be spread across multiple records. For example the number of instances can look like this:

Table 139. Example data

Count	**First record**	**Last record**
QWHS	1	1
QCCT	1	0
QDSP	50	5
QADP	0	10
QSSL	0	3
QDNS	0	1

This example shows that there were 55 dispatcher TCBs within the SMF interval.

The field `qwhs.qwhssmfc` indicates a continuation. If this bit is on, there are multiple SMF records containing information for this interval. If this bit is off, this is the last or only record.

Channel initiator statistics data records:

Use this topic as a reference for channel initiator statistics data records.

The format of the channel initiator statistics data record contains two parts:
- The first part is the channel initiator control information block, described in assembler macro `thlqual.SCSQMACS(CSQDQCCT)`. For further information, see"Channel initiator control information block."
- The second part is the channel initiator task block, described in assembler macro `thlqual.SCSQMACS(CSQDQCTA)`.

  The channel initiator task block contains information about the four types of task within the CHINIT. For further information, see:
  - "Dispatcher tasks" on page 1247
  - "Adapter tasks" on page 1248
  - "Domain Name Server (DNS) task" on page 1249
  - "SSL tasks" on page 1250

  Each task includes:
  - The elapsed time the task was active in the interval (*qcteltm*)
  - How much CPU time was using in the interval (*qctcptm*)
  - Total wait time of this task in the interval (*qctwttm*)
  - The number of requests in the interval (*qctreqn*)

  You can use this information to see how busy the task was, and determine whether you need to add more tasks based on the analysis.

  For SSL and DNS tasks, the duration of the longest request (*qctlgdu*, *qctlsdu*) and the time of day when this occurred (*qctlgdm*, *qctlsdm*) are also included.

  These can be useful to identify when channel requests took a long time. For example, a DNS lookup request going to a server outside of your enterprise taking seconds rather than milliseconds.

  The example accounting data in the following tasks has been formatted using IBM MQ SupportPac MP1B.

Both of the parts are also described in the C programming language header file `thlqual.SCSQC370(CSQDSMFC)`. Note that the field names in C are all in lowercase, for example, *qcct*, *qct_adp*.

Channel initiator control information block:

Use this topic as a reference for the channel initiator control information block.

The channel initiator control information block contains basic information for this CHINIT, including:
- CHINIT job name (*qcctjobn*)
- QSG name if it is in a QSG (*qcctqsgn*)
- Peak number used of current channels (*qcctnocc*)
- Peak number used of active channels (*qcctnoac*)
- MAXCHL - maximum permitted current channels (*qcctmxcc*)
- ACTCHL - maximum permitted active channels (*qcctmxac*)
- TCPCHL - maximum permitted TCP/IP channels (*qcctmxtp*)
- LU62CHL - maximum permitted LU62 channels (*qcctmxlu*)
- Storage used by CHINIT (*qcctstus*)

You can use this information to see if the number of active channels is approaching the configured maximum value. Note that the number of current and active channels are the values when the record was created. So, between the two intervals there might have been more than this number of channels active.

Channel information from SMF data

Here is an example of channel information from SMF data:

```
MVCA,MQPV,2014/03/18,13:00:00,VRM:800,
From 2014/03/18,12:45:00.015222 to 2014/03/18,13:00:00.083630 duration 900.068408 seconds
Peak number used of current channels.......... 1
Peak number used of active channels .......... 1
MAXCHL. Max allowed current channels..........9999
ACTCHL. Max allowed active channels...........9999
TCPCHL. Max allowed TCP/IP channels...........9999
LU62CHL. Max allowed LU62 channels............ 200
Storage used by Chinit........................ 436MB
```

You can monitor the storage usage and see whether the value is trending upwards. If the total used is approaching the total storage available, you might be running out of storage, and so might not be able to support many more channels.

If the numbers of active current channels are tending towards the maximum number of channels, you might need to increase the maximum number of channels.

Dispatcher tasks:

Example data for the dispatcher tasks, and information about how to interpret the data.

Example data

```
Task, Type, Requests, Busy %,  CPU used, CPU %, "avg CPU", "avg ET"
    ,     ,         ,       ,  Seconds,       ,  uSeconds, uSeconds
   0, DISP,    26587,    0.4,  0.592463,   0.1,        22,      127
   1, DISP,    26963,    0.3,  0.588092,   0.1,        22,      112
   2, DISP,   864329,    2.7,  2.545668,   0.3,         3,       28
   3, DISP,    26875,    0.4,  0.590825,   0.1,        22,      120
   4, DISP,    26874,    0.4,  0.603285,   0.1,        22,      123
Summ, DISP,   971628,    0.8,  4.920332,   0.1,         5,       38
```

The example data shows that there were five dispatchers. A channel is associated with a dispatcher, and the work is distributed across all the dispatchers. This example shows that one dispatcher is processing more requests than other dispatchers. This is normal, as some channels might stop, so the dispatcher is processing fewer channels, and some channels can be busier than others.

- 4.9 seconds of CPU were used by the dispatchers.
- The average request used 5 microseconds of CPU and took 38 microseconds elapsed time.
- A dispatcher is used to send and receive data over a communications network, and this is not usually dependent on external events. The average elapsed time should, therefore, be close to the average CPU time used. If the CHINIT is delayed due to lack of CPU, then the ratio of average Elapsed Time to average CPU time is much larger, compared to when the CHINIT is not delayed for CPU.
- The average CPU used per request depends on the message traffic, for example, bigger messages use more CPU than smaller messages.

The fields are calculated from:

- Duration: qwhs.qwhsdurn
- Requests : qctreqn
- Busy %: qcteltm and duration

- CPU used: qctcptm
- CPU %: qctcptm and duration
- Average CPU: qctcptm and qctreqn
- Average ET: qcteltm and qctreqn

Usually, the number of dispatchers should be less than, or equal to, the number of processors in the LPAR. If you have more dispatchers than processors in the LPAR they might compete for CPU resources. For more information about tuning your system, see SupportPac MP16.

Channels have an affinity to a dispatcher, so you might find that some dispatchers process many more requests than another dispatcher.

You can use the ALTER QMGR CHIDISPS() command to change the number of dispatchers used. Any change comes into effect the next time the CHINIT is started.

Adapter tasks:

Example data for the adapter tasks, and information about how to interpret the data.

Example data

```
Task, Type, Requests, Busy %,  CPU used, CPU %, "avg CPU", "avg ET"
    ,     ,         ,       ,   Seconds,      ,  uSeconds, uSeconds
   0, ADAP,   470297,   10.2, 41.290670,   4.6,        88,      194
   1, ADAP,    13907,    0.6,  1.589428,   0.2,       114,      365
   2, ADAP,     2517,    0.2,  0.185325,   0.0,        74,      746
   3, ADAP,     1095,    0.1,  0.085774,   0.0,        78,      907
   4, ADAP,      535,    0.1,  0.040743,   0.0,        76,      947
   5, ADAP,      220,    0.0,  0.016228,   0.0,        74,     1175
   6, ADAP,       82,    0.0,  0.005521,   0.0,        67,     1786
   7, ADAP,       80,    0.0,  0.004248,   0.0,        53,     1160
Summ, ADAP,   488733,    1.4, 43.217938,   0.6,        88,      205
```

The fields are calculated from:
- Duration: qwhs.qwhsdurn
- Requests: qctreqn
- Busy %: qcteltm and duration
- CPU used: qctcptm
- CPU %: qctcptm and duration
- Average CPU: qctcptm and qctreqn average
- ET: qcteltm and qctreqn

This example shows that there were eight adapter tasks.

Adapter number 0
- Processed the majority of the requests (470297 out of 488733)
- Was busy 10.2% of the interval
- Used 41.3 seconds of CPU

Overall
The average CPU per request was 88 microseconds of CPU and took 205 microseconds

The adapters process IBM MQ requests. Some of these requests might wait, for example, for log I/O during a commit, so the average Elapsed Time per request has little meaning.

When an IBM MQ request is made the first free adapter task is used.
- If there is at least one adapter that has been little used (less than 1%) busy, you have enough adapters.

- If at least one adapter was not used, you have enough adapters defined.
- If all the adapters were used, you might need to allocate more adapters.
- If all of the adapters were used, and they were all busy for most of the interval, you need to allocate more adapters.

You can use the ALTER QMGR CHIADAPS() command to change the number of adapters used. Any changes come into effect the next time the CHINIT is started.

Attention: If there are too many adapters acting on a small set of queues, you might get contention within the queue manager.

Related information:

ALTER QMGR

Domain Name Server (DNS) task:

Example data for the DNS tasks, and information about how to interpret the data.

```
Task, Type, Requests, Busy %,  CPU used, CPU %, "avg CPU", "avg ET",  longest,       date,            time
   ,     ,          ,       ,   Seconds,      ,  uSeconds, uSeconds, uSeconds,            ,
   0,  DNS,    14002,    0.0,  0.122578,   0.0,         9,       11,      463, 2014/03/18, 12:56:33.987671
Summ,  DNS,    14002,    0.0,  0.122578,   0.0,         9,       11,      463, 2014/03/18, 12:56:33.987671
```

The CHINIT uses a single DNS task. The example shows that the task processed 14002 requests and on average the request used 9 microseconds of CPU and took 11 microseconds of elapsed time.

The longest DNS request took 463 microseconds elapsed time, and this occurred at 12:56:33 local time.

The fields are calculated from:
- Duration: qwhs.qwhsdurn
- Requests : qctreqn
- Busy %: qcteltm and duration
- CPU used: qctcptm
- CPU %: qctcptm and duration
- Average CPU: qctcptm and qctreqn
- Average ET: qcteltm and qctreqn
- Longest: qctlgdu
- Longest at: qctlgtm

The DNS task can go out of your enterprise to look up the IP address associated with a name. If the average Elapsed time is significantly more than the average CPU time used, you might have some long requests.

If the value of the longest request time is unacceptable you should work with your network team to investigate why you are having long requests. It might be that you have an invalid name in your connections.

If the DNS task is busy for 25% of the duration, consider investigating the cause further.

Note: There are requests to the DNS task that are not DNS lookups, so you might have the number of requests being greater than zero - but no longest request information.

SSL tasks:

Example data for the SSL tasks, and information about how to interpret the data.

Example data

```
Task, Type, Requests, Busy %,  CPU used, CPU %, "avg CPU", "avg ET",  longest,       date,           time
    ,     ,         ,       ,   Seconds,      ,  uSeconds, uSeconds, uSeconds,           ,
   0,  SSL,     3112,    1.2,  0.248538,   0.3,        80,      362,     8864, 2014/03/18, 12:46:40.237697
   1,  SSL,     3070,    1.2,  0.245433,   0.3,        80,      359,     4714, 2014/03/18, 12:46:18.938022
   2,  SSL,     3170,    1.2,  0.255557,   0.3,        81,      362,     7273, 2014/03/18, 12:46:35.358145
   3,  SSL,     3060,    1.2,  0.246542,   0.3,        81,      365,    13164, 2014/03/18, 12:46:44.514045
   4,  SSL,     3120,    1.3,  0.251927,   0.3,        81,      373,    22438, 2014/03/18, 12:46:22.134123
Summ,  SSL,    15532,    1.2,  1.247998,   0.3,        80,      364,    22438, 2014/03/18, 12:46:22.134123
```

This example data shows that the average request took 364 microseconds. The longest request was for SSL task 4, took 22,438 microseconds, and occurred at 12:46:22.134123 local time.

The fields are calculated from:

- Duration: qwhs.qwhsdurn
- Requests : qctreqn
- Busy %: qcteltm and duration
- CPU used: qctcptm
- CPU %: qctcptm and duration
- Average CPU: qctcptm and qctreqn
- Average ET: qcteltm and qctreqn
- Longest: qctlsdu longest at: qctlstm

A running channel is associated with an SSL task, in a similar way that a channel is associated with a dispatcher. The SSL tasks can use the cryptographic coprocessors available to the LPAR. So, the elapsed time can include time spent on a coprocessor. You should monitor the average elapsed time throughout the day. If this time increases significantly during peak periods you should work with your MVS systems programmers, as your coprocessors might be over utilized.

If the SSL tasks are busy for a significant proportion of the interval, increasing the number of SSL tasks might help. If the SSL tasks are waiting for external resources such as a coprocesor, increasing the number of SSL tasks has little effect.

You can use the ALTER QMGR SSLTASKS() command to change the number of SSL tasks used. Any changes come into effect the next time the CHINIT is started.

Related information:
ALTER QMGR

Interpreting IBM MQ accounting data

IBM MQ accounting data is written as SMF type 116 records. Use this topic as a reference to the different types of accounting data records.

IBM MQ accounting information can be collected for the following subtypes:

0 Message manager accounting records (how much processor time was spent processing IBM MQ API calls and the number of **MQPUT** and **MQGET** calls). This information is produced when a named task disconnects from IBM MQ, and so the information contained within the record might cover many hours.

1 Accounting data for each task, at thread and queue level.

2 Additional queue-level accounting data (if the task used more queues than could fit in the subtype 1 record).

10 Accounting data for channels.

Note: Accounting information for specific channels can be enabled or suppressed by the STATCHL channel attribute, and the STATACLS queue manager attribute.

Note that:
- Subtype 0 is produced with trace class(1)
- Subtypes 1 and 2 are produced with trace class(3)
- Subtype 10 is produced with accounting trace class(4)

Subtype

Layout of an SMF type 116 record:

Use this topic as a reference to the format of an SMF type record.

The standard layout for SMF records involves three parts:

SMF header
Provides format, identification, and time and date information about the record itself.

Self-defining section
Defines the location and size of the individual data records within the SMF record.

Data records
The actual data from IBM MQ that you want to analyze.

For more information about SMF record formats, see the *MVS System Management Facilities (SMF)* manual.

The SMF header

Table 140 on page 1252 shows the format of SMF record header (SM116).

Table 140. SMF record header description

Offset: Dec	Offset: Hex	Type	Len	Name	Description	Example
0	0	Structure	28	SM116	SMF record header.	
0	0	Integer	2	SM116LEN	SMF record length.	01A4
2	2		2		Reserved.	
4	4	Integer	1	SM116FLG	System indicator.	5E
5	5	Integer	1	SM116RTY	Record type. The SMF record type, for IBM MQ accounting records this is always 116 (X'74').	74
6	6	Integer	4	SM116TME	Time when SMF moved record.	00356124
10	A	Integer	4	SM116DTE	Date when SMF moved record.	0100223F
14	E	Character	4	SM116SID	z/OS subsystem ID. Defines the z/OS subsystem on which the records were collected.	D4E5F4F1 (MV41)
18	12	Character	4	SM116SSI	IBM MQ subsystem ID.	D4D8F0F7 (MQ07)
22	16	Integer	2	SM116STF	Record subtype.	0000
24	18	Character	3	SM116REL	IBM MQ version.	F6F0F0 (600)
27	1B		1		Reserved.	
28	1C	Character	0	SM116END	End of SMF header and start of self-defining section.	
Note: The (hexadecimal) values in the right-hand column relate to Figure 107 on page 1253.						

Self-defining sections

A self-defining section of an SMF record tells you where to find an accounting record, how long it is, and how many times that type of record is repeated (with different values). The self-defining sections follow the header, at a fixed offset from the start of the SMF record.

Each self-defining section points to accounting related data. Table 141 summarizes the offsets from the start of the SMF record header.

Table 141. Offsets to self-defining sections

Record subtype (SMF116STF)	Source of accounting data	Offset of self-defining section		See...
		Dec	Hex	
All	Common header	28	X'1C'	"Common IBM MQ SMF header" on page 1255
0	Message manager	44	X'2C'	"Message manager data records" on page 1257
1	Thread identification record	36	X'24'	"Thread-level and queue-level data records" on page 1258
1	Thread-level accounting	44	X'2C'	"Thread-level and queue-level data records" on page 1258

Table 141. Offsets to self-defining sections (continued)

Record subtype (SMF116STF)	Source of accounting data	Offset of self-defining section		See...
		Dec	Hex	
1	Queue-level accounting	52	X'34'	"Thread-level and queue-level data records" on page 1258. This section is present only if the WTASWQCT field in the task-related information (WTAS) structure is non-zero.
2	Thread identification record	36	X'24'	"Thread-level and queue-level data records" on page 1258
2	Queue-level accounting	44	X'2C'	"Thread-level and queue-level data records" on page 1258
10	Channel accounting			"Channel accounting data records" on page 1260

Note: Other self-defining sections refer to data for IBM use only.

Each self-defining section is two fullwords long and has this format:

```
ssssssssllllnnnn
```

where:

ssssssss
Fullword containing the offset from start of the SMF record.

llll Halfword giving the length of this data record.

nnnn Halfword giving the number of data records in this SMF record.

Figure 107 shows an example of part of an SMF type 116 record. The numbers in the left-hand column represent the offset, in hexadecimal, from the start of the record. Each line corresponds to sixteen bytes of data, where each byte is two hexadecimal characters, for example 0C. The characters in the right-hand column represent the printable characters for each byte. Non-printable characters are shown by a period (.) character.

In this example, alternate fields in the SMF header are underlined to help you to see them; refer to Table 140 on page 1252 to identify them. The self defining section for one of the message manager accounting data records (at the offset given in Table 141 on page 1252) is shown in **bold**.

```
000000 01A40000 5E740035 61240100 223FD4E5  *....;.../.....MV*
000000 F4F1D4D8 F0F70000 F6F0F000 00000134  *41MQ07..600.....*
000000 00700001 00000054 00B00001 00000104  *................*
000000 00300001 00000000 00000000 00000000  *................*
000000 00000000 00000000 00000000 00000000  *................*
```

Figure 107. Part of an SMF record 116 showing the header and self-defining sections. Part of an SMF record 116 showing the header and self-defining sections.

The self-defining section for the type of message manager accounting data is located at offset X'2C' from the start of the SMF record and contains this information:

- The offset of the message manager accounting data is located X'00000104' bytes from the start of the SMF record.
- This message manager record is X'0030' bytes long.
- There is one record (X'0001').

Note: Always use offsets in the self-defining sections to locate the accounting records.

Processing type 116 SMF records:

Use this topic as a reference to the format of the processing type accounting record.

Any accounting data you collect from SMF must be processed to extract useful information. When you process the data, verify that the records are from IBM MQ and that they are the records you are expecting.

Validate the value of the following fields:
- SM116RTY, the SMF record number = X'74' (116)
- SM116STF, the record subtype, must be 0000, 0001, 0002, or 0010

Reading from the active SMF data sets is not supported. You must use the SMF program IFASMFDP to dump SMF records to a sequential data set so that they can be processed. For more information see "Using System Management Facility" on page 1224.

There is a C sample program called CSQ4SMFD which prints the contents of SMF type 115 and 116 records. The program is provided as source in thlqual.SCSQC37S and in executable format in thlqual.SCSQLOAD. Sample JCL is provided in thlqual.SCSQPROC(CSQ4SMFJ).

You need to update the SMFIN DD card with the name of the SMF dataset. Use the z/OS command '/D SMF' to show the name of the dataset, and you need to update the DUMPOUT DD card with the name for the output dataset.

You also need to specify the START and END times that you require.

The following sample JCL extracts SMF records:

```
//SMFDUMP EXEC PGM=IFASMFDP,REGION=0M
//SYSPRINT DD SYSOUT=
//SMFIN  DD DSN=xxxxxx.MANA,DISP=SHR
//SMFOUT  DD DSN=xxxxxx.SMFOUT,SPACE=(CYL,(1,1)),DISP=(NEW,CATLG)
//SYSIN DD *
INDD(SMFIN,OPTIONS(DUMP))
OUTDD(SMFOUT,TYPE(116))
OUTDD(SMFOUT,TYPE(115))
START(1159) END(1210)
/*
```

Common IBM MQ SMF header:

Use this topic as a reference to the common IBM MQ SMF header type accounting record.

The format of this record is described in Table 142 and in assembler macros thlqual.SCSQMACS(CSQDQWHS) and thlqual.SCSQMACS(CSQDQWHC), and C header file thlqual.SCSQC370(CSQDSMFC). The field names in C are all in lowercase, for example qwhs, qwhsnsda.

Details of the structures and fields can be found in IBM MQ supportpac MP1B.

The QWHS data includes the subsystem name. For subtype 1 records, it also shows whether there are queue-level accounting records present. If the QWHSNSDA field is 3 or less, there are not, and the corresponding self-defining section (at offset X'34') is not set.

The QWHC data gives you information about the user (for example, the user ID (QWHCAID) and the type of application (QWHCATYP)). The QWHC section is completed only for subtype 0 records. The equivalent information is present in the thread identification record for subtype 1 and 2 records.

Table 142. Structure of the common IBM MQ SMF header record QWHS

Offset: Dec	Offset: Hex	Type	Length	Name	Description
0	0	Structure	128	QWHS	
0	0		6		Reserved
6	6	Character	1	QWHSNSDA	Number of self defining sections in the SMF records
7	7		5		Reserved

126	7E		2		Reserved

Combining CICS and IBM MQ performance data:

Use this topic as a reference to the combination of IBM MQ and CICS performance data.

The common IBM MQ SMF header type accounting record section, QWHCTOKN, is used to correlate CICS type 110 SMF records with IBM MQ type 116 SMF records.

CICS generates an LU6.2 unit-of-work token, for each CICS task. The token is used to generate an accounting token that is written to QWHCTOKN in the correlation header of subtype zero records.

Details are also written to the WTIDACCT section in subtype 1 and 2 records. The accounting token enables correlation between CICS and IBM MQ performance data for a transaction.

Thread cross reference data:

Use this topic as a reference to the format of the thread cross reference type accounting record.

The interpretation of the data in the thread cross reference (QWHCCV) field varies. This depends on what the data relates to:
- CICS connections (QWHCATYP=1) - see Table 143
- IMS connections (QWHCATYP=3 or 4) - see Table 144
- Batch connections (QWHCATYP=2 or 7) - this field consists of binary zeros
- Others - no meaningful data

Table 143. Structure of the thread cross reference for a CICS system

Offset: Dec	Offset: Hex	Type	Length	Description
48	30	Character	4	CICS thread number.
52	34	Character	4	CICS transaction name.
56	38	Integer	4	CICS task number.

Some entries contain blank characters. These apply to the task, rather than to a specific transaction.

Table 144. Structure of the thread cross reference for an IMS system

Offset: Dec	Offset: Hex	Type	Length	Description
48	30	Character	4	IMS partition specification table (PST) region identifier.
52	34	Character	8	IMS program specification block (PSB) name.

Message manager data records:

Use this topic as a reference to the format of the message manager accounting records.

The message manager is the component of IBM MQ that processes all API requests. The format of the message manager accounting records is described in assembler macro thlqual.SCSQMACS(CSQDQMAC).

The QMAC data gives you information about the processor time spent processing IBM MQ calls, and counts of the number of **MQPUT** and **MQGET** requests for messages of different sizes.

Note: A single IMS application might write two SMF records. In this case, add the figures from both records to provide the correct totals for the IMS application.

Records containing zero processor time

Records are sometimes produced that contain zero processor time in the QMACCPUT field. These records occur when long running tasks identified to IBM MQ either terminate or are prompted to output accounting records by accounting trace being stopped. Such tasks exist in the CICS adapter and in the channel initiator (for distributed queuing). The number of these tasks with zero processor time depends upon how much activity there has been in the system:

- For the CICS adapter, this can result in up to nine records with zero processor time.
- For the channel initiator, the number of records with zero processor time can be up to the sum of `Adapters + Dispatchers + 6`, as defined in the queue manager attributes.

These records reflect the amount of work done under the task, and can be ignored.

Sample subtype zero accounting record:

Use this topic as a reference to the format of the subtype zero accounting records.

Figure 108 shows a type 116, subtype zero SMF record. In this figure, the SMF record header and the QMAC accounting data record are underlined. The self-defining sections are in bold.

Figure 108. Example SMF type 116, subtype zero record

Thread-level and queue-level data records:

Use this topic as a reference to the format of the thread-level and queue-level accounting records.

Thread level accounting records are collected for each task using IBM MQ. For each task, a thread-level accounting data record is written to the SMF when the task finishes. For a long running task, data is also written at the statistics interval set by the STATIME parameter of the CSQ6SYSP system parameter macro (or by the system SMF statistics broadcast), provided that the task was running the previous time statistics were gathered. In addition, accounting information is gathered about each queue that the task opens. A queue-level accounting record is written for each queue that the task has used since the thread-level accounting record was last written.

Thread-level and queue-level accounting records are produced if you specify class 3 when you start the accounting trace.

The thread level accounting information is written to an SMF type 116, subtype 1 record, and is followed by queue-level records. If the task opened many queues, further queue information is written to one or more SMF type 116 subtype 2 records. A thread identification control block is included in each subtype 1 and 2 record to enable you to relate each record to the correct task. Typically, the maximum number of queue-level records in each SMF record is about 45.

The format of the thread-level accounting record is described in assembler macro thlqual.SCSQMACS(CSQDWTAS). The format of the queue-level accounting record is described in assembler macro thlqual.SCSQMACS(CSQDWQ). The format of the thread identification record is described in assembler macro thlqual.SCSQMACS(CSQDWTID). All these records are also described in C header file thlqual.SCSQC370(CSQDSMFC). The field names in C are all in lower case, for example wtas, wtasshex.

Meaning of the channel names:

Use this topic as a reference to the meaning of channel names.

The channel name in the WTID is constructed as shown in the following example. In this example a sender channel exists from queue manager QM1 to queue manager QM2.

Table 145. Meaning of channel names

Field name	Meaning	Example
For queue manager QM1 the sender channel has the following fields set:		
WTIDCCN	The job name	QM1CHIN
WTIDCHL	The channel name	QM1.QM2
WTIDCHLC	This is defined in the CONNAME of the channel	WINMVS2B(2162)
For queue manager QM2 the receiver channel has the following fields set:		
WTIDCCN	The job name	QM2CHIN
WTIDCHL	The channel name	QM1.QM2
WTIDCHLC	Where the channel came from	9.20.101.14

Sample subtype 1 and subtype 2 records:

Use this topic as a reference to the format of the subtype 1 and subtype 2 accounting records.

Figure 109 and Figure 110 show examples of SMF type 116, subtype 1 and subtype 2 records. These two accounting records were created for a batch job that opened 80 queues. Because many queues were opened, a subtype 2 record was required to contain all the information produced.

000050  40404040 40404040 00000000 00000000  *        ........*
000060  40404040 40404040 4040               *          *
```

Figure 111. Example SMF type 116, subtype 1 record with no WQST data records

The first self-defining section starts at X'24' and is **bold** in the example; X'00000034' is the offset to the WTID data record, X'00D0' is the length of the WTID record, and X'0001' is the number of WTID records.

The second self-defining section starts at X'2C' and is in *italic* ; X'0000010C' is the offset to the WTAS data record, X'02D8' is the length of the WTAS record, and X'0001' is the number of WTAS records.

There is no self-defining section describing a WQST data record, equivalent to the third self-defining section in Figure 109 on page 1259.

Channel accounting data records:

Use this topic as a reference for channel accounting data records.

The format of the channel accounting data record is described in assembler macro `thlqual.SCSQMACS(CSQDQCST)`. The format is also described in the C programming language header file `thlqual.SCSQC370(CSQDSMFC)`. Note that the field names in C are all in lowercase, for example, *qcst*.

The channel accounting data gives you information about the status and statistics of each channel instance, including:
- Average network time (*qcstntav*)
- Average time on exit (*qcstetav*)
- Channel batch data limit (*qcstcbdl*)
- Channel batch interval (*qcstcbit*)
- Channel batch size (*qcstcbsz*)
- Channel dispatcher number (*qcstdspn*)
- Channel disposition (*qcstchdp*)
- Channel name (*qcstchnm*)
- Channel state (*qcstchst*)
- Channel started time (*qcststrt*)
- Channel status collected time (*qcstcltm*)
- Channel stopped time (*qcstludt*)
- Channel type (*qcstchty*)
- Common name (CN) from SSLCERTI (*qcstslcn*)
- Compression rate (*qcstcpra*)
- Connection name (*qcstcnnm*)
- Current shared conversations (*qcstcscv*)
- DNS resolution time (*qcstdnrt*)
- Effective value of STATCHL parameter (*qcststcl*)
- Last message time (*qcstlmst*)
- Maximum network time (qcstntmx)

- Maximum time on exit (*qcstetmx*)
- Minimum network time (qcstntmn)
- Minimum time on exit (*qcstetmn*)
- Name of the remote queue manager or application (*qcstrqmn*)
- Number of batches (*qcstbatc*)
- Number of bytes for message data (*qcstnbyt*)
- Number of bytes for persistent message data (*qcstnpby*)
- Number of bytes received for both message data and control information (*qcstbyrc*)
- Number of bytes sent for both message data and control information (*qcstbyst*)
- Number of full batches (*qcstfuba*)
- Number of messages, or number of MQI calls (*qcstnmsg*)
- Number of persistent messages (*qcstnpmg*)
- Number of put retries (*qcstptrc*)
- Number of transmission queue becoming empty (*qcstqetc*)
- Number of transmission buffers received (qcstbfrc)
- Number of transmission buffers sent (*qcstbfst*)
- Serial number from SSLPEER (*qcstslsn*)
- SSL CipherSpec (zero means SSL not used) (*qcstslcs*)
- The date and time of maximum network time (*qcstntdt*)
- The date and time of maximum time on exit (*qcstetdt*)

You can use this information to see the throughput of a channel, if the actual batches are approaching the limit, the latency of the network, information about the remote end, performance of user exit, and so on.

Here is an example of the channel accounting data which has been formatted with IBM MQ SupportPac MP1B.

The fields available are based on the display channel status command (DIS CHS) and channel statistics by IBM MQ on platforms except z/OS, with some additional fields.

```
The data and time of the start and end of the record in local time, and the duration
SMF interval start       2014/03/26,02:30:00
SMF interval end         2014/03/26,02:45:00

Tuning your IBM MQ network

Use the tuning tips in this section to help improve the performance of your queue manager network.

Tuning client and server connection channels

The default settings for client and server connection channels changed in Version 7.0 to use shared conversations. Performance enhancements for distributed severs were then introduced in Version 8.0. To benefit from the new features that were introduced alongside shared conversations, without the performance impact on the distributed server, set **SHARECNV** to 1 on your Version 8.0 server connection channels.

From Version 7.0, each channel is defined by default to run up to 10 client conversations per channel instance. Before Version 7.0, each conversation was allocated to a different channel instance. The enhancements added in Version 7.0 also include the following features:

- Bi-directional heartbeats
- Administrator stop-quiesce
- Read-ahead
- Asynchronous-consume by client applications

For some configurations, using shared conversations brings significant benefits. However, for distributed servers, processing messages on channels that use the default configuration of 10 shared conversations is on average 15% slower than on channels that do not use shared conversations. On an MQI channel instance that is sharing conversations, all of the conversations on a socket are received by the same thread. If the conversations sharing a socket are all busy, the conversational threads contend with one another to use the receiving thread. The contention causes delays, and in this situation using a smaller number of shared conversations is better.

You use the **SHARECNV** parameter to specify the maximum number of conversations to be shared over a particular TCP/IP client channel instance. For details of all possible values, and of the new features added in Version 7.0, see MQI client: Default behavior of client-connection and server-connection. If you do not need shared conversations, there are two settings that give best performance in Version 8.0:

- `SHARECNV(1)`. Use this setting whenever possible. It eliminates contention to use the receiving thread, and your client applications can take advantage of the new features added in Version 7.0. For this setting, distributed server performance is significantly improved in Version 8.0. The performance improvements apply to Version 8.0 client applications that issue non read ahead synchronous get wait

calls; for example C client MQGET wait calls. When these client applications are connected, the distributed server uses less threads and less memory and the throughput is increased.
- `SHAREcnv(0)`. The channel instance behaves exactly as if it was a Version 6.0 server or client connection channel, and you do not get the extra features such as bi-directional heartbeats that are available when you set **SHARECNV** to 1 or greater. Use a value of 0 only if you have existing client applications that do not run correctly when you set **SHARECNV** to 1 or greater.

Note: If a server has clients connected to it that are sharing conversations over a socket, and you decrease the shared conversations setting from `SHARECNV(10)` to `SHARECNV(1)`, this has the following effects:
- Increased socket usage on the server.
- Increased channel instances on the server.

In this case, you might also choose to increase the settings for **MaxChannels** and **MaxActiveChannels**.

For consistency with previous releases the default SVRCONN channel has not been updated, so you need explicitly to set **SHARECNV** to 1 or 0.

Tuning distributed publish/subscribe networks

Use the tuning tips in this section to help improve the performance of your IBM MQ distributed publish/subscribe clusters and hierarchies.

Related concepts:

"Monitoring clusters" on page 1218
Within a cluster you can monitor application messages, control messages, and logs. There are special monitoring ocnsiderations when the cluster load balances between two or more instances of a queue.

Direct routed publish/subscribe cluster performance

In direct routed publish/subscribe clusters, information such as clustered topics and proxy subscriptions is pushed to all members of the cluster, irrespective of whether all cluster queue managers are actively participating in publish/subscribe messaging. This process can create a significant additional load on the system. To reduce the effect of cluster management on performance you can perform updates at off-peak times, define a much smaller subset of queue managers involved in publish/subscribe and make that an "overlapping" cluster, or switch to using topic host routing.

There are two sources of workload on a queue manager in a publish/subscribe cluster:
- Directly handling messages for application programs.
- Handling messages and channels needed to manage the cluster.

In a typical point-to-point cluster, the cluster system workload is largely limited to information explicitly requested by members of the cluster as required. Therefore in anything other than a very large point-to-point cluster, for example one which contains thousands of queue managers, you can largely discount the performance effect of managing the cluster. However, in a direct routed publish/subscribe cluster, information such as clustered topics, queue manager membership and proxy subscriptions is pushed to all members of the cluster, irrespective of whether all cluster queue managers are actively participating in publish/subscribe messaging. This can create a significant additional load on the system. Therefore you need to consider the effect of cluster management on queue manager performance, both in its timing, and its size.

Performance characteristics of direct routed clusters

Compare a point-to-point cluster with a direct routed publish/subscribe cluster in respect of the core management tasks.

First, a point to point cluster:

1. When a new cluster queue is defined, the destination information is pushed to the full repository queue managers, and only sent to other cluster members when they first reference a cluster queue (for example, when an application attempts to open it). This information is then cached locally by the queue manager to remove the need to remotely retrieve the information each time the queue is accessed.
2. Adding a queue manager to a cluster does not directly affect the load on other queue managers. Information about the new queue manager is pushed to the full repositories, but channels to the new queue manager from other queue managers in the cluster are only created and started when traffic begins to flow to or from the new queue manager.

In summary, the load on a queue manager in a point-to-point cluster is related to the message traffic it handles for application programs and is not directly related to the size of the cluster.

Second, a direct routed publish/subscribe cluster:

1. When a new cluster topic is defined, the information is pushed to the full repository queue managers, and from there directly to all members of the cluster, causing channels to be started to each member of the cluster from the full repositories if not already started. If this is the first direct clustered topic, each queue manager member is sent information about all other queue manager members in the cluster.
2. When a subscription is created to a cluster topic on a new topic string, the information is pushed directly from that queue manager to all other members of the cluster immediately, causing channels to be started to each member of the cluster from that queue manager if not already started.
3. When a new queue manager joins an existing cluster, information about all clustered topics (and all queue manager members if a direct cluster topic is defined) is pushed to the new queue manager from the full repository queue managers. The new queue manager then synchronizes knowledge of all subscriptions to cluster topics in the cluster with all members of the cluster.

In summary, cluster management load at any queue manager in a direct routed publish/subscribe cluster grows with the number of queue managers, clustered topics, and changes to subscriptions on different topic strings within the cluster, irrespective of the local use of those cluster topics on each queue manager.

In a large cluster, or one where the rate of change of subscriptions is high, this level of cluster management can be a significant overhead across all queue managers.

Reducing the effect of direct routed publish/subscribe on performance

To reduce the effect of cluster management on the performance of a direct routed publish/subscribe cluster, consider the following options:

- Perform cluster, topic, and subscription updates at off-peak times of the day.
- Define a much smaller subset of queue managers involved in publish/subscribe, and make that an "overlapping" cluster. This cluster is then the cluster where cluster topics are defined. Although some queue managers are now in two clusters, the overall effect of publish/subscribe is reduced:
  - The size of the publish/subscribe cluster is smaller.
  - Queue managers not in the publish/subscribe cluster are much less affected by cluster management traffic.

If the previous options do not adequately resolve your performance issues, consider using a *topic host routed* publish/subscribe cluster instead. For a detailed comparison of direct routing and topic host routing in publish/subscribe clusters, see Designing publish/subscribe clusters.

Topic host routed publish/subscribe cluster performance

A topic host routed publish/subscribe cluster gives you precise control over which queue managers host each topic. These topic hosts become the *routing* queue managers for that branch of the topic tree. Moreover, queue managers without subscriptions or publishers have no need to connect with the topic hosts. This configuration can significantly reduce the number of connections between queue managers in the cluster, and the amount of information that is passed between queue managers.

A topic host routed publish/subscribe cluster behaves as follows:

- Topics are manually defined on individual *topic host* queue managers in the cluster.
- When a subscription is made on a cluster queue manager, proxy subscriptions are created only on the topic hosts.
- When an application publishes information to a topic, the receiving queue manager forwards the publication to a queue manager that hosts the topic. The topic host then sends the publication to all queue managers in the cluster that have valid subscriptions to the topic.

For a more detailed introduction to topic host routing, see Topic host routing in clusters.

For many configurations, topic host routing is a more appropriate topology than *direct routing* because it provides the following benefits:

- Improved scalability of larger clusters. Only the topic host queue managers need to be able to connect to all other queue managers in the cluster. Therefore, there are fewer channels between queue managers, and there is less inter-queue manager publish/subscribe administrative traffic than for direct routing. When subscriptions change on a queue manager, only the topic host queue managers need to be informed.
- More control over the physical configuration. With direct routing, all queue managers assume all roles, and therefore all need to be equally capable. With topic host routing, you explicitly choose the topic host queue managers. Therefore, you can ensure that those queue managers are running on adequate equipment, and you can use less powerful systems for the other queue managers.

However, topic host routing also imposes certain constraints upon your system:

- System configuration and maintenance require more planning than for direct routing. You need to decide which points to cluster in the topic tree, and the location of the topic definitions in the cluster.
- Just as for direct routed topics, when a new topic host routed topic is defined, the information is pushed to the full repository queue managers, and from there direct to all members of the cluster. This event causes channels to be started to each member of the cluster from the full repositories if not already started.
- Publications are always sent to a host queue manager from a non-host queue manager, even if there are no subscriptions in the cluster. Therefore, you should use routed topics when subscriptions are typically expected to exist, or when the overhead of global connectivity and knowledge is greater than the risk of extra publication traffic.
- Messages that are published on non-host queue managers do not go direct to the queue manager that hosts the subscription, they are always routed through a topic host queue manager. This approach can increase the total overhead to the cluster, and increase message latency and reduce performance.

  Note: For certain configurations, you can usefully remove this constraint as described in Topic host routing using centralized publishers or subscribers.
- Using a single topic host queue manager introduces a single point of failure for all messages that are published to a topic. You can remove this single point of failure by defining multiple topic hosts. However, having multiple hosts affects the order of published messages as received by subscriptions.
- Extra message load is incurred by topic host queue managers, because publication traffic from multiple queue managers needs to be processed by them. This load can be lessened: Either use multiple topic hosts for a single topic (in which case message ordering is not maintained), or use different queue managers to host routed topics for different branches of the topic tree.

Topic host routing with centralized publishers or subscribers

To remove the extra "hop" incurred when publications are always routed to subscriptions through a topic host queue manager, configure the publishers or the subscriptions on the same queue manager that hosts the topic. This approach brings maximum performance benefits in the following two cases:

- Topics with many publishers and few subscriptions. In this case, host the subscriptions on the topic host queue manager.
- Topics with few publishers and many subscriptions. In this case, host the publishers on the topic host queue manager.

The following figure shows a topic host queue manager that also hosts the subscriptions. This approach removes the extra "hop" between the publisher and the subscriber, and reduces unnecessary sharing of subscription knowledge across all members of the cluster:

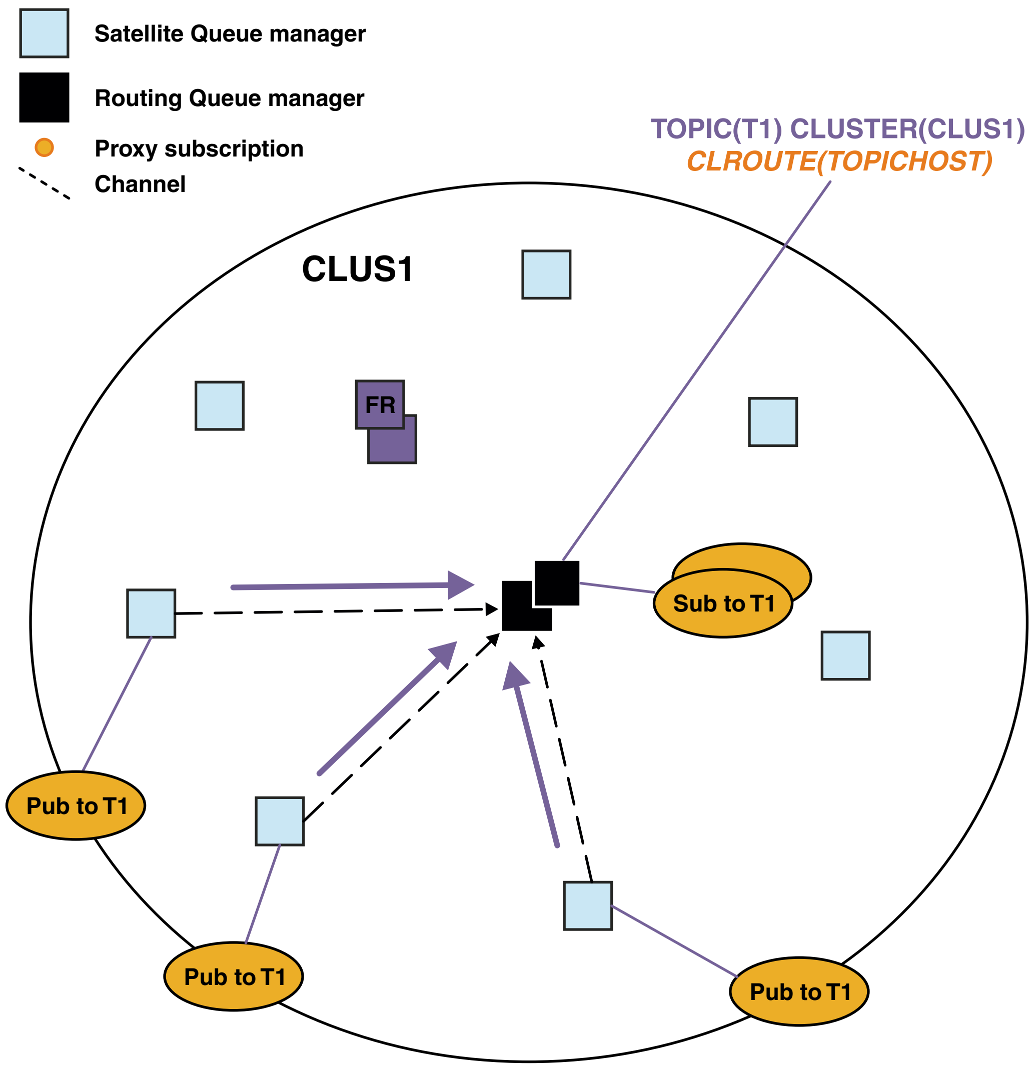

Figure 112. Hosting subscriptions on a topic host queue manager

The following figure shows a topic host queue manager that also hosts the publishers. This approach removes the extra "hop" between the publisher and the subscriber, and reduces unnecessary sharing of subscription knowledge across all members of the cluster:

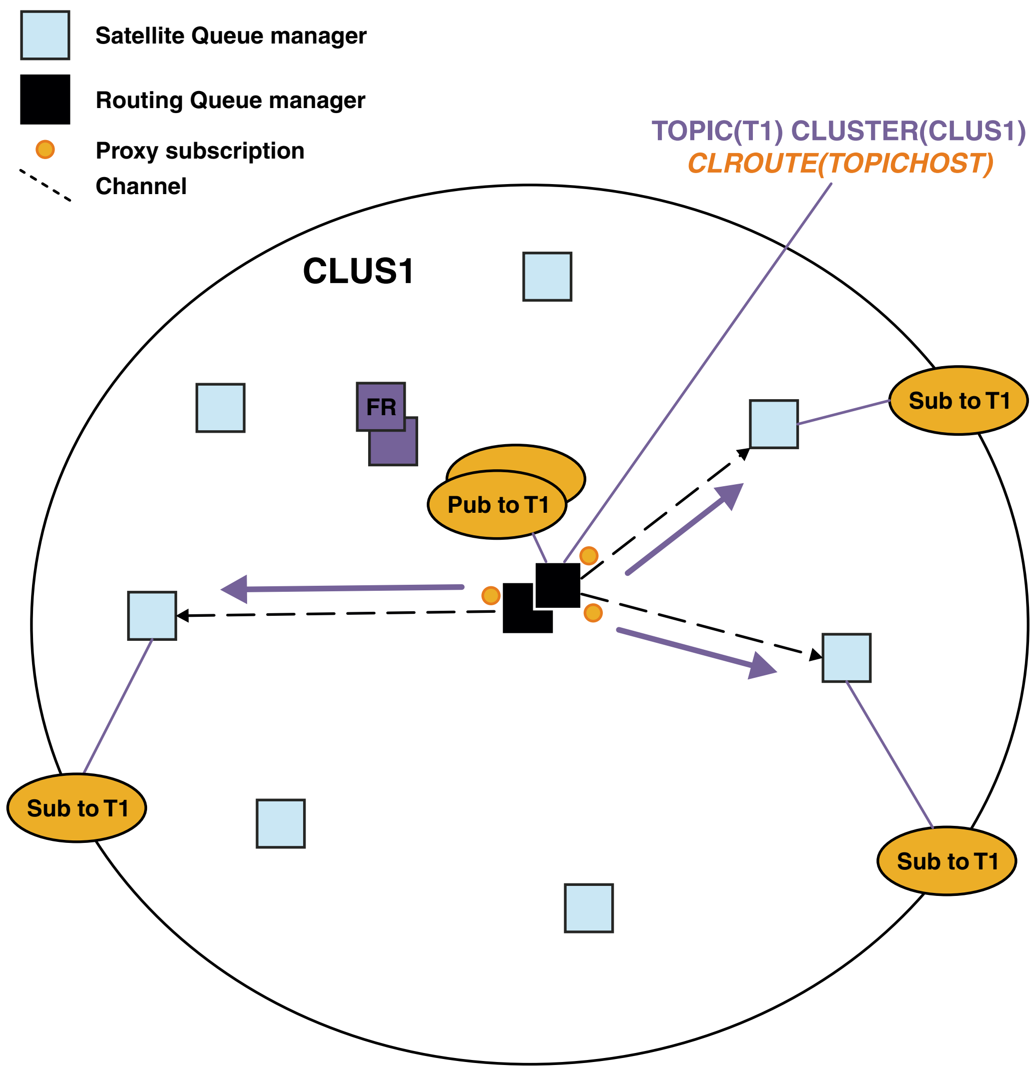

Figure 113. Hosting publications on a topic host queue manager

Balancing producers and consumers in publish/subscribe networks

An important concept in asynchronous messaging performance is *balance*. Unless message consumers are balanced with message producers, there is the danger that a backlog of unconsumed messages might build up and seriously affect the performance of multiple applications.

In a point-to-point messaging topology, the relationship between message consumers and message producers is readily understood. You can get estimates of message production and consumption, queue by queue, channel by channel. If there is a lack of balance, the bottlenecks are readily identified and then remedied.

It is harder to work out whether publishers and subscribers are balanced in a publish/subscribe topology. Start from each subscription, and work back to the queue managers having publishers on the topic. Calculate the number of publications flowing to each subscriber from each queue manager.

Each publication that matches a subscription on a remote queue manager (based on proxy subscriptions) is put to a transmission queue. If multiple remote queue managers have proxy subscriptions for that publication, multiple copies of the message are put to a transmission queue, each targeted for a different sender channel.

In a publish/subscribe cluster, those publications are targeted at the SYSTEM.INTER.QMGR.PUBS queue on the remote queue managers that host the subscriptions. In a hierarchy, each publication is targeted at the SYSTEM.BROKER.DEFAULT.STREAM queue, or any other stream queues listed in the SYSTEM.QPUBSUB.QUEUE.NAMELIST on the remote queue managers. Each queue manager processes messages arriving on that queue and delivers them to the correct subscriptions on that queue manager.

For this reason, monitor the load at the following points where bottlenecks might arise:

- Monitor the load at the individual subscription queues.
  - This bottleneck implies that the subscribing application is not consuming the publications as quick as they are being published.
- Monitor the load at the SYSTEM.INTER.QMGR.PUBS queue or the stream queues.
  - This bottleneck implies that the queue manager is receiving publications from one or more remote queue managers faster than it can distribute them to the local subscriptions.
  - When seen on a topic host queue manager when using topic host routing in a cluster, consider making additional queue managers topic hosts, allowing the publication workload to be balanced across them. However, this will affect the message ordering across publications. See Topic host routing using multiple topic hosts for a single topic.
- Monitor the load at the channels between the publishing queue manager and the subscribing queue managers, which are fed by the transmission queues on the publishing queue manager.
  - This bottleneck implies that either one or more channels is not running, or messages are being published to the local queue manager faster than the channels can deliver them to the remote queue manager.
  - When you use a publish/subscribe cluster, consider defining additional cluster receiver channels on the target queue manager. This allows the publication workload to be balanced across them. However, this affects the message ordering across publications. Also consider moving to a multiple cluster transmission queue configuration, because this can improve performance in certain circumstances.
- If the publishing application is using a queued publish/subscribe interface, monitor the load at (a) the SYSTEM.BROKER.DEFAULT.STREAM queue, and any other stream queues listed in the SYSTEM.QPUBSUB.QUEUE.NAMELIST ; and (b) the SYSTEM.BROKER.DEFAULT.SUBPOINT queue, and any other subpoint queues listed in the SYSTEM.QPUBSUB.SUBPOINT.NAMELIST .
  - This bottleneck implies that messages are being put by local publishing applications faster than the local queue manager can process the messages.

Related concepts:

"Monitoring clusters" on page 1218
Within a cluster you can monitor application messages, control messages, and logs. There are special monitoring ocnsiderations when the cluster load balances between two or more instances of a queue.

Subscription performance in publish/subscribe networks

Distributed publish/subscribe in IBM MQ works by propagating knowledge of where subscriptions to different topic strings have been created in the queue manager network. This enables the queue manager on which a message is published to identify which other queue managers require a copy of the published message, to match their subscriptions.

This approach minimizes the sending of published messages to queue managers on which no matching subscriptions exist. However, the propagation of the subscription knowledge can become a significant overhead, when the number of topic strings being subscribed to is high and constantly changing through frequent subscription creation and deletion.

You can affect performance by adjusting how publications and subscriptions are flowed around your publish/subscribe network. If your network traffic has few publications, and rapid subscription creation, deletion, or change, you can stop subscription information being flowed to all queue managers, and instead forward all publications to all queue managers in the network. You can also restrict the flow of proxy subscriptions and publications for a given topic between connected queue managers, restrict the flow of proxy subscriptions containing wildcards, and reduce the number and transient nature of topic strings.

Individual subscription propagation and *publish everywhere*

Publish everywhere is an alternative to individual subscription propagation. With individual propagation, only publications that have a matching subscription on a queue manager are forwarded to that queue manager. With *publish everywhere*, all publications are forwarded to all queue managers in the network. The receiving queue managers then deliver those publications that match local subscriptions.

Individual subscription propagation

This mechanism results in the least amount of inter-queue manager publication traffic, because only those publications that match subscriptions on a queue manager are sent.

However:

- For each individual topic string that is subscribed to, a proxy subscription is sent to other queue managers in the publish/subscribe topology. The set of queue managers depends on the routing model being used, as described in Planning your distributed publish/subscribe network.
  - This messaging overhead can be significant if there are many thousands of subscriptions to create or delete (for example, recreating all non-durable subscriptions after a restart of a queue manager), or if the set of subscriptions is changing rapidly, and each is to a different topic string.
  - The number of queue managers to which the proxy subscription is propagated also affects the scale of the overhead.
- Proxy subscriptions are flowed to other queue managers using asynchronous messaging. This has the following effect:
  - There is a delay between the creation of a subscription, and the creation, delivery, and processing of the proxy subscription by the other queue managers.
  - Messages that are published at those queue managers in that interval are not delivered to the remote subscription.

Publish everywhere

With this mechanism there is no per topic string proxy subscription overhead on the system. This means that rapid subscription creation, deletion, or change does not result in increased network load and processing.

There is also no delay between creating a subscription and publications being flowed to a queue manager, because all publications are flowed to all queue managers. Therefore there is no window in which publications are not delivered to newly-created remote subscriptions.

However:

- Sending all publications to all queue managers in the publish/subscribe topology, can result in excessive network traffic where publications do not have matching subscriptions on each queue manager.
  - The greater the number of queue managers in the topology, the greater the overhead.

You should consider using the *publish everywhere* mechanism when you expect a publication to be subscribed to from a significant proportion of your queue managers, or where the proxy subscription overheads are too great because of the frequency of subscription changes. You should use individual proxy subscription forwarding in cases where you experience increased messaging traffic when publications are sent to all queue managers, rather than to the queue managers with matching subscriptions.

You can set *publish everywhere* behavior at any level within the topic tree. To enable *publish everywhere*, you set the **PROXYSUB** parameter to FORCE for a high-level topic object. This results in a single wildcard proxy subscription that matches all topics below this topic object in the topic tree. When set it on a clustered topic object, the **PROXYSUB(FORCE)** attribute is propagated to every queue manager in the network, not just the queue manager that the topic was defined on.

Note: When used in a hierarchy, you set **PROXYSUB(FORCE)** individually on each queue manager, so the topology mechanism naturally limits the number of channels. However, when used in a cluster, many additional channels might be started:

- In a topic host routed cluster, channels are started from each queue manager to each topic host queue manager.
- In a direct routed cluster, channels are started from every queue manager to every other queue manager.

The overhead of starting many channels is most pronounced in a direct routed cluster, and can cause performance issues. See "Direct routed publish/subscribe cluster performance" on page 1263.

Other ways of restricting the flow of proxy subscriptions and publications between connected queue managers

Consolidate topic strings
The use of many distinct, transient, topic strings introduces some level of management overhead on each queue manager in the system where publishers or subscriptions are attached. You should periodically assess the use of topic strings to see whether they can be consolidated. Reducing the number and transient nature of topic strings, and therefore the publishers and subscriptions to them, reduces the impact on the system.

Restrict publication and subscription scope
For a given topic, you can use the Publication scope and Subscription scope settings to keep publications and subscriptions local to the queue manager on which they are defined.

Block subscriptions made to wildcarded topics
You can restrict the flow of proxy subscriptions containing wildcards by setting the **Topic** attribute WILDCARD to BLOCK. See Wildcards in proxy subscriptions.

See also "Balancing producers and consumers in publish/subscribe networks" on page 1267

Monitoring proxy subscription traffic in clusters

When considering the load on the system from the proxy subscription traffic, in addition to monitoring the queues listed in"Balancing producers and consumers in publish/subscribe networks" on page 1267, monitor the following cluster queues:

- The SYSTEM.INTER.QMGR.FANREQ queue on the subscriber queue manager.
- The SYSTEM.INTER.QMGR.CONTROL queue on all other queue managers in the cluster.

Any significant message backlog on these queues implies that either the rate of subscription change is too great for the system, or a queue manager is not correctly functioning in the cluster. If you suspect the problem lies with a specific queue manager, check that publish/subscribe support is not disabled for that queue manager. See **PSMODE** in ALTER QMGR.

Proxy subscriptions in a publish/subscribe network

Reducing the number of unwanted topics in the topic tree

The performance of a publish/subscribe system is improved by reducing the number of unwanted topics in the topic tree. What is an unwanted topic and how do you remove them?

You can create large numbers of topics without affecting performance adversely. However, some ways of using publish/subscribe result in continually expanding topic trees. An exceptionally large number of topics are created once and never used again. The growing number of topics might become a performance problem.

How can you avoid designs that lead to a large and growing number of unwanted topics? What can you do to help the queue manager remove unwanted topics from the topic tree?

The queue manager recognizes an unwanted topic because it has been unused for 30 minutes. The queue manager removes unused topics from the topic tree for you. The 30 minute duration can be changed by altering the queue manager attribute, **TREELIFE**. You can help the queue manager to remove unwanted topics by making sure that the topic appears to the queue manager to be unused. The section, "What is an unused topic?" explains what an unused topic is.

A programmer, designing any application, and especially designing a long running application, considers its resource usage: how much resource the program requires, are there any unbounded demands, and any resource leaks? Topics are a resource that publish/subscribe programs use. Scrutinize the use of topics just like any other resource a program uses.

What is an unused topic?

Before defining what an unused topic is, what exactly counts as a topic?

When a topic string, such as `USA/Alabama/Auburn`, is converted into a topic, the topic is added to the topic tree. Additional topic nodes, and their corresponding topics, are created in the tree, if necessary. The topic string `USA/Alabama/Auburn` is converted into a tree with three topics.
- `USA`
- `USA/Alabama`
- `USA/Alabama/Auburn`

To display all the topics in the topic tree, use the **runmqsc** command `DISPLAY TPSTATUS('#') TYPE(TOPIC)`.

An unused topic in the topic tree has the following properties.

It is not associated with a topic object

An administrative topic object has a topic string that associates it with a topic. When you define the topic object `Alabama`, if the topic, `USA/Alabama`, it is to be associated with does not exist, the topic is created from the topic string. If the topic does exist, the topic object and the topic are associated together using the topic string.

It does not have a retained publication

A topic with a retained publication results from a publisher putting a message to a topic with the option `MQPMO_RETAIN`.

Use the **runmqsc** command `DISPLAY TPSTATUS('USA/Alabama') RETAINED` to check if `USA/Alabama` has a retained publication. The response is `YES` or `NO`.

Use the **runmqsc** command `CLEAR TOPICSTR('USA/Alabama') CLTRTYPE(RETAINED)` to remove a retained publication from `USA/Alabama`.

It has no child topics

USA/Alabama/Auburn is a topic with no child topics. USA/Alabama/Auburn is the direct child topic of USA/Alabama.

Display the direct children of USA/Alabama with the **runmqsc** command DISPLAY TPSTATUS('USA/Alabama/+').

There are no active publishers to the node

An active publisher to a node is an application that has the topic open for output.

For example, an application opens the topic object named **Alabama** with open options MQOO_OUTPUT.

To display active publishers to USA/Alabama and all its children, use the **runmqsc** command DISPLAY TPSTATUS('USA/Alabama/#') TYPE(PUB) ACTCONN.

There are no active subscribers to the node

An active subscriber can either be a durable subscription, or an application that has registered a subscription to a topic with MQSUB, and not closed it.

To display active subscriptions to USA/Alabama, use the **runmqsc** command DISPLAY TPSTATUS('USA/Alabama') TYPE(SUB) ACTCONN.

To display active subscriptions to USA/Alabama and all its children, use the **runmqsc** command DISPLAY TPSTATUS('USA/Alabama/#') TYPE(SUB) ACTCONN.

Managing the number of topics in a topic tree

In summary, there are a number of ways to manage the number of topics in a topic tree.

Display TPCOUNT

Use the **runmqsc** command DISPLAY PUBSUB ALL periodically to display the **TPCOUNT** property. This is the number of topic nodes in the topic tree. If the number is growing it might indicate that a shorter TREELIFE is required, or that a redesign of the topics themselves is required.

Modify TREELIFE

An unused topic has a lifetime of 30 minutes by default. You can make the lifetime of an unused topic smaller.

For example, The **runmqsc** command, ALTER QMGR TREELIFE(900), reduces lifetime of an unused topic from 30 minutes to 15 minutes.

Exceptionally, restart the queue manager

When the queue manager is restarted, the topic tree is reinitialized from topic objects, nodes with retained publications, and durable subscriptions. Topics that had been created by the operation of publisher and subscriber programs are eliminated.

As a last resort, if the growth in unwanted topics has been the cause of performance problems in the past, restart the queue manager.

Troubleshooting and support

If you are having problems with your queue manager network or IBM MQ applications, use the techniques described to help you diagnose and solve the problems.

For an introduction to troubleshooting and support, see "Troubleshooting overview" on page 1276.

There are some initial checks that you can make for your platform to help determine the causes of some common problems. See the appropriate topic for your platform:

- Windows UNIX Linux "Making initial checks on Windows, UNIX and Linux systems" on page 1277
- IBM i "Making initial checks on IBM i" on page 1288
- z/OS "Making initial checks on z/OS" on page 1297

For information about solving problems, see "Making initial checks" on page 1277.

For information about solving problems for IBM MQ Telemetry, see "IBM MQ Telemetry troubleshooting" on page 1828.

For information about solving problems when you are using channel authentication records, see "Channel authentication records troubleshooting" on page 1779.

Information that is produced by IBM MQ can help you to find and resolve problems. For more information, see the following topics:

- "Using logs" on page 1678
- "Using trace" on page 1686
- z/OS "Problem determination on z/OS" on page 1724
- "First Failure Support Technology (FFST" on page 1666

For information about recovering after a problem, see "Recovering after failure" on page 1845.

You can also read the general troubleshooting guidance in the following topics:

- "IBM Support Assistant (ISA)" on page 1635
- "Searching knowledge bases" on page 1638
- "Contacting IBM Software Support" on page 1658
- "Getting product fixes" on page 1665

If an IBM MQ component or command has returned an error, and you want further information about a message written to the screen or the log, you can browse for details of the message, see "Reason codes and exceptions" on page 1314.

Troubleshooting overview

Troubleshooting is the process of finding and eliminating the cause of a problem. Whenever you have a problem with your IBM software, the troubleshooting process begins as soon as you ask yourself "what happened?"

A basic troubleshooting strategy at a high level involves:
1. “Recording the symptoms of the problem”
2. “Re-creating the problem”
3. “Eliminating possible causes” on page 1277

Recording the symptoms of the problem

Depending on the type of problem that you have, whether it be with your application, your server, or your tools, you might receive a message that indicates that something is wrong. Always record the error message that you see. As simple as this sounds, error messages sometimes contain codes that might make more sense as you investigate your problem further. You might also receive multiple error messages that look similar but have subtle differences. By recording the details of each one, you can learn more about where your problem exists.

Sources of error messages:
- Problems view
- Local error log
- Eclipse log
- User trace
- Service trace
- Error dialog boxes

Re-creating the problem

Think back to what steps you were doing that led to the problem. Try those steps again to see if you can easily re-create the problem. If you have a consistently repeatable test case, it is easier to determine what solutions are necessary.
- How did you first notice the problem?
- Did you do anything different that made you notice the problem?
- Is the process that is causing the problem a new procedure, or has it worked successfully before?
- If this process worked before, what has changed? (The change can refer to any type of change that is made to the system, ranging from adding new hardware or software, to reconfiguring existing software.)
- What was the first symptom of the problem that you witnessed? Were there other symptoms occurring around the same time?
- Does the same problem occur elsewhere? Is only one machine experiencing the problem or are multiple machines experiencing the same problem?
- What messages are being generated that might indicate what the problem is?

Windows UNIX Linux You can find more information about these types of question in “Making initial checks on Windows, UNIX and Linux systems” on page 1277.

Eliminating possible causes

Narrow the scope of your problem by eliminating components that are not causing the problem. By using a process of elimination, you can simplify your problem and avoid wasting time in areas that are not responsible. Consult the information in this product and other available resources to help you with your elimination process.

- Has anyone else experienced this problem? See: "Searching knowledge bases" on page 1638.
- Is there a fix you can download? See: "Getting product fixes" on page 1665.

Making initial checks

There are some initial checks that you can make that may provide answers to common problems that you may have.

Carry out the initial checks for your platform:

- Windows UNIX Linux "Making initial checks on Windows, UNIX and Linux systems"
- z/OS "Making initial checks on z/OS" on page 1297
- IBM i "Making initial checks on IBM i" on page 1288

For logging and tracing, see the following information:

- "Using logs" on page 1678
- "Using trace" on page 1686

Use the information and general advice given in the subtopics to help you rectify the problem.

Making initial checks on Windows, UNIX and Linux systems

Before you start problem determination in detail, consider whether there is an obvious cause of the problem, or an area of investigation that is likely to give useful results. This approach to diagnosis can often save a lot of work by highlighting a simple error, or by narrowing down the range of possibilities.

The cause of your problem could be in:

- IBM MQ
- The network
- The application
- Other applications that you have configured to work with IBM MQ

This section contains a list of questions to consider. As you go through the list, make a note of anything that might be relevant to the problem. Even if your observations do not suggest a cause straight away, they might be useful later if you have to carry out a systematic problem determination exercise.

- "Has IBM MQ run successfully before?" on page 1279
- "Have any changes been made since the last successful run?" on page 1280
- "Are there any error messages or return codes to explain the problem?" on page 1280
- "Can you reproduce the problem?" on page 1281

- “Are you receiving an error code when creating or starting a queue manager? (Windows only)” on page 1281
- “Does the problem affect only remote queues?” on page 1282
- “Have you obtained incorrect output?” on page 1282
- “Are some of your queues failing?” on page 1284
- “Have you failed to receive a response from a PCF command?” on page 1285
- “Has the application run successfully before?” on page 1286
- “Is your application or system running slowly?” on page 1287
- “Does the problem affect specific parts of the network?” on page 1287
- “Does the problem occur at specific times of the day?” on page 1288
- “Is the problem intermittent?” on page 1288

See the following sections for some additional tips for problem determination for system administrators and application developers.

Tips for system administrators

- Check the error logs for messages for your operating system:
  - Windows UNIX Linux “Error logs on Windows, UNIX and Linux systems” on page 1678
  - IBM i “Error logs on IBM i” on page 1683
  - z/OS “Diagnostic information produced on IBM MQ for z/OS” on page 1731
- Check the contents of `qm.ini` for any configuration changes or errors. For more information on changing configuration information, see:
  - Windows UNIX Linux Changing configuration information on Windows, UNIX and Linux systems
  - IBM i Changing configuration information on IBM i
  - z/OS Customizing your queue managers on z/OS
- If your application development teams are reporting something unexpected, you use trace to investigate the problems. For information about using trace, see “Using trace” on page 1686.

Tips for application developers

- Check the return codes from the MQI calls in your applications. For a list of reason codes, see “API reason codes” on page 1315. Use the information provided in the return code to determine the cause of the problem. Follow the steps in the Programmer response sections of the reason code to resolve the problem.
- If you are unsure whether your application is working as expected, for example, you are not unsure of the parameters being passed into the MQI or out of the MQI, you can use trace to collect information about all the inputs and outputs of your MQI calls. For more information about using trace, see “Using trace” on page 1686.
- For more information about handling errors in MQI applications, see Handling program errors.

Troubleshooting and support reference

Has IBM MQ run successfully before?

If IBM MQ has not run successfully before, it is likely that you have not yet set it up correctly. See Installing IBM MQ and select the platform, or platforms, that your enterprise uses to check that you have installed the product correctly.

To run the verification procedure, see:

- Verifying a server installation
- Verifying a client installation

Also look at Configuring for information about post-installation configuration of IBM MQ.

Have any changes been made since the last successful run?

Changes that have been made to your IBM MQ configuration, maintenance updates, or changes to other programs that interact with IBM MQ could be the cause of your problem.

When you are considering changes that might recently have been made, think about the IBM MQ system, and also about the other programs it interfaces with, the hardware, and any new applications. Consider also the possibility that a new application that you are not aware of might have been run on the system.

- Have you changed, added, or deleted any queue definitions?
- Have you changed or added any channel definitions? Changes might have been made to either IBM MQ channel definitions or any underlying communications definitions required by your application.
- Do your applications deal with return codes that they might get as a result of any changes you have made?
- Have you changed any component of the operating system that could affect the operation of IBM MQ? For example, have you modified the Windows Registry.

Have you applied any maintenance updates?

If you have applied a maintenance update to IBM MQ, check that the update action completed successfully and that no error message was produced.

- Did the update have any special instructions?
- Was any test run to verify that the update was applied correctly and completely?
- Does the problem still exist if IBM MQ is restored to the previous maintenance level?
- If the installation was successful, check with the IBM Support Center for any maintenance package errors.
- If a maintenance package has been applied to any other program, consider the effect it might have on the way IBM MQ interfaces with it.

Are there any error messages or return codes to explain the problem?

You might find error messages or return codes that help you to determine the location and cause of your problem.

IBM MQ uses error logs to capture messages concerning its own operation, any queue managers that you start, and error data coming from the channels that are in use. Check the error logs to see if any messages have been recorded that are associated with your problem.

IBM MQ also logs errors in the Windows Application Event Log. On Windows, check if the Windows Application Event Log shows any IBM MQ errors. To open the log, from the Computer Management panel, expand **Event Viewer** and select **Application**.

Windows UNIX Linux For information about the locations and contents of the error logs, see "Error logs on Windows, UNIX and Linux systems" on page 1678

For each IBM MQ Message Queue Interface (MQI) and IBM MQ Administration Interface (MQAI) call, a completion code and a reason code are returned by the queue manager or by an exit routine, to indicate the success or failure of the call. If your application gets a return code indicating that a Message Queue Interface (MQI) call has failed, check the reason code to find out more about the problem.

For a list of reason codes, see "API completion and reason codes" on page 1314.

Detailed information on return codes is contained within the description of each MQI call.

Related reference:

"PCF reason codes" on page 1541
Reason codes might be returned by a broker in response to a command message in PCF format, depending on the parameters used in that message.

"Secure Sockets Layer (SSL) and Transport Layer Security (TLS) return codes" on page 1622
IBM MQ can use Secure Sockets Layer (SSL) with the various communication protocols. Use this topic to identify the error codes that can be returned by SSL.

"WCF custom channel exceptions" on page 1627
Diagnostic messages are listed in this topic in numeric order, grouped according to the part of the WCF custom channel from which they originate.

Troubleshooting and support reference

Can you reproduce the problem?

If you can reproduce the problem, consider the conditions under which it is reproduced:

- Is it caused by a command or an equivalent administration request?

  Does the operation work if it is entered by another method? If the command works if it is entered on the command line, but not otherwise, check that the command server has not stopped, and that the queue definition of the SYSTEM.ADMIN.COMMAND.QUEUE has not been changed.
- Is it caused by a program? Does it fail on all IBM MQ systems and all queue managers, or only on some?
- Can you identify any application that always seems to be running in the system when the problem occurs? If so, examine the application to see if it is in error.

Are you receiving an error code when creating or starting a queue manager? (Windows only)

If the IBM MQ Explorer, or the **amqmdain** command, fails to create or start a queue manager, indicating an authority problem, it might be because the user under which the IBM MQ Windows service is running has insufficient rights.

Ensure that the user with which the IBM MQ Windows service is configured has the rights described in User rights required for an IBM MQ Windows Service. By default this service is configured to run as the **MUSR_MQADMIN** user. For subsequent installations, the Prepare IBM MQ Wizard creates a user account named **MUSR_MQADMINx** , where x is the next available number representing a user ID that does not exist.

Does the problem affect only remote queues?

Things to check if the problem affects only remote queues.

If the problem affects only remote queues, perform the following checks:

- Check that required channels have started, can be triggered, and any required initiators are running.
- Check that the programs that should be putting messages to the remote queues have not reported problems.
- If you use triggering to start the distributed queuing process, check that the transmission queue has triggering set on. Also, check that the trigger monitor is running.
- Check the error logs for messages indicating channel errors or problems.
- If necessary, start the channel manually.

Have you obtained incorrect output?

In this section, *incorrect output* refers to your application: not receiving a message that you were expecting it to receive; receiving a message containing unexpected or corrupted information; receiving a message that you were not expecting it to receive, for example, one that was destined for a different application.

Messages that do not arrive on the queue

If messages do not arrive when you are expecting them, check for the following:

- Has the message been put on the queue successfully?
  - Has the queue been defined correctly? For example, is MAXMSGL sufficiently large?
  - Is the queue enabled for putting?
  - Is the queue already full?
  - Has another application got exclusive access to the queue?
- Are you able to get any messages from the queue?
  - Do you need to take a sync point?

    If messages are being put or retrieved within sync point, they are not available to other tasks until the unit of recovery has been committed.
  - Is your wait interval long enough?

    You can set the wait interval as an option for the MQGET call. Ensure that you are waiting long enough for a response.
  - Are you waiting for a specific message that is identified by a message or correlation identifier (`MsgId` or `CorrelId`)?

    Check that you are waiting for a message with the correct `MsgId` or `CorrelId`. A successful MQGET call sets both these values to that of the message retrieved, so you might need to reset these values in order to get another message successfully.

    Also, check whether you can get other messages from the queue.
  - Can other applications get messages from the queue?
  - Was the message you are expecting defined as persistent?

    If not, and IBM MQ has been restarted, the message has been lost.
  - Has another application got exclusive access to the queue?

If you cannot find anything wrong with the queue, and IBM MQ is running, check the process that you expected to put the message onto the queue for the following:

- Did the application start?

  If it should have been triggered, check that the correct trigger options were specified.
- Did the application stop?
- Is a trigger monitor running?

- Was the trigger process defined correctly?
- Did the application complete correctly?

  Look for evidence of an abnormal end in the job log.
- Did the application commit its changes, or were they backed out?

If multiple transactions are serving the queue, they can conflict with one another. For example, suppose one transaction issues an MQGET call with a buffer length of zero to find out the length of the message, and then issues a specific MQGET call specifying the `MsgId` of that message. However, in the meantime, another transaction issues a successful MQGET call for that message, so the first application receives a reason code of MQRC_NO_MSG_AVAILABLE. Applications that are expected to run in a multiple server environment must be designed to cope with this situation.

Consider that the message could have been received, but that your application failed to process it in some way. For example, did an error in the expected format of the message cause your program to reject it? If so, refer to the subsequent information in this topic.

Messages that contain unexpected or corrupted information

If the information contained in the message is not what your application was expecting, or has been corrupted in some way, consider the following:
- Has your application, or the application that put the message onto the queue, changed?

  Ensure that all changes are simultaneously reflected on all systems that need to be aware of the change.

  For example, the format of the message data might have been changed, in which case, both applications must be recompiled to pick up the changes. If one application has not been recompiled, the data will appear corrupted to the other.
- Is an application sending messages to the wrong queue?

  Check that the messages your application is receiving are not intended for an application servicing a different queue. If necessary, change your security definitions to prevent unauthorized applications from putting messages on to the wrong queues.

  If your application uses an alias queue, check that the alias points to the correct queue.
- Has the trigger information been specified correctly for this queue?

  Check that your application should have started; or should a different application have started?

If these checks do not enable you to solve the problem, check your application logic, both for the program sending the message, and for the program receiving it.

Problems with incorrect output when using distributed queues

If your application uses distributed queues, consider the following points:
- Has IBM MQ been correctly installed on both the sending and receiving systems, and correctly configured for distributed queuing?
- Are the links available between the two systems?

  Check that both systems are available, and connected to IBM MQ. Check that the connection between the two systems is active.

  You can use the MQSC command PING against either the queue manager (PING QMGR) or the channel (PING CHANNEL) to verify that the link is operable.
- Is triggering set on in the sending system?
- Is the message for which you are waiting a reply message from a remote system?

  Check that triggering is activated in the remote system.
- Is the queue already full?

If so, check if the message has been put onto the dead-letter queue.

The dead-letter queue header contains a reason or feedback code explaining why the message could not be put onto the target queue. See Using the dead-letter (undelivered message) queue and MQDLH - Dead-letter header for information about the dead-letter queue header structure.

- Is there a mismatch between the sending and receiving queue managers?

  For example, the message length could be longer than the receiving queue manager can handle.
- Are the channel definitions of the sending and receiving channels compatible?

  For example, a mismatch in sequence number wrap can stop the distributed queuing component. See Distributed queuing and clusters for more information about distributed queuing.
- Is data conversion involved? If the data formats between the sending and receiving applications differ, data conversion is necessary. Automatic conversion occurs when the MQGET call is issued if the format is recognized as one of the built-in formats.

  If the data format is not recognized for conversion, the data conversion exit is taken to allow you to perform the translation with your own routines.

  Refer to Data conversion for further information about data conversion.

Are some of your queues failing?

If you suspect that the problem occurs with only a subset of queues, check the local queues that you think are having problems.

Perform the following checks:

1. Display the information about each queue. You can use the MQSC command DISPLAY QUEUE to display the information.
2. Use the data displayed to do the following checks:
   - If CURDEPTH is at MAXDEPTH, the queue is not being processed. Check that all applications are running normally.
   - If CURDEPTH is not at MAXDEPTH, check the following queue attributes to ensure that they are correct:
     - If triggering is being used:
       - Is the trigger monitor running?
       - Is the trigger depth too great? That is, does it generate a trigger event often enough?
       - Is the process name correct?
       - Is the process available and operational?
     - Can the queue be shared? If not, another application could already have it open for input.
     - Is the queue enabled appropriately for GET and PUT?
   - If there are no application processes getting messages from the queue, determine why this is so. It could be because the applications need to be started, a connection has been disrupted, or the MQOPEN call has failed for some reason.

     Check the queue attributes IPPROCS and OPPROCS. These attributes indicate whether the queue has been opened for input and output. If a value is zero, it indicates that no operations of that type can occur. The values might have changed; the queue might have been open but is now closed.

     You need to check the status at the time you expect to put or get a message.

If you are unable to solve the problem, contact your IBM Support Center for help.

Have you failed to receive a response from a PCF command?

Considerations if you have issued a command but have not received a response.

If you have issued a command but have not received a response, consider the following checks:

- Is the command server running?

  Work with the **dspmqcsv** command to check the status of the command server.

  - If the response to this command indicates that the command server is not running, use the **strmqcsv** command to start it.
  - If the response to the command indicates that the SYSTEM.ADMIN.COMMAND.QUEUE is not enabled for MQGET requests, enable the queue for MQGET requests.
- Has a reply been sent to the dead-letter queue?

  The dead-letter queue header structure contains a reason or feedback code describing the problem. See MQDLH - Dead-letter header and Using the dead-letter (undelivered message) queue for information about the dead-letter queue header structure (MQDLH).

  If the dead-letter queue contains messages, you can use the provided browse sample application (amqsbcg) to browse the messages using the MQGET call. The sample application steps through all the messages on a named queue for a named queue manager, displaying both the message descriptor and the message context fields for all the messages on the named queue.
- Has a message been sent to the error log?

  See "Error log directories" on page 1681 for further information.
- Are the queues enabled for put and get operations?
- Is the *WaitInterval* long enough?

  If your MQGET call has timed out, a completion code of MQCC_FAILED and a reason code of MQRC_NO_MSG_AVAILABLE are returned. (See WaitInterval (MQLONG) for information about the *WaitInterval* field, and completion and reason codes from MQGET.)
- If you are using your own application program to put commands onto the SYSTEM.ADMIN.COMMAND.QUEUE, do you need to take a sync point?

  Unless you have excluded your request message from sync point, you need to take a sync point before receiving reply messages.
- Are the MAXDEPTH and MAXMSGL attributes of your queues set sufficiently high?
- Are you using the *CorrelId* and *MsgId* fields correctly?

  Set the values of *MsgId* and *CorrelId* in your application to ensure that you receive all messages from the queue.

Try stopping the command server and then restarting it, responding to any error messages that are produced.

If the system still does not respond, the problem could be with either a queue manager or the whole of the IBM MQ system. First, try stopping individual queue managers to isolate a failing queue manager. If this step does not reveal the problem, try stopping and restarting IBM MQ, responding to any messages that are produced in the error log.

If the problem still occurs after restart, contact your IBM Support Center for help.

Has the application run successfully before?

Use the information in this topic to help diagnose common problems with applications.

If the problem appears to involve one particular application, consider whether the application has run successfully before.

Before you answer **Yes** to this question, consider the following:

- Have any changes been made to the application since it last ran successfully?

  If so, it is likely that the error lies somewhere in the new or modified part of the application. Take a look at the changes and see if you can find an obvious reason for the problem. Is it possible to retry using a back level of the application?
- Have all the functions of the application been fully exercised before?

  Could it be that the problem occurred when part of the application that had never been invoked before was used for the first time? If so, it is likely that the error lies in that part of the application. Try to find out what the application was doing when it failed, and check the source code in that part of the program for errors.

  If a program has been run successfully on many previous occasions, check the current queue status and the files that were being processed when the error occurred. It is possible that they contain some unusual data value that invokes a rarely-used path in the program.
- Does the application check all return codes?

  Has your IBM MQ system been changed, perhaps in a minor way, such that your application does not check the return codes it receives as a result of the change. For example, does your application assume that the queues it accesses can be shared? If a queue has been redefined as exclusive, can your application deal with return codes indicating that it can no longer access that queue?
- Does the application run on other IBM MQ systems?

  Could it be that there is something different about the way that this IBM MQ system is set up that is causing the problem? For example, have the queues been defined with the same message length or priority?

Before you look at the code, and depending upon which programming language the code is written in, examine the output from the translator, or the compiler and linkage editor, to see if any errors have been reported.

If your application fails to translate, compile, or link-edit into the load library, it will also fail to run if you attempt to invoke it. See Developing applications for information about building your application.

If the documentation shows that each of these steps was accomplished without error, consider the coding logic of the application. Do the symptoms of the problem indicate the function that is failing and, therefore, the piece of code in error? See the following section for some examples of common errors that cause problems with IBM MQ applications.

Common programming errors

The errors in the following list illustrate the most common causes of problems encountered while running IBM MQ programs. Consider the possibility that the problem with your IBM MQ system could be caused by one or more of these errors:

- Assuming that queues can be shared, when they are in fact exclusive.
- Passing incorrect parameters in an MQI call.
- Passing insufficient parameters in an MQI call. This might mean that IBM MQ cannot set up completion and reason codes for your application to process.
- Failing to check return codes from MQI requests.
- Passing variables with incorrect lengths specified.

- Passing parameters in the wrong order.
- Failing to initialize `MsgId` and `CorrelId` correctly.
- Failing to initialize `Encoding` and `CodedCharSetId` following MQRC_TRUNCATED_MSG_ACCEPTED.

Is your application or system running slowly?

If your application is running slowly, it might be in a loop, or waiting for a resource that is not available, or there might be a performance problem.

Perhaps your system is operating near the limits of its capacity. This type of problem is probably worst at peak system load times, typically at mid-morning and mid-afternoon. (If your network extends across more than one time zone, peak system load might seem to occur at some other time.)

A performance problem might be caused by a limitation of your hardware.

If you find that performance degradation is not dependent on system loading, but happens sometimes when the system is lightly loaded, a poorly-designed application program is probably to blame. This could appear to be a problem that only occurs when certain queues are accessed.

If the performance issue persists, the problem might lie with IBM MQ itself. If you suspect this, contact your IBM Support Center for help.

A common cause of slow application performance, or the build up of messages on a queue (usually a transmission queue) is one or more applications that write persistent messages outside a unit of work; for more information, see Message persistence.

Does the problem affect specific parts of the network?

You might be able to identify specific parts of the network that are affected by the problem (remote queues, for example). If the link to a remote message queue manager is not working, the messages cannot flow to a remote queue.

Check that the connection between the two systems is available, and that the intercommunication component of IBM MQ has started.

Check that messages are reaching the transmission queue, and check the local queue definition of the transmission queue and any remote queues.

Have you made any network-related changes, or changed any IBM MQ definitions, that might account for the problem?

Does the problem occur at specific times of the day?

If the problem occurs at specific times of day, it could be that it depends on system loading. Typically, peak system loading is at mid-morning and mid-afternoon, so these are the times when load-dependent problems are most likely to occur. (If your IBM MQ network extends across more than one time zone, peak system loading might seem to occur at some other time of day.)

Is the problem intermittent?

An intermittent problem could be caused by the way that processes can run independently of each other. For example, a program might issue an MQGET call without specifying a wait option before an earlier process has completed. An intermittent problem might also be seen if your application tries to get a message from a queue before the call that put the message has been committed.

Making initial checks on IBM i

IBM i

Before you start problem determination in detail, consider whether there is an obvious cause of the problem, or an area of investigation that is likely to give useful results. This approach to diagnosis can often save a lot of work by highlighting a simple error, or by narrowing down the range of possibilities.

The cause of your problem could be in any of the following:
- Hardware
- Operating system
- Related software, for example, a language compiler
- The network
- The IBM MQ product
- Your IBM MQ application
- Other applications
- Site operating procedures

This section contains a list of questions to consider. As you go through the list, make a note of anything that might be relevant to the problem. Even if your observations do not suggest a cause straight away, they might be useful later if you have to carry out a systematic problem determination exercise.

The following steps are intended to help you isolate the problem and are taken from the viewpoint of an IBM MQ application. Check all the suggestions at each stage.

1. Has IBM MQ for IBM i run successfully before?

   Yes Proceed to Step 2.

   No It is likely that you have not installed or set up IBM MQ correctly.
2. Has the IBM MQ application run successfully before?

   Yes Proceed to Step 3 on page 1289.

   No Consider the following:
   a. The application might have failed to compile or link, and fails if you attempt to invoke it. Check the output from the compiler or linker.

      Refer to the appropriate programming language reference information, or see Developing applications, for information about how to build your application.
   b. Consider the logic of the application. For example, do the symptoms of the problem indicate that a function is failing and, therefore, that a piece of code is in error.

      Check the following common programming errors:

- Assuming that queues can be shared, when they are in fact exclusive.
- Trying to access queues and data without the correct security authorization.
- Passing incorrect parameters in an MQI call; if the wrong number of parameters is passed, no attempt can be made to complete the completion code and reason code fields, and the task is ended abnormally.
- Failing to check return codes from MQI requests.
- Using incorrect addresses.
- Passing variables with incorrect lengths specified.
- Passing parameters in the wrong order.
- Failing to initialize `MsgId` and `CorrelId` correctly.

3. Has the IBM MQ application changed since the last successful run?

   Yes It is likely that the error lies in the new or modified part of the application. Check all the changes and see if you can find an obvious reason for the problem.

   a. Have all the functions of the application been fully exercised before?

      Could it be that the problem occurred when part of the application that had never been invoked before was used for the first time? If so, it is likely that the error lies in that part of the application. Try to find out what the application was doing when it failed, and check the source code in that part of the program for errors.

   b. If the program has run successfully before, check the current queue status and files that were being processed when the error occurred. It is possible that they contain some unusual data value that causes a rarely used path in the program to be invoked.

   c. The application received an unexpected MQI return code. For example:

      - Does your application assume that the queues it accesses are shareable? If a queue has been redefined as exclusive, can your application deal with return codes indicating that it can no longer access that queue?
      - Have any queue definition or security profiles been changed? An MQOPEN call could fail because of a security violation; can your application recover from the resulting return code?

      See MQI Applications reference for your programming language for a description of each return code.

   d. If you have applied any PTF to IBM MQ for IBM i, check that you received no error messages when you installed the PTF.

   No Ensure that you have eliminated all the preceding suggestions and proceed to Step 4.

4. Has the server system remained unchanged since the last successful run?

   Yes Proceed to “Problem characteristics” on page 1291.

   No Consider all aspects of the system and review the appropriate documentation on how the change might have affected the IBM MQ application. For example :

   - Interfaces with other applications
   - Installation of new operating system or hardware
   - Application of PTFs
   - Changes in operating procedures

See the following sections for some additional tips for problem determination for system administrators and application developers.

Tips for system administrators

- Check the error logs for messages for your operating system:
  - Windows UNIX Linux “Error logs on Windows, UNIX and Linux systems” on page 1678

- IBM i "Error logs on IBM i" on page 1683
- z/OS "Diagnostic information produced on IBM MQ for z/OS" on page 1731
- Check the contents of `qm.ini` for any configuration changes or errors. For more information on changing configuration information, see:
  - Windows UNIX Linux Changing configuration information on Windows, UNIX and Linux systems
  - IBM i Changing configuration information on IBM i
  - z/OS Customizing your queue managers on z/OS
- If your application development teams are reporting something unexpected, you use trace to investigate the problems. For information about using trace, see "Using trace" on page 1686.

Tips for application developers

- Check the return codes from the MQI calls in your applications. For a list of reason codes, see "API reason codes" on page 1315. Use the information provided in the return code to determine the cause of the problem. Follow the steps in the Programmer response sections of the reason code to resolve the problem.
- If you are unsure whether your application is working as expected, for example, you are not unsure of the parameters being passed into the MQI or out of the MQI, you can use trace to collect information about all the inputs and outputs of your MQI calls. For more information about using trace, see "Using trace" on page 1686.
- For more information about handling errors in MQI applications, see Handling program errors.

Problem characteristics

Perhaps by using the preliminary checks, you have found the cause of the problem. If so, you can probably now resolve it, possibly with the help of other sections in the IBM MQ product documentation, and in the libraries of other licensed programs.

If you have not yet found the cause, start to look at the problem in greater detail. Use the following questions as pointers to the problem. Answering the appropriate question, or questions, should lead you to the cause of the problem:

- "Can you reproduce the problem?"
- "Is the problem intermittent?"
- "Problems with commands" on page 1292
- "Does the problem affect all users of the IBM MQ for IBM i application?" on page 1292
- "Does the problem affect specific parts of the network?" on page 1292
- "Does the problem occur only on IBM MQ?" on page 1292
- "Does the problem occur at specific times of the day?" on page 1292
- "Have you failed to receive a response from a command?" on page 1293

Can you reproduce the problem?

If you can reproduce the problem, consider the conditions under which you do so:

- Is it caused by a command?

  Does the operation work if it is entered by another method? If the command works if it is entered on the command line, but not otherwise, check that the command server has not stopped. You must also check that the queue definition of the `SYSTEM.ADMIN.COMMAND.QUEUE` has not been changed.
- Is it caused by a program? If so, does it fail in batch? Does it fail on all IBM MQ for IBM i systems, or only on some?
- Can you identify any application that always seems to be running in the system when the problem occurs? If so, examine the application to see if it is in error.
- Does the problem occur with any queue manager, or when connected to one specific queue manager?
- Does the problem occur with the same type of object on any queue manager, or only one particular object? What happens after this object has been cleared or redefined?
- Is the problem independent of any message persistence settings?
- Does the problem occur only when sync points are used?
- Does the problem occur only when one or more queue-manager events are enabled?

Is the problem intermittent?

An intermittent problem might be caused by failing to take into account the fact that processes can run independently of each other. For example, a program might issue an MQGET call, without specifying a wait option, before an earlier process has completed. You might also encounter this problem if your application tries to get a message from a queue while the call that put the message is in-doubt (that is, before it has been committed or backed out).

Problems with commands

Use this information to avoid potential problems with special characters. Be careful when including special characters, for example backslash (\) and quotation marks (") characters, in descriptive text for some commands. If you use either of these characters in descriptive text, precede them with a backslash (\) character, for example:

- Enter \\ if you need a backslash (\) character in your text.
- Enter \" if you need quotation marks (") characters in your text.

Queue managers and their associated object names are case-sensitive. By default, IBM i uses uppercase characters, unless you surround the name in apostrophe (') characters.

For example, `MYQUEUE` and `myqueue` translate to `MYQUEUE`, whereas `'myqueue'` translates to `myqueue`.

Does the problem affect all users of the IBM MQ for IBM i application?

If the problem affects only some users, look for differences in how the users configure their systems and queue manager settings.

Check the library lists and user profiles. Can the problem be circumvented by having `*ALLOBJ` authority?

Does the problem affect specific parts of the network?

You might be able to identify specific parts of the network that are affected by the problem (remote queues, for example). If the link to a remote message queue manager is not working, the messages cannot flow to a remote queue.

Check these points:

- Is the connection between the two systems available, and has the intercommunication component of IBM MQ for IBM i started?

  Check that messages are reaching the transmission queue, the local queue definition of the transmission queue, and any remote queues.
- Have you made any network-related changes that might account for the problem or changed any IBM MQ for IBM i definitions?
- Can you distinguish between a channel definition problem and a channel message problem?

  For example, redefine the channel to use an empty transmission queue. If the channel starts correctly, the definition is correctly configured.

Does the problem occur only on IBM MQ?

If the problem occurs only on this version of IBM MQ, check the appropriate database on RETAIN, or the http://www.ibm.com/support/entry/portal/Overview/Software/WebSphere/WebSphere_MQ, to ensure that you have applied all the relevant PTFs.

Does the problem occur at specific times of the day?

If the problem occurs at specific times of day, it might be that it is dependent on system loading. Typically, peak system loading is at mid-morning and mid-afternoon, and so these times are when load-dependent problems are most likely to occur. (If your IBM MQ for IBM i network extends across more than one time zone, peak system loading might seem to occur at some other time of day.)

Have you failed to receive a response from a command?

If you have issued a command but you have not received a response, consider the following questions:

- Is the command server running?

  Work with the **DSPMQMCSVR** command to check the status of the command server.

  – If the response to this command indicates that the command server is not running, use the **STRMQMCSVR** command to start it.

  – If the response to the command indicates that the SYSTEM.ADMIN.COMMAND.QUEUE is not enabled for MQGET requests, enable the queue for MQGET requests.
- Has a reply been sent to the dead-letter queue?

  The dead-letter queue header structure contains a reason or feedback code describing the problem. See MQDLH - Dead-letter header for information about the dead-letter queue header structure (MQDLH).

  If the dead-letter queue contains messages, you can use the provided browse sample application (amqsbcg) to browse the messages using the MQGET call. The sample application steps through all the messages on a named queue for a named queue manager, displaying both the message descriptor and the message context fields for all the messages on the named queue.
- Has a message been sent to the error log?

  See "Error logs on IBM i" on page 1683 for further information.
- Are the queues enabled for put and get operations?
- Is the `WaitInterval` long enough?

  If your MQGET call has timed out, a completion code of MQCC_FAILED and a reason code of MQRC_NO_MSG_AVAILABLE are returned. (See Getting messages from a queue using the MQGET call for more information about the `WaitInterval` field, and completion and reason codes from MQGET.)
- If you are using your own application program to put commands onto the SYSTEM.ADMIN.COMMAND.QUEUE, do you need to take a sync point?

  Unless you have excluded your request message from sync point, you must take a sync point before attempting to receive reply messages.
- Are the MAXDEPTH and MAXMSGL attributes of your queues set sufficiently high?
- Are you using the `CorrelId` and `MsgId` fields correctly?

  Set the values of `MsgId` and `CorrelId` in your application to ensure that you receive all messages from the queue.

Related concepts:

"Troubleshooting and support" on page 1275
If you are having problems with your queue manager network or IBM MQ applications, use the techniques described to help you diagnose and solve the problems.

"Required authority"
Some IBM MQ commands rely on using IBM i system commands for creating and managing objects, files, and libraries.

Related reference:

"Determining problems with IBM MQ for IBM i applications" on page 1295
If you have not yet found the cause, start to look at the problem in greater detail.

Required authority

Some IBM MQ commands rely on using IBM i system commands for creating and managing objects, files, and libraries.

For example, `CRTMQM` (create queue manager) and `DLTMQM` (delete queue manager). Similarly some IBM MQ program code, for example a queue manager, relies on using IBM i system programs.

To enable this reliance, the commands and programs listed must either have `*PUBLIC *USE` authority, or explicit `*USE` authority to the IBM MQ user profiles `QMQM` and `QMQMADM`.

Such authority is applied automatically as part of the install process, and you do not need to apply it yourself.

However, if you encounter problems, here is how to do it manually:

1. Set the authorities for commands using GRTOBJAUT with an OBJTYPE(*CMD) parameter, for example:

   ```
   GRTOBJAUT OBJ(QSYS/ADDLIBLE) OBJTYPE(*CMD) USER(QMQMADM) AUT(*USE)
   ```

   - QSYS/ADDLIBLE
   - QSYS/ADDPFM
   - QSYS/CALL
   - QSYS/CHGCURLIB
   - QSYS/CHGJOB
   - QSYS/CRTJRN
   - QSYS/CRTJRNRCV
   - QSYS/CRTJOBQ
   - QSYS/CRTJOBD
   - QSYS/CRTLIB
   - QSYS/CRTMSGQ
   - QSYS/CRTPF
   - QSYS/CRTPGM
   - QSYS/CRTSRCPF
   - QSYS/DLTJRN
   - QSYS/DLTJRNRCV
   - QSYS/DLTLIB
   - QSYS/DLTMSGQ
   - QSYS/OVRPRTF
   - QSYS/RCLACTGRP
   - QSYS/RTVJRNE
   - QSYS/RCVJRNE
   - QSYS/SBMJOB
2. Set the authorities for programs using GRTOBJAUT with an OBJTYPE(*PGM) parameter, for example:

   ```
   GRTOBJAUT OBJ(QSYS/QWTSETP) OBJTYPE(*PGM) USER(QMQMADM) AUT(*USE)
   ```

   - QSYS/QWTSETP(*PGM)
   - QSYS/QSYRLSPH(*PGM)
   - QSYS/QSYGETPH(*PGM)

Determining problems with IBM MQ for IBM i applications

IBM i

If you have not yet found the cause, start to look at the problem in greater detail.

This section contains information about problems you might encounter with IBM MQ applications, commands, and messages. Use the following questions as pointers to the problem. Answering the appropriate question, or questions, should lead you to the cause of the problem.

Are some of your queues working?

If you suspect that the problem occurs with only a subset of queues, select the name of a local queue that you think is having problems.

1. Display the information about this queue, using WRKMQMQSTS or DSPMQMQ.
2. Use the data displayed to do the following checks:
   - If CURDEPTH is at MAXDEPTH, the queue is not being processed. Check that all applications are running normally.
   - If CURDEPTH is not at MAXDEPTH, check the following queue attributes to ensure that they are correct:
     - If triggering is being used:
       - Is the trigger monitor running?
       - Is the trigger depth too large?
       - Is the process name correct?
     - Can the queue be shared? If not, another application might already have it open for input.
     - Is the queue enabled appropriately for GET and PUT?
   - If there are no application processes getting messages from the queue, determine why (for example, because the applications must be started, a connection has been disrupted, or because the MQOPEN call has failed for some reason).

If you cannot solve the problem, contact your IBM support center for help.

Does the problem affect only remote queues?

If the problem affects only remote queues, check the subsequent points:

1. Check that the programs that should be putting messages to the remote queues have run successfully.
2. If you use triggering to start the distributed queuing process, check that the transmission queue has triggering set on. Also, check that the trigger monitor is running.
3. If necessary, start the channel manually. See Distributed queuing and clusters.
4. Check the channel with a PING command.

Are messages failing to arrive on the queue?

If messages do not arrive when you are expecting them, check for the following:

- Have you selected the correct queue manager, that is, the default queue manager or a named queue manager?
- Has the message been put on the queue successfully?
  - Has the queue been defined correctly, for example, is MAXMSGLEN sufficiently large?
  - Can applications put messages on the queue (is the queue enabled for putting)?
  - If the queue is already full, it might mean that an application was unable to put the required message on the queue.

- Can you get the message from the queue?
  - Must you take a sync point?

    If messages are being put or retrieved within sync point, they are not available to other tasks until the unit of recovery has been committed.
  - Is your timeout interval long enough?
  - Are you waiting for a specific message that is identified by a message identifier or correlation identifier (*MsgId* or *CorrelId*)?

    Check that you are waiting for a message with the correct *MsgId* or *CorrelId*. A successful MQGET call sets both these values to that of the message retrieved, so you might need to reset these values in order to get another message successfully.

    Also check if you can get other messages from the queue.
  - Can other applications get messages from the queue?
  - Was the message you are expecting defined as persistent?

    If not, and IBM MQ for IBM i has been restarted, the message has been lost.

If you cannot find anything wrong with the queue, and the queue manager itself is running, make the following checks on the process that you expected to put the message on to the queue:

- Did the application start?

  If it should have been triggered, check that the correct trigger options were specified.
- Is a trigger monitor running?
- Was the trigger process defined correctly?
- Did it complete correctly?

  Look for evidence of an abnormal end in the job log.
- Did the application commit its changes, or were they backed out?

If multiple transactions are serving the queue, they might occasionally conflict with one another. For example, one transaction might issue an MQGET call with a buffer length of zero to find out the length of the message, and then issue a specific MQGET call specifying the *MsgId* of that message. However, in the meantime, another transaction might have issued a successful MQGET call for that message, so the first application receives a completion code of MQRC_NO_MSG_AVAILABLE. Applications that are expected to run in a multi-server environment must be designed to cope with this situation.

Consider that the message might have been received, but that your application failed to process it in some way. For example, did an error in the expected format of the message cause your program to reject it? If so, see "Are unexpected messages received when using distributed queues?" on page 1297.

Do messages contain unexpected or corrupted information?

If the information contained in the message is not what your application was expecting, or has been corrupted in some way, consider the following points:

- Has your application, or the application that put the message on to the queue, changed?

  Ensure that all changes are simultaneously reflected on all systems that need to be aware of the change.

  For example, a copyfile formatting the message might have been changed, in which case, recompile both applications to pick up the changes. If one application has not been recompiled, the data appears corrupted to the other.
- Is an application sending messages to the wrong queue?

  Check that the messages your application is receiving are not intended for an application servicing a different queue. If necessary, change your security definitions to prevent unauthorized applications from putting messages on to the wrong queues.

If your application has used an alias queue, check that the alias points to the correct queue.

- Has the trigger information been specified correctly for this queue?

  Check that your application should have been started, or should a different application have been started?
- Has the CCSID been set correctly, or is the message format incorrect because of data conversion.

If these checks do not enable you to solve the problem, check your application logic, both for the program sending the message, and for the program receiving it.

Are unexpected messages received when using distributed queues?

If your application uses distributed queues, consider the following points:

- Has distributed queuing been correctly installed on both the sending and receiving systems?
- Are the links available between the two systems?

  Check that both systems are available, and connected to IBM MQ for IBM i. Check that the connection between the two systems is active.
- Is triggering set on in the sending system?
- Is the message you are waiting for a reply message from a remote system?

  Check that triggering is activated in the remote system.
- Is the queue already full?

  If so, it might mean that an application was unable to put the required message on to the queue. Check that the message has been put onto the undelivered-message queue.

  The dead-letter queue message header (dead-letter header structure) contains a reason or feedback code explaining why the message could not be put on to the target queue. See MQDLH - Dead-letter header or IBM i Application Programming Reference (ILE/RPG), as appropriate, for information about the dead-letter header structure.
- Is there a mismatch between the sending and receiving queue managers?

  For example, the message length could be longer than the receiving queue manager can handle.
- Are the channel definitions of the sending and receiving channels compatible?

  For example, a mismatch in sequence number wrap stops the distributed queuing component. See Distributed queuing and clusters.

Making initial checks on z/OS

Before you start problem determination in detail, consider whether there is an obvious cause of the problem, or an area of investigation that is likely to give useful results. This approach to diagnosis can often save a lot of work by highlighting a simple error, or by narrowing down the range of possibilities.

The cause of your problem could be in:

- IBM MQ
- The network
- The application
- Other applications that you have configured to work with IBM MQ

This section contains a list of questions to consider. As you go through the list, make a note of anything that might be relevant to the problem. Even if your observations do not suggest a cause straight away, they might be useful later if you have to carry out a systematic problem determination exercise.

- “Has IBM MQ for z/OS run successfully before?” on page 1299
- “Have you applied any APARs or PTFs?” on page 1300
- “Are there any error messages, return codes or other error conditions?” on page 1300

- “Has your application or IBM MQ for z/OS stopped processing work?” on page 1302
- “Is there a problem with the IBM MQ queues?” on page 1302
- “Are some of your queues working?” on page 1303
- “Are the correct queues defined?” on page 1304
- “Does the problem affect only remote or cluster queues?” on page 1304
- “Does the problem affect only shared queues?” on page 1305
- “Does the problem affect specific parts of the network?” on page 1306
- “Problems that occur at specific times of the day or affect specific users” on page 1306
- “Is the problem intermittent or does the problem occur with all z/OS, CICS, or IMS systems?” on page 1306
- “Has the application run successfully before?” on page 1307
- “Have any changes been made since the last successful run?” on page 1308
- “Do you have a program error?” on page 1309
- “Has there been an abend?” on page 1310
- “Have you obtained incorrect output?” on page 1311
- “Can you reproduce the problem?” on page 1311
- “Have you failed to receive a response from an MQSC command?” on page 1312
- “Is your application or IBM MQ for z/OS running slowly?” on page 1313

See the following sections for some additional tips for problem determination for system administrators and application developers.

Tips for system administrators

- Check the error logs for messages for your operating system:
  - Windows UNIX Linux “Error logs on Windows, UNIX and Linux systems” on page 1678
  - IBM i “Error logs on IBM i” on page 1683
  - z/OS “Diagnostic information produced on IBM MQ for z/OS” on page 1731
- Check the contents of `qm.ini` for any configuration changes or errors. For more information on changing configuration information, see:
  - Windows UNIX Linux Changing configuration information on Windows, UNIX and Linux systems
  - IBM i Changing configuration information on IBM i
  - z/OS Customizing your queue managers on z/OS
- If your application development teams are reporting something unexpected, you use trace to investigate the problems. For information about using trace, see “Using trace” on page 1686.

Tips for application developers

- Check the return codes from the MQI calls in your applications. For a list of reason codes, see “API reason codes” on page 1315. Use the information provided in the return code to determine the cause of the problem. Follow the steps in the Programmer response sections of the reason code to resolve the problem.
- If you are unsure whether your application is working as expected, for example, you are not unsure of the parameters being passed into the MQI or out of the MQI, you can use trace to collect information about all the inputs and outputs of your MQI calls. For more information about using trace, see “Using trace” on page 1686.
- For more information about handling errors in MQI applications, see Handling program errors.

Has IBM MQ for z/OS run successfully before?

Knowing whether IBM MQ for z/OS has successfully run before can help with problem determination, and there are checks you can perform to help you.

If the answer to this question is **No**, consider the following:

- Check your setup.

  If IBM MQ has not run successfully on z/OS before, it is likely that you have not yet set it up correctly. See the information about installing and customizing the queue manager in Installing the IBM MQ for z/OS product for further guidance.
- Verify the installation.
- Check that message CSQ9022I was issued in response to the START QMGR command (indicating normal completion).
- Ensure that z/OS displays IBM MQ as an installed subsystem. To determine if IBM MQ is an installed subsystem use the z/OS command `D OPDATA`.
- Check that the installation verification program (IVP) ran successfully.

- Issue the command `DISPLAY DQM` to check that the channel initiator address space is running, and that the appropriate listeners are started.

Have you applied any APARs or PTFs?

APARs and PTFs can occasionally cause unexpected problems with IBM MQ. These fixes can have been applied to IBM MQ or to other z/OS systems.

If an APAR or PTF has been applied to IBM MQ for z/OS, check that no error message was produced. If the installation was successful, check with the IBM support center for any APAR or PTF error.

If an APAR or PTF has been applied to any other product, consider the effect it might have on the way IBM MQ interfaces with it.

Ensure that you have followed any instructions in the APAR that affect your system. (For example, you might have to redefine a resource.)

Are there any error messages, return codes or other error conditions?

Use this topic to investigate error messages, return codes, and conditions where the queue manager or channel initiator terminated.

The problem might produce the following types of error message or return codes:

CSQ messages and reason codes
IBM MQ for z/OS error messages have the prefix CSQ; if you receive any messages with this prefix (for example, in the console log, or the CICS log), see IBM MQ for z/OS messages, completion, and reason codes for an explanation.

Other messages
For messages with a different prefix, look in the appropriate messages and codes topic for a suggested course of action. See "The message keyword" on page 1651 which lists possible message prefixes and appropriate manuals.

Unusual messages
Be aware of unusual messages associated with the startup of IBM MQ for z/OS, or issued while the system was running before the error occurred. Any unusual messages might indicate some system problem that prevented your application from running successfully.

Application MQI return codes
If your application gets a return code indicating that an MQI call has failed, see Return codes for a description of that return code.

Have you received an unexpected error message or return code?

If your application has received an unexpected error message, consider whether the error message has originated from IBM MQ or from another program.

IBM MQ error messages

IBM MQ for z/OS error messages are prefixed with the letters CSQ.

If you get an unexpected IBM MQ error message (for example, in the console log, or the CICS log), see IBM MQ for z/OS messages, completion, and reason codes for an explanation.

IBM MQ for z/OS messages, completion, and reason codes might give you enough information to resolve the problem quickly, or it might redirect you to another manual for further guidance. If you cannot deal with the message, you might have to contact the IBM support center for help.

Non- IBM MQ error messages

If you get an error message from another IBM program, or from the operating system, look in the messages and codes manual from the appropriate library for an explanation of what it means.

In a queue-sharing environment, look for the following error messages:
- XES (prefixed with the letters IXL)
- Db2 (prefixed with the letters DSN)
- RRS (prefixed with the letters ATR)

See “The message keyword” on page 1651 for a list of the most common message prefixes.

Unexpected return codes
If your application has received an unexpected return code from IBM MQ, see Return codes for information about how your application can handle IBM MQ return codes.

Check for error messages

Issue the DISPLAY THREAD(*) command to check if the queue manager is running. For more information about the command, see DISPLAY THREAD. If the queue manager has stopped running, look for any message that might explain the situation. Messages are displayed on the z/OS console, or on your terminal if you are using the operations and control panels. Use the DISPLAY DQM command to see if the channel initiator is working, and the listeners are active. The z/OS command

```
DISPLAY R,L
```

lists messages with outstanding replies. Check to see whether any of these replies are relevant. In some circumstances, for example, when it has used all its active logs, IBM MQ for z/OS waits for operator intervention.

No error messages issued

If no error messages have been issued, perform the following procedure to determine what is causing the problem:

1. Issue the z/OS commands

   ```
   DISPLAY A,xxxxMSTR
   DISPLAY A,xxxxCHIN
   ```

   (where xxxx is the IBM MQ for z/OS subsystem name). If you receive a message telling you that the queue manager or channel initiator has not been found, this message indicates that the subsystem has terminated. This condition could be caused by an abend or by operator shutdown of the system.
2. If the subsystem is running, you receive message IEE105I. This message includes the *CT=nnnn* field, which contains information about the processor time being used by the subsystem. Note the value of this field, and reissue the command.
   - If the *CT=* value has not changed, this indicates that the subsystem is not using any processor time. This could indicate that the subsystem is in a wait state (or that it has no work to do). If you can issue a command like DISPLAY DQM and you get output back, this indicates there is no work to do rather than a hang condition.
   - If the *CT=* value has changed dramatically, and continues to do so over repeated displays, this could indicate that the subsystem is busy or possibly in a loop.
   - If the reply indicates that the subsystem is now not found, this indicates that it was in the process of terminating when the first command was issued. If a dump is being taken, the subsystem might take a while to terminate. A message is produced at the console before terminating.

     To check that the channel initiator is working, issue the DISPLAY DQM command. If the response does not show the channel initiator working this could be because it is getting insufficient resources (like the processor). In this case, use the z/OS monitoring tools, such as RMF, to determine if there is a resource problem. If it is not, restart the channel initiator.

Has the queue manager or channel initiator terminated abnormally?

Look for any messages saying that the queue manager or channel initiator address space has abnormally terminated. If you get a message for which the system action is to terminate IBM MQ, find out whether a system dump was produced, see IBM MQ dumps.

IBM MQ for z/OS might still be running

Consider also that IBM MQ for z/OS might still be running, but only slowly. If it is running slowly, you probably have a performance problem. To confirm this, see Is your application or IBM MQ for z/OS running slowly. Refer to Dealing with performance problems for advice about what to do next.

Has your application or IBM MQ for z/OS stopped processing work?

There are several reasons why your system would unexpectedly stop processing work including problems with the queue manager, the application, z/OS, and the data sets.

There are several reasons why your system would unexpectedly stop processing work. These include:

Queue manager problems
: The queue manager might be shutting down.

Application problems
: An application programming error might mean that the program branches away from its normal processing, or the application might get in a loop. There might also have been an application abend.

IBM MQ problems
: Your queues might have become disabled for MQPUT or MQGET calls, the dead-letter queue might be full, or IBM MQ for z/OS might be in a wait state, or a loop.

z/OS and other system problems
: z/OS might be in a wait state, or CICS or IMS might be in a wait state or a loop. There might be problems at the system or sysplex level that are affecting the queue manager or the channel initiator. For example, excessive paging. It might also indicate DASD problems, or higher priority tasks with high processor usage.

Db2 and RRS problems
: Check that Db2 and RRS are active.

In all cases, carry out the following checks to determine the cause of the problem:

Is there a problem with the IBM MQ queues?

Use this topic for investigating potential problems with IBM MQ queues.

If you suspect that there is a problem affecting the queues on your subsystem, use the operations and control panels to display the system-command input queue.

If the system responds
: If the system responds, then at least one queue is working. In this case, follow the procedure in "Are some of your queues working?" on page 1303.

If the system does not respond
: The problem might be with the whole subsystem. In this instance, try stopping and restarting the queue manager, responding to any error messages that are produced.

: Check for any messages on the console needing action. Resolve any that might affect IBM MQ, such as a request to mount a tape for an archive log. See if other subsystems or CICS regions are affected.

Use the DISPLAY QMGR COMMANDQ command to identify the name of the system command input queue.

If the problem still occurs after restart
Contact your IBM support center for help (see “Contacting IBM Software Support” on page 1658).

Related concepts:

“Are the correct queues defined?” on page 1304
IBM MQ requires certain predefined queues. Problems can occur if these queues are not defined correctly.

“Does the problem affect only remote or cluster queues?” on page 1304
Use this topic for further investigation if the problem only occurs on remote or cluster queues.

“Does the problem affect only shared queues?” on page 1305
Use this topic to investigate possible queue-sharing group issues which can cause problems for shared queues.

Are some of your queues working?:

Use this topic to investigate when problems occur with a subset of your queues.

If you suspect that the problem occurs with only a subset of queues, select the name of a local queue that you think is having problems and perform the following procedures:

Display queue information
Use the DISPLAY QUEUE and DISPLAY QSTATUS commands to display information about the queue.

Is the queue being processed?

- If CURDEPTH is at MAXDEPTH, it might indicate that the queue is not being processed. Check that all applications that use the queue are running normally (for example, check that transactions in your CICS system are running or that applications started in response to Queue Depth High events are running).
- Issue DISPLAY QSTATUS(xx) IPPROCS to see if the queue is open for input. If not, start the application.
- If CURDEPTH is not at MAXDEPTH, check the following queue attributes to ensure that they are correct:
  - If triggering is being used:
    - Is the trigger monitor running?
    - Is the trigger depth too big?
    - Is the process name correct?
    - Have **all** the trigger conditions been met?

      Issue DISPLAY QSTATUS(xx) IPPROCS to see if an application has the same queue open for input. In some triggering scenarios, a trigger message is not produced if the queue is open for input. Stop the application to cause the triggering processing to be invoked.
  - Can the queue be shared? If not, another application (batch, IMS, or CICS) might already have it open for input.
  - Is the queue enabled appropriately for GET and PUT?

Do you have a long-running unit of work?
If CURDEPTH is not zero, but when you attempt to MQGET a message the queue manager replies that there is no message available, issue either DIS QSTATUS(xx) TYPE(HANDLE) to show you information about applications that have the queue open, or issue DIS CONN(xx) to give you more information about an application that is connected to the queue.

How many tasks are accessing the queues?

Issue DISPLAY QSTATUS(xx) OPPROCS IPPROCS to see how many tasks are putting messages on to, and getting messages from the queue. In a queue-sharing environment, check OPPROCS and IPPROCS on each queue manager. Alternatively, use the CMDSCOPE attribute to check all the queue managers. If there are no application processes getting messages from the queue, determine the reason (for example, because the applications need to be started, a connection has been disrupted, or because the MQOPEN call has failed for some reason).

Is this queue a shared queue? Does the problem affect only shared queues?

Check that there is not a problem with the sysplex elements that support shared queues. For example, check that there is not a problem with the IBM MQ-managed Coupling Facility list structure.

Use D XCF, STRUCTURE, STRNAME=ALL to check that the Coupling Facility structures are accessible.

Use D RRS to check that RRS is active.

Is this queue part of a cluster?

Check to see if the queue is part of a cluster (from the CLUSTER or CLUSNL attribute). If it is, verify that the queue manager that hosts the queue is still active in the cluster.

If you cannot solve the problem

Contact your IBM support center for help (see "Contacting IBM Software Support" on page 1658).

Are the correct queues defined?:

IBM MQ requires certain predefined queues. Problems can occur if these queues are not defined correctly.

Check that the system-command input queue, the system-command reply model queue, and the reply-to queue are correctly defined, and that the MQOPEN calls were successful.

If you are using the system-command reply model queue, check that it was defined correctly.

If you are using clusters, you need to define the SYSTEM.CLUSTER.COMMAND.QUEUE to use commands relating to cluster processing.

Does the problem affect only remote or cluster queues?:

Use this topic for further investigation if the problem only occurs on remote or cluster queues.

If the problem affects only remote or cluster queues, check:

Are the remote queues being accessed?

Check that the programs putting messages to the remote queues have run successfully (see "Dealing with incorrect output" on page 1762).

Is the system link active?

Use APPC or TCP/IP commands as appropriate to check whether the link between the two systems is active.

Use PING or OPING for TCP/IP or D NET ID=xxxxx, E for APPC.

Is triggering working?

If you use triggering to start the distributed queuing process, check that the transmission queue has triggering set on and that the queue is get-enabled.

Is the channel or listener running?

If necessary, start the channel or the listener manually, or try stopping and restarting the channel. See Configuring distributed queuing for more information.

Look for error messages on the startup of the channel initiator and listener. See IBM MQ for z/OS messages, completion, and reason codes and Configuring distributed queuing to determine the cause.

What is the channel status?
Check the channel status using the DISPLAY CHSTATUS (channel_name) command.

Are your process and channel definitions correct?
Check your process definitions and your channel definitions.

See Configuring distributed queuing for information about how to use distributed queuing, and for information about how to define channels.

Does the problem affect only shared queues?:

Use this topic to investigate possible queue-sharing group issues which can cause problems for shared queues.

If the problem affects only queue-sharing groups, use the VERIFY QSG function of the CSQ5PQSG utility. This command verifies that the Db2 setup is consistent in terms of the bitmap allocation fields, and object definition for the Db2 queue manager, structure, and shared queue objects, and reports details of any inconsistency that is discovered.

The following is an example of a VERIFY QSG report with errors:

```
CSQU501I  VERIFY QSG function requested
CSQU503I  QSG=SQ02, DB2 DSG=DSN710P5, DB2 ssid=DFP5
CSQU517I  XCF group CSQGSQ02 already defined
CSQU520I  Summary information for XCF group CSQGSQ02
CSQU522I  Member=MQ04, state=QUIESCED, system=MV4A
CSQU523I  User data=D4E5F4C15AD4D8F0F4404040C4C5....
CSQU522I  Member=MQ03, state=QUIESCED, system=MV4A
CSQU523I  User data=D4E5F4C15AD4D8F0F3404040C4C6....
CSQU526I  Connected to DB2 DF4A
CSQU572E  Usage map T01_ARRAY_QMGR and DB2 table CSQ.ADMIN_B_QMGR inconsistent
CSQU573E  QMGR MQ04 in table entry 1 not set in usage map
CSQU574E  QMGR 27 in usage map has no entry in table
CSQU572E  Usage map T01_ARRAY_STRUC and DB2 table CSQ.ADMIN_B_STRUCTURE inconsistent
CSQU575E  Structure APPL2 in table entry 4 not set in usage map
CSQU576E  Structure 55 in usage map has no entry in table
CSQU572E  Usage map T03_LH_ARRAY and DB2 table CSQ.OBJ_B_QUEUE inconsistent
CSQU577E  Queue MYSQ in table entry 13 not set in usage map for structure APPL1
CSQU576E  Queue 129 in usage map for structure APPL1 has no entry in table
CSQU528I  Disconnected from DB2 DF4A
CSQU148I  CSQ5PQSG Utility completed, return code=12
```

Does the problem affect specific parts of the network?

Network problems can cause related problems for MQ for z/OS. Use this topic to review possible sources of networks problems.

You might be able to identify specific parts of the network that are affected by the problem (remote queues, for example). If the link to a remote queue manager is not working, the messages cannot flow to a target queue on the target queue manager. Check that the connection between the two systems is available, and that the channel initiator and listener have been started. Use the MQSC `PING CHANNEL` command to check the connection.

Check that messages are reaching the transmission queue, and check the local queue definition of the transmission queue, and any remote queues. Use the MQSC `BYTSSENT` keyword of the `DISPLAY CHSTATUS` command to check that data is flowing along the channel. Use `DISPLAY QLOCAL (XMITQ) CURDEPTH` to check whether there are messages to be sent on the transmission queue. Check for diagnostic messages at both ends of the channel informing you that messages have been sent to the dead-letter queue.

If you are using IBM MQ clusters, check that the clustering definitions have been set up correctly.

Have you made any network-related changes that might account for the problem?

Have you changed any IBM MQ definitions, or any CICS or IMS definitions? Check the triggering attributes of the transmission queue.

Problems that occur at specific times of the day or affect specific users

Use this topic to review IBM MQ problems that occur at specific times of the day or specific groups of users.

If the problem occurs at specific times of day, it might be that it is dependent on system loading. Typically, peak system loading is at mid-morning and mid-afternoon, and so these periods are the times when load-dependent problems are most likely to occur. (If your network extends across more than one time zone, peak system loading might seem to occur at some other time of day.)

If you think that your IBM MQ for z/OS system has a performance problem, see "Dealing with performance problems on z/OS" on page 1755.

If the problem only affects some users, is it because some users do not have the correct security authorization? See User IDs for security checking for information about user IDs checked by IBM MQ for z/OS.

Is the problem intermittent or does the problem occur with all z/OS, CICS, or IMS systems?

Review this topic to consider if problems are caused by application interaction or are related to other z/OS systems.

An intermittent problem could be caused by failing to take into account the fact that processes can run independently of each other. For example, a program might issue an **MQGET** call, without specifying WAIT, before an earlier process has completed. You might also encounter this type of problem if your application tries to get a message from a queue while it is in sync point (that is, before it has been committed).

If the problem only occurs when you access a particular z/OS, IMS, or CICS system, consider what is different about this system. Also consider whether any changes have been made to the system that might affect the way it interacts with IBM MQ.

Has the application run successfully before?

Application errors can often be determined by determining if they have run successfully before or if they have produced error messages and unexpected return codes.

If the problem appears to involve one particular application, consider whether the application has run successfully before.

Before you answer `Yes` to this question, consider:

Have any changes been made to the application since it last ran successfully?
If so, it is likely that the error lies somewhere in the new or modified part of the application. Investigate the changes and see if you can find an obvious reason for the problem.

Have all the functions of the application been fully exercised before?

Did problem occur when part of the application that had never been started before was used for the first time? If so, it is likely that the error lies in that part of the application. Try to find out what the application was doing when it failed, and check the source code in that part of the program for errors.

If a program has been run successfully on many previous occasions, check the current queue status and files that were being processed when the error occurred. It is possible that they contain some unusual data value that causes a rarely used path in the program to be invoked.

Does the application check all return codes?
Has your system has been changed, perhaps in a minor way. Check the return codes your application receives as a result of the change. For example:

- Does your application assume that the queues it accesses can be shared? If a queue has been redefined as exclusive, can your application deal with return codes indicating that it can no longer access that queue?
- Have any security profiles been altered? An **MQOPEN** call might fail because of a security violation; can your application recover from the resulting return code?

Does the application expect particular message formats?
If a message with an unexpected message format has been put onto a queue (for example, a message from a queue manager on a different platform), it might require data conversion or another different form of processing.

Does the application run on other IBM MQ for z/OS systems?
Is something different about the way that this queue manager is set up that is causing the problem? For example, have the queues been defined with the same maximum message length, or default priority?

Does the application use the MQSET call to change queue attributes?
Is the application is designed to set a queue to have no trigger, then process some work, then set the queue to have a trigger? The application might have failed before the queue had been reset to have a trigger.

Does the application handle messages that cause an application to fail?
If an application fails because of a corrupted message, the message retrieved is rolled back. The next application might get the same message and fail in the same way. Ensure that applications use the backout count; when the backout count threshold has been reached, the message in question is put onto the backout queue.

If your application has never run successfully before, examine your application carefully to see if you can find any of the following errors:

Translation and compilation problems
Before you look at the code, examine the output from the translator, the compiler or assembler, and the linkage editor, to see if any errors have been reported. If your application fails to

translate, compile/assemble, or link edit into the load library, it also fails to run if you attempt to invoke it. See Developing applications for information about building your application, and for examples of the job control language (JCL) statements required.

Batch and TSO programs
For batch and TSO programs, check that the correct stub has been included. There is one batch stub and two RRS stubs. If you are using RRS, check that you are not using the MQCMIT and MQBACK calls with the CSQBRSTB stub. Use the CSQBRRSI stub if you want to continue using these calls with RRS.

CICS programs
For CICS programs, check that the program, the IBM MQ CICS stub, and the CICS stub have been linked in the correct order. Also, check that your program or transaction is defined to CICS.

IMS programs
For IMS programs, check that the link includes the program, the IBM MQ stub, and the IMS language interface module. Ensure that the correct entry point has been specified. A program that is loaded dynamically from an IMS program must have the stub and language interface module linked also if it is to use IBM MQ.

Possible code problems
If the documentation shows that each step was accomplished without error, consider the coding of the application. Do the symptoms of the problem indicate the function that is failing and, therefore, the piece of code in error? See “Do you have a program error?” on page 1309 for some examples of common errors that cause problems with IBM MQ applications.

Do applications report errors from IBM MQ ?
For example, a queue might not be enabled for "gets". It receives a return code specifying this condition but does not report it. Consider where your applications report any errors or problems.

Have any changes been made since the last successful run?

Recent changes made since the last successful run are often the source of unexpected errors. This topic contains information about some of the changes which can be investigated as part of your problem determination.

When you are considering changes that might recently have been made, think about IBM MQ, and also about the other programs it interfaces with, the hardware, and any new applications. Consider also the possibility that a new application that you don not yet know about might have been run on the system.

Has your initialization procedure been changed?
Consider whether that might be the cause of the problem. Have you changed any data sets, or changed a library definition? Has z/OS been initialized with different parameters? In addition, check for error messages sent to the console during initialization.

Have you changed any queue definitions or security profiles?
Consider whether some of your queues have been altered so that they are members of a cluster. This change might mean that messages arrive from different sources (for example, other queue managers or applications).

Have you changed any definitions in your sysplex that relate to the support and implementation of shared queues?
Consider the effect that changes to such definitions as your sysplex couple data set, or Coupling Facility resource management policy. These changes might have on the operation of shared queues. Also, consider the effect of changes to the Db2 data sharing environment.

Has any of the software on your z/OS system been upgraded to a later release?
Consider whether there are any necessary post-installation or migration activities that you need to perform.

Has your z/OS subsystem name table been changed?
Changes to levels of corequisite software like z/OS or LE might require additional changes to IBM MQ.

Do your applications deal with return codes that they might get as a result of any changes you have made? Ensure that your applications deal with any new return codes that you introduce.

Do you have a program error?

Use this topic to investigate if a program error is causing an IBM MQ problem.

The examples that follow illustrate the most common causes of problems encountered while running IBM MQ programs. Consider the possibility that the problem with your system could be caused by one of these errors.

- Programs issue MQSET to change queue attributes and fail to reset attributes of a queue. For example, setting a queue to NOTRIGGER.
- Making incorrect assumptions about the attributes of a queue. This assumption could include assuming that queues can be opened with MQOPEN when they are MQOPEN-exclusive, and assuming that queues are not part of a cluster when they are.
- Trying to access queues and data without the correct security authorization.
- Linking a program with no stub, or with the wrong stub (for example, a TSO program with the CICS stub). This can cause either a long-running unit of work, or an X'0C4' or other abend.
- Passing incorrect or invalid parameters in an MQI call; if the wrong number of parameters are passed, no attempt can be made to complete the completion code and reason code fields, and the task is abended. (This is an X'0C4' abend.)

  This problem might occur if you attempt to run an application on an earlier version of MQSeries than it was written for, where some of the MQI values are invalid.
- Failing to define the IBM MQ modules to z/OS correctly (this error causes an X'0C4' abend in CSQYASCP).
- Failing to check return codes from MQI requests.

  This problem might occur if you attempt to run an application on a later version of IBM MQ than it was written for, where new return codes have been introduced that are not checked for.
- Failing to open objects with the correct options needed for later MQI calls, for example using the MQOPEN call to open a queue but not specifying the correct options to enable the queue for subsequent MQGET calls.
- Failing to initialize *MsgId* and *CorrelId* correctly.

  This error is especially true for MQGET.
- Using incorrect addresses.
- Using storage before it has been initialized.
- Passing variables with incorrect lengths specified.
- Passing parameters in the wrong order.
- Failing to define the correct security profiles and classes to RACF.

  This might stop the queue manager or prevent you from carrying out any productive work.
- Relying on default MQI options for a ported application.

  For example, z/OS defaults to MQGET and MQPUT in sync point. The distributed-platform default is out of sync point.
- Relying on default behavior at a normal or abnormal end of a portal application.

  On z/OS, a normal end does an implicit MQCMIT and an abnormal end does an implicit rollback.

Has there been an abend?

Use this topic to investigate common causes of abends and the different types of abend that can cause problems.

If your application has stopped running, it can be caused by an abnormal termination (abend).

You are notified of an abend in one of the following places, depending on what type of application you are using:

Batch Your listing shows the abend.

CICS You see a CICS transaction abend message. If your task is a terminal task, this message is displayed on your screen. If your task is not attached to a terminal, the message is displayed on the CICS CSMT log.

IMS In all cases, you see a message at the IBM MQ for IMS master terminal and in the listing of the dependent region involved. If an IMS transaction that had been entered from a terminal was being processed, an error message is also sent to that terminal.

TSO You might see a TSO message with a return code on your screen. (Whether this message is displayed depends on the way your system is set up, and the type of error.)

Common causes of abends

Abends can be caused by the user ending the task being performed before it terminates normally; for example, if you purge a CICS transaction. Abends can also be caused by an error in an application program.

Address space dumps and transaction dumps

For some abends, an address space dump is produced. For CICS transactions, a transaction dump showing the storage areas of interest to the transaction is provided.

- If an application passes some data, the address of which is no longer valid, a dump is sometimes produced in the address space of the user.

  Note: For a batch dump, the dump is formatted and written to SYSUDUMP. For information about SYSUDUMPs, see “SYSUDUMP information” on page 1752. For CICS, a system dump is written to the SYS1.DUMP data sets, as well as a transaction dump being taken.
- If a problem with IBM MQ for z/OS itself causes an abend, an abend code of X'5C6' or X'6C6' is returned, along with an abend reason code. This reason code uniquely describes the cause of the problem. See “IBM MQ for z/OS abends” on page 1728 for information about the abend codes, and see Return codes for an explanation of the reason code.

Abnormal program termination

If your program has terminated abnormally, see “Dealing with program abends” on page 1729.

If your system has terminated abnormally, and you want to analyze the dump produced, see “IBM MQ for z/OS dumps” on page 1735. This section tells you how to format the dump, and how to interpret the data contained in it.

Have you obtained incorrect output?

Use this topic to review any incorrect output you have received.

If you have obtained what you believe to be some incorrect output, consider the following:

Classifying incorrect output
"Incorrect output⌂ might be regarded as any output that you were not expecting. However, use this term with care in the context of problem determination because it might be a secondary effect of some other type of error. For example, looping could be occurring if you get any repetitive output, even though that output is what you expected.

Error messages
IBM MQ also responds to many errors it detects by sending error messages. You might regard these messages as "incorrect output⌂, but they are only symptoms of another type of problem. If you have received an error message from IBM MQ that you were not expecting, refer to “Are there any error messages, return codes or other error conditions?” on page 1300.

Unexpected messages
If your application has not received a message that it was expecting, has received a message containing unexpected or corrupted information, or has received a message that it was not expecting (for example, one that was destined for a different application), refer to “Dealing with incorrect output” on page 1762.

Can you reproduce the problem?

Reproducing the problem can be used to assist problem determination for IBM MQ for z/OS. Use this topic to further isolate the type of problem reproduction.

If you can reproduce the problem, consider the conditions under which you can reproduce it. For example:

Is it caused by a command?
If so, is the command issued from the z/OS console, from CSQUTIL, from a program written to put commands onto the SYSTEM.COMMAND.INPUT queue, or by using the operations and control panels?

Does the command work if it is entered by another method?
If the command works when it is entered at the console, but not otherwise, check that the command server has not stopped, and that the queue definition of the SYSTEM.COMMAND.INPUT queue has not been changed.

Is the command server running?
Issue the command `DIS CMDSERV` to check.

Is it caused by an application?

If so, does it fail in CICS, IMS, TSO, or batch?

Does it fail on all IBM MQ systems, or only on some?

Is an application causing the problem?
Can you identify any application that always seems to be running in the system when the problem occurs? If so, examine the application to see if it is in error.

Have you failed to receive a response from an MQSC command?

Use this topic for investigating problems where you fail to receive a response from an MQSC command.

If you have issued an MQSC command from an application (and not from a z/OS console), but you have not received a response, consider the subsequent questions:

Is the command server running?

Check that the command server is running, as follows:

1. Use the DISPLAY CMDSERV command at the z/OS console to display the status of the command server.
2. If the command server is not running, start it using the START CMDSERV command.
3. If the command server is running, issue the DISPLAY QUEUE command. Use the name of the system-command input queue and the CURDEPTH and MAXDEPTH attributes to define the data displayed.

   If these values show that the queue is full, and the command server has been started, the messages are not being read from the queue.
4. Try stopping the command server and then restarting it, responding to any error messages that are produced.
5. Issue the display command again to see if it is working now.

Has a reply been sent to the dead-letter queue?

Use the DISPLAY QMGR DEADQ command to find out the name of the system dead-letter queue (if you do not know what it is).

Use this name in the DISPLAY QUEUE command with the CURDEPTH attribute to see if there are any messages on the queue.

The dead-letter queue message header (dead-letter header structure) contains a reason or feedback code describing the problem. (See Reason (MQLONG) for information about the dead-letter header structure.)

Are the queues enabled for PUTs and GETs?

Use the DISPLAY QUEUE command from the console to check, for example, DISPLAY QUEUE(SYSTEM.COMMAND.INPUT) PUT GET.

Is the `WaitInterval` parameter set to a sufficiently long time?

If your MQGET call has timed out, your application receives completion code of 2 and a reason code of 2033 (MQRC_NO_MSG_AVAILABLE). (See WaitInterval (MQLONG) and MQGET - Get message for information about the *WaitInterval* parameter, and completion and reason codes from MQGET.)

Is a sync point required?

If you are using your own application program to put commands onto the system-command input queue, consider whether you must take a sync point.

You must take a sync point after putting messages to a queue, and before attempting to receive reply messages, or use MQPMO_NO_SYNCPOINT when putting them. Unless you have excluded your request message from sync point, you must take a sync point before attempting to receive reply messages.

Are the `MaxDepth` and `MaxMsgL` parameters of your queues set sufficiently high?

See CSQO016E for information about defining the system-command input queue and the reply-to queue.

Are you using the *CorrelId* and *MsgId* parameters correctly?

You must identify the queue and then display the CURDEPTH. Use the DISPLAY QUEUE command from the console (for example, DISPLAY QUEUE (MY.REPLY.QUEUE) CURDEPTH), to see if there are messages on the reply-to queue that you have not received.

Set the values of `MsgId` and `CorrelId` in your application to ensure that you receive all messages from the queue.

The following questions are applicable if you have issued an MQSC command from either a z/OS console (or its equivalent), or an application, but have not received a response:

Is the queue manager still running, or did your command cause an abend?
Look for error messages indicating an abend, and if one occurred, see "IBM MQ for z/OS dumps" on page 1735.

Were any error messages issued?
Check to see if any error messages were issued that might indicate the nature of the error.

See Issuing commands for information about the different methods you can use to enter MQSC commands.

Is your application or IBM MQ for z/OS running slowly?

Slow applications can be caused by the application itself or underlying software including IBM MQ. Use this topic for initial investigations into slow applications.

If your application is running slowly, this could indicate that it is in a loop, or waiting for a resource that is not available.

Is the problem worse at peak system load times?
This could also be caused by a performance problem. Perhaps it is because your system needs tuning, or because it is operating near the limits of its capacity. This type of problem is probably worst at peak system load times, typically at mid-morning and mid-afternoon. (If your network extends across more than one time zone, peak system load might seem to you to occur at some other time.)

Does the problem occur when the system is lightly loaded?
If you find that degrading performance is not dependent on system loading, but happens sometimes when the system is lightly loaded, a poorly designed application program is probably to blame. This could manifest itself as a problem that only occurs when specific queues are accessed.

Is IBM MQ for z/OS running slowly?

The following symptoms might indicate that IBM MQ for z/OS is running slowly:

- If your system is slow to respond to commands.
- If repeated displays of the queue depth indicate that the queue is being processed slowly for an application with which you would expect a large amount of queue activity.

You can find guidance on dealing with waits and loops in "Dealing with applications that are running slowly or have stopped on z/OS" on page 1756, and on dealing with performance problems in "Dealing with performance problems on z/OS" on page 1755.

Reason codes and exceptions

You can use the following messages and reason codes to help you solve problems with your IBM MQ components or applications.

- IBM MQ AMQ messages
- "API completion and reason codes"
- "PCF reason codes" on page 1541
- "Secure Sockets Layer (SSL) and Transport Layer Security (TLS) return codes" on page 1622
- "WCF custom channel exceptions" on page 1627
- z/OS IBM MQ for z/OS messages, completion, and reason codes
- WMQ JMS Exception Messages

API completion and reason codes

For each call, a completion code and a reason code are returned by the queue manager or by an exit routine, to indicate the success or failure of the call.

For more information about the IBM MQ API, see Developing applications, and the reference information in Developing applications reference.

For a full list and explanation of the API reason codes, see "API reason codes" on page 1315.

API completion codes

The following is a list of the completion codes (MQCC) returned by IBM MQ

0: Successful completion (MQCC_OK)

The call completed fully; all output parameters have been set.

The *Reason* parameter always has the value MQRC_NONE in this case.

1: Warning (partial completion) (MQCC_WARNING)

The call completed partially. Some output parameters might have been set in addition to the *CompCode* and *Reason* output parameters.

The *Reason* parameter gives additional information.

2: Call failed (MQCC_FAILED)

The processing of the call did not complete, and the state of the queue manager is normally unchanged; exceptions are specifically noted. Only the *CompCode* and *Reason* output parameters have been set; all other parameters are unchanged.

The reason might be a fault in the application program, or it might be a result of some situation external to the program, for example the application's authority might have been revoked. The *Reason* parameter gives additional information.

Related reference:

"PCF reason codes" on page 1541
Reason codes might be returned by a broker in response to a command message in PCF format, depending on the parameters used in that message.

"Secure Sockets Layer (SSL) and Transport Layer Security (TLS) return codes" on page 1622
IBM MQ can use Secure Sockets Layer (SSL) with the various communication protocols. Use this topic to identify the error codes that can be returned by SSL.

"WCF custom channel exceptions" on page 1627
Diagnostic messages are listed in this topic in numeric order, grouped according to the part of the WCF custom channel from which they originate.

Related information:

IBM MQ AMQ messages

z/OS IBM MQ for z/OS messages, completion, and reason codes

API reason codes

The reason code parameter (*Reason*) is a qualification to the completion code parameter (*CompCode*).

If there is no special reason to report, MQRC_NONE is returned. A successful call returns MQCC_OK and MQRC_NONE.

If the completion code is either MQCC_WARNING or MQCC_FAILED, the queue manager always reports a qualifying reason; details are given under each call description.

Where user exit routines set completion codes and reasons, they should adhere to these rules. In addition, any special reason values defined by user exits should be less than zero, to ensure that they do not conflict with values defined by the queue manager. Exits can set reasons already defined by the queue manager, where these are appropriate.

Reason codes also occur in:

- The *Reason* field of the MQDLH structure
- The *Feedback* field of the MQMD structure

The following is a list of reason codes, in numeric order, providing detailed information to help you understand them, including:

- An explanation of the circumstances that have caused the code to be raised
- The associated completion code
- Suggested programmer actions in response to the code

0 (0000) (RC0): MQRC_NONE:

Explanation

The call completed normally. The completion code (*CompCode*) is MQCC_OK.

Completion Code

MQCC_OK

Programmer response

None.

900 (0384) (RC900): MQRC_APPL_FIRST:

Explanation

This is the lowest value for an application-defined reason code returned by a data-conversion exit. Data-conversion exits can return reason codes in the range MQRC_APPL_FIRST through MQRC_APPL_LAST to indicate particular conditions that the exit has detected.

Completion Code

MQCC_WARNING or MQCC_FAILED

Programmer response

As defined by the writer of the data-conversion exit.

999 (03E7) (RC999): MQRC_APPL_LAST:

Explanation

This is the highest value for an application-defined reason code returned by a data-conversion exit. Data-conversion exits can return reason codes in the range MQRC_APPL_FIRST through MQRC_APPL_LAST to indicate particular conditions that the exit has detected.

Completion Code

MQCC_WARNING or MQCC_FAILED

Programmer response

As defined by the writer of the data-conversion exit.

2001 (07D1) (RC2001): MQRC_ALIAS_BASE_Q_TYPE_ERROR:

Explanation

An MQOPEN or MQPUT1 call was issued specifying an alias queue as the destination, but the `BaseQName` in the alias queue definition resolves to a queue that is not a local queue, a local definition of a remote queue, or a cluster queue or a queue in a distribution list contains an alias queue that is pointing to a topic object

Completion Code

MQCC_FAILED

Programmer response

Correct the queue definitions.

This reason code is also used to identify the corresponding event message Alias Base Queue Type Error.

2002 (07D2) (RC2002): MQRC_ALREADY_CONNECTED:

Explanation

An MQCONN or MQCONNX call was issued, but the application is already connected to the queue manager.
- On z/OS, this reason code occurs for batch and IMS applications only; it does not occur for CICS applications.
- On UNIX, IBM i, Linux and Windows, this reason code occurs if the application attempts to create a nonshared handle when a nonshared handle exists for the thread. A thread can have no more than one nonshared handle.
- On UNIX, IBM i, Linux and Windows, this reason code occurs if an MQCONN call is issued from within an MQ channel exit, API Crossing Exit, or Async Consume Callback function, and a shared hConn is bound to this thread.
- On UNIX, IBM i, Linux and Windows, this reason code occurs if an MQCONNX call that does not specify one of the MQCNO_HANDLE_SHARE_* options is issued from within an MQ channel exit, API Crossing Exit, or Async Consume Callback function, and a shared hConn is bound to this thread
- On Windows, MTS objects do not receive this reason code, as additional connections to the queue manager are permitted.

Completion Code

MQCC_WARNING

Programmer response

None. The `Hconn` parameter returned has the same value as was returned for the previous MQCONN or MQCONNX call.

An MQCONN or MQCONNX call that returns this reason code does *not* mean that an additional MQDISC call must be issued to disconnect from the queue manager. If this reason code is returned because the application has been called in a situation where the MQCONN has already been done, do *not* issue a corresponding MQDISC, because this causes the application that issued the original MQCONN or MQCONNX call to be disconnected as well.

2003 (07D3) (RC2003): MQRC_BACKED_OUT:

Explanation

The current unit of work encountered an unrecoverable error or was backed out. This reason code is issued in the following cases:

- On an MQCMIT or MQDISC call, when the commit operation fails and the unit of work is backed out. All resources that participated in the unit of work are returned to their state at the start of the unit of work. The MQCMIT or MQDISC call completes with MQCC_WARNING in this case.
  - On z/OS, this reason code occurs only for batch applications.
- On an MQGET, MQPUT, or MQPUT1 call that is operating within a unit of work, when the unit of work already encountered an error that prevents the unit of work from being committed (for example, when the log space is exhausted). The application must issue the appropriate call to back out the unit of work. (For a unit of work that is coordinated by the queue manager, this call is the MQBACK call, although the MQCMIT call has the same effect in these circumstances.) The MQGET, MQPUT, or MQPUT1 call completes with MQCC_FAILED in this case.
  - On z/OS, this case does not occur.
- On an asynchronous consumption callback (registered by an MQCB call), the unit of work is backed out and the asynchronous consumer should call MQBACK.
  - On z/OS, this case does not occur.
- For the IBM MQ client on HP Integrity NonStop Server using TMF, this return code can occur:
  - For MQGET, MQPUT, and MQPUT1 calls, if you have an active transaction that is being coordinated by TMF, but the IBM MQ part of the transaction is rolled back because of inactivity on the transaction.
  - If the TMF/Gateway detects that TMF is rolling back the current transaction before the application finishes with it.

Completion Code

MQCC_WARNING or MQCC_FAILED

Programmer response

Check the returns from previous calls to the queue manager. For example, a previous MQPUT call might have failed.

2004 (07D4) (RC2004): MQRC_BUFFER_ERROR:

Explanation

The *Buffer* parameter is not valid for one of the following reasons:

- The parameter pointer is not valid. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)
- The parameter pointer points to storage that cannot be accessed for the entire length specified by *BufferLength*.
- For calls where *Buffer* is an output parameter: the parameter pointer points to read-only storage.

Completion Code

MQCC_FAILED

Programmer response

Correct the parameter.

2005 (07D5) (RC2005): MQRC_BUFFER_LENGTH_ERROR:

Explanation

The *BufferLength* parameter is not valid, or the parameter pointer is not valid. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)

This reason can also be returned to an MQ MQI client program on the MQCONN or MQCONNX call if the negotiated maximum message size for the channel is smaller than the fixed part of any call structure.

This reason should also be returned by the MQZ_ENUMERATE_AUTHORITY_DATA installable service component when the *AuthorityBuffer* parameter is too small to accommodate the data to be returned to the invoker of the service component.

This reason code can also be returned when a zero length multicast message has been supplied where a positive length is required.

Completion Code

MQCC_FAILED

Programmer response

Specify a value that is zero or greater. For the mqAddString and mqSetString calls, the special value MQBL_NULL_TERMINATED is also valid.

2006 (07D6) (RC2006): MQRC_CHAR_ATTR_LENGTH_ERROR:

Explanation

CharAttrLength is negative (for MQINQ or MQSET calls), or is not large enough to hold all selected attributes (MQSET calls only). This reason also occurs if the parameter pointer is not valid. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)

Completion Code

MQCC_FAILED

Programmer response

Specify a value large enough to hold the concatenated strings for all selected attributes.

2007 (07D7) (RC2007): MQRC_CHAR_ATTRS_ERROR:

Explanation

CharAttrs is not valid. The parameter pointer is not valid, or points to read-only storage for MQINQ calls or to storage that is not as long as implied by *CharAttrLength*. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)

Completion Code

MQCC_FAILED

Programmer response

Correct the parameter.

2008 (07D8) (RC2008): MQRC_CHAR_ATTRS_TOO_SHORT:

Explanation

For MQINQ calls, *CharAttrLength* is not large enough to contain all of the character attributes for which MQCA_* selectors are specified in the *Selectors* parameter.

The call still completes, with the *CharAttrs* parameter string filled in with as many character attributes as there is room for. Only complete attribute strings are returned: if there is insufficient space remaining to accommodate an attribute in its entirety, that attribute and subsequent character attributes are omitted. Any space at the end of the string not used to hold an attribute is unchanged.

An attribute that represents a set of values (for example, the namelist *Names* attribute) is treated as a single entity—either all of its values are returned, or none.

Completion Code

MQCC_WARNING

Programmer response

Specify a large enough value, unless only a subset of the values is needed.

2009 (07D9) (RC2009): MQRC_CONNECTION_BROKEN:

Explanation

Connection to the queue manager has been lost. This can occur because the queue manager has ended. If the call is an MQGET call with the MQGMO_WAIT option, the wait has been canceled. All connection and object handles are now invalid.

For MQ MQI client applications, it is possible that the call did complete successfully, even though this reason code is returned with a *CompCode* of MQCC_FAILED.

Completion Code

MQCC_FAILED

Programmer response

Applications can attempt to reconnect to the queue manager by issuing the MQCONN or MQCONNX call. It might be necessary to poll until a successful response is received.

- z/OS On z/OS for CICS applications, it is not necessary to issue the MQCONN or MQCONNX call, because CICS applications are connected automatically.

Any uncommitted changes in a unit of work should be backed out. A unit of work that is coordinated by the queue manager is backed out automatically.

z/OS For z/OS IMS check that the subsystem is started using the IMS DIS SUBSYS command, and if necessary start it using the IMS STA SUBSYS command.

Related information:

IBM MQ and IMS

2010 (07DA) (RC2010): MQRC_DATA_LENGTH_ERROR:

Explanation

The *DataLength* parameter is not valid. Either the parameter pointer is not valid, or it points to read-only storage. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)

This reason can also be returned to an MQ MQI client program on the MQGET, MQPUT, or MQPUT1 call, if the *BufferLength* parameter exceeds the maximum message size that was negotiated for the client channel.

Completion Code

MQCC_FAILED

Programmer response

Correct the parameter.

If the error occurs for an MQ MQI client program, also check that the maximum message size for the channel is big enough to accommodate the message being sent; if it is not big enough, increase the maximum message size for the channel.

2011 (07DB) (RC2011): MQRC_DYNAMIC_Q_NAME_ERROR:

Explanation

On the MQOPEN call, a model queue is specified in the *ObjectName* field of the *ObjDesc* parameter, but the *DynamicQName* field is not valid, for one of the following reasons:
- *DynamicQName* is completely blank (or blank up to the first null character in the field).
- Characters are present that are not valid for a queue name.
- An asterisk is present beyond the 33rd position (and before any null character).
- An asterisk is present followed by characters that are not null and not blank.

This reason code can also sometimes occur when a server application opens the reply queue specified by the *ReplyToQ* and *ReplyToQMgr* fields in the MQMD of a message that the server has just received. In this case the reason code indicates that the application that sent the original message placed incorrect values into the *ReplyToQ* and *ReplyToQMgr* fields in the MQMD of the original message.

Completion Code

MQCC_FAILED

Programmer response

Specify a valid name.

2012 (07DC) (RC2012): MQRC_ENVIRONMENT_ERROR:

Explanation

The call is not valid for the current environment.
- z/OS On z/OS, when one of the following applies:
  - An MQCONN or MQCONNX call was issued, but the application has been linked with an adapter that is not supported in the environment in which the application is running. For example, this can arise when the application is linked with the MQ RRS adapter, but the application is running in a Db2 Stored Procedure address space. RRS is not supported in this environment. Stored Procedures wishing to use the MQ RRS adapter must run in a Db2 WLM-managed Stored Procedure address space.
  - An MQCMIT or MQBACK call was issued, but the application has been linked with the RRS batch adapter CSQBRSTB. This adapter does not support the MQCMIT and MQBACK calls.
  - An MQCMIT or MQBACK call was issued in the CICS or IMS environment.
  - The RRS subsystem is not operational on the z/OS system that ran the application.
  - An MQCTL call with MQOP_START or an MQCB call registering an Event Listener, was issued but the application is not allowed to create a POSIX thread.
  - An IBM MQ classes for Java application has instantiated an MQQueueManager object using the CLIENT transport. The z/OS environment only supports the use of the BINDINGS transport.
- On IBM i, HP Integrity NonStop Server, UNIX systems, and Windows, when one of the following applies:
  - The application is linked to unsupported libraries.
  - The application is linked to the wrong libraries (threaded or nonthreaded).
  - An MQBEGIN, MQCMIT, or MQBACK call was issued, but an external unit-of-work manager is in use. For example, this reason code occurs on Windows when an MTS object is running as a DTC transaction. This reason code also occurs if the queue manager does not support units of work.
  - The MQBEGIN call was issued in an MQ MQI client environment.

- An MQXCLWLN call was issued, but the call did not originate from a cluster workload exit.
- An MQCONNX call was issued specifying the option MQCNO_HANDLE_SHARE_NONE from within an MQ channel exit, an API Exit, or a Callback function. The reason code occurs only if a shared hConn is bound to the application thread.
- An IBM MQ Object is unable to connect fastpath.
- An IBM MQ classes for Java application has created an MQQueueManager object that uses the CLIENT transport, and then called MQQueueManager.begin(). This method can only be called on MQQueueManager objects that use the BINDINGS transport.

- On Windows, when using the managed .NET client, an attempt was made to use one of the unsupported features:
  - Unmanaged channel exits
  - Secure Sockets Layer (SSL)
  - XA Transactions
  - Communications other than TCP/IP
  - Channel compression

Completion Code

MQCC_FAILED

Programmer response

Do one of the following (as appropriate):

- On z/OS:
  - Link the application with the correct adapter.
  - Modify the application to use the SRRCMIT and SRRBACK calls in place of the MQCMIT and MQBACK calls. Alternatively, link the application with the RRS batch adapter CSQBRRSI. This adapter supports MQCMIT and MQBACK in addition to SRRCMIT and SRRBACK.
  - For a CICS or IMS application, issue the appropriate CICS or IMS call to commit or backout the unit of work.
  - Start the RRS subsystem on the z/OS system that is running the application.
  - If your application uses Language Environment (LE) ensure that it uses the DLL interface and it runs with POSIX(ON).
  - Ensure that your application is allowed to use Unix System Services (USS).
  - Ensure that your Connection Factory definitions for local z/OS applications and WebSphere Application Server applications use Transport Type with bindings mode connections.
- In the other environments:
  - Link the application with the correct libraries (threaded or nonthreaded).
  - Remove from the application the call or feature that is not supported.
  - Change your application to run setuid, if you want to run fastpath.

2013 (07DD) (RC2013): MQRC_EXPIRY_ERROR:

Explanation

On an MQPUT or MQPUT1 call, the value specified for the *Expiry* field in the message descriptor MQMD is not valid.

V 8.0.0.4 This reason code is also generated by JMS applications specifying a delivery delay value greater than either the:
- Message expiry time specified by the application, or
- Expiry time set by the **CUSTOM**(*CAPEXPRY*) attribute of the objects used in the resolution of the target queue or topic.

Completion Code

MQCC_FAILED

Programmer response

Specify a value that is greater than zero, or the special value MQEI_UNLIMITED.

V 8.0.0.4 Ensure that the delivery delay specified by JMS applications is less than the:
- Message expiry time specified by the application, or
- Expiry time set by the **CUSTOM**(*CAPEXPRY*) attribute of the objects used in the resolution of the target queue or topic.

2014 (07DE) (RC2014): MQRC_FEEDBACK_ERROR:

Explanation

On an MQPUT or MQPUT1 call, the value specified for the *Feedback* field in the message descriptor MQMD is not valid. The value is not MQFB_NONE, and is outside both the range defined for system feedback codes and the range defined for application feedback codes.

Completion Code

MQCC_FAILED

Programmer response

Specify MQFB_NONE, or a value in the range MQFB_SYSTEM_FIRST through MQFB_SYSTEM_LAST, or MQFB_APPL_FIRST through MQFB_APPL_LAST.

2016 (07E0) (RC2016): MQRC_GET_INHIBITED:

Explanation

MQGET calls are currently inhibited for the queue, or for the queue to which this queue resolves.

Completion Code

MQCC_FAILED

Programmer response

If the system design allows get requests to be inhibited for short periods, retry the operation later.

This reason code is also used to identify the corresponding event message Get Inhibited.

System programmer action

Use ALTER QLOCAL(...) GET(ENABLED) to allow messages to be got.

2017 (07E1) (RC2017): MQRC_HANDLE_NOT_AVAILABLE:

Explanation

An MQOPEN, MQPUT1 or MQSUB call was issued, but the maximum number of open handles allowed for the current task has already been reached. Be aware that when a distribution list is specified on the MQOPEN or MQPUT1 call, each queue in the distribution list uses one handle.

- On z/OS, "task⌂ means a CICS task, a z/OS task, or an IMS-dependent region.

In addition, the MQSUB call allocates two handles when you do not provide an object handle on input.

Completion Code

MQCC_FAILED

Programmer response

Check whether the application is issuing MQOPEN calls without corresponding MQCLOSE calls. If it is, modify the application to issue the MQCLOSE call for each open object as soon as that object is no longer needed.

Also check whether the application is specifying a distribution list containing a large number of queues that are consuming all of the available handles. If it is, increase the maximum number of handles that the task can use, or reduce the size of the distribution list. The maximum number of open handles that a task can use is given by the *MaxHandles* queue manager attribute.

2018 (07E2) (RC2018): MQRC_HCONN_ERROR:

Explanation

The connection handle `Hconn` is not valid, for one of the following reasons:

- The parameter pointer is not valid, or (for the MQCONN or MQCONNX call) points to read-only storage. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)
- The value specified was not returned by a preceding MQCONN or MQCONNX call.
- The value specified has been made invalid by a preceding MQDISC call.
- The handle is a shared handle that has been made invalid by another thread issuing the MQDISC call.
- The handle is a shared handle that is being used on the MQBEGIN call (only nonshared handles are valid on MQBEGIN).
- The handle is a nonshared handle that is being used a thread that did not create the handle.
- The call was issued in the MTS environment in a situation where the handle is not valid (for example, passing the handle between processes or packages; note that passing the handle between library packages *is* supported).
- The conversion program is not defined as OPENAPI, when the MQXCNVC call is invoked by running a character conversion exit program with CICS TS 3.2 or higher. When the conversion process runs, the TCB is switched to the Quasi Reentrant (QR) TCB, making the connection incorrect.

Completion Code

MQCC_FAILED

Programmer response

Ensure that a successful MQCONN or MQCONNX call is performed for the queue manager, and that an MQDISC call has not already been performed for it. Ensure that the handle is being used within its valid scope (see the description of MQCONN in MQCONN for more information about MQCONN).

- On z/OS, also check that the application has been linked with the correct stub; this is CSQCSTUB for CICS applications, CSQBSTUB for batch applications, and CSQQSTUB for IMS applications. Also, the stub used must not belong to a release of the queue manager that is more recent than the release on which the application will run.

Ensure the character conversion exit program run by your CICS TS 3.2 or higher application, which invokes the MQXCNVC call, is defined as OPENAPI. This definition prevents the 2018 MQRC_HCONN_ERROR error caused by from an incorrect connection, and allows the MQGET to complete.

2019 (07E3) (RC2019): MQRC_HOBJ_ERROR:

Explanation

The object handle *Hobj* is not valid, for one of the following reasons:
- The parameter pointer is not valid, or (for the MQOPEN call) points to read-only storage. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)
- The value specified was not returned by a preceding MQOPEN call.
- The value specified has been made invalid by a preceding MQCLOSE call.
- The handle is a shared handle that has been made invalid by another thread issuing the MQCLOSE call.
- The handle is a nonshared handle that is being used by a thread that did not create the handle.
- The call is MQGET or MQPUT, but the object represented by the handle is not a queue.

Completion Code

MQCC_FAILED

Programmer response

Ensure that a successful MQOPEN call is performed for this object, and that an MQCLOSE call has not already been performed for it. Ensure that the handle is being used within its valid scope (see the description of MQOPEN in MQOPEN for more information).

2020 (07E4) (RC2020): MQRC_INHIBIT_VALUE_ERROR:

Explanation

On an MQSET call, the value specified for either the MQIA_INHIBIT_GET attribute or the MQIA_INHIBIT_PUT attribute is not valid.

Completion Code

MQCC_FAILED

Programmer response

Specify a valid value for the *InhibitGet* or *InhibitPut* queu attribute.

2021 (07E5) (RC2021): MQRC_INT_ATTR_COUNT_ERROR:

Explanation

On an MQINQ or MQSET call, the *IntAttrCount* parameter is negative (MQINQ or MQSET), or smaller than the number of integer attribute selectors (MQIA_*) specified in the *Selectors* parameter (MQSET only). This reason also occurs if the parameter pointer is not valid. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)

Completion Code

MQCC_FAILED

Programmer response

Specify a value large enough for all selected integer attributes.

2022 (07E6) (RC2022): MQRC_INT_ATTR_COUNT_TOO_SMALL:

Explanation

On an MQINQ call, the *IntAttrCount* parameter is smaller than the number of integer attribute selectors (MQIA_*) specified in the *Selectors* parameter.

The call completes with MQCC_WARNING, with the *IntAttrs* array filled in with as many integer attributes as there is room for.

Completion Code

MQCC_WARNING

Programmer response

Specify a large enough value, unless only a subset of the values is needed.

2023 (07E7) (RC2023): MQRC_INT_ATTRS_ARRAY_ERROR:

Explanation

On an MQINQ or MQSET call, the *IntAttrs* parameter is not valid. The parameter pointer is not valid (MQINQ and MQSET), or points to read-only storage or to storage that is not as long as indicated by the *IntAttrCount* parameter (MQINQ only). (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)

Completion Code

MQCC_FAILED

Programmer response

Correct the parameter.

2024 (07E8) (RC2024): MQRC_SYNCPOINT_LIMIT_REACHED:

Explanation

An MQGET, MQPUT, or MQPUT1 call failed because it would have caused the number of uncommitted messages in the current unit of work to exceed the limit defined for the queue manager (see the `MaxUncommittedMsgs` queue-manager attribute). The number of uncommitted messages is the sum of the following since the start of the current unit of work:

- Messages put by the application with the MQPMO_SYNCPOINT option
- Messages retrieved by the application with the MQGMO_SYNCPOINT option
- Trigger messages and COA report messages generated by the queue manager for messages put with the MQPMO_SYNCPOINT option
- COD report messages generated by the queue manager for messages retrieved with the MQGMO_SYNCPOINT option
- On HP Integrity NonStop Server , this reason code occurs when the maximum number of I/O operations in a single TM/MP transaction has been exceeded.

When publishing messages out of syncpoint to topics it is possible to receive this reason code; see Publications under syncpoint for more information.

Completion Code

MQCC_FAILED

Programmer response

Check whether the application is looping. If it is not, consider reducing the complexity of the application. Alternatively, increase the queue-manager limit for the maximum number of uncommitted messages within a unit of work.

- On z/OS, the limit for the maximum number of uncommitted messages can be changed by using the ALTER QMGR command.
- On IBM i , the limit for the maximum number of uncommitted messages can be changed by using the CHGMQM command.
- On HP Integrity NonStop Server , the application should cancel the transaction and retry with a smaller number of operations in the unit of work. See the *MQSeries for Tandem NonStop Kernel System Management Guide* for more details.

2025 (07E9) (RC2025): MQRC_MAX_CONNS_LIMIT_REACHED:

Explanation

The MQCONN or MQCONNX call was rejected because the maximum number of concurrent connections has been exceeded.

- On z/OS, the connection limits are 32767 for both TSO and Batch.
- On IBM i, HP Integrity NonStop Server, UNIX systems, and Windows, this reason code can also occur on the MQOPEN call.
- When using Java applications, the connection manager might define a limit to the number of concurrent connections.

  Note: The application using IBM MQ might have delegated the management of connections to a framework or connection pool, for example, a Java EE application server, an application framework such as Spring, an IBM Container (for IBM Cloud (formerly Bluemix®)), or a combination of these. For more information, see Use JMS connection pools.

Completion Code

MQCC_FAILED

Programmer response

Either increase the size of the appropriate parameter value, or reduce the number of concurrent connections.

Related information:

Connection pooling in IBM MQ classes for Java

2026 (07EA) (RC2026): MQRC_MD_ERROR:

Explanation

The MQMD structure is not valid, for one of the following reasons:

- The *StrucId* field is not MQMD_STRUC_ID.
- The *Version* field specifies a value that is not valid or not supported.
- The parameter pointer is not valid. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)
- The queue manager cannot copy the changed structure to application storage, even though the call is successful. This can occur, for example, if the pointer points to read-only storage.

Completion Code

MQCC_FAILED

Programmer response

Ensure that input fields in the MQMD structure are set correctly.

2027 (07EB) (RC2027): MQRC_MISSING_REPLY_TO_Q:

Explanation

On an MQPUT or MQPUT1 call, the *ReplyToQ* field in the message descriptor MQMD is blank, but one or both of the following is true:

- A reply was requested (that is, MQMT_REQUEST was specified in the *MsgType* field of the message descriptor).
- A report message was requested in the *Report* field of the message descriptor.

Completion Code

MQCC_FAILED

Programmer response

Specify the name of the queue to which the reply message or report message is to be sent.

2029 (07ED) (RC2029): MQRC_MSG_TYPE_ERROR:

Explanation

Either:

- On an MQPUT or MQPUT1 call, the value specified for the *MsgType* field in the message descriptor (MQMD) is not valid.
- A message processing program received a message that does not have the expected message type. For example, if the IBM MQ command server receives a message which is not a request message (MQMT_REQUEST) then it rejects the request with this reason code.

Completion Code

MQCC_FAILED

Programmer response

Specify a valid value for the *MsgType* field. In the case where a request is rejected by a message processing program, refer to the documentation for that program for details of the message types that it supports.

2030 (07EE) (RC2030): MQRC_MSG_TOO_BIG_FOR_Q:

Explanation

An MQPUT or MQPUT1 call was issued to put a message on a queue, but the message was too long for the queue and MQMF_SEGMENTATION_ALLOWED was not specified in the *MsgFlags* field in MQMD. If segmentation is not allowed, the length of the message cannot exceed the lesser of the queue *MaxMsgLength* attribute and queue-manager *MaxMsgLength* attribute.

- On z/OS, the queue manager does not support the segmentation of messages; if MQMF_SEGMENTATION_ALLOWED is specified, it is accepted but ignored.

This reason code can also occur when MQMF_SEGMENTATION_ALLOWED *is* specified, but the nature of the data present in the message prevents the queue manager splitting it into segments that are small enough to place on the queue:

- For a user-defined format, the smallest segment that the queue manager can create is 16 bytes.
- For a built-in format, the smallest segment that the queue manager can create depends on the particular format, but is greater than 16 bytes in all cases other than MQFMT_STRING (for MQFMT_STRING the minimum segment size is 16 bytes).

MQRC_MSG_TOO_BIG_FOR_Q can also occur in the *Feedback* field in the message descriptor of a report message; in this case it indicates that the error was encountered by a message channel agent when it attempted to put the message on a remote queue.

Completion Code

MQCC_FAILED

Programmer response

Check whether the *BufferLength* parameter is specified correctly; if it is, do one of the following:

- Increase the value of the queue's *MaxMsgLength* attribute; the queue-manager's *MaxMsgLength* attribute may also need increasing.
- Break the message into several smaller messages.

- Specify MQMF_SEGMENTATION_ALLOWED in the *MsgFlags* field in MQMD; this will allow the queue manager to break the message into segments.

2031 (07EF) (RC2031): MQRC_MSG_TOO_BIG_FOR_Q_MGR:

Explanation

An MQPUT or MQPUT1 call was issued to put a message on a queue, but the message was too long for the queue manager and MQMF_SEGMENTATION_ALLOWED was not specified in the *MsgFlags* field in MQMD. If segmentation is not allowed, the length of the message cannot exceed the lesser of the queue-manager *MaxMsgLength* attribute and queue *MaxMsgLength* attribute.

This reason code can also occur when MQMF_SEGMENTATION_ALLOWED *is* specified, but the nature of the data present in the message prevents the queue manager splitting it into segments that are small enough for the queue-manager limit:
- For a user-defined format, the smallest segment that the queue manager can create is 16 bytes.
- For a built-in format, the smallest segment that the queue manager can create depends on the particular format, but is greater than 16 bytes in all cases other than MQFMT_STRING (for MQFMT_STRING the minimum segment size is 16 bytes).

MQRC_MSG_TOO_BIG_FOR_Q_MGR can also occur in the *Feedback* field in the message descriptor of a report message; in this case it indicates that the error was encountered by a message channel agent when it attempted to put the message on a remote queue.

This reason also occurs if a channel, through which the message is to pass, has restricted the maximum message length to a value that is actually less than that supported by the queue manager, and the message length is greater than this value.
- On z/OS, this return code is issued only if you are using CICS for distributed queuing. Otherwise, MQRC_MSG_TOO_BIG_FOR_CHANNEL is issued.

Completion Code

MQCC_FAILED

Programmer response

Check whether the *BufferLength* parameter is specified correctly; if it is, do one of the following:
- Increase the value of the queue-manager's *MaxMsgLength* attribute; the queue's *MaxMsgLength* attribute may also need increasing.
- Break the message into several smaller messages.
- Specify MQMF_SEGMENTATION_ALLOWED in the *MsgFlags* field in MQMD; this will allow the queue manager to break the message into segments.
- Check the channel definitions.

2033 (07F1) (RC2033): MQRC_NO_MSG_AVAILABLE:

Explanation

An MQGET call was issued, but there is no message on the queue satisfying the selection criteria specified in MQMD (the *MsgId* and *CorrelId* fields), and in MQGMO (the *Options* and *MatchOptions* fields). Either the MQGMO_WAIT option was not specified, or the time interval specified by the *WaitInterval* field in MQGMO has expired. This reason is also returned for an MQGET call for browse, when the end of the queue has been reached.

This reason code can also be returned by the mqGetBag and mqExecute calls. mqGetBag is similar to MQGET. For the mqExecute call, the completion code can be either MQCC_WARNING or MQCC_FAILED:

- If the completion code is MQCC_WARNING, some response messages were received during the specified wait interval, but not all. The response bag contains system-generated nested bags for the messages that were received.
- If the completion code is MQCC_FAILED, no response messages were received during the specified wait interval.

Completion Code

MQCC_WARNING or MQCC_FAILED

Programmer response

If this is an expected condition, no corrective action is required.

If this is an unexpected condition, check that:

- The message was put on the queue successfully.
- The unit of work (if any) used for the MQPUT or MQPUT1 call was committed successfully.
- The options controlling the selection criteria are specified correctly. All of the following can affect the eligibility of a message for return on the MQGET call:
  - MQGMO_LOGICAL_ORDER
  - MQGMO_ALL_MSGS_AVAILABLE
  - MQGMO_ALL_SEGMENTS_AVAILABLE
  - MQGMO_COMPLETE_MSG
  - MQMO_MATCH_MSG_ID
  - MQMO_MATCH_CORREL_ID
  - MQMO_MATCH_GROUP_ID
  - MQMO_MATCH_MSG_SEQ_NUMBER
  - MQMO_MATCH_OFFSET
  - Value of *MsgId* field in MQMD
  - Value of *CorrelId* field in MQMD

Consider waiting longer for the message.

2034 (07F2) (RC2034): MQRC_NO_MSG_UNDER_CURSOR:

Explanation

An MQGET call was issued with either the MQGMO_MSG_UNDER_CURSOR or the MQGMO_BROWSE_MSG_UNDER_CURSOR option. However, the browse cursor is not positioned at a retrievable message. This is caused by one of the following:

- The cursor is positioned logically before the first message (as it is before the first MQGET call with a browse option has been successfully performed).
- The message the browse cursor was positioned on has been locked or removed from the queue (probably by some other application) since the browse operation was performed.
- The message the browse cursor was positioned on has expired.

Completion Code

MQCC_FAILED

Programmer response

Check the application logic. This may be an expected reason if the application design allows multiple servers to compete for messages after browsing. Consider also using the MQGMO_LOCK option with the preceding browse MQGET call.

2035 (07F3) (RC2035): MQRC_NOT_AUTHORIZED:
General explanation

Explanation

The user of the application or channel that produced the error, is not authorized to perform the operation attempted:

- On an MQCONN or MQCONNX call, the user is not authorized to connect to the queue manager.
  - On z/OS, for CICS applications, MQRC_CONNECTION_NOT_AUTHORIZED is issued instead.
- On an MQCONNX call, the length of the user ID or password is greater than the maximum length permitted. The maximum length of the user ID is dependent on the platform. For more information, see User IDs.
- On an MQOPEN or MQPUT1 call, the user is not authorized to open the object for the option(s) specified.
  - On z/OS, if the object being opened is a model queue, this reason also arises if the user is not authorized to create a dynamic queue with the required name.
- On an MQCLOSE call, the user is not authorized to delete the object, which is a permanent dynamic queue, and the `Hobj` parameter specified on the MQCLOSE call is not the handle returned by the MQOPEN call that created the queue.
- On a command, the user is not authorized to issue the command, or to access the object it specifies.
- On an MQSUB call, the user is not authorized to subscribe to the topic.
- On an MQSUB call, using non-managed destination queues, the user is not authorized to use the destination queue.

This reason code can also occur in the `Feedback` field in the message descriptor of a report message; in this case it indicates that the error was encountered by a message channel agent when it attempted to put the message on a remote queue.

Completion Code

MQCC_FAILED

Programmer response

Ensure that the correct queue manager or object was specified, and that appropriate authority exists.

This reason code is also used to identify the corresponding event message,
- MQCONN or MQCONNX Not Authorized (type 1).
- MQOPEN or MQPUT1 Not Authorized (type 2).
- MQCLOSE Not Authorized (type 3).
- Command Not Authorized (type 4).
- MQSUB Not Authorized (type 5).
- MQSUB destination Not Authorized (type 6).

Specific problems generating RC2035

JMSWMQ2013 invalid security authentication

See Invalid security authentication for information when your IBM MQ JMS application fails with security authentication errors.

MQRC_NOT_AUTHORIZED on a queue or channel

See MQRC_NOT_AUTHORIZED on a queue for information when MQRC 2035 (MQRC_NOT_AUTHORIZED) is returned where a user is not authorized to perform the function. Determine which object the user cannot access and provide the user access to the object.

MQRC_NOT_AUTHORIZED (AMQ4036 on a client) as an administrator

See MQRC_NOT_AUTHORIZED as an administrator for information when MQRC 2035 (MQRC_NOT_AUTHORIZED) is returned where you try to use a user ID that is an IBM MQ Administrator, to remotely access the queue manager through a client connection.

MQS_REPORT_NOAUTH

See MQS_REPORT_NOAUTH for information on using this environment variable to better diagnose return code 2035 (MQRC_NOT_AUTHORIZED). The use of this environment variable generates errors in the queue manager error log, but does not generate a Failure Data Capture (FDC).

MQSAUTHERRORS

See MQSAUTHERRORS for information on using this environment variable to generate FDC files related to return code 2035 (MQRC_NOT_AUTHORIZED). The use of this environment variable generates an FDC, but does not generate errors in the queue manager error log.

2036 (07F4) (RC2036): MQRC_NOT_OPEN_FOR_BROWSE:

Explanation

An MQGET call was issued with one of the following options:
- MQGMO_BROWSE_FIRST
- MQGMO_BROWSE_NEXT
- MQGMO_BROWSE_MSG_UNDER_CURSOR
- MQGMO_MSG_UNDER_CURSOR

but either the queue had not been opened for browse, or you are using IBM MQ Multicast messaging.

Completion Code

MQCC_FAILED

Programmer response

Specify MQOO_BROWSE when the queue is opened.

If you are using IBM MQ Multicast messaging, you cannot specify browse options with an MQGET call.

2037 (07F5) (RC2037): MQRC_NOT_OPEN_FOR_INPUT:

Explanation

An MQGET call was issued to retrieve a message from a queue, but the queue had not been opened for input.

Completion Code

MQCC_FAILED

Programmer response

Specify one of the following when the queue is opened:
- MQOO_INPUT_SHARED
- MQOO_INPUT_EXCLUSIVE
- MQOO_INPUT_AS_Q_DEF

2038 (07F6) (RC2038): MQRC_NOT_OPEN_FOR_INQUIRE:

Explanation

An MQINQ call was issued to inquire object attributes, but the object had not been opened for inquire.

An MQINQ call was issued for a topic handle in IBM MQ Multicast.

Completion Code

MQCC_FAILED

Programmer response

Specify MQOO_INQUIRE when the object is opened.

MQINQ is not supported for topic handles in IBM MQ Multicast.

2039 (07F7) (RC2039): MQRC_NOT_OPEN_FOR_OUTPUT:

Explanation

An MQPUT call was issued to put a message on a queue, but the queue had not been opened for output.

Completion Code

MQCC_FAILED

Programmer response

Specify MQOO_OUTPUT when the queue is opened.

2040 (07F8) (RC2040): MQRC_NOT_OPEN_FOR_SET:

Explanation

An MQSET call was issued to set queue attributes, but the queue had not been opened for set.

An MQSET call was issued for a topic handle in IBM MQ Multicast.

Completion Code

MQCC_FAILED

Programmer response

Specify MQOO_SET when the object is opened.

MQSET is not supported for topic handles in IBM MQ Multicast.

2041 (07F9) (RC2041): MQRC_OBJECT_CHANGED:

Explanation

Object definitions that affect this object have been changed since the `Hobj` handle used on this call was returned by the MQOPEN call. For more information about the MQOPEN call, see MQOPEN.

This reason does not occur if the object handle is specified in the `Context` field of the `PutMsgOpts` parameter on the MQPUT or MQPUT1 call.

Completion Code

MQCC_FAILED

Programmer response

Issue an MQCLOSE call to return the handle to the system. It is then usually sufficient to reopen the object and retry the operation. However, if the object definitions are critical to the application logic, an MQINQ call can be used after reopening the object, to obtain the new values of the object attributes.

2042 (07FA) (RC2042): MQRC_OBJECT_IN_USE:

Explanation

An MQOPEN call was issued, but the object in question has already been opened by this or another application with options that conflict with those specified in the `Options` parameter. This arises if the request is for shared input, but the object is already open for exclusive input; it also arises if the request is for exclusive input, but the object is already open for input (of any sort).

MCAs for receiver channels, or the intra-group queuing agent (IGQ agent), may keep the destination queues open even when messages are not being transmitted; this results in the queues appearing to be "in use". Use the MQSC command DISPLAY QSTATUS to find out who is keeping the queue open.
- On z/OS, this reason can also occur for an MQOPEN or MQPUT1 call, if the object to be opened (which can be a queue, or for MQOPEN a namelist or process object) is in the process of being deleted.

Completion Code

MQCC_FAILED

Programmer response

System design should specify whether an application is to wait and retry, or take other action.

2043 (07FB) (RC2043): MQRC_OBJECT_TYPE_ERROR:

Explanation

On the MQOPEN or MQPUT1 call, the *ObjectType* field in the object descriptor MQOD specifies a value that is not valid. For the MQPUT1 call, the object type must be MQOT_Q.

Completion Code

MQCC_FAILED

Programmer response

Specify a valid object type.

2044 (07FC) (RC2044): MQRC_OD_ERROR:

Explanation

On the MQOPEN or MQPUT1 call, the object descriptor MQOD is not valid, for one of the following reasons:
- The *StrucId* field is not MQOD_STRUC_ID.
- The *Version* field specifies a value that is not valid or not supported.
- The parameter pointer is not valid. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)
- The queue manager cannot copy the changed structure to application storage, even though the call is successful. This can occur, for example, if the pointer points to read-only storage.

Completion Code

MQCC_FAILED

Programmer response

Ensure that input fields in the MQOD structure are set correctly.

2045 (07FD) (RC2045): MQRC_OPTION_NOT_VALID_FOR_TYPE:

Explanation

On an MQOPEN or MQCLOSE call, an option is specified that is not valid for the type of object or queue being opened or closed.

For the MQOPEN call, this includes the following cases:
- An option that is inappropriate for the object type (for example, MQOO_OUTPUT for an MQOT_PROCESS object).
- An option that is unsupported for the queue type (for example, MQOO_INQUIRE for a remote queue that has no local definition).
- One or more of the following options:
  - MQOO_INPUT_AS_Q_DEF
  - MQOO_INPUT_SHARED
  - MQOO_INPUT_EXCLUSIVE
  - MQOO_BROWSE

  - MQOO_INQUIRE
  - MQOO_SET

  when either:

  - the queue name is resolved through a cell directory, or
  - *ObjectQMgrName* in the object descriptor specifies the name of a local definition of a remote queue (to specify a queue-manager alias), and the queue named in the *RemoteQMgrName* attribute of the definition is the name of the local queue manager.

For the MQCLOSE call, this includes the following case:

- The MQCO_DELETE or MQCO_DELETE_PURGE option when the queue is not a dynamic queue.

This reason code can also occur on the MQOPEN call when the object being opened is of type MQOT_NAMELIST, MQOT_PROCESS, or MQOT_Q_MGR, but the *ObjectQMgrName* field in MQOD is neither blank nor the name of the local queue manager.

Completion Code

MQCC_FAILED

Programmer response

Specify the correct option. For the MQOPEN call, ensure that the *ObjectQMgrName* field is set correctly. For the MQCLOSE call, either correct the option or change the definition type of the model queue that is used to create the new queue.

2046 (07FE) (RC2046): MQRC_OPTIONS_ERROR:

Explanation

The *Options* parameter or field contains options that are not valid, or a combination of options that is not valid.

- For the MQOPEN, MQCLOSE, MQXCNVC, mqBagToBuffer, mqBufferToBag, mqCreateBag, and mqExecute calls, *Options* is a separate parameter on the call.

  This reason also occurs if the parameter pointer is not valid. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)
- For the MQBEGIN, MQCONNX, MQGET, MQPUT, and MQPUT1 calls, *Options* is a field in the relevant options structure (MQBO, MQCNO, MQGMO, or MQPMO).
- For more information about option errors for IBM MQ Multicast see: MQI concepts and how they relate to multicast.

Completion Code

MQCC_FAILED

Programmer response

Specify valid options. Check the description of the *Options* parameter or field to determine which options and combinations of options are valid. If multiple options are being set by adding the individual options together, ensure that the same option is not added twice. For more information, see Rules for validating MQI options.

2047 (07FF) (RC2047): MQRC_PERSISTENCE_ERROR:

Explanation

On an MQPUT or MQPUT1 call, the value specified for the *Persistence* field in the message descriptor MQMD is not valid.

Completion Code

MQCC_FAILED

Programmer response

Specify one of the following values:
- MQPER_PERSISTENT
- MQPER_NOT_PERSISTENT
- MQPER_PERSISTENCE_AS_Q_DEF

2048 (0800) (RC2048): MQRC_PERSISTENT_NOT_ALLOWED:

Explanation

On an MQPUT or MQPUT1 call, the value specified for the *Persistence* field in MQMD (or obtained from the *DefPersistence* queue attribute) specifies MQPER_PERSISTENT, but the queue on which the message is being placed does not support persistent messages. Persistent messages cannot be placed on temporary dynamic queues.

This reason code can also occur in the *Feedback* field in the message descriptor of a report message; in this case it indicates that the error was encountered by a message channel agent when it attempted to put the message on a remote queue.

Completion Code

MQCC_FAILED

Programmer response

Specify MQPER_NOT_PERSISTENT if the message is to be placed on a temporary dynamic queue. If persistence is required, use a permanent dynamic queue or predefined queue in place of a temporary dynamic queue.

Be aware that server applications are recommended to send reply messages (message type MQMT_REPLY) with the same persistence as the original request message (message type MQMT_REQUEST). If the request message is persistent, the reply queue specified in the *ReplyToQ* field in the message descriptor MQMD cannot be a temporary dynamic queue. Use a permanent dynamic queue or predefined queue as the reply queue in this situation.

On z/OS, you cannot put persistent messages to a shared queue if the CFSTRUCT that the queue uses is defined with RECOVER(NO). Either put only non-persistent messages to this queue or change the CFSTRUCT definition to RECOVER(YES). If you put a persistent message to a queue that uses a CFSTRUCT with RECOVER(NO) the put will fail with MQRC_PERSISTENT_NOT_ALLOWED.

2049 (0801) (RC2049): MQRC_PRIORITY_EXCEEDS_MAXIMUM:

Explanation

An MQPUT or MQPUT1 call was issued, but the value of the *Priority* field in the message descriptor MQMD exceeds the maximum priority supported by the local queue manager, as shown by the *MaxPriority* queue-manager attribute. The message is accepted by the queue manager, but is placed on the queue at the queue manager's maximum priority. The *Priority* field in the message descriptor retains the value specified by the application that put the message.

Completion Code

MQCC_WARNING

Programmer response

None required, unless this reason code was not expected by the application that put the message.

2050 (0802) (RC2050): MQRC_PRIORITY_ERROR:

Explanation

An MQPUT or MQPUT1 call was issued, but the value of the *Priority* field in the message descriptor MQMD is not valid. The maximum priority supported by the queue manager is given by the *MaxPriority* queue-manager attribute.

Completion Code

MQCC_FAILED

Programmer response

Specify a value in the range zero through *MaxPriority*, or the special value MQPRI_PRIORITY_AS_Q_DEF.

2051 (0803) (RC2051): MQRC_PUT_INHIBITED:

Explanation

MQPUT and MQPUT1 calls are currently inhibited for the queue, or for the queue to which this queue resolves.

This reason code can also occur in the *Feedback* field in the message descriptor of a report message; in this case it indicates that the error was encountered by a message channel agent when it attempted to put the message on a remote queue.

Completion Code

MQCC_FAILED

Programmer response

If the system design allows put requests to be inhibited for short periods, retry the operation later.

This reason code is also used to identify the corresponding event message Put Inhibited.

System programmer action

Use ALTER QLOCAL(...) PUT(ENABLED) to allow messages to be put.

2052 (0804) (RC2052): MQRC_Q_DELETED:

Explanation

An *Hobj* queue handle specified on a call refers to a dynamic queue that has been deleted since the queue was opened. For more information about the deletion of dynamic queues, see the description of MQCLOSE in MQCLOSE.

- On z/OS, this can also occur with the MQOPEN and MQPUT1 calls if a dynamic queue is being opened, but the queue is in a logically-deleted state. See MQCLOSE for more information about this.

Completion Code

MQCC_FAILED

Programmer response

Issue an MQCLOSE call to return the handle and associated resources to the system (the MQCLOSE call will succeed in this case). Check the design of the application that caused the error.

2053 (0805) (RC2053): MQRC_Q_FULL:

Explanation

An MQPUT or MQPUT1 call, or a command, failed because the queue is full, that is, it already contains the maximum number of messages possible, as specified by the *MaxQDepth* queue attribute.

This reason code can also occur in the *Feedback* field in the message descriptor of a report message; in this case it indicates that the error was encountered by a message channel agent when it attempted to put the message on a remote queue.

Completion Code

MQCC_FAILED

Programmer response

Retry the operation later. Consider increasing the maximum depth for this queue, or arranging for more instances of the application to service the queue.

This reason code is also used to identify the corresponding event message Queue Full.

2055 (0807) (RC2055): MQRC_Q_NOT_EMPTY:

Explanation

An MQCLOSE call was issued for a permanent dynamic queue, but the call failed because the queue is not empty or still in use. One of the following applies:

- The MQCO_DELETE option was specified, but there are messages on the queue.
- The MQCO_DELETE or MQCO_DELETE_PURGE option was specified, but there are uncommitted get or put calls outstanding against the queue.

See the usage notes pertaining to dynamic queues for the MQCLOSE call for more information.

This reason code is also returned from a command to clear or delete or move a queue, if the queue contains uncommitted messages (or committed messages in the case of delete queue without the purge option).

Completion Code

MQCC_FAILED

Programmer response

Check why there might be messages on the queue. Be aware that the *CurrentQDepth* queue attribute might be zero even though there are one or more messages on the queue; this can happen if the messages have been retrieved as part of a unit of work that has not yet been committed. If the messages can be discarded, try using the MQCLOSE call with the MQCO_DELETE_PURGE option. Consider retrying the call later.

2056 (0808) (RC2056): MQRC_Q_SPACE_NOT_AVAILABLE:

Explanation

An MQPUT or MQPUT1 call was issued, but there is no space available for the queue on disk or other storage device.

This reason code can also occur in the *Feedback* field in the message descriptor of a report message; in this case it indicates that the error was encountered by a message channel agent when it attempted to put the message on a remote queue.

- On z/OS, this reason code does not occur.

Completion Code

MQCC_FAILED

Programmer response

Check whether an application is putting messages in an infinite loop. If not, make more disk space available for the queue.

2057 (0809) (RC2057): MQRC_Q_TYPE_ERROR:

Explanation

One of the following occurred:
- On an MQOPEN call, the `ObjectQMgrName` field in the object descriptor MQOD or object record MQOR specifies the name of a local definition of a remote queue (to specify a queue-manager alias), and in that local definition the `RemoteQMgrName` attribute is the name of the local queue manager. However, the `ObjectName` field in MQOD or MQOR specifies the name of a model queue on the local queue manager; this is not allowed. For more information, see MQOPEN.
- On an MQPUT1 call, the object descriptor MQOD or object record MQOR specifies the name of a model queue.
- On a previous MQPUT or MQPUT1 call, the `ReplyToQ` field in the message descriptor specified the name of a model queue, but a model queue cannot be specified as the destination for reply or report messages. Only the name of a predefined queue, or the name of the *dynamic* queue created from the model queue, can be specified as the destination. In this situation the reason code MQRC_Q_TYPE_ERROR is returned in the `Reason` field of the MQDLH structure when the reply message or report message is placed on the dead-letter queue.

Completion Code

MQCC_FAILED

Programmer response

Specify a valid queue.

This reason code is also used to identify the corresponding event message Queue Type Error.

2058 (080A) (RC2058): MQRC_Q_MGR_NAME_ERROR:

Explanation

On an MQCONN or MQCONNX call, the value specified for the `QMgrName` parameter is not valid or not known. This reason also occurs if the parameter pointer is not valid. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)
- z/OS On z/OS for CICS applications, this reason can occur on *any* call if the original connect specified an incorrect or unrecognized name.

z/OS For CICS, this reason can be caused by the wrong resync value. For example, Groupresync is specified and the queue manager is not in a queue sharing group.

This reason code can also occur if an MQ MQI client application attempts to connect to a queue manager within an MQ-client queue-manager group (see the `QMgrName` parameter of MQCONN), and either:
- Queue-manager groups are not supported.
- There is no queue-manager group with the specified name.

z/OS For IMS adapter on z/OS, this can be caused by the library containing your CSQQDEFV module being after the SCSQAUTH data set in steplib. Move your library above the SCSQAUTH data set.

Completion Code

MQCC_FAILED

Programmer response

Use an all-blank name if possible, or verify that the name used is valid.

If you are using CICS Resyncmember(Groupresync), use the queue-sharing group (QSG) name in the MQNAME rather than the queue manager name.

2059 (080B) (RC2059): MQRC_Q_MGR_NOT_AVAILABLE:

Explanation

This error occurs:

1. On an MQCONN or MQCONNX call, the queue manager identified by the *QMgrName* parameter is not available for connection.
   - On z/OS:
     - For batch applications, this reason can be returned to applications running in LPARs that do not have a queue manager installed.
     - For CICS applications, this reason can occur on any call if the original connect specified a queue manager with a name that was recognized, but which is not available.
   - On IBM i, this reason can also be returned by the MQOPEN and MQPUT1 calls, when MQHC_DEF_HCONN is specified for the *Hconn* parameter by an application running in compatibility mode.
2. On an MQCONN or MQCONNX call from an IBM MQ MQI client application:
   - Attempting to connect to a queue manager within an MQ-client queue-manager group when none of the queue managers in the group is available for connection (see the *QMgrName* parameter of the MQCONN call).
   - If the client channel fails to connect, perhaps because of an error with the client-connection or the corresponding server-connection channel definitions.
3. If a command uses the *CommandScope* parameter specifying a queue manager that is not active in the queue-sharing group.
4. In a multiple installation environment, where an application attempts to connect to a queue manager associated with an installation of IBM WebSphere MQ Version 7.1, or later, but has loaded libraries from IBM WebSphere MQ Version 7.0.1. IBM WebSphere MQ Version 7.0.1 cannot load libraries from other versions of IBM MQ.

Completion Code

MQCC_FAILED

Programmer response

Ensure that the queue manager has been started. If the connection is from a client application, check the channel definitions, channel status, and error logs.

In a multiple installation environment, ensure that IBM WebSphere MQ Version 7.1, or later, libraries are loaded by the operating system. For more information, see Connecting applications in a multiple installation environment.

2061 (080D) (RC2061): MQRC_REPORT_OPTIONS_ERROR:

Explanation

An MQPUT or MQPUT1 call was issued, but the *Report* field in the message descriptor MQMD contains one or more options that are not recognized by the local queue manager. The options that cause this reason code to be returned depend on the destination of the message; see the description of REPORT in Report options and message flags for more details.

This reason code can also occur in the *Feedback* field in the MQMD of a report message, or in the *Reason* field in the MQDLH structure of a message on the dead-letter queue; in both cases it indicates that the destination queue manager does not support one or more of the report options specified by the sender of the message.

Completion Code

MQCC_FAILED

Programmer response

Do the following:
- Ensure that the *Report* field in the message descriptor is initialized with a value when the message descriptor is declared, or is assigned a value prior to the MQPUT or MQPUT1 call. Specify MQRO_NONE if no report options are required.
- Ensure that the report options specified are valid; see the *Report* field described in the description of MQMD in Report options and message flags for valid report options.
- If multiple report options are being set by adding the individual report options together, ensure that the same report option is not added twice.
- Check that conflicting report options are not specified. For example, do not add both MQRO_EXCEPTION and MQRO_EXCEPTION_WITH_DATA to the *Report* field; only one of these can be specified.

2062 (080E) (RC2062): MQRC_SECOND_MARK_NOT_ALLOWED:

Explanation

An MQGET call was issued specifying the MQGMO_MARK_SKIP_BACKOUT option in the *Options* field of MQGMO, but a message has already been marked within the current unit of work. Only one marked message is allowed within each unit of work.

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

Modify the application so that no more than one message is marked within each unit of work.

2063 (080F) (RC2063): MQRC_SECURITY_ERROR:

Explanation

An MQCONN, MQCONNX, MQOPEN, MQSUB, MQPUT1, or MQCLOSE call was issued, but it failed because a security error occurred.

- On z/OS, there are two possible reasons for this:
  - An MQCONN or MQCONNX call was issued to connect to the queue manager using the BINDINGS transport, passing in a username or password, or both, that were longer than 8 characters.
  - The security error was returned by the External Security Manager.
- If you are using AMS, this could be a set up issue.
- If you are using connection authentication with an LDAP server, this could be as a result of connectivity failure to the LDAP server, or an error from the LDAP server.

Completion Code

MQCC_FAILED

Programmer response

Note the error from the security manager, and contact your system programmer or security administrator.

- If you are using AMS, you should check the queue manager error logs.
- On z/OS, ensure that both the username and password specified, when connecting to the queue manager, have a maximum length of 8 characters.
- On IBM i, the FFST log will contain the error information.
- If you are using LDAP, use DISPLAY QMSTATUS to check the status of the connection to the LDAP server, and check the queue manager error logs for any error messages.

2065 (0811) (RC2065): MQRC_SELECTOR_COUNT_ERROR:

Explanation

On an MQINQ or MQSET call, the `SelectorCount` parameter specifies a value that is not valid. This reason also occurs if the parameter pointer is not valid. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)

Completion Code

MQCC_FAILED

Programmer response

Specify a value in the range 0 through 256.

2066 (0812) (RC2066): MQRC_SELECTOR_LIMIT_EXCEEDED:

Explanation

On an MQINQ or MQSET call, the *SelectorCount* parameter specifies a value that is larger than the maximum supported (256).

Completion Code

MQCC_FAILED

Programmer response

Reduce the number of selectors specified on the call; the valid range is 0 through 256.

2067 (0813) (RC2067): MQRC_SELECTOR_ERROR:

Explanation

An MQINQ or MQSET call was issued, but the *Selectors* array contains a selector that is not valid for one of the following reasons:

- The selector is not supported or out of range.
- The selector is not applicable to the type of object with attributes that are being inquired upon or set.
- The selector is for an attribute that cannot be set.

This reason also occurs if the parameter pointer is not valid. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)

An MQINQ call was issued for a managed handle in IBM MQ Multicast, inquiring a value other than *Current Depth*.

Completion Code

MQCC_FAILED

Programmer response

Ensure that the value specified for the selector is valid for the object type represented by *Hobj*. For the MQSET call, also ensure that the selector represents an integer attribute that can be set.

MQINQ for managed handles in IBM MQ Multicast can only inquire on *Current Depth*.

2068 (0814) (RC2068): MQRC_SELECTOR_NOT_FOR_TYPE:

Explanation

On the MQINQ call, one or more selectors in the *Selectors* array is not applicable to the type of the queue with attributes that are being inquired upon.

This reason also occurs when the queue is a cluster queue that resolved to a remote instance of the queue. In this case only a subset of the attributes that are valid for local queues can be inquired. See the usage notes in the description of MQINQ in MQINQ - Inquire object attributes for more information about MQINQ.

The call completes with MQCC_WARNING, with the attribute values for the inapplicable selectors set as follows:
- For integer attributes, the corresponding elements of *IntAttrs* are set to MQIAV_NOT_APPLICABLE.
- For character attributes, the appropriate parts of the *CharAttrs* string are set to a character string consisting entirely of asterisks (*).

Completion Code

MQCC_WARNING

Programmer response

Verify that the selector specified is the one that was intended.

If the queue is a cluster queue, specifying one of the MQOO_BROWSE, MQOO_INPUT_*, or MQOO_SET options in addition to MQOO_INQUIRE forces the queue to resolve to the local instance of the queue. However, if there is no local instance of the queue the MQOPEN call fails.

2069 (0815) (RC2069): MQRC_SIGNAL_OUTSTANDING:

Explanation

An MQGET call was issued with either the MQGMO_SET_SIGNAL or MQGMO_WAIT option, but there is already a signal outstanding for the queue handle *Hobj*.

This reason code occurs only in the following environments: z/OS, Windows 95, Windows 98.

Completion Code

MQCC_FAILED

Programmer response

Check the application logic. If it is necessary to set a signal or wait when there is a signal outstanding for the same queue, a different object handle must be used.

2070 (0816) (RC2070): MQRC_SIGNAL_REQUEST_ACCEPTED:

Explanation

An MQGET call was issued specifying MQGMO_SET_SIGNAL in the *GetMsgOpts* parameter, but no suitable message was available; the call returns immediately. The application can now wait for the signal to be delivered.

- On z/OS, the application should wait on the Event Control Block pointed to by the *Signal1* field.
- On Windows 95, Windows 98, the application should wait for the signal Windows message to be delivered.

This reason code occurs only in the following environments: z/OS, Windows 95, Windows 98.

Completion Code

MQCC_WARNING

Programmer response

Wait for the signal; when it is delivered, check the signal to ensure that a message is now available. If it is, reissue the MQGET call.

- On z/OS, wait on the ECB pointed to by the *Signal1* field and, when it is posted, check it to ensure that a message is now available.
- On Windows 95, Windows 98, the application (thread) should continue executing its message loop.

2071 (0817) (RC2071): MQRC_STORAGE_NOT_AVAILABLE:

Explanation

The call failed because there is insufficient main storage available.

Completion Code

MQCC_FAILED

Programmer response

Ensure that active applications are behaving correctly, for example, that they are not looping unexpectedly. If no problems are found, make more main storage available.

- On z/OS, if no application problems are found, ask your system programmer to increase the size of the region in which the queue manager runs.

2072 (0818) (RC2072): MQRC_SYNCPOINT_NOT_AVAILABLE:

Explanation

Either the MQGMO_SYNCPOINT option was used with an MQGET call, or the MQPMO_SYNCPOINT option was used with an MQPUT or MQPUT1 call, but the local queue manager was unable to honor the request. If the queue manager does not support units of work, the *SyncPoint* queue-manager attribute has the value MQSP_NOT_AVAILABLE.

This reason code can also occur on the MQGET, MQPUT, and MQPUT1 calls when an external unit-of-work coordinator is used. If that coordinator requires an explicit call to start the unit of work, but the application has not issued that call before the MQGET, MQPUT, or MQPUT1 call, reason code MQRC_SYNCPOINT_NOT_AVAILABLE is returned.

- IBM i On IBM i, this reason code means that IBM i Commitment Control is not started, or is unavailable for use by the queue manager.
- On HP Integrity NonStop Server, this reason code means that the client has detected that the application has an active transaction that is being coordinated by the Transaction Management Facility (TMF), but that a z/OS queue manager is unable to be coordinated by TMF.

This reason code can also be returned if the MQGMO_SYNCPOINT or the MQPMO_SYNCPOINT option was used for IBM MQ Multicast messaging. Transactions are not supported for multicast.

Completion Code

MQCC_FAILED

Programmer response

Remove the specification of MQGMO_SYNCPOINT or MQPMO_SYNCPOINT, as appropriate.

- IBM i On IBM i, ensure that Commitment Control is started. If this reason code occurs after Commitment Control is started, contact your system programmer.
- On HP Integrity NonStop Server, ensure that your z/OS queue manager has the relevant APAR applied. Check with the IBM support center for APAR details.

2075 (081B) (RC2075): MQRC_TRIGGER_CONTROL_ERROR:

Explanation

On an MQSET call, the value specified for the MQIA_TRIGGER_CONTROL attribute selector is not valid.

Completion Code

MQCC_FAILED

Programmer response

Specify a valid value.

2076 (081C) (RC2076): MQRC_TRIGGER_DEPTH_ERROR:

Explanation

On an MQSET call, the value specified for the MQIA_TRIGGER_DEPTH attribute selector is not valid.

Completion Code

MQCC_FAILED

Programmer response

Specify a value that is greater than zero.

2077 (081D) (RC2077): MQRC_TRIGGER_MSG_PRIORITY_ERR:

Explanation

On an MQSET call, the value specified for the MQIA_TRIGGER_MSG_PRIORITY attribute selector is not valid.

Completion Code

MQCC_FAILED

Programmer response

Specify a value in the range zero through the value of *MaxPriority* queue-manager attribute.

2078 (081E) (RC2078): MQRC_TRIGGER_TYPE_ERROR:

Explanation

On an MQSET call, the value specified for the MQIA_TRIGGER_TYPE attribute selector is not valid.

Completion Code

MQCC_FAILED

Programmer response

Specify a valid value.

2079 (081F) (RC2079): MQRC_TRUNCATED_MSG_ACCEPTED:

Explanation

On an MQGET call, the message length was too large to fit into the supplied buffer. The MQGMO_ACCEPT_TRUNCATED_MSG option was specified, so the call completes. The message is removed from the queue (subject to unit-of-work considerations), or, if this was a browse operation, the browse cursor is advanced to this message.

The `DataLength` parameter is set to the length of the message before truncation, the `Buffer` parameter contains as much of the message as fits, and the MQMD structure is filled in.

Completion Code

MQCC_WARNING

Programmer response

None, because the application expected this situation.

2080 (0820) (RC2080): MQRC_TRUNCATED_MSG_FAILED:

Explanation

On an MQGET call, the message length was too large to fit into the supplied buffer. The MQGMO_ACCEPT_TRUNCATED_MSG option was *not* specified, so the message has not been removed from the queue. If this was a browse operation, the browse cursor remains where it was before this call, but if MQGMO_BROWSE_FIRST was specified, the browse cursor is positioned logically before the highest-priority message on the queue.

The `DataLength` field is set to the length of the message before truncation, the `Buffer` parameter contains as much of the message as fits, and the MQMD structure is filled in.

Completion Code

MQCC_WARNING

Programmer response

Supply a buffer that is at least as large as `DataLength`, or specify MQGMO_ACCEPT_TRUNCATED_MSG if not all of the message data is required.

2082 (0822) (RC2082): MQRC_UNKNOWN_ALIAS_BASE_Q:

Explanation

An MQOPEN or MQPUT1 call was issued specifying an alias queue as the target, but the *BaseQName* in the alias queue attributes is not recognized as a queue name.

This reason code can also occur when *BaseQName* is the name of a cluster queue that cannot be resolved successfully.

MQRC_UNKNOWN_ALIAS_BASE_Q might indicate that the application is specifying the **ObjectQmgrName** of the queue manager that it is connecting to, and the queue manager that is hosting the alias queue. This means that the queue manager looks for the alias target queue on the specified queue manager and fails because the alias target queue is not on the local queue manager. Leave the **ObjectQmgrName** parameter blank so that the clustering decides which queue manager to route to.

Completion Code

MQCC_FAILED

Programmer response

Correct the queue definitions.

This reason code is also used to identify the corresponding event message Unknown Alias Base Queue.

If the reason code is seen by an application that is using IBM MQ classes for JMS, modify the JMS queue object definition that is used by the application so that the **QMANAGER** property is set to the empty string (""). This setting ensures that the clustering decides which queue manager to route to.

2085 (0825) (RC2085): MQRC_UNKNOWN_OBJECT_NAME:

Explanation

An MQOPEN, MQPUT1 , or MQSUB call was issued, but the object identified by the *ObjectName* and *ObjectQMgrName* fields in the object descriptor MQOD cannot be found. One of the following applies:

- The *ObjectQMgrName* field is one of the following:
  - Blank
  - The name of the local queue manager
  - The name of a local definition of a remote queue (a queue-manager alias) in which the *RemoteQMgrName* attribute is the name of the local queue manager

  but no object with the specified *ObjectName* and *ObjectType* exists on the local queue manager.
- The object being opened is a cluster queue that is hosted on a remote queue manager, but the local queue manager does not have a defined route to the remote queue manager.
- The object being opened is a queue definition that has QSGDISP(GROUP). Such definitions cannot be used with the MQOPEN, MQPUT1 , or MQSUB calls.
- The MQOD in the failing application specifies the name of the local queue manager in *ObjectQMgrName*. The local queue manager does not host the particular cluster queue specified in *ObjectName*.

  The solution in this environment is to leave *ObjectQMgrName* of the MQOD blank.

This can also occur in response to a command that specifies the name of an object or other item that does not exist.

Completion Code

MQCC_FAILED

Programmer response

Specify a valid object name. Ensure that the name is padded with blanks at the end, if necessary. If this is correct, check the object definitions.

This reason code is also used to identify the corresponding event message Unknown Object Name.

2086 (0826) (RC2086): MQRC_UNKNOWN_OBJECT_Q_MGR:

Explanation

On an MQOPEN or MQPUT1 call, the *ObjectQMgrName* field in the object descriptor MQOD does not satisfy the naming rules for objects. For more information, see ObjectQMgrName (MQCHAR48).

This reason also occurs if the *ObjectType* field in the object descriptor has the value MQOT_Q_MGR, and the *ObjectQMgrName* field is not blank, but the name specified is not the name of the local queue manager.

Completion Code

MQCC_FAILED

Programmer response

Specify a valid queue manager name. To refer to the local queue manager, a name consisting entirely of blanks or beginning with a null character can be used. Ensure that the name is padded with blanks at the end, or terminated with a null character if necessary.

2087 (0827) (RC2087): MQRC_UNKNOWN_REMOTE_Q_MGR:

Explanation

On an MQOPEN or MQPUT1 call, an error occurred with the queue-name resolution, for one of the following reasons:

- *ObjectQMgrName* is blank or the name of the local queue manager, *ObjectName* is the name of a local definition of a remote queue (or an alias to one), and one of the following is true:
  - *RemoteQMgrName* is blank or the name of the local queue manager. Note that this error occurs even if *XmitQName* is not blank.
  - *XmitQName* is blank, but there is no transmission queue defined with the name of *RemoteQMgrName*, and the *DefXmitQName* queue-manager attribute is blank.
  - *RemoteQMgrName* and *RemoteQName* specify a cluster queue that cannot be resolved successfully, and the *DefXmitQName* queue-manager attribute is blank.
  - On z/OS only, the *RemoteQMgrName* is the name of a queue manager in the Queue Sharing group but intra-group queuing is disabled.
- *ObjectQMgrName* is the name of a local definition of a remote queue (containing a queue-manager alias definition), and one of the following is true:
  - *RemoteQName* is not blank.
  - *XmitQName* is blank, but there is no transmission queue defined with the name of *RemoteQMgrName*, and the *DefXmitQName* queue-manager attribute is blank.
- *ObjectQMgrName* is not:
  - Blank

  - The name of the local queue manager
  - The name of a transmission queue
  - The name of a queue-manager alias definition (that is, a local definition of a remote queue with a blank *RemoteQName*)

  but the *DefXmitQName* queue-manager attribute is blank and the queue manager is not part of a queue-sharing group with intra-group queuing enabled.
- *ObjectQMgrName* is the name of a model queue.
- The queue name is resolved through a cell directory. However, there is no queue defined with the same name as the remote queue manager name obtained from the cell directory, and the *DefXmitQName* queue-manager attribute is blank.

Completion Code

MQCC_FAILED

Programmer response

Check the values specified for *ObjectQMgrName* and *ObjectName*. If these are correct, check the queue definitions.

This reason code is also used to identify the corresponding event message Unknown Remote Queue Manager.

2090 (082A) (RC2090): MQRC_WAIT_INTERVAL_ERROR:

Explanation

On the MQGET call, the value specified for the *WaitInterval* field in the *GetMsgOpts* parameter is not valid.

Completion Code

MQCC_FAILED

Programmer response

Specify a value greater than or equal to zero, or the special value MQWI_UNLIMITED if an indefinite wait is required.

2091 (082B) (RC2091): MQRC_XMIT_Q_TYPE_ERROR:

Explanation

On an MQOPEN or MQPUT1 call, a message is to be sent to a remote queue manager. The *ObjectName* or *ObjectQMgrName* field in the object descriptor specifies the name of a local definition of a remote queue but one of the following applies to the *XmitQName* attribute of the definition:

- *XmitQName* is not blank, but specifies a queue that is not a local queue
- *XmitQName* is blank, but *RemoteQMgrName* specifies a queue that is not a local queue

This reason also occurs if the queue name is resolved through a cell directory, and the remote queue manager name obtained from the cell directory is the name of a queue, but this is not a local queue.

Completion Code

MQCC_FAILED

Programmer response

Check the values specified for *ObjectName* and *ObjectQMgrName*. If these are correct, check the queue definitions.

This reason code is also used to identify the corresponding event message Transmission Queue Type Error.

2092 (082C) (RC2092): MQRC_XMIT_Q_USAGE_ERROR:

Explanation

On an MQOPEN or MQPUT1 call, a message is to be sent to a remote queue manager, but one of the following occurred:

- *ObjectQMgrName* specifies the name of a local queue, but it does not have a *Usage* attribute of MQUS_TRANSMISSION.
- The *ObjectName* or *ObjectQMgrName* field in the object descriptor specifies the name of a local definition of a remote queue but one of the following applies to the *XmitQName* attribute of the definition:
  - *XmitQName* is not blank, but specifies a queue that does not have a *Usage* attribute of MQUS_TRANSMISSION
  - *XmitQName* is blank, but *RemoteQMgrName* specifies a queue that does not have a *Usage* attribute of MQUS_TRANSMISSION
  - *XmitQName* specifies the queue SYSTEM.QSG.TRANSMIT.QUEUE the IGQ queue manager attribute indicates that IGQ is DISABLED.
- The queue name is resolved through a cell directory, and the remote queue manager name obtained from the cell directory is the name of a local queue, but it does not have a *Usage* attribute of MQUS_TRANSMISSION.

Completion Code

MQCC_FAILED

Programmer response

Check the values specified for *ObjectName* and *ObjectQMgrName*. If these are correct, check the queue definitions.

This reason code is also used to identify the corresponding event message Transmission Queue Usage Error.

2093 (082D) (RC2093): MQRC_NOT_OPEN_FOR_PASS_ALL:

Explanation

An MQPUT call was issued with the MQPMO_PASS_ALL_CONTEXT option specified in the *PutMsgOpts* parameter, but the queue had not been opened with the MQOO_PASS_ALL_CONTEXT option.

Completion Code

MQCC_FAILED

Programmer response

Specify MQOO_PASS_ALL_CONTEXT (or another option that implies it) when the queue is opened.

2094 (082E) (RC2094): MQRC_NOT_OPEN_FOR_PASS_IDENT:

Explanation

An MQPUT call was issued with the MQPMO_PASS_IDENTITY_CONTEXT option specified in the *PutMsgOpts* parameter, but the queue had not been opened with the MQOO_PASS_IDENTITY_CONTEXT option.

Completion Code

MQCC_FAILED

Programmer response

Specify MQOO_PASS_IDENTITY_CONTEXT (or another option that implies it) when the queue is opened.

2095 (082F) (RC2095): MQRC_NOT_OPEN_FOR_SET_ALL:

Explanation

An MQPUT call was issued with the MQPMO_SET_ALL_CONTEXT option specified in the *PutMsgOpts* parameter, but the queue had not been opened with the MQOO_SET_ALL_CONTEXT option.

Completion Code

MQCC_FAILED

Programmer response

Specify MQOO_SET_ALL_CONTEXT when the queue is opened.

2096 (0830) (RC2096): MQRC_NOT_OPEN_FOR_SET_IDENT:

Explanation

An MQPUT call was issued with the MQPMO_SET_IDENTITY_CONTEXT option specified in the `PutMsgOpts` parameter, but the queue had not been opened with the MQOO_SET_IDENTITY_CONTEXT option.

Completion Code

MQCC_FAILED

Programmer response

Specify MQOO_SET_IDENTITY_CONTEXT (or another option that implies it) when the queue is opened.

2097 (0831) (RC2097): MQRC_CONTEXT_HANDLE_ERROR:

Explanation

On an MQPUT or MQPUT1 call, MQPMO_PASS_IDENTITY_CONTEXT or MQPMO_PASS_ALL_CONTEXT was specified, but the handle specified in the `Context` field of the `PutMsgOpts` parameter is either not a valid queue handle, or it is a valid queue handle but the queue was not opened with MQOO_SAVE_ALL_CONTEXT.

Completion Code

MQCC_FAILED

Programmer response

Specify MQOO_SAVE_ALL_CONTEXT when the queue referred to is opened.

2098 (0832) (RC2098): MQRC_CONTEXT_NOT_AVAILABLE:

Explanation

On an MQPUT or MQPUT1 call, MQPMO_PASS_IDENTITY_CONTEXT or MQPMO_PASS_ALL_CONTEXT was specified, but the queue handle specified in the `Context` field of the `PutMsgOpts` parameter has no context associated with it. This arises if no message has yet been successfully retrieved with the queue handle referred to, or if the last successful MQGET call was a browse.

This condition does not arise if the message that was last retrieved had no context associated with it.

- On z/OS, if a message is received by a message channel agent that is putting messages with the authority of the user identifier in the message, this code is returned in the `Feedback` field of an exception report if the message has no context associated with it.

Completion Code

MQCC_FAILED

Programmer response

Ensure that a successful nonbrowse get call has been issued with the queue handle referred to.

2099 (0833) (RC2099): MQRC_SIGNAL1_ERROR:

Explanation

An MQGET call was issued, specifying MQGMO_SET_SIGNAL in the *GetMsgOpts* parameter, but the *Signal1* field is not valid.

- On z/OS, the address contained in the *Signal1* field is not valid, or points to read-only storage. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)
- On Windows 95, Windows 98, the window handle in the *Signal1* field is not valid.

This reason code occurs only in the following environments: z/OS, Windows 95, Windows 98.

Completion Code

MQCC_FAILED

Programmer response

Correct the setting of the *Signal1* field.

2100 (0834) (RC2100): MQRC_OBJECT_ALREADY_EXISTS:

Explanation

An MQOPEN call was issued to create a dynamic queue, but a queue with the same name as the dynamic queue already exists.

- On z/OS, a rare "race condition⌂ can also give rise to this reason code; see the description of reason code MQRC_NAME_IN_USE for more details.

Completion Code

MQCC_FAILED

Programmer response

If supplying a dynamic queue name in full, ensure that it obeys the naming conventions for dynamic queues; if it does, either supply a different name, or delete the existing queue if it is no longer required. Alternatively, allow the queue manager to generate the name.

If the queue manager is generating the name (either in part or in full), reissue the MQOPEN call.

2101 (0835) (RC2101): MQRC_OBJECT_DAMAGED:

Explanation

The object accessed by the call is damaged and cannot be used. For example, this might be because the definition of the object in main storage is not consistent, or because it differs from the definition of the object on disk, or because the definition on disk cannot be read. The object can be deleted, although it might not be possible to delete the associated user space.

- On z/OS, this reason occurs when the Db2 list header or structure number associated with a shared queue is zero. This situation arises as a result of using the MQSC command DELETE CFSTRUCT to delete the Db2 structure definition. The command resets the list header and structure number to zero for each of the shared queues that references the deleted CF structure.

Completion Code

MQCC_FAILED

Programmer response

It might be necessary to stop and restart the queue manager, or to restore the queue-manager data from backup storage.

- On IBM i, HP Integrity NonStop Server, and UNIX systems, consult the FFST record to obtain more detail about the problem.
- On z/OS, delete the shared queue and redefine it using the MQSC command DEFINE QLOCAL. This automatically defines a CF structure and allocates list headers for it.

2102 (0836) (RC2102): MQRC_RESOURCE_PROBLEM:

Explanation

There are insufficient system resources to complete the call successfully. On z/OS this can indicate that Db2 errors occurred when using shared queues, or that the maximum number of shared queues that can be defined in a single coupling facility list structure has been reached.

Completion Code

MQCC_FAILED

Programmer response

Run the application when the machine is less heavily loaded.

- On z/OS, check the operator console for messages that might provide additional information.
- On IBM i, HP Integrity NonStop Server, and UNIX systems, consult the FFST record to obtain more detail about the problem.

2103 (0837) (RC2103): MQRC_ANOTHER_Q_MGR_CONNECTED:
Explanation

An MQCONN or MQCONNX call was issued, but the thread or process is already connected to a different queue manager. The thread or process can connect to only one queue manager at a time.
- On z/OS, this reason code does not occur.
- On Windows, MTS objects do not receive this reason code, as connections to other queue managers are allowed.

Completion Code

MQCC_FAILED

Programmer response

Use the MQDISC call to disconnect from the queue manager that is already connected, and then issue the MQCONN or MQCONNX call to connect to the new queue manager.

Disconnecting from the existing queue manager closes any queues that are currently open; it is suggested that any uncommitted units of work are committed or backed out before the MQDISC call is issued.

2104 (0838) (RC2104): MQRC_UNKNOWN_REPORT_OPTION:

Explanation

An MQPUT or MQPUT1 call was issued, but the *Report* field in the message descriptor MQMD contains one or more options that are not recognized by the local queue manager. The options are accepted.

The options that cause this reason code to be returned depend on the destination of the message; see the description of REPORT in Report options and message flags for more information.

Completion Code

MQCC_WARNING

Programmer response

If this reason code is expected, no corrective action is required. If this reason code is not expected, do the following:
- Ensure that the *Report* field in the message descriptor is initialized with a value when the message descriptor is declared, or is assigned a value prior to the MQPUT or MQPUT1 call.
- Ensure that the report options specified are valid; see the *Report* field described in the description of MQMD in MQMD - Message descriptor for valid report options.
- If multiple report options are being set by adding the individual report options together, ensure that the same report option is not added twice.
- Check that conflicting report options are not specified. For example, do not add both MQRO_EXCEPTION and MQRO_EXCEPTION_WITH_DATA to the *Report* field; only one of these can be specified.

2105 (0839) (RC2105): MQRC_STORAGE_CLASS_ERROR:

Explanation

The MQPUT or MQPUT1 call was issued, but the storage-class object defined for the queue does not exist.

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

Create the storage-class object required by the queue, or modify the queue definition to use an existing storage class. The name of the storage-class object used by the queue is given by the `StorageClass` queue attribute.

2106 (083A) (RC2106): MQRC_COD_NOT_VALID_FOR_XCF_Q:

Explanation

An MQPUT or MQPUT1 call was issued, but the `Report` field in the message descriptor MQMD specifies one of the MQRO_COD_* options and the target queue is an XCF queue. MQRO_COD_* options cannot be specified for XCF queues.

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

Remove the relevant MQRO_COD_* option.

2107 (083B) (RC2107): MQRC_XWAIT_CANCELED:

Explanation

An MQXWAIT call was issued, but the call has been canceled because a STOP CHINIT command has been issued (or the queue manager has been stopped, which causes the same effect). See MQXWAIT for more information about the MQXWAIT call.

Completion Code

MQCC_FAILED

Programmer response

Tidy up and terminate.

2108 (083C) (RC2108): MQRC_XWAIT_ERROR:

Explanation

An MQXWAIT call was issued, but the invocation was not valid for one of the following reasons:
- The wait descriptor MQXWD contains data that is not valid.
- The linkage stack level is not valid.
- The addressing mode is not valid.
- There are too many wait events outstanding.

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

Obey the rules for using the MQXWAIT call. For more information about MQWAIT, see MQXWAIT.

2109 (083D) (RC2109): MQRC_SUPPRESSED_BY_EXIT:

Explanation

On any call other than MQCONN or MQDISC, the API crossing exit suppressed the call.

Completion Code

MQCC_FAILED

Programmer response

Obey the rules for MQI calls that the exit enforces. To find out the rules, see the writer of the exit.

2110 (083E) (RC2110): MQRC_FORMAT_ERROR:

Explanation

An MQGET call was issued with the MQGMO_CONVERT option specified in the *GetMsgOpts* parameter, but the message cannot be converted successfully due to an error associated with the message format. Possible errors include:
- The format name in the message is MQFMT_NONE.
- A user-written exit with the name specified by the *Format* field in the message cannot be found.
- The message contains data that is not consistent with the format definition.

The message is returned unconverted to the application issuing the MQGET call, the values of the *CodedCharSetId* and *Encoding* fields in the *MsgDesc* parameter are set to those of the message returned, and the call completes with MQCC_WARNING.

If the message consists of several parts, each of which is described by its own *CodedCharSetId* and *Encoding* fields (for example, a message with format name MQFMT_DEAD_LETTER_HEADER), some parts may be converted and other parts not converted. However, the values returned in the various *CodedCharSetId* and *Encoding* fields always correctly describe the relevant message data.

Completion Code

MQCC_WARNING

Programmer response

Check the format name that was specified when the message was put. If this is not one of the built-in formats, check that a suitable exit with the same name as the format is available for the queue manager to load. Verify that the data in the message corresponds to the format expected by the exit.

2111 (083F) (RC2111): MQRC_SOURCE_CCSID_ERROR:

Explanation

The coded character-set identifier from which character data is to be converted is not valid or not supported.

This can occur on the MQGET call when the MQGMO_CONVERT option is included in the *GetMsgOpts* parameter; the coded character-set identifier in error is the *CodedCharSetId* field in the message being retrieved. In this case, the message data is returned unconverted, the values of the *CodedCharSetId* and *Encoding* fields in the *MsgDesc* parameter are set to those of the message returned, and the call completes with MQCC_WARNING.

This reason can also occur on the MQGET call when the message contains one or more MQ header structures (MQCIH, MQDLH, MQIIH, MQRMH), and the *CodedCharSetId* field in the message specifies a character set that does not have SBCS characters for the characters that are valid in queue names. MQ header structures containing such characters are not valid, and so the message is returned unconverted. The Unicode character set UCS-2 is an example of such a character set.

If the message consists of several parts, each of which is described by its own *CodedCharSetId* and *Encoding* fields (for example, a message with format name MQFMT_DEAD_LETTER_HEADER), some parts may be converted and other parts not converted. However, the values returned in the various *CodedCharSetId* and *Encoding* fields always correctly describe the relevant message data.

This reason can also occur on the MQXCNVC call; the coded character-set identifier in error is the *SourceCCSID* parameter. Either the *SourceCCSID* parameter specifies a value that is not valid or not supported, or the *SourceCCSID* parameter pointer is not valid. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)

This reason can also occur on a MQSETMP/MQINQMP/MQDLTMP call when the application issuing the calls does not use Language Environment (LE) and defines CCSID values of MQCCSI_APPL (-3) for message property names and string property values.

Completion Code

MQCC_WARNING or MQCC_FAILED

Programmer response

Check the character-set identifier that was specified when the message was put, or that was specified for the *SourceCCSID* parameter on the MQXCNVC call. If this is correct, check that it is one for which queue-manager conversion is supported. If queue-manager conversion is not supported for the specified character set, conversion must be carried out by the application.

If this reason happens as result of a MQSETMP/MQINQMP/MQDLTMP call issued in a non-LE application program that has specified CCSID as MQCCSI_APPL (-3) then applications should be changed to specify the CCSID value used by the application to encode the property names or property string values.

Your applications should override the value of MQCCSI_APPL (-3) with the correct CCSID used as described in Redefinition of MQCCSI_APPL, or they should set the explicit CCSID value used to encode text strings in MQCHARV or similar structures.

2112 (0840) (RC2112): MQRC_SOURCE_INTEGER_ENC_ERROR:

Explanation

On an MQGET call, with the MQGMO_CONVERT option included in the *GetMsgOpts* parameter, the *Encoding* value in the message being retrieved specifies an integer encoding that is not recognized. The message data is returned unconverted, the values of the *CodedCharSetId* and *Encoding* fields in the *MsgDesc* parameter are set to those of the message returned, and the call completes with MQCC_WARNING.

If the message consists of several parts, each of which is described by its own *CodedCharSetId* and *Encoding* fields (for example, a message with format name MQFMT_DEAD_LETTER_HEADER), some parts may be converted and other parts not converted. However, the values returned in the various *CodedCharSetId* and *Encoding* fields always correctly describe the relevant message data.

This reason code can also occur on the MQXCNVC call, when the *Options* parameter contains an unsupported MQDCC_SOURCE_* value, or when MQDCC_SOURCE_ENC_UNDEFINED is specified for a UCS-2 code page.

Completion Code

MQCC_WARNING or MQCC_FAILED

Programmer response

Check the integer encoding that was specified when the message was put. If this is correct, check that it is one for which queue-manager conversion is supported. If queue-manager conversion is not supported for the required integer encoding, conversion must be carried out by the application.

2113 (0841) (RC2113): MQRC_SOURCE_DECIMAL_ENC_ERROR:

Explanation

On an MQGET call with the MQGMO_CONVERT option included in the *GetMsgOpts* parameter, the *Encoding* value in the message being retrieved specifies a decimal encoding that is not recognized. The message data is returned unconverted, the values of the *CodedCharSetId* and *Encoding* fields in the *MsgDesc* parameter are set to those of the message returned, and the call completes with MQCC_WARNING.

If the message consists of several parts, each of which is described by its own *CodedCharSetId* and *Encoding* fields (for example, a message with format name MQFMT_DEAD_LETTER_HEADER), some parts may be converted and other parts not converted. However, the values returned in the various *CodedCharSetId* and *Encoding* fields always correctly describe the relevant message data.

Completion Code

MQCC_WARNING

Programmer response

Check the decimal encoding that was specified when the message was put. If this is correct, check that it is one for which queue-manager conversion is supported. If queue-manager conversion is not supported for the required decimal encoding, conversion must be carried out by the application.

2114 (0842) (RC2114): MQRC_SOURCE_FLOAT_ENC_ERROR:

Explanation

On an MQGET call, with the MQGMO_CONVERT option included in the *GetMsgOpts* parameter, the *Encoding* value in the message being retrieved specifies a floating-point encoding that is not recognized. The message data is returned unconverted, the values of the *CodedCharSetId* and *Encoding* fields in the *MsgDesc* parameter are set to those of the message returned, and the call completes with MQCC_WARNING.

If the message consists of several parts, each of which is described by its own *CodedCharSetId* and *Encoding* fields (for example, a message with format name MQFMT_DEAD_LETTER_HEADER), some parts may be converted and other parts not converted. However, the values returned in the various *CodedCharSetId* and *Encoding* fields always correctly describe the relevant message data.

Completion Code

MQCC_WARNING

Programmer response

Check the floating-point encoding that was specified when the message was put. If this is correct, check that it is one for which queue-manager conversion is supported. If queue-manager conversion is not supported for the required floating-point encoding, conversion must be carried out by the application.

2115 (0843) (RC2115): MQRC_TARGET_CCSID_ERROR:

Explanation

The coded character-set identifier to which character data is to be converted is not valid or not supported.

This can occur on the MQGET call when the MQGMO_CONVERT option is included in the *GetMsgOpts* parameter; the coded character-set identifier in error is the *CodedCharSetId* field in the *MsgDesc* parameter. In this case, the message data is returned unconverted, the values of the *CodedCharSetId* and *Encoding* fields in the *MsgDesc* parameter are set to those of the message returned, and the call completes with MQCC_WARNING.

This reason can also occur on the MQGET call when the message contains one or more MQ header structures (MQCIH, MQDLH, MQIIH, MQRMH), and the *CodedCharSetId* field in the *MsgDesc* parameter specifies a character set that does not have SBCS characters for the characters that are valid in queue names. The Unicode character set UCS-2 is an example of such a character set.

This reason can also occur on the MQXCNVC call; the coded character-set identifier in error is the *TargetCCSID* parameter. Either the *TargetCCSID* parameter specifies a value that is not valid or not supported, or the *TargetCCSID* parameter pointer is not valid. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)

Completion Code

MQCC_WARNING or MQCC_FAILED

Programmer response

Check the character-set identifier that was specified for the *CodedCharSetId* field in the *MsgDesc* parameter on the MQGET call, or that was specified for the *SourceCCSID* parameter on the MQXCNVC call. If this is correct, check that it is one for which queue-manager conversion is supported. If queue-manager conversion is not supported for the specified character set, conversion must be carried out by the application.

2116 (0844) (RC2116): MQRC_TARGET_INTEGER_ENC_ERROR:

Explanation

On an MQGET call with the MQGMO_CONVERT option included in the *GetMsgOpts* parameter, the *Encoding* value in the *MsgDesc* parameter specifies an integer encoding that is not recognized. The message data is returned unconverted, the values of the *CodedCharSetId* and *Encoding* fields in the *MsgDesc* parameter are set to those of the message being retrieved, and the call completes with MQCC_WARNING.

This reason code can also occur on the MQXCNVC call, when the *Options* parameter contains an unsupported MQDCC_TARGET_* value, or when MQDCC_TARGET_ENC_UNDEFINED is specified for a UCS-2 code page.

Completion Code

MQCC_WARNING or MQCC_FAILED

Programmer response

Check the integer encoding that was specified. If this is correct, check that it is one for which queue-manager conversion is supported. If queue-manager conversion is not supported for the required integer encoding, conversion must be carried out by the application.

2117 (0845) (RC2117): MQRC_TARGET_DECIMAL_ENC_ERROR:

Explanation

On an MQGET call with the MQGMO_CONVERT option included in the *GetMsgOpts* parameter, the *Encoding* value in the *MsgDesc* parameter specifies a decimal encoding that is not recognized. The message data is returned unconverted, the values of the *CodedCharSetId* and *Encoding* fields in the *MsgDesc* parameter are set to those of the message returned, and the call completes with MQCC_WARNING.

Completion Code

MQCC_WARNING

Programmer response

Check the decimal encoding that was specified. If this is correct, check that it is one for which queue-manager conversion is supported. If queue-manager conversion is not supported for the required decimal encoding, conversion must be carried out by the application.

2118 (0846) (RC2118): MQRC_TARGET_FLOAT_ENC_ERROR:

Explanation

On an MQGET call with the MQGMO_CONVERT option included in the *GetMsgOpts* parameter, the *Encoding* value in the *MsgDesc* parameter specifies a floating-point encoding that is not recognized. The message data is returned unconverted, the values of the *CodedCharSetId* and *Encoding* fields in the *MsgDesc* parameter are set to those of the message returned, and the call completes with MQCC_WARNING.

Completion Code

MQCC_WARNING

Programmer response

Check the floating-point encoding that was specified. If this is correct, check that it is one for which queue-manager conversion is supported. If queue-manager conversion is not supported for the required floating-point encoding, conversion must be carried out by the application.

2119 (0847) (RC2119): MQRC_NOT_CONVERTED:

Explanation

An MQGET call was issued with the MQGMO_CONVERT option specified in the *GetMsgOpts* parameter, but an error occurred during conversion of the data in the message. The message data is returned unconverted, the values of the *CodedCharSetId* and *Encoding* fields in the *MsgDesc* parameter are set to those of the message returned, and the call completes with MQCC_WARNING.

If the message consists of several parts, each of which is described by its own *CodedCharSetId* and *Encoding* fields (for example, a message with format name MQFMT_DEAD_LETTER_HEADER), some parts may be converted and other parts not converted. However, the values returned in the various *CodedCharSetId* and *Encoding* fields always correctly describe the relevant message data.

This error may also indicate that a parameter to the data-conversion service is not supported.

Completion Code

MQCC_WARNING

Programmer response

Check that the message data is correctly described by the *Format*, *CodedCharSetId* and *Encoding* parameters that were specified when the message was put. Also check that these values, and the *CodedCharSetId* and *Encoding* specified in the *MsgDesc* parameter on the MQGET call, are supported for queue-manager conversion. If the required conversion is not supported, conversion must be carried out by the application.

2120 (0848) (RC2120): MQRC_CONVERTED_MSG_TOO_BIG:

Explanation

On an MQGET call with the MQGMO_CONVERT option included in the *GetMsgOpts* parameter, the message data expanded during data conversion and exceeded the size of the buffer provided by the application. However, the message had already been removed from the queue because prior to conversion the message data could be accommodated in the application buffer without truncation.

The message is returned unconverted, with the *CompCode* parameter of the MQGET call set to MQCC_WARNING. If the message consists of several parts, each of which is described by its own character-set and encoding fields (for example, a message with format name MQFMT_DEAD_LETTER_HEADER), some parts may be converted and other parts not converted. However, the values returned in the various character-set and encoding fields always correctly describe the relevant message data.

This reason also occurs on the MQXCNVC call, when the *TargetBuffer* parameter is too small to accommodate the converted string, and the string has been truncated to fit in the buffer. The length of valid data returned is given by the *DataLength* parameter; in the case of a DBCS string or mixed SBCS/DBCS string, this length may be *less than* the length of *TargetBuffer*.

Completion Code

MQCC_WARNING

Programmer response

For the MQGET call, check that the exit is converting the message data correctly and setting the output length *DataLength* to the appropriate value. If it is, the application issuing the MQGET call must provide a larger buffer for the *Buffer* parameter.

For the MQXCNVC call, if the string must be converted without truncation, provide a larger output buffer.

2121 (0849) (RC2121): MQRC_NO_EXTERNAL_PARTICIPANTS:

Explanation

An MQBEGIN call was issued to start a unit of work coordinated by the queue manager, but no participating resource managers have been registered with the queue manager. As a result, only changes to MQ resources can be coordinated by the queue manager in the unit of work.

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows.

Completion Code

MQCC_WARNING

Programmer response

If the application does not require non-MQ resources to participate in the unit of work, this reason code can be ignored or the MQBEGIN call removed. Otherwise consult your system programmer to determine why the required resource managers have not been registered with the queue manager; the queue manager's configuration file might be in error.

2122 (084A) (RC2122): MQRC_PARTICIPANT_NOT_AVAILABLE:

Explanation

An MQBEGIN call was issued to start a unit of work coordinated by the queue manager, but one or more of the participating resource managers that had been registered with the queue manager is not available. As a result, changes to those resources cannot be coordinated by the queue manager in the unit of work.

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows.

Completion Code

MQCC_WARNING

Programmer response

If the application does not require non-MQ resources to participate in the unit of work, this reason code can be ignored. Otherwise consult your system programmer to determine why the required resource managers are not available. The resource manager might have been halted temporarily, or there might be an error in the queue manager's configuration file.

2123 (084B) (RC2123): MQRC_OUTCOME_MIXED:

Explanation

The queue manager is acting as the unit-of-work coordinator for a unit of work that involves other resource managers, but one of the following occurred:
- An MQCMIT or MQDISC call was issued to commit the unit of work, but one or more of the participating resource managers backed-out the unit of work instead of committing it. As a result, the outcome of the unit of work is mixed.
- An MQBACK call was issued to back out a unit of work, but one or more of the participating resource managers had already committed the unit of work.

This reason code occurs in the following environments: AIX, HP-UX, Solaris, Windows.

Completion Code

MQCC_FAILED

Programmer response

Examine the queue-manager error logs for messages relating to the mixed outcome; these messages identify the resource managers that are affected. Use procedures local to the affected resource managers to resynchronize the resources.

This reason code does not prevent the application initiating further units of work.

2124 (084C) (RC2124): MQRC_OUTCOME_PENDING:

Explanation

The queue manager is acting as the unit-of-work coordinator for a unit of work that involves other resource managers, and an MQCMIT or MQDISC call was issued to commit the unit of work, but one or more of the participating resource managers has not confirmed that the unit of work was committed successfully.

The completion of the commit operation will happen at some point in the future, but there remains the possibility that the outcome will be mixed.

AIX HP-UX Solaris Windows This reason code occurs in the following environments: AIX, HP-UX, Solaris, Windows.

z/OS On z/OS, this situation can occur if a queue manager loses connectivity to a coupling facility structure while a unit of work that affects messages on shared queues is being committed or backed out.

Completion Code

MQCC_WARNING

Programmer response

AIX HP-UX Solaris Windows Use the normal error-reporting mechanisms to determine whether the outcome was mixed. If it was, take appropriate action to resynchronize the resources.

AIX HP-UX Solaris Windows This reason code does not prevent the application initiating further units of work.

z/OS If this reason code was returned as a result of loss of connectivity to a coupling facility structure on z/OS, the operation will be completed either when the queue manager reconnects to the affected structure, or when another queue manager in the queue-sharing group is able to perform peer recovery on the structure.

2125 (084D) (RC2125): MQRC_BRIDGE_STARTED:

Explanation

The IMS bridge has been started.

Completion Code

MQCC_WARNING

Programmer response

None. This reason code is only used to identify the corresponding event message Bridge Started.

2126 (084E) (RC2126): MQRC_BRIDGE_STOPPED:

Explanation

The IMS bridge has been stopped.

Completion Code

MQCC_WARNING

Programmer response

None. This reason code is only used to identify the corresponding event message Bridge Stopped.

2127 (084F) (RC2127): MQRC_ADAPTER_STORAGE_SHORTAGE:

Explanation

On an MQCONN call, the adapter was unable to acquire storage.

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

Notify the system programmer. The system programmer should determine why the system is short on storage, and take appropriate action, for example, increase the region size on the step or job card.

2128 (0850) (RC2128): MQRC_UOW_IN_PROGRESS:

Explanation

An MQBEGIN call was issued to start a unit of work coordinated by the queue manager, but a unit of work is already in existence for the connection handle specified. This may be a global unit of work started by a previous MQBEGIN call, or a unit of work that is local to the queue manager or one of the cooperating resource managers. No more than one unit of work can exist concurrently for a connection handle.

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows.

Completion Code

MQCC_FAILED

Programmer response

Review the application logic to determine why there is a unit of work already in existence. Move the MQBEGIN call to the appropriate place in the application.

2129 (0851) (RC2129): MQRC_ADAPTER_CONN_LOAD_ERROR:

Explanation

On an MQCONN call, the connection handling module could not be loaded, so the adapter could not link to it. The connection handling module name is:

- CSQBCON for batch applications
- CSQQCONN or CSQQCON2 for IMS applications

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

Ensure that the correct library concatenation has been specified in the batch application program execution JCL, and in the queue-manager startup JCL.

2130 (0852) (RC2130): MQRC_ADAPTER_SERV_LOAD_ERROR:

Explanation

On an MQI call, the batch adapter could not load one of the following API service module, and so could not link to it:

- CSQBSRV
- CSQAPEPL
- CSQBCRMH
- CSQBAPPL

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

Ensure that the correct library concatenation has been specified in the batch application program execution JCL, and in the queue-manager startup JCL.

2131 (0853) (RC2131): MQRC_ADAPTER_DEFS_ERROR:

Explanation

On an MQCONN call, the subsystem definition module (CSQBDEFV for batch and CSQQDEFV for IMS) does not contain the required control block identifier.

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

Check your library concatenation. If this is correct, check that the CSQBDEFV or CSQQDEFV module contains the required subsystem ID.

2132 (0854) (RC2132): MQRC_ADAPTER_DEFS_LOAD_ERROR:

Explanation

On an MQCONN call, the subsystem definition module (CSQBDEFV for batch and CSQQDEFV for IMS) could not be loaded.

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

Ensure that the correct library concatenation has been specified in the application program execution JCL, and in the queue-manager startup JCL.

2133 (0855) (RC2133): MQRC_ADAPTER_CONV_LOAD_ERROR:

Explanation

On an MQGET call, the adapter (batch or IMS) could not load the data conversion services modules.

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

Ensure that the correct library concatenation has been specified in the batch application program execution JCL, and in the queue-manager startup JCL.

2134 (0856) (RC2134): MQRC_BO_ERROR:

Explanation

On an MQBEGIN call, the begin-options structure MQBO is not valid, for one of the following reasons:
- The *StrucId* field is not MQBO_STRUC_ID.
- The *Version* field is not MQBO_VERSION_1.
- The parameter pointer is not valid. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)
- The queue manager cannot copy the changed structure to application storage, even though the call is successful. This can occur, for example, if the pointer points to read-only storage.

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Ensure that input fields in the MQBO structure are set correctly.

2135 (0857) (RC2135): MQRC_DH_ERROR:

Explanation

An MQPUT or MQPUT1 call was issued, but the message data contains an MQDH structure that is not valid. Possible errors include the following:
- The *StrucId* field is not MQDH_STRUC_ID.
- The *Version* field is not MQDH_VERSION_1.
- The *StrucLength* field specifies a value that is too small to include the structure plus the arrays of MQOR and MQPMR records.
- The *CodedCharSetId* field is zero, or a negative value that is not valid.
- The *BufferLength* parameter of the call has a value that is too small to accommodate the structure (the structure extends beyond the end of the message).

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Check that the fields in the structure are set correctly. Ensure that the application sets the *CodedCharSetId* field to a valid value (note: MQCCSI_DEFAULT, MQCCSI_EMBEDDED, MQCCSI_Q_MGR, and MQCCSI_UNDEFINED are *not* valid in this field).

2136 (0858) (RC2136): MQRC_MULTIPLE_REASONS:

Explanation

An MQOPEN, MQPUT or MQPUT1 call was issued to open a distribution list or put a message to a distribution list, but the result of the call was not the same for all of the destinations in the list. One of the following applies:

- The call succeeded for some of the destinations but not others. The completion code is MQCC_WARNING in this case.
- The call failed for all of the destinations, but for differing reasons. The completion code is MQCC_FAILED in this case.

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_WARNING or MQCC_FAILED

Programmer response

Examine the MQRR response records to identify the destinations for which the call failed, and the reason for the failure. Ensure that sufficient response records are provided by the application on the call to enable the error(s) to be determined. For the MQPUT1 call, the response records must be specified using the MQOD structure, and not the MQPMO structure.

2137 (0859) (RC2137): MQRC_OPEN_FAILED:

Explanation

A queue or other MQ object could not be opened successfully, for one of the following reasons:

- An MQCONN or MQCONNX call was issued, but the queue manager was unable to open an object that is used internally by the queue manager. As a result, processing cannot continue. The error log will contain the name of the object that could not be opened.
- An MQPUT call was issued to put a message to a distribution list, but the message could not be sent to the destination to which this reason code applies because that destination was not opened successfully by the MQOPEN call. This reason occurs only in the *Reason* field of the MQRR response record.

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Do one of the following:

- If the error occurred on the MQCONN or MQCONNX call, ensure that the required objects exist by running the following command and then retrying the application:
  ```
  STRMQM -c qmgr
  ```
  where `qmgr` should be replaced by the name of the queue manager.

- If the error occurred on the MQPUT call, examine the MQRR response records specified on the MQOPEN call to determine the reason that the queue failed to open. Ensure that sufficient response records are provided by the application on the call to enable the error(s) to be determined.

2138 (085A) (RC2138): MQRC_ADAPTER_DISC_LOAD_ERROR:

Explanation

On an MQDISC call, the disconnect handling module (CSQBDSC for batch and CSQQDISC for IMS) could not be loaded, so the adapter could not link to it.

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

Ensure that the correct library concatenation has been specified in the application program execution JCL, and in the queue-manager startup JCL. Any uncommitted changes in a unit of work should be backed out. A unit of work that is coordinated by the queue manager is backed out automatically.

2139 (085B) (RC2139): MQRC_CNO_ERROR:

Explanation

On an MQCONNX call, the connect-options structure MQCNO is not valid, for one of the following reasons:
- The *StrucId* field is not MQCNO_STRUC_ID.
- The *Version* field specifies a value that is not valid or not supported.
- The parameter pointer is not valid. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)
- The queue manager cannot copy the changed structure to application storage, even though the call is successful. This can occur, for example, if the parameter pointer points to read-only storage.

This reason code occurs in the following environments: AIX, HP-UX, z/OS, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Ensure that input fields in the MQCNO structure are set correctly.

2140 (085C) (RC2140): MQRC_CICS_WAIT_FAILED:

Explanation

On any MQI call, the CICS adapter issued an EXEC CICS WAIT request, but the request was rejected by CICS.

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

Examine the CICS trace data for actual response codes. The most likely cause is that the task has been canceled by the operator or by the system.

2141 (085D) (RC2141): MQRC_DLH_ERROR:

Explanation

An MQPUT or MQPUT1 call was issued, but the message data contains an MQDLH structure that is not valid. Possible errors include the following:

- The *StrucId* field is not MQDLH_STRUC_ID.
- The *Version* field is not MQDLH_VERSION_1.
- The *CodedCharSetId* field is zero, or a negative value that is not valid.
- The *BufferLength* parameter of the call has a value that is too small to accommodate the structure (the structure extends beyond the end of the message).

This reason code occurs in the following environments: AIX, HP-UX, z/OS, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Check that the fields in the structure are set correctly. Ensure that the application sets the *CodedCharSetId* field to a valid value (note: MQCCSI_DEFAULT, MQCCSI_EMBEDDED, MQCCSI_Q_MGR, and MQCCSI_UNDEFINED are *not* valid in this field).

2142 (085E) (RC2142): MQRC_HEADER_ERROR:

Explanation

An MQPUT or MQPUT1 call was issued, but the message data contains an MQ header structure that is not valid. Possible errors include the following:

- The *StrucId* field is not valid.
- The *Version* field is not valid.
- The *StrucLength* field specifies a value that is too small.
- The *CodedCharSetId* field is zero, or a negative value that is not valid.
- The *BufferLength* parameter of the call has a value that is too small to accommodate the structure (the structure extends beyond the end of the message).

This reason code occurs in the following environments: AIX, HP-UX, z/OS, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Check that the fields in the structure are set correctly. Ensure that the application sets the *CodedCharSetId* field to a valid value (note: MQCCSI_DEFAULT, MQCCSI_EMBEDDED, MQCCSI_Q_MGR, and MQCCSI_UNDEFINED are *not* valid in this field).

2143 (085F) (RC2143): MQRC_SOURCE_LENGTH_ERROR:

Explanation

On the MQXCNVC call, the *SourceLength* parameter specifies a length that is less than zero or not consistent with the string's character set or content (for example, the character set is a double-byte character set, but the length is not a multiple of two). This reason also occurs if the *SourceLength* parameter pointer is not valid. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)

This reason code can also occur on the MQGET call when the MQGMO_CONVERT option is specified. In this case it indicates that the MQRC_SOURCE_LENGTH_ERROR reason was returned by an MQXCNVC call issued by the data conversion exit.

Completion Code

MQCC_WARNING or MQCC_FAILED

Programmer response

Specify a length that is zero or greater. If the reason code occurs on the MQGET call, check that the logic in the data-conversion exit is correct.

2144 (0860) (RC2144): MQRC_TARGET_LENGTH_ERROR:

Explanation

On the MQXCNVC call, the `TargetLength` parameter is not valid for one of the following reasons:
- `TargetLength` is less than zero.
- The `TargetLength` parameter pointer is not valid. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)
- The MQDCC_FILL_TARGET_BUFFER option is specified, but the value of `TargetLength` is such that the target buffer cannot be filled completely with valid characters. This can occur when `TargetCCSID` is a pure DBCS character set (such as UCS-2), but `TargetLength` specifies a length that is an odd number of bytes.

This reason code can also occur on the MQGET call when the MQGMO_CONVERT option is specified. In this case it indicates that the MQRC_TARGET_LENGTH_ERROR reason was returned by an MQXCNVC call issued by the data conversion exit.

Completion Code

MQCC_WARNING or MQCC_FAILED

Programmer response

Specify a length that is zero or greater. If the MQDCC_FILL_TARGET_BUFFER option is specified, and `TargetCCSID` is a pure DBCS character set, ensure that `TargetLength` specifies a length that is a multiple of two.

If the reason code occurs on the MQGET call, check that the logic in the data-conversion exit is correct.

2145 (0861) (RC2145): MQRC_SOURCE_BUFFER_ERROR:

Explanation

On the MQXCNVC call, the `SourceBuffer` parameter pointer is not valid, or points to storage that cannot be accessed for the entire length specified by `SourceLength`. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)

This reason code can also occur on the MQGET call when the MQGMO_CONVERT option is specified. In this case it indicates that the MQRC_SOURCE_BUFFER_ERROR reason was returned by an MQXCNVC call issued by the data conversion exit.

Completion Code

MQCC_WARNING or MQCC_FAILED

Programmer response

Specify a valid buffer. If the reason code occurs on the MQGET call, check that the logic in the data-conversion exit is correct.

2146 (0862) (RC2146): MQRC_TARGET_BUFFER_ERROR:

Explanation

On the MQXCNVC call, the *TargetBuffer* parameter pointer is not valid, or points to read-only storage, or to storage that cannot be accessed for the entire length specified by *TargetLength*. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)

This reason code can also occur on the MQGET call when the MQGMO_CONVERT option is specified. In this case it indicates that the MQRC_TARGET_BUFFER_ERROR reason was returned by an MQXCNVC call issued by the data conversion exit.

Completion Code

MQCC_WARNING or MQCC_FAILED

Programmer response

Specify a valid buffer. If the reason code occurs on the MQGET call, check that the logic in the data-conversion exit is correct.

2148 (0864) (RC2148): MQRC_IIH_ERROR:

Explanation

An MQPUT or MQPUT1 call was issued, but the message data contains an MQIIH structure that is not valid. Possible errors include the following:

- The *StrucId* field is not MQIIH_STRUC_ID.
- The *Version* field is not MQIIH_VERSION_1.
- The *StrucLength* field is not MQIIH_LENGTH_1.
- The *BufferLength* parameter of the call has a value that is too small to accommodate the structure (the structure extends beyond the end of the message).

This reason code occurs in the following environments: AIX, HP-UX, z/OS, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Check that the fields in the structure are set correctly.

2149 (0865) (RC2149): MQRC_PCF_ERROR:

Explanation

An MQPUT or MQPUT1 call was issued to put a message containing PCF data, but the length of the message does not equal the sum of the lengths of the PCF structures present in the message. This can occur for messages with the following format names:
- MQFMT_ADMIN
- MQFMT_EVENT
- MQFMT_PCF

This reason code occurs in the following environments: AIX, HP-UX, z/OS, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Ensure that the length of the message specified on the MQPUT or MQPUT1 call equals the sum of the lengths of the PCF structures contained within the message data.

2150 (0866) (RC2150): MQRC_DBCS_ERROR:

Explanation

An error was encountered attempting to convert a double-byte character set (DBCS) string. This can occur in the following cases:
- On the MQXCNVC call, when the *SourceCCSID* parameter specifies the coded character-set identifier of a double-byte character set, but the *SourceBuffer* parameter does not contain a valid DBCS string. This may be because the string contains characters that are not valid DBCS characters, or because the string is a mixed SBCS/DBCS string and the shift-out/shift-in characters are not correctly paired. The completion code is MQCC_FAILED in this case.
- On the MQGET call, when the MQGMO_CONVERT option is specified. In this case it indicates that the MQRC_DBCS_ERROR reason code was returned by an MQXCNVC call issued by the data conversion exit. The completion code is MQCC_WARNING in this case.

Completion Code

MQCC_WARNING or MQCC_FAILED

Programmer response

Specify a valid string.

If the reason code occurs on the MQGET call, check that the data in the message is valid, and that the logic in the data-conversion exit is correct.

2152 (0868) (RC2152): MQRC_OBJECT_NAME_ERROR:

Explanation

An MQOPEN or MQPUT1 call was issued to open a distribution list (that is, the `RecsPresent` field in MQOD is greater than zero), but the `ObjectName` field is neither blank nor the null string.

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

If it is intended to open a distribution list, set the `ObjectName` field to blanks or the null string. If it is not intended to open a distribution list, set the `RecsPresent` field to zero.

2153 (0869) (RC2153): MQRC_OBJECT_Q_MGR_NAME_ERROR:

Explanation

An MQOPEN or MQPUT1 call was issued to open a distribution list (that is, the `RecsPresent` field in MQOD is greater than zero), but the `ObjectQMgrName` field is neither blank nor the null string.

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

If it is intended to open a distribution list, set the `ObjectQMgrName` field to blanks or the null string. If it is not intended to open a distribution list, set the `RecsPresent` field to zero.

2154 (086A) (RC2154): MQRC_RECS_PRESENT_ERROR:

Explanation

An MQOPEN or MQPUT1 call was issued, but the call failed for one of the following reasons:
- `RecsPresent` in MQOD is less than zero.
- `ObjectType` in MQOD is not MQOT_Q, and `RecsPresent` is not zero. `RecsPresent` must be zero if the object being opened is not a queue.
- IBM MQ Multicast is being used and `RecsPresent` in MQOD is not set to zero. IBM MQ Multicast does not use distribution lists.

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

If it is intended to open a distribution list, set the *ObjectType* field to MQOT_Q and *RecsPresent* to the number of destinations in the list. If it is not intended to open a distribution list, set the *RecsPresent* field to zero.

2155 (086B) (RC2155): MQRC_OBJECT_RECORDS_ERROR:

Explanation

An MQOPEN or MQPUT1 call was issued to open a distribution list (that is, the *RecsPresent* field in MQOD is greater than zero), but the MQOR object records are not specified correctly. One of the following applies:

- *ObjectRecOffset* is zero and *ObjectRecPtr* is zero or the null pointer.
- *ObjectRecOffset* is not zero and *ObjectRecPtr* is not zero and not the null pointer.
- *ObjectRecPtr* is not a valid pointer.
- *ObjectRecPtr* or *ObjectRecOffset* points to storage that is not accessible.

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Ensure that one of *ObjectRecOffset* and *ObjectRecPtr* is zero and the other nonzero. Ensure that the field used points to accessible storage.

2156 (086C) (RC2156): MQRC_RESPONSE_RECORDS_ERROR:

Explanation

An MQOPEN or MQPUT1 call was issued to open a distribution list (that is, the *RecsPresent* field in MQOD is greater than zero), but the MQRR response records are not specified correctly. One of the following applies:

- *ResponseRecOffset* is not zero and *ResponseRecPtr* is not zero and not the null pointer.
- *ResponseRecPtr* is not a valid pointer.
- *ResponseRecPtr* or *ResponseRecOffset* points to storage that is not accessible.

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Ensure that at least one of *ResponseRecOffset* and *ResponseRecPtr* is zero. Ensure that the field used points to accessible storage.

2157 (086D) (RC2157): MQRC_ASID_MISMATCH:

Explanation

On any MQI call, the caller's primary ASID was found to be different from the home ASID.

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

Correct the application (MQI calls cannot be issued in cross-memory mode). Any uncommitted changes in a unit of work should be backed out. A unit of work that is coordinated by the queue manager is backed out automatically.

2158 (086E) (RC2158): MQRC_PMO_RECORD_FLAGS_ERROR:

Explanation

An MQPUT or MQPUT1 call was issued to put a message, but the `PutMsgRecFields` field in the MQPMO structure is not valid, for one of the following reasons:

- The field contains flags that are not valid.
- The message is being put to a distribution list, and put message records have been provided (that is, `RecsPresent` is greater than zero, and one of `PutMsgRecOffset` or `PutMsgRecPtr` is nonzero), but `PutMsgRecFields` has the value MQPMRF_NONE.
- MQPMRF_ACCOUNTING_TOKEN is specified without either MQPMO_SET_IDENTITY_CONTEXT or MQPMO_SET_ALL_CONTEXT.

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Ensure that `PutMsgRecFields` is set with the appropriate MQPMRF_* flags to indicate which fields are present in the put message records. If MQPMRF_ACCOUNTING_TOKEN is specified, ensure that either MQPMO_SET_IDENTITY_CONTEXT or MQPMO_SET_ALL_CONTEXT is also specified. Alternatively, set both `PutMsgRecOffset` and `PutMsgRecPtr` to zero.

2159 (086F) (RC2159): MQRC_PUT_MSG_RECORDS_ERROR:

Explanation

An MQPUT or MQPUT1 call was issued to put a message to a distribution list, but the MQPMR put message records are not specified correctly. One of the following applies:
- *PutMsgRecOffset* is not zero and *PutMsgRecPtr* is not zero and not the null pointer.
- *PutMsgRecPtr* is not a valid pointer.
- *PutMsgRecPtr* or *PutMsgRecOffset* points to storage that is not accessible.

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Ensure that at least one of *PutMsgRecOffset* and *PutMsgRecPtr* is zero. Ensure that the field used points to accessible storage.

2160 (0870) (RC2160): MQRC_CONN_ID_IN_USE:

Explanation

On an MQCONN call, the connection identifier assigned by the queue manager to the connection between a CICS or IMS allied address space and the queue manager conflicts with the connection identifier of another connected CICS or IMS system. The connection identifier assigned is as follows:
- For CICS, the applid
- For IMS, the IMSID parameter on the IMSCTRL (sysgen) macro, or the IMSID parameter on the execution parameter (EXEC card in IMS control region JCL)
- For batch, the job name
- For TSO, the user ID

A conflict arises only if there are two CICS systems, two IMS systems, or one each of CICS and IMS, having the same connection identifiers. Batch and TSO connections need not have unique identifiers.

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

Ensure that the naming conventions used in different systems that might connect to the queue manager do not conflict.

2161 (0871) (RC2161): MQRC_Q_MGR_QUIESCING:

Explanation

An MQI call was issued, but the call failed because the queue manager is quiescing (preparing to shut down).

When the queue manager is quiescing, the MQOPEN, MQPUT, MQPUT1, and MQGET calls can still complete successfully, but the application can request that they fail by specifying the appropriate option on the call:
- MQOO_FAIL_IF_QUIESCING on MQOPEN
- MQPMO_FAIL_IF_QUIESCING on MQPUT or MQPUT1
- MQGMO_FAIL_IF_QUIESCING on MQGET

Specifying these options enables the application to become aware that the queue manager is preparing to shut down.
- On z/OS:
  - For batch applications, this reason can be returned to applications running in LPARs that do not have a queue manager installed.
  - For CICS applications, this reason can be returned when no connection was established.
- On IBM i for applications running in compatibility mode, this reason can be returned when no connection was established.

Completion Code

MQCC_FAILED

Programmer response

The application should tidy up and end. If the application specified the MQOO_FAIL_IF_QUIESCING, MQPMO_FAIL_IF_QUIESCING, or MQGMO_FAIL_IF_QUIESCING option on the failing call, the relevant option can be removed and the call reissued. By omitting these options, the application can continue working to complete and commit the current unit of work, but the application does not start a new unit of work.

2162 (0872) (RC2162): MQRC_Q_MGR_STOPPING:

Explanation

An MQI call was issued, but the call failed because the queue manager is shutting down. If the call was an MQGET call with the MQGMO_WAIT option, the wait has been canceled. No more MQI calls can be issued.

For MQ MQI client applications, it is possible that the call did complete successfully, even though this reason code is returned with a `CompCode` of MQCC_FAILED.
- On z/OS, the MQRC_CONNECTION_BROKEN reason may be returned instead if, as a result of system scheduling factors, the queue manager shuts down before the call completes.

Completion Code

MQCC_FAILED

Programmer response

The application should tidy up and end. If the application is in the middle of a unit of work coordinated by an external unit-of-work coordinator, the application should issue the appropriate call to back out the unit of work. Any unit of work that is coordinated by the queue manager is backed out automatically.

2163 (0873) (RC2163): MQRC_DUPLICATE_RECOV_COORD:

Explanation

On an MQCONN or MQCONNX call, a recovery coordinator already exists for the connection name specified on the connection call issued by the adapter.

A conflict arises only if there are two CICS systems, two IMS systems, or one each of CICS and IMS, having the same connection identifiers. Batch and TSO connections need not have unique identifiers.

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

Ensure that the naming conventions used in different systems that might connect to the queue manager do not conflict.

2173 (087D) (RC2173): MQRC_PMO_ERROR:

Explanation

On an MQPUT or MQPUT1 call, the MQPMO structure is not valid, for one of the following reasons:
- The *StrucId* field is not MQPMO_STRUC_ID.
- The *Version* field specifies a value that is not valid or not supported.
- The parameter pointer is not valid. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)
- The queue manager cannot copy the changed structure to application storage, even though the call is successful. This can occur, for example, if the pointer points to read-only storage.

Completion Code

MQCC_FAILED

Programmer response

Ensure that input fields in the MQPMO structure are set correctly.

2182 (0886) (RC2182): MQRC_API_EXIT_NOT_FOUND:

Explanation

The API crossing exit entry point could not be found.

Completion Code

MQCC_FAILED

Programmer response

Check the entry point name is valid for the library module.

2183 (0887) (RC2183): MQRC_API_EXIT_LOAD_ERROR:

Explanation

The API crossing exit module could not be linked to. If this message is returned when the API crossing exit is called *after* the process has been run, the process itself might have completed correctly.

Completion Code

MQCC_FAILED

Programmer response

Ensure that the correct library concatenation has been specified, and that the API crossing exit module is executable and correctly named. Any uncommitted changes in a unit of work should be backed out. A unit of work that is coordinated by the queue manager is backed out automatically.

2184 (0888) (RC2184): MQRC_REMOTE_Q_NAME_ERROR:

Explanation

On an MQOPEN or MQPUT1 call, one of the following occurred:
- A local definition of a remote queue (or an alias to one) was specified, but the *RemoteQName* attribute in the remote queue definition is entirely blank. Note that this error occurs even if the *XmitQName* in the definition is not blank.
- The *ObjectQMgrName* field in the object descriptor is not blank and not the name of the local queue manager, but the *ObjectName* field is blank.

Completion Code

MQCC_FAILED

Programmer response

Alter the local definition of the remote queue and supply a valid remote queue name, or supply a nonblank *ObjectName* in the object descriptor, as appropriate.

This reason code is also used to identify the corresponding event message Remote Queue Name Error.

2185 (0889) (RC2185): MQRC_INCONSISTENT_PERSISTENCE:

Explanation

An MQPUT call was issued to put a message in a group or a segment of a logical message, but the value specified or defaulted for the *Persistence* field in MQMD is not consistent with the current group and segment information retained by the queue manager for the queue handle. All messages in a group and all segments in a logical message must have the same value for persistence, that is, all must be persistent, or all must be nonpersistent.

If the current call specifies MQPMO_LOGICAL_ORDER, the call fails. If the current call does not specify MQPMO_LOGICAL_ORDER, but the previous MQPUT call for the queue handle did, the call succeeds with completion code MQCC_WARNING.

This reason code occurs in the following environments: AIX, HP-UX, z/OS, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_WARNING or MQCC_FAILED

Programmer response

Modify the application to ensure that the same value of persistence is used for all messages in the group, or all segments of the logical message.

2186 (088A) (RC2186): MQRC_GMO_ERROR:

Explanation

On an MQGET call, the MQGMO structure is not valid, for one of the following reasons:
- The *StrucId* field is not MQGMO_STRUC_ID.
- The *Version* field specifies a value that is not valid or not supported.
- The parameter pointer is not valid. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)
- The queue manager cannot copy the changed structure to application storage, even though the call is successful. This can occur, for example, if the pointer points to read-only storage.

Completion Code

MQCC_FAILED

Programmer response

Ensure that input fields in the MQGMO structure are set correctly.

2187 (088B) (RC2187): MQRC_CICS_BRIDGE_RESTRICTION:

Explanation

It is not permitted to issue MQI calls from user transactions that are run in an MQ/CICS bridge environment where the bridge exit also issues MQI calls. The MQI call fails. If it occurs in the bridge exit, it results in a transaction abend. If it occurs in the user transaction, it can result in a transaction abend.

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

The transaction cannot be run using the MQ/CICS bridge. Refer to the appropriate CICS manual for information about restrictions in the MQ/CICS bridge environment.

2188 (088C) (RC2188): MQRC_STOPPED_BY_CLUSTER_EXIT:

Explanation

An MQOPEN, MQPUT, or MQPUT1 call was issued to open or put a message on a cluster queue, but the cluster workload exit rejected the call.

This reason code occurs in the following environments: AIX, HP-UX, z/OS, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Check the cluster workload exit to ensure that it has been written correctly. Determine why it rejected the call and correct the problem.

2189 (088D) (RC2189): MQRC_CLUSTER_RESOLUTION_ERROR:

Explanation

An MQOPEN, MQPUT, or MQPUT1 call was issued to open or put a message on a cluster queue, but the queue definition could not be resolved correctly because a response was required from the repository manager but none was available.

This reason code occurs in the following environments: AIX, HP-UX, z/OS, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Check that the repository manager is operating and that the queue and channel definitions are correct.

2190 (088E) (RC2190): MQRC_CONVERTED_STRING_TOO_BIG:

Explanation

On an MQGET call with the MQGMO_CONVERT option included in the `GetMsgOpts` parameter, a string in a fixed-length field in the message expanded during data conversion and exceeded the size of the field. When this happens, the queue manager tries discarding trailing blank characters and characters following the first null character to make the string fit, but in this case there were insufficient characters that could be discarded.

This reason code can also occur for messages with a format name of MQFMT_IMS_VAR_STRING. When this happens, it indicates that the IMS variable string expanded such that its length exceeded the capacity of the 2 byte binary length field contained within the structure of the IMS variable string. (The queue manager never discards trailing blanks in an IMS variable string.)

The message is returned unconverted, with the `CompCode` parameter of the MQGET call set to MQCC_WARNING. If the message consists of several parts, each of which is described by its own character-set and encoding fields (for example, a message with format name MQFMT_DEAD_LETTER_HEADER), some parts might be converted and other parts not converted. However, the values returned in the various character-set and encoding fields always correctly describe the relevant message data.

This reason code does not occur if the string can be made to fit by discarding trailing blank characters.

Completion Code

MQCC_WARNING

Programmer response

Check that the fields in the message contain the correct values, and that the character-set identifiers specified by the sender and receiver of the message are correct. If they are, the layout of the data in the message must be modified to increase the lengths of the field, or fields so that there is sufficient space to permit the string, or strings to expand when converted.

2191 (088F) (RC2191): MQRC_TMC_ERROR:

Explanation

An MQPUT or MQPUT1 call was issued, but the message data contains an MQTMC2 structure that is not valid. Possible errors include the following:
- The `StrucId` field is not MQTMC_STRUC_ID.
- The `Version` field is not MQTMC_VERSION_2.
- The `BufferLength` parameter of the call has a value that is too small to accommodate the structure (the structure extends beyond the end of the message).

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Check that the fields in the structure are set correctly.

2192 (0890) (RC2192): MQRC_PAGESET_FULL:

Explanation

Former name for MQRC_STORAGE_MEDIUM_FULL.

2192 (0890) (RC2192): MQRC_STORAGE_MEDIUM_FULL:

Explanation

An MQI call or command was issued to operate on an object, but the call failed because the external storage medium is full. One of the following applies:

- A page-set data set is full (nonshared queues only).
- A coupling-facility structure is full (shared queues only).
- A coupling-facility is full. This situation can arise when the coupling facility structure is configured to use SCM storage (SCMMAXSIZE configured in CFRM policy) and messages are offloaded to SCM storage because the coupling facility structure has reached 90% threshold. Additional SCM use requires further augmented storage for the structure and there is insufficient storage in the coupling-facility to support this.
- The SMDS was full.

You can get this reason code when the page set or SMDS were expanding, but the space was not yet available. Check the messages in the job log to see the status of any expansion.

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

Check which queues contain messages and look for applications that might be filling the queues unintentionally. Be aware that the queue that has caused the page set or coupling-facility structure to become full is not necessarily the queue referenced by the MQI call that returned MQRC_STORAGE_MEDIUM_FULL.

Check that all of the usual server applications are operating correctly and processing the messages on the queues.

If the applications and servers are operating correctly, increase the number of server applications to cope with the message load, or request the system programmer to increase the size of the page-set data sets.

2193 (0891) (RC2193): MQRC_PAGESET_ERROR:

Explanation

An error was encountered with the page set while attempting to access it for a locally defined queue. This could be because the queue is on a page set that does not exist. A console message is issued that tells you the number of the page set in error. For example if the error occurred in the TEST job, and your user identifier is ABCDEFG, the message is:

```
CSQI041I CSQIALLC JOB TEST USER ABCDEFG HAD ERROR ACCESSING PAGE SET 27
```

If this reason code occurs while attempting to delete a dynamic queue with MQCLOSE, the dynamic queue has not been deleted.

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

Check that the storage class for the queue maps to a valid page set using the DISPLAY Q(xx) STGCLASS, DISPLAY STGCLASS(xx), and DISPLAY USAGE PSID commands. If you are unable to resolve the problem, notify the system programmer who should:

- Collect the following diagnostic information:
  - A description of the actions that led to the error
  - A listing of the application program being run at the time of the error
  - Details of the page sets defined for use by the queue manager
- Attempt to re-create the problem, and take a system dump immediately after the error occurs
- Contact your IBM Support Center

2194 (0892) (RC2194): MQRC_NAME_NOT_VALID_FOR_TYPE:

Explanation

An MQOPEN call was issued to open the queue manager definition, but the *ObjectName* field in the *ObjDesc* parameter is not blank.

Completion Code

MQCC_FAILED

Programmer response

Ensure that the *ObjectName* field is set to blanks.

2195 (0893) (RC2195): MQRC_UNEXPECTED_ERROR:

Explanation

The call was rejected because an unexpected error occurred.

Completion Code

MQCC_FAILED

Programmer response

Check the application's parameter list to ensure, for example, that the correct number of parameters was passed, and that data pointers and storage keys are valid. If the problem cannot be resolved, contact your system programmer.

- On z/OS, check the joblog and logrec, and whether any information has been displayed on the console. If this error occurs on an MQCONN or MQCONNX call, check that the subsystem named is an active MQ subsystem. In particular, check that it is not a Db2 subsystem. If the problem cannot be resolved, rerun the application with a CSQSNAP DD card (if you have not already got a dump) and send the resulting dump to IBM.
- On IBM i, consult the FFST record to obtain more detail about the problem.
- On HP Integrity NonStop Server, and UNIX systems, consult the FDC file to obtain more detail about the problem.

2196 (0894) (RC2196): MQRC_UNKNOWN_XMIT_Q:

Explanation

On an MQOPEN or MQPUT1 call, a message is to be sent to a remote queue manager. The *ObjectName* or the *ObjectQMgrName* in the object descriptor specifies the name of a local definition of a remote queue (in the latter case queue-manager aliasing is being used), but the *XmitQName* attribute of the definition is not blank and not the name of a locally-defined queue.

Completion Code

MQCC_FAILED

Programmer response

Check the values specified for *ObjectName* and *ObjectQMgrName*. If these are correct, check the queue definitions.

This reason code is also used to identify the corresponding event message Unknown Transmission Queue.

2197 (0895) (RC2197): MQRC_UNKNOWN_DEF_XMIT_Q:

Explanation

An MQOPEN or MQPUT1 call was issued specifying a remote queue as the destination. If a local definition of the remote queue was specified, or if a queue-manager alias is being resolved, the *XmitQName* attribute in the local definition is blank.

Because there is no queue defined with the same name as the destination queue manager, the queue manager has attempted to use the default transmission queue. However, the name defined by the *DefXmitQName* queue-manager attribute is not the name of a locally-defined queue.

Completion Code

MQCC_FAILED

Programmer response

Correct the queue definitions, or the queue-manager attribute.

This reason code is also used to identify the corresponding event message Unknown Default Transmission Queue.

2198 (0896) (RC2198): MQRC_DEF_XMIT_Q_TYPE_ERROR:

Explanation

An MQOPEN or MQPUT1 call was issued specifying a remote queue as the destination. Either a local definition of the remote queue was specified, or a queue-manager alias was being resolved, but in either case the *XmitQName* attribute in the local definition is blank.

Because there is no transmission queue defined with the same name as the destination queue manager, the local queue manager has attempted to use the default transmission queue. However, although there is a queue defined by the *DefXmitQName* queue-manager attribute, it is not a local queue.

Completion Code

MQCC_FAILED

Programmer response

Do one of the following:
- Specify a local transmission queue as the value of the *XmitQName* attribute in the local definition of the remote queue.
- Define a local transmission queue with a name that is the same as that of the remote queue manager.
- Specify a local transmission queue as the value of the *DefXmitQName* queue-manager attribute.

See XmitQName for more information about transmission queue names.

This reason code is also used to identify the corresponding event message Default Transmission Queue Type Errorr.

2199 (0897) (RC2199): MQRC_DEF_XMIT_Q_USAGE_ERROR:

Explanation

An MQOPEN or MQPUT1 call was issued specifying a remote queue as the destination. Either a local definition of the remote queue was specified, or a queue-manager alias was being resolved, but in either case the *XmitQName* attribute in the local definition is blank.

Because there is no transmission queue defined with the same name as the destination queue manager, the local queue manager has attempted to use the default transmission queue. However, the queue defined by the *DefXmitQName* queue-manager attribute does not have a *Usage* attribute of MQUS_TRANSMISSION.

This reason code is returned from MQOPEN or MQPUT1, if the queue manager's Default Transmission Queue is about to be used, but the name of this queue is SYSTEM.CLUSTER.TRANSMIT.QUEUE. This queue is reserved for clustering, so it is not valid to set the queue manager's Default Transmission Queue to this name.

Completion Code

MQCC_FAILED

Programmer response

Do one of the following:
- Specify a local transmission queue as the value of the *XmitQName* attribute in the local definition of the remote queue.
- Define a local transmission queue with a name that is the same as that of the remote queue manager.
- Specify a different local transmission queue as the value of the *DefXmitQName* queue-manager attribute.
- Change the *Usage* attribute of the *DefXmitQName* queue to MQUS_TRANSMISSION.

See XmitQName for more information about transmission queue names.

This reason code is also used to identify the corresponding event message Default Transmission Queue Usage Error.

2201 (0899) (RC2201): MQRC_NAME_IN_USE:

Explanation

An MQOPEN call was issued to create a dynamic queue, but a queue with the same name as the dynamic queue already exists. The existing queue is one that is logically deleted, but for which there are still one or more open handles. For more information, see MQOPEN.

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

Either ensure that all handles for the previous dynamic queue are closed, or ensure that the name of the new queue is unique; see the description for reason code MQRC_OBJECT_ALREADY_EXISTS.

2202 (089A) (RC2202): MQRC_CONNECTION_QUIESCING:

Explanation

This reason code is issued when the connection to the queue manager is in quiescing state, and an application issues one of the following calls:

- MQCONN or MQCONNX
- MQOPEN, with no connection established, or with MQOO_FAIL_IF_QUIESCING included in the *Options* parameter
- MQGET, with MQGMO_FAIL_IF_QUIESCING included in the *Options* field of the *GetMsgOpts* parameter
- MQPUT or MQPUT1, with MQPMO_FAIL_IF_QUIESCING included in the *Options* field of the *PutMsgOpts* parameter

MQRC_CONNECTION_QUIESCING is also issued by the message channel agent (MCA) when the queue manager is in quiescing state.

Completion Code

MQCC_FAILED

Programmer response

The application should tidy up and terminate. Any uncommitted changes in a unit of work should be backed out.

2203 (089B) (RC2203): MQRC_CONNECTION_STOPPING:

Explanation

This reason code is issued when the connection to the queue manager is shutting down, and the application issues an MQI call. No more message-queuing calls can be issued. For the MQGET call, if the MQGMO_WAIT option was specified, the wait is canceled.

Note that the MQRC_CONNECTION_BROKEN reason may be returned instead if, as a result of system scheduling factors, the queue manager shuts down before the call completes.

MQRC_CONNECTION_STOPPING is also issued by the message channel agent (MCA) when the queue manager is shutting down.

For MQ MQI client applications, it is possible that the call did complete successfully, even though this reason code is returned with a *CompCode* of MQCC_FAILED.

Completion Code

MQCC_FAILED

Programmer response

The application should tidy up and terminate. Any uncommitted changes in a unit of work should be backed out. A unit of work that is coordinated by the queue manager is backed out automatically.

2204 (089C) (RC2204): MQRC_ADAPTER_NOT_AVAILABLE:

Explanation

This is issued only for CICS applications, if any call is issued and the CICS adapter (a Task Related User Exit) has been disabled, or has not been enabled.

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

The application should tidy up and terminate. Any uncommitted changes in a unit of work should be backed out. A unit of work that is coordinated by the queue manager is backed out automatically.

2206 (089E) (RC2206): MQRC_MSG_ID_ERROR:

Explanation

An MQGET call was issued to retrieve a message using the message identifier as a selection criterion, but the call failed because selection by message identifier is not supported on this queue.

- On z/OS, the queue is a shared queue, but the *IndexType* queue attribute does not have an appropriate value:
  - If selection is by message identifier alone, *IndexType* must have the value MQIT_MSG_ID.
  - If selection is by message identifier and correlation identifier combined, *IndexType* must have the value MQIT_MSG_ID or MQIT_CORREL_ID. However, the match-any values of MQCI_NONE and MQMI_NONE respectively are exceptions to this rule, and result in the 2206 MQRC_MSG_ID_ERROR reason code.
- On HP Integrity NonStop Server, a key file is required but has not been defined.

Completion Code

MQCC_FAILED

Programmer response

Do one of the following:

- Modify the application so that it does not use selection by message identifier: set the *MsgId* field to MQMI_NONE and do not specify MQMO_MATCH_MSG_ID in MQGMO.
- On z/OS, change the *IndexType* queue attribute to MQIT_MSG_ID.
- On HP Integrity NonStop Server, define a key file.

2207 (089F) (RC2207): MQRC_CORREL_ID_ERROR:

Explanation

An MQGET call was issued to retrieve a message using the correlation identifier as a selection criterion, but the call failed because selection by correlation identifier is not supported on this queue.

- On z/OS, the queue is a shared queue, but the *IndexType* queue attribute does not have an appropriate value:
  - If selection is by correlation identifier alone, *IndexType* must have the value MQIT_CORREL_ID.
  - If selection is by correlation identifier and message identifier combined, *IndexType* must have the value MQIT_CORREL_ID or MQIT_MSG_ID.
- On HP Integrity NonStop Server, a key file is required but has not been defined.

Completion Code

MQCC_FAILED

Programmer response

Do one of the following:

- On z/OS, change the *IndexType* queue attribute to MQIT_CORREL_ID.
- On HP Integrity NonStop Server, define a key file.
- Modify the application so that it does not use selection by correlation identifier: set the *CorrelId* field to MQCI_NONE and do not specify MQMO_MATCH_CORREL_ID in MQGMO.

2208 (08A0) (RC2208): MQRC_FILE_SYSTEM_ERROR:

Explanation

An unexpected return code was received from the file system, in attempting to perform an operation on a queue.

This reason code occurs only on VSE/ESA.

Completion Code

MQCC_FAILED

Programmer response

Check the file system definition for the queue that was being accessed. For a VSAM file, check that the control interval is large enough for the maximum message length allowed for the queue.

2209 (08A1) (RC2209): MQRC_NO_MSG_LOCKED:

Explanation

An MQGET call was issued with the MQGMO_UNLOCK option, but no message was currently locked.

Completion Code

MQCC_WARNING

Programmer response

Check that a message was locked by an earlier MQGET call with the MQGMO_LOCK option for the same handle, and that no intervening call has caused the message to become unlocked.

2210 (08A2) (RC2210): MQRC_SOAP_DOTNET_ERROR:

Explanation

This exception has been received from an external .NET environment. For more information, see the inner exception that is contained within the received exception message.

Completion Code

MQCC_FAILED

Programmer response

Refer to the .NET documentation for information about the inner exception. Follow the corrective action recommended there.

2211 (08A3) (RC2211): MQRC_SOAP_AXIS_ERROR:

Explanation

An exception from the Axis environment has been received and is included as a chained exception.

Completion Code

MQCC_FAILED

Programmer response

Refer to the Axis documentation for details about the chained exception. Follow the corrective action recommended there.

2212 (08A4) (RC2212): MQRC_SOAP_URL_ERROR:

Explanation

The SOAP URL has been specified incorrectly.

Completion Code

MQCC_FAILED

Programmer response

Correct the SOAP URL and rerun.

2217 (08A9) (RC2217): MQRC_CONNECTION_NOT_AUTHORIZED:

Explanation

This reason code occurs only on z/OS.

If the queue manager has been configured to use Advanced Message Security this reason code is returned if an error occurs in security processing.

This reason code might indicate a privacy security policy has been defined for the target queue that does not identify any recipients.

This reason code is also returned to CICS applications if the CICS subsystem is not authorized to connect to the queue manager.

Completion Code

MQCC_FAILED

Programmer response

Ensure that the subsystem is authorized to connect to the queue manager.

2218 (08AA) (RC2218): MQRC_MSG_TOO_BIG_FOR_CHANNEL:

Explanation

A message was put to a remote queue, but the message is larger than the maximum message length allowed by the channel. This reason code is returned in the *Feedback* field in the message descriptor of a report message.

- On z/OS, this return code is issued only if you are not using CICS for distributed queuing. Otherwise, MQRC_MSG_TOO_BIG_FOR_Q_MGR is issued.

Completion Code

MQCC_FAILED

Programmer response

Check the channel definitions. Increase the maximum message length that the channel can accept, or break the message into several smaller messages.

2219 (08AB) (RC2219): MQRC_CALL_IN_PROGRESS:

Explanation

The application issued an MQI call whilst another MQI call was already being processed for that connection. Only one call per application connection can be processed at a time.

Concurrent calls can arise when an application uses multiple threads, or when an exit is invoked as part of the processing of an MQI call. For example, a data-conversion exit invoked as part of the processing of the MQGET call may try to issue an MQI call.

- On z/OS, concurrent calls can arise only with batch or IMS applications; an example is when a subtask ends while an MQI call is in progress (for example, an MQGET that is waiting), and there is an end-of-task exit routine that issues another MQI call.
- On Windows, concurrent calls can also arise if an MQI call is issued in response to a user message while another MQI call is in progress.
- If the application is using multiple threads with shared handles, MQRC_CALL_IN_PROGRESS occurs when the handle specified on the call is already in use by another thread and MQCNO_HANDLE_SHARE_NO_BLOCK was specified on the MQCONNX call.

Completion Code

MQCC_FAILED

Programmer response

Ensure that an MQI call cannot be issued while another one is active. Do not issue MQI calls from within a data-conversion exit.

- On z/OS, if you want to provide a subtask to allow an application that is waiting for a message to arrive to be canceled, wait for the message by using MQGET with MQGMO_SET_SIGNAL, rather than MQGMO_WAIT.

2220 (08AC) (RC2220): MQRC_RMH_ERROR:

Explanation

An MQPUT or MQPUT1 call was issued, but the message data contains an MQRMH structure that is not valid. Possible errors include the following:

- The *StrucId* field is not MQRMH_STRUC_ID.
- The *Version* field is not MQRMH_VERSION_1.
- The *StrucLength* field specifies a value that is too small to include the structure plus the variable-length data at the end of the structure.
- The *CodedCharSetId* field is zero, or a negative value that is not valid.
- The *BufferLength* parameter of the call has a value that is too small to accommodate the structure (the structure extends beyond the end of the message).

This reason code occurs in the following environments: AIX, HP-UX, z/OS, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Check that the fields in the structure are set correctly. Ensure that the application sets the *CodedCharSetId* field to a valid value (note: MQCCSI_DEFAULT, MQCCSI_EMBEDDED, MQCCSI_Q_MGR, and MQCCSI_UNDEFINED are *not* valid in this field).

2222 (08AE) (RC2222): MQRC_Q_MGR_ACTIVE:

Explanation

This condition is detected when a queue manager becomes active.
- On z/OS, this event is not generated for the first start of a queue manager, only on subsequent restarts.

Completion Code

MQCC_WARNING

Programmer response

None. This reason code is only used to identify the corresponding event message Queue Manager Active.

2223 (08AF) (RC2223): MQRC_Q_MGR_NOT_ACTIVE:

Explanation

This condition is detected when a queue manager is requested to stop or quiesce.

Completion Code

MQCC_WARNING

Programmer response

None. This reason code is only used to identify the corresponding event message Queue Manager Not Active.

2224 (08B0) (RC2224): MQRC_Q_DEPTH_HIGH:

Explanation

An MQPUT or MQPUT1 call has caused the queue depth to be incremented to, or greater than, the limit specified in the *QDepthHighLimit* attribute.

Completion Code

MQCC_WARNING

Programmer response

None. This reason code is only used to identify the corresponding event message Queue Depth High.

2225 (08B1) (RC2225): MQRC_Q_DEPTH_LOW:

Explanation

An MQGET call has caused the queue depth to be decremented to, or less than, the limit specified in the *QDepthLowLimit* attribute.

Completion Code

MQCC_WARNING

Programmer response

None. This reason code is only used to identify the corresponding event message Queue Depth Low.

2226 (08B2) (RC2226): MQRC_Q_SERVICE_INTERVAL_HIGH:

Explanation

No successful gets or puts have been detected within an interval that is greater than the limit specified in the *QServiceInterval* attribute.

Completion Code

MQCC_WARNING

Programmer response

None. This reason code is only used to identify the corresponding event message Queue Service Interval High.

2227 (08B3) (RC2227): MQRC_Q_SERVICE_INTERVAL_OK:

Explanation

A successful get has been detected within an interval that is less than or equal to the limit specified in the *QServiceInterval* attribute.

Completion Code

MQCC_WARNING

Programmer response

None. This reason code is only used to identify the corresponding event message Queue Service Interval OK.

2228 (08B4) (RC2228): MQRC_RFH_HEADER_FIELD_ERROR:

Explanation

An expected RFH header field was not found or had an invalid value. If this error occurs in an IBM MQ SOAP listener, the missing or erroneous field is either the *contentType* field or the *transportVersion* field or both.

Completion Code

MQCC_FAILED

Programmer response

If this error occurs in an IBM MQ SOAP listener, and you are using the IBM-supplied sender, contact your IBM Support Center. If you are using a bespoke sender, check the associated error message, and that the RFH2 section of the SOAP/MQ request message contains all the mandatory fields, and that these fields have valid values.

2229 (08B5) (RC2229): MQRC_RAS_PROPERTY_ERROR:

Explanation

There is an error related to the RAS property file. The file might be missing, it might be not accessible, or the commands in the file might be incorrect.

Completion Code

MQCC_FAILED

Programmer response

Look at the associated error message, which explains the error in detail. Correct the error and try again.

2232 (08B8) (RC2232): MQRC_UNIT_OF_WORK_NOT_STARTED:

Explanation

An MQGET, MQPUT or MQPUT1 call was issued to get or put a message within a unit of work, but no TM/MP transaction had been started. If MQGMO_NO_SYNCPOINT is not specified on MQGET, or MQPMO_NO_SYNCPOINT is not specified on MQPUT or MQPUT1 (the default), the call requires a unit of work.

Completion Code

MQCC_FAILED

Programmer response

Ensure a TM/MP transaction is available, or issue the MQGET call with the MQGMO_NO_SYNCPOINT option, or the MQPUT or MQPUT1 call with the MQPMO_NO_SYNCPOINT option, which will cause a transaction to be started automatically.

2233 (08B9) (RC2233): MQRC_CHANNEL_AUTO_DEF_OK:

Explanation

This condition is detected when the automatic definition of a channel is successful. The channel is defined by the MCA.

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_WARNING

Programmer response

None. This reason code is only used to identify the corresponding event message Channel Auto-definition OK.

2234 (08BA) (RC2234): MQRC_CHANNEL_AUTO_DEF_ERROR:

Explanation

This condition is detected when the automatic definition of a channel fails; this might be because an error occurred during the definition process, or because the channel automatic-definition exit inhibited the definition. Additional information is returned in the event message indicating the reason for the failure.

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_WARNING

Programmer response

This reason code is only used to identify the corresponding event message Channel Auto-definition Error.

Examine the additional information returned in the event message to determine the reason for the failure.

2235 (08BB) (RC2235): MQRC_CFH_ERROR:

Explanation

An MQPUT or MQPUT1 call was issued, but the message data contains an MQCFH structure that is not valid.

This reason code occurs in the following environments: AIX, HP-UX, z/OS, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Check that the fields in the structure are set correctly.

2236 (08BC) (RC2236): MQRC_CFIL_ERROR:

Explanation

An MQPUT or MQPUT1 call was issued, but the message data contains an MQCFIL or MQRCFIL64 structure that is not valid.

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Check that the fields in the structure are set correctly.

2237 (08BD) (RC2237): MQRC_CFIN_ERROR:

Explanation

An MQPUT or MQPUT1 call was issued, but the message data contains an MQCFIN or MQCFIN64 structure that is not valid.

This reason code occurs in the following environments: AIX, HP-UX, z/OS, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Check that the fields in the structure are set correctly.

2238 (08BE) (RC2238): MQRC_CFSL_ERROR:

Explanation

An MQPUT or MQPUT1 call was issued, but the message data contains an MQCFSL structure that is not valid.

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Check that the fields in the structure are set correctly.

2239 (08BF) (RC2239): MQRC_CFST_ERROR:

Explanation

An MQPUT or MQPUT1 call was issued, but the message data contains an MQCFST structure that is not valid.

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Check that the fields in the structure are set correctly.

2241 (08C1) (RC2241): MQRC_INCOMPLETE_GROUP:

Explanation

An operation was attempted on a queue using a queue handle that had an incomplete message group. This reason code can arise in the following situations:

- On the MQPUT call, when the application specifies MQPMO_LOGICAL_ORDER and attempts to put a message that is not in a group. The completion code is MQCC_FAILED in this case.
- On the MQPUT call, when the application does *not* specify MQPMO_LOGICAL_ORDER, but the previous MQPUT call for the queue handle did specify MQPMO_LOGICAL_ORDER. The completion code is MQCC_WARNING in this case.
- On the MQGET call, when the application does *not* specify MQGMO_LOGICAL_ORDER, but the previous MQGET call for the queue handle did specify MQGMO_LOGICAL_ORDER. The completion code is MQCC_WARNING in this case.
- On the MQCLOSE call, when the application attempts to close the queue that has the incomplete message group. The completion code is MQCC_WARNING in this case.

If there is an incomplete logical message as well as an incomplete message group, reason code MQRC_INCOMPLETE_MSG is returned in preference to MQRC_INCOMPLETE_GROUP.

This reason code occurs in the following environments: AIX, HP-UX, z/OS, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_WARNING or MQCC_FAILED

Programmer response

If this reason code is expected, no corrective action is required. Otherwise, ensure that the MQPUT call for the last message in the group specifies MQMF_LAST_MSG_IN_GROUP.

2242 (08C2) (RC2242): MQRC_INCOMPLETE_MSG:

Explanation

An operation was attempted on a queue using a queue handle that had an incomplete logical message. This reason code can arise in the following situations:

- On the MQPUT call, when the application specifies MQPMO_LOGICAL_ORDER and attempts to put a message that is not a segment, or that has a setting for the MQMF_LAST_MSG_IN_GROUP flag that is different from the previous message. The completion code is MQCC_FAILED in this case.
- On the MQPUT call, when the application does *not* specify MQPMO_LOGICAL_ORDER, but the previous MQPUT call for the queue handle did specify MQPMO_LOGICAL_ORDER. The completion code is MQCC_WARNING in this case.
- On the MQGET call, when the application does *not* specify MQGMO_LOGICAL_ORDER, but the previous MQGET call for the queue handle did specify MQGMO_LOGICAL_ORDER. The completion code is MQCC_WARNING in this case.
- On the MQCLOSE call, when the application attempts to close the queue that has the incomplete logical message. The completion code is MQCC_WARNING in this case.

This reason code occurs in the following environments: AIX, HP-UX, z/OS, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_WARNING or MQCC_FAILED

Programmer response

If this reason code is expected, no corrective action is required. Otherwise, ensure that the MQPUT call for the last segment specifies MQMF_LAST_SEGMENT.

2243 (08C3) (RC2243): MQRC_INCONSISTENT_CCSIDS:

Explanation

An MQGET call was issued specifying the MQGMO_COMPLETE_MSG option, but the message to be retrieved consists of two or more segments that have differing values for the `CodedCharSetId` field in MQMD. This can arise when the segments take different paths through the network, and some of those paths have MCA sender conversion enabled. The call succeeds with a completion code of MQCC_WARNING, but only the first few segments that have identical character-set identifiers are returned.

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_WARNING

Programmer response

Remove the MQGMO_COMPLETE_MSG option from the MQGET call and retrieve the remaining message segments one by one.

2244 (08C4) (RC2244): MQRC_INCONSISTENT_ENCODINGS:

Explanation

An MQGET call was issued specifying the MQGMO_COMPLETE_MSG option, but the message to be retrieved consists of two or more segments that have differing values for the *Encoding* field in MQMD. This can arise when the segments take different paths through the network, and some of those paths have MCA sender conversion enabled. The call succeeds with a completion code of MQCC_WARNING, but only the first few segments that have identical encodings are returned.

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_WARNING

Programmer response

Remove the MQGMO_COMPLETE_MSG option from the MQGET call and retrieve the remaining message segments one by one.

2245 (08C5) (RC2245): MQRC_INCONSISTENT_UOW:

Explanation

One of the following applies:

- An MQPUT call was issued to put a message in a group or a segment of a logical message, but the value specified or defaulted for the MQPMO_SYNCPOINT option is not consistent with the current group and segment information retained by the queue manager for the queue handle.

  If the current call specifies MQPMO_LOGICAL_ORDER, the call fails. If the current call does not specify MQPMO_LOGICAL_ORDER, but the previous MQPUT call for the queue handle did, the call succeeds with completion code MQCC_WARNING.
- An MQGET call was issued to remove from the queue a message in a group or a segment of a logical message, but the value specified or defaulted for the MQGMO_SYNCPOINT option is not consistent with the current group and segment information retained by the queue manager for the queue handle.

  If the current call specifies MQGMO_LOGICAL_ORDER, the call fails. If the current call does not specify MQGMO_LOGICAL_ORDER, but the previous MQGET call for the queue handle did, the call succeeds with completion code MQCC_WARNING.

This reason code occurs in the following environments: AIX, HP-UX, z/OS, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_WARNING or MQCC_FAILED

Programmer response

Modify the application to ensure that the same unit-of-work specification is used for all messages in the group, or all segments of the logical message.

2246 (08C6) (RC2246): MQRC_INVALID_MSG_UNDER_CURSOR:

Explanation

An MQGET call was issued specifying the MQGMO_COMPLETE_MSG option with either MQGMO_MSG_UNDER_CURSOR or MQGMO_BROWSE_MSG_UNDER_CURSOR, but the message that is under the cursor has an MQMD with an `Offset` field that is greater than zero. Because MQGMO_COMPLETE_MSG was specified, the message is not valid for retrieval.

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Reposition the browse cursor so that it is located on a message with an `Offset` field in MQMD that is zero. Alternatively, remove the MQGMO_COMPLETE_MSG option.

2247 (08C7) (RC2247): MQRC_MATCH_OPTIONS_ERROR:

Explanation

An MQGET call was issued, but the value of the `MatchOptions` field in the `GetMsgOpts` parameter is not valid, for one of the following reasons:
- An undefined option is specified.
- All of the following are true:
  - MQGMO_LOGICAL_ORDER is specified.
  - There is a current message group or logical message for the queue handle.
  - Neither MQGMO_BROWSE_MSG_UNDER_CURSOR nor MQGMO_MSG_UNDER_CURSOR is specified.
  - One or more of the MQMO_* options is specified.
  - The values of the fields in the `MsgDesc` parameter corresponding to the MQMO_* options specified, differ from the values of those fields in the MQMD for the message to be returned next.
- On z/OS, one or more of the options specified is not valid for the index type of the queue.

This reason code occurs in the following environments: AIX, HP-UX, z/OS, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Ensure that only valid options are specified for the field.

2248 (08C8) (RC2248): MQRC_MDE_ERROR:

Explanation

An MQPUT or MQPUT1 call was issued, but the message data contains an MQMDE structure that is not valid. Possible errors include the following:

- The `StrucId` field is not MQMDE_STRUC_ID.
- The `Version` field is not MQMDE_VERSION_2.
- The `StrucLength` field is not MQMDE_LENGTH_2.
- The `CodedCharSetId` field is zero, or a negative value that is not valid.
- The `BufferLength` parameter of the call has a value that is too small to accommodate the structure (the structure extends beyond the end of the message).

This reason code occurs in the following environments: AIX, HP-UX, z/OS, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Check that the fields in the structure are set correctly. Ensure that the application sets the `CodedCharSetId` field to a valid value (note: MQCCSI_DEFAULT, MQCCSI_EMBEDDED, MQCCSI_Q_MGR, and MQCCSI_UNDEFINED are *not* valid in this field).

2249 (08C9) (RC2249): MQRC_MSG_FLAGS_ERROR:

Explanation

An MQPUT or MQPUT1 call was issued, but the `MsgFlags` field in the message descriptor MQMD contains one or more message flags that are not recognized by the local queue manager. The message flags that cause this reason code to be returned depend on the destination of the message; see the description of REPORT in Report options and message flags for more information.

This reason code can also occur in the `Feedback` field in the MQMD of a report message, or in the `Reason` field in the MQDLH structure of a message on the dead-letter queue; in both cases it indicates that the destination queue manager does not support one or more of the message flags specified by the sender of the message.

This reason code occurs in the following environments: AIX, HP-UX, z/OS, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Do the following:

- Ensure that the `MsgFlags` field in the message descriptor is initialized with a value when the message descriptor is declared, or is assigned a value prior to the MQPUT or MQPUT1 call. Specify MQMF_NONE if no message flags are needed.

- Ensure that the message flags specified are valid; see the *MsgFlags* field described in the description of MQMD in MsgFlags (MQLONG) for valid message flags.
- If multiple message flags are being set by adding the individual message flags together, ensure that the same message flag is not added twice.
- On z/OS, ensure that the message flags specified are valid for the index type of the queue; see the description of the *MsgFlags* field in MQMD for further details.

2250 (08CA) (RC2250): MQRC_MSG_SEQ_NUMBER_ERROR:

Explanation

An MQGET, MQPUT, or MQPUT1 call was issued, but the value of the *MsgSeqNumber* field in the MQMD or MQMDE structure is less than one or greater than 999 999 999.

This error can also occur on the MQPUT call if the *MsgSeqNumber* field would have become greater than 999 999 999 as a result of the call.

This reason code occurs in the following environments: AIX, HP-UX, z/OS, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Specify a value in the range 1 through 999 999 999. Do not attempt to create a message group containing more than 999 999 999 messages.

2251 (08CB) (RC2251): MQRC_OFFSET_ERROR:

Explanation

An MQPUT or MQPUT1 call was issued, but the value of the *Offset* field in the MQMD or MQMDE structure is less than zero or greater than 999 999 999.

This error can also occur on the MQPUT call if the *Offset* field would have become greater than 999 999 999 as a result of the call.

This reason code occurs in the following environments: AIX, HP-UX, z/OS, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Specify a value in the range 0 through 999 999 999. Do not attempt to create a message segment that would extend beyond an offset of 999 999 999.

2252 (08CC) (RC2252): MQRC_ORIGINAL_LENGTH_ERROR:

Explanation

An MQPUT or MQPUT1 call was issued to put a report message that is a segment, but the `OriginalLength` field in the MQMD or MQMDE structure is either:

- Less than the length of data in the message, or
- Less than one (for a segment that is not the last segment), or
- Less than zero (for a segment that is the last segment)

This reason code occurs in the following environments: AIX, HP-UX, z/OS, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Specify a value that is greater than zero. Zero is valid only for the last segment.

2253 (08CD) (RC2253): MQRC_SEGMENT_LENGTH_ZERO:

Explanation

An MQPUT or MQPUT1 call was issued to put the first or an intermediate segment of a logical message, but the length of the application message data in the segment (excluding any MQ headers that may be present) is zero. The length must be at least one for the first or intermediate segment.

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Check the application logic to ensure that segments are put with a length of one or greater. Only the last segment of a logical message is permitted to have a length of zero.

2255 (08CF) (RC2255): MQRC_UOW_NOT_AVAILABLE:

Explanation

An MQGET, MQPUT, or MQPUT1 call was issued to get or put a message outside a unit of work, but the options specified on the call required the queue manager to process the call within a unit of work. Because there is already a user-defined unit of work in existence, the queue manager was unable to create a temporary unit of work for the duration of the call.

This reason occurs in the following circumstances:
- On an MQGET call, when the MQGMO_COMPLETE_MSG option is specified in MQGMO and the logical message to be retrieved is persistent and consists of two or more segments.
- On an MQPUT or MQPUT1 call, when the MQMF_SEGMENTATION_ALLOWED flag is specified in MQMD and the message requires segmentation.

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Issue the MQGET, MQPUT, or MQPUT1 call inside the user-defined unit of work. Alternatively, for the MQPUT or MQPUT1 call, reduce the size of the message so that it does not require segmentation by the queue manager.

2256 (08D0) (RC2256): MQRC_WRONG_GMO_VERSION:

Explanation

An MQGET call was issued specifying options that required an MQGMO with a version number not less than MQGMO_VERSION_2, but the MQGMO supplied did not satisfy this condition.

This reason code occurs in the following environments: AIX, HP-UX, z/OS, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Modify the application to pass a version-2 MQGMO. Check the application logic to ensure that the *Version* field in MQGMO has been set to MQGMO_VERSION_2. Alternatively, remove the option that requires the version-2 MQGMO.

2257 (08D1) (RC2257): MQRC_WRONG_MD_VERSION:

Explanation

An MQGET, MQPUT, or MQPUT1 call was issued specifying options that required an MQMD with a version number not less than MQMD_VERSION_2, but the MQMD supplied did not satisfy this condition.

This reason code occurs in the following environments: AIX, HP-UX, z/OS, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Modify the application to pass a version-2 MQMD. Check the application logic to ensure that the `Version` field in MQMD has been set to MQMD_VERSION_2. Alternatively, remove the option that requires the version-2 MQMD.

2258 (08D2) (RC2258): MQRC_GROUP_ID_ERROR:

Explanation

An MQPUT or MQPUT1 call was issued to put a distribution-list message that is also a message in a group, a message segment, or has segmentation allowed, but an invalid combination of options and values was specified. All of the following are true:

- MQPMO_LOGICAL_ORDER is not specified in the `Options` field in MQPMO.
- Either there are too few MQPMR records provided by MQPMO, or the `GroupId` field is not present in the MQPMR records.
- One or more of the following flags is specified in the `MsgFlags` field in MQMD or MQMDE:
  - MQMF_SEGMENTATION_ALLOWED
  - MQMF_*_MSG_IN_GROUP
  - MQMF_*_SEGMENT
- The `GroupId` field in MQMD or MQMDE is not MQGI_NONE.

This combination of options and values would result in the same group identifier being used for all of the destinations in the distribution list; this is not permitted by the queue manager.

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Specify MQGI_NONE for the `GroupId` field in MQMD or MQMDE. Alternatively, if the call is MQPUT specify MQPMO_LOGICAL_ORDER in the `Options` field in MQPMO.

2259 (08D3) (RC2259): MQRC_INCONSISTENT_BROWSE:

Explanation

An MQGET call was issued with the MQGMO_BROWSE_NEXT option specified, but the specification of the MQGMO_LOGICAL_ORDER option for the call is different from the specification of that option for the previous call for the queue handle. Either both calls must specify MQGMO_LOGICAL_ORDER, or neither call must specify MQGMO_LOGICAL_ORDER.

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Add or remove the MQGMO_LOGICAL_ORDER option as appropriate. Alternatively, to switch between logical order and physical order, specify the MQGMO_BROWSE_FIRST option to restart the scan from the beginning of the queue, omitting or specifying MQGMO_LOGICAL_ORDER as required.

2260 (08D4) (RC2260): MQRC_XQH_ERROR:

Explanation

An MQPUT or MQPUT1 call was issued, but the message data contains an MQXQH structure that is not valid. Possible errors include the following:
- The *StrucId* field is not MQXQH_STRUC_ID.
- The *Version* field is not MQXQH_VERSION_1.
- The *BufferLength* parameter of the call has a value that is too small to accommodate the structure (the structure extends beyond the end of the message).

This reason code occurs in the following environments: AIX, HP-UX, z/OS, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Check that the fields in the structure are set correctly.

2261 (08D5) (RC2261): MQRC_SRC_ENV_ERROR:

Explanation

This reason occurs when a channel exit that processes reference messages detects an error in the source environment data of a reference message header (MQRMH). One of the following is true:

- *SrcEnvLength* is less than zero.
- *SrcEnvLength* is greater than zero, but there is no source environment data.
- *SrcEnvLength* is greater than zero, but *SrcEnvOffset* is negative, zero, or less than the length of the fixed part of MQRMH.
- *SrcEnvLength* is greater than zero, but *SrcEnvOffset* plus *SrcEnvLength* is greater than *StrucLength*.

The exit returns this reason in the *Feedback* field of the MQCXP structure. If an exception report is requested, it is copied to the *Feedback* field of the MQMD associated with the report.

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Specify the source environment data correctly.

2262 (08D6) (RC2262): MQRC_SRC_NAME_ERROR:

Explanation

This reason occurs when a channel exit that processes reference messages detects an error in the source name data of a reference message header (MQRMH). One of the following is true:

- *SrcNameLength* is less than zero.
- *SrcNameLength* is greater than zero, but there is no source name data.
- *SrcNameLength* is greater than zero, but *SrcNameOffset* is negative, zero, or less than the length of the fixed part of MQRMH.
- *SrcNameLength* is greater than zero, but *SrcNameOffset* plus *SrcNameLength* is greater than *StrucLength*.

The exit returns this reason in the *Feedback* field of the MQCXP structure. If an exception report is requested, it is copied to the *Feedback* field of the MQMD associated with the report.

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Specify the source name data correctly.

2263 (08D7) (RC2263): MQRC_DEST_ENV_ERROR:

Explanation

This reason occurs when a channel exit that processes reference messages detects an error in the destination environment data of a reference message header (MQRMH). One of the following is true:

- *DestEnvLength* is less than zero.
- *DestEnvLength* is greater than zero, but there is no destination environment data.
- *DestEnvLength* is greater than zero, but *DestEnvOffset* is negative, zero, or less than the length of the fixed part of MQRMH.
- *DestEnvLength* is greater than zero, but *DestEnvOffset* plus *DestEnvLength* is greater than *StrucLength*.

The exit returns this reason in the *Feedback* field of the MQCXP structure. If an exception report is requested, it is copied to the *Feedback* field of the MQMD associated with the report.

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Specify the destination environment data correctly.

2264 (08D8) (RC2264): MQRC_DEST_NAME_ERROR:

Explanation

This reason occurs when a channel exit that processes reference messages detects an error in the destination name data of a reference message header (MQRMH). One of the following is true:

- *DestNameLength* is less than zero.
- *DestNameLength* is greater than zero, but there is no destination name data.
- *DestNameLength* is greater than zero, but *DestNameOffset* is negative, zero, or less than the length of the fixed part of MQRMH.
- *DestNameLength* is greater than zero, but *DestNameOffset* plus *DestNameLength* is greater than *StrucLength*.

The exit returns this reason in the *Feedback* field of the MQCXP structure. If an exception report is requested, it is copied to the *Feedback* field of the MQMD associated with the report.

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Specify the destination name data correctly.

2265 (08D9) (RC2265): MQRC_TM_ERROR:

Explanation

An MQPUT or MQPUT1 call was issued, but the message data contains an MQTM structure that is not valid. Possible errors include the following:

- The *StrucId* field is not MQTM_STRUC_ID.
- The *Version* field is not MQTM_VERSION_1.
- The *BufferLength* parameter of the call has a value that is too small to accommodate the structure (the structure extends beyond the end of the message).

This reason code occurs in the following environments: AIX, HP-UX, z/OS, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Check that the fields in the structure are set correctly.

2266 (08DA) (RC2266): MQRC_CLUSTER_EXIT_ERROR:

Explanation

An MQOPEN, MQPUT, or MQPUT1 call was issued to open or put a message on a cluster queue, but the cluster workload exit defined by the queue-manager's *ClusterWorkloadExit* attribute failed unexpectedly or did not respond in time. Subsequent MQOPEN, MQPUT, and MQPUT1 calls for this queue handle are processed as though the *ClusterWorkloadExit* attribute were blank.

- On z/OS, a message giving more information about the error is written to the system log, for example message CSQV455E or CSQV456E.

This reason code occurs in the following environments: AIX, HP-UX, z/OS, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Check the cluster workload exit to ensure that it has been written correctly.

2267 (08DB) (RC2267): MQRC_CLUSTER_EXIT_LOAD_ERROR:

Explanation

An MQCONN or MQCONNX call was issued to connect to a queue manager, but the queue manager was unable to load the cluster workload exit. Execution continues without the cluster workload exit.
- On z/OS, if the cluster workload exit cannot be loaded, a message is written to the system log, for example message CSQV453I. Processing continues as though the *ClusterWorkloadExit* attribute had been blank.

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_WARNING

Programmer response

Ensure that the queue-manager's *ClusterWorkloadExit* attribute has the correct value, and that the exit has been installed into the correct location.

2268 (08DC) (RC2268): MQRC_CLUSTER_PUT_INHIBITED:

Explanation

An MQOPEN call with the MQOO_OUTPUT and MQOO_BIND_ON_OPEN options in effect was issued for a cluster queue, but the call failed because all of the following are true:
- All instances of the cluster queue are currently put-inhibited (that is, all of the queue instances have the *InhibitPut* attribute set to MQQA_PUT_INHIBITED).
- There is no local instance of the queue. (If there is a local instance, the MQOPEN call succeeds, even if the local instance is put-inhibited.)
- There is no cluster workload exit for the queue, or there is a cluster workload exit but it did not choose a queue instance. (If the cluster workload exit does choose a queue instance, the MQOPEN call succeeds, even if that instance is put-inhibited.)

If the MQOO_BIND_NOT_FIXED option is specified on the MQOPEN call, the call can succeed even if all of the queues in the cluster are put-inhibited. However, a subsequent MQPUT call may fail if all of the queues are still put-inhibited at the time of the MQPUT call.

This reason code occurs in the following environments: AIX, HP-UX, z/OS, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

If the system design allows put requests to be inhibited for short periods, retry the operation later. If the problem persists, determine why all of the queues in the cluster are put-inhibited.

2269 (08DD) (RC2269): MQRC_CLUSTER_RESOURCE_ERROR:

Explanation

An MQOPEN, MQPUT, or MQPUT1 call was issued for a cluster queue, but an error occurred whilst trying to use a resource required for clustering.

This reason code occurs in the following environments: AIX, HP-UX, z/OS, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Do the following:
- Check that the SYSTEM.CLUSTER.* queues are not put inhibited or full.
- Check the event queues for any events relating to the SYSTEM.CLUSTER.* queues, as these may give guidance as to the nature of the failure.
- Check that the repository queue manager is available.
- On z/OS, check the console for signs of the failure, such as full page sets.

2270 (08DE) (RC2270): MQRC_NO_DESTINATIONS_AVAILABLE:

Explanation

An MQPUT or MQPUT1 call was issued to put a message on a cluster queue, but at the time of the call there were no longer any instances of the queue in the cluster. The message therefore could not be sent.

This situation can occur when MQOO_BIND_NOT_FIXED is specified on the MQOPEN call that opens the queue, or MQPUT1 is used to put the message.

This reason code occurs in the following environments: AIX, HP-UX, z/OS, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Check the queue definition and queue status to determine why all instances of the queue were removed from the cluster. Correct the problem and rerun the application.

2271 (08DF) (RC2271): MQRC_CONN_TAG_IN_USE:

Explanation

An MQCONNX call was issued specifying one of the MQCNO_*_CONN_TAG_* options, but the call failed because the connection tag specified by *ConnTag* in MQCNO is in use by an active process or thread, or there is an unresolved unit of work that references this connection tag.

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

The problem is likely to be transitory. The application should wait a short while and then retry the operation.

2272 (08E0) (RC2272): MQRC_PARTIALLY_CONVERTED:

Explanation

On an MQGET call with the MQGMO_CONVERT option included in the *GetMsgOpts* parameter, one or more MQ header structures in the message data could not be converted to the specified target character set or encoding. In this situation, the MQ header structures are converted to the queue-manager's character set and encoding, and the application data in the message is converted to the target character set and encoding. On return from the call, the values returned in the various *CodedCharSetId* and *Encoding* fields in the *MsgDesc* parameter and MQ header structures indicate the character set and encoding that apply to each part of the message. The call completes with MQCC_WARNING.

This reason code usually occurs when the specified target character set is one that causes the character strings in the MQ header structures to expand beyond the lengths of their fields. Unicode character set UCS-2 is an example of a character set that causes this to happen.

Completion Code

MQCC_FAILED

Programmer response

If this is an expected situation, no corrective action is required.

If this is an unexpected situation, check that the MQ header structures contain valid data. If they do, specify as the target character set a character set that does not cause the strings to expand.

2273 (08E1) (RC2273): MQRC_CONNECTION_ERROR:

Explanation

An MQCONN or MQCONNX call failed for one of the following reasons:

- The installation and customization options chosen for IBM MQ do not allow connection by the type of application being used.
- The system parameter module is not at the same release level as the queue manager.
- The channel initiator is not at the same release level as the queue manager.
- An internal error was detected by the queue manager.

Completion Code

MQCC_FAILED

Programmer response

None, if the installation and customization options chosen for IBM MQ do not allow all functions to be used.

Otherwise, if this occurs while starting the channel initiator, ensure that the queue manager and the channel initiator are both at the same release level and that their started task JCL procedures both specify the same level of IBM MQ program libraries; if this occurs while starting the queue manager, relinkedit the system parameter module (CSQZPARM) to ensure that it is at the correct level. If the problem persists, contact your IBM support center.

2274 (08E2) (RC2274): MQRC_OPTION_ENVIRONMENT_ERROR:

Explanation

An MQGET call with the MQGMO_MARK_SKIP_BACKOUT option specified was issued from a Db2 Stored Procedure. The call failed because the MQGMO_MARK_SKIP_BACKOUT option cannot be used from a Db2 Stored Procedure.

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

Remove the MQGMO_MARK_SKIP_BACKOUT option from the MQGET call.

2277 (08E5) (RC2277): MQRC_CD_ERROR:

Explanation

An MQCONNX call was issued to connect to a queue manager, but the MQCD channel definition structure addressed by the `ClientConnOffset` or `ClientConnPtr` field in MQCNO contains data that is not valid. Consult the error log for more information about the nature of the error.

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Ensure that input fields in the MQCD structure are set correctly.

2278 (08E6) (RC2278): MQRC_CLIENT_CONN_ERROR:

Explanation

An MQCONNX call was issued to connect to a queue manager, but the MQCD channel definition structure is not specified correctly. One of the following applies:

- `ClientConnOffset` is not zero and `ClientConnPtr` is not zero and not the null pointer.
- `ClientConnPtr` is not a valid pointer.
- `ClientConnPtr` or `ClientConnOffset` points to storage that is not accessible.

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems. It also occurs in Java applications when a client channel definition table (CCDT) is specified to determine the name of the channel, but the table itself cannot be found.

Completion Code

MQCC_FAILED

Programmer response

Ensure that at least one of `ClientConnOffset` and `ClientConnPtr` is zero. Ensure that the field used points to accessible storage. Ensure that the URL of the client channel definition table is correct.

2279 (08E7) (RC2279): MQRC_CHANNEL_STOPPED_BY_USER:

Explanation

This condition is detected when the channel has been stopped by an operator. The reason qualifier identifies the reasons for stopping.

Completion Code

MQCC_WARNING

Programmer response

None. This reason code is only used to identify the corresponding event message Channel Stopped By User.

2280 (08E8) (RC2280): MQRC_HCONFIG_ERROR:

Explanation

The configuration handle `Hconfig` specified on the MQXEP call or MQZEP call is not valid. The MQXEP call is issued by an API exit function; the MQZEP call is issued by an installable service.
- On z/OS, this reason code does not occur.

Completion Code

MQCC_FAILED

Programmer response

Specify the configuration handle that was provided by the queue manager:
- On the MQXEP call, use the handle passed in the `Hconfig` field of the MQAXP structure.
- On the MQZEP call, use the handle passed to the installable service's configuration function on the component initialization call. For more information about installable services, see Installable services and components for UNIX, Linux and Windows .

2281 (08E9) (RC2281): MQRC_FUNCTION_ERROR:

Explanation

An MQXEP or MQZEP call was issued, but the function identifier `Function` specified on the call is not valid, or not supported by the installable service being configured.
- On z/OS, this reason code does not occur.

Completion Code

MQCC_FAILED

Programmer response

Do the following:
- For the MQXEP call, specify one of the MQXF_* values.
- For the MQZEP call, specify an MQZID_* value that is valid for the installable service being configured. See MQZEP to determine which values are valid.

2282 (08EA) (RC2282): MQRC_CHANNEL_STARTED:

Explanation

One of the following has occurred:
- An operator has issued a Start Channel command.
- An instance of a channel has been successfully established. This condition is detected when Initial Data negotiation is complete and resynchronization has been performed where necessary such that message transfer can proceed.

Completion Code

MQCC_WARNING

Programmer response

None. This reason code is only used to identify the corresponding event message Channel Started.

2283 (08EB) (RC2283): MQRC_CHANNEL_STOPPED:

Explanation

This condition is detected when the channel has been stopped. The reason qualifier identifies the reasons for stopping.

Completion Code

MQCC_WARNING

Programmer response

None. This reason code is only used to identify the corresponding event message Channel Stopped.

2284 (08EC) (RC2284): MQRC_CHANNEL_CONV_ERROR:

Explanation

This condition is detected when a channel is unable to do data conversion and the MQGET call to get a message from the transmission queue resulted in a data conversion error. The conversion reason code identifies the reason for the failure.

Completion Code

MQCC_WARNING

Programmer response

None. This reason code is only used to identify the corresponding event message Channel Conversion Error.

2285 (08ED) (RC2285): MQRC_SERVICE_NOT_AVAILABLE:

Explanation

This reason should be returned by an installable service component when the requested action cannot be performed because the required underlying service is not available.

- On z/OS, this reason code does not occur.

Completion Code

MQCC_FAILED

Programmer response

Make the underlying service available.

2286 (08EE) (RC2286): MQRC_INITIALIZATION_FAILED:

Explanation

This reason should be returned by an installable service component when the component is unable to complete initialization successfully.

- On z/OS, this reason code does not occur.

Completion Code

MQCC_FAILED

Programmer response

Correct the error and retry the operation.

2287 (08EF) (RC2287): MQRC_TERMINATION_FAILED:

Explanation

This reason should be returned by an installable service component when the component is unable to complete termination successfully.

- On z/OS, this reason code does not occur.

Completion Code

MQCC_FAILED

Programmer response

Correct the error and retry the operation.

2288 (08F0) (RC2288): MQRC_UNKNOWN_Q_NAME:

Explanation

This reason should be returned by the MQZ_LOOKUP_NAME installable service component when the name specified for the *QName* parameter is not recognized.
- On z/OS, this reason code does not occur.

Completion Code

MQCC_FAILED

Programmer response

None. See Installable services and components for UNIX, Linux and Windows for more information about installable services.

2289 (08F1) (RC2289): MQRC_SERVICE_ERROR:

Explanation

This reason should be returned by an installable service component when the component encounters an unexpected error.
- On z/OS, this reason code does not occur.

Completion Code

MQCC_FAILED

Programmer response

Correct the error and retry the operation.

2290 (08F2) (RC2290): MQRC_Q_ALREADY_EXISTS:

Explanation

This reason should be returned by the MQZ_INSERT_NAME installable service component when the queue specified by the *QName* parameter is already defined to the name service.
- On z/OS, this reason code does not occur.

Completion Code

MQCC_FAILED

Programmer response

None. See Installable services and components for UNIX, Linux and Windows for more information about installable services.

2291 (08F3) (RC2291): MQRC_USER_ID_NOT_AVAILABLE:

Explanation

This reason should be returned by the MQZ_FIND_USERID installable service component when the user ID cannot be determined.
- On z/OS, this reason code does not occur.

Completion Code

MQCC_FAILED

Programmer response

None. See Installable services and components for UNIX, Linux and Windows for more information about installable services.

2292 (08F4) (RC2292): MQRC_UNKNOWN_ENTITY:

Explanation

This reason should be returned by the authority installable service component when the name specified by the *EntityName* parameter is not recognized.
- On z/OS, this reason code does not occur.

Completion Code

MQCC_FAILED

Programmer response

Ensure that the entity is defined.

2294 (08F6) (RC2294): MQRC_UNKNOWN_REF_OBJECT:

Explanation

This reason should be returned by the MQZ_COPY_ALL_AUTHORITY installable service component when the name specified by the *RefObjectName* parameter is not recognized.
- On z/OS, this reason code does not occur.

Completion Code

MQCC_FAILED

Programmer response

Ensure that the reference object is defined. See Installable services and components for UNIX, Linux and Windows for more information about installable services.

2295 (08F7) (RC2295): MQRC_CHANNEL_ACTIVATED:

Explanation

This condition is detected when a channel that has been waiting to become active, and for which a Channel Not Activated event has been generated, is now able to become active because an active slot has been released by another channel.

This event is not generated for a channel that is able to become active without waiting for an active slot to be released.

Completion Code

MQCC_WARNING

Programmer response

None. This reason code is only used to identify the corresponding event message Channel Activated.

2296 (08F8) (RC2296): MQRC_CHANNEL_NOT_ACTIVATED:

Explanation

This condition is detected when a channel is required to become active, either because it is starting or because it is about to make another attempt to establish connection with its partner. However, it is unable to do so because the limit on the number of active channels has been reached.

- On z/OS, the maximum number of active channels is given by the ACTCHL queue manager attribute.
- In other environments, the maximum number of active channels is given by the MaxActiveChannels parameter in the qm.ini file.

The channel waits until it is able to take over an active slot released when another channel ceases to be active. At that time a Channel Activated event is generated.

Completion Code

MQCC_WARNING

Programmer response

None. This reason code is only used to identify the corresponding event message Channel Not Activated.

2297 (08F9) (RC2297): MQRC_UOW_CANCELED:

Explanation

An MQI call was issued, but the unit of work (TM/MP transaction) being used for the MQ operation had been canceled. This may have been done by TM/MP itself (for example, due to the transaction running for too long, or exceeding audit trail sizes), or by the application program issuing an ABORT_TRANSACTION. All updates performed to resources owned by the queue manager are backed out.

Completion Code

MQCC_FAILED

Programmer response

Refer to the operating system's *Transaction Management Operations Guide* to determine how the Transaction Manager can be tuned to avoid the problem of system limits being exceeded.

2298 (08FA) (RC2298): MQRC_FUNCTION_NOT_SUPPORTED:

Explanation

The function requested is not available in the current environment.

Completion Code

MQCC_FAILED

Programmer response

Remove the call from the application.

This reason code can be used when the call requires resources or functionality that is restricted by the queue manager OPMODE setting.

If you get this reason code with CICS group connect, check that the queue manager attribute GROUPUR is enabled.

2299 (08FB) (RC2299): MQRC_SELECTOR_TYPE_ERROR:

Explanation

The *`Selector`* parameter has the wrong data type; it must be of type `Long`.

Completion Code

MQCC_FAILED

Programmer response

Declare the *`Selector`* parameter as `Long`.

2300 (08FC) (RC2300): MQRC_COMMAND_TYPE_ERROR:

Explanation

The mqExecute call was issued, but the value of the MQIASY_TYPE data item in the administration bag is not MQCFT_COMMAND.

Completion Code

MQCC_FAILED

Programmer response

Ensure that the MQIASY_TYPE data item in the administration bag has the value MQCFT_COMMAND.

2301 (08FD) (RC2301): MQRC_MULTIPLE_INSTANCE_ERROR:

Explanation

The *Selector* parameter specifies a system selector (one of the MQIASY_* values), but the value of the *ItemIndex* parameter is not MQIND_NONE. Only one instance of each system selector can exist in the bag.

Completion Code

MQCC_FAILED

Programmer response

Specify MQIND_NONE for the *ItemIndex* parameter.

2302 (08FE) (RC2302): MQRC_SYSTEM_ITEM_NOT_ALTERABLE:

Explanation

A call was issued to modify the value of a system data item in a bag (a data item with one of the MQIASY_* selectors), but the call failed because the data item is one that cannot be altered by the application.

Completion Code

MQCC_FAILED

Programmer response

Specify the selector of a user-defined data item, or remove the call.

2303 (08FF) (RC2303): MQRC_BAG_CONVERSION_ERROR:

Explanation

The mqBufferToBag or mqGetBag call was issued, but the data in the buffer or message could not be converted into a bag. This occurs when the data to be converted is not valid PCF.

Completion Code

MQCC_FAILED

Programmer response

Check the logic of the application that created the buffer or message to ensure that the buffer or message contains valid PCF.

If the message contains PCF that is not valid, the message cannot be retrieved using the mqGetBag call:
- If one of the MQGMO_BROWSE_* options was specified, the message remains on the queue and can be retrieved using the MQGET call.
- In other cases, the message has already been removed from the queue and discarded. If the message was retrieved within a unit of work, the unit of work can be backed out and the message retrieved using the MQGET call.

2304 (0900) (RC2304): MQRC_SELECTOR_OUT_OF_RANGE:

Explanation

The *Selector* parameter has a value that is outside the valid range for the call. If the bag was created with the MQCBO_CHECK_SELECTORS option:

- For the mqAddInteger call, the value must be within the range MQIA_FIRST through MQIA_LAST.
- For the mqAddString call, the value must be within the range MQCA_FIRST through MQCA_LAST.

If the bag was not created with the MQCBO_CHECK_SELECTORS option:

- The value must be zero or greater.

Completion Code

MQCC_FAILED

Programmer response

Specify a valid value.

2305 (0901) (RC2305): MQRC_SELECTOR_NOT_UNIQUE:

Explanation

The *ItemIndex* parameter has the value MQIND_NONE, but the bag contains more than one data item with the selector value specified by the *Selector* parameter. MQIND_NONE requires that the bag contain only one occurrence of the specified selector.

This reason code also occurs on the mqExecute call when the administration bag contains two or more occurrences of a selector for a required parameter that permits only one occurrence.

Completion Code

MQCC_FAILED

Programmer response

Check the logic of the application that created the bag. If correct, specify for *ItemIndex* a value that is zero or greater, and add application logic to process all of the occurrences of the selector in the bag.

Review the description of the administration command being issued, and ensure that all required parameters are defined correctly in the bag.

2306 (0902) (RC2306): MQRC_INDEX_NOT_PRESENT:

Explanation

The specified index is not present:
- For a bag, this means that the bag contains one or more data items that have the selector value specified by the *Selector* parameter, but none of them has the index value specified by the *ItemIndex* parameter. The data item identified by the *Selector* and *ItemIndex* parameters must exist in the bag.
- For a namelist, this means that the index parameter value is too large, and outside the range of valid values.

Completion Code

MQCC_FAILED

Programmer response

Specify the index of a data item that does exist in the bag or namelist. Use the mqCountItems call to determine the number of data items with the specified selector that exist in the bag, or the nameCount method to determine the number of names in the namelist.

2307 (0903) (RC2307): MQRC_STRING_ERROR:

Explanation

The *String* parameter is not valid. Either the parameter pointer is not valid, or it points to read-only storage. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)

Completion Code

MQCC_FAILED

Programmer response

Correct the parameter.

2308 (0904) (RC2308): MQRC_ENCODING_NOT_SUPPORTED:

Explanation

The *Encoding* field in the message descriptor MQMD contains a value that is not supported:
- For the mqPutBag call, the field in error resides in the *MsgDesc* parameter of the call.
- For the mqGetBag call, the field in error resides in:
  - The *MsgDesc* parameter of the call if the MQGMO_CONVERT option was specified.
  - The message descriptor of the message about to be retrieved if MQGMO_CONVERT was *not* specified.

Completion Code

MQCC_FAILED

Programmer response

The value must be MQENC_NATIVE.

If the value of the *Encoding* field in the message is not valid, the message cannot be retrieved using the mqGetBag call:

- If one of the MQGMO_BROWSE_* options was specified, the message remains on the queue and can be retrieved using the MQGET call.
- In other cases, the message has already been removed from the queue and discarded. If the message was retrieved within a unit of work, the unit of work can be backed out and the message retrieved using the MQGET call.

2309 (0905) (RC2309): MQRC_SELECTOR_NOT_PRESENT:

Explanation

The *Selector* parameter specifies a selector that does not exist in the bag.

Completion Code

MQCC_FAILED

Programmer response

Specify a selector that does exist in the bag.

2310 (0906) (RC2310): MQRC_OUT_SELECTOR_ERROR:

Explanation

The *OutSelector* parameter is not valid. Either the parameter pointer is not valid, or it points to read-only storage. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)

Completion Code

MQCC_FAILED

Programmer response

Correct the parameter.

2311 (0907) (RC2311): MQRC_STRING_TRUNCATED:

Explanation

The string returned by the call is too long to fit in the buffer provided. The string has been truncated to fit in the buffer.

Completion Code

MQCC_FAILED

Programmer response

If the entire string is required, provide a larger buffer. On the mqInquireString call, the *StringLength* parameter is set by the call to indicate the size of the buffer required to accommodate the string without truncation.

2312 (0908) (RC2312): MQRC_SELECTOR_WRONG_TYPE:

Explanation

A data item with the specified selector exists in the bag, but has a data type that conflicts with the data type implied by the call being used. For example, the data item might have an integer data type, but the call being used might be mqSetString, which implies a character data type.

This reason code also occurs on the mqBagToBuffer, mqExecute, and mqPutBag calls when mqAddString or mqSetString was used to add the MQIACF_INQUIRY data item to the bag.

Completion Code

MQCC_FAILED

Programmer response

For the mqSetInteger and mqSetString calls, specify MQIND_ALL for the *ItemIndex* parameter to delete from the bag all existing occurrences of the specified selector before creating the new occurrence with the required data type.

For the mqInquireBag, mqInquireInteger, and mqInquireString calls, use the mqInquireItemInfo call to determine the data type of the item with the specified selector, and then use the appropriate call to determine the value of the data item.

For the mqBagToBuffer, mqExecute, and mqPutBag calls, ensure that the MQIACF_INQUIRY data item is added to the bag using the mqAddInteger or mqSetInteger calls.

2313 (0909) (RC2313): MQRC_INCONSISTENT_ITEM_TYPE:

Explanation

The mqAddInteger or mqAddString call was issued to add another occurrence of the specified selector to the bag, but the data type of this occurrence differed from the data type of the first occurrence.

This reason can also occur on the mqBufferToBag and mqGetBag calls, where it indicates that the PCF in the buffer or message contains a selector that occurs more than once but with inconsistent data types.

Completion Code

MQCC_FAILED

Programmer response

For the mqAddInteger and mqAddString calls, use the call appropriate to the data type of the first occurrence of that selector in the bag.

For the mqBufferToBag and mqGetBag calls, check the logic of the application that created the buffer or sent the message to ensure that multiple-occurrence selectors occur with only one data type. A message that contains a mixture of data types for a selector cannot be retrieved using the mqGetBag call:

- If one of the MQGMO_BROWSE_* options was specified, the message remains on the queue and can be retrieved using the MQGET call.
- In other cases, the message has already been removed from the queue and discarded. If the message was retrieved within a unit of work, the unit of work can be backed out and the message retrieved using the MQGET call.

2314 (090A) (RC2314): MQRC_INDEX_ERROR:

Explanation

An index parameter to a call or method has a value that is not valid. The value must be zero or greater. For bag calls, certain MQIND_* values can also be specified:

- For the mqDeleteItem, mqSetInteger and mqSetString calls, MQIND_ALL and MQIND_NONE are valid.
- For the mqInquireBag, mqInquireInteger, mqInquireString, and mqInquireItemInfo calls, MQIND_NONE is valid.

Completion Code

MQCC_FAILED

Programmer response

Specify a valid value.

2315 (090B) (RC2315): MQRC_SYSTEM_BAG_NOT_ALTERABLE:

Explanation

A call was issued to add a data item to a bag, modify the value of an existing data item in a bag, or retrieve a message into a bag, but the call failed because the bag is one that had been created by the system as a result of a previous mqExecute call. System bags cannot be modified by the application.

Completion Code

MQCC_FAILED

Programmer response

Specify the handle of a bag created by the application, or remove the call.

2316 (090C) (RC2316): MQRC_ITEM_COUNT_ERROR:

Explanation

The mqTruncateBag call was issued, but the *ItemCount* parameter specifies a value that is not valid. The value is either less than zero, or greater than the number of user-defined data items in the bag.

This reason also occurs on the mqCountItems call if the parameter pointer is not valid, or points to read-only storage. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)

Completion Code

MQCC_FAILED

Programmer response

Specify a valid value. Use the mqCountItems call to determine the number of user-defined data items in the bag.

2317 (090D) (RC2317): MQRC_FORMAT_NOT_SUPPORTED:

Explanation

The *Format* field in the message descriptor MQMD contains a value that is not supported:

- In an administration message, the format value must be one of the following: MQFMT_ADMIN, MQFMT_EVENT, MQFMT_PCF. For the mqPutBag call, the field in error resides in the *MsgDesc* parameter of the call. For the mqGetBag call, the field in error resides in the message descriptor of the message about to be retrieved.
- On z/OS, the message was put to the command input queue with a format value of MQFMT_ADMIN, but the version of MQ being used does not support that format for commands.

Completion Code

MQCC_FAILED

Programmer response

If the error occurred when putting a message, correct the format value.

If the error occurred when getting a message, the message cannot be retrieved using the mqGetBag call:

- If one of the MQGMO_BROWSE_* options was specified, the message remains on the queue and can be retrieved using the MQGET call.
- In other cases, the message has already been removed from the queue and discarded. If the message was retrieved within a unit of work, the unit of work can be backed out and the message retrieved using the MQGET call.

2318 (090E) (RC2318): MQRC_SELECTOR_NOT_SUPPORTED:

Explanation

The *Selector* parameter specifies a value that is a system selector (a value that is negative), but the system selector is not one that is supported by the call.

Completion Code

MQCC_FAILED

Programmer response

Specify a selector value that is supported.

2319 (090F) (RC2319): MQRC_ITEM_VALUE_ERROR:

Explanation

The mqInquireBag or mqInquireInteger call was issued, but the `ItemValue` parameter is not valid. Either the parameter pointer is not valid, or it points to read-only storage. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)

Completion Code

MQCC_FAILED

Programmer response

Correct the parameter.

2320 (0910) (RC2320): MQRC_HBAG_ERROR:

Explanation

A call was issued that has a parameter that is a bag handle, but the handle is not valid. For output parameters, this reason also occurs if the parameter pointer is not valid, or points to read-only storage. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)

Completion Code

MQCC_FAILED

Programmer response

Correct the parameter.

2321 (0911) (RC2321): MQRC_PARAMETER_MISSING:

Explanation

An administration message requires a parameter that is not present in the administration bag. This reason code occurs only for bags created with the MQCBO_ADMIN_BAG or MQCBO_REORDER_AS_REQUIRED options.

Completion Code

MQCC_FAILED

Programmer response

Review the description of the administration command being issued, and ensure that all required parameters are present in the bag.

2322 (0912) (RC2322): MQRC_CMD_SERVER_NOT_AVAILABLE:

Explanation

The command server that processes administration commands is not available.

Completion Code

MQCC_FAILED

Programmer response

Start the command server.

2323 (0913) (RC2323): MQRC_STRING_LENGTH_ERROR:

Explanation

The *StringLength* parameter is not valid. Either the parameter pointer is not valid, or it points to read-only storage. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)

Completion Code

MQCC_FAILED

Programmer response

Correct the parameter.

2324 (0914) (RC2324): MQRC_INQUIRY_COMMAND_ERROR:

Explanation

The mqAddInquiry call was used previously to add attribute selectors to the bag, but the command code to be used for the mqBagToBuffer, mqExecute, or mqPutBag call is not recognized. As a result, the correct PCF message cannot be generated.

Completion Code

MQCC_FAILED

Programmer response

Remove the mqAddInquiry calls and use instead the mqAddInteger call with the appropriate MQIACF_*_ATTRS or MQIACH_*_ATTRS selectors.

2325 (0915) (RC2325): MQRC_NESTED_BAG_NOT_SUPPORTED:

Explanation

A bag that is input to the call contains nested bags. Nested bags are supported only for bags that are output from the call.

Completion Code

MQCC_FAILED

Programmer response

Use a different bag as input to the call.

2326 (0916) (RC2326): MQRC_BAG_WRONG_TYPE:

Explanation

The *Bag* parameter specifies the handle of a bag that has the wrong type for the call. The bag must be an administration bag, that is, it must be created with the MQCBO_ADMIN_BAG option specified on the mqCreateBag call.

Completion Code

MQCC_FAILED

Programmer response

Specify the MQCBO_ADMIN_BAG option when the bag is created.

2327 (0917) (RC2327): MQRC_ITEM_TYPE_ERROR:

Explanation

The mqInquireItemInfo call was issued, but the *ItemType* parameter is not valid. Either the parameter pointer is not valid, or it points to read-only storage. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)

Completion Code

MQCC_FAILED

Programmer response

Correct the parameter.

2328 (0918) (RC2328): MQRC_SYSTEM_BAG_NOT_DELETABLE:

Explanation

An mqDeleteBag call was issued to delete a bag, but the call failed because the bag is one that had been created by the system as a result of a previous mqExecute call. System bags cannot be deleted by the application.

Completion Code

MQCC_FAILED

Programmer response

Specify the handle of a bag created by the application, or remove the call.

2329 (0919) (RC2329): MQRC_SYSTEM_ITEM_NOT_DELETABLE:

Explanation

A call was issued to delete a system data item from a bag (a data item with one of the MQIASY_* selectors), but the call failed because the data item is one that cannot be deleted by the application.

Completion Code

MQCC_FAILED

Programmer response

Specify the selector of a user-defined data item, or remove the call.

2330 (091A) (RC2330): MQRC_CODED_CHAR_SET_ID_ERROR:

Explanation

The *CodedCharSetId* parameter is not valid. Either the parameter pointer is not valid, or it points to read-only storage. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)

Completion Code

MQCC_FAILED

Programmer response

Correct the parameter.

2331 (091B) (RC2331): MQRC_MSG_TOKEN_ERROR:

Explanation

An MQGET call was issued to retrieve a message using the message token as a selection criterion, but the options specified are not valid, because MQMO_MATCH_MSG_TOKEN was specified with either MQGMO_WAIT or MQGMO_SET_SIGNAL.

An Async Consumer was registered to retrieve a message using the message token as a selection criterion, but when the delivery of messages for this consumer was started no message matching the message token was available for delivery to the consumer. As a result the consumer is suspended.

Completion Code

MQCC_FAILED

Programmer response

If this reason code is returned from an MQGET call, either remove the MQMO_MATCH_MSG_TOKEN match option, or remove the MQGMO_WAIT, or MQGMO_SET_SIGNAL option which was specified.

If this reason code is returned to an Async Consume Event Handler, then the consumer has been suspended and no further messages will be delivered to the consumer. The consumer should be de-registered or modified to select a different message using the MQCB call.

2332 (091C) (RC2332): MQRC_MISSING_WIH:

Explanation

An MQPUT or MQPUT1 call was issued to put a message on a queue with an `IndexType` attribute that had the value MQIT_MSG_TOKEN, but the `Format` field in the MQMD was not MQFMT_WORK_INFO_HEADER. This error occurs only when the message arrives at the destination queue manager.

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

Modify the application to ensure that it places an MQWIH structure at the start of the message data, and sets the `Format` field in the MQMD to MQFMT_WORK_INFO_HEADER. Alternatively, change the `ApplType` attribute of the process definition used by the destination queue to be MQAT_WLM, and specify the required service name and service step name in its `EnvData` attribute.

2333 (091D) (RC2333): MQRC_WIH_ERROR:

Explanation

An MQPUT or MQPUT1 call was issued, but the message data contains an MQWIH structure that is not valid. Possible errors include the following:

- The *StrucId* field is not MQWIH_STRUC_ID.
- The *Version* field is not MQWIH_VERSION_1.
- The *StrucLength* field is not MQWIH_LENGTH_1.
- The *CodedCharSetId* field is zero, or a negative value that is not valid.
- The *BufferLength* parameter of the call has a value that is too small to accommodate the structure (the structure extends beyond the end of the message).
- On z/OS, this error also occurs when the *IndexType* attribute of the queue is MQIT_MSG_TOKEN, but the message data does not begin with an MQWIH structure.

Completion Code

MQCC_FAILED

Programmer response

Check that the fields in the structure are set correctly. Ensure that the application sets the *CodedCharSetId* field to a valid value (note: MQCCSI_DEFAULT, MQCCSI_EMBEDDED, MQCCSI_Q_MGR, and MQCCSI_UNDEFINED are *not* valid in this field).

- On z/OS, if the queue has an *IndexType* of MQIT_MSG_TOKEN, ensure that the message data begins with an MQWIH structure.

2334 (091E) (RC2334): MQRC_RFH_ERROR:

Explanation

An MQPUT or MQPUT1 call was issued, but the message data contains an MQRFH or MQRFH2 structure that is not valid. Possible errors include the following:

- The *StrucId* field is not MQRFH_STRUC_ID.
- The *Version* field is not MQRFH_VERSION_1 (MQRFH), or MQRFH_VERSION_2 (MQRFH2).
- The *StrucLength* field specifies a value that is too small to include the structure plus the variable-length data at the end of the structure.
- The *CodedCharSetId* field is zero, or a negative value that is not valid.
- The *BufferLength* parameter of the call has a value that is too small to accommodate the structure (the structure extends beyond the end of the message).

Completion Code

MQCC_FAILED

Programmer response

Check that the fields in the structure are set correctly. Ensure that the application sets the *CodedCharSetId* field to a valid value (note: MQCCSI_DEFAULT, MQCCSI_EMBEDDED, MQCCSI_Q_MGR, and MQCCSI_UNDEFINED are *not* valid in this field).

2335 (091F) (RC2335): MQRC_RFH_STRING_ERROR:

Explanation

The contents of the *NameValueString* field in the MQRFH structure are not valid. *NameValueString* must adhere to the following rules:

- The string must consist of zero or more name/value pairs separated from each other by one or more blanks; the blanks are not significant.
- If a name or value contains blanks that are significant, the name or value must be enclosed in double quotation marks.
- If a name or value itself contains one or more double quotation marks, the name or value must be enclosed in double quotation marks, and each embedded double quotation mark must be doubled.
- A name or value can contain any characters other than the null, which acts as a delimiter. The null and characters following it, up to the defined length of *NameValueString*, are ignored.

The following is a valid *NameValueString*:

```
Famous_Words "The program displayed ""Hello World"""
```

Completion Code

MQCC_FAILED

Programmer response

Modify the application that generated the message to ensure that it places in the *NameValueString* field data that adheres to the rules. Check that the *StrucLength* field is set to the correct value.

2336 (0920) (RC2336): MQRC_RFH_COMMAND_ERROR:

Explanation

The message contains an MQRFH structure, but the command name contained in the *NameValueString* field is not valid.

Completion Code

MQCC_FAILED

Programmer response

Modify the application that generated the message to ensure that it places in the *NameValueString* field a command name that is valid.

2337 (0921) (RC2337): MQRC_RFH_PARM_ERROR:

Explanation

The message contains an MQRFH structure, but a parameter name contained in the *NameValueString* field is not valid for the command specified.

Completion Code

MQCC_FAILED

Programmer response

Modify the application that generated the message to ensure that it places in the *NameValueString* field only parameters that are valid for the specified command.

2338 (0922) (RC2338): MQRC_RFH_DUPLICATE_PARM:

Explanation

The message contains an MQRFH structure, but a parameter occurs more than once in the *NameValueString* field when only one occurrence is valid for the specified command.

Completion Code

MQCC_FAILED

Programmer response

Modify the application that generated the message to ensure that it places in the *NameValueString* field only one occurrence of the parameter.

2339 (0923) (RC2339): MQRC_RFH_PARM_MISSING:

Explanation

The message contains an MQRFH structure, but the command specified in the *NameValueString* field requires a parameter that is not present.

Completion Code

MQCC_FAILED

Programmer response

Modify the application that generated the message to ensure that it places in the *NameValueString* field all parameters that are required for the specified command.

2340 (0924) (RC2340): MQRC_CHAR_CONVERSION_ERROR:

Explanation

This reason code is returned by the Java MQQueueManager constructor when a required character-set conversion is not available. The conversion required is between two nonUnicode character sets.

This reason code occurs in the following environment: MQ Classes for Java on z/OS.

Completion Code

MQCC_FAILED

Programmer response

Ensure that the National Language Resources component of the z/OS Language Environment is installed, and that conversion between the IBM-1047 and ISO8859-1 character sets is available.

2341 (0925) (RC2341): MQRC_UCS2_CONVERSION_ERROR:

Explanation

This reason code is returned by the Java MQQueueManager constructor when a required character set conversion is not available. The conversion required is between the UCS-2 Unicode character set and the character set of the queue manager which defaults to IBM-500 if no specific value is available.

Completion Code

MQCC_FAILED

Programmer response

Ensure that the relevant Unicode conversion tables are available for the JVM. For z/OS ensure that the Unicode conversion tables are available to the z/OS Language Environment. The conversion tables should be installed as part of the z/OS C/C++ optional feature. Refer to the *z/OS C/C++ Programming Guide* for more information about enabling UCS-2 conversions.

2342 (0926) (RC2342): MQRC_DB2_NOT_AVAILABLE:

Explanation

An MQOPEN, MQPUT1, or MQSET call, or a command, was issued to access a shared queue, but it failed because the queue manager is not connected to a Db2 subsystem. As a result, the queue manager is unable to access the object definition relating to the shared queue.

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

Configure the Db2 subsystem so that the queue manager can connect to it.

2343 (0927) (RC2343): MQRC_OBJECT_NOT_UNIQUE:

Explanation

An MQOPEN or MQPUT1 call, or a command, was issued to access a queue, but the call failed because the queue specified cannot be resolved unambiguously. There exists a shared queue with the specified name, and a nonshared queue with the same name.

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

One of the queues must be deleted. If the queue to be deleted contains messages, use the MQSC command MOVE QLOCAL to move the messages to a different queue, and then use the command DELETE QLOCAL to delete the queue.

2344 (0928) (RC2344): MQRC_CONN_TAG_NOT_RELEASED:

Explanation

An MQDISC call was issued when there was a unit of work outstanding for the connection handle. For CICS, IMS, and RRS connections, the MQDISC call does not commit or back out the unit of work. As a result, the connection tag associated with the unit of work is not yet available for reuse. The tag becomes available for reuse only when processing of the unit of work has been completed.

This reason code occurs only on z/OS.

Completion Code

MQCC_WARNING

Programmer response

Do not try to reuse the connection tag immediately. If the MQCONNX call is issued with the same connection tag, and that tag is still in use, the call fails with reason code MQRC_CONN_TAG_IN_USE.

2345 (0929) (RC2345): MQRC_CF_NOT_AVAILABLE:

Explanation

An MQI call was issued to access a shared queue, but the call failed either because connectivity was lost to the coupling facility (CF) where the CF structure specified in the queue definition was allocated, or because allocation of the CF structure failed because there is no suitable CF to hold the structure, based on the preference list in the active CFRM policy.

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

If connectivity was lost to the CF where the structure was allocated, and the queue manager has been configured to tolerate the failure and rebuild the structure, no action should be necessary. Otherwise, make available a coupling facility with one of the names specified in the CFRM policy, or modify the CFRM policy to specify the names of coupling facilities that are available.

2346 (092A) (RC2346): MQRC_CF_STRUC_IN_USE:

Explanation

An MQI call or command was issued to operate on a shared queue, but the call failed because the coupling-facility structure specified in the queue definition is unavailable. The coupling-facility structure can be unavailable because a structure dump is in progress, or new connectors to the structure are currently inhibited, or an existing connector to the structure failed or disconnected abnormally and clean-up is not yet complete.

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

Typically, this is a temporary problem: wait for a while then retry the operation.

If the problem does not resolve itself, then connectivity problems experienced during the recovery of structures in the coupling facility could have occurred. In this case, restart the queue manager which reported the error. Resolve all the connectivity problems concerning the coupling facility before restarting the queue manager.

2347 (092B) (RC2347): MQRC_CF_STRUC_LIST_HDR_IN_USE:

Explanation

An MQGET, MQOPEN, MQPUT1, or MQSET call was issued to access a shared queue, but the call failed because the list header associated with the coupling-facility structure specified in the queue definition is temporarily unavailable. The list header is unavailable because it is undergoing recovery processing.

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

The problem is temporary; wait a short while and then retry the operation.

2348 (092C) (RC2348): MQRC_CF_STRUC_AUTH_FAILED:

Explanation

An MQOPEN or MQPUT1 call was issued to access a shared queue, but the call failed because the user is not authorized to access the coupling-facility structure specified in the queue definition.

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

Modify the security profile for the user identifier used by the application so that the application can access the coupling-facility structure specified in the queue definition.

2349 (092D) (RC2349): MQRC_CF_STRUC_ERROR:

Explanation

An MQOPEN or MQPUT1 call was issued to access a shared queue, but the call failed because the coupling-facility structure name specified in the queue definition is not defined in the CFRM data set, or is not the name of a list structure.

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

Modify the queue definition to specify the name of a coupling-facility list structure that is defined in the CFRM data set.

2350 (092E) (RC2350): MQRC_CONN_TAG_NOT_USABLE:

Explanation

An MQCONNX call was issued specifying one of the MQCNO_*_CONN_TAG_* options, but the call failed because the connection tag specified by *ConnTag* in MQCNO is being used by the queue manager for recovery processing, and this processing is delayed pending recovery of the coupling facility.

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

The problem is likely to persist. Consult the system programmer to ascertain the cause of the problem.

2351 (092F) (RC2351): MQRC_GLOBAL_UOW_CONFLICT:

Explanation

An attempt was made to use inside a global unit of work a connection handle that is participating in another global unit of work. This can occur when an application passes connection handles between objects where the objects are involved in different DTC transactions. Because transaction completion is asynchronous, it is possible for this error to occur *after* the application has finalized the first object and committed its transaction.

This error does not occur for nontransactional MQI calls.

This reason code occurs only on Windows and z/OS.

Completion Code

MQCC_FAILED

Programmer response

Check that the "MTS Transaction Support⌂ attribute defined for the object's class is set correctly. If necessary, modify the application so that the connection handle is not used by objects participating in different units of work.

2352 (0930) (RC2352): MQRC_LOCAL_UOW_CONFLICT:

Explanation

An attempt was made to use inside a global unit of work a connection handle that is participating in a queue-manager coordinated local unit of work. This can occur when an application passes connection handles between objects where one object is involved in a DTC transaction and the other is not.

This error does not occur for nontransactional MQI calls.

This reason code occurs only on Windows and z/OS.

Completion Code

MQCC_FAILED

Programmer response

Check that the "MTS Transaction Support⌂ attribute defined for the object's class is set correctly. If necessary, modify the application so that the connection handle is not used by objects participating in different units of work.

2353 (0931) (RC2353): MQRC_HANDLE_IN_USE_FOR_UOW:

Explanation

An attempt was made to use outside a unit of work a connection handle that is participating in a global unit of work.

This error can occur when an application passes connection handles between objects where one object is involved in a DTC transaction and the other is not. Because transaction completion is asynchronous, it is possible for this error to occur *after* the application has finalized the first object and committed its transaction.

This error can also occur when a single object that was created and associated with the transaction loses that association whilst the object is running. The association is lost when DTC terminates the transaction independently of MTS. This might be because the transaction timed out, or because DTC shut down.

This error does not occur for nontransactional MQI calls.

This reason code occurs only on Windows.

Completion Code

MQCC_FAILED

Programmer response

Check that the "MTS Transaction Support" attribute defined for the object's class is set correctly. If necessary, modify the application so that objects executing within different units of work do not try to use the same connection handle.

2354 (0932) (RC2354): MQRC_UOW_ENLISTMENT_ERROR:

Explanation

This reason code can occur for various reasons and occurs only on Windows , and HP Integrity NonStop Server .

On Windows, the most likely reason is that an object created by a DTC transaction does not issue a transactional MQI call until after the DTC transaction timed out. (If the DTC transaction times out after a transactional MQI call has been issued, reason code MQRC_HANDLE_IN_USE_FOR_UOW is returned by the failing MQI call.)

On HP Integrity NonStop Server, this reason occurs:

- On a transactional MQI call when the client encounters a configuration error preventing it from enlisting with the TMF/Gateway, therefore preventing participation within a global unit of work that is coordinated by the Transaction Management Facility (TMF).
- If a client application makes an enlistment request before the TMF/Gateway completes recovery of in-doubt transactions, the request is held for up to 1 second. If recovery does not complete within that time, the enlistment is rejected.

Another cause of MQRC_UOW_ENLISTMENT_ERROR is incorrect installation; On Windows, for example, the Windows NT Service pack must be installed after the Windows NT Option pack.

Completion Code

MQCC_FAILED

Programmer response

On Windows, check the DTC "Transaction timeout" value. If necessary, verify the Windows NT installation order.

On HP Integrity NonStop Server this might be a configuration error. The client issues a message to the client error log providing extra information about the configuration error. Contact your system administrator to resolve the indicated error.

2355 (0933) (RC2355): MQRC_UOW_MIX_NOT_SUPPORTED:

Explanation

This reason code occurs only on Windows when you are running a version of the queue manager before version 5.2. , and on HP Integrity NonStop Server .

On Windows, the following explanations might apply:
- The mixture of calls that is used by the application to perform operations within a unit of work is not supported. In particular, it is not possible to mix within the same process a local unit of work that is coordinated by the queue manager with a global unit of work that is coordinated by DTC (Distributed Transaction Coordinator).
- An application might cause this mixture to arise if some objects in a package are coordinated by DTC and others are not. It can also occur if transactional MQI calls from an MTS client are mixed with transactional MQI calls from a library package transactional MTS object.
- No problem arises if all transactional MQI calls originate from transactional MTS objects, or all transactional MQI calls originate from non-transactional MTS objects. But when a mixture of styles is used, the first style that is used fixes the style for the unit of work, and subsequent attempts to use the other style within the process fail with reason code MQRC_UOW_MIX_NOT_SUPPORTED.
- When an application is run twice, scheduling factors in the operating system mean that it is possible for the queue-manager-coordinated transactional calls to fail in one run, and for the DTC-coordinated transactional calls to fail in the other run.

On HP Integrity NonStop Server it is not possible, within a single IBM MQ connection, to issue transactional MQI calls under the coordination of the Transaction Management Facility (TMF) if transactional MQI calls have already been made within a local unit of work that is coordinated by the queue manager until the local unit of work is completed by issuing either MQCMIT or MQBACK.

Completion Code

MQCC_FAILED

Programmer response

On Windows, check that the "MTS Transaction Support" attribute defined for the object's class is set correctly. If necessary, modify the application so that objects that run within different units of work do not try to use the same connection handle.

On HP Integrity NonStop Server, if a local unit of work that is coordinated by the queue manager is in progress, it must either be completed by issuing MQCMIT, or rolled back by issuing MQBACK before issuing any transactional MQI calls under the coordination of TMF.

2356 (0934) (RC2356): MQRC_WXP_ERROR:

Explanation

An MQXCLWLN call was issued from a cluster workload exit to obtain the address of the next record in the chain, but the workload exit parameter structure *ExitParms* is not valid, for one of the following reasons:

- The parameter pointer is not valid. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)
- The *StrucId* field is not MQWXP_STRUC_ID.
- The *Version* field is not MQWXP_VERSION_2.
- The *CacheContext* field does not contain the value passed to the exit by the queue manager.

Completion Code

MQCC_FAILED

Programmer response

Ensure that the parameter specified for *ExitParms* is the MQWXP structure that was passed to the exit when the exit was invoked.

2357 (0935) (RC2357): MQRC_CURRENT_RECORD_ERROR:

Explanation

An MQXCLWLN call was issued from a cluster workload exit to obtain the address of the next record in the chain, but the address specified by the *CurrentRecord* parameter is not the address of a valid record. *CurrentRecord* must be the address of a destination record (MQWDR), queue record (MQWQR), or cluster record (MQWCR) residing within the cluster cache.

Completion Code

MQCC_FAILED

Programmer response

Ensure that the cluster workload exit passes the address of a valid record residing in the cluster cache.

2358 (0936) (RC2358): MQRC_NEXT_OFFSET_ERROR:

Explanation

An MQXCLWLN call was issued from a cluster workload exit to obtain the address of the next record in the chain, but the offset specified by the *NextOffset* parameter is not valid. *NextOffset* must be the value of one of the following fields:

- *ChannelDefOffset* field in MQWDR
- *ClusterRecOffset* field in MQWDR
- *ClusterRecOffset* field in MQWQR
- *ClusterRecOffset* field in MQWCR

Completion Code

MQCC_FAILED

Programmer response

Ensure that the value specified for the *NextOffset* parameter is the value of one of the fields listed.

2359 (0937) (RC2359): MQRC_NO_RECORD_AVAILABLE:

Explanation

An MQXCLWLN call was issued from a cluster workload exit to obtain the address of the next record in the chain, but the current record is the last record in the chain.

Completion Code

MQCC_FAILED

Programmer response

None.

2360 (0938) (RC2360): MQRC_OBJECT_LEVEL_INCOMPATIBLE:

Explanation

An MQOPEN or MQPUT1 call, or a command, was issued, but the definition of the object to be accessed is not compatible with the queue manager to which the application has connected. The object definition was created or modified by a different version of the queue manager.

If the object to be accessed is a queue, the incompatible object definition could be the object specified, or one of the object definitions used to resolve the specified object (for example, the base queue to which an alias queue resolves, or the transmission queue to which a remote queue or queue-manager alias resolves).

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

The application must be run on a queue manager that is compatible with the object definition. .

2361 (0939) (RC2361): MQRC_NEXT_RECORD_ERROR:

Explanation

An MQXCLWLN call was issued from a cluster workload exit to obtain the address of the next record in the chain, but the address specified for the *NextRecord* parameter is either null, not valid, or the address of read-only storage. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)

Completion Code

MQCC_FAILED

Programmer response

Specify a valid address for the *NextRecord* parameter.

2362 (093A) (RC2362): MQRC_BACKOUT_THRESHOLD_REACHED:

Explanation

This reason code occurs only in the *Reason* field in an MQDLH structure, or in the *Feedback* field in the MQMD of a report message.

A JMS ConnectionConsumer found a message that exceeds the queue's backout threshold. The queue does not have a backout requeue queue defined, so the message was processed as specified by the disposition options in the *Report* field in the MQMD of the message.

On queue managers that do not support the *BackoutThreshold* and *BackoutRequeueQName* queue attributes, JMS ConnectionConsumer uses a value of 20 for the backout threshold. When the *BackoutCount* of a message reaches this threshold, the message is processed as specified by the disposition options.

If the *Report* field specifies one of the MQRO_EXCEPTION_* options, this reason code appears in the *Feedback* field of the report message. If the *Report* field specifies MQRO_DEAD_LETTER_Q, or the disposition report options remain at the default, this reason code appears in the *Reason* field of the MQDLH.

Completion Code

None

Programmer response

Investigate the cause of the backout count being greater than the threshold. To correct this, define the backout queue for the queue concerned.

2363 (093B) (RC2363): MQRC_MSG_NOT_MATCHED:

Explanation

This reason code occurs only in the `Reason` field in an MQDLH structure, or in the `Feedback` field in the MQMD of a report message.

While performing Point-to-Point messaging, JMS encountered a message matching none of the selectors of ConnectionConsumers monitoring the queue. To maintain performance, the message was processed as specified by the disposition options in the `Report` field in the MQMD of the message.

If the `Report` field specifies one of the MQRO_EXCEPTION_* options, this reason code appears in the `Feedback` field of the report message. If the `Report` field specifies MQRO_DEAD_LETTER_Q, or the disposition report options remain at the default, this reason code appears in the `Reason` field of the MQDLH.

Completion Code

None

Programmer response

To correct this, ensure that the ConnectionConsumers monitoring the queue provide a complete set of selectors. Alternatively, set the QueueConnectionFactory to retain messages.

2364 (093C) (RC2364): MQRC_JMS_FORMAT_ERROR:

Explanation

This reason code is generated by JMS applications that use either:
- ConnectionConsumers
- Activation Specifications
- WebSphere Application Server Listener Ports

and connect to an IBM MQ queue manager using IBM MQ messaging provider migration mode. When the IBM MQ classes for JMS encounter a message that cannot be parsed (for example, the message contains an invalid RFH2 header) the message is processed as specified by the disposition options in the `Report` field in the MQMD of the message.

If the `Report` field specifies one of the MQRO_EXCEPTION_* options, this reason code appears in the `Feedback` field of the report message. If the `Report` field specifies MQRO_DEAD_LETTER_Q, or the disposition report options remain at the default, this reason code appears in the `Reason` field of the MQDLH.

Completion Code

None

Programmer response

Investigate the origin of the message.

2365 (093D) (RC2365): MQRC_SEGMENTS_NOT_SUPPORTED:

Explanation

An MQPUT call was issued to put a segment of a logical message, but the queue on which the message is to be placed has an *IndexType* of MQIT_GROUP_ID. Message segments cannot be placed on queues with this index type.

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

Modify the application to put messages that are not segments; ensure that the MQMF_SEGMENT and MQMF_LAST_SEGMENT flags in the *MsgFlags* field in MQMD are not set, and that the *Offset* is zero. Alternatively, change the index type of the queue.

2366 (093E) (RC2366): MQRC_WRONG_CF_LEVEL:

Explanation

An MQOPEN or MQPUT1 call was issued specifying a shared queue, but the queue requires a coupling-facility structure with a different level of capability.

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

Ensure that the coupling-facility structure used for the queue is at the level required to support the capabilities that the queue provides.

You can use the DISPLAY CFSTRUCT command to display the level, and ALTER CFSTRUCT() CFLEVEL() command to modify the level; see The MQSC commands.

2367 (093F) (RC2367): MQRC_CONFIG_CREATE_OBJECT:

Explanation

This condition is detected when an object is created.

Completion Code

MQCC_WARNING

Programmer response

None. This reason code is only used to identify the corresponding event message Create object.

2368 (0940) (RC2368): MQRC_CONFIG_CHANGE_OBJECT:

Explanation

This condition is detected when an object is changed.

Completion Code

MQCC_WARNING

Programmer response

None. This reason code is only used to identify the corresponding event message Change object.

2369 (0941) (RC2369): MQRC_CONFIG_DELETE_OBJECT:

Explanation

This condition is detected when an object is deleted.

Completion Code

MQCC_WARNING

Programmer response

None. This reason code is only used to identify the corresponding event message Delete object.

2370 (0942) (RC2370): MQRC_CONFIG_REFRESH_OBJECT:

Explanation

This condition is detected when an object is refreshed.

Completion Code

MQCC_WARNING

Programmer response

None. This reason code is only used to identify the corresponding event message Refresh object.

2371 (0943) (RC2371): MQRC_CHANNEL_SSL_ERROR:

Explanation

This condition is detected when a connection cannot be established due to an SSL key-exchange or authentication failure.

Completion Code

MQCC_WARNING

Programmer response

None. This reason code is only used to identify the corresponding event message Channel SSL Error.

2373 (0945) (RC2373): MQRC_CF_STRUC_FAILED:

Explanation

An MQI call or command was issued to access a shared queue, but the call failed because the coupling-facility structure used for the shared queue had failed.

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

Report the problem to the operator or administrator, who should use the MQSC command RECOVER CFSTRUCT to initiate recovery of the coupling-facility structure, unless automatic recovery has been enabled for the structure.

2374 (0946) (RC2374): MQRC_API_EXIT_ERROR:

Explanation

An API exit function returned an invalid response code, or failed in some other way.

This reason code occurs in the following environments: AIX, HP-UX, Solaris, Windows.

Completion Code

MQCC_FAILED

Programmer response

Check the exit logic to ensure that the exit is returning valid values in the *ExitResponse* and *ExitResponse2* fields of the MQAXP structure. Consult the FFST record to see if it contains more detail about the problem.

2375 (0947) (RC2375): MQRC_API_EXIT_INIT_ERROR:

Explanation

The queue manager encountered an error while attempting to initialize the execution environment for an API exit function.

This reason code occurs in the following environments: AIX, HP-UX, Solaris, Windows.

Completion Code

MQCC_FAILED

Programmer response

Consult the FFST record to obtain more detail about the problem.

2376 (0948) (RC2376): MQRC_API_EXIT_TERM_ERROR:

Explanation

The queue manager encountered an error while attempting to terminate the execution environment for an API exit function.

This reason code occurs in the following environments: AIX, HP-UX, Solaris, Windows.

Completion Code

MQCC_FAILED

Programmer response

Consult the FFST record to obtain more detail about the problem.

2377 (0949) (RC2377): MQRC_EXIT_REASON_ERROR:

Explanation

An MQXEP call was issued by an API exit function, but the value specified for the `ExitReason` parameter is either not valid, or not supported for the specified function identifier `Function`.

This reason code occurs in the following environments: AIX, HP-UX, Solaris, Windows.

Completion Code

MQCC_FAILED

Programmer response

Modify the exit function to specify a value for `ExitReason` that is valid for the specified value of `Function`.

2378 (094A) (RC2378): MQRC_RESERVED_VALUE_ERROR:

Explanation

An MQXEP call was issued by an API exit function, but the value specified for the `Reserved` parameter is not valid. The value must be the null pointer.

This reason code occurs in the following environments: AIX, HP-UX, Solaris, Windows.

Completion Code

MQCC_FAILED

Programmer response

Modify the exit to specify the null pointer as the value of the `Reserved` parameter.

2379 (094B) (RC2379): MQRC_NO_DATA_AVAILABLE:

Explanation

This reason should be returned by the MQZ_ENUMERATE_AUTHORITY_DATA installable service component when there is no more authority data to return to the invoker of the service component.
- On z/OS, this reason code does not occur.

Completion Code

MQCC_FAILED

Programmer response

None.

2380 (094C) (RC2380): MQRC_SCO_ERROR:

Explanation

On an MQCONNX call, the MQSCO structure is not valid for one of the following reasons:
- The *StrucId* field is not MQSCO_STRUC_ID.
- The *Version* field specifies a value that is not valid or not supported.

This reason code occurs in the following environments: AIX, HP-UX, Solaris, Windows.

Completion Code

MQCC_FAILED

Programmer response

Correct the definition of the MQSCO structure.

2381 (094D) (RC2381): MQRC_KEY_REPOSITORY_ERROR:

Explanation

On an MQCONN or MQCONNX call, the location of the key repository is either not specified, not valid, or results in an error when used to access the key repository. The location of the key repository is specified by one of the following:
- The value of the MQSSLKEYR environment variable (MQCONN or MQCONNX call), or
- The value of the *KeyRepository* field in the MQSCO structure (MQCONNX call only).

For the MQCONNX call, if both MQSSLKEYR and *KeyRepository* are specified, the latter is used.

This reason code occurs in the following environments: AIX, HP-UX, Solaris, Windows.

Completion Code

MQCC_FAILED

Programmer response

Specify a valid location for the key repository.

2382 (094E) (RC2382): MQRC_CRYPTO_HARDWARE_ERROR:

Explanation

On an MQCONN or MQCONNX call, the configuration string for the cryptographic hardware is not valid, or results in an error when used to configure the cryptographic hardware. The configuration string is specified by one of the following:
- The value of the MQSSLCRYP environment variable (MQCONN or MQCONNX call), or
- The value of the *CryptoHardware* field in the MQSCO structure (MQCONNX call only).

For the MQCONNX call, if both MQSSLCRYP and *CryptoHardware* are specified, the latter is used.

This reason code occurs in the following environments: AIX, HP-UX, Solaris, Windows.

Completion Code

MQCC_FAILED

Programmer response

Specify a valid configuration string for the cryptographic hardware.

2383 (094F) (RC2383): MQRC_AUTH_INFO_REC_COUNT_ERROR:

Explanation

On an MQCONNX call, the *AuthInfoRecCount* field in the MQSCO structure specifies a value that is less than zero.

This reason code occurs in the following environments: AIX, HP-UX, Solaris, Windows.

Completion Code

MQCC_FAILED

Programmer response

Specify a value for *AuthInfoRecCount* that is zero or greater.

2384 (0950) (RC2384): MQRC_AUTH_INFO_REC_ERROR:

Explanation

On an MQCONNX call, the MQSCO structure does not specify the address of the MQAIR records correctly. One of the following applies:
- *AuthInfoRecCount* is greater than zero, but *AuthInfoRecOffset* is zero and *AuthInfoRecPtr* is the null pointer.
- *AuthInfoRecOffset* is not zero and *AuthInfoRecPtr* is not the null pointer.
- *AuthInfoRecPtr* is not a valid pointer.
- *AuthInfoRecOffset* or *AuthInfoRecPtr* points to storage that is not accessible.

This reason code occurs in the following environments: AIX, HP-UX, Solaris, Windows.

Completion Code

MQCC_FAILED

Programmer response

Ensure that one of *AuthInfoRecOffset* or *AuthInfoRecPtr* is zero and the other nonzero. Ensure that the field used points to accessible storage.

2385 (0951) (RC2385): MQRC_AIR_ERROR:

Explanation

On an MQCONNX call, an MQAIR record is not valid for one of the following reasons:
- The *StrucId* field is not MQAIR_STRUC_ID.
- The *Version* field specifies a value that is not valid or not supported.

This reason code occurs in the following environments: AIX, HP-UX, Solaris, Windows.

Completion Code

MQCC_FAILED

Programmer response

Correct the definition of the MQAIR record.

2386 (0952) (RC2386): MQRC_AUTH_INFO_TYPE_ERROR:

Explanation

On an MQCONNX call, the *AuthInfoType* field in an MQAIR record specifies a value that is not valid.

This reason code occurs in the following environments: AIX, HP-UX, Solaris, Windows.

Completion Code

MQCC_FAILED

Programmer response

Specify MQAIT_CRL_LDAP for *AuthInfoType*.

2387 (0953) (RC2387): MQRC_AUTH_INFO_CONN_NAME_ERROR:

Explanation

On an MQCONNX call, the *AuthInfoConnName* field in an MQAIR record specifies a value that is not valid.

This reason code occurs in the following environments: AIX, HP-UX, Solaris, Windows.

Completion Code

MQCC_FAILED

Programmer response

Specify a valid connection name.

2388 (0954) (RC2388): MQRC_LDAP_USER_NAME_ERROR:

Explanation

On an MQCONNX call, an LDAP user name in an MQAIR record is not specified correctly. One of the following applies:

- *LDAPUserNameLength* is greater than zero, but *LDAPUserNameOffset* is zero and *LDAPUserNamePtr* is the null pointer.
- *LDAPUserNameOffset* is nonzero and *LDAPUserNamePtr* is not the null pointer.
- *LDAPUserNamePtr* is not a valid pointer.
- *LDAPUserNameOffset* or *LDAPUserNamePtr* points to storage that is not accessible.

This reason code occurs in the following environments: AIX, HP-UX, Solaris, Windows.

Completion Code

MQCC_FAILED

Programmer response

Ensure that one of *LDAPUserNameOffset* or *LDAPUserNamePtr* is zero and the other nonzero. Ensure that the field used points to accessible storage.

2389 (0955) (RC2389): MQRC_LDAP_USER_NAME_LENGTH_ERR:

Explanation

On an MQCONNX call, the *LDAPUserNameLength* field in an MQAIR record specifies a value that is less than zero.

This reason code occurs in the following environments: AIX, HP-UX, Solaris, Windows.

Completion Code

MQCC_FAILED

Programmer response

Specify a value for *LDAPUserNameLength* that is zero or greater.

2390 (0956) (RC2390): MQRC_LDAP_PASSWORD_ERROR:

Explanation

On an MQCONNX call, the *LDAPPassword* field in an MQAIR record specifies a value when no value is allowed.

This reason code occurs in the following environments: AIX, HP-UX, Solaris, Windows.

Completion Code

MQCC_FAILED

Programmer response

Specify a value that is blank or null.

2391 (0957) (RC2391): MQRC_SSL_ALREADY_INITIALIZED:

Explanation

An MQCONN or MQCONNX call was issued when a connection is already open to the same queue manager. There is a conflict between the SSL options of the connections for one of three reasons:
- The SSL configuration options are different between the first and second connections.
- The existing connection was specified without SSL configuration options, but the second connection has SSL configuration options specified.
- The existing connection was specified with SSL configuration options, but the second connection does not have any SSL configuration options specified.

The connection to the queue manager completed successfully, but the SSL configuration options specified on the call were ignored; the existing SSL environment was used instead.

This reason code occurs in the following environments: AIX, HP-UX, Solaris, Windows.

Completion Code

MQCC_WARNING

Programmer response

If the application must be run with the SSL configuration options defined on the MQCONN or MQCONNX call, use the MQDISC call to sever the connection to the queue manager and then stop the application. Alternatively run the application later when the SSL environment has not been initialized.

2392 (0958) (RC2392): MQRC_SSL_CONFIG_ERROR:

Explanation

On an MQCONNX call, the MQCNO structure does not specify the MQSCO structure correctly. One of the following applies:
- *SSLConfigOffset* is nonzero and *SSLConfigPtr* is not the null pointer.
- *SSLConfigPtr* is not a valid pointer.
- *SSLConfigOffset* or *SSLConfigPtr* points to storage that is not accessible.

This reason code occurs in the following environments: AIX, HP-UX, Solaris, Windows.

Completion Code

MQCC_FAILED

Programmer response

Ensure that one of *SSLConfigOffset* or *SSLConfigPtr* is zero and the other nonzero. Ensure that the field used points to accessible storage.

2393 (0959) (RC2393): MQRC_SSL_INITIALIZATION_ERROR:

Explanation

An MQCONN or MQCONNX call was issued with SSL configuration options specified, but an error occurred during the initialization of the SSL environment.

This reason code occurs in the following environments: AIX, HP-UX, Solaris, Windows.

Completion Code

MQCC_FAILED

Programmer response

Check that the SSL installation is correct.

2394 (095A) (RC2394): MQRC_Q_INDEX_TYPE_ERROR:

Explanation

An MQGET call was issued specifying one or more of the following options:
- MQGMO_ALL_MSGS_AVAILABLE
- MQGMO_ALL_SEGMENTS_AVAILABLE
- MQGMO_COMPLETE_MSG
- MQGMO_LOGICAL_ORDER

but the call failed because the queue is not indexed by group identifier. These options require the queue to have an `IndexType` of MQIT_GROUP_ID.

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

Redefine the queue to have an `IndexType` of MQIT_GROUP_ID. Alternatively, modify the application to avoid using the options listed.

2395 (095B) (RC2395): MQRC_CFBS_ERROR:

Explanation

An MQPUT or MQPUT1 call was issued, but the message data contains an MQCFBS structure that is not valid.

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Check that the fields in the structure are set correctly.

2396 (095C) (RC2396): MQRC_SSL_NOT_ALLOWED:

Explanation

A connection to a queue manager was requested, specifying SSL encryption. However, the connection mode requested is one that does not support SSL (for example, bindings connect).

Completion Code

MQCC_FAILED

Programmer response

Modify the application to request client connection mode, or to disable SSL encryption.

Note: Using a non null setting, including blanks, for the connection's cipher suite property can also cause this error.

2397 (095D) (RC2397): MQRC_JSSE_ERROR:

Explanation

JSSE reported an error (for example, while connecting to a queue manager using SSL encryption). The MQException object containing this reason code references the Exception thrown by JSSE; this can be obtained by using the MQException.getCause() method. From JMS, the MQException is linked to the thrown JMSException.

This reason code occurs only with Java applications.

Completion Code

MQCC_FAILED

Programmer response

Inspect the causal exception to determine the JSSE error.

2398 (095E) (RC2398): MQRC_SSL_PEER_NAME_MISMATCH:

Explanation

The application attempted to connect to the queue manager using SSL encryption, but the distinguished name presented by the queue manager does not match the specified pattern.

Completion Code

MQCC_FAILED

Programmer response

Check the certificates used to identify the queue manager. Also check the value of the sslPeerName property specified by the application.

2399 (095F) (RC2399): MQRC_SSL_PEER_NAME_ERROR:

Explanation

The application specified a peer name of incorrect format.

Completion Code

MQCC_FAILED

Programmer response

Check the value of the sslPeerName property specified by the application.

2400 (0960) (RC2400): MQRC_UNSUPPORTED_CIPHER_SUITE:

Explanation

A connection to a queue manager was requested, specifying SSL encryption. However, JSSE reported that it does not support the CipherSuite specified by the application.

This reason code occurs only with Java applications.

Completion Code

MQCC_FAILED

Programmer response

Check the CipherSuite specified by the application. Note that the names of JSSE CipherSuites differ from their equivalent CipherSpecs used by the queue manager.

Also, check that JSSE is correctly installed.

2401 (0961) (RC2401): MQRC_SSL_CERTIFICATE_REVOKED:

Explanation

A connection to a queue manager was requested, specifying SSL encryption. However, the certificate presented by the queue manager was found to be revoked by one of the specified CertStores.

This reason code occurs only with Java applications.

Completion Code

MQCC_FAILED

Programmer response

Check the certificates used to identify the queue manager.

2402 (0962) (RC2402): MQRC_SSL_CERT_STORE_ERROR:

Explanation

A connection to a queue manager was requested, specifying SSL encryption. However, none of the CertStore objects provided by the application could be searched for the certificate presented by the queue manager. The MQException object containing this reason code references the Exception encountered when searching the first CertStore; this can be obtained using the MQException.getCause() method. From JMS, the MQException is linked to the thrown JMSException.

This reason code occurs only with Java applications.

Completion Code

MQCC_FAILED

Programmer response

Inspect the causal exception to determine the underlying error. Check the CertStore objects provided by your application. If the causal exception is a java.lang.NoSuchElementException, ensure that your application is not specifying an empty collection of CertStore objects.

2406 (0966) (RC2406): MQRC_CLIENT_EXIT_LOAD_ERROR:

Explanation

The external user exit required for a client connection could not be loaded because the shared library specified for it cannot be found, or the entry point specified for it cannot be found.

This reason code occurs only with Java applications.

Completion Code

MQCC_FAILED

Programmer response

Ensure that the correct library has been specified, and that the path variable for the machine environment includes the relevant directory. Ensure also that the entry point has been named properly and that the named library does export it.

2407 (0967) (RC2407): MQRC_CLIENT_EXIT_ERROR:

Explanation

A failure occurred while executing a non-Java user exit for a client connection.

This reason code occurs only with Java applications.

Completion Code

MQCC_FAILED

Programmer response

Check that the non-Java user exit can accept the parameters and message being passed to it and that it can handle error conditions, and that any information that the exit requires, such as user data, is correct and available.

2409 (0969) (RC2409): MQRC_SSL_KEY_RESET_ERROR:

Explanation

On an MQCONN or MQCONNX call, the value of the SSL key reset count is not in the valid range of 0 through 999 999 999.

The value of the SSL key reset count is specified by either the value of the MQSSLRESET environment variable (MQCONN or MQCONNX call), or the value of the *KeyResetCount* field in the MQSCO structure (MQCONNX call only). For the MQCONNX call, if both MQSSLRESET and *KeyResetCount* are specified, the latter is used. MQCONN or MQCONNX

If you specify an SSL/TLS secret key reset count in the range 1 byte through 32Kb, SSL/TLS channels will use a secret key reset count of 32Kb. This is to avoid the overhead of excessive key resets which would occur for small SSL/TLS secret key reset values.

Completion Code

MQCC_FAILED

Programmer response

Check that the fields in the structure and the MQSSLRESET environment variable are set correctly.

2411 (096B) (RC2411): MQRC_LOGGER_STATUS:

Explanation

This condition is detected when a logger event occurs.

Completion Code

MQCC_WARNING

Programmer response

None. This reason code is only used to identify the corresponding event message Logger.

2412 (096C) (RC2412): MQRC_COMMAND_MQSC:

Explanation

This condition is detected when an MQSC command is executed.

Completion Code

MQCC_WARNING

Programmer response

None. This reason code is only used to identify the corresponding event message Command.

2413 (096D) (RC2413): MQRC_COMMAND_PCF:

Explanation

This condition is detected when a PCF command is executed.

Completion Code

MQCC_WARNING

Programmer response

None. This reason code is only used to identify the corresponding event message Command.

2414 (096E) (RC2414): MQRC_CFIF_ERROR:

Explanation

An MQPUT or MQPUT1 call was issued, but the message data contains an MQCFIF structure that is not valid.

This reason code occurs in the following environments: AIX, HP-UX, z/OS, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Check that the fields in the structure are set correctly.

2415 (096F) (RC2415): MQRC_CFSF_ERROR:

Explanation

An MQPUT or MQPUT1 call was issued, but the message data contains an MQCFSF structure that is not valid.

This reason code occurs in the following environments: AIX, HP-UX, z/OS, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Check that the fields in the structure are set correctly.

2416 (0970) (RC2416): MQRC_CFGR_ERROR:

Explanation

An MQPUT or MQPUT1 call was issued, but the message data contains an MQCFGR structure that is not valid.

This reason code occurs in the following environments: AIX, HP-UX, z/OS, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Check that the fields in the structure are set correctly.

2417 (0971) (RC2417): MQRC_MSG_NOT_ALLOWED_IN_GROUP:

An explanation of the error, completion code, and programmer response.

Explanation

An MQPUT or MQPUT1 call was issued to put a message in a group but it is not valid to put such a message in a group. An example of an invalid message is a PCF message where the Type is MQCFT_TRACE_ROUTE.

You cannot use grouped or segmented messages with Publish/Subscribe.

Completion Code

MQCC_FAILED

Programmer response

Remove the invalid message from the group.

2418 (0972) (RC2418): MQRC_FILTER_OPERATOR_ERROR:

Explanation

The **Operator** parameter supplied is not valid.

If it is an input variable then the value is not one of the MQCFOP_* constant values. If it is an output variable then the parameter pointer is not valid, or it points to read-only storage. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredicatable results occur.)

Completion Code

MQCC_FAILED

Programmer response

Correct the parameter.

2419 (0973) (RC2419): MQRC_NESTED_SELECTOR_ERROR:

Explanation

An mqAddBag call was issued, but the bag to be nested contained a data item with an inconsistent selector. This reason only occurs if the bag into which the nested bag was to be added was created with the MQCBO_CHECK_SELECTORS option.

Completion Code

MQCC_FAILED

Programmer response

Ensure that all data items within the bag to be nested have selectors that are consistent with the data type implied by the item.

2420 (0974) (RC2420): MQRC_EPH_ERROR:

Explanation

An MQPUT or MQPUT1 call was issued, but the message data contains an MQEPH structure that is not valid. Possible errors include the following:
- The `StrucId` field is not MQEPH_STRUC_ID.
- The `Version` field is not MQEPH_VERSION_1.
- The `StrucLength` field specifies a value that is too small to include the structure plus the variable-length data at the end of the structure.
- The `CodedCharSetId` field is zero, or a negative value that is not valid.
- The `Flags` field contains an invalid combination of MQEPH_* values.
- The `BufferLength` parameter of the call has a value that is too small to accommodate the structure, so the structure extends beyond the end of the message.

Completion Code

MQCC_FAILED

Programmer response

Check that the fields in the structure are set correctly. Ensure that the application sets the `CodedCharSetId` field to a valid value; note that MQCCSI_DEFAULT, MQCCSI_EMBEDDED, MQCCSI_Q_MGR, and MQCCSI_UNDEFINED are not valid in this field.

2421 (0975) (RC2421): MQRC_RFH_FORMAT_ERROR:

Explanation

The message contains an MQRFH structure, but its format is incorrect. If you are using IBM MQ SOAP, the error is in an incoming SOAP/MQ request message.

Completion Code

MQCC_FAILED

Programmer response

If you are using IBM MQ SOAP with the IBM-supplied sender, contact your IBM support center. If you are using IBM MQ SOAP with a bespoke sender, check that the RFH2 section of the SOAP/MQ request message is in valid RFH2 format.

2422 (0976) (RC2422): MQRC_CFBF_ERROR:

Explanation

An MQPUT or MQPUT1 call was issued, but the message data contains an MQCFBF structure that is not valid.

This reason code occurs in the following environments: AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.

Completion Code

MQCC_FAILED

Programmer response

Check that the fields in the structure are set correctly.

2423 (0977) (RC2423): MQRC_CLIENT_CHANNEL_CONFLICT:

Explanation

A client channel definition table (CCDT) was specified for determining the name of the channel, but the name has already been defined.

This reason code occurs only with Java applications.

Completion Code

MQCC_FAILED

Programmer response

Change the channel name to blank and try again.

2424 (0978) (RC2424): MQRC_SD_ERROR:

Explanation

On the MQSUB call, the Subscription Descriptor MQSD is not valid, for one of the following reasons:
- The StrucId field is not MQSD_SCTRUC_ID.
- The Version field specifies a value that is not valid or not supported.
- The parameter pointer is not valid (it is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results can occur).
- The queue manager cannot copy the changes structure to application storage, even though the call is successful. This can occur, for example, if the pointer points to read-only storage.

Completion Code

MQCC_FAILED

Programmer Response

Ensure that input fields in the MQSD structure are set correctly.

2425 (0979) (RC2425): MQRC_TOPIC_STRING_ERROR:

Explanation

On the MQOPEN or MQPUT1 call in the Object Descriptor MQOD, or on the MQSUB call in the Subscription Descriptor MQSD the resultant full topic string is not valid.

One of the following applies:
- ObjectName contains the name of a TOPIC object with a TOPICSTR attribute that contains an empty topic string.
- The fully resolved topic string contains the escape character `'%'` and it is not followed by one of the characters, `'*', '?' or '%'`, and the MQSO_WILDCARD_CHAR option has been used on an MQSUB call.
- On an MQOPEN, conversion cannot be performed using the CCSID specified in the MQOD structure.
- The topic string is greater than 255 characters when using IBM MQ Multicast messaging.

Completion Code

MQCC_FAILED

Programmer Response

Ensure that there are no invalid topic string characters in either ObjectString or ObjectName.

If using IBM MQ Multicast messaging, ensure that the topic string is less than 255 characters.

2426 (097A) (RC2426): MQRC_STS_ERROR:

Explanation

On an MQSTAT call, the MQSTS structure is not valid, for one of the following reasons:
- The StrucId field is not MQSTS_STRUC_ID.
- The Version field specifies a value that is not valid or not supported.
- The parameter pointer is not valid. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)
- The queue manager cannot copy the changed structure to application storage, even though the call is successful. This can occur, for example, if the pointer points to read-only storage.

Completion Code

MQCC_FAILED

Programmer Response

Ensure that input fields in the MQSTS structure are set correctly.

2428 (097C) (RC2428): MQRC_NO_SUBSCRIPTION:

Explanation

An MQSUB call using option MQSO_RESUME was made specifying a full subscription name that does not match any existing subscription.

Completion Code

MQCC_FAILED

Programmer Response

Ensure that the subscription exists and that the full subscription name is correctly specified in your application. The full subscription name is built from the ConnTag field specified at connection time in the MQCNO structure and the SubName field specified at MQSUB time in the MQSD structure.

2429 (097D) (RC2429): MQRC_SUBSCRIPTION_IN_USE:

Explanation

An MQSUB call using option MQSO_RESUME was made specifying a full subscription name that is in use.

Completion Code

MQCC_FAILED

Programmer Response

Ensure that the subscription name is correctly specified in your application. The subscription name is specified in the SubName field in the MQSD structure.

2430 (097E) (RC2430): MQRC_STAT_TYPE_ERROR:

Explanation

The STS parameter contains options that are not valid for the MQSTAT call. This reason also occurs if the parameter pointer is not valid. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)

Programmer response

Specify a valid MQSTS structure as a parameter on the call to MQSTAT.

2431 (097F) (RC2431): MQRC_SUB_USER_DATA_ERROR:

Explanation

On the MQSUB call in the Subscription Descriptor MQSD the SubUserData field is not valid. One of the following applies:

- SubUserData.VSLength is greater than zero, but SubUserData.VSOffset is zero and SubUserData.VSPtr is the null pointer.
- SubUserData.VSOffset is nonzero and SubUserData.VSPtr is not the null pointer (that is, it appears both fields are being used where only one is allowed).
- SubUserData.VSPtr is not a valid pointer.
- SubUserData.VSOffset or SubUserData.VSPtr points to storage that is not accessible.
- SubUserData.VSLength exceeds the maximum length allowed for this field.

Completion Code

MQCC_FAILED

Programmer Response

Ensure that one of SubUserData.VSOffset or SubUserData.VSPtr is zero and the other nonzero. Ensure that the field used points to accessible storage. Specify a length that does not exceed the maximum length allowed for this field.

2432 (0980) (RC2432): MQRC_SUB_ALREADY_EXISTS:

Explanation

An MQSUB call was issued to create a subscription, using the MQSO_CREATE option, but a subscription using the same SubName and ObjectString already exists.

Completion Code

MQCC_FAILED

Programmer Response

Ensure that the SubName and ObjectString input fields in the MQSD structure are set correctly, or use the MQSO_RESUME option to get a handle for the subscription that already exists.

2434 (0982) (RC2434): MQRC_IDENTITY_MISMATCH:

Explanation

An MQSUB call using either MQSO_RESUME or MQSO_ALTER was made against a subscription that has the MQSO_FIXED_USERID option set, by a userid other than the one recorded as owning the subscription.

Completion Code

MQCC_FAILED

Programmer Response

Correct the full subscription name to one that is unique, or update the existing subscription to allow different userids to use it by using the MQSO_ANY_USERID option from an application running under the owning userid.

2435 (0983) (RC2435): MQRC_ALTER_SUB_ERROR:
Explanation

An MQSUB call using option MQSO_ALTER was made changing a subscription that was created with the MQSO_IMMUTABLE option.

Completion Code

MQCC_FAILED

Programmer Response

Remove the subscription using MQCLOSE and re-create it with MQSUB with the attributes set correctly.

2436 (0984) (RC2436): MQRC_DURABILITY_NOT_ALLOWED:

Explanation

An MQSUB call using the MQSO_DURABLE option failed. This can be for one of the following reasons:
- The topic subscribed to is defined as DURSUB(NO).
- The queue named SYSTEM.DURABLE.SUBSCRIBER.QUEUE is not available.
- The topic subscribed to is defined as both MCAST(ONLY) and DURSUB(YES) (or DURSUB(ASPARENT) and the parent is DURSUB(YES)).

Completion Code

MQCC_FAILED

Programmer Response

Durable subscriptions are stored on the SYSTEM.DURABLE.SUBSCRIBER.QUEUE. Ensure that this queue is available for use. Possible reasons for failure include the queue being full, the queue being put inhibited, the queue not existing, or (on z/OS) the pageset the queue is defined to use doesn't exist.

If the topic subscribed to is defined as DURSUB(NO) either alter the administrative topic node to use DURSUB(YES) or use the MQSO_NON_DURABLE option instead.

If the topic subscribed to is defined as MCAST(ONLY) when using IBM MQ Multicast messaging, alter the topic to use DURSUB(NO).

2437 (0985) (RC2437): MQRC_NO_RETAINED_MSG:

Explanation

An MQSUBRQ call was made to a topic to request that any retained publications for this topic are sent to the subscriber. However, there are no retained publications currently stored for this topic.

Completion Code

MQCC_FAILED

Programmer Response

Ensure that publishers to the topic are marking their publication to be retained and that publications are being made to this topic.

2438 (0986) (RC2438): MQRC_SRO_ERROR:

Explanation

On the MQSUBRQ call, the Subscription Request Options MQSRO is not valid, for one of the following reasons:
- The StrucId field is not MQSRO_STRUC_ID.
- The Version field specifies a value that is not valid or not supported.
- The parameter pointer is not valid. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)
- The queue manager cannot copy the changed structure to application storage, even though the call is successful. This can occur, for example, if the pointer points to read-only storage.

Completion Code

MQCC_FAILED

Programmer Response

Ensure that input fields in the MQSRO structure are set correctly.

2440 (0988) (RC2440): MQRC_SUB_NAME_ERROR:

Explanation

On the MQSUB call in the Subscription Descriptor MQSD the SubName field is not valid or has been omitted. This is required if the MQSD option MQSO_DURABLE is specified, but may also be used if MQSO_DURABLE is not specified.

One of the following applies:
- SubName.VSLength is greater than zero, but SubName.VSOffset is zero and SubName.VSPtr is the null pointer.
- SubName.VSOffset is nonzero and SubName.VSPtr is not the null pointer (that is, it appears both fields are being used where only one is allowed).
- SubName.VSPtr is not a valid pointer.

- SubName.VSOffset or SubName.VSPtr points to storage that is not accessible.
- SubName.VSLength is zero but this field is required.
- SubName.VSLength exceeds the maximum length allowed for this field.

Completion Code

MQCC_FAILED

Programmer Response

Ensure that SubName is specified and SubName.VSLength is nonzero. Ensure that one of SubName.VSOffset or SubName.VSPtr is zero and the other nonzero. Ensure that the field used points to accessible storage. Specify a length that does not exceed the maximum length allowed for this field.

This code can be returned if the sd.Options flags MQSO_CREATE and MQSO_RESUME are set together and sd.SubName is not initialized. You must also initialize the MQCHARV structure for sd.SubName, even if there is no subscription to resume; see Example 2: Managed MQ subscriber for more details.

2441 (0989) (RC2441): MQRC_OBJECT_STRING_ERROR:

Explanation

On the MQOPEN or MQPUT1 call in the Object Descriptor MQOD, or on the MQSUB call in the Subscription Descriptor MQSD the ObjectString field is not valid.

One of the following applies:
- ObjectString.VSLength is greater than zero, but ObjectString.VSOffset is zero and ObjectString.VSPtr is the null pointer.
- ObjectString.VSOffset is nonzero and ObjectString.VSPtr is not the null pointer (that is, it appears both fields are being used where only one is allowed).
- ObjectString.VSPtr is not a valid pointer.
- ObjectString.VSOffset or ObjectString.VSPtr points to storage that is not accessible.
- ObjectString.VSLength exceeds the maximum length allowed for this field.

Completion Code

MQCC_FAILED

Programmer Response

Ensure that one of ObjectString.VSOffset or ObjectString.VSPtr is zero and the other nonzero. Ensure that the field used points to accessible storage. Specify a length that does not exceed the maximum length allowed for this field.

2442 (098A) (RC2442): MQRC_PROPERTY_NAME_ERROR:

Explanation

An attempt was made to set a property with an invalid name. Using any of the following settings results in this error:

- The name contains an invalid character.
- The name begins "JMS" or "usr.JMS" and the JMS property is not recognized.
- The name begins "mq" in any mixture of lowercase or uppercase and is not "mq_usr" and contains more than one "." character (U+002E). Multiple "." characters are not allowed in properties with those prefixes.
- The name is "NULL", "TRUE", "FALSE", "NOT", "AND", "OR", "BETWEEN", "LIKE", "IN", "IS" and "ESCAPE" or is one of these keywords prefixed by "usr.".
- The name begins with "Body" or "Root" (except for names beginning "Root.MQMD.").
- A "." character must not be followed immediately by another "." character.
- The "." character cannot be the last character in a property name.

Completion Code

MQCC_FAILED

Programmer Response

Valid property names are described in the IBM MQ documentation. Ensure that all properties in the message have valid names before reissuing the call.

2443 (098B) (RC2443): MQRC_SEGMENTATION_NOT_ALLOWED:

Explanation

An MQPUT or MQPUT1 call was issued to put a segmented message or a message that may be broken up into smaller segments (MQMF_SEGMENTATION_ALLOWED). The message was found to contain one or more MQ-defined properties in the message data; MQ-defined properties are not valid in the message data of a segmented message.

IBM MQ Multicast cannot use segmented messages.

Completion Code

MQCC_FAILED

Programmer Response

Remove the invalid properties from the message data or prevent the message from being segmented.

2444 (098C) (RC2444): MQRC_CBD_ERROR:

Explanation

a MQCB call the MQCBD structure is not valid for one of the following reasons:
- The StrucId field is not MQCBD_STRUC_ID
- The Version field is specifies a value that is not valid or is not supported
- The parameter pointer is not valid. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)

Completion Code

MQCC_FAILED

Programmer Response

Ensure that input fields in the MQCBD structure are set correctly.

2445 (098D) (RC2445): MQRC_CTLO_ERROR:

Explanation

On a MQCTL call the MQCTLO structure is not valid for one of the following reasons:
- The StrucId field is not MQCTLO_STRUC_ID
- The Version field is specifies a value that is not valid or is not supported
- The parameter pointer is not valid. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)

Completion Code

MQCC_FAILED

Programmer Response

Ensure that input fields in the MQCTLO structure are set correctly.

2446 (098E) (RC2446): MQRC_NO_CALLBACKS_ACTIVE:

Explanation

An MQCTL call was made with an Operation of MQOP_START_WAIT and has returned because there are no currently defined callbacks which are not suspended.

Completion Code

MQCC_FAILED

Programmer Response

Ensure that there is at least one registered, resumed consumer function.

2448 (0990) (RC2448): MQRC_CALLBACK_NOT_REGISTERED:

Explanation

An attempt to issue an MQCB call has been made against an object handle which does not currently have a registered callback.

Completion Code

MQCC_FAILED

Programmer Response

Ensure that a callback has been registered against the object handle.

2449 (0991) (RC2449): MQRC_OPERATION_NOT_ALLOWED:

Explanation

An MQCTL call was made with an Operation that is not allowed because of the state of asynchronous consumption on the hConn is currently in.

If Operation was MQOP_RESUME, the operation is not allowed because the state of asynchronous consumption on the hConn is STOPPED. Re-issue MQCTL with the MQOP_START Operation.

If Operation was MQOP_SUSPEND, the operation is not allowed because the state of asynchronous consumption on the hConn is STOPPED. If you need to get your hConn into a SUSPENDED state, issue MQCTL with the MQOP_START Operation followed by MQCTL with MQOP_SUSPEND.

If Operation was MQOP_START, the operation is not allowed because the state of asynchronous consumption on the hConn is SUSPENDED. Re-issue MQCTL with the MQOP_RESUME Operation.

If Operation was MQOP_START_WAIT, the operation is not allowed because either
- The state of asynchronous consumption on the hConn is SUSPENDED. Re-issue MQCTL with the MQOP_RESUME Operation.
- The state of asynchronous consumption on the hConn is already STARTED. Do not mix the use of MQOP_START and MQOP_START_WAIT within one application.

Completion Code

MQCC_FAILED

Programmer Response

Re-issue the MQCTL call with the correct Operation.

2457 (0999) (RC2457): MQRC_OPTIONS_CHANGED:

Explanation

An MQGET call on a queue handle opened using MQOO_READ_AHEAD (or resolved to that value through the queue's default value) has altered an option that is required to be consistent between MQGET calls.

Completion Code

MQCC_FAILED

Programmer Response

Keep all required MQGET options the same between invocations of MQGET, or use MQOO_NO_READ_AHEAD when opening the queue.

2458 (099A) (RC2458): MQRC_READ_AHEAD_MSGS:

Explanation

On an MQCLOSE call, the option MQCO_QUIESCE was used and there are still messages stored in client read ahead buffer that were sent to the client ahead of an application requesting them and have not yet been consumed by the application.

Completion Code

MQCC_WARNING

Programmer Response

Continue to consume messages using the queue handle until there are no more available and then issue the MQCLOSE again, or choose to discard these messages by issuing the MQCLOSE call with the MQCO_IMMEDIATE option instead.

2459 (099B) (RC2459): MQRC_SELECTOR_SYNTAX_ERROR:

Explanation

An MQOPEN, MQPUT1 or MQSUB call was issued but a selection string was specified which contained a syntax error.

Completion Code

MQCC_FAILED

Programmer Response

See Message selector syntax and ensure that you have correctly followed the rules for specifying selection strings. Correct any syntax errors and resubmit the MQ API call for which the error occurred.

2460 (099C) (RC2460): MQRC_HMSG_ERROR:

Explanation

On an MQCRTMH, MQDLTMH, MQSETMP, MQINQMP or MQDLT call, a message handle supplied is not valid, for one of the following reasons:

- The parameter pointer is not valid, or (for the MQCRTMH call) points to read-only storage. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)
- The value specified was not returned by a preceding MQCRTMH call.
- The value specified has been made invalid by a preceding MQDLTMH call.

Completion Code

MQCC_FAILED

Programmer Response

Ensure that a successful MQCRTMH call is performed for the connection, and that an MQDLTMH call has not already been performed for it. Ensure that the handle is being used within its valid scope, for more information, see MQCRTMH - Create message handle.

2461 (099D) (RC2461): MQRC_CMHO_ERROR:

Explanation

On an MQCRTMH call, the create message handle options structure MQCMHO is not valid, for one of the following reasons:

- The StrucId field is not MQCMHO_STRUC_ID.
- The Version field specifies a value that is not valid or not supported.
- The parameter pointer is not valid. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)

Completion Code

MQCC_FAILED

Programmer Response

Ensure that input fields in the MQCMHO structure are set correctly.

2462 (099E) (RC2462): MQRC_DMHO_ERROR:

Explanation

On an MQDLTMH call, the delete message handle options structure MQDMHO is not valid, for one of the following reasons:
- The StrucId field is not MQCMHO_STRUC_ID.
- The Version field specifies a value that is not valid or not supported.
- The parameter pointer is not valid. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)

Completion Code

MQCC_FAILED

Programmer Response

Ensure that input fields in the MQDMHO structure are set correctly.

2463 (099F) (RC2463): MQRC_SMPO_ERROR:

Explanation

On an MQSETMP call, the set message property options structure MQSMPO is not valid, for one of the following reasons:
- The StrucId field is not MQSMPO_STRUC_ID.
- The Version field specifies a value that is not valid or not supported.
- The parameter pointer is not valid. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)

Completion Code

MQCC_FAILED

Programmer Response

Ensure that input fields in the MQSMPO structure are set correctly.

2464 (09A0) (RC2464): MQRC_IMPO_ERROR:

Explanation

On an MQINQMP call, the inquire message property options structure MQIMPO is not valid, for one of the following reasons:
- The StrucId field is not MQIMPO_STRUC_ID.
- The Version field specifies a value that is not valid or not supported.
- The parameter pointer is not valid. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)
- The queue manager cannot copy the changed structure to application storage, even though the call is successful. This can occur, for example, if the pointer points to read-only storage.

Completion Code

MQCC_FAILED

Programmer Response

Ensure that input fields in the MQIMPO structure are set correctly.

2465 (09A1) (RC2465): MQRC_PROPERTY_NAME_TOO_BIG:

Explanation

On an MQINQMP call, IBM MQ attempted to copy the name of the inquired property into the location indicated by the ReturnedName field of the InqPropOpts parameter but the buffer was too small to contain the full property name. The call failed but the VSLength field of the ReturnedName of the InqPropOpts parameter indicates how large the ReturnedName buffer needs to be.

Completion Code

MQCC_FAILED

Programmer response

The full property name can be retrieved by calling MQINQMP again with a larger buffer for the returned name, also specifying the MQIMPO_INQ_PROP_UNDER_CURSOR option. This will inquire on the same property.

2466 (09A2) (RC2466): MQRC_PROP_VALUE_NOT_CONVERTED:

Explanation

An MQINQMP call was issued with the MQIMPO_CONVERT_VALUE option specified in the InqPropOpts parameter, but an error occurred during conversion of the value of the property. The property value is returned unconverted, the values of the ReturnedCCSID and ReturnedEncoding fields in the InqPropOpts parameter are set to those of the value returned.

Completion Code

MQCC_FAILED

Programmer Response

Check that the property value is correctly described by the ValueCCSID and ValueEncoding parameters that were specified when the property was set. Also check that these values, and the RequestedCCSID and RequestedEncoding specified in the InqPropOpts parameter of the MQINQMP call, are supported for MQ conversion. If the required conversion is not supported, conversion must be carried out by the application.

2467 (09A3) (RC2467): MQRC_PROP_TYPE_NOT_SUPPORTED:

Explanation

An MQINQMP call was issued and the property inquired has an unsupported data type. A string representation of the value is returned and the TypeString field of the InqPropOpts parameter can be used to determine the data type of the property.

Completion Code

MQCC_WARNING

Programmer Response

Check whether the property value was intended to have a data type indicated by the TypeString field. If so the application must decide how to interpret the value. If not modify the application that set the property to give it a supported data type.

2469 (09A5) (RC2469): MQRC_PROPERTY_VALUE_TOO_BIG:

Explanation

On an MQINQMP call, the property value was too large to fit into the supplied buffer. The DataLength field is set to the length of the property value before truncation and the Value parameter contains as much of the value as fits.

On an MQMHBUF call, the BufferLength was less than the size of the properties to be put in the buffer. In this case the call fails. The DataLength field is set to the length of the properties before truncation.

Completion Code

MQCC_WARNING

MQCC_FAILED

Programmer Response

Supply a buffer that is at least as large as DataLength if all of the property value data is required and call MQINQMP again with the MQIMPO_INQ_PROP_UNDER_CURSOR option specified.

2470 (09A6) (RC2470): MQRC_PROP_CONV_NOT_SUPPORTED:

Explanation

On an MQINQMP call, the MQIMPO_CONVERT_TYPE option was specified to request that the property value be converted to the supplied data type before the call returned. Conversion between the actual and requested property data types is not supported. The Type parameter indicates the data type of the property value.

Completion Code

MQCC_FAILED

Programmer Response

Either call MQINQMP again without MQIMPO_CONVERT_TYPE specified, or request a data type for which conversion is supported.

2471 (09A7) (RC2471): MQRC_PROPERTY_NOT_AVAILABLE:

Explanation

On an MQINQMP call, no property could be found that matched the specified name. When iterating through multiple properties, possibly using a name containing a wildcard character, this indicates that all properties matching the name have now been returned.

Completion Code

MQCC_FAILED

Programmer response

Ensure that the correct property name was specified. If the name contains a wildcard character specify option MQIMPO_INQ_FIRST to begin iterating over the properties again.

2472 (09A8) (RC2472): MQRC_PROP_NUMBER_FORMAT_ERROR:

Explanation

On an MQINQMP call, conversion of the property value was requested. The format of the property is invalid for conversion to the requested data type.

Completion Code

MQCC_FAILED

Programmer Response

Ensure that the correct property name and data type were specified. Ensure that the application setting the property gave it the correct format. See the documentation for the MQINQMP call for details on the formats required for data conversion of property values.

2473 (09A9) (RC2473): MQRC_PROPERTY_TYPE_ERROR:

Explanation

On an MQSETMP call, the Type parameter does not specify a valid MQTYPE_* value. For properties beginning "Root.MQMD." or "JMS" the specified Type must correspond to the data type of the matching MQMD or JMS header field:

- For MQCHARn or Java String fields use MQTYPE_STRING.
- For MQLONG or Java int fields use MQTYPE_INT32.
- For MQBYTEn fields use MQTYPE_BYTE_STRING.
- For Java long fields use MQTYPE_INT64.

On an MQINQMP call, the Type parameter is not valid. Either the parameter pointer is not valid, the value is invalid, or it points to read-only storage. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)

Completion Code

MQCC_FAILED

Programmer Response

Correct the parameter.

2478 (09AE) (RC2478): MQRC_PROPERTIES_TOO_BIG:

Explanation

An MQPUT or MQPUT1 call was issued to put a message on a queue, but the properties of the message were too large. The length of the properties cannot exceed the value of the **MaxPropertiesLength** queue manager attribute. This return code will also be issued if a message with headers greater than 511 KB is put to a shared queue.

Completion Code

MQCC_FAILED

Programmer Response

Consider one of the following actions:
- Reduce the number or the size of the properties associated with the message. This could include moving some of the properties into the application data.
- Increase the value of the MaxPropertiesLength queue manager attribute.

2479 (09AF) (RC2479): MQRC_PUT_NOT_RETAINED:

Explanation

An MQPUT or MQPUT1 call was issued to publish a message on a topic, using the MQPMO_RETAIN option, but the publication was unable to be retained. The publication is not published to any matching subscribers.

Completion Code

MQCC_FAILED

Programmer Response

Retained publications are stored on the SYSTEM.RETAINED.PUB.QUEUE. Ensure that this queue is available for use by the application. Possible reasons for failure include the queue being full, the queue being put inhibited, or the queue not existing.

2480 (09B0) (RC2480): MQRC_ALIAS_TARGTYPE_CHANGED:

Explanation

An MQPUT or MQPUT1 call was issed to publish a message on a topic. One of the subscriptions matching this topic was made with a destination queue that was an alias queue which originally referenced a queue, but now references a topic object, which is not allowed. In this situation the reason code MQRC_ALIAS_TARGTYPE_CHANGED is returned in the Feedback field in the MQMD of a report message, or in the Reason field in the MQDLH structure of a message on the dead-letter queue.

Completion Code

MQCC_FAILED

Programmer Response

Find the subscriber that is using an alias queue which references a topic object and change it to reference a queue again, or change the subscription to reference a different queue.

2481 (09B1) (RC2481): MQRC_DMPO_ERROR:

Explanation

On an MQDLTMP call, the delete message property options structure MQDMPO is not valid, for one of the following reasons:
- The StrucId field is not MQDMPO_STRUC_ID.
- The Version field specifies a value that is not valid or not supported.
- The parameter pointer is not valid. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)

Completion Code

MQCC_FAILED

Programmer Response

Ensure that input fields in the MQDMPO structure are set correctly.

2482 (09B2) (RC2482): MQRC_PD_ERROR:

Explanation

On an MQSETMP or MQINQMP call, the property descriptor structure MQPD is not valid, for one of the following reasons:
- The StrucId field is not MQPD_STRUC_ID.
- The Version field specifies a value that is not valid or not supported.
- The parameter pointer is not valid. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)
- The Context field contains an unrecognized value.

Completion Code

MQCC_FAILED

Programmer Response

Ensure that input fields in the MQPD structure are set correctly.

2483 (09B3) (RC2483): MQRC_CALLBACK_TYPE_ERROR:

Explanation

An MQCB call was made with an Operation of MQOP_REGISTER with an incorrect value for CallbackType

Completion Code

MQCC_FAILED

Programmer Response

Ensure that the CallbackType field of the MQCBDO is specified correctly.

2484 (09B4) (RC2484): MQRC_CBD_OPTIONS_ERROR:

Explanation

An MQCB call was made with an Operation of MQOP_REGISTER with an incorrect value for the Options field of the MQCBD.

Completion Code

MQCC_FAILED

Programmer Response

Ensure that the Options are specified correctly.

2485 (09B5) (RC2485): MQRC_MAX_MSG_LENGTH_ERROR:

Explanation

An MQCB call was made with an Operation of MQOP_REGISTER with an incorrect value for the MaxMsgLength field of the MQCBD.

Completion Code

MQCC_FAILED

Programmer Response

Ensure that the MaxMsgLength are specified correctly.

2486 (09B6) (RC2486): MQRC_CALLBACK_ROUTINE_ERROR:

Explanation

An MQCB call was made with an Operation of MQOP_REGISTER failed for one of the following reasons:

- Both CallbackName and CallbackFunction are specified. Only one must be specified on the call.
- The call was made from an environment not supporting function pointers.
- A programming language that does not support Function pointer references.

Completion Code

MQCC_FAILED

Programmer Response

Ensure that the CallbackName value is specified correctly.

2487 (09B7) (RC2487): MQRC_CALLBACK_LINK_ERROR:

Explanation

On an MQCTL call, the callback handling module (CSQBMCSM or CSQBMCSX for batch and DFHMQMCM for CICS) could not be loaded, so the adapter could not link to it.

This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer Response

Ensure that the correct library concatenation has been specified in the application program execution JCL, and in the queue-manager startup JCL. Any uncommitted changes in a unit of work should be backed out. A unit of work that is coordinated by the queue manager is backed out automatically.

2488 (09B8) (RC2488): MQRC_OPERATION_ERROR:

Explanation

An MQCTL or MQCB call was made with an invalid parameter.

There is a conflict with the value specified for **`Operation`** parameter.

This error can be caused by an invalid value in the **`Operation`** parameter, no registered consumers when using MQOP_START or MQOP_START_WAIT parameter, and trying to use non-threaded libraries with asynchronous API calls.

Completion Code

MQCC_FAILED

Programmer Response

Investigate the application program and verify the **`Operation`** parameter options are correct. Ensure you have link edited the application with the correct version of the threading libraries for asynchronous functions.

2489 (09B9) (RC2489): MQRC_BMHO_ERROR:
Explanation

On an MQBUFMH call, the buffer to message handle options structure MQBMHO is not valid, for one of the following reasons:
- • The StrucId field is not MQBMHO_STRUC_ID.
- • The Version field specifies a value that is not valid or not supported.
- • The parameter pointer is not valid. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)

Completion Code

MQCC_FAILED

Programmer Response

Ensure that input fields in the MQBMHO structure are set correctly.

2490 (09BA) (RC2490): MQRC_UNSUPPORTED_PROPERTY:

Explanation

A message was found to contain a property that the queue manager does not support. The operation that failed required all the properties to be supported by the queue manager. This can occur on the MQPUT/MQPUT1 call or when a message is about to be sent down a channel to a queue manager than does not support message properties.

Completion Code

MQCC_FAILED

Programmer Response

Determine which property of the message is not supported by the queue manager and decide whether to remove the property from the message or connect to a queue manager which does support the property.

2492 (09BC) (RC2492): MQRC_PROP_NAME_NOT_CONVERTED:

Explanation

An MQINQMP call was issued with the MQIMPO_CONVERT_VALUE option specified in the InqPropOpts parameter, but an error occurred during conversion of the returned name of the property. The returned name is unconverted

Completion Code

MQCC_WARNING

Programmer Response

Check that the character set of the returned name was correctly described when the property was set. Also check that these values, and the RequestedCCSID and RequestedEncoding specified in the InqPropOpts parameter of the MQINQMP call, are supported for MQ conversion. If the required conversion is not supported, conversion must be carried out by the application.

2494 (09BE) (RC2494): MQRC_GET_ENABLED:

Explanation

This reason code is returned to an asynchronous consumer at the time a queue that was previously inhibited for get has been re-enabled for get.

Completion Code

MQCC_WARNING

Programmer Response

None. This reason code is used to inform the application of the change in state of the queue.

2495 (09BF) (RC2495): MQRC_MODULE_NOT_FOUND:

Explanation

A native shared library could not be loaded.

Completion Code

MQCC_FAILED

Programmer Response

This problem could be caused by either of the two following reasons:

- A MQCB call was made with an Operation of MQOP_REGISTER specifying a *CallbackName* which could not be found. Ensure that the *CallbackName* value is specified correctly.
- The Java MQ code could not load a Java native shared library. This error can occur if a Java application is running in a 32-bit JRE but has been configured to load the 64-bit Java Native Libraries. Check the associated Exception stack and FFST. Ensure that the JNI shared library is specified correctly. Check also that you have specified `-Djava.library.path=/opt/mqm/java/lib`, or equivalent, when invoking the Java program.

Related information:

The Java Native Interface (JNI) libraries required by IBM MQ classes for JMS applications

2496 (09C0) (RC2496): MQRC_MODULE_INVALID:

Explanation

An MQCB call was made with an Operation of MQOP_REGISTER, specifying a CallbackName which is not a valid load module.

Completion Code

MQCC_FAILED

Programmer Response

Ensure that the CallbackName value is specified correctly.

2497 (09C1) (RC2497): MQRC_MODULE_ENTRY_NOT_FOUND:

Explanation

An MQCB call was made with an Operation of MQOP_REGISTER and the CallbackName identifies a function name which can't be found in the specified library.

Completion Code

MQCC_FAILED

Programmer response

Ensure that the CallbackName value is specified correctly.

2498 (09C2) (RC2498): MQRC_MIXED_CONTENT_NOT_ALLOWED:

Explanation

An attempt was made to set a property with mixed content. For example, if an application set the property "x.y" and then attempted to set the property "x.y.z" it is unclear whether in the property name hierarchy "y" contains a value or another logical grouping. Such a hierarchy would be "mixed content" and this is not supported. Setting a property which would cause mixed content is not allowed. A hierarchy within a property name is created using the "." character (U+002E).

Completion Code

MQCC_FAILED

Programmer Response

Valid property names are described in the IBM MQ documentation. Change the property name hierarchy so that it no longer contains mixed content before re-issuing the call.

2499 (09C3) (RC2499): MQRC_MSG_HANDLE_IN_USE:

Explanation

A message property call was called (MQCRTMH, MQDLTMH, MQSETMP, MQINQMP, MQDLTMP or MQMHBUF) specifying a message handle that is already in use on another API call. A message handle may only be used on one call at a time.

Concurrent use of a message handle can arise, for example, when an application uses multiple threads.

Completion Code

MQCC_FAILED

Programmer response

Ensure that the message handle cannot be used while another call is in progress.

2500 (09C4) (RC2500): MQRC_HCONN_ASYNC_ACTIVE:

Explanation

An attempt to issue an MQI call has been made while the connection is started.

Completion Code

MQCC_FAILED

Programmer Response

Stop or suspend the connection using the MQCTL call and retry the operation.

2501 (09C5) (RC2501): MQRC_MHBO_ERROR:

Explanation

On an MQMHBUF call, the message handle to buffer options structure MQMHBO is not valid, for one of the following reasons:
- The StrucId field is not MQMHBO_STRUC_ID.
- The Version field specifies a value that is not valid or not supported.
- The parameter pointer is not valid. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)

Completion Code

MQCC_FAILED

Programmer Response

Ensure that input fields in the MQMHBO structure are set correctly.

2502 (09C6) (RC2502): MQRC_PUBLICATION_FAILURE:

Explanation

An MQPUT or MQPUT1 call was issued to publish a message on a topic. Delivery of the publication to one of the subscribers failed and due to the combination of the syncpoint option used and either:

- • The PMSGDLV attribute on the administrative TOPIC object if it was a persistent message.
- • The NPMSGDLV attribute on the administrative TOPIC object if it was a non-persistent message.

The publication has not been delivered to any of the subscribers.

Completion Code

MQCC_FAILED

Programmer response

Find the subscriber or subscribers who are having problems with their subscription queue and resolve the problem, or change the setting of the PMSGDLV or NPMSGDLV attributes on the TOPIC so that problems with one subscriber do not have an effect on other subscribers. Retry the MQPUT.

2503 (09C7) (RC2503): MQRC_SUB_INHIBITED:

Explanation

MQSUB calls are currently inhibited for the topic subscribed to.

Completion Code

MQCC_FAILED

Programmer Response

If the system design allows subscription requests to be inhibited for short periods, retry the operation later.

2504 (09C8) (RC2504): MQRC_SELECTOR_ALWAYS_FALSE:

Explanation

An MQOPEN, MQPUT1 or MQSUB call was issued but a selection string was specified which will never select a message

Completion Code

MQCC_FAILED

Programmer Response

Verify that the logic of the selection string which was passed in on the API is as expected. Make any necessary corrections to the logic of the string and resubmit the MQ API call for which the message occurred.

2507 (09CB) (RC2507): MQRC_XEPO_ERROR:

Explanation

On an MQXEP call, the exit options structure MQXEPO is not valid, for one of the following reasons:
- The StrucId field is not MQXEPO_STRUC_ID.
- The Version field specifies a value that is not valid or not supported.
- The parameter pointer is not valid. (It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.)

Completion Code

MQCC_FAILED

Programmer Response

Ensure that input fields in the MQXEPO structure are set correctly.

2509 (09CD) (RC2509): MQRC_DURABILITY_NOT_ALTERABLE:
Explanation

An MQSUB call using option MQSO_ALTER was made changing the durability of the subscription. The durability of a subscription cannot be changed.

Completion Code

MQCC_FAILED

Programmer Response

Remove the subscription using MQCLOSE and re-create it with MQSUB with the attributes set correctly, or change the durability option used on the MQSUB call so that it matches the existing subscription.

2510 (09CE) (RC2510): MQRC_TOPIC_NOT_ALTERABLE:
Explanation

An MQSUB call using option MQSO_ALTER was made changing the one or more of the fields in the MQSD that provide the topic being subscribed to. These fields are the ObjectName, ObjectString, or wildcard options. The topic subscribed to cannot be changed.

Completion Code

MQCC_FAILED

Programmer Response

Remove the subscription using MQCLOSE and re-create it with MQSUB with the attributes set correctly, or change the attributes and options used on the MQSUB call so that it matches the existing subscription.

2512 (09D0) (RC2512): MQRC_SUBLEVEL_NOT_ALTERABLE:
Explanation

An MQSUB call using option MQSO_ALTER was made changing the SubLevel of the subscription. The SubLevel of a subscription cannot be changed.

Completion Code

MQCC_FAILED

Programmer Response

Remove the subscription using MQCLOSE and re-create it with MQSUB with the attributes set correctly, or change the SubLevel field used on the MQSUB call so that it matches the existing subscription.

2513 (09D1) (RC2513): MQRC_PROPERTY_NAME_LENGTH_ERR:

Explanation

An attempt was made to set, inquire or delete a property with an invalid name. This is for one of the following reasons:
- The VSLength field of the property name was set to less than or equal to zero.
- The VSLength field of the property name was set to greater than the maximum allowed value (see constant MQ_MAX_PROPERTY_NAME_LENGTH).
- The VSLength field of the property name was set to MQVS_NULL_TERMINATED and the property name was greater than the maximum allowed value.

Completion Code

MQCC_FAILED

Programmer Response

Valid property names are described in the IBM MQ documentation. Ensure that the property has a valid name length before issuing the call again.

2514 (09D2) (RC2514): MQRC_DUPLICATE_GROUP_SUB:

Explanation

An MQSUB call using option MQSO_GROUP_SUB was made creating a new grouped subscription but, although it has a unique SubName, it matches the Full topic name of an existing subscription in the group.

Completion Code

MQCC_FAILED

Programmer Response

Correct the Full topic name used so that it does not match any existing subscription in the group, or correct the grouping attributes if, either a different group was intended or the subscription was not intended to be grouped at all.

2515 (09D3) (RC2515): MQRC_GROUPING_NOT_ALTERABLE:
Explanation

An MQSUB call was made using option MQSO_ALTER on a grouped subscription, that is one made with the option MQSO_GROUP_SUB. Grouping of subscriptions is not alterable.

Completion Code

MQCC_FAILED

Programmer response

Remove the subscription using MQCLOSE and re-create it with MQSUB with the attributes set correctly, or change the various grouping fields used on the MQSUB call so that it matches the existing subscription.

2516 (09D4) (RC2516): MQRC_SELECTOR_INVALID_FOR_TYPE:

Explanation

A SelectionString may only be specified in the MQOD for an MQOPEN/MQPUT1 if the following is true:
- ObjectType is MQOT_Q
- The queue is being opened using one of the MQOO_INPUT_* open options.

Completion Code

MQCC_FAILED

Programmer Response

Modify the value of ObjectType to be MQOT_Q and ensure that the queue is being opened using one of the MQOO_INPUT_* options.

2517 (09D5) (RC2517): MQRC_HOBJ_QUIESCED:

Explanation

The HOBJ has been quiesced but there are no messages in the read ahead buffer which match the current selection criteria. This reason code indicates that the read ahead buffer is not empty.

Completion Code

MQCC_FAILED

Programmer Response

This reason code indicates that all messages with the current selection criteria have been processed. Do one of the following:
- If no further messages need to be processed issue an MQCLOSE without the MQCO_QUIESCE option. Any messages in the read ahead buffer will be discarded.
- Relax the current selection criteria by modifying the values in the MQGMO and reissue the call. Once all messages have been consumed the call will return MQRC_HOBJ_QUIESCED_NO_MSGS.

2518 (09D6) (RC2518): MQRC_HOBJ_QUIESCED_NO_MSGS:

Explanation

The HOBJ has been quiesced and the read ahead buffer is now empty. No further messages will be delivered to this HOBJ

Completion Code

MQCC_FAILED

Programmer Response

Issue MQCLOSE against the HOBJ.

2519 (09D7) (RC2519): MQRC_SELECTION_STRING_ERROR:
Explanation

The SelectionString must be specified according to the description of how to use an MQCHARV structure. Examples of why this error was returned:
- SelectionString.VSLength is greater than zero, but SelectionString.VSOffset is zero and SelectionString.VSPtr is a null pointer.
- SelectionString.VSOffset is nonzero and SelectionString.VSPtr is not the null pointer (that is, it appears both fields are being used where only one is allowed).
- SelectionString.VSPtr is not a valid pointer.
- SelectionString.VSOffset or SelectionString.VSPtr points to storage that is not accessible.
- SelectionString.VSLength exceeds the maximum length allowed for this field. The maximum length is determined by MQ_SELECTOR_LENGTH.

Completion Code

MQCC_FAILED

Programmer Response

Modify the fields of the MQCHARV so that it follows the rules for a valid MQCHARV structure.

2520 (09D8) (RC2520): MQRC_RES_OBJECT_STRING_ERROR:

Explanation

On the MQOPEN or MQPUT1 call in the Object Descriptor MQOD, or on the MQSUB call in the Subscription Descriptor MQSD the ResObjectString field is not valid.

One of the following applies:
- ResObjectString.VSLength is greater than zero, but ResObjectString.VSOffset is zero and ResObjectString.VSPtr is the null pointer.
- ResObjectString.VSOffset is nonzero and ResObjectString.VSPtr is not the null pointer (that is, it appears both fields are being used where only one is allowed).
- ResObjectString.VSPtr is not a valid pointer.
- ResObjectString.VSOffset or ResObjectString.VSPtr points to storage that is not accessible.
- ResObjectString.VSBufSize is MQVS_USE_VSLENGTH and one of ResObjectString.VSOffset or ResObjectString.VSPtr have been provided.

Completion Code

MQCC_FAILED

Programmer Response

Ensure that one of ResObjectString.VSOffset or ResObjectString.VSPtr is zero and the other nonzero and that the buffer length is provided in ResObjectString.VSBufSize. Ensure that the field used points to accessible storage.

2521 (09D9) (RC2521): MQRC_CONNECTION_SUSPENDED:

Explanation

An MQCTL call with Operation MQOP_START_WAIT has returned because the asynchronous consumption of messages has been suspended. This can be for the following reasons:

- The connection was explicitly suspended using MQCTL with Operation MQOP_SUSPEND
- All consumers have been either unregistered or suspended.

Completion Code

MQCC_WARNING

Programmer Response

If this is an expected condition, no corrective action required. If this is an unexpected condition check that:

- At least one consumer is registered and not suspended
- The connection has not been suspended

2522 (09DA) (RC2522): MQRC_INVALID_DESTINATION:

Explanation

An MQSUB call failed because of a problem with the destination where publications messages are to be sent, so an object handle cannot be returned to the application and the subscription is not made. This can be for one of the following reasons:

- The MQSUB call used MQSO_CREATE, MQSO_MANAGED and MQSO_NON_DURABLE and the model queue referred to by MNDURMDL on the administrative topic node does not exist
- The MQSUB call used MQSO_CREATE, MQSO_MANAGED and MQSO_DURABLE and the model queue referred to by MDURMDL on the administrative topic node does not exist, or has been defined with a DEFTYPE of TEMPDYN.
- The MQSUB call used MQSO_CREATE or MQSO_ALTER on a durable subscription and the object handle provided referred to a temporary dynamic queue. This is not an appropriate destination for a durable subscription.
- The MQSUB call used MQSO_RESUME and a Hobj of MQHO_NONE, to resume an administratively created subscription, but the queue name provided in the DEST parameter of the subscription does not exist.
- The MQSUB call used MQSO_RESUME and a Hobj of MQHO_NONE, to resume a previously created API subscription, but the queue previously used no longer exists.

Completion Code

MQCC_FAILED

Programmer Response

Ensure that the model queues referred to by MNDURMDL and MDURMDL exist and have an appropriate DEFTYPE. Create the queue referred to by the DEST parameter in an administrative subscription if one is being used. Alter the subscription to use an existing queue if the previously used one does not exist.

2523 (09DB) (RC2523): MQRC_INVALID_SUBSCRIPTION:

Explanation

An MQSUB call using MQSO_RESUME or MQSO_ALTER failed because the subscription named is not valid for use by applications. This can be for one of the following reasons:
- The subscription is the SYSTEM.DEFAULT.SUB subscription which is not a valid subscription and should only be used to fill in the default values on DEFINE SUB commands.
- The subscription is a proxy type subscription which is not a valid subscription for an application to resume and is only used to enable publications to be forwarded between queue managers.
- The subscription has expired and is no longer valid for use.

Completion Code

MQCC_FAILED

Programmer Response

Ensure the subscription named in SubName field is not one of the invalid ones listed. If you have a handle open to the subscription already it must have expired. Use MQCLOSE to close the handle and then if necessary create a new subscription.

2524 (09DC) (RC2524): MQRC_SELECTOR_NOT_ALTERABLE:

Explanation

An MQSUB call was issued with the MQSO_ALTER option and the MQSD contained a SelectionString. It is not valid to alter the SelectionString of a subscription.

Completion Code

MQCC_FAILED

Programmer response

Ensure that the SelectionString field of the MQSD does not contain a valid VSPtr and that the VSLength is set to zero when making a call to MQSUB.

2525 (09DD) (RC2525): MQRC_RETAINED_MSG_Q_ERROR:

Explanation

An MQSUB call which did not use the MQSO_NEW_PUBLICATIONS_ONLY option, or an MQSUBRQ call, failed because the retained publications which exist for the topic string subscribed to cannot be retrieved from the SYSTEM.RETAINED.PUB.QUEUE. This can be for one of the following reasons:

- The queue has become damaged or has been deleted.
- The queue has been set to GET(DISABLED).
- Messages have been removed from this queue directly.

An error message will be written to the log giving more details about the problem with the SYSTEM.RETAINED.PUB.QUEUE.

When this return code occurs on an MQSUB call, it can only occur using the MQSO_CREATE option, and in this case the subscription is not created.

Completion Code

MQCC_FAILED

Programmer Response

If this occurs on an MQSUB call, re-issue the MQSUB call using the option MQSO_NEW_PUBLICATIONS_ONLY, which will mean no previously retained publications are sent to this subscription, or fix the SYSTEM.RETAINED.PUB.QUEUE so that messages can be retrieved from it and re-issue the MQSUB call.

If this occurs on an MQSUBRQ call, fix the SYSTEM.RETAINED.PUB.QUEUE so that messages can be retrieved from it and re-issue the MQSUBRQ call.

2526 (09DE) (RC2526): MQRC_RETAINED_NOT_DELIVERED:

Explanation

An MQSUB call which did not use the MQSO_NEW_PUBLICATIONS_ONLY option or an MQSUBRQ call, failed because the retained publications which exist for the topic string subscribed to cannot be delivered to the subscription destination queue and have subsequently failed to be delivered to the dead-letter queue.

When this return code occurs on an MQSUB call, it can only occur using the MQSO_CREATE option, and in this case the subscription is not created.

Completion Code

MQCC_FAILED

Programmer response

Fix the problems with the destination queue and the dead-letter queue and re-issue the MQSUB or MQSUBRQ call.

2527 (09DF) (RC2527): MQRC_RFH_RESTRICTED_FORMAT_ERR:

Explanation

A message was put to a queue containing an MQRFH2 header which included a folder with a restricted format. However, the folder was not in the required format. These restrictions are:
- If NameValueCCSID of the folder is 1208 then only single byte UTF-8 characters are allowed in the folder, group or element names.
- Groups are not allowed in the folder.
- The values of properties may not contain any characters that require escaping.
- Only Unicode character U+0020 will be treated as white space within the folder.
- The folder tag does not contain the content attribute.
- The folder must not contain a property with a null value.

The <mq> folder requires formatting of this restricted form.

Completion Code

MQCC_FAILED

Programmer Response

Change the message to include valid MQRFH2 folders.

2528 (09E0) (RC2528): MQRC_CONNECTION_STOPPED:

Explanation

An MQCTL call was issued to start the asynchronous consumption of messages, but before the connection was ready to consume messages it was stopped by one of the message consumers.

Completion Code

MQCC_FAILED

Programmer Response

If this is an expected condition, no corrective action required. If this is an unexpected condition check whether an MQCTL with Operation MQOP_STOP was issued during the MQCBCT_START callback function.

2529 (09E1) (RC2529): MQRC_ASYNC_UOW_CONFLICT:

Explanation

An MQCTL call with Operation MQOP_START was issued to start the asynchronous consumption of messages, but the connection handle used already has a global unit of work outstanding. MQCTL cannot be used to start asynchronous consumption of messages while a unit of work is in existence unless the MQOP_START_WAIT Operation is used

Completion Code

MQCC_FAILED

Programmer Response

Issue an MQCMIT on the connection handle to commit the unit of work and then reissue the MQCTL call, or issue an MQCTL call using Operation MQOP_START_WAIT to use the unit of work from within the asynchronous consumption callback functions.

2530 (09E2) (RC2530): MQRC_ASYNC_XA_CONFLICT:

Explanation

An MQCTL call with Operation MQOP_START was issued to start the asynchronous consumption of messages, but an external XA syncpoint coordinator has already issued an xa_open call for this connection handle. XA transactions must be done using the MQOP_START_WAIT Operation.

Completion Code

MQCC_FAILED

Programmer Response

Reissue the MQCTL call using Operation MQOP_START_WAIT.

2531 (09E3) (RC2531): MQRC_PUBSUB_INHIBITED:

Explanation

MQSUB, MQOPEN, MQPUT, and MQPUT1 calls are currently inhibited for all publish/subscribe topics, either with the queue manager attribute PSMODE or because processing of publish/subscribe state at queue manager start-up has failed, or has not yet completed.

Completion Code

MQCC_FAILED

Programmer Response

If this queue manager does not intentionally inhibit publish/subscribe, investigate any error messages that describe the failure at queue manager start-up, or wait until start-up processing completes. If the queue manager is a member of cluster, then start-up is not complete until the channel initiator has also started. On z/OS, if you get this return code from the Chinit for the SYSTEM.BROKER.DEFAULT.STREAM queue or topic, then the Chinit is busy processing work, and the pubsub task starts later. Use the DISPLAY PUBSUB command to check the status of the publish/subscribe engine to ensure that it is ready for use. Additionally, on z/OS you might receive an information message CSQM076I.

2532 (09E4) (RC2532): MQRC_MSG_HANDLE_COPY_FAILURE:

Explanation

An MQGET call was issued specifying a valid `MsgHandle` in which to retrieve any properties of the message. After the message had been removed from the queue the application could not allocate enough storage for the properties of the message. The message data is available to the application but the properties are not. Check the queue manager error logs for more information about how much storage was required.

Completion Code

MQCC_WARNING

Programmer response

Raise the memory limit of the application to allow it store the properties.

2533 (09E5) (RC2533): MQRC_DEST_CLASS_NOT_ALTERABLE:
Explanation

An MQSUB call using option MQSO_ALTER was made changing the use of the MQSO_MANAGED option on the subscription. The destination class of a subscription cannot be changed. When the MQSO_MANAGED option is not used, the queue provided can be changed, but the class of destination (managed or not) cannot be changed.

Completion Code

MQCC_FAILED

Programmer Response

Remove the subscription using MQCLOSE and re-create it with MQSUB with the attributes set correctly, or change the use of the MQSO_MANAGED option used on the MQSUB call so that it matches the existing subscription.

2534 (09E6) (RC2534): MQRC_OPERATION_NOT_ALLOWED:

Explanation

An MQCTL call was made with an Operation that is not allowed because of the state of asynchronous consumption on the hConn is currently in.

If Operation was MQOP_RESUME, the operation is not allowed because the state of asynchronous consumption on the hConn is STOPPED. Re-issue MQCTL with the MQOP_START Operation.

If Operation was MQOP_SUSPEND, the operation is not allowed because the state of asynchronous consumption on the hConn is STOPPED. If you need to get your hConn into a SUSPENDED state, issue MQCTL with the MQOP_START Operation followed by MQCTL with MQOP_SUSPEND.

If Operation was MQOP_START, the operation is not allowed because the state of asynchronous consumption on the hConn is SUSPENDED. Re-issue MQCTL with the MQOP_RESUME Operation.

If Operation was MQOP_START_WAIT, the operation is not allowed because either:

- The state of asynchronous consumption on the hConn is SUSPENDED. Re-issue MQCTL with the MQOP_RESUME Operation.
- The state of asynchronous consumption on the hConn is already STARTED. Do not mix the use of MQOP_START and MQOP_START_WAIT within one application.

Completion Code

MQCC_FAILED

Programmer Response

Re-issue the MQCTL call with the correct Operation.

2535 (09E7): MQRC_ACTION_ERROR:
Explanation

An MQPUT call was issued, but the value of the Action field in the PutMsgOpts parameter is not a valid MQACTP_* value.

Completion Code

MQCC_FAILED

Programmer response

Specify a valid value for the field.

2537 (09E9) (RC2537): MQRC_CHANNEL_NOT_AVAILABLE:

Explanation

An MQCONN call was issued from a client to connect to a queue manager but the channel is not currently available. Common causes of this reason code are:
- The channel is currently in stopped state.
- The channel has been stopped by a channel exit.
- The queue manager has reached its maximum allowable limit for this channel from this client.
- The queue manager has reached its maximum allowable limit for this channel.
- The queue manager has reached its maximum allowable limit for all channels.

Completion Code

MQCC_FAILED

Programmer Response

Examine the queue manager and client error logs for messages explaining the cause of the problem.

This reason code is also used to identify the corresponding event message Channel Not Available.

2538 (09EA) (RC2538): MQRC_HOST_NOT_AVAILABLE:

Explanation

An MQCONN call was issued from a client to connect to a queue manager but the attempt to allocate a conversation to the remote system failed. Common causes of this reason code are:

- The listener has not been started on the remote system.
- The connection name in the client channel definition is incorrect.
- The network is currently unavailable.
- A firewall blocking the port, or protocol-specific traffic.
- The security call initializing the IBM MQ client is blocked by a security exit on the SVRCONN channel at the server.

Completion Code

MQCC_FAILED

Programmer Response

Examine the client error log for messages explaining the cause of the problem.

If you are using a Linux server, and receiving a 2538 return code when trying to connect to a queue manager, ensure that you check your internal firewall configuration.

To diagnose the problem, issue the following commands to temporarily turn off the internal Linux firewall :

```
/etc/init.d/iptables save
/etc/init.d/iptables stop
```

To turn the internal Linux firewall back on, issue the command:

```
/etc/init.d/iptables start
```

To permanently turn off the internal Linux firewall, issue the command:

```
chkconfig iptables off
```

2539 (09EB) (RC2539): MQRC_CHANNEL_CONFIG_ERROR:

Explanation

An MQCONN call was issued from a client to connect to a queue manager but the attempt to establish communication failed. Common causes of this reason code are:

- The server and client cannot agree on the channel attributes to use.
- There are errors in one or both of the QM.INI or MQCLIENT.INI configuration files.
- The server machine does not support the code page used by the client.

Completion Code

MQCC_FAILED

Programmer Response

Examine the queue manager and client error logs for messages explaining the cause of the problem.

2540 (09EC) (RC2540): MQRC_UNKNOWN_CHANNEL_NAME:

Explanation

An MQCONN call was issued from a client to connect to a queue manager but the attempt to establish communication failed because the queue manager did not recognize the channel name.

Completion Code

MQCC_FAILED

Programmer response

Ensure that the client is configured to use the correct channel name.

2541 (09ED) (RC2541): MQRC_LOOPING_PUBLICATION:

Explanation

A Distributed Pub/Sub topology has been configured with a combination of Pub/Sub clusters and Pub/Sub Hierarchies such that some, or all, of the queue managers have been connected in a loop. A looping publication has been detected and put onto the dead-letter queue.

Completion Code

MQCC_FAILED

Programmer response

Examine the hierarchy and correct the loop.

2543 (09EF) (RC2543): MQRC_STANDBY_Q_MGR:

Explanation

The application attempted to connect to a standby queue manager instance.

Standby queue manager instances do not accept connections. To connect to the queue manager, you must connect to its active instance.

Completion Code

MQCC_FAILED

Programmer response

Connect the application to an active queue manager instance.

2544 (09F0) (RC2544): MQRC_RECONNECTING:

Explanation

The connection has started reconnecting.

If an event handler has been registered with a reconnecting connection, it is called with this reason code when reconnection attempts begin.

Completion Code

MQCC_WARNING

Programmer response

Let IBM MQ continue with its next reconnection attempt, change the interval before the reconnection, or stop the reconnection. Change any application state that depends on the reconnection.

Note: Reconnection might start while the application is in the middle of an MQI call.

2545 (09F1) (RC2545): MQRC_RECONNECTED:

Explanation

The connection reconnected successfully and all handles are reinstated.

If reconnection succeeds, an event handler registered with the connection is called with this reason code.

Completion Code

MQCC_OK

Programmer response

Set any application state that depends on the reconnection.

Note: Reconnection might finish while the application is in the middle of an MQI call.

2546 (09F2) (RC2546): MQRC_RECONNECT_QMID_MISMATCH:

Explanation

A reconnectable connection specified MQCNO_RECONNECT_Q_MGR and the connection attempted to reconnect to a different queue manager.

Completion Code

MQCC_FAILED

Programmer response

Ensure that the configuration for a reconnectable client resolves to a single queue manager.

If the application does not require reconnection to exactly the same queue manager, use the MQCONNX option MQCNO_RECONNECT.

2547 (09F3) (RC2547): MQRC_RECONNECT_INCOMPATIBLE:

Explanation

An MQI option is incompatible with reconnectable connections.

This error indicates that the option relies on information in a queue manager that is lost during reconnection. For example, the option MQPMO_LOGICAL_ORDER, requires the queue manager to remember information about logical message ordering that is lost during reconnection.

Completion Code

MQCC_FAILED

Programmer response

Modify your application to remove the incompatible option, or do not allow the application to be reconnectable.

2548 (09F4) (RC2548): MQRC_RECONNECT_FAILED:

Explanation

After reconnecting, an error occurred while reinstating the handles for a reconnectable connection.

For example, an attempt to reopen a queue that had been open when the connection broke, failed.

Completion Code

MQCC_FAILED

Programmer response

Investigate the cause of the error in the error logs. Consider using the MQSTAT API to find further details of the failure.

2549 (09F5) (RC2549): MQRC_CALL_INTERRUPTED:

Explanation

MQPUT, MQPUT1, or MQCMIT was interrupted and reconnection processing cannot reestablish a definite outcome.

This reason code is returned to a client that is using a reconnectable connection if the connection is broken between sending the request to the queue manager and receiving the response, and if the outcome is not certain. For example, an interrupted MQPUT of a persistent message outside sync point might or might not have stored the message. Alternatively an interrupted MQPUT1 of a persistent message or message with default persistence (which could be persistent) outside sync point might or might not have stored the message. The timing of the failure affects whether the message remains on the queue or not. If MQCMIT was interrupted the transaction might or might not have been committed.

Completion Code

MQCC_FAILED

Programmer response

Repeat the call following reconnection, but be aware that in some cases, repeating the call might be misleading.

The application design determines the appropriate recovery action. In many cases, getting and putting persistent messages inside sync point resolves indeterminate outcomes. Where persistent messages need to be processed outside sync point, it might be necessary to establish whether the interrupted operation succeeded before the interruption and repeating it if it did not.

2550 (09F6) (RC2550): MQRC_NO_SUBS_MATCHED:

Explanation

An MQPUT or MQPUT1 call was successful but no subscriptions matched the topic.

Completion Code

MQCC_WARNING

Programmer response

No response is required, unless this reason code was not expected by the application that put the message.

2551 (09F7) (RC2551): MQRC_SELECTION_NOT_AVAILABLE:

Explanation

An MQSUB call subscribed to publications using a SelectionString. IBM MQ is unable to accept the call because it does not follow the rules for specifying selection strings, which are documented in Message selector syntax. It is possible that the selection string is acceptable to an extended message selection provider, however no extended message selection provider was available to validate the selection string. If a subscription is being created, the MQSUB fails; otherwise MQSUB completes with a warning.

An MQPUT or MQPUT1 call published a message and at least one subscriber had a content filter but IBM MQ could not determine whether the publication should be delivered to the subscriber (for example, because no extended message selection provider was available to validate the selection string). The MQPUT or MQPUT1 call will fail with MQRC_SELECTION_NOT_AVAILABLE and no subscribers will receive the publication.

Completion Code

MQCC_WARNING or MQCC_FAILED

Programmer response

If it was intended that the selection string should be handled by the extended message selection provider, ensure that the extended message selection provider is correctly configured and running. If extended message selection was not intended, see Message selector syntax and ensure that you have correctly followed the rules for specifying selection strings.

If a subscription is being resumed, the subscription will not be delivered any messages until a extended message selection provider is available and a message matches the SelectionString of the resumed subscription.

2552 (09F8) (RC2552): MQRC_CHANNEL_SSL_WARNING:
Explanation

An SSL security event has occurred. This is not fatal to an SSL connection but is likely to be of interest to an administrator.

Completion code

MQCC_WARNING

Programmer response

None. This reason code is only used to identify the corresponding event message Channel SSL Warning.

2553 (09F9) (RC2553): MQRC_OCSP_URL_ERROR:
Explanation

The OCSPResponderURL field does not contain a correctly formatted HTTP URL.

Completion code

MQCC_FAILED

Programmer response

Check and correct the OCSPResponderURL. If you do not intend to access an OCSP responder, set the AuthInfoType of the authentication information object to MQAIT_CRL_LDAP.

2554 (09FA) (RC2554): MQRC_CONTENT_ERROR:

Explanation

There are 2 explanations for reason code 2554:
1. An MQPUT call was issued with a message where the content could not be parsed to determine whether the message should be delivered to a subscriber with an extended message selector. No subscribers will receive the publication.
2. MQRC_CONTENT_ERROR can be returned from MQSUB and MQSUBRQ if a selection string selecting on the content of the message was specified.

Completion Code

MQCC_FAILED

Programmer response

There are 2 programmer responses for reason code 2554 because there are two causes:
1. If reason code 2554 was issued because of reason 1 then check for error messages from the extended message selection provider and ensure that the message content is well formed before retrying the operation.
2. If reason code 2554 was issued because of reason 2 then because the error occurred at the time that the retained message was published, either a system administrator must clear the retained queue, or you cannot specify a selection string selecting on the content.

2555 (09FB) (RC2555): MQRC_RECONNECT_Q_MGR_REQD:

Explanation

The `MQCNO_RECONNECT_Q_MGR` option is required.

An option, such `MQMO_MATCH_MSG_TOKEN` in an MQGET call or opening a durable subscription, was specified in the client program that requires re-connection to the same queue manager.

Completion Code

`MQCC_FAILED`

Programmer response

Change the MQCONNX call to use `MQCNO_RECONNECT_Q_MGR`, or modify the client program not to use the conflicting option.

2556 (09FC) (RC2556): MQRC_RECONNECT_TIMED_OUT:

Explanation

A reconnection attempt timed out.

The failure might occur in any MQI verb if a connection is configured to reconnect. You can customize the timeout in the MQClient.ini file

Completion Code

MQCC_FAILED

Programmer response

Look at the error logs to find out why reconnection did not complete within the time limit.

2557 (09FD) (RC2557): MQRC_PUBLISH_EXIT_ERROR:

Explanation

A publish exit function returned an invalid response code, or failed in some other way. This can be returned from the MQPUT, MQPUT1, MQSUB and MQSUBRQ function calls. This reason code does not occur on IBM MQ for z/OS.

Completion Code

MQCC_FAILED

Programmer response

Check the publish exit logic to ensure that the exit is returning valid values in the ExitResponse field of the MQPSXP structure. Consult the IBM MQ error log files and FFST records for more details about the problem.

2558 (09FE) (RC2558): MQRC_COMMINFO_ERROR:

Explanation

The configuration of either the name of the COMMINFO object or the object itself is incorrect.

Completion Code

MQCC_FAILED

Programmer response

Check the configuration of the TOPIC and COMMINFO objects and retry the operation.

2560 (0A00) (RC2560): MQRC_MULTICAST_ONLY:

Explanation

An attempt was made to use a topic which is defined as multicast only in a non-multicast way. Possible causes for this error are:

1. An MQPUT1 call was issued to the topic
2. An MQOPEN call was issued using the MQOO_NO_MULTICAST option
3. An MQSUB call was issued using the MQSO_NO_MULTICAST option
4. The application is connected directly through bindings, that is, there is no client connection
5. The application is being run from a release prior to Version 7.1

Completion Code

MQCC_FAILED

Programmer response

Either change the topic definition to enable non-multicast, or change the application.

2561 (0A01) (RC2561): MQRC_DATA_SET_NOT_AVAILABLE:

Explanation

An IBM MQI call or command was issued to operate on a shared queue, but the call failed because the data for the shared message has been offloaded to a shared message data set that is temporarily unavailable to the current queue manager. This can occur either because of a problem in accessing the data set or because the data set was previously found to be damaged, and is awaiting completion of recovery processing.

This return code can also occur if the shared message data set has not been defined for the queue manager being used. You might be using the wrong queue manager in the queue-sharing group.

- This reason code occurs only on z/OS.

Completion Code

MQCC_FAILED

Programmer response

The problem is temporary; wait a short while, and then retry the operation.

Use `DIS CFSTRUCT(...) SMDSCONN(*)` to display the status of the SMDS connection.

To start the connection if the STATUS is not OPEN, use `STA SMDSCONN(*) CFSTRUCT(...)`.

Use `DISPLAY CFSTATUS(...) TYPE(SMDS)` and check the status is active on the queue manager that you are using.

2562 (0A02) (RC2562): MQRC_GROUPING_NOT_ALLOWED:

Explanation

An MQPUT call was issued to put a grouped message to a handle which is publishing over multicast.

Completion Code

MQCC_FAILED

Programmer response

Either change the topic definition to disable multicast or change the application to not use grouped messages.

2563 (0A03) (RC2563): MQRC_GROUP_ADDRESS_ERROR:

Explanation

An MQOPEN or MQSUB call was issued to a multicast topic which has been defined with an incorrect group address field.

Completion Code

MQCC_FAILED

Programmer response

Correct the group address field in the COMMINFO definition linked to the TOPIC object.

2564 (0A04) (RC2564): MQRC_MULTICAST_CONFIG_ERROR:

Explanation

An MQOPEN, MQSUB or MQPUT call was issued which invoked the multicast component. The call failed because the multicast configuration is incorrect.

Completion Code

MQCC_FAILED

Programmer response

Check the multicast configuration and error logs and retry the operation.

2565 (0A05) (RC2565): MQRC_MULTICAST_INTERFACE_ERROR:

Explanation

An MQOPEN, MQSUB or MQPUT call was made which attempted to a network interface for multicast. The interface returned an error. Possible causes for the error are:

1. The required network interface does not exist.
2. The interface is not active.
3. The interface does not support the required IP version.

Completion Code

MQCC_FAILED

Programmer response

Verify that the IP address and the system network configuration are valid. Check the multicast configuration and error logs and retry the operation.

2566 (0A06) (RC2566): MQRC_MULTICAST_SEND_ERROR:

Explanation

An MQPUT call was made which attempted to send multicast traffic over the network. The system failed to send one or more network packets.

Completion Code

MQCC_FAILED

Programmer response

Verify that the IP address and the system network configuration are valid. Check the multicast configuration and error logs and retry the operation.

2567 (0A07) (RC2567): MQRC_MULTICAST_INTERNAL_ERROR:

Explanation

An MQOPEN, MQSUB or MQPUT call was issued which invoked the multicast component. An internal error occurred which prevented the operation completing successfully.

Completion Code

MQCC_FAILED

Programmer response

Tell the systems administrator.

2568 (0A08) (RC2568): MQRC_CONNECTION_NOT_AVAILABLE:

Explanation

An MQCONN or MQCONNX call was made when the queue manager was unable to provide a connection of the requested connection type on the current installation. A client connection cannot be made on a server only installation. A local connection cannot be made on a client only installation.

This error can also occur when IBM MQ fails an attempt to load a library from the installation that the requested queue manager is associated with.

Completion Code

MQCC_FAILED

Programmer response

Ensure that the connection type requested is applicable to the type of installation. If the connection type is applicable to the installation then consult the error log for more information about the nature of the error.

2569 (0A09) (RC2569): MQRC_SYNCPOINT_NOT_ALLOWED:

Explanation

An MQPUT or MQPUT1 call using MQPMO_SYNCPOINT was made to a topic that is defined as MCAST(ENABLED). This is not allowed.

Completion Code

MQCC_FAILED

Programmer response

Change the application to use MQPMO_NO_SYNCPOINT, or alter the topic to disable the use of Multicast and retry the operation.

2577 (0A11) (RC2577): MQRC_CHANNEL_BLOCKED:

Explanation

An inbound channel attempted to connect to the queue manager but was blocked due to matching a Channel Authentication rule.

Completion Code

MQCC_WARNING

Programmer response

None. This reason code is only used to identify the corresponding event message Channel Blocked.

2578 (0A12) (RC2578): MQRC_CHANNEL_BLOCKED_WARNING:

Explanation

An inbound channel attempted to connect to the queue manager and would have been blocked due to matching a Channel Authentication rule, however the rule was defined with WARN(YES) so the rule did not block the connection.

Completion Code

MQCC_WARNING

Programmer response

None. This reason code is only used to identify the corresponding event message Channel Blocked.

2583 (0A17) (RC2583): MQRC_INSTALLATION_MISMATCH:

Explanation

The application attempted to connect to a queue manager that is not associated with the same IBM MQ installation as the loaded libraries.

Completion Code

MQCC_FAILED

Programmer response

An application must use the libraries from the installation the queue manager is associated with. If the *AMQ_SINGLE_INSTALLATION* environment variable is set, you must ensure that the application connects only to queue managers associated with a single installation. Otherwise, if IBM MQ is unable to automatically locate the correct libraries, you must modify the application, or the library search path, to ensure that the correct libraries are used.

2587 (0A1B) (RC2587): MQRC_HMSG_NOT_AVAILABLE:

Explanation

On an MQGET, MQPUT, or MQPUT1 call, a message handle supplied is not valid with the installation the queue manager is associated with. The message handle was created by MQCRTMH specifying the MQHC_UNASSOCIATED_HCONN option. It can be used only with queue managers associated with the first installation used in the process.

Completion Code

MQCC_FAILED

Programmer response

To pass properties between two queue managers associated with different installations, convert the message handle retrieved using MQGET into a buffer using the MQMHBUF call. Then pass that buffer into the MQPUT or MQPUT1 call of the other queue manager. Alternatively, use the **`setmqm`** command to associate one of the queue managers with the installation that the other queue manager is using. Using the **`setmqm`** command might change the version of IBM MQ that the queue manager uses.

2589 (0A1D) (RC2589) MQRC_INSTALLATION_MISSING:

Explanation

On an MQCONN or MQCONNX call, an attempt was made to connect to a queue manager where the associated installation is no longer installed.

Completion Code

MQCC_FAILED

Programmer response

Associate the queue manager with a different installation using the **setmqm** command before attempting to connect to the queue manager again.

2590 (0A1E) (RC2590): MQRC_FASTPATH_NOT_AVAILABLE:

Explanation

On an MQCONNX call, the MQCNO_FASTPATH_BINDING option was specified. However, a fastpath connection to the queue manager cannot be made. This issue can occur when a non-fastpath connection to a queue manager was made in the process before this MQCONNX call.

Completion Code

MQCC_FAILED

Programmer response

Either change all MQCONNX calls within the process to be fastpath, or use the *AMQ_SINGLE_INSTALLATION* environment variable to restrict connections to a single installation, allowing the queue manager to accept fastpath and non-fastpath connections from the same process, in any order.

2591 (0A1F) (RC2591): MQRC_CIPHER_SPEC_NOT_SUITE_B:

Explanation

A client application is configured for NSA Suite B compliant operation but the CipherSpec for the client connection channel is not permitted at the configured Suite B security level. This can occur for Suite B CipherSpecs which fall outside the currently configured security level, for example if ECDHE_ECDSA_AES_128_GCM_SHA256 (which is 128-bit Suite B) is used when only the 192-bit Suite B security level is configured

For more information about which CipherSpecs are Suite B compliant, refer to Specifying CipherSpecs.

Completion Code

MQCC_FAILED

Programmer response

Select an appropriate CipherSpec which is permitted at the configured Suite B security level.

2592 (0A20) (RC2592): MQRC_SUITE_B_ERROR:

Explanation

The configuration of Suite B is invalid. For example, an unrecognized value was specified in the **MQSUITEB** environment variable, the **EncryptionPolicySuiteB** SSL stanza setting or the MQSCO **EncryptionPolicySuiteB** field.

Completion Code

MQCC_FAILED

Programmer response

Determine the fault in the Suite B configuration and amend.

2593 (0A21)(RC2593): MQRC_CERT_VAL_POLICY_ERROR:

Explanation

The certificate validation policy configuration is invalid. An unrecognized or unsupported value was specified in the **MQCERTVPOL** environment variable, the **CertificateValPolicy** SSL stanza setting or the MQSCO **CertificateValPolicy** field.

Completion Code

MQCC_FAILED

Programmer response

Specify a valid certificate validation policy which is supported on the current platform.

2594 (0A22)(RC2594): MQRC_PASSWORD_PROTECTION_ERROR:

Explanation

An MQCONN or MQCONNX call was issued from a client connected application, but it failed to agree a password protection algorithm with the queue manager. For unencrypted channels, IBM MQ Version 8.0 clients try to agree a password protection mechanism to avoid sending passwords in plain text across a network.

The usual cause of this error is that the user has set the PasswordProtection attribute in the Channels stanza of mqclient.ini (or qm.ini) to ALWAYS, but the version of IBM MQ that is installed on the remote system does not support password protection.

Java and JMS clients must enable MQCSP authentication mode in order to use the PasswordProtection feature. See Connection authentication with the Java client.

Completion Code

MQCC_FAILED

Programmer response

Consider changing the PasswordProtection attribute or use SSL/TLS to protect passwords instead. If you are using SSL/TLS, you must not use a null cipher because it would send passwords in plain text which provides no protection.

More information can be found in the error log in message AMQ9296.

2595 (0A23)(RC2595): MQRC_CSP_ERROR:

Explanation

The connect call failed because the MQCSP structure was not valid for one of the following reasons:
- The **`StrucId`** field is not MQCSP_STRUC_ID
- The **`Version`** field specifies a value that is not valid or not supported.
- The **`AuthenticationType`** field specifies a value that is not valid or not supported.
- The user identifier is incorrectly specified.
- The password is incorrectly specified.

Completion Code

MQCC_FAILED

Programmer response

Ensure that the MQCSP structure is correct.

z/OS On z/OS:
- Check that the IBM MQ libraries in STEPLIB are at the same or a higher level than the queue manager.
- If you are using USS, check that the LIBPATH has matching libraries, for example `LIBPATH=$LIBPATH:"/mqm/V8R0M0/java/lib/"`.

2596 (0A24)(RC2596): MQRC_CERT_LABEL_NOT_ALLOWED:

Explanation

The channel definition specifies a certificate label but the environment does not support certificate label configuration.

Completion Code

MQCC_FAILED

Programmer response

Either, remove the certificate label from the channel definition, or change the configuration to ignore the label.

2598 (0A26)(RC2598): MQRC_ADMIN_TOPIC_STRING_ERROR: V 8.0.0.2

Explanation

This error can occur when calling MQSUB or MQOPEN. Publishing to an IBM MQ administrative topic string, starting `$SYS/MQ/` is not permitted.

When subscribing to an IBM MQ administrative topic string, the use of wildcard characters is restricted. See System topics for monitoring and activity trace for details.

Completion Code

MQCC_FAILED

Programmer response

Change the configuration to publish to an administrative topic string that does not start `$SYS/MQ/`.

6100 (17D4) (RC6100): MQRC_REOPEN_EXCL_INPUT_ERROR:

Explanation

An open object does not have the correct ImqObject **open options** and requires one or more additional options. An implicit reopen is required but closure has been prevented.

Closure has been prevented because the queue is open for exclusive input and closure might result in the queue being accessed by another process or thread, before the queue is reopened by the process or thread that presently has access.

This reason code occurs in the IBM MQ C++ environment.

Completion Code

MQCC_FAILED

Programmer response

Set the **open options** explicitly to cover all eventualities so that implicit reopening is not required.

6101 (17D5) (RC6101): MQRC_REOPEN_INQUIRE_ERROR:

Explanation

An open object does not have the correct ImqObject **open options** and requires one or more additional options. An implicit reopen is required but closure has been prevented.

Closure has been prevented because one or more characteristics of the object need to be checked dynamically prior to closure, and the **open options** do not already include MQOO_INQUIRE.

This reason code occurs in the IBM MQ C++ environment.

Completion Code

MQCC_FAILED

Programmer response

Set the **open options** explicitly to include MQOO_INQUIRE.

6102 (17D6) (RC6102): MQRC_REOPEN_SAVED_CONTEXT_ERR:

Explanation

An open object does not have the correct ImqObject **open options** and requires one or more additional options. An implicit reopen is required but closure has been prevented.

Closure has been prevented because the queue is open with MQOO_SAVE_ALL_CONTEXT, and a destructive get has been performed previously. This has caused retained state information to be associated with the open queue and this information would be destroyed by closure.

This reason code occurs in the IBM MQ C++ environment.

Completion Code

MQCC_FAILED

Programmer response

Set the **open options** explicitly to cover all eventualities so that implicit reopening is not required.

6103 (17D7) (RC6103): MQRC_REOPEN_TEMPORARY_Q_ERROR:

Explanation

An open object does not have the correct ImqObject **open options** and requires one or more additional options. An implicit reopen is required but closure has been prevented.

Closure has been prevented because the queue is a local queue of the definition type MQQDT_TEMPORARY_DYNAMIC, that would be destroyed by closure.

This reason code occurs in the IBM MQ C++ environment.

Completion Code

MQCC_FAILED

Programmer response

Set the **open options** explicitly to cover all eventualities so that implicit reopening is not required.

6104 (17D8) (RC6104): MQRC_ATTRIBUTE_LOCKED:

Explanation

An attempt has been made to change the value of an attribute of an object while that object is open, or, for an ImqQueueManager object, while that object is connected. Certain attributes cannot be changed in these circumstances. Close or disconnect the object (as appropriate) before changing the attribute value.

An object might have been connected, opened, or both unexpectedly and implicitly to perform an MQINQ call. Check the attribute cross-reference table in C++ and MQI cross-reference to determine whether any of your method invocations result in an MQINQ call.

This reason code occurs in the IBM MQ C++ environment.

Completion Code

MQCC_FAILED

Programmer response

Include MQOO_INQUIRE in the ImqObject **open options** and set them earlier.

6105 (17D9) (RC6105): MQRC_CURSOR_NOT_VALID:

Explanation

The browse cursor for an open queue has been invalidated since it was last used by an implicit reopen.

This reason code occurs in the IBM MQ C++ environment.

Completion Code

MQCC_FAILED

Programmer response

Set the ImqObject **open options** explicitly to cover all eventualities so that implicit reopening is not required.

6106 (17DA) (RC6106): MQRC_ENCODING_ERROR:

Explanation

The encoding of the (next) message item needs to be MQENC_NATIVE for pasting.

This reason code occurs in the IBM MQ C++ environment.

Completion Code

MQCC_FAILED

6107 (17DB) (RC6107): MQRC_STRUC_ID_ERROR:

Explanation

The structure id for the (next) message item, which is derived from the 4 characters beginning at the data pointer, is either missing or is inconsistent with the class of object into which the item is being pasted.

This reason code occurs in the IBM MQ C++ environment.

Completion Code

MQCC_FAILED

6108 (17DC) (RC6108): MQRC_NULL_POINTER:

Explanation

A null pointer has been supplied where a nonnull pointer is either required or implied.

This reason code occurs in the IBM MQ C++ environment.

Completion Code

MQCC_FAILED

6109 (17DD) (RC6109): MQRC_NO_CONNECTION_REFERENCE:

Explanation

The **connection reference** is null. A connection to an ImqQueueManager object is required.

This reason code occurs in the IBM MQ C++ environment.

Completion Code

MQCC_FAILED

6110 (17DE) (RC6110): MQRC_NO_BUFFER:

Explanation

No buffer is available. For an ImqCache object, one cannot be allocated, denoting an internal inconsistency in the object state that should not occur.

This reason code occurs in the IBM MQ C++ environment.

Completion Code

MQCC_FAILED

6111 (17DF) (RC6111): MQRC_BINARY_DATA_LENGTH_ERROR:

Explanation

The length of the binary data is inconsistent with the length of the target attribute. Zero is a correct length for all attributes.

- The correct length for an **accounting token** is MQ_ACCOUNTING_TOKEN_LENGTH.
- The correct length for an **alternate security id** is MQ_SECURITY_ID_LENGTH.
- The correct length for a **correlation id** is MQ_CORREL_ID_LENGTH.
- The correct length for a **facility token** is MQ_FACILITY_LENGTH.
- The correct length for a **group id** is MQ_GROUP_ID_LENGTH.
- The correct length for a **message id** is MQ_MSG_ID_LENGTH.
- The correct length for an **instance id** is MQ_OBJECT_INSTANCE_ID_LENGTH.
- The correct length for a **transaction instance id** is MQ_TRAN_INSTANCE_ID_LENGTH.
- The correct length for a **message token** is MQ_MSG_TOKEN_LENGTH.

This reason code occurs in the IBM MQ C++ environment.

Completion Code

MQCC_FAILED

6112 (17E0) (RC6112): MQRC_BUFFER_NOT_AUTOMATIC:

Explanation

A user-defined (and managed) buffer cannot be resized. A user-defined buffer can only be replaced or withdrawn. A buffer must be automatic (system-managed) before it can be resized.

This reason code occurs in the IBM MQ C++ environment.

Completion Code

MQCC_FAILED

Programmer response

6113 (17E1) (RC6113): MQRC_INSUFFICIENT_BUFFER:

Explanation

There is insufficient buffer space available after the data pointer to accommodate the request. This might be because the buffer cannot be resized.

This reason code occurs in the IBM MQ C++ environment.

Completion Code

MQCC_FAILED

6114 (17E2) (RC6114): MQRC_INSUFFICIENT_DATA:

Explanation

There is insufficient data after the data pointer to accommodate the request.

This reason code occurs in the IBM MQ C++ environment.

Completion Code

MQCC_FAILED

6115 (17E3) (RC6115): MQRC_DATA_TRUNCATED:

Explanation

Data has been truncated when copying from one buffer to another. This might be because the target buffer cannot be resized, or because there is a problem addressing one or other buffer, or because a buffer is being downsized with a smaller replacement.

This reason code occurs in the IBM MQ C++ environment.

Completion Code

MQCC_FAILED

6116 (17E4) (RC6116): MQRC_ZERO_LENGTH:

Explanation

A zero length has been supplied where a positive length is either required or implied.

This reason code occurs in the IBM MQ C++ environment.

Completion Code

MQCC_FAILED

6117 (17E5) (RC6117): MQRC_NEGATIVE_LENGTH:

Explanation

A negative length has been supplied where a zero or positive length is required.

This reason code occurs in the IBM MQ C++ environment.

Completion Code

MQCC_FAILED

6118 (17E6) (RC6118): MQRC_NEGATIVE_OFFSET:

Explanation

A negative offset has been supplied where a zero or positive offset is required.

This reason code occurs in the IBM MQ C++ environment.

Completion Code

MQCC_FAILED

6119 (17E7) (RC6119): MQRC_INCONSISTENT_FORMAT:

Explanation

The format of the (next) message item is inconsistent with the class of object into which the item is being pasted.

This reason code occurs in the IBM MQ C++ environment.

Completion Code

MQCC_FAILED

6120 (17E8) (RC6120): MQRC_INCONSISTENT_OBJECT_STATE:

Explanation

There is an inconsistency between this object, which is open, and the referenced ImqQueueManager object, which is not connected.

This reason code occurs in the IBM MQ C++ environment.

Completion Code

MQCC_FAILED

6121 (17E9) (RC6121): MQRC_CONTEXT_OBJECT_NOT_VALID:

Explanation

The ImqPutMessageOptions **context reference** does not reference a valid ImqQueue object. The object has been previously destroyed.

This reason code occurs in the IBM MQ C++ environment.

Completion Code

MQCC_FAILED

6122 (17EA) (RC6122): MQRC_CONTEXT_OPEN_ERROR:

Explanation

The ImqPutMessageOptions **context reference** references an ImqQueue object that could not be opened to establish a context. This might be because the ImqQueue object has inappropriate **open options**. Inspect the referenced object **reason code** to establish the cause.

This reason code occurs in the IBM MQ C++ environment.

Completion Code

MQCC_FAILED

6123 (17EB) (RC6123): MQRC_STRUC_LENGTH_ERROR:

Explanation

The length of a data structure is inconsistent with its content. For an MQRMH, the length is insufficient to contain the fixed fields and all offset data.

This reason code occurs in the IBM MQ C++ environment.

Completion Code

MQCC_FAILED

6124 (17EC) (RC6124): MQRC_NOT_CONNECTED:

Explanation

A method failed because a required connection to a queue manager was not available, and a connection cannot be established implicitly because the IMQ_IMPL_CONN flag of the ImqQueueManager **behavior** class attribute is FALSE.

This reason code occurs in the IBM MQ C++ environment.

Completion Code

MQCC_FAILED

Programmer response

Establish a connection to a queue manager and retry.

6125 (17ED) (RC6125): MQRC_NOT_OPEN:

Explanation

A method failed because an object was not open, and opening cannot be accomplished implicitly because the IMQ_IMPL_OPEN flag of the ImqObject **behavior** class attribute is FALSE.

This reason code occurs in the IBM MQ C++ environment.

Completion Code

MQCC_FAILED

Programmer response

Open the object and retry.

6126 (17EE) (RC6126): MQRC_DISTRIBUTION_LIST_EMPTY:

Explanation

An ImqDistributionList failed to open because there are no ImqQueue objects referenced.

This reason code occurs in the IBM MQ C++ environment.

Completion Code

MQCC_FAILED

Programmer response

Establish at least one ImqQueue object in which the **distribution list reference** addresses the ImqDistributionList object, and retry.

6127 (17EF) (RC6127): MQRC_INCONSISTENT_OPEN_OPTIONS:

Explanation

A method failed because the object is open, and the ImqObject **open options** are inconsistent with the required operation. The object cannot be reopened implicitly because the IMQ_IMPL_OPEN flag of the ImqObject **behavior** class attribute is false.

This reason code occurs in the IBM MQ C++ environment.

Completion Code

MQCC_FAILED

Programmer response

Open the object with appropriate ImqObject **open options** and retry.

6128 (17FO) (RC6128): MQRC_WRONG_VERSION:

Explanation

A method failed because a version number specified or encountered is either incorrect or not supported.

For the ImqCICSBridgeHeader class, the problem is with the **version** attribute.

This reason code occurs in the IBM MQ C++ environment.

Completion Code

MQCC_FAILED

Programmer response

If you are specifying a version number, use one that is supported by the class. If you are receiving message data from another program, ensure that both programs are using consistent and supported version numbers.

6129 (17F1) (RC6129): MQRC_REFERENCE_ERROR:

Explanation

An object reference is invalid.

There is a problem with the address of a referenced object. At the time of use, the address of the object is nonnull, but is invalid and cannot be used for its intended purpose.

This reason code occurs in the IBM MQ C++ environment.

Completion Code

MQCC_FAILED

Programmer response

Check that the referenced object is neither deleted nor out of scope, or remove the reference by supplying a null address value.

PCF reason codes

Reason codes might be returned by a broker in response to a command message in PCF format, depending on the parameters used in that message.

For more information about PCFs, see Introduction to Programmable Command Formats, Automating administration tasks, and Using Programmable Command Formats.

The following is a list of PCF reason codes, in numeric order, providing detailed information to help you understand them, including:
- An explanation of the circumstances that have caused the code to be raised
- The associated completion code
- Suggested programmer actions in response to the code

Related reference:

"API completion and reason codes" on page 1314
For each call, a completion code and a reason code are returned by the queue manager or by an exit routine, to indicate the success or failure of the call.

"Secure Sockets Layer (SSL) and Transport Layer Security (TLS) return codes" on page 1622
IBM MQ can use Secure Sockets Layer (SSL) with the various communication protocols. Use this topic to identify the error codes that can be returned by SSL.

"WCF custom channel exceptions" on page 1627
Diagnostic messages are listed in this topic in numeric order, grouped according to the part of the WCF custom channel from which they originate.

IBM MQ AMQ messages

z/OS IBM MQ for z/OS messages, completion, and reason codes

3001 (0BB9) (RC3001): MQRCCF_CFH_TYPE_ERROR

Explanation

Type not valid.

The MQCFH *Type* field value was not valid.

Programmer response

Specify a valid type.

3002 (0BBA) (RC3002): MQRCCF_CFH_LENGTH_ERROR

Explanation

Structure length not valid.

The MQCFH *StrucLength* field value was not valid.

Programmer response

Specify a valid structure length.

3003 (0BBB) (RC3003): MQRCCF_CFH_VERSION_ERROR

Explanation

Structure version number is not valid.

The MQCFH *Version* field value was not valid.

Note that z/OS requires MQCFH_VERSION_3.

Programmer response

Specify a valid structure version number.

3004 (0BBC) (RC3004): MQRCCF_CFH_MSG_SEQ_NUMBER_ERR

Explanation

Message sequence number not valid.

The MQCFH *MsgSeqNumber* field value was not valid.

Programmer response

Specify a valid message sequence number.

3005 (0BBD) (RC3005): MQRCCF_CFH_CONTROL_ERROR

Explanation

Control option not valid.

The MQCFH *Control* field value was not valid.

Programmer response

Specify a valid control option.

3006 (0BBE) (RC3006): MQRCCF_CFH_PARM_COUNT_ERROR

Explanation

Parameter count not valid.

The MQCFH *ParameterCount* field value was not valid.

Programmer response

Specify a valid parameter count.

3007 (0BBF) (RC3007): MQRCCF_CFH_COMMAND_ERROR

Explanation

Command identifier not valid.

The MQCFH *Command* field value was not valid.

Programmer response

Specify a valid command identifier.

3008 (0BC0) (RC3008): MQRCCF_COMMAND_FAILED

Explanation

Command failed.

The command has failed.

Programmer response

Refer to the previous error messages for this command.

3009 (0BC1) (RC3009): MQRCCF_CFIN_LENGTH_ERROR

Explanation

Structure length not valid.

The MQCFIN or MQCFIN64 *StrucLength* field value was not valid.

Programmer response

Specify a valid structure length.

3010 (0BC2) (RC3010): MQRCCF_CFST_LENGTH_ERROR

Explanation

Structure length not valid.

The MQCFST *StrucLength* field value was not valid. The value was not a multiple of four or was inconsistent with the MQCFST *StringLength* field value.

Programmer response

Specify a valid structure length.

3011 (0BC3) (RC3011): MQRCCF_CFST_STRING_LENGTH_ERR

Explanation

String length not valid.

The MQCFST *StringLength* field value was not valid. The value was negative or greater than the maximum permitted length of the parameter specified in the *Parameter* field.

Programmer response

Specify a valid string length for the parameter.

3012 (0BC4) (RC3012): MQRCCF_FORCE_VALUE_ERROR

Explanation

Force value not valid.

The force value specified was not valid.

Programmer response

Specify a valid force value.

3013 (0BC5) (RC3013): MQRCCF_STRUCTURE_TYPE_ERROR

Explanation

Structure type not valid.

The structure *Type* value was not valid.

Programmer response

Specify a valid structure type.

3014 (0BC6) (RC3014): MQRCCF_CFIN_PARM_ID_ERROR

Explanation

Parameter identifier is not valid.

The MQCFIN or MQCFIN64 *Parameter* field value was not valid.

Programmer response

Specify a valid parameter identifier.

3015 (0BC7) (RC3015): MQRCCF_CFST_PARM_ID_ERROR

Explanation

Parameter identifier is not valid.

The MQCFST *Parameter* field value was not valid.

Programmer response

Specify a valid parameter identifier.

3016 (0BC8) (RC3016): MQRCCF_MSG_LENGTH_ERROR

Explanation

Message length not valid.

The message data length was inconsistent with the length implied by the parameters in the message, or a positional parameter was out of sequence.

Programmer response

Specify a valid message length, and check that positional parameters are in the correct sequence.

3017 (0BC9) (RC3017): MQRCCF_CFIN_DUPLICATE_PARM

Explanation

Duplicate parameter.

Two MQCFIN or MQCFIN64 or MQCFIL or MQCFIL64 structures, or any two of those types of structure, with the same parameter identifier were present.

Programmer response

Check for and remove duplicate parameters.

3018 (0BCA) (RC3018): MQRCCF_CFST_DUPLICATE_PARM

Explanation

Duplicate parameter.

Two MQCFST structures, or an MQCFSL followed by an MQCFST structure, with the same parameter identifier were present.

Programmer response

Check for and remove duplicate parameters.

3019 (0BCB) (RC3019): MQRCCF_PARM_COUNT_TOO_SMALL

Explanation

Parameter count too small.

The MQCFH *ParameterCount* field value was less than the minimum required for the command.

Programmer response

Specify a parameter count that is valid for the command.

3020 (0BCC) (RC3020): MQRCCF_PARM_COUNT_TOO_BIG

Explanation

Parameter count too big.

The MQCFH *ParameterCount* field value was more than the maximum for the command.

Programmer response

Specify a parameter count that is valid for the command.

3021 (0BCD) (RC3021): MQRCCF_Q_ALREADY_IN_CELL

Explanation

Queue already exists in cell.

An attempt was made to define a queue with cell scope, or to change the scope of an existing queue from queue-manager scope to cell scope, but a queue with that name already existed in the cell.

Programmer response

Do one of the following:
- Delete the existing queue and retry the operation.
- Change the scope of the existing queue from cell to queue-manager and retry the operation.
- Create the new queue with a different name.

3022 (0BCE) (RC3022): MQRCCF_Q_TYPE_ERROR

Explanation

Queue type not valid.

The *QType* value was not valid.

Programmer response

Specify a valid queue type.

3023 (0BCF) (RC3023): MQRCCF_MD_FORMAT_ERROR

Explanation

Format not valid.

The MQMD *Format* field value was not MQFMT_ADMIN.

Programmer response

Specify the valid format.

3024 (0BD0) (RC3024): MQRCCF_CFSL_LENGTH_ERROR

Explanation

Structure length not valid.

The MQCFSL *StrucLength* field value was not valid. The value was not a multiple of four or was inconsistent with the MQCFSL *StringLength* field value.

Programmer response

Specify a valid structure length.

3025 (0BD1) (RC3025): MQRCCF_REPLACE_VALUE_ERROR

Explanation

Replace value not valid.

The *Replace* value was not valid.

Programmer response

Specify a valid replace value.

3026 (0BD2) (RC3026): MQRCCF_CFIL_DUPLICATE_VALUE

Explanation

Duplicate parameter value.

In the MQCFIL or MQCFIL64 structure, there was a duplicate parameter value in the list.

Programmer response

Check for and remove duplicate parameter values.

3027 (0BD3) (RC3027): MQRCCF_CFIL_COUNT_ERROR

Explanation

Count of parameter values not valid.

The MQCFIL or MQCFIL64 *Count* field value was not valid. The value was negative or greater than the maximum permitted for the parameter specified in the *Parameter* field.

Programmer response

Specify a valid count for the parameter.

3028 (0BD4) (RC3028): MQRCCF_CFIL_LENGTH_ERROR

Explanation

Structure length not valid.

The MQCFIL or MQCFIL64 *StrucLength* field value was not valid.

Programmer response

Specify a valid structure length.

3029 (0BD5) (RC3029): MQRCCF_MODE_VALUE_ERROR

Explanation

Mode value not valid.

The *Mode* value was not valid.

Programmer response

Specify a valid mode value.

3029 (0BD5) (RC3029): MQRCCF_QUIESCE_VALUE_ERROR

Explanation

Former name for MQRCCF_MODE_VALUE_ERROR.

3030 (0BD6) (RC3030): MQRCCF_MSG_SEQ_NUMBER_ERROR

Explanation

Message sequence number not valid.

The message sequence number parameter value was not valid.

Programmer response

Specify a valid message sequence number.

3031 (0BD7) (RC3031): MQRCCF_PING_DATA_COUNT_ERROR

Explanation

Data count not valid.

The Ping Channel `DataCount` value was not valid.

Programmer response

Specify a valid data count value.

3032 (0BD8) (RC3032): MQRCCF_PING_DATA_COMPARE_ERROR

Explanation

Ping Channel command failed.

The Ping Channel command failed with a data compare error. The data offset that failed is returned in the message (with parameter identifier MQIACF_ERROR_OFFSET).

Programmer response

Consult your systems administrator.

3033 (0BD9) (RC3033): MQRCCF_CFSL_PARM_ID_ERROR

Explanation

Parameter identifier is not valid.

The MQCFSL `Parameter` field value was not valid.

Programmer response

Specify a valid parameter identifier.

3034 (0BDA) (RC3034): MQRCCF_CHANNEL_TYPE_ERROR

Explanation

Channel type not valid.

The `ChannelType` specified was not valid, or did not match the type of an existing channel being copied, changed or replaced, or the command and the specified disposition cannot be used with that type of channel.

Programmer response

Specify a valid channel name, type, or disposition.

3035 (0BDB) (RC3035): MQRCCF_PARM_SEQUENCE_ERROR

Explanation

Parameter sequence not valid.

The sequence of parameters is not valid for this command.

Programmer response

Specify the positional parameters in a valid sequence for the command.

3036 (0BDC) (RC3036): MQRCCF_XMIT_PROTOCOL_TYPE_ERR

Explanation

Transmission protocol type not valid.

The *TransportType* value was not valid.

Programmer response

Specify a valid transmission protocol type.

3037 (0BDD) (RC3037): MQRCCF_BATCH_SIZE_ERROR

Explanation

Batch size not valid.

The batch size specified was not valid.

Programmer response

Specify a valid batch size value.

3038 (0BDE) (RC3038): MQRCCF_DISC_INT_ERROR

Explanation

Disconnection interval not valid.

The disconnection interval specified was not valid.

Programmer response

Specify a valid disconnection interval.

3039 (0BDF) (RC3039): MQRCCF_SHORT_RETRY_ERROR

Explanation

Short retry count not valid.

The *ShortRetryCount* value was not valid.

Programmer response

Specify a valid short retry count value.

3040 (0BE0) (RC3040): MQRCCF_SHORT_TIMER_ERROR

Explanation

Short timer value not valid.

The *ShortRetryInterval* value was not valid.

Programmer response

Specify a valid short timer value.

3041 (0BE1) (RC3041): MQRCCF_LONG_RETRY_ERROR

Explanation

Long retry count not valid.

The long retry count value specified was not valid.

Programmer response

Specify a valid long retry count value.

3042 (0BE2) (RC3042): MQRCCF_LONG_TIMER_ERROR

Explanation

Long timer not valid.

The long timer (long retry wait interval) value specified was not valid.

Programmer response

Specify a valid long timer value.

3043 (0BE3) (RC3043): MQRCCF_SEQ_NUMBER_WRAP_ERROR

Explanation

Sequence wrap number not valid.

The *SeqNumberWrap* value was not valid.

Programmer response

Specify a valid sequence wrap number.

3044 (0BE4) (RC3044): MQRCCF_MAX_MSG_LENGTH_ERROR

Explanation

Maximum message length not valid.

The maximum message length value specified was not valid.

Programmer response

Specify a valid maximum message length.

3045 (0BE5) (RC3045): MQRCCF_PUT_AUTH_ERROR

Explanation

Put authority value not valid.

The *PutAuthority* value was not valid.

Programmer response

Specify a valid authority value.

3046 (0BE6) (RC3046): MQRCCF_PURGE_VALUE_ERROR

Explanation

Purge value not valid.

The *Purge* value was not valid.

Programmer response

Specify a valid purge value.

3047 (0BE7) (RC3047): MQRCCF_CFIL_PARM_ID_ERROR

Explanation

Parameter identifier is not valid.

The MQCFIL or MQCFIL64 `Parameter` field value was not valid, or specifies a parameter that cannot be filtered, or that is also specified as a parameter to select a subset of objects.

Programmer response

Specify a valid parameter identifier.

3048 (0BE8) (RC3048): MQRCCF_MSG_TRUNCATED

Explanation

Message truncated.

The command server received a message that is larger than its maximum valid message size.

Programmer response

Check the message contents are correct.

3049 (0BE9) (RC3049): MQRCCF_CCSID_ERROR

Explanation

Coded character-set identifier error.

In a command message, one of the following occurred:
- The *CodedCharSetId* field in the message descriptor of the command does not match the coded character-set identifier of the queue manager at which the command is being processed, or
- The *CodedCharSetId* field in a string parameter structure within the message text of the command is not
  - MQCCSI_DEFAULT, or
  - the coded character-set identifier of the queue manager at which the command is being processed, as in the *CodedCharSetId* field in the message descriptor.

The error response message contains the correct value.

This reason can also occur if a ping cannot be performed because the coded character-set identifiers are not compatible. In this case the correct value is not returned.

Programmer response

Construct the command with the correct coded character-set identifier, and specify this in the message descriptor when sending the command. For ping, use a suitable coded character-set identifier.

3050 (0BEA) (RC3050): MQRCCF_ENCODING_ERROR

Explanation

Encoding error.

The *Encoding* field in the message descriptor of the command does not match that required for the platform at which the command is being processed.

Programmer response

Construct the command with the correct encoding, and specify this in the message descriptor when sending the command.

3052 (0BEC) (RC3052): MQRCCF_DATA_CONV_VALUE_ERROR

Explanation

Data conversion value not valid.

The value specified for *DataConversion* is not valid.

Programmer response

Specify a valid value.

3053 (0BED) (RC3053): MQRCCF_INDOUBT_VALUE_ERROR

Explanation

In-doubt value not valid.

The value specified for *InDoubt* is not valid.

Programmer response

Specify a valid value.

3054 (0BEE) (RC3054): MQRCCF_ESCAPE_TYPE_ERROR

Explanation

Escape type not valid.

The value specified for *EscapeType* is not valid.

Programmer response

Specify a valid value.

3062 (0BF6) (RC3062): MQRCCF_CHANNEL_TABLE_ERROR

Explanation

Channel table value not valid.

The *ChannelTable* specified was not valid, or was not appropriate for the channel type specified on an Inquire Channel or Inquire Channel Names command.

Programmer response

Specify a valid channel table value.

3063 (0BF7) (RC3063): MQRCCF_MCA_TYPE_ERROR

Explanation

Message channel agent type not valid.

The *MCAType* value specified was not valid.

Programmer response

Specify a valid value.

3064 (0BF8) (RC3064): MQRCCF_CHL_INST_TYPE_ERROR

Explanation

Channel instance type not valid.

The *ChannelInstanceType* specified was not valid.

Programmer response

Specify a valid channel instance type.

3065 (0BF9) (RC3065): MQRCCF_CHL_STATUS_NOT_FOUND

Explanation

Channel status not found.

For Inquire Channel Status, no channel status is available for the specified channel. This might indicate that the channel has not been used.

Programmer response

None, unless this is unexpected, in which case consult your systems administrator.

3066 (0BFA) (RC3066): MQRCCF_CFSL_DUPLICATE_PARM

Explanation

Duplicate parameter.

Two MQCFSL structures, or an MQCFST followed by an MQCFSL structure, with the same parameter identifier were present.

Programmer response

Check for and remove duplicate parameters.

3067 (0BFB) (RC3067): MQRCCF_CFSL_TOTAL_LENGTH_ERROR

Explanation

Total string length error.

The total length of the strings (not including trailing blanks) in a MQCFSL structure exceeds the maximum allowable for the parameter.

Programmer response

Check that the structure has been specified correctly, and if so reduce the number of strings.

3068 (0BFC) (RC3068): MQRCCF_CFSL_COUNT_ERROR

Explanation

Count of parameter values not valid.

The MQCFSL *Count* field value was not valid. The value was negative or greater than the maximum permitted for the parameter specified in the *Parameter* field.

Programmer response

Specify a valid count for the parameter.

3069 (0BFD) (RC3069): MQRCCF_CFSL_STRING_LENGTH_ERR

Explanation

String length not valid.

The MQCFSL *StringLength* field value was not valid. The value was negative or greater than the maximum permitted length of the parameter specified in the *Parameter* field.

Programmer response

Specify a valid string length for the parameter.

3070 (0BFE) (RC3070): MQRCCF_BROKER_DELETED

Explanation

Broker has been deleted.

When a broker is deleted using the `dltmqbrk` command, all broker queues created by the broker are deleted. Before this can be done the queues are emptied of all command messages; any that are found are placed on the dead-letter queue with this reason code.

Programmer response

Process the command messages that were placed on the dead-letter queue.

3071 (0BFF) (RC3071): MQRCCF_STREAM_ERROR

Explanation

Stream name is not valid.

The stream name parameter is not valid. Stream names must obey the same naming rules as for IBM MQ queues.

Programmer response

Retry the command with a valid stream name parameter.

3072 (0C00) (RC3072): MQRCCF_TOPIC_ERROR

Explanation

Topic name is invalid.

A command has been sent to the broker containing a topic name that is not valid. Note that wildcard topic names are not allowed for *Register Publisher* and *Publish* commands.

Programmer response

Retry the command with a valid topic name parameter. Up to 256 characters of the topic name in question are returned with the error response message. If the topic name contains a null character, this is assumed to terminate the string and is not considered to be part of it. A zero length topic name is not valid, as is one that contains an escape sequence that is not valid.

3073 (0C01) (RC3073): MQRCCF_NOT_REGISTERED

Explanation

Subscriber or publisher is not registered.

A *Deregister* command has been issued to remove registrations for a topic, or topics, for which the publisher or subscriber is not registered. If multiple topics were specified on the command, it fails with a completion code of MQCC_WARNING if the publisher or subscriber was registered for some, but not all, of the topics specified. This error code is also returned to a subscriber issuing a *Request Update* command for a topic for which he does not have a subscription.

Programmer response

Investigate why the publisher or subscriber is not registered. In the case of a subscriber, the subscriptions might have expired, or been removed automatically by the broker if the subscriber is no longer authorized.

3074 (0C02) (RC3074): MQRCCF_Q_MGR_NAME_ERROR

Explanation

An invalid or unknown queue manager name has been supplied.

A queue manager name has been supplied as part of a publisher or subscriber identity. This might have been supplied as an explicit parameter or in the *ReplyToQMgr* field in the message descriptor of the command. Either the queue manager name is not valid, or in the case of a subscriber identity, the subscriber's queue could not be resolved because the remote queue manager is not known to the broker queue manager.

Programmer response

Retry the command with a valid queue manager name. If appropriate, the broker includes a further error reason code within the error response message. If one is supplied, follow the guidance for that reason code in "Reason codes and exceptions" on page 1314 to resolve the problem.

3075 (0C03) (RC3075): MQRCCF_INCORRECT_STREAM

Explanation

Stream name does not match the stream queue it was sent to.

A command has been sent to a stream queue that specified a different stream name parameter.

Programmer response

Retry the command either by sending it to the correct stream queue or by modifying the command so that the stream name parameter matches.

3076 (0C04) (RC3076): MQRCCF_Q_NAME_ERROR

Explanation

An invalid or unknown queue name has been supplied.

A queue name has been supplied as part of a publisher or subscriber identity. This might have been supplied as an explicit parameter or in the *ReplyToQ* field in the message descriptor of the command. Either the queue name is not valid, or in the case of a subscriber identity, the broker has failed to open the queue.

Programmer response

Retry the command with a valid queue name. If appropriate, the broker includes a further error reason code within the error response message. If one is supplied, follow the guidance for that reason code in "Reason codes and exceptions" on page 1314 to resolve the problem.

3077 (0C05) (RC3077): MQRCCF_NO_RETAINED_MSG

Explanation

No retained message exists for the topic specified.

A *Request Update* command has been issued to request the retained message associated with the specified topic. No retained message exists for that topic.

Programmer response

If the topic or topics in question should have retained messages, the publishers of these topics might not be publishing with the correct publication options to cause their publications to be retained.

3078 (0C06) (RC3078): MQRCCF_DUPLICATE_IDENTITY

Explanation

Publisher or subscriber identity already assigned to another user ID.

Each publisher and subscriber has a unique identity consisting of a queue manager name, a queue name, and optionally a correlation identifier. Associated with each identity is the user ID under which that publisher or subscriber first registered. A specific identity can be assigned only to one user ID at a time. While the identity is registered with the broker all commands wanting to use it must specify the correct user ID. When a publisher or a subscriber no longer has any registrations with the broker the identity can be used by another user ID.

Programmer response

Either retry the command using a different identity or remove all registrations associated with the identity so that it can be used by a different user ID. The user ID to which the identity is currently assigned is returned within the error response message. A *Deregister* command could be issued to remove these registrations. If the user ID in question cannot be used to execute such a command, you need to have the necessary authority to open the SYSTEM.BROKER.CONTROL.QUEUE using the MQOO_ALTERNATE_USER_AUTHORITY option.

3079 (0C07) (RC3079): MQRCCF_INCORRECT_Q

Explanation

Command sent to wrong broker queue.

The command is a valid broker command but the queue it has been sent to is incorrect. `Publish` and `Delete Publication` commands need to be sent to the stream queue, all other commands need to be sent to the SYSTEM.BROKER.CONTROL.QUEUE.

Programmer response

Retry the command by sending it to the correct queue.

3080 (0C08) (RC3080): MQRCCF_CORREL_ID_ERROR

Explanation

Correlation identifier used as part of an identity is all binary zeros.

Each publisher and subscriber is identified by a queue manager name, a queue name, and optionally a correlation identifier. The correlation identifier is typically used to allow multiple subscribers to share the same subscriber queue. In this instance a publisher or subscriber has indicated within the Registration or Publication options supplied on the command that their identity does include a correlation identifier, but a valid identifier has not been supplied. The <RegOpt>CorrelAsId</RegOpt> has been specified, but the correlation identifier of the message is nulls.

Programmer response

Change the program to retry the command ensuring that the correlation identifier supplied in the message descriptor of the command message is not all binary zeros.

3081 (0C09) (RC3081): MQRCCF_NOT_AUTHORIZED

Explanation

Subscriber has insufficient authority.

To receive publications a subscriber application needs both browse authority for the stream queue that it is subscribing to, and put authority for the queue that publications are to be sent to. Subscriptions are rejected if the subscriber does not have both authorities. In addition to having browse authority for the stream queue, a subscriber would also require `altusr` authority for the stream queue to subscribe to certain topics that the broker itself publishes information on. These topics start with the MQ/SA/ prefix.

Programmer response

Ensure that the subscriber has the necessary authorities and reissue the request. The problem might occur because the subscriber's user ID is not known to the broker. This can be identified if a further error reason code of MQRC_UNKNOWN_ENTITY is returned within the error response message.

3082 (0C0A) (RC3082): MQRCCF_UNKNOWN_STREAM

Explanation

Stream is not known by the broker or could not be created.

A command message has been put to the SYSTEM.BROKER.CONTROL.QUEUE for an unknown stream. This error code is also returned if dynamic stream creation is enabled and the broker failed to create a stream queue for the new stream using the SYSTEM.BROKER.MODEL.STREAM queue.

Programmer response

Retry the command for a stream that the broker supports. If the broker should support the stream, either define the stream queue manually, or correct the problem that prevented the broker from creating the stream queue itself.

3083 (0C0B) (RC3083): MQRCCF_REG_OPTIONS_ERROR

Explanation

Invalid registration options have been supplied.

The registration options (between <RegOpt> and </RegOpt>) provided on a command are not valid.

Programmer response

Retry the command with a valid combination of options.

3084 (0C0C) (RC3084): MQRCCF_PUB_OPTIONS_ERROR

Explanation

Invalid publication options have been supplied.

The publication options provided on a Publish command are not valid.

Programmer response

Retry the command with a valid combination of options.

3085 (0C0D) (RC3085): MQRCCF_UNKNOWN_BROKER

Explanation

Command received from an unknown broker.

Within a multi-broker network, related brokers pass subscriptions and publications between each other as a series of command messages. One such command message has been received from a broker that is not, or is no longer, related to the detecting broker.

Programmer response

This situation can occur if the broker network is not quiesced while topology changes are made to the network.

If you are removing a broker from the topology when the queue manager is inactive, your changes are propagated at queue manager restart.

If you are removing a broker from the topology when the queue manager is active, make sure the channels are also active, so that your changes are immediately propagated.

3086 (0C0E) (RC3086): MQRCCF_Q_MGR_CCSID_ERROR

Explanation

Queue manager coded character set identifier error.

The coded character set value for the queue manager was not valid.

Programmer response

Specify a valid value.

3087 (0C0F) (RC3087): MQRCCF_DEL_OPTIONS_ERROR

Explanation

Invalid delete options have been supplied.

The options provided with a *Delete Publication* command are not valid.

Programmer response

Retry the command with a valid combination of options.

3088 (0C10) (RC3088): MQRCCF_CLUSTER_NAME_CONFLICT

Explanation

ClusterName and *ClusterNamelist* attributes conflict.

The command was rejected because it would have resulted in the *ClusterName* attribute and the *ClusterNamelist* attribute both being nonblank. At least one of these attributes must be blank.

Programmer response

If the command specified one of these attributes only, you must also specify the other one, but with a value of blanks. If the command specified both attributes, ensure that one of them has a value of blanks.

3089 (0C11) (RC3089): MQRCCF_REPOS_NAME_CONFLICT

Explanation

RepositoryName and *RepositoryNamelist* attributes conflict.

Either:
- The command was rejected because it would have resulted in the *RepositoryName* and *RepositoryNamelist* attributes both being nonblank. At least one of these attributes must be blank.
- For a Reset Queue Manager Cluster command, the queue manager does not provide a full repository management service for the specified cluster. That is, the *RepositoryName* attribute of the queue manager is not the specified cluster name, or the namelist specified by the *RepositoryNamelist* attribute does not contain the cluster name.

Programmer response

Reissue the command with the correct values or on the correct queue manager.

3090 (0C12) (RC3090): MQRCCF_CLUSTER_Q_USAGE_ERROR

Explanation

Queue cannot be a cluster queue.

The command was rejected because it would have resulted in a cluster queue also being a transmission queue, which is not permitted, or because the queue in question cannot be a cluster queue.

Programmer response

Ensure that the command specifies either:
- The *Usage* parameter with a value of MQUS_NORMAL, or
- The *ClusterName* and *ClusterNamelist* parameters with values of blanks.
- A *QName* parameter with a value that is not one of these reserved queues:
  - SYSTEM.CHANNEL.INITQ
  - SYSTEM.CHANNEL.SYNCQ
  - SYSTEM.CLUSTER.COMMAND.QUEUE
  - SYSTEM.CLUSTER.REPOSITORY.QUEUE
  - SYSTEM.COMMAND.INPUT
  - SYSTEM.QSG.CHANNEL.SYNCQ
  - SYSTEM.QSG.TRANSMIT.QUEUE

3091 (0C13) (RC3091): MQRCCF_ACTION_VALUE_ERROR

Explanation

Action value not valid.

The value specified for *Action* is not valid. There is only one valid value.

Programmer response

Specify MQACT_FORCE_REMOVE as the value of the *Action* parameter.

3092 (0C14) (RC3092): MQRCCF_COMMS_LIBRARY_ERROR

Explanation

Library for requested communications protocol could not be loaded.

The library needed for the requested communications protocol could not be loaded.

Programmer response

Install the library for the required communications protocol, or specify a communications protocol that has already been installed.

3093 (0C15) (RC3093): MQRCCF_NETBIOS_NAME_ERROR

Explanation

NetBIOS listener name not defined.

The NetBIOS listener name is not defined.

Programmer response

Add a local name to the configuration file and retry the operation.

3094 (0C16) (RC3094): MQRCCF_BROKER_COMMAND_FAILED

Explanation

The broker command failed to complete.

A broker command was issued but it failed to complete.

Programmer response

Diagnose the problem using the provided information and issue a corrected command.

For more information, look at the IBM MQ error logs.

3095 (0C17) (RC3095): MQRCCF_CFST_CONFLICTING_PARM

Explanation

Conflicting parameters.

The command was rejected because the parameter identified in the error response was in conflict with another parameter in the command.

Programmer response

Consult the description of the parameter identified to ascertain the nature of the conflict, and the correct command.

3096 (0C18) (RC3096): MQRCCF_PATH_NOT_VALID

Explanation

Path not valid.

The path specified was not valid.

Programmer response

Specify a valid path.

3097 (0C19) (RC3097): MQRCCF_PARM_SYNTAX_ERROR

Explanation

Syntax error found in parameter.

The parameter specified contained a syntax error.

Programmer response

Check the syntax for this parameter.

3098 (0C1A) (RC3098): MQRCCF_PWD_LENGTH_ERROR

Explanation

Password length error.

The password string length is rounded up by to the nearest eight bytes. This rounding causes the total length of the *SSLCryptoHardware* string to exceed its maximum.

Programmer response

Decrease the size of the password, or of earlier fields in the *SSLCryptoHardware* string.

3150 (0C4E) (RC3150): MQRCCF_FILTER_ERROR

Explanation

Filter not valid. This could be because either:

1. In an inquire command message, the specification of a filter is not valid.
2. In a publish/subscribe command message, the content-based filter expression supplied in the publish/subscribe command message contains invalid syntax, and cannot be used.

Programmer response

1. Correct the specification of the filter parameter structure in the inquire command message.
2. Correct the syntax of the filter expression in the publish/subscribe command message. The filter expression is the value of the `Filter` tag in the `psc` folder in the MQRFH2 structure. See the *Websphere MQ Integrator V2 Programming Guide* for details of valid syntax.

3151 (0C4F) (RC3151): MQRCCF_WRONG_USER

Explanation

Wrong user.

A publish/subscribe command message cannot be executed on behalf of the requesting user because the subscription that it would update is already owned by a different user. A subscription can be updated or deregistered only by the user that originally registered the subscription.

Programmer response

Ensure that applications that need to issue commands against existing subscriptions are running under the user identifier that originally registered the subscription. Alternatively, use different subscriptions for different users.

3152 (0C50) (RC3152): MQRCCF_DUPLICATE_SUBSCRIPTION

Explanation

The subscription already exists.

A matching subscription already exists.

Programmer response

Either modify the new subscription properties to distinguish it from the existing subscription or deregister the existing subscription. Then reissue the command.

3153 (0C51) (RC3153): MQRCCF_SUB_NAME_ERROR

Explanation

The subscription name parameter is in error.

Either the subscription name is of an invalid format or a matching subscription already exists with no subscription name.

Programmer response

Either correct the subscription name or remove it from the command and reissue the command.

3154 (0C52) (RC3154): MQRCCF_SUB_IDENTITY_ERROR

Explanation

The subscription identity parameter is in error.

Either the supplied value exceeds the maximum length allowed or the subscription identity is not currently a member of the subscription's identity set and a Join registration option was not specified.

Programmer response

Either correct the identity value or specify a Join registration option to add this identity to the identity set for this subscription.

3155 (0C53) (RC3155): MQRCCF_SUBSCRIPTION_IN_USE

Explanation

The subscription is in use.

An attempt to modify or deregister a subscription was attempted by a member of the identity set when they were not the only member of this set.

Programmer response

Reissue the command when you are the only member of the identity set. To avoid the identity set check and force the modification or deregistration remove the subscription identity from the command message and reissue the command.

3156 (0C54) (RC3156): MQRCCF_SUBSCRIPTION_LOCKED

Explanation

The subscription is locked.

The subscription is currently exclusively locked by another identity.

Programmer response

Wait for this identity to release the exclusive lock.

3157 (0C55) (RC3157): MQRCCF_ALREADY_JOINED

Explanation

The identity already has an entry for this subscription.

A Join registration option was specified but the subscriber identity was already a member of the subscription's identity set.

Programmer response

None. The command completed, this reason code is a warning.

3160 (0C58) (RC3160): MQRCCF_OBJECT_IN_USE

Explanation

Object in use by another command.

A modification of an object was attempted while the object was being modified by another command.

Programmer response

Retry the command.

3161 (0C59) (RC3161): MQRCCF_UNKNOWN_FILE_NAME

Explanation

File not defined to CICS.

A file name parameter identifies a file that is not defined to CICS.

Programmer response

Provide a valid file name or create a CSD definition for the required file.

3162 (0C5A) (RC3162): MQRCCF_FILE_NOT_AVAILABLE

Explanation

File not available to CICS.

A file name parameter identifies a file that is defined to CICS, but is not available.

Programmer response

Check that the CSD definition for the file is correct and enabled.

3163 (0C5B) (RC3163): MQRCCF_DISC_RETRY_ERROR

Explanation

Disconnection retry count not valid.

The *DiscRetryCount* value was not valid.

Programmer response

Specify a valid count.

3164 (0C5C) (RC3164): MQRCCF_ALLOC_RETRY_ERROR

Explanation

Allocation retry count not valid.

The *AllocRetryCount* value was not valid.

Programmer response

Specify a valid count.

3165 (0C5D) (RC3165): MQRCCF_ALLOC_SLOW_TIMER_ERROR

Explanation

Allocation slow retry timer value not valid.

The *AllocRetrySlowTimer* value was not valid.

Programmer response

Specify a valid timer value.

3166 (0C5E) (RC3166): MQRCCF_ALLOC_FAST_TIMER_ERROR

Explanation

Allocation fast retry timer value not valid.

The *AllocRetryFastTimer* value was not valid.

Programmer response

Specify a valid value.

3167 (0C5F) (RC3167): MQRCCF_PORT_NUMBER_ERROR

Explanation

Port number value not valid.

The *PortNumber* value was not valid.

Programmer response

Specify a valid port number value.

3168 (0C60) (RC3168): MQRCCF_CHL_SYSTEM_NOT_ACTIVE

Explanation

Channel system is not active.

An attempt was made to start a channel while the channel system was inactive.

Programmer response

Activate the channel system before starting a channel.

3169 (0C61) (RC3169): MQRCCF_ENTITY_NAME_MISSING

Explanation

Entity name required but missing.

A parameter specifying entity names must be supplied.

Programmer response

Specify the required parameter.

3170 (0C62) (RC3170): MQRCCF_PROFILE_NAME_ERROR

Explanation

Profile name not valid.

A profile name is not valid. Profile names might include wildcard characters or might be given explicitly. If you give an explicit profile name, then the object identified by the profile name must exist. This error might also occur if you specify more than one double asterisk in a profile name.

Programmer response

Specify a valid name.

3171 (0C63) (RC3171): MQRCCF_AUTH_VALUE_ERROR

Explanation

Authorization value not valid.

A value for the *AuthorizationList* or *AuthorityRemove* or *AuthorityAdd* parameter was not valid.

Programmer response

Specify a valid value.

3172 (0C64) (RC3172): MQRCCF_AUTH_VALUE_MISSING

Explanation

Authorization value required but missing.

A parameter specifying authorization values must be supplied.

Programmer response

Specify the required parameter.

3173 (0C65) (RC3173): MQRCCF_OBJECT_TYPE_MISSING

Explanation

Object type value required but missing.

A parameter specifying the object type must be supplied.

Programmer response

Specify the required parameter.

3174 (0C66) (RC3174): MQRCCF_CONNECTION_ID_ERROR

Explanation

Error in connection id parameter.

The `ConnectionId` specified was not valid.

Programmer response

Specify a valid connection id.

3175 (0C67) (RC3175): MQRCCF_LOG_TYPE_ERROR

Explanation

Log type not valid.

The log type value specified was not valid.

Programmer response

Specify a valid log type value.

3176 (0C68) (RC3176): MQRCCF_PROGRAM_NOT_AVAILABLE

Explanation

Program not available.

A request to start or stop a service failed because the request to start the program failed. This could be because the program could not be found at the specified location, or that insufficient system resources are available currently to start it.

Programmer response

Check that the correct name is specified in the definition of the service, and that the program is in the appropriate libraries, before retrying the request.

3177 (0C69) (RC3177): MQRCCF_PROGRAM_AUTH_FAILED

Explanation

Program not available.

A request to start or stop a service failed because the user does not have sufficient access authority to start the program at the specified location.

Programmer response

Correct the progam name and location, and the user's authority, before retrying the request.

3200 (0C80) (RC3200): MQRCCF_NONE_FOUND

Explanation

No items found matching request criteria.

An Inquire command found no items that matched the specified name and satisfied any other criteria requested.

3201 (0C81) (RC3201): MQRCCF_SECURITY_SWITCH_OFF

Explanation

Security refresh or reverification not processed, security switch set OFF.

Either
- a Reverify Security command was issued, but the subsystem security switch is off, so there are no internal control tables to flag for reverification; or
- a Refresh Security command was issued, but the security switch for the requested class or the subsystem security switch is off.

The switch in question might be returned in the message (with parameter identifier MQIACF_SECURITY_SWITCH).

3202 (0C82) (RC3202): MQRCCF_SECURITY_REFRESH_FAILED

Explanation

Security refresh did not take place.

A SAF RACROUTE REQUEST=STAT call to your external security manager (ESM) returned a non-zero return code. In consequence, the requested security refresh could not be done. The security item affected might be returned in the message (with parameter identifier MQIACF_SECURITY_ITEM).

Possible causes of this problem are:
- The class is not installed
- The class is not active
- The external security manager (ESM) is not active
- The RACF z/OS router table is incorrect

Programmer response

For information about resolving the problem, see the explanations of messages CSQH003I and CSQH004I.

3203 (0C83) (RC3203): MQRCCF_PARM_CONFLICT

Explanation

Incompatible parameters or parameter values.

The parameters or parameter values for a command are incompatible. One of the following occurred:
- A parameter was not specified that is required by another parameter or parameter value.
- A parameter or parameter value was specified that is not allowed with some other parameter or parameter value.
- The values for two specified parameters were not both blank or non-blank.
- The values for two specified parameters were incompatible.

The parameters in question might be returned in the message (with parameter identifiers MQIACF_PARAMETER_ID).

Programmer response

Reissue the command with correct parameters and values.

3204 (0C84) (RC3204): MQRCCF_COMMAND_INHIBITED

Explanation

Commands not allowed at present time.

The queue manager cannot accept commands at the present time, because it is restarting or terminating, or because the command server is not running.

3205 (0C85) (RC3205): MQRCCF_OBJECT_BEING_DELETED

Explanation

Object is being deleted.

The object specified on a command is in the process of being deleted, so the command is ignored.

3207 (0C87) (RC3207): MQRCCF_STORAGE_CLASS_IN_USE

Explanation

Storage class is active or queue is in use.

The command for a local queue involved a change to the *StorageClass* value, but there are messages on the queue, or other threads have the queue open.

Programmer response

Remove the messages from the queue, or wait until any other threads have closed the queue.

3208 (0C88) (RC3208): MQRCCF_OBJECT_NAME_RESTRICTED

Explanation

Incompatible object name and type.

The command used a reserved object name with an incorrect object type or subtype. The object is only allowed to be of a predetermined type, as listed in the explanation of message CSQM108I.

3209 (0C89) (RC3209): MQRCCF_OBJECT_LIMIT_EXCEEDED

Explanation

Local queue limit exceeded.

The command failed because no more local queues could be defined. There is an implementation limit of 524 287 for the total number of local queues that can exist. For shared queues, there is a limit of 512 queues in a single coupling facility structure.

Programmer response

Delete any existing queues that are no longer required.

3210 (0C8A) (RC3210): MQRCCF_OBJECT_OPEN_FORCE

Explanation

Object is in use, but could be changed specifying *Force* as MQFC_YES.

The object specified is in use. This could be because it is open through the API, or for certain parameter changes, because there are messages currently on the queue. The requested changes can be made by specifying *Force* as MQFC_YES on a Change command.

Programmer response

Wait until the object is not in use. Alternatively specify *Force* as MQFC_YES for a change command.

3211 (0C8B) (RC3211): MQRCCF_DISPOSITION_CONFLICT

Explanation

Parameters are incompatible with disposition.

The parameters or parameter values for a command are incompatible with the disposition of an object. One of the following occurred:
- A value specified for the object name or other parameter is not allowed for a local queue with a disposition that is shared or a model queue used to create a dynamic queue that is shared.
- A value specified for a parameter is not allowed for an object with such disposition.
- A value specified for a parameter must be non-blank for an object with such disposition.
- The *CommandScope* and *QSGDisposition* or *ChannelDisposition* parameter values are incompatible.
- The action requested for a channel cannot be performed because it has the wrong disposition.

The parameter and disposition in question may be returned in the message (with parameter identifiers MQIACF_PARAMETER_ID and MQIA_QSG_DISP).

Programmer response

Reissue the command with correct parameters and values.

3212 (0C8C) (RC3212): MQRCCF_Q_MGR_NOT_IN_QSG

Explanation

Queue manager is not in a queue-sharing group.

The command or its parameters are not allowed when the queue manager is not in a queue-sharing group. The parameter in question might be returned in the message (with parameter identifier MQIACF_PARAMETER_ID).

Programmer response

Reissue the command correctly.

3213 (0C8D) (RC3213): MQRCCF_ATTR_VALUE_FIXED

Explanation

Parameter value cannot be changed.

The value for a parameter cannot be changed. The parameter in question might be returned in the message (with parameter identifier MQIACF_PARAMETER_ID).

Programmer response

To change the parameter, the object must be deleted and then created again with the new value.

3215 (0C8F) (RC3215): MQRCCF_NAMELIST_ERROR

Explanation

Namelist is empty or wrong type.

A namelist used to specify a list of clusters has no names in it or does not have type MQNT_CLUSTER or MQNT_NONE.

Programmer response

Reissue the command specifying a namelist that is not empty and has a suitable type.

3217 (0C91) (RC3217): MQRCCF_NO_CHANNEL_INITIATOR

Explanation

Channel initiator not active.

The command requires the channel initiator to be started.

3218 (0C93) (RC3218): MQRCCF_CHANNEL_INITIATOR_ERROR

Explanation

Channel initiator cannot be started, or no suitable channel initiator is available.

This might occur because of the following reasons:
- The channel initiator cannot be started because:
  - It is already active.
  - There are insufficient system resources.
  - The queue manager was shutting down.
- The shared channel cannot be started because there was no suitable channel initiator available for any active queue manager in the queue-sharing group. This could be because:
  - No channel initiators are running.
  - The channel initiators that are running are too busy to allow any channel, or a channel of the particular type, to be started.

3222 (0C96) (RC3222): MQRCCF_COMMAND_LEVEL_CONFLICT

Explanation

Incompatible queue manager command levels.

Changing the *CFLevel* parameter of a CF structure, or deleting a CF structure, requires that all queue managers in the queue-sharing group have a command level of at least 530. Some of the queue managers have a level less than 530.

3223 (0C97) (RC3223): MQRCCF_Q_ATTR_CONFLICT

Explanation

Queue attributes are incompatible.

The queues involved in a Move Queue command have different values for one or more of these attributes: *DefinitionType*, *HardenGetBackout*, *Usage*. Messages cannot be moved safely if these attributes differ.

3224 (0C98) (RC3224): MQRCCF_EVENTS_DISABLED

Explanation

Events not enabled.

The command required performance or configuration events to be enabled.

Programmer response

Use the Change Queue manager command to enable the events if required.

3225 (0C99) (RC3225): MQRCCF_COMMAND_SCOPE_ERROR

Explanation

Queue-sharing group error.

While processing a command that used the *CommandScope* parameter, an error occurred while trying to send data to the coupling facility.

Programmer response

Notify your system programmer.

3226 (0C9A) (RC3226): MQRCCF_COMMAND_REPLY_ERROR

Explanation

Error saving command reply information.

While processing a command that used the *CommandScope* parameter, or a command for the channel initiator, an error occurred while trying to save information about the command.

Programmer response

The most likely cause is insufficient storage. If the problem persists, you may need to restart the queue manager after making more storage available.

3227 (0C9B) (RC3227): MQRCCF_FUNCTION_RESTRICTED

Explanation

Restricted command or parameter value used.

The command, or the value specified for one of its parameters, is not allowed because the installation and customization options chosen do not allow all functions to be used. The parameter in question might be returned in the message (with parameter identifier MQIACF_PARAMETER_ID).

3228 (0C9C) (RC3228): MQRCCF_PARM_MISSING

Explanation

Required parameter not specified.

The command did not specify a parameter or parameter value that was required. It might be for one of the following reasons:
- A parameter that is always required.
- A parameter that is one of a set of two or more alternative required parameters.
- A parameter that is required because some other parameter was specified.
- A parameter that is a list of values which has too few values.

The parameter in question might be returned in the message (with parameter identifier MQIACF_PARAMETER_ID).

Programmer response

Reissue the command with correct parameters and values.

3229 (0C9D) (RC3229): MQRCCF_PARM_VALUE_ERROR

Explanation

Parameter value invalid.

The value specified for a parameter was not acceptable. It might be for one of the following reasons:
- Outside the acceptable numeric range for the parameter.
- Not one of a list of acceptable values for the parameter.
- Using characters that are invalid for the parameter.
- Completely blank, when such is not allowed for the parameter.
- A filter value that is invalid for the parameter being filtered.

The parameter in question might be returned in the message (with parameter identifier MQIACF_PARAMETER_ID).

Programmer response

Reissue the command with correct parameters and values.

3230 (0C9E) (RC3230): MQRCCF_COMMAND_LENGTH_ERROR

Explanation

Command exceeds allowable length.

The command is so large that its internal form has exceeded the maximum length allowed. The size of the internal form of the command is affected by both the length, and the complexity of the command.

3231 (0C9F) (RC3231): MQRCCF_COMMAND_ORIGIN_ERROR

Explanation

Command issued incorrectly.

The command cannot be issued using command server. This is an internal error.

Programmer response

Notify your system programmer.

3232 (0CA0) (RC3232): MQRCCF_LISTENER_CONFLICT

Explanation

Address conflict for listener.

A listener was already active for a port and IP address combination that conflicted with the *Port* and *IPAddress* values specified by a Start Channel Listener or Stop Channel Listener command. The *Port* and *IPAddress* value combination specified must match a combination for which the listener is active. It cannot be a superset or a subset of that combination.

Programmer response

Reissue the command with correct values, if required.

3233 (0CA1) (RC3233): MQRCCF_LISTENER_STARTED

Explanation

Listener is started.

An attempt was made to start a listener, but it is already active for the requested *TransportType*, *InboundDisposition*, *Port*, and *IPAddress* values. The requested parameter values might be returned in the message, if applicable (with parameter identifiers MQIACH_XMIT_PROTOCOL_TYPE, MQIACH_INBOUND_DISP, MQIACH_PORT_NUMBER, MQCACH_IP_ADDRESS).

3234 (0CA2) (RC3234): MQRCCF_LISTENER_STOPPED

Explanation

Listener is stopped.

An attempt was made to stop a listener, but it is not active or already stopping for the requested `TransportType`, `InboundDisposition`, `Port`, and `IPAddress` values. The requested parameter values might be returned in the message, if applicable (with parameter identifiers MQIACH_XMIT_PROTOCOL_TYPE, MQIACH_INBOUND_DISP, MQIACH_PORT_NUMBER, MQCACH_IP_ADDRESS).

3235 (0CA3) (RC3235): MQRCCF_CHANNEL_ERROR

Explanation

Channel command failed.

A channel command failed because of an error in the channel definition, or at the remote end of the channel, or in the communications system. An error identifier value *nnn* may be returned in the message (with parameter identifier MQIACF_ERROR_ID).

Programmer response

For information about the error, see the explanation of the corresponding error message. Error *nnn* generally corresponds to message CSQX *nnn*, although there are some exceptions. z/OS For more information, see Distributed queuing message codes.

3236 (0CA4) (RC3236): MQRCCF_CF_STRUC_ERROR

Explanation

CF structure error.

A command could not be processed because of a coupling facility or CF structure error. It might be:
- A Backup CF Structure or Recover CF Structure command when the status of the CF structure is unsuitable. In this case, the CF structure status might be returned in the message together with the CF structure name (with parameter identifiers MQIACF_CF_STRUC_STATUS and MQCA_CF_STRUC_NAME).
- A command could not access an object because of an error in the coupling facility information, or because a CF structure has failed. In this case, the name of the object involved might be returned in the message (with parameter identifier MQCA_Q_NAME, for example).
- A command involving a shared channel could not access the channel status or synchronization key information.

Programmer response

In the case of a Backup CF Structure or Recover CF Structure command, take action appropriate to the CF structure status reported.

In other cases, check for error messages on the console log that might relate to the problem. Check whether the coupling facility structure has failed and check that Db2 is available.

3237 (0CA5) (RC3237): MQRCCF_UNKNOWN_USER_ID

Explanation

User identifier not found.

A user identifier specified in a Reverify Security command was not valid because there was no entry found for it in the internal control table. This could be because the identifier was entered incorrectly in the command, or because it was not in the table (for example, because it had timed-out). The user identifier in question might be returned in the message (with parameter identifier MQCACF_USER_IDENTIFIER).

3238 (0CA6) (RC3238): MQRCCF_UNEXPECTED_ERROR

Explanation

Unexpected or severe error.

An unexpected or severe error or other failure occurred. A code associated with the error might be returned in the message (with parameter identifier MQIACF_ERROR_ID).

Programmer response

Notify your system programmer.

3239 (0CA7) (RC3239): MQRCCF_NO_XCF_PARTNER

Explanation

MQ is not connected to the XCF partner.

The command involving the IMS bridge cannot be processed because MQ is not connected to the XCF partner. The group and member names of the XCF partner in question might be returned in the message (with parameter identifiers MQCA_XCF_GROUP_NAME and MQCA_XCF_MEMBER_NAME).

3240 (0CA8) (RC3240): MQRCCF_CFGR_PARM_ID_ERROR

Explanation

Parameter identifier is not valid.

The MQCFGR `Parameter` field value was not valid.

Programmer response

Specify a valid parameter identifier.

3241 (0CA9) (RC3241): MQRCCF_CFIF_LENGTH_ERROR

Explanation

Structure length not valid.

The MQCFIF *StrucLength* field value was not valid.

Programmer response

Specify a valid structure length.

3242 (0CAA) (RC3242): MQRCCF_CFIF_OPERATOR_ERROR

Explanation

Parameter count not valid.

The MQCFIF *Operator* field value was not valid.

Programmer response

Specify a valid operator value.

3243 (0CAB) (RC3243): MQRCCF_CFIF_PARM_ID_ERROR

Explanation

Parameter identifier is not valid.

The MQCFIF *Parameter* field value was not valid, or specifies a parameter that cannot be filtered, or that is also specified as a parameter to select a subset of objects.

Programmer response

Specify a valid parameter identifier.

3244 (0CAC) (RC3244): MQRCCF_CFSF_FILTER_VAL_LEN_ERR

Explanation

Filter value length not valid.

The MQCFSF *FilterValueLength* field value was not valid.

Programmer response

Specify a valid length.

3245 (0CAD) (RC3245): MQRCCF_CFSF_LENGTH_ERROR

Explanation

Structure length not valid.

The MQCFSF *StrucLength* field value was not valid.

Programmer response

Specify a valid structure length.

3246 (0CAE) (RC3246): MQRCCF_CFSF_OPERATOR_ERROR

Explanation

Parameter count not valid.

The MQCFSF *Operator* field value was not valid.

Programmer response

Specify a valid operator value.

3247 (0CAF) (RC3247): MQRCCF_CFSF_PARM_ID_ERROR

Explanation

Parameter identifier is not valid.

The MQCFSF *Parameter* field value was not valid.

Programmer response

Specify a valid parameter identifier.

3248 (0CB0) (RC3248): MQRCCF_TOO_MANY_FILTERS

Explanation

Too many filters.

The command contained more than the maximum permitted number of filter structures.

Programmer response

Specify the command correctly.

3249 (0CB1) (RC3249): MQRCCF_LISTENER_RUNNING

Explanation

Listener is running.

An attempt was made to perform an operation on a listener, but it is currently active.

Programmer response

Stop the listener if required.

3250 (0CB2) (RC3250): MQRCCF_LSTR_STATUS_NOT_FOUND

Explanation

Listener status not found.

For Inquire Listener Status, no listener status is available for the specified listener. This might indicate that the listener has not been used.

Programmer response

None, unless this is unexpected, in which case consult your systems administrator.

3251 (0CB3) (RC3251): MQRCCF_SERVICE_RUNNING

Explanation

Service is running.

An attempt was made to perform an operation on a service, but it is currently active.

Programmer response

Stop the service if required.

3252 (0CB4) (RC3252): MQRCCF_SERV_STATUS_NOT_FOUND

Explanation

Service status not found.

For Inquire Service Status, no service status is available for the specified service. This might indicate that the service has not been used.

Programmer response

None, unless this is unexpected, in which case consult your systems administrator.

3253 (0CB5) (RC3253): MQRCCF_SERVICE_STOPPED

Explanation

Service is stopped.

An attempt was made to stop a service, but it is not active or already stopping.

3254 (0CB6) (RC3254): MQRCCF_CFBS_DUPLICATE_PARM

Explanation

Duplicate parameter.

Two MQCFBS structures with the same parameter identifier were present.

Programmer response

Check for and remove duplicate parameters.

3255 (0CB7) (RC3255): MQRCCF_CFBS_LENGTH_ERROR

Explanation

Structure length not valid.

The MQCFBS *StrucLength* field value was not valid.

Programmer response

Specify a valid structure length.

3256 (0CB8) (RC3256): MQRCCF_CFBS_PARM_ID_ERROR

Explanation

Parameter identifier is not valid.

The MQCFBS *Parameter* field value was not valid.

Programmer response

Specify a valid parameter identifier.

3257 (0CB9) (RC3257): MQRCCF_CFBS_STRING_LENGTH_ERR

Explanation

String length not valid.

The MQCFBS *StringLength* field value was not valid. The value was negative or greater than the maximum permitted length of the parameter specified in the *Parameter* field.

Programmer response

Specify a valid string length for the parameter.

3258 (0CBA) (RC3258): MQRCCF_CFGR_LENGTH_ERROR

Explanation

Structure length not valid.

The MQCFGR *StrucLength* field value was not valid.

Programmer response

Specify a valid structure length.

3259 (0CBB) (RC3259): MQRCCF_CFGR_PARM_COUNT_ERROR

Explanation

Parameter count not valid.

The MQCFGR *ParameterCount* field value was not valid. The value was negative or greater than the maximum permitted for the parameter identifier specified in the *Parameter* field.

Programmer response

Specify a valid count for the parameter.

3260 (0CBC) (RC3260): MQRCCF_CONN_NOT_STOPPED

Explanation

Connection not stopped.

The Stop Connection command could not be executed, so the connection was not stopped.

3261 (0CBD) (RC3261): MQRCCF_SERVICE_REQUEST_PENDING

Explanation

A Suspend or Resume Queue Manager command was issued, or a Refresh Security command, but such a command is currently in progress.

Programmer response

Wait until the current request completes, then reissue the command if necessary.

3262 (0CBE) (RC3262): MQRCCF_NO_START_CMD

Explanation

No start command.

The service cannot be started because no start command is specified in the service definition.

Programmer response

Correct the definition of the service.

3263 (0CBF) (RC3263): MQRCCF_NO_STOP_CMD

Explanation

No stop command.

The service cannot be stopped because no stop command is specified in the service definition.

Programmer response

Correct the definition of the service.

3264 (0CC0) (RC3264): MQRCCF_CFBF_LENGTH_ERROR

Explanation

Structure length not valid.

The MQCFBF *StrucLength* field value was not valid.

Programmer response

Specify a valid structure length.

3265 (0CC1) (RC3265): MQRCCF_CFBF_PARM_ID_ERROR

Explanation

Parameter identifier is not valid.

The MQCFBF *Parameter* field value was not valid.

Programmer response

Specify a valid parameter identifier.

3266 (0CC2) (RC3266): MQRCCF_CFBF_FILTER_VAL_LEN_ERR

Explanation

Filter value length not valid.

The MQCFBF *FilterValueLength* field value was not valid.

Programmer response

Specify a valid length.

3267 (0CC3) (RC3267): MQRCCF_CFBF_OPERATOR_ERROR

Explanation

Parameter count not valid.

The MQCFBF *Operator* field value was not valid.

Programmer response

Specify a valid operator value.

3268 (0CC4) (RC3268): MQRCCF_LISTENER_STILL_ACTIVE

Explanation

Listener still active.

An attempt was made to stop a listener, but it failed and the listener is still active. For example, the listener might still have active channels.

Programmer response

Wait for the active connections to the listener to complete before trying the request again.

3269 (0CC5) (RC3269): MQRCCF_DEF_XMIT_Q_CLUS_ERROR

Explanation

The specified queue is not allowed to be used as the default transmission queue because it is reserved for use exclusively by clustering.

Programmer response

Change the value of the Default Transmission Queue, and try the command again.

3300 (0CE4) (RC3300): MQRCCF_TOPICSTR_ALREADY_EXISTS

Explanation

The topic string specified already exists in another topic object.

Programmer response

Verify that the topic string used is correct.

3301 (0CE5) (RC3301): MQRCCF_SHARING_CONVS_ERROR

Explanation

An invalid value has been given for SharingConversations parameter in the Channel definition

Programmer response

Correct the value used in the PCF SharingConversations (MQCFIN) parameter; see Change, Copy, and Create Channel for more information.

3302 (0CE6) (RC3302): MQRCCF_SHARING_CONVS_TYPE

Explanation

SharingConversations parameter is not allowed for this channel type.

Programmer response

See Change, Copy, and Create Channel to ensure that the channel type is compatible with the SharingConversations parameter.

3303 (0CE7) (RC3303): MQRCCF_SECURITY_CASE_CONFLICT

Explanation

A Refresh Security PCF command was issued, but the case currently in use differs from the system setting and if refreshed would result in the set of classes using different case settings.

Programmer response

Check that the class used is set up correctly and that the system setting is correct. If a change in case setting is required, issue the REFRESH SECURITY(*) command to change all classes.

3305 (0CE9) (RC3305): MQRCCF_TOPIC_TYPE_ERROR

Explanation

An Inquire or Delete Topic PCF command was issued with an invalid TopicType parameter.

Programmer response

Correct the TopicType parameter and reissue the command. For more details on the TopicType, see Change, Copy, and Create Topic.

3306 (0CEA) (RC3306): MQRCCF_MAX_INSTANCES_ERROR

Explanation

An invalid value was given for the maximum number of simultaneous instances of a server-connection channel (MaxInstances) for the channel definition.

Programmer response

See Change, Copy, and Create Channel for more information and correct the PCF application.

3307 (0CEB) (RC3307): MQRCCF_MAX_INSTS_PER_CLNT_ERR

Explanation

An invalid value was given for the MaxInstancesPerClient property.

Programmer response

See Change, Copy, and Create Channel for the range of values and correct the application.

3308 (0CEC) (RC3308): MQRCCF_TOPIC_STRING_NOT_FOUND

Explanation

When processing an Inquire Topic Status command, the topic string specified did not match any topic nodes in the topic tree.

Programmer response

Verify the topic string is correct.

3309 (0CED) (RC3309): MQRCCF_SUBSCRIPTION_POINT_ERR

Explanation

The Subscription point was not valid. Valid subscription points are the topic strings of the topic objects listed in the SYSTEM.QPUBSUB.SUBPOINT.NAMELIST.

Programmer response

Use a subscription point that matches the topic string of a topic object listed in the SYSTEM.QPUBSUB.SUBPOINT.NAMELIST (or remove the subscription point parameter and this uses the default subscription point)

3311 (0CEF) (RC2432): MQRCCF_SUB_ALREADY_EXISTS

Explanation

When processing a Copy or Create Subscription command, the target *Subscription* identifier exists.

Programmer response

If you are trying to copy an existing subscription, ensure that the *ToSubscriptionName* parameter contains a unique value. If you are trying to create a Subscription ensure that the combination of the *SubName* parameter, and *TopicObject* parameter or *TopicString* parameter are unique.

3314 (0CF2) (RC3314): MQRCCF_DURABILITY_NOT_ALLOWED

Explanation

An MQSUB call using the MQSO_DURABLE option failed. This can be for one of the following reasons:
- The topic subscribed to is defined as DURSUB(NO).
- The queue named SYSTEM.DURABLE.SUBSCRIBER.QUEUE is not available.
- The topic subscribed to is defined as both MCAST(ONLY) and DURSUB(YES) (or DURSUB(ASPARENT) and the parent is DURSUB(YES)).

Completion Code

MQCC_FAILED

Programmer Response

Durable subscriptions are stored on the SYSTEM.DURABLE.SUBSCRIBER.QUEUE. Ensure that this queue is available for use. Possible reasons for failure include the queue being full, the queue being put inhibited, the queue not existing, or (on z/OS) the pageset the queue is defined to use doesn't exist.

If the topic subscribed to is defined as DURSUB(NO) either alter the administrative topic node to use DURSUB(YES) or use the MQSO_NON_DURABLE option instead.

If the topic subscribed to is defined as MCAST(ONLY) when using IBM MQ Multicast messaging, alter the topic to use DURSUB(NO).

3317 (0CF5) (RC3317): MQRCCF_INVALID_DESTINATION

Explanation

The Subscription or Topic object used in a Change, Copy, Create or Delete PCF command is invalid.

Programmer response

Investigate and correct the required parameters for the specific command you are using. For more details, see Change, Copy, and Create Subscription.

3318 (0CF6) (RC3318): MQRCCF_PUBSUB_INHIBITED

Explanation

MQSUB, MQOPEN, MQPUT and MQPUT1 calls are currently inhibited for all publish/subscribe topics, either by means of the queue manager attribute PSMODE or because processing of publish/subscribe state at queue manager start-up has failed, or has not yet completed.

Completion Code

MQCC_FAILED

Programmer response

If this queue manager does not intentionally inhibit publish/subscribe, investigate any error messages that describe the failure at queue manager start-up, or wait until start-up processing completes. You can use the DISPLAY PUBSUB command to check the status of the publish/subscribe engine to ensure it is ready for use, and additionally on z/OS you will receive an information message CSQM076I.

3326 (0CFE) (RC3326): MQRCCF_CHLAUTH_TYPE_ERROR

Explanation

Channel authentication record type not valid.

The **`type`** parameter specified on the **`set`** command was not valid.

Programmer response

Specify a valid type.

3327 (0CFF) (RC3327): MQRCCF_CHLAUTH_ACTION_ERROR

Explanation

Channel authentication record action not valid.

The **`action`** parameter specified on the **`set`** command was not valid.

Programmer response

Specify a valid action.

3335 (0D07) (RC3335): MQRCCF_CHLAUTH_USRSRC_ERROR

Explanation

Channel authentication record user source not valid.

The **`user source`** parameter specified on the **`set`** command was not valid.

Programmer response

Specify a valid user source.

3336 (0D08) (RC3336): MQRCCF_WRONG_CHLAUTH_TYPE
Explanation

Parameter not allowed for this channel authentication record type.

The parameter is not allowed for the type of channel authentication record being set. Refer to the description of the parameter in error to determine the types of record for which this parameter is valid.

Programmer response

Remove the parameter.

3337 (0D09) (RC3337): MQRCCF_CHLAUTH_ALREADY_EXISTS
Explanation

Channel authentication record already exists

An attempt was made to add a channel authentication record, but it already exists.

Programmer response

Specify action as MQACT_REPLACE.

3338 (0D0A) (RC3338): MQRCCF_CHLAUTH_NOT_FOUND
Explanation

Channel authentication record not found.

The specified channel authentication record does not exist.

Programmer response

Specify a channel authentication record that exists.

3339 (0D0B) (RC3339): MQRCCF_WRONG_CHLAUTH_ACTION
Explanation

Parameter not allowed for this action on a channel authentication record.

The parameter is not allowed for the action being applied to a channel authentication record. Refer to the description of the parameter in error to determine the actions for which this parameter is valid.

Programmer response

Remove the parameter.

3340 (0D0C) (RC3340): MQRCCF_WRONG_CHLAUTH_USERSRC

Explanation

Parameter not allowed for this channel authentication record user source value.

The parameter is not allowed for a channel authentication record with the value that the **`user source`** field contains. Refer to the description of the parameter in error to determine the values of user source for which this parameter is valid.

Programmer response

Remove the parameter.

3341 (0D0D) (RC3341): MQRCCF_CHLAUTH_WARN_ERROR

Explanation

Channel authentication record **`warn`** value not valid.

The **`warn`** parameter specified on the **`set`** command was not valid.

Programmer response

Specify a valid value for **`warn`**.

3342 (0D0E) (RC3342): MQRCCF_WRONG_CHLAUTH_MATCH

Explanation

Parameter not allowed for this channel authentication record **`match`** value.

The parameter is not allowed for an **`inquire channel authentication record`** command with the value that the **`match`** field contains. Refer to the description of the parameter in error to find the values of **`match`** for which this parameter is valid.

Programmer response

Remove the parameter.

3343 (0D0F) (RC3343): MQRCCF_IPADDR_RANGE_CONFLICT

Explanation

A channel authentication record contained an IP address with a range that overlapped an existing range. A range must be a superset or subset of any existing ranges for the same channel profile name, or completely separate.

Programmer response

Specify a range that is a superset or subset of an existing range, or is completely separate to all existing ranges.

3344 (0D10) (RC3344): MQRCCF_CHLAUTH_MAX_EXCEEDED
Explanation

A channel authentication record was set taking the total number of entries for that type on a single channel profile over the maximum number allowed.

Programmer response

Remove some channel authentication records to make room.

3345 (0D11) (RC3345): MQRCCF_IPADDR_ERROR
Explanation

A channel authentication record contained an invalid IP address, or invalid wildcard pattern to match against IP addresses.

Programmer response

Specify a valid IP address or pattern.

Related information:

Generic IP addresses

3346 (0D12) (RC3346): MQRCCF_IPADDR_RANGE_ERROR
Explanation

A channel authentication record contained an IP address with a range that was invalid, for example, the lower number is higher than or equal to the upper number of the range.

Programmer response

Specify a valid range in the IP address.

3347 (0D13) (RC3347): MQRCCF_PROFILE_NAME_MISSING

Explanation

Profile name missing.

A profile name was required for the command but none was specified.

Programmer response

Specify a valid profile name.

3348 (0D14) (RC3348): MQRCCF_CHLAUTH_CLNTUSER_ERROR
Explanation

Channel authentication record **`client user`** value not valid.

The **`client user`** value contains a wildcard character, which is not allowed.

Programmer response

Specify a valid value for the client user field.

3349 (0D15) (RC3349): MQRCCF_CHLAUTH_NAME_ERROR
Explanation

Channel authentication record channel name not valid.

When a channel authentication record specifies an IP address to block, the **`channel name`** value must be a single asterisk (*).

Programmer response

Enter a single asterisk in the channel name.

3350 (0D16) (RC3350): MQRCCF_CHLAUTH_RUNCHECK_ERROR
Runcheck command is using generic values.

Explanation

An Inquire Channel Authentication Record command using MQMATCH_RUNCHECK was issued, but one or more of the input fields on the command were provided with generic values, which is not allowed.

Programmer response

Enter non-generic values for channel name, address, one of the client user ID or remote queue manager and SSL Peer Name if used.

3353 (0D19) (RC3353): MQRCCF_SUITE_B_ERROR
Invalid values have been specified.

Explanation

An invalid combination of values has been specified for the **`MQIA_SUITE_B_STRENGTH`** parameter.

Programmer response

Review the combination entered and retry with appropriate values.

3363 (0D23) (RC3363): MQRCCF_CLUS_XMIT_Q_USAGE_ERROR

Explanation

If the local queue attribute **CLCHNAME** is set, the attribute **USAGE** must be set to XMITQ.

On z/OS, if the local queue attribute **CLCHNAME** is set, the attribute **INDXTYPE** must be set to **CORRELID**, and the transmission queue must not be a shared queue.

The **CLCHNAME** attribute is a generic cluster-sender channel name. It identifies the cluster-sender channel that transfers messages in a transmission queue to another queue manager.

Programmer response

Modify the application to set the **CLCHNAME** to blanks, or not set the **CLCHNAME** attribute at all, on queues other than transmission queues.

On z/OS, ensure that the transmission queue is indexed by correlation ID and the queue is not a shared queue.

3364 (0D24) (RC3364): MQRCCF_CERT_VAL_POLICY_ERROR

Explanation

An invalid certificate validation policy value was specified for the **MQIA_CERT_VAL_POLICY** attribute. The specified value is unknown or is not supported on the current platform.

Programmer response

Review the value specified and try again with an appropriate certificate validation policy.

3366 (0D26) (RC3366): MQRCCF_REVDNS_DISABLED

Explanation

A runcheck command completed successfully returning the records to be used. However, some Channel Authentication Records exist containing hostnames, and hostname reverse lookup is currently disabled, so these records will not have been matched against. This reason code is returned as an MQCC_WARNING.

Programmer response

If reverse lookup is correctly disabled, even though some Channel Authentication Records exist containing hostnames, this warning can be ignored.

If channel authentication records containing hostnames should be being matched against, and therefore reverse lookup of hostname should not currently be disabled, issue a Change Queue Manager command to re-enable it.

If reverse lookup for hostnames is correctly disabled and there should not be any Channel Authentication Records containing hostnames, issue a Set Channel Authentication Record to remove them.

3370 (0D2A) (RC3370): MQRCCF_CHLAUTH_CHKCLI_ERROR

Explanation

Channel authentication record check client not valid.

The check client parameter specified on the set command was not valid.

Programmer response

Specify a valid user source.

3377 (0D31) (RC3377): MQRCCF_TOPIC_RESTRICTED

V 8.0.0.2

Explanation

This error can occur when creating or modifying a topic object. One or more attributes of the topic object are not supported on an IBM MQ administrative topic.

Programmer response

Modify the configuration to adhere to the documented restrictions.

4001 (0FA1) (RC4001): MQRCCF_OBJECT_ALREADY_EXISTS

Explanation

Object already exists.

An attempt was made to create an object, but the object already existed and the *Replace* parameter was not specified as MQRP_YES.

Programmer response

Specify *Replace* as MQRP_YES, or use a different name for the object to be created.

4002 (0FA2) (RC4002): MQRCCF_OBJECT_WRONG_TYPE

Explanation

Object has wrong type or disposition.

An object already exists with the same name but a different subtype or disposition from that specified by the command.

Programmer response

Ensure that the specified object is the same subtype and disposition.

4003 (0FA3) (RC4003): MQRCCF_LIKE_OBJECT_WRONG_TYPE

Explanation

New and existing objects have different subtype.

An attempt was made to create an object based on the definition of an existing object, but the new and existing objects had different subtypes.

Programmer response

Ensure that the new object has the same subtype as the one on which it is based.

4004 (0FA4) (RC4004): MQRCCF_OBJECT_OPEN

Explanation

Object is open.

An attempt was made to operate on an object that was in use.

Programmer response

Wait until the object is not in use, and then retry the operation. Alternatively specify *Force* as MQFC_YES for a change command.

4005 (0FA5) (RC4005): MQRCCF_ATTR_VALUE_ERROR

Explanation

Attribute value not valid or repeated.

One or more of the attribute values specified are not valid or are repeated. The error response message contains the failing attribute selectors (with parameter identifier MQIACF_PARAMETER_ID).

Programmer response

Specify the attribute values correctly.

4006 (0FA6) (RC4006): MQRCCF_UNKNOWN_Q_MGR

Explanation

Queue manager not known.

The queue manager specified was not known.

Programmer response

Specify the name of the queue manager to which the command is sent, or blank.

4007 (0FA7) (RC4007): MQRCCF_Q_WRONG_TYPE

Explanation

Action not valid for the queue of specified type.

An attempt was made to perform an action on a queue of the wrong type.

Programmer response

Specify a queue of the correct type.

4008 (0FA8) (RC4008): MQRCCF_OBJECT_NAME_ERROR

Explanation

Name not valid.

An object or other name name was specified using characters that were not valid.

Programmer response

Specify only valid characters for the name.

4009 (0FA9) (RC4009): MQRCCF_ALLOCATE_FAILED

Explanation

Allocation failed.

An attempt to allocate a conversation to a remote system failed. The error might be due to an entry in the channel definition that is not valid, or it might be that the listening program at the remote system is not running.

Programmer response

Ensure that the channel definition is correct, and start the listening program if necessary. If the error persists, consult your systems administrator.

4010 (0FAA) (RC4010): MQRCCF_HOST_NOT_AVAILABLE

Explanation

Remote system not available.

An attempt to allocate a conversation to a remote system was unsuccessful. The error might be transitory, and the allocate might succeed later. This reason can occur if the listening program at the remote system is not running.

Programmer response

Ensure that the listening program is running, and retry the operation.

4011 (0FAB) (RC4011): MQRCCF_CONFIGURATION_ERROR

Explanation

Configuration error.

There was a configuration error in the channel definition or communication subsystem, and allocation of a conversation was not possible. This might be caused by one of the following:

- For LU 6.2, either the *ModeName* or the *TpName* is incorrect. The *ModeName* must match that on the remote system, and the *TpName* must be specified. (On IBM i, these are held in the communications Side Object.)
- For LU 6.2, the session might not be established.
- For TCP, the *ConnectionName* in the channel definition cannot be resolved to a network address. This might be because the name has not been correctly specified, or because the name server is not available.
- The requested communications protocol might not be supported on the platform.

Programmer response

Identify the error and take appropriate action.

4012 (0FAC) (RC4012): MQRCCF_CONNECTION_REFUSED

Explanation

Connection refused.

The attempt to establish a connection to a remote system was rejected. The remote system might not be configured to allow a connection from this system.

- For LU 6.2 either the user ID or the password supplied to the remote system is incorrect.
- For TCP the remote system might not recognize the local system as valid, or the TCP listener program might not be started.

Programmer response

Correct the error or restart the listener program.

4013 (0FAD) (RC4013): MQRCCF_ENTRY_ERROR

Explanation

Connection name not valid.

The connection name in the channel definition could not be resolved into a network address. Either the name server does not contain the entry, or the name server was not available.

Programmer response

Ensure that the connection name is correctly specified and that the name server is available.

4014 (0FAE) (RC4014): MQRCCF_SEND_FAILED

Explanation

Send failed.

An error occurred while sending data to a remote system. This might be caused by a communications failure.

Programmer response

Consult your systems administrator.

4015 (0FAF) (RC4015): MQRCCF_RECEIVED_DATA_ERROR

Explanation

Received data error.

An error occurred while receiving data from a remote system. This might be caused by a communications failure.

Programmer response

Consult your systems administrator.

4016 (0FB0) (RC4016): MQRCCF_RECEIVE_FAILED

Explanation

Receive failed.

The receive operation failed.

Programmer response

Correct the error and retry the operation.

4017 (0FB1) (RC4017): MQRCCF_CONNECTION_CLOSED

Explanation

Connection closed.

An error occurred while receiving data from a remote system. The connection to the remote system has unexpectedly terminated.

Programmer response

Contact your systems administrator.

4018 (0FB2) (RC4018): MQRCCF_NO_STORAGE

Explanation

Not enough storage available.

Insufficient storage is available.

Programmer response

Consult your systems administrator.

4019 (0FB3) (RC4019): MQRCCF_NO_COMMS_MANAGER

Explanation

Communications manager not available.

The communications subsystem is not available.

Programmer response

Ensure that the communications subsystem has been started.

4020 (0FB4) (RC4020): MQRCCF_LISTENER_NOT_STARTED

Explanation

Listener not started.

The listener program could not be started. Either the communications subsystem has not been started, or the number of current channels using the communications subsystem is the maximum allowed, or there are too many jobs waiting in the queue.

Programmer response

Ensure the communications subsystem is started or retry the operation later. Increase the number of current channels allowed, if appropriate.

4024 (0FB8) (RC4024): MQRCCF_BIND_FAILED

Explanation

Bind failed.

The bind to a remote system during session negotiation has failed.

Programmer response

Consult your systems administrator.

4025 (0FB9) (RC4025): MQRCCF_CHANNEL_INDOUBT

Explanation

Channel in-doubt.

The requested operation cannot complete because the channel is in doubt.

Programmer response

Examine the status of the channel, and either restart a channel to resolve the in-doubt state, or resolve the channel.

4026 (0FBA) (RC4026): MQRCCF_MQCONN_FAILED

Explanation

MQCONN call failed.

Programmer response

Check whether the queue manager is active.

4027 (0FBB) (RC4027): MQRCCF_MQOPEN_FAILED

Explanation

MQOPEN call failed.

Programmer response

Check whether the queue manager is active, and the queues involved are correctly set up.

4028 (0FBC) (RC4028): MQRCCF_MQGET_FAILED

Explanation

MQGET call failed.

Programmer response

Check whether the queue manager is active, and the queues involved are correctly set up, and enabled for MQGET.

4029 (0FBD) (RC4029): MQRCCF_MQPUT_FAILED

Explanation

MQPUT call failed.

Programmer response

Check whether the queue manager is active, and the queues involved are correctly set up, and not inhibited for puts.

4030 (0FBE) (RC4030): MQRCCF_PING_ERROR

Explanation

Ping error.

A ping operation can only be issued for a sender or server channel. If the local channel is a receiver channel, you must issue the ping from a remote queue manager.

Programmer response

Reissue the ping request for a different channel of the correct type, or for a receiver channel from a different queue manager.

4031 (0FBF) (RC4031): MQRCCF_CHANNEL_IN_USE

Explanation

Channel in use.

An attempt was made to perform an operation on a channel, but the channel is currently active.

Programmer response

Stop the channel or wait for it to terminate.

4032 (0FC0) (RC4032): MQRCCF_CHANNEL_NOT_FOUND

Explanation

Channel not found.

The channel specified does not exist.

Programmer response

Specify the name of a channel which exists.

4033 (0FC1) (RC4033): MQRCCF_UNKNOWN_REMOTE_CHANNEL

Explanation

Remote channel not known.

There is no definition of the referenced channel at the remote system.

Programmer response

Ensure that the local channel is correctly defined. If it is, add an appropriate channel definition at the remote system.

4034 (0FC2) (RC4034): MQRCCF_REMOTE_QM_UNAVAILABLE

Explanation

Remote queue manager not available.

The channel cannot be started because the remote queue manager is not available.

Programmer response

Start the remote queue manager.

4035 (0FC3) (RC4035): MQRCCF_REMOTE_QM_TERMINATING

Explanation

Remote queue manager terminating.

The channel is ending because the remote queue manager is terminating.

Programmer response

Restart the remote queue manager.

4036 (0FC4) (RC4036): MQRCCF_MQINQ_FAILED

Explanation

MQINQ call failed.

Programmer response

Check whether the queue manager is active.

4037 (0FC5) (RC4037): MQRCCF_NOT_XMIT_Q

Explanation

Queue is not a transmission queue.

The queue specified in the channel definition is not a transmission queue, or is in use.

Programmer response

Ensure that the queue is specified correctly in the channel definition, and that it is correctly defined to the queue manager.

4038 (0FC6) (RC4038): MQRCCF_CHANNEL_DISABLED

Explanation

Channel disabled.

An attempt was made to use a channel, but the channel was disabled (that is, stopped).

Programmer response

Start the channel.

4039 (0FC7) (RC4039): MQRCCF_USER_EXIT_NOT_AVAILABLE

Explanation

User exit not available.

The channel was terminated because the user exit specified does not exist.

Programmer response

Ensure that the user exit is correctly specified and the program is available.

4040 (0FC8) (RC4040): MQRCCF_COMMIT_FAILED

Explanation

Commit failed.

An error was received when an attempt was made to commit a unit of work.

Programmer response

Consult your systems administrator.

4041 (0FC9) (RC4041): MQRCCF_WRONG_CHANNEL_TYPE

Explanation

Parameter not allowed for this channel type.

The parameter is not allowed for the type of channel being created, copied, or changed. Refer to the description of the parameter in error to determine the types of channel for which the parameter is valid

Programmer response

Remove the parameter.

4042 (0FCA) (RC4042): MQRCCF_CHANNEL_ALREADY_EXISTS

Explanation

Channel already exists.

An attempt was made to create a channel but the channel already existed and *Replace* was not specified as MQRP_YES.

Programmer response

Specify *Replace* as MQRP_YES or use a different name for the channel to be created.

4043 (0FCB) (RC4043): MQRCCF_DATA_TOO_LARGE

Explanation

Data too large.

The data to be sent exceeds the maximum that can be supported for the command.

Programmer response

Reduce the size of the data.

4044 (0FCC) (RC4044): MQRCCF_CHANNEL_NAME_ERROR

Explanation

Channel name error.

The *ChannelName* parameter contained characters that are not allowed for channel names.

Programmer response

Specify a valid name.

4045 (0FCD) (RC4045): MQRCCF_XMIT_Q_NAME_ERROR

Explanation

Transmission queue name error.

The *XmitQName* parameter contains characters that are not allowed for queue names. This reason code also occurs if the parameter is not present when a sender or server channel is being created, and no default value is available.

Programmer response

Specify a valid name, or add the parameter.

4047 (0FCF) (RC4047): MQRCCF_MCA_NAME_ERROR

Explanation

Message channel agent name error.

The *MCAName* value contained characters that are not allowed for program names on the platform in question.

Programmer response

Specify a valid name.

4048 (0FD0) (RC4048): MQRCCF_SEND_EXIT_NAME_ERROR

Explanation

Channel send exit name error.

The *SendExit* value contained characters that are not allowed for program names on the platform in question.

Programmer response

Specify a valid name.

4049 (0FD1) (RC4049): MQRCCF_SEC_EXIT_NAME_ERROR

Explanation

Channel security exit name error.

The *SecurityExit* value contained characters that are not allowed for program names on the platform in question.

Programmer response

Specify a valid name.

4050 (0FD2) (RC4050): MQRCCF_MSG_EXIT_NAME_ERROR

Explanation

Channel message exit name error.

The *MsgExit* value contained characters that are not allowed for program names on the platform in question.

Programmer response

Specify a valid name.

4051 (0FD3) (RC4051): MQRCCF_RCV_EXIT_NAME_ERROR

Explanation

Channel receive exit name error.

The *ReceiveExit* value contained characters that are not allowed for program names on the platform in question.

Programmer response

Specify a valid name.

4052 (0FD4) (RC4052): MQRCCF_XMIT_Q_NAME_WRONG_TYPE

Explanation

Transmission queue name not allowed for this channel type.

The *XmitQName* parameter is only allowed for sender or server channel types.

Programmer response

Remove the parameter.

4053 (0FD5) (RC4053): MQRCCF_MCA_NAME_WRONG_TYPE

Explanation

Message channel agent name not allowed for this channel type.

The *MCAName* parameter is only allowed for sender, server or requester channel types.

Programmer response

Remove the parameter.

4054 (0FD6) (RC4054): MQRCCF_DISC_INT_WRONG_TYPE

Explanation

Disconnection interval not allowed for this channel type.

The *DiscInterval* parameter is only allowed for sender or server channel types.

Programmer response

Remove the parameter.

4055 (0FD7) (RC4055): MQRCCF_SHORT_RETRY_WRONG_TYPE

Explanation

Short retry parameter not allowed for this channel type.

The *ShortRetryCount* parameter is only allowed for sender or server channel types.

Programmer response

Remove the parameter.

4056 (0FD8) (RC4056): MQRCCF_SHORT_TIMER_WRONG_TYPE

Explanation

Short timer parameter not allowed for this channel type.

The *ShortRetryInterval* parameter is only allowed for sender or server channel types.

Programmer response

Remove the parameter.

4057 (0FD9) (RC4057): MQRCCF_LONG_RETRY_WRONG_TYPE

Explanation

Long retry parameter not allowed for this channel type.

The *LongRetryCount* parameter is only allowed for sender or server channel types.

Programmer response

Remove the parameter.

4058 (0FDA) (RC4058): MQRCCF_LONG_TIMER_WRONG_TYPE

Explanation

Long timer parameter not allowed for this channel type.

The *LongRetryInterval* parameter is only allowed for sender or server channel types.

Programmer response

Remove the parameter.

4059 (0FDB) (RC4059): MQRCCF_PUT_AUTH_WRONG_TYPE

Explanation

Put authority parameter not allowed for this channel type.

The *PutAuthority* parameter is only allowed for receiver or requester channel types.

Programmer response

Remove the parameter.

4061 (0FDD) (RC4061): MQRCCF_MISSING_CONN_NAME

Explanation

Connection name parameter required but missing.

The *ConnectionName* parameter is required for sender or requester channel types, but is not present.

Programmer response

Add the parameter.

4062 (0FDE) (RC4062): MQRCCF_CONN_NAME_ERROR

Explanation

Error in connection name parameter.

The *ConnectionName* parameter contains one or more blanks at the start of the name.

Programmer response

Specify a valid connection name.

4063 (0FDF) (RC4063): MQRCCF_MQSET_FAILED

Explanation

MQSET call failed.

Programmer response

Check whether the queue manager is active.

4064 (0FE0) (RC4064): MQRCCF_CHANNEL_NOT_ACTIVE

Explanation

Channel not active.

An attempt was made to stop a channel, but the channel was already stopped.

Programmer response

No action is required.

4065 (0FE1) (RC4065): MQRCCF_TERMINATED_BY_SEC_EXIT

Explanation

Channel terminated by security exit.

A channel security exit terminated the channel.

Programmer response

Check that the channel is attempting to connect to the correct queue manager, and if so that the security exit is specified correctly, and is working correctly, at both ends.

4067 (0FE3) (RC4067): MQRCCF_DYNAMIC_Q_SCOPE_ERROR

Explanation

Dynamic queue scope error.

The *Scope* attribute of the queue is to be MQSCO_CELL, but this is not allowed for a dynamic queue.

Programmer response

Predefine the queue if it is to have cell scope.

4068 (0FE4) (RC4068): MQRCCF_CELL_DIR_NOT_AVAILABLE

Explanation

Cell directory is not available.

The *Scope* attribute of the queue is to be MQSCO_CELL, but no name service supporting a cell directory has been configured.

Programmer response

Configure the queue manager with a suitable name service.

4069 (0FE5) (RC4069): MQRCCF_MR_COUNT_ERROR

Explanation

Message retry count not valid.

The *MsgRetryCount* value was not valid.

Programmer response

Specify a value in the range 0-999 999 999.

4070 (0FE6) (RC4070): MQRCCF_MR_COUNT_WRONG_TYPE

Explanation

Message-retry count parameter not allowed for this channel type.

The *MsgRetryCount* parameter is allowed only for receiver and requester channels.

Programmer response

Remove the parameter.

4071 (0FE7) (RC4071): MQRCCF_MR_EXIT_NAME_ERROR

Explanation

Channel message-retry exit name error.

The *MsgRetryExit* value contained characters that are not allowed for program names on the platform in question.

Programmer response

Specify a valid name.

4072 (0FE8) (RC4072): MQRCCF_MR_EXIT_NAME_WRONG_TYPE

Explanation

Message-retry exit parameter not allowed for this channel type.

The *MsgRetryExit* parameter is allowed only for receiver and requester channels.

Programmer response

Remove the parameter.

4073 (0FE9) (RC4073): MQRCCF_MR_INTERVAL_ERROR

Explanation

Message retry interval not valid.

The *MsgRetryInterval* value was not valid.

Programmer response

Specify a value in the range 0-999 999 999.

4074 (0FEA) (RC4074): MQRCCF_MR_INTERVAL_WRONG_TYPE

Explanation

Message-retry interval parameter not allowed for this channel type.

The *MsgRetryInterval* parameter is allowed only for receiver and requester channels.

Programmer response

Remove the parameter.

4075 (0FEB) (RC4075): MQRCCF_NPM_SPEED_ERROR

Explanation

Nonpersistent message speed not valid.

The *NonPersistentMsgSpeed* value was not valid.

Programmer response

Specify MQNPMS_NORMAL or MQNPMS_FAST.

4076 (0FEC) (RC4076): MQRCCF_NPM_SPEED_WRONG_TYPE

Explanation

Nonpersistent message speed parameter not allowed for this channel type.

The *NonPersistentMsgSpeed* parameter is allowed only for sender, receiver, server, requester, cluster sender, and cluster receiver channels.

Programmer response

Remove the parameter.

4077 (0FED) (RC4077): MQRCCF_HB_INTERVAL_ERROR

Explanation

Heartbeat interval not valid.

The *HeartbeatInterval* value was not valid.

Programmer response

Specify a value in the range 0-999 999.

4078 (0FEE) (RC4078): MQRCCF_HB_INTERVAL_WRONG_TYPE

Explanation

Heartbeat interval parameter not allowed for this channel type.

The *HeartbeatInterval* parameter is allowed only for receiver and requester channels.

Programmer response

Remove the parameter.

4079 (0FEF) (RC4079): MQRCCF_CHAD_ERROR

Explanation

Channel automatic definition error.

The *ChannelAutoDef* value was not valid.

Programmer response

Specify MQCHAD_ENABLED or MQCHAD_DISABLED.

4080 (0FF0) (RC4080): MQRCCF_CHAD_WRONG_TYPE

Explanation

Channel automatic definition parameter not allowed for this channel type.

The *ChannelAutoDef* parameter is allowed only for receiver and server-connection channels.

Programmer response

Remove the parameter.

4081 (0FF1) (RC4081): MQRCCF_CHAD_EVENT_ERROR

Explanation

Channel automatic definition event error.

The *ChannelAutoDefEvent* value was not valid.

Programmer response

Specify MQEVR_ENABLED or MQEVR_DISABLED.

4082 (0FF2) (RC4082): MQRCCF_CHAD_EVENT_WRONG_TYPE

Explanation

Channel automatic definition event parameter not allowed for this channel type.

The *ChannelAutoDefEvent* parameter is allowed only for receiver and server-connection channels.

Programmer response

Remove the parameter.

4083 (0FF3) (RC4083): MQRCCF_CHAD_EXIT_ERROR

Explanation

Channel automatic definition exit name error.

The *ChannelAutoDefExit* value contained characters that are not allowed for program names on the platform in question.

Programmer response

Specify a valid name.

4084 (0FF4) (RC4084): MQRCCF_CHAD_EXIT_WRONG_TYPE

Explanation

Channel automatic definition exit parameter not allowed for this channel type.

The *ChannelAutoDefExit* parameter is allowed only for receiver and server-connection channels.

Programmer response

Remove the parameter.

4085 (0FF5) (RC4085): MQRCCF_SUPPRESSED_BY_EXIT

Explanation

Action suppressed by exit program.

An attempt was made to define a channel automatically, but this was inhibited by the channel automatic definition exit. The *AuxErrorDataInt1* parameter contains the feedback code from the exit indicating why it inhibited the channel definition.

Programmer response

Examine the value of the *AuxErrorDataInt1* parameter, and take any action that is appropriate.

4086 (0FF6) (RC4086): MQRCCF_BATCH_INT_ERROR

Explanation

Batch interval not valid.

The batch interval specified was not valid.

Programmer response

Specify a valid batch interval value.

4087 (0FF7) (RC4087): MQRCCF_BATCH_INT_WRONG_TYPE

Explanation

Batch interval parameter not allowed for this channel type.

The *BatchInterval* parameter is allowed only for sender and server channels.

Programmer response

Remove the parameter.

4088 (0FF8) (RC4088): MQRCCF_NET_PRIORITY_ERROR

Explanation

Network priority value is not valid.

Programmer response

Specify a valid value.

4089 (0FF9) (RC4089): MQRCCF_NET_PRIORITY_WRONG_TYPE

Explanation

Network priority parameter not allowed for this channel type.

The *NetworkPriority* parameter is allowed for sender and server channels only.

Programmer response

Remove the parameter.

4090 (0FFA) (RC4090): MQRCCF_CHANNEL_CLOSED

Explanation

Channel closed.

The channel was closed prematurely. This can occur because a user stopped the channel while it was running, or a channel exit decided to close the channel.

Programmer response

Determine the reason that the channel was closed prematurely. Restart the channel if required.

4092 (0FFC) (RC4092): MQRCCF_SSL_CIPHER_SPEC_ERROR

Explanation

SSL cipher specification not valid.

The *SSLCipherSpec* specified is not valid.

Programmer response

Specify a valid cipher specification.

4093 (0FFD) (RC4093): MQRCCF_SSL_PEER_NAME_ERROR

Explanation

SSL peer name not valid.

The *SSLPeerName* specified is not valid.

Programmer response

Specify a valid peer name.

4094 (0FFE) (RC4094): MQRCCF_SSL_CLIENT_AUTH_ERROR

Explanation

SSL client authentication not valid.

The *SSLClientAuth* specified is not valid.

Programmer response

Specify a valid client authentication.

4095 (0FFF) (RC4095): MQRCCF_RETAINED_NOT_SUPPORTED

Explanation

Retained messages used on restricted stream.

An attempt has been made to use retained messages on a publish/subscribe stream defined to be restricted to JMS usage. JMS does not support the concept of retained messages and the request is rejected.

Programmer response

Either modify the application not to use retained messages, or modify the broker *JmsStreamPrefix* configuration parameter so that this stream is not treated as a JMS stream.

Secure Sockets Layer (SSL) and Transport Layer Security (TLS) return codes

IBM MQ can use Secure Sockets Layer (SSL) with the various communication protocols. Use this topic to identify the error codes that can be returned by SSL.

The table in this appendix documents the return codes, in decimal form, from the Secure Sockets Layer (SSL) that can be returned in messages from the distributed queuing component.

If the return code is not listed, or if you want more information, see the *IBM Global Security Kit return codes* here: ../../SSPREK_6.1.0/com.ibm.itame.doc_6.1/am61_messages25.htm.

Table 146. SSL return codes

Return code (decimal)	Explanation
1	Handle is not valid.
3	An internal error has occurred.
4	Insufficient storage is available
5	Handle is in the incorrect state.
6	Key label is not found.
7	No certificates available.
8	Certificate validation error.
9	Cryptographic processing error.
10	ASN processing error.
11	LDAP processing error.
12	An unexpected error has occurred.
102	Error detected while reading key database or SAF key ring.
103	Incorrect key database record format.
106	Incorrect key database password.
109	No certificate authority certificates.
201	No key database password supplied.
202	Error detected while opening the key database.
203	Unable to generate temporary key pair
204	Key database password is expired.
302	Connection is active.
401	Certificate is expired or is not valid yet.
402	No SSL cipher specifications.
403	No certificate received from partner.
405	Certificate format is not supported.
406	Error while reading or writing data.
407	Key label does not exist.
408	Key database password is not correct.
410	SSL message format is incorrect.
411	Message authentication code is incorrect.
412	SSL protocol or certificate type is not supported.
413	Certificate signature is incorrect.
414	Certificate is not valid.
415	SSL protocol violation.
416	Permission denied.
417	Self-signed certificate cannot be validated.
420	Socket closed by remote partner.
421	SSL V2 cipher is not valid.
422	SSL V3 cipher is not valid.
427	LDAP is not available.

Table 146. SSL return codes (continued)

Return code (decimal)	Explanation
428	Key entry does not contain a private key.
429	SSL V2 header is not valid.
431	Certificate is revoked.
432	Session renegotiation is not allowed.
433	Key exceeds allowable export size.
434	Certificate key is not compatible with cipher suite.
435	Certificate authority is unknown.
436	Certificate revocation list cannot be processed.
437	Connection closed.
438	Internal error reported by remote partner.
439	Unknown alert received from remote partner.
501	Buffer size is not valid.
502	Socket request would block.
503	Socket read request would block.
504	Socket write request would block.
505	Record overflow.
601	Protocol is not SSL V3 or TLS V1.
602	Function identifier is not valid.
701	Attribute identifier is not valid.
702	The attribute has a negative length, which is invalid.
703	The enumeration value is invalid for the specified enumeration type.
704	Invalid parameter list for replacing the SID cache routines.
705	The value is not a valid number.
706	Conflicting parameters were set for additional certificate validation
707	The AES cryptographic algorithm is not supported.
708	The PEERID does not have the correct length.
1501	GSK_SC_OK
1502	GSK_SC_CANCEL
1601	The trace started successfully.
1602	The trace stopped successfully.
1603	No trace file was previously started so it cannot be stopped.
1604	Trace file already started so it cannot be started again.
1605	Trace file cannot be opened. The first parameter of gsk_start_trace() must be a valid full path filename.

In some cases, the secure sockets library reports a certificate validation error in an AMQ9633 error message. Table 2 lists the certificate validation errors that can be returned in messages from the distributed queuing component.

Table 147. Certificate validation errors.

A table listing return codes and explanations for certificate validation errors that can be returned in messages from the distributed queuing component.

Return code (decimal)	Explanation
575001	Internal error
575002	ASN error due to a malformed certificate
575003	Cryptographic error
575004	Key database error
575005	Directory error
575006	Invalid implementation library
575008	No appropriate validator
575009	The root CA is not trusted
575010	No certificate chain was built
575011	Digital signature algorithm mismatch
575012	Digital signature mismatch
575013	X.509 version does not allow Key IDs
575014	X.509 version does not allow extensions
575015	Unknown X.509 certificate version
575016	The certificate validity range is invalid
575017	The certificate is not yet valid
575018	The certificate has expired
575019	The certificate contains unknown critical extensions
575020	The certificate contains duplicate extensions
575021	The issuers directory name does not match the issuer's issuer
575022	The Authority Key ID serial number value does not match the serial number of the issuer
575023	The Authority Key ID and Subject Key ID do not match
575024	Unrecognized issuer alternative name
575025	The certificate Basic Constraints forbid use as a CA
575026	The certificate has a non-zero Basic Constraints path length but is not a CA
575027	The certificate Basic Constraints maximum path length was exceeded
575028	The certificate is not permitted to sign other certificates
575029	The certificate is not signed by a CA
575030	Unrecognized Subject Alternative Name
575031	The certificate chain is invalid
575032	The certificate is revoked
575033	Unrecognized CRL distribution point
575034	Name chaining failed
575035	Certificate is not in a chain
575036	The CRL is not yet valid
575037	The CRL has expired
575038	The certificate version does not allow critical extensions

Table 147. Certificate validation errors (continued).

A table listing return codes and explanations for certificate validation errors that can be returned in messages from the distributed queuing component.

Return code (decimal)	Explanation
575039	Unknown CRL distribution points
575040	No CRLs for CRL distribution points
575041	Indirect CRLs are not supported
575042	Missing issuing CRL distribution point name
575043	Distribution points do not match
575044	No available CRL data source
575045	CA Subject name is null
575046	Distinguished names do not chain
575047	Missing Subject Alternative Name
575048	Unique ID mismatch
575049	Name not permitted
575050	Name excluded
575051	CA certificate is missing Critical Basic Constraints
575052	Name constraints are not critical

z/OS IBM MQ for z/OS messages, completion, and reason codes

WCF custom channel exceptions

Diagnostic messages are listed in this topic in numeric order, grouped according to the part of the WCF custom channel from which they originate.

Reading a message

For each message, this information is provided:

- The message identifier, in two parts:
  1. The characters "WCFCH" which identify the message as being from the WCF custom channel for IBM MQ
  2. A four-digit decimal code followed by the character 'E'
- The text of the message.
- An explanation of the message giving further information.
- The response required from the user. In some cases, particularly for information messages, the response required might be "none".

Message variables

Some messages display text or numbers that vary according to the circumstances causing the message to occur; these circumstances are known as *message variables*. The message variables are indicated as {0}, {1}, and so on.

In some cases a message might have variables in the Explanation or Response. Find the values of the message variables by looking in the error log. The complete message, including the Explanation and the Response, is recorded there.

The following message types are described:

WCFCH0001E-0100E: General/State messages

Use the following information to understand WCFCH0001E-0100E general/state messages.

WCFCH0001E
An object cannot be opened because its state is '{0}'.

Explanation
An internal error has occurred.

Response
Use the standard facilities supplied with your system to record the problem identifier and to save any generated output files. Use either the IBM MQ support web page, or the IBM SupportAssistant web page, to see if a solution is already available. If you cannot find a match, contact your IBM support center. Do not discard these files until the problem has been resolved.

WCFCH0002E
An object cannot be closed because its state is '{0}'.

Explanation
An internal error has occurred.

Response
Use the standard facilities supplied with your system to record the problem identifier and to save any generated output files. Use either the IBM MQ support web page, or the IBM SupportAssistant web page, to see if a solution is already available. If you cannot find a match, contact your IBM support center. Do not discard these files until the problem has been resolved.

WCFCH0003E
An object cannot be used because its state is '{0}'.

Explanation
An internal error has occurred.

Response
Use the standard facilities supplied with your system to record the problem identifier and to save any generated output files. Use either the IBM MQ support web page, or the IBM SupportAssistant web page, to see if a solution is already available. If you cannot find a match, contact your IBM support center. Do not discard these files until the problem has been resolved.

WCFCH0004E
The specified 'Timeout' value '{0}' is out of range.

Explanation
The value is out of range, it must be greater than or equal to 'TimeSpan.Zero'.

Response
Specify a value which is in range or, to disable Timeout, specify a 'TimeSpan.MaxValue' value.

WCFCH0005E
The operation did not complete within the specified time of '{0}' for endpoint address '{1}'.

Explanation
A timeout occurred.

Response
Investigate the cause for the timeout.

WCFCH0006E
The parameter '{0}' is not of the expected type '{1}'

Explanation
A parameter with an unexpected type has been passed to a method call.

Response
Review the exception stack trace for further information.

WCFCH0007E
The parameter '{0}' must not be null.

Explanation
A method has been called with a required parameter set to a null value.

Response
Modify the application to provide a value for this parameter.

WCFCH0008E
An error occurred while processing an operation for endpoint address '{0}'.

Explanation
The operation failed to complete.

Response
Review the linked exceptions and stack trace for further information.

WCFCH0101E-0200E: URI Properties messages

Use the following information to understand WCFCH0101E-0200E URI properties messages.

WCFCH0101E
The endpoint URI must start with the valid character string '{0}'.

Explanation
The endpoint URI is incorrect, it must start with a valid character string.

Response
Specify an endpoint URI which starts with a valid character string.

WCFCH0102E
The endpoint URI must contain a '{0}' parameter with a value.

Explanation
The endpoint URI is incorrect, a parameter and its value are missing.

Response
Specify an endpoint URI with a value for this parameter.

WCFCH0103E
The endpoint URI must contain a '{0}' parameter with a value of '{1}'.

Explanation
The endpoint URI is incorrect, the parameter must contain the correct value.

Response
Specify an endpoint URI with a correct parameter and value.

WCFCH0104E
The endpoint URI contains a '{0}' parameter with an invalid value of '{1}'.

Explanation
The endpoint URI is incorrect, a valid parameter value must be specified.

Response
Specify an endpoint URI with a correct value for this parameter.

WCFCH0105E
The endpoint URI contains a '{0}' parameter with an invalid queue or queue manager name.

Explanation
The endpoint URI is incorrect, a valid queue and queue manager name must be specified.

Response
Specify an endpoint URI with valid values for the queue and the queue manager.

WCFCH0106E
The '{0}' property is a required property and must appear as the first property in the endpoint URI.

Explanation
The endpoint URI is incorrect, a parameter is either missing or in the wrong position.

Response
Specify an endpoint URI which contains this property as the first parameter.

WCFCH0107E
The property '{1}' cannot be used when the binding property is set to '{0}'.

Explanation
The endpoint URI connectionFactory parameter is incorrect, an invalid combination of properties has been used.

Response
Specify an endpoint URI connectionFactory which contains a valid combination of properties or binding.

WCFCH0109E
Property '{1}' must also be specified when property '{0}' is specified.

Explanation
The endpoint URI connectionFactory parameter is incorrect, it contains an invalid combination of properties.

Response
Specify an endpoint URI connectionFactory which contains a valid combination of properties.

WCFCH0110E
Property '{0}' has an invalid value '{1}'.

Explanation
The endpoint URI connectionFactory parameter is incorrect, the property does not contain a valid value.

Response
Specify an endpoint URI connectionFactory which contains a valid value for the property.

WCFCH0111E
: The value '{0}' is not supported for the binding mode property. XA operations are not supported.

Explanation
: The endpoint URI connectionFactory parameter is incorrect, the binding mode is not supported.

Response
: Specify an endpoint URI connectionFactory which contains a valid value for the binding mode.

WCFCH0112E
: The endpoint URI '{0}' is badly formatted.

Explanation
: The endpoint URI must follow the format described in the documentation.

Response
: Review the endpoint URI to ensure that it contains a valid value.

WCFCH0201E-0300E: Factory/Listener messages

Use the following information to understand WCFCH0201E-0300E factory/listener messages.

WCFCH0201E
: Channel shape '{0}' is not supported.

Explanation
: The users application or the WCF service contract has requested a channel shape which is not supported.

Response
: Identify and use a channel shape which is supported by the channel.

WCFCH0202E
: '{0}' MessageEncodingBindingElements have been specified.

Explanation
: The WCF binding configuration used by an application contains more than one message encoder.

Response
: Specify no more then 1 MessageEncodingBindingElement in the binding configuration.

WCFCH0203E
: The endpoint URI address for the service listener must be used exactly as provided.

Explanation
: The binding information for the endpoint URI address must specify a value of 'Explicit' for the 'listenUriMode' parameter.

Response
: Change the parameter value to 'Explicit'.

WCFCH0204E
: SSL is not supported for managed client connections [endpoint URI: '{0}'].

Explanation
: The endpoint URI specifies an SSL connection type which is only supported for unmanaged client connections.

Response
: Modify the channels binding properties to specify an unmanaged client connection mode.

WCFCH0301E-0400E: Channel messages

Use the following information to understand WCFCH0301E-0400E channel messages.

WCFCH0301E
: The URI scheme '{0}' is not supported.

Explanation
: The requested endpoint contains a URI scheme which is not supported by the channel.

Response
: Specify a valid scheme for the channel.

WCFCH0302E
: The received message '{0}' was not a JMS bytes or a JMS text message.

Explanation
: A message has been received but it is not of the correct type. It must be either a JMS bytes message or a JMS text message.

Response
: Check the origin and contents of the message and determine the cause for it being incorrect.

WCFCH0303E
: 'ReplyTo' destination missing.

Explanation
: A reply cannot be sent because the original request does not contain a 'ReplyTo' destination.

Response
: Investigate the reason for the missing destination value.

WCFCH0304E
: The connection attempt to queue manager '{0}' failed for endpoint '{1}'

Explanation
: The queue manager could not be contacted at the given address.

Response
: Review the linked exception for further details.

WCFCH0305E
: The connection attempt to the default queue manager failed for endpoint '{0}'

Explanation
: The queue manager could not be contacted at the given address.

Response
: Review the linked exception for further details.

WCFCH0306E
: An error occurred while attempting to receive data from endpoint '{0}'

Explanation
: The operation could not be completed.

Response
: Review the linked exception for further details.

WCFCH0307E
: An error occurred while attempting to send data for endpoint '{0}'

Explanation
: The operation could not be completed.

Response
: Review the linked exception for further details.

WCFCH0308E
An error occurred while attempting to close the channel for endpoint '{0}'

Explanation
The operation could not be completed.

Response
Review the linked exception for further details.

WCFCH0309E
An error occurred while attempting to open the channel for endpoint '{0}'

Explanation
The operation could not be completed.

Response
The endpoint might be down, unavailable, or unreachable, review the linked exception for further details.

WCFCH0310E
The timeout '{0}' was exceeded while attempting to receive data from endpoint '{0}'

Explanation
The operation did not complete in the time allowed.

Response
Review the system status and configuration and increase the timeout if required.

WCFCH0311E
The timeout '{0}' was exceeded while attempting to send data for endpoint '{0}'

Explanation
The operation did not complete in the time allowed.

Response
Review the system status and configuration and increase the timeout if required.

WCFCH0312E
The timeout '{0}' was exceeded while attempting to close the channel for endpoint '{0}'

Explanation
The operation did not complete in the time allowed.

Response
Review the system status and configuration and increase the timeout if required.

WCFCH0313E
The timeout '{0}' was exceeded while attempting to open the channel for endpoint '{0}'

Explanation
The operation did not complete in the time allowed.

Response
The endpoint might be down, unavailable, or unreachable, review the system status and configuration and increase the timeout if required.

WCFCH0401E-0500E: Binding messages

Use the following information to understand WCFCH0401E-0500E binding messages.

WCFCH0401E
: No context.

Explanation
: An internal error has occurred.

Response
: Use the standard facilities supplied with your system to record the problem identifier and to save any generated output files. Use either the IBM Support Portal for IBM MQ (see http://www.ibm.com/support/entry/portal/Overview/Software/WebSphere/WebSphere_MQ), or the IBM Support Assistant (at http://www.ibm.com/software/support/isa/), to see if a solution is already available. If you cannot find a match, contact your IBM support center. Do not discard these files until the problem has been resolved.

WCFCH0402E
: Channel type '{0}' is not supported.

Explanation
: The users application or the WCF service contract has requested a channel shape which is not supported.

Response
: Identify and use a channel shape which is supported by the channel.

WCFCH0403E
: No exporter.

Explanation
: An internal error has occurred.

Response
: Use the standard facilities supplied with your system to record the problem identifier and to save any generated output files. Use either the IBM Support Portal for IBM MQ (see http://www.ibm.com/support/entry/portal/Overview/Software/WebSphere/WebSphere_MQ), or the IBM Support Assistant (at http://www.ibm.com/software/support/isa/), to see if a solution is already available. If you cannot find a match, contact your IBM support center. Do not discard these files until the problem has been resolved.

WCFCH0404E
: The WS-Addressing version '{0}' is not supported.

Explanation
: The addressing version specified is not supported.

Response
: Specify an addressing version which is supported.

WCFCH0405E
: No importer.

Explanation
: An internal error has occurred.

Response
: Use the standard facilities supplied with your system to record the problem identifier and to save any generated output files. Use either the IBM Support Portal for IBM MQ (see http://www.ibm.com/support/entry/portal/Overview/Software/WebSphere/WebSphere_MQ), or the IBM Support Assistant (at http://www.ibm.com/software/support/isa/), to see if a solution is already available. If you cannot find a match, contact your IBM support center. Do not discard these files until the problem has been resolved.

WCFCH0406E
Endpoint 'Binding' value missing.

Explanation
An internal error has occurred.

Response
Use the standard facilities supplied with your system to record the problem identifier and to save any generated output files. Use either the IBM Support Portal for IBM MQ (see http://www.ibm.com/support/entry/portal/Overview/Software/WebSphere/WebSphere_MQ), or the IBM Support Assistant (at http://www.ibm.com/software/support/isa/), to see if a solution is already available. If you cannot find a match, contact your IBM support center. Do not discard these files until the problem has been resolved.

WCFCH0501E-0600E: Binding properties messages

Use the following information to understand WCFCH0501E-0600E binding properties messages.

WCFCH0501E
The binding property '{0}' has an invalid value '{1}'.

Explanation
An invalid value has been specified for a binding property.

Response
Specify a valid value for the property.

WCFCH0601E-0700E: Async operations messages

Use the following information to understand WCFCH0601E-0700E async operations messages.

WCFCH0601E
The async result parameter '{0}' object is not valid for this call.

Explanation
An invalid async result object has been provided.

Response
Specify a valid value for the parameter.

IBM Support Assistant (ISA)

The IBM Support Assistant (ISA) helps you to resolve questions and problems with IBM software products by providing access to support-related information and troubleshooting tools.

ISA is available at no charge to install on your computer; you then install the relevant product add-ons. ISA has a built-in user guide, and the ISA download package includes a quick start installation and configuration guide. This topic contains a brief overview of the features of the ISA Workbench Version 4; you can find more detailed information on the IBM SupportAssistant web page.

From the ISA home page you can search for information, analyze problems, and collect data to send to IBM.

Find information
Click **Find Information** to search multiple information sources concurrently. You can search the following sources.
- IBM software support documents
- IBM developerWorks®
- IBM news groups and forums
- Google Web search
- Guided troubleshooter content
- Product documentation

Analyze problem
Click **Analyze Problem** to access diagnostic tools or a guided troubleshooter, or to collect data. More tools might be made available periodically, so check for updates by clicking **Find new add-ons**.

Collect and send data
Click **Collect and Send Data** to complete the following tasks.
- Collect diagnostic data automatically from a local or remote computer.
- Send files to IBM Support for problem determination.
- Create and submit a new problem report.
- View or update an existing problem report.

For information on installing the ISA, see "Installing the IBM Support Assistant (ISA)."

Related concepts:

"Troubleshooting overview" on page 1276
Troubleshooting is the process of finding and eliminating the cause of a problem. Whenever you have a problem with your IBM software, the troubleshooting process begins as soon as you ask yourself "what happened?"

Related tasks:

"Searching knowledge bases" on page 1638
If you have a problem with your IBM software, you want it resolved quickly. Begin by searching the available knowledge bases to determine whether the resolution to your problem is already documented.

"Contacting IBM Software Support" on page 1658
Grade the severity of the problem, describe the problem and gather background information, then report the problem to IBM Software Support.

Installing the IBM Support Assistant (ISA)

You can install the IBM Support Assistant (ISA) from the ISA downloads Web page.

Before you begin

Before you start:

Read the concept topic about the "IBM Support Assistant (ISA)" on page 1635.

About this task

Follow these steps to install ISA on your computer:

Procedure

1. Go to the IBM SupportAssistant web page to download the installation package.
2. Log in by using your IBM ID and password. If you do not have an IBM ID, click **Get an IBM ID** to create one.
3. Select the version of ISA that you want and click **Continue**.
4. Click **View license** to read the license agreement in a separate window, then select **I agree** and click **I confirm**.
5. Select the relevant operating system, click **Download now**, and save the compressed file to a temporary directory.
6. Extract the files from the compressed file to a temporary directory. The files that you extract include a quick start guide that tells you how to install, upgrade, and configure ISA.
7. Follow the instructions in the quick start guide to install ISA.

Results

When you have installed ISA successfully, you can use the desktop icon to open it, or you can click **Programs** > **IBM Support Assistant** > **IBM Support Assistant**. (The exact name of the entry in the Start menu depends on the version of ISA that you have installed.)

What to do next

Now that you have installed ISA, install the WMQ add-on, as described in "Updating the IBM Support Assistant (ISA)."

Updating the IBM Support Assistant (ISA)

You can update ISA by installing product and tool add-ons.

Before you begin

Before you start:

1. Read the concept topic about the "IBM Support Assistant (ISA)" on page 1635.
2. Install the IBM Support Assistant.

About this task

To install product add-ons and tool add-ons, complete the following steps.

Procedure

1. Open the IBM Support Assistant by clicking **Programs** > **IBM Support Assistant** > **IBM Support Assistant**.
2. Click **Update** > **Find New** and select either **Product Add-ons** or **Tools Add-ons**.
3. Select the appropriate product add-ons to install and click **Next**. Add-ons are categorized by product family, therefore expand **WebSphere** and select IBM MQ.
4. Select the appropriate tool add-ons and click **Next**.
5. Read and accept the license agreement and click **Next**.
6. Click **Finish** to install the selected add-ons.
7. When the installation completes, click **Finish**, then click **Yes** to restart ISA.

What to do next

When you have installed the add-ons in successfully, click **Find Information** to search various forms of information for the products that you have selected. You can also use ISA to analyze problems and collect and send data to IBM.

Searching knowledge bases

If you have a problem with your IBM software, you want it resolved quickly. Begin by searching the available knowledge bases to determine whether the resolution to your problem is already documented.

Before you begin

1. If you have not already installed the IBM Support Assistant, you can find instructions about how to do so in "Updating the IBM Support Assistant (ISA)" on page 1637.
2. Install the IBM Support Assistant WMQ plug-in by following the instructions in "Installing the IBM Support Assistant (ISA)" on page 1636.

Procedure

1. **Search the product documentation**

   IBM provides extensive documentation in the form of online product documentation hosted in IBM Knowledge Center. A downloadable version of the product documentation can be installed on your local machine or on a local intranet. You can use the search function of the product documentation to query conceptual and reference information as well as detailed instructions for completing tasks.
2. **Search the IBM database for similar problems**

   IBM keeps records of all known problems with its licensed programs on its software support database (RETAIN). IBM support center staff continually update this database as new problems are found, and they regularly search the database to see if problems they are told about are already known. You can use one of the IBM search tools to search the database, or you can contact IBM support center to perform the search for you. For more information about searching the IBM database, see "Searching the IBM database for similar problems, and solutions" on page 1639.
3. **Search the Internet**

   If you cannot find an answer to your question in the product documentation, search the Internet for the latest, most complete information that might help you resolve your problem, including:
   - IBM technotes
   - IBM downloads
   - IBM Redbooks
   - IBM developerWorks
   - Forums and newsgroups
   - Internet search engines

   You can use the IBM Support Assistant (ISA) to help in your search of knowledge bases. With ISA, you can:
   - Query multiple sources of support information
   - Access available diagnostic tools
   - Collect diagnostic data automatically
   - Send files to IBM Support for problem determination
   - Create and submit a new problem report
   - View or update an existing problem report

   For more information, see "IBM Support Assistant (ISA)" on page 1635.

Related concepts:

"Troubleshooting and support" on page 1275
If you are having problems with your queue manager network or IBM MQ applications, use the techniques described to help you diagnose and solve the problems.

"IBM Support Assistant (ISA)" on page 1635
The IBM Support Assistant (ISA) helps you to resolve questions and problems with IBM software products by providing access to support-related information and troubleshooting tools.

Related tasks:

"Contacting IBM Software Support" on page 1658
Grade the severity of the problem, describe the problem and gather background information, then report the problem to IBM Software Support.

Searching the IBM database for similar problems, and solutions

IBM maintain a database of known problems, and solutions to some of those problems. Use this topic to understand how to best search the database.

IBM keeps records of all known problems with its licensed programs on its software support database (RETAIN). IBM support center staff continually update this database as new problems are found, and they regularly search the database to see if problems they are told about are already known.

If you have access to one of the IBM search tools such as INFORMATION/ACCESS OR INFORMATION/SYSTEM you can look on the RETAIN database yourself. If not, you can contact the IBM support center to perform the search for you.

You can search the database using a string of keywords to see if a similar problem already exists. This section explains how to search the database using keywords.

You can use the keyword string (also called the symptom string) that appears in a dump or SYS1.LOGREC record to search the database, or you can build your own keyword string z/OS from the procedure described in "Building a keyword string" on page 1643. Before you use the procedures in this section, make some initial checks by searching through the following appropriate product documentation section specific to your platform:

- Windows UNIX Linux "Making initial checks on Windows, UNIX and Linux systems" on page 1277
- IBM i "Making initial checks on IBM i" on page 1288
- z/OS "Making initial checks on z/OS" on page 1297

If the search is successful, you find a similar problem description and, usually, a fix. If the search is unsuccessful, you should use these keywords when contacting IBM for additional assistance, or when documenting a possible *authorized program analysis report* (APAR).

Searching the IBM software support database is most effective if you:

- Always spell keywords the way they are spelled in this documentation
- Include all the appropriate keywords in any discussion with your IBM support center

Use the following topics to find out more about searching the IBM database for problems:

- "The search argument process" on page 1640
- "The keyword format" on page 1641
- z/OS "Building a keyword string" on page 1643
- "SDB format symptom-to-keyword cross reference" on page 1655
- "IBM MQ component and resource manager identifiers" on page 1657

The search argument process

Use this topic to understand how to search the RETAIN database.

Use the following procedure when searching the IBM software support database:

1. Using INFORMATION/ACCESS or INFORMATION/SYSTEM, search the database using the keywords you have developed. z/OS Details on how to construct suitable keywords are given in "Building a keyword string" on page 1643

   Note: Do *not* use both the CSECT keyword and the load module modifier keyword at the same time for the first search. z/OS Refer to "Load module modifier keyword" on page 1649 for additional information.
2. Compare each matching APAR closing description with the current failure symptoms.
3. If you find an appropriate APAR, apply the correction or PTF.
4. If you do not find an appropriate APAR, vary the search argument by following the suggestions provided under "Techniques for varying the search process."

Related concepts:

"APARs and PTFs" on page 1664
After a problem is confirmed an APAR can be raised and a PTF released. Use this topic to understand the APAR and PTF process.

Techniques for varying the search process:

You can widen or narrow the scope of your search or you can alter the keywords to make the search more precise.

To vary your search, follow these guidelines:

Dropping keywords to widen your search

If you used a complete set of keywords z/OS (as described in "Building a keyword string" on page 1643) and could not find any problem descriptions to examine, drop one or more of the following keywords and try again:

- Release-level keyword
- Load Module modifier keyword
- Recovery routine modifier keyword
- CSECT keyword

Adding keywords to narrow your search

If you tried to search with an incomplete set of keywords and found too many problem descriptions to examine, add keywords to narrow your search. For example, for storage manager abends (which produce a reason code beginning with X'00E2'), you use the CSECT name recorded in the VRA to narrow or vary the search.

Making your set of keywords more precise

If you tried to search with a complete set of keywords and found too many matching descriptions and if you received a 4-byte IBM MQ abend reason code, you might be able to make your set of keywords more precise. z/OS Look up the 4-byte abend reason code in IBM MQ for z/OS messages, completion, and reason codes to find additional information available for this problem.

Replacing keywords to locate problems

If your type-of-failure keyword is WAIT, LOOP, or PERFM, and if you did not find a matching problem description, replace that keyword with one of the other two listed here. Sometimes a problem that appears to be a performance problem might actually be a WAIT or LOOP; likewise, a problem that seems to be a WAIT or a LOOP might actually be recorded as a performance problem.

Using message numbers in your search
If your type-of-failure keyword is MSGx and you received more than one message near the time of the problem, repeat the search replacing the message number in the keyword with the number of each related message in turn.

Using DOC as a keyword in your search
If your type-of-failure keyword is MSGx, PERFM, or INCORROUT, and if the problem occurred immediately after you performed some action that an IBM MQ documentation told you to perform, the problem could be recorded as a DOC type of failure. In this case, try searching with DOC as your type-of-failure keyword, rather than with MSGx, PERFM, or INCORROUT.

The keyword format

Searches can be performed using free format keywords or structured database (SDB) format keywords. Use this topic to understand how to perform searches using different keyword formats.

The keyword formats

The keywords z/OS in "Building a keyword string" on page 1643 are described in two distinct formats: the z/OS, or free format; and the structured database (SDB) format. Structured symptoms are also called RETAIN symptoms and "failure keywords⌂.

If your installation has a tool for performing structured searches, you can use the SDB format. Otherwise, you should use the free format. For both formats, your choice of keywords depends on the type of failure that occurred.

- Free format
- Structured database (SDB) format

Free format

A free form keyword can consist of any piece of data that is related to the problem. To help you search the database, a set of keywords has been defined, and you can use them to narrow your search. (For example, if you know the name of the CSECT in error, you can use this to search, but if you add the MSGxx or ABEND keyword, your search will be more precise.)

The following list shows keywords defined for use in a free format search:

Table 148. Keywords defined for use in a free format search

Keyword	Meaning
ABEND	Abnormal termination of a task; no error message.
ABENDxx	Abnormal termination of a task; xx is the abend code.
ABENDUxx	User abend; xx is the abend code.
DOC	Documentation discrepancy that caused a problem.
HALTxx	Halt; xx is the halt number.
INCORROUT	Any incorrect data output, except performance degradation.
INTEG	Integrity problem.
LOOP	Loop.
MSGxx	Any message; xx is the message identifier.
PERFM	Performance degradation.

Table 148. Keywords defined for use in a free format search (continued)

Keyword	Meaning
PROCCHK	Processor check.
PROGCH	Program check.
WAIT	Wait condition; undocumented and no identifier.
WAITxx	System wait condition; xx is the identifier.

Structured database (SDB) format

The structured symptoms consist of a prefix keyword, which identifies the type of symptom, followed by a slash (/) and the data portion of the symptom.

- The prefix keyword has one through eight characters.
- All characters must be alphanumeric, #, @, or $.
- At least one character of data is required.
- The maximum length, including the prefix, is 15 characters.

For example, the following is a structured symptom string for a message identifier of CSQC223D:

```
MS/CSQC223D
```

The following list shows the structured symptom strings:

Table 149. Keywords defined for use in a structured format search

Keyword	Meaning
AB	Abend code.
FLDS	Name of a field or control block involved with the problem.
LVLS	Level of the base system or licensed program.
MS	Message identifier.
OPCS	Operation code (opcode) for software, such as an assembler-language opcode.
PCSS	Program command or other software statement, such as JCL, a parameter, or a data set name.
PIDS	Program identifier for a component involved in the problem.
PRCS	Program return code, generated by software, including reason codes and condition codes.
PTFS	Program temporary fix (PTF) for software associated with a problem.
PUBS	Identifier of a publication associated with a problem.
RECS	Record associated with a problem.
REGS	Register for a software program associated with a problem. The value can be the register/PSW difference (*rrddd*), which the STATUS FAILDATA subcommand of IPCS provides for abends. The difference (*ddd*) is a hexadecimal offset from a probable base register or branch register (*rr*).
RIDS	Routine identifier, such as the name of a CSECT or subroutine. If the RIDS/ value has no suffix, the value is a CSECT name. The following suffixes are supported: • #L for a load module • #R for a recovery routine

Table 149. Keywords defined for use in a structured format search (continued)

Keyword	Meaning
VALU	Value in a field or register. One of the following qualifiers is required as the first character of the value: • B for a bit value • C for a character value • H for a hexadecimal value
WS	Wait state code issued by the system, or device-issued wait code. One of the following qualifiers is required as the first character of the value: • D for disabled wait (system disabled for I/O or external interrupts) • E for enabled wait

For more information about which prefix keyword to use for which type of symptom, see "SDB format symptom-to-keyword cross reference" on page 1655.

Building a keyword string

This section describes a systematic way of selecting *keywords* to describe a failure in IBM MQ for z/OS. Keywords are predefined words or abbreviations that identify aspects of a program failure.

To determine which IBM MQ for z/OS keywords to use and the procedures for selecting them, see the flowchart in Figure 114 on page 1644.

To begin selecting your keywords:

1. Follow the procedures in "The component-identifier keyword" on page 1645 and "The release-level keyword" on page 1646. Do this for all failures.
2. Follow one of the type-of-failure keyword procedures.
3. Identify the area of the failure using CSECT and modifier keywords when appropriate. The procedures in this section refer you to these steps as needed.
4. Follow "Searching the IBM database for similar problems, and solutions" on page 1639 to learn how to search the database with your set of keywords. Do this for all failures.

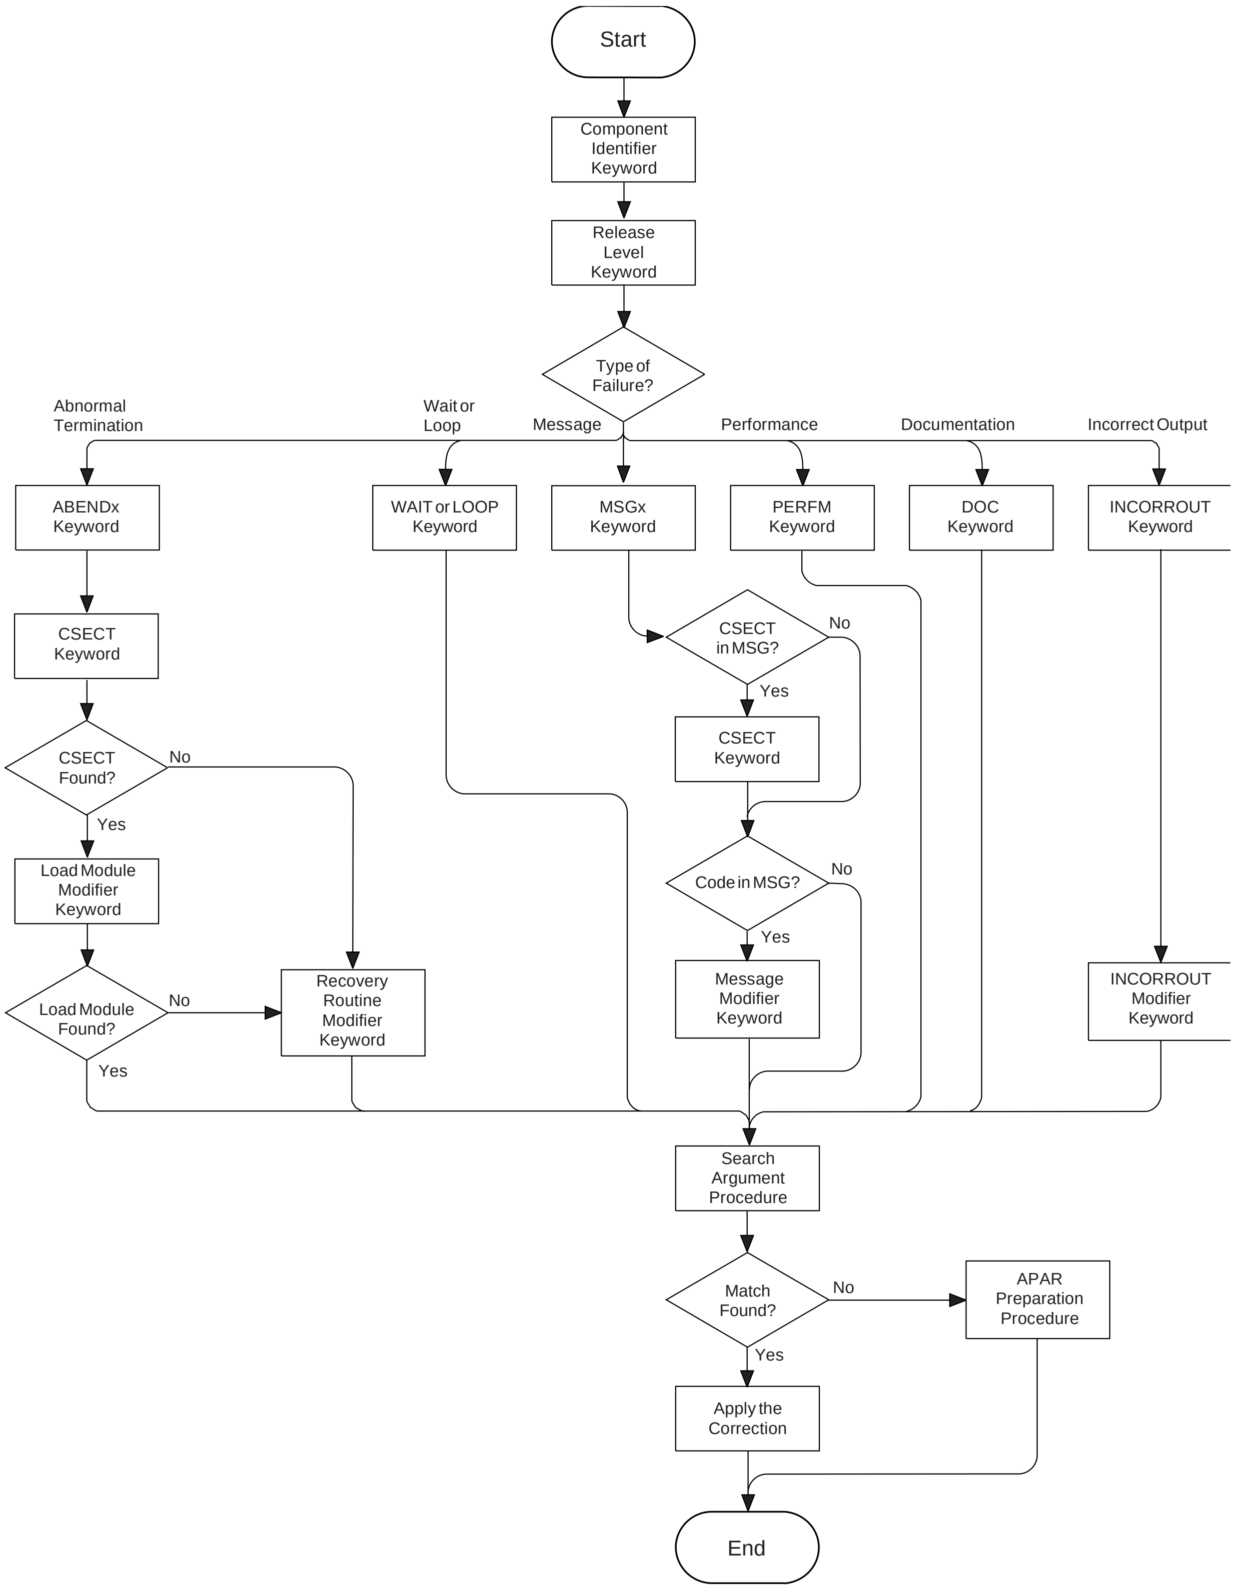

Figure 114. High-level flowchart of various sets of keywords

Use the following topics to build a keyword string for searching the IBM database for problems:

- "The component-identifier keyword" on page 1645
- "The release-level keyword" on page 1646

- "Type-of-failure keyword" on page 1646
- "The abend keyword, and its associated keywords" on page 1647
- "Wait and loop keywords" on page 1650
- "The message keyword" on page 1651
- "Performance keyword" on page 1653
- "Documentation keyword" on page 1653
- "Incorrect output keyword" on page 1654

Related concepts:

"The search argument process" on page 1640
Use this topic to understand how to search the RETAIN database.

"The keyword format" on page 1641
Searches can be performed using free format keywords or structured database (SDB) format keywords. Use this topic to understand how to perform searches using different keyword formats.

"APARs and PTFs" on page 1664
After a problem is confirmed an APAR can be raised and a PTF released. Use this topic to understand the APAR and PTF process.

Related reference:

"SDB format symptom-to-keyword cross reference" on page 1655
You can use structured database (SDB) formats to search the RETAIN database.

"IBM MQ component and resource manager identifiers" on page 1657
Use this topic as a reference for component-identifiers, and resource manager identifiers.

The component-identifier keyword:

You can use the component-identifier as a keyword to search the IBM documentation and software support database for known problems and solutions.

The *component-identifier keyword* identifies the library within the IBM software support database that contains *authorized program analysis reports* (APARs) and *program temporary fixes* (PTFs) for the product.

The component-identifier keyword for IBM MQ for z/OS is **5655R3600** .

This section describes how to determine the nine-digit component identifier keyword for your failure to verify that the problem was caused by IBM MQ for z/OS. If the component identifier is not 5655R3600, the problem could be caused by another product.

If the problem caused a dump, display the dump title, locate the COMP= label, and note the first five characters following that label. If these characters are **R3600** , the problem was caused by IBM MQ for z/OS. Append those five characters to **5655** and use this as the first keyword in your search argument.

```
ssnm,ABN=compltn-reason,U=userid,C=compid.release.comp-function,
M=module, LOC=loadmod.csect+csect_offset
```

If you cannot use the dump title, display the z/OS SYMPTOM STRING in the formatted dump. Note the nine characters following the PIDS/ label.

Related concepts:

"IBM MQ for z/OS dumps" on page 1735
Use this topic for information about the use of dumps in problem determination. It describes the steps you should take when looking at a dump produced by an IBM MQ for z/OS address space.

The release-level keyword:

You can use the release-level as a keyword to search the IBM documentation and software support database for known problems and solutions.

The *release-level keyword* narrows the symptom search to your specific release level. Using this keyword is optional, but suggested, when searching the IBM software support database. It is required, however, when an APAR is submitted.

Locate the three-digit release identifier in the dump title. It follows COMP= R3600, for example:

```
COMP= R3600. 710
```

Add the release-level to your keyword string, in one of the formats shown:

Free format
```
5655R3600  R710
```

Structured format
```
PIDS/ 5655R3600 LVLS/  710
```

Type-of-failure keyword:

You can use the type-of-failure as a keyword to search the IBM documentation and software support database for known problems and solutions.

To narrow your search, use one or more of the type-of-failure and modifier keywords to describe an external symptom of a program failure. The various types of failures are shown in Table 150. Use this table to find the name and page number of the keyword that best matches your problem.

Table 150. Types of IBM MQ for z/OS failures

Problem	Procedure
Abend of the subsystem or task	"The abend keyword, and its associated keywords" on page 1647
Unexpected program suspension	"Wait and loop keywords" on page 1650
Uncontrolled program looping (often signaled by repeating messages or output)	"Wait and loop keywords" on page 1650
Errors signaled by or associated with messages	"The message keyword" on page 1651
Performance degradation	"Performance keyword" on page 1653
Documentation problem	"Documentation keyword" on page 1653
Unexpected or missing output	"Incorrect output keyword" on page 1654

The abend keyword, and its associated keywords:

The abend keyword is often seen in association with other keywords. These keywords can be used together to form a keyword string.

Use the ABEND keyword when the subsystem or task terminates abnormally. This procedure describes how to locate the abend completion code and the abend reason code (if there is one), and how to use them in a set of keywords. Check the SYS1.LOGREC to determine how many abends there were. Sometimes an earlier abend causes a secondary abend that causes a dump. If no dump has been taken, try searching the database with a minimum symptom string (the component-identifier, and release-level keywords). If you cannot find any information that seems to relate to your problem, contact your IBM support center.

When an IBM MQ for z/OS abend occurs, you will see one of the following symptoms:
- An IEA911E message from z/OS, indicating that an SVC dump occurred. See "IEA911E message."
- The CSQV086E message QUEUE MANAGER ABNORMAL TERMINATION REASON=xxxxxxxx. See "CSQV086E message" on page 1648.
- "CSECT keyword" on page 1649
- "Load module modifier keyword" on page 1649
- "Recovery routine modifier keyword" on page 1650

IEA911E message:

The message code IEA911E can be analyzed to give further information about abends.

You can use the information from the IEA911E message to extract further details about the abend code. Use the following steps to assist with the analysis:
1. Use the `DISPLAY DUMP,TITLE` command on the console to display the SVC dump title for this abend, or use one of the methods described in "IBM MQ for z/OS dumps" on page 1735 to look at the dump title in the dump.

   Note: If the first five characters of the COMP field are not R3600, or the dump title is not of the same form as Figure 135 on page 1751 or Figure 136 on page 1752, the problem was not caused by IBM MQ for z/OS, or you are looking at the wrong dump.
2. Locate the 3-character completion code following the word ABND.
   - If the completion code is X'071', or X'122', the operator pressed the RESTART key or canceled the job, probably to break a loop. Verify that this is the case, and turn to "Wait and loop keywords" on page 1650.
   - Otherwise, add this to your keyword string, in one of the formats shown in this topic (in this example, X'0C4' is used):

     Free format
     ```
     5655R3600  R710 ABEND0C4
     ```

     Structured format
     ```
     PIDS/ 5655R3600 LVLS/ 710 AB/S00C4
     ```
3. Some abends also have reason codes. These reason codes are usually found in message CSQV086E, and register 15 at the time of the abend. Locate the reason code for the abend either:
   - In the 4-byte reason code field in a dump title generated by IBM MQ for z/OS
   - In the registers at time of error in the abstract information section of the dump
   - From the value of register 15 in the error summary display
4. If the completion code is X'5C6', review the diagnostic information for the reason code in IBM MQ for z/OS messages, completion, and reason codes. Follow any procedures recommended there.

If the completion code is anything else, and you have found a reason code, check the value against the description of the abend code in the *MVS System Codes* manual to see if it is valid for the abend completion code.

5. Add the reason code to the keyword string (in this example X'00E20015' is used):

   Free format
   ```
   5655R3600  R710 ABEND5C6 RC00E20015
   ```
   Structured format
   ```
   PIDS/ 5655R3600 LVLS/ 710 AB/S05C6 PRCS/00E20015
   ```
   Refer to “CSECT keyword” on page 1649.

CSQV086E message:

The text from the message code CSQV086E can be analyzed to give further information about abends.

You can use the information from the CSQV086E message to extract further details about the abend code. Use the following steps to assist with the analysis:

1. Issue the DISPLAY DUMP command to see whether any SVC dumps occurred near the time the message appeared. (See the *MVS System Commands* manual if necessary.)
2. If there was only one SVC dump for the abend, follow the procedure starting at step 1 on page 1647.
3. If there were two or more SVC dumps, follow the steps here.
   a. Read the sections under IBM MQ for z/OS messages, completion, and reason codes that describe the reason code appearing in your message, and any reason codes appearing in the SVC dump titles. Reason codes appear after the completion code in the SVC dump title. For an example, see “Analyzing the dump and interpreting dump titles” on page 1750.
   b. Compare the reason codes in the SVC dumps to determine which dump relates to the CSQV086E message.
   c. Use that SVC dump and follow the procedure starting at step 1 on page 1647.
4. If there were two or more different abends, follow the steps here:
   a. Determine which abend was the original cause by reviewing the time stamps in the SYS1.LOGREC entries.
   b. Use that SVC dump and follow the procedure starting at step 1 on page 1647.
5. If there were no SVC dumps for the abend, follow the steps here.
   a. Locate the 4-byte reason code in the message.
   b. Review the diagnostic information in IBM MQ for z/OS messages, completion, and reason codes. Follow any procedures recommended there.
   c. Add this to your keyword string, in one of the formats shown in this topic (in this example, a reason code of X'00D93001' is used):

      Free format
      ```
      5655R3600  R710 ABEND6C6 RC00D93001
      ```
      Structured format
      ```
      PIDS/ 5655R3600 LVLS/ 710 AB/S06C6 PRCS/00D93001
      ```
      Refer to “CSECT keyword” on page 1649.

CSECT keyword:

The CSECT keyword and parameter is often associated with an abend code and can assist with identifying where the abend problem occurred.

To find the name of the failing CSECT, locate the LOC= label; the second word following it is the CSECT name. For an example, see "Analyzing the dump and interpreting dump titles" on page 1750.

Any CSECT name you locate should begin with the letters CSQ or CMQ. If you find a CSECT name with a different prefix, the problem is probably not in IBM MQ for z/OS.

Add the CSECT name to your keyword string:

Free format
`5655R3600  R710 ABEND0C4` **`CSQVATRM`**

Structured format
`PIDS/ 5655R3600 LVLS/ 710 AB/S00C4` **`RIDS/CSQVATRM`**

If required, narrow your search further by referring to "Load module modifier keyword."

If you cannot find the CSECT, see "Recovery routine modifier keyword" on page 1650.

Load module modifier keyword:

The Load module modifier keyword and parameter is often associated with an abend code and can assist with identifying where the abend problem occurred.

Use the load module modifier keyword to identify the name of the load module involved if your search using the CSECT keyword was unsuccessful, or yielded too many possible matches:
- If your search was unsuccessful, replace the CSECT name with the load module name and try again.
- If your search yielded too many possible matches, add the load module name to your string to further narrow the search.

All IBM MQ for z/OS load module names begin with CSQ or CMQ. If you follow these instructions and find a load module name with a different prefix, the problem is in another product.

To locate the load module name, locate the first word following the label LOC=. This is the load module name, and it precedes the CSECT name. (For an example, see "Analyzing the dump and interpreting dump titles" on page 1750.)

Add the load module name to your keyword string, or substitute it for the CSECT name as appropriate. If you are using the structured format, follow the name of the module with the characters #L to indicate that this is a load module. Search the database again using the revised keyword string. (See "Searching the IBM database for similar problems, and solutions" on page 1639.)

Free format
`5655R3600  R710 ABEND5C6 RC00E50013` **`CSQSLD1`** `CSQSVSTK` (with load module name and then CSECT name)

`5655R3600  R710 ABEND5C6 RC00E50013` **`CSQSLD1`** (with load module name only)

Structured format
`PIDS/ 5655R3600 LVLS/ 710 AB/S05C6 PRCS/00E50013` **`RIDS/CSQSLD1#L`** `RIDS/CSQSVSTK` (with load module name and then CSECT name)

`PIDS/ 5655R3600 LVLS/ 710 AB/S05C6 PRCS/00E50013` **`RIDS/CSQSLD1#L`** (with load module name only)

Recovery routine modifier keyword:

The Recovery routine modifier keyword and parameter is often associated with an abend code and can assist with identifying where the abend problem occurred.

Include the name of the recovery routine only when you could not determine the names of the CSECT and load module involved at the time of failure, after looking in both the SVC dump and the SYS1.LOGREC entry.

To obtain the recovery routine name, locate the area of the dump title containing the symbol M=. The word following this identifies the functional recovery routine (FRR) or the extended specify task abnormal exit (ESTAE). For an example, see "Analyzing the dump and interpreting dump titles" on page 1750.

Add this word to your keyword string. If you are using the structured format, follow the name of the module with the characters #R to indicate that this is a recovery routine. Search the database (see "Searching the IBM database for similar problems, and solutions" on page 1639).

Free format

```
5655R3600  R710 ABEND5C6 RC00E20015 CSQTFRCV
```

Structured format

```
PIDS/ 5655R3600 LVLS/ 710 AB/S05C6 PRCS/00E20015 RIDS/CSQTFRCV#R
```

Wait and loop keywords:

The keywords wait and loop can be used as part of a string for searching the IBM documentation and IBM software support database. This can assist in identifying known problems and resolutions.

If the problem occurred immediately after you did something an IBM MQ manual told you to do, the problem might be related to the documentation. If you think that this is the case, see "Documentation keyword" on page 1653.

If you have verified that the wait or loop problem cannot be resolved through other means, use the following procedure:

1. Add WAIT or LOOP to your keyword string, in one of the formats shown in this topic (in this example **WAIT** is used).

   Free format

   ```
   5655R3600  R710 WAIT
   ```

   Structured format

   ```
   PIDS/ 5655R3600 LVLS/ 710 WAIT
   ```
2. See "Searching the IBM database for similar problems, and solutions" on page 1639.

The message keyword:

The message keyword can be used to search the IBM documentation and software support database for known problems and solutions

Use the MSG keyword if an error is associated with an IBM MQ for z/OS message. If you received multiple messages for one error, search the database using the first message issued. If unsuccessful, search the database using the next message, then the next, and so on.

To see if other messages related to your problem have been issued, check the console for IBM MQ for z/OS messages, as well as messages issued by other products. If any message is prefixed with "IEC⌂, indicating it was issued by data management services, check the SYSLOG for messages that identify associated data set problems. SYSLOG can also help to diagnose user errors.

If your message was issued immediately after you did something that an IBM MQ manual told you to do, the problem might be related to the documentation rather than to the message. If this is the case, refer to “Documentation keyword” on page 1653. Otherwise, compare the message prefix with those shown in the table Message Prefixes to determine the appropriate procedure to follow.

Table 151. Message prefixes

Prefix	**Component**	**Procedure**
AMQ	IBM MQ (not z/OS)	Consult IBM MQ messages
AMT	IBM MQ	Consult the Business Integration - IBM MQ SupportPacs for details of the MA0F SupportPac

Related concepts:

"Procedure for IBM MQ for z/OS messages"
The IBM MQ messages can be analyzed for the possible cause of an error. To do this you must analyze the text of the message and use the components of the text to search the IBM software support database.

Procedure for IBM MQ for z/OS messages:

The IBM MQ messages can be analyzed for the possible cause of an error. To do this you must analyze the text of the message and use the components of the text to search the IBM software support database.

Analyze the text of the any IBM MQ messages and use the parts of the text, for example CSECT names, variables and message codes, to search IBM software support database for known problems and resolutions.

1. Check whether the name of the CSECT issuing the message appears. This name follows the message number. If no CSECT name appears, only one CSECT can issue this message.
2. Determine whether the message contains any variables, such as return or reason codes.
3. If no CSECT name appears, add the message number to your keyword string, in one of the formats shown in this topic (in this example, message CSQJ006I is used):

   Free format
   ```
   5655R3600  R710 MSGCSQJ006I
   ```
   Structured format
   ```
   PIDS/ 5655R3600 LVLS/ R710 MS/CSQJ006I
   ```
4. If a CSECT name does appear, add both the message number and the CSECT name to your keyword string, in one of the formats shown here (in this example, a message number of CSQJ311I and a CSECT name of CSQJC005 are used):

   Free format
   ```
   5655R3600  R710 MSGCSQJ311I CSQJC005
   ```
   Structured format
   ```
   PIDS/ 5655R3600 LVLS/ 710 MS/CSQJ311I RIDS/CSQJC005
   ```
5. If the message contains return or reason codes, add these to your keyword string, in one of the formats shown in this topic:

   Free format
   ```
   5655R3600  R710 MSGCSQM002I RCE
   ```
   Structured format
   ```
   PIDS/ 5655R3600 LVLS/ R710 MS/CSQM002I PRCS/0000000E
   ```
6. If the message contains any other types of variables, append them to your keyword string.

   Free format
   ```
   5655R3600  R710 MSGCSQJ104I OPEN
   ```
   Structured format
   ```
   PIDS/ 5655R3600 LVLS/ R710 MS/CSQJ1041 MS/OPEN
   ```
7. See "Searching the IBM database for similar problems, and solutions" on page 1639.

Performance keyword:

The performance keyword can be used to search the IBM documentation and software support database for known problems and solutions.

You can resolve most performance problems through system tuning, which should be handled by the IBM MQ for z/OS system administrator. Before following the procedure show in this topic, use this checklist to verify that the performance problem cannot be resolved through other means:

- See "Dealing with performance problems on z/OS" on page 1755 to determine if you can change the way you have designed your IBM MQ for z/OS subsystem and applications to improve their performance.
- Verify that the performance problem is not related to a WAIT or LOOP. See "Dealing with applications that are running slowly or have stopped on z/OS" on page 1756.
- If the problem occurred immediately after you did something an IBM MQ manual told you to do, the problem might be related to the manual. See "Documentation keyword."
- If performance degraded after someone tuned IBM MQ for z/OS, verify that the tuning options selected were appropriate. Perhaps you can resolve the problem by choosing other options.

If you have verified that the performance problem cannot be resolved through other means, use the following procedure:

1. Record the actual performance, expected performance, and source of expected performance criteria.
2. Add PERFM to your keyword string, as shown in the following example, and see "Searching the IBM database for similar problems, and solutions" on page 1639.

   Free format
   ```
   5655R3600  R710 PERFM
   ```
   Structured format
   ```
   PIDS/ 5655R3600 LVLS/ 710 PERFM
   ```
3. If required, you can narrow your search by adding free-format keywords that describe what you were doing when you experienced the performance problem.

Documentation keyword:

The documentation keyword can be used to search the IBM software support database for known problems and solutions.

The DOC keyword identifies problems caused by incorrect or missing information in an IBM MQ manual. It is possible that a documentation problem could be detected when trying to resolve problems with messages, incorrect output, and performance.

Use the following procedure if you need to use the DOC keyword in your keyword string:

1. Locate the incomplete or erroneous information. Note the page, or topic number, and describe the error and the resulting problem.
2. Add the document number, hyphens omitted, to your keyword string, in one of the formats shown here (in this example, the document number for this manual (GC34-6600-01) is used):

   Free format
   ```
   5655R3600  R710 DOC GC34660001
   ```
   Structured format
   ```
   PIDS/ 5655R3600 LVLS/ 710 PUBS/ GC34660001
   ```

   See "Searching the IBM database for similar problems, and solutions" on page 1639.

   If your search is unsuccessful, follow Step 3 on page 1654.

3. Broaden your search by replacing the last two digits with two asterisks (**). This searches for all problems on that document, rather than on a specific release of the document.

   Free format
   ```
   5655R3600  R710 DOC GC346600 **
   ```

   Structured format
   ```
   PIDS/ 5655R3600 LVLS/ 710 PUBS/GC346600 **
   ```

   If your search is unsuccessful, follow Step 4.
4. If the problem is severe, consider initiating a DOC APAR. Use the information gathered in Step 1, and see "APARs and PTFs" on page 1664.
5. If the problem is less severe, send your comments electronically by clicking the `Feedback` option at the end of each product documentation topic.

   Corrections resulting from readers' comments are included in future editions of the manual but are not included in the software support database.

Incorrect output keyword:

You can use the incorrect output keywords to search the IBM software support database for known problems and solutions.

Use the INCORROUT keyword when output was expected but not received, or when output was different from expected. However, if this problem occurred after you did something that IBM MQ documentation told you to do, the documentation could be in error. If this is the case, see "Documentation keyword" on page 1653.

1. Add **INCORROUT** to your existing keyword string.

   Free format
   ```
   5655R3600  R710 INCORROUT
   ```

   Structured format
   ```
   PIDS/ 5655R3600 LVLS/ 710 INCORROUT
   ```
2. Determine the function and secondary modifier keywords for your problem from Table 152 and Table 153 on page 1655.
3. Add the modifier keywords to your string and use it to search the database. See "Searching the IBM database for similar problems, and solutions" on page 1639.

   Free format
   ```
   5655R3600  R710 INCORROUT RECOVERY BACKOUT
   ```

   Structured format
   ```
   PIDS/ 5655R3600 LVLS/ 710 INCORROUT RECOVERY BACKOUT
   ```

Table 152. INCORROUT modifier keywords: RECOVERY

Secondary keywords	Problem occurrence
none	During recovery
BACKOUT	At backout time
CHECKPOINT	At checkpoint time
COMMIT	At commit time
LOGGING	During logging
RECOVER	During attempt to recover in-doubt
RESTART	During restart process

Table 153. INCORROUT modifier keywords: UTILITY

Secondary keywords	Problem occurrence
none	While running a utility
CSQ1LOGP	While running CSQ1LOGP
CHANGE LOG	While using the Change Log Inventory utility or CSQJUFMT
PRINT LOGMAP	While using the Print Log Map utility
COMMAND	While running the COMMAND function or SDEFS
COPY	While running the COPY function or SCOPY
EMPTY	While running the EMPTY function
FORMAT	While running the FORMAT function, COPYPAGE, RESETPAGE or PAGEINFO
LOAD	While running the LOAD function
CSQUDLQH	While running the dead.letter.queue handler
CSQ5PQSG	While running CSQ5PQSG

SDB format symptom-to-keyword cross reference

You can use structured database (SDB) formats to search the RETAIN database.

Structured database (SDB) format is one of the formats that you can use for searching the RETAIN database. Structured symptoms are also called RETAIN symptoms and "failure keywords⌂. Table 154 lists which prefix keyword to use for which symptom.

“Searching the IBM database for similar problems, and solutions” on page 1639 provides details about searching RETAIN.

Table 154. SDB format symptom-to-keyword cross-reference

Symptom	Keyword	Symptom	Keyword
abend	AB/	access method	RIDS/
address	ADRS/	APAR	PTFS/
assembler macro	RIDS/	assembler message	MS/
CLIST	RIDS/	command	PCSS/
compiler message	MS/	completion code	PRCS/

wait (coded)	WS/	wait (uncoded)	WAIT*

Note: An asterisk (*) indicates that there is no prefix keyword for this type of problem. Use the type-of-failure keyword shown for searches of the software support database.

IBM MQ component and resource manager identifiers

Use this topic as a reference for component-identifiers, and resource manager identifiers.

The component-identifier keyword identifies the library within the IBM software support database that contains *authorized program analysis reports* (APARs) and *program temporary fixes* (PTFs) for the product. Resource manager identifiers (RMIDs) are used to limit the volume of data collected in a trace.

Table 155. IBM MQ component and resource manager identifiers

ID	Prefix	Hex ID	Component name	RMID
-	AMT	-	AMI	-

Contacting IBM Software Support

Grade the severity of the problem, describe the problem and gather background information, then report the problem to IBM Software Support.

Before you begin

Ensure that your company has an active IBM software subscription and support contract, and that you are authorized to submit problems to IBM:

- If you use IBM distributed software products (including, but not limited to, Tivoli, Lotus, and Rational® products, as well as Db2 and WebSphere products that run on Windows or UNIX and Linux operating systems), enroll in Passport Advantage® in one of the following ways:
  - Online: Go to the Passport Advantage web page, then click the **Subscription and Support** tab.
  - By telephone: Go to the Software Support Handbook, click **Contacts**, then **Worldwide contacts**.
- If you use IBM eServer software products, you can purchase a software subscription and support agreement by working directly with an IBM marketing representative or an IBM Business Partner. These eServer products include, but are not limited to, Db2 and WebSphere products that run in zSeries, pSeries, and iSeries environments.
- You might also have an IBMLink, CATIA, Linux, S/390, iSeries, pSeries, zSeries, or other support agreement.
- If you are not sure what type of software subscription and support contract you need, call 1-800-IBMSERV (1-800-426-7378) in the United States or, from other countries, go to the Software Support Handbook, click **Contacts**, then **Worldwide contacts**.

About this task

Follow the steps in this topic to fully describe the problem and contact IBM Software Support.

If the problem that you submit is for a software defect or for missing or inaccurate documentation, IBM Software Support might create an Authorized Program Analysis Report (APAR). The APAR describes the problem in detail. Whenever possible, IBM Software Support provides a workaround for you to implement until the APAR is resolved and a fix is delivered.

IBM publishes resolved APARs on the IBM product support web pages daily, so that other users who experience the same problem can benefit from the same resolutions.

Procedure

1. Determine the business severity level for the problem.

   When you report a problem to IBM, you will be asked to supply a severity level. Therefore, you need to understand and assess the effect on your business of the problem that you are reporting. Use the following criteria:

Severity	**Effect on business**
Severity 1	**Critical** effect on business: You are unable to use the program, resulting in a critical effect on operations. This condition requires an immediate solution.
Severity 2	**Significant** effect on business: The program is usable but is severely limited.
Severity 3	**Some** effect on business: The program is usable with less significant features (not critical to operations) unavailable.
Severity 4	**Minimal** effect on business: The problem has little effect on operations, or a reasonable workaround to the problem has been implemented.

When deciding the severity of the problem, take care not to understate it, or to overstate it. The support center procedures depend on the severity level so that the most appropriate use can be made of the center's skills and resources. A severity level 1 problem is normally dealt with immediately.

2. Describe the problem and gather background information.

   You might find the information you need in your own in-house tracking system for problems. You can also use the IBM Support Assistant to collect data automatically, as described in the next step, and you can use a "Problem reporting sheet" on page 1660.

   Be as specific as possible. Include all relevant background information so that IBM Software Support specialists can help you to solve the problem efficiently. To save time, know the answers to these questions:

   - What was the source of the problem within your system software; that is, the program that seems to be the cause of the problem.
   - What software versions were you running when the problem occurred?
   - Do you have logs, traces, and messages that are related to the problem symptoms?
   - Can the problem be re-created? If so, what steps led to the failure?
   - Have any changes been made to the system? For example:
     - Hardware changes
     - Operating system upgrades
     - Networking software updates
     - Changes in the level of licensed programs
     - PTFs applied
     - Additional features used
     - Application programs changed
     - Unusual operator action
     - z/OS Regenerations
   - Are you currently using a workaround for this problem? If so, be prepared to explain it when you report the problem.

   z/OS See also "Extra inputs needed when reporting z/OS problems" on page 1661.

3. Report the problem to IBM Software Support.

   You can submit a problem report in one of three ways:

   - Use the IBM Support Assistant. To collect data automatically and submit a request to IBM Software Support, open the IBM Support Assistant and click **Service**. For more information, see "IBM Support Assistant (ISA)" on page 1635.
   - Submit a New service request online.
   - Telephone the support center for your country. To find the number to call, go to the Software Support Handbook, click **Contacts**, then **Worldwide contacts**. Your first contact at the support center is the call receipt operator, who takes initial details and puts your problem on a queue. You are then contacted by a support center representative.

When you contact the support center, whether by telephone or electronically, you need to state the name of your organization and your *access code*. Your access code is a unique code authorizing you to use IBM Software Support, and you provide it every time you contact the center. This information is used to access your customer profile, which contains information about your address, relevant contact names, telephone numbers, and details of the IBM products at your installation.

The support center needs to know whether this is a new problem, or a further communication regarding an existing one. If it is new, it is assigned a unique *incident number*. A *problem management record* (PMR) is opened on the RETAIN system, where all activity associated with your problem is recorded. The problem remains "open" until you are in agreement with the support center that it has been resolved and can now be closed. Make a note of the incident number. The support center expects you to quote the incident number in all future communications connected with this problem.

You might be asked to give values from a formatted dump or trace table, or to carry out some special activity, for example to set a trap, or to use trace with a specific type of selectivity, and then to report the results. You will be given guidance by the support center on how to obtain this information.

What to do next

You can inquire any time at your support center on how your PMR is progressing, particularly if it is a problem of high severity.

How your problem is then progressed depends on its nature. The representative who handles the problem gives you guidance. The possibilities are described in "What happens next" on page 1663.

Related tasks:

"Getting product fixes" on page 1665
A product fix might be available to resolve your problem. You can determine what fixes are available by launching a query from the IBM Support Assistant.

Problem reporting sheet

A problem reporting sheet helps you gather the background information that you need when reporting a problem to the IBM support center.

There are two advantages to using a problem reporting sheet when you contact the IBM support center:

- In a telephone conversation, you are better prepared to respond to questions if you have all your findings before you on a sheet of paper.
- You can use the information for planning, organizing, and establishing your priorities for controlling and resolving the problem.

```

Figure 115. Sample problem reporting sheet

Extra inputs needed when reporting z/OS problems

z/OS

When you report an IBM MQ for z/OS problem to IBM Support, you need to provide additional inputs to those that are needed for other platforms.

The core documentation that is required for reporting an IBM MQ problem on any platform is described in “Contacting IBM Software Support” on page 1658.

As a rule, the total documentation you need to submit for a problem includes all the material you need yourself to do problem determination. Some of the documentation is common to all IBM MQ for z/OS problems, and some is specific to particular types of problem.

Make sure that the problem you have described can be seen in the documentation you send. If the problem has ambiguous symptoms, you need to reveal the sequence of events leading to the failure. Tracing is valuable in this respect but you need to provide details that trace cannot give. You are encouraged to annotate your documentation, if your annotation is legible and does not cover up vital information. You can highlight any data in hardcopy you send, using transparent highlighting markers. You can also write notes in the margins, preferably using a red pen so that the notes are not overlooked.

Finally, note that if you send too little documentation, or if it is unreadable, the support team will have to return your problem marked "insufficient documentation". It is, therefore, worthwhile preparing your documentation carefully and sending everything relevant to the problem.

The additional documentation needed is described in the next section. However, these are only guidelines. You must find out from the IBM support center representative precisely what documentation you need to send for your specific problem.

Additional documentation needed for problems with IBM MQ for z/OS

Here is a list of the additional documentation you might be asked to submit:

- Any hardcopy or softcopy illustrating the symptoms of the problem.
- The dump of the problem, see “Getting a dump” on page 1736.
- The appropriate SYS1.LOGREC records, see “SYS1.LOGREC information” on page 1754.
- The system log.
- A portion of the IBM MQ for z/OS job log.
- Trace records, see “Using trace for problem determination on z/OS” on page 1697.
- Trace information produced by the CICS or IMS adapter, see “Other types of trace” on page 1703.
- Buffer pool statistics, see the sections on using SMF and type 115 records in Configuring z/OS.
- Listings of relevant application programs.
- A list of PTFs and APARs applied.

  Use the following sample JCL produce a list of all the PTFs, APARs, user modifications, and product code that has been installed in the global zone specified by SMPCSI:

  ```
  //SMPELIST EXEC PGM=GIMSMP,REGION=4096K
  //SMPCSI  DD DSN=shlqual.global.csi,DISP=SHR
  //SYSPRINT DD SYSOUT=*
  //SMPCNTL  DD *
  SET BOUNDARY(GLOBAL) .
  LIST
  SYSMODS
  APARS
  FUNCTIONS
  PTFS
  USERMODS
  ALLZONES .
  /*
  ```
- Dump of coupling facility administration structure, see Figure 132 on page 1738.
- Dump of coupling facility application structure, see Figure 132 on page 1738.
- Dump of other queue managers in queue-sharing group, see Figure 128 on page 1737.
- Definitions of the objects in your system.

  You can find these by using the DISPLAY command for each type of object, for example:

  ```
  DISPLAY QUEUE (*) ALL
  ```

  Or, if you regularly make a backup of your object using the MAKEDEF feature of CSQUTIL COMMAND function, the output from that backup job.
- Your IBM MQ Db2 tables.

You can get these by using the sample job CSQ45STB in thlqual.SCSQPROCS to produce a report of all the Db2 tables used by IBM MQ.

You might also be asked for the IBM MQ for z/OS symptom string, or for any keywords associated with the problem. The primary keywords are ABEND, WAIT, LOOP, PERFM, INCORROUT, MSG, and DOC, corresponding exactly with the problem classification types used in “Building a keyword string” on page 1643. Strings containing other keywords are also useful. These are not predefined, and might include such items as a message or message number, an abend code, any parameters known to be associated with the problem, or, for example, STARTUP or INITIALIZATION. The keywords are then used by IBM Support as search arguments, to see if your problem is a known one.

Because of the size of SVC dumps in the cross memory environment, you might want to transfer the SYS1.DUMPxx data set to a tape or like device. You can use the PRDMP service aid program to transfer the SYS1.DUMPxx data set contents to another data set for archiving until the problem is resolved. Alternatively, your support center representative might give you the address of an FTP site where you can send your dump electronically. Each tape should be sent with the following associated information:

- The PMR number assigned by IBM
- A list of data sets on the tape (application source program, JCL, or data)
- A list of how the tape was made, including:
  - The exact JCL listing or the commands used
  - The recording mode and density
  - Tape labeling
  - The record format, logical record length, and block size used for each data set

When the support team receives the package, this is noted on your PMR record on the RETAIN system.

What happens next

After you contact the IBM support center, details of your problem are passed to the appropriate support group. The problems are dealt with in order of receipt and severity level.

At first, an IBM support center representative uses the keywords that you have provided to search the RETAIN database. If your problem is found to be one already known to IBM, and a fix has been devised for it, a *program temporary fix* (PTF) can be dispatched to you quickly. Alternatively, you might be asked to try running your installation using different settings.

If the RETAIN search is unsuccessful, you might be asked to provide more information about your problem.

If the problem requires a change to the code or documentation, an *authorized program analysis report* (APAR) is submitted. This is dealt with by the IBM support group or *change team* and provides a means of tracking the change.

It might be necessary to have several follow-up communications, depending on the complexity of the symptoms and your system environment. In every case, the actions taken by you and the support center are entered in the original PMR. The representative can then be acquainted with the full history of the problem before the next communication.

APARs and PTFs

After a problem is confirmed an APAR can be raised and a PTF released. Use this topic to understand the APAR and PTF process.

An APAR

An *authorized program analysis report* (APAR) is the means by which a problem with an IBM program is documented, tracked, and corrected. It is also used to track problems with IBM documents.

An APAR is raised by the IBM change team when a new problem is reported for which a program or documentation change is required. It is separate to the PMR that is raised when you report first report the problem.

When the change team solves the problem, they might produce a local fix enabling you to get your system running properly again. Finally, a *program temporary fix* (PTF) is produced to replace the module in error, and the APAR is closed.

The APAR process

The first step in the APAR process is that an IBM support center representative enters your APAR into the RETAIN system. The APAR text contains a description of your problem. If you have found a means of getting round the problem, details of this are entered as well. Your name is also entered, so that the support center knows whom to contact if the change team needs to ask anything further about the APAR documentation.

When the APAR has been entered, you are given an APAR number. You must write this number on all the documentation you submit to the change team. This number is always associated with the APAR and its resolution and, if a code change is required, with the fix as well.

During the APAR process, the change team might ask you to test the fix on your system.

Lastly, you need to apply the PTF resulting from the APAR when it becomes available.

Applying the fix

When the change team have created a fix for your problem, they might want you to test it on your system.

When the team is confident that the fix is satisfactory, the APAR is certified and the APAR is closed.

Occasionally, the solution to the APAR requires a change to the documentation only. In some circumstances, the APAR might be closed with a classification code of **FIN**, which means that if there is a subsequent release of IBM MQ, a fix for this problem can be provided at this time.

The APAR becomes a PTF

If the solution requires a code change to the current release, when the APAR is closed the change is distributed as a PTF.

If you want a PTF to resolve a specific problem, you can order it explicitly by its PTF number through the IBM support center. For more information, see the IBM MQ Support, Migration PTFs web page.

Getting product fixes

A product fix might be available to resolve your problem. You can determine what fixes are available by launching a query from the IBM Support Assistant.

Before you begin

1. If you have not already installed the IBM Support Assistant, you can find instructions about how to do so in "Installing the IBM Support Assistant (ISA)" on page 1636.
2. Install the IBM Support Assistant WMQ plug-in by following the instructions in "Updating the IBM Support Assistant (ISA)" on page 1637.

About this task

To launch a query from the IBM Support Assistant:

1. Open the IBM Support Assistant from the Start menu by clicking **Programs** > **IBM Support Assistant** > **IBM Support Assistant**.
2. Click **Product Information**, **WMQ**, **Support page**, **Download**, then **Recommended fixes**. This Web page provides links to the latest available maintenance for the in-service products.

To receive weekly e-mail notifications about fixes and other news about IBM products, follow these steps.

Procedure

1. From the support site (IBM MQ support web page), click **Subscribe to this product** in the Notifications box on the page.
2. If you have already registered for "Notifications", skip to the next step. If you have not registered, click **register now** on the sign-in page and follow the on-screen instructions.
3. Sign in to "My notifications".
4. Click the **Subscribe** tab. A list of products families is shown.
5. In the Software column, click **WebSphere**. A list of products is shown.
6. Select the product for which you want to receive notifications (for example, **IBM MQ**), then click **Continue**.
7. Set options to determine what notifications you receive, how often you receive them, and to which folder they are saved, then click **Submit**.

Related concepts:

"Troubleshooting and support" on page 1275
If you are having problems with your queue manager network or IBM MQ applications, use the techniques described to help you diagnose and solve the problems.

"Troubleshooting overview" on page 1276
Troubleshooting is the process of finding and eliminating the cause of a problem. Whenever you have a problem with your IBM software, the troubleshooting process begins as soon as you ask yourself "what happened?"

Related tasks:

"Contacting IBM Software Support" on page 1658
Grade the severity of the problem, describe the problem and gather background information, then report the problem to IBM Software Support.

"Searching knowledge bases" on page 1638
If you have a problem with your IBM software, you want it resolved quickly. Begin by searching the available knowledge bases to determine whether the resolution to your problem is already documented.

Related information:

Applying and removing maintenance

First Failure Support Technology (FFST

First Failure Support Technology™ (FFST) for IBM MQ provides information about events that, in the case of an error, can help IBM support personnel to diagnose the problem.

First Failure Data Capture (FFDC) provides an automated snapshot of the system environment when an internal event occurs. In the case of an error, this snapshot is used by IBM support personnel to provide a better understanding of the state of the system and IBM MQ when the problem occurred.

The information about an event is contained in an FFST file. In IBM MQ, FFST files have a file type of FDC. FFST files do not always indicate an error. An FFST might be informational.

Monitoring and housekeeping

Here are some tips to help you with managing FFST events:

- Monitor FFST events for your system, and ensure that appropriate and timely remedial action is taken when an event occurs. In some cases, the FDC files might be expected and can therefore be ignored, for example FFST events that arise when IBM MQ processes are ended by the user. By appropriate monitoring, you can determine which events are expected, and which events are not.
- FFST events are also produced for events outside IBM MQ. For example, if there is a problem with the IO subsystem or network, this problem can be reported in an FDC type file. These types of event are outside the control of IBM MQ and you might need to engage third parties to investigate the root cause.
- Ensure that good housekeeping of FFST files is carried out. The files must be archived and the directory or folder must be cleared to ensure that only the most recent and relevant FDC files are available, should the support team need them.

Use the information in the following links to find out the names, locations, and contents of FFST files in different platforms.

- "FFST: IBM MQ classes for JMS" on page 1667
- Windows "FFST: IBM MQ for Windows" on page 1670
- UNIX Linux "FFST: IBM MQ for UNIX and Linux systems" on page 1672

- "FFST: IBM MQ for HP Integrity NonStop Server" on page 1676

Related concepts:

"Troubleshooting and support" on page 1275
If you are having problems with your queue manager network or IBM MQ applications, use the techniques described to help you diagnose and solve the problems.

"Troubleshooting overview" on page 1276
Troubleshooting is the process of finding and eliminating the cause of a problem. Whenever you have a problem with your IBM software, the troubleshooting process begins as soon as you ask yourself "what happened?"

"Using logs" on page 1678
There are a variety of logs that you can use to help with problem determination and troubleshooting.

z/OS "Problem determination on z/OS" on page 1724
IBM MQ for z/OS, CICS, Db2, and IMS produce diagnostic information which can be used for problem determination.

Related tasks:

"Using trace" on page 1686
You can use different types of trace to help you with problem determination and troubleshooting.

"Searching knowledge bases" on page 1638
If you have a problem with your IBM software, you want it resolved quickly. Begin by searching the available knowledge bases to determine whether the resolution to your problem is already documented.

"Contacting IBM Software Support" on page 1658
Grade the severity of the problem, describe the problem and gather background information, then report the problem to IBM Software Support.

FFST: IBM MQ classes for JMS

Describes the name, location, and contents of the First Failure Support Technology (FFST) files that are generated by the IBM MQ classes for JMS.

When using the IBM MQ classes for JMS, FFST information is recorded in a file in a directory that is called `FFDC`, which by default is a subdirectory of the current working directory for the IBM MQ classes for JMS application that was running when the FFST was generated. If the property com.ibm.msg.client.commonservices.trace.outputName has been set in the IBM MQ classes for JMS configuration file, the FFDC directory is a subdirectory of the directory that the property points to. For information about the IBM MQ classes for JMS , see The IBM MQ classes for JMS configuration file.

An FFST file contains one FFST record. Each FFST record contains information about an error that is normally severe, and possibly unrecoverable. These records typically indicate either a configuration problem with the system or an internal error within the IBM MQ classes for JMS .

FFST files are named `JMSC` *`nnnn`*`.FDC`, where *nnnn* starts at 1. If the full file name already exists, this value is incremented by one until a unique FFST file name is found.

An instance of an IBM MQ classes for JMS application writes FFST information to multiple FFST files. If multiple errors occur during a single execution of the application, each FFST record is written to a different FFST file.

Sections of an FFST record

An FFST record that is generated by the IBM MQ classes for JMS contains the following sections:

The header
A header, indicating the time when the FFST record was created, the platform that the IBM MQ classes for JMS application is running on, and the internal method that was being called. The header also contains a probe identifier, which uniquely identifies the place within the IBM MQ classes for JMS that generated the FFST record.

Data Some internal data that is associated with the FFST record.

Version information
Information about the version of the IBM MQ classes for JMS being used by the application that generated the FFST record.

Stack Trace
The Java stack trace for the thread that generated the FFST record.

Property Store Contents
A list of all of the Java system properties that have been set on the Java Runtime Environment that the IBM MQ classes for JMS application is running in.

WorkQueueMananger Contents
Information about the internal thread pool that is used by the IBM MQ classes for JMS .

Runtime properties
Details about the amount of memory and the number of processors available on the system where the IBM MQ classes for JMS application is running.

Component Manager Contents
Some information about the internal components that are loaded by the IBM MQ classes for JMS .

Provider Specific information
Information about all of the active JMS Connections, JMS Sessions, MessageProducer, and MessageConsumer objects currently being used by the IBM MQ classes for JMS application that was running when the FFST was generated. This information includes the name of the queue manager that JMS Connections and JMS Sessions are connected to, and the name of the IBM MQ queue or topic objects that are being used by MessageProducers and MessageConsumers.

All Thread information
Details about the state of all of the active threads in the Java Runtime Environment that the IBM MQ classes for JMS application was running in when the FFST record was generated. The name of each thread is shown, together with a Java stack trace for every thread.

Example FFST log file

A typical FFST log is shown in Figure 116 on page 1669

Overview of JMS System
Num. Connections : 3
```

The information in the header, Data, and Stack Trace sections of the FFST record are used by IBM to assist in problem determination. In many cases, there is little that the system administrator can do when an FFST record is generated, apart from raising problems through the IBM Support Center.

Suppressing FFST records

An FFST file that is generated by the IBM MQ classes for JMS contain one FFST record. If a problem occurs multiple times during the execution of an IBM MQ classes for JMS application, multiple FFST files with the same probe identifier are generated. This might not be desirable. The property com.ibm.msg.client.commonservices.ffst.suppress can be used to suppress the production of FFST files. This property must be set in the IBM MQ classes for JMS configuration file used by the application, and can take the following values:

0: Output all FFDC files (default).

-1: Output only the first FFST file for a probe identifier.

integer: Suppress all FFST files for a probe identifier except those files that are a multiple of this number.

FFST: IBM MQ for Windows

Describes the name, location, and contents of the First Failure Support Technology (FFST) files for Windows systems.

In IBM MQ for Windows, FFST information is recorded in a file in the `C:\Program Files\IBM\WebSphere MQ\errors` directory.

An FFST file contains one or more records. Each FFST record contains information about an error that is normally severe, and possibly unrecoverable. These records typically indicate either a configuration problem with the system or an IBM MQ internal error.

FFST files are named `AMQ` *`nnnnn.mm`*`.FDC`, where:

nnnnn
: Is the ID of the process reporting the error

mm
: Starts at 0. If the full file name already exists, this value is incremented by one until a unique FFST file name is found. An FFST file name can already exist if a process is reused.

An instance of a process will write all FFST information to the same FFST file. If multiple errors occur during a single execution of the process, an FFST file can contain many records.

When a process writes an FFST record it also sends a record to the Event Log. The record contains the name of the FFST file to assist in automatic problem tracking. The Event log entry is made at the application level.

A typical FFST log is shown in Figure 117 on page 1671.

Figure 117. Sample IBM MQ for Windows First Failure Symptom Report

The Function Stack and Trace History are used by IBM to assist in problem determination. In many cases there is little that the system administrator can do when an FFST record is generated, apart from raising problems through the IBM Support Center.

In certain circumstances a small dump file can be generated in addition to an FFST file and placed in the `C:\Program Files\IBM\WebSphere MQ\errors` directory. A dump file will have the same name as the FFST file, in the form `AMQnnnnn.mm.dmp`. These files can be used by IBM to assist in problem determination.

First Failure Support Technology (FFST) files and Windows clients

The files are produced already formatted and are in the errors subdirectory of the IBM MQ MQI client installation directory.

These are normally severe, unrecoverable errors and indicate either a configuration problem with the system or an IBM MQ internal error.

The files are named `AMQnnnnn.mm.FDC`, where:
- `nnnnn` is the process ID reporting the error
- `mm` is a sequence number, normally 0

When a process creates an FFST it also sends a record to the system log. The record contains the name of the FFST file to assist in automatic problem tracking.

The system log entry is made at the “user.error” level.

First Failure Support Technology is explained in detail in First Failure Support Technology (FFST).

FFST: IBM MQ for UNIX and Linux systems

Describes the name, location, and contents of the First Failure Support Technology (FFST) files for UNIX and Linux systems.

For IBM MQ on UNIX and Linux systems, FFST information is recorded in a file in the `/var/mqm/errors` directory.

An FFST file contains one or more records. Each FFST record contains information about an error that is normally severe, and possibly unrecoverable. These records indicate either a configuration problem with the system or an IBM MQ internal error.

FFST files are named `AMQ` *nnnnn.mm*`.FDC`, where:

nnnnn
: Is the ID of the process reporting the error

mm
: Starts at 0. If the full file name already exists, this value is incremented by one until a unique FFST file name is found. An FFST file name can already exist if a process is reused.

An instance of a process will write all FFST information to the same FFST file. If multiple errors occur during a single execution of the process, an FFST file can contain many records.

In order to read the contents of a FFST file, you must be either the creator of the file, or a member of the mqm group.

When a process writes an FFST record, it also sends a record to syslog. The record contains the name of the FFST file to assist in automatic problem tracking. The syslog entry is made at the *user.error* level. See the operating-system documentation about `syslog.conf` for information about configuring this.

Some typical FFST data is shown in Figure 118 on page 1673.

Figure 118. FFST report for IBM MQ for UNIX systems

The Function Stack and Trace History are used by IBM to assist in problem determination. In many cases there is little that the system administrator can do when an FFST report is generated, apart from raising problems through the IBM Support Center.

However, there are some problems that the system administrator might be able to solve. If the FFST shows *out of resource* or *out of space on device* descriptions when calling one of the IPC functions (for example, **semop** or **shmget**), it is likely that the relevant kernel parameter limit has been exceeded.

If the FFST report shows a problem with **setitimer** , it is likely that a change to the kernel timer parameters is needed.

To resolve these problems, increase the IPC limits, rebuild the kernel, and restart the machine.

First Failure Support Technology (FFST) files and UNIX and Linux clients

FFST logs are written when a severe IBM MQ error occurs. They are written to the directory `/var/mqm/errors`.

These are normally severe, unrecoverable errors and indicate either a configuration problem with the system or an IBM MQ internal error.

The files are named `AMQnnnnn.mm.FDC`, where:
- `nnnnn` is the process id reporting the error
- `mm` is a sequence number, normally 0

When a process creates an FFST it also sends a record to the system log. The record contains the name of the FFST file to assist in automatic problem tracking.

The system log entry is made at the "user.error" level.

First Failure Support Technology is explained in detail in First Failure Support Technology (FFST).

FFST: IBM MQ for IBM i

Describes the name, location, and contents of the First Failure Support Technology (FFST) files for IBM i systems.

For IBM i, FFST information is recorded in a stream file in the `/QIBM/UserData/mqm/errors` directory.

These errors are normally severe, unrecoverable errors, and indicate either a configuration problem with the system or an IBM MQ internal error.

The stream files are named `AMQ` *`nnnnn.mm`*`.FDC`, where:

nnnnn	Is the ID of the process reporting the error
mm	Is a sequence number, normally 0

A copy of the job log of the failing job is written to a file with the same name as the .FDC file. The file name ends with .JOB.

Some typical FFST data is shown in the following example.

```

Note:

1. The `MQM Trace History` section is a log of the 200 most recent function trace statements, and is recorded in the FFST report regardless of any TRCMQM settings.
2. The queue manager details are recorded only for jobs that are connected to a queue manager subpool.
3. When the failing component is `xehAS400ConditionHandler`, additional data is logged in the errors directory giving extracts from the job log relating to the exception condition.

The function stack and trace history are used by IBM to assist in problem determination. In most cases, there is little that the system administrator can do when an FFST report is generated, apart from raising problems through the IBM Support Center.

FFST: IBM MQ for HP Integrity NonStop Server

Describes the name, location, and contents of the First Failure Support Technology™ (FFST™) files for HP Integrity NonStop Server systems.

In IBM MQ client for HP Integrity NonStop Server systems, FFST information is recorded in a file in the `<mqpath>/var/mqm/errors` directory.

An FFST file contains one or more records. Each FFST record contains information about an error that is normally severe, and possibly unrecoverable. These records indicate either a configuration problem with the system or an IBM MQ internal error.

FFST files are named `AMQ.nnn.xx.ppp.qq.FDC`, where:

nnn The name of the process that is reporting the error.

xx The processor number on which the process is running.

ppp The PIN of the process that you are tracing.

qq A sequence that starts at 0. If the full file name exists, this value is incremented by one until a unique FFST file name is found. An FFST file name can exist if a process is reused.

Each field can contain fewer or more digits than shown in the example.

An instance of a process writes all FFST information to the same FFST file. If multiple errors occur during a single execution of the process, an FFST file can contain many records.

To read the contents of an FFST file, you must be either the creator of the file, or a member of the mqm group.

When a process writes an FFST record, it also creates an EMS event.

Figure 119 on page 1677 shows a typical FFST report for an IBM MQ client on a HP Integrity NonStop Server system:

Figure 119. Sample FFST data

The Function Stack and Trace History are used by IBM to help problem determination. In many cases, there is little that the system administrator can do when an FFST report is generated, apart from raising problems through the IBM Support Center. However, there are some problems that the system administrator might be able to solve, for example, if the FFST report shows `Out of resource` or `Out of space on device`.

For more information about FFST, see “First Failure Support Technology (FFST” on page 1666.

Using logs

There are a variety of logs that you can use to help with problem determination and troubleshooting.

Use the following links to find out about the logs available for your platform and how to use them:

- Windows UNIX Linux “Error logs on Windows, UNIX and Linux systems”
- IBM i “Error logs on IBM i” on page 1683
- “Error logs on HP Integrity NonStop Server” on page 1682

z/OS On z/OS error messages are written to:

- The z/OS system console
- The channel-initiator job log

It is possible to suppress or exclude some messages on both distributed and z/OS systems.

For details of suppressing some messages on distributed systems, see Queue manager error logs.

z/OS On z/OS, if you are using the z/OS message processing facility to suppress messages, the console messages can be suppressed. See IBM MQ for z/OS concepts for more information.

z/OS For information about error messages, console logs, and dumps on IBM MQ for z/OS, see Problem determination on z/OS.

Error logs on Windows, UNIX and Linux systems

About error log files, and an example.

At installation time, an `errors` subdirectory is created in the `/var/mqm` file path under UNIX and Linux systems, and in the installation directory, for example `C:\Program Files\IBM\WebSphere MQ\` file path under Windows systems. The `errors` subdirectory can contain up to three error log files named:

- AMQERR01.LOG
- AMQERR02.LOG
- AMQERR03.LOG

For more information about directories where log files are stored, see “Error log directories” on page 1681.

After you have created a queue manager, it creates three error log files when it needs them. These files have the same names as those files in the system error log directory. That is, AMQERR01, AMQERR02, and AMQERR03, and each has a default capacity of 2 MB (2 097 152 bytes). The capacity can be altered in the `Extended` queue manager properties page from the IBM MQ Explorer, or in the `QMErrorLog` stanza in the qm.ini file. These files are placed in the `errors` subdirectory in the queue manager data directory that you selected when you installed IBM MQ or created your queue manager. The default location for the `errors` subdirectory is `/var/mqm/qmgrs/` *qmname* file path under UNIX and Linux systems, and `C:\Program Files\IBM\WebSphere MQ\qmgrs\` *qmname* `\errors` file path under Windows systems.

As error messages are generated, they are placed in AMQERR01. When AMQERR01 gets bigger than 2 MB (2 097 152 bytes) it is copied to AMQERR02. Before the copy, AMQERR02 is copied to AMQERR03.LOG. The previous contents, if any, of AMQERR03 are discarded.

The latest error messages are thus always placed in AMQERR01, the other files being used to maintain a history of error messages.

All messages relating to channels are also placed in the appropriate error files belonging to the queue manager, unless the queue manager is unavailable, or its name is unknown. In which case, channel-related messages are placed in the system error log directory.

To examine the contents of any error log file, use your usual system editor.

An example of an error log

Figure 120 shows an extract from an IBM MQ error log:

```
17/11/2004 10:32:29 - Process(2132.1) User(USER_1) Program(runmqchi.exe)
Host(HOST_1) Installation(Installation1)
VRMF(7.1.0.0) QMgr (A.B.C)
AMQ9542: Queue manager is ending.

EXPLANATION:
The program will end because the queue manager is quiescing.
ACTION:
None.
----- amqrimna.c : 931 -------------------------------------------------------
```

Figure 120. Sample IBM MQ error log

Operator messages

Operator messages identify normal errors, typically caused directly by users doing things like using parameters that are not valid on a command. Operator messages are national-language enabled, with message catalogs installed in standard locations.

These messages are written to the associated window, if any. In addition, some operator messages are written to the AMQERR01.LOG file in the queue manager directory, and others to the equivalent file in the system error log directory.

Error log access restrictions

Certain error log directories and error logs have access restrictions.

To gain the following access permissions, a user or application must be a member of the mqm group:

- Read and write access to all queue manager error log directories.
- Read and write access to all queue manager error logs.
- Write access to the system error logs.

If an unauthorized user or application attempts to write a message to a queue manager error log directory, the message is redirected to the system error log directory.

Ignoring error codes under UNIX and Linux systems

On UNIX and Linux systems, if you do not want certain error messages to be written to a queue manager error log, you can specify the error codes that are to be ignored using the QMErrorLog stanza.

For more information, see Queue manager error logs.

Ignoring error codes under Windows systems

On Windows systems, the error message is written to both the IBM MQ error log and the Windows Application Event Log. The error messages written to the Application Event Log includes messages of error severity, warning severity, and information severity. If you do not want certain error messages to be written to the Windows Application Event Log, you can specify the error codes that are to be ignored in the Windows registry.

Use the following registry key:

```
HKLM\Software\IBM\WebSphere MQ\Installation\MQ_INSTALLATION_NAME\IgnoredErrorCodes
```

where *MQ_INSTALLATION_NAME* is the installation name associated with a particular installation of IBM MQ.

The value that you set it to is an array of strings delimited by the NULL character, with each string value relating to the error code that you want ignored from the error log. The complete list is terminated with a NULL character, which is of type REG_MULTI_SZ.

For example, if you want IBM MQ to exclude error codes AMQ3045, AMQ6055, and AMQ8079 from the Windows Application Event Log, set the value to:

```
AMQ3045\0AMQ6055\0AMQ8079\0\0
```

The list of messages you want to exclude is defined for all queue managers on the machine. Any changes you make to the configuration will not take effect until each queue manager is restarted.

Error log directories

IBM MQ uses a number of error logs to capture messages concerning its own operation of IBM MQ, any queue managers that you start, and error data coming from the channels that are in use. The location of the error logs depends on whether the queue manager name is known and whether the error is associated with a client.

The location the error logs are stored in depends on whether the queue manager name is known and whether the error is associated with a client. *MQ_INSTALLATION_PATH* represents the high level directory where IBM MQ is installed.

- If the queue manager name is known, the location of the error log is shown in Table 156.

Table 156. Queue manager error log directory

Platform	Directory
UNIX and Linux systems	`/var/mqm/qmgrs/` *qmname* `/errors`
Windows systems	*MQ_INSTALLATION_PATH*`\QMGRS\` *qmname* `\ERRORS\AMQERR01.LOG`

- If the queue manager name is not known, the location of the error log is shown in Table 157.

Table 157. System error log directory

Platform	Directory
UNIX and Linux systems	`/var/mqm/errors`
Windows systems	*MQ_INSTALLATION_PATH*`\QMGRS\@SYSTEM\ERRORS\AMQERR01.LOG`

- If an error has occurred with a client application, the location of the error log on the client is shown in Table 158.

Table 158. Client error log directory

Platform	Directory
UNIX and Linux systems	`/var/mqm/errors`
Windows systems	`MQ_DATA_PATH\ERRORS\AMQERR01.LOG`

In IBM MQ for Windows, an indication of the error is also added to the Application Log, which can be examined with the Event Viewer application provided with Windows systems.

Early errors

There are a number of special cases where these error logs have not yet been established and an error occurs. IBM MQ attempts to record any such errors in an error log. The location of the log depends on how much of a queue manager has been established.

If, because of a corrupt configuration file for example, no location information can be determined, errors are logged to an errors directory that is created at installation time on the root directory (`/var/mqm` or `C:\Program Files\IBM\WebSphere MQ`).

If IBM MQ can read its configuration information, and can access the value for the Default Prefix, errors are logged in the errors subdirectory of the directory identified by the Default Prefix attribute. For example, if the default prefix is `C:\Program Files\IBM\WebSphere MQ`, errors are logged in `C:\Program Files\IBM\WebSphere MQ\errors`.

For further information about configuration files, see Changing IBM MQ and queue manager configuration information.

Note: Errors in the Windows Registry are notified by messages when a queue manager is started.

Error logs on HP Integrity NonStop Server

Use this information to understand the IBM MQ client on HP Integrity NonStop Server error logs, together with an example.

At installation time, an errors subdirectory is created in the `<mqpath>/var/mqm` file path. The errors subdirectory can contain up to three error log files named:

- `AMQERR01.LOG`
- `AMQERR02.LOG`
- `AMQERR03.LOG`

As error messages are generated, they are written to `AMQERR01.LOG`. When `AMQERR01.LOG` gets bigger than 2 MB (2 097 152 bytes), it is copied to `AMQERR02.LOG`. Before the copy, `AMQERR02.LOG` is copied to `AMQERR03.LOG`. The previous contents, if any, of `AMQERR03.LOG` are discarded.

The latest error messages are therefore always placed in `AMQERR01.LOG`. The other log files are used to maintain a history of error messages.

To examine the contents of any error log file, use your system editor. The contents of the log files can read by any user, but write access requires the user to be a member of the mqm group.

An example of an error log

Figure 121 shows an extract from an IBM MQ error log:

```
04/30/13 06:18:22 - Process(320406477.1) User(MYUSER) Program(nssfcps_c)
                    Host(myhost)
                    VRMF(7.1.0.0)
AMQ9558: The remote channel 'SYSTEM.DEF.SVRCONN' on host 'hostname
(x.x.x.x)(1414)' is not currently available.

EXPLANATION:
The channel program ended because an instance of channel 'SYSTEM.DEF.SVRCONN'
could not be started on the remote system. This could be for one of the
following reasons:

The channel is disabled.

The remote system does not have sufficient resources to run another instance of
the channel.

In the case of a client-connection channel, the limit on the number of
instances configured for the remote server-connection channel was reached.

ACTION:
Check the remote system to ensure that the channel is able to run. Try the
operation again.

```

Figure 121. Sample IBM MQ error log

Error logs on IBM i

IBM i

Use this information to understand the IBM MQ for IBM i error logs.

By default, only members of the QMQMADM group can access error logs. To give users access to error logs, who are not members of this group, set **`ValidateAuth`** to *No* and grant those users *PUBLIC authority. See Filesystem for more information.

IBM MQ uses a number of error logs to capture messages concerning the operation of IBM MQ itself, any queue managers that you start, and error data coming from the channels that are in use.

At installation time, a `/QIBM/UserData/mqm/errors` subdirectory is created in the IFS.

The location of the error logs depends on whether the queue manager name is known.

In the IFS:
- If the queue manager name is known and the queue manager is available, error logs are located in:
  `/QIBM/UserData/mqm/qmgrs/`*`qmname`*`/errors`
- If the queue manager is not available, error logs are located in:
  `/QIBM/UserData/mqm/errors`

You can use the system utility EDTF to browse the errors directories and files. For example:

```
EDTF '/QIBM/UserData/mqm/errors'
```

Alternatively, you can use option 23 against the queue manager from the WRKMQM panel.

The errors subdirectory can contain up to three error log files named:
- `AMQERR01.LOG`
- `AMQERR02.LOG`
- `AMQERR03.LOG`

After you have created a queue manager, three error log files are created when they are needed by the queue manager. These files have the same names as the `/QIBM/UserData/mqm/errors` ones, that is AMQERR01, AMQERR02, and AMQERR03, and each has a capacity of 2 MB (2 097 152 bytes). The files are placed in the errors subdirectory of each queue manager that you create, that is `/QIBM/UserData/mqm/qmgrs/`*`qmname`*`/errors`.

As error messages are generated, they are placed in AMQERR01. When AMQERR01 gets bigger than 2 MB (2 097 152 bytes), it is copied to AMQERR02. Before the copy, AMQERR02 is copied to AMQERR03.LOG. The previous contents, if any, of AMQERR03 are discarded.

The latest error messages are thus always placed in AMQERR01, the other files being used to maintain a history of error messages.

All messages relating to channels are also placed in the appropriate errors files of the queue manager, unless the name of their queue manager is unknown or the queue manager is unavailable. When the queue manager name is unavailable or its name cannot be determined, channel-related messages are placed in the `/QIBM/UserData/mqm/errors` subdirectory.

To examine the contents of any error log file, use your system editor, EDTF, to view the stream files in the IFS.

Note:
1. Do not change ownership of these error logs.
2. If any error log file is deleted, it is automatically re-created when the next error message is logged.

Early errors

There are a number of special cases where the error logs have not yet been established and an error occurs. IBM MQ attempts to record any such errors in an error log. The location of the log depends on how much of a queue manager has been established.

If, because of a corrupted configuration file, for example, no location information can be determined, errors are logged to an errors directory that is created at installation time.

If both the IBM MQ configuration file and the DefaultPrefix attribute of the AllQueueManagers stanza are readable, errors are logged in the errors subdirectory of the directory identified by the DefaultPrefix attribute.

Operator messages

Operator messages identify normal errors, typically caused directly by users doing things like using parameters that are not valid on a command. Operator messages are national language enabled, with message catalogs installed in standard locations.

These messages are written to the job log, if any. In addition, some operator messages are written to the `AMQERR01.LOG` file in the queue manager directory, and others to the `/QIBM/UserData/mqm/errors` directory copy of the error log.

An example IBM MQ error log

Figure 122 on page 1685 shows a typical extract from an IBM MQ error log.

Grade the severity of the problem, describe the problem and gather background information, then report the problem to IBM Software Support.

Using trace on Windows

Use the **strmqtrc** and **endmqtrc** commands or the MQ Explorer interface to start and end tracing.

Windows uses the following commands for the client trace facility:

strmqtrc
  to start tracing

endmqtrc
  to end tracing

The output files are created in the `MQ_DATA_PATH/trace` directory.

Trace files on IBM MQ for Windows

Trace files are named `AMQ` *`ppppp. qq`*`.TRC` where the variables are:

ppppp
  The ID of the process reporting the error.

qq
  A sequence number, starting at 0. If the full file name exists, this value is incremented by one until a unique trace file name is found. A trace file name can exist if a process is reused.

Note:
1. The process identifier can contain fewer, or more, digits than shown in the example.
2. There is one trace file for each process running as part of the entity being traced.

To format or view a trace file, you must be either the creator of the trace file, or a member of the mqm group.

SSL trace files have the names `AMQ.SSL.TRC` and `AMQ.SSL.TRC.1`. You cannot format SSL trace files; send them unchanged to IBM support.

How to start and stop a trace

Enable or modify tracing using the **`strmqtrc`** control command (see strmqtrc). To stop tracing, use the **`endmqtrc`** control command (see endmqtrc).

In IBM MQ for Windows systems, you can also start and stop tracing using the MQ Explorer, as follows:
1. Start the MQ Explorer from the **Start** menu.
2. In the Navigator View, right-click the **IBM MQ** tree node, and select **Trace...**. The Trace Dialog is displayed.
3. Click **Start** or **Stop** as appropriate.

Selective component tracing

Use the `-t` and `-x` options to control the amount of trace detail to record. By default, all trace points are enabled. You can specify the points that you do not want to trace using the `-x` option. So if, for example, you want to trace only data flowing over communications networks, use:

```
strmqtrc -x all -t comms
```

For detailed information about the trace command, see strmqtrc.

Selective process tracing

Use the `-p` option of the **`strmqtrc`** command control to restrict trace generation to specified named processes. For example, to trace all threads that result from any running process called amqxxx.exe, use the following command:

```
strmqtrc -p amqxxx.exe
```

For detailed information about the trace command, see strmqtrc.

For Java components of IBM MQ, for example the IBM MQ Explorer and the Java implementation of IBM MQ Transport for SOAP, diagnostic information is output using the standard IBM MQ diagnostic facilities or by Java diagnostic classes.

Using trace on UNIX and Linux systems

Use the **strmqtrc** and **endmqtrc** commands to start and end tracing, and **dspmqtrc** to display a trace file

UNIX and Linux systems use the following commands for the IBM MQ MQI client trace facility:

strmqtrc
to start tracing

endmqtrc
to end tracing

dspmqtrc <filename>
to display a formatted trace file

The trace facility uses a number of files, which are:

- One file for each entity being traced, in which trace information is recorded
- One additional file on each machine, to provide a reference for the shared memory used to start and end tracing
- One file to identify the semaphore used when updating the shared memory

Files associated with trace are created in a fixed location in the file tree, which is `/var/mqm/trace`.

All client tracing takes place to files in this directory.

You can handle large trace files by mounting a temporary file system over this directory.

On AIX you can use AIX system trace in addition to using the strmqtrc and endmqtrc commands. For more information, see "Tracing with the AIX system trace" on page 1690.

Trace files on IBM MQ for UNIX and Linux systems

Trace files are created in the directory `/var/mqm/trace`.

Note: You can accommodate the production of large trace files by mounting a temporary file system over the directory that contains your trace files. Alternatively, rename the trace directory and create the symbolic link `/var/mqm/trace` to a different directory.

Trace files are named `AMQ` *`ppppp. qq`*`.TRC` where the variables are:

ppppp
: The ID of the process reporting the error.

qq
: A sequence number, starting at 0. If the full file name exists, this value is incremented by one until a unique trace file name is found. A trace file name can exist if a process is reused.

Note:

1. The process identifier can contain fewer, or more, digits than shown in the example.
2. There is one trace file for each process running as part of the entity being traced.

To format or view a trace file, you must be either the creator of the trace file, or a member of the mqm group.

SSL trace files have the names `AMQ.SSL.TRC` and `AMQ.SSL.TRC.1`. You cannot format SSL trace files; send them unchanged to IBM support.

How to start and stop a trace

In IBM MQ for UNIX and Linux systems, you enable or modify tracing using the **`strmqtrc`** control command (see strmqtrc). To stop tracing, you use the **`endmqtrc`** control command (see endmqtrc). On IBM MQ for Linux (x86 and x86-64 platforms) systems, you can alternatively use the MQ Explorer to start and stop tracing. However, you can trace only everything using the function provided, equivalent to using the commands `strmqtrc -e` and `endmqtrc -e`.

Trace output is unformatted; use the **`dspmqtrc`** control command to format trace output before viewing. For example, to format all trace files in the current directory use the following command:

```
dspmqtrc *.TRC
```

For detailed information about the control command, **`dspmqtrc`**, see dspmqtrc.

Selective component tracing on IBM MQ for UNIX and Linux systems

Use the `-t` and `-x` options to control the amount of trace detail to record. By default, all trace points are enabled. Specify the points you do not want to trace using the `-x` option. If, for example, you want to trace, for queue manager QM1, only output data associated with using Secure Sockets Layer (SSL) channel security, use:

```
strmqtrc -m QM1 -t ssl
```

For detailed information about the trace command, see strmqtrc.

Selective component tracing on IBM MQ for AIX

Use the environment variable MQS_TRACE_OPTIONS to activate the high detail and parameter tracing functions individually.

Because MQS_TRACE_OPTIONS enables tracing to be active without high detail and parameter tracing functions, you can use it to reduce the effect on performance and trace size when you are trying to reproduce a problem with tracing switched on.

Only set the environment variable MQS_TRACE_OPTIONS if you have been instructed to do so by your service personnel.

Typically MQS_TRACE_OPTIONS must be set in the process that starts the queue manager, and before the queue manager is started, or it is not recognized. Set MQS_TRACE_OPTIONS before tracing starts. If it is set after tracing starts it is not recognized.

Selective process tracing on IBM MQ for UNIX and Linux systems

Use the `-p` option of the **strmqtrc** command control to restrict trace generation to specified named processes. For example, to trace all threads that result from any running process called `amqxxx`, use the following command:

```
strmqtrc -p amqxxx
```

For detailed information about the trace command, see strmqtrc.

"Using trace on Windows" on page 1686
Use the **strmqtrc** and **endmqtrc** commands or the MQ Explorer interface to start and end tracing.

Tracing with the AIX system trace

In addition to the IBM MQ trace, IBM MQ for AIX users can use the standard AIX system trace.

AIX system tracing is a two-step process:

1. Gathering the data
2. Formatting the results

IBM MQ uses two trace hook identifiers:

X'30D' This event is recorded by IBM MQ on entry to or exit from a subroutine.

X'30E' This event is recorded by IBM MQ to trace data such as that being sent or received across a communications network.

Trace provides detailed execution tracing to help you to analyze problems. IBM service support personnel might ask for a problem to be re-created with trace enabled. The files produced by trace can be **very** large so it is important to qualify a trace, where possible. For example, you can optionally qualify a trace by time and by component.

There are two ways to run trace:

1. Interactively.

   The following sequence of commands runs an interactive trace on the program `myprog` and ends the trace.

   ```
   trace -j30D,30E -o trace.file
   ->!myprog
   ->q
   ```

2. Asynchronously.

   The following sequence of commands runs an asynchronous trace on the program `myprog` and ends the trace.

```
trace -a -j30D,30E -o trace.file
myprog
trcstop
```

You can format the trace file with the command:

```
trcrpt -t MQ_INSTALLATION_PATH/lib/amqtrc.fmt trace.file > report.file
```

`MQ_INSTALLATION_PATH` represents the high-level directory in which IBM MQ is installed.

`report.file` is the name of the file where you want to put the formatted trace output.

Note: **All** IBM MQ activity on the machine is traced while the trace is active.

Using trace on HP Integrity NonStop Server

Use the **strmqtrc** and **endmqtrc** commands to start and end tracing, and **dspmqtrc** to display a trace file.

Use the following commands on the IBM MQ client for HP Integrity NonStop Server system to use the IBM MQ client trace facility:

strmqtrc
    To start tracing

endmqtrc
    To end tracing

dspmqtrc <filename>
    To display a formatted trace file

The trace facility creates a file for each entity that is being traced. The trace files are created in a fixed location, which is `<mqpath>/var/mqm/trace`. You can handle large trace files by mounting a temporary file system over this directory.

Trace files are named `AMQ.nnn.xx.ppp.qq.TRC` where:

nnn	The name of the process.
xx	The processor number on which the process is running.
ppp	The PIN of the process that you are tracing.
qq	A sequence number, starting at 0. If the full file name exists, this value is incremented by one until a unique trace file name is found. A trace file name can exist if a process is reused.

Note:
1. Each field can contain fewer, or more, digits than shown in the example.
2. There is one trace file for each process that is running as part of the entity that is being traced.

Trace files are created in a binary format. To format or view a trace file use the **dspmqtrc** command, you must be either the creator of the trace file, or a member of the mqm group. For example, to format all trace files in the current directory use the following command:

```
dspmqtrc *.TRC
```

For more information about the control command **dspmqtrc**, see dspmqtrc.

How to start and stop a trace

On IBM MQ client for HP Integrity NonStop Server systems, you can enable or modify tracing by using the **strmqtrc** control command, for more information, see strmqtrc. To stop tracing, use the **endmqtrc** control command, for more information, see endmqtrc.

The control commands **strmqtrc** and **endmqtrc** affect tracing only for those processes that are running in one specific processor. By default, this processor is the same as the one in your OSS shell. To enable or end tracing for processes that are running in another processor, you must precede the **strmqtrc** or **endmqtrc** commands with `run -cpu=n` at an OSS shell command prompt, where `n` is the processor number. Here is an example of how to enter the **strmqtrc** command at an OSS shell command prompt:

```
run -cpu=2 strmqtrc
```

This command enables tracing for all processes that are running in processor 2.

The `-m` option to select a queue manager is not relevant for use on the IBM MQ client for HP Integrity NonStop Server . Specifying the `-m` option produces an error.

Use the `-t` and `-x` options to control the amount of trace detail to record. By default, all trace points are enabled. Specify the points that you do not want to trace by using the `-x` option.

Using trace on IBM MQ server on IBM i

IBM i

Use the TRCMQM command to start and stop tracing and specify the type of trace that you require.

There are two stages in using trace:

1. Decide whether you want early tracing. Early tracing lets you trace the creation and startup of queue managers. Note, however, that early trace can easily generate large amounts of trace, because it is implemented by tracing all jobs for all queue managers. To enable early tracing, use TRCMQM with the TRCEARLY parameter set to *YES.
2. Start tracing work using `TRCMQM` **ON*. To stop the trace, you have two options:
   - `TRCMQM` **OFF*, to stop collecting trace records for a queue manager. The trace records are written to files in the `/QIBM/UserData/mqm/trace` directory.
   - `TRCMQM` **END*, to stop collecting trace records for all queue managers and to disable early trace. This option ignores the value of the TRCEARLY parameter.

Specify the level of detail you want, using the TRCLEVEL parameter set to one of the following values:

**DFT*
For minimum-detail level for flow processing trace points.

**DETAIL*
For high-detail level for flow processing trace points.

**PARMS*
For default-detail level for flow processing trace points.

Specify the type of trace output you want, using the OUTPUT parameter set to one of the following values:

***MQM**
Collect binary IBM MQ trace output in the directory specified by the TRCDIR parameter. This value is the default value.

***MQMFMT**
Collect formatted IBM MQ trace output in the directory specified by the TRCDIR parameter.

***PEX**
Collect Performance Explorer (PEX) trace output

***ALL**
Collect both IBM MQ unformatted trace and PEX trace output

Selective trace

You can reduce the amount of trace data being saved, improving runtime performance, using the command `TRCMQM` with `F4=prompt`, then `F9` to customize the TRCTYPE and EXCLUDE parameters:

TRCTYPE
Specifies the type of trace data to store in the trace file. If you omit this parameter, all trace points except those trace points specified in EXCLUDE are enabled.

EXCLUDE
Specifies the type of trace data to omit from the trace file. If you omit this parameter, all trace points specified in TRCTYPE are enabled.

The options available on both TRCTYPE and EXCLUDE are:

***ALL (TRCTYPE only)**
All the trace data as specified by the following keywords is stored in the trace file.

trace-type-list
You can specify more than one option from the following keywords, but each option can occur only once.

***API** Output data for trace points associated with the MQI and major queue manager components.

***CMTRY**
Output data for trace points associated with comments in the IBM MQ components.

***COMMS**
Output data for trace points associated with data flowing over communications networks.

***CSDATA**
Output data for trace points associated with internal data buffers in common services.

***CSFLOW**
Output data for trace points associated with processing flow in common services.

***LQMDATA**
Output data for trace points associated with internal data buffers in the local queue manager.

***LQMFLOW**
Output data for trace points associated with processing flow in the local queue manager.

***OTHDATA**
Output data for trace points associated with internal data buffers in other components.

***OTHFLOW**
Output data for trace points associated with processing flow in other components.

***RMTDATA**
Output data for trace points associated with internal data buffers in the communications component.

***RMTFLOW**
Output data for trace points associated with processing flow in the communications component.

***SVCDATA**
Output data for trace points associated with internal data buffers in the service component.

***SVCFLOW**
Output data for trace points associated with processing flow in the service component.

***VSNDATA**
Output data for trace points associated with the version of IBM MQ running.

Wrapping trace

Use the MAXSTG parameter to wrap trace, and to specify the maximum size of storage to be used for the collected trace records.

The options are:

**DFT*
Trace wrapping is not enabled. For each job, trace data is written to a file with the suffix .TRC until tracing is stopped.

maximum-K-bytes
Trace wrapping is enabled. When the trace file reaches its maximum size, it is renamed with the suffix .TRS, and a new trace file with suffix .TRC is opened. Any existing .TRS file is deleted. Specify a value in the range 1 through 16 000.

Formatting trace output

To format any trace output:

- Enter the QShell
- Enter the command

```
/QSYS.LIB/QMQM.LIB/DSPMQTRC.PGM [-t Format] [-h] [-s]
[-o OutputFileName] InputFileName
```

where:

`InputFileName`
Is a required parameter specifying the name of the file containing the unformatted trace. For example `/QIBM/UserData/mqm/trace/AMQ12345.TRC`.

`-t` *`FormatTemplate`*
Specifies the name of the template file containing details of how to display the trace. The default value is `/QIBM/ProdData/mqm/lib/amqtrc.fmt`.

`-h` Omit header information from the report.

`-s` Extract trace header and put to stdout.

`-o` *`output_filename`*
The name of the file into which to write formatted data.

You can also specify `dspmqtrc *` to format all trace.

Using trace on IBM MQ client on IBM i

IBM i

On IBM i, there is no Control Language (CL) command to capture the trace when using a standalone IBM MQ MQI client. STRMQTRC and ENDMQTRC programs can be used to enable and disable the trace.

Example for start trace:

```
CALL PGM(QMQM/STRMQTRC) PARM('-e' '-t' 'all' '-t' 'detail')
Where -e option requests early tracing of all the process -t option for trace type
```

To end the trace

```
CALL PGM(QMQM/ENDMQTRC) PARM('-e')
```

- Optional parameters:

  -t *TraceType*

  The points to trace and the amount of trace detail to record. By default all trace points are enabled and a default-detail trace is generated.

  Alternatively, you can supply one or more of the options in Table 1. For each *TraceType* value you specify, including -t all, specify either -t parms or -t detail to obtain the appropriate level of trace detail. If you do not specify either -t parms or -t detail for any particular trace type, only a default-detail trace is generated for that trace type.

  If you supply multiple trace types, each must have its own -t flag. You can include any number of -t flags, if each has a valid trace type associated with it.

  It is not an error to specify the same trace type on multiple -t flags.

  See the following table for allowed values for *TraceType*.

Table 159. TraceType values

Value	**Description**
all	Output data for every trace point in the system (the default). Using *all* activates tracing at default detail level.
api	Output data for trace points associated with the message queue interface (MQI) and major queue manager components.
commentary	Output data for trace points associated with comments in the IBM MQ components.
comms	Output data for trace points associated with data flowing over communications networks.
csdata	Output data for trace points associated with internal data buffers in common services.
csflows	Output data for trace points associated with processing flow in common services.
detail	Activate tracing at high-detail level for flow processing trace points.
lqmdata	Output data for trace points associated with internal data buffers in the local queue manager.
lqmflows	Output data for trace points associated with processing flow in the local queue manager.
otherdata	Output data for trace points associated with internal data buffers in other components.
otherflows	Output data for trace points associated with processing flow in other components.
parms	Activate tracing at default-detail level for flow processing trace points.
remotedata	Output data for trace points associated with internal data buffers in the communications component.
remoteflows	Output data for trace points associated with processing flow in the communications component.
servicedata	Output data for trace points associated with internal data buffers in the service component.
serviceflows	Output data for trace points associated with processing flow in the service component.
versiondata	Output data for trace points associated with the version of IBM MQ running.

-x *TraceType*
: The points not to trace. By default all trace points are enabled and a default-detail trace is generated. The *TraceType* values you can specify are the same as the values listed for the -t flag in Table 1.

  You can use the -x flag with *TraceType* values to exclude those trace points you do not want to record. Excluding specified trace points is useful in reducing the amount of trace produced.

  If you supply multiple trace types, each must have its own -x flag. You can include any number of -x flags, if each has a valid *TraceType* associated with it.

-s Reports the tracing options that are currently in effect. You must use this parameter on its own with no other parameters.

A limited number of slots are available for storing trace commands. When all slots are in use, then no more trace commands can be accepted unless they replace an existing slot. Slot numbers are not fixed, so if the command in slot number 0 is removed, for example by an **endmqtrc** command, then all the other slots move up, with slot 1 becoming slot 0, for example. An asterisk (*) in a field means that no value is defined, and is equivalent to the asterisk wildcard.

-l *MaxSize*
The maximum size of a trace file (`AMQppppp.qq.TRC`) in megabytes (MB). For example, if you specify a *MaxSize* of 1, the size of the trace is limited to 1 MB.

When a trace file reaches the specified maximum, it is renamed to `AMQppppp.qq.TRS` and a new `AMQppppp.qq.TRC` file is started. If a previous copy of an `AMQppppp.qq.TRS` file exists, it is deleted.

The highest value that *MaxSize* can be is 2048 MB.

-e Requests early tracing of all processes

For more details see the **strmqtrc** command

- To end the trace:

```
/QSYS.LIB/QMQM.LIB/ENDMQTRC.PGM [-e] [-a]
```

where:

-e Ends early tracing of all processes.

Using **endmqtrc** with no parameters has the same effect as **endmqtrc -e**. You cannot specify the -e flag with the -m flag, the -i flag, or the -p flag.

-a Ends all tracing.

For more details see the endmqtrc **endmqtrc** command

- To display a formatted trace file:

```
/QSYS.LIB/QMQM.LIB/DSPMQTRC.pgm
```

To examine FFST files, see the First Failure Support Technology (FFST) for IBM MQ for IBM i.

Using trace for problem determination on z/OS

z/OS

There are different trace options that can be used for problem determination with IBM MQ. Use this topic to understand the different options and how to control trace.

The trace facilities available with IBM MQ for z/OS are:
- The user parameter (or API) trace
- The IBM internal trace used by the support center
- The channel initiator trace
- The line trace

Use the following links to find out how to collect and interpret the data produced by the user parameter trace, and describes how to produce the IBM internal trace for use by the IBM support center. There is also information about the other trace facilities that you can use with IBM MQ.
- Controlling the GTF for your z/OS system
- Controlling the IBM MQ trace for each queue manager subsystem for which you want to collect data
- "Formatting and identifying the control block information" on page 1700
- "Interpreting the trace information" on page 1701

If trace data is not produced, check the following:
- Was the GTF started correctly, specifying EIDs 5E9, 5EA, and 5EE on the USRP option?
- Was the START TRACE(GLOBAL) command entered correctly, and were the relevant classes specified?

For more information about other trace options available on z/OS, see "Other types of trace" on page 1703.

The MQI call and user parameter, and z/OS generalized trace facility (GTF)

Use this topic to understand how to control GTF and IBM MQ trace.

You can obtain information about MQI calls and user parameters passed by some IBM MQ calls on entry to, and exit from, IBM MQ. To do this, use the global trace in conjunction with the z/OS generalized trace facility (GTF).

Controlling the GTF:

Use this topic to understand how to start and stop the GTF.

- Starting the GTF
- Stopping the GTF

Starting the GTF

When you start the GTF, specify the USRP option. You are prompted to enter a list of event identifiers (EIDs). The EIDs used by IBM MQ are:

5E9	To collect information about control blocks on entry to IBM MQ
5EA	To collect information about control blocks on exit from IBM MQ

Sometimes, if an error occurs that you cannot solve yourself, you might be asked by your IBM support center to supply other, internal, trace information for them to analyze. The additional type of trace is:

5EE	To collect information internal to IBM MQ

You can also use the JOBNAMEP option, specifying the batch, CICS, IMS, or TSO job name, to limit the trace output to specific jobs. Figure 123 on page 1699 illustrates sample startup for the GTF, specifying the four EIDs, and a jobname. The lines shown in bold type **like this** are the commands that you enter at the console; the other lines are prompts and responses.

For more information about starting the GTF trace, see the *MVS Diagnosis: Tools and Service Aids* manual.

where:

     xx is the name of the GTF procedure to use (optional), and yy is an
     identifier for this occurrence of GTF trace.

     xxxx is the name of the queue manager and zzzzzzzz is
     a batch job or CICS region name. Up to 5 job names can be listed.
```

Figure 123. Example startup of GTF to use with the IBM MQ trace

When using GTF, specify the primary job name (CHINIT, CICS, or batch) in addition to the queue manager name (xxxxMSTR).

Stopping the GTF

When you stop the GTF, you must specify the additional identifier (**yy**) used at startup. Figure 124 illustrates a sample stop command for the GTF. The commands shown in bold type **like this** are the commands that you enter at the console.

```
 STOP yy
```

Figure 124. Example of GTF Stop command to use with the IBM MQ trace

Related information:

Generating IBM MQ GTF trace on IBM z/OS

Controlling the trace within IBM MQ:

IBM MQ for z/OS trace is controlled using MQSC commands. Use this topic to understand how to control the trace, and the type of trace information that is output.

Use the START TRACE command, specifying type GLOBAL to start writing IBM MQ records to the GTF. You must also specify dest(GTF), for example in the following command:

```
/cpf start trace(G)class(2,3)dest(GTF)
```

To define the events that you want to produce trace data for, use one or more of the following classes:

CLASS	Event traced
2	Record the MQI call and MQI parameters when a completion code other than MQRC_NONE is detected.
3	Record the MQI call and MQI parameters on entry to and exit from the queue manager.

After the trace has started, you can display information about, alter the properties of, and stop, the trace with the following commands:
- DISPLAY TRACE
- ALTER TRACE
- STOP TRACE

To use any of the trace commands, you must have one of the following:
- Authority to issue start and stop trace commands (trace authority)
- Authority to issue the display trace command (display authority)

Note:
1. The trace commands can also be entered through the initialization input data sets.
2. The trace information produced will also include details of syncpoint flows - for example PREPARE and COMMIT.

For information about these commands, see MQSC commands.

Formatting and identifying the control block information:

After capturing a trace, the output must be formatted and the IBM MQ control blocks identified.
- Formatting the information
- Identifying the control blocks associated with IBM MQ
- Identifying the event identifier associated with the control block

Formatting the information

To format the user parameter data collected by the global trace, use either the batch job shown in Figure 125 on page 1701 or the IPCS `GTFTRACE USR(` *xxx* `)` command, where *xxx* is:

5E9	To format information about control blocks on entry to IBM MQ MQI calls
5EA	To format information about control blocks on exit from IBM MQ MQI calls
5EE	To format information about IBM MQ internals

You can also specify the JOBNAME(*jobname*) parameter to limit the formatted output to specific jobs.

```
//S1 EXEC PGM=IKJEFT01,DYNAMNBR=20,REGION=4096K
//IPCSPARM DD DSN=SYS1.PARMLIB,DISP=SHR
//IPCSDDIR DD DSN=thlqual.ipcs.dataset.directory,DISP=SHR
//SYSTSPRT DD SYSOUT=*,DCB=(LRECL=137)
//IPCSTOC  DD SYSOUT=*
//GTFIN    DD DSN=gtf.trace,DISP=SHR
//SYSTSIN  DD *
IPCS
SETDEF FILE(GTFIN) NOCONFIRM
GTFTRACE USR(5E9,5EA,5EE)
/*
//STEPLIB  DD  DSN=thlqual.SCSQAUTH,DISP=SHR
```

Figure 125. Formatting the GTF output in batch. thlqual is your high level qualifier for IBM MQ data sets, and gtf.trace is the name of the data set containing your trace information. You must also specify your IPCS data set directory.

Identifying the control blocks associated with IBM MQ

The format identifier for the IBM MQ trace is D9. This value appears at the beginning of each formatted control block in the formatted GTF output, in the form:

```
USRD9
```

Identifying the event identifier associated with the control block

The trace formatter inserts one of the following messages at the top of each control block. These indicate whether the data was captured on entry to or exit from IBM MQ

- CSQW072I ENTRY: MQ user parameter trace
- CSQW073I EXIT: MQ user parameter trace

Related concepts:

"Controlling the GTF" on page 1698
Use this topic to understand how to start and stop the GTF.

Interpreting the trace information:

The GTFTRACE produced by IBM MQ can be examined to determine possible errors with invalid addresses, invalid control blocks, and invalid data.

When you look at the data produced by the GTFTRACE command, consider the following points:

- If the control block consists completely of zeros, it is possible that an error occurred while copying data from the user's address space. This might be because an invalid address was passed.
- If the first part of the control block contains non-null data, but the rest consists of zeros, it is again possible that an error occurred while copying data from the user's address space, for example, the control block was not placed entirely within valid storage. This might also be due to the control block not being initialized correctly.
- If the error occurred on exit from IBM MQ, it is possible that IBM MQ might not write the data to the user's address space. The data displayed is the version that it was attempting to copy to the user's address space.

The following tables show details of the control blocks that are traced.

Table 160 on page 1702 illustrates which control blocks are traced for different MQI calls.

Table 160. Control blocks traced for IBM MQ MQI calls

MQI call	Entry	Exit
MQCB	MQCBD, MQMD, MQGMO	MQCBD, MQMD, MQGMO
MQCLOSE	None	None
MQGET	MQMD, MQGMO	MQMD, MQGMO, and the first 256 bytes of message data
MQINQ	Selectors (if *SelectorCount* is greater than 0)	Selectors (if *SelectorCount* is greater than 0) Integer attributes (if *IntAttrCount* is greater than 0) Character attributes (if *CharAttrLength* is greater than 0)
MQOPEN	MQOD	MQOD
MQPUT	MQMD, MQPMO, and the first 256 bytes of message data	MQMD, MQPMO, and the first 256 bytes of message data
MQPUT1	MQMD, MQOD, MQPMO, and the first 256 bytes of message data	MQMD, MQOD, MQPMO, and the first 256 bytes of message data
MQSET	Selectors (if *SelectorCount* is greater than 0) Integer attributes (if *IntAttrCount* is greater than 0) Character attributes (if *CharAttrLength* is greater than 0)	Selectors (if *SelectorCount* is greater than 0) Integer attributes (if *IntAttrCount* is greater than 0) Character attributes (if *CharAttrLength* is greater than 0)
MQSTAT	MQSTS	MQSTS
MQSUB	MQSD, MQSD.ObjectString, MQSD.SubName, MQSD.SubUserData, MQSD.SelectionString, MQSD.ResObjectString	MQSD, MQSD.ObjectString, MQSD.SubName, MQSD.SubUserData, MQSD.SelectionString, MQSD.ResObjectString
MQSUBRQ	MQSRO	MQSRO

Note: In the special case of an **MQGET** call with the WAIT option, a double entry is seen if there is no message available at the time of the **MQGET** request, but a message subsequently becomes available before the expiry of any time interval specified.

This is because, although the application has issued a single **MQGET** call, the adapter is performing the wait on behalf of the application and when a message becomes available it reissues the call. So in the trace it appears as a second **MQGET** call.

Information about specific fields of the queue request parameter list is also produced in some circumstances. The fields in this list are identified as follows:

Identifier	Description
Action	Requested action
BufferL	Buffer length
CBD	Address of callback descriptor
CompCode	Completion code
CharAttL	Character attributes length
DataL	Data length
Hobj	Object handle

Identifier	Description
Hsub	Subscription handle
IntAttC	Count of integer attributes
pObjDesc	Object descriptor
Oper	Operation
Options	Options
pBuffer	Address of buffer
pCharAtt	Address of character attributes
pCTLO	Address of control callback options
pECB	Address of ECB used in get
pGMO	Address of get message options
pIntAtt	Address of integer attributes
pMsgDesc	Address of message descriptor
pPMO	Address of put message options
pSD	Address of subscription descriptor
pSelect	Address of selectors
pSRQOpt	Address of subscription request options
pSTS	Address of status structure
Reason	Reason code
RSVn	Reserved for IBM
SelectC	Selector count
Thread	Thread
Type	Requested type
UOWInfo	Information about the unit of work
Userid	CICS or IMS user ID, for batch or TSO this is zero

Other types of trace

There are other trace facilities available for problem determination. Use this topic to investigate channel initiator trace, line trace, CICS adapter trace, SSL trace, and z/OS trace.

It can be helpful to use the following trace facilities with IBM MQ.

- The channel initiator trace
- The line trace
- The CICS adapter trace
- System SSL trace
- z/OS z/OS traces

The channel initiator trace

See Figure 130 on page 1737 for information about how to get a dump of the channel initiator address space. Note that dumps produced by the channel initiator do not include trace data space. The trace data space, which is called CSQXTRDS, contains trace information. You can request this by specifying it on a slip trap or when you use the dump command.

You can run the trace using the START TRACE command. You can also set this trace to start automatically using the TRAXSTR queue manager attribute. For more information about how to do this, see ALTER QMGR.

You can display this trace information by entering the IPCS command:

```
LIST 1000. DSPNAME(CSQXTRDS)
```

You can format it using the command:

```
CTRACE COMP(CSQXssnm)
```

where *ssnm* is the subsystem name.

The line trace

A wrap-around line trace exists for each channel. This trace is kept in a 4 KB buffer for each channel in the channel initiator address space. Trace is produced for each channel, so it is ideal for problems where a channel appears to be hung, because information can be collected about the activity of this channel long after the normal trace has wrapped.

The line trace is always active; you cannot turn it off. It is available for both LU 6.2 and TCP channels and should reduce the number of times a communications trace is required.

You can view the trace as unformatted trace that is written to CSQSNAP. You can display the trace by following these steps:

1. Ensure that the CHIN procedure has a SNAP DD statement.
2. Start a CHIN trace, specifying IFCID 202 as follows:
   ```
   START TRACE(CHINIT) CLASS(4) IFCID(202)
   ```
3. Display the channel status for those channels for which the line trace is required:
   ```
   DISPLAY CHSTATUS(channel) SAVED
   ```

   This dumps the current line for the selected channels to CSQSNAP. See "Snap dumps" on page 1753 for further information.

   Note:

   a. The addresses of the storage dump are incorrect because the CSQXFFST mechanism takes a copy of the storage before writing it to CSQSNAP.
   b. The dump to CSQSNAP is only produced the first time you run the DISPLAY CHSTATUS SAVED command. This is to prevent getting dumps each time you run the command.

      To obtain another dump of line trace data, you must stop and restart the current trace.

      1) You can use a selective STOP TRACE command to stop just the trace that was started to gather the line trace data. To do this, note the TRACE NUMBER assigned to the trace as shown in this example:
         ```
         +ssid START TRACE(CHINIT) CLASS(4) IFCID(202)
              CSQW130I +ssid 'CHINIT' TRACE STARTED, ASSIGNED TRACE NUMBER 01
         ```
      2) To stop the trace, issue the following command:
         ```
         +ssid STOP TRACE(CHINIT) TNO(01)
         ```
      3) You can then enter another START TRACE command with a DISPLAY CHSTATUS SAVED command to gather more line trace data to CSQSNAP.
4. The line trace buffer is unformatted. Each entry starts with a clock, followed by a time stamp, and an indication of whether this is an OUTBOUND or INBOUND flow. Use the time stamp information to find the earliest entry.

The CICS adapter trace

The CICS adapter writes entries to the CICS trace if your trace number is set to a value in the range 0 through 199 (decimal), and if either:
- CICS user tracing is enabled, or
- CICS internal/auxiliary trace is enabled

You can enable CICS tracing in one of two ways:
- Dynamically, using the CICS-supplied transaction CETR
- By ensuring that the USERTR parameter in the CICS system initialization table (SIT) is set to YES

For more information about enabling CICS trace, see the *CICS Problem Determination Guide*.

The CICS trace entry originating from the CICS adapter has a value AP0 *000*, where *000* is the hexadecimal equivalent of the decimal value of the CICS adapter trace number you specified.

The trace entries are shown in "CICS adapter trace entries."

System SSL trace

You can collect System SSL trace using the SSL Started Task. The details of how to set up this task are in the *System Secure Sockets Layer Programming* documentation, SC24-5901. A trace file is generated for each SSLTASK running in the CHINIT address space.

z/OS

z/OS traces

z/OS traces, which are common to all products operating as formal subsystems of z/OS, are available for use with IBM MQ. For information about using and interpreting this trace facility, see the *MVS Diagnosis: Tools and Service Aids* manual.

CICS adapter trace entries:

Use this topic as a reference for CICS adapter trace entries.

The CICS trace entry for these values is AP0 xxx (where xxx is the hexadecimal equivalent of the trace number you specified when the CICS adapter was enabled). These trace entries are all issued by CSQCTRUE, except CSQCTEST, which is issued by CSQCRST and CSQCDSP.

Table 161. CICS adapter trace entries

Name	Description	Trace sequence	Trace data
CSQCABNT	Abnormal termination	Before issuing END_THREAD ABNORMAL to IBM MQ. This is due to the end of the task and therefore an implicit backout could be performed by the application. A ROLLBACK request is included in the END_THREAD call in this case.	Unit of work information. You can use this information when finding out about the status of work. (For example, it can be verified against the output produced by the DISPLAY THREAD command, or the log print utility.)
CSQCAUID	Bridge security	Before validating bridge user password or PassTicket.	User ID.
CSQCBACK	Syncpoint backout	Before issuing BACKOUT to IBM MQ. This is due to an explicit backout request from the application.	Unit of work information.

Table 161. CICS adapter trace entries (continued)

Name	Description	Trace sequence	Trace data
CSQCCONX	MQCONNX	Before issuing **MQCONNX** to IBM MQ.	Connection tag.
CSQCCCRC	Completion code and reason code	After unsuccessful return from API call.	Completion code and reason code.
CSQCCOMM	Syncpoint commit	Before issuing COMMIT to IBM MQ. This can be due to a single-phase commit request or the second phase of a two-phase commit request. The request is due to a explicit syncpoint request from the application.	Unit of work information.
CSQCDCFF	IBM use only		
CSQCDCIN	IBM use only		
CSQCDCOT	IBM use only		
CSQCEXER	Execute resolve	Before issuing EXECUTE_RESOLVE to IBM MQ.	The unit of work information of the unit of work issuing the EXECUTE_RESOLVE. This is the last in-doubt unit of work in the resynchronization process.
CSQCGETW	GET wait	Before issuing CICS wait.	Address of the ECB to be waited on.
CSQCGMGD	GET message data	After successful return from **MQGET** .	Up to 40 bytes of the message data.
CSQCGMGH	GET message handle	Before issuing **MQGET** to IBM MQ.	Object handle.
CSQCGMGI	Get message ID	After successful return from **MQGET** .	Message ID and correlation ID of the message.
CSQCHCER	Hconn error	Before issuing any MQ verb.	Connection handle.
CSQCINDL	In-doubt list	After successful return from the second INQUIRE_INDOUBT.	The in-doubt units of work list.
CSQCINDO	IBM use only		
CSQCINDS	In-doubt list size	After successful return from the first INQUIRE_INDOUBT and the in-doubt list is not empty.	Length of the list; divided by 64 gives the number of in-doubt units of work.
CSQCINDW	Syncpoint in doubt	During syncpoint processing, CICS is in doubt as to the disposition of the unit of work.	Unit of work information.
CSQCINQH	INQ handle	Before issuing **MQINQ** to IBM MQ.	Object handle.
CSQCLOSH	CLOSE handle	Before issuing **MQCLOSE** to IBM MQ.	Object handle.
CSQCLOST	Disposition lost	During the resynchronization process, CICS informs the adapter that it has been cold started so no disposition information regarding the unit of work being resynchronized is available.	Unit of work ID known to CICS for the unit of work being resynchronized.

Table 161. CICS adapter trace entries (continued)

Name	Description	Trace sequence	Trace data
CSQCNIND	Disposition not in doubt	During the resynchronization process, CICS informs the adapter that the unit of work being resynchronized should not have been in doubt (that is, perhaps it is still running).	Unit of work ID known to CICS for the unit of work being resynchronized.
CSQCNORT	Normal termination	Before issuing END_THREAD NORMAL to IBM MQ. This is due to the end of the task and therefore an implicit syncpoint commit might be performed by the application. A COMMIT request is included in the END_THREAD call in this case.	Unit of work information.
CSQCOPNH	OPEN handle	After successful return from **MQOPEN** .	Object handle.
CSQCOPNO	OPEN object	Before issuing **MQOPEN** to IBM MQ.	Object name.
CSQCPMGD	PUT message data	Before issuing **MQPUT** to IBM MQ.	Up to 40 bytes of the message data.
CSQCPMGH	PUT message handle	Before issuing **MQPUT** to IBM MQ.	Object handle.
CSQCPMGI	PUT message ID	After successful **MQPUT** from IBM MQ.	Message ID and correlation ID of the message.
CSQCPREP	Syncpoint prepare	Before issuing PREPARE to IBM MQ in the first phase of two-phase commit processing. This call can also be issued from the distributed queuing component as an API call.	Unit of work information.
CSQCP1MD	PUTONE message data	Before issuing **MQPUT1** to IBM MQ.	Up to 40 bytes of data of the message.
CSQCP1MI	PUTONE message ID	After successful return from **MQPUT1** .	Message ID and correlation ID of the message.
CSQCP1ON	PUTONE object name	Before issuing **MQPUT1** to IBM MQ.	Object name.
CSQCRBAK	Resolved backout	Before issuing RESOLVE_ROLLBACK to IBM MQ.	Unit of work information.
CSQCRCMT	Resolved commit	Before issuing RESOLVE_COMMIT to IBM MQ.	Unit of work information.
CSQCRMIR	RMI response	Before returning to the CICS RMI (resource manager interface) from a specific invocation.	Architected RMI response value. Its meaning depends of the type of the invocation. To determine the type of invocation, look at previous trace entries produced by the CICS RMI component.
CSQCRSYN	Resync	Before the resynchronization process starts for the task.	Unit of work ID known to CICS for the unit of work being resynchronized.
CSQCSETH	SET handle	Before issuing **MQSET** to IBM MQ.	Object handle.
CSQCTASE	IBM use only		

Table 161. CICS adapter trace entries (continued)

Name	Description	Trace sequence	Trace data
CSQCTEST	Trace test	Used in EXEC CICS ENTER TRACE call to verify the trace number supplied by the user or the trace status of the connection.	No data.

Tracing TLS and SSL: `runmqakm` and iKeyman and iKeycmd functions

How to request **`runmqakm`** tracing and iKeyman and iKeycmd tracing.

iKeyman and iKeycmd trace

To request iKeyman tracing, execute the iKeyman command for your platform with the following -D flags.

For Windows UNIX and Linux systems:

```
strmqikm -Dkeyman.debug=true -Dkeyman.jnitracing=ON
```

To request iKeycmd tracing, run the iKeycmd command for your platform with the following -D flags.

For Windows UNIX and Linux systems:

```
runmqckm -Dkeyman.debug=true -Dkeyman.jnitracing=ON
```

iKeyman and iKeycmd write three trace files to the directory from which you start them, so consider starting iKeyman or iKeycmd from the trace directory to which the runtime TLS or SSL trace is written: `/var/mqm/trace` on UNIX and Linux systems and *`MQ_INSTALLATION_PATH`*`/trace` on Windows. *`MQ_INSTALLATION_PATH`* represents the high-level directory in which IBM MQ is installed.

The trace file generated by iKeyman and iKeycmd has the following format:

```
debugTrace. n
```

where *n* is an incrementing number starting at 0.

`runmqakm` trace

To request **`runmqakm`** tracing, execute the **`runmqakm`** command with the following flags:

```
runmqakm -trace filename
```

where *filename* is the name of the trace file to create. You cannot format the **`runmqakm`** trace file. Send it unchanged to IBM support. The **`runmqakm`** trace file is a binary file and, if it is transferred to IBM support via FTP, it must be transferred in binary transfer mode.

Runtime TLS and SSL trace

On UNIX, Linux, and Windows systems, you can independently request trace information for iKeyman, iKeycmd, the runtime TLS or SSL functions, or a combination of these.

The runtime TLS trace files have the names AMQ.TLS.TRC and AMQ.TLS.TRC.1 and the SSL trace files have the names AMQ.SSL.TRC and AMQ.SSL.TRC.1. You cannot format any of the TLS or SSL trace files; send them unchanged to IBM support. The TLS and SSL trace files are binary files and, if they are transferred to IBM support via FTP, they must be transferred in binary transfer mode.

Use the **strmqtrc** and **endmqtrc** commands or the MQ Explorer interface to start and end tracing.

Tracing IBM MQ classes for JMS applications

The trace facility in IBM MQ classes for JMS is provided to help IBM Support to diagnose customer issues. Various properties control the behavior of this facility.

If you are asked to provide trace output to investigate an issue, use one of the options mentioned below:

- If the issue is easy to recreate, then collect an IBM MQ classes for JMS trace by using a Java System Property. For more information, see "Collecting an IBM MQ classes for JMS trace by using a Java system property" on page 1710.
- If an application needs to run for a period of time before the issue occurs, collect an IBM MQ classes for JMS trace by using the IBM MQ classes for JMS configuration file. For more information, see "Collecting an IBM MQ classes for JMS trace by using the IBM MQ classes for JMS configuration file" on page 1711.
- To generate a trace from an application that is currently running, collect the IBM MQ classes for JMS trace dynamically by using the traceControl utility. For more information, see "Collecting an IBM MQ classes for JMS trace dynamically by using the traceControl utility" on page 1712.

If you are unsure which option to use, contact your IBM Support representative and they will be able to advise you on the best way to collect trace for the issue that you are seeing.

If a severe or unrecoverable error occurs, First Failure Support Technology (FFST) information is recorded in a file with a name of the format `JMSCC` *`xxxx`*`.FDC` where *`xxxx`* is a four-digit number. This number is incremented to differentiate `.FDC` files.

`.FDC` files are always written to a subdirectory called `FFDC`. The subdirectory is in one of two locations, depending on whether trace is active:

Trace is active, and *`traceOutputName`* is set
The FFDC directory is created as a subdirectory of the directory to which the trace file is being written.

Trace is not active or *`traceOutputName`* is not set
The FFDC directory is created as a subdirectory of the current working directory.

For more information about FFST in IBM MQ classes for JMS, see "FFST: IBM MQ classes for JMS" on page 1667.

The JSE common services uses `java.util.logging` as its trace and logging infrastructure. The root object of this infrastructure is the LogManager. The log manager has a reset method that closes all handlers and sets the log level to `null`, which in effect turns off all the trace. If your application or application server calls java.util.logging.LogManager.getLogManager().reset(), it closes all trace, which might prevent you from diagnosing any problems. To avoid closing all trace, create a LogManager class with an overridden reset() method that does nothing, as shown in the following example:

```
package com.ibm.javaut.tests;
import java.util.logging.LogManager;
public class JmsLogManager extends LogManager {
 // final shutdown hook to ensure that the trace is finally shutdown
 // and that the lock file is cleaned-up
 public class ShutdownHook extends Thread{
  public void run(){
   doReset();
  }
 }
  public JmsLogManager(){
  // add shutdown hook to ensure final cleanup
  Runtime.getRuntime().addShutdownHook(new ShutdownHook());
 }
  public void reset() throws SecurityException {
  // does nothing
 }
 public void doReset(){
  super.reset();
 }
        }
```

The shutdown hook is necessary to ensure that trace is properly shut down when the JVM finishes. To use the modified log manager instead of the default one, add a system property to the JVM startup:

```
java -Djava.util.logging.manager=com. mycompany.logging.LogManager ...
```

Collecting an IBM MQ classes for JMS trace by using a Java system property

For issues that can be reproduced in a short amount of time, IBM MQ classes for JMS trace should be collected by setting a Java system property when starting the application.

About this task

To collect a trace by using a Java system property, complete the following steps.

Procedure

Run the application that is going to be traced by using the following command:

```
java -Dcom.ibm.msg.client.commonservices.trace.status=ON application_name
```

When the application starts, the IBM MQ classes for JMS start writing trace information to a trace file in the application's current working directory. The name of the trace file depends on the environment that the application is running in:

- For IBM MQ classes for JMS for Version 8.0.0, Fix Pack 6 or earlier, trace is written to a file called `mqjms_%PID%.trc`.
- V 8.0.0.7 From Version 8.0.0, Fix Pack 7, if the application has loaded the IBM MQ classes for JMS from the JAR file `com.ibm.mqjms.jar`, trace is written to a file called `mqjms_%PID%.trc`.
- V 8.0.0.7 From Version 8.0.0, Fix Pack 7, if the application has loaded the IBM MQ classes for JMS from the relocatable JAR file `com.ibm.mq.allclient.jar`, trace is written to a file called `mqjavaclient_%PID%.trc`.

where *%PID%* is the process identifier of the application that is being traced.
The application stops writing information to the trace file when it is stopped.
If the application has to run for a long period of time before the issue that the trace is being collected for occurs, then the trace file could potentially be very large. In this situation, consider collecting trace by

using the IBM MQ classes for JMS configuration file (see "Collecting an IBM MQ classes for JMS trace by using the IBM MQ classes for JMS configuration file"). When enabling trace in this way, it is possible to control the amount of trace data that the IBM MQ classes for JMS generate.

Collecting an IBM MQ classes for JMS trace by using the IBM MQ classes for JMS configuration file

If an application must run for a long period of time before an issue occurs, IBM MQ classes for JMS trace should be collected by using the IBM MQ classes for JMS configuration file. The configuration file allows you to specify various options to control the amount of trace data that is collected.

About this task

To collect a trace by using the IBM MQ classes for JMS configuration file, complete the following steps.

Procedure

1. Create an IBM MQ classes for JMS configuration file. For more information about this file, see The IBM MQ classes for JMS configuration file.
2. Edit the IBM MQ classes for JMS configuration file so that the property **`com.ibm.msg.client.commonservices.trace.status`** is set to the value `ON`.
3. Optional: Edit the other properties that are listed in the IBM MQ classes for JMS configuration file Java Standard Edition Trace Settings.
4. Run the IBM MQ classes for JMS application by using the following command:

   ```
   java -Dcom.ibm.msg.client.config.location=config_file_url
   application_name
   ```

   where *config_file_url* is a uniform resource locator (URL) that specifies the name and location of the IBM MQ classes for JMS configuration file. URLs of the following types are supported: `http`, `file`, `ftp`, and `jar`.

   Here is an example of a Java command:

   ```
   java -Dcom.ibm.msg.client.config.location=file:/D:/mydir/myjms.config
   MyAppClass
   ```

   This command identifies the IBM MQ classes for JMS configuration file as the file `D:\mydir\myjms.config` on the local Windows system.

   By default, the IBM MQ classes for JMS start writing trace information to a trace file in the application's current working directory when the application starts up. The name of the trace file depends on the environment that the application is running in:

   - For IBM MQ classes for JMS for Version 8.0.0, Fix Pack 6 or earlier, trace is written to a file called `mqjms_%PID%.trc`.
   - V 8.0.0.7 From Version 8.0.0, Fix Pack 7, if the application has loaded the IBM MQ classes for JMS from the JAR file `com.ibm.mqjms.jar`, trace is written to a file called `mqjms_%PID%.trc`.
   - V 8.0.0.7 From Version 8.0.0, Fix Pack 7, if the application has loaded the IBM MQ classes for JMS from the relocatable JAR file `com.ibm.mq.allclient.jar`, trace is written to a file called `mqjavaclient_%PID%.trc`.

   where *%PID%* is the process identifier of the application that is being traced.

   To change the name of the trace file, and the location where it is written, ensure that the IBM MQ classes for JMS configuration file that the application uses contains an entry for the property **`com.ibm.msg.client.commonservices.trace.outputName`**. The value for the property can be either of the following:

   - The name of the trace file that is created in the application's working directory.
   - The fully qualified name of the trace file, including the directory in which the file is created.

For example, to configure the IBM MQ classes for JMS to write trace information for an application to a file called `C:\Trace\trace.trc`, the IBM MQ classes for JMS configuration file that the application uses needs to contain the following entry:

```
com.ibm.msg.client.commonservices.trace.outputName=C:\Trace\trace.trc
```

Collecting an IBM MQ classes for JMS trace dynamically by using the traceControl utility

The traceControl utility that is shipped with the IBM MQ classes for JMS allows trace to be collected from a running application. This can be very useful if IBM Support need to see a trace from an application once an issue has occurred, or if trace needs to be collected from a critical application that cannot be stopped.

About this task

For more information about the traceControl utility, see "Controlling trace in a running process by using IBM MQ classes for Java and IBM MQ classes for JMS" on page 1721.

To collect a trace by using the traceControl utility, complete the following steps.

Procedure

1. Bring up a command prompt, and navigate to the directory *MQ_INSTALLATION_PATH*`\java\lib`.
2. Run the command:
   ```
   java -jar com.ibm.mq.traceControl -list
   ```
   This command brings up a list of all of the Java processes on the system.
3. Identify the process identifier for the IBM MQ classes for JMS application that needs to be traced, and run the command:
   ```
   java -jar com.ibm.mq.traceControl -i process identifier -enable
   ```
   Trace is now turned on for the application.

   When trace is enabled, the IBM MQ classes for JMS start writing trace information to a trace file in the application's current working directory. The name of the trace file depends on the environment that the application is running in:
   - For IBM MQ classes for JMS for Version 8.0.0, Fix Pack 6 or earlier, trace is written to a file called `mqjms_`*%PID%*`.trc`.
   - V 8.0.0.7 From Version 8.0.0, Fix Pack 7, if the application has loaded the IBM MQ classes for JMS from the JAR file `com.ibm.mq.jar`, trace is written to a file called `mqjava_`*%PID%*`.trc`.
   - V 8.0.0.7 From Version 8.0.0, Fix Pack 7, if the application has loaded the IBM MQ classes for JMS from the relocatable JAR file `com.ibm.mq.allclient.jar`, trace is written to a file called `mqjavaclient_`*%PID%*`.trc`.

   where *%PID%* is the process identifier of the application that is being traced.
4. To turn trace off, run the command:
   ```
   java -jar com.ibm.mq.traceControl -i process identifier -disable
   ```

Tracing using `MQJMS_TRACE_LEVEL`

To maintain backwards compatibility, the trace parameters used by Version 6.0 of IBM MQ classes for JMS are still supported. **`MQJMS_TRACE_LEVEL`** is deprecated for any new application.

This information has been removed. For information on how to enable trace, see "Tracing IBM MQ classes for JMS applications" on page 1709.

Tracing IBM MQ classes for Java applications

The trace facility in IBM MQ classes for Java is provided to help IBM Support to diagnose customer issues. Various properties control the behavior of this facility.

About this task

If you are asked to provide trace output to investigate an issue, use one of the options mentioned below:

- If the issue is easy to recreate, then collect an IBM MQ classes for Java trace by using a Java System Property. For more information, see "Collecting an IBM MQ classes for Java trace by using a Java system property" on page 1714.
- If an application needs to run for a period of time before the issue occurs, collect an IBM MQ classes for Java trace by using the IBM MQ classes for Java configuration file. For more information, see "Collecting an IBM MQ classes for Java trace by using the IBM MQ classes for Java configuration file" on page 1715.
- To generate a trace from an application that is currently running, collect the IBM MQ classes for Java trace dynamically by using the traceControl utility. For more information, see "Collecting an IBM MQ classes for Java trace dynamically by using the traceControl utility" on page 1716.

If you are unsure which option to use, contact your IBM Support representative and they will be able to advise you on the best way to collect trace for the issue you are seeing.

If a severe or unrecoverable error occurs, First Failure Support Technology (FFST) information is recorded in a file with a name of the format `JAVACC` *`xxxx`*`.FDC` where *`xxxx`* is a four-digit number. It is incremented to differentiate `.FDC` files.

`.FDC` files are always written to a subdirectory called `FFDC`. The subdirectory is in one of two locations, depending on whether trace is active:

Trace is active, and *`traceOutputName`* is set
: The FFDC directory is created as a subdirectory of the directory to which the trace file is being written.

Trace is not active or *`traceOutputName`* is not set
: The FFDC directory is created as a subdirectory of the current working directory.

The JSE common services uses `java.util.logging` as its trace and logging infrastructure. The root object of this infrastructure is the LogManager. The log manager has a reset method, which closes all handlers and sets the log level to `null`, which in effect turns off all the trace. If your application or application server calls java.util.logging.LogManager.getLogManager().reset(), it closes all trace, which might prevent you from diagnosing any problems. To avoid closing all trace, create a LogManager class with an overridden reset() method that does nothing, as in the following example.

```
package com.ibm.javaut.tests;
import java.util.logging.LogManager;
public class JmsLogManager extends LogManager {
        // final shutdown hook to ensure that the trace is finally shutdown
        // and that the lock file is cleaned-up
        public class ShutdownHook extends Thread{
                public void run(){
                        doReset();
                }
        }
                public JmsLogManager(){
                // add shutdown hook to ensure final cleanup
                Runtime.getRuntime().addShutdownHook(new ShutdownHook());
        }
                public void reset() throws SecurityException {
                // does nothing
        }
        public void doReset(){
                super.reset();
        }
        }
```

The shutdown hook is necessary to ensure that trace is properly shutdown when the JVM finishes. To use the modified log manager instead of the default one, add a system property to the JVM startup:

`java -Djava.util.logging.manager=com.` *`mycompany`*`.logging.LogManager ...`

Collecting an IBM MQ classes for Java trace by using a Java system property

For issues that can be reproduced in a short amount of time, IBM MQ classes for Java trace should be collected by setting a Java system property when starting the application.

About this task

To collect a trace by using a Java system property, complete the following steps.

Procedure

Run the application that is going to be traced by using the following command:

`java -Dcom.ibm.msg.client.commonservices.trace.status=ON` *`application_name`*

When the application starts, the IBM MQ classes for Java start writing trace information to a trace file in the application's current working directory. The name of the trace file depends on the environment that the application is running in:

- For IBM MQ classes for Java for Version 8.0.0, Fix Pack 6 or earlier, trace is written to a file called `mqjms_`*`%PID%`*`.trc`.
- V 8.0.0.7 From Version 8.0.0, Fix Pack 7, if the application has loaded the IBM MQ classes for Java from the JAR file `com.ibm.mq.jar`, trace is written to a file called `mqjava_`*`%PID%`*`.trc`.
- V 8.0.0.7 From Version 8.0.0, Fix Pack 7, if the application has loaded the IBM MQ classes for Java from the relocatable JAR file `com.ibm.mq.allclient.jar`, trace is written to a file called `mqjavaclient_`*`%PID%`*`.trc`.

where *%PID%* is the process identifier of the application that is being traced.
The application stops writing information to the trace file when it is stopped.
If the application has to run for a long period of time before the issue that the trace is being collected for occurs, then the trace file could potentially be very large. In this situation, consider collecting trace by using the IBM MQ classes for Java configuration file (see "Collecting an IBM MQ classes for Java trace by using the IBM MQ classes for Java configuration file" on page 1715). When enabling trace in this way, it is possible to control the amount of trace data that the IBM MQ classes for Java generates.

Collecting an IBM MQ classes for Java trace by using the IBM MQ classes for Java configuration file

If an application must run for a long period of time before an issue occurs, IBM MQ classes for Java trace should be collected by using the IBM MQ classes for Java configuration file. The configuration file allows you to specify various options to control the amount of trace data that is collected.

About this task

To collect a trace by using the IBM MQ classes for Java configuration file, complete the following steps.

Procedure

1. Create an IBM MQ classes for Java configuration file. For more information about this file, see The IBM MQ classes for Java configuration file.
2. Edit the IBM MQ classes for Java configuration file so that the property **`com.ibm.msg.client.commonservices.trace.status`** is set to the value `ON`.
3. Optional: Edit the other properties that are listed in the IBM MQ classes for Java configuration file Java Standard Edition Trace Settings.
4. Run the IBM MQ classes for Java application by using the following command:

   ```
   java -Dcom.ibm.msg.client.config.location=config_file_url
   application_name
   ```

   where *config_file_url* is a uniform resource locator (URL) that specifies the name and location of the IBM MQ classes for Java configuration file. URLs of the following types are supported: `http`, `file`, `ftp`, and `jar`.

   Here is an example of a Java command:

   ```
   java -Dcom.ibm.msg.client.config.location=file:/D:/mydir/myJava.config
   MyAppClass
   ```

   This command identifies the IBM MQ classes for Java configuration file as the file `D:\mydir\myJava.config` on the local Windows system.

   By default, the IBM MQ classes for Java start writing trace information to a trace file in the application's current working directory when the application starts up. The name of the trace file depends on the environment that the application is running in:

   - For IBM MQ classes for Java for Version 8.0.0, Fix Pack 6 or earlier, trace is written to a file called `mqjms_%PID%.trc`.
   - V 8.0.0.7 From Version 8.0.0, Fix Pack 7, if the application has loaded the IBM MQ classes for Java from the JAR file `com.ibm.mq.jar`, trace is written to a file called `mqjava_%PID%.trc`.
   - V 8.0.0.7 From Version 8.0.0, Fix Pack 7, if the application has loaded the IBM MQ classes for Java from the relocatable JAR file `com.ibm.mq.allclient.jar`, trace is written to a file called `mqjavaclient_%PID%.trc`.

   where *%PID%* is the process identifier of the application that is being traced.

   To change the name of the trace file, and the location where it is written, ensure that the IBM MQ classes for Java configuration file that the application uses contains an entry for the property **`com.ibm.msg.client.commonservices.trace.outputName`**. The value for the property can be either of the following:

   - The name of the trace file that is created in the application's working directory.
   - The fully qualified name of the trace file, including the directory in which the file is created.

   For example, to configure the IBM MQ classes for Java to write trace information for an application to a file called `C:\Trace\trace.trc`, the IBM MQ classes for Java configuration file that the application uses needs to contain the following entry:

   ```
   com.ibm.msg.client.commonservices.trace.outputName=C:\Trace\trace.trc
   ```

Collecting an IBM MQ classes for Java trace dynamically by using the traceControl utility

The traceControl utility that is shipped with the IBM MQ classes for Java allows trace to be collected from a running application. This can be very useful if IBM Support need to see a trace from an application once an issue has occurred, or if trace needs to be collected from a critical application that cannot be stopped.

About this task

For more information about the traceControl utility, see "Controlling trace in a running process by using IBM MQ classes for Java and IBM MQ classes for JMS" on page 1721.

To collect a trace by using the traceControl utility, complete the following steps.

Procedure

1. Bring up a command prompt, and navigate to the directory `MQ_INSTALLATION_PATH\java\lib`.
2. Run the command:
   ```
   java -jar com.ibm.mq.traceControl -list
   ```
   This command brings up a list of all of the Java processes on the system.
3. Identify the process identifier for the IBM MQ classes for Java application that needs to be traced, and run the command:
   ```
   java -jar com.ibm.mq.traceControl -i process identifier -enable
   ```
   Trace is now turned on for the application.

   When trace is enabled, the IBM MQ classes for Java start writing trace information to a trace file in the application's current working directory. The name of the trace file depends on the environment that the application is running in:
   - For IBM MQ classes for Java for Version 8.0.0, Fix Pack 6 or earlier, trace is written to a file called `mqjms_%PID%.trc`.
   - V 8.0.0.7 From Version 8.0.0, Fix Pack 7, if the application has loaded the IBM MQ classes for Java from the JAR file `com.ibm.mq.jar`, trace is written to a file called `mqjava_%PID%.trc`.
   - V 8.0.0.7 From Version 8.0.0, Fix Pack 7, if the application has loaded the IBM MQ classes for Java from the relocatable JAR file `com.ibm.mq.allclient.jar`, trace is written to a file called `mqjavaclient_%PID%.trc`.

   where *%PID%* is the process identifier of the application that is being traced.
4. To turn trace off, run the command:
   ```
   java -jar com.ibm.mq.traceControl -i process identifier -disable
   ```

Tracing the IBM MQ Resource Adapter

The ResourceAdapter object encapsulates the global properties of the IBM MQ resource adapter. To enable trace of the IBM MQ resource adapter, properties need to be defined in the ResourceAdapter object.

The ResourceAdapter object has two sets of properties:

- Properties associated with diagnostic tracing
- Properties associated with the connection pool managed by the resource adapter

The way you define these properties depends on the administration interfaces provided by your application server.

Table 162 lists the properties of the ResourceAdapter object that are associated with diagnostic tracing.

Table 162. Properties of the ResourceAdapter object that are associated with diagnostic tracing

Name of property	**Type**	**Default value**	**Description**
traceEnabled	String	false	A flag to enable or disable diagnostic tracing. If the value is false, tracing is turned off.
traceLevel	String	3	The level of detail in a diagnostic trace. The value can be in the range 0, which produces no trace, to 10, which provides the most detail. See Table 163 for a description of each level.
logWriterEnabled	String	true	A flag to enable or disable the sending of a diagnostic trace to a LogWriter object provided by the application server. If the value is true, the trace is sent to a LogWriter object. If the value is false, any LogWriter object provided by the application server is not used.

Table 163 describes the levels of detail for diagnostic tracing.

Table 163. The levels of detail for diagnostic tracing

Level number	**Level of detail**
0	No trace.
1	The trace contains error messages.
3	The trace contains error and warning messages.
6	The trace contains error, warning, and information messages.
8	The trace contains error, warning, and information messages, and entry and exit information for methods.
9	The trace contains error, warning, and information messages, entry and exit information for methods, and diagnostic data.
10	The trace contains all trace information.

Note: Any level that is not included in this table is equivalent to the next lowest level. For example, specifying a trace level of 4 is equivalent to specifying a trace level of 3. However, the levels that are not included might be used in future releases of the IBM MQ resource adapter, so it is better to avoid using these levels.

If diagnostic tracing is turned off, error and warning messages are written to the system error stream. If diagnostic tracing is turned on, error messages are written to the system error stream and to the trace destination, but warning messages are written only to the trace destination. However, the trace contains warning messages only if the trace level is 3 or higher. By default, the trace destination is the current working directory, but if the logWriterEnabled property is set, the trace is sent to the application server.

In general, the ResourceAdapter object requires no administration. However, to enable diagnostic tracing on UNIX and Linux systems for example, you can set the following properties:

```
traceEnabled:    true
traceLevel:      10
```

These properties have no effect if the resource adapter has not been started, which is the case, for example, when applications using IBM MQ resources are running only in the client container. In this situation, you can set the properties for diagnostic tracing as Java Virtual Machine (JVM) system properties. You can set the properties by using the -D flag on the **java** command, as in the following example:

```
java ... -DtraceEnabled=true -DtraceLevel=6
```

You do not need to define all the properties of the ResourceAdapter object. Any properties left unspecified take their default values. In a managed environment, it is better not to mix the two ways of specifying properties. If you do mix them, the JVM system properties take precedence over the properties of the ResourceAdapter object.

Tracing additional IBM MQ Java components

For Java components of IBM MQ, for example the IBM MQ Explorer and the Java implementation of IBM MQ Transport for SOAP, diagnostic information is output using the standard IBM MQ diagnostic facilities or by Java diagnostic classes.

Diagnostic information in this context consists of trace, first-failure data capture (FFDC) and error messages.

You can choose to have this information produced using IBM MQ facilities or the facilities of IBM MQ classes for Java or IBM MQ classes for JMS, as appropriate. Generally use the IBM MQ diagnostic facilities if they are available on the local system.

You might want to use the Java diagnostics in the following circumstances:

- On a system on which queue managers are available, if the queue manager is managed separately from the software you are running.
- To reduce performance effect of IBM MQ trace.

To request and configure diagnostic output, two system properties are used when starting an IBM MQ Java process:

- System property com.ibm.mq.commonservices specifies a standard Java property file, which contains a number of lines which are used to configure the diagnostic outputs. Each line of code in the file is free-format, and is terminated by a new line character.
- System property com.ibm.mq.commonservices.diagid associates trace and FFDC files with the process which created them.

For information about using the com.ibm.mq.commonservices properties file to configure diagnostics information, see “Using com.ibm.mq.commonservices” on page 1719.

For instructions on locating trace information and FFDC files, see “Java trace and FFDC files” on page 1720.

Using com.ibm.mq.commonservices

The com.ibm.mq.commonservices properties file contains the following entries relating to the output of diagnostics from the Java components of IBM MQ.

Note that case is significant in all these entries:

Diagnostics.Java= *options*
: Which components are traced using Java trace. Options are one or more of *explorer*, *soap*, and *wmqjavaclasses*, separated by commas, where "explorer" refers to the diagnostics from the IBM MQ Explorer, "soap" refers to the diagnostics from the running process within IBM MQ Transport for SOAP, and "wmqjavaclasses" refers to the diagnostics from the underlying IBM MQ Java classes. By default no components are traced.

Diagnostics.Java.Trace.Detail= *high* | *medium* | *low*
: Detail level for Java trace. The *high* and *medium* detail levels match those used in IBM MQ tracing but *low* is unique to Java trace. This property is ignored if Diagnostics.Java is not set. The default is *medium*.

Diagnostics.Java.Trace.Destination.File= *enabled* | *disabled*
: Whether Java trace is written to a file. This property is ignored if Diagnostics.Java is not set. The default is *disabled*.

Diagnostics.Java.Trace.Destination.Console= *enabled* | *disabled*
: Whether Java trace is written to the system console. This property is ignored if Diagnostics.Java is not set. The default is *disabled*.

Diagnostics.Java.Trace.Destination.Pathname= *dirname*
: The directory to which Java trace is written. This property is ignored if Diagnostics.Java is not set or Diagnostics.Java.Trace.Destination.File=disabled. On UNIX and Linux systems, the default is /var/mqm/trace if it is present, otherwise the Java console (System.err). On Windows, the default is the system console.

Diagnostics.Java.FFDC.Destination.Pathname= *dirname*
: The directory to which Java FFDC output is written. The default is the current working directory.

Diagnostics.Java.Errors.Destination.Filename= *filename*
: The fully qualified file name to which Java error messages are written. The default is AMQJAVA.LOG in the current working directory.

An example of a com.ibm.mq.commonservices properties file is given in Figure 126 on page 1720. Lines beginning with the number sign (#) are treated as comments.

```
#
# Java diagnostics for WebSphere MQ Transport for SOAP
# and the WebSphere MQ Java Classes are both enabled
#
Diagnostics.Java=soap,wmqjavaclasses
#
# High detail Java trace
#
Diagnostics.Java.Trace.Detail=high
#
# Java trace is written to a file and not to the console.
#
Diagnostics.Java.Trace.Destination.File=enabled
Diagnostics.Java.Trace.Destination.Console=disabled
#
# Directory for Java trace file
#
Diagnostics.Java.Trace.Destination.Pathname=c:\\tracedir
#
# Directory for First Failure Data Capture
#
Diagnostics.Java.FFDC.Destination.Pathname=c:\\ffdcdir
#
# Directory for error logging
#
Diagnostics.Java.Errors.Destination.Filename=c:\\errorsdir\\SOAPERRORS.LOG
#
```

Figure 126. Sample com.ibm.mq.commonservices properties file

A sample properties file, WMQSoap_RAS.properties, is also supplied as part of the " Java messaging and SOAP transport" install option.

Java trace and FFDC files

File name conventions for Java trace and FFDC files.

When Java trace is generated for IBM MQ Transport for SOAP, it is written to a file with a name of the format `AMQ.` *`diagid`*`.` *`counter`*`.TRC`. Here, *diagid* is the value of the system property com.ibm.mq.commonservices.diagid associated with this Java process, as described earlier in this section, and *counter* is an integer greater than or equal to 0. All letters in the name are in uppercase, matching the naming convention used for normal IBM MQ trace.

If com.ibm.mq.commonservices.diagid is not specified, the value of *diagid* is the current time, in the format `YYYYMMDDhhmmssmmm`.

When Java trace is generated for the MQ Explorer, it is written to file with a name of the format `AMQYYYYMMDDHHmmssmmm.TRC.n`. Each time MQ Explorer trace is run, the trace facility renames all previous trace files by incrementing the file suffix `.n` by one. The trace facility then creates a new file with the suffix `.0` that is always the latest.

The IBM MQ Java classes trace file has a name based on the equivalent IBM MQ Transport for SOAP Java trace file. The name differs in that it has the string .JC added before the .TRC string, giving a format of `AMQ.` *`diagid`*`.` *`counter`*`.JC.TRC`.

When Java FFDC is generated for the MQ Explorer or for IBM MQ Transport for SOAP, it is written to a file with a name of the format `AMQ.` *`diagid`*`.` *`counter`*`.FDC` where *diagid* and *counter* are as described for Java trace files.

Java error message output for the MQ Explorer and for IBM MQ Transport for SOAP is written to the file specified by *Diagnostics.Java.Errors.Destination.Filename* for the appropriate Java process. The format of these files matches closely the format of the standard IBM MQ error logs.

When a process is writing trace information to a file, it appends to a single trace output file for the lifetime of the process. Similarly, a single FFDC output file is used for the lifetime of a process.

All trace output is in the UTF-8 character set.

Controlling trace in a running process by using IBM MQ classes for Java and IBM MQ classes for JMS

The IBM MQ classes for Java and IBM MQ classes for JMS register a Standard MBean that allows suitable Java Management Extensions (JMX) tools to control certain aspects of trace behavior for a client process.

Principles

As an alternative to the well-known general-purpose tools like `jconsole` you can use a command-line tool in the form of an executable JAR file to access these facilities.

The JAR file is called `com.ibm.mq.traceControl.jar` and is stored in the `java/lib` subdirectory of the IBM MQ installation.

Note: Depending on configuration, JMX tools can be used either locally (on the same system as the process) or remotely. The local case is discussed initially.

Finding the process

To control a process, you must establish a JMX connection it. To control a process locally, you must specify its identifier.

To display a summary of running Java processes with their identifiers, run the executable JAR file with the option `-list`. This option produces a list of identifiers and descriptions for the processes that are found.

Examining trace status

When you have found the identifier for the relevant process, run the executable JAR file with the options `-i identifier -status`, where 'identifier' is the identifier of the process you want to change. These options display the status, either `enabled` or `disabled`, for the process, and the information about where the process is running, the name of the trace file, and a tree that represents the inclusion and exclusion of packages in trace.

Enabling and disabling trace

To enable trace for a process, run the executable JAR file with the options `-i identifier -enable`.

To disable trace for a process, run the executable JAR file with the options `-i identifier -disable`.

Note: You can choose only one option from the set `-status`, `-enable`, and `-disable`.

Including and excluding packages

To include a package in trace for a process, run the executable JAR file with the options `-i identifier -ip` *`package_name`*, where *package_name* is the name of your package.

To exclude a package from trace for a process, run the executable JAR file with the options `-i identifier -ep` *package_name*.

Note: You can use multiple `-ip` and `-ep` options. These options are not checked for consistency.

When you specify a package for exclusion or inclusion, the handling of packages that have matching prefixes is not affected. For example, excluding the package com.ibm.mq.jms from trace would not exclude com.ibm.mq, com.ibm.msq.client.jms, or com.ibm.mq.remote.api, but it would exclude com.ibm.mq.jms.internal.

```
C:>java -jar MQ_INSTALLATION_PATH/java/lib/com.ibm.mq.traceControl.jar -list
10008 : 'MQSample'
9004 : ' MQ_INSTALLATION_PATH/java/lib/com.ibm.mq.traceControl.jar -list'

C:>java -jar MQ_INSTALLATION_PATH/java/lib/com.ibm.mq.traceControl.jar -i 10008 -status

com - Included
acme - Included
banana - Included
shake - Included
split - Excluded
ibm - Included
mq - Included
jms - Included
```

The package inclusion-exclusion tree

The tracing mechanism for IBM MQ classes for Java and IBM MQ classes for JMS tracks the inclusion and exclusion of packages by means of a tree structure, starting from a root node. In the tree structure each node represents one element of a package name, identified by the package name element and containing a trace status which can be either `Included` or `Excluded`. For example the package com.ibm.mq would be represented by three nodes identified by the strings com, ibm, and mq.

Initially, the tree usually contains entries to include most packages, but the header and pcf packages are excluded as they generate a lot of noise. So the initial tree will look something like

```
root - Included
com - Included
ibm - Included
mq - Included
headers - Excluded
pcf - Excluded
```

When the trace facility is determining whether to include or exclude a package, it matches leading portions of the package name to the nodes in the tree as far as possible and takes the status of the last matched node. At the initial state of the tree, the packages com.ibm.msg.client and com.ibm.mq.jms would be included, as the last nodes in the tree that matches them (com->ibm and com->ibm->mq respectively) are marked as *Included*. Conversely, the package com.ibm.headers.internal would be excluded as the last matching node in the tree (com->ibm->mq->headers) is marked as *Excluded*.

As further changes are made to the tree by using the `com.ibm.mq.TraceControl.jar`, it is important to remember that inclusion or exclusion only affects a package and child packages. So, given the initial state that is shown previously, specifying `-ep com.ibm.mq.jms`, would update the tree to look like:

```
root - Included
com - Included
ibm - Included
mq - Included
headers - Excluded
jms - Excluded
pcf - Excluded
```

Which would exclude packages com.ibm.mq.jms, and com.ibm.mq.jms.internal, without affecting packages outside the com.ibm.mq.jms.* hierarchy.

If `-ip com.ibm.mq.jms.admin` is specified next, the tree would look like:

```
root - Included
com - Included
ibm - Included
mq - Included
headers - Excluded
jms - Excluded
admin - Included
pcf - Excluded
```

Which would still exclude packages com.ibm.mq.jms, com.ibm.mq.jms.internal, but now the packages com.ibm.mq.jms.admin, and com.ibm.mq.jms.admin.internal are included in trace.

Connecting remotely

You can connect remotely only if the process was started with a JMX agent that is enabled for remote connection, and that uses the `-Dcom.sun.management.jmxremote.port=port_number` system setting.

After you have started with this system setting, you can run the executable JAR file with the options `-h` *`host_name`* `-p` *`port_number`* in place of the `-i` *`identifier`* option, where *host_name* is the name of the host you wish to connect to and *port_number* is the name of the port to be used.

Note: You must ensure that you take appropriate steps to minimize security risks by enabling SSL for the connection. See the Oracle documentation on JMX for further details http://www.oracle.com.

Limitations

The following limitations exist:

- For non-IBM JVMs, the tool must be started with `tools.jar` added to its class path. The command that is on these platforms is :

```
java -cp <MQ_INSTALL_DIR>/java/lib/com.ibm.mq.traceControl.jar;<JAVA_HOME>/lib/tools/jar com.ibm.msg.client.commonservice
```

- Local attach is controlled by user ID. The tool must be run under the same ID as the process that is to be controlled.

Problem determination on z/OS

z/OS

IBM MQ for z/OS, CICS, Db2, and IMS produce diagnostic information which can be used for problem determination.

This section contains information about the following topics:

- The recovery actions attempted by the queue manager when a problem is detected.
- IBM MQ for z/OS abends, and the information produced when an abend occurs.
- The diagnostic information produced by IBM MQ for z/OS, and additional sources of useful information.

The type of information provided to help with problem determination and application debugging depends on the type of error encountered, and the way your subsystem is set up.

See the following links for more information about problem determination and diagnostic information on IBM MQ for z/OS:

- "IBM MQ for z/OS performance constraints" on page 1725
- "IBM MQ for z/OS recovery actions" on page 1727
- "IBM MQ for z/OS abends" on page 1728

You can use different types of trace to help you with problem determination and troubleshooting.

IBM MQ for z/OS performance constraints

Use this topic to investigate z/OS resources that can cause performance constraints.

There are a number of decisions to be made when customizing IBM MQ for z/OS that can affect the way your systems perform. These decisions include:

- The size and placement of data sets
- The allocation of buffers
- The distribution of queues among page sets, and Coupling Facility structures
- The number of tasks that you allow to access the queue manager at any one time

Log buffer pools

Insufficient log buffers can cause applications to wait until a log buffer is available, which can affect IBM MQ performance. RMF reports might show heavy I/O to volumes that hold log data sets.

There are three parameters you can use to tune log buffers. The most important is OUTBUFF. If the log manager statistic QJSTWTB is greater than 0, increase the size of the log buffer. This parameter controls the number of buffers to be filled before they are written to the active log data sets (in the range 1 - 256). Commits and out-of-syncpoint processing of persistent messages cause log buffers to be written out to the log. As a result this parameter might have little effect except when processing large messages, and the number of commits or out of sync point messages is low. These parameters are specified in the CSQ6LOGP macro (see Using CSQ6LOGP for details), and the significant ones are:

OUTBUFF
This parameter controls the size of the output buffer (in the range 40 KB through 4000 KB).

WRTHRSH
This parameter controls the number of buffers to be filled before they are written to the active log data sets (in the range 1 through 256).

You must also be aware of the LOGLOAD parameter of the CSQ6SYSP macro. This parameter specifies the number of log records that are written between checkpoint records. The range is 200 through 16 000 000 but a typical value for a large system is 500 000. If a value is too small you receive frequent checkpoints, which consume processor time and can cause additional disk I/O.

Buffer pool size

There is a buffer pool associated with each page set. You can specify the number of buffers in the buffer pool using the DEFINE BUFFPOOL command.

Incorrect specification of buffer pool size can adversely affect IBM MQ performance. The smaller the buffer pool, the more frequently physical I/O is required. RMF might show heavy I/O to volumes that hold page sets. For buffer pools with only short-lived messages the buffer manager statistics QPSTSLA, QPSTSOS, and QPSTRIO must typically be zero. For other buffer pools, QPSTSOS and QPSTSTLA must be zero.

Distribution of data sets on available DASD

The distribution of page data sets on DASD can have a significant effect on the performance of IBM MQ.

Place log data sets on low usage volumes with log *n* and log *n+1* on different volumes. Ensure that dual logs are placed on DASD on different control units and that the volumes are not on the same physical disk.

Distribution of queues on page sets

The distribution of queues on page sets can affect performance. This change in performance can be indicated by poor response times experienced by transactions using specific queues that reside on heavily used page sets. RMF reports might show heavy I/O to volumes containing the affected page sets.

You can assign queues to specific page sets by defining storage class (STGCLASS) objects specifying a particular page set, and then defining the STGCLASS parameter in the queue definition. It is a good idea to define heavily used queues on different page sets in this way.

Distribution of queues on Coupling Facility structures

The distribution of queues on Coupling Facility structures can affect performance.

A queue-sharing group can connect to up to 64 Coupling Facility structures, one of which must be the administration structure. You can use the remaining 63 Coupling Facility structures for IBM MQ data with each structure holding up to 512 queues. If you need more than one Coupling Facility structure, separate the queues across several structures based on the function of the queue.

There are some steps you can take to maximize efficiency:
- Delete any Coupling Facility structures you no longer require.
- Place all the queues used by an application on the same Coupling Facility to make application processing efficient.
- If work is particularly performance sensitive, choose a faster Coupling Facility structure.

Consider that if you lose a Coupling Facility structure, you lose any non-persistent messages stored in it. The loss of these non-persistent messages can cause consistency problems if queues are spread across various Coupling Facility structures. To use persistent messages, you must define the Coupling Facility structures with at least CFLEVEL(3) and RECOVER(YES).

Limitation of concurrent threads

The number of tasks accessing the queue manager can also affect performance, particularly if there are other constraints, such as storage, or there are many tasks accessing a few queues. The symptoms can be heavy I/O against one or more page sets, or poor response times from tasks known to access the same queues. The number of threads in IBM MQ is limited to 32767 for both TSO and Batch.

In a CICS environment, you can use CICS MAXTASK to limit concurrent access.

Using the IBM MQ trace for administration

Although you might have to use specific traces on occasion, using the trace facility has a negative effect on the performance of your systems.

Consider what destination you want your trace information sent to. Using the internal trace table saves I/O, but it is not large enough for traces that produce large volumes of data.

The statistics trace gathers information at intervals. The intervals are controlled by the STATIME parameter of the CSQ6SYSP macro, described in Using CSQ6SYSP. An accounting trace record is produced when the task or channel ends, which might be after many days.

You can limit traces by class, resource manager identifier (RMID), and instrumentation facility identifier (IFCID) to reduce the volume of data collected. See START TRACE for more information.

IBM MQ for z/OS recovery actions

z/OS

Use this topic to understand some of the recovery actions for user detected and queue manager detected errors.

IBM MQ for z/OS can recover from program checks caused by incorrect user data. A completion and reason code are issued to the caller. These codes are documented in IBM MQ for z/OS messages, completion, and reason codes.

Program errors

Program errors might be associated with user application program code or IBM MQ code, and fall into two categories:
- User detected errors
- Subsystem detected errors

User detected errors

User detected errors are detected by the user (or a user-written application program) when the results of a service request are not as expected (for example, a nonzero completion code). The collection of problem determination data cannot be automated because detection occurs after the IBM MQ function has completed. Rerunning the application with the IBM MQ user parameter trace facility activated can provide the data needed to analyze the problem. The output from this trace is directed to the *generalized trace facility* (GTF).

You can turn the trace on and off using an operator command. See “Using trace for problem determination on z/OS” on page 1697 for more information.

Queue manager detected errors

The queue manager detects errors such as:
- A program check
- A data set filling up
- An internal consistency error

IBM MQ analyzes the error and takes the following actions:
- If the problem was caused by a user or application error (such as an invalid address being used), the error is reflected back to the application by completion and reason codes.

- If the problem was not caused by a user or application error (for example, all available DASD has been used, or the system detected an internal inconsistency), IBM MQ recovers if possible, either by sending completion and reason codes to the application, or if this is not possible, by stopping the application.
- If IBM MQ cannot recover, it terminates with a specific reason code. An SVC dump is typically taken recording information in the *system diagnostic work area* (SDWA) and *variable recording area* (VRA) portions of the dump, and an entry is made in SYS1.LOGREC.

IBM MQ for z/OS abends

Abends can occur in WebSphere for z/OS or other z/OS systems. Use this topic to understand the IBM MQ system abend codes and how to investigate abends which occur in CICS, IMS, and z/OS.

IBM MQ for z/OS uses two system abend completion codes, X'5C6' and X'6C6'. These codes identify:

- Internal errors encountered during operation
- Diagnostic information for problem determination
- Actions initiated by the component involved in the error

X'5C6'
An X'5C6' abend completion code indicates that IBM MQ has detected an internal error and has terminated an internal task (TCB) or a user-connected task abnormally. Errors associated with a X'5C6' abend completion code might be preceded by a z/OS system code, or by internal errors.

Examine the diagnostic material generated by the X'5C6' abend to determine the source of the error that actually resulted in a subsequent task or subsystem termination.

X'6C6'
An X'6C6' abend completion code indicates that IBM MQ has detected a severe error and has terminated the queue manager abnormally. When a X'6C6' is issued, IBM MQ has determined that continued operation could result in the loss of data integrity. Errors associated with a X'6C6' abend completion code might be preceded by a z/OS system error, one or more X'5C6' abend completion codes, or by error message CSQV086E indicating abnormal termination of IBM MQ.

Table 164 summarizes the actions and diagnostic information available to IBM MQ for z/OS when these abend completion codes are issued. Different pieces of this information are relevant in different error situations. The information produced for a particular error depends upon the specific problem. For more information about the z/OS services that provide diagnostic information, see “Diagnostic information produced on IBM MQ for z/OS” on page 1731.

Table 164. Abend completion codes

	X'5C6'	**X'6C6'**
Explanation	• Error during IBM MQ normal operation	• Severe error; continued operation might jeopardize data integrity
System action	• Internal IBM MQ task is abended • Connected user task is abended	• The entire IBM MQ subsystem is abended • User task with an active IBM MQ connection might be abnormally terminated with a X'6C6' code • Possible MEMTERM (memory termination) of connected allied address space
Diagnostic information	• SVC dump • SYS1.LOGREC entry • VRA data entries	• SYS1.LOGREC • VRA data entries

Table 164. Abend completion codes (continued)

	X'5C6'	**X'6C6'**
Associated reason codes	• IBM MQ abend reason code • Associated z/OS system codes	• Subsystem termination reason code • z/OS system completion codes and X'5C6' codes that precede the X'6C6' abend
Location of accompanying codes	• SVC dump title • Message CSQW050I • Register 15 of SDWA section 'General Purpose Registers at Time of Error' • SYS1.LOGREC entries • VRA data entries	• SYS1.LOGREC • VRA data entries • Message CSQV086E, which is sent to z/OS system operator

"IBM MQ for z/OS dumps" on page 1735
Use this topic for information about the use of dumps in problem determination. It describes the steps you should take when looking at a dump produced by an IBM MQ for z/OS address space.

Dealing with program abends

Abends can occur with applications and other z/OS systems. Use this topic to investigate the various types of abends that can occur when using IBM MQ for z/OS.

Types of abend

Program abends can be caused by applications failing to check, and respond to, reason codes from IBM MQ. For example, if a message has not been received, using fields that would have been set up in the message for calculation might cause X'0C4' or X'0C7' abends (ASRA abends in CICS).

The following pieces of information indicate a program abend:

- Error messages from IBM MQ in the console log
- CICS error messages
- CICS transaction dumps
- IMS region dumps
- IMS messages on user or master terminal
- Program dump information in batch or TSO output
- Abend messages in batch job output
- Abend messages on the TSO screen

If you have an abend code, see one of the following manuals for an explanation of the cause of the abend:

- For IBM MQ for z/OS abends (abend codes X'5C6' and X'6C6'), see IBM MQ for z/OS messages, completion, and reason codes

- For batch abends, the *MVS System Codes* manual
- For CICS abends, the *CICS Messages and Codes* manual
- For IMS abends, the *IMS/ESA Messages and Codes* manual
- For Db2 abends, the *Db2 Messages and Codes* manual
- For RRS abends, the *MVS System Messages* manual
- For XES abends, the *MVS System Messages* manual

Batch abends

Batch abends cause an error message containing information about the contents of registers to be displayed in the syslog. TSO abends cause an error message containing similar information to be produced on the TSO screen. A SYSUDUMP is taken if there is a SYSUDUMP DD statement for the step (see "IBM MQ for z/OS dumps" on page 1735).

CICS transaction abends

CICS transaction abends are recorded in the CICS CSMT log, and a message is produced at the terminal (if there is one). A CICS AICA abend indicates a possible loop. See "Dealing with loops" on page 1760 for more information. If you have a CICS abend, using CEDF and the CICS trace might help you to find the cause of the problem. See the *CICS Problem Determination Guide* for more information.

IMS transaction abends

IMS transaction abends are recorded on the IMS master terminal, and an error message is produced at the terminal (if there is one). If you have an IMS abend, see the *IMS/ESA Diagnosis Guide and Reference* manual.

CICS, IMS, and z/OS abends

Use this topic to investigate abends from CICS, IMS, and z/OS.

CICS abends

A CICS abend message is sent to the terminal, if the application is attached to one, or to the CSMT log. CICS abend codes are explained in the *CICS Messages and Codes* manual.

The CICS adapter issues abend reason codes beginning with the letter Q (for example, QDCL). These codes are documented in IBM MQ for z/OS messages, completion, and reason codes

IMS abends

An IMS application might abend in one of the following circumstances:
- A normal abend.
- An IMS pseudo abend, with an abend code such as U3044 resulting from an error in an ESAF exit program.
- Abend 3051 or 3047, when the REO (region error option) has been specified as "Q" or "A", and an IMS application attempts to reference a non-operational external subsystem, or when resources are unavailable at the time when a thread is created.

An IMS message is sent to the user terminal or job output, and the IMS master terminal. The abend might be accompanied by a region dump.

z/OS abends

During IBM MQ operation, an abend might occur with a z/OS system completion code. If you receive a z/OS abend, see the appropriate z/OS publication.

Diagnostic information produced on IBM MQ for z/OS

z/OS

Use this topic to investigate some of the diagnostic information produced by z/OS that can be useful in problem determination and understand how to investigate error messages, dumps, console logs, job output, symptom strings, and queue output.

IBM MQ for z/OS functional recovery routines use z/OS services to provide diagnostic information to help you in problem determination.

The following z/OS services provide diagnostic information:

SVC dumps
The IBM MQ abend completion code X'5C6' uses the z/OS SDUMP service to create SVC dumps. The content and storage areas associated with these dumps vary, depending on the specific error and the state of the queue manager at the time the error occurred.

SYS1.LOGREC
Entries are requested in the SYS1.LOGREC data set at the time of the error using the z/OS SETRP service. The following are also recorded in SYS1.LOGREC:

- Subsystem abnormal terminations
- Secondary abends occurring in a recovery routine
- Requests from the recovery termination manager

Variable recording area (VRA) data
Data entries are added to the VRA of the SDWA by using a z/OS VRA defined key. VRA data includes a series of diagnostic data entries common to all IBM MQ for z/OS abend completion codes. Additional information is provided during initial error processing by the invoking component recovery routine, or by the recovery termination manager.

IBM MQ for z/OS provides unique messages that, together with the output of dumps, are aimed at providing sufficient data to allow diagnosis of the problem without having to try to reproduce it. This is known as first failure data capture.

Error messages

IBM MQ produces an error message when a problem is detected. IBM MQ diagnostic messages begin with the prefix CSQ. Each error message generated by IBM MQ is unique; that is, it is generated for one and only one error. Information about the error can be found in IBM MQ for z/OS messages, completion, and reason codes.

The first three characters of the names of IBM MQ modules are also usually CSQ. The exceptions to this are modules for C++ (IMQ), and the header files (CMQ). The fourth character uniquely identifies the component. These identifiers are listed in “IBM MQ component and resource manager identifiers” on page 1657. Characters five through eight are unique within the group identified by the first four characters.

Make sure that you have some documentation on application messages and codes for programs that were written at your installation, as well as viewing IBM MQ for z/OS messages, completion, and reason codes

There might be some instances when no message is produced, or, if one is produced, it cannot be communicated. In these circumstances, you might have to analyze a dump to isolate the error to a particular module. For more information about the use of dumps, see “IBM MQ for z/OS dumps” on page 1735.

Dumps

Dumps are an important source of detailed information about problems. Whether they are as the result of an abend or a user request, they allow you to see a snapshot of what was happening at the moment the dump was taken. “IBM MQ for z/OS dumps” on page 1735 contains guidance about using dumps to locate problems in your IBM MQ system. However, because they only provide a snapshot, you might need to use them with other sources of information that cover a longer period of time, such as logs.

Snap dumps are also produced for specific types of error in handling MQI calls. The dumps are written to the CSQSNAP DD.

Console logs and job output

You can copy console logs into a permanent data set, or print them as required. If you are only interested in specific events, you can select which parts of the console log to print.

Job output includes output produced from running the job, as well as that from the console. You can copy this output into permanent data sets, or print it as required. You might need to collect output for all associated jobs, for example CICS, IMS, and IBM MQ.

Symptom strings

Symptom strings display important diagnostic information in a structured format. When a symptom string is produced, it is available in one or more of the following places:
- On the z/OS system console
- In SYS1.LOGREC
- In any dump taken

Figure 127 shows an example of a symptom string.

```
PIDS/ 5655R3600 RIDS/CSQMAIN1 AB/S6C6 PRCS/0E30003
```

Figure 127. Sample symptom string

The symptom string provides a number of keywords that you can use to search the IBM software support database. If you have access to one of the optional search tools, you can search the database yourself. If you report a problem to the IBM support center, you are often asked to quote the symptom string. (For more information about searching the IBM software support database, See “Searching the IBM database for similar problems, and solutions” on page 1639.)

Although the symptom string is designed to provide keywords for searching the database, it can also give you a lot of information about what was happening at the time the error occurred, and it might suggest an obvious cause or a promising area to start your investigation. See “Building a keyword string” on page 1643 for more information about keywords.

Queue information

You can display information about the status of queues by using the operations and control panels. Alternatively you can enter the DISPLAY QUEUE and DISPLAY QSTATUS commands from the z/OS console.

Note: If the command was issued from the console, the response is copied to the console log, allowing the documentation to be kept together compactly.

Other sources of information

Use this topic to investigate other sources of information for problem determination.

You might find the following items of documentation useful when solving problems with IBM MQ for z/OS.

- Your own documentation
- Documentation for the products you are using
- Source listings and link-edit maps
- Change log
- System configuration charts
- Information from the DISPLAY CONN command

Your own documentation

Your own documentation is the collection of information produced by your organization about what your system and applications should do, and how they are supposed to do it. How much of this information you need depends on how familiar you are with the system or application in question, and could include:

- Program descriptions or functional specifications
- Flowcharts or other descriptions of the flow of activity in a system
- Change history of a program
- Change history of your installation
- Statistical and monitoring profile showing average inputs, outputs, and response times

Documentation for the products you are using

The documentation for the product you are using are the InfoCenters in the IBM MQ library, and in the libraries for any other products you use with your application.

Make sure that the level of any documentation you refer to matches the level of the system you are using. Problems often arise through using either obsolete information, or information about a level of a product that is not yet installed.

Source listings and link-edit maps

Include the source listings of any applications written at your installation with your set of documentation. (They can often be the largest single element of documentation.) Make sure that you include the relevant output from the linkage editor with your source listings to avoid wasting time trying to find your way through a load module with an out-of-date link map. Be sure to include the JCL at the beginning of your listings, to show the libraries that were used and the load library the load module was placed in.

Change log

The information in the change log can tell you of changes made in the data processing environment that might have caused problems with your application program. To get the most out of your change log, include the data concerning hardware changes, system software (such as z/OS and IBM MQ) changes, application changes, and any modifications made to operating procedures.

System configuration charts

System configuration charts show what systems are running, where they are running, and how the systems are connected to each other. They also show which IBM MQ, CICS, or IMS systems are test systems and which are production systems.

Information from the DISPLAY CONN command

The DISPLAY CONN command provides information about which applications are connected to a queue manager, and information to help you to diagnose those that have a long-running unit of work. You could collect this information periodically and check it for any long-running units of work, and display the detailed information about that connection.

Diagnostic aids for CICS

You can use the CICS diagnostic transactions to display information about queue manager tasks, and MQI calls. Use this topic to investigate these facilities.

You can use the CKQC transaction (the CICS adapter control panels) to display information about queue manager tasks, and what state they are in (for example, a GET WAIT). See Administering IBM MQ for z/OS for more information about CKQC.

The application development environment is the same as for any other CICS application, and so you can use any tools normally used in that environment to develop IBM MQ applications. In particular, the *CICS execution diagnostic facility* (CEDF) traps entry to and exit from the CICS adapter for each MQI call, as well as trapping calls to all CICS API services. Examples of the output produced by this facility are given in Examples of CEDF output.

The CICS adapter also writes trace entries to the CICS trace. These entries are described in "CICS adapter trace entries" on page 1705.

Additional trace and dump data is available from the CICS region. These entries are as described in the *CICS Problem Determination Guide*.

Diagnostic aids for IMS

Use this topic to investigate IMS diagnostic facilities.

The application development environment is the same as for any other IMS application, and so any tools normally used in that environment can be used to develop IBM MQ applications.

Trace and dump data is available from the IMS region. These entries are as described in the *IMS/ESA Diagnosis Guide and Reference* manual.

Diagnostic aids for Db2

Use this topic to investigate references for Db2 diagnostic tools.

Refer to the following manuals for help in diagnosing Db2 problems:
- *Db2 for z/OS Diagnosis Guide and Reference*
- *Db2 Messages and Codes*

IBM MQ for z/OS dumps

z/OS

Use this topic for information about the use of dumps in problem determination. It describes the steps you should take when looking at a dump produced by an IBM MQ for z/OS address space.

How to use dumps for problem determination

When solving problems with your IBM MQ for z/OS system, you can use dumps in two ways:
- To examine the way IBM MQ processes a request from an application program.

  To do this, you typically need to analyze the whole dump, including control blocks and the internal trace.
- To identify problems with IBM MQ for z/OS itself, under the direction of IBM support center personnel.

Use the instructions in the following topics to get and process a dump:
- “Getting a dump” on page 1736
- “Using the z/OS DUMP command” on page 1737
- “Processing a dump using the IBM MQ for z/OS dump display panels” on page 1738
- “Processing a dump using line mode IPCS” on page 1742
- “Processing a dump using IPCS in batch” on page 1750

The dump title might provide sufficient information in the abend and reason codes to resolve the problem. You can see the dump title in the console log, or by using the z/OS command `DISPLAY DUMP,TITLE`. The format of the dump title is explained in “Analyzing the dump and interpreting dump titles” on page 1750. For information about the IBM MQ for z/OS abend codes, see “IBM MQ for z/OS abends” on page 1728, and abend reason codes are documented in IBM MQ for z/OS messages, completion, and reason codes.

If there is not enough information about your problem in the dump title, format the dump to display the other information contained in it.

See the following topics for information about different types of dumps:
- “SYSUDUMP information” on page 1752
- “Snap dumps” on page 1753

- “SYS1.LOGREC information” on page 1754
- “SVC dumps” on page 1754

Use this topic to investigate some of the diagnostic information produced by z/OS that can be useful in problem determination and understand how to investigate error messages, dumps, console logs, job output, symptom strings, and queue output.

Getting a dump

Use this topic to understand the different dump types for problem determination.

The following table shows information about the types of dump used with IBM MQ for z/OS and how they are initiated. It also shows how the dump is formatted:

Table 165. Types of dump used with IBM MQ for z/OS

Dump type	Data set	Output type	Formatted by	Caused by
SVC	Defined by system	Machine readable	IPCS in conjunction with an IBM MQ for z/OS verb exit	z/OS or IBM MQ for z/OS functional recovery routine detecting error, or the operator entering the z/OS DUMP command
SYSUDUMP	Defined by JCL (SYSOUT=A)	Formatted	Normally SYSOUT=A	An abend condition (only taken if there is a SYSUDUMP DD statement for the step)
Snap	Defined by JCL CSQSNAP (SYSOUT=A)	Formatted	Normally SYSOUT=A	Unexpected MQI call errors reported to adapters, or FFST information from the channel initiator
Stand-alone	Defined by installation (tape or disk)	Machine readable	IPCS in conjunction with an IBM MQ for z/OS verb exit	Operator IPL of the stand-alone dump program

IBM MQ for z/OS recovery routines request SVC dumps for most X'5C6' abends. The exceptions are listed in “SVC dumps” on page 1754. SVC dumps issued by IBM MQ for z/OS are the primary source of diagnostic information for problems.

If the dump is initiated by the IBM MQ subsystem, information about the dump is put into area called the *summary portion*. This contains information that the dump formatting program can use to identify the key components.

For more information about SVC dumps, see the *MVS Diagnosis: Tools and Service Aids* manual.

Using the z/OS DUMP command

To resolve a problem, IBM can ask you to create a dump file of the queue manager address space, channel initiator address space, or coupling facilities structures. Use this topic to understand the commands to create these dump files.

You might be asked to create dump file for any or several of the following items for IBM to resolve the problem:

- Main IBM MQ address space
- Channel initiator address space
- Coupling facility application structure
- Coupling facility administration structure for your queue-sharing group

Figure 128 through to Figure 132 on page 1738 show examples of the z/OS commands to do this, assuming a subsystem name of CSQ1.

Figure 132. Dumping a coupling facility structure

Processing a dump using the IBM MQ for z/OS dump display panels

You can use commands available through IPCS panels to process dumps. Use this topic to understand the IPCS options.

IBM MQ for z/OS provides a set of panels to help you process dumps. The following section describes how to use these panels:

1. From the IPCS PRIMARY OPTION MENU, select **ANALYSIS - Analyze dump contents** (option 2).

   The IPCS MVS ANALYSIS OF DUMP CONTENTS panel is displayed.
2. Select **COMPONENT - MVS component data** (option 6).

   The IPCS MVS DUMP COMPONENT DATA ANALYSIS panel is displayed. The appearance of the panel depends on the products installed at your installation, but will be similar to the panel shown in IPCS MVS Dump Component Data Analysis panel:

```
---------------- IPCS MVS DUMP COMPONENT DATA ANALYSIS -------------
OPTION ===>                                               SCROLL ===

To display information, specify "S option name" or enter S to the
left of the option desired.  Enter ? to the left of an option to
display help regarding the component support.

  Name     Abstract
  ALCWAIT  Allocation wait summary
  AOMDATA  AOM analysis
  ASMCHECK Auxiliary storage paging activity
  ASMDATA  ASM control block analysis
  AVMDATA  AVM control block analysis
  COMCHECK Operator communications data
  CSQMAIN  WebSphere MQ dump formatter panel interface
  CSQWDMP  WebSphere MQ dump formatter
  CTRACE   Component trace summary
  DAEDATA  DAE header data
  DIVDATA  Data-in-virtual storage
```

Figure 133. IPCS MVS Dump Component Data Analysis panel

3. Select **CSQMAIN IBM MQ dump formatter panel interface** by typing s beside the line and pressing Enter.

   If this option is not available, it is because the member CSQ7IPCS is not present; you should see Configuring z/OS for more information about installing the IBM MQ for z/OS dump formatting member.

   Note: If you have already used the dump to do a preliminary analysis, and you want to reexamine it, select **CSQWDMP IBM MQ dump formatter** to display the formatted contents again, using the default options.
4. The IBM MQ for z/OS - DUMP ANALYSIS menu is displayed. Use this menu to specify the action that you want to perform on a system dump.

```
---------------IBM WebSphere MQ for z/OS - DUMP ANALYSIS----------------
 COMMAND ===>

      1 Display all dump titles 00 through 99
      2 Manage the dump inventory
      3 Select a dump

      4 Display address spaces active at time of dump
      5 Display the symptom string
      6 Display the symptom string and other related data
      7 Display LOGREC data from the buffer in the dump
      8 Format and display the dump

      9 Issue IPCS command or CLIST

(c) Copyright IBM Corporation 1993, 2005. All rights reserved.

  F1=Help    F3=Exit   F12=Cancel
```

5. Before you can select a particular dump for analysis, the dump you require must be present in the dump inventory. To ensure that this is so, perform the following steps:
   a. If you do not know the name of the data set containing the dump, specify option 1 - **Display all dump titles xx through xx**.

      This displays the dump titles of all the dumps contained in the SYS1.DUMP data sets (where xx is a number in the range 00 through 99). You can limit the selection of data sets for display by using the xx fields to specify a range of data set numbers.

If you want to see details of all available dump data sets, set these values to 00 and 99.

Use the information displayed to identify the dump you want to analyze.

b. If the dump has not been copied into another data set (that is, it is in one of the SYS1.DUMP data sets), specify option 2 - **Manage the dump inventory**

   The dump inventory contains the dump data sets that you have used. Because the SYS1.DUMP data sets are reused, the name of the dump that you identified in step 5a on page 1739 might be in the list displayed. However, this entry refers to the previous dump that was stored in this data set, so delete it by typing DD next to it and pressing Enter. Then press F3 to return to the DUMP ANALYSIS MENU.

6. Specify option 3 - **Select a dump**, to select the dump that you want to work with. Type the name of the data set containing the dump in the Source field, check that NOPRINT and TERMINAL are specified in the Message Routing field (this is to ensure that the output is directed to the terminal), and press Enter. Press F3 to return to the DUMP ANALYSIS MENU.
7. Having selected a dump to work with, you can now use the other options on the menu to analyze the data in different parts of the dump:
   - To display a list of all address spaces active at the time the dump was taken, select option 4.
   - To display the symptom string, select option 5. If you want to use the symptom string to search the RETAIN database for solutions to similar problems, refer to “Searching the IBM database for similar problems, and solutions” on page 1639.
   - To display the symptom string and other serviceability information, including the variable recording area of the system diagnostic work area (SDWA), select option 6.
   - To format and display the data contained in the in-storage LOGREC buffer, select option 7.

     It could be that the abend that caused the dump was not the original cause of the error, but was caused by an earlier problem. To determine which LOGREC record relates to the cause of the problem, go to the bottom of the data set, type `FIND ERRORID: PREV`, and press Enter. The header of the latest LOGREC record is displayed, for example:

```
JOBNAME: NONE-FRR
 ERRORID: SEQ=00081  CPU=0040  ASID=0033  TIME=14:42:47.1

SEARCH ARGUMENT ABSTRACT

   PIDS/5655R3600 RIDS/CSQRLLM1#L RIDS/CSQRRHSL AB/S05C6
   PRCS/00D10231 REGS/0C1F0 RIDS/CSQVEUS2#R

   SYMPTOM            DESCRIPTION
   -------            -----------
   PIDS/5655R3600     PROGRAM ID: 5655R3600
.
.
.
```

     Note the program identifier (if it is not 5655R3600, the problem was not caused by IBM MQ for z/OS and you could be looking at the wrong dump). Also note the value of the TIME field. Repeat the command to find the previous LOGREC record, and note the value of the TIME field again. If the two values are close to each other (say, within about one or two tenths of a second), they could both relate to the same problem.

     You can use the symptom string from the LOGREC record related to the error to search the RETAIN database for solutions to similar problems (see “Searching the IBM database for similar problems, and solutions” on page 1639).
   - To format and display the dump, select option 8. The FORMAT AND DISPLAY THE DUMP panel is displayed:

```
---------IBM MQ for z/OS - FORMAT AND DISPLAY DUMP--------
COMMAND ===>

1 Display the control blocks and trace
2 Display just the control blocks
3 Display just the trace

Options:

Use the summary dump? . . . . . . . . . . . . . . __ 1 Yes
2 No

Subsystem name (required if summary dump not used) ____

Address space identifier or ALL. . . . . . . . . . ALL_

F1=Help  F3=Exit  F12=Cancel
```

- Use this panel to format your selected system dump. You can choose to display control blocks, data produced by the internal trace, or both, which is the default.

  Note: You cannot do this for dumps from the channel initiator, or for dumps of coupling facility structures.
  - To display the whole of the dump, that is:
    - The dump title
    - The variable recording area (VRA) diagnostic information report
    - The save area trace report
    - The control block summary
    - The trace table

    select option 1.
  - To display the information listed for option 1, without the trace table, select option 2.
  - To display the information listed for option 1, without the control blocks, select option 3.

  You can also use the following options:
  - **Use the Summary Dump?**

    Use this field to specify whether you want IBM MQ to use the information contained in the summary portion when formatting the selected dump. The default setting is YES.

    Note: If a summary dump has been taken, it might include data from more than one address space.
  - **Subsystem name**

    Use this field to identify the subsystem with the dump data you want to display. This is only required if there is no summary data (for example, if the operator requested the dump), or if you have specified NO in the **Use the summary dump?** field.

    If you do not know the subsystem name, type `IPCS SELECT ALL` at the command prompt, and press Enter to display a list of all the jobs running at the time of the error. If one of the jobs has the word ERROR against it in the SELECTION CRITERIA column, make a note of the name of that job. The job name is of the form *xxxx* MSTR, where *xxxx* is the subsystem name.

```
IPCS OUTPUT STREAM ------------------------
COMMAND ===>
ASID JOBNAME ASCBADDR SELECTION CRITERIA
---- -------- -------- ------------------
0001 *MASTER* 00FD4D80 ALL
0002 PCAUTH  00F8AB80 ALL
0003 RASP   00F8C100 ALL
0004 TRACE  00F8BE00 ALL
0005 GRS   00F8BC00 ALL
0006 DUMPSRV 00F8DE00 ALL
0008 CONSOLE 00FA7E00 ALL
0009 ALLOCAS 00F8D780 ALL
000A SMF   00FA4A00 ALL
000B VLF   00FA4800 ALL
000C LLA   00FA4600 ALL
000D JESM   00F71E00 ALL
001F MQM1MSTR 00FA0680 ERROR ALL
```

If no job has the word ERROR against it in the SELECTION CRITERIA column, select option 0 - DEFAULTS on the main IPCS Options Menu panel to display the IPCS Default Values panel. Note the address space identifier (ASID) and press F3 to return to the previous panel. Use the ASID to determine the job name; the form is *xxxx* MSTR, where *xxxx* is the subsystem name.

The following command shows which ASIDs are in the dump data set:

```
LDMP DSN('SYS1.DUMPxx') SELECT(DUMPED) NOSUMMARY
```

This shows the storage ranges dumped for each address space.

Press F3 to return to the FORMAT AND DISPLAY THE DUMP panel, and type this name in the **Subsystem name** field.

– **Address space identifier**

  Use this field if the data in a dump comes from more than one address space. If you only want to look at data from a particular address space, specify the identifier (ASID) for that address space.

  The default value for this field is ALL, which displays information about all the address spaces relevant to the subsystem in the dump. Change this field by typing the 4-character ASID over the value displayed.

  Note: Because the dump contains storage areas common to all address spaces, the information displayed might not be relevant to your problem if you specify the address space identifier incorrectly. In this case, return to this panel, and enter the correct address space identifier.

Processing a dump using line mode IPCS

Use the IPCS commands to format a dump.

To format the dump using line mode IPCS commands, select the dump required by issuing the command:

```
SETDEF DSN('SYS1.DUMP xx ')
```

(where `SYS1.DUMP` *xx* is the name of the data set containing the dump). You can then use IPCS subcommands to display data from the dump.

See the following topics for information on how to format different types of dumps using IPCS commands:

- "Formatting an IBM MQ for z/OS dump"
- "Formatting a dump from the channel initiator" on page 1749

Formatting an IBM MQ for z/OS dump:

Use this topic to understand how to format a queue manager dump using line mode IPCS commands.

The IPCS VERBEXIT CSQWDMP invokes the IBM MQ for z/OS dump formatting program (CSQWDPRD), and enables you to format an SVC dump to display IBM MQ data. You can restrict the amount of data that is displayed by specifying parameters.

IBM Service Personnel might require dumps of your coupling facility administration structure and application structures for your queue-sharing group, with dumps of queue managers in the queue-sharing group, to aid problem diagnosis. For information on formatting a coupling facility list structure, and the STRDATA subcommand, see the *MVS IPCS Commands* book.

Note: This section describes the parameters required to extract the necessary data. Separate operands by commas, not blanks. A blank that follows any operand in the control statement terminates the operand list, and any subsequent operands are ignored. Table 166 explains each keyword that you can specify in the control statement for formatting dumps.

Table 166. Keywords for the IBM MQ for z/OS dump formatting control statement

Keyword	Description
SUBSYS= *aaaa*	Use this keyword if the summary dump portion is not available, or not to be used, to give the name of the subsystem to format information for. *aaaa* is a 1 through 4-character subsystem name.
ALL (default)	All control blocks and the trace table.
AA	Data is displayed for all IBM MQ for z/OS control blocks in all address spaces.
DIAG=Y	Print diagnostic information. Use only under guidance from IBM service personnel. DIAG=N (suppresses the formatting of diagnostic information) is the default.
EB= *nnnnnnnn*	Only the trace points associated with this EB thread are displayed (the format of this keyword is EB= *nnnnnnnn* where *nnnnnnnn* is the 8-digit address of an EB thread that is contained in the trace). You must use this in conjunction with the TT keyword.
LG	All control blocks.
PTF=Y, LOAD= *load module name*	A list of PTFs at the front of the report (from MEPL). PTF=N (suppresses the formatting of such a list) is the default. The optional load subparameter allows you to specify the name of a load module, up to a maximum of 8 characters, for which to format a PTF report.

Table 166. Keywords for the IBM MQ for z/OS dump formatting control statement (continued)

Keyword	Description
SA= *hhhh*	The control blocks for a specified address space. Use either of the following formats: • SA= *hh* or • SA= *hhhh* where *h* represents a hexadecimal digit.
SG	A subset of system-wide control blocks.
TT ,HANDLES=x ,LOCKS=x ,INSYNCS=x ,URINFO=ALL/LONG	Format trace table Indicate threads with greater than x handles Indicate threads with greater than x locks Indicate threads with greater than x insync operations Show UR info for ALL threads or for long-running threads

Table 167details the dump formatting keywords that you can use to format the data relating to individual resource managers.

You cannot use these keywords in conjunction with any of the keywords inTable 166 on page 1743.

Table 167. Resource manager dump formatting keywords

Keyword	What is formatted

BMC=1
BMC=2(*buffer pool number*)
BMC=3(xx/yyyyyy)
BMC=4(xx/yyyyyy)
	Buffer manager data. BMC=1 formats control blocks of all buffers.
	BMC=2 formats data relating to the buffer identified in the 2-digit *buffer pool number*.
	BMC=3 and BMC=4 display a page from a pageset, if the page is present in a buffer. (The difference between BMC=3 and BMC=4 is the route taken to the page.)

BUFL= *<nnnnnnnnnnn>*	Storage access buffer allocation `sz`.
CALLD=Y =W	Show arrow for call depth in `TT`. and indent trace entry.
CALLTIME=Y	Print call time on exit trace.
CB= *(<addr>/[<strmodel>])*	Format address as IBM MQ block.
CBF=1	CBF report level 1.
CCB=S	Show the Composite Capability Block (CCB) for system EBs in TT.
CFS=1	CFS report level 1.
CFS=2	CFS report level 2.

CHLAUTH=1/2
ONAM=<20 chars>
	CHLAUTH report level.
	The optional ONAM subparameter allows you to specify the object name, up to a maximum of 20 characters, to limit data printed to objects starting with characters in ONAM.

CLXQ=1	Cluster XMITQ report level 1.

Table 167. Resource manager dump formatting keywords (continued)

Keyword	What is formatted

CLXQ=2
 	
ONAM=<20 chars>
	Cluster XMITQ report level 2.
	
	The optional ONAM subparameter allows you to specify the object name, up to a maximum of 20 characters, to limit data printed to objects starting with characters in ONAM.

CMD=0/1/2	Command trace table display level.
D=1/2/3	Detail level for some reports.
Db2=1	Db2 report level 1.

DMC=1,
 	
ONAM=<48 chars>
	DMC report level 1.
	
	The optional ONAM subparameter allows you to specify the object name, up to a maximum of 48 characters, to limit data printed to objects starting with characters in ONAM.

DMC=2,
 	
ONAM=<48 chars>
	DMC report level 2.
	
	The optional ONAM subparameter allows you to limit the objects printed to those with names beginning with the characters specified in ONAM (up to a maximum of 48 characters).

DMC=3,
 	
ONAM=<48 chars>
	DMC report level 3.
	
	The optional ONAM subparameter allows you to limit the objects printed to those with names beginning with the characters specified in ONAM (up to a maximum of 48 characters).

GR=1	Group indoubt report level 1.
IMS=1	IMS report level 1

Table 168. Resource manager dump formatting keywords (J -P)

Keyword	What is formatted
JOBNAME= *xxxxxxxx*	Job name
LKM=1	LKM report level 1.

Table 168. Resource manager dump formatting keywords (J -P) (continued)

Keyword	**What is formatted**
LKM=2/3, ,NAME=<up to 48 chars> ,NAMEX= *xxxxxxxxxxxxxxxx* ,NAMESP=1/2/3/4/5/6/7/8 ,TYPE=DMCP/QUALNM/TOPIC/ STGCLASS ,QUAL=GET/PUT/CRE/DFXQ/ PGSYNC/CHGCNT/ DELETE/EXPIRE LKM=3 LKM=4 ,JOBNAME= *xxxxxxxx* ,ASID= *xxxx*	LKM report level 2/3. Name (character) Name (Hex) Namespace Lock type Lock qualification LKM report level 3 LKM report level 4
LMC=1	LMC report level 1.
MAXTR= *nnnnnnnnn*	Max trace entries to format
MHASID= *xxxx*	Message handle ASID for properties
MMC=1 OBJ=MQLO/MQSH/MQRO/ MQAO/MQMO/MCHL/ MNLS/MSTC/MPRC/ : ' MAUT ONAM	MMC report level 1 Object type The optional ONAM subparameter allows you to limit the objects printed to those with names beginning with the characters specified in ONAM (up to a maximum of 48 characters).

MMC=2
 	
ONAM=<48 chars>
	MMC report level 2
	
	The optional ONAM subparameter allows you to limit the objects printed to those with names beginning with the characters specified in ONAM (up to a maximum of 48 characters).

MSG=*nnnnnnnnnnnnnnnn*
 	
MASID=*xxxx*
 	
LEN=*xxxxxxxx*
 	
MSGD=S/D
	Format the message at pointer.
	
	MASID allows storage in other address spaces.
	
	LEN limits amount of storage to format.
	
	MSGD controls level of detail.

MSGD=S/D	Message details in DMC=3, BMC=3/4, PSID reports. The parameter controls level of details, S is summary and D is detailed.
MSGH = *nnnnnnnnnnnnnnnn*	Message handle
MT	Message properties trace
MQVCX	MQCHARVs in hexadecimal format

Table 168. Resource manager dump formatting keywords (J -P) (continued)

Keyword	What is formatted
PROPS= *nnnnnnnnnnnnnnnn*	Message properties pointer
PSID= *nnnnnnnn*	Pageset to format page
PSTRX	Properties strings in hex format

Table 169. Resource manager dump formatting keywords (R -Z)

Keyword	What is formatted
RPR= *nnnnnnnn*	Page or record to format
SHOWDEL	Show deleted records for DMC=3
SMC=1/2/3	Storage manager
TC= * A E 0	TT data char format, concatenated print all in suitable character set always print ASCII always print EBCDIC never print either
TFMT=H/M	Time format - human or STCK
THR= *nnnnnnnn*	Thread address
THR=*/2/3	Set thread report level
TOP=1	TOP report level 1
TOP=2	TOP report level 2
TOP= *nnnnnnnnnnnnnnnn* /TSTR=<48 chars> /TSTRX=<hex 1208 str>	Tnode 64bit address or Topic string (wildcard with % at start or end)' This will be converted EBCDIC to ASCII, but only invariant characters Hexadecimal of topic string in 1208 always wildcard character at start.
TOP=3	TOP report level 3
TOP=4	TOP report level 4

TSEG=M(RU)/Q(P64)
 	
I(NTERPOLATE)
 	
F(WD)
 	
D(EBUG)
	Search process for 64-bit trace
	
	Guess missing TSEG address or addresses
	
	Force forward sort
	
	Debug search process

TSEG=(M,Q,I,F,D)	Specify multiple TSEG options
W=0/1/2/3	TT width format
XA=1	XA report level 1
ZMH = *nnnnnnnnnnnnnnnn*	ZST message handle

If the dump is initiated by the operator, there is no information in the summary portion of the dump.Table 170 on page 1748shows additional keywords that you can use in the CSQWDMP control statement.

Table 170. Summary dump keywords for the IBM MQ for z/OS dump formatting control statement

Keyword	Description
SUBSYS= *aaaa*	Use this keyword if the summary dump portion is not available, or not to be used, to give the name of the subsystem to format information for. *aaaa* is a 1 through 4-character subsystem name.
SUMDUMP=NO	Use this keyword if the dump has a summary portion, but you do not want to use it. (You would usually only do this if so directed by your IBM support center.)

The following list shows some examples of how to use these keywords:

- For default formatting of all address spaces, using information from the summary portion of the dump, use:
  ```
  VERBX CSQWDMP
  ```
- To display the trace table from a dump of subsystem named MQMT, which was initiated by an operator (and so does not have a summary portion) use:
  ```
  VERBX CSQWDMP 'TT,SUBSYS=MQMT'
  ```
- To display all the control blocks and the trace table from a dump produced by a subsystem abend, for an address space with ASID (address space identifier) 1F, use:
  ```
  VERBX CSQWDMP 'TT,LG,SA=1F'
  ```
- To display the portion of the trace table from a dump associated with a particular EB thread, use:
  ```
  VERBX CSQWDMP 'TT,EB= nnnnnnnn '
  ```
- To display message manager 1 report for local non-shared queue objects with a name begins with 'ABC' use:
  ```
  VERBX CSQWDMP 'MMC=1,ONAM=ABC,Obj=MQLO'
  ```

Table 171shows some other commands that are used frequently for analyzing dumps. For more information about these subcommands, see the *MVS IPCS Commands* manual.

Table 171. IPCS subcommands used for dump analysis

Subcommand	Description
STATUS	To display data usually examined during the initial part of the problem determination process.
STRDATA LISTNUM(ALL) ENTRYPOS(ALL) DETAIL	To format coupling facility structure data.
VERBEXIT LOGDATA	To format the in-storage LOGREC buffer records present before the dump was taken. LOGDATA locates the LOGREC entries that are contained in the LOGREC recording buffer and invokes the EREP program to format and print the LOGREC entries. These entries are formatted in the style of the normal detail edit report.
VERBEXIT TRACE	To format the system trace entries for all address spaces.
VERBEXIT SYMPTOM	To format the symptom strings contained in the header record of a system dump such as stand-alone dump, SVC dump, or an abend dump requested with a SYSUDUMP DD statement.
VERBEXIT GRSTRACE	To format diagnostic data from the major control blocks for global resource serialization.
VERBEXIT SUMDUMP	To locate and display the summary dump data that an SVC dump provides.
VERBEXIT DAEDATA	To format the dump analysis and elimination (DAE) data for the dumped system.

Related concepts:

"Formatting a dump from the channel initiator"
Use this topic to understand how to format a channel initiator dump using line mode IPCS commands.

Formatting a dump from the channel initiator:

Use this topic to understand how to format a channel initiator dump using line mode IPCS commands.

The IPCS VERBEXIT CSQXDPRD enables you to format a channel initiator dump. You can select the data that is formatted by specifying keywords.

This section describes the keywords that you can specify.

Table 172 describes the keywords that you can specify with CSQXDPRD.

Table 172. Keywords for the IPCS VERBEXIT CSQXDPRD

Keyword	What is formatted
SUBSYS= *aaaa*	The control blocks of the channel initiator associated with the named subsystem. It is required for all new formatted dumps.
CHST=1, CNAM= *channel name*, DUMP=S|F|C	All channel information. The optional CNAM subparameter allows you to specify the name of a channel, up to a maximum of 20 characters, for which to format details. The optional DUMP subparameter allows you to control the extent of formatting, as follows: • Specify DUMP=S (for "short") to format the first line of the hexadecimal dump of the channel data. • Specify DUMP=F (for "full") to format all lines of the data. • Specify DUMP=C (for "compressed⌂) to suppress the formatting of all duplicate lines in the data containing only X'00'. This is the default option
CHST=2, CNAM= *channel name*,	A summary of all channels, or of the channel specified by the CNAM keyword. See CHST=1 for details of the CNAM subparameter.
CHST=3, CNAM= *channel name*,	Data provided by CHST=2 and a program trace, line trace and formatted semaphore table print of all channels in the dump. See CHST=1 for details of the CNAM subparameter.
CLUS=1	Cluster report including the cluster repository known on the queue manager.
CLUS=2	Cluster report showing cluster registrations.

CTRACE=S|F,
 	
DPRO= *nnnnnnnn*,
 	
TCB= *nnnnnnn*
	Select either a short (CTRACE=S) or full (CTRACE=F) CTRACE.
	
	The optional DPRO subparameter allows you to specify a CTRACE for the DPRO specified.
	
	The optional TCB subparameter allows you to specify a CTRACE for the job specified.

DISP=1, DUMP=S|F|C	Dispatcher report See CHST=1 for details of the DUMP subparameter.
BUF=1	Buffer report
XSMF=1	Format channel initiator SMF data that is available in a dump.

"Processing a dump using the IBM MQ for z/OS dump display panels" on page 1738
You can use commands available through IPCS panels to process dumps. Use this topic to understand the IPCS options.

"Processing a dump using line mode IPCS" on page 1742
Use the IPCS commands to format a dump.

"Analyzing the dump and interpreting dump titles"
Use this topic to understand how dump titles are formatted, and how to analyze a dump.

Analyzing the dump and interpreting dump titles

Use this topic to understand how dump titles are formatted, and how to analyze a dump.

- Analyzing the dump
- Dump title variation with PSW and ASID

Analyzing the dump

The dump title includes the abend completion and reason codes, the failing load module and CSECT names, and the release identifier. For more information on the dump title see Dump title variation with PSW and ASID

The formats of SVC dump titles vary slightly, depending on the type of error.

Figure 135 shows an example of an SVC dump title. Each field in the title is described after the figure.

```
ssnm,ABN=5C6-00D303F2,U=AUSER,C=R3600. 710.LOCK-CSQL1GET,
 M=CSQGFRCV,LOC=CSQLLPLM.CSQL1GET+0246
```

Figure 135. Sample SVC dump title

`ssnm,ABN=compltn-reason`

- `ssnm` is the name of the subsystem that issued the dump.
- `compltn` is the 3-character hexadecimal abend completion code (in this example, X'5C6'), prefixed by U for user abend codes.
- `reason` is the 4-byte hexadecimal reason code (in this example, X'00D303F2').

Note: The abend and reason codes might provide sufficient information to resolve the problem. See the IBM MQ for z/OS messages, completion, and reason codes for an explanation of the reason code.

`U=userid`

- `userid` is the user identifier of the user (in this example, AUSER). This field is not present for channel initiators.

`C=compid.release.comp-function`

- `compid` is the last 5 characters of the component identifier (explained in "The component-identifier keyword" on page 1645). The value R3600 uniquely identifies IBM MQ for z/OS.
- `release` is a 3-digit code indicating the version, release, and modification level of IBM MQ for z/OS (in this example, 710).
- `comp` is an acronym for the component in control at the time of the abend (in this example, LOCK).
- `function` is the name of a function, macro, or routine in control at the time of abend (in this example, CSQL1GET). This field is not always present.

`M=module`

- `module` is the name of the FRR or ESTAE recovery routine (in this example, CSQGFRCV). This field is not always present.

  Note: This is not the name of the module where the abend occurred; that is given by `LOC`.

`LOC=loadmod.csect+csect_offset`

- `loadmod` is the name of the load module in control at the time of the abend (in this example, CSQLLPLM). This might be represented by an asterisk if it is unknown.
- `csect` is the name of the CSECT in control at the time of abend (in this example, CSQL1GET).
- `csect_offset` is the offset within the failing CSECT at the time of abend (in this example, 0246).

Note: The value of `csect_offset` might vary if service has been applied to this CSECT, so do not use this value when building a keyword string to search the IBM software support database.

Dump title variation with PSW and ASID

Some dump titles replace the load module name, CSECT name, and CSECT offset with the PSW (program status word) and ASID (address space identifier). Figure 136 on page 1752 illustrates this format.

```
ssnm,ABN=compltn-reason,U=userid,C=compid.release.comp-function,
 M=module,PSW=psw_contents,ASID=address_space_id
```

Figure 136. Dump title with PSW and ASID

psw_contents

- The PSW at the time of the error (for example, X'077C100000729F9C').

address_space_id

- The address space in control at the time of the abend (for example, X'0011'). This field is not present for a channel initiator.

SYSUDUMP information

The z/OS system can create SYSUDUMPs, which can be used as part of problem determination. This topic shows a sample SYSUDUMP output and gives a reference to the tools for interpreting SYSUDUMPs.

SYSUDUMP dumps provide information useful for debugging batch and TSO application programs. For more information about SYSUDUMP dumps, see the *MVS Diagnosis: Tools and Service Aids* manual.

Figure 137 on page 1753 shows a sample of the beginning of a SYSUDUMP dump.

Figure 137. Sample beginning of a SYSUDUMP

Snap dumps

Snap dump data sets are controlled by z/OS JCL command statements. Use this topic to understand the CSQSNAP DD statement.

Snap dumps are always sent to the data set defined by the CSQSNAP DD statement. They can be issued by the adapters or the channel initiator.

- Snap dumps are issued by the batch, CICS, IMS, or RRS adapter when an unexpected error is returned by the queue manager for an MQI call. A full dump is produced containing information about the program that caused the problem.

  For a snap dump to be produced, the CSQSNAP DD statement must be in the batch application JCL, CICS JCL, or IMS dependent region JCL.
- Snap dumps are issued by the channel initiator in specific error conditions instead of a system dump. The dump contains information relating to the error. Message CSQX053E is also issued at the same time.

  To produce a snap dump, the CSQSNAP DD statement must be in the channel initiator started-task procedure.

SYS1.LOGREC information

Use this topic to understand how the z/OS SYS1.LOGREC information can assist with problem determination.

IBM MQ for z/OS and SYS1.LOGREC

The SYS1.LOGREC data set records various errors that different components of the operating system encounter. For more information about using SYS1.LOGREC records, see the *MVS Diagnosis: Tools and Service Aids* manual.

IBM MQ for z/OS recovery routines write information in the *system diagnostic work area* (SDWA) to the SYS1.LOGREC data set when retry is attempted, or when percolation to the next recovery routine occurs. Multiple SYS1.LOGREC entries can be recorded, because two or more retries or percolations might occur for a single error.

The SYS1.LOGREC entries recorded near the time of abend might provide valuable historical information about the events leading up to the abend.

Finding the applicable SYS1.LOGREC information

To obtain a SYS1.LOGREC listing, either:

- Use the EREP service aid, described in the *MVS Diagnosis: Tools and Service Aids* manual to format records in the SYS1.LOGREC data set.
- Specify the VERBEXIT LOGDATA keyword in IPCS.
- Use option 7 on the DUMP ANALYSIS MENU (refer to "Processing a dump using the IBM MQ for z/OS dump display panels" on page 1738).

Only records available in storage when the dump was requested are included. Each formatted record follows the heading `*****LOGDATA*****`.

SVC dumps

Use this topic to understand how to suppress SVC dumps, and reasons why SVC dumps are not produced.

When SVC dumps are not produced

Under some circumstances, SVC dumps are not produced. Generally, dumps are suppressed because of time or space problems, or security violations. The following list summarizes other reasons why SVC dumps might not be produced:

- The z/OS *serviceability level indication processing* (SLIP) commands suppressed the abend.

  The description of IEACMD00 in the *MVS Initialization and Tuning Reference* manual lists the defaults for SLIP commands executed at IPL time.
- The abend reason code was one that does not require a dump to determine the cause of abend.
- SDWACOMU or SDWAEAS (part of the system diagnostic work area, SDWA) was used to suppress the dump.

Suppressing IBM MQ for z/OS dumps using z/OS DAE

You can suppress SVC dumps that duplicate previous dumps. The *MVS Diagnosis: Tools and Service Aids* manual gives details about using z/OS *dump analysis and elimination* (DAE).

To support DAE, IBM MQ for z/OS defines two *variable recording area* (VRA) keys and a minimum symptom string. The two VRA keys are:

- KEY VRADAE (X'53'). No data is associated with this key.

- KEY VRAMINSC (X'52') DATA (X'08')

IBM MQ for z/OS provides the following data for the minimum symptom string in the *system diagnostic work area* (SDWA):

- Load module name
- CSECT name
- Abend code
- Recovery routine name
- Failing instruction area
- REG/PSW difference
- Reason code
- Component identifier
- Component subfunction

Dumps are considered duplicates for the purpose of suppressing duplicate dumps if eight (the X'08' from the VRAMINSC key) of the nine symptoms are the same.

Dealing with performance problems on z/OS

Use this topic to investigate performance problems in more detail.

Performance problems are characterized by the following:

- Poor response times in online transactions
- Batch jobs taking a long time to complete
- The transmission of messages is slow

Performance problems can be caused by many factors, from a lack of resource in the z/OS system as a whole, to poor application design.

The following topics present problems and suggested solutions, starting with problems that are relatively simple to diagnose, such as DASD contention, through problems with specific subsystems, such as IBM MQ and CICS or IMS.

- "IBM MQ for z/OS system considerations" on page 1756
- "CICS constraints" on page 1756
- "Dealing with applications that are running slowly or have stopped on z/OS" on page 1756

Remote queuing problems can be due to network congestion and other network problems. They can also be caused by problems at the remote queue manager.

Related concepts:

"Making initial checks" on page 1277
There are some initial checks that you can make that may provide answers to common problems that you may have.

"Dealing with incorrect output" on page 1762
Incorrect output can be missing, unexpected, or corrupted information. Read this topic to investigate further.

IBM MQ for z/OS system considerations

The z/OS system is an area that requires examination when investigating performance problems.

You might already be aware that your z/OS system is under stress because these problems affect many subsystems and applications.

You can use the standard monitoring tools such as Resource Monitoring Facility (RMF) to monitor and diagnose these problems. They might include:

- Constraints on storage (paging)
- Constraints on processor cycles
- Constraints on DASD
- Channel path usage

Use normal z/OS tuning techniques to resolve these problems.

CICS constraints

CICS constraints can also have an adverse effect on IBM MQ performance. Use this topic for further information about CICS constraints.

Performance of IBM MQ tasks can be affected by CICS constraints. For example, your system might have reached MAXTASK, forcing transactions to wait, or the CICS system might be short on storage. For example, CICS might not be scheduling transactions because the number of concurrent tasks has been reached, or CICS has detected a resource problem. If you suspect that CICS is causing your performance problems (for example because batch and TSO jobs run successfully, but your CICS tasks time out, or have poor response times), see the *CICS Problem Determination Guide* and the *CICS Performance Guide*.

Note: CICS I/O to transient data extrapartition data sets uses the z/OS RESERVE command. This could affect I/O to other data sets on the same volume.

Dealing with applications that are running slowly or have stopped on z/OS

Waits and loops can exhibit similar symptoms. Use the links in this topic to help differentiate between waits and loops.

Waits and loops are characterized by unresponsiveness. However, it can be difficult to distinguish between waits, loops, and poor performance.

Any of the following symptoms might be caused by a wait or a loop, or by a badly tuned or overloaded system:

- An application that appears to have stopped running (if IBM MQ for z/OS is still responsive, this problem is probably caused by an application problem)
- An MQSC command that does not produce a response
- Excessive use of processor time

To perform the tests shown in these topics, you need access to the z/OS console, and to be able to issue operator commands.

- "Distinguishing between waits and loops" on page 1757

- "Dealing with waits" on page 1758
- "Dealing with loops" on page 1760

Related concepts:

"Making initial checks" on page 1277
There are some initial checks that you can make that may provide answers to common problems that you may have.

Distinguishing between waits and loops:

Waits and loops on IBM MQ can present similar symptoms. Use this topic to help determine if you are experiencing a wait of a loop.

Because waits and loops can be difficult to distinguish, in some cases you need to carry out a detailed investigation before deciding which classification is right for your problem.

This section gives you guidance about choosing the best classification, and advice on what to do when you have decided on a classification.

Waits

For problem determination, a wait state is regarded as the state in which the execution of a task has been suspended. That is, the task has started to run, but has been suspended without completing, and has subsequently been unable to resume.

A problem identified as a wait in your system could be caused by any of the following:
- A wait on an MQI call
- A wait on a CICS or IMS call
- A wait for another resource (for example, file I/O)
- An ECB wait
- The CICS or IMS region waiting
- TSO waiting
- IBM MQ for z/OS waiting for work
- An apparent wait, caused by a loop
- Your task is not being dispatched by CICS or MVS due to higher priority work
- Db2 or RRS are inactive

Loops

A loop is the repeated execution of some code. If you have not planned the loop, or if you have designed it into your application but it does not terminate for some reason, you get a set of symptoms that vary depending on what the code is doing, and how any interfacing components and products react to it. In some cases, at first, a loop might be diagnosed as a wait or performance problem, because the looping task competes for system resources with other tasks that are not involved in the loop. However, a loop consumes resources but a wait does not.

An apparent loop problem in your system could be caused by any of the following:
- An application doing a lot more processing than usual and therefore taking much longer to complete
- A loop in application logic
- A loop with MQI calls
- A loop with CICS or IMS calls
- A loop in CICS or IMS code

- A loop in IBM MQ for z/OS

Symptoms of waits and loops

Any of the following symptoms could be caused by a wait, a loop, or by a badly tuned or overloaded system:
- Timeouts on MQGET WAITs
- Batch jobs suspended
- TSO session suspended
- CICS task suspended
- Transactions not being started because of resource constraints, for example CICS MAX task
- Queues becoming full, and not being processed
- System commands not accepted, or producing no response

Related concepts:

"Dealing with waits"
Waits can occur in batch or TSO applications, CICS transactions, and other components. Use this topic to determine where waits can occur.

"Dealing with loops" on page 1760
Loops can occur in different areas of a z/OS system. Use this topic to help determine where a loop is occurring.

Dealing with waits:

Waits can occur in batch or TSO applications, CICS transactions, and other components. Use this topic to determine where waits can occur.

When investigating what appears to be a problem with tasks or subsystems waiting, it is necessary to take into account the environment in which the task or subsystem is running.

It might be that your z/OS system is generally under stress. In this case, there can be many symptoms. If there is not enough real storage, jobs experience waits at paging interrupts or swap-outs. Input/output (I/O) contention or high channel usage can also cause waits.

You can use standard monitoring tools, such as *Resource Monitoring Facility* (RMF) to diagnose such problems. Use normal z/OS tuning techniques to resolve them.

Is a batch or TSO program waiting?

Consider the following points:

Your program might be waiting on another resource
For example, a VSAM control interval (CI) that another program is holding for update.

Your program might be waiting for a message that has not yet arrived
This condition might be normal behavior if, for example, it is a server program that constantly monitors a queue.

Alternatively, your program might be waiting for a message that has arrived, but has not yet been committed.

Issue the DIS CONN(*) TYPE(HANDLE) command and examine the queues in use by your program.

If you suspect that your program has issued an MQI call that did not involve an MQGET WAIT, and control has not returned from IBM MQ, take an SVC dump of both the batch or TSO job, and the IBM MQ subsystem before canceling the batch or TSO program.

Also consider that the wait state might be the result of a problem with another program, such as an abnormal termination (see “Messages do not arrive when expected” on page 1763), or in IBM MQ itself (see “Is IBM MQ waiting for z/OS ?” on page 1760). Refer to “IBM MQ for z/OS dumps” on page 1735 (specifically Figure 128 on page 1737) for information about obtaining a dump.

If the problem persists, refer to “Searching the IBM database for similar problems, and solutions” on page 1639 and “Contacting IBM Software Support” on page 1658 for information about reporting the problem to IBM.

Is a CICS transaction waiting?

Consider the following points:

CICS might be under stress
This might indicate that the maximum number of tasks allowed (MAXTASK) has been reached, or a short on storage (SOS) condition exists. Check the console log for messages that might explain this (for example, SOS messages), or see the *CICS Problem Determination Guide*.

The transaction might be waiting for another resource
For example, this might be file I/O. You can use CEMT INQ TASK to see what the task is waiting for. If the resource type is MQSERIES your transaction is waiting on IBM MQ (either in an **MQGET** WAIT or a task switch). Otherwise see the *CICS Problem Determination Guide* to determine the reason for the wait.

The transaction might be waiting for IBM MQ for z/OS
This might be normal, for example, if your program is a server program that waits for messages to arrive on a queue. Otherwise it might be the result of a transaction abend, for example (see “Messages do not arrive when expected” on page 1763). If so, the abend is reported in the CSMT log.

The transaction might be waiting for a remote message
If you are using distributed queuing, the program might be waiting for a message that has not yet been delivered from a remote system (for further information, refer to “Problems with missing messages when using distributed queuing” on page 1764).

If you suspect that your program has issued an MQI call that did not involve an **MQGET** WAIT (that is, it is in a task switch), and control has not returned from IBM MQ, take an SVC dump of both the CICS region, and the IBM MQ subsystem before canceling the CICS transaction. Refer to “Dealing with loops” on page 1760 for information about waits. Refer to “IBM MQ for z/OS dumps” on page 1735 (specifically Figure 128 on page 1737) for information about obtaining a dump.

If the problem persists, refer to “Searching the IBM database for similar problems, and solutions” on page 1639 and “Contacting IBM Software Support” on page 1658 for information about reporting the problem to IBM.

Is Db2 waiting?

If your investigations indicate that Db2 is waiting, check the following:

1. Use the Db2 -DISPLAY THREAD(*) command to determine if any activity is taking place between the queue manager and the Db2 subsystem.
2. Try and determine whether any waits are local to the queue manager subsystems or are across the Db2 subsystems.

Is RRS active?

- Use the D RRS command to determine if RRS is active.

Is IBM MQ waiting for z/OS ?

If your investigations indicate that IBM MQ itself is waiting, check the following:

1. Use the DISPLAY THREAD(*) command to check if anything is connected to IBM MQ.
2. Use SDSF DA, or the z/OS command `DISPLAY A,xxxxMSTR` to determine whether there is any processor usage (as shown in "Has your application or IBM MQ for z/OS stopped processing work?" on page 1302).
   - If IBM MQ is using some processor time, reconsider other reasons why IBM MQ might be waiting, or consider whether this is actually a performance problem.
   - If there is no processor activity, check whether IBM MQ responds to commands. If you can get a response, reconsider other reasons why IBM MQ might be waiting.
   - If you cannot get a response, check the console log for messages that might explain the wait (for example, IBM MQ might have run out of active log data sets, and be waiting for offload processing).

If you are satisfied that IBM MQ has stalled, use the STOP QMGR command in both QUIESCE and FORCE mode to terminate any programs currently being executed.

If the STOP QMGR command fails to respond, cancel the queue manager with a dump, and restart. If the problem recurs, refer to "Contacting IBM Software Support" on page 1658 for further guidance.

Related concepts:

"Distinguishing between waits and loops" on page 1757
Waits and loops on IBM MQ can present similar symptoms. Use this topic to help determine if you are experiencing a wait of a loop.

"Dealing with loops"
Loops can occur in different areas of a z/OS system. Use this topic to help determine where a loop is occurring.

Dealing with loops:

Loops can occur in different areas of a z/OS system. Use this topic to help determine where a loop is occurring.

The following topics describe the various types of loop that you might encounter, and suggest some responses.

Is a batch application looping?

If you suspect that a batch or TSO application is looping, use the console to issue the z/OS command `DISPLAY JOBS,A` (for a batch application) or `DISPLAY TS,A` (for a TSO application). Note the CT values from the data displayed, and repeat the command.

If any task shows a significant increase in the CT value, it might be that the task is looping. You could also use SDSF DA, which shows you the percentage of processor that each address space is using.

Is a batch job producing a large amount of output?

An example of this behavior might be an application that browses a queue and prints the messages. If the browse operation has been started with BROWSE FIRST, and subsequent calls have not been reset to BROWSE NEXT, the application browses, and prints the first message on the queue repeatedly.

You can use SDSF DA to look at the output of running jobs if you suspect that it might be causing a problem.

Does a CICS region show heavy processor activity?

It might be that a CICS application is looping, or that the CICS region itself is in a loop. You might see AICA abends if a transaction goes into a tight (unyielding) loop.

If you suspect that CICS, or a CICS application is looping, see the *CICS Problem Determination Guide*.

Does an IMS region show heavy processor activity?

It might be that an IMS application is looping. If you suspect this behavior, see *IMS Diagnosis Guide and Reference* l.

Is the queue manager showing heavy processor activity?

Try to enter an MQSC DISPLAY command from the console. If you get no response, it is possible that the queue manager is looping. Follow the procedure shown in "Has your application or IBM MQ for z/OS stopped processing work?" on page 1302 to display information about the processor time being used by the queue manager. If this command indicates that the queue manager is in a loop, take a memory dump, cancel the queue manager and restart.

If the problem persists, see "Searching the IBM database for similar problems, and solutions" on page 1639 and "Contacting IBM Software Support" on page 1658 for information about reporting the problem to IBM.

Is a queue, page set, or Coupling Facility structure filling up unexpectedly?

If so, it might indicate that an application is looping, and putting messages on to a queue. (It might be a batch, CICS, or TSO application.)

Identifying a looping application

In a busy system, it might be difficult to identify which application is causing the problem. If you keep a cross-reference of applications to queues, terminate any programs or transactions that might be putting messages on to the queue. Investigate these programs or transactions before using them again. (The most likely culprits are new, or changed applications; check your change log to identify them.)

Try issuing a DISPLAY QSTATUS command on the queue. This command returns information about the queue that might help to identify which application is looping.

Incorrect triggering definitions

It might be that a getting application has not been triggered because of incorrect object definitions, for example, the queue might be set to NOTRIGGER.

Distributed queuing

Using distributed queuing, a symptom of this problem might be a message in the receiving system indicating that **MQPUT** calls to the dead-letter queue are failing. This problem might be caused because the dead-letter queue has also filled up. The dead-letter queue message header (dead-letter header structure) contains a reason or feedback code explaining why the message might not be put on to the target queue. See MQDLH - Dead-letter header for information about the dead-letter header structure.

Allocation of queues to page sets

If a particular page set frequently fills up, there might be a problem with the allocation of queues to page sets. See IBM MQ for z/OS performance constraints for more information.

Shared queues

Is the Coupling Facility structure full? The z/OS command DISPLAY CF displays information about Coupling Facility storage including the total amount, the total in use, and the total free control and non-control storage. The RMF Coupling Facility Usage Summary Report provides a more permanent copy of this information.

Are a task, and IBM MQ for z/OS, showing heavy processor activity?

In this case, a task might be looping on MQI calls (for example, browsing the same message repeatedly).

Related concepts:

"Distinguishing between waits and loops" on page 1757
Waits and loops on IBM MQ can present similar symptoms. Use this topic to help determine if you are experiencing a wait of a loop.

"Dealing with waits" on page 1758
Waits can occur in batch or TSO applications, CICS transactions, and other components. Use this topic to determine where waits can occur.

Dealing with incorrect output

Incorrect output can be missing, unexpected, or corrupted information. Read this topic to investigate further.

The term "incorrect output⌂ can be interpreted in many different ways, and its meaning for problem determination with this product documentation is explained in "Have you obtained incorrect output?" on page 1311.

The following topics contains information about the problems that you could encounter with your system and classify as incorrect output:

- Application messages that do not arrive when you are expecting them
- Application messages that contain the wrong information, or information that has been corrupted

Additional problems that you might encounter if your application uses distributed queues are also described.

"Making initial checks" on page 1277
There are some initial checks that you can make that may provide answers to common problems that you may have.

"Dealing with performance problems on z/OS" on page 1755
Use this topic to investigate performance problems in more detail.

Messages do not arrive when expected

Missing messages can have different causes. Use this topic to investigate the causes further.

If messages do not arrive on the queue when you are expecting them, check for the following:

Has the message been put onto the queue successfully?

Did IBM MQ issue a return and reason code for the MQPUT, for example:

- Has the queue been defined correctly, for example is MAXMSGL large enough? (reason code 2030).
- Can applications put messages on to the queue (is the queue enabled for MQPUT calls)? (reason code 2051).
- Is the queue already full? This could mean that an application could not put the required message on to the queue (reason code 2053).

Is the queue a shared queue?

- Have Coupling Facility structures been defined successfully in the CFRM policy data set? Messages held on shared queues are stored inside a Coupling Facility.
- Have you activated the CFRM policy?

Is the queue a cluster queue?

If it is, there might be multiple instances of the queue on different queue managers. This means that the messages could be on a different queue manager.

- Did you want the message to go to a cluster queue?
- Is your application designed to work with cluster queues?
- Did the message get put to a different instance of the queue from that expected?

Check any cluster-workload exit programs to see that they are processing messages as intended.

Do your gets fail?

- Does the application need to take a syncpoint?

  If messages are being put or got within syncpoint, they are not available to other tasks until the unit of recovery has been committed.
- Is the time interval on the MQGET long enough?

  If you are using distributed processing, you should allow for reasonable network delays, or problems at the remote end.
- Was the message you are expecting defined as persistent?

  If not, and the queue manager has been restarted, the message will have been deleted. Shared queues are an exception because nonpersistent messages survive a queue manager restart.
- Are you waiting for a specific message that is identified by a message or correlation identifier (`MsgId` or `CorrelId`)?

  Check that you are waiting for a message with the correct `MsgId` or `CorrelId`. A successful MQGET call sets both these values to that of the message got, so you might need to reset these values to get another message successfully.

  Also check if you can get other messages from the queue.
- Can other applications get messages from the queue?

If so, has another application already retrieved the message?

If the queue is a shared queue, check that applications on other queue managers are not getting the messages.

If you cannot find anything wrong with the queue, and the queue manager itself is running, make the following checks on the process that you expected to put the message on to the queue:

- Did the application get started?

  If it should have been triggered, check that the correct trigger options were specified.
- Is a trigger monitor running?
- Was the trigger process defined correctly (both to IBM MQ for z/OS and CICS or IMS)?
- Did it complete correctly?

  Look for evidence of an abend, for example, in the CICS log.
- Did the application commit its changes, or were they backed out?

  Look for messages in the CICS log indicating this.

If multiple transactions are serving the queue, they might occasionally conflict with one another. For example, one transaction might issue an MQGET call with a buffer length of zero to find out the length of the message, and then issue a specific MQGET call specifying the `MsgId` of that message. However, while this is happening, another transaction might have issued a successful MQGET call for that message, so the first application receives a completion code of MQRC_NO_MSG_AVAILABLE. Applications that are expected to run in a multi-server environment must be designed to cope with this situation.

Have any of your systems suffered an outage? For example, if the message you were expecting should have been put on to the queue by a CICS application, and the CICS system went down, the message might be in doubt. This means that the queue manager does not know whether the message should be committed or backed out, and so has locked it until this is resolved when resynchronization takes place.

Note: The message is deleted after resynchronization if CICS decides to back it out.

Also consider that the message could have been received, but that your application failed to process it in some way. For example, did an error in the expected format of the message cause your program to reject it? If so, refer to "Messages contain unexpected or corrupted information" on page 1767.

Problems with missing messages when using distributed queuing

Use this topic tom understand possible causes of missing messages when using distributed queuing.

If your application uses distributed queuing, consider the following points:

Has distributed queuing been correctly installed on both the sending and receiving systems?
: Ensure that the instructions about installing the distributed queue management facility in Configuring z/OS have been followed correctly.

Are the links available between the two systems?
: Check that both systems are available, and connected to IBM MQ for z/OS. Check that the LU 6.2 or TCP/IP connection between the two systems is active or check the connection definitions on any other systems that you are communicating with.

  See Monitoring and performance for more information about trace-route messaging in a network.

Is the channel running?

- Issue the following command for the transmission queue:

  ```
  DISPLAY QUEUE (qname) IPPROCS
  ```

  If the value for IPPROCS is 0, this means that the channel serving this transmission queue is not running.
- Issue the following command for the channel:

```
DISPLAY CHSTATUS (channel-name) STATUS MSGS
```

Use the output produced by this command to check that the channel is serving the correct transmission queue and that it is connected to the correct target machine and port. You can determine whether the channel is running from the STATUS field. You can also see if any messages have been sent on the channel by examining the MSGS field.

If the channel is in RETRYING state, this is probably caused by a problem at the other end. Check that the channel initiator and listener have been started, and that the channel has not been stopped. If somebody has stopped the channel, you need to start it manually.

Is triggering set on in the sending system?
Check that the channel initiator is running.

Does the transmission queue have triggering set on?
If a channel is stopped under specific circumstances, triggering can be set off for the transmission queue.

Is the message you are waiting for a reply message from a remote system?
Check the definitions of the remote system, as previously described, and check that triggering is activated in the remote system. Also check that the LU 6.2 connection between the two systems is not single session (if it is, you cannot receive reply messages).

Check that the queue on the remote queue manager exists, is not full, and accepts the message length. If any of these criteria are not fulfilled, the remote queue manager tries to put the message on the dead-letter queue. If the message length is longer than the maximum length that the channel permits, the sending queue manager tries to put the message on its dead-letter queue.

Is the queue already full?

This could mean that an application could not put the required message on to the queue. If this is so, check if the message has been put on to the dead-letter queue.

The dead-letter queue message header (dead-letter header structure) contains a reason or feedback code explaining why the message could not be put on to the target queue. See MQDLH - Dead-letter header for more information about the dead-letter header structure.

Is there a mismatch between the sending and receiving queue managers?
For example, the message length could be longer than the receiving queue manager can handle. Check the console log for error messages.

Are the channel definitions of the sending and receiving channels compatible?
For example, a mismatch in the wrap value of the sequence number stops the channel. See Distributed queuing and clusters.

Has data conversion been performed correctly?
If a message has come from a different queue manager, are the CCSIDs and encoding the same, or does data conversion need to be performed.

Has your channel been defined for fast delivery of nonpersistent messages?
If your channel has been defined with the NPMSPEED attribute set to FAST (the default), and the channel has stopped for some reason and then been restarted, nonpersistent messages might have been lost. See Nonpersistent message speed (NPMSPEED) for more information about fast messages.

Is a channel exit causing the messages to be processed in an unexpected way?
For example, a security exit might prevent a channel from starting, or an *ExitResponse* of MQXCC_CLOSE_CHANNEL might terminate a channel.

Problems with getting messages when using message grouping

Use this topic to understand some of the issues with getting messages when using message grouping.

Is the application waiting for a complete group of messages?

Ensure all the messages in the group are on the queue. If you are using distributed queuing, see "Problems with missing messages when using distributed queuing" on page 1764. Ensure the last message in the group has the appropriate MsgFlags set in the message descriptor to indicate that it is the last message. Ensure the message expiry of the messages in the group is set to a long enough interval that they do not expire before they are retrieved.

If messages from the group have already been retrieved, and the get request is not in logical order, turn off the option to wait for a complete group when retrieving the other group messages.

If the application issues a get request in logical order for a complete group, and midway through retrieving the group it cannot find a message:

Ensure that no other applications are running against the queue and getting messages. Ensure that the message expiry of the messages in the group is set to a long enough interval that they do not expire before they are retrieved. Ensure that no one has issued the CLEAR QUEUE command. You can retrieve incomplete groups from a queue by getting the messages by group ID, without specifying the logical order option.

Finding messages sent to a cluster queue

Use this topic to understand some of the issues involved with finding messages sent to a cluster queue.

Before you can use the techniques described in these topics to find a message that did not arrive at a cluster queue, you need to determine the queue managers that host the queue to which the message was sent. You can determine this in the following ways:

- You can use the DISPLAY QUEUE command to request information about cluster queues.
- You can use the name of the queue and queue manager that is returned in the MQPMO structure.

  If you specified the MQOO_BIND_ON_OPEN option for the message, these fields give the destination of the message. If the message was not bound to a particular queue and queue manager, these fields give the name of the first queue and queue manager to which the message was sent. In this case, it might not be the ultimate destination of the message.

Finding messages sent to the IBM MQ - IMS bridge

Use this topic to understand possible causes for missing messages sent to the IBM MQ - IMS bridge.

If you are using the IBM MQ - IMS bridge, and your message has not arrived as expected, consider the following:

Is the IBM MQ - IMS bridge running?

Issue the following command for the bridge queue:

```
DISPLAY QSTATUS(qname) IPPROCS CURDEPTH
```

The value of IPPROCS should be 1; if it is 0, check the following:

- Is the queue a bridge queue?
- Is IMS running?
- Has OTMA been started?
- Is IBM MQ connected to OTMA?

  Note: There are two IBM MQ messages that you can use to establish whether you have a connection to OTMA. If message CSQ2010I is present in the job log of the task, but message CSQ2011I is not present, IBM MQ is connected to OTMA. This message also tells you to which IBM MQ system OTMA is connected. For more information about the content of these messages, see IBM MQ for z/OS messages, completion, and reason codes.

Within the queue manager there is a task processing each IMS bridge queue. This task gets from the queue, sends the request to IMS, and then does a commit. If persistent messages are used, then the commit requires disk I/O and so the process takes longer than for non-persistent messages. The time to process the get, send, and commit, limits the rate at which the task can process messages. If the task can keep up with the workload then the current depth is close to zero. If you find that the current depth is often greater than zero you might be able to increase throughput by using two queues instead of one.

Use the IMS command `/DIS OTMA` to check that OTMA is active.

If your messages are flowing to IMS, check the following:

- Use the IMS command `/DIS TMEMBER client TPIPE ALL` to display information about IMS Tpipes. From this you can determine the number of messages enqueued on, and dequeued from, each Tpipe. (Commit mode 1 messages are not usually queued on a Tpipe.)
- Use the IMS command `/DIS A` to show whether there is a dependent region available for the IMS transaction to run in.
- Use the IMS command `/DIS TRAN trancode` to show the number of messages queued for a transaction.
- Use the IMS command `/DIS PROG progname` to show if a program has been stopped.

Was the reply message sent to the correct place?

Issue the following command:

```
DISPLAY QSTATUS(*) CURDEPTH
```

Does the CURDEPTH indicate that there is a reply on a queue that you are not expecting?

Messages contain unexpected or corrupted information

Use this topic to understand some of the issues that can cause unexpected or corrupted output.

If the information contained in the message is not what your application was expecting, or has been corrupted in some way, consider the following points:

Has your application, or the application that put the message on to the queue changed?

Ensure that all changes are simultaneously reflected on all systems that need to be aware of the change.

For example, a copybook formatting the message might have been changed, in which case, both applications have to be recompiled to pick up the changes. If one application has not been recompiled, the data will appear corrupt to the other.

Check that no external source of data, such as a VSAM data set, has changed. This could also invalidate your data if any necessary recompilations have not been done. Also check that any CICS maps and TSO panels that you are using for input of message data have not changed.

Is an application sending messages to the wrong queue?

Check that the messages your application is receiving are not intended for an application servicing a different queue. If necessary, change your security definitions to prevent unauthorized applications from putting messages on to the wrong queues.

If your application has used an alias queue, check that the alias points to the correct queue.

If you altered the queue to make it a cluster queue, it might now contain messages from different application sources.

Has the trigger information been specified correctly for this queue?

Check that your application should have been started, or should a different application have been started?

Has data conversion been performed correctly?

If a message has come from a different queue manager, are the CCSIDs and encoding the same, or does data conversion need to be performed.

Check that the `Format` field of the MQMD structure corresponds with the content of the message. If not, the data conversion process might not have been able to deal with the message correctly.

If these checks do not enable you to solve the problem, check your application logic, both for the program sending the message, and for the program receiving it.

Dealing with issues when capturing SMF data for the channel initiator (CHINIT)

Channel accounting and CHINIT statistics SMF data might not be captured for various reasons.

For more information, see:

Related information:

Layout of SMF records for the channel initiator

Troubleshooting channel accounting data

Checks to carry out if channel accounting SMF data is not being produced for channels.

Procedure

1. Check that you have STATCHL set, either at the queue manager or the channel level.
   - A value of OFF at channel level means that data is not collected for this channel.
   - A value of OFF at queue manager level means data is not collected for channels with STATCHL(QMGR).
   - A value of NONE (only applicable at queue manager level) means data is not collected for all channels, regardless of their STATCHL setting.
2. For client channels check that STATCHL is set at the queue manager level.
3. For automatically defined cluster sender channels, check that the STATACLS is set.
4. Issue the display trace command. You need TRACE(A) CLASS(4) enabled for channel accounting data to be collected.
5. If the trace is enabled, SMF data is written:
   - On a timed interval, depending on the value of the STATIME system parameter. A value of zero means that the SMF statistics broadcast is used. Use the DIS SYSTEM command to display the value of STATIME.
   - If the SET SYSTEM command is issued to change the value of the STATIME system parameter.
   - When the CHINIT is shut down.
   - If the STOP TRACE(A) CLASS(4) is issued, any accounting data is written out.
6. SMF might hold the data in memory before writing it out to the SMF data sets or the SMF structure. Issue the MVS command **`D SMF,O`** and note the MAXDORM value. SMF can keep the data in memory for the MAXDORM period before writing it out.

Related information:

Planning for channel initiator SMF data

Interpreting IBM MQ performance statistics

Troubleshooting CHINIT statistics data

Checks to carry out if CHINIT statistics SMF data is not being produced.

Procedure

1. Issue the display trace command. You need TRACE(S) CLASS(4) enabled for information about the CHINIT.
2. If the trace is enabled, SMF data is written:
   - On a timed interval, depending on the value of the STATIME system parameter. A value of zero means that the SMF statistics broadcast is used. Use the DIS SYSTEM command to display the value of STATIME.
   - If the SET SYSTEM command is issued to change the value of the STATIME system parameter.
   - When the CHINIT is shut down.
   - If the STOP TRACE(S) CLASS(4) is issued, any statistics data is written out.
3. SMF can hold the data in memory before writing it out to the SMF data sets or the SMF structure. Issue the MVS command **`D SMF,O`** and note the MAXDORM value. SMF can keep the data in memory for the MAXDORM period before writing it out.

Problem determination in DQM

Aspects of problem determination relating to distributed queue management (DQM) and suggested methods of resolving problems.

Some of the problems that are described are platform and installation specific. Where this is the case, it is made clear in the text.

IBM MQ provides a utility to assist with problem determination named **`amqldmpa`**. During the course of problem determination, your IBM service representative might ask you to provide output from the utility.

Your IBM service representative will provide you with the parameters you require to collect the appropriate diagnostic information, and information on how you send the data you record to IBM.

Attention: You should not rely on the format of the output from this utility, as the format is subject to change without notice.

Problem determination for the following scenarios is discussed:

- "Error message from channel control" on page 1770
- "Ping" on page 1771
- "Dead-letter queue considerations" on page 1771
- "Validation checks" on page 1772
- "In-doubt relationship" on page 1772
- "Channel startup negotiation errors" on page 1772
- "When a channel refuses to run" on page 1773
- "Retrying the link" on page 1775
- "Data structures" on page 1776
- "User exit problems" on page 1776
- "Disaster recovery" on page 1776
- "Channel switching" on page 1777

- “Connection switching” on page 1777
- “Client problems” on page 1777
- “Error logs” on page 1778
- “Message monitoring” on page 1779

Related concepts:

“Troubleshooting and support” on page 1275
If you are having problems with your queue manager network or IBM MQ applications, use the techniques described to help you diagnose and solve the problems.

“Making initial checks on Windows, UNIX and Linux systems” on page 1277
Before you start problem determination in detail, consider whether there is an obvious cause of the problem, or an area of investigation that is likely to give useful results. This approach to diagnosis can often save a lot of work by highlighting a simple error, or by narrowing down the range of possibilities.

z/OS “Making initial checks on z/OS” on page 1297
Before you start problem determination in detail, consider whether there is an obvious cause of the problem, or an area of investigation that is likely to give useful results. This approach to diagnosis can often save a lot of work by highlighting a simple error, or by narrowing down the range of possibilities.

IBM i “Making initial checks on IBM i” on page 1288
Before you start problem determination in detail, consider whether there is an obvious cause of the problem, or an area of investigation that is likely to give useful results. This approach to diagnosis can often save a lot of work by highlighting a simple error, or by narrowing down the range of possibilities.

“Reason codes and exceptions” on page 1314
You can use the following messages and reason codes to help you solve problems with your IBM MQ components or applications.

Related information:

Configuring distributed queuing

Communications protocol return codes

Error message from channel control

Problems found during normal operation of the channels are reported to the system console and to the system log. In IBM MQ for Windows they are reported to the channel log. Problem diagnosis starts with the collection of all relevant information from the log, and analysis of this information to identify the problem.

However, this could be difficult in a network where the problem may arise at an intermediate system that is staging some of your messages. An error situation, such as transmission queue full, followed by the dead-letter queue filling up, would result in your channel to that site closing down.

In this example, the error message you receive in your error log will indicate a problem originating from the remote site, but may not be able to tell you any details about the error at that site.

You need to contact your counterpart at the remote site to obtain details of the problem, and to receive notification of that channel becoming available again.

Ping

Ping is useful in determining whether the communication link and the two message channel agents that make up a message channel are functioning across all interfaces.

Ping makes no use of transmission queues, but it does invoke some user exit programs. If any error conditions are encountered, error messages are issued.

To use ping, you can issue the MQSC command PING CHANNEL. On z/OS z/OS IBM i and i5/OS , you can also use the panel interface to select this option.

On UNIX platforms, IBM i i5/OS, and Windows, you can also use the MQSC command PING QMGR to test whether the queue manager is responsive to commands.

Dead-letter queue considerations

In some IBM MQ implementations the dead-letter queue is referred to as an *undelivered-message queue*.

If a channel ceases to run for any reason, applications will probably continue to place messages on transmission queues, creating a potential overflow situation. Applications can monitor transmission queues to find the number of messages waiting to be sent, but this would not be a normal function for them to carry out.

When this occurs in a message-originating node, and the local transmission queue is full, the application's PUT fails.

When this occurs in a staging or destination node, there are three ways that the MCA copes with the situation:

1. By calling the message-retry exit, if one is defined.
2. By directing all overflow messages to a *dead-letter queue* (DLQ), returning an exception report to applications that requested these reports.

   Note: In distributed-queuing management, if the message is too big for the DLQ, the DLQ is full, or the DLQ is not available, the channel stops and the message remains on the transmission queue. Ensure your DLQ is defined, available, and sized for the largest messages you handle.
3. By closing down the channel, if neither of the previous options succeeded.
4. By returning the undelivered messages back to the sending end and returning a full report to the reply-to queue (MQRC_EXCEPTION_WITH_FULL_DATA and MQRO_DISCARD_MSG).

If an MCA is unable to put a message on the DLQ:

- The channel stops
- Appropriate error messages are issued at the system consoles at both ends of the message channel
- The unit of work is backed out, and the messages reappear on the transmission queue at the sending channel end of the channel
- Triggering is disabled for the transmission queue

Validation checks

A number of validation checks are made when creating, altering, and deleting channels, and where appropriate, an error message returned.

Errors may occur when:

- A duplicate channel name is chosen when creating a channel
- Unacceptable data is entered in the channel parameter fields
- The channel to be altered is in doubt, or does not exist

In-doubt relationship

If a channel is in doubt, it is usually resolved automatically on restart, so the system operator does not need to resolve a channel manually in normal circumstances. See In-doubt channels for further information.

Channel startup negotiation errors

During channel startup, the starting end has to state its position and agree channel running parameters with the corresponding channel. It may happen that the two ends cannot agree on the parameters, in which case the channel closes down with error messages being issued to the appropriate error logs.

Shared channel recovery

The following table shows the types of shared-channel failure and how each type is handled.

Type of failure:	**What happens:**
Channel initiator communications subsystem failure	The channels dependent on the communications subsystem enter channel retry, and are restarted on an appropriate queue-sharing group channel initiator by a load-balanced start command.
Channel initiator failure	The channel initiator fails, but the associated queue manager remains active. The queue manager monitors the failure and initiates recovery processing.
Queue manager failure	The queue manager fails (failing the associated channel initiator). Other queue managers in the queue-sharing group monitor the event and initiate peer recovery.
Shared status failure	Channel state information is stored in Db2, so a loss of connectivity to Db2 becomes a failure when a channel state change occurs. Running channels can carry on running without access to these resources. On a failed access to Db2, the channel enters retry.

Shared channel recovery processing on behalf of a failed system requires connectivity to Db2 to be available on the system managing the recovery to retrieve the shared channel status.

When a channel refuses to run

If a channel refuses to run, there are a number of potential reasons.

Carry out the following checks:

- Check that DQM and the channels have been set up correctly. This is a likely problem source if the channel has never run. Reasons could be:
  - A mismatch of names between sending and receiving channels (remember that uppercase and lowercase letters are significant)
  - Incorrect channel types specified
  - The sequence number queue (if applicable) is not available, or is damaged
  - The dead-letter queue is not available
  - The sequence number wrap value is different on the two channel definitions
  - A queue manager or communication link is not available
  - A receiver channel might be in STOPPED state
  - The connection might not be defined correctly
  - There might be a problem with the communications software (for example, is TCP running?)
- It is possible that an in-doubt situation exists, if the automatic synchronization on startup has failed for some reason. This is indicated by messages on the system console, and the status panel may be used to show channels that are in doubt.

  The possible responses to this situation are:
  - Issue a Resolve channel request with Backout or Commit.

    You need to check with your remote link supervisor to establish the number of the last-committed unit of work ID (LUWID) committed. Check this against the last number at your end of the link. If the remote end has committed a number, and that number is not yet committed at your end of the link, then issue a RESOLVE COMMIT command.

    In all other cases, issue a RESOLVE BACKOUT command.

    The effect of these commands is that backed out messages reappear on the transmission queue and are sent again, while committed messages are discarded.

    If in doubt yourself, perhaps backing out with the probability of duplicating a sent message would be the safer decision.
  - Issue a RESET CHANNEL command.

    This command is for use when sequential numbering is in effect, and should be used with care. Its purpose is to reset the sequence number of messages and you should use it only after using the RESOLVE command to resolve any in-doubt situations.
- Windows UNIX IBM i z/OS When sequential numbering is being used, and a sender channel starts up after being reset, the sender channel takes two actions:
  - It tells the receiver channel that it has been reset.
  - It specifies the next message sequence number that is to be used by both the sender and receiver channels.
- If the status of a receiver end of the channel is STOPPED, it can be reset by starting the receiver end.

  Note: This does not start the channel, it merely resets the status. The channel must still be started from the sender end.

Triggered channels

If a triggered channel refuses to run, investigate the possibility of in-doubt messages here: "When a channel refuses to run" on page 1773

Another possibility is that the trigger control parameter on the transmission queue has been set to NOTRIGGER by the channel. This happens when:

- There is a channel error.
- The channel was stopped because of a request from the receiver.
- The channel was stopped because of a problem on the sender that requires manual intervention.

After diagnosing and fixing the problem, start the channel manually.

An example of a situation where a triggered channel fails to start is as follows:

1. A transmission queue is defined with a trigger type of FIRST.
2. A message arrives on the transmission queue, and a trigger message is produced.
3. The channel is started, but stops immediately because the communications to the remote system are not available.
4. The remote system is made available.
5. Another message arrives on the transmission queue.
6. The second message does not increase the queue depth from zero to one, so no trigger message is produced (unless the channel is in RETRY state). If this happens, restart the channel manually.

On IBM MQ for z/OS, if the queue manager is stopped using MODE(FORCE) during channel initiator shutdown, it might be necessary to manually restart some channels after channel initiator restart.

Conversion failure

Another reason for the channel refusing to run could be that neither end is able to carry out necessary conversion of message descriptor data between ASCII and EBCDIC, and integer formats. In this instance, communication is not possible.

Network problems

There are a number of things to check if you are experiencing network problems.

When using LU 6.2, make sure that your definitions are consistent throughout the network. For example, if you have increased the RU sizes in your CICS Transaction Server for z/OS or Communications Manager definitions, but you have a controller with a small MAXDATA value in its definition, the session might fail if you attempt to send large messages across the network. A symptom of this problem might be that channel negotiation takes place successfully, but the link fails when message transfer occurs.

When using TCP, if your channels are unreliable and your connections break, you can set a KEEPALIVE value for your system or channels. You do this using the SO_KEEPALIVE option to set a system-wide value.

z/OS On IBM MQ for z/OS, you also have the following options:

- Use the Keepalive Interval channel attribute (KAINT) to set channel-specific keepalive values.
- Use the RCVTIME and RCVTMIN channel initiator parameters.

These options are discussed in Checking that the other end of the channel is still available, and Keepalive Interval (KAINT).

Adopting an MCA

The Adopt MCA function enables IBM MQ to cancel a receiver channel and to start a new one in its place.

For more information about this function, see Adopting an MCA.

Registration time for DDNS

When a group TCP/IP listener is started, it registers with DDNS. But there can be a delay until the address is available to the network. A channel that is started in this period, and which targets the newly registered generic name, fails with an 'error in communications configuration' message. The channel then goes into retry until the name becomes available to the network. The length of the delay is dependent on the name server configuration used.

Dial-up problems

IBM MQ supports connection over dial-up lines but you should be aware that with TCP, some protocol providers assign a new IP address each time you dial in. This can cause channel synchronization problems because the channel cannot recognize the new IP addresses and so cannot ensure the authenticity of the partner. If you encounter this problem, you need to use a security exit program to override the connection name for the session.

This problem does not occur when an IBM MQ for IBM i, UNIX systems, or Windows systems product is communicating with another product at the same level, because the queue manager name is used for synchronization instead of the IP address.

Retrying the link

An error scenario may occur that is difficult to recognize. For example, the link and channel may be functioning perfectly, but some occurrence at the receiving end causes the receiver to stop. Another unforeseen situation could be that the receiver system has run out of memory and is unable to complete a transaction.

You need to be aware that such situations can arise, often characterized by a system that appears to be busy but is not actually moving messages. You need to work with your counterpart at the far end of the link to help detect the problem and correct it.

Retry considerations

If a link failure occurs during normal operation, a sender or server channel program will itself start another instance, provided that:
1. Initial data negotiation and security exchanges are complete
2. The retry count in the channel definition is greater than zero

Note: For IBM i, UNIX systems, and Windows, to attempt a retry a channel initiator must be running. In platforms other than IBM MQ for IBM i, UNIX systems, and Windows systems, this channel initiator must be monitoring the initiation queue specified in the transmission queue that the channel is using.

Shared channel recovery on z/OS:

See “Shared channel recovery” on page 1772, which includes a table that shows the types of shared-channel failure and how each type is handled.

Data structures

Data structures are needed for reference when checking logs and trace entries during problem diagnosis.

More information can be found in Channel-exit calls and data structures and Developing applications reference.

User exit problems

The interaction between the channel programs and the user-exit programs has some error-checking routines, but this facility can only work successfully when the user exits obey certain rules.

These rules are described in Channel-exit programs for messaging channels. When errors occur, the most likely outcome is that the channel stops and the channel program issues an error message, together with any return codes from the user exit. Any errors detected on the user exit side of the interface can be determined by scanning the messages created by the user exit itself.

You might need to use a trace facility of your host system to identify the problem.

Disaster recovery

Disaster recovery planning is the responsibility of individual installations, and the functions performed may include the provision of regular system 'snapshot' dumps that are stored safely off-site. These dumps would be available for regenerating the system, should some disaster overtake it. If this occurs, you need to know what to expect of the messages, and the following description is intended to start you thinking about it.

First a recap on system restart. If a system fails for any reason, it may have a system log that allows the applications running at the time of failure to be regenerated by replaying the system software from a syncpoint forward to the instant of failure. If this occurs without error, the worst that can happen is that message channel syncpoints to the adjacent system may fail on startup, and that the last batches of messages for the various channels will be sent again. Persistent messages will be recovered and sent again, nonpersistent messages may be lost.

If the system has no system log for recovery, or if the system recovery fails, or where the disaster recovery procedure is invoked, the channels and transmission queues may be recovered to an earlier state, and the messages held on local queues at the sending and receiving end of channels may be inconsistent.

Messages may have been lost that were put on local queues. The consequence of this happening depends on the particular IBM MQ implementation, and the channel attributes. For example, where strict message sequencing is in force, the receiving channel detects a sequence number gap, and the channel closes down for manual intervention. Recovery then depends upon application design, as in the worst case the sending application may need to restart from an earlier message sequence number.

Channel switching

A possible solution to the problem of a channel ceasing to run would be to have two message channels defined for the same transmission queue, but with different communication links. One message channel would be preferred, the other would be a replacement for use when the preferred channel is unavailable.

If triggering is required for these message channels, the associated process definitions must exist for each sender channel end.

To switch message channels:
- If the channel is triggered, set the transmission queue attribute NOTRIGGER.
- Ensure the current channel is inactive.
- Resolve any in-doubt messages on the current channel.
- If the channel is triggered, change the process attribute in the transmission queue to name the process associated with the replacement channel.

  In this context, some implementations allow a channel to have a blank process object definition, in which case you may omit this step as the queue manager will find and start the appropriate process object.
- Restart the channel, or if the channel was triggered, set the transmission queue attribute TRIGGER.

Connection switching

Another solution would be to switch communication connections from the transmission queues.

To do this:
- If the sender channel is triggered, set the transmission queue attribute NOTRIGGER.
- Ensure the channel is inactive.
- Change the connection and profile fields to connect to the replacement communication link.
- Ensure that the corresponding channel at the remote end has been defined.
- Restart the channel, or if the sender channel was triggered, set the transmission queue attribute TRIGGER.

Client problems

A client application may receive an unexpected error return code, for example:
- Queue manager not available
- Queue manager name error
- Connection broken

Look in the client error log for a message explaining the cause of the failure. There may also be errors logged at the server, depending on the nature of the failure.

Terminating clients

Even though a client has terminated, it is still possible for its surrogate process to be holding its queues open. Normally this will only be for a short time until the communications layer notifies that the partner has gone.

Error logs

IBM MQ error messages are placed in different error logs depending on the platform. There are error logs for:

- Windows
- UNIX systems
- z/OS

Error logs for Windows

IBM MQ for Windows uses a number of error logs to capture messages concerning the operation of IBM MQ itself, any queue managers that you start, and error data coming from the channels that are in use.

The location the error logs are stored in depends on whether the queue manager name is known and whether the error is associated with a client.

- If the queue manager name is known and the queue manager is available:
  ```
  <install directory>\QMGRS\QMgrName\ERRORS\AMQERR01.LOG
  ```
- If the queue manager is not available:
  ```
  <install directory>\QMGRS\@SYSTEM\ERRORS\AMQERR01.LOG
  ```
- If an error has occurred with a client application:
  ```
  <install directory>\ERRORS\AMQERR01.LOG
  ```

On Windows, you should also examine the Windows application event log for relevant messages.

Error logs on UNIX and Linux systems

IBM MQ on UNIX and Linux systems uses a number of error logs to capture messages concerning the operation of IBM MQ itself, any queue managers that you start, and error data coming from the channels that are in use. The location the error logs are stored in depends on whether the queue manager name is known and whether the error is associated with a client.

- If the queue manager name is known:
  ```
  /var/mqm/qmgrs/QMgrName/errors
  ```
- If the queue manager name is not known (for example when there are problems in the listener or SSL handshake):
  ```
  /var/mqm/errors
  ```

When a client is installed, and there is a problem in the client application, the following log is used:

- If an error has occurred with a client application:
  ```
  /var/mqm/errors/
  ```

Error logs on z/OS

Error messages are written to:
- The z/OS system console
- The channel-initiator job log

If you are using the z/OS message processing facility to suppress messages, the console messages might be suppressed. See Planning your IBM MQ environment on z/OS.

Message monitoring

If a message does not reach its intended destination, you can use the IBM MQ display route application, available through the control command **dspmqrte** , to determine the route a message takes through the queue manager network and its final location.

The IBM MQ display route application is described in the IBM MQ display route application section.

Channel authentication records troubleshooting

If you are having problems using channel authentication records, check whether the problem is described in the following information.

What address are you presenting to the queue manager?

The address that your channel presents to the queue manager depends on the network adapter being used. For example, if the CONNAME you use to get to the listener is "localhost", you present 127.0.0.1 as your address; if it is the real IP address of your computer, then that is the address you present to the queue manager. You might invoke different authentication rules for 127.0.0.1 and your real IP address.

Using BLOCKADDR with channel names

If you use SET CHLAUTH TYPE(BLOCKADDR), it must have the generic channel name CHLAUTH(*) and nothing else. You must block access from the specified addresses using any channel name.

z/OS

CHLAUTH(*) on z/OS systems

On z/OS, a channel name including the asterisk (*) must be enclosed in quotation marks. This rule also applies to the use of a single asterisk to match all channel names. Thus, where you would specify CHLAUTH(*) on other platforms, on z/OS you must specify CHLAUTH('*').

Behavior of SET CHLAUTH command over queue manager restart

If the SYSTEM.CHLAUTH.DATA.QUEUE, has been deleted or altered in a way that it is no longer accessible i.e. PUT(DISABLED), the `SET CHLAUTH` command will only be partially successful. In this instance, `SET CHLAUTH` will update the in-memory cache, but will fail when hardening.

This means that although the rule put in place by the `SET CHLAUTH` command may be operable initially, the effect of the command will not persist over a queue manager restart. The user should investigate, ensuring the queue is accessible and then reissue the command (using `ACTION(REPLACE)`) before cycling the queue manager.

If the SYSTEM.CHLAUTH.DATA.QUEUE remains inaccessible at queue manager startup, the cache of saved rules cannot be loaded and all channels will be blocked until the queue and rules become accessible.

z/OS

Maximum size of ADDRESS and ADDRLIST on z/OS systems

On z/OS, the maximum size for the ADDRESS and ADDRLIST fields are 48 characters. Some IPv6 address patterns could be longer than this limit, for example '0000-ffff:0000-ffff:0000-ffff:0000-ffff:0000-ffff:0000-ffff:0000-ffff:0000-ffff'. In this case, you could use '*' instead.

If you want to use a pattern more than 48 characters long, try to express the requirement in a different way. For example, instead of specifying

'0001-fffe:0001-fffe:0001-fffe:0001-fffe:0001-fffe:0001-fffe:0001-fffe:0001-fffe' as the address pattern for a USERSRC(MAP), you could specify three rules:
- USERSRC(MAP) for all addresses (*)
- USERSRC(NOACCESS) for address '0000:0000:0000:0000:0000:0000:0000:0000'
- USERSRC(NOACCESS) for address 'ffff:ffff:ffff:ffff:ffff:ffff:ffff:ffff'

Commands troubleshooting

- **Scenario:** You receive errors when you use special characters in descriptive text for some commands.
- **Explanation:** Some characters, for example, back slash (\) and double quote (") characters have special meanings when used with commands.
- **Solution:** Precede special characters with a \, that is, enter \\ or \" if you want \ or " in your text. Not all characters are allowed to be used with commands. For more information about characters with special meanings and how to use them, see Characters with special meanings.

Distributed publish/subscribe troubleshooting

Use the advice given in the subtopics to help you to detect and deal with problems when you use publish/subscribe clusters or hierarchies.

Before you begin

If your problems relate to clustering in general, rather than to publish/subscribe messaging using clusters, see“Queue manager clusters troubleshooting” on page 1805.

There are also some helpful troubleshooting tips in Design considerations for retained publications in publish/subscribe clusters.

Configuring a publish/subscribe cluster

Designing publish/subscribe clusters

Distributed publish/subscribe system queue errors

Routing for publish/subscribe clusters: Notes on behavior

Use the advice given here to help you to detect and deal with routing problems when you are using clustered publish/subscribe messaging.

For information about status checking and troubleshooting for any queue manager cluster, see “Queue manager clusters troubleshooting” on page 1805.

- All clustered definitions of the same named topic object in a cluster must have the same **CLROUTE** setting. You can check the **CLROUTE** setting for all topics on all hosts in the cluster using the following MQSC command:

  ```
  display tcluster(*) clroute
  ```

- The **CLROUTE** property has no effect unless the topic object specifies a value for the **CLUSTER** property.
- Check that you have spelled the cluster name correctly on your topic. You can define a cluster object such as a topic before defining the cluster. Therefore, when you define a cluster topic, no validation is done on the cluster name because it might not yet exist. Consequently, the product does not alert you to misspelt cluster names.
- When you set the **CLROUTE** property, if the queue manager knows of a clustered definition of the same object from another queue manager that has a different **CLROUTE** setting, the system generates an `MQRCCF_CLUSTER_TOPIC_CONFLICT` exception. However, through near simultaneous object definition on different queue managers, or erratic connectivity with full repositories, differing definitions might be created. In this situation the full repository queue managers arbitrate, accepting one definition and reporting an error for the other one. To get more information about the conflict, use the following MQSC command to check the cluster state of all topics on all queue managers in the cluster:

  ```
  display tcluster(*) clstate
  ```

  A state of `invalid`, or `pending` (if this does not soon turn to active), indicates a problem. If an invalid topic definition is detected, identify the incorrect topic definition and remove it from the cluster. The full repositories have information about which definition was accepted and which was rejected, and the queue managers that created the conflict have some indication of the nature of the problem. See also CLSTATE in DISPLAY TOPIC.
- Setting the **CLROUTE** parameter at a point in the topic tree causes the entire branch beneath it to route topics in that way. You cannot change the routing behavior of a sub-branch of this branch. For this reason, defining a topic object for a lower or higher node in the topic tree with a different **CLROUTE** setting is rejected with an `MQRCCF_CLUSTER_TOPIC_CONFLICT` exception.
- You can use the following MQSC command to check the topic status of all the topics in the topic tree:

  ```
  display tpstatus('#')
  ```

  If you have a large number of branches in the topic tree, the previous command might display status for an inconveniently large number of topics. If that is the case, you can instead display a manageably small branch of the tree, or an individual topic in the tree. The information displayed includes the topic string, cluster name and cluster route setting. It also includes the publisher count and subscription count (number of publishers and subscribers), to help you judge whether the number of users of this topic is as you expect.
- Changing the cluster routing of a topic in a cluster is a significant change to the publish/subscribe topology. After a topic object has been clustered (through setting the **CLUSTER** property) you cannot change the value of the **CLROUTE** property. The object must be un-clustered (**CLUSTER** set to **' '**) before you can change the value. Un-clustering a topic converts the topic definition to a local topic, which results in a period during which publications are not delivered to subscriptions on remote queue managers; this should be considered when performing this change. See The effect of defining a non-cluster topic with the same name as a cluster topic from another queue manager. If you try to change the value of the **CLROUTE** property while it is clustered, the system generates an `MQRCCF_CLROUTE_NOT_ALTERABLE` exception.
- For topic host routing, you can explore alternative routes through the cluster by adding and removing the same cluster topic definition on a range of cluster queue managers. To stop a given queue manager from acting as a topic host for your cluster topic, either delete the topic object, or use the `PUB(DISABLED)` setting to quiesce message traffic for this topic, as discussed in Special handling for the PUB parameter. Do not un-cluster the topic by setting the **CLUSTER** property to **' '**, because removing the cluster name converts the topic definition to a local topic, and prevents the clustering behavior of the topic when used from this queue manager. See The effect of defining a non-cluster topic with the same name as a cluster topic from another queue manager.
- You cannot change the cluster of a sub-branch of the topic tree when the branch has already been clustered to a different cluster and **CLROUTE** is set to `TOPICHOST`. If such a definition is detected at define time, the system generates an `MQRCCF_CLUSTER_TOPIC_CONFLICT` exception. Similarly, inserting a newly

clustered topic definition at a higher node for a different cluster generates an exception. Because of the clustering timing issues previously described, if such an inconsistency is later detected, the queue manager issues errors to the queue manager log.

Configuring a publish/subscribe cluster

Designing publish/subscribe clusters

Checking proxy subscription locations

A proxy subscription enables a publication to flow to a subscriber on a remote queue manager. If your subscribers are not getting messages that are published elsewhere in the queue manager network, check that your proxy subscriptions are where you expect them to be.

Missing proxy subscriptions can show that your application is not subscribing on the correct topic object or topic string, or that there is a problem with the topic definition, or that a channel is not running or is not configured correctly.

To show proxy subscriptions, use the following MQSC command:

```
display sub(*) subtype(proxy)
```

Proxy subscriptions are used in all distributed publish/subscribe topologies (hierarchies and clusters). For a topic host routed cluster topic, a proxy subscription exists on each topic hosts for that topic. For a direct routed cluster topic, the proxy subscription exists on every queue manager in the cluster. Proxy subscriptions can also be made to exist on every queue manager in the network by setting the `proxysub(force)` attribute on a topic.

See also Subscription performance in publish/subscribe networks.

Resynchronization of proxy subscriptions

Under normal circumstances, queue managers automatically ensure that the proxy subscriptions in the system correctly reflect the subscriptions on each queue manager in the network. Should the need arise, you can manually resynchronize a queue manager's local subscriptions with the proxy subscriptions that it propagated across the network using the **`REFRESH QMGR TYPE(PROXYSUB)`** command. However, you should do so only in exceptional circumstances.

When to manually resynchronize proxy subscriptions

When a queue manager is receiving subscriptions that it should not be sent, or not receiving subscriptions that it should receive, you should consider manually resynchronizing the proxy subscriptions. However, resynchronization temporarily creates a sudden additional proxy subscription load on the network, originating from the queue manager where the command is issued. For this reason, do not manually resynchronize unless IBM MQ service, IBM MQ documentation, or error logging instructs you to do so.

You do not need to manually resynchronize proxy subscriptions if automatic revalidation by the queue manager is about to occur. Typically, a queue manager revalidates proxy subscriptions with affected directly-connected queue managers at the following times:

- When forming a hierarchical connection
- When modifying the **`PUBSCOPE`** or **`SUBSCOPE`** or **`CLUSTER`** attributes on a topic object
- When restarting the queue manager

Sometimes a configuration error results in missing or extraneous proxy subscriptions:

- Missing proxy subscriptions can be caused if the closest matching topic definition is specified with **Subscription scope** set to `Queue Manager` or with an empty or incorrect cluster name. Note that **Publication scope** does not prevent the sending of proxy subscriptions, but does prevent publications from being delivered to them.
- Extraneous proxy subscriptions can be caused if the closest matching topic definition is specified with **Proxy subscription behavior** set to `Force`.

When configuration errors cause these problems, manual resynchronization does not resolve them. In these cases, amend the configuration.

The following list describes the exceptional situations in which you should manually resynchronize proxy subscriptions:
- After issuing a **REFRESH CLUSTER** command on a queue manager in a publish/subscribe cluster.
- When messages in the queue manager error log tell you to run the **REFRESH QMGR TYPE(REPOS)** command.
- When a queue manager cannot correctly propagate its proxy subscriptions, perhaps because a channel has stopped and all messages cannot be queued for transmission, or because operator error has caused messages to be incorrectly deleted from the `SYSTEM.CLUSTER.TRANSMIT.QUEUE` queue.
- When messages are incorrectly deleted from other system queues.
- When a **DELETE SUB** command is issued in error on a proxy subscription.
- As part of disaster recovery.

How to manually resynchronize proxy subscriptions

First rectify the original problem (for example by restarting the channel), then issue the following command on the queue manager:

```
REFRESH QMGR TYPE(PROXYSUB)
```

When you issue this command, the queue manager sends, to each of its directly-connected queue managers, a list of its own topic strings for which proxy subscriptions should exist. The directly-connected queue managers then update their held proxy subscriptions to match the list. Next, the directly-connected queue managers send back to the originating queue manager a list of their own topic strings for which proxy subscriptions should exist, and the originating queue manager updates its held proxy subscriptions accordingly.

Important usage notes:
- Publications missed due to proxy subscriptions not being in place are not recovered for the affected subscriptions.
- Resynchronization requires the queue manager to start channels to other queue managers. If you are using direct routing in a cluster, or you are using topic host routing and this command is issued on a topic host queue manager, the queue manager will start channels to all other queue managers in the cluster, even those that have not performed publish/subscribe work. Therefore the queue manager that you are refreshing must have enough capability to cope with communicating with every other queue manager in the cluster.
- z/OS If this command is issued on z/OS when the CHINIT is not running, the command is queued up and processed when the CHINIT starts.

REFRESH CLUSTER considerations for publish/subscribe clusters

Loop detection in a distributed publish/subscribe network

In a distributed publish/subscribe network, it is important that publications and proxy subscriptions cannot loop, because this would result in a flooded network with connected subscribers receiving multiple copies of the same original publication.

The proxy subscription aggregation system described in Proxy subscriptions in a publish/subscribe network does not prevent the formation of a loop, although it will prevent the perpetual looping of proxy subscriptions. Because the propagation of publications is determined by the existence of proxy subscriptions, they can enter a perpetual loop. Websphere MQ V7.0 uses the following technique to prevent publications from perpetually looping:

As publications move around a publish/subscribe topology each queue manager adds a unique fingerprint to the message header. Whenever a publish/subscribe queue manager receives a publication from another publish/subscribe queue manager, the fingerprints held in the message header are checked. If its own fingerprint is already present, the publication has fully circulated around a loop, so the queue manager discards the message, and adds an entry to the error log.

Note: Within a loop, publications are propagated in both directions around the loop, and each queue manager within the loop receives both publications before the originating queue manager discards the looped publications. This results in subscribing applications receiving duplicate copies of publications until the loop is broken.

Loop detection fingerprint format

The loop detection fingerprints are inserted into an RFH2 header or flow as part of the V8.0 protocol. An RFH2 programmer needs to understand the header and pass on the fingerprint information intact. earlier versions of IBM Integration Bus use RFH1 headers which do not contain the fingerprint information.

```
<ibm>
  <Rfp>uuid1</Rfp>
  <Rfp>uuid2</Rfp>
  <Rfp>uuid3</Rfp>
  . . .
</ibm>
```

<ibm> is the name of the folder that holds the list of routing fingerprints containing the unique user identifier (uuid) of each queue manager that has been visited.

Every time that a message is published by a queue manager, it adds its uuid into the <ibm> folder using the <Rfp> (routing fingerprint) tag. Whenever a publication is received, IBM MQ uses the message properties API to iterate through the <Rfp> tags to see if that particular uuid value is present. Because of the way that the WebSphere Platform Messaging component of IBM MQ attaches to IBM Integration Bus through a channel and RFH2 subscription when using the queued publish/subscribe interface, IBM MQ also creates a fingerprint when it receives a publication by that route.

The goal is to not deliver any RFH2 to an application if it is not expecting any, simply because we have added in our fingerprint information.

Whenever an RFH2 is converted into message properties, it will also be necessary to convert the <ibm> folder; this removes the fingerprint information from the RFH2 that is passed on or delivered to applications that have used the IBM MQ V7.0, or later, API.

JMS applications do not see the fingerprint information, because the JMS interface does not extract that information from the RFH2, and therefore does not hand it on to its applications.

The Rfp message properties are created with `propDesc.CopyOptions = MQCOPY_FORWARD` and `MQCOPY_PUBLISH`. This has implications for applications receiving and then republishing the same message. It means that such an application can continue the chain of routing fingerprints by using `PutMsgOpts.Action = MQACTP_FORWARD`, but must be coded appropriately to remove its own fingerprint from the chain. By default the application uses `PutMsgOpts.Action = MQACTP_NEW` and starts a new chain.

IBM MQ client for HP Integrity NonStop Server troubleshooting

Provides information to help you to detect and deal with problems when you are using the IBM MQ client for HP Integrity NonStop Server.

Toggling between the use of IBM MQ and TMF transactions on a single connection

If an IBM MQ client for HP Integrity NonStop Server application toggles between the use of IBM MQ and TMF transactions on a single connection, then IBM MQ operations such as MQPUT and MQGET might fail with a return code of "2072 (0818) (RC2072): MQRC_SYNCPOINT_NOT_AVAILABLE" on page 1352. Errors and a first failure symptom report for the client application are generated in the IBM MQ client for HP Integrity NonStop Server errors directory.

This error occurs because mixed TMF and IBM MQ transactions on a single connection are not supported.

Use the standard facilities that are supplied with your system to record the problem identifier and to save any generated output files. Use either the IBM MQ Support site: http://www.ibm.com/software/integration/wmq/support/, or the IBM Support Assistant (ISA): http://www.ibm.com/software/support/isa/ to check whether a solution is already available. If you are unable to find a solution, contact your IBM support center. Do not discard these files until the problem is resolved.

Java and JMS troubleshooting

Use the advice that is given here to help you to resolve common problems that can arise when you are using Java or JMS applications.

About this task

The subtopics in this section provide advice to help you to detect and deal with problems that you might encounter under the following circumstances:
- When using the IBM MQ resource adapter
- When connecting to a queue manager with a specified provider version

JMS provider version troubleshooting

Use the advice that is given here to help you to resolve common problems that can arise when you are connecting to a queue manager with a specified provider version.

JMS 2.0 function is not supported with this connection error

- **Error code:** JMSCC5008
- **Scenario:** You receive a `JMS 2.0 function is not supported with this connection` error.
- **Explanation:** The use of the JMS 2.0 functionality is only supported when connecting to an IBM MQ Version 8.0 queue manager that is using IBM MQ messaging provider Version 8 mode.
- **Solution:** Change the application to not use the JMS 2.0 function, or ensure that the application connects to an IBM MQ Version 8.0 queue manager that is using IBM MQ messaging provider Version 8 mode.

JMS 2.0 API is not supported with this connection error

- **Error code:** JMSCC5007
- **Scenario:** You receive a `JMS 2.0 API is not supported with this connection` error.
- **Explanation:** The use of the JMS 2.0 API is only supported when you are connecting to an IBM MQ Version 7 or Version 8 queue manager that is using IBM MQ messaging provider Normal or Version 8 mode. You might, for example, receive this error if you are attempting to connect to a Version 6 queue manager or if you are connecting by using migration mode. This typically happens if SHARECNV(0) or PROVIDER_VERSION=6 is specified.
- **Solution:** Change the application to not use the JMS 2.0 API, or ensure that the application connects to an IBM MQ Version 7 or Version 8 queue manager by using IBM MQ messaging provider Normal or Version 8 mode.

Queue manager command level did not match the requested provider version error

- **Error code:** JMSFMQ0003
- **Scenario:** You receive a `queue manager command level did not match the requested provider version`error.

- **Explanation:** The queue manager version that is specified in the provider version property on the connection factory is not compatible with the requested queue manager. For example, you might have specified PROVIDER_VERSION=8, and attempt to connect to a queue manager with a command level less than 800, such as 750.
- **Solution:** Modify the connection factory to connect to a queue manager that can support the provider version required.

For more information about provider version, see Rules for selecting the IBM MQ messaging provider mode.

Configuring the JMS **PROVIDERVERSION** property

PCF processing in JMS

IBM MQ Programmable Change Format (PCF) messages are a flexible, powerful way in which to query and modify attributes of a queue manager, and the PCF classes provided in the IBM MQ classes for Java provide a convenient way of accessing their functionality in a Java application. The functionality can also be accessed from IBM MQ classes for JMS, however there is a potential problem.

The common model for processing PCF responses in JMS

A common approach to processing PCF responses in JMS is to extract the bytes payload of the message, wrap it in a `DataInputStream` and pass it to the `com.ibm.mq.headers.pcf.PCFMessage` constructor.

```
Message m = consumer.receive(10000);
//Reconstitute the PCF response.
ByteArrayInputStream bais =
    new ByteArrayInputStream(((BytesMessage)m).getBody(byte[].class));
DataInput di = new DataInputStream(bais);
 PCFMessage pcfResponseMessage = new PCFMessage(di);
```

See Using the IBM MQ Headers package for some examples.

Unfortunately this is not a totally reliable approach for all platforms - in general the approach works for big-endian platforms, but not for little-endian platforms.

What is the problem?

The problem is that in parsing the message headers, the `PCFMessage` class has to deal with issues of numeric encoding - the headers contain length fields which are in some encoding, that is big-endian or little-endian.

If you pass a "pure" `DataInputStream` to the constructor, the `PCFMessage` class has no good indication of the encoding, and has to assume a default - quite possibly incorrectly.

If this situation arises, you will probably see a "MQRCCF_STRUCTURE_TYPE_ERROR" (reason code 3013) in the constructor:

```
com.ibm.mq.headers.MQDataException: MQJE001: Completion Code '2', Reason '3013'.
        at com.ibm.mq.headers.pcf.PCFParameter.nextParameter(PCFParameter.java:167)
        at com.ibm.mq.headers.pcf.PCFMessage.initialize(PCFMessage.java:854)
        at com.ibm.mq.headers.pcf.PCFMessage.<init>(PCFMessage.java:156)
```

This message almost invariably means that the encoding has been misinterpreted. The probable reason for this is that the data that has been read is little-endian data which has been interpreted as big-endian.

The solution

The way to avoid this problem is to pass the `PCFMessage` constructor something which will tell the constructor the numeric encoding of the data it is working with.

To do this, make an MQMessage from the data received.

The following code is an outline example of the code you might use.

Attention: The code is an outline example only and does not contain any error handling information.

```
// get a response into a JMS Message
Message receivedMessage = consumer.receive(10000);
BytesMessage bytesMessage = (BytesMessage) receivedMessage;
byte[] bytesreceived = new byte[(int) bytesMessage.getBodyLength()];
bytesMessage.readBytes(bytesreceived);

// convert to MQMessage then to PCFMessage
MQMessage mqMsg = new MQMessage();
mqMsg.write(bytesreceived);
mqMsg.encoding = receivedMessage.getIntProperty("JMS_IBM_Encoding");
mqMsg.format = receivedMessage.getStringProperty("JMS_IBM_Format");
mqMsg.seek(0);

PCFMessage pcfMsg = new PCFMessage(mqMsg);
```

JMS connection pool error handling

Connection pool error handling is carried out by various methods of a purge policy.

The connection pool purge policy comes into operation if an error is detected when an application is using a JMS connection to a JMS provider. The connection manager can either:

- Close only the connection that encountered the problem. This is known as the FailingConnectionOnly purge policy and is the default behavior.

  Any other connections created from the factory, that is, those in use by other applications, and those that are in the free pool of the factory, are left alone.
- Close the connection that encountered the problem, throw away any connections in the free pool of the factory, and mark any in-use connections as stale.

  The next time the application that is using the connection tries to perform a connection-based operation, the application receives a StaleConnectionException. For this behavior, set the purge policy to Entire Pool.

Purge policy - failing connection only

Use the example described in How MDB listener ports use the connection pool. Two MDBs are deployed into the application server, each one using a different listener port. The listener ports both use the jms/CF1 connection factory.

After 600 seconds, you stop the first listener, and the connection that this listener port was using is returned to the connection pool.

If the second listener encounters a network error while polling the JMS destination, the listener port shuts down. Because the purge policy for the jms/CF1 connection factory is set to FailingConnectionOnly, the connection manager throws away only the connection that was used by the second listener. The connection in the free pool remains where it is.

If you now restart the second listener, the connection manager passes the connection from the free pool to the listener.

Purge policy - entire pool

For this situation, assume that you have three MDBs installed into your application server, each one using its own listener port. The listener ports have created connections from the jms/CF1 factory. After a period of time you stop the first listener, and its connection, c1, is put into the jms/CF1 free pool.

When the second listener detects a network error, it shuts itself down and closes `c2`. The connection manager now closes the connection in the free pool. However, the connection being used by third listener remains.

What should you set the purge policy to?

As previously stated, the default value of the purge policy for JMS connection pools is `FailingConnectionOnly`.

However, setting the purge policy to `EntirePool` is a better option. In most cases, if an application detects a network error on its connection to the JMS provider, it is likely that all open connections created from the same connection factory have the same problem.

If the purge policy is set to `FailingConnectionOnly`, the connection manager leaves all of the connections in the free pool. The next time an application tries to create a connection to the JMS provider, the connection manager returns one from the free pool if there is one available. However, when the application tries to use the connection, it encounters the same network problem as the first application.

Now, consider the same situation with the purge policy set to `EntirePool`. As soon as the first application encounters the network problem, the connection manager discards the failing connection and closes all connections in the free pool for that factory.

When a new application starts up and tries to create a connection from the factory, the connection manager tries to create a new one, as the free pool is empty. Assuming that the network problem has been resolved, the connection returned to the application is valid.

Troubleshooting JMSCC0108 messages

There are a number of steps that you can take to prevent a `JMSCC0108` message from occurring when you are using activation specifications and WebSphere Application Server listener ports that are running in Application Server Facilities (ASF) mode.

When you are using activation specifications and WebSphere Application Server listener ports that are running in ASF mode, which is the default mode of operation, it is possible that the following message might appear in the application server log file:

```
JMSCC0108: The IBM MQ classes for JMS had detected a message, ready for asynchronous delivery to an application.
When delivery was attempted, the message was no longer available.
```

Use the information in this topic to understand why this message appears, and the possible steps that you can take to prevent it from occurring.

How activation specifications and listener ports detect and process messages

An activation specification or WebSphere Application Server listener port performs the following steps when it starts up:

1. Create a connection to the queue manager that they have been set to use.
2. Open the JMS destination on that queue manager that they have been configured to monitor.
3. Browse that destination for messages.

When a message is detected, the activation specification or listener port performs the following steps:

1. Constructs an internal message reference that represents the message.
2. Gets a server session from its internal server session pool.
3. Loads the server session up with the message reference.
4. Schedules a piece of work with the application server Work Manager to run the server session and process the message.

The activation specification or listener port then goes back to monitoring the destination again, looking for another message to process.

The application server Work Manager runs the piece of work that the activation specification or listener port submitted on a new server session thread. When started, the thread completes the following actions:

- Starts either a local or global (XA) transaction, depending on whether the message-driven bean requires XA transactions or not, as specified in the message-driven bean's deployment descriptor.
- Gets the message from the destination by issuing a destructive MQGET API call.
- Runs the message-driven bean's onMessage() method.
- Completes the local or global transaction, once the onMessage() method has finished.
- Return the server session back to the server session pool.

Why the JMSCC0108 message occurs, and how to prevent it

The main activation specification or listener port thread browses messages on a destination. It then asks the Work Manager to start a new thread to destructively get the message and process it. This means that it is possible for a message to be found on a destination by the main activation specification or listener port thread, and no longer be available by the time the server session thread attempts to get it. If this happens, then the server session thread writes the following message to the application server's log file:

```
JMSCC0108: The IBM MQ classes for JMS had detected a message, ready for asynchronous delivery to an application.
When delivery was attempted, the message was no longer available.
```

There are two reasons why the message is no longer on the destination when the server session thread tries to get it:

- Reason 1: The message has been consumed by another application
- Reason 2: The message has expired

Reason 1: The message has been consumed by another application

If two or more activation specifications and/or listener ports are monitoring the same destination, then it is possible that they could detect the same message and try to process it. When this happens:

- A server session thread started by one activation specification or listener port gets the message and delivers it to a message-driven bean for processing.
- The sever session thread started by the other activation specification or listener port tries to get the message, and finds that it is no longer on the destination.

If an activation specification or listener port is connecting to a queue manager in any of the following ways, the messages that the main activation specification or listener port thread detects are marked:

- A queue manager on any platform, using IBM MQ messaging provider normal mode.
- A queue manager on any platform, using IBM MQ messaging provider normal mode with restrictions
- A queue manager running on z/OS, using IBM MQ messaging provider migration mode.

Marking a message prevents any other activation specification or listener port from seeing that message, and trying to process it.

By default, messages are marked for five seconds. After the message has been detected and marked, the five second timer starts. During these five seconds, the following steps must be carried out:

- The activation specification or listener port must get a server session from the server session pool.
- The server session must be loaded with details of the message to process.
- The work must be scheduled.
- The Work Manager must process the work request and start the server session thread.
- The server session thread needs to start either a local or global transaction.

- The server session thread needs to destructively get the message.

On a busy system, it might take longer than five seconds for these steps to be carried out. If this happens, then the mark on the message is released. This means that other activation specifications or listener ports can now see the message, and can potentially try to process it, which can result in the `JMSCC0108` message being written to the application server's log file.

In this situation, you should consider the following options:

- Increase the value of the queue manager property Message mark browse interval (MARKINT), to give the activation specification or listener port that originally detected the message more time to get it. Ideally, the property should be set to a value greater than the time taken for your message-driven beans to process messages. This means that, if the main activation specification or listener port thread blocks waiting for a server session because all of the server sessions are busy processing messages, then the message should still be marked when a server session becomes available. Note that the MARKINT property is set on a queue manager, and so is applicable to all applications that browse messages on that queue manager.
- Increase the size of the server session pool used by the activation specification or listener port. This would mean that there are more server sessions available to process messages, which should ensure that messages can be processed within the specified mark interval. One thing to note with this approach is that the activation specification or listener port will now be able to process more messages concurrently, which could impact the overall performance of the application server.

If an activation specification or listener port is connecting to a queue manager running on a platform other than z/OS, using IBM MQ messaging provider migration mode, the marking functionality is not available. This means that it is not possible to prevent two or more activation specifications and/or listener ports from detecting the same message and trying to process it. In this situation, the `JMSCC0108` message is expected.

Reason 2: The message has expired

The other reason that a `JMSCC0108` message is generated is if the message has expired in between being detected by the activation specification or listener port and being consumed by the server session. If this happens, when the server session thread tries to get the message, it finds that it is no longer there and so reports the `JMSCC0108` message.

Increasing the size of the server session pool used by the activation specification or listener port can help here. Increasing the server session pool size means that there are more server sessions available to process messages, which can potentially mean that the message is processed before it expires. It is important to note that the activation specification or listener port is now able to process more messages concurrently, which could impact the overall performance of the application server.

Problem determination for the IBM MQ resource adapter

When using the IBM MQ resource adapter, most errors cause exceptions to be thrown, and these exceptions are reported to the user in a manner that depends on the application server. The resource adapter makes extensive use of linked exceptions to report problems. Typically, the first exception in a chain is a high-level description of the error, and subsequent exceptions in the chain provide the more detailed information that is required to diagnose the problem.

For example, if the IVT program fails to obtain a connection to a IBM MQ queue manager, the following exception might be thrown:

```
javax.jms.JMSException: MQJCA0001: An exception occurred in the JMS layer.
See the linked exception for details.
```

Linked to this exception is a second exception:

```
javax.jms.JMSException: MQJMS2005: failed to create an MQQueueManager for
'localhost:ExampleQM'
```

This exception is thrown by IBM MQ classes for JMS and has a further linked exception:

```
com.ibm.mq.MQException: MQJE001: An MQException occurred: Completion Code 2,
Reason 2059
```

This final exception indicates the source of the problem. Reason code 2059 is MQRC_Q_MGR_NOT_AVAILABLE, which indicates that the queue manager specified in the definition of the ConnectionFactory object might not have been started.

If the information provided by exceptions is not sufficient to diagnose a problem, you might need to request a diagnostic trace. For information about how to enable diagnostic tracing, see Configuration of the IBM MQ resource adapter.

Configuration problems commonly occur in the following areas:
- Deploying the resource adapter
- Deploying MDBs
- Creating connections for outbound communication

Related information:

Using the IBM MQ resource adapter

Problems in deploying the resource adapter

If the resource adapter fails to deploy, check that Java EE Connector Architecture (JCA) resources are configured correctly. If IBM MQ is already installed, check that the correct versions of the JCA and IBM MQ classes for JMS are in the class path.

Failures in deploying the resource adapter are generally caused by not configuring JCA resources correctly. For example, a property of the ResourceAdapter object might not be specified correctly, or the deployment plan required by the application server might not be written correctly. Failures might also occur when the application server attempts to create objects from the definitions of JCA resources and bind the objects into the Java Naming Directory Interface (JNDI) namespace, but certain properties are not specified correctly or the format of a resource definition is incorrect.

The resource adapter can also fail to deploy because it loaded incorrect versions of JCA or IBM MQ classes for JMS classes from JAR files in the class path. This type of failure can commonly occur on a system where IBM MQ is already installed. On such a system, the application server might find existing copies of the IBM MQ classes for JMS JAR files and load classes from them in preference to the classes supplied in the IBM MQ resource adapter RAR file.

What is installed for IBM MQ classes for JMS

Configuring the application server to use the latest resource adapter maintenance level

Problems in deploying MDBs

Failures when the application server attempts to start message delivery to an MDB might be caused by an error in the definition of the associated ActivationSpec object, or by missing resources.

Failures might occur when the application server attempts to start message delivery to an MDB. This type of failure is typically caused by an error in the definition of the associated ActivationSpec object, or because the resources referenced in the definition are not available. For example, the queue manager might not be running, or a specified queue might not exist.

An ActivationSpec object attempts to validate its properties when the MDB is deployed. Deployment then fails if the ActivationSpec object has any properties that are mutually exclusive or does not have all the required properties. However, not all problems associated with the properties of the ActivationSpec object can be detected at this time.

Failures to start message delivery are reported to the user in a manner that depends on the application server. Typically, these failures are reported in the logs and diagnostic trace of the application server. If enabled, the diagnostic trace of the IBM MQ resource adapter also records these failures.

Problems in creating connections for outbound communication

A failure in outbound communication can occur if a ConnectionFactory object cannot be found, or if the ConnectionFactory object is found but a connection cannot be created. There are various reasons for either of these problems.

Failures in outbound communication typically occur when an application attempts to look up and use a ConnectionFactory object in a JNDI namespace. A JNDI exception is thrown if the ConnectionFactory object cannot be found in the namespace. A ConnectionFactory object might not be found for the following reasons:

- The application specified an incorrect name for the ConnectionFactory object.
- The application server was not able to create the ConnectionFactory object and bind it into the namespace. In this case, the startup logs of the application server typically contain information about the failure.

If the application successfully retrieves the ConnectionFactory object from the JNDI namespace, an exception might still be thrown when the application calls the ConnectionFactory.createConnection() method. An exception in this context indicates that it is not possible to create a connection to an IBM MQ queue manager. Here are some common reasons why an exception might be thrown:

- The queue manager is not available, or cannot be found using the properties of the ConnectionFactory object. For example, the queue manager is not running, or the specified host name, IP address, or port number of the queue manager is incorrect.
- The user is not authorized to connect to the queue manager. For a client connection, if the createConnection() call does not specify a user name, and the application server supplies no user identity information, the JVM process ID is passed to the queue manager as the user name. For the connection to succeed, this process ID must be a valid user name in the system on which the queue manager is running.
- The ConnectionFactory object has a property called ccdtURL and a property called channel. These properties are mutually exclusive.
- On an SSL connection, the SSL-related properties, or the SSL-related attributes in the server connection channel definition, have not been specified correctly.
- The sslFipsRequired property has different values for different JCA resources. For more information about this limitation, see Limitations of the IBM MQ resource adapter.

Using IBM MQ connection property override

V 8.0.0.4

Connection property override allows you to change the details that are used by a client application to connect to a queue manager, without modifying the source code.

About this task

Sometimes, it is not possible to modify the source code for an application, for example, if the application is a legacy application and the source code is no longer available.

In this situation, if an application needs to specify different properties when it is connecting to a queue manager, or is required to connect to a different queue manager, then you can use the connection override functionality to specify the new connection details or queue manager name.

The connection property override is supported for two clients:
- IBM MQ classes for JMS
- IBM MQ classes for Java

You can override the properties that you want to change by defining them in a configuration file that is then read by the IBM MQ classes for JMS or IBM MQ classes for Java at startup.

When the connection override functionality is in use, all applications that are running inside the same Java runtime environment pick up and use the new property values. If multiple applications that are using either the IBM MQ classes for JMS or the IBM MQ classes for Java are running inside the same Java runtime environment, it is not possible to just override properties for individual applications.

Important: This functionality is only supported for situations where it is not possible to modify the source code for an application. It must not be used for applications where the source code is available and can be updated.

Using IBM MQ classes for JMS

Using IBM MQ classes for Java

Using connection property override in IBM MQ classes for JMS

V 8.0.0.4

If a connection factory is created programmatically, and it is not possible to modify the source code for the application that creates it, then the connection override functionality can be used to change the properties that the connection factory uses when a connection is created. However, the use of the connection override functionality with connection factories defined in JNDI is not supported.

About this task

In the IBM MQ classes for JMS, details about how to connect to a queue manager are stored in a connection factory. Connection factories can either be defined administratively and stored in a JNDI repository, or created programmatically by an application by using Java API calls.

If an application creates a connection factory programmatically, and it is not possible to modify the source code for that application, the connection override functionality allows you to override the connection factory properties in the short term. In the long term, though, you must put plans in place to allow the connection factory used by the application to be modified without using the connection override functionality.

If the connection factory that is created programmatically by an application is defined to use a Client Channel Definition Table (CCDT), then the information in the CCDT is used in preference to the overridden properties. If the connection details that the application uses need to be changed, then a new version of the CCDT must be created and made available to the application.

The use of the connection override functionality with connection factories defined in JNDI is not supported. If an application uses a connection factory that is defined in JNDI, and the properties of that connection factory need to be changed, then the definition of the connection factory must be updated in JNDI. Although the connection override functionality is applied to these connection factories (and the overridden properties take precedence over the properties in the connection factory definition that is looked up in JNDI), this use of the connection override functionality is not supported.

Important: The connection override functionality affects all of the applications that are running inside of a Java runtime environment, and applies to all of the connection factories used by those applications. It is not possible to just override properties for individual connection factories or applications.

When an application uses a connection factory to create a connection to a queue manager, the IBM MQ classes for JMS look at the properties that have been overridden and use those property values when creating the connection, rather than the values for the same properties in the connection factory.

For example, suppose a connection factory has been defined with the PORT property set to 1414. If the connection override functionality has been used to set the PORT property to 1420, then when the connection factory is used to create a connection, the IBM MQ classes for JMS use a value of 1420 for the PORT property, rather than 1414.

To modify any of the connection properties that are used when creating a JMS connection from a connection factory, the following steps need to be carried out:
1. Add the properties to be overridden to an IBM MQ classes for JMS configuration file.
2. Enable the connection override functionality.
3. Start the application, specifying the configuration file.

Procedure

1. Add the properties to be overridden to an IBM MQ classes for JMS configuration file.
   a. Create a file containing the properties and values that need to be overridden in the standard Java properties format. For details about how you create a properties file, see The IBM MQ classes for JMS configuration file.
   b. To override a property, add an entry to the properties file. Any IBM MQ classes for JMS connection factory property can be overridden. Add each required entry in the following format:
   ```
   jmscf.<property name>=<value>
   ```

where *<property name>* is the JMS administration property name or XMSC constant for the property that needs to be overridden. For a list of connection factory properties, see Properties of IBM MQ classes for JMS objects.

For example, to set the name of the channel that an application should use to connect to a queue manager, you can add the following entry to the properties file:

```
jmscf.channel=MY.NEW.SVRCONN
```

2. Enable the connection override functionality. To enable connection override, set the **com.ibm.msg.client.jms.overrideConnectionFactory** property to be true so that the properties that are specified in the properties file are used to override the values that are specified in the application. You can either set the extra property as another property in the configuration file itself, or pass the property as a Java system property by using:

```
-Dcom.ibm.msg.client.jms.overrideConnectionFactory=true
```

3. Start the application, specifying the configuration file. Pass the properties file that you created to the application at run time by setting the Java system property:

```
-Dcom.ibm.msg.client.config.location
```

Note that the location of the configuration file must be specified as a URI, for example:

```
-Dcom.ibm.msg.client.config.location=file:///jms/jms.config
```

Results

When the connection override functionality is enabled, the IBM MQ classes for JMS write an entry to the jms log whenever a connection is made. The information in the log shows the connection factory properties that were overridden when the connection was created, as shown in the following example entry:

```
Overriding ConnectionFactory properties:
        Overriding property channel:
             Original value = MY.OLD.SVRCONN
             New value      = MY.NEW.SVRCONN
```

Related information:

Creating and configuring connection factories and destinations in an IBM MQ classes for JMS application

Configuring connection factories and destinations in a JNDI namespace

Using connection property override in IBM MQ classes for Java

V 8.0.0.4

In the IBM MQ classes for Java, connection details are set as properties using a combination of different values. The connection override functionality can be used to override the connection details that an application uses if it is not possible to modify the source code for the application.

About this task

The different values that are used to set the connection properties are a combination of:

- Assigning values to static fields on the **MQEnvironment** class.

- Setting property values in the properties `Hashtable` in the **`MQEnvironment`** class.
- Setting property values in a `Hashtable` passed into an **`MQQueueManager`** constructor.

These properties are then used when an application constructs an MQQueueManager object, which represents a connection to a queue manager.

If it is not possible to modify the source code for an application that uses the IBM MQ classes for Java to specify different properties that must be used when creating a connection to a queue manager, the connection override functionality allows you to override the connection details in the short term. In the long term, though, you must put plans in place to allow the connection details used by the application to be modified without using the connection override functionality.

When an application creates an MQQueueManager, the IBM MQ classes for Java look at the properties that have been overridden and use those property values when creating a connection to the queue manager, rather than the values in any of the following locations:
- The static fields on the MQEnvironment class
- The properties Hashtable stored in the MQEnvironment class
- The properties Hashtable that is passed into an MQQueueManager constructor

For example, suppose an application creates an MQQueueManager, passing in a properties Hashtable that has the CHANNEL property set to MY.OLD.CHANNEL. If the connection override functionality has been used to set the CHANNEL property to MY.NEW.CHANNEL, then when the MQQueueManager is constructed, the IBM MQ classes for Java attempt to create a connection to the queue manager by using the channel MY.NEW.CHANNEL rather than MY.OLD.CHANNEL.

Note: If an MQQueueManager is configured to use a Client Channel Definition Table (CCDT), then the information in the CCDT is used in preference to the overridden properties. If the connection details that the application creating the MQQueueManager uses need to be changed, then a new version of the CCDT must be created and made available to the application.

To modify any of the connection properties that are used when creating an MQQueueManager, the following steps need to be carried out:
1. Create a properties file called `mqclassesforjava.config`.
2. Enable the connection property override functionality by setting the **`OverrideConnectionDetails`** property to true.
3. Start the application, specifying the configuration file as part of the Java invocation.

Procedure

1. Create a properties file called `mqclassesforjava.config` containing the properties and values that need to be overridden. It is possible to override 13 properties that are used by the IBM MQ classes for Java when connecting to a queue manager as part of the MQQueueManager constructor. The names of these properties, and the keys that must be specified when you are overriding them, are shown in the following table:

Table 173. Properties that can be overridden

Property	Property key
CCSID	$CCSID_PROPERTY
Channel	$CHANNEL_PROPERTY
Connect options	$CONNECT_OPTIONS_PROPERTY
Hostname	$HOST_NAME_PROPERTY
SSL key reset	$SSL_RESET_COUNT_PROPERTY
Local address	$LOCAL_ADDRESS_PROPERTY
Queue manager name	qmgr
Password	$PASSWORD_PROPERTY
Port	$PORT_PROPERTY
Cipher suite	$SSL_CIPHER_SUITE_PROPERTY
FIPS required	$SSL_FIPS_REQUIRED_PROPERTY
SSL peer name	$SSL_PEER_NAME_PROPERTY
User ID	$USER_ID_PROPERTY

Note: All of the property keys start with the $ character, except for the queue manager name. The reason for this is because the queue manager name is passed in to the MQQueueManager constructor as an argument, rather than being set as either a static field on the MQEnvironment class, or a property in a Hashtable, and so internally this property needs to be treated slightly differently from the other properties.

To override a property, add an entry in the following format to the properties file:

```
mqj.<property key>=<value>
```

For example, to set the name of the channel to be used when creating MQQueueManager objects, you can add the following entry to the properties file:

```
mqj.$CHANNEL_PROPERTY=MY.NEW.CHANNEL
```

To change the name of the queue manager that an MQQueueManager object connects to, you can add the following entry to the properties file:

```
mqj.qmgr=MY.OTHER.QMGR
```

2. Enable the connection override functionality by setting the **`com.ibm.mq.overrideConnectionDetails`** property to be true. Setting the property **`com.ibm.mq.overrideConnectionDetails`** to be true means that the properties that are specified in the properties file are used to override the values specified in the application. You can either set the extra property as another property in the configuration file itself, or pass the property as a system property, by using:

```
-Dcom.ibm.mq.overrideConnectionDetails=true
```

3. Start the application. Pass the properties file you created to the client application at run time by setting the Java system property:

```
-Dcom.ibm.msg.client.config.location
```

Note that the location of the configuration file must be specified as a URI, for example:

```
-Dcom.ibm.msg.client.config.location=file:///classesforjava/mqclassesforjava.config
```

Overriding connection properties: example with IBM MQ classes for JMS

V 8.0.0.4

This example shows how to override properties when you are using the IBM MQ classes for JMS.

About this task

The following code example shows how an application creates a ConnectionFactory programmatically:

```
JmsSampleApp.java
...
JmsFactoryFactory jmsff;
JmsConnectionFactory jmsConnFact;

jmsff = JmsFactoryFactory.getInstance(JmsConstants.WMQ_PROVIDER);
jmsConnFact = jmsff.createConnectionFactory();

jmsConnFact.setStringProperty(WMQConstants.WMQ_HOST_NAME,"127.0.0.1");
jmsConnFact.setIntProperty(WMQConstants.WMQ_PORT, 1414);
jmsConnFact.setStringProperty(WMQConstants.WMQ_QUEUE_MANAGER,"QM_V80");
jmsConnFact.setStringProperty(WMQConstants.WMQ_CHANNEL,"MY.CHANNEL");
jmsConnFact.setIntProperty(WMQConstants.WMQ_CONNECTION_MODE,
                           WMQConstants.WMQ_CM_CLIENT);
...
```

The ConnectionFactory is configured to connect to the queue manager QM_V80 using the CLIENT transport and channel MY.CHANNEL.

You can override the connection details by using a properties file, and force the application to connect to a different channel, by using the following procedure.

Procedure

1. Create an IBM MQ classes for JMS configuration file that is called `jms.config` in the /*<userHome>* directory (where *<userHome>* is your home directory). Create this file with the following contents:

```
jmscf.CHANNEL=MY.TLS.CHANNEL
jmscf.SSLCIPHERSUITE=TLS_RSA_WITH_AES_128_CBC_SHA256
```

2. Run the application, passing the following Java system properties into the Java runtime environment that the application is running in:

```
-Dcom.ibm.msg.client.config.location=file:///<userHome>/jms.config
-Dcom.ibm.msg.client.jms.overrideConnectionFactory=true
```

Results

Carrying out this procedure overrides the ConnectionFactory that was created programmatically by the application, so that when the application creates a connection, it tries to connect by using the channel MY.TLS.CHANNEL and the cipher suite TLS_RSA_WITH_AES_128_CBC_SHA256.

Resolving problems with IBM MQ MQI clients

This collection of topics contains information about techniques for solving problems in IBM MQ MQI client applications.

An application running in the IBM MQ MQI client environment receives MQRC_* reason codes in the same way as IBM MQ server applications. However, there are additional reason codes for error conditions associated with IBM MQ MQI clients. For example:

- Remote machine not responding
- Communications line error
- Invalid machine address

The most common time for errors to occur is when an application issues an MQCONN or MQCONNX and receives the response MQRC_Q_MQR_NOT_AVAILABLE. Look in the client error log for a message explaining the failure. There might also be errors logged at the server, depending on the nature of the failure. Also, check that the application on the IBM MQ MQI client is linked with the correct library file.

IBM MQ MQI client fails to make a connection

An MQCONN or MQCONNX might fail because there is no listener program running on the server, or during protocol checking.

When the IBM MQ MQI client issues an MQCONN or MQCONNX call to a server, socket and port information is exchanged between the IBM MQ MQI client and the server. For any exchange of information to take place, there must be a program on the server with the role to 'listen' on the communications line for any activity. If there is no program doing this, or there is one but it is not configured correctly, the MQCONN or MQCONNX call fails, and the relevant reason code is returned to the IBM MQ MQI client application.

If the connection is successful, IBM MQ protocol messages are exchanged and further checking takes place. During the IBM MQ protocol checking phase, some aspects are negotiated while others cause the connection to fail. It is not until all these checks are successful that the MQCONN or MQCONNX call succeeds.

For information about the MQRC_* reason codes, see API reason codes.

Stopping IBM MQ MQI clients

Even though an IBM MQ MQI client has stopped, it is still possible for the associated process at the server to be holding its queues open. The queues are not closed until the communications layer detects that the partner has gone.

If sharing conversations is enabled, the server channel is always in the correct state for the communications layer to detect that the partner has gone.

Error messages with IBM MQ MQI clients

When an error occurs with an IBM MQ MQI client system, error messages are put into the IBM MQ system error files.

- On UNIX and Linux systems, these files are found in the `/var/mqm/errors` directory
- On Windows, these files are found in the errors subdirectory of the IBM MQ MQI client installation. Usually this directory is `C:\Program Files\IBM\WebSphere MQ\errors`.
- On IBM i, these files are found in the `/QIBM/UserData/mqm/errors` directory

Certain client errors can also be recorded in the IBM MQ error files associated with the server to which the client was connected.

Multicast troubleshooting

The following hints and tips are in no significant order, and might be added to when new versions of the documentation are released. They are subjects that, if relevant to the work that you are doing, might save you time.

Testing multicast applications on a non-multicast network

Use this information to learn how to test IBM MQ Multicast applications locally instead of over a multicast network.

When developing or testing multicast applications you might not yet have a multicast enabled network. To run the application locally, you must edit the `mqclient.ini` file as shown in the following example:

Edit the `Interface` parameter in the `Multicast` stanza of the *`MQ_DATA_PATH`* `/mqclient.ini`:

```
Multicast:
Interface      = 127.0.0.1
```

where *`MQ_DATA_PATH`* is the location of the IBM MQ data directory (`/var/mqm/mqclient.ini`).

The multicast transmissions now only use the local loopback adapter.

Setting the appropriate network for multicast traffic

When developing or testing multicast applications, after testing them locally, you might want to test them over a multicast enabled network. If the application only transmits locally, you might have to edit the `MQClient.ini` file as shown later in this section. If the machine setup is using multiple network adapters, or a virtual private network (VPN) for example, the **`Interface`** parameter in the `MQClient.ini` file must be set to the address of the network adapter you want to use.

If the `Multicast` stanza exists in the `MQClient.ini` file, edit the **`Interface`** parameter as shown in the following example:

Change:

```
Multicast:
Interface       = 127.0.0.1
```

To:

```
Multicast:
Interface       = IPAddress
```

where *IPAddress* is the IP address of the interface on which multicast traffic flows.

If there is no `Multicast` stanza in the `MQClient.ini` file, add the following example:

```
Multicast:
Interface       = IPAddress
```

where *IPAddress* is the IP address of the interface on which multicast traffic flows.

The multicast applications now run over the multicast network.

Multicast topic string is too long

If your IBM MQ Multicast topic string is rejected with reason code MQRC_TOPIC_STRING_ERROR, it might be because the string is too long.

WebSphereMQ Multicast has a 255 character limit for topic strings. This limitation means that care must be taken with the names of nodes and leaf-nodes within the tree; if the names of nodes and leaf-nodes are too long, the topic string might exceed 255 characters and return the “2425 (0979) (RC2425): MQRC_TOPIC_STRING_ERROR” on page 1482 reason code. It is recommended to make topic strings as short as possible because longer topic strings might have a detrimental effect on performance.

Multicast topic topology issues

Use these examples to understand why certain IBM MQ Multicast topic topologies are not recommended.

As was mentioned in IBM MQ Multicast topic topology, IBM MQ Multicast support requires that each subtree has its own multicast group and data stream within the total hierarchy. Do not use a different multicast group address for a subtree and its parent.

The *classful network* IP addressing scheme has designated address space for multicast address. The full multicast range of IP address is `224.0.0.0` to `239.255.255.255`, but some of these addresses are reserved. For a list of reserved address either contact your system administrator or see http://www.iana.org/assignments/multicast-addresses for more information. It is recommended that you use the locally scoped multicast address in the range of `239.0.0.0` to `239.255.255.255`.

Recommended multicast topic topology

This example is the same as the one from IBM MQ Multicast topic topology, and shows 2 possible multicast data streams. Although it is a simple representation, it demonstrates the kind of situation that IBM MQ Multicast was designed for, and is shown here to contrast the second example:

```
DEF COMMINFO(MC1) GRPADDR(227.20.133.1)

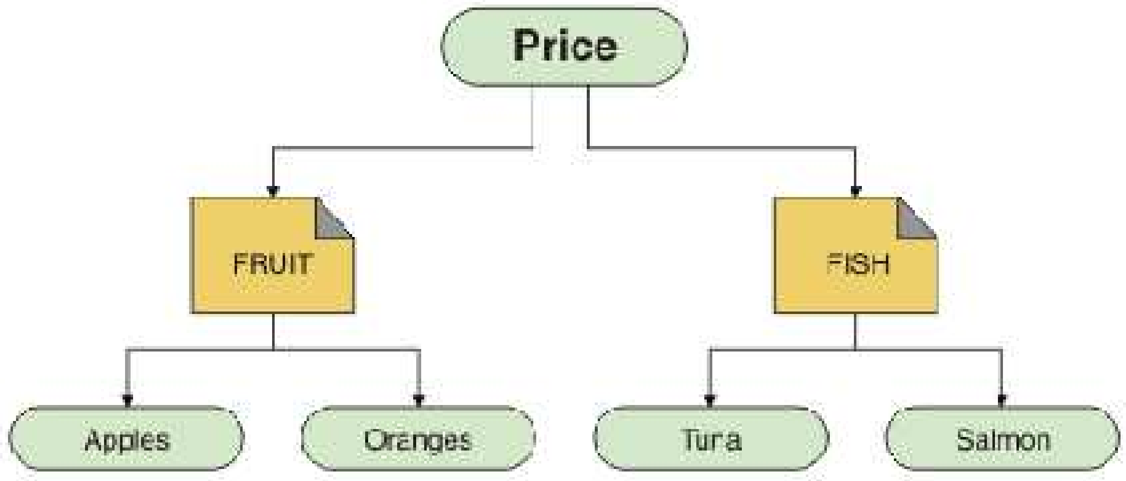
DEF COMMINFO(MC2) GRPADDR(227.20.133.2)
```

where *227.20.133.1* and *227.20.133.2* are valid multicast addresses.

These topic definitions are used to create a topic tree as shown in the following diagram:

```
DEFINE TOPIC(FRUIT) TOPICSTRING('Price/FRUIT') MCAST(ENABLED) COMMINFO(MC1)

DEFINE TOPIC(FISH) TOPICSTRING('Price/FISH') MCAST(ENABLED) COMMINFO(MC2)
```



Each multicast communication information (COMMINFO) object represents a different stream of data because their group addresses are different. In this example, the topic `FRUIT` is defined to use COMMINFO object `MC1`, and the topic `FISH` is defined to use COMMINFO object `MC2` .

IBM MQ Multicast has a 255 character limit for topic strings. This limitation means that care must be taken with the names of nodes and leaf-nodes within the tree; if the names of nodes and leaf-nodes are too long, the topic string might exceed 255 characters and return the `MQRC_TOPIC_STRING_ERROR` reason code.

Non-recommended multicast topic topology

This example extends the previous example by adding another topic object called `ORANGES` which is defined to use another COMMINFO object definition (`MC3`):

```
DEF COMMINFO(MC1) GRPADDR(227.20.133.1
)

DEF COMMINFO(MC2) GRPADDR(227.20.133.2)

DEF COMMINFO(MC3) GRPADDR(227.20.133.3)
```

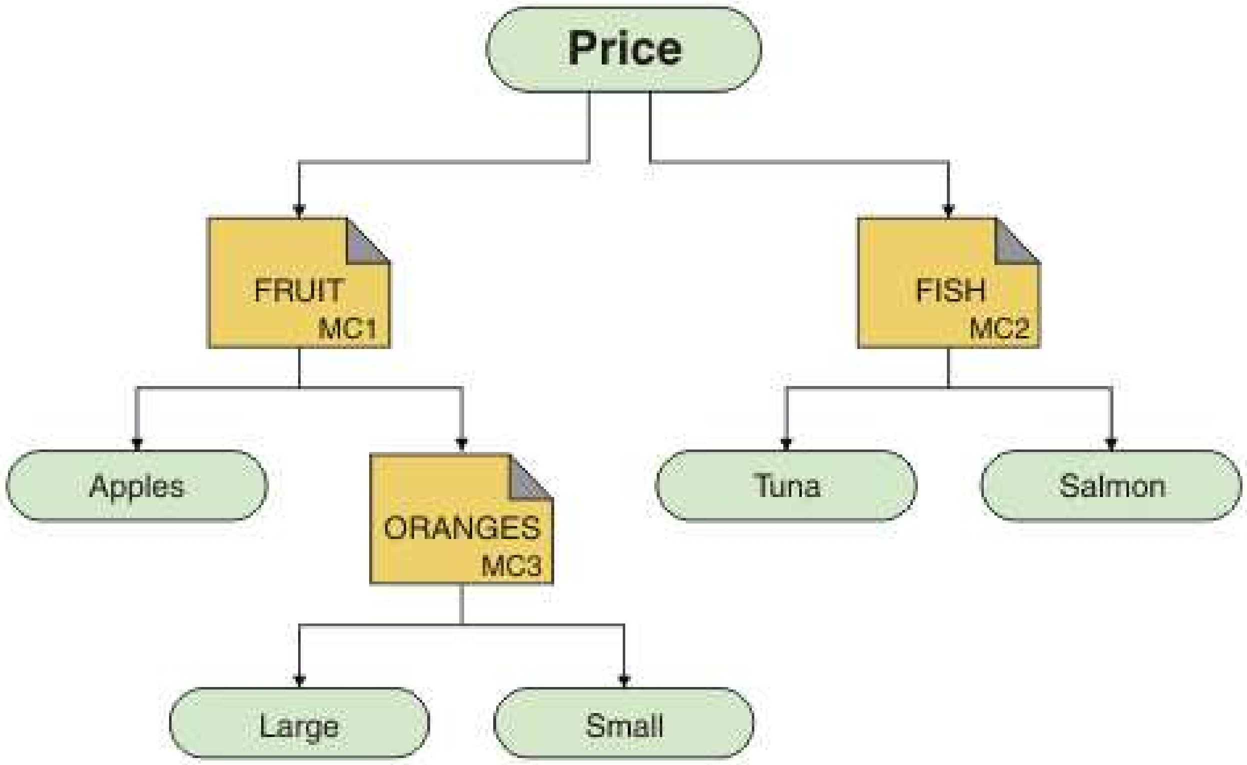
where *227.20.133.1*, *227.20.133.2*, and *227.20.133.3* are valid multicast addresses.

These topic definitions are used to create a topic tree as shown in the following diagram:

```
DEFINE TOPIC(FRUIT) TOPICSTRING('Price/FRUIT') MCAST(ENABLED) COMMINFO(MC1)
```

```
DEFINE TOPIC(FISH) TOPICSTRING('Price/FISH') MCAST(ENABLED) COMMINFO(MC2)
```

```
DEFINE TOPIC(ORANGES) TOPICSTRING('Price/FRUIT/ORANGES') MCAST(ENABLED) COMMINFO(MC3)
```



While this kind of multicast topology is possible to create, it is not recommended because applications might not receive the data that they were expecting.

An application subscribing on `'Price/FRUIT/#'` receives multicast transmission on the `COMMINFO MC1` group address. The application expects to receive publications on all topics at or below that point in the topic tree.

However, the messages created by an application publishing on `'Price/FRUIT/ORANGES/Small'` are not received by the subscriber because the messages are sent on the group address of `COMMINFO MC3`.

Queue manager clusters troubleshooting

Use the checklist given here, and the advice given in the subtopics, to help you to detect and deal with problems when you use queue manager clusters.

Before you begin

If your problems relate to publish/subscribe messaging using clusters, rather than to clustering in general, see "Routing for publish/subscribe clusters: Notes on behavior" on page 1780.

Procedure

- Check that your cluster channels are all paired.

  Each cluster sender channel connects to a cluster receiver channel of the same name. If there is no local cluster receiver channel with the same name as the cluster sender channel on the remote queue manager, then it won't work.
- Check that your channels are running. No channels should be in `RETRYING` state permanently.

  Show which channels are running using the following command:

  ```
  runmqsc display chstatus(*)
  ```

  If you have channels in `RETRYING` state, there might be an error in the channel definition, or the remote queue manager might not be running. While channels are in this state, messages are likely to build up on transmit queues. If channels to full repositories are in this state, then the definitions of cluster objects (for example queues and queue managers) become out-of-date and inconsistent across the cluster.
- Check that no channels are in `STOPPED` state.

  Channels go into `STOPPED` state when you stop them manually. Channels that are stopped can be restarted using the following command:

  ```
  runmqsc start channel(xyz)
  ```

  A clustered queue manager auto-defines cluster channels to other queue managers in a cluster, as required. These auto-defined cluster channels start automatically as needed by the queue manager, unless they were previously stopped manually. If an auto-defined cluster channel is stopped manually , the queue manager remembers that it was manually stopped and does not start it automatically in the future. If you need to stop a channel, either remember to restart it again at a convenient time, or else issue the following command:

  ```
  stop channel(xyz) status(inactive)
  ```

  The `status(inactive)` option allows the queue manager to restart the channel at a later date if it needs to do so.
- Check that all queue managers in the cluster are aware of all the full repositories.

  You can do this using the following command:

  ```
  runmqsc display clusqmgr(*) qmtype
  ```

  Partial repositories might not be aware of all other partial repositories. All full repositories should be aware of all queue managers in the cluster. If cluster queue managers are missing, this might mean that certain channels are not running correctly.
- Check that every queue manager (full repositories and partial repositories) in the cluster has a manually defined cluster receiver channel running and is defined in the correct cluster.

  To see which other queue managers are talking to a cluster receiver channel, use the following command:

  ```
  runmqsc display channel(*) rqmname
  ```

Check that each manually defined cluster receiver has a **conname** parameter defined to be `ipaddress(port)`. Without a correct connection name, the other queue manager does not know the connection details to use when connecting back.

- Check that every partial repository has a manually defined cluster sender channel running to a full repository, and defined in the correct cluster.

  The cluster sender channel name must match the cluster receiver channel name on the other queue manager.
- Check that every full repository has a manually defined cluster sender channel running to every other full repository, and defined in the correct cluster.

  The cluster sender channel name must match the cluster receiver channel name on the other queue manager. Each full repository does not keep a record of what other full repositories are in the cluster. It assumes that any queue manager to which it has a manually defined cluster sender channel is a full repository.
- Check the dead letter queue.

  Messages that the queue manager cannot deliver are sent to the dead letter queue.
- Check that, for each partial repository queue manager, you have defined a single cluster-sender channel to one of the full repository queue managers. This channel acts as a "bootstrap" channel through which the partial repository queue manager initially joins the cluster.
- Check that the intended full repository queue managers are actual full repositories and are in the correct cluster.

  You can do this using the following command:

  ```
  runmqsc display qmgr repos reposnl
  ```
- Check that messages are not building up on transmit queues or system queues.

  You can check transmit queues using the following command:

  ```
  runmqsc display ql(*) curdepth where (usage eq xmitq)
  ```

  You can check system queues using the following command:

  ```
  display ql(system*) curdepth
  ```

Related information:

Configuring a queue manager cluster

A cluster-sender channel is continually trying to start

Check the queue manager and listener are running, and the cluster-sender and cluster-receiver channel definitions are correct.

Symptom

```
1 : display chs(*)
AMQ8417: Display Channel Status details.
CHANNEL(DEMO.QM2)                       XMITQ(SYSTEM.CLUSTER.TRANSMIT.QUEUE)
CONNAME(computer.ibm.com(1414))
CURRENT                                 CHLTYPE(CLUSSDR)
STATUS(RETRYING)
```

Cause

1. The remote queue manager is not available.
2. An incorrect parameter is defined either for the local manual cluster-sender channel or the remote cluster-receiver channel.

Solution

Check whether the problem is the availability of the remote queue manager.

1. Are there any error messages?
2. Is the queue manager active?
3. Is the listener running?
4. Is the cluster-sender channel able to start?

If the remote queue manager is available, is there a problem with a channel definition? Check the definition type of the cluster queue manager to see if the channel is continually trying to start; for example:

```
1 : dis clusqmgr(*) deftype where(channel eq DEMO.QM2)
AMQ8441: Display Cluster Queue Manager details.
CLUSQMGR(QM2) CHANNEL(DEMO.QM2) CLUSTER(DEMO)
DEFTYPE(CLUSSDRA)
```

If the definition type is `CLUSSDR` the channel is using the local manual cluster-sender definition. Alter any incorrect parameters in the local manual cluster-sender definition and restart the channel.

If the definition type is either `CLUSSDRA` or `CLUSSDRB` the channel is using an auto-defined cluster-sender channel. The auto-defined cluster-sender channel is based on the definition of a remote cluster receiver channel. Alter any incorrect parameters in the remote cluster receiver definition. For example, the `conname` parameter might be incorrect:

```
1 : alter chl(demo.qm2) chltype(clusrcvr) conname('newhost(1414)')
AMQ8016: WebSphere MQ channel changed.
```

Changes to the remote cluster-receiver definition are propagated out to any cluster queue managers that are interested. The corresponding auto-defined channels are updated accordingly. You can check that the updates have been propagated correctly by checking the changed parameter. For example:

```
1 : dis clusqmgr(qm2) conname
AMQ8441: Display Cluster Queue Manager details.
CLUSQMGR(QM2) CHANNEL(DEMO.QM2) CLUSTER(DEMO) CONNAME(newhost(1414))
```

If the auto-defined definition is now correct, restart the channel.

DISPLAY CLUSQMGR shows CLUSQMGR names starting SYSTEM.TEMP.

The queue manager has not received any information from the full repository queue manager that the manually defined CLUSSDR channel points to. Check that the cluster channels are defined correctly.

Symptom

```
1 : display clusqmgr(*)
AMQ8441: Display Cluster Queue Manager details.
CLUSQMGR(QM1)             CLUSTER(DEMO)
CHANNEL(DEMO.QM1)
AMQ8441: Display Cluster Queue Manager details.
CLUSQMGR(SYSTEM.TEMPUUID.computer.hursley.ibm.com(1414))
CLUSTER(DEMO)             CHANNEL(DEMO.QM2)
```

Cause

The queue manager has not received any information from the full repository queue manager that the manually defined CLUSSDR channel points to. The manually defined `CLUSSDR` channel must be in running state.

Solution

Check that the `CLUSRCVR` definition is also correct, especially its `CONNAME` and `CLUSTER` parameters. Alter the channel definition, if the definition is wrong.

You also need to give the correct authority to the SYSTEM.CLUSTER.TRANSMIT.QUEUE by issuing the following command:

```
setmqaut -m <QMGR Name> -n SYSTEM.CLUSTER.TRANSMIT.QUEUE -t q -g mqm +all
```

It might take some time for the remote queue managers to attempt a new restart, and start their channels with the corrected definition.

Return code= 2035 `MQRC_NOT_AUTHORIZED`

The RC2035 reason code is displayed for various reasons including an error on opening a queue or a channel, an error received when you attempt to use a user ID that has administrator authority, an error when using an IBM MQ JMS application, and opening a queue on a cluster. MQS_REPORT_NOAUTH and MQSAUTHERRORS can be used to further diagnose RC2035.

Specific problems

See "Specific problems generating RC2035" on page 1335 for information on:
- JMSWMQ2013 invalid security authentication
- MQRC_NOT_AUTHORIZED on a queue or channel
- MQRC_NOT_AUTHORIZED (AMQ4036 on a client) as an administrator
- MQS_REPORT_NOAUTH and MQSAUTHERRORS environment variables

Opening a queue in a cluster

The solution for this error depends on whether the queue is on z/OS or not. On z/OS use your security manager. On other platforms create a local alias to the cluster queue, or authorize all users to have access to the transmission queue.

Symptom

Applications receive a return code of 2035 MQRC_NOT_AUTHORIZED when trying to open a queue in a cluster.

Cause

Your application receives the return code of MQRC_NOT_AUTHORIZED when trying to open a queue in a cluster. The authorization for that queue is correct. It is likely that the application is not authorized to put to the cluster transmission queue.

Solution

The solution depends on whether the queue is on z/OS or not. See the related information topic.

Return code= 2085 MQRC_UNKNOWN_OBJECT_NAME when trying to open a queue in the cluster

Symptom

Applications receive a return code of 2085 MQRC_UNKNOWN_OBJECT_NAME when trying to open a queue in the cluster.

Cause

The queue manager where the object exists or this queue manager might not have successfully entered the cluster.

Solution

Make sure that they can each display all the full repositories in the cluster. Also make sure that the CLUSSDR channels to the full repositories are trying to start.

If the queue is in the cluster, check that you have used appropriate open options. You cannot get messages from a remote cluster queue, so make sure that the open options are for output only.

```
1 : display clusqmgr(*) qmtype status
AMQ8441: Display Cluster Queue Manager details.
CLUSQMGR(QM1)         CLUSTER(DEMO)
CHANNEL(DEMO.QM1)     QMTYPE(NORMAL)
AMQ8441: Display Cluster Queue Manager details.
CLUSQMGR(QM2)         CLUSTER(DEMO)
CHANNEL(DEMO.QM2)     QMTYPE(REPOS)
STATUS(RUNNING)
AMQ8441: Display Cluster Queue Manager details.
CLUSQMGR(QM3)         CLUSTER(DEMO)
CHANNEL(DEMO.QM3)     QMTYPE(REPOS)
STATUS(RUNNING)
```

Return code= 2189 `MQRC_CLUSTER_RESOLUTION_ERROR` when trying to open a queue in the cluster

Make sure that the CLUSSDR channels to the full repositories are not continually trying to start.

Symptom

Applications receive a return code of 2189 MQRC_CLUSTER_RESOLUTION_ERROR when trying to open a queue in the cluster.

Cause

The queue is being opened for the first time and the queue manager cannot contact any full repositories.

Solution

Make sure that the CLUSSDR channels to the full repositories are not continually trying to start.

```
1 : display clusqmgr(*) qmtype status
AMQ8441: Display Cluster Queue Manager details.
CLUSQMGR(QM1)         CLUSTER(DEMO)
CHANNEL(DEMO.QM1)     QMTYPE(NORMAL)
AMQ8441: Display Cluster Queue Manager details.
CLUSQMGR(QM2)         CLUSTER(DEMO)
CHANNEL(DEMO.QM2)     QMTYPE(REPOS)
STATUS(RUNNING)
AMQ8441: Display Cluster Queue Manager details.
CLUSQMGR(QM3)         CLUSTER(DEMO)
CHANNEL(DEMO.QM3)     QMTYPE(REPOS)
STATUS(RUNNING)
```

Return code=2082 MQRC_UNKNOWN_ALIAS_BASE_Q opening a queue in the cluster

Applications get rc=2082 MQRC_UNKNOWN_ALIAS_BASE_Q when trying to open a queue in the cluster.

Problem

An MQOPEN or MQPUT1 call was issued specifying an alias queue as the target, but the *BaseQName* in the alias queue attributes is not recognized as a queue name.

This reason code can also occur when *BaseQName* is the name of a cluster queue that cannot be resolved successfully.

MQRC_UNKNOWN_ALIAS_BASE_Q might indicate that the application is specifying the **ObjectQmgrName** of the queue manager that it is connecting to, and the queue manager that is hosting the alias queue. This means that the queue manager looks for the alias target queue on the specified queue manager and fails because the alias target queue is not on the local queue manager.

Solution

Leave the **ObjectQmgrName** parameter blank, so that the clustering decides which queue manager to route to.

Messages are not arriving on the destination queues

Make sure that the corresponding cluster transmission queue is empty and also that the channel to the destination queue manager is running.

Symptom

Messages are not arriving on the destination queues.

Cause

The messages might be stuck at their origin queue manager.

Solution

1. Identify the transmission queue that is sending messages to the destination and the status of the channel.

```
1 : dis clusqmgr(QM1) CHANNEL(*) STATUS DEFTYPE QMTYPE XMITQ
AMQ8441: Display Cluster Queue Manager details.
CLUSQMGR(QM1)     CLUSTER(DEMO)
CHANNEL(DEMO.QM1) DEFTYPE(CLUSSDRA)
QMTYPE(NORMAL)    STATUS(RUNNING)
XMITQ(SYSTEM.CLUSTER.TRANSMIT.DEMO.QM1)
```

2. Make sure that the cluster transmission queue is empty.

```
1 : display ql(SYSTEM.CLUSTER.TRANSMIT.DEMO.QM1) curdepth
AMQ8409: Display Queue details.
QUEUE(SYSTEM.CLUSTER.TRANSMIT.DEMO.QM1) CURDEPTH(0)
```

Messages put to a cluster alias queue go to `SYSTEM.DEAD.LETTER.QUEUE`

A cluster alias queue resolves to a local queue that does not exist.

Symptom

Messages put to an alias queue go to `SYSTEM.DEAD.LETTER.QUEUE` with reason MQRC_UNKNOWN_ALIAS_BASE_Q.

Cause

A message is routed to a queue manager where a clustered alias queue is defined. A local target queue is not defined on that queue manager. Because the message was put with the `MQOO_BIND_ON_OPEN` open option, the queue manager cannot requeue the message.

When `MQOO_BIND_ON_OPEN` is used, the cluster queue alias is firmly bound. The resolved name is the name of the target queue and any queue manager on which the cluster queue alias is defined. The queue manager name is placed in the transmission queue header. If the target queue does not exist on the queue manager to which the message is sent, the message is put on the dead letter queue. The destination is not recomputed, because the transmission header contains the name of the target queue manager resolved by `MQOO_BIND_ON_OPEN`. If the alias queue had been opened with `MQOO_BIND_NOT_FIXED`, then the transmission queue header would contain a blank queue manager name, and the destination would be recomputed. In which case, if the local queue is defined elsewhere in the cluster, the message would be sent there.

Solution

1. Change all alias queue definitions to specify `DEFBIND ( NOTFIXED)`.
2. Use `MQOO_BIND_NOT_FIXED` as an open option when the queue is opened.
3. If you specify `MQOO_BIND_ON_OPEN`, ensure that a cluster alias that resolves to a local queue defined on the same queue manager as the alias.

A queue manager has out of date information about queues and channels in the cluster

Symptom

DISPLAY QCLUSTER and DISPLAY CLUSQMGR show objects which are out of date.

Cause

Updates to the cluster only flow between the full repositories over manually defined CLUSSDR channels. After the cluster has formed CLUSSDR channels display as DEFTYPE (CLUSSDRB) channels because they are both manual and automatic channels. There must be enough CLUSSDR channels to form a complete network between all the full repositories.

Solution

- Check that the queue manager where the object exists and the local queue manager are still connected to the cluster.
- Check that each queue manager can display all the full repositories in the cluster.
- Check whether the CLUSSDR channels to the full repositories are continually trying to restart.
- Check that the full repositories have enough CLUSSDR channels defined to correctly connect them together.

```
1 : dis clusqmgr(QM1) CHANNEL(*) STATUS DEFTYPE QMTYPE
XMITQ
AMQ8441: Display Cluster Queue Manager details.
CLUSQMGR(QM1)     CLUSTER(DEMO)
CHANNEL(DEMO.QM1) DEFTYPE(CLUSSDRA)
QMTYPE(NORMAL)    STATUS(RUNNING)
XMITQ(SYSTEM.CLUSTER.TRANSMIT.DEMO.QM1)
AMQ8441: Display Cluster Queue Manager details.
CLUSQMGR(QM2)     CLUSTER(DEMO)
CHANNEL(DEMO.QM2) DEFTYPE(CLUSRCVR)
QMTYPE(REPOS)
XMITQ(SYSTEM.CLUSTER.TRANSMIT.DEMO.QM2)
AMQ8441: Display Cluster Queue Manager details.
CLUSQMGR(QM3)     CLUSTER(DEMO)
CHANNEL(DEMO.QM3) DEFTYPE(CLUSSDRB)
QMTYPE(REPOS)     STATUS(RUNNING)
XMITQ(SYSTEM.CLUSTER.TRANSMIT.DEMO.QM3)
AMQ8441: Display Cluster Queue Manager details.
CLUSQMGR(QM4)     CLUSTER(DEMO)
CHANNEL(DEMO.QM4) DEFTYPE(CLUSSDRA)
QMTYPE(NORMAL)    STATUS(RUNNING)
XMITQ(SYSTEM.CLUSTER.TRANSMIT.DEMO.QM4)
```

No changes in the cluster are being reflected in the local queue manager

The repository manager process is not processing repository commands, possibly because of a problem with receiving or processing messages in the command queue.

Symptom

No changes in the cluster are being reflected in the local queue manager.

Cause

The repository manager process is not processing repository commands.

Solution

1. Check that the SYSTEM.CLUSTER.COMMAND.QUEUE is empty.

   ```
   1 : display ql(SYSTEM.CLUSTER.COMMAND.QUEUE) curdepth
   AMQ8409: Display Queue details.
   QUEUE(SYSTEM.CLUSTER.COMMAND.QUEUE) CURDEPTH(0)
   ```

2. z/OS Check that the channel initiator is running on z/OS.
3. Check that there are no error messages in the error logs indicating the queue manager has a temporary resource shortage.

DISPLAY CLUSQMGR displays a queue manager twice

Use the RESET CLUSTER command to remove all traces of an old instance of a queue manager.

```
1 : display clusqmgr(QM1) qmid
AMQ8441: Display Cluster Queue Manager details.
CLUSQMGR(QM1)                          CLUSTER(DEMO)
CHANNEL(DEMO.QM1)                      QMID(QM1_2002-03-04_11.07.01)
AMQ8441: Display Cluster Queue Manager details.
CLUSQMGR(QM1)                          CLUSTER(DEMO)
CHANNEL(DEMO.QM1)                      QMID(QM1_2002-03-04_11.04.19)
```

The cluster functions correctly with the older version of the queue manager being ignored. After about 90 days, the cluster's knowledge of the older version of the queue manager expires, and is deleted automatically. However you might prefer to delete this information manually.

Cause

1. The queue manager might have been deleted and then re-created and redefined.
2. It might have been cold-started on z/OS, without first following the procedure to remove a queue manager from a cluster.

Solution

To remove all trace of the queue manager immediately use the RESET CLUSTER command from a full repository queue manager. The command removes the older unwanted queue manager and its queues from the cluster.

```
2 : reset cluster(DEMO) qmid('QM1_2002-03-04_11.04.19') action(FORCEREMOVE) queues(yes)
AMQ8559: RESET CLUSTER accepted.
```

Using the RESET CLUSTER command stops auto-defined cluster sender channels for the affected queue manager. You must manually restart any cluster sender channels that are stopped, after completing the RESET CLUSTER command.

A queue manager does not rejoin the cluster

After issuing a RESET or REFRESH cluster command the channel from the queue manager to the cluster might be stopped. Check the cluster channel status and restart the channel.

Symptom

A queue manager does not rejoin a cluster after issuing the RESET CLUSTER and REFRESH CLUSTER commands.

Cause

A side effect of the RESET and REFRESH commands might be that a channel is stopped. A channel is stopped in order that the correct version of the channel runs when RESET or REFRESH command is completed.

Solution

Check that the channels between the problem queue manager and the full repositories are running and use the START CHANNEL command if necessary.

Clustering: Using REFRESH CLUSTER best practices

Workload balancing set on a cluster-sender channel is not working

Any workload balancing you specify on a cluster-sender channel is likely to be ignored. Instead, specify the cluster workload channel attributes on the cluster-receiver channel at the target queue manager.

Symptom

You have specified one or more cluster workload channel attributes on a cluster-sender channel. The resulting workload balancing is not as you were expecting.

Cause

Any workload balancing you specify on a cluster-sender channel is likely to be ignored. For an explanation of this, see Cluster channels. Note that you still get some form of workload balancing, based either on cluster defaults or on properties set on the matching cluster-receiver channel at the target queue manager.

Solution

Specify the cluster workload channel attributes on the cluster-receiver channel at the target queue manager.

Out of date information in a restored cluster

After restoring a queue manager, its cluster information is out of date. Refresh the cluster information with the **REFRESH CLUSTER** command.

Problem

After an image backup of QM1, a partial repository in cluster DEMO has been restored and the cluster information it contains is out of date.

Solution

On QM1, issue the command REFRESH CLUSTER(DEMO).

Note: For large clusters, use of the **REFRESH CLUSTER** command can be disruptive to the cluster while it is in progress, and again at 27 day intervals thereafter when the cluster objects automatically send status updates to all interested queue managers. See Refreshing in a large cluster can affect performance and availability of the cluster.

When you run REFRESH CLUSTER(DEMO) on QM1, you remove all the information QM1 has about the cluster DEMO, except for QM1's knowledge of itself and its own queues, and of how to access the full repositories in the cluster. QM1 then contacts the full repositories, and tells them about itself and its queues. QM1 is a partial repository, so the full repositories don't immediately tell QM1 about all the other partial repositories in the cluster. Instead, QM1 slowly builds up its knowledge of the other partial repositories through information it receives as and when each of the other queues and queue managers is next active in the cluster.

Cluster queue manager force removed from a full repository by mistake

Restore the queue manager to the full repository by issuing the command **REFRESH CLUSTER** on the queue manager that was removed from the repository.

Problem

The command, RESET CLUSTER(DEMO) QMNAME(QM1) ACTION(FORCEREMOVE) was issued on a full repository in cluster DEMO by mistake.

Solution

On QM1, issue the command REFRESH CLUSTER(DEMO).

Note: For large clusters, use of the **REFRESH CLUSTER** command can be disruptive to the cluster while it is in progress, and again at 27 day intervals thereafter when the cluster objects automatically send status updates to all interested queue managers. See Refreshing in a large cluster can affect performance and availability of the cluster.

Possible repository messages deleted

Messages destined for a queue manager were removed from the SYSTEM.CLUSTER.TRANSMIT.QUEUE in other queue managers. Restore the information by issuing the REFRESH CLUSTER command on the affected queue manager.

Problem

Messages destined for QM1 were removed from the SYSTEM.CLUSTER.TRANSMIT.QUEUE in other queue managers and they might have been repository messages.

Solution

On QM1, issue the command REFRESH CLUSTER(DEMO).

Note: For large clusters, use of the **REFRESH CLUSTER** command can be disruptive to the cluster while it is in progress, and again at 27 day intervals thereafter when the cluster objects automatically send status updates to all interested queue managers. See Refreshing in a large cluster can affect performance and availability of the cluster.

QM1 removes all information it has about the cluster DEMO, except that relating to the cluster queue managers which are the full repositories in the cluster. Assuming that this information is still correct, QM1 contacts the full repositories. QM1 informs the full repositories about itself and its queues. It recovers the information for queues and queue managers that exist elsewhere in the cluster as they are opened.

Two full repositories moved at the same time

If you move both full repositories to new network addresses at the same time, the cluster is not updated with the new addresses automatically. Follow the procedure to transfer the new network addresses. Move the repositories one at a time to avoid the problem.

Problem

Cluster DEMO contains two full repositories, QM1 and QM2. They were both moved to a new location on the network at the same time.

Solution

1. Alter the CONNAME in the CLUSRCVR and CLUSSDR channels to specify the new network addresses.
2. Alter one of the queue managers (QM1 or QM2) so it is no longer a full repository for any cluster.
3. On the altered queue manager, issue the command REFRESH CLUSTER(*) REPOS(YES).

   Note: For large clusters, use of the **REFRESH CLUSTER** command can be disruptive to the cluster while it is in progress, and again at 27 day intervals thereafter when the cluster objects automatically send status updates to all interested queue managers. See Refreshing in a large cluster can affect performance and availability of the cluster.
4. Alter the queue manager so it is acting as a full repository.

Recommendation

You could avoid the problem as follows:

1. Move one of the queue managers, for example QM2, to its new network address.
2. Alter the network address in the QM2 CLUSRCVR channel.
3. Start the QM2 CLUSRCVR channel.
4. Wait for the other full repository queue manager, QM1, to learn the new address of QM2.
5. Move the other full repository queue manager, QM1, to its new network address.

6. Alter the network address in the QM1 CLUSRCVR channel.
7. Start the QM1 CLUSRCVR channel.
8. Alter the manually defined CLUSSDR channels for the sake of clarity, although at this stage they are not needed for the correct operation of the cluster.

The procedure forces QM2 to reuse the information from the correct CLUSSDR channel to re-establish contact with QM1 and then rebuild its knowledge of the cluster. Additionally, having once again contacted QM1, it is given its own correct network address based on the CONNAME in QM2 CLUSRCVR definition.

Unknown state of a cluster

Restore the cluster information in all the full repositories to a known state by rebuilding the full repositories from all the partial repositories in the cluster.

Problem

Under normal conditions the full repositories exchange information about the queues and queue managers in the cluster. If one full repository is refreshed, the cluster information is recovered from the other.

The problem is how to completely reset all the systems in the cluster to restore a known state to the cluster.

Solution

To stop cluster information being updated from the unknown state of the full repositories, all the CLUSRCVR channels to full repositories are stopped. The CLUSSDR channels change to inactive.

When you refresh the full repository systems, none of them are able to communicate, so they start from the same cleared state.

When you refresh the partial repository systems, they rejoin the cluster and rebuild it to the complete set of queue managers and queues. The cluster information in the rebuilt full is restored to a known state.

Note: For large clusters, use of the **REFRESH CLUSTER** command can be disruptive to the cluster while it is in progress, and again at 27 day intervals thereafter when the cluster objects automatically send status updates to all interested queue managers. See Refreshing in a large cluster can affect performance and availability of the cluster.

1. On all the full repository queue managers, follow these steps:
   a. Alter queue managers that are full repositories so they are no longer full repositories.
   b. Resolve any in doubt CLUSSDR channels.
   c. Wait for the CLUSSDR channels to become inactive.
   d. Stop the CLUSRCVR channels.
   e. When all the CLUSRCVR channels on all the full repository systems are stopped, issue the command REFRESH CLUSTER(DEMO) REPOS(YES).
   f. Alter the queue managers so they are full repositories.
   g. Start the CLUSRCVR channels to re-enable them for communication.
2. On all the partial repository queue managers, follow these steps:
   a. Resolve any in doubt CLUSSDR channels.
   b. Make sure all CLUSSDR channels on the queue manager are stopped or inactive.
   c. Issue the command REFRESH CLUSTER(DEMO) REPOS(YES).

What happens when a cluster queue manager fails

When a cluster queue manager fails, some undelivered messages are sent to other queue managers in the cluster. Messages that are in-flight wait until the queue manager is restarted. Use a high-availability mechanism to restart a queue manager automatically.

Problem

If a message-batch is sent to a particular queue manager and that queue manager becomes unavailable, what happens at the sending queue manager?

Explanation

Except for non-persistent messages on an NPMSPEED(FAST) channel, the undelivered batch of messages is backed out to the cluster transmission queue on the sending queue manager. On an NPMSPEED(FAST) channel, non-persistent messages are not batched, and one might be lost.

- Indoubt messages, and messages that are bound to the unavailable queue manager, wait until the queue manager becomes available again.
- Other messages are delivered to alternative queue managers selected by the workload management routine.

Solution

The unavailable cluster queue manager can be restarted automatically, either by being configured as a multi-instance queue manager, or by a platform-specific high availability mechanism.

What happens when a repository fails

How you know a repository has failed and what to do to fix it?

Problem

1. Cluster information is sent to repositories (whether full or partial) on a local queue called `SYSTEM.CLUSTER.COMMAND.QUEUE`. If this queue fills up, perhaps because the queue manager has stopped working, the cluster-information messages are routed to the dead-letter queue.
2. The repository runs out of storage.

Solution

1. Monitor the messages on your queue manager log z/OS or z/OS system console to detect if `SYSTEM.CLUSTER.COMMAND.QUEUE` is filling up. If it is, you need to run an application to retrieve the messages from the dead-letter queue and reroute them to the correct destination.
2. If errors occur on a repository queue manager, messages tell you what error has occurred and how long the queue manager waits before trying to restart.
   - z/OS On IBM MQ for z/OS, the `SYSTEM.CLUSTER.COMMAND.QUEUE` is disabled for MQGET.
   - When you have identified and resolved the error, enable the `SYSTEM.CLUSTER.COMMAND.QUEUE` so that the queue manager can restart successfully.
3. In the unlikely event of the repository running out of storage, storage allocation errors are sent to the queue-manager log z/OS or z/OS system console. To fix the storage problem, stop and then restart the queue manager. When the queue manager is restarted, more storage is automatically allocated to hold all the repository information.

What happens if a cluster queue is disabled for MQPUT

All instances of a cluster queue that is being used for workload balancing might be disabled for MQPUT. Applications putting a message to the queue either receive a `MQRC_CLUSTER_PUT_INHIBITED` or a `MQRC_PUT_INHIBITED` return code . You might want to modify this behavior.

Problem

When a cluster queue is disabled for MQPUT, its status is reflected in the repository of each queue manager that is interested in that queue. The workload management algorithm tries to send messages to destinations that are enabled for MQPUT. If there are no destinations enabled for MQPUT and no local instance of a queue, an MQOPEN call that specified `MQOO_BIND_ON_OPEN` returns a return code of `MQRC_CLUSTER_PUT_INHIBITED` to the application. If `MQOO_BIND_NOT_FIXED` is specified, or there is a local instance of the queue, an MQOPEN call succeeds but subsequent MQPUT calls fail with return code `MQRC_PUT_INHIBITED`.

Solution

You can write a user exit program to modify the workload management routines so that messages can be routed to a destination that is disabled for MQPUT.

A message can arrive at a destination that is disabled for MQPUT. The message might have been in flight at the time the queue became disabled, or a workload exit might have chosen the destination explicitly. The workload management routine at the destination queue manager has a number of ways to deal with the message:

- Choose another appropriate destination, if there is one.
- Place the message on the dead-letter queue.
- Return the message to the originator, if there is no dead-letter queue

Queue managers troubleshooting

Use the advice given here to help you to resolve common problems that can arise when you use queue managers.

Queue manager unavailable error

- **Scenario:** You receive a *queue manager unavailable* error.
- **Explanation:** Configuration file errors typically prevent queue managers from being found, and result in *queue manager unavailable* errors. On Windows, problems in the qm.ini file can cause *queue manager unavailable* errors when a queue manager is started.
- **Solution:** Ensure that the configuration files exist, and that the IBM MQ configuration file references the correct queue manager and log directories. On Windows, check for problems in the qm.ini file.

Undelivered messages troubleshooting

Use the advice given here to help you to resolve problems when messages do are not delivered successfully.

- **Scenario:** Messages do not arrive on a queue when you are expecting them.
- **Explanation:** Messages that cannot be delivered for some reason are placed on the dead-letter queue.
- **Solution:** You can check whether the queue contains any messages by issuing an MQSC DISPLAY QUEUE command.

  If the queue contains messages, you can use the provided browse sample application (amqsbcg) to browse messages on the queue using the MQGET call. The sample application steps through all the messages on a named queue for a named queue manager, displaying both the message descriptor and the message context fields for all the messages on the named queue.

You must decide how to dispose of any messages found on the dead-letter queue, depending on the reasons for the messages being put on the queue. Problems might occur if you do not associate a dead-letter queue with each queue manager.

For more information about dead-letter queues and handling undelivered messages, see Working with dead-letter queues.

TLS/SSL troubleshooting information

Use the information listed here to help you solve problems with your TLS/SSL system.

Overview

For the error caused by *Using non-FIPS cipher with FIPS enabled on client*, you receive the following error message:

JMSCMQ001

IBM MQ call failed with completion code *2 ('MQCC_FAILED')* reason *2397 ('MQRC_JSSE_ERROR')*

For every other problem documented within this topic you receive either the previous error message, or the following error message, or both:

JMSWMQ0018

Failed to connect to queue manager *'queue-manager-name'* with connection mode *'connection-mode'* and host name *'host-name'*

For each problem documented within this topic, the following information is provided:
- Output from the sample `SystemOut.log` or `Console`, detailing the cause of the exception..
- Queue manager error log information.
- Solution to the problem.

Note:
- You should always list out the stacks and the cause of the first exception.
- Whether or not the error information is written to the `stdout` log file depends on how the application is written, and on which framework you are using.
- The sample code includes stacks and line numbers. This information is useful guidance, but the stacks and line numbers are likely to change from one fix pack to another. You should use the stacks and line numbers as a guide to locating the correct section, and not use the information specifically for diagnostic purposes.

Cipher suite not set on client

Output

Caused by:

```
com.ibm.mq.jmqi.JmqiException: CC=2;RC=2397;AMQ9641: Remote CipherSpec error for channel

Queue manager error logs

AMQ9636: SSL distinguished name does not match peer name, channel *'SYSTEM.DEF.SVRCONN'*.

Solution

Ensure the value of SSLPEER set on the server-connection channel matches the distinguished name of the certificate.

SSLPEER set on client does not match certificate

Output

Caused by:

```
com.ibm.mq.jmqi.JmqiException: CC=2;RC=2398;AMQ9636: SSL distinguished name does not match peer name,
channel '?'. [CN=JohnDoe, O=COMPANY, L=YOURSITE, C=XX]

at com.ibm.jsse2.qc.a(qc.java:207)
```

Queue manager error logs

AMQ9660: SSL key repository: password stash file absent or unusable.

Solution

Ensure that a password stash file has been associated with the key database file in the same directory, and that the user ID, under which IBM MQ is running, has read access to both files.

IBM MQ Telemetry troubleshooting

Look for a troubleshooting task to help you solve a problem with running IBM MQ Telemetry applications.

Related information:
IBM MQ Telemetry

Location of telemetry logs, error logs, and configuration files

Find the logs, error logs, and configuration files used by IBM MQ Telemetry.

Note: The examples are coded for Windows systems. Change the syntax to run the examples on AIX or Linux systems.

Server-side logs

The installation wizard for IBM MQ Telemetry writes messages to its installation log:

```
WMQ program directory\mqxr
```

The telemetry (MQXR) service writes messages to the IBM MQ queue manager error log, and FDC files to the IBM MQ error directory:

```
 WMQ data directory\Qmgrs\qMgrName\errors\AMQERR01.LOG
WMQ data directory\errors\AMQ nnn.n.FDC
```

It also writes a log for the telemetry (MQXR) service. The log displays the properties the service started with, and errors it has found acting as a proxy for an MQTT client. For example, unsubscribing from a subscription that the client did not create. The log path is:

```
WMQ data directory\Qmgrs\qMgrName\errors\mqxr.log
```

The IBM MQ telemetry sample configuration created by IBM MQ explorer starts the telemetry (MQXR) service using the command **`runMQXRService`**, which is in *`WMQ Telemetry install directory`*`\bin`. This command writes to:

```
 WMQ data directory\Qmgrs\qMgrName\mqxr.stdout
WMQ data directory\Qmgrs\qMgrName\mqxr.stderr
```

Modify **`runMQXRService`** to display the paths configured for the telemetry (MQXR) service, or to echo the initialization before starting the telemetry (MQXR) service.

Server-side configuration files

Telemetry channels and telemetry (MQXR) service

Restriction: The format, location, content, and interpretation of the telemetry channel configuration file might change in future releases. You must use IBM MQ Explorer to configure telemetry channels.

IBM MQ Explorer saves telemetry configurations in the `mqxr_win.properties` file on Windows systems, and the `mqxr_unix.properties` file on AIX or Linux systems. The properties files are saved in the telemetry configuration directory:

```
WMQ data directory\Qmgrs\qMgrName\mqxr
```

Figure 138. Telemetry configuration directory on Windows

```
/var/mqm/qmgrs/qMgrName/mqxr
```

Figure 139. Telemetry configuration directory on AIX or Linux

JVM Set Java properties that are passed as arguments to the telemetry (MQXR) service in the file, `java.properties`. The properties in the file are passed directly to the JVM running the telemetry (MQXR) service. They are passed as additional JVM properties on the Java command line. Properties set on the command line take precedence over properties added to the command line from the `java.properties` file.

Find the `java.properties` file in the same folder as the telemetry configurations. See Figure 138 on page 1829 and Figure 139.

Modify `java.properties` by specifying each property as a separate line. Format each property exactly as you would to pass the property to the JVM as an argument. For example:

```
-Xmx1024m
-Xms1024m
```

JAAS The JAAS configuration file is described in Telemetry channel JAAS configuration, which includes the sample JAAS configuration file, JAAS.config, shipped with IBM MQ Telemetry.

If you configure JAAS, you are almost certainly going to write a class to authenticate users to replace the standard JAAS authentication procedures.

To include your Login class in the class path used by the telemetry (MQXR) service class path, provide an IBM MQ `service.env` configuration file.

Set the class path for your JAAS LoginModule in `service.env`. You cannot use the variable, `%classpath%` in `service.env`. The class path in `service.env` is added to the class path already set in the telemetry (MQXR) service definition.

Display the class paths that are being used by the telemetry (MQXR) service by adding `echo set classpath` to `runMQXRService.bat`. The output is sent to `mqxr.stdout`.

The default location for the `service.env` file is:

```
WMQ data directory\service.env
```

Override these settings with a `service.env` file for each queue manager in:

```
WMQ data directory\Qmgrs\qMgrName\service.env
```

```
CLASSPATH= WMQ Install Directory\mqxr\samples
```

Note: `service.env` must not contain any variables. Substitute the actual value of *`WMQ Install Directory`*.

Figure 140. Sample `service.env` for Windows.

A sample `service.env` file to use the sample `LoginModule.class`.

Trace See"Tracing the telemetry (MQXR) service" on page 1832. The parameters to configure trace are stored in two files:

```
  WMQ data directory\Qmgrs\qMgrName\mqxr\trace.config
 WMQ data directory\Qmgrs\qMgrName\mqxr\mqxrtrace.properties
```

Client-side log files

The default file persistence class in the Java SE MQTT client supplied with IBM WebSphere MQ Telemetry creates a folder with the name: *clientIdentifier*-**tcp***hostNameport* or *clientIdentifier*-**ssl***hostNameport* in the client working directory. The folder name tells you the `hostName` and `port` used in the connection attempt. The folder contains messages that have been stored by the persistence class. The messages are deleted when they have been delivered successfully.

The folder is deleted when a client, with a clean session, ends.

If client trace is turned on, the unformatted log is, by default, stored in the client working directory. The trace file is called `mqtt- n.trc`

Client-side configuration files

Set trace and SSL properties for the MQTT Java client using Java property files, or set the properties programmatically. Pass the properties to the MQTT Java client using the JVM `-D` switch: for example,

```
Java -Dcom.ibm.micro.client.mqttv3.trace=c:\\MqttTrace.properties
-Dcom.ibm.ssl.keyStore=C:\\MyKeyStore.jks
```

See“Tracing the MQTT v3 Java client” on page 1833.For links to client API documentation for the MQTT client libraries, see MQTT client programming reference.

MQTT v3 Java client reason codes

Look up the causes of reason codes in an MQTT v3 Java client exception or throwable.

Table 174. MQTT v3 Java client reason codes

Reason code	Value	Cause
REASON_CODE_BROKER_UNAVAILABLE	3	
REASON_CODE_CLIENT_ALREADY_CONNECTED	32100	The client is already connected.
REASON_CODE_CLIENT_ALREADY_DISCONNECTED	32101	The client is already disconnected.
REASON_CODE_CLIENT_DISCONNECT_PROHIBITED	32107	Thrown when an attempt to call MqttClient.disconnect has been made from within a method on MqttCallback.
REASON_CODE_CLIENT_DISCONNECTING	32102	The client is currently disconnecting and cannot accept any new work.
REASON_CODE_CLIENT_EXCEPTION	0	Client encountered an exception.
REASON_CODE_CLIENT_NOT_CONNECTED	32104	The client is not connected to the server.
REASON_CODE_CLIENT_TIMEOUT	32000	Client timed out while waiting for a response from the server.
REASON_CODE_FAILED_AUTHENTICATION	4	Authentication with the server has failed, due to a bad user name or password.
REASON_CODE_INVALID_CLIENT_ID	2	The server has rejected the supplied client ID.
REASON_CODE_INVALID_PROTOCOL_VERSION	1	The protocol version requested is not supported by the server.
REASON_CODE_NO_MESSAGE_IDS_AVAILABLE	32001	Internal error, caused by no new message IDs being available.
REASON_CODE_NOT_AUTHORIZED	5	Not authorized to perform the requested operation.
REASON_CODE_SERVER_CONNECT_ERROR	32103	Unable to connect to server.
REASON_CODE_SOCKET_FACTORY_MISMATCH	32105	Server URI and supplied SocketFactory do not match.
REASON_CODE_SSL_CONFIG_ERROR	32106	SSL configuration error.
REASON_CODE_UNEXPECTED_ERROR	6	An unexpected error has occurred.

Tracing the telemetry (MQXR) service

Follow these instructions to start a trace of the telemetry service, set the parameters that control the trace, and find the trace output.

Before you begin

Tracing is a support function. Follow these instructions if an IBM service engineer asks you to trace your telemetry (MQXR) service. The product documentation does not document the format of the trace file, or how to use it to debug a client.

About this task

You can use the IBM MQ **strmqtrc** and **endmqtrc** commands to start and stop IBM MQ trace. **strmqtrc** captures trace for the telemetry (MQXR) service. When using **strmqtrc**, there is a delay of up to a couple of seconds before the telemetry service trace is started. For further information about IBM MQ trace, see Tracing. Alternatively, you can trace the telemetry service by using the following procedure:

Procedure

1. Set the trace options to control the amount of detail and the size of the trace. The options apply to a trace started with either the **strmqtrc** or the **controlMQXRChannel** command.

   Set the trace options in the following files:

   `mqxrtrace.properties`

   `trace.config`

   The files are in the following directory:
   - On Windows systems: *`WebSphere MQ data directory`*`\qmgrs\`*`qMgrName`*`\mqxr`.
   - On AIX or Linux systems: `var/mqm/qmgrs/`*`qMgrName`*`/mqxr`.
2. Open a command window in the following directory:
   - On Windows systems: *`WebSphere MQ installation directory`*`\mqxr\bin`.
   - On AIX or Linux systems: `/opt/mqm/mqxr/bin`.
3. Run the following command to start an `SYSTEM.MQXR.SERVICE` trace:

```
►►─┬─./controlMQXRChannel.sh─┬──-qmgr=──qMgrName──-mode=──┬─starttrace─┬────────────────────►
   └─controlMQXRChannel.bat──┘                            └─stoptrace──┘

►─┬─────────────────────────────┬──────────────────────────────────────────────────────────►◄
  └─-clientid=──ClientIdentifier─┘
```

Mandatory parameters

`qmgr=` *`qmgrName`*
: Set *qmgrName* to the queue manager name

`mode= starttrace | stoptrace`
: Set starttrace to begin tracing or to stoptrace to end tracing

Optional parameters

`clientid=` *`ClientIdentifier`*
: Set *ClientIdentifier* to the `ClientIdentifier` of a client. clientid filters trace to a single client. Run the trace command multiple times to trace multiple clients.

For example:

```
/opt/mqm/mqxr/bin/controlMQXRChannel.sh -qmgr=QM1 -mode=starttrace -clientid= problemclient
```

Results

To view the trace output, go to the following directory:

- On Windows systems: `WebSphere MQ data directory\trace`.
- On AIX or Linux systems: `/var/mqm/trace`.

Trace files are named `mqxr_PPPPP.trc`, where `PPPPP` is the process ID.

Related information:

strmqtrc

Tracing the MQTT v3 Java client

Follow these instructions to create an MQTT Java client trace and control its output.

Before you begin

Tracing is a support function. Follow these instructions if an IBM service engineer asks you to trace your MQTT Java client. The product documentation does not document the format of the trace file, or how to use it to debug a client.

Trace only works for the IBM MQ Telemetry Java client.

About this task

Note: The examples are coded for Windows. Change the syntax to run the examples on Linux[7] .

Procedure

1. Create a Java properties file containing the trace configuration.

   In the properties file specify the following optional properties. If a property key is specified more than once, the last occurrence sets the property.

   a. `com.ibm.micro.client.mqttv3.trace.outputName`

      The directory to write the trace file to. It defaults to the client working directory. The trace file is called `mqtt-` *`n`*`.trc`.

      ```
      com.ibm.micro.client.mqttv3.trace.outputName=c:\\MQTT_Trace
      ```

   b. `com.ibm.micro.client.mqttv3.trace.count`

      The number of trace files to write. The default is one file, of unlimited size.

      ```
      com.ibm.micro.client.mqttv3.trace.count=5
      ```

   c. `com.ibm.micro.client.mqttv3.trace.limit`

      The maximum size of file to write, the default is 500000. The limit only applies if more than one trace file is requested.

      ```
      com.ibm.micro.client.mqttv3.trace.limit=100000
      ```

   d. `com.ibm.micro.client.mqttv3.trace.client.` *`clientIdentifier`*`.status`

      Turn trace on or off, per client. If *`clientIdentifier`* `=*`, trace is turned on or off for all clients. By default, trace is turned off for all clients.

      ```
      com.ibm.micro.client.mqttv3.trace.client.*.status=on
      com.ibm.micro.client.mqttv3.trace.client.Client10.status=on
      ```

2. Pass the trace properties file to the JVM using a system property.

   ```
   -Dcom.ibm.micro.client.mqttv3.trace=c:\\MqttTrace.properties
   ```

3. Run the client.

7. Java uses the correct path delimiter. You can code the delimiter in a property file as '/' or '\\' ; '\' is the escape character

4. Convert the trace file from binary encoding to text or `.html`. Use the following command:

   ```
   com.ibm.micro.client.mqttv3.internal.trace.TraceFormatter [-i traceFile] [-o outputFile] [-h] [-d
   time]
   ```

   where the arguments are:

   -? Displays help

   -i traceFile
   Required. Passes in the input file (for example, `mqtt-0.trc`).

   -o outputFile
   Required. Defines the output file (for example, `mqtt-0.trc.html` or `mqtt-0.trc.txt`).

   -h Output as HTML. The output files extension must be `.html`. If not specified, the output is plain text.

   -d time
   Indents a line with `*` if the time difference in milliseconds is greater than or equal to (>=) time. Not applicable for HTML output.

   The following example will output the trace file in HTML format

   ```
   com.ibm.micro.client.mqttv3.internal.trace.TraceFormatter -i mqtt-0.trc -o mqtt-0.trc.html -h
   ```

   The second example will output the trace file as plain text, with any consecutive timestamps that have milliseconds with a difference of 50 or greater indented with an asterisk (`*`).

   ```
   com.ibm.micro.client.mqttv3.internal.trace.TraceFormatter -i mqtt-0.trc -o mqtt-0.trc.txt -d 50
   ```

   The final example will output the trace file as plain text:

   ```
   com.ibm.micro.client.mqttv3.internal.trace.TraceFormatter -i mqtt-0.trc -o mqtt-0.trc.txt
   ```

System requirements for using SHA-2 cipher suites with MQTT channels

If you use a version of Java that supports SHA-2 cipher suites, you can use these suites to secure your MQTT (telemetry) channels and client apps.

For IBM MQ Version 8.0 , which includes the telemetry (MQXR) service, the minimum Java version is Java 7 from IBM , SR6. SHA-2 cipher suites are supported by default in Java 7 from IBM, SR4 onwards. You can therefore use SHA-2 cipher suites with the telemetry (MQXR) service to secure your MQTT (telemetry) channels.

If you are running an MQTT client with a different JRE, you need to ensure that it also supports the SHA-2 cipher suites. Details of the SHA-2 cipher suite support for each client is given in System requirements for using SHA-2 cipher suites with MQTT clients.

Resolving problem: MQTT client does not connect

Resolve the problem of an MQTT client program failing to connect to the telemetry (MQXR) service.

Before you begin

Is the problem at the server, at the client, or with the connection? Have you have written your own MQTT v3 protocol handling client, or an MQTT client application using the C or Java IBM MQTT clients?

Run the verification application supplied with IBM MQ Telemetry on the server, and check that the telemetry channel and telemetry (MQXR) service are running correctly. Then transfer the verification application to the client, and run the verification application there.

About this task

There are a number of reasons why an MQTT client might not connect, or you might conclude it has not connected, to the telemetry server.

Procedure

1. Consider what inferences can be drawn from the reason code that the telemetry (MQXR) service returned to MqttClient.Connect. What type of connection failure is it?

Option	**Description**
`REASON_CODE_INVALID_PROTOCOL_VERSION`	Make sure that the socket address corresponds to a telemetry channel, and you have not used the same socket address for another broker.
`REASON_CODE_INVALID_CLIENT_ID`	Check that the client identifier is no longer than 23 bytes, and contains only characters from the range: `A-Z, a-z, 0-9, './_%`
`REASON_CODE_SERVER_CONNECT_ERROR`	Check that the telemetry (MQXR) service and the queue manager are running normally. Use **`netstat`** to check that the socket address is not allocated to another application.

   If you have written an MQTT client library rather than use one of the libraries provided by IBM MQ Telemetry, look at the `CONNACK` return code.

   From these three errors you can infer that the client has connected to the telemetry (MQXR) service, but the service has found an error.

2. Consider what inferences can be drawn from the reason codes that the client produces when the telemetry (MQXR) service does not respond:

Option	**Description**
`REASON_CODE_CLIENT_EXCEPTION` `REASON_CODE_CLIENT_TIMEOUT`	Look for an FDC file at the server; see "Server-side logs" on page 1829. When the telemetry (MQXR) service detects the client has timed out, it writes a first-failure data capture (FDC) file. It writes an FDC file whenever the connection is unexpectedly broken.

The telemetry (MQXR) service might not have responded to the client, and the timeout at the client expires. The IBM MQ Telemetry Java client only hangs if the application has set an indefinite timeout. The client throws one of these exceptions after the timeout set for MqttClient.Connect expires with an undiagnosed connection problem.

Unless you find an FDC file that correlates with the connection failure you cannot infer that the client tried to connect to the server:

a. Confirm that the client sent a connection request.

   Check the TCPIP request with a tool such as **`tcpmon`**, available from (for example) http://code.google.com/p/tcpmon/

b. Does the remote socket address used by the client match the socket address defined for the telemetry channel?

   The default file persistence class in the Java SE MQTT client supplied with IBM WebSphere MQ Telemetry creates a folder with the name: *clientIdentifier*-**tcp***hostNameport* or *clientIdentifier*-**ssl***hostNameport* in the client working directory. The folder name tells you the `hostName` and `port` used in the connection attempt ; see "Client-side log files" on page 1830.

c. Can you ping the remote server address?

d. Does **`netstat`** on the server show the telemetry channel is running on the port the client is connecting too?

3. Check whether the telemetry (MQXR) service found a problem in the client request.

   The telemetry (MQXR) service writes errors it detects into `mqxr.log`, and the queue manager writes errors into `AMQERR01.LOG` ; see

4. Attempt to isolate the problem by running another client.

   - Run the MQTT sample application using the same telemetry channel.
   - Run the **`wmqttSample`** GUI client to verify the connection. Get **`wmqttSample`** by downloading SupportPac IA92.

     Note: Older versions of IA92 do not include the MQTT v3 Java client library.

   Run the sample programs on the server platform to eliminate uncertainties about the network connection, then run the samples on the client platform.

5. Other things to check:

   a. Are tens of thousands of MQTT clients trying to connect at the same time?

      Telemetry channels have a queue to buffer a backlog of incoming connections. Connections are processed in excess of 10,000 a second. The size of the backlog buffer is configurable using the telemetry channel wizard in IBM MQ Explorer. Its default size is 4096. Check that the backlog has not been configured to a low value.

   b. Are the telemetry (MQXR) service and queue manager still running?

   c. Has the client connected to a high availability queue manager that has switched its TCPIP address?

   d. Is a firewall selectively filtering outbound or return data packets?

Resolving problem: MQTT client connection dropped

Find out what is causing a client to throw unexpected ConnectionLost exceptions after successfully connecting and running for either a short or long while.

Before you begin

The MQTT client has connected successfully. The client might be up for a long while. If clients are starting with only a short interval between them, the time between connecting successfully and the connection being dropped might be short.

It is not hard to distinguish a dropped connection from a connection that was successfully made, and then later dropped. A dropped connection is defined by the MQTT client calling the MqttCallback.ConnectionLost method. The method is only called after the connection has been successfully established. The symptom is different to MqttClient.Connect throwing an exception after receiving a negative acknowledgment or timing out.

If the MQTT client application is not using the MQTT client libraries supplied by IBM MQ, the symptom depends on the client. In the MQTT v3 protocol, the symptom is a lack of timely response to a request to the server, or the failure of the TCP/IP connection.

About this task

The MQTT client calls MqttCallback.ConnectionLost with a throwable exception in response to any server-side problems encountered after receiving a positive connection acknowledgment. When an MQTT client returns from MqttTopic.publish and MqttClient.subscribe the request is transferred to an MQTT client thread that is responsible for sending and receiving messages. Server-side errors are reported asynchronously by passing a throwable exception to the ConnectionLost callback method.

The telemetry (MQXR) service always writes a first-failure data capture file if it drops the connection.

Procedure

1. Has another client started that used the same `ClientIdentifier` ?

   If a second client is started, or the same client is restarted, using the same `ClientIdentifier`, the first connection to the first client is dropped.
2. Has the client accessed a topic that it is not authorized to publish or subscribe to?

   Any actions the telemetry service takes on behalf of a client that return `MQCC_FAIL` result in the service dropping the client connection.

   The reason code is not returned to the client.
   - Look for log messages in the `mqxr.log` and `AMQERR01.LOG` files for the queue manager the client is connected to; see "Server-side logs" on page 1829.
3. Has the TCP/IP connection dropped?

   A firewall might have a low timeout setting for marking a TCPIP connection as inactive, and dropped the connection.
   - Shorten the inactive TCPIP connection time using `MqttConnectOptions.setKeepAliveInterval`.

Resolving problem: Lost messages in an MQTT application

Resolve the problem of losing a message. Is the message non-persistent, sent to the wrong place, or never sent? A wrongly coded client program might lose messages.

Before you begin

How certain are you that the message you sent, was lost? Can you infer that a message is lost because the message was not received? If message is a publication, which message is lost: the message sent by the publisher, or the message sent to the subscriber? Or did the subscription get lost, and the broker is not sending publications for that subscription to the subscriber?

If the solution involves distributed publish/subscribe, using clusters or publish/subscribe hierarchies, there are numerous configuration issues that might result in the appearance of a lost message.

If you sent a message with "At least once" or "At most once" quality of service, it is likely that the message you think is lost was not delivered in the way you expected. It is unlikely that the message has been wrongly deleted from the system. It might have failed to create the publication or the subscription you expected.

The most important step you take in doing problem determination of lost messages is to confirm the message is lost. Recreate the scenario and lose more messages. Use the "At least once" or "At most once" quality of service to eliminate all cases of the system discarding messages.

About this task

There are four legs to diagnosing a lost message.

1. "Fire and forget" messages working as-designed. "Fire and forget" messages are sometimes discarded by the system.
2. Configuration: setting up publish/subscribe with the correct authorities in a distributed environment is not straightforward.
3. Client programming errors: the responsibility for message delivery is not solely the responsibility of code written by IBM.
4. If you have exhausted all these possibilities, you might decide to involve IBM service.

Procedure

1. If the lost message had the "Fire and forget" quality of service, set the "At least once" or "At most once" quality of service. Attempt to lose the message again.
   - Messages sent with "Fire and forget" quality of service are thrown away by IBM MQ in a number of circumstances:
     - Communications loss and channel stopped.
     - Queue manager shut down.
     - Excessive number of messages.
   - The delivery of "Fire and forget" messages depends upon the reliability of TCP/IP. TCP/IP continues to send data packets again until their delivery is acknowledged. If the TCP/IP session is broken, messages with the "Fire and forget" quality of service are lost. The session might be broken by the client or server closing down, a communications problem, or a firewall disconnecting the session.
2. Check that client is restarting the previous session, in order to send undelivered messages with "At least once" or "At most once" quality of service again.
   a. If the client application is using the Java SE MQTT client, check that it sets MqttClient.CleanSession to `false`
   b. If you are using different client libraries, check that a session is being restarted correctly.

3. Check that the client application is restarting the same session, and not starting a different session by mistake.

   To start the same session again, `cleanSession = false`, and the `Mqttclient.clientIdentifier` and the `MqttClient.serverURI` must be the same as the previous session.
4. If a session closes prematurely, check that the message is available in the persistence store at the client to send again.
   a. If the client application is using the Java SE MQTT client, check that the message is being saved in the persistence folder; see "Client-side log files" on page 1830
   b. If you are using different client libraries, or you have implemented your own persistence mechanism, check that it is working correctly.
5. Check that no one has deleted the message before it was delivered.

   Undelivered messages awaiting delivery to MQTT clients are stored in `SYSTEM.MQTT.TRANSMIT.QUEUE`. Messages awaiting delivery to the telemetry server are stored by the client persistence mechanism; see Message persistence in MQTT clients.
6. Check that the client has a subscription for the publication it expects to receive.

   List subscriptions using MQ Explorer, or by using **runmqsc** or PCF commands. All MQTT client subscriptions are named. They are given a name of the form: *ClientIdentifier*:*Topic name*
7. Check that the publisher has authority to publish, and the subscriber to subscribe to the publication topic.

   ```
   dspmqaut -m qMgr -n topicName -t topic -p user ID
   ```

   In a clustered publish/subscribe system, the subscriber must be authorized to the topic on the queue manager to which the subscriber is connected. It is not necessary for the subscriber to be authorized to subscribe to the topic on the queue manager where the publication is published. The channels between the queue managers must be correctly authorized to pass on the proxy subscription and forward the publication.

   Create the same subscription and publish to it using IBM MQ Explorer. Simulate your application client publishing and subscribing by using the client utility. Start the utility from IBM MQ Explorer and change its user ID to match the one adopted by your client application.
8. Check that the subscriber has permission to put the publication on the `SYSTEM.MQTT.TRANSMIT.QUEUE`.

   ```
   dspmqaut -m qMgr -n queueName -t queue -p user ID
   ```
9. Check that the IBM MQ point-to-point application has authority to put its message on the `SYSTEM.MQTT.TRANSMIT.QUEUE`.

   ```
   dspmqaut -m qMgr -n queueName -t queue -p user ID
   ```

   See Sending a message to a client directly.

Resolving problem: Telemetry (MQXR) service does not start

Resolve the problem of the telemetry (MQXR) service failing to start. Check the IBM MQ Telemetry installation and no files are missing, moved, or have the wrong permissions. Check the paths used by the telemetry (MQXR) service locate the telemetry (MQXR) service programs.

Before you begin

The WebSphere MQ Telemetry feature is installed. The IBM MQ Explorer has a Telemetry folder in **IBM MQ > Queue Managers >** ***qMgrName*** **> Telemetry**. If the folder does not exist, the installation has failed.

The Telemetry (MQXR) service must have been created for it to start. If the telemetry (MQXR) service has not been created, then run the **Define sample configuration...** wizard in the `Telemetry` folder.

If the telemetry (MQXR) service has been started before, then additional **Channels** and **Channel Status** folders are created under the `Telemetry` folder. The Telemetry service, `SYSTEM.MQXR.SERVICE`, is in the **Services** folder. It is visible if the Explorer radio button to show System Objects is clicked.

Right click `SYSTEM.MQXR.SERVICE` to start and stop the service, show its status, and display whether your user ID has authority to start the service.

About this task

The `SYSTEM.MQXR.SERVICE` telemetry (MQXR) service fails to start. A failure to start manifests itself in two different ways:

1. The start command fails immediately.
2. The start command succeeds, and is immediately followed by the service stopping.

Procedure

1. Start the service

   Result The service stops immediately. A window displays an error message; for example:

   ```
   IBM MQ cannot process the request because the
   executable specified cannot be started. (AMQ4160)
   ```

   Reason

   Files are missing from the installation, or the permissions on installed files are set wrongly.

   The IBM MQ Telemetry feature is installed only on one of a pair of highly available queue managers. If the queue manager instance switches over to a standby, it tries to start `SYSTEM.MQXR.SERVICE`. The command to start the service fails because the telemetry (MQXR) service is not installed on the standby.

   Investigation

   Look in error logs; see "Server-side logs" on page 1829.

   Actions

   Install, or uninstall and reinstall the IBM MQ Telemetry feature.

2. Start the service; wait for 30 seconds; refresh the Explorer and check the service status.

   Result The service starts and then stops.

   Reason

   `SYSTEM.MQXR.SERVICE` started the **`runMQXRService`** command, but the command failed.

   Investigation

   Look in error logs; see "Server-side logs" on page 1829.

See if the problem occurs with only the sample channel defined. Backup and the clear the contents of the *WMQ data directory*\Qmgrs*qMgrName*\mqxr\ directory. Run the sample configuration wizard and try to start the service.

Actions
Look for permission and path problems.

Resolving problem: JAAS login module not called by the telemetry service

Find out if your JAAS login module is not being called by the telemetry (MQXR) service, and configure JAAS to correct the problem.

Before you begin

You have modified *WMQ installation directory*\mqxr\samples\LoginModule.java to create your own authentication class *WMQ installation directory*\mqxr\samples\samples\LoginModule.class. Alternatively, you have written your own JAAS authentication classes and placed them in a directory of your choosing. After some initial testing with the telemetry (MQXR) service, you suspect that your authentication class is not being called by the telemetry (MQXR) service.

Note: Guard against the possibility that your authentication classes might be overwritten by maintenance being applied to IBM MQ. Use your own path for authentication classes, rather than a path within the IBM MQ directory tree.

About this task

The task uses a scenario to illustrate how to resolve the problem. In the scenario, a package called security.jaas contains a JAAS authentication class called JAASLogin.class. It is stored in the path C:\WMQTelemetryApps\security\jaas. Refer to Telemetry channel JAAS configuration for help in configuring JAAS for IBM MQ Telemetry. The example, "Example JAAS configuration" on page 1842 is a sample configuration.

Procedure

1. Look in mqxr.log for an exception thrown by javax.security.auth.login.LoginException.

   See "Server-side logs" on page 1829 for the path to mqxr.log, and Figure 147 on page 1844 for an example of the exception listed in the log.
2. Correct your JAAS configuration by comparing it with the worked example in "Example JAAS configuration" on page 1842.
3. Replace your login class by the sample JAASLoginModule, after refactoring it into your authentication package and deploy it using the same path. Switch the value of loggedIn between true and false.

   If the problem goes away when loggedIn is true, and appears the same when loggedIn is false, the problem lies in your login class.
4. Check whether the problem is with authorization rather than authentication.
   a. Change the telemetry channel definition to perform authorization checking using a fixed user ID. Select a user ID that is a member of the mqm group.
   b. Rerun the client application.

      If the problem disappears, the solution lies with the user ID being passed for authorization. What is the user name being passed? Print it to file from your login module. Check its access permissions using IBM MQ Explorer, or **dspmqauth**.

Example JAAS configuration

Use the **New telemetry channel** wizard, in IBM MQ Explorer, to configure a telemetry channel. The client connects on port 1884, and connects to the `JAASMCAUser` telemetry channel. Figure 141 shows an example of the telemetry properties file created by the telemetry wizard. Do not edit this file directly. The channel authenticates using JAAS, using the configuration called `JAASConfig`. Once the client has authenticated, it uses the user ID `Admin` to authorize its access to IBM MQ objects.

```
com.ibm.mq.MQXR.channel/JAASMCAUser: \
com.ibm.mq.MQXR.Port=1884;\
com.ibm.mq.MQXR.JAASConfig=JAASConfig;\
com.ibm.mq.MQXR.UserName=Admin;\
com.ibm.mq.MQXR.StartWithMQXRService=true
```

Figure 141. `WMQ Installation directory\data\qmgrs\qMgrName\mqxr\mqxr_win.properties`

The JAAS configuration file has a stanza named `JAASConfig` that names the Java class `security.jaas.JAASLogin`, which `JAAS` is to use to authenticate clients.

```
JAASConfig {
  security.jaas.JAASLogin required debug=true;
};
```

Figure 142. `WMQ Installation directory\data\qmgrs\qMgrName\mqxr\jaas.config`

When `SYSTEM.MQTT.SERVICE` starts, it adds the path in Figure 143 to its classpath.

```
CLASSPATH=C:\WMQTelemtryApps;
```

Figure 143. `WMQ Installation directory\data\qmgrs\qMgrName\service.env`

Figure 144 shows the additional path in Figure 143 added to the classpath that is set up for the telemetry (MQXR) service.

```
CLASSPATH=;C:\IBM\MQ\Program\mqxr\bin\\..\lib\MQXRListener.jar;
C:\IBM\MQ\Program\mqxr\bin\\..\lib\WMQCommonServices.jar;
C:\IBM\MQ\Program\mqxr\bin\\..\lib\objectManager.utils.jar;
C:\IBM\MQ\Program\mqxr\bin\\..\lib\com.ibm.micro.xr.jar;
C:\IBM\MQ\Program\mqxr\bin\\..\..\java\lib\com.ibm.mq.jmqi.jar;
C:\IBM\MQ\Program\mqxr\bin\\..\..\java\lib\com.ibm.mqjms.jar;
C:\IBM\MQ\Program\mqxr\bin\\..\..\java\lib\com.ibm.mq.jar;
C:\WMQTelemtryApps;
```

Figure 144. Classpath output from runMQXRService.bat

The output in Figure 145 on page 1843 shows that the telemetry (MQXR) service has started with the channel definition shown in Figure 141.

```
21/05/2010 15:32:12 [main] com.ibm.mq.MQXRService.MQXRPropertiesFile
AMQXR2011I: Property com.ibm.mq.MQXR.channel/JAASMCAUser value
com.ibm.mq.MQXR.Port=1884;
com.ibm.mq.MQXR.JAASConfig=JAASConfig;
com.ibm.mq.MQXR.UserName=Admin;
com.ibm.mq.MQXR.StartWithMQXRService=true
```

Figure 145. WMQ Installation directory\data\qmgrs\qMgrName\errors\ mqxr.log

When the client application connects to the JAAS channel, if `com.ibm.mq.MQXR.JAASConfig=JAASWrongConfig` does not match the name of a JAAS stanza in the `jaas.config` file, the connection fails, and the client throws an exception with a return code of `0` ; see Figure 146. The second exception, `Client is not connected (32104)`, was thrown because the client attempted to disconnect when it was not connected.

```

```

Figure 146. Exception thrown connecting com.ibm.mq.id.PubAsyncRestartable

`mqxr.log` contains additional output shown in Figure 146.

The error is detected by JAAS which throws `javax.security.auth.login.LoginException` with the cause `No LoginModules configured for JAAS`. It could be caused, as in Figure 147 on page 1844, by a bad configuration name. It might also be the result of other problems JAAS has encountered loading the JAAS configuration.

If no exception is reported by JAAS, JAAS has successfully loaded the `security.jaas.JAASLogin` class named in the `JAASConfig` stanza.

```
21/05/2010 12:06:12 [ServerWorker0] com.ibm.mq.MQXRService.MQTTCommunications
AMQXR2050E: Unable to load JAAS config: JAASWrongConfig.
The following exception occurred javax.security.auth.login.LoginException:
No LoginModules configured for JAAS
```

Figure 147. `mqxr.log` - error loading JAAS configuration

Resolving problem: Starting or running the daemon

Consult the IBM MQ MQTT daemon for devices console log, turn on tracing, or use the symptom table in this topic to troubleshoot problems with the daemon.

Before you begin

Note: The daemon for devices is no longer available. For an alternative solution, see the eclipse.org "Mosquitto" project (https://eclipse.org/mosquitto).

Procedure

1. Check the console log.

   If the daemon is running in the foreground, the console messages are written to the terminal window. If the daemon has been started in the background, the console is where you have redirected `stdout` to.
2. Restart the daemon.

   Changes to the configuration file are not activated until the daemon is restarted.
3. Consult Table 175:

Table 175. Symptom table

Problem	**Suggested solution**

The following message is displayed when you start the daemon on Windows:
 	
`The system cannot execute the specified program`
or
`The application has failed to start because its side-by-side configuration is incorrect.`
	Install Microsoft Visual C++ 2008 Redistributable Package.

Two or more daemons or MQTT-capable servers are inter-connected by a bridge or bridges, and the processor is showing excessive load.	There is possibly a message loop, with one or more messages being repeatedly passed from one server to another. Examine the topic parameters in the configuration files. Use more specific topics where possible. Broad wildcard characters in both directions are the most common cause of connection loops.
The bridge is unable to connect to a remote MQTT-capable server that other MQTT clients can connect to.	The remote server might be incompatible with attempts to determine if the remote server is also an MQTT daemon for devices. Try setting **`try_private`** to `off` to disable special processing to eliminate message loops.
This message is printed when a bridge is configured: `Warning: Connect was not first packet on socket 1888, got CONNACK.`	You have probably configured a bridge to loop back to the local daemon. Loopback is not supported.

Resolving problem: MQTT clients not connecting to the daemon

Clients are not connecting to the daemon, or the daemon is not connecting to other daemons or to an IBM MQ telemetry channel.

Before you begin

Note: The daemon for devices is no longer available. For an alternative solution, see the eclipse.org "Mosquitto" project (https://eclipse.org/mosquitto).

About this task

Trace each MQTT packet sent and received by the daemon.

Procedure

Set the **`trace_output`** parameter to `protocol` in the daemon configuration file or send a command to the daemon.
See Transfer messages between the IBM MQ MQTT daemon for devices and IBM MQ.
Using the protocol setting, the daemon prints a message to the console describing each MQTT packet it sends and receives.

Recovering after failure

Follow a set of procedures to recover after a serious problem.

About this task

Use the recovery methods described here if you cannot resolve the underlying problem by using the diagnostic techniques described throughout the Troubleshooting and support section. If your problem cannot be resolved by using these recovery techniques, contact your IBM Support Center.

Procedure

See the following links for instructions on how to recover from different types of failures:
- "Disk drive failures" on page 1846
- "Damaged queue manager object" on page 1847
- "Damaged single object" on page 1847
- "Automatic media recovery failure" on page 1847

z/OS

See the following links for instructions on how to recover from different types of failures on IBM MQ for z/OS:

- z/OS "Shared queue problems" on page 1849
- z/OS "Active log problems" on page 1849
- z/OS "Archive log problems" on page 1855
- z/OS "BSDS problems" on page 1857
- z/OS "Page set problems" on page 1864
- z/OS "Coupling facility and Db2 problems" on page 1865
- z/OS "Problems with long-running units of work" on page 1868
- z/OS "IMS-related problems" on page 1869

- z/OS "Hardware problems" on page 1871

Related concepts:

"Troubleshooting and support" on page 1275
If you are having problems with your queue manager network or IBM MQ applications, use the techniques described to help you diagnose and solve the problems.

"Troubleshooting overview" on page 1276
Troubleshooting is the process of finding and eliminating the cause of a problem. Whenever you have a problem with your IBM software, the troubleshooting process begins as soon as you ask yourself "what happened?"

"Making initial checks on Windows, UNIX and Linux systems" on page 1277
Before you start problem determination in detail, consider whether there is an obvious cause of the problem, or an area of investigation that is likely to give useful results. This approach to diagnosis can often save a lot of work by highlighting a simple error, or by narrowing down the range of possibilities.

Related tasks:

"Contacting IBM Software Support" on page 1658
Grade the severity of the problem, describe the problem and gather background information, then report the problem to IBM Software Support.

Backing up and restoring IBM MQ

z/OS Planning for backup and recovery on z/OS

Disk drive failures

You might have problems with a disk drive containing either the queue manager data, the log, or both. Problems can include data loss or corruption. The three cases differ only in the part of the data that survives, if any.

In ***all*** cases first check the directory structure for any damage and, if necessary, repair such damage. If you lose queue manager data, the queue manager directory structure might have been damaged. If so, re-create the directory tree manually before you restart the queue manager.

If damage has occurred to the queue manager data files, but not to the queue manager log files, then the queue manager will normally be able to restart. If any damage has occurred to the queue manager log files, then it is likely that the queue manager will not be able to restart.

Having checked for structural damage, there are a number of things you can do, depending on the type of logging that you use.

- **Where there is major damage to the directory structure or any damage to the log**, remove all the old files back to the `QMgrName` level, including the configuration files, the log, and the queue manager directory, restore the last backup, and restart the queue manager.
- **For linear logging with media recovery**, ensure that the directory structure is intact and restart the queue manager. If the queue manager restarts, check, using MQSC commands such as DISPLAY QUEUE, whether any other objects have been damaged. Recover those you find, using the **rcrmqobj** command. For example:

  ```
  rcrmqobj -m QMgrName -t all *
  ```

  where `QMgrName` is the queue manager being recovered. `-t all *` indicates that all damaged objects of any type are to be recovered. If only one or two objects have been reported as damaged, you can specify those objects by name and type here.
- **For linear logging with media recovery and with an undamaged log**, you might be able to restore a backup of the queue manager data leaving the existing log files and log control file unchanged. Starting the queue manager applies the changes from the log to bring the queue manager back to its state when the failure occurred.

This method relies on two things:

1. You must restore the checkpoint file as part of the queue manager data. This file contains the information determining how much of the data in the log must be applied to give a consistent queue manager.
2. You must have the oldest log file required to start the queue manager at the time of the backup, and all subsequent log files, available in the log file directory.

If this is not possible, restore a backup of both the queue manager data and the log, both of which were taken at the same time. This causes message integrity to be lost.

- **For circular logging**, if the queue manager log files are damaged, restore the queue manager from the latest backup that you have. Once you have restored the backup, restart the queue manager and check for damaged objects. However, because you do not have media recovery, you must find other ways of re-creating the damaged objects.

  If the queue manager log files are not damaged, the queue manager will normally be able to restart. Following the restart you must identify all damaged objects, then delete and redefine them.

Damaged queue manager object

What to do if the queue manager reports a damaged object during normal operation.

There are two ways of recovering in these circumstances, depending on the type of logging you use:

- **For linear logging**, manually delete the file containing the damaged object and restart the queue manager. (You can use the **dspmqfls** command to determine the real, file-system name of the damaged object.) Media recovery of the damaged object is automatic.
- **For circular logging**, restore the last backup of the queue manager data and log, and restart the queue manager.

  There is a further option if you are using circular logging. For a damaged queue, or other object, delete the object and define the object again. In the case of a queue, this option does not allow you to recover any data on the queue.

  Note: Restoring from backup is likely to be out of date, due to the fact that you must have your queue manager shutdown in order to get a clean backup of the queue files.

Damaged single object

If a single object is reported as damaged during normal operation, for linear logging you can re-create the object from its media image. However, for circular logging you cannot re-create a single object.

Automatic media recovery failure

If a local queue required for queue manager startup with a linear log is damaged, and the automatic media recovery fails, restore the last backup of the queue manager data and log and restart the queue manager.

Example recovery procedures on z/OS

Use this topic as a reference for various recovery procedures.

This topic describes procedures for recovering IBM MQ after various error conditions. These error conditions are grouped in the following categories:

Table 176. Example recovery procedures

Problem category	Problem	Where to look next
Shared queue problems	Conflicting definitions for both private and shared queues.	"Shared queue problems" on page 1849
Active log problems	• Dual logging is lost. • Active log has stopped. • One or both copies of the active log data set are damaged. • Write errors on active log data set. • Active log is becoming full or is full. • Read errors on active log data set.	"Active log problems" on page 1849
Archive log problems	• Insufficient DASD space to complete offloading active log data sets. • Offload task has terminated abnormally. • Archive data set allocation problem. 1 • Read I/O errors on the archive data set during restart.	"Archive log problems" on page 1855
BSDS problems	• Error opening BSDS. • Log content does not correspond with BSDS information. • Both copies of the BSDS are damaged. • Unequal time stamps. • Dual BSDS data sets are out of synchronization. • I/O error on BSDS.	"BSDS problems" on page 1857
Page set problems	• Page set full. • A page set has an I/O error.	"Page set problems" on page 1864
coupling facility and Db2 problems	• Storage medium full. • Db2 system fails. • Db2 data-sharing group fails. • Db2 and the coupling facility fail.	"Coupling facility and Db2 problems" on page 1865
Unit of work problems	A long-running unit of work is encountered.	"Problems with long-running units of work" on page 1868
IMS problems	• An IMS application terminates abnormally. • The IMS adapter cannot connect to IBM MQ. • IMS not operational.	"IMS-related problems" on page 1869
Hardware problems	Media recovery procedures	"Hardware problems" on page 1871

Shared queue problems

Problems occur if IBM MQ discovers that a page set based queue, and a shared queue of the same name are defined.

Symptoms
IBM MQ issues the following message:

```
CSQI063E +CSQ1 QUEUE queue-name IS BOTH PRIVATE AND SHARED
```

During queue manager restart, IBM MQ discovered that a page set based queue and a shared queue of the same name coexist.

System action
Once restart processing has completed, any **MQOPEN** request to that queue name fails, indicating the coexistence problem.

System programmer action
None.

Operator action
Delete one version of the queue to allow processing of that queue name. If there are messages on the queue that must be kept, you can use the MOVE QLOCAL command to move them to the other queue.

Active log problems

Use this topic to resolve different problems with the active logs.

This topic covers the following active log problems:

- "Dual logging is lost"
- "Active log stopped" on page 1850
- "One or both copies of the active log data set are damaged" on page 1850
- "Write I/O errors on an active log data set" on page 1851
- "I/O errors occur while reading the active log" on page 1852
- "Active log is becoming full" on page 1853
- Active log is full

Dual logging is lost

Symptoms
IBM MQ issues the following message:

```
CSQJ004I +CSQ1 ACTIVE LOG COPY n INACTIVE, LOG IN SINGLE MODE,
          ENDRBA=...
```

Having completed one active log data set, IBM MQ found that the subsequent (COPY n) data sets were not offloaded or were marked stopped.

System action
IBM MQ continues in single mode until offloading has been completed, then returns to dual mode.

System programmer action
None.

Operator action
Check that the offload process is proceeding and is not waiting for a tape mount. You might need to run the print log map utility to determine the state of all data sets. You might also need to define additional data sets.

Active log stopped

Symptoms
IBM MQ issues the following message:

```
CSQJ030E +CSQ1 RBA RANGE startrba TO endrba NOT AVAILABLE IN ACTIVE
          LOG DATA SETS
```

System action
The active log data sets that contain the RBA range reported in message CSQJ030E are unavailable to IBM MQ. The status of these logs is STOPPED in the BSDS. The queue manager terminates with a dump.

System programmer action
You must resolve this problem before restarting the queue manager. The log RBA range must be available for IBM MQ to be recoverable. An active log that is marked as STOPPED in the BSDS will never be reused or archived and this creates a hole in the log.

Look for messages that indicate why the log data set has stopped, and follow the instructions for those messages.

Modify the BSDS active log inventory to reset the STOPPED status. To do this, follow this procedure after the queue manager has terminated:

1. Use the print log utility (CSQJU004) to obtain a copy of the BSDS log inventory. This shows the status of the log data sets.
2. Use the DELETE function of the change log inventory utility (CSQJU003) to delete the active log data sets that are marked as STOPPED.
3. Use the NEWLOG function of CSQJU003 to add the active logs back into the BSDS inventory. The starting and ending RBA for each active log data set must be specified on the NEWLOG statement. (The correct values to use can be found from the print log utility report obtained in Step 1.)
4. Rerun CSQJU004. The active log data sets that were marked as STOPPED are now shown as NEW and NOT REUSABLE. These active logs will be archived in due course.
5. Restart the queue manager.

Note: If your queue manager is running in dual BSDS mode, you must update both BSDS inventories.

One or both copies of the active log data set are damaged

Symptoms
IBM MQ issues the following messages:

```
CSQJ102E +CSQ1 LOG RBA CONTENT OF LOG DATA SET DSNAME=...,
          STARTRBA=..., ENDRBA=...,
          DOES NOT AGREE WITH BSDS INFORMATION
CSQJ232E +CSQ1 OUTPUT DATA SET CONTROL INITIALIZATION PROCESS FAILED
```

System action
Queue manager startup processing is terminated.

System programmer action
If one copy of the data set is damaged, carry out these steps:

1. Rename the damaged active log data set and define a replacement data set.
2. Copy the undamaged data set to the replacement data set.
3. Use the change log inventory utility to:
   - Remove information relating to the damaged data set from the BSDS.
   - Add information relating to the replacement data set to the BSDS.
4. Restart the queue manager.

If both copies of the active log data sets are damaged, the current page sets are available, **and the queue manager shut down cleanly**, carry out these steps:

1. Rename the damaged active log data sets and define replacement data sets.
2. Use the change log records utility to:
   - Remove information relating to the damaged data set from the BSDS.
   - Add information relating to the replacement data set to the BSDS.
3. Rename the current page sets and define replacement page sets.
4. Use CSQUTIL (FORMAT and RESETPAGE) to format the replacement page sets and copy the renamed page sets to them. The RESETPAGE function also resets the log information in the replacement page sets.

If the queue manager did not shut down cleanly, you must either restore your system from a previous known point of consistency, or perform a cold start (described in Reinitializing a queue manager).

Operator action
None.

Write I/O errors on an active log data set

Symptoms
IBM MQ issues the following message:

```
CSQJ105E +CSQ1 csect-name LOG WRITE ERROR DSNAME=...,
          LOGRBA=..., ERROR STATUS=ccccffss
```

System action
IBM MQ carries out these steps:

1. Marks the log data set that has the error as TRUNCATED in the BSDS.
2. Goes on to the next available data set.
3. If dual active logging is used, truncates the other copy at the same point.

The data in the truncated data set is offloaded later, as usual.

The data set will be reused on the next cycle.

System programmer action

None.

Operator action

If errors on this data set still exist, shut down the queue manager after the next offload process. Then use Access Method Services (AMS) and the change log inventory utility to add a replacement. (For instructions, see Changing the BSDS.)

I/O errors occur while reading the active log

Symptoms

IBM MQ issues the following message:

```
CSQJ106E +CSQ1 LOG READ ERROR DSNAME=..., LOGRBA=...,
         ERROR STATUS=ccccffss
```

System action

This depends on when the error occurred:

- If the error occurs during the offload process, the process tries to read the RBA range from a second copy.
  - If no second copy exists, the active log data set is stopped.
  - If the second copy also has an error, only the original data set that triggered the offload process is stopped. The archive log data set is then terminated, leaving a gap in the archived log RBA range.
  - This message is issued:

```
CSQJ124E +CSQ1 OFFLOAD OF ACTIVE LOG SUSPENDED FROM
         RBA xxxxxx TO RBA xxxxxx DUE TO I/O ERROR
```

  - If the second copy is satisfactory, the first copy is not stopped.
- If the error occurs during recovery, IBM MQ provides data from specific log RBAs requested from another copy or archive. If this is unsuccessful, recovery does not succeed, and the queue manager terminates abnormally.
- If the error occurs during restart, if dual logging is used, IBM MQ continues with the alternative log data set, otherwise the queue manager ends abnormally.

System programmer action

Look for system messages, such as IEC prefixed messages, and try to resolve the problem using the recommended actions for these messages.

If the active log data set has been stopped, it is not used for logging. The data set is not deallocated; it is still used for reading. Even if the data set is not stopped, an active log data set that gives persistent errors should be replaced.

Operator action

None.

Replacing the data set

How you replace the data set depends on whether you are using single or dual active logging.

If you are using dual active logging:

1. Ensure that the data has been saved.

   The data is saved on the other active log and this can be copied to a replacement active log.
2. Stop the queue manager and delete the data set with the error using Access Method Services.

3. Redefine a new log data set using Access Method Services DEFINE so that you can write to it. Use DFDSS or Access Method Services REPRO to copy the good log in to the redefined data set so that you have two consistent, correct logs again.
4. Use the change log inventory utility, CSQJU003, to update the information in the BSDS about the corrupted data set as follows:
   a. Use the DELETE function to remove information about the corrupted data set.
   b. Use the NEWLOG function to name the new data set as the new active log data set and give it the RBA range that was successfully copied.

      You can run the DELETE and NEWLOG functions in the same job step. Put the DELETE statement before NEWLOG statement in the SYSIN input data set.
5. Restart the queue manager.

If you are using single active logging:

1. Ensure that the data has been saved.
2. Stop the queue manager.
3. Determine whether the data set with the error has been offloaded:
   a. Use the CSQJU003 utility to list information about the archive log data sets from the BSDS.
   b. Search the list for a data set with an RBA range that includes the RBA of the corrupted data set.
4. If the corrupted data set has been offloaded, copy its backup in the archive log to a new data set. Then, skip to step 6.
5. If an active log data set is stopped, an RBA is not offloaded. Use DFDSS or Access Method Services REPRO to copy the data from the corrupted data set to a new data set.

   If further I/O errors prevent you from copying the entire data set, a gap occurs in the log.

   Note: Queue manager restart will not be successful if a gap in the log is detected.
6. Use the change log inventory utility, CSQJU003, to update the information in the BSDS about the corrupted data set as follows:
   a. Use the DELETE function to remove information about the corrupted data set.
   b. Use the NEWLOG function to name the new data set as the new active log data set and to give it the RBA range that was successfully copied.

      The DELETE and NEWLOG functions can be run in the same job step. Put the DELETE statement before NEWLOG statement in the SYSIN input data set.
7. Restart the queue manager.

Active log is becoming full

The active log can fill up for several reasons, for example, delays in offloading and excessive logging. If an active log runs out of space, this has serious consequences. When the active log becomes full, the queue manager halts processing until an offload process has been completed. If the offload processing stops when the active log is full, the queue manager can end abnormally. Corrective action is required before the queue manager can be restarted.

Symptoms

Because of the serious implications of an active log becoming full, the queue manager issues the following warning message when the last available active log data set is 5% full:

```
CSQJ110E +CSQ1 LAST COPYn ACTIVE LOG DATA SET IS nnn PERCENT FULL
```

and reissues the message after each additional 5% of the data set space is filled. Each time the message is issued, the offload process is started.

System action
Messages are issued and offload processing started. If the active log becomes full, further actions are taken. See “Active log is full”

System programmer action
Use the DEFINE LOG command to dynamically add further active log data sets. This permits IBM MQ to continue its normal operation while the error causing the offload problems is corrected. For more information about the DEFINE LOG command, see DEFINE LOG.

Active log is full

Symptoms
When the active log becomes full, the queue manager halts processing until an offload process has been completed. If the offload processing stops when the active log is full, the queue manager can end abnormally. Corrective action is required before the queue manager can be restarted.

IBM MQ issues the following message:

```
CSQJ111A +CSQ1 OUT OF SPACE IN ACTIVE LOG DATA SETS
```

and an offload process is started. The queue manager then halts processing until the offload process has been completed.

System action
IBM MQ waits for an available active log data set before resuming normal IBM MQ processing. Normal shut down, with either QUIESCE or FORCE, is not possible because the shutdown sequence requires log space to record system events related to shut down (for example, checkpoint records). If the offload processing stops when the active log is full, the queue manager stops with an X'6C6' abend; restart in this case requires special attention. For more details, see “Problem determination on z/OS” on page 1724.

System programmer action
You can provide additional active log data sets before restarting the queue manager. This permits IBM MQ to continue its normal operation while the error causing the offload process problems is corrected. To add new active log data sets, use the change log inventory utility (CSQJU003) when the queue manager is not active. For more details about adding new active log data sets, see Changing the BSDS.

Consider increasing the number of logs by:

1. Making sure that the queue manager is stopped, then using the Access Method Services DEFINE command to define a new active log data set.
2. Defining the new active log data set in the BSDS using the change log inventory utility (CSQJU003).

When you restart the queue manager, offloading starts automatically during startup, and any work that was in progress when IBM MQ was forced to stop is recovered.

Operator action
Check whether the offload process is waiting for a tape drive. If it is, mount the tape. If you cannot mount the tape, force IBM MQ to stop by using the z/OS CANCEL command.

Archive log problems

Use this topic to investigate, and resolve problems with the archive logs.

This topic covers the following archive log problems:

- "Allocation problems"
- "Offload task terminated abnormally"
- "Insufficient DASD space to complete offload processing" on page 1856
- "Read I/O errors on the archive data set while IBM MQ is restarting" on page 1857

Allocation problems

Symptoms

IBM MQ issues message: CSQJ103E

```
CSQJ103E +CSQ1 LOG ALLOCATION ERROR DSNAME=dsname,
         ERROR STATUS=eeeeiiii, SMS REASON CODE=sss
```

z/OS dynamic allocation provides the ERROR STATUS. If the allocation was for offload processing, the following message is also displayed: CSQJ115E:

```
CSQJ115E +CSQ1 OFFLOAD FAILED, COULD NOT ALLOCATE AN ARCHIVE
         DATA SET
```

System action

The following actions take place:

- If the input is needed for recovery, and recovery is not successful, and the queue manager ends abnormally.
- If the active log had become full and an offload task was scheduled but not completed, the offload task tries again the next time it is triggered. The active log does not reuse a data set that has not yet been archived.

System programmer action

None.

Operator action

Check the allocation error code for the cause of the problem, and correct it. Ensure that drives are available, and either restart or wait for the offload task to be retried. Be careful if a DFP/DFSMS ACS user-exit filter has been written for an archive log data set, because this can cause a device allocation error when the queue manager tries to read the archive log data set.

Offload task terminated abnormally

Symptoms

No specific IBM MQ message is issued for write I/O errors.

Only a z/OS error recovery program message appears. If you get IBM MQ message CSQJ128E, the offload task has ended abnormally.

System action

The following actions take place:

- The offload task abandons the output data set; no entry is made in the BSDS.
- The offload task dynamically allocates a new archive and restarts offloading from the point at which it was previously triggered.
- If an error occurs on the new data set:

– In dual archive mode, message CSQJ114I is generated and the offload processing changes to single mode:

```
CSQJ114I +CSQ1 ERROR ON ARCHIVE DATA SET, OFFLOAD
         CONTINUING WITH ONLY ONE ARCHIVE DATA SET BEING
         GENERATED
```

– In single archive mode, the output data set is abandoned. Another attempt to process this RBA range is made the next time offload processing is triggered.

– The active log does not wrap around; if there are no more active logs, data is not lost.

System programmer action
None.

Operator action
Ensure that offload task is allocated on a reliable drive and control unit.

Insufficient DASD space to complete offload processing

Symptoms
While offloading the active log data sets to DASD, the process terminates unexpectedly. IBM MQ issues message CSQJ128E:

```
CSQJ128E +CSQ1 LOG OFF-LOAD TASK FAILED FOR ACTIVE LOG nnnnn
```

The error is preceded by z/OS messages IEC030I, IEC031I, or IEC032I.

System action
IBM MQ de-allocates the data set on which the error occurred. If IBM MQ is running in dual archive mode, IBM MQ changes to single archive mode and continues the offload task. If the offload task cannot be completed in single archive mode, the active log data sets cannot be offloaded, and the state of the active log data sets remains NOT REUSABLE. Another attempt to process the RBA range of the abandoned active log data sets is made the next time the offload task is triggered.

System programmer action
The most likely causes of these symptoms are:

- The size of the archive log data set is too small to contain the data from the active log data sets during offload processing. All the secondary space allocations have been used. This condition is normally accompanied by z/OS message IEC030I. The return code in this message might provide further explanations for the cause of these symptoms.

  To solve the problem

  1. Issue the command `CANCEL <queue-manager name>` to cancel the queue manager job
  2. Increase the primary or secondary allocations (or both) for the archive log data set (in the CSQ6ARVP system parameters), or reduce the size of the active log data set.

     If the data to be offloaded is large, you can mount another online storage volume or make one available to IBM MQ.
  3. Restart the queue manager.

- All available space on the DASD volumes to which the archive data set is being written has been exhausted. This condition is normally accompanied by z/OS message IEC032I.

  To solve the problem, make more space available on the DASD volumes, or make another online storage volume available for IBM MQ.

- The primary space allocation for the archive log data set (as specified in the CSQ6ARVP system parameters) is too large to allocate to any available online DASD device. This condition is normally accompanied by z/OS message IEC032I.

  To solve the problem, make more space available on the DASD volumes, or make another online storage volume available for IBM MQ. If this is not possible, you must adjust the value of PRIQTY in the CSQ6ARVP system parameters to reduce the primary allocation. (For details, see Using CSQ6ARVP.)

  Note: If you reduce the primary allocation, you might have to increase the size of the secondary space allocation to avoid future abends.

Operator action
: None.

Read I/O errors on the archive data set while IBM MQ is restarting

Symptoms
: No specific IBM MQ message is issued; only the z/OS error recovery program message appears.

System action
: This depends on whether a second copy exists:
  - If a second copy exists, it is allocated and used.
  - If a second copy does not exist, restart is not successful.

System programmer action
: None.

Operator action
: Try to restart, using a different drive.

BSDS problems

Use this topic to investigate, and resolve problems with BSDS.

For background information about the bootstrap data set (BSDS), see the Planning your IBM MQ environment on z/OS .

This topic describes the following BSDS problems:
- "Error occurs while opening the BSDS" on page 1858
- "Log content does not agree with the BSDS information" on page 1858
- "Both copies of the BSDS are damaged" on page 1858
- "Unequal time stamps" on page 1859
- "Out of synchronization" on page 1860
- "I/O error" on page 1861
- "Log range problems" on page 1861

Normally, there are two copies of the BSDS, but if one is damaged, IBM MQ immediately changes to single BSDS mode. However, the damaged copy of the BSDS must be recovered before restart. If you are in single mode and damage the only copy of the BSDS, or if you are in dual mode and damage both copies, use the procedure described in Recovering the BSDS.

This section covers some of the BSDS problems that can occur at startup. Problems *not* covered here include:
- RECOVER BSDS command errors (messages CSQJ301E - CSQJ307I)
- Change log inventory utility errors (message CSQJ123E)
- Errors in the BSDS backup being dumped by offload processing (message CSQJ125E)

Error occurs while opening the BSDS

Symptoms

IBM MQ issues the following message:

```
CSQJ100E +CSQ1 ERROR OPENING BSDSn DSNAME=..., ERROR STATUS=eeii
```

where *eeii* is the VSAM return code. For information about VSAM codes, see the *DFSMS/MVS Macro Instructions for Data Sets* documentation.

System action

During system initialization, the startup is terminated.

During a RECOVER BSDS command, the system continues in single BSDS mode.

System programmer action

None.

Operator action

Carry out these steps:

1. Run the print log map utility on both copies of the BSDS, and compare the lists to determine which copy is accurate or current.
2. Rename the data set that had the problem, and define a replacement for it.
3. Copy the accurate data set to the replacement data set, using Access Method Services.
4. Restart the queue manager.

Log content does not agree with the BSDS information

Symptoms

IBM MQ issues the following message:

```
CSQJ102E +CSQ1 LOG RBA CONTENT OF LOG DATA SET DSNAME=...,
          STARTRBA=..., ENDRBA=...,
          DOES NOT AGREE WITH BSDS INFORMATION
```

This message indicates that the change log inventory utility was used incorrectly or that a down-level data set is being used.

System action

Queue manager startup processing is terminated.

System programmer action

None.

Operator action

Run the print log map utility and the change log inventory utility to print and correct the contents of the BSDS.

Both copies of the BSDS are damaged

Symptoms

IBM MQ issues the following messages:

```
CSQJ107E +CSQ1 READ ERROR ON BSDS
         DSNAME=... ERROR STATUS=0874
CSQJ117E +CSQ1 REG8 INITIALIZATION ERROR READING BSDS
         DSNAME=... ERROR STATUS=0874
CSQJ119E +CSQ1 BOOTSTRAP ACCESS INITIALIZATION PROCESSING FAILED
```

System action
Queue manager startup processing is terminated.

System programmer action
Carry out these steps:

1. Rename the data set, and define a replacement for it.
2. Locate the BSDS associated with the most recent archive log data set, and copy it to the replacement data set.
3. Use the print log map utility to print the contents of the replacement BSDS.
4. Use the print log records utility to print a summary report of the active log data sets missing from the replacement BSDS, and to establish the RBA range.
5. Use the change log inventory utility to update the missing active log data set inventory in the replacement BSDS.
6. If dual BSDS data sets had been in use, copy the updated BSDS to the second copy of the BSDS.
7. Restart the queue manager.

Operator action
None.

Unequal time stamps

Symptoms
IBM MQ issues the following message:

```
CSQJ120E +CSQ1 DUAL BSDS DATA SETS HAVE UNEQUAL TIME STAMPS,
         SYSTEM BSDS1=...,BSDS2=...,
         UTILITY BSDS1=...,BSDS2=...
```

The possible causes are:

- One copy of the BSDS has been restored. All information about the restored BSDS is down-level. The down-level BSDS has the lower time stamp.
- One of the volumes containing the BSDS has been restored. All information about the restored volume is down-level. If the volume contains any active log data sets or IBM MQ data, they are also down-level. The down-level volume has the lower time stamp.
- Dual logging has degraded to single logging, and you are trying to start without recovering the damaged log.
- The queue manager terminated abnormally after updating one copy of the BSDS but before updating the second copy.

System action
IBM MQ attempts to resynchronize the BSDS data sets using the more recent copy. If this fails, queue manager startup is terminated.

System programmer action
None.

Operator action

If automatic resynchronization fails, carry out these steps:

1. Run the print log map utility on both copies of the BSDS, compare the lists to determine which copy is accurate or current.
2. Rename the down-level data set and define a replacement for it.
3. Copy the good data set to the replacement data set, using Access Method Services.
4. If applicable, determine whether the volume containing the down-level BSDS has been restored. If it has been restored, all data on that volume, such as the active log data, is also down-level.

   If the restored volume contains active log data and you were using dual active logs on separate volumes, you need to copy the current version of the active log to the down-level log data set. See Recovering logs for details of how to do this.

Out of synchronization

Symptoms

IBM MQ issues the following message during queue manager initialization:

```
CSQJ122E +CSQ1 DUAL BSDS DATA SETS ARE OUT OF SYNCHRONIZATION
```

The system time stamps of the two data sets are identical. Differences can exist if operator errors occurred while the change log inventory utility was being used. (For example, the change log inventory utility was only run on one copy.) The change log inventory utility sets a private time stamp in the BSDS control record when it starts, and a close flag when it ends. IBM MQ checks the change log inventory utility time stamps and, if they are different, or they are the same but one close flag is not set, IBM MQ compares the copies of the BSDSs. If the copies are different, CSQJ122E is issued.

This message is also issued by the BSDS conversion utility if two input BSDS are specified and a record is found that differs between the two BSDS copies. This situation can arise if the queue manager terminated abnormally prior to the BSDS conversion utility being run.

System action

Queue manager startup or the utility is terminated.

System programmer action

None.

Operator action

If the error occurred during queue manager initialization, carry out these steps:

1. Run the print log map utility on both copies of the BSDS, and compare the lists to determine which copy is accurate or current.
2. Rename the data set that had the problem, and define a replacement for it.
3. Copy the accurate data set to the replacement data set, using access method services.
4. Restart the queue manager.

If the error occurred when running the BSDS conversion utility, carry out these steps:

1. Attempt to restart the queue manager and shut it down cleanly before attempting to run the BSDS conversion utility again.
2. If this does not solve the problem, run the print log map utility on both copies of the BSDS, and compare the lists to determine which copy is accurate or current.
3. Change the JCL used to invoke the BSDS conversion utility to specify the current BSDS in the SYSUT1 DD statement, and remove the SYSUT2 DD statement, before submitting the job again.

I/O error

Symptoms
IBM MQ changes to single BSDS mode and issues the user message:

```
CSQJ126E +CSQ1 BSDS ERROR FORCED SINGLE BSDS MODE
```

This is followed by one of the following messages:

```
CSQJ107E +CSQ1 READ ERROR ON BSDS
          DSNAME=... ERROR STATUS=...

CSQJ108E +CSQ1 WRITE ERROR ON BSDS
          DSNAME=... ERROR STATUS=...
```

System action
The BSDS mode changes from dual to single.

System programmer action
None.

Operator action
Carry out these steps:
1. Use Access Method Services to rename or delete the damaged BSDS and to define a new BSDS with the same name as the BSDS that had the error. Example control statements can be found in job CSQ4BREC in thlqual.SCSQPROC.
2. Issue the IBM MQ command RECOVER BSDS to make a copy of the good BSDS in the newly allocated data set and reinstate dual BSDS mode. See also Recovering the BSDS.

Log range problems

Symptoms

IBM MQ has issued message CSQJ113E when reading its own log, or message CSQJ133E or CSQJ134E when reading the log of a queue manager in the queue-sharing group. This can happen when you do not have the archive logs needed to restart the queue manager or recover a CF structure.

System action

Depending upon what log record is being read and why, the requestor might end abnormally with a reason code of `X'00D1032A'`.

System programmer action

Run the print log map utility (CSQJU004) to determine the cause of the error. When message CSQJ133E or CSQJ134E has been issued, run the utility against the BSDS of the queue manager indicated in the message.

If you have:
- Deleted the entry with the log range (containing the log RBA or LRSN indicated in the message) from the BSDS, and
- Not deleted or reused the data set

you can add the entry back into the BSDS using the following procedure:

1. Identify the data set containing the required RBA or LRSN, by looking at an old copy of the contents of BSDS, or by running CSQJU004 against a backup of the BSDS.
2. Add the data set back into the BSDS using the change log inventory utility (CSQJU003).
3. Restart the queue manager.

If an archive log data set has been deleted, you will not be able to recover the page set or CF structure that needs the archive logs. Identify the reason that the queue manager needs to read the log record, then take one of the following actions depending on the page set or CF structure affected.

Page sets

Message CSQJ113E during the recovery phase of queue manager restart indicates that the log is needed to perform media recovery to bring a page set up to date.

Identify the page sets that need the deleted log data set for media recovery, by looking at the media recovery RBA in the CSQI1049I message issued for each page set during queue manager restart, then perform the following actions.

- **Page set zero**

  You can recover the objects on page set zero, by using the following procedure.

  Attention: All data in all other page sets will be lost when you carry out the procedure.

  1. Use function SDEFS of the CSQUTIL utility to produce a file of IBM MQ DEFINE commands.
  2. Format page set zero using CSQUTIL, then redefine the other page sets as described in the next section.
  3. Restart the queue manager.
  4. Use CSQUTIL to redefine the objects using the DEFINE commands produced by the utility in step 1.
- **Page sets 1-99**

  Use the following procedure to redefine the page sets.

  Attention: Any data on the page set is lost when you carry out this operation.

  1. If you can access the page set without any I/O errors, reformat the page set using the CSQUTIL utility with the command FORMAT TYPE(NEW).
  2. If I/O errors occurred when accessing the page set, delete the page set and recreate it.

     If you want the page set to be the same size as before, use the command LISTCAT ENT(*dsname*) ALLOC to obtain the existing space allocations, and use these in the z/OS DEFINE CLUSTER command.

     Format the new page set using the CSQUTIL utility with the command FORMAT TYPE(NEW).
  3. Restart the queue manager. You might have to take certain actions, such as resetting channels or resolving indoubt channels.

CF structures

Messages CSQJ113E, CSQJ133E, or CSQJ134E, during the recovery of a CF structure, indicate that the logs needed to recover the structure are not available on at least one member of the queue-sharing group.

Take one of the following actions depending on the structure affected:

Application CF structure

Issue the command RECOVER CFSTRUCT(*structure-name*) TYPE(PURGE).

This process empties the structure, so any messages on the structure are lost.

CSQSYSAPPL structure
Contact your IBM support center.

Administration structure
This structure is rebuilt using log data since the last checkpoint on each queue manager, which should be in active logs.

If you get this error during administration structure recovery, contact your IBM support center as this indicates that the active log is not available.

Once you have recovered the page set or CF structure, perform a backup of the logs, BSDS, page sets, and CF structures.

To prevent this problem from occurring again, increase the:
- Archive log retention (ARCRETN) value to be longer, and
- Increase the frequency of the CF structure backups.

Recovering a CF structure

Conceptually, the data from the previously backed up CF structure is read from the IBM MQ log; the log is read forwards from the backup and any changes are reapplied to the restored structure.

About this task

The log range to use is found from the latest backup of each structure to be recovered, to the current time. The log range is identified by log range sequence number (LRSN) values.

A LRSN uses the 6 most significant digits of a 'store clock value'.

Note that the whole log (back to the time the structure was created) is read, if you have not done a backup of the structure.

Procedure

1. Check that the logs from each queue manage in the queue-sharing group (QSG) are read for records in this LSRN range. Note that the logs are read backwards.
2. Check that a list of changes for each structure to be recovered is built.
3. Data from the coupling facility (CF) structure backup is read and the data is restored. For example, if the backup was done on queue manager `A`, and the recovery is running on queue manager `B`, queue manager `B` reads the logs from queue manager `A` to restore the structure.

   When the start of the backup of the CF structure is read, an internal task is started to take the restored data for the structure and merge it with the changes read from the log.
4. Check that processing continues for each structure being restored.

Example

In the following example, the command RECOVER CFSTRUCT(APP3) has been issued, and the following messages produced:

```
04:00:00 CSQE132I CDL2 CSQERRPB Structure recovery started, using log range from LRSN=CC56D01026CC
to LRSN=CC56DC368924
This is the start of reading the logs backwards from each qmgr in the QSG from the time
of failure to the to the structure backup. The LRSN values give the ranges being used.
Log records for all structures (just one structure in this example) being recovered are
processed at the same time.

04:02:00 CSQE133I CDL2 CSQERPLS Structure recovery reading log backwards, LRSN=CC56D0414372
This message is produced periodically to show the process

04:02:22 CSQE134I CDL2 CSQERRPB Structure recovery reading log completed
```

```
The above process of replaying the logs backwards has finished,

04:02:22 CSQE130I CDL2 CSQERCF2 Recovery of structure APP3 started, using CDL1 log range
from RBA=000EE86D902E to RBA=000EF5E8E4DC
The task to process the data for APP3 has been started. The last backup of CF structure
APP3 was done on CDL1 within the given RBA range, so this log range has to be read.

04:02:29 CSQE131I CDL2 CSQERCF2 Recovery of structure APP3 completed
The data merge has completed. The structure is recovered.
```

Page set problems

Use this topic to investigate, and resolve problems with the page sets.

This topic covers the problems that you might encounter with page sets:

- "Page set I/O errors" describes what happens if a page set is damaged.
- "Page set full" on page 1865 describes what happens if there is not enough space on the page set for any more MQI operations.

Page set I/O errors

Problem
A page set has an I/O error.

Symptoms
This message is issued:

```
CSQP004E +CSQ1 csect-name I/O ERROR STATUS ret-code
PSID psid RBA rba
```

System action
The queue manager terminates abnormally.

System programmer action
None.

Operator action
Repair the I/O error cause.

If none of the page sets are damaged, restart the queue manager. IBM MQ automatically restores the page set to a consistent state from the logs.

If one or more page sets are damaged:

1. Rename the damaged page sets and define replacement page sets.
2. Copy the most recent backup page sets to the replacement page sets.
3. Restart the queue manager. IBM MQ automatically applies any updates that are necessary from the logs.

You cannot restart the queue manager if page set zero is not available. If one of the other page sets is not available, you can comment out the page set DD statement in the queue manager start-up JCL procedure. This lets you defer recovery of the defective page set, enabling other users to continue accessing IBM MQ.

When you add the page set back to the JCL procedure, system restart reads the log from the point where the page set was removed from the JCL to the end of the log. This procedure could take a long time if numerous data has been logged.

A reason code of MQRC_PAGESET_ERROR is returned to any application that tries to access a queue defined on a page set that is not available.

When you have restored the defective page set, restore its associated DD statement and restart the queue manager.

The operator actions described here are only possible if all log data sets are available. If your log data sets are lost or damaged, see Restarting if you have lost your log data sets.

Page set full

Problem
: There is not enough space on a page set for one of the following:

  - **MQPUT** or **MQPUT1** calls to be completed
  - Object manipulation commands to be completed (for example, DEFINE QLOCAL)
  - **MQOPEN** calls for dynamic queues to be completed

Symptoms
: The request fails with reason code MQRC_STORAGE_MEDIUM_FULL. The queue manager cannot complete the request because there is not enough space remaining on the page set.

  Reason code MQRC_STORAGE_MEDIUM_FULL can occur even when the page set expand attribute is set to EXPAND(USER). Before the reason code MQRC_STORAGE_MEDIUM_FULL is returned to the application code, the queue manager will attempt to expand the page set and retry the API request. On a heavily loaded system it is possible that the expanded storage can be used by other IO operations before the retry of the API. See Managing page sets.

  The cause of this problem could be messages accumulating on a transmission queue because they cannot be sent to another system.

System action
: Further requests that use this page set are blocked until enough messages are removed or objects deleted to make room for the new incoming requests.

Operator action
: Use the IBM MQ command DISPLAY USAGE PSID(*) to identify which page set is full.

System programmer action
: You can either enlarge the page set involved or reduce the loading on that page set by moving queues to another page set. See Managing page sets for more information about these tasks. If the cause of the problem is messages accumulating on the transmission queue, consider starting distributed queuing to transmit the messages.

Coupling facility and Db2 problems

Use this topic to investigate, and resolve problems with the coupling facility, and Db2.

This section covers the problems that you might encounter with the coupling facility and Db2:

- “Storage medium full”
- “A Db2 system fails” on page 1866
- “A Db2 data-sharing group fails” on page 1867
- “Db2 and the coupling facility fail” on page 1867

Storage medium full

Problem
: A coupling facility structure is full.

Symptoms
: If a queue structure becomes full, return code MQRC_STORAGE_MEDIUM_FULL is returned to the application.

If the administration structure becomes full, the exact symptoms depend on which processes experience the error, they might range from no responses to CMDSCOPE(GROUP) commands, to queue manager failure as a result of problems during commit processing.

System programmer action

You can use IBM MQ to inhibit **MQPUT** operations to some of the queues in the structure to prevent applications from writing more messages, start more applications to get messages from the queues, or quiesce some of the applications that are putting messages to the queue.

Alternatively you can use XES facilities to alter the structure size in place. The following z/OS command alters the size of the structure:

```
SETXCF START,ALTER,STRNAME= structure-name,SIZE= newsize
```

where `newsize` is a value that is less than the value of MAXSIZE specified on the CFRM policy for the structure, but greater than the current coupling facility size.

You can monitor the utilization of a coupling facility structure with the DISPLAY CFSTATUS command.

A Db2 system fails

If a Db2 subsystem that IBM MQ is connected to fails, IBM MQ attempts to reconnect to the subsystem, and continue working. If you specified a Db2 group attach name in the QSGDATA parameter of the CSQ6SYSP system parameter module, IBM MQ reconnects to another active Db2 that is a member of the same data-sharing group as the failed Db2, if one is available on the same z/OS image.

There are some queue manager operations that do not work while IBM MQ is not connected to Db2. These are:

- Deleting a shared queue or group object definition.
- Altering, or issuing **MQSET** on, a shared queue or group object definition. The restriction of **MQSET** on shared queues means that operations such as triggering or the generation of performance events do not work correctly.
- Defining new shared queues or group objects.
- Displaying shared queues or group objects.
- Starting, stopping, or other actions for shared channels.
- Reading the shared queue definition from Db2 the first time that the shared queue is open by issuing an MQOPEN.

Other IBM MQ API operations continue to function as normal for shared queues, and all IBM MQ operations can be performed against the queue manager private versions (COPY objects) built from GROUP objects. Similarly, any shared channels that are running continue normally until they end or have an error, when they go into retry state.

When IBM MQ reconnects to Db2, resynchronization is performed between the queue manager and Db2. This involves notifying the queue manager of new objects that have been defined in Db2 while it was disconnected (other queue managers might have been able to continue working as normal on other z/OS images through other Db2 subsystems), and updating object attributes of shared queues that have changed in Db2. Any shared channels in retry state are recovered.

If a Db2 fails, it might have owned locks on Db2 resources at the time of failure. In some cases, this might make certain IBM MQ objects unavailable to other queue managers that are not otherwise affected. To resolve this, restart the failed Db2 so that it can perform recovery processing and release the locks.

A Db2 data-sharing group fails

If an entire Db2 data-sharing group fails, recovery might be to the time of failure, or to a previous point in time.

In the case of recovery to the point of failure, IBM MQ reconnects when Db2 has been recovered, the resynchronization process takes places, and normal queue manager function is resumed.

However, if Db2 is recovered to a previous point in time, there might be inconsistencies between the actual queues in the coupling facility structures and the Db2 view of those queues. For example, at the point in time Db2 is recovered to, a queue existed that has since been deleted and its location in the coupling facility structure reused by the definition of a new queue that now contains messages.

If you find yourself in this situation, you must stop all the queue managers in the queue-sharing group, clear out the coupling facility structures, and restart the queue managers. You must then use IBM MQ commands to define any missing objects. To do this, use the following procedure:

1. Prevent IBM MQ from reconnecting to Db2 by starting Db2 in utility mode, or by altering security profiles.
2. If you have any important messages on shared queues, you might be able to offload them using the COPY function of the CSQUTIL utility program, but this might not work.
3. Terminate all queue managers.
4. Use the following z/OS command to clear all structures:

```
SETXCF FORCE,STRUCTURE,STRNAME=
```

5. Restore Db2 to a historical point in time.
6. Reestablish queue manager access to Db2.
7. Restart the queue managers.
8. Recover the IBM MQ definitions from backup copies.
9. Reload any offloaded messages to the shared queues.

When the queue managers restart, they attempt to resynchronize local COPY objects with the Db2 GROUP objects. This might cause IBM MQ to attempt to do the following:

- Create COPY objects for old GROUP objects that existed at the point in time Db2 has recovered to.
- Delete COPY objects for GROUP objects that were created since the point in time Db2 has recovered to and so do not exist in the database.

The DELETE of COPY objects is attempted with the NOPURGE option, so it fails for queue managers that still have messages on these COPY queues.

Db2 and the coupling facility fail

If the coupling facility fails, the queue manager might fail, and Db2 will also fail if it is using this coupling facility.

Recover Db2 using Db2 recovery procedures. When Db2 has been restarted, you can restart the queue managers. The CF administration structure will also have failed, but this is rebuilt by restarting all the queue managers within the queue-sharing group.

If a single application structure within the coupling facility suffers a failure, the effect on the queue manager depends on the level of the queue manager and the CFLEVEL of the failed CF structure:

- If the CF application structure is CFLEVEL(3) or higher and RECOVER is set to YES, it will not be usable until you recover the CF structure by issuing an MQSC RECOVER CFSTRUCT command to the queue manager that will do the recovery. You can specify a single CF structure to be recovered, or you can recover several CF structures simultaneously. The queue manager performing the recovery locates the relevant backups on all the other queue managers' logs using the data in Db2 and the bootstrap data sets. The queue manager replays these backups in the correct time sequence across the queue sharing group, from just before the last backup through to the point of failure. If a recoverable application structure has failed, any further application activity is prevented until the structure has been recovered. If the administration structure has also failed, all the queue managers in the queue-sharing group must be started before the RECOVER CFSTRUCT command can be issued. All queue managers can continue working with local queues and queues in other CF structures during recovery of a failed CF structure.
- If the CF application structure is CFLEVEL(3) or higher and RECOVER is set to NO, the structure is automatically reallocated by the next **MQOPEN** request performed on a queue defined in the structure. All messages are lost, as the structure can only contain non-persistent messages.
- If the CF application structure has a CFLEVEL less than 3, the queue manager fails. On queue manager restart, peer recovery attempts to connect to the structure, detect that the structure has failed and allocate a new version of the structure. All messages on shared queues that were in CF structures affected by the coupling facility failure are lost.

Since IBM WebSphere MQ Version 7.1, queue managers in queue-sharing-groups have been able to tolerate loss of connectivity to coupling facility structures without failing. If the structure has experienced a connection failure, attempts are made to rebuild the structure in another coupling facility with better connectivity in order to regain access to shared queues as soon as possible.

Problems with long-running units of work

Use this topic to investigate, and resolve problems with long-running units of work.

This topic explains what to do if you encounter a long-running unit of work during restart. In this context, this means a unit of work that has been active for a long time (possibly days or even weeks) so that the origin RBA of the unit of work is outside the scope of the current active logs. This means that restart could take a long time, because all the log records relating to the unit of work have to be read, which might involve reading archive logs.

Old unit of work found during restart

Problem
: A unit of work with an origin RBA that predates the oldest active log has been detected during restart.

Symptoms
: IBM MQ issues the following message:

```
CSQR020I +CSQ1 OLD UOW FOUND
```

System action
: Information about the unit of work is displayed, and message CSQR021D is issued, requesting a response from the operator.

System programmer action
: None.

Operator action
: Decide whether to commit the unit of work or not. If you choose not to commit the unit of work, it is handled by normal restart recovery processing. Because the unit of work is old, this is likely to involve using the archive log, and so takes longer to complete.

IMS-related problems

Use this topic to investigate, and resolve problems with IMS and IBM MQ..

This topic includes plans for the following problems that you might encounter in the IMS environment:

- “IMS cannot connect to IBM MQ”
- “IMS application problem”
- “IMS is not operational” on page 1870

IMS cannot connect to IBM MQ

Problem
: The IMS adapter cannot connect to IBM MQ.

Symptoms

IMS remains operative. The IMS adapter issues these messages for control region connect:

- CSQQ001I
- CSQQ002E
- CSQQ003E
- CSQQ004E
- CSQQ005E
- CSQQ007E

For details, see the IBM MQ for z/OS messages, completion, and reason codes documentation.

If an IMS application program tries to access IBM MQ while the IMS adapter cannot connect, it can either receive a completion code and reason code, or terminate abnormally. This depends on the value of the REO option in the SSM member of IMS PROCLIB.

System action

All connection errors are also reported in the IMS message DFS3611.

System programmer action

None.

Operator action

Analyze and correct the problem, then restart the connection with the IMS command:

```
/START SUBSYS subsysname
```

IMS requests the adapter to resolve in-doubt units of recovery.

IMS application problem

Problem

An IMS application terminates abnormally.

Symptoms

The following message is sent to the user's terminal:

```
DFS555I  TRANSACTION tran-id ABEND abcode
MSG IN PROCESS: message data:
```

where *tran-id* represents any IMS transaction that is terminating abnormally and *abcode* is the abend code.

System action
IMS requests the adapter to resolve the unit of recovery. IMS remains connected to IBM MQ.

System programmer action
None.

Operator action
As indicated in message DFS554A on the IMS master terminal.

IMS is not operational

Problem
IMS is not operational.

Symptoms
More than one symptom is possible:

- IMS waits or loops

  IBM MQ cannot detect a wait or loop in IMS, so you must find the origin of the wait or loop. This can be IMS, IMS applications, or the IMS adapter.
- IMS terminates abnormally.
  - See the manuals *IMS/ESA Messages and Codes* and *IMS/ESA Failure Analysis Structure Tables* for more information.
  - If threads are connected to IBM MQ when IMS terminates, IBM MQ issues message CSQ3201E. This message indicates that IBM MQ end-of-task (EOT) routines have been run to clean up and disconnect any connected threads.

System action
IBM MQ detects the IMS error and:

- Backs out in-flight work.
- Saves in-doubt units of recovery to be resolved when IMS is reconnected.

System programmer action
None.

Operator action
Resolve and correct the problem that caused IMS to terminate abnormally, then carry out an emergency restart of IMS. The emergency restart:

- Backs out in-flight transactions that changed IMS resources.
- Remembers the transactions with access to IBM MQ that might be in doubt.

You might need to restart the connection to IBM MQ with the IMS command:

```
/START SUBSYS subsysname
```

During startup, IMS requests the adapter to resolve in-doubt units of recovery.

Hardware problems

Use this topic as a starting point to investigate hardware problems.

If a hardware error causes data to be unreadable, IBM MQ can still be recovered by using the *media recovery* technique:

1. To recover the data, you need a backup copy of the data. Use DFDSS or Access Method Services REPRO regularly to make a copy of your data.
2. Reinstate the most recent backup copy.
3. Restart the queue manager.

The more recent your backup copy, the more quickly your subsystem can be made available again.

When the queue manager restarts, it uses the archive logs to reinstate changes made since the backup copy was taken. You must keep sufficient archive logs to enable IBM MQ to reinstate the changes fully. Do not delete archive logs until there is a backup copy that includes all the changes in the log.

- Send an email to ibmkc@us.ibm.com
- Use the form on the web here: www.ibm.com/software/data/rcf/

When you send information to IBM, you grant IBM a nonexclusive right to use or distribute your comments in any way it believes appropriate, without incurring any obligation to you.

Include the following information:
- Your name and address
- Your email address
- Your telephone or fax number
- The publication title and order number
- The topic and page number related to your comment
- The text of your comment

IBM or any other organizations will only use the personal information that you supply to contact you about the issues that you submit.

Thank you for your participation.
